Abstract

AIM: To investigate the in vitro anti-hepatocellular carcinoma (HCC) activity of docetaxel against SMMC-7721 HCC cells and its possible mechanism.

METHODS: The HCC cells were given different concentrations of docetaxel and their growth was measured by colony forming assay. Cell cycle and apoptosis were analyzed by flow cytometry and fluorescence microscopy (acridine orange/ethidium bromide double staining, AO/EB), as well as electronic microscopy. The SMMC-7721 HCC cell reactive oxygen species (ROS) and glutathione (GSH) were measured after given docetaxel.

RESULTS: Docetaxel inhibited the hepatocellular carcinoma cells growth in a concentration dependent manner with $IC_{50} 5 \times 10^{-10}$ M. Marked cell apoptosis and G2/M phase arrest were observed after treatment with docetaxel $\geq 10^{-8}$ M. Docetaxel promoted SMMC-7721 HCC cells ROS generation and GSH deletion.

CONCLUSION: Docetaxel suppressed the growth of SMMC-7721 HCC cells in vitro by causing apoptosis and G2/M phase arrest of the human hepatoma cells, and ROS and GSH may play a key role in the inhibition of growth and induction of apoptosis.

INTRODUCTION

Docetaxel is a new taxoid structurally similar to paclitaxel, a semisynthetic product of a renewable resource, the needles of the European yew, *Taxus baccata* L. In comparison to paclitaxel, docetaxel is more potent as an inhibitor of microtubule depolymerization^[1]. Docetaxel has shown an active effect against cancers^[2-5]. Current studies have shown that docetaxel combined with other chemotherapeutic drugs has higher anticancer efficacy and reduced side effects in patients with breast, pancreatic, gastric, urothelial carcinomas^[6-9]. But there is limited data about that in hepatocellular carcinoma and thus needs further investigation. Human hepatocellular carcinoma (HCC) is one of the major causes of death worldwide^[10-12], and

surgical resection is the only curative therapy^[13]. However it has limitations for patients with multiple type or metastatic tumors. Searching for effective chemotherapeutic agents is important to improve the survival rate of patients with advanced or recurrent HCC after surgical treatment. HCC is usually insensitive to chemotherapeutic drugs currently used in clinical setting, and there is thus an urgent need for the evaluation of new active drugs against HCC. HCC is well known for its expression of multidrug resistance (MDR) gene and its poor response to chemotherapeutic agents, but it has been found that docetaxel is effective in treating mice bearing xenografts of MDR protein positive human tumors^[14], also a low efflux of docetaxel from tumor cells being observed^[15]. These results suggest that docetaxel may be effective in the treatment of HCC. But the related information is limited and the mechanism of docetaxel remains to be elucidated. This study is to investigate its growth inhibition and induction of apoptosis effect and the mechanism in human SMMC-7721 hepatocellular cell line, and to provide the theoretical basis for clinical application in patients with HCC.

MATERIALS AND METHODS

Reagents

Docetaxel (Rhône-Poulenc Rorer Pharmaceuticals Inc.) was stored as 100 μ M stock solution in absolute ethanol at -80°C . This solution was further diluted in the medium and used in the cell culture immediately before each experiment.

Cell cultures

Human hepatocellular carcinoma SMMC-7721 cell line was obtained from Liver Cancer Institute of Fudan University. The cells were cultured in flasks with RPMI1640 (Gibco BRL, Grand Island, NY) medium supplemented with 100 IU/ml penicillin, 100 μ g/ml streptomycin and 10 % new born bovine serum (Hyclone, Logan, UT) and maintained at 37°C in humidified atmosphere containing 5 % CO_2 .

Colony forming assay

Exponential growth phase SMMC-7721 cells were seeded in 60 mm culture plate (Corning, NY) at a density of 200 cells/plate, after 24hr, the media was discarded and replaced with equal volume of fresh media containing different doses of docetaxel (0, 10^{-11} , 10^{-10} , 10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} M). 24hr later docetaxel containing media was again discarded and replaced by media without containing docetaxel. The cells were cultured continually for 9 days. The colonies were fixed with 95 % ethanol and stained with Giemsa, and manually counted. Colonies ≥ 50 cells were considered survivors. All experiments were conducted in triplicate.

Flow cytometric analysis of DNA content after docetaxel treatment

After exponential growth phase SMMC-7721 cells were treated with different doses of docetaxel (0, 10^{-11} , 10^{-10} , 10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} M) for 24hr and harvested with 0.25 % trypsin and resuspended in RPMI1640 media. 1×10^6 cells was centrifuged at 300 g for 5 minutes and then washed once with PBS. The cell pellets were added with 100 % precooled ethanol at 4°C

for 4hr, centrifuged at 300 g for 5 minutes and then washed once, resuspended with PBS (1×10^6 cells/ml). The cells were added 500 u Rnase, incubated at 37 °C for 30 minutes, washed with PBS. 1×10^6 cells were stained with 50 µg/ml PI for 20 minutes in the dark. The DNA content of each cell was measured using a Becton Dickinson FACSCalibur flow cytometer and analyzed with ModFit LT software (San Jose, CA).

Morphological study with fluorescence microscope

Exponential growth phase SMMC-7721 cells were treated with 10nM docetaxel for 24hr and 48hr and harvested with 0.25 % trypsin and resuspended in RPMI1640 medium. 1×10^6 cells were washed once and resuspended with PBS. 25 µl of the cells suspension was mixed with 1 µl of dye mixture containing AO 100 µg/ml and EB 100 µg/ml in PBS^[16]. The cells were visualized immediately under a fluorescence microscope, the peak excitation wave length was 490 nm.

Transmission electron microscopic observation

After exponential growth phase SMMC-7721 cells treated with 10nM docetaxel for 24hr and 48hr, they were fixed in Karnovsky solution, followed by cacodylate buffer for ultrastructural examination. The cells were postfixed in 1 % osmium tetroxide and dehydrated for staining with uranyl acetate and lead citrate. Thin sections were observed under electron microscope.

ROS measurement

After exponential growth phase SMMC-7721 cells were treated with different doses of docetaxel (0.25 nM, 0.5 nM, 10 nM) for 24hr, the cells were incubated with 2', 7'-dichlorofluorescein diacetate (DCF/DA; 5 µM; Sigma) at 37 °C for 50 minutes to estimate the ROS level. The cells were harvested and detected immediately for fluorescence intensity detection on Becton Dickinson FACSCalibur flow cytometer and data were acquired and analyzed using FACS/CELLQuest software (San Jose, CA) on a Power Macintosh 7600/120 computer (Apple Computers, Cupertino, CA)^[17], three independent experiments were repeated in each drug treated group and the control group was not given docetaxel but incubated with DCF/DA. All experiments were conducted in triplicate.

Determination of intracellular GSH content

The determination of intracellular GSH content was conducted according to Shen *et al*^[18] with modification. Briefly after logarithmic growth phase SMMC-7721 cells ($\geq 10^6$) were

treated with different doses of docetaxel (0.25 nM, 0.5 nM, 10 nM) for 24hr, harvested by trypsination, washed, resuspended in PBS and counted under phase contrast microscope. The cells suspension was centrifuged at 300 g for 5 minutes, the cell pellets were added 0.75 ml distilled water and 0.25 ml thioisalicic acid to precipitate the protein. After centrifugation at 12 000 g for 5 minutes at 4 °C, the supernatant was used for GSH assay. The control group was not given docetaxel. All experiments were conducted in triplicate.

Statistical analysis

The intracellular GSH content was expressed as mean \pm SD. Their differences between drug treated groups and the control group were analyzed with Student's *t*-test.

RESULTS

Effect of docetaxel on SMMC-7721 cells growth inhibition

The colony forming ability decreased gradually with increasing dose of docetaxel treatment, when the docetaxel concentration was increased to 10^{-8} M, the colony forming inhibition rate attained 100 % with $IC_{50} 5 \times 10^{-10}$ M (0.5 nM) (Figure 1).

Figure 1 The survival fraction of SMMC-7721 cells treated with docetaxel for 24hr.

Effect on of docetaxel cell cycle and apoptosis of SMMC-7721 cells

As demonstrated in Figure 2, docetaxel induced a marked apoptosis at 10^{-8} M for 24hr, and caused cells G2/M phase arrest mainly at 10^{-7} M and 10^{-6} M, at 10^{-6} M the G2/M phase cells accounted for 96.1 %.

Figure 2 Cell cycle changes and apoptosis induction in SMMC-7721 cells treated with docetaxel for 24hr. Cells were treated with docetaxel at 0M(A), 10^{-11} M(B), 10^{-10} M(C), 10^{-9} M(D), 10^{-8} M(E), 10^{-7} M(F), 10^{-6} M(G). A marked apoptosis was induced at 10^{-8} M, and a peaked G2/M phase accumulation was caused at 10^{-6} M. Ap:apoptosis.

Morphological observation with fluorescence microscope

After the SMMC-7721 cells were given 10^{-8} M docetaxel for 24hr, the early apoptotic cells could be observed: because of their cells membrane integrity, the cells were stained green with AO, the nuclei exhibited bright condensed chromatin or fragmented, some cells blebbed. After the cells being treated for 48hr, some late apoptotic cells could be observed: Since their cell membrane lost integrity, they were stained red with EB, the apoptotic bodies could be seen clearly. On the contrary, the untreated cells did not show these apoptotic characteristics (Figure 3).

Figure 3 Morphological study with fluorescence microscope. After the SMMC-7721 cells were given 10^{-8} M docetaxel for 24hr (A), the cells were stained green with AO, the nuclei exhibited bright condensed chromatin or fragmented, some cells blebbed. After being treated for 48hr (B), cells were stained red with EB, the apoptotic bodies could be seen clearly. On the contrary, the untreated cells (C) did not show these apoptotic characteristics.

Transmission electron microscopic observation

After treatment with 10^{-8} M docetaxel for 24hr, the chromatin of some SMMC-7721 cells was located along the nuclear edges or formed irregularly shaped crescents at the nuclear edges, or became condensed or fragmented; Some cells nuclear membrane became irregular; The vacuole in some cytoplasm could be observed (Figure 4).

Effect of docetaxel on intracellular ROS

As demonstrated in Figure 5, The SMMC-7721 cells ROS level (corresponding to the fluorescence intensity) increased after

treatment with 0.25 nM, 0.5 nM, 10 nM docetaxel. In comparison with the control group, the ROS level increased by 1.69, 1.78 and 1.80 times respectively.

Figure 4 Transmission electron microscopic observation. After treatment with 10^{-8} M docetaxel for 24hr, the chromatin of some SMMC-7721 cells was located along the nuclear edges or formed irregularly shaped crescents at the nuclear edges (A, C), or became condensed or fragmented (A, B); The vacuole could be observed in some cytoplasm (A, C).

Figure 5 The effect of docetaxel on the formation of ROS in SMMC-7721 cells. Data are from three independent experiments.

Effect of docetaxel on intracellular GSH

The control group intracellular GSH content was 11.6 ± 1.1 fmol/cell, after treatment with docetaxel 0.25 nM, 0.5 nM, 10 nM for 24hr, the SMMC-7721 cells GSH decreased to 4.7 ± 0.7 fmol/cell, 3.0 ± 0.5 fmol/cell, 1.0 ± 0.1 fmol/cell respectively, there was a significant difference between the drug treated groups and the control group ($P < 0.05$).

DISCUSSION

In the present study, we used colony forming assay to observe the effect of docetaxel on the growth of the human hepatocellular carcinoma SMMC-7721 cells in vitro, indicating that docetaxel can inhibit the SMMC-7721 cells growth and in concentration dependent manners, at 10^{-8} M the survival fraction decreased to 0 (Figure 1). A previous study demonstrated that docetaxel showed cytotoxic effect on other human hepatoma cell lines^[17], together with this report, our result suggests that

the growth-inhibiting effect of docetaxel may be a general phenomenon for human hepatocellular carcinoma cells. Also the flow cytometry showed that docetaxel causes SMMC-7721 cells apoptosis at a low dose (10^{-8} M), which was confirmed by fluorescence microscope, transmission electron microscope, and at 10^{-7} M, 10^{-6} M induced a marked G2/M phase arrest without apparent apoptosis, this phenomenon seems to suggest that docetaxel can induce apoptosis independent of G2/M phase arrest in SMMC-7721 cells.

In order to elucidate the mechanisms of the anti-hepatocellular carcinoma action of docetaxel, we examined its possible effect on cell cycle kinetics of SMMC-7721 cells. As demonstrated in Figure 2, following treatment with docetaxel for 24hr, the G2/M phase cells increased with docetaxel doses increasing from 10^{-8} M, at 10^{-6} M the G2/M phase cells accounted for 96.1 %. This result indicates that high dose of docetaxel blocks cell cycle at G2/M phase, disturbs mitosis and inhibits SMMC-7721 cells growth. In this clinical setting, such information may be useful for liver carcinoma therapy with docetaxel and other cytotoxic drugs which affect cell cycle progression.

According to Figure 1, docetaxel could inhibit SMMC-7721 cells at very low doses, the IC_{50} is 5×10^{-10} M. This dose of docetaxel had no significant effect on the cell apoptosis or cell cycle progression, which was confirmed by flow cytometry. In order to elucidate the mechanism underlying this phenomenon, the intracellular ROS and GSH were further investigated in this study. Our results indicated that docetaxel both at $1/2IC_{50}$, IC_{50} and apoptosis-inducing dose (10nM) could cause significantly increased ROS levels (Figure 5) and significantly decreased GSH, compared with those of the control.

It has been reported that tumor cells have persistently higher levels of ROS^[19]. The relationship between ROS and apoptosis, cell growth inhibition has been broadly investigated. ROS has been found to regulate translocation of NF- κ B^[20] as well as translocation of p53 and the p53-mediated apoptosis pathway^[21,22]. Also it has been found that induction of apoptosis was accompanied with the generation of intracellular ROS prior to the activation of caspase-3^[23] and down-regulation of Bcl-2^[24]. Simizu *et al.* reported that some anticancer agents, including vinblastin and camptothecin, induced cells apoptosis with the generation of ROS^[25]. Recently it was reported that arsenic trioxide and L-S,R-buthionine sulfoximine (BSO) combination treatment enhanced hepatocellular carcinoma cells apoptosis through increased production of ROS^[26]. Also it was reported ROS played a mediatory role in the synergistic interaction between 1, 25-dihydroxyvitamin D (3) and anticancer cytokines^[27], modulation of the ROS production intra and extracellularly may influence the cell survival during oxidative insults^[28].

Accordingly, we speculate that docetaxel-induced high level ROS may be involved in the growth inhibition and apoptosis of SMMC-7721 cells.

In order to confirm the SMMC-7721 cells redox status after docetaxel treatment, the intracellular GSH content was also investigated. Our result demonstrated that the intracellular GSH decreased significantly ($P < 0.05$) after both $1/2IC_{50}$, IC_{50} and apoptosis-inducing dose docetaxel treatment, compared with that of the control group. This indicates that the decrease of GSH may be involved in the SMMC-7721 cells growth inhibition and apoptosis caused by docetaxel. Liu *et al.* found *Salvia miltiorrhiza* inhibited human hepatoma HepG2 cells growth and induced apoptosis involving in intracellular GSH deletion^[29], early studies have also demonstrated that the onset of apoptosis was associated with a fall of intracellular GSH in different cellular systems^[30]. And GSH could significantly reduce apoptosis mediated by a monoclonal antibody directed to Fas antigen, and apoptosis could be nearly completely

prevented by GSH^[31]. GSH is an important cellular thiol which is regarded as the major determinant of the intracellular redox potential, on the other hand, apoptosis may be regulated by the redox status within the cells^[32]. Loss of GSH was shown to be tightly coupled with a number of down-stream events in apoptosis, in caspase activation and events in chromatin^[33], and GSH depletion may act as a link between oxidative stress and ceramide-mediated apoptosis^[34]. Also it was found that decreased cells proliferation associated with decreased levels of intracellular GSH, and blockade of GSH synthesis enhanced ROS production and suppressed cells proliferation^[35], cells with compromised cellular GSH were susceptible to redox imbalance-induced inhibition of proliferation^[36].

In summary, the present study demonstrates that docetaxel has profound effects on SMMC-7721 hepatocellular carcinoma cells in vitro. It reduces the proliferation of these cells, causes changes in their morphology, and induces cell death by apoptosis. It leads to ROS generation and GSH deletion, subsequently results in redox imbalance in SMMC-7721 cells, and it is speculated that the redox imbalance caused by docetaxel may play an important role in the growth inhibition and induction of apoptosis of SMMC-7721 cells. As far as we know, there is few report concerning the redox imbalance and docetaxel. Our results not only provide the basis for further in vivo and clinical research in hepatocellular carcinoma, but also contribute to understanding of the pharmacology of docetaxel further.

Abstract

AIM: To investigate the anti-cancer effect and the immunological mechanism of ultrasound-guided intratumoral injection of Chinese medicine "Star-99" in hepatocellular carcinoma (HCC) of nude mice.

METHODS: Twenty-eight human hepatocellular carcinoma SMMC-7721 transplanted nude mice, 14 of hypodermically implanted and 14 of orthotopic liver transplanted, were randomly divided into three groups of which 14 mice with Star-99, and 7 with ethanol and saline respectively. Ten days after the transplantation the medicines were injected into the tumors of all the nude mice once every 5 days. After 4 injections the nude mice were killed. The diameters of three dimension of the tumors were measured by high frequency ultrasound before and after the treatment and the tumor growth indexes* (TGI) were calculated. Radioimmunoassay was used to detect the serum levels of interleukin-2 (IL-2) and tumor necrosis factor (TNF)-alpha. The tumor tissues were sent for flow cytometry (FCM) DNA analysis. Apoptotic cells were visualized by TUNEL assay. All the experiments were carried out by double blind method.

RESULTS: The TGI of Star-99 group (0.076 ± 0.024) was markedly lower than that of the saline group (4.654 ± 1.283) ($P < 0.01$). It also seemed to be lower than that of the ethanol group (0.082 ± 0.028), but not significantly different ($P > 0.05$). Serum levels of IL-2 and TNF- α were markedly higher than those of ethanol group and saline groups ($P < 0.05$). The mean apoptotic index (AI: percentage of TUNEL signal positive cells) in Star-99 group ($48.98 \pm 5.09\%$) was significantly higher than that of the ethanol group ($11.95 \pm 2.24\%$) and the saline group ($10.48 \pm 3.85\%$) ($P < 0.01$). FCM DNA analysis showed that the appearance rate of the apoptosis peak in Star-99 group was 92.9%, markedly higher than that of the ethanol group (14.3%) and the saline group (0.0%) ($P < 0.01$). Correlation ($r = 0.499$, $P < 0.05$) was found between AI and serum level of TNF- α .

CONCLUSION: Star-99 has an effect on the elevation of the serum levels of IL-2 and TNF- α . It indicates that Star-99 has the function of enhancing the cellular immunity and inducing cancer cell apoptosis. The correlation between AI and serum level of TNF- α indicates that the elevation of the serum of TNF- α induced by Star-99 may be an important factor in the promotion of the hepatic cancer cell apoptosis. Star-99 has strong effects on the inhibition and destruction

of cancer cells. Its curative effect is as good as ethanol. Its major mechanisms can be as follows: (1) it increases the serum levels of IL-2 and TNF- α and triggers cellular immunity. (2) It can induce cancer cells apoptosis, the effective mechanism of the Star-99 is different from that of the ethanol. The mechanisms of triggering the immunologic function of the organism and inducing cell apoptosis are, of particular significance. This study will provide a new pathway of drug administration and an experimental basis for the treatment of HCC with Chinese herbal, and the study of Star-99 in the treatment of tumor is of profound significance with good prospects.

INTRODUCTION

The ultrasound-guided percutaneous intratumoral injection with ethanol, in treatment of hepatocellular carcinoma (HCC), has been widely used in the clinic in recent years since the report by the Japanese scholars (1983)^[1-3]. Yet there are certain limitations in this treatment that lead us to search for newer drug that we have been studied for many years. In 1999, we discovered that the compound Chinese medicine "Star-99" had anti-cancer effect. In order to probe the effective mechanism of the ultrasound-guided intratumoral injection of HCC with Star-99, we detected the serum levels of interleukin-2 (IL-2) and tumor necrosis factor (TNF)-alpha, and conducted FCM DNA analysis and TUNEL assay to observe the phenomenon of apoptosis and to appraise the biological effect of Star-99.

MATERIALS AND METHODS

Experimental animal

For the experiment, we used 28 BALB/CA nude mice, which were 5-8 weeks old, provided by the Medical Experimental Animal Unit of Anti-cancer Center of Xia Men University, China. The average weight of the nude mice was 18 ± 2.1 grams. The mice were raised in the layer drift shelves under aseptic condition. The cages, cushion, drinking water and standard forage were provided by Shanghai Bikai Company periodically.

Animal model production of human HCC

Human HCC SMMC-7721 cellular cultural suspension was centrifuged and the supernatant was removed. Then the cellular cultural liquid was added to make up 5×10^7 cells per milliliter. Subcutaneous injection was taken in the back of a nude mouse with 0.2 ml liquid. When the tumor grew to 1 cm in diameter, part of it was taken out under the aseptic condition and cut into small pieces in the size of $0.2 \times 0.2 \times 0.2$ cm, which were transplanted subcutaneously at the back of other nude mice with a canula needle and underwent passages from generation to generation. The nude mice, under general anesthesia with

sodium pentothal injected intraperitoneally. The process was as follows: The abdomen of the mouse was incised 1 cm in length deep to peritoneum on the linea alba below the xiphoid process. The liver was squeezed out, a piece of tumor was embedded into the liver with canula needle, the needle aperture was blocked with gelatin sponge to stop bleeding, then the liver was sent back into the abdomen, the peritoneum and skin were sutured and the process of orthotopic liver transplantation was completed.

Experimental method

Twenty-eight human HCC transplanted nude mice, including 14 implanted hypodermically and the other 14 with liver transplanted orthotopically, were randomly divided into three groups: the Star-99 group containing 14 nude mice, the ethanol group and the saline group containing 7 nude mice each. The three dimensional diameters of the tumor were measured by high frequency ultrasound (Aloka 5500 with 10MHz probe) after 10 days transplantation of HCC. Then 0.1 ml Star-99, ethanol and saline were respectively injected into the center of the tumor with No.5 needle. The nude mice were killed after being injected every 5 days for a total of 4 injections in each mouse. The three dimensional diameters of the tumor were measured again before the mice were killed. Mice blood was obtained from the eye socket, and the sera were separated by low velocity centrifugation. The Radioimmunoassay (RIA) kit was purchased from Beijing East Asian Institute of Immunology. Sn-682 Radioimmunoassay γ counting apparatus was used to detect the serum levels of IL-2 and TNF- α . The apoptotic cells were visualized by terminal deoxynucleotidyl transferase (TdT)-mediated dUTP nick end labelling (TUNEL). The TUNEL kit (POD) was purchased from Roche Molecular Biochemicals. The assay performance followed the technical manual and the references^[4-7]. It was TUNEL positive when the nucleolus appeared evidently brown granule. Ten high power fields were observed in each slide and at least 1 000 positive cells were calculated at random. The cellular suspension made by fresh tumor tissues was analyzed by FCM DNA. The appearance rates of the heteroploidy peak and apoptosis peak were analyzed. Double blind method was applied in this experiment.

Observation indexes

The tumor growth index (TGI) was calculated by the formula: volume of tumor (after treatment-before treatment) / volume of tumor (before treatment). The serum levels of IL-2 and TNF- α were determined. The apoptotic index (AI; percentage of TUNEL signal positive cells) were calculated as the TUNEL-positive cells / the total number of cancer cells $\times 100\%$. The appearance rates of the heteroploidy peak and apoptosis peak of the tumor tissue were analyzed by FCM DNA. The correlation coefficient between AI and serum levels of TNF- α was calculated.

Statistics method

The results were expressed as the mean \pm SD. The data were analyzed by one-way ANOVA with Student's *t* test, chi-square test and liner regression analysis. Value of $P < 0.05$ was considered significant.

RESULTS

The tumor growth index

Table 1 showed that the growth index of Star-99 group was markedly lower than that of the saline group ($P < 0.01$). It was also lower than that of the ethanol group, but there was no significant difference between them ($P > 0.05$).

Table 1 Comparison of the growth index of Star-99, ethanol and saline groups

Groups	<i>n</i>	\bar{x}	SD	<i>P</i>
Star-99 (A)	14	0.076	± 0.024	A, B >0.05
Ethanol (B)	7	0.082	± 0.028	B, C <0.01
Saline (C)	7	4.654	± 1.283	A, C <0.01

The serum levels of IL-2 and TNF- α after treatment

Table 2 showed that the serum levels of IL-2 and TNF- α in the Star-99 group were 6.63 ± 1.39 ng/ml and 3.98 ± 1.05 ng/ml, markedly higher than those of the ethanol and the saline groups ($P < 0.05$).

Table 2 Comparison of the serum levels of IL-2 and TNF- α after treatment in the three groups

Groups	<i>n</i>	IL-2 (ng/ml)	TNF- α (ng/ml)	<i>P</i>
Star-99 (A)	14	6.63 ± 1.39	3.98 ± 1.05	A:B <0.05
Ethanol (B)	7	4.22 ± 1.23	2.95 ± 1.01	A:C <0.05
Saline (C)	7	4.51 ± 0.84	2.84 ± 1.05	B:C >0.05

The apoptotic index of Star-99, ethanol and saline groups after treatment

Table 3 showed that the AI in Star-99 group ($48.98 \pm 5.09\%$) was significantly higher than that of the ethanol group ($11.95 \pm 2.24\%$) and the saline group ($10.48 \pm 3.85\%$) ($P < 0.01$), (Figure 1).

Table 3 Comparison of the apoptotic index of Star-99, ethanol and saline groups after treatment

Groups	<i>n</i>	AI (%)	<i>P</i>
Star-99 (A)	14	48.98 ± 5.09	A:B <0.01
Ethanol (B)	7	11.95 ± 2.24	B:C >0.05
Saline (C)	7	10.48 ± 3.85	A:C <0.01

Figure 1 TUNEL marker (Nucleolus with brown granule indicated positive). A: Star-99 group; B: saline group; $\times 400$.

FCM DNA analysis

Table 4 showed the results of FCM DNA analysis of the tumor tissues of the three groups. The appearance rate of the heteroploidy peak after the treatment was 57.1 % in the saline group (Figure 2), markedly higher than that of the ethanol group (0.0 %) and the Star-99 group (7.1 %) ($P<0.01$). Another remarkable characteristic was that 92.9 % of the Star-99 group appeared apoptosis peaks formed by the cells in the sub G_1 period (Figure 3), markedly higher than that of the ethanol group and the saline group, which were 14.3 % (1/7) and 0.0 (0/7), respectively ($P<0.01$).

Table 4 Comparison of the appearance rates of the hereroploidy and apoptosis peak after treatment in the three groups

Groups	n	Hereroploidy peak (%)	P	Apoptosis peak (%)	P
Star-99 (A)	14	7.1 (1/14)	A:B>0.05	92.9 (13/14)	A:B<0.01
Ethanol (B)	7	0.0 (0/7)	B:C<0.05	14.3 (1/7)	B:C>0.05
Saline (C)	7	57.1 (4/7)	A:C<0.05	0.0 (0/7)	A:C<0.01

Figure 2 FCM DNA analysis showed the hereroploidy peak in the saline group. (Yellow peak).

Figure 3 FCM DNA analysis showed the apoptosis peak in the Star-99 group. (Blue peak).

The relationship between HCC apoptosis and serum levels of TNF- α

There was close relationship between HCC apoptosis and serum level of TNF- α . Significant correlation ($r=0.499$, $P<0.05$) was found between AI and serum levels of TNF- α .

DISCUSSION

At present, many kinds of ultrasound-guided interventional therapy have been practiced by clinicians such as laser^[8,9], microwave^[10-13], radio frequency^[14-19] and high energy focus

ultrasound^[20,21] since 1990s. The efficacy are as good as that of surgical resection^[2, 22-24]. Early In 1985, the American National Cancer Institute considered biotherapy as the fourth modality in cancer treatment as it attacked the tumor cells directly; furthermore, it stimulates the immune system of the host. The present study provided a new avenue to combat the tumor from immunologic point of view. As shown in this experiment, the Star-99 has marked effect on the growth restraint of the tumor, the effectiveness is more or less equivalent to that of the ethanol.

The two important cytokines IL-2 and TNF- α can be used as biological response modifiers (BRM). IL-2 can enhance the activity of lymphocyte and the killing effect of CTL, NK and LAK cells, induce secretion of cytokine. The serum level of IL-2 reflects the host immunologic function to a certain degree^[25]. In this experiment, the serum level of IL-2 in the Star-99 group was 6.63 ± 1.39 ng/ml, markedly higher than those of ethanol and saline groups ($P<0.05$). In another experiment of this study, the electron microscopy showed many lymphocytes in the tumor tissues of the Star-99 group^[26]. Figure 4 showed the microvilli on the surface of the lymphocytes attacked the cancer cells. The membrane of tumor cell in contact with the sensitized T lymphocyte became broken with the organelle and the nucleus dissolved and the vacuolation of the cytoplasm as well. This phenomenon further illustrate that the Star-99 could stimulate or induce the cellular immunity function of the organism. TNF- α is mainly produced by macrophage and activated T lymphocyte which can inhibit or destroy the cancer cells. It can also induce apoptosis by combining with TNF receptor and resulting in chain reactions^[27,28]. In the Star-99 group, the serum level of TNF- α was 3.98 ± 1.05 ng/ml, markedly higher than those of ethanol and saline groups. Significant correlation ($r=0.499$, $P<0.05$) was found between AI and serum levels of TNF- α . It indicated that the elevation of the serum TNF- α induced by Star-99 might be an important factor in the promotion of the HCC cells apoptosis.

Figure 4 Many lymphocytes could be seen in the tumor tissues and the microvilli on the surface of the lymphocytes attacking the cancer cells in the Star-99 group (The right figure is a magnified image).

Cancer growth not only depends on proliferation^[29-35] but also on the reduced apoptosis^[36-39]. At present time, cancer therapy is now focusing on promoting apoptosis^[40,41]. The apoptotic cells could be identified by TUNEL assay^[15,42]. In this experiment, the apoptotic index in Star-99 group ($48.98 \pm 5.09\%$) was significantly higher than that in the ethanol group ($11.95 \pm 2.24\%$) and the saline group ($10.48 \pm 3.85\%$) ($P < 0.01$), which was consistent with the result of FCM DNA analysis, the appearance rate of the apoptosis peak in Star-99 group was 92.9 %, markedly higher than that of the ethanol group (14.3 %) and the saline group (0.0 %) ($P < 0.01$). These results showed that although the cancer cells in ethanol group were destroyed which was different from that by means of apoptosis. In the Star-99 group it was mainly by induction of apoptosis.

The results of this study illustrated that the compound Chinese medicine Star-99 has the strong effect on the growth restraint of the tumor. Apart from its direct destruction of cancer cells, the mechanism of the efficacy may be due to: (1) It can increase the serum levels of IL-2 and TNF- α and trigger the cellular immunity. (2) It can induce apoptosis of the cancer cells. The anti-cancer effect of Star-99 is more or less equivalent to the ethanol, but by different mechanisms. Based on the above findings, Star-99 may have great significance and good prospects in the future treatment of HCC.

Abstract

AIM: To evaluate the value of right trisectionectomy, previously named right trisegmentectomy, in the treatment of primary liver cancer by summarizing our 13-year experience for this procedure.

METHODS: Thirty three primary liver cancer patients undergoing right trisectionectomy from Apr. 1987 to Dec. 1999 were investigated retrospectively. The impacts in survival of patients by cancerous biological behavior, such as tumor thrombi and satellite nodules, were discussed respectively. All right trisectionectomies were performed under normothermic interruption of porta hepatis at single time. Ultrasonic dissector (CUSA system 200) was used in dissection of hepatic parenchyma from Nov. 1992, instead of finger fracture.

RESULTS: 1-, 3- and 5-year survival rates were 71.9 %, 40.6 % and 34.4 %, respectively. The longest survival term with free cancer was 150 months (alive). There were no significant differences in survival curves between cases with and without tumor thrombi (right branch of portal vein) and satellite nodules. Operative mortality was 3.0 % (1/33). Main surgical complications occurred in 5 cases.

CONCLUSION: Right trisectionectomy should be regarded as an effective and safe procedure for huge primary liver cancers and is worth using more widely.

INTRODUCTION

It has been documented that primary liver cancer has been the more common cancer killer worldwide, especially in the areas with high incidence, such as China^[1]. Several methods has been developed for the therapy of the malignancy^[2-11]. The outcomes have taken marked progress, but recurrence and metastasis rates remain high^[12,13]. Up to now, the difficult point is still existing in treatment of large liver cancers, due to worse results and higher risk^[14,15]. Since the middle of last century^[16], right trisectionectomy (previous trisegmentectomy) has been used for huge hepatic neoplasms covering right and left medial section. In 1975, Starzl described and clearly defined in detail a safe technique of the right trisectionectomy^[17]. Then he reported on 30 cases of the operation in 1980, including malignant and benign hepatic lesion^[18]. In the past two decades, some papers described the

procedure in treatment of hepatic malignant neoplasm, such as liver infiltration of gallbladder cancer and metastatic and primary liver cancer^[19-23]. Most reports demonstrated that right trisectionectomy was effective in extensive hepatic malignancy, based on some individuals with long-term survival^[19, 20]. But the risk (morbidity and mortality) of liver resection remains high according to some authors^[20, 22, 23], especially for primary liver cancer with cirrhosis. It is related to the fact that most primary liver cancer patients have a history of hepatitis and suffer a higher incidence of hepatic failure after major resection. Another reason perhaps, is occurrence of bleeding during the operation. Currently, we lack data about comprehensive evaluation of right trisectionectomy in treatment of primary liver cancer. In this study, we investigate 33 cases of right trisectionectomies retrospectively to explore the value of the procedure to deal with primary liver cancer patients.

MATERIALS AND METHODS

Patients

From April 1987 to December 1999, total of 459 primary liver cancer patients were hepatomized. Of them, 33 cases of right trisectionectomies were performed. There were 24 (72.7 %) males and 9 (27.3 %) females. Ages ranged from 15 to 69 years (mean \pm SD, 45.9 \pm 16.7 years). Hepatitis B surface antigen (HBsAg): 28 (84.8 %) were positive and 5 (15.2 %) were negative. There were 8 (24.2 %) with slight cirrhosis and 25 (75.8 %) without. Child-Pugh's classification: 22 (66.7 %) were A grade and 11 (33.3 %) were B grade when the patients were hospitalized, but they were all A grade before surgical procedures through positive hepatic protective therapy. α -fetoprotein (AFP): 27 (81.8 %) were elevated and 6 (18.2 %) were normal. And the highest value of AFP was 20 000 ng/ml. Sizes of tumor ranged from 8 to 20 cm (mean \pm SD, 13.9 \pm 3.4 cm). Staging (TNM^[24]) of Cancer: All tumors were stage IV_A (T₄N₀M₀). Pathology: 27 (81.8 %) were hepatocellular carcinoma, 2 (6.1 %) were cholangiocarcinoma and 4 (12.1 %) were mixed hepatocellular-cholangiocarcinoma. There were 17 cases (51.5 %) with tumor thrombi in the right branch of the portal vein. 19 macroscopic satellite nodules were found in 15 cases (45.5 %), and they didn't presented in left lateral section of the liver.

Evaluation for feasibility of surgery

The feasibility of right trisectionectomy for each patient was considered carefully according to the following standards: (1) Tumors (including satellite nodules no more than 2) were limited in right and left medial section of the liver. There weren't any evidence about cancer invasion in left lateral section. (2) Tumor masses had clear borders or pseudocapsule, and without tumor thrombus in trunk of portal vein and hepatic vein. (3) No evidence for distant metastasis. (4) Compensative enlargement of left lateral section. (5) Child-Pugh's classification of liver function was A and indocyanine green retention rate at 15 minutes (ICGR15)^[25] was lower than 15 % before surgery. (6) Serum bilirubin smaller than 34 mmol·L⁻¹, serum albumin higher than 30 g·L⁻¹ and serum prothrombin time larger than 60 % before surgery.

The situations of tumor were detected chiefly by image examinations, including B-type ultrasonography, computed tomography (CT), magnetic resonance imaging (MRI) and

angiography. To assess liver function reserve of these patients before operation, we adopted classical Child-Pugh's classification, ICGR test and some concrete parameters, as described in standards. 146 cases of huge primary liver cancer were eliminated from the indication according to above standards. Of them, 69 cases were due to advanced tumor and the rest 77 due to bad liver function reserve.

Surgical procedures

All of the right trisectionectomies were on standard style, i.e. the resection edges were along the falciform ligaments of the liver and removed blocks were Couinaud segments 4 to 8. From November 1992, the ultrasonic dissector (CUSA system 200) was adopted for dissecting hepatic parenchyma, instead of previous finger fracture technique, introduced by Lin *et al.*^[26]. The procedures were all performed under normothermic interruption of porta hepatis at single time. Interruption lasted 15 to 40 minutes (mean \pm SD, 25.3 \pm 6.8 minutes). The total surgical time ranged from 165 to 312 minutes (mean \pm SD, 236 \pm 63 minutes). The amount of bleeding ranged from 300 to 3 000 ml (mean \pm SD, 1 240 \pm 560 ml). The quantities of transfused blood ranged from 0 to 2 200 ml (mean \pm SD, 1 020 \pm 550 ml). There were 2 cases that did not require blood transfusion during right trisectionectomy. For dissection of the liver parenchyma, we used finger fracture in 9 cases (27.3 %) before November 1992 and ultrasonic dissector (CUSA System 200) in 24 cases (72.7 %) after the time. Net weight of specimens ranged from 1 500 to 3 100 g (mean \pm SD, 2 330 \pm 520 g).

Adjuvant therapy and follow-up

All patients were covered in our strict follow-up after the procedure. AFP, B-type ultrasonography, computed tomography (CT) magnetic resonance imaging (MRI) and angiography were used as monitors of recurrence and metastasis. Moreover, follow-ups by mail, E-mail and telephone were taken for patients without reexaminations every year. Follow-up terms were 3 to 150 months. The latest follow-up was in November 2000 and survival terms of patients alive were calculated to October 2000. When the recurrences were

found, they were treated by transcatheter arterial chemoembolization (TACE), percutaneous ethanol injection (PEI) etc. 11 patients underwent TACE, 5 patients underwent PEI and 7 patients underwent both.

Statistical analysis

Survival curves were analyzed by Kaplan-Meier and Log rank test. The χ^2 and Student *t* test were used to determine comparability of groups. Statistically significant *P* value was defined as <0.05.

RESULTS

Survival rates, recurrence and metastasis after right trisectionectomy

The postoperative survival rates at 1-, 2-, 3-, 4- and 5-years were 71.9 %, 50 %, 40.6 %, 37.5 % and 34.4 %, respectively (Kaplan-Meier method). Ten cases have survived from 13 to 150 months according to the November 2000 follow-up. Survival curve of all patients is shown in Figure 1. The longest tumor-free survival term was 150 months (alive). The clinicopathological features in cases with and without satellite nodules and tumor thrombi in the right branch of the portal vein are shown in Table 1, and their survival curves were presented in Figure 2 and 3, there were no significant differences (*P*>0.05, Log rank test). During follow-up term, recurrence and metastasis of cancer was found in 27 patients (81.8 %).

Operative mortality after right trisectionectomy

There was one patient who died of hepatic failure within one month after the operation. The operative mortality was 3.0 % (1/33).

Surgical complications after right trisectionectomy

There were 5 cases (15.2%) that developed main surgical complications after right trisectionectomies, including 2 cases of hepatic failure, 2 cases of bile leakage and 1 case of secondary bleeding. Four patients recovered by positive reoperation excluding 1 case of hepatic failure.

DISCUSSION

In the therapy of primary liver malignancy, curative hepatic resection has been regarded as a primary method for radical treatment. But for hepatoma mainly in the right lobe and which invades the medial section of the left lobe, resection has always been difficult. Despite the fact that there has been research about right trisectionectomy, previous trisegmentectomy, mortality and morbidity remains high. There are few studies with large sample groups of primary liver cancer patients treated with right trisectionectomy. Starzl^[18] reported on 19 cases of primary hepatic malignant tumors (14 primary liver cancers and 5 other types of tumors) treated by the procedure. The 1-year survival rate was more than 50 %. Holbrook *et al*^[27] reported on 13-years of experience in resection of malignant primary liver tumors, including 9 right trisectionectomies. Overall 1-, 2-, 3-, and 5-year survival rates were 57 %, 52 %, 40 % and 33 %, respectively. Mortality was 7 % and

complication incidence was 26 %. Kumada *et al*^[28] reported on 11 cases of tri- and bi-sectionectomy for HCC, mean survival time was 16 months, mortality was 15.4 %. We had reported 4 right trisectionectomies to treat extensive primary liver cancers in 1991^[29]. Three cases survived more than 1 year. From April 1987 to December 1999, we performed 33 right trisectionectomies for primary liver cancer patients, 1-, 2-, 3-, 4- and 5-year survival rates were 71.9 %, 50 %, 40.6 %, 37.5 % and 34.4 %, respectively. The longest term of survival with free cancer was 150 months. Mortality was 3.0 % and the surgical complication rate was 15.2 %. These results are related to new advances in liver surgery. To control severe intraoperative bleeding, we used normothermic interruption of the porta hepatis at single time. Previously, we reported on 20 cases of hemihepatectomy using this interruption method. Manipulation appeared simple and convenient. Mortality was 0 %^[30]. These data suggested that normothermic interruption of the porta hepatis at single time should be regarded as an effective and safe method to limit bleeding in liver surgery. There were two patients in this study that were trisectionectomized without blood transfusion. Besides, the use of ultrasonic dissector in later period made the operative fields more clear. Thus, manipulations became more convenient and accurate. Meanwhile, the low incidence of complications and mortality were related to the accurate estimation of liver functional reserve prior to operation. We adopted the Child-Pugh's classification, some detailed parameters and ICGR test. Child-Pugh's classification was a classical method for estimating liver function. It could become more accurate if helped by other concrete markers, such as serum bilirubin, prothrombin time and albumin. Besides, ICGR test, a proven sensitive indicator of liver function reserve^[25], also provided important information. Our experience is that the combination of these parameters could accurately predict liver function reserve.

In the present study, we analyzed the influence of some pathological features on outcome of right trisectionectomy for huge primary liver cancers. The clinicopathological features showed in Table 1 suggested the comparability between patients with and without tumor thrombi or satellite nodules (all $P>0.05$). And no significant differences could be found in their survival curves ($P>0.05$), in spite of some differences in these curves. These findings suggest that surgeons should use curative resection in therapy of huge tumors, even in those with a few satellite nodules and tumor thrombi, if the tumor thrombi are only in the right branch of the portal vein, a satisfactory effect could be expected.

In conclusion, right trisectionectomy is an effective and safe procedure and should become one of strategies, and surgical arts in the treatment of huge tumor of primary liver cancers.

Abstract

AIM: To investigate the role of glycylproline dipeptidyl aminopeptidase (GPDA) isoenzyme in the diagnosis of primary hepatocellular carcinoma (PHC), especially in patients with negative alpha-fetoprotein (AFP).

METHODS: A stage gradient polyacrylamide gel discontinuous electrophoresis system was developed to separate serum GPDA isoenzymes, which were determined in 102 patients with PHC, 45 cases with liver cirrhosis, 24 cases with chronic hepatitis, 35 cases with benign liver space-occupying lesions, 20 cases with metastatic liver cancer and 50 cases with extra-hepatic cancer, as well as 80 healthy subjects. The relationships between GPDA isoenzymes and AFP, the sizes of tumors, as well as alanine aminotransferase (ALT) were also analyzed.

RESULTS: Serum GPDA was separated into two isoenzymes, GPDA-S and GPDA-F. The former was positive in all subjects, while the latter was found mainly in majority of PHC (85.3 %) and a few cases with liver cirrhosis (11.1 %), chronic hepatitis (33.3 %), metastatic liver cancer (15.0 %) and non-hepatic cancer (16.0 %). GPDA-F was negative in all healthy subjects and patients with benign liver space-occupying lesions, including abscess, cysts and angioma. There was no correlation between GPDA-F and AFP concentration or tumor size. GPDA-F was consistently positive and not correlated with ALT in PHC, but GPDA-F often converted to negative as decline of ALT in benign liver diseases. The electrophoretic migration of GPDA-F became sluggish after the treatment of neuraminidase.

CONCLUSION: GPDA-F is a new useful serum marker for PHC. Measurement of serum GPDA-F is helpful in diagnosis of PHC, especially in patients with negative AFP. GPDA-F is one kind of glycoproteins rich in sialic acid.

INTRODUCTION

Glycylproline dipeptidyl aminopeptidase (GPDA) was discovered by Hapsu-Hava and Glenner in 1966^[1]. It is widely distributed in human and animal tissues and catalyzes the

hydrolysis of N-terminal glycylproline from glycylprolyl- β -naphthylamide and glycylproline- β -nitroanilide. It was reported that serum GPDA activity increased in the patients with hepatobiliary diseases and in experimental hepatic cancer^[2, 3]. Further studies demonstrated that GPDA activity was significantly higher in human hepatic cancer and embryonal tissues than in healthy adult liver tissues^[4]. However, serum GPDA cannot be used as a marker for PHC due to its low sensitivity and specificity in diagnosis.

In order to improve the diagnostic value of GPDA for PHC, a stage gradient polyacrylamide gel discontinuous electrophoresis system was established to separate serum GPDA into two isoenzymes, and clinical significances of serum GPDA isoenzymes in diagnosis of PHC were studied.

MATERIALS AND METHODS

Patients and healthy subjects

The resources of all patients in this study were from Affiliated Hospital of Nantong Medical College. The diagnosis of PHC met the diagnostic criterion of Liver Cancer Branch Committee of Chinese Anti-cancer Association. The diagnosis in 35 patients was confirmed pathologically. The origins of 20 metastatic liver cancers were gastrointestinal tract cancer (16 cases), lung cancer (2 cases) and breast cancer (2 cases). The origins in 50 cases with extra-hepatic cancer were gastrointestinal tract (22 cases), pancreas (5 cases), bile duct (6 cases), ovary (8 cases), bladder (4 cases), lung (4 cases) and kidney (1 case). Thirty-five benign liver space-occupying lesions were composed of 8 liver abscess, 2 liver cysts and 25 liver angioma. The diagnoses of 45 cases with hepatic cirrhosis and 24 chronic hepatitis were based on clinical manifestations and liver biopsy. The control samples came from healthy blood donor.

Detection of GPDA isoenzymes

Separation of GPDA isoenzymes was performed on stage gradient polyacrylamide gel with a vertical slab electrophoresis apparatus. The gel consists of one layer of stack gel and two layers of separating gels. The following solutions were used for the preparation of gels: (1) Solution A: 30 % acrylamide containing 0.8 % bisacrylamide; (2) Solution B: 4.95 % Tris base containing 0.05 % TEMED, pH6.9; (3) Solution C: 0.14 % ammonium persulfate. A gel of dimensions of 12.0 cm \times 10.0 cm \times 0.15 cm was prepared and loaded with 20 μ l of serum. The gel run at a constant voltage of 60 V for the first three hours and then at the voltage of 100 V for another 16 hours. After the electrophoresis, the gel was incubated at 37 $^{\circ}$ C for 30 min with a piece of acetate cellulose membrane of the gel size pre-soaked with a substrate solution, which consists of 15 mg of glycylproline- β -nitroanilide, 4.8 ml of 100 mmol \cdot L⁻¹ Tris-glycylglycine (pH 8.4), 0.1 ml of 100 ml \cdot L⁻¹ sodium nitrite and 0.1 ml of 50 g \cdot L⁻¹ N-(naphthyl)-ethylenediamine dihydrochloride. Finally red GPDA isoenzyme bands were visualized soon by immersing the acetate cellulose membrane into a solution composed of 100 ml \cdot L⁻¹ trichloroacetic acid and 250 ml \cdot L⁻¹ glycerol.

Measurement of AFP and ALT

ALT was measured with the method recommended by International Federation of Clinical Chemistry^[5] and AFP was determined with routine radioimmunoassay.

Treatment of serum with neuraminidase

Serum was incubated with 10 u/ml neuraminidase at 37 °C for 15 hr before electrophoresis.

Statistical analysis

Chi-square test and student *t* tests were used. $P < 0.05$ was considered as statistically significant.

RESULTS

Serum GPDA isoenzyme in patients with PHC and other diseases

Serum GPDA was separated into two isoenzyme bands with the electrophoresis system (Figure 1). The band in the anode was called as GPDA-F (fast band) and the band in cathode as GPDA-S (slow band). GPDA-S was positive in all subjects, including healthy persons and patients, while positive rates of GPDA-F varied in different diseases. GPDA-F was found in most patients with PHC and a few patients with benign liver diseases and extra-hepatic cancer, but no GPDA-F was found in all healthy persons and the patients with benign liver space-occupying lesions (Table 1). In patients with PHC, positive GPDA-F was considered as true positive and negative GPDA-F as false negative, while in patients with other diseases positive GPDA-F was considered as false positive and negative GPDA-F as true negative. Therefore, the sensitivity, specificity and accuracy of GPDA-F in diagnosis of PHC were 85.3 %, 86.2 % and 85.9 % respectively (Table 1).

Figure 1 Serum GPDA isoenzymes separated with polyacrylamide electrophoresis. (Lane 1: healthy subject; lane 2: liver angioma; lane 3: chronic hepatitis; lane 4: liver cirrhosis; lane 5: PHC).

Table 1 Results of serum GPDA-F in patients and healthy subjects

	GPDA-F (+)		GPDA-F (-)	
	<i>n</i>	%	<i>n</i>	%
Healthy subjects	0	0	80	100.0
PHC	87 ^a	85.3	15	14.7
Liver cirrhosis	5	11.1	40	88.9
Chronic hepatitis	8	33.3	16	66.7
Benign liver space-occupying lesions	0	0	35	100.0
Metastatic hepatic cancer	3	15.0	17	85.0
Extra-hepatic cancer	8	16.0	42	84.0

^a $P < 0.05$ vs other groups. True positive (TP)=87; False positive (FP)=24(5+8+0+3+8); False negative (FN)=15; True negative (TN)=150(40+16+35+17+42); Sensitivity=TP/(TP+FN)×100 %; Specificity=TN/(TN+FP)×100 %; Diagnostic accuracy=(TP+TN)/(TP+TN+FP+FN)×100 %.

The complementary value of GPDA-F and AFP for PHC

There was no correlation between positive rates of GPDA-F and AFP concentration (Table 2). GPDA-F was positive in 75.0 % PHC cases with negative AFP (<50 ng/ml). If positive GPDA-F and AFP≥50 ng/ml were set as diagnostic criterion of PHC, the

sensitivity of AFP was 72.5 % and that of AFP with GPDA-F would reach up to 91.2 %. The diagnostic accuracy was also increased with the combination of AFP and GPDA-F (Table 3).

Table 2 Relationship between AFP and GPDA-F in sera of cases with PHC

AFP(ng/ml)	<i>n</i>	GPDA-F(+)
<50	28	21(75.0%)
≥400	12	11(91.6%)
>400	62	55(88.7%)

Table 3 Diagnostic value of both AFP and GPDA-F in PHC

	Sensitivity (%)	Specificity (%)	Accuracy (%)
AFP alone	72.5	95.2	85.0
GPDA-F alone	85.3	87.1	86.3
AFP and GPDA-F	91.2	84.7	88.5

The relationship between GPDA-F and tumor size

One hundred and two cases with PHC were divided into two groups based on size of tumor, 23 cases were small liver cancer with tumor diameter ≤5 cm and 79 cases were advanced liver cancer with tumor diameter >5 cm. Positive rate of GPDA-F was 78.3 % (18/23) in small liver cancer, and 87.3 % (69/79) in advanced liver cancer. However, there was no statistical difference between the two groups ($P > 0.05$).

Characteristics of GPDA-F in PHC and benign liver diseases

In order to know whether GPDA-F is associated with inflammation of hepatocytes, GPDA-F and ALT were measured simultaneously. There was no significant difference of ALT activities between positive and negative GPDA-F groups in PHC, but ALT activities in positive GPDA-F group were significantly higher than that in negative group in liver cirrhosis and chronic hepatitis (Table 4), suggesting that GPDA-F was associated with elevated ALT in benign liver diseases, but not in PHC. It was also found that GPDA-F often converted to negative with the decrease of ALT in benign liver diseases but no in PHC (data not shown).

Table 4 Relationship between GPDA-F and ALT in different liver diseases

	ALT ($\bar{x} \pm s$, u/L)		
	PHC	Hepatic cirrhosis	Chronic hepatitis
Negative GPDA-F	31.0±9.6	31.6±3.6 ^a	67.3±13.2 ^a
Positive GPDA-F	50.1±10.2	67.6±31.6	159.8±46.6

^a $P < 0.05$ vs positive GPDA-F group.

Effects of neuraminidase on GPDA-F

Serum was treated with neuraminidase before electrophoresis as mentioned in materials and methods. The migration rate of GPDA-F became slower than that of GPDA-S following treatment of neuraminidase, while GPDA-S was not obviously affected (Figure 2).

Figure 2 The effect of neuraminidase on migration of serum GPDA isoenzymes. (Lane 1: before treatment of neuraminidase; lane 2: after treatment of neuraminidase).

DISCUSSION

PHC is one of the most severe malignancies and ranks second mortality in malignant tumors in China^[6,7]. The prognosis is poor due to its delayed diagnosis and low resectable rate. Thus early diagnosis is important to improve the prognosis. Tumor markers are very useful in diagnosis. AFP is the most widely used tumor marker for PHC with a positive rate from 60 % to 70 %^[8-11]. AFP-L-3, one of the glycoforms of AFP, has higher specificity for PHC. However, it cannot increase the diagnostic sensitivity^[12-16]. Many studies have focused on other tumor markers to improve the diagnostic sensitivity for PHC. It has been found that there are some tumor markers, which are complementary to AFP in diagnosis of PHC, such as des-gamma-carboxy prothrombin (PIVKA-II)^[17-23], γ -glutamyltransferase isoenzyme^[24-26], transforming growth factor- β 1^[27-29] and α -L-fucosidase^[30-34].

In present study, we have investigated the value of GPDA isoenzymes in diagnosis of PHC. With a stage gradient polyacrylamide gel electrophoresis system, serum GPDA has been separated into two isoenzymes, GPDA-F and GPDA-S. GPDA-F was often detected in sera of patients with PHC, with a much higher positive rate than in other liver diseases, including liver cirrhosis, chronic hepatitis, metastatic liver cancer and extra-hepatic tumors; while GPDA-F was negative in healthy subjects and patients with benign liver space-occupying lesions. The sensitivity and specificity of GPDA-F in diagnosis of PHC were 85.3 % and 86.2 %, respectively. These results indicate that GPDA-F may be a valuable serum marker for PHC.

Serum GPDA-F in patients with benign liver diseases possibly originates from the inflammatory hepatocytes because in such cases positive GPDA-F was often accompanied by elevated ALT and changed to negative with the decline of ALT. On the contrary, GPDA-F in PHC is persistently positive and not correlated with ALT. Therefore, simultaneous determination and follow-up of ALT may help to rule out the false positive GPDA-F in benign liver diseases. It is known that some serum hepatoma markers are of predictive and early diagnostic value for PHC, such as AFP, des-gamma-carboxy prothrombin and gamma-glutamyltransferase isoenzyme II^[21-23, 26]. Whether persistent positive of GPDA-F in a few cases of liver cirrhosis is the precursor of hepatocarcinogenesis needs further investigation.

Although the diagnostic efficiency for PHC has been greatly improved in recent years with the use of many advanced image techniques, it is still difficult to make the diagnosis in some cases, especially for those at early stage or with negative AFP. Present study showed that GPDA-F and AFP were complementary for diagnosis of PHC. In these data, GPDA-F was positive in 75 % PHC cases of negative AFP but negative in all benign liver space-occupying lesions. Therefore, GPDA-F is of special value for the differential diagnosis of liver space-occupying lesions of unknown nature. Our data also showed that there was no correlation between tumor size and GPDA-F. In 23 cases of small liver cancer, the positive rate of GPDA-F was 78.3 %, suggesting that GPDA-F may be a good marker of PHC at early stage.

The exact mechanism by which GPDA-F appears in the sera of PHC cases is not clarified. It is possible that GPDA-F is produced by hepatoma tissues and then released into blood, since GPDA-F was only found in sera of those PHC cases in whose hepatoma tissues GPDA-F was positive (unpublished data). The electrophoretic migration of GPDA-F became slower than its isoenzyme GPDA-S after treatment with neuraminidase, indicating that GPDA-F is a kind of glycoprotein rich in sialic acids in its sugar chain. Therefore, the modification of the sugar chain after GPDA protein synthesis may be the main process of the production of GPDA-F. It has been known that several

kinds of glycoproteins synthesized by hepatoma cells are different from those produced by hepatocytes. For example, AFP and alpha-1-antitrypsin have higher percentage of lens culinaris agglutinin-reactive species in hepatocellular carcinoma than in benign liver diseases. It is also clear that the fucosylation of the sugar chain at the innermost N-acetylglucosamine is the molecular basis of this variation^[35, 36]. Whether there is the difference of fucosylation of GPDA isoenzymes between hepatocellular carcinoma and benign liver diseases needs to be studied further.

Abstract

AIM: To construct and express ODC recombinant gene for further exploring its potential use in early diagnosis of colorectal carcinoma.

METHODS: Total RNA was extracted from colon cancer tissues and amplified by reverse-transcription PCR with two primers, which span the whole coding region of ODC. The synthesized ODC cDNA was cloned into vector pQE-30 at restriction sites BamH I and Sal I which constituted recombinant expression plasmid pQE30-ODC. The sequence of inserted fragment was confirmed by DNA sequencing, the fusion protein including 6His-tag was facilitated for purification by Ni-NTA chromatographic column.

RESULTS: ODC expression vector was constructed and confirmed with restriction enzyme digestion and subsequent DNA sequencing. The DNA sequence matching on NCBI Blast showed 99 % affinity. The vector was transformed into *E. coli* M15 and expressed. The expressed ODC protein was verified with Western blotting.

CONCLUSION: The ODC prokaryote expression vector is constructed and thus greatly facilitates to study the role of ODC in colorectal carcinoma.

INTRODUCTION

Ornithine decarboxylase (ODC) is the first key enzyme of the biosynthesis of polyamine which catalyzes the decarboxylation of the amino acid ornithine to the diamine putrescine. Its activation regulates the metabolism of spermidine, spermine and their precursor putrescine. Activity of polyamine biosynthesis is closely associated with the proceeding of

physiological cell growth, proliferation and regeneration^[1] and pathological proliferation^[2]. It is necessary for cell to progress into S phase, or polyamine depletion arrest cells in G1^[3]. ODC activity and polyamine concentration in colorectal cancers are significantly elevated compared with that in normal adjacent and healthy control tissues on rodents^[4-7] and human beings. ODC repressor (eg. Difluoromethylornithine) has been considered to be one of the molecular targeted interventions of colon cancer^[8]. The changing of ODC activity is an early event during the expression of malignancy. In this study, an ODC expression vector expressing a 6His-tag fusion protein was successfully constructed. The 6His-tag enabled us to purify the fusion protein with high purity.

MATERIALS AND METHODS

Materials

Trizol, RNA extract reagent, were purchased from Life Technologies Inc. RT-PCR kit, T-A clone kit, DNA marker and all restrictive enzymes were purchased from TaKaRa Shuzo Co.Ltd. Primers were synthesized by Sangon. The QIAquick Gel Extraction Kit, and expression system were got from QIAGEN. Protein marker was purchased from Shanghai Lizhudongfeng biotechnologies Co.Ltd. Standard ODC was purchased from Sigma.

Tissues

Colorectal carcinoma and respective adjacent normal colorectal mucus were obtained during surgery. Once the specimens were removed during operation, the necrotic and ulcerated tumors were removed and the normal mucosa was dissociated from the muscle and connective tissue. All specimens were then kept in liquid nitrogen until further use.

Extraction of total RNA

The total cellular RNA was extracted from normal and cancer tissues, respectively. The method of RNA extraction was similar to the Trizol RNA extraction protocol (Life Technologies Inc.). The concentration of RNA extracted was determined at wavelength of 260nm using U-2000 spectrophotometer (HITACH Ltd, Tokyo, Japan).

Reverse transcription polymerase chain reaction (RT-PCR)

The sequence of ODC primers was as follows, up-stream primer: 5' - gca ggatcc acc atg aac aac ttt ggt aa; down-stream primer: 5' -gaa gtcgac cta cac att aat act agc cg. The 5' primer recognized the start codon of ODC in exon 3, and the 3' primer recognized the end-codon in exon 12. Restriction sites were BamH I and Sal I. The first strand of cDNA was synthesized at 55 °C for 30 min in the presence of AMV reverse transcriptase (0.5 unit/μl), RNase inhibitor 1 unit/ml, dNTP 1.0 mM, Mg²⁺ 2.5 mM. The PCR was processed through 35 cycles of denature (1 min at 95 °C), annealing (1.5 min at 58 °C), and extension (1 min at 72 °C) (Perkin-Elmer2400 PCR apparatus).

Purification of PCR product and T-A cloning

The PCR products were separated in 1 % agarose gel, and the

band containing ODC cDNA was cut off and placed into the QIAquick spin column, the ODC cDNA was purified and linked to plasmid pMD-18 with a polyA linker. The recombinant was transformed into *E. coli* DH5 α and selected by selective culture medium containing ampicillin.

Construction of pQE30-ODC

The pMD-ODC and pQE30 were digested by restrictive enzymes BamH I and SalI. The inserted fragment of pMD-ODC was collected from electrophoretic gel, then it was ligated with the linearized pQE30 by T4 Ligase at 18 °C overnight. The recombinant was transformed into *E. coli* DH5 α by CaCl₂ method and selected by agar plate containing ampicillin and confirmed by restriction enzyme mapping. The positive recombinant was transformed into *E. coli* M15. The sequence of inserted fragment was confirmed by DNA sequencing (Shanghai Sangon Bioengineering Co.Ltd.).

The expression of ODC fusion protein

The ampicillin-resistant colony of *E. coli* cells transformed with plasmid were cultured in LB cultural medium containing 100 mg/L ampicillin and 25 mg/L Kanamycin, and induced by 1 mM IPTG. The cultured cells were harvested at 1, 2, 3, 4hr after culture, respectively. The optimum time of maximum expression of proteins was analyzed through SDS-PAGE. The expressed ODC protein was tested through Western blot with specific antiserum.

RESULTS

RT-PCR amplification of ODC encoding sequence

RT-PCR was done with total RNA template extracted from human colon cancer. The designed primers include encoding sequence of ODC. Electrophoresis of RT-PCR products confirmed the length of RT-PCR fragment (1 480 bp) (Figure 1).

The purified ODC cDNA was ligated to pMD-18 by T-A complimentary pairing. ODC cDNA was inserted into pQE30 at BamH I and Sal I sites (Figure 2).

Sequence analysis

Sequence of inserted DNA was analyzed with automatic sequence analyzer and found to be about 1 500 bp in size and showed 99 % affinity in comparison with DNA sequence published on line [gi: 4505488].

SDS-PAGE and western blotting

Inserted ODC gene was expressed significantly in the prokaryotic expression system, and specific strip at 50kDa was demonstrated in Western blot. The optimum induction period is 4hr after administration of IPTG (Figure 3, 4).

Figure 4 Western blot shows a strip of 50kD indicating the expression of ODC protein.

DISCUSSION

The polyamines are naturally occurring aliphatic polycations found in almost all living cells^[9]. They are positively charged at neutral pH and the charge is distributed along the length of the molecule. This facilitates their interaction with anionic molecules such as DNA and RNA^[9,10]. Polyamines have been shown to be essential for optimal rates of cell growth and differentiation, with high concentrations being found in rapidly growing cells and tissues^[11].

Cancer cells always have a higher intracellular polyamine content than the equivalent normal tissue^[12-15]. In addition to changes in polyamine content, ODC activity has also been found to be increased significantly in colon adenocarcinoma tissue compared to microscopically normal tissue from the same patients^[13,16]. Similar findings were observed in human colonic surgical specimens with both ODC activity and polyamine content of the malignant tissue being increased^[16,17]. Intratumour content of spermidine and spermine was increased in line with the increase in ODC activity.

Ornithine decarboxylase (ODC) is a rate-limiting enzyme in the biosynthesis of polyamines, and is induced in response to many growth stimuli such as hormones, growth factors, and tumor promoters, it has a rapid turnover rate with half-life at 15 minutes^[18]. Numerous studies have demonstrated that regulation of ODC can occur at multiple levels, including the transcription of protooncogene c-myc^[19-22], mRNA translation^[10,23,24], protein turnover^[10,25,26], and post-transcriptional interactions and modifications^[27-30]. Recent studies focus intensely on ODC and

polyamine regulation as therapeutic targets. Inhibitors of ODC were found to suppress tumor formation in experimental models of bladder, breast, colon, and skin carcinogenesis^[31-35].

Colorectal cancer is a major health problem in the western world and is associated with significant morbidity and mortality. First-line therapy is radical surgery with adjuvant chemotherapy commonly being treatment with antimetabolites such as 5-fluorouracil^[30]. Although great clinical efforts have been made for the therapy of colorectal cancer with new technologies, such as CT or MRI colography^[4,14], there is still much to be done on the early diagnosis and treatment. It is suggested that ODC activity and polyamine content may have interest in the diagnosis of malignancy and prognosis^[15]. As the change of ODC activity is an early event in the development of the disease, it may be helpful for early screening and diagnosis of colon cancer.

We designed two primers from human ODC gene including the start codon (ATG) in exon 3 and the termination codon (TAG) so as to amplify the whole encoding sequence about 1 480 bp of ODC. The exons encode a protein is identical to the 461-amino acid sequence derived from human ODC.

The restriction fragment mapping of the recombinant, pQE 30-ODC, indicated that the inserted fragment was about 1.5kb, which was consistent with the encoding sequence of ODC. ODC activity in the lysate of transformed M15 was demonstrated through Western blot. The expressed fusion protein is about 50kDa, which is similar to the known ODC protein. The construction and expression of recombinant ODC provide a tool for ODC related further study.

Abstract

AIM: To evaluate results of pre-operative radiochemotherapy followed by surgery for 15 patients with locally advanced un-resectable rectal cancer.

METHODS: 15 patients with advanced non-resectable rectal cancer were treated with pre-operative irradiation of 40-46 Gy plus concomitant chemotherapy (5-FU+LV and 5'-DFuR) (RCS group). For comparison, 27 similar patients, treated by preoperative radiotherapy (40-50 Gy) plus surgery were served as control (RS group).

RESULTS: No radiochemotherapy or radiotherapy was interrupted and then was delayed because of toxicities in both groups. The radical resectability rate was 73.3 % in the RCS group and 37.0 % ($P=0.024$) in RS group. Sphincter preservation rates were 26.6 % and 3.7 % respectively ($P=0.028$). Sphincter preservation rates of lower rectal cancer were 27.3 % and 0.0 % respectively ($P=0.014$). Response rates of RCS and RS groups were 46.7 % and 18.5 % ($P=0.053$). The tumor downstage rates were 8 (53.3 %) and 9 (33.3 %) in these groups ($P=0.206$). The 3-year overall survival rates were 66.7 % and 55.6 % ($P=0.485$), and the disease free survival rates were 40.1 % and 33.2 % ($P=0.663$). The 3-year local recurrent rates were 26.7 % and 48.1 % ($P=0.174$). No obvious late effects were found in either groups.

CONCLUSION: High resectability is possible following pre-operative radiochemotherapy and can have more sphincters preserved. It is important to improve the quality of the patients' life even without increasing the survival or local control rates. Preoperative radiotherapy with concomitant full course chemotherapy (5-Fu+LV and 5'-DFuR) is effective and safe.

INTRODUCTION

Neoadjuvant treatment is delivered as radiotherapy (RT) or radiochemotherapy (RCT) prior to surgery with the aim to devitalize primary and metastatic tumor cells and to shrink the tumor so that resection is facilitated even in case of primarily

nonresectable cases^[1-6]. The trials of several "neoadjuvant" radiochemotherapy have generated clear evidence downstaging is possible, resectability rates are increased, local relapse rates decreased, and survival rates possibly improved. Preoperative radiochemotherapy has been regarded as 'standard' therapy^[1,7].

The infusional chemotherapy protocol of 5-FU demonstrated a higher response rate and a marginal survival benefit in advanced colorectal cancer^[8]. The toxicity was lower in the infusion protocol than that in bolus protocol^[9]. In chemoradiotherapy with the infusion protocol, this advantage can still work and have a theoretically better chance of drug-radiation interaction as well^[10]. However, i.v. chemotherapy, either by infusion or bolus, is still a major source of discomfort to the patients.

Oral administration enables sustained exposure to 5-FU, avoids the technical barrier of intravenous (IV) administration and allows significant flexibility in choice of the dosage regimens, provided that efficacy is not compromised^[11,12]. Doxifluridine (5'-deoxy-5-fluorouridine, 5'-DFuR) is synthetic 5-deoxy-nucleoside derivative. In experimental murine tumor systems, doxifluridine has achieved a therapeutic index of 10-15 times greater than that of 5-FU or other fluoropyrimidines^[13]. This drug has been shown to be an effective agent when administered orally^[14]. The use of oral doxifluridine and leucovorin in chemoradiotherapy provides several advantages. Administration of the drug during the entire radiotherapy course offers more chances of interaction between the drug and radiation, similar to infusion chemoradiotherapy; i.v. infusion-associated complications can be avoided. The use of oral chemotherapy also provides convenience and a comfortable environment of drug administration to patients.

In our study, 15 patients received mean dose of 41.5 Gy of pelvic irradiation with concurrent chemotherapy of 5-FU+leucovorin (LV) was administered by bolus injection during d1-3 and d26-28 of RT. 5'-DFuR were given during d4-25 of RT (RCS group). 27 similar patients treated by preoperative radiotherapy (mean dose of 42.6 Gy) were served as control (RS group). The points of the study were to evaluate the toxicity, resectability rates and relative response rates of the treatment, 3-year survival rates and 3-year recurrent rates in the two groups.

MATERIALS AND METHODS

Patients

Patients with advanced non-resectable rectal cancer were considered eligible for radiochemotherapy plus surgery study (RCS group) if they fulfilled the following criteria: Below 72 years old, KPS of 60 or over, histologically confirmed adenocarcinoma of the rectum, advanced tethered and fixed primary tumor that were considered unresectable by surgeon. From December 1995 to January 1997, 15 patients were entered in the study. They were 12 men and 3 women and age ranging from 33 to 72 years (mean 50.6). For comparison, 27 similar patients, treated by preoperative radiotherapy (40-50 Gy) plus surgery served as control (RS group). They were 21 men and 6 women and age ranging from 18 to 71 (mean 58).

Table 1 summarized the main demography and baseline characteristics of all eligible patients. The two groups were well matched for all evaluated characteristics. All tumors of

two groups were middle and lower rectal cancers (5-11 cm from anus). 11 and 20 lower rectal cancers in RCS group and RS group respectively. Before starting treatment all patients underwent a general examination and got CBC done. These examinations were repeated every week during the treatment period and before operation ultrasound and/or CT or MRI and digital examination were mandatory. Digital examination was done every week.

Table 1 Patient demography and disease characteristics at baseline

Parameter	RCS group	RS group
Male/female	12/3	21/6
Age(years):median(range)	56(33-72)	58(18-71)
Karnofsky performance status	70-90	70-90

TNM staging		
T3N0M0	5	14
T3N1M0	0	3
T4N0M0	6	3
T4N1M0	4	5
T4N2M0	0	2

Treatment

Radiation was delivered by linear accelerator (10 MV X-ray). Similar fields were used for treatment in both groups. The initial pelvic radiation therapy volume of AP/PA ports and two lateral fields treated to 4 000 cGy. The use of a boost field to the primary tumor bed and immediately adjacent lymph nodes were given in some patients. Total doses of 4 000cGy to 4 600 cGy (mean 4 150 cGy) were delivered in 4 to 5 weeks in RCS group. Total doses of 4 000cGy to 5 000cGy (mean 4 260 cGy) were delivered in 4 to 5 weeks in RS group. In RCS group, chemotherapy was given concomitantly and consisted of two courses of 5-FU at a dose of 500 mg/m²/day plus leucovorin at a dose of 300 mg by intravenous injection for 3 days in week 1 and week 4, 5'-DFuR was administered orally at a dose of 200 mg three times daily concomitantly during radiotherapy between interval of the two courses of intravenous chemotherapy. All patients in two groups underwent subsequent surgery 4 to 5 weeks after the preoperative treatment. 4 to 6 courses adjuvant chemotherapy (5-FU based) were given after surgery in two groups.

Evaluation of patients

Assessments of tumor dimensions and involved sites were performed before the start of treatment and were scheduled after week 4. Tumor dimensions were assessed by use of computed tomography scans, x-rays, magnetic resonance imaging. Tumor response classification was based on standard World Health Organization criteria. Disappearance of all known disease at all involved sites was considered a complete response (CR). Partial response (PR) was defined as residual disease with a decrease=50 % in sum of the products greatest perpendicular diameters (SPD) of all indicator lesions. Progressive disease (PD) was defined as the appearance of a

new lesion or an increase of 25 % in the SPD. Stable disease (SD) was defined as no change in SPD or a change not reaching to PR or PD. Total response rate was defined as CR plus PR. Surgical treatment results were summarized (the radical resectability rate, sphincter preservation rate and complication).

Patients were followed up every 3 months after the end of treatment with progression and survival of the disease recorded. The duration of follow-up ranged from 36-61 months (mean 43). Disease progression and survival time were analyzed according to Kaplan-Meier estimates and compared using the log-rank test. A one-sided chi-square test was used at an alpha level of 2.5 % to compare response data in two patient groups. The data of toxicity were scored retrospectively according to the World Health Organization (WHO) toxicity evaluation.

RESULTS

Tumor response

No radiochemotherapy or radiotherapy was interrupted and was then delayed because of toxicities in both groups. Obvious pain relief has been achieved in all patients of two groups presenting with buttock/sciatic/perineal pain, usually within days of commencing radiochemotherapy/radiotherapy. The median time of obvious pain relief was 7 days (range 5-10) in RCS group, 10 days (range 7-18) in RS group.

11 radical resection, 3 palliative surgery and 1 cytoreductive surgery were undertaken in RCS group. 10 radical resection, 15 palliative surgery and 2 cytoreductive surgery were undertaken in RS group. Table 2 summarizes the radical resectability, sphincter preservation, lower rectal cancer sphincter preservation, response and tumor downstage rates of the two groups. Pathologic complete response (pCR) of the primary tumor was observed in two patients of RCS group.

Table 2 The radical resectability, sphincter preservation, lower rectal cancer sphincter preservation, response and tumor downstage rates in the two groups

Parameter	RCS group	RS group	P
Radical resectability rate	73.3%	37.0%	0.024
Sphincter preservation rate	26.6%	3.7%	0.028
Lower rectal cancer sphincter preservation rate	27.3%	0.0%	0.014
Response rate	46.7%	18.5%	0.053
Tumor downstage rate	53.3%	33.3%	0.206

Follow-up results

In Table 3 the 3-year overall survival rates, the disease free survival rates and the 3-year local recurrent rates are compared in the patients of two groups. Four patients of RCS group had good to excellent sphincter function.

Table 3 The 3-year overall survival, disease free survival and local recurrent rates of the patients of two groups

Parameter	RCS group	RS group	P
3-year overall survival rate	66.7%	55.6%	0.485
3-year disease free survival rate	40.1%	33.2%	0.663
3-year local recurrent rate	26.7%	48.1%	0.174

Toxicity

Patients were scored according to the WHO grading. A detailed description of acute toxicities was given in Table 4. The most relevant toxic reactions included rectal tenesmus, diarrhea and perianal area skin reaction. No toxic death was observed in

this study. No patient interrupted the radiochemotherapy and delayed the operation because of these acute toxicities. Total incidence of grade 3/4 toxicity were 73.3 % in RCS group, 44.4 % in RS group ($P=0.071$) respectively. No severe late toxicity was found in the two groups.

Table 4 WHO modified scale for acute toxicity

Site	Grading (RCS group)					Grading (RS group)				
	0	1	2	3	4	0	1	2	3	4
Hematologic:										
Neutropenia	8	2	4	1	0	19	3	5	0	0
Non-hematologic:										
Small bowel	4	3	7	3	0	6	9	10	2	0
Bladder	6	4	5	0	0	10	11	6	0	0
Skin	0	2	6	7	0	0	10	8	9	0

DISCUSSION

Preoperative radiotherapy (RT) (45 Gy) with continuous infusion of 5-FU for 5 days per week with or without CDDP were used by the M.D. Anderson group^[15] in locally advanced tethered and fixed primary rectal cancer to downstage the tumors. It was concluded that preoperative radiochemotherapy decreased the local recurrence rate as compared to preoperative radiotherapy only, with no increase of surgical morbidity and late morbidity after a follow-up of 3 years. In this study, the acute toxicities of grade 3 in RCS group were more pronounced than that in RS group but without statistical differences and no patient had interrupted the radiochemotherapy and delayed the operation because of these acute toxicities. University of Uppsala study^[16] proved that the volume of bowel under radiation, rather than the energy of the radiation influence postoperative mortality, and emphasize the importance of precise radiotherapy planning to minimize normal tissue toxic reactions.

Continuous infusion of 5-FU led to significantly higher response rates than bolus 5-FU, and a meta-analysis identified a statistically significant increase in overall survival^[17]. However, this improvement was the only report, and other trials had failed to repeat the significant survival benefit. Continuous infusion 5-FU is not routinely practised, partly because of its inconvenience and cost and partly due to central venous access that might cause significant complications in 15 % to 20 % of patients^[18], including infections, bleeding, thrombosis, and pneumothorax. Each of these complications has a negative impact on quality of life. Several of the new chemotherapy drugs used in colorectal cancer also appear to be radiosensitizers. Pilot and phase II trials incorporating irinotecan and oxaliplatin^[19] into 5-FU-plus-radiation program are currently used, with encouraging results. Similarly, the oral 5-FU prodrugs^[20,21] represent promising new agents to combine with radiation. The oral route not only makes these drugs convenient to the patient but also gives prolonged therapeutic serum levels, simulating continuous venous infusion, which may be the preferable fluoropyrimidine schedule for radiosensitization.

5-FU as a radiosensitizer was given by continuous infusion. 5'-DFuR kills cancer cell through PyNPase transformation. The study by Watanabe *et al.*^[22] found that fifty three patients with advanced colorectal cancer when given single oral doses of 5'-DFuR, high 5-FU concentration and PyNPase activity were noted in tumor tissue and lymph nodes. Effective 5-FU concentration in tumor tissue was maintained even 24 hours after treatment. Effective lymph node concentration of 5-FU was maintained even 8 hours after treatment. PyNPase activity in tumor tissue was significantly higher than that in the normal

intestinal mucosa ($P<0.05$). In this study, pre-operative radiochemotherapy was well tolerated. The relatively high rate of curative resections indicates that 5-FU and Oral 5'-DFuR treatment as radiosensitizers, maintaining higher concentrations of 5-FU during RT, are safe and effective. The aim of giving two courses of 5-FU intravenous injection was to relieve the local symptoms of the patients with local advanced rectal cancer and to improve systemic treatment efficacy. The appropriate dosage of oral 5'-DFuR as radiosensitizer during RT should be further studied.

Sphincter preservation rate and sphincter preservation rate of lower rectal cancer in RCS group were significantly higher than that of RS group. Therefore, this study at least demonstrates that sphincter preservation operation did not decrease local control and survival rates, although when local control and survival rates were analyzed, the RCS group had no significant advantage compared with RS group. But it is very important to meet the request of sphincter preservation by the rectal cancer patients and to improve their quality of life.

Local failure rates are high for locally irresectable primary or recurrent colorectal cancer, even when chemoradiation therapy is employed. A tumor-free surgical resection margins are paramount to achieve cure^[23-25]. In this study, the radical resectability rate in the RCS group was significantly higher than that in RS group, but without significant decrease local relapse rate, and no significant improvement of survival rate. Therefore, further study of this modality of treatment should be continued^[26-32].

Abstract

AIM: To compare the racial differences of anatomical distribution of colorectal cancer (CRC) and determine the association of age, gender and time with anatomical distribution between patients from America (white) and China (oriental).

METHODS: Data was collected from 690 consecutive patients in Cleveland Clinic Florida, U.S.A. and 870 consecutive patients in Nan Fang Hospital affiliated to the First Military Medical University, China over the past 11 years from 1990 to 2000. All patients had colorectal adenocarcinoma diagnosed by histology and underwent surgery.

RESULTS: The anatomical subsite distribution of tumor, age and gender were significantly different between white and oriental patients. Lesions in the proximal colon ($P<0.001$) were found in 36.3 % of white vs 26.0 % of oriental patients and cancers located in the distal colon and rectum in 63.7 % of white and 74 % of oriental patients ($P<0.001$). There was a trend towards the redistribution from distal colon and rectum to proximal colon in white males over time, especially in older patients (>80 years). No significant change of anatomical distribution occurred in white women and Oriental patients. The mean age at diagnosis was 69.0 years in white patients and 48.3 years in Oriental patients ($P<0.001$).

CONCLUSION: This is the first study comparing the anatomical distribution of colorectal cancers in whites and Chinese patients. White Americans have a higher risk of proximal CRC and this risk increased with time. The proportion of white males with CRC also increased with time. Chinese patients were more likely to have distal CRC and developed the disease at a significantly earlier age than white patients. These findings have enhanced our understanding of the disease process of colorectal cancer in these two races.

INTRODUCTION

Colorectal cancer (CRC) is one of the most common cancers in the world and the second leading cause of cancer death in the United States^[1, 2]. It is estimated that 552 000 Americans died of cancer in the year 2000; about 55 000 of these cancer deaths were attributed to CRC. In recent years, the incidence of CRC has increased rapidly in China making it the fourth leading cause of cancer mortality in China^[3]. In general, majority of these cancers are distally located. During the last two decades many investigators have noted that the incidence rate of CRC vary widely by race and gender and the location also has changed with time^[4-15], with a trend towards redistribution of primary CRC from left to right^[16, 17]. Proximal cancers have a tendency to present at a more advanced stage and are associated with a poor prognosis. Increasing age, female gender, black, non-Hispanic race and the presence of comorbid illnesses were factors associated with a greater likelihood of developing colorectal cancer in a proximal location. Black patients with colon cancer are more likely to have a poorer survival than white patients^[13, 18-21]. However, it is not clear whether there are any differences in anatomical distribution of primary colorectal cancer between American (white) and Chinese (oriental) patients.

We hypothesized that there are significant differences of anatomical distribution of primary colorectal cancers between the white (American) and oriental (Chinese) patients. The purpose of this study is to compare the differences in anatomical distribution of colorectal cancers and to describe any association of age, gender and time with primary CRC in white and oriental patients.

MATERIALS AND METHODS

A retrospective study was undertaken. Data was collected from 690 consecutive white patients in Cleveland Clinic Florida U.S.A. and 870 consecutive Chinese patients in Nan Fang Hospital affiliated to the First Military Medical University in southern China over the past 11 years from 1990 to 2000. All the patients with CRC were diagnosed by histology and underwent surgery. Anatomical location of primary colorectal adenocarcinoma, race, age at diagnosis, gender and year of diagnosis were noted. Descriptive data on the type of treatment, patterns of recurrence and metastasis, survival, and the coexistence of disease were not the focus of our analysis. The Z-test and Fisher's Exact Test were performed to detect statistically significant differences in anatomical site distribution, age and gender over time between the white and oriental groups. In this study "proximal colon" includes the cecum, ascending colon, hepatic flexure, transverse colon and splenic flexure; "distal colon" includes the descending colon, sigmoid colon and rectum^[22].

RESULTS

664 Consecutive white patients in Cleveland Clinic Florida and 816 consecutive oriental patients in Nan Fang Hospital in China had documented histological diagnosis of colorectal

adenocarcinomas (Table 1). Patients with a diagnosis of adenocarcinoma only were included in this study.

Table 1 Histological diagnosis of patients with colorectal cancer

	No of patients (%)	
	White	Oriental
Adenocarcinoma	664 (96.2)	816 (93.8)
Nonadenocarcinoma	26 (3.8)	54 (6.2)
Total	690 (100.0)	870 (100.0)

Anatomical subsite distribution

Data on the anatomical distribution, race and gender in the two groups are shown in Table 2. The anatomical distribution of the lesions was markedly different between the two races. Comparison showed that 36.3 % of whites *vs* 26.0 % of oriental patients ($P<0.001$) had lesions in the proximal colon and 63.7 % of whites *vs* 74 % of orientals ($P<0.001$) had cancers located in the distal colon. The proportions of cancers located in the cecum, ascending and descending colon in white patients were higher than those in the orientals ($P<0.01$). Rectal and hepatic flexure tumors were less frequent in whites than in the orientals ($P<0.001$). There was no significant difference between cancers located in the transverse colon, splenic flexure and sigmoid colon.

Gender

Analysis by gender conforms to the overall racial differences. The proportions of cecal tumors was higher in the white men ($P<0.001$) and women ($P<0.001$) compared with their Oriental

counterparts. Ascending and descending colon cancers were also significantly more common in white men ($P<0.05$) but not in women ($P>0.05$). Rectal cancers were significantly more common in oriental men ($P<0.001$) and women ($P<0.001$). Oriental patients also had significantly more hepatic flexure cancers among men ($P<0.001$) and women ($P<0.001$). There was no significant difference in the rates of transverse colon, splenic flexure or sigmoid colon cancers.

There was a significant gender difference between the races (Table 3). The male: female ratio was slightly higher in whites (1.49:1) as compared with oriental patients (1.22:1). The gender ratio (m:f) in whites was 1.43:1 for proximal tumors and 1.52:1 for distal tumors; in oriental patients the ratio was 1.06:1 for proximal tumors and 1.29:1 for distal tumors.

Age

The mean age at diagnosis was 69.8 years (range 20-91) in white patients *vs* 48.3 years (range 13-84) years in oriental patients; oriental patients were therefore younger by twenty-one years ($P<0.001$). Incidence of CRC generally increased with age; it peaked between 70-79 years in white patients, whereas the highest incidence in oriental patients was observed between 50-59 years ($P<0.001$) (Figure 1).

We have further analyzed the age related distribution of proximal and distal tumors in the two racial groups (Figure 2). In white patients, the incidence of proximal tumors had an early peak by the age of 29 years; the incidence then declined significantly so that the lowest rates of proximal lesions were found in the 30-59 years; the incidence of proximal tumors then gradually rose to a peak at 70-79 years. There was a significant difference in the proportions of proximal tumors

	Yellow	109 ^c	103 ^a	1.06	340 ^c	264 ^a	1.29	449	367	1.22

^a $P<0.05$, ^b $P<0.01$, ^c $P<0.001$.

between various age groups: 0-29 years vs 30-59 years as well as 30-59 years vs. 60 years and older ($P<0.001$). In oriental patients, the curve for incidence of proximal lesions was relatively flat. Young patients between 0-29 years had the lowest rate which was significantly lower than patients above 30 years ($P<0.001$). The curves for proximal cancers in White and Oriental patients diverge at the extremes of age and there were significant differences between the two races at 0-29 years as well as above 70 years ($P<0.01$). In White patients, there was a marked increase in the rates of proximal tumors whereas the frequency of distal tumors decreased with age. This trend was not observed in Oriental patients (Figure 2).

Figure 1 Age related incidence of colorectal cancers in two races.

Figure 2 Age-related distribution of cancers.

Time

Generally, there was an increase in the proportion of white men with colorectal cancer from 1.37:1 during 90-95 to 1.58:1 during 96-2000 ($P<0.05$) (Table 3). This increase was especially seen in proximal cancers of whites which increased from 1.19:1 in 90-95 to 1.63:1 in 96-2000 ($P<0.01$); the gender ratio among whites for distal cancers changed from 1.47:1 in 90-95 to 1.55:1 in 96-2000 ($P>0.05$). There was no significant change in the gender distribution of oriental patients ($P>0.05$) between these two time periods.

Table 3 shows that in whites the proportion of proximal cancers increased from 34.6 % in 1990-1995 to 37.5 % between 1996-2000 and distal cancers decreased from 65.4 % to 62.5 % of all cancers between the same periods of time. There was a trend towards a redistribution of primary colorectal cancers from distal to proximal colon, but the difference was not significant. When we further compared the relationship between anatomical distribution and gender, a marked trend was found towards the redistribution of primary colorectal cancers from distal colorectum to proximal colon in white men with time, especially in the 80-99 years group, but this change was not significant ($P>0.05$) (Figure 3). No significant change of anatomical distribution of tumor occurred in Oriental patients

over time ($P>0.05$); in whom the proportion of cancers on the proximal side remained significantly higher. In addition, the proportion of proximal tumors remained significantly lower in white than in oriental patients.

Figure 3 Gender and time based distribution of colorectal adenocarcinomas. The Y-axis shows percentage of tumors.

DISCUSSION

An important aspect of colorectal cancer is its anatomical site of origin, the majority of these cancers being diagnosed in the distal colon and rectum. Epidemiological characteristics of colorectal cancer differ by anatomical subsite, which suggests that other underlying subsite-specific differences may be present. There is evidence of a steady migration of colorectal cancer from distal to more proximal sites^[17], although a decrease in proximal cancers was reported^[22]. This is the first study comparing the anatomical distribution of colorectal cancers in these two large racial groups - American and Chinese. The study demonstrates that the most frequent anatomical subsite of origin of primary colorectal adenocarcinomas is the same - the rectum and sigmoid colon, in American and Chinese patients. The proportion of cancers located in the cecum and ascending colon in whites are significantly higher than those in the oriental patients; the latter did have significantly more tumors in the rectum. The proportion of cancers located in the transverse and sigmoid colon was similar in the two groups. Overall, the frequency of lesions in the proximal colon of white patients (36.3 %) was markedly higher than that of oriental patients (26.0 %). Likewise, the proportion of tumors located in the distal colon of oriental patients (74 %) was significantly higher than that of whites (63.7 %). CRC is considered a disease of western developed countries, which has an approximately 10 times greater incidence than developing countries of Africa^[23]. In general, the developed countries have a predominance of left-sided cancers, whereas low-risk communities have a higher proportion of right-sided cancers^[24]. Compared with America, China is a low risk community. The reasons for the significantly higher incidence of right-sided CRC in white patients are still not clear.

Many hypotheses have been developed based on histological differences between the left and right colon, differences in their functions, sex hormones, diet, and genetics. Proximal and distal sections of the colon also have different embryologic origins and morphology. The proximal colon is primarily involved with water absorption and solidification of fecal contents for storage. It is likely that there are differences in sensitivity and exposure to carcinogens for the proximal and distal sections of colon. There might even be differences in the etiologic agent between right-sided and left sided colorectal cancers; a study showed that different carcinogens produced cancers in different parts of the large bowel in experimental animals^[20].

No specific carcinogen has been found to cause CRC in humans, but the differences in the epidemiological patterns of CRC among various populations suggest the role of an environmental or dietary etiologic agent^[25]. The higher consumption of refined carbohydrates and fat and less dietary fiber may contribute to the increased incidence of colorectal cancers in the western countries^[16, 26]. Increased dietary fat resulted in increased bile acids in the intestine, a possible mechanism for carcinogenesis^[27]. High concentrations of fecal bile acids have been observed in people who eat a high fat diet. Bile acids in turn caused colonic bacteria to produce increased amounts of secondary bile acids and other metabolic by products, compounds that may be associated with the high risk of large bowel cancer^[19, 28-30].

Dietary fiber may play an important protective role against colorectal cancer by diluting the fecal concentration of mutagens and bile acids, and by altering the colonic luminal environment^[31]. Even the type of dietary fiber may be important in reducing the fecal mutagenic activity^[31]. It is said that, it is imperative to point out that the evidence linking fiber and colorectal cancer is not conclusive. Dietary fiber probably protects against carcinogenesis, if it is present in the diet from an early age^[32].

Another possible factor increasing the risk of rectal cancer is consumption of large amounts of alcoholic beverages, particularly beer. For example, alcohol has been shown to increase the relative risk for colon cancer by 1.71 when prospective study is made in black and white patients. In contrast, increased amount of vitamin C intake may be protective against rectal cancer^[22, 24, 33-34].

We have observed a trend toward a redistribution of CRC from distal to proximal in white men, especially in the older men, a finding that is similar to others in the literature which showed a trend towards the redistribution of primary CRC from left to right with increasing time^[35]. We found no significant change in the anatomical distribution of colorectal cancer in white women and oriental patients, the distribution remaining fairly stable in these two groups.

In recent years, the male: female ratio for CRC rose in many published reports^[4, 36]. This study showed that overall rates of colorectal cancers were higher among men than women in both races, but the proportion of white men was greater than that of oriental men, especially for proximal cancers. Between the periods 1990-95 and 1996-2000, we found the male-female ratio in whites rose from 1.19:1 to 1.68:1 for proximal colon cancers and 1.47:1 to 1.55:1 for distal colon cancers; over the same periods, in Oriental patients, the male-female ratio declined from 1.12:1 to 1:1 for proximal and rose from 1.27:1 to 1.30:1 for distal cancers (Table 3). There was no significant change in the oriental race, a finding in agreement with others^[9].

This gender-based disparity is largely unexplained. Recently it has been suggested that hormone replacement therapy may decrease the incidence of colorectal cancer in females. Female sex hormones are known to affect cholesterol metabolism which in turn affects bile acid production, a pathway linked to the development of colorectal cancer. Differences in bile acid metabolism between the proximal and distal colon may contribute to the gender-based disparity in colorectal cancer risk^[24].

Age at diagnosis was significantly different between the races. The mean age was 69.8 years in whites and 48.3 years in oriental patients; oriental patients being diagnosed about twenty-one years earlier. The whites presented most commonly between 70-79 years, but the oriental patients had the highest rate of presentation between 50-59 years. The greater proportion of proximal tumors with increasing age in older white patients has also been noted by others^[15, 37-40]. This trend was not observed in oriental patients. There was a higher

incidence of CRC in younger oriental patients of both sexes, the reasons for which are unknown.

The explanation for differences among racial or ethnic groups may lie in host, environmental, or behavioral factors that act alone or in combination. Heredity plays only a small role. As for colorectal adenocarcinoma, patients in China share the epidemiological characteristics of developing countries. It seems that behavioral factors, such as the dietary habits of Americans and Chinese are more likely to contribute to the difference.

We found that white Americans have a higher risk of proximal CRC and this risk increased with time. The proportion of white males with CRC also increased with time. Chinese patients were more likely to have distal CRC and developed the disease at a significantly earlier age than white patients. As colorectal cancer is one of the most common cancers in the world, it is important to conduct further study to explain subsite differences between the races and sexes. Evaluation of such differences will improve our understanding of colorectal carcinogenesis and may help formulate preventive strategies and perhaps guide research on therapy.

Abstract

AIM: A single-chain antibody fragment, ND-1scFv, against human colorectal carcinoma was constructed and expressed in *E.coli*, and its biodistribution and pharmacokinetic properties were studied in mice bearing tumor.

METHODS: V_H and V_L genes were amplified from hybridoma cell IC-2, secreting monoclonal antibody ND-1, by RT-PCR, and connected by linker $(Gly_4Ser)_3$ to form scFv gene, which was cloned into expression vector pET 28a(+) and finally expressed in *E.coli*. The expressed product ND-1scFv was purified by metal affinity chromatography using Ni-NTA, its purity and biological activity were determined using SDS-PAGE and ELISA. ND-1scFv was labeled with ^{99m}Tc , and then injected into mice bearing colorectal carcinoma xenograft for pharmacokinetic study *in vivo*.

RESULTS: SDS-PAGE analysis showed that the relative molecular weight of recombinant protein was 30kDa with purity of 94 %. ELISA assay revealed that ND-1scFv retained the immunoactivity of parent mAb, being capable of binding specifically to human colorectal carcinoma cell line expressing associated antigen. Radiolabeled ND-1scFv exhibited rapid tumor targeting, with specific distribution in mice bearing colorectal carcinoma xenograft observed as early as 1 h following injection. *In vivo* pharmacokinetic studies also demonstrated that ND-1scFv had very rapid plasma clearance ($T_{1/2\alpha}$ of 5.7 min, $T_{1/2\beta}$ of 2.6 h).

CONCLUSION: ND-1scFv shows significant immunoactivity, and better pharmacokinetic and biodistribution characteristics compared with intact mAbs, demonstrating the possibility as a carrier for tumor-imaging.

INTRODUCTION

Colorectal carcinoma is one of the common malignant tumors with relatively high incidence, occupying the fourth rate of mortality in China. Therefore, efficient diagnosis and

therapeutic approaches are important for colorectal carcinoma research. Although in recent years some progress has been made in respect to application of monoclonal antibodies for the therapy and diagnosis of colorectal carcinoma, most mAbs are of murine origin, so that repeated administration can induce human anti-mouse antibodies (HAMA), moreover, intact mAbs are generally too large (M_r 150 000) to penetrate tumor masses, which can severely limit the efficacy of antibody in clinical utilization^[1]. To overcome such deficiencies, gene engineering antibody, including human origin antibodies, single chain Fv (scFv), human-murine chimed antibodies are developed to improve murine origin mAbs^[2-9]. ScFv, which is comprised of immunoglobulin heavy- and light-chain variable regions that are connected by a short peptide linker, is the gene engineered antibody employed most widely at present. The main advantages of scFv over intact mAbs and Fab fragment are their small size (M_r 30 000, amounting to one sixth of intact mAbs), making them penetrate a solid tumor mass rapidly and evenly. In addition, the lack of Fc domains makes them less immunogenic responsive and less capable of binding to Fc receptors distributed on normal cells. These characteristics make scFv potentially useful in tumor diagnosis and therapy as a carrier^[10,11].

ND-1 is a murine monoclonal antibody against tumor-associated antigen LEA, mainly expressed in human colorectal carcinoma, developed by Jindan Song in 1986, which was obtained by immunizing Balb/c mouse with CCL-187 human colorectal carcinoma cell line. The histochemical determination of one thousand pathologic samples showed that ND-1 binded specifically to well differentiated and moderately differentiated colorectal carcinoma tissues and its specificity is superior to mAbs against CEA. ^{131}I labeled ND-1 also exhibited excellent imaging of tumor tissue in mice bearing colorectal carcinoma xenograft. We constructed a scFv by gene engineering technology from the V_L and V_H of ND-1, a monoclonal antibody against human colorectal carcinoma, and determined the biological properties of ND-1 scFv *in vivo* and *in vitro*.

MATERIALS AND METHODS

Materials

IC-2 is murine hybridoma cell that secretes monoclonal antibody ND-1 against human colorectal carcinoma. Both IC-2 and HeLa human cervical carcinoma cell line were from our group. pET28a(+) expression vector and *E. coli* BL21 were kindly provided by Dr. YH. Chen. CCL-187 human colorectal carcinoma cell line was kindly provided by Tumor Research Institution of Medical College of Harvard University. pMD18-T vector, *E. coli* JM109 component cell, DNA polymerase, restriction enzyme, and DNA recovery kit were purchased from TarkaRa Biotechnology (Dalian, China). mRNA purification kit and T4 DNA ligase were bought from Pharmacia Biotech. Anti-His6 tag antibody was from Invitrogen. Ni-NTA resin was provided by Qaigen company. MDP and ^{99m}Tc were kindly provided by Department of Nuclear Medicine at China Medical University. Heavy chain primer 1 and 2, light chain primer mix, linker primer mix, and RS primer mix was purchased from Pharmacia Biotech.

Genetic construction of ND-1scFv

ND-1scFv gene was constructed as previously described. Briefly, mRNA was extracted from 5×10^6 hybridoma cells IC-2 and cDNA was synthesized by reverse transcription using random primer. V_H and V_L gene were separately amplified from the cDNA by PCR using heavy chain primer and light primer mix. The V_H and V_L gene fragments were recovered and mixed in equimolar ratios for two PCR reactions, the first one using linker primer mix for 7 cycles, followed by the second one using RS primer mix for 30 cycles. As a result, V_H and V_L gene fragments were connected to form scFv gene by extension overlap splicing PCR, and then, obtained ND-1 scFv gene was cloned into pMD18-T, and transformed into *E. coli* JM109, positive clones were identified by colony PCR and DNA sequencing.

Oligonucleotide primers S1 and S2 were designed to add *EcoRI* site at the 5' end of ND-1scFv, and *HindIII* site, *Sall* site at the 3' end. S1: 5' ACTGAATTCATGGCCAGGTGCAGCTGCAGC 3', S2: 5' CGCAAGCTTCTAGTCGAC TTTCCAGCTTGGTC 3'. pMD18-T-ND-1scFv was used as template for a PCR by primer S1 and S2, and the product was cloned into the vector pET28a(+) after digestion with *EcoRI* and *HindIII*, and then transformed into competent *E. coli* BL21 cells for protein expression.

DNA sequencing

ND-1scFv genes cloned into pMD18T and pET28a(+) were sequenced by the dideoxy chain termination method with M13 primer, T7 promoter primer and T7 terminator primer.

Expression and purification of ND-1scFv

E. coli BL21 cells containing pET28a(+)-ND-1scFv plasmid were grown in 100 ml LB broth with 50 µg/ml kanamycin at 37 °C, when O.D₆₀₀ of the culture attained about 0.6, IPTG was added in a final concentration of 1 mmol, and cells were shaken at 37 °C, after 3.5 h, the culture was centrifuged at 5 000 rpm for 10 min, the cell pellet was treated with lyses solution. After sonication and centrifugation, inclusion body containing scFv protein was solubilized and denatured in the presence of 6 mol/L Guanidine hydrochloride. Affinity chromatography on Ni-NTA resin was performed to purify scFv, the column was eluted with 8 mol/L urea at pH8.0, pH6.5 and pH4.2, and the component of pH4.2, containing scFv, was collected, following renaturing by dialysis. Purity and concentration of protein were determined with Bradford assay.

ELISA assay for activity of ND-1scFv

CCL-187 cells and HeLa cells (5×10^4) were grown in 96-well microtiter plates at 37 °C for 24 h, then fixed with 2.5 % glutaraldehyde and blocked with 1 % BSA, followed by incubation with ND-1IgG or ND-1scFv at 37 °C for 2 h; after washing 3 times with PBS, anti-His6 antibody was added into wells with ND-1scFv and incubated as above, the plate was washed and HRP-labeled goat anti-mouse IgG was added into both ND-1IgG and ND-1scFv wells, incubating at 37 °C for 2 h, substrate TMB was added, incubated in darkness for 30 min, the reaction was terminated with 1N H₂SO₄; PBS was used as a negative control.

Tumor model

Human colorectal carcinoma cells (1×10^6) were injected s.c. into the back of athymic mice (nu/nu) (4-6 weeks old). When a tumor developed at 0.5-1.5 cm in diameter, biodistribution and pharmacokinetics were studied.

Biodistribution and pharmacokinetics studies

ND-1scFv and ND-1IgG were labeled with ^{99m}Tc using MDP.

Excess β-mercaptoethanol was added to the solution containing ND-1scFv and ND-1IgG, reduced product (1 mg) was mixed with 40 µl MDP (2.5 mg/ml) and 370 MBq ^{99m}Tc. Biodistribution study was performed using tumor-bearing mice injected i.p. with 0.2 ml ^{99m}Tc-ND-1scFv, the mice were killed at different periods. Blood, tumor and all the main organs were collected and weighed. The radioactivity was counted in a gamma scintillation counter. The T/NT value for each organ was calculated.

Pharmacokinetic study was performed by the tumor-bearing mice injected via the tail vein with 0.1 ml ^{99m}Tc-ND-1scFv and ^{99m}Tc-ND-1 IgG. Blood samples were obtained via tail bleeds at 0, 5, 10, 15, 30, 60, 120, 180 min and 24 h after injection, the radioactivity was counted in a gamma scintillation counter, and pharmacokinetic parameters were calculated.

RESULTS

Clone of ND-1scFv gene

V_H and V_L gene were amplified from hybridoma cell IC-2 that secreted monoclonal antibody against human colorectal carcinoma, and then were connected by a linker (Gly₃Ser)₄ using extension overlap splicing PCR to construct scFv gene, which had *EcoRI* site at 5' end and *HindIII* site at 3' end. scFv gene was cloned into the vector pET28a(+) and expressed in *E. coli* BL21. Restriction enzyme digestion analysis showed scFv gene had been accurately inserted into vector pET28a(+). Sequence analysis revealed that scFv gene consisted of 732bp, encoding 243 amino acids. Of which, 354bp for heavy chain gene, was located upstream of scFv gene, and 330bp for the light chain gene, was located downstream. They were connected by a 45bp linker sequence. The deduced protein sequence of ND-1scFv was showed in Figure 1.

Figure 1 Amino acid sequences of ND-1scFv deduced from nucleotide sequences.

Expression and purification of ND-1scFv

Plasmid ND-1scFv-pET28a(+) was transformed into *E. coli* BL21, the protein was expressed with induction of IPTG. SDS-PAGE analysis showed that the lysates of BL21 cell expressing scFv protein exhibited a new protein band with molecular weight at 30kDa (Figure 2). Because a sequence encoding a short peptide His-tag exists at the upstream of multi-clone site (MCS) of vector pET28a(+), ND-1scFv was expressed as a recombinant fusion protein with His tag, consisting of 26kDa for scFv and 4kDa for His-tag and its upstream sequence, which was consistent with the theoretically predicted value. SDS-PAGE analysis also showed that no new protein component was found in the supernatant of cell lysate of *E. coli* BL21 induced by IPTG, which indicated scFv protein was expressed in the form of inclusion body. Inclusion body protein was purified by metal affinity chromatography using Ni-NTA resin which could bind to the His-tag protein marker located on the N terminal end of scFv specifically, purity of purified scFv was 94 % purity.

Figure 2 Expressed ND-1scFv. M: Protein marker; 1: Expression of pET28a(+)-ND-1scFv without induction; 2: Expression of pET28a(+)-ND-1scFv with induction of IPTG; 3: purified ND-1scFv protein.

Determination of immunoactivity of ND-1scFv

The immunoreactivity of purified ND-1scFv was determined by ELISA, the result revealed that scFv exhibited an immunoreactivity similar to the parent ND-1 antibody, and showed strong binding to CCL-187 cells expressing colorectal carcinoma associated antigen LEA, and weak binding to LEA-negative HeLa cells. This suggested that scFv had excellent specificity and still retained higher activity after undergoing refolding and purifying procedures.

Table 1 Immune activity of ND-1scFv determined by ELISA

Sample	OD _{450nm} ($\bar{x} \pm s$)	
	CCL-187	HeLa
ND-1IgG	1.92±0.28	0.20±0.06
ND-1scFv	0.87±0.17	0.19±0.03
PBS	0.14±0.03	0.13±0.01

In vivo distribution studies

ND-1scFv was labeled with ^{99m}Tc. ^{99m}Tc-ND-1scFv was injected into mice bearing the CCL-187 xenograft for biodistribution studies. Radioactivity in blood, tumor and normal tissue was determined at 1 and 3 h following injection, and the ratios of radioactivity between tumor tissue and normal tissue (T/NT) were evaluated. The result showed that labeled scFv displayed rapid localization in tumors, accumulation was found in tumors in high concentrations 1 hour after injection, and scFv uptake in tumor was significantly higher than that in other normal tissues (Table 2).

Table 2 Distribution of ^{99m}Tc- labeled ND-1scFv in mice-bearing tumor ($\bar{x} \pm s$)

Tissue	T/NT value	
	1 h	3 h
Blood	2.61±0.97	2.16±1.05
Liver	1.20±0.40	1.75±1.10
Spleen	2.72±0.10	1.23±0.65
Kidney	0.07±0.05	0.26±0.01
Heart	1.75±0.51	1.90±0.60
Lung	0.83±0.31	0.62±0.16

Pharmacokinetic studies

Studies were conducted to define the pharmacokinetic properties of plasma clearance of ^{99m}Tc labeled ND-1scFv in mice bearing tumor (Table 3). Compared with intact ND-1 IgG, ^{99m}Tc-ND-1scFv exhibited an extremely rapid clearance

from the plasma, 80 % of the scFv was cleared out of the plasma pool at 15 min following injection, T_{1/2}α phase for the scFv was 5.7 min, T_{1/2}β phase was 2.6 h, while T_{1/2}α and T_{1/2}β for the ND-1 were 60 min and 18 h, respectively.

Table 3 Pharmacokinetic parameter of ^{99m}Tc-labeled ND-1scFv in mice-bearing tumor

	ND-1IgG	ND-1scFv
Alpha half-life (min)	5.7	60
Beta half-life (h)	2.6	18

DISCUSSION

The critical issue in application of mAbs is its high specificity and good *in vivo* biological features. In this study, single chain Fv ND-1scFv against human colorectal carcinoma was constructed by fusing gene of variable region of heavy chain with gene of variable region of light chain, and the ND-1scFv protein was functionally expressed in *E.coli*. ELISA analysis showed that ND-1scFv had an immunoactivity similar to the parent ND-1 mAbs, and binded specifically to the CCL-187 human colorectal carcinoma cell that expressed associated antigen LEA. This suggests that ND-1 mAb with only a Fv segment still retained its immunoactivity of binding to corresponding antigens, which is consistent to the previous reports. In addition, ND-1scFv also exhibited excellent specific distribution and pharmacokinetic characteristic in tumor-bearing mice.

A linker sequence was required to connect V_H and V_L for the construction of scFv, the linker widely used at present was a 15-amino acid sequence consisting of repetition of four Gly and one Ser (GGGGS)^[12-15]. In this study, the (Gly₄Ser)₃ sequence was used, and the fusion molecule was constructed in V_H-linker-V_L order, the expressed ND-1scFv protein retained favorable stability during the renaturing and dialyzing, and retained biological activity similar to the parent antibody. In addition, a *SalI* site was provided at scFv 3' end except for adding a *HindIII* site for ligasing the vector. In another experiment, we have already constructed a fusion protein of ND-1scFv and yeast cytosine deaminase using the same restriction site.

E.coli gene expression system is known as the earliest developed and most widely applied system for gene engineering. Although expressed proteins are usually lack of the effective modification such as glycosylation, there are some evidences suggesting that a variety of antibody fragments expressed in *E.coli* were able to fold and assemble correctly into bioactive products without the processing^[16-20], which was also confirmed in own studies. pET vector which belongs to the T7 expression system propagating in *E.coli* was used to express of ND-1scFv. This vector contains T7 promoter, which can achieve high level controlled gene transcription in the presence of T7 RNA polymerase^[19,21-24]. ND-1scFv protein was intensively expressed to 17 % of the total bacterial protein. In addition, a 6×His tag sequence exists at the upstream of clone site in the pET vector, which was expressed in the form of fusion protein with the downstream scFv. Since it did not influence the bioactivity of expressed products, no enzyme hydrolysis process was required to remove it from the final products. This simplified the whole expression procedure. It was even more worth noticing that this sequence could be used as a protein marker for the determination and purification of expressed proteins^[25-27]. ND-1scFv protein was purified by metal affinity chromatography using Ni-NTA resin which can bind to His tag specifically located on -NH₃ of scFv. SDS-PAGE analysis showed that the purity of ND-1scFv was as

high as 94 %, and the concentration was 1.5 mg/ml, demonstrating its potential usefulness in clinical application.

After being reconstructed into small molecules, the molecular weight of mAbs usually reduced to as 1/3 or 1/6 of intact mAbs, which significantly increased their penetrability to tumor tissue. Related experimental observation revealed that intact mAbs mainly concentrated nearby the blood vessel, while scFv seemed to be distributed uniformly within the tumor tissue and performing targeting function with high efficiency^[28,29]. Furthermore, scFv exhibited two-phase pharmacokinetic characteristic *in vivo*, its $T_{1/2\alpha}$ (equilibrium phase) is much shorter than that of intact mAbs, implying that the *in vivo* equilibrated distribution of scFv may be reached rapidly, and its penetration into the interior of solid tumor could be achieved in a short time. In our experiment, ^{99m}Tc labeled ND-1scFv accumulated in tumor tissue in high concentration rapidly only 1 h after being injected into mice bearing xenograft. The radioactivity was significantly higher than that in most of normal tissues, while intact ND-1 required 20-24 h to obtain similar accumulation. Plasma pharmacokinetic studies in mice bearing tumor also showed a rapid plasma clearance of ND-1scFv superior to intact ND-1. Strong penetrability, rapid localization and elimination are the main biological behavior of scFv *in vivo*, making it an ideal localizing diagnostic agent for clinical applications. These were further validated by the immunoimaging experiments in mice bearing tumor using a various of scFvs against different tumor antigen^[30-32]. Hitherto, the superiority of ND-1 developed by our group over the commercial product, mAb vs CEA, both in specificity and affinity, has been demonstrated in a number *in vivo* and *in vitro* experiments. Thus ND-1scFv, constructed from V_H and V_L of ND-1, may provide a new approach for clinical diagnosis and treatment of human colorectal carcinoma.

In this study, we observed that labeled scFv simultaneously accumulated intensively in kidney and in tumors of mice bearing xenograft, which also has been reported by other researchers^[30]. On one hand, relative small size of scFv promotes its rapid uptake by kidney, so that the accumulation in kidney occurs shortly after injection, on the other hand, the half life of ^{99m}Tc is shorter, which, although beneficial for *in vivo* fast imaging, also increases the uptake of labeled scFv by kidney^[28]. Recently, Goel *et al*^[33,34] constructed divalent [sc(Fv)₂] and tetravalent {[sc(Fv)₂]₂} by covalent interaction, which increased the valence of scFvs and improved their affinity. Compared to the monovalent scFv, the divalent scFvs showed approximately 20-fold higher affinities. Furthermore, the molecular weight of multivalent scFvs was larger than scFv, but still smaller than intact IgG, so the *in vivo* pharmacokinetic behavior would be more promising^[35-40]. Some researchers suggested that this uptake also may be related to the IP of the scFv, thus, there exists the possibility of directly modifying the isoelectric point of the scFv by introducing mutation in framework regions. A lower IP may reduce non-specific uptake into tissues such as the kidney^[31]. The ND-1scFv constructed in this study retained the immunoactivity of parent mAbs and the clinical application are demonstrated preliminarily in radiolabelling experiment with mice bearing tumor. With further development, it may become a promising targeting carrier for clinical diagnosis.

Abstract

AIM: To determine whether one genotype (A or non-A genotypes of HBV) predominated over the other during the course of HBV infection.

METHODS: Four baboons were inoculated with HBV. DNA was extracted from serum obtained at monthly intervals post-inoculation for 52 weeks and HBV DNA was amplified using primers specific for the core region containing an insert characteristic of genotype A (nt 2 354-2 359, numbering from the *EcoRI* site). The amplicons were cloned into PCR-Script™ and a minimum of 15 clones per time point were sequenced in both directions.

RESULTS: Both genotypes persisted for the entire follow-up period of 52 weeks. Genotype non-A predominated in two baboons and genotype A in one baboon. Neither genotype predominated in the fourth baboon, as shown at a 5 % level of testing.

CONCLUSION: No conclusions concerning the dominance of either genotype or the natural progression or replication rates of HBV could be drawn because the pattern of the genotypes found may have been caused by sampling fluctuations at the time of DNA extraction and cloning as a result of the very low viral loads in the baboon sera.

INTRODUCTION

Xenografts from closely related non-human primates or pigs have been suggested as one way to alleviate the chronic shortage of donor organs for human liver transplantation. Baboons (*Papio* species) which are phylogenetically close to humans, have reasonably large livers, and are not endangered. They have already been the source of xenografts for two humans undergoing liver transplantation^[1-3] (as well as for a few patients receiving kidney or heart transplants^[2, 4-6]). The use of liver xenografts would, however, be precluded if they

were infected by zoonotic pathogens. In addition, because chronic hepatitis C and B virus infections are now the most frequent causes of end-stage liver disease requiring transplantation in humans^[7], the donor livers should be resistant to infection with these viruses. Our study has previously shown that Chacma baboons (*Papio ursinus orientalis*) are resistant to infection of hepatitis C virus^[8] but are susceptible to infection of hepatitis B virus (HBV)^[9].

In the latter study^[9], pooled serum from three patients with acute hepatitis B (the serum of all three was HBV surface (HBsAg)- and e antigen (HBeAg)-positive and had high titers of HBV DNA) had been injected into the baboons. Direct sequencing of HBV DNA amplified at various times post-inoculation indicated that the baboons had been inoculated with a mixed population of HBV. Cloning of the HBV DNA amplified from the inoculum revealed that it fortuitously contained approximately equal proportions of A and non-A genotypes of HBV. HBV has been classified into genotypes A-H, with an intergenotypic diversity of at least 8 %^[10-13]. Genotype A accounts for 80 % and genotype D for 10 % of the genotypes found in southern Africa, with the other genotypes being either absent or present in very few isolates^[14]. HBV genotypes have a characteristic geographical distribution^[15], which help in tracing the route of HBV infection^[16], and may influence the severity and outcome of infection with this virus^[17]. However, little is known about the natural progression and severity of the infection when more than one genotype is present^[18].

Co-infection with two or more genotypes may be the consequence of multiple exposures to infection at an early age when immune responses are immature or in older individuals with immune disorders^[19], or the result from genotype changes during seroconversion from e antigen positivity to negativity^[20]. Documented cases of co-infection with more than one genotype of HBV were rare^[18, 19, 21, 22], and the natural progression of HBV infection in this circumstance has not been thoroughly evaluated. In one patient studied recently, infection with genotypes D and A (with D predominant) was serologically "silent" (HBsAg-negative but HBV DNA-positive), although with pathological consequences because the patient was cirrhotic and died of liver failure^[18]. This patient may be of particular interest in view of our failure to detect HBsAg in the serum of our HBV DNA-positive inoculated baboons^[9]. Therefore, the opportunity was taken in the present study to monitor the changes over time in the relative proportions of genotypes A and non-A in the inoculated baboons and to ascertain if the two genotypes differed in their rate of replication or in their ability to persist in the inoculated baboons.

MATERIALS AND METHODS

Samples

For this study, serum samples which were collected at 4-weekly intervals from 4 baboons infected by inoculated HBV^[9] were analyzed which was started at week 8,. Because the initial phases of the study included the housing and inoculation of the baboons, the collection of serum samples were carried out at the Medical University of Southern Africa, this study was

undertook with the permission given by the Animal Ethics Committee of that institution. The Committee approved the procedures, and the care of the baboons according to its guidelines and those of the South African Medical Research Council. Each of the baboons had received intravenous injection of 1 ml pooled serum obtained from 3 HBV surface antigen (HBsAg) and HBV e antigen (HBeAg)-positive patients with clinically-overt acute hepatitis B. The concentration of HBV DNA in the pooled sera was 2 133 pg/ml (which was 2 982 pg/ml in another laboratory) using the Digene Hybrid Capture System (Digene Diagnosis Inc., Beltsville, MD, USA); the values in the individual isolates were 2 870 pg/ml, 6 660 pg/ml and 692 pg/ml, respectively. Using methods of amplification and cloning (see below), the HBV DNA amplified from the pooled inoculum was shown to contain equal proportions of genotype A and non-A of HBV. All of the baboon sera were tested for HBsAg, anti-HBc, and anti-HBs using commercially available assays (Abbott Laboratories, Chicago, IL, USA). All serum samples were stored at -20 °C.

PCR assay of HBV

HBV DNA levels were assessed with a quantitative PCR assay (Amplicor™ HBV monitor test, Roche Diagnostics). Briefly, 50 µl of serum were prepared with pre-treatment with polyethylene glycol, alkaline lysis of the pelleted viral particles, and neutralization of the lysate. After adding a fixed amount of internal standard and a PCR mix, 30 cycles of PCR amplification were performed according to the manufacturer's instructions. Biotinylated amplicons were captured on streptavidin-coated microwells and hybridized with specific dinitrophenyl-labelled oligonucleotide probes. It was incubated with alkaline phosphatase conjugated anti-DNP antibodies and a colorimetric substrate, then a kinetic of O.D. determination of HBV DNA levels was performed. The limit of detection of this PCR assay was 400 copies of viral genome per ml, and quantitation was linear up to 4×10^7 copies per ml^[23,24].

DNA extraction

DNA was extracted from serum using the QIAamp blood kit (Qiagen Inc., Hilden Germany), according to the manufacturer's instructions and as previously described^[25]. Known positive and negative sera, as well as best quality water were used as controls for the extraction procedure.

PCR of HBV DNA

HBV DNA in the core region was amplified using primers designed to amplify all the HBV genotypes (Table 1A and 1B). PCR was performed in 25 µL and 50 µL final reaction volumes for the first and second rounds, respectively. The reaction for the first round of the PCR consisted of 0.02 U/µL Dynazyme™ Taq DNA polymerase (version 2.0, Finnzymes OY, Espoo, Finland), 200 µmol/L of each of the nucleotide triphosphates, 1 µmol/L of each of the primers, 4 mmol/L MgCl₂ and 10 mmol/L Tris-HCl (pH 8.8 at 25 °C), 50 mmol/L KCl, and 0.1 % Triton® X-100. The reaction mixture for the second round of the PCR was the same as for the first round except that 1.5 mmol/L MgCl₂ was used. A third round of PCR was used on the serum from those time points that were negative after 2 rounds of PCR. The reaction mixture was the same as for the second round of PCR except that concentrations of MgCl₂ of 1.0 mmol/L, 1.5 mmol/L, and 1.5 mmol/L, were used for the first, second, and third rounds of PCR, respectively. All PCR assays were performed in a programmable thermal cycler (Perkin Elmer, Norwalk, CT, USA) with the 3-step cycling profile shown in Table 1B. Sera positive for HBsAg, HBeAg, and HBV DNA detected by slot-blot hybridization were used as positive controls and best quality water instead

of DNA as negative controls. To avoid cross-contamination and false-positive results, the precautions and procedures recommended by Kwok and Higuchi^[26] were strictly adhered to DNA extraction, the various stages of PCR amplification, and gel electrophoresis were performed in physically separate venues.

(+) sense; (-) anti-sense. ^aDenotes the nucleotide position of hepatitis B virus *adv* genome (GenBank accession #V00866) where the *EcoRI* cleavage site is position 1. ^bSize of the amplicons in base pairs.

Detection of amplified products

A 5 µl aliquot of the amplified PCR product was electrophoresed in a 2 % agarose gel. Bands of the appropriate size (Table 1A and 1B) were visualised under ultraviolet light after ethidium bromide staining.

Cloning and nucleotide sequencing

Following the double or triple round PCR, amplicons were cloned using PCR-Script (Stratagene, La Jolla, CA, USA). Plasmid DNA was extracted using the QIAprep spin miniprep kit (Qiagen Inc., Hilden, Germany) and restricted with *Pvu II* to confirm the presence of the correct insert (Table 1A and 1B). Sequencing of positive clones was performed using the T7 Sequenase Version 2.0 DNA sequencing kit (Amersham Life Science Inc., Cleveland, OH, USA). Sequences were analyzed in both forward and reverse directions with primers T3 and T7 on 8 % glycerol-tolerant acrylamide gels and autoradiographed. The number of clones of A and non-A genotypes obtained at each time point was used as a measure of the relative proportions of the two genotypes in the serum at that time.

Statistical analysis

Fisher's Exact test and the Chi-squared tests were used for statistical analysis, where appropriate.

RESULTS

HBV DNA was detected in the serum using either double or triple round PCR in the four inoculated baboons at various time points during the 52-week follow up period. For baboons 1 and 13 HBV DNA concentration was determined at various time of post-inoculation using the Amplicor HBV Monitor™ Test (Table 2). When serum was available for further analysis and HBV DNA was successfully amplified, the amplicons were cloned and sequenced. Genotype A was distinguished from the other genotypes by the sequence 5' CGGGAC3' (nt 2 354-nt 2 359, numbering from the Eco R1 site) that is specific to this genotype (Figure 1). Depletion of inoculum serum prevented us from amplifying the S region and carrying out restriction fragment length polymorphisms in order to assign the non-A genotype to one of genotypes B to H. Although we could not preclude the possibility that the non-A isolates were comprised of more than one genotype, the most likely genotype would be genotype D, the genotype besides A commonly found in South Africa^[14].

Figure 1 Sequence profiles of the core region (nucleotides 2 340-2 368 numbering from the *EcoRI* site) showing the insertion of 5' CGGGAC3' (nucleotide 2 354-2 359) found in genotype A and its absence in genotypes non-A. Tracks G, A, T and C are labelled.

Table 2 HBV DNA levels measured by the amplicor HBV monitor test

Time of post-inoculation (months)	HBV DNA Levels (genomes/ml)									
	2	3	4	5	6	7	8	9	10	10
Baboon 1	<400	<400	4 338	3 711	ns	ns	<400	ns	<400	<400
Baboon 13	<400	ns	ns	ns	ns	ns	2 6216	1 003	ns	ns

Notes: ns: no serum available.

Figure 2 showed the relative concentration of genotypes A and non-A at the various time points represented as a percentage of the total number of clones obtained and sequenced at that time point. The hypothesis of equal proportions of the genotypes over time was rejected for all four baboons ($P < 0.002$ in each instance). For each specific time/baboon combination, the hypothesis that the proportions of genotype A and non-A were equal was rejected in all but 4 cases, namely, at 10 months for baboons 2 and 12, and at 11 months for baboons 1 and 13.

Genotype non-A predominated in two baboons (baboon 2 and 13) and genotype A in one baboon (baboon 1); neither genotype predominated in the fourth baboon (baboon 12), as shown at a 5 % level of testing. In the three baboons in which one or other genotype predominated, there was at least one time-point at which the non-dominant genotype was present in the highest concentration at a proportion significantly different from zero.

Figure 2 The change of genotype of hepatitis B virus at various time of post-infection which was represented as a percentage. The number of clones sequenced at each time point was showed in brackets. *ino: inoculum.

DISCUSSION

Neither HBsAg nor antibody to HBsAg (anti-HBs) was detected by conventional tests in the serum of the four inoculated baboons at any time during the 52 weeks they were monitored^[9]. HBV DNA identical to either the A or non-A HBV genotypes inoculated was, however, detected in each baboon throughout the follow-up period, and the presence of anti-HBc and Dane particles, small spherical particles and tubular particles was demonstrated in the serum at 16 weeks^[9]. The viral titers in the baboons were low (Table 2), as shown by the need to use nested PCR amplification to detect HBV DNA at all time points and three rounds of amplification at some time-points. No biochemical evidence of liver injury was evident at any stage and liver histology was normal at 52 weeks. These findings together suggested that the animals had become chronic asymptomatic carriers of the virus.

We had hoped that a clear pattern of different rates of replication of the two genotypes would be evident. However, no uniform pattern could be discerned in the relative concentration of genotypes A and non-A during the 52 weeks (Figure 2). Other explanations of a technical nature for the varying concentrations of the genotypes were needed therefore to be considered. One possibility was that the number of clones sampled at each time-point was too small to accurately assess the relative proportions of the genotypes in the serum at that time. This explanation was not supported by statistical analysis of the numbers of clones involved at each time point. A more likely explanation was that the low copy number of the genotypes resulted in sampling error at the time of HBV DNA extraction and cloning. This explanation was particularly apposite for the genotype pattern in baboon 13, in which genotype A alone was found in a single sample, whereas at all other time-points on either side of this sample, genotype non-A either predominated or was the sole genotype cloned (Figure 2A). It was also relevant that the conditions created in the study were artificial on two counts: the approximately equal concentrations of the two genotypes inoculated into the baboons resulted from the pooling of three serum samples from different patients, and we were assessing the effects of a human virus injected into a non-human primate.

Jeantet and co-workers were able to clone and sequence entire HBV genomes and found a number of mutations in the surface, precore and other regions affecting expression of the surface gene in both genotypes^[18]. The A genotype was fully replication competent, although, surprisingly, this was not true of the predominant D genotype. Sequencing of the subgenomic amplicons of HBV from our infected baboons did not reveal any mutations in the core region of the HBV isolates. Full genome analysis was impossible in our study because the study was carried out retrospectively. Either the serum samples were depleted or when serum was available full genome amplification did not work, possibly because of the low viral load.

The very low concentrations of HBV in the serum of the infected baboons (Table 2) and the resulting likelihood of sampling error during viral DNA extraction and cloning prevented us from drawing firm conclusions about the natural progression over time of genotypes A and non-A replication in baboons. The study did however show that both genotypes persisted for the entire period of 52-week of follow-up.

Abstract

AIM: To evaluate the level of sperm chromosome aberrations in male patients with hepatitis B, and to directly detect whether there are HBV DNA integrations in sperm chromosomes of hepatitis B patients.

METHODS: Sperm chromosomes of 14 tested subjects (5 healthy controls, 9 patients with HBV infection, including 1 with acute hepatitis B, 2 with chronic active hepatitis B, 4 with chronic persistent hepatitis B, 2 chronic HBsAg carriers with no clinical symptoms) were prepared using interspecific *in vitro* fertilization between zona-free golden hamster ova and human spermatozoa, and the frequencies of aberration spermatozoa were compared between subjects of HBV infection and controls. Fluorescence *in situ* hybridization (FISH) to sperm chromosome spreads was carried out with biotin-labeled full length HBV DNA probe to detect the specific HBV DNA sequences in the sperm chromosomes.

RESULTS: The total frequency of sperm chromosome aberrations in HBV infection group (14.8 %, 33/223) was significantly higher than that in the control group (4.3 %, 5/116). Moreover, the sperm chromosomes in HBV infection patients commonly presented stickiness, clumping, failure to staining, etc, which would affect the analysis of sperm chromosomes. Specific fluorescent signal spots for HBV DNA were seen in sperm chromosomes of one patient with chronic persistent hepatitis. In 9 (9/42) sperm chromosome complements containing fluorescent signal spots, one presented 5 obvious FISH spots, others presented 2 to 4 signals. There was significant difference of fluorescence intensity among the signal spots. The distribution of signal sites among chromosomes was random.

CONCLUSION: HBV infection can bring about mutagenic effects on sperm chromosomes. Integrations of viral DNA into sperm chromosomes which are multisites and

nonspecific, can further increase the instability of sperm chromosomes. This study suggested that HBV infection can create extensively hereditary effects by alteration genetic constituent and/or induction chromosome aberrations, as well as the possibility of vertical transmission of HBV via the germ line to the next generation.

INTRODUCTION

Hepatitis B virus (HBV) infection is a serious public health problem worldwide^[1-3], especially in Far-East Asia such as China. During HBV infection, HBV can be found in saliva, vaginal secretions, semen and other tissues beyond the liver and blood^[4-6]. It is well established that HBV DNA could integrate not only into the host hepatocytes but also into sperm cells^[7-19]. Extensive studies have confirmed that HBV DNA integrated into the hepatocytes will increase chromosome instability and cause genetic recombination and hepatocarcinogenesis^[7-17]. In this study, in order to clarify the inheritable influence of HBV on sperm chromosomes, we used interspecific *in vitro* fertilization with zona-free hamster eggs to prepare sperm chromosomes and compared the aberration frequencies of sperm chromosomes between patients with hepatitis B and the controls. In addition, FISH technique with HBV DNA as a probe was used to detect HBV sequences in sperm chromosomes and to analyze features of sperm chromosomes integrated HBV DNA. The genetic significance of the results from this investigation was discussed.

MATERIALS AND METHODS

Subjects

Nine men with HBV infection, including 1 subject with acute hepatitis, 6 with chronic hepatitis (2 with chronic active hepatitis, 4 with chronic persistent hepatitis), 2 chronic HBsAg carriers with no clinical symptoms, and 5 healthy men as controls were studied. The age range was from 22 to 38 years old (mean 27), without the history of exposure of radiation and use of mutagenic agent. The status of the markers of HBV infection of the subjects tested was listed in Table 1.

Preparation of sperm chromosomes

The technique of interspecific *in vitro* fertilization of zona-free golden hamster was used to prepare the sperm chromosomes. Those procedures included the treatment of semen samples from the tested subjects, superovulation of golden hamsters and egg processing, insemination and postinsemination culture and preparation of chromosome slides^[20,21].

Analysis of aberrations of sperm chromosome

Sperm chromosome slides were stained with 10-fold diluted

Giemsa in 50 ml Sorensen's buffer, pH6.8, for 20-30 min and observed under the light microscope. After the observation, the slides were stored at -70 °C for FISH test. Frequency distributions of spermatozoa with chromosome aberrations were evaluated by using Chi-square test.

Fluorescence in situ hybridization of sperm chromosomes

Labeling HBV DNA probe with biotin Recombinant plasmid, pHBV-1 containing 3.2kb HBV genomic DNA, was taken to amplify according to the routine method^[22]. The 3.2kb HBV DNA probe with its vector (altogether 6.2kb) was labeled with biotin-14-dATP by nick translation (GIBCOBRL No. 18247-015). Unincorporated nucleotides were separated by cold ethanol precipitation method.

In situ hybridization Sperm chromosome slides were orderly treated with RNase (Sigma) at 100 mg/L for 60 min at 37 °C, then at 50 mg/L pepsin (Sigma) in 0.01N HCl for 10 min at 37 °C, at last at 1 % polyformaldehyde in PBS for 10 min at room temperature. Chromosomes were denatured at 75 °C for 4 min in 70 % formamide in 2×SSC. *In situ* hybridization with denatured DNA probe mentioned above was performed with a modification of the procedure described by our previous paper^[23]. Briefly, 10 µl hybridization buffer (50 % deionized formamide, 10 % dextran sulfate, and 2×SSC) containing 40 ng/µl biotin-labeled HBV DNA probe, 500 ng/µl sheared salmon sperm DNA was placed on each slide. A coverslip (18×18 mm) was then applied and sealed with rubber cement, followed by overnight incubation in a humidified chamber at 37 °C.

Detection of hybridization signals Post-hybridization washing was carried out, referring to Korenberg's methods for mapping small DNA probes^[24], once in 40 % formamide, 2×SSC for 10 min at 40 °C, then twice, each for 5 min, in 2×SSC at room temperature. Hybridization signals were detected with FITC-conjugated avidin and amplified with goat biotinylated anti-avidin antibody followed by another layer of FITC-avidin (avidin and anti-avidin, Vector Laboratories). To increase the intensity of the hybridization signal, a second round of amplification was applied by sandwich method as above. In order to reduce the nonspecific binding, the slides were preincubated in 4×SSC with 15 % nonfat dry milk for 10 min at 37 °C prior to each step of immunological reactions. The chromosomes were counterstained with propidium iodide (PI, Sigma) and 4, 6-diamidino-2-phenylindole (DAPI, Sigma), 2 µg/ml each in PBS/glycerol (1:9, v/v) containing 0.2 % (1,4)-diazobicyclo-(2, 2, 2) octane (DABCO, Sigma) as an anti-fade

agent. Photograghy was taken under a fluorescence microscope (BH-2, Olympus) with the G excitation filter, EY-455 help excitation filter and Y-475 barrier filter, using Fuji ASA 400 color film.

RESULTS

Analysis of chromosomal quality

Under the same conditions of the experiment, sperm of the subjects with HBV infection as well as healthy controls appeared to be able to penetrate into zona-free hamster oocytes and to develop to the first-cleavage metaphase. However, the quality of metaphase spreads of sperm chromosomes had significant difference between the above two groups ($P<0.005$, χ^2 -test). The quality of a number of sperm chromosome plates of the subjects with HBV infection was low, showing generally hard to be stained, stickiness of chromosome, clumping, tortuosity and so on, making the analyzable metaphase spreads greatly decreased. Whereas, few of these phenomena occurred in the controls although a small proportion of sperm chromosome plates of the controls could not be analyzed because of poor separation of chromosomes (Table 2).

Incidence of chromosome aberrations

Among the analyzable metaphase spreads, chromosome aberrations observed included numerical anomaly (aneuploidy), gap, ring chromosome, triradial, dicentric chromosome, pulverization, acentric fragment and deletion, orderly. Of the 233 analyzable sperm metaphase spreads in the hepatitis group, 33 (14.8 %) complements contained chromosome aberrations, being significantly higher than 5 (4.3 %) chromosome aberrations in the control group ($P<0.005$, χ^2 -test).

Signals of in situ hybridization

Using specific whole length HBV DNA as probe to perform *in situ* hybridization on sperm chromosome slides, the sperm metaphases of one patient with chronic persistent hepatitis (subject 6) presented positive signals, all other tested subjects' spermatozoa (50 per subject), as well as all hamster oocytes (more than 200) did not have FISH signal (Table 1). Of 42 chromosome complements of subject 6 with chronic persistent hepatitis, 9 complements showed clearly twin yellow spots on some chromosomes. In 9 sperm metaphase spreads with positive signals, one had 5 signals on different chromosomes, the rest ranged from 2 to 4 spots involving unrelated

chromosomes. The intensity of signal presented distinct difference among the spots. Positive signals detected were not identical in the chromosomes and in distribution (Figure1).

Figure 1 Detection of HBV DNA sequences in sperm chromosomes by FISH with biotinylated whole length HBV DNA probe: (A) a well separated chromosome plate from one patient (subject 6) with chronic persistent hepatitis, with three fluorescent signals on different chromosomes; (B) a poorly separated chromosome plate from the same patient with five fluorescent signals.

DISCUSSION

Our studies showed that the frequency of sperm chromosomal aberrations was greatly elevated after the infection of hepatitis B virus, and FISH could directly visualize the integration of HBV DNA sequences into sperm chromosomes. These results suggested that HBV infection could produce inheritable biological effects by carrying genetic materials damaged by virus or carrying altered genetic constituent due to the insertions of virus DNA in germ cells. As we know, this is the first report about the influence of biological factors on human sperm chromosomes.

In our study, we unexpectedly found that the sperm chromosomes frequently presented stickiness, faint stain and extreme tortuosity in the tested subjects with HBV infection and analyzable metaphases were low. Nevertheless, these changes were not found in the healthy controls under the strictly identical conditions. A previous report demonstrated that this manifestation had occurred in the chromosomes of somatic cells of HB patients with positive HBsAg^[25]. The reasons of causing chromosomal stickiness in the HBV infection patients were unclear. The possibilities we considered might include the following events: First, antigen components of HBV such as core protein might interfere with the assembly of chromosome from chromatin due to its interaction with histones, it was confirmed that the core protein of HBV had participated in the organization of nucleosomes with histones in the hepatitis B virus minichromosome^[26,27], so the condensation degree of chromosome was decreased and staining of chromosome became more difficult. Second, local despiralizations in the chromosomes occurred due to virus or its components. Third, premature chromosome condensation (PCC) might be induced by HBV, because virus-induced PCC was a common phenomenon^[28]. Chromosome stickiness itself may be a manifestation of chromosomal pulverizations.

Previous reports have indicated that HBV infection can induce genetic alterations in somatic cells including hepatocytes and blood cells etc, showing increase of the rate of chromosomal aberrations or SCEs^[29-35]. It was reported that influenza in spermatocytes of mice could greatly induce the

increase of chromosomal anomalies^[36]. Our studies revealed that the incidence of chromosomal aberrations in the HBV infection group was significantly higher than that in the controls. Although in the present study the individual sample sizes and analyzable chromosome numbers were not large enough and it was difficult to compare the differences of rates and types of aberrations among the different clinical and serological states of HBV infection, there were some features worthy to be considered: First, the incidence of chromosome aberrations did not appear to be closely correlated with the seminal fluid status of HBV infection; Second, the chromosome pulverizations were not observed in the controls but were present in 4 sperm cells in the HBV infection group; Third, subject 6 with proven HBV integrations in the sperm chromosomes had prominently higher level of chromosomal aberration than the other HBV infection subjects; Fourth, the chromosome breakages were more frequent in the HBV infection group than that in the controls.

FISH onto sperm chromosomes by specific HBV DNA as a probe had showed positive signals in an HBV patient. The results directly indicated that HBV could penetrate blood-testis barrier and enter male germ line and integrate into their genome. So the possibility of vertical transmission of HBV via the germ cells was further confirmed^[18,19]. Our preliminary observations showed that HBV integrations into sperm chromosomes had the feature of multi-site integrations and that the predilection site of HBV insertion into chromosomes seemed to be unlikely present. These results were similar with other previous reports about HBV-related hepatocellular carcinoma either in HCC-derived cell lines or in liver tumor samples^[7-17,32,33]. During spermatogenesis, the stem cells sequentially undergo proliferation by mitosis and differentiation into spermatocytes and formation into spermatozoa by meiosis. The occurred important events of meiosis were the pairing and recombination of chromosomes during the prophase of meiosis I^[37]. Thus it was possible that relocation of viral sequences and multi-site integrations could occur via genetic recombination when HBV was inserted into male reproductive cells, but the genetic effect of initial HBV insertion into various spermatogenic stages must have been greatly various. If the insertion occurred in stem cells, their all daughter cells would carry the integrated form of viral DNA and the effects would be long-term. In our studies, we were surprised by the fact that FISH showed strong signals in a patient using single small DNA probe. The reasonable explanations for this result included that the copies of HBV strand-invasion may be multiple, HBV sequence generated duplications *in situ* after the invasion into host genome, during the processes of making spermatozoa, unequal cross-over or DNA rearrangements occurred repeatedly due to HBV insertion into DNA of stem cells. According to the sperm chromosome aberration analysis (Table 2), such a subject with HBV integrations had relatively higher incidence of sperm chromosome aberration than that in other subjects without HBV integration. This correlation implied that viral DNA integrations into germ line significantly increased the instability of gametic genome. Thus, HBV integration into sperm cells would create extensively inheritable effects including offspring from such sperm fusion with ovum presenting HBV infection status in newborn infant and producing congenital or hereditary disease (for example, embryonal tumor) by altering genetic constituent and/or inducing mutations^[38-40].

We conclude that HBV infection can bring about mutagenic effects on sperm chromosomes which show that the incidence of sperm chromosome aberrations is significantly elevated after the infection of HBV. Integrations of viral DNA into sperm chromosomes with feature of multisites and nonspecific can further increase the instability of sperm chromosomes. Our

study suggests that HBV infection can create extensively inheritable effects not only by altering genetic constituent and/or inducing mutations but also possibly by vertical transmission of HBV via the germ line to the next generation.

Abstract

AIM: To determine the prevalences of TTV and HGV infections among blood donors and patients with chronic liver disease in Korea, to investigate the association of TTV and HGV infections with blood transfusion, and to assess the correlation between TTV and HGV viremia and hepatic damage.

METHODS: A total of 391 serum samples were examined in this study. Samples were obtained from healthy blood donors ($n=110$), hepatitis B surface antigen (HBsAg)-positive donors ($n=112$), anti-hepatitis C virus (anti-HCV)-positive donors ($n=69$), patients with type B chronic liver disease ($n=81$), and patients with type C chronic liver disease ($n=19$). TTV DNA was detected using the hemi-nested PCR. HGV RNA was tested using RT-PCR. A history of blood transfusion and serum levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were also determined.

RESULTS: TTV DNA was detected in 8.2 % of healthy blood donors, 16.1 % of HBsAg-positive donors, 20.3 % of anti-HCV-positive donors, 21.0 % of patients with type B chronic liver disease, and 21.1 % of patients with type C chronic liver disease. HGV RNA was detected in 1.8 % of healthy blood donors, 1.8 % of HBsAg-positive donors, 17.4 % of anti-HCV-positive donors, 13.6 % of patients with type B chronic liver disease, and 10.5 % of patients with type C chronic liver disease. The prevalence of TTV and HGV infections in HBV- or HCV-positive donors and patients was significantly higher than in healthy blood donors ($P<0.05$), except for the detection rate of HGV in HBsAg-positive donors which was the same as for healthy donors. There was a history of transfusion in 66.7 % of TTV DNA-positive patients and 76.9 % of HGV RNA-positive patients ($P<0.05$). No significant increase in serum ALT and AST was detected in the TTV- or HGV-positive donors and patients.

CONCLUSION: TTV and HGV infections are more frequently found in donors and patients infected with HBV or HCV than in healthy blood donors. However, there is no significant association between TTV or HGV infections and liver injury.

INTRODUCTION

A novel human DNA virus, TT virus (TTV), was first discovered in the sera of three Japanese patients with post-transfusion hepatitis in 1997^[1]. TTV is a non-enveloped, single-stranded virus related to the Circoviridae family^[2,3]. Hepatitis G virus (HGV) is an enveloped RNA virus member of the Flaviviridae family^[4]. TTV and HGV infections in healthy blood donors as well as in patients with liver disease have been recently reported in many areas of the world^[3-22]. However, the role of these viruses in disease remains uncertain. Information regarding TTV and HGV infections in the Korean population is limited. Hepatitis B virus (HBV) and hepatitis C virus (HCV) are the viral agents most readily implicated in causing a liver disease in Korea^[23,24]. The aims of this study were to determine the prevalence of TTV and HGV in Korean blood donors and patients with type B or C chronic liver disease, to investigate the association between blood transfusion and TTV and HGV infections, and to assess the correlation between TTV and HGV viremia and hepatic damage.

MATERIALS AND METHODS

Materials

A total of 291 blood samples, derived from 110 healthy donors, 112 hepatitis B surface antigen (HBsAg)-positive donors, and 69 anti-hepatitis C virus antibody (anti-HCV Ab)-positive donors, were collected at the Kwangju-Chonnam Red Cross Blood Center. A total of 100 blood samples were obtained from 81 patients with type B chronic liver disease (46 chronic hepatitis, 15 liver cirrhosis, and 20 hepatocellular carcinoma) and 19 patients with type C chronic liver disease (10 chronic hepatitis and 9 hepatocellular carcinoma) at the Chonnam National University Hospital.

Serological and chemical studies

Blood samples were centrifuged and stored at -70 °C within hours of collection. HBsAg and anti-HCV Ab were tested with enzyme immunoassay (AxSYM, Abbott Laboratories, USA). Immunoblot assay (ProfiBlot IIN, SLT Lab Instruments, Austria) was used to confirm anti-HCV. Serum levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were also measured using an autoanalyzer (Hitachi 747, Hitachi, Japan).

DNA extraction and TTV PCR

DNA was extracted from 250 µL of sera using a kit (DNAzol, Molecular Research Center, USA) according to the manufacturer's guidelines. Nucleic acids were dissolved in 50 µL of NaOH (8 mM). A 7 µL volume was then removed and used for amplification of TTV DNA. The PCR reaction was performed in a volume of 50 µL containing 10 mM Tris-HCl

(pH 8.3), 50 mM KCl, 1.5 mM MgCl₂, 200 μM dNTPs, 0.5 μM of NG059 (5' -ACAGACAGAGGAGAAGGCAACATG-3') as the sense primer, 0.5 μM of NG063 (5' -CTGGCATTTCACATTTCCTCAAAGTT-3') as the antisense primer, and 2 U of Taq polymerase to amplify a 286-bp product. The second-round PCR was done under identical conditions, except that the template was 5 μL product from the first-round PCR, and the sense primer was 0.5 μM of NG061 (5' -GGCAACATGTTATG GATAGACTGG-3'). The size of the second-round PCR product was 271 bp. Each PCR was performed in a programmable thermal cycler (GeneAmp PCR System 9 600, Perkin-Elmer Cetus, USA). The PCR program consisted of 35 cycles of denaturation for 15 seconds at 95 °C, annealing for 30 seconds at 58 °C, and extension for 30 seconds at 72 °C, followed by a final extension for 10 minutes at 72 °C. The amplification products were separated by 2 % agarose gel electrophoresis, stained with ethidium bromide, and photographed under UV light.

Nucleotide sequencing

To ascertain the specificity of the PCR products, DNA sequences of the amplified product were determined. The PCR product was purified with a PCR purification kit (Boehringer Mannheim, Mannheim, Germany). Nucleotide sequences of the amplicon were directly determined using an AccuPower DNA sequencing kit (Bioneer, Korea). The sequence homology between the PCR products and published TTV DNA was examined. Two randomly selected PCR products were sequenced, both of which were positive for TTV DNA. Sequence comparison with databases confirmed the specific amplification of TTV genomic DNA.

RNA extraction and HGV RT-PCR

To detect HGV RNA in a sample, nucleic acids were isolated from 250 μL of serum using Trizol LS Reagent (GIBCO, USA) and a reverse-transcription PCR (RT-PCR) was performed. A total of 35 cycles of PCR (94 °C for 30 seconds, 50 °C for 30 seconds, and 72 °C for 60 seconds for each cycle) were completed in a programmable thermal cycler (GeneAmp PCR System 9 600, Perkin-Elmer Cetus, USA). The size of the PCR product was 234 bp. The amplification products were separated by 2 % agarose gel electrophoresis, stained with ethidium bromide, and photographed under UV light.

Transfusion history

To examine the association of TTV and HGV infections with blood transfusion, previous transfusion history was investigated in both patients with chronic liver disease and blood donors, by examining their medical records or via telephone interviews.

Statistical analysis

Statistical analysis was conducted using the Chi-square test and analysis of variance (ANOVA). Statistical significance was set when $P < 0.05$.

RESULTS

Prevalences of TTV DNA and HGV RNA

The prevalences of TTV and HGV infections in blood donors and patients with chronic liver disease were shown in Table 1. TTV DNA was detected in 8.2 % (9/110) of healthy blood donors, 16.1 % (18/112) of HBsAg-positive donors, 20.3 % (14/69) of anti-HCV-positive donors, 21.0 % (17/81) of patients with type B chronic liver disease, and 21.1 % (4/19) of patients with type C chronic liver disease. The TTV prevalence was significantly higher both in HBsAg-positive or anti-HCV-positive donors and in patients with chronic liver disease than

in healthy blood donors ($P < 0.05$). HGV RNA was detected in 1.8 % (2/110) of healthy blood donors, 1.8 % (2/112) of HBsAg-positive donors, 17.4 % (12/69) of anti-HCV-positive donors, 13.6 % (11/81) of patients with type B chronic liver disease, and 10.5 % (2/19) of patients with type C chronic liver disease. The HGV prevalence was significantly lower in healthy blood donors or HBsAg-positive donors than in patients with chronic liver disease and anti-HCV-positive donors ($P < 0.05$). The detection rates for TTV or HGV were not significantly different between the three types of chronic liver disease. The TTV prevalence was about 4.6 times higher than the HGV prevalence in healthy blood donors. Co-infection of TTV and HGV was also observed in ten cases of HBV- or HCV-infected patients and donors.

Table 1 The prevalence of TTV and HGV infections in blood donors and patients with chronic liver disease from Korea

Subject	n	TTV (%)	HGV (%)	TTV & HGV (%)
Healthy blood donors	110	9 (8.2)	2 (1.8)	0 (0.0)
HBsAg(+) donors	112	18 (16.1) ^a	2 (1.8)	0 (0.0)
Anti-HCV(+) donors	69	14 (20.3) ^a	12 (17.4) ^b	3 (4.3)
Patients with type B chronic liver disease	81	17 (21.0) ^a	11 (13.6) ^b	6 (7.4)
Chronic hepatitis	6	10(21.7)	5 (10.9)	3 (6.5)
Liver cirrhosis	15	3 (20.0)	3 (20.0)	2 (13.3)
Hepatocellular carcinoma	20	4(20.0)	3 (20.0)	1 (5.0)
Patients with type C chronic liver disease	19	4 (21.1) ^a	2 (10.5) ^b	1 (5.3)
Chronic hepatitis	10	2 (20.0)	1 (10.0)	0 (0.0)
Hepatocellular carcinoma	9	2 (22.2)	1 (11.1)	1 (11.1)
Total	391	62 (15.9)	29 (7.4)	10 (2.6)

^a $P < 0.05$ vs healthy blood donors, ^b $P < 0.05$ vs healthy blood donors or HBsAg-positive donors.

Association of TTV and HGV infections with blood transfusion

To investigate the association of TTV and HGV infections with blood transfusion, the medical records for the previous transfusion history were reviewed in patients with chronic liver disease. The rate of transfusion history was higher in TTV- or HGV-positive patients than in TTV- or HGV-negative patients ($P < 0.05$) (Table 2).

Table 2 Transfusion history according to the detection of TTV and HGV in patients with chronic liver disease

Group	n	Transfusion history	
		Yes (%)	No (%)
TTV Positive	21	14 (66.7) ^a	7 (33.3)
TTV Negative	77	33 (42.9)	44 (57.1)
HGV Positive	13	10 (76.9)	3 (23.1)
HGV Negative	85	37 (43.5)	48 (56.5)
Total	98	47 (48.0)	51 (52.0)

^a $P < 0.05$ vs TTV- or HGV-negative patients.

Correlation between TTV or HGV viremia and hepatic damage

To evaluate the correlation between TTV or HGV infections and hepatic damage, the serum levels of ALT and AST were measured in all subjects (data not shown). No significant increase in serum ALT and AST was observed in TTV- or HGV-positive blood donors, compared with TTV- or HGV-negative donors. In addition, TTV or HGV co-infection did

not elicit any further significant increase in ALT and AST levels in patients with chronic liver disease. Furthermore, no increase in ALT and AST was observed in HBV- or HCV-positive patients or donors infected with both TTV and HGV. These observations suggested that there is no significant association between TTV or HGV infections and hepatic injury.

DISCUSSION

TTV was detected in 8.2 % of healthy blood donors from Korea. The prevalence of TTV infection among blood donors in other countries is 1.9 % in the United Kingdom^[5], 3.2 % in Germany^[6], 7.5-10 % in the United States^[7, 8], 12 % in Japan^[3], 29.4 % in Egypt^[9], 36 % in Thailand^[10], and 62 % in Brazil^[11]. These differences in prevalence between countries could be due to the different geographical distribution of TTV infections, and the heterogeneity and variability of TTV isolates^[3, 5]. Variation could also arise due to different experimental methods to determine TTV infection, such as the primers used, and the sensitivity of the PCR methods employed^[8, 25]. The primer used in our study was identical to that used in the aforementioned countries, suggesting that the discrepancies of TTV prevalence between countries were not due to variation in the primer used. The detection rate of HGV RNA in blood donors from many other countries ranged from 0.5 to 7.4 %^[19-22]. In healthy Korean blood donors, the detection rate of HGV was 1.8 %, and the prevalence of TTV was higher (about 4.6 times) than that of HGV.

We observed TTV and HGV co-infection in subjects with HBV or HCV findings that had also been reported elsewhere^[12-18]. The co-infection rate of TTV in HBV- and HCV-infected subjects was similar, a finding also reported by others^[10, 12]. However, there was some difference in the co-infection rate of HGV between HBV and HCV. The prevalence of HGV in HBsAg-positive donors was lower than in patients with chronic liver disease and also anti-HCV-positive donors. Giulivi *et al.* have reported similar findings^[26]. The discrepancy in the co-infection rate of HGV between HBV- and HCV-positive donors may have clinical significance. With the exception of HGV co-infection in HBV-positive donors, both HBV- and HCV-infected subjects had a higher detection rate of TTV or HGV than healthy donors. This suggested that HBV- or HCV-infected subjects had a greater exposure to a risk factor for viral infections. These viruses may also share a common route of transmission.

A total of 66.7 % of TTV DNA-positive patients and 76.9 % of HGV RNA-positive patients had a history of blood transfusion. This suggests the possibility of viral transmission via blood transfusion. TTV and HGV are prevalent in the sera of persons with hemophilia, intravenous drug users, and hemodialysis patients^[3, 8, 21, 27]. However, our results indicate that TTV and HGV were observed in donors and patients without a transfusion history, which suggests a non-parenteral route of transmission. TTV and HGV have reportedly been detected in urine, feces, and breast milk^[6, 28, 29]. Thus, TTV and HGV might be transmitted via several parenteral and non-parenteral routes.

No significant increase in ALT or AST was observed in healthy donors or liver disease patients infected with either TTV or HGV, compared to subjects without these viral infections. Kao *et al.* reported that TTV infection does not affect the disease process of type B or C hepatitis, or the response to interferon treatment^[15]. Oguchi *et al.* demonstrated that a TTV carrier state was maintained without hepatitis in hemodialysis patients over a 5-year follow-up period^[30]. Alter *et al.* showed that HGV infection was not associated with hepatitis and did not worsen the course of concurrent HCV infection^[31]. Considering all these results, TTV or HGV

infection seems not to be related to the initiation or potentiation of hepatic damage, which therefore suggests that the routine screening test for TTV and HGV on donated blood is not necessary. At present there also is no country that conducts the screening test for these viral infections.

Abstract

AIM: To evaluate the potential of laparoscopy in the diagnosis of cirrhosis and outcome of interferon treatment in HCV-infected patients.

METHODS: In this retrospective study, diagnostic laparoscopy with laparoscopic liver biopsy was performed in 72 consecutive patients with chronic HCV infection. The presence or absence of cirrhosis was analyzed macroscopically by laparoscopy and microscopically by liver biopsy specimens. Clinical and laboratory data and outcome of interferon-alfa treatment were compared between cirrhotic and noncirrhotic patients.

RESULTS: Laparoscopically, cirrhosis was seen in 29.2 % (21/72) and non-cirrhosis in 70.8 % (51/72) of patients. Cirrhotic patients were significantly older with a significant longer duration of HCV infection than noncirrhotic patients. Laboratory parameters (AST, γ -GT, γ -globulin fraction) were measured significantly higher as well as significantly lower (prothrombin index, platelet count) in cirrhotic patients than in non-cirrhotic patients. Histologically, cirrhosis was confirmed in 11.1 % (8/72) and non cirrhosis in 88.9 % (64/72). Patients with macroscopically confirmed cirrhosis ($n=21$) showed histologically cirrhosis in 38.1 % (8/21) and histologically non-cirrhosis in 61.9 % (13/21). In contrast, patients with macroscopically non-cirrhosis ($n=51$) showed histologically non cirrhosis in all cases (51/51). Thirty-nine of 72 patients were treated with interferon-alfa, resulting in 35.9 % (14/39) patients with sustained response and 64.1 % (25/39) with non response. Non-responders showed significantly more macroscopically cirrhosis than sustained responders. In contrast, there were no significant histological differences between non-responders and sustained responders.

CONCLUSION: Diagnostic laparoscopy is more accurate than liver biopsy in recognizing cirrhosis in patients with chronic HCV infection. Liver biopsy is the best way to assess inflammatory grade and fibrotic stage. The invasive marker for staging, prognosis and management, and treatment outcome of chronic HCV-infected patients need further research and clinical trials. Laparoscopy should be performed for recognition of cirrhosis if this parameter is found to be of prognostic and therapeutic relevance in patients with chronic HCV infection.

INTRODUCTION

Hepatitis C virus (HCV) infection is the leading cause of chronic liver disease. Up to 85 % of HCV-infected patients develop chronic liver disease without elimination of the virus^[1-3]. Chronic HCV infected patients develop cirrhosis in 7 % and 20 % after 20 and 40 years of infection^[4], while symptoms and alarming biochemical markers appear late^[5,6]. Patients with cirrhosis secondary to chronic HCV infection also have an increased risks for development of hepatocellular carcinoma (HCC), estimated to be between 1-4 % per year^[7].

The diagnostic spectrum for chronic hepatitis C includes biochemical parameters, antibodies against HCV, qualitative and quantitative HCV RNA with genotyping, abdominal ultrasound and liver histology. Random core biopsy analysis can reveal information about the inflammatory grade and fibrotic stage of chronic HCV infection^[8]. Diagnosis of compensated liver cirrhosis can be made with a high accuracy neither by percutaneous liver biopsy nor by ultrasound^[9]. In comparison with percutaneous liver biopsy, laparoscopy allows macroscopic inspection of both liver lobes that might variate during progression of liver disease^[10]. Percutaneous liver biopsy only allows the interpretation of a small biopsy. It has been reported that histological analysis fail with error ranges above 25 % in the diagnosis of cirrhosis in chronic liver disease^[11,12], especially during the early phase of cirrhosis (Child A) and macronodular cirrhosis^[13]. In a retrospective study, Ponichik *et al.* compared the presence of cirrhosis in 434 patients by liver biopsy and laparoscopy. Cirrhosis was seen laparoscopically in 169 patients and was confirmed in 115 patients histologically. In contrast, only 2 of 265 histologically confirmed cirrhotic livers were macroscopically without cirrhosis^[14]. Ultrasound guided liver biopsy can result in a false negative histology due to the puncture of a regenerative nodule^[15]. Cardi *et al.* showed superiority of laparoscopy over ultrasonography in diagnosis of widespread liver diseases^[16]. Oberti *et al.* reported that only prothrombin index and serum hyaluronate were sensitive parameters for screening cirrhosis^[17]. Early cirrhosis may often be missed due to clinical inapparence especially in patients with chronic HCV infection and accurate noninvasive markers of disease activity and fibrosis are not available^[18]. The absence of early cirrhosis in chronic HCV infected patients might be a potential field for diagnostic laparoscopy that is not performed routinely and patients with early cirrhosis can be enrolled in the screening programs for HCC, too.

In the treatment of chronic HCV infection has proved beneficial interferon-alfa in the last two decades^[19-23]. Old age, high level of viraemia, HCV genotype II (1b), long duration of disease, high levels of hepatic iron store, especially the advanced liver damage represented by dimension of fibrosis were considered to be negative predictive factors in the outcome of interferon treatment^[22,24-34]. Two studies focused exclusively on interferon treatment in patients with HCV related cirrhosis^[35,36]. After introduction of pegylated interferon given only once a week, HCV-infected patients with cirrhosis or bridging fibrosis were treated in a clinical trial^[37]. These data implicated that HCV infected patients with liver cirrhosis need different therapeutic schedules with longer duration and higher dose of interferon.

Since cirrhosis is a negative predictor for antiviral therapy in chronic HCV-infected patients and liver histology might underestimate the frequency of cirrhosis, the aim of this retrospective study was to evaluate the potential of laparoscopy in the diagnosis of cirrhosis and outcome of interferon treatment in this particular group of patients.

MATERIALS AND METHODS

Patients

Laparoscopy and laparoscopic liver biopsy were performed in 72 chronic HCV-infected patients. Diagnosis of chronic HCV infection was based on elevated liver enzymes for at least 6 months, detection of anti-HCV antibodies in ELISA (2nd generation) and HCV RNA by RT/PCR. Patients with active viral coinfections (HBV, HIV, CMV, EBV), evidence for autoimmune hepatitis with positive serologic constellation of specific autoantibodies (ANA, AMA, anti-SLA, SMA, anti-LKM), alcohol and/or i.v. drug abusers and patients with signs of liver cirrhosis and/or hepatic decompensation (e.g. ascites, gastrointestinal bleeding, etc.) were excluded. Each patient was asked to sign a written informing consent for diagnostic laparoscopy and liver biopsy.

Biochemical and serological analysis

Serum levels of ALT, AST, γ -GT, AP and CHE, as well as concentrations of serum bilirubin, prothrombin index, γ -globuline fraction and platelet count were measured by established routine methods before laparoscopy, during and after interferon treatment. Anti-HCV antibodies were analyzed using an ELISA (2nd generation, Ortho Diagnostic Systems, Raritan, NJ, USA) according to the instructions of the manufacturer.

Detection of HCV RNA and determination of HCV genotypes

According to Okamoto *et al.* and Simmonds *et al.*^[38,39] determination of serum HCV RNA by a nested RT/PCR technique and determination of genotypes by a restriction enzyme analysis were carried out as described previously^[40].

Laparoscopy

Abdominal ultrasound, electrocardiogram and, in patients older than 60 years, a chest X-ray were performed before laparoscopy. The evening before laparoscopy, each patient received 75 mg promethazin orally. Two hours before examination, 50 mg promethazin and 30 minutes before exploration 50 mg pethidin and 0.5 mg atropine were injected intramuscularly. If necessary, patients received sedativa or analgetics during the laparoscopic intervention. During laparoscopy, each patient was given continuously an isotonic electrolyte solution intravenously. Patients were monitored by pulsoxymetry. After local anesthesia, the pneumoperitoneum was installed by puncturing at Monros' point with the Verres needle followed by insufflation of 2-3 L nitrous oxide. After insertion of the laparoscope in a trocar with a safety shield at Kalks' point, macroscopic exploration of liver, spleen and peritoneum followed. Liver biopsies were taken generally from an area on the anterior surface of the left lobe of the liver or of macroscopic suspect areas using a Menghini needle, at least 2 cm from the liver edge, containing at least five portal areas. Macroscopic diagnosis of cirrhosis was made based on the following criteria: (1) diffuse nodules on the liver surface, or (2) shallow nodules (i.e., nodules usually of large diameter, slightly protruding from the liver surface) if the liver was hard on palpation and rigid on lifting with a blunt probe and if clearcut features of portal hypertension were observed^[41,42].

Histopathological evaluation

Formalin-fixed and paraffin-embedded liver biopsies were

stained with hematoxylin-eosin, trichrome and by applying the Prussian blue reaction as described previously^[43]. One pathologist examined samples unblindedly. A modified "Histology Activity Index" (HAI) on the basis of reported staging scores served to assess the stage of fibrosis^[44-46]. Absent portal fibrosis was staged as fibrosis score I (HAI^b=0, no fibrosis), mild to moderate fibrosis as stage II (HAI^b=1, fibrotic portal expansion), marked fibrosis as stage III (HAI^b=3, bridging fibrosis) and complete fibrosis as cirrhosis (HAI^b=4).

Interferon treatment

Patients received recombinant interferon-alfa 2a (Roferon A, Hoffmann-La Roche, Basel, Switzerland) for initial treatment of chronic HCV infection. In our retrospective study, a dose of 6 MU three times a week was administered for 12 months according to Chemello *et al.*^[47]. Patients were classified as sustained responders if serum transaminases normalized (biochemical response) and serum HCV RNA became undetectable (virological response) during the treatment and at 6 months after the end of treatment (follow-up). During the follow-up, the re-emergence of both parameters after the end of treatment was defined as relapse. Patients with no improvement of biochemical or virological parameters within the first 3 months of treatment were classified as non-responders and treatment was stopped. For statistical analysis patients with relapse and non-response were classified as non-responders and compared with sustained responders. Patients who finished their course of treatment and 6 months of follow-up after the end of treatment were analysed.

Statistical analysis

Significant levels of differences between values were analyzed using the Chi-square test, Mann-Whitney test and student's *t*-test as indicated.

RESULTS

Mean ($M \pm SD$) age of the 72 patients (49 % female, 51 % male) with chronic HCV infection was 46.8 ± 12.1 years with a range of 27-72 years. Route and date of HCV infection were identified in 44 patients. The duration of HCV infection was 15.4 ± 9.7 years and route of viral transmission was blood transfusion in 23 %, intravenous drug abuse in 18 % and anti-D prophylaxis in 3 %.

Laparoscopy found no severe complications. Liver biopsy caused mild bleeding in 6 (8 %) patients which was controlled during laparoscopy by local compression. None of the patients required blood transfusion. One patient developed a mesenteric emphysema after insufflation of nitrous oxide.

Cirrhosis was found by laparoscopy in 21/72 (29.2 %) patients and by histology in 8/72 (11.1 %) patients. According to HAI, patients with macroscopic cirrhosis by laparoscopy ($n=21$) showed histologically fibrosis stage I in 14.3 % (3/21), fibrosis stage II in 19 % (4/21), fibrosis stage III in 28.6 % (6/21) and cirrhosis in 38.1 % (8/21) (Table 1). Therefore 13/21 (61.9 %) macroscopic cirrhosis was not identified histologically. No cirrhosis was detected by laparoscopy in 51/72 (70.8 %) patients. According to HAI, patients without macroscopic cirrhosis ($n=51$) showed histologically fibrosis stage I in 58.8 % (30/51), fibrosis stage II in 31.4 % (16/51), fibrosis stage III in 9.8 % (5/51) and cirrhosis in 0 (0/51).

For statistical analysis, patients were divided into two groups. Group A represented patients with macroscopic cirrhosis ($n=21$) and group B patients without macroscopic cirrhosis ($n=51$) diagnosed by laparoscopic criteria. The mean ($M \pm SD$) age of patients in group A was 56.4 ± 9.4 years, being significantly higher than in group B aged 41.7 ± 11.2 years ($P < 0.02$). There were 10 men and 11 women in group A and 27 men and 24 women in group B (n.s.). Mean ($M \pm SD$)

duration of chronic HCV infection in 44 patients of group A was 23.2 ± 8.3 years, being significantly longer than in patients without macroscopic cirrhosis (group B) aged 10.4 ± 5.7 years ($P < 0.02$) (Table 2). In blood chemistry, patients of group A had significantly higher AST, γ -GT and γ -globulin fraction in serum electrophoresis as well as significant lower prothrombin index and platelet count than patients of group B. No significant differences were found for ALT, AP, bilirubin and cholinesterase in both groups (Table 3). According to the Child-Pugh-Turcotte classification, 18 of the 21 patients with macroscopic cirrhosis were classified as Child A, 3 Child B and none Child C. In comparison of histological cirrhosis (8/21) and histologic non cirrhosis (13/21) of group A with macroscopic cirrhosis ($n=21$), significant differences were only found in AST and γ -GT (Table 4). Differences were not significant in prothrombin index, γ -globuline fraction and platelet count between cirrhosis (8/21) and histologic non-cirrhosis (13/21) of group A with macroscopic cirrhosis ($n=21$) (Table 4).

Table 1 Outcome of macroscopic laparoscopic exploration and histological analysis in 72 patients with chronic HCV infection

Histology (fibrosis stage score)	Laparoscopy	
	Patients without signs of cirrhosis ($n=51$)	Patients with signs of cirrhosis ($n=21$)
Fibrosis I	30	3
Fibrosis II	16	4
Fibrosis III	5	6
Cirrhosis	0	8

Absent portal fibrosis was judged as fibrosis score I ($\text{HAI}^b=0$, no fibrosis), mild to moderate fibrosis as stage II ($\text{HAI}^b=1$, fibros portal expansion), marked fibrosis as stage III ($\text{HAI}^b=3$, bridging fibrosis), and complete fibrosis as cirrhosis ($\text{HAI}^b=4$).

Table 2 Demographic and clinical data of patients with and without laparoscopically diagnosed cirrhosis

	Laparoscopy		<i>P</i>
	Patients with signs of Cirrhosis ($n=21$)	Patients without signs of Cirrhosis ($n=51$)	
Age (years)	56.36 ± 9.42	41.7 ± 11.2	$<0.02^a$
Duration of disease (years) ($n=44$)	23.2 ± 8.3	10.4 ± 5.68	$<0.02^a$
Sex ratio (m/f)	10/11	27/24	ns

^aStudent's *t*-test (unpaired); ns=not significant, years were showed as mean \pm standard deviation. Duration of disease could be evaluated in 44 cases by patients' history.

Table 3 Laboratory data of patients with and without laparoscopic macroscopic evidence of cirrhosis

Laboratory data	Laparoscopy		<i>P</i>
	Patients with evidence of cirrhosis ($n=21$)	Patients without evidence of cirrhosis ($n=51$)	
AST (U/l)	59.7 ± 54.2	29.3 ± 19.6	<0.02
ALT (U/l)	82.5 ± 70.3	72.6 ± 47.2	ns
γ -GT (U/l)	72.6 ± 78.4	34.1 ± 38.2	<0.02
AP (U/l)	129.8 ± 48.9	137.5 ± 49.6	ns
Bilirubin (mg/dl)	1.1 ± 0.93	1.86 ± 6.23	ns
CHE (U/l)	5114 ± 1331	5910 ± 1001	ns
Prothrombin index (%)	93.8 ± 12.6	102.2 ± 6.3	<0.02
γ -globuline fraction (%)	19.9 ± 6.5	13.7 ± 2.9	<0.02
Platelet count (cell/ μ l)	$172\ 940 \pm 65068$	$253\ 230 \pm 57096$	<0.02

All data were showed as mean \pm standard deviation. Statistical analysis was performed by applying Mann-Whitney test. ns=not significant.

Table 4 Comparing laboratory data of patients with macroscopic laparoscopic signs of cirrhosis

Laboratory data	Histological analysis		<i>P</i>
	No cirrhosis ($n=13$)	Cirrhosis ($n=8$)	
AST (U/l)	35.9 ± 24.9	87.7 ± 67.8	<0.02
ALT (U/l)	64.9 ± 72.2	97.0 ± 66.34	ns
γ -GT (U/l)	51.64 ± 39.78	103.0 ± 104.6	<0.02
AP (U/l)	126.3 ± 54.6	144.6 ± 39.6	ns
Bilirubin (mg/dl)	0.36 ± 0.5	1.4 ± 3.438	ns
CHE (U/l)	5129 ± 1861	4685 ± 1773	ns
Prothrombin index (%)	95.8 ± 10.6	90.7 ± 14.3	ns
γ -globuline fraction (%)	16.3 ± 3.2	19.6 ± 10.6	ns
Platelet count (cells/ μ l)	$180\ 700 \pm 56\ 240$	$167\ 000 \pm 77\ 110$	ns

All data were showed as mean \pm standard deviation, statistical analysis were performed by Mann-Whitney test. ns=not significant.

Thirty-nine patients were treated with interferon-alfa 2a and followed up for 6 months after the end of treatment. HCV genotyping was performed in all 39 patients before start of therapy. HCV genotype II (1b) was the predominant genotype. The HCV genotypes of the 39 patients were 23 II (1b), 5 I (1a), 3 IV (2b), 5 V (3a) and 3 I (1a) combined with II (1b). Patients with macroscopic cirrhosis showed no significant difference of genotype distribution as compared with patients without cirrhosis. Interferon treatment resulted in 14/39 (35.9 %) sustained responders and 25/39 (64.1 %) non-responders including 2 relapsers. According to HCV genotype distribution, a significant higher rate of genotype II (1b) was observed in non-responders than sustained responders ($P < 0.02$). Non-responders had a higher rate of macroscopic cirrhosis than sustained responders ($P < 0.02$) (Table 5).

Table 5 Comparisons in pretreatment parameters between patients with sustained response and patients with non-response to interferon treatment ($n=39$)

	Sustained-responders	Non-responders	<i>P</i>
Number (%)	14 (35.9 %)	25 (64.1 %)	
Age (years)	50.6 ± 13.9	47.2 ± 10.6	ns
Genotype 1b (%)	5 (35.7 %)	18 (72 %)	$<0.02^a$
Fibrosis staging score (%)			
I	7 (50.0 %)	9 (36.0 %)	
II	3 (21.4 %)	8 (32.0 %)	
III	3 (21.4 %)	3 (12.0 %)	
Cirrhosis	1 (7.0 %)	5 (20.0 %)	ns
Laparoscopic evidence of cirrhosis (%)	2 (14.2 %)	9 (36.0 %)	$<0.02^a$

Data of age were showed as mean \pm standard deviation; ^aChi-square test, ns=not significant.

DISCUSSION

Diagnostic laparoscopy is recommended in the diagnosis of peritoneal diseases, evaluation of ascites of unknown origin, staging of abdominal cancer and chronic and focal liver disease^[48]. Laparoscopy is commonly not performed for the diagnosis of cirrhosis in patients with chronic HCV. The availability of percutaneous liver biopsy guided by ultrasound, CT- or MRI-scan offers selected biopsy of an suspicious area in the liver. The rate of laparoscopic liver biopsies in gastroenterology declined and also the number of training programs for this procedure^[49]. However, all imaging procedures do not allow a direct viewing of the liver. The direct

visual inspection of the liver and the abdomen is the privilege of laparoscopy.

In this study, more chronic HCV infected patients had been diagnosed of cirrhosis macroscopically by laparoscopic inspection of the liver than histologically by using the Menghini needle for laparoscopic liver biopsy. All patients with histological cirrhosis also had cirrhosis macroscopically, but 13/21 patients with macroscopic cirrhosis had no cirrhosis histologically. This discrepancy implicates an underestimation of cirrhosis in chronic HCV-infected patients, if diagnosis of cirrhosis is based only on liver biopsy using the Menghini needle. Poniachik *et al.* investigated the role of laparoscopy and laparoscopic liver biopsy in the diagnosis of cirrhosis in 434 patients with chronic liver disease including 169 patients with laparoscopic evidence of cirrhosis. The histological sampling error was 32 % among patients documented to have cirrhosis by laparoscopy^[14]. The selection of a suction or cutting needle for liver biopsy has a major impact at the stage of cirrhosis. The use of a cutting needle like Vim-Silverman or Tru-Cut is reported to give a more representative histology than suction needles like Menghini, Klatskin or Jamshidi, because fibrotic tissue tends to fragment with the use of suction needle^[49,50]. In a randomized study on 1192 patients with diffuse liver disease, Colombo *et al* investigated percutaneous liver biopsies comparing the Tru-Cut and the Menghini needle. For diagnosing cirrhosis accuracy of the Tru-Cut needle is significantly better (89.5 %) than the Menghini needle (65.5 %). Complication rates were very low with both needles^[51].

Comparing laparoscopy and laparoscopic biopsy for diagnosis of cirrhosis, laparoscopic diagnosis of macroscopic cirrhosis was of higher value than histological diagnosis of microscopic cirrhosis regarding blood chemistry and the response to interferon therapy. The rate of non-response to interferon therapy was 64.1 % in our study. Significant parameters for non-response were genotype II (1b) and laparoscopic evidence of cirrhosis, but not histological diagnosis of cirrhosis. Nowadays, new therapeutic regimes have replaced interferon monotherapy. The combination of interferon-alfa with ribavirin improved sustained response rate for chronic HCV-infected patients^[52] and for relapsers and non-responders after initially interferon monotherapy^[53-55]. Increased efficacy was shown with pegylated interferon as compared with standard interferons in cirrhotic and noncirrhotic patients with chronic hepatitis C^[37,56,57] and currently standard therapy is pegylated interferon in combination with ribavirin^[8]. In this treatment situation, the role of liver biopsy has increasingly been discussed^[58]. If patients with positive predictors of virological response, such as low viral load and infection with genotype 2 or 3, can be treated and have very high chances of response, a biopsy that reveals mild histologic changes may do little to dissuade the clinician and patients from immediate treatment^[8]. Liver biopsy may become recommended only in those patients whose pretreatment characteristics predict the lowest success rate^[8]. Paired liver biopsy specimens enable staging of inflammation and fibrosis before and after treatment to define histological response in those patients. Compared with our data, the rate of cirrhosis before treatment will be underestimated without performing laparoscopy in those patients. Both procedures, liver biopsy and laparoscopy, are invasive, but accurate noninvasive markers for staging disease activity, fibrosis and cirrhosis are not available^[18]. Our rate of complications related to laparoscopy and laparoscopic liver biopsy was 10 % and no severe complication was observed. These data are in accordance with other reports^[11,42,59-62]. The rate of severe complications using blind percutaneous liver biopsy is reported to be 0.3-1.5 % and is almost comparable with laparoscopic liver biopsy^[41,63-67]. Diagnostic laparoscopy and laparoscopic

liver biopsy are a safe and invasive procedure in patients with compensated liver disease. Minilaparoscopy has increasingly emerged as a less invasive diagnostic method in this field^[68].

Based on our data, diagnostic laparoscopy is indicated for recognition of early cirrhosis in patients with chronic HCV infection. In fact, as early diagnosis of cirrhosis affects management of chronic HCV infected patients, it should be the key factor in the decision-making process.

Abstract

AIM: To study the level of membrane interleukin-2 receptor (mIL-2R) on surface of peripheral blood mononuclear cells (PBMC) and the therapeutic efficacy of alpha 2b interferon on the treatment of HCV-RNA in PBMC of patients with chronic hepatitis C and to compare the negative rates of HCV-RNA in PBMC, HCV-RNA and anti-HCV in serum.

METHODS: Before and after treatment of alpha 2b interferon, the level of mIL-2R of patients with chronic hepatitis C was detected by biotin-streptavidin (BSA). The therapeutic group (26 cases) was treated with alpha 2b interferon (3 MU/d) and control therapeutic group (22 cases) was treated with routine drugs (VitC, aspartic acid). The total course of treatment with alpha 2b interferon and routine drug was six months and per course of the treatment was three months. The levels of HCV-RNA in PBMC, HCV-RNA and anti-HCV in serum were detected before and after a course of the treatment.

RESULTS: Before and after treatment of alpha 2b interferon and routine drugs, the levels of mIL-2R in silence stage were $(3.44 \pm 0.77) \%$ and $(2.95 \pm 0.72) \%$, the levels of mIL-2R in inducement stage were $(33.62 \pm 3.95) \%$ and $(30.04 \pm 3.73) \%$. There was a significant difference between two groups ($P < 0.01$ - $P < 0.05$). After treatment of alpha 2b interferon with 3 MU/d for two courses of the treatment, the total negative rates of HCV-RNA in the PBMC and HCV-RNA, anti-HCV in serum were 42.31 % (11/26), 57.69 % (15/26), 65.38 % (17/26) respectively. After the treatment of routine drug, the negative rates of HCV-RNA in PBMC and HCV-RNA, anti-HCV in serum were 13.64 % (3/22), 22.73 % (5/22), 27.27 % (6/22) respectively. There was high significant difference in the group treated with alpha 2b interferon and the group treated with routine drugs ($P < 0.01$ - $P < 0.05$).

CONCLUSION: The mIL-2R can be induced by alpha 2b interferon during the treatment. The alpha 2b interferon has a definite effect on the treatment of HCV-RNA in PBMC.

The curative effect of alpha 2b interferon is better than that of the routine drugs.

Wang J, Xiang GJ, Liu BX. Effect of alpha 2b interferon on inducement of mIL-2R and treatment of HCV in PBMC from patients with chronic viral hepatitis C. *World J Gastroenterol* 2003; 9(4): 751-754

<http://www.wjgnet.com/1007-9327/9/751.htm>

INTRODUCTION

Treatment of interferon on the chronic viral hepatitis C has been shown to have a good curative effect on inhibition of HCV replication, reduction in transmission level in serum and liver cells^[1-8], but the improvement in clinical condition was not obvious and its effective rate was only 50 %^[9-17]. The curative effect of interferon was based on virostatic replication of HCV in serum and some improvement of liver function. The literatures show that the peripheral blood mononuclear cells (PBMC) have large different active immune cells and membrane interleukin-2 receptor (mIL-2R) is an important symbol of active T cells, and the immune function of PBMC will be inhibited after being infected by HCV and the scavenging effect limited^[18,19]. In order to study the effect of interferon on treatment of HCV in PBMC and the effect of interferon on inducement to mIL-2R, forty-eight patients with typical chronic hepatitis C were observed.

MATERIALS AND METHODS

Clinical data

Forty-eight patients with chronic viral hepatitis C were selected from the Second Miner Hospital of Huainan and our teaching hospital during 1997/03-2000/05. The total number of patients was 48 (male 27, female 21) and range of age was from 18 to 57 years old (average 37.3). The clinical diagnosis was based on the modified diagnosis criterion being affirmed on the Chinese viral hepatitis conference in Xian (2000). The patients all needed the following qualifications: (1) The positivity of anti-HCV in serum for more than six months. (2) The HCV-RNA in peripheral blood mononuclear cells and serum were positive. (3) The patients had been eliminated the infection of hepatitis A, B, D, E and G viruses. (4) There were no any systemic treatment of antiviral medicine, immunomodulator, cortical hormone for the patients. The normal control was 20 healthy students (male 12, female 8) with range age from 20 to 23 years old (average 22.5).

Treatment medicine

The alpha 2b interferon was produced by High Science and Technology of Anke Biology in Anhui Province.

Treatment methods

The patients with chronic hepatitis C were divided into two groups with treatment of alpha 2b interferon 3MU (26 cases)

and routine medicine (22 cases) respectively. The total course of treatment lasted sixty months, and per course was three months. Alpha 2b interferon was given intramuscularly injection (im) qd for two weeks and then alt dieb for two courses of treatment. The routine treatment group (22 cases) was given with Vit C, Aspartic acid, etc for six months.

Reagents

The diagnostic reagent of anti-HCV was purchased from Huamei Bioengineering Company of Shanghai, No:980811. The diagnostic reagent of HCV-RNA with RT-PCR was purchased from Shanghai Zhongya Gene Institute, No: 980805. The diagnostic reagent of mIL-2R was purchased from Immunology Institute of Shanghai. The lymphocytes separation medium was purchased from the Second Reagent Factory of Shanghai, No:970505. The reagent of RPMI 1640 culture was produced by Sigma (USA).

Instruments

The analysis instrument of Spector-I was made in USA; MDF-135 CO₂ incubator was made in Japan; The instrument for gene amplification (Hema-8000) was made in Hema Company of China.

Methods

The total volume of 5 ml peripheral venous blood from patients with hepatitis C before breakfast was taken before and after treatment, and distributed a sterile Eppendorf tube and an anticoagulant tube (heparin) respectively. For detection of anti-HCV, the process was performed strictly according to the direction, and with two blank, two negative and two positive pores as controls in each test. The average titer was examined by the analyser Spector-I. The average OD titer of test sample ≥ 2.1 times of average OD titer in negative control was considered to be positive. Detection of HCV-RNA in PBMC with RT-nested-PCR: After the heparin anticoagulant blood mixed with the equal volume Hank's liquid without Ca²⁺ and Mg²⁺, lymphocytes separation medium was used to separate the PBMC. The cells were washed twice with Hank's liquid without Ca²⁺, Mg²⁺ and diluted to (1-3)×10⁶/ml before detection of HCV-RNA. A positive and a negative control were set up at the same time for comparison in each test. The RT-nested-PCR was made by reverse transcription and primer selected from non-coded region and part of C region of HCV. The specific amplified fragment length was 248 bp. The synthesis parameters for cDNA were 94 °C 40 s, 55 °C 40 s, 72 °C 1 min, for 30 circles. The amplification parameters for cDNA were 94 °C 50 s, 55 °C 40 s and 72 °C 90 s, 35 circles, including initial denaturation for 4 min at 94 °C and last extension for 5 min at 72 °C. The amplification product was run for electrophoresis on gel with 2 % EB. The result that was uniform to the positive control was considered to be positive. The detection of mIL-2R in silence and inducement stages: 10 μ l suspension of the PBMC was smeared on the slide and left dry naturally and fixed with acetone for fifteen minutes or twenty minutes. The 10 μ l anti-Tac antibody was mixed with the membrane of smears. The cells were grown in continuous culture (37 °C, 50 ml·L⁻¹ CO₂ in atmosphere) for thirty minutes. The immune sheet glass pores were measured after staining with the color-developing agent and several washings with Tris Buffer Solution (TBS). Of the PBMC suspension, 0.5 ml was mixed with RPMI 1640 culture liquid, which had PHA 200 mg·L⁻¹. The cells were grown in continuous culture (37 °C, 50 ml·L⁻¹ CO₂ in atmosphere) 72 h and its mIL-2R induced by PHA could be measured by the antibodies against membrane of T cells. The Tac with biotin and SA-HRP were smeared on different sheet glasses. The immune

sheet glass pores were measured after staining with the color-developing agent and several washings with TBS. The total number of 200 PBMC was counted and its positive cells were statistically analyzed with the help of high power lens. The positive criterion was that the color of cytoplasm or cell membrane was brown.

Statistical analysis

Statistical analysis included analysis of Chi-square (χ^2) and *t* test.

RESULTS

The forty-eight patients with chronic hepatitis C were divided into two groups and treated with alpha 2b interferon (26 cases) and routine drugs (22 cases) respectively. The results had been shown that the high negative rates of anti-HCV and HCV-RNA in serum were in the group with treatment of alpha 2b interferon. There was very significant difference before and after treatment of alpha 2b interferon ($P<0.01$ - $P<0.05$, Table 1). The negative rate of HCV-RNA between in PBMC and in serum was similar ($P>0.05$, Table 2). The level of mIL-2R in situation of silence and inducement stages after treatment with alpha 2b interferon was higher than that after treatment with routine drugs ($P<0.05$, Table 3).

Table 1 The detective results of HCV-RNA in serum and PBMC after treatment with alpha 2b interferon (*n*, %)

Group	<i>n</i>	HCV-RNA in PBMC		HCV-RNA in serum		Anti-HCV	
		Negative	Negative rate	Negative	Negative rate	Negative	Negative rate
Interferon treatment	26	11	42.31 ^a	15	57.69 ^a	17	65.38 ^b
Routin treatment	22	3	13.64	5	22.73	6	27.27

^a $P<0.05$, ^b $P<0.01$ vs interferon treatment.

Table 2 The results of negative rate of HCV-RNA in serum and PBMC

HCV-RNA in serum	HCV-RNA in PBMC		Total	χ^2	<i>P</i>
	+	-			
+	7	4	11	0.75	>0.05
-	8	7	15		
Total	15	11	26		

Table 3 The level of mIL-2R before and after treatment of interferon (*n*, $\bar{x}\pm s$, %)

Group	<i>n</i>	mIL-2R (in silence)		mIL-2R (inducement)	
		Before treatment	After treatment	Before treatment	After treatment
Interferon treatment	26	2.63±0.70	3.44±0.77 ^{bcd}	30.34±3.55	33.62±3.95 ^{cd}
Routin treatment	22	2.43±0.78	2.95±0.72 ^{ad}	30.07±3.87	30.04±3.73 ^d
Normal control	20	4.54±1.48		37.42±4.10	

^a $P<0.05$, ^b $P<0.01$ vs before and after treatment, ^c $P<0.05$, ^d $P<0.01$ vs interferon treatment.

DISCUSSION

There are three kinds of interferon, α , β , γ . Interferon alpha is the most active one. Alpha 2b interferon can not enter into the host cells and kill the virus directly, but can induce the production of protein kinase (2', 5' AS) in the infected cells.

The protein kinase and 2', 5' AS can be produced after being infected by virus in cells. The degradation of virus-RNA can be made by endogenous ednonuclease induced with activated 2', 5' AS so that the necessary enzyme activity for synthesis of ribose is killed, the synthetic protein of virus can be decreased, the growth of hepatitis virus C is inhibited^[20-30].

The reports have been shown that interferon has definite curative effect of the treatment of chronic hepatitis C and elimination of HCV-RNA, anti-HCV in serum. Therefore, HCV-RNA is an important index to evaluate condition of the patient's^[4]. HCV-RNA in PBMC is a direct evidence of the existence of extrahepatic or latent infection, and is one of important reasons causing the chronicity of viral hepatitis C^[28-31]. The results of Table 1 had shown that the rate of change HCV-RNA into negative in PBMC and serum after treatment of alpha 2b interferon was similar between two groups ($P>0.05$). The curative effect was higher in the treatment group with alpha 2b interferon than that with routine treatment ($P<0.05$ - $P<0.01$). This result had showed that the inducing capability of alpha 2b interferon in lymphocytes of the patients was strong, and the high effect against HCV would be taken by activated lymphocytes obviously. Although the negative rate of HCV-RNA in PBMC was lower than that in serum, there was no significant difference ($P>0.05$). The results had shown that alpha 2b interferon had high effect on HCV-RNA both in PBMC and in serum. There were four cases of chronic hepatitis C with negative in serum and positive in PBMC. It indicated that with the T lymphocytes activation, multiple cell factors were released, that inhibited the replication of free HCV-RNA in serum, but not the HCV-RNA in PBMC. The cellular immune function was disorder in different extent in patients with chronic hepatitis C and so was their response to interferon and anti-HCV^[32-37]. Otherwise, the low level of membrane interleukin-2 receptor (mIL-2R) on the surface of PBMC decreased the activity in chronic hepatitis C, which limited the inducement of protein kinase and the activity of 2', 5' AS to eliminate HCV-RNA^[38].

Anti-HCV is an important index for the diagnosis of HCV and is one of the evidences for evaluating the curative effect on the treatment of hepatitis C. The anti-HCV diagnostic kits of the second generation were used in our laboratory testing for core antigen, NS₃, NS₄ and had high specificity and sensitivity^[39,40]. The rate of negative change of HCV-RNA was higher in alpha 2b interferon treatment group than that in routine treatment group ($P<0.01$). Among the twenty-six cases, there were six cases with anti-HCV(-) in serum and HCV-RNA(+) in PBMC, two cases with anti-HCV(-) in serum and HCV-RNA(+) in serum. This result showed that even the anti-HCV in serum became negative, HCV-RNA not stopping replication completely, some HCV-RNA could still be detected in some patients^[6]. The probable reasons were: (1) After being treatment of alpha 2b interferon, the level of anti-HCV in serum decreased obviously and could not be detected by routine test. (2) The degree of variation of HCV is high, the hydrophilic peptid chain on core protein is subjective to escape the attack of CTL and keep the infection persist in chronic state. (3) The variant antigen of HCV can not match the antibody produced.

mIL-2R is an important symbol of active T cells and plays key role on biologic effect of IL-2 and its level can reflect the course of activity of T cells and immune state^[38-41]. The levels of mIL-2R in silence stage detected by BSA were lower in patients with hepatitis C than those in normal controls ($P<0.01$). The probable reasons are: (1) The mIL-2R on surface of some T cells can be restrained by HCV. (2) The degree of variation of HCV is high, the hydrophilic peptid chain on core protein is subjective to escape the attack of CTL and keep the infection persist in chronic state. (3) The variant antigen of HCV can not match the antibody produced. A lot of soluble interleukin-

2 receptor (sIL-2R) can be released after replication of HCV-RNA in PBMC so that the expression of mIL-2R was restrained. It is not only a kind of manifestation of disorder and low cellular immune to HCV but also one of reasons of chronic hepatitis C. Some T cells receptor (TCR) on surface of some Tc cells can combine with the complement (HCV-MHC-I) and some perforation proteins can be released so that many liver cells will be injured. The sIL-2R, a kind of restrained factor, as well as mIL-2R all can combine with IL-2 competitively and induce infection of HCV from activity to chronicity. With the inducement of PHA, the level of mIL-2R in silence and inducement stages was obviously increased. This result showed that the mIL-2R could be induced by PHA and had strong compete ability against sIL-2R in serum.

After inducement of PHA, the level of mIL-2R of patients in inducement stage was higher than that in silence stage, and lower than that in normal controls ($P<0.01$). The results of our study showed that the effect of PHA was infirm for patients with hepatitis C and was similar to the reports published. The level of mIL-2R in silence and inducement stages were higher after treatment of alpha 2b interferon than that before treatment of alpha 2b interferon ($P<0.01$). The active T cells and high level of mIL-2R can be induced by alpha 2b interferon during the treatment. The results showed that alpha 2b interferon not only can induce the protein kinase and 2', 5' AS but also stimulate T cells and induce the effect of Tc cells against infected cells.

In conclusion, some active T cells and mIL-2R can be induced during the treatment of alpha 2b interferon. The patients with viremia are sensitive to treatment of alpha 2b interferon that have good effect on negative change of HCV-RNA in PBMC and serum and anti-HCV in serum. If the treatment time of alpha 2b interferon prolongs, the negative rate of anti-HCV and HCV-RNA will increase simultaneously. In treatment of HCV with alpha 2b interferon, the value of negative change of HCV-RNA in serum alone is limited. In well equipped hospital both HCV-RNA in serum and PBMC can be examined at the same time.

Abstract

AIM: To determine the prevalence of *Helicobacter pylori* (*H. pylori*) infection, the serum anti-*H. pylori* immunoglobulin G (IgG) and IgA antibody responses, and the value of clinical presentations in diagnosis of *H. pylori* infection in patients with gastric atrophy, intestinal metaplasia and dysplasia.

METHODS: *H. pylori* infection was detected by histology in 209 patients with mild chronic atrophic gastritis (CAG, $n=76$), severe CAG ($n=22$), mild intestinal metaplasia (IM, $n=22$), severe IM ($n=58$), or dysplasia (DYS, $n=31$). Serum anti-*H. pylori* IgG and IgA were double sampled and evaluated by enzyme-linked immunosorbent assays. 35 clinical presentations were observed and their relationship with *H. pylori* infection was analyzed by the *k*-means cluster method.

RESULTS: Both IgG and IgA levels in *H. pylori* positive patients were significantly higher than those negative for *H. pylori* ($P<0.001-0.01$). The prevalence of *H. pylori* was highest in severe IM (84.5 %), and lowest in mild CAG (51.3 %) ($P<0.01$). They were similar in severe CAG (68.2 %), mild IM (72.7 %), and DYS (67.7 %). In *H. pylori* positive patients, the IgG levels in severe CAG were significantly higher than those in mild CAG ($P<0.01$). In *H. pylori* negative patients, both IgG and IgA levels increased remarkably in severe IM, compared to those in mild IM ($P<0.01-0.05$). *H. pylori* infection exhibited no association with patient's gender (62.1 % in males; 71.7 % in females) and age ($r=0.0814$, $P=0.241$). The diagnostic accuracy based on 35 clinical presentations was 65.7 %. It could be improved by 5.7 % when only the assemblage of digestive symptoms were engaged, or by 8.6 % when the pathogenic factors, general status and grossoscopy were combined. The diagnostic accuracy could be decreased when only the general symptoms were engaged, or when the pathogenic factors were accompanied with some common digestive symptoms.

CONCLUSION: *H. pylori* infection is a major risk factor for the process from atrophy, IM to DYS of gastric mucosa. Serum IgG and IgA are good indicators to evaluate this

progress with a certain rearrange. Investigation on the effective assemblages of clinical presentations may provide a better understanding in the pathogenesis, diagnosis and treatment for *H. pylori* infection.

INTRODUCTION

The persistence or repeated infection of pathogenic factors in the stomach may result in the chronic process of gastritis with glandular atrophy (AT), intestinal metaplasia (IM), dysplasia (DYS) and so on at different stages, which indicates diversiform prognosis. The roles of immune reactions in *Helicobacter pylori* (*H. pylori*) pathogenesis and chronic gastritis (CG) are research areas of rapid progress^[1-4]. It is now recognized that the clinical detection of serum antibody is effective in monitoring the *H. pylori* infection^[5,6]. However, *H. pylori* infection and the levels of serum anti-*H. pylori* immunoglobulin antibodies at different stages of CG are not fully investigated. Moreover, the complex clinical manifestations of *H. pylori* infection and associated CG leads to a diagnostic and therapeutic dilemma for CG^[7].

To determine the prevalence of *H. pylori* infection, the serum anti-*H. pylori* immunoglobulin G (IgG) and IgA antibody responses, and the value of clinical presentations in diagnosis of *H. pylori* infection in patients with gastric atrophy, intestinal metaplasia and dysplasia a population-based investigation was designed and a novel analytic method was proposed in this work. The study also took a different perspective in assessing the association between *H. pylori* infection and clinical presentations.

MATERIALS AND METHODS

Patients

A total of two hundred and nine patients with chronic gastritis, who were diagnosed through gastroscopy and mucosal biopsy, were included in the present study. All patients, who resided in Shandong province, were investigated by the Institute of Basic Theory, Chinese Academy of Traditional Chinese Medicine from 1999 to 2001. Among them 103 were males and 106 were females, aged from 45 to 72 with a mean age of 55 years old. Gastric biopsies were histologically evaluated for activity and chronicity of gastritis, and the presence of AT and/or IM according to the criterion of the visual analogue scale in Sydney classification and grading of gastritis^[8]. The patients consisted of 76 with mild chronic atrophic gastritis (CAG), 22 with severe (CAG), 22 with mild IM, 58 with severe IM and 31 with DYS accompanied with mild IM. All patients had not received any anti-*H. pylori* treatment.

Diagnosis of *H. pylori* infection

Two hundred and nine specimens of gastric mucosa were obtained from each patient via endoscopy. Gastric mucosa was sampled from the area of greater curvature at gastric antrum, and *H. pylori* was determined by pathological staining with hematoxylin and eosin (HE) followed by Giemsa staining. Under microscope, *Helicobacter-like organisms* can be identified as a typical curve like S or C. They look like a short bacilli or globular body with a slight curve.

Detection of anti-*H. pylori* IgG and IgA antibodies

Blood was sampled twice from patients. Enzyme-linked immunoadsorbent assays (ELISA) were used to detect the levels of serum anti-*H. pylori* IgG and IgA antibodies. The test kits for the detection of anti-*H. pylori* -IgG and anti-*H. pylori* -IgA were purchased from Bioseed Co., USA. The value of the optical density (OD) was read by a microtiter plate reader at 450 nm.

Clinical presentations observation

35 clinical presentations were observed as follows: (1) Symptoms of the digestive system including appetite, distending fullness in the stomach, stomachache, distending fullness in the abdomen, pain in the hypochondrium, pain in the abdomen, singultus, nausea, vomit, acid regurgitation and epigastric upset, and heartburn; (2) General status including ear, eye, physique, complexion, stool, urine, oropharynx, taste, swollen, head, limbs, chest, hand and foot; (3) Spirit and psychological status including spirit, sleep, and emotion; (4) Glossoscopy including quality of tongue, body of tongue, and fur of tongue and (5) Pathogenic factors including smoking, alcohol, dietary bias, and dietary regularity. Each investigated symptom consisted of two to four subordinate items.

Statistical analysis

A SPSS 10.0 statistical package program was used for data analysis. The variables were processed by chi-square test, student's *t* test, ANOVA analysis, and bivariate correlate analysis, where appropriate.

k-means cluster analysis

The *k*-means cluster analysis method has been applied in many areas including data mining, statistics, biology, and machine learning, and so on^[9]. In this study, the relationship between the *H. pylori* infection and the 35 clinical presentations of patients was analyzed by this method. The diagnostic accuracy was obtained by the *k*-means algorithms. The distance between clusters was further verified by an ANOVA test.

RESULTS

As shown in Table 1, the detected positive rates of *H. pylori* varied were 72.7 % (16/22) in mild IM, 84.5 % (49/58) in severe IM, 67.7 % (21/31) in DYS, 51.3 % (39/76) in mild CAG, and 68.2 % (15/22) in severe CAG, respectively. Analyses of chi-square test showed that the detected positive rates of *H. pylori* were similar in mild IM, mild CAG, DYS, and severe CAG groups. The *H. pylori* positive rate in severe IM group was statistically higher than those in other groups (all *P*<0.01).

Table 2 shows the detective positive rates of *H. pylori* for the CG patients in relation to gender and age. There was no significant difference between the male (62.1 %, 64/103) and the female patients (71.7 %, 76/106) (*P*>0.05). The *H. pylori* infection rate was highest in the ages from 42 to 49 (59/80, 73.8 %). However, the ANOVA analysis showed that there was no significant difference among four groups with different ages (*P*>0.05). Bivariate correlation analysis also indicated that the detected positive rate of *H. pylori* was not remarkably associated with the age of patients (*r*=0.0814, *P*=0.241).

Table 3 lists the levels of serum anti-*H. pylori* IgG and IgA at different stage of CG. Both serum anti-*H. pylori* IgG and IgA levels were remarkably higher in *H. pylori* positive patients than those negative for *H. pylori* (*P*<0.001-0.01). In *H. pylori* positive patients the IgG level was significantly greater in severe CAG than in mild CAG (*P*<0.01). In *H. pylori* negative patients both the serum IgG and IgA levels increased significantly in severe IM, compared to those in mild IM (*P*<0.01-0.05). There was no significant difference in IgG and IgA levels between mild and severe IM in the presence of *H. pylori* infection (*P*>0.05).

Table 1 The detected positive rates of *H. pylori* at different stages of CG

<i>H. pylori</i>	Mild CAG	Severe CAG	Mild IM	Severe IM	DYS	Total
Number	76	22	22	58	31	209

CAG, chronic atrophic gastritis; IM, intestinal metaplasia; DYS, dysplasia. (1) The first detection. (2) The second detection. ^a*P*<0.01, ^b*P*<0.001, *H. pylori* (+) vs. *H. pylori* (-). ^c*P*<0.05, *H. pylori* (+) mild CAG vs. *H. pylori* (+) severe CAG; ^d*P*<0.05, *H. pylori* (-) mild IM vs. *H. pylori* (-) severe IM.

Table 4 Diagnostic accuracy of *H. pylori* infection determined by different assemblages of symptoms

Attributes	Assemblages of symptoms	Accuracy (%)	
		<i>H. pylori</i> (+)	<i>H. pylori</i> (-)
Pathogenic factors and general status	Smoking, alcohol, limbs, hand and foot (all ^a)	70.7%	42.3%
Pathogenic factors, general status and tongue	Smoking, alcohol, dietary regularity, limbs, and tongue quality (all ^a)	74.3%	39.1%
Pathogenic factors and digestive symptoms	Smoking, alcohol, limbs, hand and foot, distending fullness in the stomach, stomachache, distending fullness in the abdomen, and nausea (all ^a)	51.4%	52.2%
Digestive symptoms	Appetite, distending fullness in the stomach, stomachache, distending fullness in the abdomen, pain in the hypochondrium, pain in the abdomen, singultus, nausea, vomit, acid regurgitation and epigastric upset, heartburn, and stool (all ^a)	71.4%	26.1%
Digestive symptoms and tongue	Distending fullness in the stomach, stomachache, pain in the abdomen, nausea, and fur of tongue (all ^a)	72.1%	26.1%
General status	Taste, swollen, head, limbs, chest, hand and foot, spirit and sleep, emotion, complexion (all ^a)	50.7%	40.6%
Total symptoms	35 items ^b	65.7 %	40.6 %

^a $P<0.05-0.001$, the difference between two classes tested by the ANOVA analysis. ^b $P<0.05-0.001$, except dietary bias, dietary regularity, urine, oropharynx, eye, ear, physique, tongue quality, and tongue body.

Table 4 shows the diagnostic accuracy of *H. pylori* infection determined by different assemblages of clinical presentations. The overall diagnostic accuracy based on 35 presentations was 65.7 %. It could be improved by 5.7 % when the only digestive symptoms were engaged, or by 8.6 % when further information were referred such as the assemblage of pathogenic factors (smoking, alcohol), general status (tired limbs), and tongue observation according to the traditional Chinese medicine (TCM) method. However, the diagnostic accuracy could be decreased by the improper assemblages such as the general symptoms only, the pathogenic factors accompanied with some common digestive symptoms (distending fullness in the stomach, stomachache, distending fullness in the abdomen, and nausea) which had no special significance for the positive or negative *H. pylori*.

DISCUSSION

An increasing number of studies support a close relationship between *H. pylori* infection and CG, as previous described. However, the correlation between *H. pylori* infection, serum antibody and clinical symptoms at different stages of CG has not been well investigated so far. The chi-square test results in Table 1 show that the detected positive rates of *H. pylori* increase significantly in patients with mild CAG (51.3 %, 39/76), DYS and mild IM (67.7 %, 21/31), severe CAG (68.2 %, 15/22), and mild IM (72.7 %, 16/22). They reach the highest value in patients with severe IM (84.5 %, 49/58) ($P<0.01$). However, *H. pylori* infection exhibited no remarkable association with patient's gender (62.1 % in males; 71.7 % in females) and age ($r=0.08$, $P=0.241$).

It has been reported that the adherence of *H. pylori* may play an important role in the pathogenesis of severe histological changes in CAG^[10], IM^[11] and DYS^[12]. Our investigation further explored the statistic probability of *H. pylori* infection at different stages of CG. Based on these, we suggest that *H. pylori* infection may be the key factor in accelerating the occurrence and development of CG, since *H. pylori* is a pathogenic bacterium that can adhere to gastric mucosa until the atrophy and intestinal metaplasia occurring in the course of CG.

A mostly pathological mechanism of *H. pylori* infection is the immunopathological response of host. When CG occurs, a detectable specific humoral immunological response will be established. The appearance of serum antibodies such as IgG and IgA may indicate an extensive immunoreaction causing by *H. pylori* infection. The serum anti-*H. pylori*-IgG antibody,

therefore, acts as a highly accurate, simple and noninvasive method in monitoring the status of *H. pylori* infection^[5, 13]. In our study, both serum anti-*H. pylori* IgG and IgA are remarkably higher in *H. pylori* positive patients than those negative for *H. pylori* ($P<0.001-0.01$). On the one hand, in the presence of *H. pylori* infection the IgG level in severe CAG increased significantly, compared to those in mild CAG ($P<0.01$). These imply that the serum anti-*H. pylori* IgG and IgA are appropriate indicators to evaluate the status of *H. pylori* infection in the process of CG. On the other hand, in absence of *H. pylori* infection both serum IgG and IgA are significantly greater in severe IM than those in mild IM ($P<0.01-0.05$), whereas no significant difference ($P>0.05$) was observed between mild and severe IM in the presence of *H. pylori* infection. The increase of antibody may be due to the reminiscence of *H. pylori* infection, resulting in a certain arrearage between serum antibody and *H. pylori*. It is reported that the IgA response of gastric mucoa in CG patients can be detected even in the quiescent period of negative *H. pylori* infection due to the recent exposure to the bacterial antigens^[6].

The clinical situations of CG patients are intricate. They are divergent by the pathological changes of gastric mucosa, and are affected by environmental factors^[14, 15]. By means of the cluster analysis method, we found that the proper assemblages such as digestive symptoms, pathogenic factors (smoking, alcohol), general status (tired limbs), and the tongue could improve the diagnostic accuracy of *H. pylori* infection. However, the improper assemblages, such as the general symptoms only, or the pathogenic factors accompanied with some common digestive symptoms decreased the diagnostic accuracy. A preferable symptomatic assemblage has been proposed in the present study. Based on this, the diagnostic accuracies of up to 74.3 % and 40.5 %, respectively, for positivity and negativity of *H. pylori* infection have been obtained. It has been demonstrated clinically that smoking, alcohol^[16] and the tongue change^[17] are pathogenic factors for the *H. pylori* infection. Our study indicates that the symptomatic assemblages rather than an individual factor are closely related to the clinic significance of *H. pylori* infection. Furthermore, it has been known that the validity of CG treatment in traditional Chinese medicine (TCM) is based on the differentiation of symptom-complexes^[18, 19]. Our investigation suggests that *H. pylori*-related symptomatic assemblages can be taken into consideration in practicality and methodology during the diagnoses and treatment of CG. More effective symptomatic assemblages and their effects

on *H. pylori* infection are still required.

In conclusion, the early genesis and further progression of CG are associated with *H. pylori* infection, which can be characterized by the increase of serum anti-*H. pylori* IgG and IgA with a certain arrearage. Due to the intricate clinical situation of CG, effective symptomatic assemblages are required in diagnosing *H. pylori* infection.

Abstract

AIM: To study the effects of liver specific antigen (LSA) on the immunoreaction of liver allotransplantation and its significance.

METHODS: Orthotopic liver transplantation was used in this study. Group I: syngeneic control (Wistar-to-Wistar); Group II: acute rejection (SD-to-Wistar). Group III: acute rejection treated by intramuscular injection of cyclosporine A (CsA) (SD-to-Wistar+CsA). Group IV: Intrathymic inoculation of SD rat LSA one week before transplantation (LSA+SD-to-Wistar). The common situation and survival time, rejection grades, NF- κ B activity of splenocytes and intragraft cytokine gene expression were observed to analyze the acute rejection severity and immune state of animals.

RESULTS: The common situation of Wistar-to-Wistar group was very good after the transplantation and no signs of rejection were found. Recipients of SD-to-Wistar group lost body weight progressively. All died within 9 to 13 days after transplantation with the median survival time of 10.7 ± 0.51 days. It was an optimal control for acute rejection. The common situation of SD-to-Wistar+CsA group was bad during CsA medication but only with mild rejection. As for LSA+SD-to-Wistar group, 5 of 6 recipients survived for a long time and common situation was remarkably better than that of SD-to-Wistar group and SD-to-Wistar+CsA group. Its rejection grades were significantly lower than that of SD-to-Wistar group ($P=0.026$). Furthermore, no significant discrepancies of rejection were found between SD-to-Wistar group and LSA+SD-to-Wistar group at day7 and day12 ($P=0.067$). NF- κ B activity, IFN- γ and IL-2mRNA expression were significantly inhibited in LSA+SD-to-Wistar group compared with that of SD-to-Wistar group ($P<0.05$).

CONCLUSION: LSA is an important transplantation antigen which involves in the immunorejection of liver transplantation directly. We reported for the first time that intrathymic inoculation of LSA can induce immunotolerance of liver allotransplantation and grafts can survive for a long time thereby, thus leading to a novel way to liver transplantation immunotolerance.

INTRODUCTION

Although MHC-antigens have been extensively studied, the problem of rejection in liver transplantation was not resolved completely. Liver transplantation are not strict for HLA matching and both grafts and recipients can survive for a long time after immunotherapy^[1]. On the other hand, given HLA multiple loci matching in some cases, the likelihood of grafts dysfunction and rejection increased, which suggested that matching for HLA type may exert a dualistic effect on liver transplantation^[1,2]. No satisfactory explanations have been made about it up to date; and most studies were limited to HLA antigens themselves with the results still remaining controversial.

The specific antigens expressed only in liver cell membrane or liver cytoplasm and encoded by loci not linked to the MHC gene were called liver specific antigen (LSA). It was reported that this antigen could be detected in sera of almost all liver allotransplantation recipients but its effects remained unknown yet^[3]. Thus in this experiment, we aimed to find whether LSA was an transplantation antigen and its possible mechanism of inducing the tolerance of liver allotransplantation using intrathymic LSA inoculation pathway. And the roles of LSA in thymus tolerance were discussed in this research too.

MATERIALS AND METHODS

Materials

Inbred male Wistar and male SD rats weighing 200 to 250 g were purchased from Shanghai Experimental Animal Center; there were also materials used in this study as following: [γ -³²P]ATP (Furui bioengineering Corp, Beijing); EMSA assay kit (Promega); NF- κ B double stranded oligonucleotide, 5' - A G T T G A G G G A C T T T C C C A G G C - 3' , 3' - T C A A C T C C C C T G A A G G G T C C G - 5' (Santa Cruz), NF- κ B double stranded mutant oligonucleotide, 5' - A G T T G A G G - C G A C T T T C C C A G G C - 3' , 3' - T C A A C T C C G C T G A A G G G T C C G - 5' (Santa Cruz); TRIzol Reagent (Gibco, BRL); MuLV (MBI, Fermentas); Ultracentrifugator (Beckman); CHRIST lyophilizer (B.Braun Biotech).

Methods

Isolation of LSA Preparation of liver specific protein S100 was carried out by the method previously described^[4]. The protein contents was measured according to the method of Bradford. Then the protein was lyophilized by CHRIST lyophilizer and stored at -80 °C.

Surgical procedure, experimental groups and sample harvesting Rats were anesthetized with ether inhalation. Orthotopic rat liver transplantation was performed by Kamada's two-cuff technique^[5]. The animals surviving less

then 3 days after the transplantation were attributed to technical errors and were excluded from this study. Wistar rats serving as recipients were randomly divided into four groups, Group I: syngeneic control (Wistar-to-Wistar); Group II: acute rejection (SD-to-Wistar); Group III: acute rejection treated with intramuscular injection of CsA 3.0 mg/kg/d (SD-to-Wistar+CsA); Group IV: Intrathymic inoculation of 10 mg SD rat LSA one week before transplantation (LSA+SD-to-Wistar). All groups were subdivided into day 1, 3, 5, 7, 12 subgroup ($n=3$ each) after the transplantation respectively for sample harvesting and another subgroups ($n=6$) for observation of common situation and survival time. For observation of common situation and survival time in Group III, after the therapy of CsA for 12 days, animals received no additional immunosuppression. Graft specimens were harvested to determine morphological changes and cytokine gene expression. Recipient splenocytes were isolated and the NF- κ B activity were determined.

Histopathological examination Grafted liver samples were fixed in 10 % buffered formalin and embed in paraffin. Five micrometers thick sections were affixed to slides, deparaffinized, and stained with hematoxylin and eosin to assess morphologic changes and severity of acute rejection by the Kemnitz' s standard^[6].

Cytokine reverse transcription-polymerase chain reaction Primer sequences and reaction conditions: Primers sequences used were as follow: IL-2 sense primer, 5' - GACGCTTGCTCCTTGT CA-3', IL-2 antisense primer, 5' - ACCACAGTTGCTGGCTCATC-3' (size 3 72bp); IFN- γ sense primer, 5' - ACTGCAAGGCACACTCATT-3', IFN- γ antisense primer, 5' - AGGTGCGAT TCGATGACACT-3' (size 235bp); β -actin sense primer, 5' - TCGTACCA CTGGCATTGTGA-3', β -actin antisense primer, 5' - TCCTGCTTGCTGATCCACAT-3' (size 645bp). Amplifications were performed under the following conditions: 95 °C for 2 minutes, 94 °C for 45 seconds, 56 °C for 45 seconds, 72 °C for 45 seconds, totally 32 cycles. The final extension step was performed by one cycle at 72 °C for 10 minutes. Reaction buffer: 10×Buffer 2.5 μ l, 10 mM dNTP 1 μ l, MgCl 2 μ l, cDNA 2 μ l and 1 μ l of each primer, ddH₂O was added to get the final volume of 25 μ l. RT-PCR: Total RNA was prepared from grafted liver with TRIzol Reagent according to the manufacturer' s recommendations. For cDNA synthesis, 4 μ g total RNA was reverse transcribed with MuLV reverse transcriptase according to the manufacturer' s recommendations. Two microliters from the resulting cDNA solution were then amplified using specific oligonucleotides under the reaction conditions using β -actin as a "housekeeping gene" in a volume of 25 μ l PCR buffer. Reaction products were run by electrophoresis on a 1.5 % agarose gel for 30-40 min at 100 V in 0.5×Tris/borate/EDTA buffer, and visualized with ethidium bromide under UV light. Relative expression of cytokines were defined as optical density ratio (cytokine/ β -actin) analyzed by Kodak digital science scanning system.

NF- κ B activity of splenocytes and EMSA competitive inhibition NF- κ B activity was detected by gel electrophoretic mobility shift assay (EMSA): Splenocytes of recipients were isolated and nuclear extracts were prepared according to the method described by Kravchenko^[7]. The contents of protein were determined by the method of Bradford. NF- κ B oligonucleotide was end-labeled with [γ -³²P]ATP according to the manufacturer' s recommendations. For EMSA, 10 μ g of each nuclear extract was mixed with 5×binding buffer at room temperature for 10 min. Then 1 μ l [γ -³²P] ATP-labeled double strand NF- κ B oligonucleotide probe was added in and incubated at room temperature for 20 min. The DNA/protein complex was electrophoresed on 4 % nondenaturing polyacrylamide gels in 0.5×Tris/borate/EDTA buffer to

separate probe binding to NF- κ B and free probe. Radioactive bands were detected by autoradiography at -70 °C followed by radiography to detect the level of retardation. The results were expressed as relative optical density (ROD)^[8]. To study whether the method of EMSA was specific, standard nuclear extract of Hela cells was used to bind with NF- κ B protein. The specificity of binding was confirmed by 100 fold excess unlabeled NF- κ B oligonucleotide as a specific competitor, 100 fold excess unlabeled non-related oligonucleotide as a nonspecific competitor and 100 fold excess unlabeled mutant NF- κ B oligonucleotide as a mutant competitor. All unlabeled oligonucleotides were preincubated with Hela nuclear extract at room temperature for 10 min then labeled NF- κ B oligonucleotide was added. The left steps were the same as mentioned above.

Statistics analysis

All data were expressed as mean \pm SD and analyzed by one-way repeated measures analysis of variance (ANOVA) using SPSS software (version 11.0 for windows). Pearson correlation analysis was used between parameters. $P<0.05$ was considered as statistically significant.

RESULTS

Postoperative common situation and survival time

The common situation of rats in the Wistar-to-Wistar group was very good after the transplantation. Recipients drank normally after 3rd day of posttransplantation. Normal coat recovered at day 7 with increase of body weight and all recipients survived for a long time. Recipients of rats in the SD-to-Wistar group ate badly with tarnished coat and progressive loss of body weight; all died within 9 to 13 days after the transplantation; median survival time was 10.7 ± 0.51 days. Although 5 of 6 recipients of rats in the SD-to-Wistar+CsA group survived for a long time (one dead from abdominal inflammation and liver abscess day on 14 after the transplantation), they also drank badly with tarnished coat and ceased increase of body weight during CsA medication, which recovered after the cease of drug treatment. As for the LSA+SD-to-Wistar group, 5 of 6 recipients survived for a long time (one dead of bile duct obstruction on day 15 after the transplantation) and their common situation were remarkably better than that of rats in the SD-to-Wistar group and SD-to-Wistar+CsA group.

Histopathologic examination

No signs of rejection were found at any time point in the Wistar-to-Wistar group with minimal portal inflammatory infiltrates. In the SD-to-Wistar group, a few portal lymphocyte infiltrations combined with minimal vein endothelialitis on day 1 was found but there was no evidence of rejection. Significant portal lymphocyte infiltration with degeneration of hepatic parenchyma in some cases can be found on day 3 and day 5 with average rejection grade of 1.83 and 2.67, respectively. Severe inflammatory cells infiltration, severe vein subendothelialitis with bridging hepatocellular necrosis could be found on both day 7 and day 12 with rejection grade of 2.87 and 3, respectively. Owing to the immunosuppressive effect of CsA, rejection was greatly inhibited in the SD-to-Wistar+CsA group. No evidence of rejection was found at the first three time points. But mixed inflammatory infiltration and endothelialitis could be found on day 7 and day 12, in which grade 1 rejection was diagnosed. As for the LSA+ SD-to-Wistar group, rejection grades was 0 and 1 on day 1 and 3, respectively. Mixed but mainly lymphocytic infiltration was found in both portal tract and parenchyma without focal necrosis of the hepatic parenchyma on day 5, 7 and 12. Thus their rejection grades were all defined as 1.25 which were significantly lower

than that in the SD-to-Wistar group ($P=0.026$). Furthermore, no significant discrepancies of rejection grades on day 7 and day 12 were found between the SD-to-Wistar+CsA group and LSA+SD-to-Wistar group ($P=0.067$) (Figure 1).

Figure 1 Rejection grades of grafted liver in different groups. Data were expressed as mean±SD. I, Wistar-Wistar group; II, SD-Wistar group; III, SD-Wistar+CsA group; IV, LSA+SD-Wistar group; Rejection grades of group IV were significantly lower than that in group II at all but day 1 time point. No significant discrepancies were found between group IV and group III on day 7 and day 12 time points. ^a $P<0.05$ vs group II, ^b $P>0.05$ vs group III.

Expression of cytokine gene

The kinetic changes of intragraft IL-2 mRNA expression in different groups were shown in Figure 2: no expression was detected at any time point in the Wistar-to-Wistar and the SD-to-Wistar+CsA group, whereas high level expression was detected at all time points in the SD-to-Wistar group and reached to the peak on day 7 and 12 after the transplantation ($P<0.001$, vs the Wistar -to-Wistar group). Low level expression was only detected on day 5 in the LSA+SD-to-Wistar group which was significantly lower than that in the SD-to-Wistar group ($P<0.001$). Intragraft IFN- γ mRNA expression in different groups was shown in Figure 3. Very weak IFN- γ mRNA expression was detected at any time point in the Wistar-to-Wistar group after the liver transplantation, whereas there was very strong expression in the SD-to-Wistar group at all time points ($P=0.006$, vs the Wistar -to-Wistar group). The expression of IFN- γ mRNA was significantly inhibited in the SD-to-Wistar+CsA group which was significantly lower than that in the SD-to-Wistar group ($P<0.001$). As for group IV, its kinetic change was similar to that in the SD-to-Wistar group but was significantly lower than that in the SD-to-Wistar group at any time points ($P=0.046$). Expression of IL-2 and IFN- γ mRNA was correlated to the histopathological damage.

Figure 2 The kinetic change of intragraft IL-2mRNA expression in different groups. I, Wistar-Wistar group; II, SD-Wistar group; III, SD-Wistar+CsA group; IV, LSA+SD-Wistar group; IL-2mRNA expression of group IV were significantly lower than that in group II at all time point ($P<0.05$).

Figure 3 The kinetic change of Intragraft IFN- γ mRNA expression in different groups. I, Wistar-Wistar group; II, SD-Wistar group; III, SD-Wistar+CsA group; IV, LSA+SD-Wistar group; IL-2mRNA expression of group IV were significantly lower than that in group II at all time point ($P<0.05$).

Figure 4 EMSA specific competitive inhibition. Lane 1, negative control; Lane 2, positive control; Lane 3, specific competition; Lane 4, non-specific competition; Lane 5, mutant competition.

Figure 5 NF- κ B activity of splenocytes at different time points after the transplantation. A, Wistar-Wistar group; B, SD-Wistar group; C, SD-Wistar+CsA group; D, LSA+SD-Wistar group; E, the kinetic change of NF- κ B activity. NF- κ B activity of group IV were significantly lower than that in group II at all time point ($P<0.05$).

EMSA specific competitive inhibition and NF- κ B activity of splenocytes

The results of EMSA competitive inhibition showed that no NF- κ B activity was found after the specific competition, whereas NF- κ B activity was the same as the positive control after the nonspecific competition and mutant competition (Figure 4). This results showed that this method was specific. NF- κ B activity of splenocytes in Figure 5 showed the autoradiographic results of splenocyte NF- κ B DNA binding activity in different groups (A, B, C, D). Low NF- κ B activity was only detected on day 5 and day 7 in the Wistar-to-Wistar syngeneic group after the transplantation. In contrast, NF- κ B activity increased from day 3 after the transplantation in the SD-to-Wistar group and was significantly higher than that in the syngeneic group at all time points ($P=0.001$). Only very weak DNA binding activity was found on day 12 in the SD-to-Wistar+CsA group and NF- κ B activity was also inhibited in the LSA+SD-to-Wistar group which was significantly lower than that in the SD-to-Wistar group ($P=0.003$). NF- κ B activity was significantly inhibited in the SD-to-Wistar+CsA and LSA+SD-to-Wistar group (Figure 5E).

Correlation analysis

A good correlation was found between the activity of NF- κ B and intragraft IL-2 as well as IFN- γ mRNA expression in this study (pearson correlation analysis, $r=0.737$ and $r=0.742$ respectively, $P<0.01$, $n=20$). While intragraft IL-2 and IFN- γ mRNA expression were correlated to histopathological damage (pearson correlation analysis, $r=0.856$ and $r=0.680$ respectively, $P<0.01$, $n=20$).

DISCUSSION

Allotransplantation tolerance can be induced by intrathymic inoculation of donor cellular antigen^[9-12], and also by intrathymic inoculation of donor soluble MHC antigen^[13-15]. However, intrathymic inoculation of donor soluble non-MHC antigen have not been reported heretofore. In this study, we inoculated donor LSA into recipient thymus before the liver transplantation so that rejection was greatly inhibited. Only mild rejection was found in grafts and was significantly lower than that in the non-LSA inoculated group and similar to that in the CsA treated group. Recipients survived for a long time due to the induction of immunotolerance.

Although the rejection grades in the LSA+SD-to-Wistar group was increased obviously from day 3 and peaked at day 5 after transplantation, there was no significant difference between time points except for day 1 ($P>0.05$). This rejection kinetic change in the LSA+SD-to-Wistar group was similar to that in the Wistar -Wistar group and was significantly lower than that in the SD-to-Wistar group ($P=0.026$). Furthermore, the rejection grades in the LSA+SD-to-Wistar group did not significantly differ from that in the SD-to-Wistar+CsA group on day 7 and day 12 time point after the transplantation ($P=0.067$), which showed that intrathymic inoculation of LSA could greatly alleviate rejection. However, rejection in the SD-to-Wistar group was increased continuously and the rejection grade on day 3 after the transplantation was significantly different from its peak one ($P<0.05$). It was an optimal acute rejection control. As for the SD-to-Wistar+CsA group, rejection was greatly suppressed due to the effect of CsA and recipients survived for a long time, which was consistent with previous reports^[16]. The rejection grades in all but SD-to-Wistar+CsA group was increased rapidly within groups when compared with that on day 1 after the transplantation (Figure 1) showed that the high immunoresponses starting from day 3 to day 5 after the transplantation was the "rejection crisis" phase^[17].

Rejection crisis phase in the SD-to-Wistar+CsA group was postponed to start from day 5 to day 7 after the transplantation due to the strong immunosuppressive effect of CsA. Meanwhile, that rejection grades was not increase on day 7 after the transplantation both in the SD-to-Wistar+CsA group and LSA+SD-to-Wistar group and recipients survived for a long time suggested that the pathological damage in these two groups may be "self-limited". Given longer harvesting time point, more could probably be found.

For the expression of IL-2mRNA, the most related cytokine to rejection, detected using RT-PCR in grafts, low level expression was only detected on day 5 in the LSA+SD-to-Wistar group and it was significantly lower than that in the SD-to-Wistar group ($P<0.001$) (Figure 2). Although the expression of IFN- γ mRNA, another important cytokine to rejection, was slightly higher than that in the Wistar-to-Wistar group ($P=0.427$), it was also significantly inhibited in the LSA+SD-to-Wistar group ($P<0.046$, vs SD-to-Wistar group) (Figure3). IL-2 and IFN- γ are the representative cytokines secreted by Th1 cells which play important roles in transplant rejection^[18-20]. Both intragraft IFN- γ mRNA and protein were increased when grafts were rejected^[21,22]. IFN- γ not only increases expression of MHC class I and class II antigens of intragraft, but stimulates cells without expression of MHC class II antigens at quiescent state to express MHC class II antigens^[23]. Thus inhibiting the synthesis and secretion of IL-2 and IFN- γ is one of the mainly target for preventing transplantation rejection all the while.

As an important nuclear transcription factor, NF- κ B is a specific sequence binding protein which can bind to promoters or enhancers of multiple genes including closely related cytokines and adhesion molecules to organ transplantation rejection^[24], thus extensively regulating the expression of these genes. Apart from that the change of NF- κ B activity exerts crucial effects on the proliferation and activation of immune cells, NF- κ B is also an important antiapoptotic nuclear factor^[25,26]. So the change of NF- κ B activity may play a crucial role in the immunoresponses and directly influence the immunoreaction after the transplantation. In its quiescent state, NF- κ B is localized in cytoplasm in a complex with its inhibitory proteins (I κ Bs)^[27,28], which mask its nuclear localization signal and prevent its from translocation to the nucleus. NF- κ B is activated through phosphorylation and I κ Bs is subsequently degraded and then translocated into nucleus to bind with specific DNA sequences to regulate the expression of related genes^[26]. NF- κ B regulates the transcription of IL-2 mRNA through binding to its binding sites in down-stream of IL-2 gene promoter. It has been demonstrated *in vitro* that activated NF- κ B can directly result in high level expression of IL-2 mRNA and promote the proliferation and activation of T lymphocyte^[29]. IFN- γ gene belongs to lymphokine gene family and is related to transplantation rejection. Its transcription parallels that of other lymphokine genes such as IL-2 whose promoter activity can be enhanced by NF- κ B protein^[30,31]. In this regard, the ubiquitous factor NF- κ B controlling a number of cytokines may have roles in the transcription of IFN- γ gene. It has also been demonstrated that NF- κ B interacts with NF-AT to coregulate the gene expression of IFN- γ *in vitro*^[32] but not *in vivo* especially in the organ transplantation rejection. We used rat orthotopic liver transplantation model to study the relationship between the activity of NF- κ B and the expression of IL-2 and IFN- γ mRNA and its mechanisms with or without CsA and LAS treatment. A good correlation was found between the activity of NF- κ B and the expression of intragraft IL-2 as well as IFN- γ mRNA in this study (pearson correlation analysis, $r=0.737$ and $r=0.742$ respectively, $P<0.01$, $n=20$). While the expression of intragraft IL-2 and IFN- γ mRNA were correlated

to the histopathological damage (pearson correlation analysis, $r=0.856$ and $r=0.680$ respectively, $P<0.01$, $n=20$). Thus it is believable that allotransplantation rejection is partly due to the activation of NF- κ B at least. Both CsA and intrathymic inoculation of donor LSA can inhibit the activity of NF- κ B and further inhibit the expression of IL-2 and IFN- γ mRNA and rejection after the transplantation.

We preliminarily discuss the specific tolerance mechanisms induced by LSA: T lymphocytes recognition process of tissue specific antigens is MHC-restricted which includes direct and indirect recognition and the latter is the main one. In this experiment, before the transplantation, protein antigen was used to inoculate recipient thymus. No APC and MHC molecules of donor existed, so the recognition of LSA should be indirect. Modern immunology believes that TCR recognizes neither MHC molecules nor antigen peptides alone. What it recognizes is surface information of MHC-antigen peptides complex. So it is believed that although LSA is organ specific, space conformation, electric charge qualities and distributions of MHC-antigen peptides complex are not the same due to its polymorphism, thus activating allolymphocytes^[33]. But large numbers of activated lymphocytes may be clonally deleted due to high dose antigen immunization, which coincides with the "high-dose/activation- associated tolerance" mechanism^[34]; In addition, thymus reeducation may also be one of the mechanisms of this tolerance. T lymphocytes of recipient recognize donor LSA as self by reeducation mechanism.

Therefore it was postulated that given multiple MHC loci matching, the processing ability of tissue specific antigens by recipient MHC molecules will be enhanced or be equal to that of by donor's, thus bring about indirect recognition of T lymphocytes changing into direct recognition and increasing the occurrence of hepatopathy and rejection after the transplantation. This may be one of the reasons why multiple MHC loci matching, especially DR matching, can increase the rates of grafted liver dysfunction and rejection^[1,2]. This may be just as what Desquenne postulated that it should make it easier to induce tolerance of skin antigen as well as other tissue specific antigen when MHC incompatibilities prevail^[35]. Besides, special attention must be paid to the LSA+SD-to-Wistar group. The common situation of recipients without any transient immunosuppression were much better than that in the non-LSA or CsA-treated group and no such complications as inflammations happened. It showed that the tolerance did not result from down-regulation of body's immunofunction, in contrast recipients' immunofunction was normal. This is perhaps the optimal condition to induce donor specific tolerance and do not affect body's immunofunction. Reasonable explanation is that strong immunoreaction towards to liver parenchymal cells happened when transplanted liver was rejected. Thus the tolerance induced by LSA is towards to hepatocytes and is in real sense a donor and organ specific one.

The results of this experiment not only demonstrated that thymus had unusual effects on the tolerance induction, but also that allotolerance to non-MHC antigen can be induced after contacting of thymus microenvironment to non-MHC antigen. It may suggest that if immunodominant character or immunodominant non-MHC antigens were identified, differences of other MHC and non-MHC antigen may be neglected, thus leading to long-term allografts survival across complete MHC barrier. It also suggested that MHC antigens may be not the only obstacles to successful transplantation. It is reported here for the first time that intrathymic inoculation of LSA can induce permanent and specific immunotolerance of liver allotransplantation, which show that hepatocytes are directly involved in the immunoreaction of liver transplantation. It's an important supplement to the traditional theory of liver

transplantation rejection which considers that rejection is mainly involved in liver vascular bed, bile ducts and nonparenchymal cells, thus leading to a novel way to liver transplantation immunotolerance.

Abstract

AIM: To investigate the expression of growth hormone receptor (GHR) and mRNA of GHR in cirrhotic livers of rats with the intension to find the basis for application of recombinant human growth hormone (rhGH) to patients with liver cirrhosis.

METHODS: Hepatic cirrhosis was induced in Sprague-Dawley rats by administration of thioacetamide intraperitoneally for 9-12 weeks. Collagenase IV was perfused in situ for isolation of hepatocytes. The expression of GHR and its mRNA in cirrhotic livers was studied with radio-ligand binding assay, RT-PCR and digital image analysis.

RESULTS: One class of specific growth hormone-binding site, GHR, was detected in hepatocytes and hepatic tissue of cirrhotic livers. The binding capacity of GHR (R_T , fmol/mg protein) in rat cirrhotic liver tissue (30.8 ± 1.9) was significantly lower than that in normal control (74.9 ± 3.9) at the time point of the ninth week after initiation of induction of cirrhosis ($n=10$, $P<0.05$), and it decreased gradually along with the accumulation of collagen in the process of formation and development of liver cirrhosis ($P<0.05$). The number of binding sites ($\times 10^4/\text{cell}$) of GHR on rat cirrhotic hepatocytes (0.86 ± 0.16) was significantly lower than that (1.28 ± 0.24) in control ($n=10$, $P<0.05$). The binding affinity of GHR among liver tissue, hepatocytes of various groups had no significant difference ($P>0.05$). The expression of GHR mRNA (riOD, pixel) in rat cirrhotic hepatic tissues (23.3 ± 3.1) was also significantly lower than that (29.3 ± 3.4) in normal control ($n=10$, $P<0.05$).

CONCLUSION: The growth hormone receptor was expressed in a reduced level in liver tissue of cirrhotic rats, and lesser expression of growth hormone receptors was found in a later stage of cirrhosis. The reduced expression of growth hormone receptor was partly due to its decreased expression on cirrhotic hepatocytes and the reduced expression of its mRNA in cirrhotic liver tissue.

INTRODUCTION

Liver cirrhosis is a common pathway of a variety of chronic liver diseases^[1] and is associated with high protein catabolism, low anabolism and negative nitrogen balance^[2] resulting in hypoproteinemia which contributes to ascites, dysfunction of coagulation and suppressed immune responses^[3] as pathophysiological outcomes. In fact, progressive nutrition deficiencies and muscle wasting are universal problems and critical predictors of morbidity, mortality and survival^[4,5] after surgical intervention. Early reports showed that cirrhotic patients requiring emergency abdominal surgery exhibited a higher mortality^[6]. In retrospective studies of liver transplant recipients, protein-calorie malnutrition had been associated with adverse outcomes in patients with end-stage liver diseases^[7,8]. A prospective study showed that cirrhotic patients with hypermetabolism and body mass loss had a much higher mortality rate after liver transplantation than those with normometabolism^[9]. Nutritional support is critical for patients with hepatic cirrhosis. Yet, studies have shown that aggressive nutritional support is essential but not effective enough to prevent protein loss and optimize the care of these patients in severe catabolic illness, including cirrhosis^[10,11].

Recent research has investigated the role of exogenous growth factor therapy in catabolic illness. Recombinant human growth hormone (rhGH) has been used in catabolic states such as after abdominal operation^[12], organ transplantation^[13], major trauma^[14] and severe burns^[15] to enable them to survive an aggressive surgery and gain access to a new life^[16]. After treatment of rhGH, donor site healing rate in children with severe burns enhanced and thus decreased a 14-day hospitalization time^[17-19]. Mortality rates in severely burned adults dropped 26 %^[20]. Cell-mediated immunity significantly enhanced, wound infection rates and length of hospitalization in a large group of post surgical patients decreased^[21]. Some clinical trial reported that growth hormone enhanced nitrogen retention in patients with chronic obstructive lung diseases^[22], severe sepsis^[23,24] and wasting status of AIDS^[25,26] and in fasted adult volunteers. Although there are many controversies^[27-31], it has been confirmed that rhGH is an effective drug to accelerate protein anabolism^[32] and plays a central role in metabolic intervention with a significant cost-effect benefit^[33].

The action of growth hormone depends on its binding with growth hormone receptor on cell membrane^[34]. Whether the cirrhotic hepatocytes express growth hormone receptors (GHR), and the relationship between the GHR expression and the staging of liver cirrhosis are not clear. So, we adopted multiple techniques such as radioligand binding assay and RT-PCR to measure the changes of GHR and its mRNA in an experimental liver cirrhosis model at cellular and histological levels for understanding of biological feature of expression of GHR in cirrhotic hepatocytes.

MATERIALS AND METHODS

Induction of liver cirrhosis

Liver cirrhosis in rats was induced by daily intraperitoneal injection of 3 % thioacetamide (TAA, Shanghai, China) 50 mg/kg for 9 to 12 weeks^[35,36]. Two hundreds male Sprague-Dawley rats (200-300 g, Medical Animal Center, Sun Yat-Sen University) were randomized and allotted to two groups, normal group ($n=82$) received saline intraperitoneally everyday; and cirrhotic group ($n=118$) received drugs for induction of hepatic cirrhosis. From each group, 80 rats were available for analysis. Rats were fed with regular chow and water *ad libitum* in cages placed in a room with 12-hour light-dark cycle and constant humidity and temperature (25 °C).

At the 3rd, 6th, 9th, 12th week and the 15th week (3 weeks after withdrawal of TAA) after induction of liver cirrhosis 10 rats from each group were fasted overnight and sacrificed. Liver tissue samples were obtained after hepatic sinusoids were flushed by perfusion of liver with normal saline through the portal vein. Tissue samples from the right major liver lobe were obtained and frozen in liquid nitrogen immediately and then stored at -80 °C until use, or fixed in 10 % neutral buffered formaldehyde solution and dehydrated and embedded in paraffin for regular pathological examination.

Digital image analysis

Liver collagen content was calculated by histomorphometric measurement in 4- μ m sections with Masson's trichrome stain. Under photographic analytic microscope (Carl Zeiss Axiotron, OPTON, Germany), three random areas in each section of liver slide were chosen and captured in RGB format with 24-bit true colors at a resolution of 768 \times 512 in real time by the JVC ky-F30B 3-CCD color video camera with digital conversion connected with a computer system of Kontron IBAS2.5 (OPTON, Germany) for digital image analysis. The total area and the area of fibrosis with positive staining were automatically selected, outlined and evaluated by planimetry. The relative content of collagen (RCC %) was expressed as a percentage of positive staining area in the total area^[37,38].

Hepatocyte isolation

At 9-12 weeks of the study, livers in 10 rats from each group were perfused *in situ* through portal vein with collagenase (type IV, 90 or 120 U/ml)^[39,40]. Hepatocytes were isolated at 4 °C by centrifugation (50 \times g, 5 min or 1 \times g, 10 min). Cells were re-suspended for radio-ligand binding assay in RPMI 1640 medium without serum to a final concentration of 1.0 \times 10⁶ cell/ml with a purity of more than 98 % and a viability of more than 90 % determined by trypan-blue exclusion.

Total RNA isolation

Total RNA of liver tissue was prepared from 10 rats in each group at the 9th week during the induction of cirrhosis by a single-step method^[41]. Integrity and quality of RNA were tested by electrophoresis in 1 % agarose-formaldehyde gels stained with ethidium bromide. The RNA concentration was evaluated

at spectrophotometric absorbance at 260 nm.

Primers for RT-PCR

Primers for the PCR amplification of GHR transcripts were purchased from Sangon Co. (Shanghai, China). The primers used for detection of GHR mRNA by RT-PCR were specific for the intracellular domain of the rat GHR, thus excluding detection of the smaller transcripts encoding GH-binding protein (GHRP)^[42]. The forward primer (GHR4548) was 5' - *ATGTGAGATCCAGACAACG-3' with the first base *A at the 5' end as an unmatched base of the original G and spanned from 876 to 894 located in exon 7 and the reverse one 5' - ATGTCAGGGTCATAACAGC-3' spanned from 1 356 to 1 374 located in exon 10. The PCR product was supposed to be 499 bp in length.

RT-PCR

RT-PCR was performed using the MasterAmp™ RT-PCR kit (Epicentre, Madison, USA) for detection of GHR mRNA^[43]. The procedure of RT-PCR was similar to that of literature^[44]. Negative controls in RT-PCR included reactions in the absence of RNA sample or primers or RT reaction to detect possible contamination of genomic DNA in RNA samples. The experiment was considered ineffective if there was any incidental band in lane of negative control. 10 μ l of each PCR products was subjected to electrophoresis for about 1 hour on 1 % agarose gel using electrophoresis apparatus (Bio-Rad, UK) and visualized by staining with ethidium bromide. The bands were observed using a ultraviolet gel device (UVI, UK) and captured into its computer system for digital image analysis. The level of GHR mRNA in each sample was expressed as: iOD (pixel)=the average optical density of each band \times its area (pixel).

Membrane microsome preparation

The microsomal liver membrane fraction was prepared by differential centrifugation of liver homogenate according to Papotti^[45]. About 1 g tissue from rat livers was chopped and homogenized with an electric homogenizer (Vorsicht, Malaysia) in ice-cold (4 °C) phosphate buffer (PBS) containing 0.25 M sucrose. The mixture was centrifuged at 1 500 \times g for 15 minutes. The supernatant was collected and centrifuged at 30 000 \times g for 30 minutes. The pellet was re-suspended in 3M MgCl₂ for 5 minutes to remove endogenous GH binding^[46] and centrifuged, the pellet was suspended in PBS. Protein concentration of the solution was determined by Lowry method.

GH binding assay

In radioreceptor assay, 100 μ l (approximately 20 000 cpm) of ¹²⁵I-hGH (NEN Inc, Boston, USA) with a specific activity of about 108 μ Ci/ μ g, 100 μ l of unlabeled hGH in PBS and 100 μ l of liver membrane microsomes or liver cells were mixed and incubated at 4 °C over night. Parallel incubations were performed with various amounts of hGH (0-3nM divided into 7-9 concentration gradients) in duplicate. An excess of hGH was used to determine nonspecific binding. At the end of the incubation, bound and free hormones were separated by filtration (0.18 μ m mesh filters, Shanghai, China)^[47]. The pellets on membrane were subjected to a gamma counter (SN γ 682, Rihuan, Shanghai, China). GH binding affinity constant (K_d, nM) and binding capacity (R_t, fmol/mg protein) or numbers of ¹²⁵I-GH binding sites of hepatocytes (\times 10⁴/cell) were calculated by Scatchard analysis using the LIGAND program^[48,49].

Statistical analysis

Results were expressed as the mean \pm SEM ($\bar{x} \pm s$) and analyzed by ANOVA and least significant difference (LSD) method with an acceptance of significance as $P < 0.05$.

RESULTS

Changes of lobular structure and RCC in the development of liver cirrhosis

In control group, no evident pathological change of lobular structure was found in liver tissue over 15 weeks. In cirrhotic model group, 4 stages of pathological changes were manifested during the development of liver cirrhosis: (1) scattered necrosis and cellular degeneration at the 3rd week; (2) fibrous proliferation at the 6th week; (3) pseudo-lobule formation at the 9th week; (4) massive nodule formation at the 12th week and (5) partial reversion of cirrhosis at the 15th week.

In control group, there was no significant change of RCC ($P>0.05$) among the different time points during the period of 15 weeks (Table 1). While compared with that of the control group at the same time point, RCC kept no significant change at the 3rd week ($P>0.05$) and increased significantly at the 6th, 9th, 12th and 15th week respectively ($P<0.05$) in the cirrhotic model group. When compared among the different time points in the cirrhotic model group, RCC increased gradually at the 3rd, 6th, 9th week and reached to its turning point at the 12th week ($P<0.05$), then went down, but still above normal level at the 15th week.

Table 1 Dynamic alteration of RCC, R_T and K_d in cirrhotic liver tissues

^a $P<0.05$ vs a previous time point, ^b $P<0.05$ vs control group. RCC: relative content of collagen (%) indicating severity of liver fibrosis; R_T : total binding capacity of receptors (fmol/mg protein) corresponding to the quantity of receptors; K_d : dissociation constant in equilibrium (nM) which is equal to the affinity of receptors.

GH binding in the development of liver cirrhosis

GH binding assay was carried out using liver membrane microsomes from rats at different time points in various groups and specific binding for ¹²⁵I-hGH was detected in all samples. The Scatchard analysis of GH binding capacity (R_T) and affinity (K_d) on each sample was performed and a single class of specific GH-binding sites on liver cell membranes, that is GHR, was revealed in both normal and cirrhotic liver tissue samples by linear Scatchard plots (Figure 1).

No significant change of R_T and K_d was found in liver tissue samples during the period of 15 weeks in control group ($P>0.05$) (Table 1 and Figure 1). While compared with that of the control group at the same time point, R_T decreased significantly ($P<0.05$) at the 3rd, 6th, 9th, 12th and 15th week although no change of K_d was observed in cirrhotic model group. When compared among the different time points in the cirrhotic model group, R_T decreased gradually at the 3rd, 6th, 9th week and reached to its lowest point ($P<0.05$) at the 12th week, then increased but still under normal level at the 15th week.

The correlation analysis manifested a significant negative linear correlation between R_T and RCC in rat liver cirrhotic tissue ($r=-0.82$, $n=50$, $P<0.05$) (Figure 2).

Quantitative analysis of GH binding sites on rats hepatocytes

There were linear Scatchard plots of normal and cirrhotic hepatocytes, which indicated the presence of a single class of

specific GH-binding sites, GHR, on hepatocyte membranes. The quantity of GH-binding sites ($\times 10^4$ /cell) on hepatocytes of cirrhotic model group (0.86 ± 0.16) was significantly less than that (1.28 ± 0.24) in normal control group ($n=10$, $P<0.05$) while the affinity (K_d , nM) of hepatocytes from model group (0.56 ± 0.08) and control group (0.61 ± 0.11) was similar ($n=10$, $P>0.05$).

Figure 1 Scatchard analysis of GH-binding in rat liver tissue. Microsomes of liver tissues were incubated with ¹²⁵I-labeled hGH and increased concentrations of unlabeled hGH. The bound/free radioactivity ratio (Y axis) was plotted as a rectilinear function of bound hormone (X axis). GH binding capacities (B_{max} =intercept on X axis, $R_T=B_{max}$ /protein concentration) and affinities (K_d =negative reciprocal of slope) were calculated from the competition assays by Scatchard analysis.

Figure 2 Correlation between R_T (quantity of GHR) and RCC (degree of cirrhosis) in rat cirrhotic liver samples.

GHR mRNA detected by RT-PCR

A specific band of RT-PCR products (499 bp in length) was detected in liver tissue samples from both control group and cirrhotic model group, indicating that GHR mRNA was expressed in both groups. The level of GHR mRNA (iOD, pixel) in cirrhotic liver (23.3 ± 3.1) was lower than that (29.3 ± 3.4) in normal liver ($n=10$, $P<0.05$) (Figure 3).

Figure 3 Comparison of GHR mRNA expression in liver tissue in normal control group and cirrhotic model group (the result of RT-PCR). Lane M: 100 bp DNA ladder; Lane 1: Normal control group; Lane 2: Cirrhotic model group.

DISCUSSION

Much has been done regarding the expression of GHR and signal transduction^[34, 47, 50, 51], but the expression of GHR in some pathological states such as cirrhotic hepatocytes, malignant cells is not clear. Chang^[52] reported that ¹²⁵I-rhGH binding activity in 6 cases of hepatocellular carcinoma and adjacent cirrhotic liver tissue could not be detected and believed that the GHR in cirrhotic hepatic tissue disappeared although the study only examined one aspect of the GHR, GH binding. Another study^[53] showed that specific binding of ¹²⁵I-hGH in liver tissue from liver transplant of 17 cases with end-stage liver diseases was lower than that in normal control, but only in 3 cirrhotic livers Scatchard analysis was performed for calculation of GH binding capacity and affinity. In this setting of tissue-based GH binding assay, it was not convincing enough to clear up the controversy about the expression of GHR on cirrhotic liver cells. So, GH binding assay at cellular level was used to analyze the expression of GHR on hepatocytes or in liver tissue of rats with cirrhosis. We have demonstrated that the growth hormone receptor was expressed on cirrhotic hepatocytes and lesser expression of GHR was found in a later stage of cirrhosis.

In present study, ¹²⁵I-hGH binding activity of cirrhotic hepatic tissue was studied with radioligand binding assay, and a single class of growth hormone specific binding sites with normal affinity was detected in the cirrhotic hepatic tissue, which indicated the expression of GHR in cirrhotic hepatic tissue. These results were compatible with those of clinical specimens from liver transplants^[53].

The relationship between the GHR expression in cirrhotic tissue and the stage of liver cirrhosis has not been reported. In our study, ¹²⁵I-hGH binding capacity (*i.e.* the quantity of GHR) decreased significantly even in the early stage of cirrhosis, and gradually decreased during the development of liver fibrosis and dropped to the lowest level in late stage of cirrhosis on week 12 after induction of hepatic cirrhosis, then increased but still below the normal level after withdrawal of TAA. This implicated that the quantity of GHR in liver tissue altered dynamically without any significant change of GH binding affinity over the development or recovery of liver cirrhosis. In other words, GHR expression was suppressed in the process of formation of liver cirrhosis. The more severe the cirrhosis was, the more significant the down regulation of GHR expression would be.

GH binding varied among liver samples^[47,53]. Our results indicated that GH binding capacity in rat cirrhotic liver tissue differed in various stages of liver cirrhosis, and only slight variation (data not listed) of such binding was found in liver tissue with the same time point during the development of cirrhosis. Therefore, histological staging of liver cirrhosis was one of the important factors predisposing the down-regulation of GHR expression^[54].

Fibrotic tissue accumulated in the portal area during the reconstruction of lobule of cirrhotic liver while hepatocytes regenerated continuously after repeated necrosis in the development of liver cirrhosis. The fibrous structure, hepatocytes and interstitial cells with heterogeneous distribution and various combination in cirrhotic tissue should be considered respectively as we analyzed the expression of growth hormone receptor. In the present study, the result of GH-binding capacity (R_T) in cirrhotic liver tissue indicated the GHR expression on membrane microsomes in hepatocytes and interstitial cells and could be affected by non-parenchymal cells rather than fibrotic tissue^[53]. The quantitative measurement of GH binding sites on parenchymal cells from cirrhotic livers had not been reported previously. Therefore Scatchard analysis was resorted to again and a single class of growth hormone

specific binding sites with normal affinity was detected in isolated cirrhotic hepatocytes, suggesting the expression of GHR on cirrhotic hepatocytes disassociated *in vitro*. It was found that the binding sites on cirrhotic hepatocytes was significantly decreased as compared with that on normal hepatocytes, which implied that cirrhotic hepatocytes expressed GHR in a reduced level without any significant difference of binding affinity. So, the decreased expression of GHR in cirrhotic liver tissue should be attributed not only to accumulation of interstitial cells but to the reduced expression of GHR on cirrhotic hepatocytes themselves also.

It is possible that the reduced level of GH binding is partly owing to the reduced population of hepatocytes and increased numbers of interstitial cells in cirrhotic livers. But the mechanisms of the reduced GHR expression on cirrhotic hepatocytes has not been defined yet. The reduced GH binding level was unlikely due to changes in the receptor itself. Occupancy of the receptors by endogenous GH and ligand-induced internalization of GHR may affect the measurement of the binding, since dissociation of GH from its receptor and recycling of GHR is incomplete in several hours^[55]. Therefore, GH binding was determined on microsomes that had been desaturated by exposure to 3M MgCl₂ for 5 minutes^[46]. It was reported that the specific binding of ¹²⁵I-labelled bovine GH to a GHR-enriched low density membrane fraction from regenerating rat liver was reduced to 10-35 % between 12 and 24 h and remained low until 48 h after partial hepatectomy^[46], which indicated the amount of functional GHR on hepatocytes was decreased with repeated degeneration, necrosis and regeneration in the microenvironment of cirrhosis. In this situation several cytokines such as IL-1 β , TNF- α and glucocorticoids seemed to be involved in the likely mechanism of the reduced GHR expression^[40, 56, 57].

It is necessary to investigate the changes of GHR and its mRNA simultaneously in order to understand the biological events at different levels. Shen^[53] reported that the reduced expression of GHR mRNA identified by ribonuclease protection assay in human cirrhotic livers was in the similar order of magnitude as reduction in GH binding. Relative quantity of GHR mRNA in liver tissue of cirrhotic rats was tested with RT-PCR assay and a similar result of our study indicated that the expression of GHR mRNA in cirrhotic liver tissue was lower than that in normal controls. Accordingly, it was suggested that the reduced GH binding may be secondary to reduced GHR gene expression and decreased GHR synthesis.

In summary, GH binding assay with staging analysis of liver cirrhosis was applied and our study showed that the growth hormone receptor was expressed with normal binding affinity on cirrhotic hepatocytes and expression of growth hormone receptors in a later stage of cirrhosis reduced significantly. These results implicated that there was a physiological basis of GHR for GH action in cirrhotic livers, but the sensitivity of cirrhotic hepatocytes to growth hormone might be decreased. Further investigations should be concentrated on the signal transduction of GHR in cirrhotic hepatocytes^[58].

Abstract

AIM: To investigate the effects of methionine/valine-depleted enteral nutrition (EN) on RNA, DNA and protein metabolism in tumor-bearing (TB) rats.

METHODS: Sprague-Dawley (SD) rats underwent jejunostomy for nutritional support. A suspension of Walker-256 carcinosarcoma cells was subcutaneously inoculated. 48 TB rats were randomly divided in 4 groups: A, B, C and D. The TB rats had respectively received jejunal feedings supplemented with balanced amino acids, methionine-depleted, balanced amino acids and valine-depleted for 6 days before injection of 740 KBq ^3H -methionine/valine via jejunum. The ^3H incorporation rate of the radioactivity into RNA, DNA and proteins in tumor tissues at 0.5, 1, 2, 4 h postinjection of tracers was assessed with liquid scintillation counter.

RESULTS: Incorporation of ^3H into proteins in groups B and D was $(0.500\pm0.020)\%$ to $(3.670\pm0.110)\%$ and $(0.708\pm0.019)\%$ to $(3.813\pm0.076)\%$ respectively, lower than in groups A $[(0.659\pm0.055)\%$ to $(4.492\pm0.108)\%]$ and C $[(0.805\pm0.098)\%$ to $(4.180\pm0.018)\%]$. Incorporation of ^3H into RNA, DNA in group B was $(0.237\pm0.075)\%$ and $(0.231\pm0.052)\%$ respectively, lower than in group A ($P<0.01$). There was no significant difference in uptake of ^3H by RNA and DNA between group C and D ($P>0.05$).

CONCLUSION: Protein synthesis was inhibited by methionine/valine starvation in TB rats and nucleic acid synthesis was reduced after methionine depletion, thus resulting in suppression of tumor growth.

INTRODUCTION

Parenteral nutrition (PN) is now a supportive therapy commonly used for cancer patients. However, some studies have suggested that PN with amino acid balanced solutions may prompt tumor

growth^[1-3]. Previous studies have shown that tumor growth was inhibited by a diet or PN lacking in methionine/valine. However, the mechanism is not yet known^[4-15]. In this study, we prepared methionine/valine-free amino acid imbalance solutions to investigate the effects of methionine/valine depleted EN on RNA, DNA and protein metabolism in TB rats.

MATERIALS AND METHODS

Radiopharmaceuticals

^3H -methionine (^3H -Met, specific activity of $148\text{ MBq}\cdot\text{mg}^{-1}$) and ^3H -valine (^3H -Val, specific activity of $240\text{ MBq}\cdot\text{mg}^{-1}$) was purchased from Chinese institute of atomic energy. The radiochemical purity was over 95 %.

Catheterization of jejunostomy

SD rats weighing $(160\pm20)\text{ g}$ were purchased from the animal center of Wuhan University, China. They were allowed to acclimate for one week. After fasting for 12 hours, rats were anesthetized with i.p. sodium pentobarbital ($40\text{ mg}\cdot\text{kg}^{-1}$). The animals were undergone catheterization of jejunostomy (day 0). A silicone rubber catheter (2 mm ID, 3 mm OD) was inserted into the proximal jejunum. The catheter passed through a subcutaneous tunnel and emerged between the scapulae. The catheter was sutured to the animal's back to protect the lines and was connected to a swivel so that animals can move without any restrictions in individual metabolic cages. The cannulation system consists of an microinfusion pump, a swivel, rat-harness and a silicone-tube-jejunostomy. Coprophagy was prevented by an own model of faecal collection cup. Animals were fasted for 48 hours after operation but they were provided with water ad libitum, and then given normal rat diets.

Preparation of TB rats

Walker-256 carcinosarcoma cells were obtained from Chinese Center of Culture Preservation. On day 0, the rats were inoculated subcutaneously in the right flank with 10^7 tumor cells of approximately 0.1 ml of cell suspension. Tumors were palpable in 7 days after transplantation.

Jejunal feeding

Enteral feedings were found to be a safe and cost-effective method for providing nutrition to cancer-bearing patients. On day 8, 48 TB rats were randomly divided into four groups (12 rats per group) and received enteral nutrition (jejunal feeding): Group A: TB rats were fed enteral nutrition solutions composed of balanced amino acids for 6 days before injection of 740 KBq ^3H -MET.

Group B: TB rats were fed methionine-depleted enteral nutrition solutions for 6 days before injection of 740 KBq ^3H -Met.

Group C: TB rats were fed enteral nutrition solutions composed of balanced amino acids for 6 days before injection of 740 KBq ^3H -Val.

Group D: TB rats were fed valine-depleted enteral nutrition solutions for 6 days before injection of 740 KBq ^3H -Val.

TB rats received continuous jejunal tube infusion with pump

for nutritional support at a daily dose of 330 ml·kg⁻¹, non-protein calorie was approximately 1160K J·kg⁻¹. A microinfusion pump was used for constant administration of EN solutions. TB rats were not fed during the entire infusion experiment, however they had free access to water.

Composition of amino acid solutions

Table 1 lists the components of amino acid solutions.

Table 1 Composition of amino acid solutions (g·L⁻¹)

Amino acids	Balanced amino acids (Group A, C)	Methionine-depleted (Group B)	Valine-depleted (Group D)
Isoleucine	5.5	5.5	5.5
Leucine	7.5	7.5	7.5
Lysine	7.0	7.0	7.0
Methionine	6.0	-	6.0
Phenylalanine	4.0	4.0	4.0
Threonine	5.0	5.0	5.0
Tryptophan	1.5	1.5	1.5
Valine	6.0	6.0	-
Arginine	6.0	6.0	6.0
Histidine	3.0	3.0	3.0
Proline	4.0	4.0	4.0
Tyrosine	1.0	1.0	1.0
Alanine	20.0	20.0	20.0
Glycine	7.5	7.5	7.5
Aspartic acid	4.0	4.0	4.0
Total amino acid	88.0	82.0	82.0
Total N	14.1	13.1	13.1

Composition of EN solutions

Table 2 summarizes the daily EN compositions infused into various groups.

Table 2 Compositions of EN solutions (ml·L⁻¹)

Amino acids	Balanced amino acids (group A, C)	Methionine-depleted (group B)	Valine-depleted (group D)
Amino acid solutions	350	350	350
50 % Glucose	300	300	300
20 % Intralipid	100	100	100
Electrolytes, vitamins	250	250	250
Total calorie (KJ·L ⁻¹)	3 513.3	3 507.9	3 507.9
Total N (g·L ⁻¹)	4.9	4.6	4.6
Non-protein calorie/N	122	131	131

Specimen sampling

After the infusions were completed, three rats per group were respectively killed by cervical dislocation at 0.5, 1, 2 and 4 hours postinjection of tracers. The whole tumor was dissected and used for the tissue uptake of radioactivity.

Nucleic acid and protein analysis

To assess the incorporation of the radioactivity into macromolecular materials, portions of the tumor tissues (70-120 mg) were divided into the acid-soluble fraction (ASF) and the acid-precipitate fraction (APF). Radiolabeled APF was divided into four fractions: lipids, RNA, DNA and proteins. To analyze ³H-Met and ³H-Val metabolites, the tumor tissues were homogenized in 1 ml of ice-cold 0.4 M HClO₄. The homogenate was centrifuged at 3 000 rpm for 5 min. The precipitate was resuspended in 1 ml of 0.4 M HClO₄. This wash was repeated twice. The precipitate was resuspended in 5 ml of CHCl₃:CH₃OH (2:1, V/V). After centrifugation at 3 000

rpm for 10 min, the CHCl₃:CH₃OH phase was separated. This extraction was repeated twice. The combined CHCl₃:CH₃OH fraction contains radiolabeled lipids. The precipitate was dissolved in 1 ml of 0.3 M KOH. After incubation of the solution at 37 °C for 1 hour to hydrolyze RNA, 0.32 ml of 3 N HClO₄ was added. The mixture was kept on ice for 5 min. The precipitate was then separated and washed with 1 ml 0.5 M HClO₄ as described above. The combined supernatant was designated as the alkaline-labile fraction containing the RNA hydrolysate. The precipitate was resuspended in 1 ml of 0.5 M HClO₄ and heated at 90 °C for 15 min to hydrolyze DNA. The solution was kept on ice for 5 min, and precipitate was separated and washed with 0.4 M HClO₄ twice. The combined supernatant and the final precipitate were assessed as the acid-labile fraction containing hydrolysates of DNA and protein fraction, respectively.

The radioactivities of fractions were counted by liquid scintillation counter. The tissue radioactivity was expressed as differential uptake ratio (DUR).

$$\text{DUR} = \frac{\text{Counts of tumor tissue (cpm)/sample weight (g)}}{\text{Injection dose counts (cpm)/body weight (g)}}$$

Statistical analysis

Student *t* test was used to examine the data. The difference was considered significant when *P* value was less than 0.05.

RESULTS

Three TB rats died of intestinal fistula, diarrhea, infection of abdominal cavity. Table 3 represented incorporation of ³H into nucleic acids and proteins in TB rats after treatment.

DISCUSSION

Influence of Methionine/Valine-depleted enteral nutrition on protein metabolism in TB rats

Patients with malignant tumors often show severe protein-amino acid metabolism disorder and uncorrectable negative nitrogen balance. Researchers have begun to reconsider the prescription of amino acid imbalance solution for cancer patients. Total parenteral nutrition deprived of methionine or valine cause tumor growth inhibition, but also have no significantly negative influences on the host animals^[16-18].

Table 3 shows the ³H incorporation rate in tumor tissues at

various times after ^3H -Met/Val injections. Regardless of Methionine/Valine-depleted enteral nutrition, the radioactivity into nucleic acids and proteins increased with time. In proteins we found an accumulation of the label which was up to 3-10-fold higher than in DNA and RNA. It represents the principle pathway for methionine and valine anabolism. Accumulation of ^3H -Met/Val into malignant tissue is thought to be due to amino acid metabolism of cancer cells such as increased active transport and incorporation of amino acid into protein fractions. In the complete absence of Methionine or Valine, the ^3H incorporation rate of the radioactivity into proteins in tumor tissues was from 75.8 % to 87.9 % of the control value. That is to say, in agreement with Xiao's study^[5], protein synthesis was inhibited by methionine/valine depletion, in this case suppressing tumor growth^[19-26].

Although essential amino acids are indispensable for physical well-being, the body lacks the ability to synthesize these compounds. Amino acids are an important materials of protein synthesis, amino acid imbalance are considered to principally involving alterations in intracellular protein synthesis, the deprivation of essential amino acids (Met, Val) leads to inhibit activity of tumor growth^[27,28].

Influence of Methionine/Valine-depleted enteral nutrition on RNA and DNA in TB rats

Methionine adenosyltransferase is the enzyme which is responsible for the synthesis of S-adenosyl-L-methionine (SAM) using methionine and adenosine triphosphate (ATP). Most of SAM are used in transmethylation reaction in which methyl groups are added to compounds and SAM is converted to S-adenosylhomocysteine. SAM is the principal biological methyl donor. SAM can easily transfer its methyl group to a large variety of acceptor substrates including rRNA, tRNA, mRNA, DNA, proteins, phospholipids, biological amines, and a long list of small molecules^[29-33]. So ^3H -Met is also incorporated into nucleic acids by transmethylation via S-adenosyl-L-methionine. Methionine depleted enteral nutrition can decrease methylation of tumor tissues and lead to further reduction in nucleic acid synthesis and inhibition of cancer growth at molecular levels.

Table 3 showed that the RNA and DNA incorporation rate in group B was lower than in control group (group A). Based on these findings, cancer cells were known to have lower levels of DNA and RNA synthesis on methionine-depleted enteral nutrition.

Theoretically, it is considered that ^3H -Val is incorporated into proteins but not into other high-molecular materials such as nucleic acids. The incorporation of ^3H -Val was detected in nucleic acids at negligible amounts, which possibly reflects contamination by labeled proteins during the experimental processes. However, because no metabolic pathway for the DNA incorporation of ^3H -Val is considered, the radioactivity in the acid-labile fraction is probably derived from basic proteins such as chromosomal histones.

Abstract

AIM: To study the effect of progesterone on contractile activity of isolated gastric strips in rats.

METHODS: Wistar rats were sacrificed to remove whole stomach. Then, the stomach was opened and the mucosal layer was removed. Parallel to either the circular or the longitudinal fibers, muscle strips were cut from fundus, body, antrum and pylorus. Each muscle strip was suspended in a tissue chamber containing 5 mL Krebs solution. Then the motility of gastric strips in tissue chambers was simultaneously recorded. The preparations were subjected to 1 g load tension and washed with 5 ml Krebs solution every 20 min. After 1 h equilibration, progesterone or antagonists were added in the tissue chamber separately. The antagonists were added 3 min before using progesterone ($50 \mu\text{mol} \cdot \text{L}^{-1}$).

RESULTS: Progesterone decreased the resting tension of fundus and body longitudinal muscle (LM) ($P < 0.05$). It inhibited the mean contractile amplitude of body and antrum LM and circular muscle (CM), and the motility index of pyloric CM ($P < 0.05$). The inhibition of progesterone on the mean contractile amplitude could be partially blocked by phentolamine in LM of the stomach body (the mean contractile amplitude of body LM decreased from -7.5 ± 5.5 to -5.2 ± 4.5 $P < 0.01$), and by phentolamine or indomethacin in CM of body (The inhibition of progesterone on the mean contractile amplitude of body CM decreased from -5.6 ± 3.0 to -3.6 ± 2.7 by phentolamine and from -5.6 ± 3.0 to -3.5 ± 2.5 by indomethacin, $P < 0.01$). Hexamethonium, propranolol and L-NNA (inhibitor of NO synthetase) didn't affect the action of progesterone ($P > 0.05$).

CONCLUSION: The study suggested that progesterone can inhibit the contractile activity of isolated gastric strips in rats and the mechanism seems to be a direct one except that the action on gastric body is mediated through prostaglandin and adrenergic α receptor partly.

INTRODUCTION

Nausea and vomiting are extremely common complaints of pregnancy and may precede even the patients are aware that she is pregnant^[1-4]. However, it's mechanism is poorly understood. The questions of whether gastric emptying of solids and liquids differs in men and women and whether emptying is influenced by the action of sex hormones on gastric smooth muscle remain unresolved^[5-8]. Whether gastric emptying of solids and liquids differs in women during the menstrual cycle is controversial^[9-12]. The results of several clinical and physiological studies have suggested that the aforementioned complaints of pregnancy may be related, at least in part, to decrease of resting tension within the lower esophageal sphincter and changes in gastric motility^[3,13-15]. The fact that a high serum sex hormone concentration is the characteristic of pregnancy tempts researchers to investigate the hormonal factor associated with gastrointestinal dysmotility. However, so far, the effect of pregnancy and sex hormone on gastric motility remains controversial. We studied the action of progesterone on the gastric strips in rats and explored the possible mechanism concerned.

MATERIALS AND METHODS

Materials

Progesterone, purchased from sigma, was dissolved and diluted in 1, 2-propanecol; hexamethonium and N^w-Nitro-L-Arginine (L-NNA), Sigma; indomethacin, Jiangsu Taicang Pharmaceutical Factory; propranolol, Beijing Second Pharmaceutical Factory; Phentolamine, Beijing Thirteen Pharmaceutical Factory; 1, 2-propanecol, Tianjing Chemical Factory; Krebs buffer solution [$\text{mmol} \cdot \text{L}^{-1}$: NaCl 120, 6, KCl 5.9, NaH_2PO_4 1.2, MgCl_2 1.2, NaHCO_3 15.4, CaCl_2 2.5, $\text{C}_6\text{H}_{12}\text{O}_6$ 11.5, $\text{pH}=7.4$].

JZ-BK external isometric force transducer, BK company; LMS-ZB two channel recorder, Chengdu Equipment Factory.

Wistar rats, 200-250 g, were provided by the Animal Center of Lanzhou Medical College.

Methods

Wistar rats were fasted with free access to water for 24 h, and sacrificed to remove whole stomach. Then, the stomach was opened along the great curvature, and rinsed with Krebs solution. The stomach was pinned on a wax block with mucosa side up, and the mucosal layer was gently rubbed with a tweezers. Parallel to either the circular or the longitudinal fibers, muscle strips ($8 \times 2 \text{ mm}$) were cut and named longitudinal muscle (LM) of fundus, circular muscle (CM) and LM of body and antrum and CM of pylorus^[16,17].

Each muscle strip with the mucosa removed was suspended in a tissue chamber containing 5 mL Krebs solution, constantly warmed by circulating water jacket at 37°C and supplied with 95 % O_2 and 5 % CO_2 . One end of the strip was fixed to a hook on the bottom of the chamber while the other end was connected by a thread to an external isometric force transducer at the top. Motility of gastric strips in tissue chambers were simultaneously recorded on recorders. Preparations were subjected to 1 g load tension and washed with 5 ml Krebs

solution every 20 min. After 1 h equilibration, progesterone (5, 10, 50 $\mu\text{mol} \cdot \text{L}^{-1}$) or antagonist was added in the tissue chamber (all were the final concentration) separately 3 min before using progesterone (50 $\mu\text{mol} \cdot \text{L}^{-1}$)^[16-20].

Analysis of data

We measured the resting tension of all strips, the mean contractile amplitude of body and antrum strips, and the motility index ($\text{MI} = \Sigma [\text{amplitude} \times \text{duration}]$) of pyloric strip. Frequencies of contraction were determined by counting the contraction waves. Values of the results was presented as $\bar{x} \pm s$. Statistical significances were measured by t test^[16,17].

RESULTS

Effect of progesterone on spontaneous contraction of gastric strips

Progesterone significantly decreased the resting tension of fundus and body LM (Table 1). It decreased the mean contractile amplitude of body and antrum, and the motility index of pylorus (Table 2). However it didn't influence the gastric contractile frequency ($P > 0.05$).

Effect of antagonists added progesterone on spontaneous contraction of gastric strips

Hexamethonium (10 $\mu\text{mol} \cdot \text{L}^{-1}$), L-NNA (100 $\mu\text{mol} \cdot \text{L}^{-1}$) or propranolol (1 $\mu\text{mol} \cdot \text{L}^{-1}$) added 3 min before admistrated progesterone didn't influence the decreasing effect of progesterone on the gastric strips in rats ($P > 0.05$), but phentolamine (1 $\mu\text{mol} \cdot \text{L}^{-1}$) partly blocked its effect on the mean contractile amplitude of body LM and CM, and indomethacin (10 $\mu\text{mol} \cdot \text{L}^{-1}$) also decreased the effect on the mean contractile amplitude of body CM (Table 3).

DISCUSSION

It has been shown from humans and animals that pregnancy is associated with alternations in the motor activity of the gastrointestinal tract, such as decreased gallbladder contractivity and lower esophageal sphincter pressure, reduced gastric emptying, small intestine and colonic transit^[13-15,21-29]. Although the factors responsible for the impaired gastric motility are obscure, there is evidence to suggest that pregnancy is associated with disturbances in the myoelectric and mechanical properties of gastrointestinal smooth muscle.

Table 1 Effect of progesterone on the resting tension of gastric smooth muscle in rats

Progesterone $\mu\text{mol} \cdot \text{L}^{-1}$	Resting tension/g					
	Fundus	Body		Antrum		Pylorus
	LM	LM	CM	LM	CM	CM
5	-0.08 \pm 0.12 ^a	-0.008 \pm 0.08	0	0.01 \pm 0.05	0	0
10	-0.08 \pm 0.08 ^b	-0.05 \pm 0.11	-0.03 \pm 0.06	0.04 \pm 0.09	0	0
50	-0.09 \pm 0.06 ^d	-0.12 \pm 2.0 ^a	0.01 \pm 0.15	0.02 \pm 0.04	0	-0.03 \pm 0.10

The values were expressed as differences in resting tension between 3 min before and after the addition of progesterone (5, 10 and 50 $\mu\text{mol} \cdot \text{L}^{-1}$) (The same in Tab 2). The resting tension of each strip in control (progesterone 0 $\mu\text{mol} \cdot \text{L}^{-1}$) was 1. LM: longitudinal muscle; CM: circular muscle. $\bar{x} \pm s$, $n=12$, ^a $P < 0.05$, ^b $P < 0.01$, ^d $P < 0.001$, vs control by paired t test.

Table 2 Effect of progesterone on the mean contractile amplitude of body and antrum, and the motility index of pylorus in rats

Progesterone $\mu\text{mol} \cdot \text{L}^{-1}$		Contractile amplitude/mm				Motility index/ $\text{cm} \cdot \text{s}^{-1}$
		Body		Antrum		Pylorus
		LM	CM	LM	CM	CM
5	B	13.4 \pm 17.0	12.0 \pm 13.2	13.6 \pm 8.6	14.1 \pm 15.0	92.4 \pm 16.2
	C	0.2 \pm 0.4	-0.9 \pm 3.0	-0.5 \pm 0.8 ^a	-0.8 \pm 1.7	1.7 \pm 4.8
10	B	12.8 \pm 17.6	11.2 \pm 14.0	14.0 \pm 7.1	13.6 \pm 12.9	98.5 \pm 20.0

50	B	12.0 \pm 16.9	11.8 \pm 12.9	12.6 \pm 8.0	12.6 \pm 14.8	110.2 \pm 22.8
	C	-7.5 \pm 5.5 ^a	-5.6 \pm 3.0 ^d	-5.4 \pm 3.8 ^d	-5.8 \pm 3.8 ^d	-47.4 \pm 31.2 ^d

B: basic values in 3 min before addition of progesterone; C: changes in 3 min after addition of progesterone (The same in Tab 3). $\bar{x} \pm s$, $n=12$. ^a $P < 0.05$, ^b $P < 0.01$, ^d $P < 0.001$, vs corresponding B by paired t test.

Table 3 Effect of progesterone on the mean contractile amplitude of body after indomethacin or phentolamine pretreatment in rats

Gastric body muscle	Contractile amplitude/mm									
	Pr		I + Pr				Ph + Pr			
	B	C	B	C	B	C	B	C	B	C
LM	12.0 \pm 16.9	-7.5 \pm 5.5 ^b	12.9 \pm 17.1	-0.1 \pm 6.0	12.5 \pm 18.4	-8.2 \pm 6.9 ^b	12.1 \pm 19.2	1.4 \pm 3.8	15.4 \pm 16.5	-5.2 \pm 4.5 ^d
CM	11.8 \pm 12.9	-5.6 \pm 3.0 ^b	12.2 \pm 14.0	1.2 \pm 5.2	12.6 \pm 13.2	-3.5 \pm 2.5 ^d	11.7 \pm 12.6	0.2 \pm 0.5	11.4 \pm 13.0	-3.6 \pm 2.7 ^d

Phentolamine (1 $\mu\text{mol} \cdot \text{L}^{-1}$) or indomethacin (10 $\mu\text{mol} \cdot \text{L}^{-1}$) was added 3 min before the addition of progesterone (50 $\mu\text{mol} \cdot \text{L}^{-1}$). $\bar{x} \pm s$, $n=12$. Pr: progesterone, I: indomethacin, Ph: phentolamine. ^b $P < 0.001$ vs corresponding B by paired t test; ^d $P < 0.01$ vs Pr alone by two samples mean t test.

In our study, progesterone decreased the resting tension of fundus, which might be a cause of changed gastric motility during pregnancy. It had been agreed that decreased fundic resting tension mainly influenced the gastric emptying of liquids. Ryan also reported^[30] that pregnancy was associated with decreased gastric emptying of liquids in the guinea pig. The observation in our study that hexamethonium, L-NNA and propranolol didn't influence the effect of progesterone suggesting that the action of progesterone was not mediated via NO, β or N_1 receptors. Since phentolamine blocked partly the effect of body LM and CM, and indomethacin decreased that of body CM showed that the effect of the hormone on body LM partly via a receptor, and on body CM via prostaglandin and a receptor. In addition, the effect of progesterone might act on gastric smooth muscle cells directly. Progesterone receptor had been found in normal human gastric tissues. Another evidence was addition of progesterone to isolated denervated gallbladder muscle strips inhibited contraction in response to both acetylcholine or cholecystokinin^[31].

Parkman reported^[14] that spontaneous and bethanechol induced phasic antrum contraction of pregnant guinea pigs were significantly reduced in force compared with control virgin animals, and intracellular electrical recordings were obtained from antral smooth muscle cells to investigate the mechanism of the decreased contractivity of antral smooth muscle during pregnancy. The results showed that there were similar resting membrane potentials, slow wave frequency and slow wave duration vs those of the control, but the upstroke amplitude, plateau amplitude and number of spike per slow wave decreased significantly. Further study suggested that the decreased force of spontaneous antral contractions was associated with a reduction in the underlying electrical slow wave depolarization. Electrogastrogram recordings also suggested that gastric dysrhythmias were objective pathophysiologic event associated with symptoms of nausea and vomiting during pregnancy^[14,32,33].

Exogenous progesterone also inhibited the myoelectric and mechanical activity of gastrointestinal smooth muscle. Electrical spike potentials recorded from chronically implanted electrodes in the antrum and jejunum of ovariectomized dogs by Milenory decreased after 4 d of progesterone addition ($2 \text{ mg} \cdot \text{kg}^{-1} \cdot \text{d}^{-1}$) and the propagation velocity of the basic electrical rhythm from the antral region of the progesterone-treated animals also decreased^[34]. In another example, progesterone had been shown to reduce the propagation velocity of gastrointestinal slow waves possibly by decreasing the degree of electrical coupling between smooth muscle cells^[35]. Dysrhythmias were also induced in healthy, nonpregnant women by administration of progesterone in the dose that reproduces plasma level seen in pregnancy. The above results suggested that the inhibitory effect of progesterone on the gastric smooth muscle may contribute to the gastric dysmotility during pregnancy.

Abstract

AIM: To study the relative efficacy of cisapride, metoclopramide, domperidone, erythromycin and mosapride on gastric emptying (GE) and small intestinal transit (SIT) in morphine treated mice.

METHODS: Phenol red marker meal was employed to estimate GE and SIT in Swiss albino mice of either sex. The groups included were control, morphine 1 mg/kg (s.c. 15 min before test meal) alone or with (45 min before test meal p.o.) cisapride 10 mg/kg, metoclopramide 20 mg/kg, domperidone 20 mg/kg, erythromycin 6 mg/kg and mosapride 20 mg/kg.

RESULTS: Cisapride, metoclopramide and mosapride were effective in enhancing gastric emptying significantly ($P < 0.001$) whereas other prokinetic agents failed to do so in normal mice. Metoclopramide completely reversed morphine induced delay in gastric emptying followed by mosapride. Metoclopramide alone was effective when given to normal mice in increasing the SIT. Cisapride, though it did not show any significant effect on SIT in normal mice, was able to reverse morphine induced delay in SIT significantly ($P < 0.001$) followed by metoclopramide and mosapride.

CONCLUSION: Metoclopramide and cisapride are most effective in reversing morphine-induced delay in gastric emptying and small intestinal transit in mice respectively.

INTRODUCTION

Opioids are effective analgesics for moderate to severe pain^[1]. Morphine is the most commonly prescribed opioid agonist for the treatment of chronic pain^[2,3]. However, when opioids are given to alleviate pain they cause undesirable gastrointestinal (GI) side effects namely nausea, vomiting and reduced gastrointestinal transit^[4]. Reduced GI transit can cause gastroesophageal reflux disease, bloating and idiopathic constipation^[5].

The pathophysiology of GI delay due to opioids has been well described. Possible etiologies include increased stationary segmentation, reduced peristalsis and depression of secretory activity^[6]. Due to the paucity of the data to guide practitioners

in the management of GI side effects of opioids much of the information is extrapolated from different patient populations experiencing the same symptoms due to different etiologies.

Use of opioid antagonists such as naloxone, nalmefene, for opioid-induced GI delay^[7-10], is limited by their cost and tendency to cause withdrawal symptoms in the doses used^[10,11]. Peripherally acting methyl naltrexone and ADL-2698 (Alvimopan) are in the stage of investigational^[11].

Mosapride, cisapride, metoclopramide, erythromycin and domperidone are commonly used prokinetic agents. At present, the data supporting their relative efficacy in opioid induced GI delay are lacking. Further their distinct mechanism of action leaves a scope for variation in their efficacy. The present work attempts to study the relative efficacy of various prokinetic drugs such as cisapride, metoclopramide, domperidone, erythromycin and mosapride on small intestinal transit (SIT) and gastric emptying (GE) in morphine treated mice.

MATERIALS AND METHODS

Animals

Randomly bred healthy adult Swiss albino mice of either sex weighing between 20-25 g were obtained from JIPMER animal house, Pondicherry. One week prior to the experimentation, six mice were housed in separate cages and had free access to food and water. The experiments were conducted between 09:00 AM and 1:00 PM. The animals were fed with the pellets obtained from Prestige Agro-industries, Aurangabad. The study was approved by the institutional animal ethics committee.

Drugs and chemicals

Morphine sulphate (Govt. opium and alkaloid works, Ghazipur), cisapride (Torrent Pharmaceuticals, Ahmedabad), metoclopramide hydrochloride (Ipca laboratories Ltd., Mumbai), domperidone (Torrent Pharmaceuticals, Ahmedabad), erythromycin ethylsuccinate (Emil pharmaceutical industries Pvt Ltd, Thane), mosapride citrate (Alembic chemical works Co. Ltd. Vadodara) and Thiopentone sodium (Abbot laboratories, Mumbai) were used. Other chemicals used were of analytical grade. Carboxymethyl cellulose (1 %, 0.2 ml) was used as vehicle to administer prokinetic drugs.

Phenol red meal

Phenol red indicator weighing 25 mg was dissolved in 50 ml of distilled water and filtered. The filtrate was heated to 70 °C and methylcellulose (0.75 g) was added to it with continuous stirring. The mixture was then cooled to 37 °C.

Gastric emptying (GE) and small intestinal transit (SIT)

The standard method of phenol red marker meal as performed by earlier workers was employed^[12,13]. Mice were deprived of food for 24 h prior to experimentation but had free access to water, and 0.5 ml of phenol red meal was administered with the aid of the oral feeding syringe. Animals were killed by cervical dislocation under i.v. thiopentone sodium anesthesia 15 min after the administration of the meal. Abdomen was

opened and stomach was dissected out after careful ligation at the cardiac and pyloric ends, and was washed with normal saline. The stomach was cut into pieces and homogenized with 25 ml of 0.1 N NaOH. To this 5 ml homogenate 0.5 ml of trichloroacetic acid (20 % w/v) was added and centrifuged at 3 000 rpm for 20 minutes. To one ml of supernatant 4 ml of 0.5 N NaOH was added. The absorbance of this pink colored liquid was measured using spectrophotometer at 560nm (Model: HITACHI 150-20). This correlates with the concentration of phenol red in the stomach, which in turn depends upon the gastric emptying. The percentage gastric emptying is derived as $(1-X/Y) \times 100$ where, X is absorbance of phenol red recovered from the stomach of animals sacrificed 15 minutes after test meal. Y is mean ($n=5$) absorbance of phenol red recovered from the stomachs of control animals (killed at 0 min following test meal).

The small intestine was dissected out from the pylorus and ileocaecal junction and the point to which meal had traversed was secured with thread to avoid change in the length of the transit due to handling. The total length of the small intestine and distance traveled by phenol red meal was measured. The small intestinal transit (SIT) was calculated considering the distance traveled by phenol red meal divided by total length of the small intestine multiplied by 100. Small intestinal transit was expressed as mean \pm sem. The observer was blinded for the drugs administered to the mice.

Drug treatment

Control groups received the equal volumes of vehicle through corresponding routes. The groups included were control, morphine 1 mg/kg (s.c.), cisapride 10 mg/kg (p.o.), metoclopramide 20 mg/kg (p.o.), domperidone 20 mg/kg (p.o.), erythromycin 6 mg/kg (p.o.) and mosapride 20 mg/kg (p.o.). The doses were selected based on the earlier reports^[14,17], recommended clinical doses^[18,20] and prior pilot experiments. Cisapride, metoclopramide, domperidone, erythromycin and mosapride in the dose mentioned above were given alone 45 minutes before the administration of phenol red meal. Morphine (s.c.) was injected 15 minutes before the administration of the meal.

Statistical analysis

Statistical analysis was carried out using Graph pad (Prism) soft ware. One way analysis of variance (ANOVA) for small intestinal transit and gastric emptying was applied separately followed by bonferroni post-test for multiple comparisons. Values were expressed as mean \pm sem. $P < 0.05$ was considered significant.

RESULTS

Since significant difference was not noticed among inter-day and animals receiving saline or 1 % carboxymethyl cellulose, data from these groups were pooled to serve as control group. Similar results obtained from morphine (1 mg/kg s.c.) treated groups were pooled. Morphine in the dose of 1 mg/kg (s.c.) caused significant decrease (61 %) in SIT ($P < 0.001$) and (43 %) in gastric emptying ($P < 0.05$).

Gastric emptying

Cisapride, metoclopramide and mosapride in the doses employed increased gastric emptying significantly ($P < 0.001$) by 126 %, 102 %, 89 % respectively compared with control animals, while domperidone and erythromycin failed to show any significant effect (Table 1, Figure 1). When combined with morphine (1 mg/kg s.c.) only metoclopramide and mosapride reversed morphine induced delay significantly ($P < 0.05$) (Table 2, Figure 2).

Domperidone (20) p.o.	32.16±3.48	28.63±2.47
Erythromycin (6) p.o.	29.39±2.53	31.19±1.08
Mosapride (20) p.o.	38.59±1.98 ^c	38.01±1.61 ^d

Each value represents mean \pm sem, $n=5$ in treatment group and $n=10$ in control and morphine treated group. ^aprokinetic agents were given 45 minutes and morphine 15 minutes prior to the test meal. ^a $P < 0.05$ and ^b $P < 0.001$ vs control group. ^c $P < 0.05$ and ^d $P < 0.001$ vs morphine treated group.

Small intestinal transit

Only metoclopramide *per se*, significantly ($P < 0.001$) increased SIT by 50 % (Figure 3). However, when combined with morphine (1 mg/kg, s.c.) cisapride showed maximum efficacy followed by mosapride and metoclopramide (Figure 4). Domperidone and erythromycin did not exhibit any significant effect (Table 2).

Figure 3 Effect of various prokinetic agents on small intestinal transit in mice. (^aProkinetic agents were administered orally 45 minutes prior to test meal).

Figure 4 Effect of Prokinetic agents on morphine induced delay of small intestinal transit in mice. (^aProkinetic agents were administered orally 45 minutes and morphine s.c. 15 minutes prior to test meal).

DISCUSSION

Opioids cause decrease in gastric emptying and intestinal motility, which leads to nausea, abdominal bloating and constipation^[21]. Both exogenous and endogenous opioids inhibit propulsive movements of the intestine by interfering with the enteric regulation of propulsive motility^[22]. They interact with μ and δ opioid receptors and cause decrease in cyclic AMP. Opioids increase the calcium dependent potassium conductance and thus, hyperpolarize myenteric neurons, which reduce the entry of calcium during the action potential leading to decrease in intracellular calcium and thereby decreasing peristalsis^[23].

In mice μ agonists administered subcutaneously produced dose-related inhibitions of gastrointestinal transit^[24]. In our study there was significant decrease (61 %) in SIT with morphine (1 mg/kg s.c.) compared with control animals ($P < 0.001$). Decrease in SIT seen with 1 mg/kg (s.c) of morphine is in agreement with earlier reports^[14,16,17].

Prokinetic agents used to reverse morphine induced delay in GI transit showed variation in their efficacy. Cisapride (10 mg/kg, p.o.) though, did not show significant increase in SIT compared with control, it was most effective in reversing morphine induced delay in SIT (Figure 4). This finding is consistent with a clinical study where the effect of cisapride

was significantly greater than that of metoclopramide^[16]. Cisapride in the dose of 10 mg/kg (p.o.) showed significant increase in gastric emptying when compared with control animals but in morphine induced delay in gastric emptying it fails to show significant effect in overcoming the inhibition (Table 2).

Rectal administration of cisapride 30 mg 8th hourly had modest benefit in reversing small intestinal transit following intravenous meperidine in patients undergoing major abdominal surgery^[25]. This may reflect an inability of cisapride to attain effective plasma concentrations when given rectally and this is supported by another report where rectal cisapride was not able to overcome gastric stasis produced by morphine^[26]. Above observations indicate that in morphine treated mice, cisapride is more effective in reversing morphine induced delay in SIT rather than delay in gastric emptying.

Similar differential effect of metoclopramide and cisapride on the abdominal surgery induced decrease in transit was seen in which metoclopramide further inhibited whereas cisapride ameliorated the inhibition of transit^[27].

In our study metoclopramide (20 mg/kg p.o.) was found to be the most effective prokinetic agent when compared to control animals (Figure 3). Metoclopramide is a 5-HT₄ agonist, 5-HT₃ antagonist and antagonises the inhibitory effect of dopamine in the gastrointestinal tract. Despite above actions, it was only marginally effective in reversing morphine induced delay in SIT (Figure 2).

Metoclopramide in the dose of 20 mg/kg p.o. significantly increased gastric emptying when compared with controls (Table 1). In morphine induced gastric emptying delay, it reversed the morphine effect completely (Figure 2). In a clinical study conducted by McNeill *et al.*, it was shown that i.v. metoclopramide antagonised the opioid premedication induced delay in gastric emptying but not i.m. metoclopramide^[28]. There is also evidence that the effectiveness of metoclopramide may depend on the route of administration^[29,30].

Domperidone is a peripherally acting dopamine antagonist. Domperidone (20 mg/kg, p.o.) alone did not show any significant prokinetic effect as against control animals (Table 2). In our study, it was seen that in reversing morphine induced delay, though it could not significantly increase SIT, its efficacy was similar to that of metoclopramide (Figure 4). Since there is a risk of extrapyramidal effects with metoclopramide, domperidone may be useful in opioid induced delay in gastrointestinal transit where metoclopramide is contraindicated. Domperidone in the dose of 20 mg/kg p.o. did not show any significant increase in gastric emptying in normal and morphine treated animals (Table 1 and Table 2).

Erythromycin, a motilinomimetic in the dose of 6 mg/kg (p.o.) did not show any significant prokinetic effect (Table 1) and had the least efficacy in reversing morphine induced delay in gastrointestinal transit (Table 2). Erythromycin in the dose of 1 mg/kg did not show any effect in postoperative ileus^[27]. Erythromycin even at 40 mg/kg did not show any prokinetic effect in rats though motilin immunoreactivity has been demonstrated in the rat intestine^[31]. The motilin receptor status of mouse upper GI tract is not documented. De Winter *et al.* suggested by their experiments that rat might not be the ideal species to test erythromycin^[27]. The fact that erythromycin was not effective in our study indicates that mice too may not be the ideal species for these type of studies.

Mosapride, a derivative of cisapride so far was not tested in morphine-induced delay in small intestinal transit. In our study though it did not show significant prokinetic effect in the dose (20 mg/kg p.o.) used, however it was less effective than 10 mg cisapride in reversing morphine induced delay in SIT. Efficacy of mosapride and metoclopramide in reversing morphine effect on GE cannot be differentiated from the available data.

A look at the SIT values (Table 1) indicates that metoclopramide has maximum efficacy in normal mice while cisapride is most efficacious in reversing morphine induced delay in SIT followed by metoclopramide and mosapride (Table 2). The above differences may be due to interactions taking place at various levels viz. the central and the peripheral nervous system. It is known that morphine suppresses the cholinergic outflow^[32], while metoclopramide enhance cholinergic outflow^[20] via 5-HT₄ and D₂ receptor interaction. It is also known that cisapride is non-selective 5-HT₄ receptor agonist with affinity for D₂, 5-HT₂, α_1 adrenergic and muscarinic receptors^[33]. Further, mosapride a 5-HT₄ agonist shows efficacy less than cisapride in reversing morphine effects on SIT and less than metoclopramide in GE. The intrinsic activity of mosapride was less than that observed for cisapride which indicates that it may act as a partial agonist^[34]. Role of heterogenicity in 5-HT₄ receptors in the differential effect of 5-HT₄ agonists cannot be ruled out^[35].

Mechanism underlying the stimulation of gastric and small intestinal motility by prokinetic agents is 5-HT₄ receptor activation that involve cholinergic nerves. However the mechanism underlying the different profile of the effect of 5-HT₄ agonists on gastric emptying and small intestinal transit remains unexplained.

Gastric emptying in normal mice was enhanced by cisapride, metoclopramide and mosapride (Figure 1) but in morphine treated mice metoclopramide was most effective followed by mosapride (Figure 2). This suggests that in morphine treated mice, 5-HT₄ pathways may not play a major role. Effect of cisapride and metoclopramide on other receptors contributes predominantly in reversing the effect of morphine on SIT and gastric emptying respectively.

Results of this study and earlier reports indicate that efficacy of prokinetic agents is dependent on factors such as pathophysiology, species, site of gastrointestinal tract and pharmacological profile of the drug.

CONCLUSIONS

Morphine in the dose of 1 mg/kg (s.c.) inhibited the small intestinal transit by 61 % and to a lesser extent, gastric emptying (43 %) under the experimental conditions. Metoclopramide has significant prokinetic effect when compared with cisapride, domperidone, mosapride and erythromycin in normal mice. Metoclopramide, cisapride and mosapride enhance gastric emptying significantly compared to domperidone and erythromycin in normal mice. All the prokinetic agents used in our study differ in their prokinetic effects in counteracting the effect of morphine induced GI inertia. Cisapride is most effective in reversing morphine induced SIT delay followed by metoclopramide and mosapride. In morphine-induced GE delay metoclopramide is most effective followed by mosapride.

Abstract

AIM: To explore different roles of transforming growth factor beta (TGF- β) and bone morphogenetic proteins (BMPs) in hepatic stellate cell proliferation and trans-differentiation.

METHODS: Hepatic stellate cells were isolated from male Sprague-Dawley rats. Sub-cultured hepatic stellate cells were employed for cell proliferation assay with WST-1 reagent and Western blot analysis with antibody against smooth muscle alpha actin (SMA).

RESULTS: The results indicated that TGF- β 1 significantly inhibited cell proliferation at concentration as low as 0.1 ng/ml, but both BMP-2 and BMP-4 did not affect cell proliferation at concentration as high as 10 ng/ml. The effect on hepatic stellate cell trans-differentiation was similar between TGF- β 1 and BMPs. However, BMPs was more potent at trans-differentiation of hepatic stellate cells than TGF- β 1. In addition, we observed that TGF- β 1 transient reduced the abundance of SMA in hepatic stellate cells.

CONCLUSION: TGF- β may be more important in regulation of hepatic stellate cell proliferation while BMPs may be the major cytokines regulating hepatic stellate cell trans-differentiation.

INTRODUCTION

Transforming growth factor beta (TGF- β) and bone morphogenetic proteins (BMPs) are the members of TGF- β superfamily^[7, 23]. Their biological effects are mediated through the receptors that have serine-threonine kinase activity^[1, 24]. However, they bind to their respective receptors. Moreover, the molecules involved in their signal transduction are different. It is generally considered that signal transduction pathway of BMPs is mediated by Smads 1, 5, and 8, while the signaling molecules of TGF- β are Smads 2 and Smads 3^[17, 29, 33]. The role of TGF- β in hepatic fibrogenesis has been investigated

because of the effect of TGF- β on extracellular matrix (ECM) production and degradation^[3, 27, 32]. But the effects of BMP on hepatic fibrogenesis have not been studied extensively. With recent understanding of hepatic fibrogenesis, hepatic stellate cells play an important role in the development of hepatic fibrosis^[8, 14]. It is documented that hepatic stellate cells are the main cell type that synthesize and secrete ECM in the liver. In addition, hepatic stellate cells migrate, proliferate and contract in response to liver injury, which contribute to the development of scar formation and portal hypertension. The effects of TGF- β 1 on hepatic stellate cell proliferation and activation have been documented with some studies showed the inhibitory effect of TGF- β 1^[2, 6, 25, 26] while others exhibited no effect on hepatic stellate cell proliferation^[20, 28]. However, there are no reports about the effects of BMPs on hepatic stellate cell proliferation and trans-differentiation. Therefore, the objective of this study is to examine the effects of TGF- β 1 and BMPs on rat hepatic stellate cell proliferation and expression of smooth muscle alpha actin (SMA) - a marker of hepatic stellate cell trans-differentiation.

MATERIALS AND METHODS

Materials

Collagenase D, pronase, DNase 1, cell proliferation reagent WST-1, and monoclonal antibody against smooth muscle alpha actin were purchased from Roche Diagnostics (Laval Quebec). Rabbit antibody against mouse IgG conjugated to horseradish peroxidase, and Enhanced Chemiluminescence Detection Kit were from Amersham Pharmacia Biotech, Inc. (Baie d'Urfe, Quebec). Dulbecco's Modified Eagle Medium (DMEM), fetal bovine serum (FBS) and Nycodenz were obtained from GIBCO/BRL (Burlington, Ontario). TGF- β 1, BMP-2 and BMP-4 were purchased from R&D systems (Minneapolis, MN).

Isolation of rat hepatic stellate cells

Male Sprague-Dawley rats (450-550 gram body weight) were purchased from Central Animal Care of the University of Manitoba and maintained under 12-hour light/dark cycles with food and water ad libitum. In conducting the research described in this report, all animals received humane care in compliance with the Institution's guidelines (Animal Protocol No. 98-053), which is in accordance with the Canadian Council on Animal Care's criteria. Hepatic stellate cells were isolated from rat liver by two steps of collagenase and pronase methods as previously described^[10]. The liver was perfused via the portal vein first with Ca²⁺ free Hanks' balanced salt solution (HBSS), pH7.4, for 10 minutes at 37 °C and then with Ca²⁺ HBSS containing 0.125 mg/ml collagenase D, 0.5 mg/ml pronase and 15 μ g/ml DNase 1 for 20 minutes. After being dispersed gently, the cells were incubated with 0.125 mg/ml collagenase D, 0.5 mg/ml pronase and 15 μ g/ml DNase 1 for another 12 minutes with constant low speed stirring at 37 °C. Cell suspension was filtered through a 100 μ m mesh. After removing hepatocytes

by centrifugation at 500 rpm on a bench-top centrifuge, Hepatic stellate cells were separated from other non-parenchymal cells by density gradient centrifugation on 11.3 % Nycodenz with sodium chloride at 1 400 g for 17 minutes at 8 °C. Hepatic stellate cells were harvested from the interface between suspension buffer on the top and 11.3 % Nycodenz solution, washed and plated on uncoated plastic tissue culture dishes (Costar) at a density of 25 000 cells/cm². Hepatic stellate cells were identified by the typical star-like configuration under light microscopic appearance. The purity was always higher than 95 %. Hepatic stellate cells were incubated in DMEM supplemented with 10 % FBS, antibiotics (100 IU/ml penicillin and 100 mg/ml streptomycin) and 2 mM L-glutamine at 37 °C in a humidified atmosphere of 5 % CO₂. The first change of culture medium was made 24 hours after seeding and then change the medium every 48 hours. Sub-cultured Hepatic stellate cells were obtained from 9-day-old primary culture hepatic stellate cells by detaching from the dishes with trypsin-EDTA.

Cell proliferation assay

Cell proliferation was measured by cell proliferation reagents WST-1^[12]. Sub-cultured hepatic stellate cells (2×10^3) in 200 μ l culture medium were seeded into 96 well plates. After incubation for 24 hours, the medium was changed with 100 μ l of fresh culture medium containing different concentrations of recombinant TGF- β 1, BMP-2 and BMP-4. The media and reagents were changed every other day. Cell proliferation was documented after 3, 6, 9 days of treatment. At the end of treatment, 10 μ l of WST-1 reagent were added into wells and incubated for 2 hours. The absorbance of the treated samples against a blank control was measured using a THERMOMax microplate reader (ELISA) (molecular Devices Co., Menlo Park, CA) with 420nm as detection wavelength and 650nm as reference wavelength for WST-1 assay.

Western blot analyses of SMA

Sub-cultured hepatic stellate cells were lysed in 100 μ l protein extract solution (1 mM Tris-HCl pH7.5, 1 mM EDTA pH 8.0, 10 mM NaCl, 1 % sodium dodecyl sulfate (SDS), 1 mM PMSF and 0.25 M sucrose)^[11]. Cell membrane was broken by sonicating the cells for 1 minutes with Sonicator (Vibra Cell, Sonics and Material Inc. Danbury, CT) and cell debris was pelleted by centrifugation at 14 000 rpm at 4 °C for 5 minutes. Protein concentration was determined by Lowry method^[9]. 20 μ g of protein from each sample was mixed with gel loading buffer (2 \times : 125 mM Tris-HCl, pH6.8, 4 % SDS, 20 % glycerol, 0.1 % bromophenol blue and 2.5 % β -mercaptoethanol), boiled for 5 minutes, separated on 12 % SDS-polyacrylamide gel under reducing conditions, and transferred to Nitroplus-2000 membrane (Micron Separations Inc. Westborough, MA). Nonspecific antibody binding was blocked by pre-incubation of the membranes in 1 \times Tris-buffered-saline (TBS) containing 5 % skim milk for 1 hour at room temperature. Membranes were then incubated overnight at 4 °C with primary antibody against SMA at dilution of 1:1 000 in 1 \times TBS containing 2 % skim milk. After washing, they were incubated for 1 hour at room temperature with sheep anti-mouse IgG at 1:1 000 dilutions. Bands were visualized by employing the enhanced chemiluminescence kit per the manufacturer's instruction.

Statistical analyses

Statistical significance of differences was performed by employing the ANOVA and Fisher's PLSD test as Post hoc test with StatView software (version 5.0, SAS Institute Inc. Cary, NC). Differences were considered to be significant when *P* was less than 0.05.

RESULTS

Effect of TGF- β 1, BMP2 and BMP4 on rat hepatic stellate cell proliferation

Effect of TGF- β 1, BMP2 and BMP4 on rat hepatic stellate cell proliferation was shown in Figure 1. TGF- β 1 significantly inhibited hepatic stellate cell proliferation after 6 days of incubation at the concentrations of 0.1, 0.5 and 1 ng/ml, respectively, *P*<0.05 (Figure 1A). The inhibition was more dramatic at 9-days treatment of TGF- β 1, *P*<0.01. However, both BMP2 and BMP4 did not affect hepatic stellate cell proliferation at the concentration as high as 10 ng/ml (Figure 1B and 1C).

Figure 1 Regulating effect of TGF- β 1, BMP-2 and BMP-4 on the proliferation of rat hepatic stellate cells. Hepatic stellate cells were incubated with TGF- β 1 (A), BMP-2 (B) and BMP-4 (C) as described in Materials and methods. The data represent mean \pm SE from ten wells. The experiments were repeated two times. Denotes: a represents ^a*P*<0.05 vs the concentrations of 0.1, 0.5 and 1 ng/ml, b means ^b*P*<0.01 vs the concentrations of 0.1, 0.5 and 1 ng/ml.

Effect of TGF- β 1, BMP-2 and BMP-4 on SMA expression

TGF- β 1, BMP-2 and BMP-4 increased the expression of SMA, which is well recognized by the antibody as a 42-kDa protein. BMP-2 and BMP-4 seemed to have more potent effect on the expression of SMA than TGF- β 1. After incubation with TGF-

$\beta 1$ (concentrations from 0.1 to 1 ng/ml) for 3 days, SMA level was only elevated about 50 % as compared with control group (Figure 2). While after BMP-2 or BMP-4 treatment, SMA level was two to four times higher than that of the untreated group (Figure 3). Moreover, we observed that the abundance of SMA in hepatic stellate cells was reduced after 3 hours of TGF- $\beta 1$ treatment. The abundance of SMA was reduced to about 20 % of original level and the level of SMA was elevated (about 60 % higher than original level) after 18 hours' treatment (Figure 4).

Figure 2 Regulating effect of TGF- $\beta 1$ on rat hepatic stellate cell trans-differentiation. Hepatic stellate cells were incubated with different concentrations of TGF- $\beta 1$ for three days. The media and TGF- $\beta 1$ were changed every other day. Western blot was performed as described in Materials and methods. The top panel represents typical Western blot of SMA. The lower panel represents histogram of densitometric data from four-separated Western blot (mean \pm SE).

Figure 3 Regulating effect of BMP-2 and BMP-4 on hepatic stellate cell trans-differentiation. Hepatic stellate cells were incubated with different concentrations of BMP-2 or BMP-4 for three days. The media and BMPs were changed every other day. Western blot was performed as described in Materials and methods. The top panel represents typical Western blot of SMA. The lower panel represents histogram of densitometric data from four-separated Western blot (mean \pm SE).

Figure 4 Regulating effect of TGF- $\beta 1$ on SMA protein expression. Hepatic stellate cells were cultured for three days and the media were removed. Media with 1 ng/ml TGF- $\beta 1$ or saline were added into culture dishes and cells were collected at different times as indicated. The data represent mean \pm SE from four experiments.

DISCUSSION

Hepatic stellate cells are non-parenchymal liver cells located at the perisinusoidal space. Recent studies have demonstrated that these cells proliferate and activate in response to liver injury. It is now established that hepatic stellate cells are the cell type involved in hepatic fibrogenesis^[4,5]. It is known that the proliferation of these cells is one response during hepatic fibrogenetic process. The other feature of these cells is their trans-differentiation, which is indicated by increased expression of SMA^[19]. During the trans-differentiation process of hepatic stellate cells, these cells are trans-differentiated into myofibroblast-like phenotype. To understand hepatic fibrogenesis, it is important to know the mechanism of proliferation and trans-differentiation of hepatic stellate cells. In this report, we employed TGF- $\beta 1$ and BMPs to examine their effects on hepatic stellate cell proliferation and trans-differentiation. Our study indicated that both TGF- $\beta 1$ and BMPs were important in the trans-differentiation of hepatic stellate cells. However, BMP-2 and BMP-4 had more potent effect on trans-differentiation of these cells than TGF- $\beta 1$ did. The difference can be due to the different signaling proteins involved in TGF- $\beta 1$ and BMPs signal transduction. It is known that Smads are the intracellular molecules for both TGF- β and BMP signal transduction pathways^[17, 29, 33]. However, Smad-2 and Smad-3 are believed to mediate TGF- β signal transduction while Smad-1, Smad-5 and Smad-8 mediate BMP signaling^[13, 16, 18, 21]. It has been demonstrated that Smad-3 is not necessary to the trans-differentiation of hepatic stellate cells but is required for TGF- $\beta 1$ mediated cell proliferation^[31]. Although TGF- $\beta 1$ had some effect on the trans-differentiation of hepatic stellate cells in this study, it might not be related to Smad-2 and Smad-3. It has been documented that TGF- $\beta 1$ can phosphorylate Smad-1 in human breast cancer cells^[22]. However, it still remained to be tested what is the mechanism mediating the transient reduction of SMA by TGF- $\beta 1$ in hepatic stellate cells. The direct TGF- $\beta 1$ regulation of SMA gene expression could not be excluded.

The inhibitory effect of TGF- $\beta 1$ on hepatic stellate cell proliferation was consistent with effect of TGF- $\beta 1$ on most mammalian cells. It inhibited the proliferation of hepatic stellate

cells. Studies relating the effect of TGF- β 1 on hepatic stellate cell proliferation from other groups have revealed some conflicting results. Most of the studies indicated that TGF- β 1 inhibited the proliferation of hepatic stellate cells^[2, 6, 25, 26, 28] while few studies had found no significant effect on these cell proliferation^[14, 20]. The difference of TGF- β 1 regulation of hepatic stellate cells may be related to stage of cell differentiation or the period of TGF- β 1 treatment. One of the interesting findings in this study is that both BMP-2 and BMP-4 did not affect the proliferation of hepatic stellate cells. It is well known that the main role of BMPs is bone morphogenesis, which is a sequential cascade with three key phases: chemotaxis and mitosis of mesenchymal cells, differentiation of the mesenchymal cells initially into cartilage, and replacement of the cartilage by bone. Its function is more related to differentiation then proliferation^[15, 30]. Therefore, no effect of BMPs on hepatic stellate cell proliferation is well consistent with their functions.

CONCLUSION

Our study documented that both TGF- β and BMPs play important roles in hepatic stellate cell proliferation and trans-differentiation. TGF- β is more important in the regulation of hepatic stellate cell proliferation while BMPs is more potent in the regulation of trans-differentiation of hepatic stellate cells. However, the *in vitro* observations of TGF- β and/or BMPs on hepatic stellate cell proliferation and trans-differentiation may represent one aspect of the complex interaction among varieties of factors in human body.

Abstract

AIM: To investigate Tie-2 expression during the repair of acetic acid-induced gastric ulcers in rats treated with recombinant human IL-11 (rhIL-11) and in untreated control animals.

METHODS: Gastric ulcers were induced in male Wistar rats by applying acetic acid to the fundus of the stomach. RhIL-11 (100 µg/kg twice daily, subcutaneously) was administered from two days before ulcer induction and continued for five days after the induction. Control rats received bovine serum albumin. Gastric specimens were collected at 3 and 5 days after the induction of ulcer for immunohistochemical observation, Western blotting, and reverse transcription polymerase chain reaction (RT-PCR).

RESULTS: Immunohistochemical and Western blot analysis demonstrated that Tie-2 expression was enhanced in the rhIL-11-treated rats compared with the control animals at both intervals.

CONCLUSION: These findings suggested that IL-11 could accelerate ulcer healing, in part, by up-regulating Tie-2 expression and promoting angiogenesis.

INTRODUCTION

IL-11 is a kind of pleiotropic cytokine that stimulates stem cell proliferation and affects multiple types of cells^[1]. RhIL-

11 may be useful in accelerating the recovery of both hematopoietic cells and gastrointestinal mucosal cells after cytotoxic therapies^[2]. RhIL-11 is in Phase II clinical trials for the treatment of thrombocytopenia that occurs secondary to chemotherapy^[3]. Gross and microscopic evidence suggested that rhIL-11 treatment could improve acute colitis caused by both chemically-induced damage and chronic inflammatory bowel disease^[4]. Bruce *et al*^[5] recently reported that short-term treatment with rhIL-11 was well tolerated in patients with active Crohn's disease. Our previous study demonstrated that rhIL-11 facilitates gastric ulcer healing in rats^[6].

Angiogenesis is critical to ulcer healing since it regulates nutrient and oxygen delivery to the injured site and, thus, controls the healing rate. Tie-2 (tek) is a member of the endothelial cell-specific receptor tyrosine kinase family^[7, 8], and is essential for the formation of the embryonic vasculature^[9]. Our recent study suggests that Tie-2 plays an important role in the angiogenesis associated with the healing of gastric ulcers^[10]. The present study examined the effect of IL-11 on Tie-2 expression in acetic acid-induced gastric ulcers by comparing with in the rhIL-11-treated and control rats.

MATERIALS AND METHODS

Materials

This study was approved by the Animal Care Committee of Nagasaki University. Male Wistar rats, purchased from Charles River Japan (Atsugi, Japan) at 7 weeks of age, were housed 3 or 4 per cage in an air-conditioned room (24 °C, 12 hr light cycle) at the Laboratory Animal Center of Nagasaki University. The animals were fed with laboratory chow (F2, Japan CLEA, Tokyo, Japan) and tap water ad libitum.

Induction of gastric ulcer

Gastric ulcers were induced by luminal application of a 40 % acetic acid solution as reported previously^[11]. Under ether anesthesia, the stomach was exposed via a midline incision and the anterior and posterior walls of the gastric fundus were clamped together with ring forceps (ID, 6 mm). The acetic acid solution was injected into the clamped portion through the forestomach using 21 gauge needles. After forty-five seconds, the acid solution was removed, the abdomen closed and the animals fed and housed as above.

Treatment

RhIL-11 (Genetics Institute, Andover, MA, USA), courtesy of Yamanouchi Pharmaceutical Co., Ltd. (Tokyo, Japan), was diluted in 0.1 % bovine serum albumin (BSA) and administered subcutaneously (100 µg/kg/twice daily) for seven consecutive days beginning two days before ulcer induction as described previously ($n=16$)^[12]. Control animals ($n=16$) received the same volume of 0.1 % BSA twice daily. Eight rhIL-11-treated and eight untreated rats were sacrificed 3 and 5 days after the induction of gastric ulcers. Gastric tissues were collected for Western blot analysis, and reverse transcription polymerase chain reaction (RT-PCR). Tissues were fixed in 4 % paraformaldehyde solution for immunohistochemical examination of Tie-2 expression.

Immunohistochemistry analysis

Paraformaldehyde-fixed and paraffin-embedded tissues were cut into 4 μ m sections, deparaffinized in xylene and rehydrated in phosphate-buffered saline. The tissues were subsequently preincubated in 3 % H_2O_2 for 30 minutes, followed by incubation in bovine serum to prevent nonspecific binding, and then incubated overnight at 4 °C (2 μ g/ml) with rabbit anti-mouse Tie-2 (C-20, Santa Cruz Biotechnology, Inc., Santa Cruz, CA). The slides were subsequently incubated in biotinylated anti-rabbit immunoglobulin G followed by avidin-horseradish peroxidase and the reaction product was resolved using DAB (Vectastain ABC kit; Vector Laboratories, Burlingame, CA).

Western blot analysis

Fresh gastric tissues obtained from ulcerated areas were immediately frozen, suspended in RIPA buffer (50 mM Tris, 150 mM NaCl, 1 % NP-40, 1 % sodium deoxycholate and 0.05 % SDS, pH 7.4), broken into pieces on ice and subjected to three freeze-thaw cycles. Insoluble cell debris was removed by centrifugation at 14 000 \times g at 0 °C for 10 minutes. The protein concentrations in the resultant supernates were quantified using a protein assay reagent (Bio-Rad Laboratories, Hercules, CA). Data from four rats were recorded at each time point and the assays were performed in duplicate. The proteins (30 μ g) were separated by polyacrylamide gel electrophoresis (PAGE) under denaturing and reducing conditions, and transferred to a Hybond ECL Nitrocellulose Membrane (Amersham Life Science, Buckinghamshire, U.K.). The membranes were rinsed in TBS, blocked with 5 % low-fat dried milk in TBS containing 0.1 % Tween 20 (TTBS), and incubated for 2 hours at room temperature in a 1:500 dilution of mouse anti-rat Tie-2 antibodies. After extensive washing with TTBS, the membranes were incubated for 1 hour in TTBS with 1:2 000 dilution of horseradish-peroxidase-conjugated goat anti-mouse immunoglobulin G containing 3 % low-fat dried milk. The membranes were washed, developed with a horseradish peroxidase chemiluminescence detection reagent (ECL Plus System, Amersham, N.D.), and exposed to Hyperfilm ECL (Amersham).

RT-PCR analysis

Total RNA was prepared from gastric tissue using the acid guanidine phenol method. RNA (1 μ g) was incubated at 37 °C for 1 hour in 50 μ l reverse transcriptase buffer containing 20 units RNasin (Promega Corp., Madison, WI), 100 pmol of random hexamer primers (Boehringer Mannheim, Germany), and 400 units Moloney murine leukemic virus reverse transcriptase (GIBCO/BRL). Reverse transcription was terminated by heating to 95 °C for 10 minutes, and 20 % of the resulting cDNA was used for PCR. PCR samples were incubated with 50 pmol of each primer and 2.5 units of Taq DNA polymerase. The rat Tie-2 PCR primers were as followings: 5' -TGTTCTGTGCCACAGGCTG-3' (sense) and 5' -CACTGTCCCATCCGGCTTCA-3' (antisense). The human β -actin PCR primers were as followings: 5' -TCCTCCCTGGAGAAGAGCTA-3' (sense) and 5' -AGTACTTGCGCTCAGGAGGA-3' (antisense). The Tie-2 and β -actin primers were predicted to amplify 317 and 313 bp DNA products, respectively. Primer pairs were chosen to span introns of their respective rat genes. Samples were subjected to 40 cycles of PCR amplification, each cycle consisting of denaturation at 95 °C for 3 minutes, annealing at 50 °C for 1 minute, and primer extension at 72 °C for 1 minute. An aliquot of each amplification mixture was subjected to electrophoresis on 2 % agarose gel, and DNA was visualized by ethidium bromide staining.

RESULTS

Immunohistochemistry results

Immunohistochemical staining of Tie-2 was weakly positive in the endothelial cells of pre-existing vessels in the gastric wall. Tie-2 expression in the endothelial cells of new capillaries was enhanced in the rhIL-11-treated rats (Figure 1A) compared with the control rats (Figure 1B) after 3 and 5 days of the induction of ulcers.

Figure 1 Three days after the induction of gastric ulcers, Tie-2 expression in the endothelial cells of new capillaries was enhanced in the rhIL-11-treated rats (A) in comparison to the untreated control animals (B).

Figure 2 Western blots demonstrating Tie-2 expression. RhIL-11 treatment increased Tie-2 expression significantly 3 and 5 days after the induction of gastric ulcers compared with untreated control rats.

Figure 3 RT-PCR analysis of Tie-2 mRNA expression in ulcerative gastric tissues, using the specific primer pairs predicted to amplify Tie-2 (317 bp) and β -actin (313 bp). Lanes 1-4: rhIL-11-treated rats on days 3 (lane 2) and 5 (lane 4) and the untreated control rats on day 3 (lane 1) and 5 (lane 3).

Western blotting results

A major band of 125 KD representing Tie-2 protein was detected in the Western blots. Tie-2 expression was increased significantly after the appearance of ulcers in the rhIL-11-treated rats compared with the untreated control animals on day 3 and day5 (Figure2).

RT-PCR results

Tie-2 mRNA was detected between rhIL-11-treated rats and the control animals after 3 and 5 days of the induction of gastric ulceration. β -actin mRNA, a constitutively expressed transcript, was detected in all of the samples from both the rhIL-11 and untreated rats (Figure3).

DISCUSSION

Angiogenesis occurs in many physiological and pathological processes, including embryonic development, wound healing, and tumor growth^[13,14]. Ulcer healing consists of two processes, epithelial regeneration and mesenchymal reconstruction. The process of mesenchymal reconstruction consists of angiogenesis, fibrosis and smooth muscle regeneration. Therefore, angiogenesis is central to the formation of granulation tissue since newly formed vessels are required to supply oxygen and nutrients to the regenerating tissue. Tie-2 is a receptor tyrosine kinase expressed by endothelial cells^[15,16] and it has been reported to play an important role in embryonic angiogenesis^[17]. Furthermore, our own recent study revealed that Tie-2 was important in the angiogenesis that occurs during the healing of gastric ulcers^[10].

Our previous study was the first to demonstrate that IL-11 could promote gastric ulcer healing in rat model^[6]. This effect of IL-11 on the repair of mucosal injury most likely reflects its trophic action on mucosal epithelial and smooth muscle cells. RhIL-11 also exhibits an anti-apoptotic effect on the gastric mucosa. RhIL-11 most likely acts on epithelial cells via the regeneration of epithelial cell facilitated by IL-11 receptor. Concomitant smooth muscle hyperplasia may induce tissue contraction, thus promoting healing. The importance of smooth muscle contraction at the base of the ulcer has been previously demonstrated^[18]. Interestingly, IL-11 inhibits the production of nitric oxide, an agent that can relax smooth muscle cells^[19].

Our immunohistochemical and Western blot data showing that rhIL-11 enhanced Tie-2 expression suggest that IL-11 accelerates healing by promoting angiogenesis. The results of this study demonstrate that rhIL-11 up-regulates Tie-2 expression during the healing of gastric ulcer in rats and suggest that rhIL-11 may have clinical benefits in the treatment of gastric ulcers.

Abstract

AIM: To investigate the changes of microvascular architecture, ultrastructure and permeability of rat jejunal villi at different ages.

METHODS: Microvascular corrosion casting, scanning electron microscopy, transmission electron microscopy and Evans blue infiltration technique were used in this study.

RESULTS: The intestinal villous plexus of adult rats consisted of arterioles, capillary network and venules. The marginal capillary extended to the base part of the villi and connected to the capillary networks of adjacent villi. In newborn rats, the villous plexus was rather simple, and capillary network was not formed. The villous plexus became cone-shaped and was closely arrayed in ablation rats. In adult rats, the villous plexus became tongue-shaped and was enlarged both in height and width. In aged rats, the villous plexus shrank in volume and became shorter and narrower. The diametral ratio of villous arteriole to villous venule increased as animals became older. The number of endothelial holes, the thickness of basal membrane and the permeability of microvasculature were increased over the entire course of development from newborn period to aged period.

CONCLUSION: The digestive and absorptive functions of the rat jejunum at different ages are highly dependent upon the state of villous microvascular architecture and permeability, and blood circulation is enhanced by collateral branches such as marginal capillary, through which blood is drained to the capillary networks of adjacent villi.

Chen YM, Zhang JS, Duan XL. Changes of microvascular architecture, ultrastructure and permeability of rat jejunal villi at different ages. *World J Gastroenterol* 2003; 9(4): 795-799 <http://www.wjgnet.com/1007-9327/9/795.htm>

INTRODUCTION

The microvasculature of intestinal villi play an important role in the process of digestion, absorption and mucosal barrier protection^[1,2]. Intestinal diseases, such as diarrhea and enteritis, are reported to be related to the change of microvasculature^[3,4].

More recent studies on the intestinal microvasculature demonstrated that the damage to surface microvasculature is an early event inducing mucosal injury in the intestine^[5-7]. However, these studies were only limited in collecting pathological or clinical data, and tissue materials were obtained from adult subjects^[8-10]. In addition, little information is available regarding the changes of microvasculature throughout different age periods. Therefore, the current work was meant to elucidate the morphological and permeability changes of jejunal microvasculature at different ages. Microvascular corrosion casting technique, scanning electron microscopy (SEM), transmission electron microscopy (TEM), Evans blue infiltration methods were used and morphometry was conducted in this study.

MATERIALS AND METHODS

Animals

Fifty-four male Sprague-Dawley rats were used. They were divided into 4 groups according to their ages after birth: (1) newborn rats (1 day, $n=9$); (2) ablation rats (3 weeks, $n=15$); (3) adult rats (3 months, $n=15$) and (4) aged rats (24 months, $n=15$). For the groups with 15 animals, six were used for corrosion casting, three were observed under TEM, the other six were used to determine the permeability with Evans blue infiltration technique. The newborn rats were too small to be used in determining the permeability. All rats were fasting for 12 hours prior to each experiment.

Microvascular corrosion casting and SEM

Methyl-methacrylate and methacrylate were mixed at a ratio of 9:1. Polymerization was allowed by adding benzoyl-methacrylate at 80 °C. The viscosity of this solution was maintained to a level corresponding to that of 30 % glycerine. The solution was cooled for later use. The microvascular architecture was then performed in the following procedure. Animals were deeply anesthetized with ether and a catheter was inserted into the thoracic aorta. One percent of saline solution (500 ml/kg i.m.) was perfused to flush the blood out of cardiovascular system, and this step was immediately followed by a perfusion of 5 ml methyl-methacrylate. Meanwhile, the same volume of the pre-prepared solution mixed with N, N-dimethylaniline (1 % of the total volume) was added, serving as a polymerization accelerator. twelve hours later when polymerization was completed, the small intestine was sampled and stored in a 10 % NaOH solution for 1-2 weeks. The tissue was rinsed with tap water until the corroded tissue was washed out, and then trimmed under the dissection microscope and dried at 40 °C for 48 hours. The dried tissue was then coated using an IB-3 ionic splashing and shooting device. Photomicrographs were taken under a Hitachi S-570 scanning electron microscope.

TEM

Small pieces of the jejunum were immersed in phosphate-buffered 3 % glutaraldehyde for 2 hours, and then postfixed in phosphate-buffered 1 % OsO₄ for 2 hours. After postfixation, the tissue was dehydrated with ethanol and embedded in Epon

812. Ultra-thin sections stained with uranyl acetate and lead citrate were observed and photomicrographs were taken under a Hitachi TEM S-600.

Quantification of microvascular permeability of the jejunal tissue

Evans blue was used to measure the permeability of microvasculature. Rats were anesthetized with ether, and Evans blue (75 mg/kg i.m.) in 0.9 % saline solution was injected into a femoral vein. Two hours later, rats were perfused transcardially with 0.9 % saline solution (500 ml/kg i.m.). Evans blue was extracted from the jejunum by incubation in 5 ml of formamide at 54 °C for 24 hours. Evans blue was then quantified by measuring its absorption at wavelength of 620 nm using spectrometer. Results were expressed as µg Evans blue/gram fresh tissue.

Data processing

According to the methods of stereology^[11], the measurement and calculation of the thickness of basal membrane (nm), the number of endothelial hole (per mm capillary perimeter) and plasmalemmal vesicles (per mm² endothelium) were conducted on the photographs of TEM. Results were expressed as mean ± SEM, and statistics was performed using Student's *t* test.

RESULTS

Microvascular architecture of adult rats villi

The villous plexi stood on the surface of the ileum. Between the adjacent villous plexi there were numerous different cryptal plexi. The villous plexus consisted of villous arteriole, villous capillary network and the villous venule. The villous capillaries connected to each other in a form of "net-basket" (Figure 1). The villous arteriole coming from the arterial plexus in the submucosa reached the base of the villi through the cryptal plexus gap, extending to the tip along the axis of the villi. The villous arterioles did not bifurcate within the villi, but formed the villous capillary network at the tips of the villi in the pattern of a "netted bag". This villous capillary wrapped the villous arteriole. The villous venules were formed in the middle and upper part of the villi, through which the blood from capillary venules converged into the venous plexus in the submucosa (Figure 1).

In addition, there was a straight capillary along the margin of the villous capillary network, and it is called marginal capillary. Its diameter was twice that of its adjacent capillaries (Figures 1 and 2). This capillary ran along the villous margin and did not merge into the villous venules of itself. It reached the base of the villi and connected to the basal part of its adjacent villous capillary networks (Figure 2).

Changes of microvascular architecture of jejunal villi at different ages

In newborn rats, the villous plexus was rather simple and was composed of only one or two loops of capillary vessels. A capillary network was not formed at this age and villous arteriole and venule could not be differentiated (Figure 3). For the ablactation rats, the villous plexus became cone-shaped and was closely arrayed. The marginal capillary was as wide as villous arteriole. Each villous plexus had only one villous venule and was formed in the basal part of the villi. However, the diametral ratio of villous arteriole to it was very small (Figure 4). In adult rats, the villous plexus became tongue-shaped and was enlarged both in height and width. Each villous plexus usually had one villous venule which was formed in the middle and upper part of the villi, but the wide villi had two venules that were zygomorphous (Figure 1). In the aged rats, the villous plexus shrank in volume and became shorter and narrower. The capillaries were irregularly arrayed (Figure 5). The villous arteriole became wider and lower than villous venule (Figure 6). The diametral ratio of villous arteriole to venule was increased as animals became older (Table 1).

Changes of endothelial ultrastructure of villous capillary at different ages

Under TEM, the endothelium of capillary in the vicinity of epithelium of villi was so polarized that the nucleus was far away from epithelium and the side near the epithelium was thin. In the endothelium of newborn rats, bigger nucleus, more cytoplasm as well as several plasmalemmal vesicles were seen, but no endothelial hole and basal membrane were observed. However, endothelial hole and basal membrane were found in ablactation animals (Figure 7). For the adult rats, a plenty of plasmalemmal vesicles were noticed in the endothelium (Figure 8). The endothelium in the aged rats, however, became thinner whereas its basal membrane became thicker. Endothelial holes were found to be increased whereas plasmalemmal vesicles were decreased (Figure 9). The number of endothelial holes, the thickness of basal membrane and the permeability of microvasculature were increased over the entire course of development from newborn period to aged period (Table 2).

Changes of microvascular permeability of villi at different ages

The microvascular permeability at different ages was determined with Evans Blue infiltration technique. The amount of Evans blue that penetrated into intestinal tissue was 28.1 µg/g tissue in ablactation rats and 64.4 µg/g tissue in adult rats. The microvascular permeability of the aged rats was twice as high as that of the adult rats (Table 2).

Table 1 Comparison of the microvascular architecture of villi at different ages (mean±SEM)

	Ablactation rats	Adult rats	Aged rats
Diameter of arteriole (µm)	6.17±1.51	10.47±2.25 ^a	16.73±3.28 ^c
Diameter of venule (µm)	20.43±3.17	25.45±3.07 ^b	25.50±3.34
Ratio: arteriole/venule	0.30±0.04	0.41±0.04 ^a	0.65±0.06 ^c

^a*P*<0.01, ^b*P*<0.05 vs ablactation rats; ^c*P*<0.01 vs adult rats.

Table 2 Comparison of the endothelial ultrastructure of villi at different ages (mean±SEM)

	Newborn	Ablactation	Adult	Aged rats
Endothelial holes (number/µm)		3.01±0.38	3.51±0.35 ^b	5.19±0.48 ^d
Plasmalemmal vesicles (number/0.1 µm ²)	17.7±4.25	39.1±10.36 ^a	75.3±12.13 ^c	38.0±11.14 ^d
Basal membrane (nm)		25.2±5.26	43.5±5.86 ^c	60.5±6.89 ^d
Vascular permeability (µg/g)		28.1±4.64	64.4±9.34 ^c	116.4±15.63 ^d

DISCUSSION

Injection of certain materials into blood vessels enables three dimensional visualization of vascular architecture and has provided abundant information which is not available by reconstruction of serial sections^[12-14]. A line of evidence demonstrated in rats, horses and human embryos, that the "fountain type" microvascular architecture of mammalian small

intestine is common^[15-17]. Among these studies, Ohashi *et al*^[16] found that two or more villous venules originating in the base of villi. The results of our study appear to suggest that the villous venules of the rat small intestine are formed in the middle and upper part of the villi, not in the base and at the tip. The villous venules are shorter than villous arterioles, and do not form arterio-venous anastomoses. There is big difference

in diameter between villous venules and villous arteries. The former is about one third of that of the latter. All of these properties are important in creating a low blood pressure and speedy circulatory system in the villous capillary network, which is important to the process of nutritional absorption and transportation^[18].

We found that branching did not take place when the villous arterioles climbed towards the tip of the villous and the capillary networks were not formed until the villous arteria reached the tip of the villous. After entering the villi, blood was supplied to the tip portion of villi and partially to its surrounding area. The cryptal plexus mainly supplied the blood to the basal part of the villi, which lacked artery terminals and branches. Therefore, this collateral circulation can provide blood supplies to the villi. Although there was supplementary blood supply in the base of the villi, blood supply was inefficient due to a long distance of transportation from the branching point at the tips of villi which were full of arterial blood^[19]. Therefore, the villi at the tip received much more arterial blood supply than in the base. From the base to the tip of the villi, the absorption rate of epithelium increased proportionately with the volume of its blood supply. However, there were still aging cells at the tip of villous that were less dynamic physiologically than the younger cells at the basal part. The cells of villi at the tip might not be able to adapt themselves very well to any abnormal blood circulation, and therefore would easily lose their normal physiology under certain harsh conditions^[20]. Injuries due to hypoxia usually emerged later in both intestinal crypts and basal part of villi than in the apical area of villi^[21]. This may indicate that the crypts, as compared with villi, are relatively more resistant to hypoxic injuries. Such resistance is important in maintaining the optimal endocrine function and the regenerative capability of mucosa even after shock resulting from excessive blood loss.

Our results also showed that there were marginal capillaries on both sides of the small intestinal villi. These capillaries descended from the apical part of the villi to the basal part along its margin. It crossed the cryptal plexus and connected to the capillary network. So far, there have been no report regarding this connection. Before this study, it had been considered that there was only one venous return path from the small intestinal capillary. In other words, blood from capillary venules converged into the venous plexus in the submucosa^[16,17,22]. Studies on marginal capillary have been developed since Mohiuddin^[19] described the marginal capillary. It was reported recently that marginal capillary was more manifest in jejunum than in ileum^[23,24], but its relationship with its adjacent villous plexus was not found in both jejunum and ileum. It is thus considered that the marginal capillary transports blood to the villous margin. Therefore, the findings from the this study regarding the marginal capillary and its relation with its adjacent villi suggest that the collateral circulation may exist before the venous return from the villi. That is, the marginal capillary delivers blood partially into the adjacent villous capillary networks. This architecture of the villous plexus may have been adapted to the movement of intestines as well as to the digestive and absorptive activities. After eating, the small intestine speeds up its motility. Villi not only have tight contacts with the chyme but also are subjected to mechanical pressure from the passing chyme. If the villous venules are depressed, blood return to the villi will be blocked. Therefore, blood can be collected into the adjacent villous plexi through the marginal capillary. This helps maintain a normal blood circulation in the villi, and their digestive and absorptive functions are carried out normally.

In the newborn rat villi, capillary network was not formed although only simple microvascular architecture was formed. The later developed capillary network is probably due to the

formation of slender transcapillary tissue pillars, which give rise to new vascular meshes^[25,26]. During villous formation, the developing vascular nets played an important role and the apical capillary loop in a villous was anchored to epithelial basal membrane or to the adjoining matrixes^[27]. After 3 weeks, the villous microvascular architecture tended to grow in full scale. During ablation period, the villous capillary network was formed, and the diametral ratio of villous arteriole to villous venule was one-third, which consolidated the normal digestion and absorption. The villous plexus in adult rats became higher and wider, providing more nutrition for the body. In aged rats, the tip of the villous plexus caved in, the position of villous venule was relatively high. The increases in diametral ratio of villous arteriole to villous venule caused high blood pressure, which degraded the transportation and absorption of nutrition. All of these demonstrate the important role of the vascular architecture in maintaining an efficient absorption of nutrition for the malfunctioned intestines in the aged animals.

The primary penetrating vessels in the submucosa formed an extensive submucosal plexus that supplied the tunica serosa, tunica muscularis, and tunica mucosa^[28]. Fewer branches of this plexus supply the muscle layers, and most of branches run towards the mucosa and to supply blood to the villous and the cryptal plexus^[29]. Therefore the vascular permeability mainly depends on the villous plexus, namely vascular architecture and endothelial structure. Under normal physiological condition, small molecules can easily enter or come out of blood vessels, but the large size substances must be transported through endothelial hole or plasmalemmal vesicle^[30]. Since there were no endothelial holes and very few plasmalemmal vesicles in newborn rats, these large size substances must be selected to pass through the endothelium, which may be a protection for the immature immune system. The emergence of a few of endothelial holes and plasmalemmal vesicles during ablation period indicate that the big molecular substances can be transported. The endothelium of adult rats have a plenty of plasmalemmal vesicles, and microvascular permeability was twice as high as that of the ablation rats. In the aged rats, the endothelium became thinner, and the number of plasmalemmal vesicles became smaller while the number of endothelial holes became bigger. The diametral ratio of villous arteriole to villous venule increased as animals become older. The blood pressure was higher in old rat villi. The larger number of endothelial holes and higher blood pressure resulted in double increase in the microvascular permeability of the aged rats as compared with the adult rats. The thickened basal membrane may be due to a compensatory response, which may prevent any injurants from entering the blood vessels in the aged rats. Based upon the above information, one can say that aging or degradation of blood vessels may underlie the mechanisms of systematic aging.

In summary, the microvascular architectures of rat intestinal villi are complex. Each villi has its own blood supply and venous return paths. Furthermore, one villi can supply blood to its adjacent villi through the marginal capillary. These complex connections in the villi help avoid a shortage of blood supply or blockade of venous blood return. Normal digestive and absorptive functions are thus protected. With regard to the small intestine of other species, whether there is a marginal capillary and venous return collateral circulation is a matter of future study.

Abstract

AIM: To study the detail mechanism of interaction between PKC and GRK₂ and the effect of GRK₂ on activity of PKC.

METHODS: The cDNA of pleckstrin homology (PH) domain located in GRK₂ residue 548 to 660 was amplified by PCR with the mRNA of human GRK₂ (β1-adrenergic receptor kinase) as template isolated from human fresh placenta, the expression vector pGEX-PH inserted with the above cDNA sequence for GRK₂ PH domain protein and the expression vectors for GST (glutathion-s-transferase) -GRK₂ PH domain fusion protein, BTK (Bruton's tyrosine kinase) PH domain and GST protein were constructed. The expression of GRK₂ in culture mammalian cells (6 cell lines: PC-3, MDCK, SGC7901, Jurkat cell etc.) was determined by SDS-PAGE and Co-immunoprecipitation. The binding of GRK₂ PH domain, GST-GRK₂ PH domain fusion protein and BTK PH domain to PKC *in Vitro* were detected by SDS-PAGE and Western blot, upon prolonged stimulation of epinephrine, the binding of GRK₂ to PKC was also detected by western blot and Co-immunoprecipitation.

RESULTS: The binding of GRK₂ PH domain to PKC *in Vitro* was confirmed by western blot, as were the binding upon prolonged stimulation of epinephrine and the binding of BTK PH domain to PKC. In the present study, GRK₂ PH domain was associated with PKC and down-regulated PKC activity, but Btk PH domain up-regulated PKC activity as compared with GRK₂ PH domain.

CONCLUSION: GRK₂ can bind with PKC and down-regulated PKC activity.

INTRODUCTION

G protein-coupled receptor kinase-2 (GRK), also known as β1-adrenergic receptor kinase (β-ARK1), plays an important role in agonist-induced desensitization of the β-adrenergic

receptors. Activation of protein kinase C (PKC) is able to stimulate phosphorylation and activation of GRKs and induce desensitization of G protein-coupled receptor. However, the detail mechanism of interaction between PKC and GRK₂ and the effect of GRK₂ on activity of PKC remain unknown. Pleckstrin homology (PH) domain is a kind of functional domain containing 120 amino acids, which exist on many protein molecules that involved in cellular signal transduction. A PH domain located in GRK₂ residue 548 to 660 may play a significant role in mediating interaction between PKC and GRK₂. In the present study, we showed that PKC could associate with PH domain of GRK₂ in pull-down assay *in vitro*. Co-immunoprecipitation displayed binding of PKC to GRK₂ in intact Jurkat cells after prolonged stimulation of epinephrine. Assay of PKCβ1 kinase activity indicated that the binding of the PH domain of GRK₂ to PKCβ1 could down-regulate the activity of PKCβ1 kinase. Thus, GRK₂ may play a negative feedback regulatory role on PKCβ1 activity in interaction between GRK₂ and PKCβ1.

G protein-coupled receptor kinase-2 is a member of the GRK family existing of at least 6 GRKs^[1]. GRKs are implicated in agonist-induced phosphorylation and homologous desensitization of G protein-coupled receptor (GPR). Phosphorylation sites of the GPR by GRK are located in the carboxyl tail of the receptor and involved amino acid residues at positions serine 404 408, and 410^[2]. These phosphorylation sites are thought to initiate desensitization of GPR.

It has been recently reported that protein kinase C (PKC) could phosphorylate and activate GRK which sequentially mediated desensitization of GPR^[3]. In addition, PKC could directly phosphorylate GPR and initiate desensitization of the receptors^[4]. Thus, PKC likely participates in phosphorylation and homologous desensitization of adrenergic receptor at multiple levels. Furthermore, both activated GRK and PKC are recruited to the specific membrane and GRK may localize on the membrane via its PH domain binding to phosphatidylinositol phosphates. Both recruitment to membrane will facilitate the association of PKC with GRK. Deletion or mutation of the PH domain will abolish GRK faculty of phosphorylating and activating GPR^[5]. PH domain of GRK plays a pivotal role in mediating the phosphorylation and desensitization of the receptors. However, as to detail mechanism of PKC, how to interact with and activate GRK remains unclear.

PH domain has been distinguished from more than 100 molecules that are implicated in signaling and other biological function. The main function of PH domains is to mediate protein-phospholipid and protein-protein interaction. Up to now, several molecules such as phosphatidylinositol phosphates, Gβγ, RACK1, PKC, Gα subunit-12 and F-actin have been identified as ligands of PH domains. It was reported by Yao *et al* (1994)^[6] that the PH domain of Btk and Itk interacted with protein kinase C. Afterwards, the interactions between PKC and other PH domains of the molecules were also confirmed by different groups. Those PH domains that bind to PKC share a high homology in 1st-4th β strands^[7] which forms a relatively reserved face binding to PKC. But other PH domains that can interact with PKC remain to be identified.

PKC is a family of serine/threonine protein kinase, which plays significant roles in numerous cellular responses (including cell proliferation, differentiation, growth control, tumor progression, apoptosis etc.)^[8]. Besides the event of PKC phosphorylating GRK₂ discussed above, PKC can phosphorylate GRK₅ and modulate the activity of GRK₅^[9]; PKC can also lead to olfactory signal termination and desensitization^[17] via other GRK₂; Agonist stimulation results in oxytocin receptor interaction with GRK and PKC^[10]. Moreover, PKC presents a manner of phosphorylating directly to muscarinic receptor and leading to the desensitization receptor^[11].

Like most interaction between signaling molecules, PKC is likely associated with GRK₂ before phosphorylating and activating GRK₂. To elucidate detail mechanism of interaction between GRK₂ and PKC, we reported the study on interaction between PKC and GRK₂. It is expected that present study will provide new insights into understanding of the modulation mechanism of PKC in GRK₂ mediating signaling pathway. It is also expected that the present investigation can illustrate the importance of the GRK₂ PH domain in interaction with PKC.

MATERIALS AND METHODS

Materials

Anti-GRK₂, anti-PKC β 1 and secondary antibodies conjugated with horseradish peroxidase were purchased from Santa Cruz Biotechnology. **PKC assay kit (Sigma TECTTM PKC assay system) and reverse transcription kit** were from Promega. **Glutathione-agarose beads** was from Sigma. **Expression vector pGEX-4T-1 and ECL detection kit** (for western blotting) were from Amersham Pharmacia Biotech. **PVDF membrane** was from Millipore. **Rabbit IgG** was from Sino-American company (China). **Protein A-agarose** was from Pierce Inc.

Methods

Construction of expression vector pGEX-PH The mRNA of human GRK₂ (β 1-adrenergic receptor kinase) was isolated from fresh human placenta^[12], and reverse transcription was performed according to the kit protocol. cDNA of PH domain (residue 548 to 660)^[13] was amplified by PCR with oligonucleotides containing BamHI sites (forward, CGGGATCCGGCCACGAGGAAGACTAC) and EcoRI sites (reverse, GGAATTCTCACCGCTGCACCAGCTGCTG). The products were purified from agarose gel and the resulting fragments were digested with Bam HI and EcoRI, respectively. The resulting fragments were ligated in frame between Bam HI and EcoRI sites of plasmid pUC-19. The resulting plasmid (termed pUC-PH) was resolved by sequencing. The fragments were excised from pUC-PH and ligated in frame into expression vector pGEX-4T-1, named pGEX-PH.

Expression and purification of GST fusion protein GST-GRK₂ PH domain, Btk PH domain and GST were expressed in *Escherichia coli* strain DH5 α . Here was Btk PH domain positive control^[6]. The expression was induced with 0.2 mM of IPTG at 26 °C for 1 hour in LB medium containing 1 % glucose. Briefly, the bacteria were resuspended in ice-cold STE buffer (10 mM Tris-HCl, 150 mM NaCl, 1.0 mM EDTA, 1.0 mM phenylmethylsulfonyl fluoride and 0.1 mg/ml lysozyme, pH 8.0) on ice for 20 min. The treated bacteria were added dithiothreitol to 5.0 mM and sarkosyl to 1.5 % on ice until the solution became viscous, and then lysed by sonicate (30-40 output, 1 min \times 2, at 4 °C). Cell lysate was centrifuged at 10 000 \times g for 20 min at 4 °C. Component of both supernatant and the pellet was separated by SDS-PAGE to determine the distribution of the fusion protein. The supernatant was added Triton X-100 to 2 %, and then filtered with 0.45 mm membrane. The solution was saved as the fraction containing interested

proteins, and then the treated glutathione-agarose beads were added to solution at 4 °C for 2 hours with occasional gentle mixing. The beads were washed with PBS and centrifuged at 800 \times g, 4 °C for 3 min \times 5 times. The pellet was subjected to SDS-PAGE in 12 % gels. In order to utilize 1 equivalent amount of GST and fusion proteins for the following assay, the protein concentration was modulated according to band sizes in SDS-GAGE gel.

Determination of GRK2 expression in mammalian cell lines MDCK, SGC7901, DU145, PC-3, U937 and Jurkat cells were maintained in Dulbecco's modified eagle's medium or 1640 medium with 10 % (v/v) new born bovine serum and a 5 % CO₂ humidified atmosphere at 37 °C. In brief, the 10⁷ cells were harvested by centrifuging or scraping off, respectively, washed by PBS at 4 °C and then incubated with 1 ml of lysis buffer (20 mM Tris-HCl, pH 7.5, 10 mM KCl, 1 mM EDTA, 0.5 mM phenylmethylsulfonyl fluoride, 10 μ g/ml leupeptin and 1 μ g/ml aprotinin) on ice for 20 min with casually and vigorously vortexing. The mixtures were centrifuged at 12 000 \times g for 10 min at 4 °C. The supernatants were saved as GRK₂-contained or PKC-contained preparations for western blot.

Cell culture and lysis Jurkat T lymphocytes were maintained as above with RPMI 1640 medium. The 2 \times 10⁷ cells were divided into 2 parts and were serum-freed for 8 h. followed by 0.5 h treatment without (Control) or with epinephrine. The stimulation was stopped by removal of the medium and adding 3 ml of ice-cold phosphate-buffered saline, which was also used for two similar washing steps with centrifugation at 500 \times g for 5 min.

Protein-protein interaction assay Approximately 20 μ g of the GST and GST fusion proteins immobilized on glutathione-agarose beads was incubated with the 0.3 ml of Jurkat T lymphocyte supernatant at room temperature for 2 hours with gentle mixing. The beads were then washed five times with 1 ml of ice-cold PBST (PBS with 0.05 % tween-20). The eventual bead pellet was resolved by SDS-PAGE. Equivalent amount of the fusion protein or GST alone was used for the following assay.

Western blot-the resolved proteins were electrotransferred onto PVDF membrane. The membrane was blocked by incubating with 5 % gelatin in PBST at 37 °C for 1 h with gentle vibration, and then incubated with 1 μ g of anti-PKC β 1 antibody at 4 °C overnight. The membrane was then washed 5 times with PBST and incubated with horseradish peroxidase-conjugated anti-rabbit secondary antibody at room temperature for 1 h with gentle vibration. The membrane was finally washed 6 times with PBST to remove unbound secondary antibody and visualized by using ECL (Amersham Pharmacia Biotech).

Co-immunoprecipitation assays 10⁷ Jurkat cells were lysed in 1 ml of lysis buffer (20 mM sodium phosphate, pH 7.5, 500 mM NaCl, 0.1 % SDS, 1 % NP-40, 0.5 % sodium deoxycholate, 0.02 % sodium azide, 0.5 mM phenylmethylsulfonyl fluoride, 2 μ g/ml leupeptin and 2 μ g/ml aprotinin). Briefly, 10 μ g of anti-PKC β 1, or anti-GRK₂ antibodies and rabbit IgG were added to 200 μ l of the lysate, respectively, then the samples were incubated overnight at 4 °C. The products were added 40 ml of immobilized protein A (Pierce Inc) and incubated at room temperature for 2 h with gentle mixing. The products were added 0.5 ml lysis buffer (without protease inhibitor) and centrifuged at 500 \times g, 4 °C for 3 min. The supernatant was discarded and this procedure was repeated for 6 times. In brief, the pellets were subjected to SDS-PAGE. The proteins were electrotransferred onto PVDF membranes. The membranes were blocked with gelatin and incubated with anti-PKC β 1 or anti-GRK₂ antibodies, respectively. The membranes were probed and visualized as described above.

PKC kinase assay The fusion proteins and GST were purified as described above, and washed extensively with PBST. After washing, the GST-fusion proteins and GST were eluted with

20 mM of reduced glutathione in 50 mM Tris·HCl (pH 8.0). The eluted proteins were concentrated using a Centricon (Millipore). Protein concentrations were determined with Bradford reagent (Bio-Rad). Equivalent amounts of the protein were added to the 100 μ l lysate of Jurkat cells. According to manufacturer's instruction (Sigma TECTTM PKC assay system), the activity of PKC in the lysate was determined by subtracting the radioactivity of the reaction with control buffer and 100 μ M PKC peptide inhibitor from that of the reaction without activated buffer nor the PKC inhibitor. The experiment was performed in triplicate samples for each groups. The data were presented as percentage of PKC activity and the control was used as 100 %.

RESULTS

Binding of GRK₂ PH domain to PKC *in vitro*

To search for potential binding between the expressed proteins (GST-GRK₂ PH domain, GST-Btk PH domain and GST) and PKC β 1, the proteins immobilized on glutathione-agarose beads were added to lysate of Jurkat cells, and then the products were subjected to SDS-PAGE and Western blot. The potential PKC β 1 was probed with anti-PKC β 1 antibody. As shown in Figure 1, the GST fusion proteins encompassing GRK₂ PH domain and GST-Btk PH domain associated specifically with PKC β 1 because the GST did not pull out PKC β 1 under the same experimental conditions. Binding of Btk PH domain to PKC β 1 was formerly approved. We confirmed the binding of GRK₂ PH domain to PKC β 1 which was specific *in vitro*.

Figure 1 The binding of PH domain to PKC by Western blot with the antibody to PKC. Lane 1, 2, 3, 4 and 5 were the GST-PH domains of IRS-1, GRF/c, β -ARK1, PLC γ /n and Btk, respectively; lane 6 was the GST; lane 7 was lysate of Jurkat cells.

Determination of expression of GRK₂ in cultured mammalian cells

In order to detect the association of GRK₂ with PKC *in vivo*, GRK₂ expression of 6 cell lines were confirmed by western blot in advance. The same amount of the protein was utilized in SDS-PAGE. The results indicated GRK₂ were expressed in PC-3, MDCK, 7901 and Jurkat cell lines. The GRK₂-antibody could react with GRK₂ in MDCK and 7901 cell lines, and the antibody could specifically recognize GRK₂ in Jurkat cells. Thus, the following Co-immunoprecipitation assays was performed in Jurkat cells.

Figure 2 The expressing of GRK₂ by Western blot with the antibody to GRK₂. Lane 1, 2, 3, 4 were the results of Western blot in PC-3, MDCK, 7901 and Jurkat cell line respectively. Lane 5, 6 was GST.

Binding of GRK₂ to PKC upon prolonged stimulation of epinephrine

Phosphorylation and activation of GRK by PKC enhance desensitization of G protein-coupled receptor. In the pull-down assay, our result indicated that the PH domain of GRK₂ was associated specifically with PKC *in vitro*. To determine the

association of PKC with GRK₂ *in vivo* after stimulation of the agonist of β -ARK, 100 μ M epinephrine was added to the cells in 1640 medium for 30 min. Co-immunoprecipitation was performed with specific anti-GRK₂ and anti-PKC antibodies in co-precipitation and detection of PKC and GRK. After stimulation of 100 μ M epinephrine for 30 min, PKC was detected out in the precipitate of GRK antibody and GRK was detected out in precipitate of PKC antibody, respectively. In contrast, the PKC did not bind to GRK₂ in the intact cells without stimulation of epinephrine. Thus, the results indicated that the association of PKC with GRK₂ was involved in GRK₂ activation and desensitization of G protein-coupled receptor.

Figure 3 After stimulation of epinephrine, Co-immunoprecipitation was performed with anti-GRK₂ and anti-PKC in co-precipitation and detection of PKC and GRK₂. Lane 1 was PKC detected in precipitate of GRK antibody, lane 2 was GRK₂ detected in precipitate of PKC antibody. Lane 3 indicated the PKC did not bind to GRK₂ in the intact cells without stimulation of epinephrine, lane 4 was the lysate of Jurkat cell.

Effects of GRK₂ and Btk PH domains on PKC activity

Effects of proteins on PKC activity were determined as described under the experimental Procedures. After purification as described above, the expressed proteins were eluted and dialysed in PBS. Equivalent amounts (20 μ g) of GST-GRK₂ PH domain, GST-Btk PH domain and GST were added to the lysate of Jurkat cell lysate (100 μ l) in determining PKC activity. When Btk associated with PKC, Btk activity was down-regulated by PKC and PKC activity was up-regulated by Btk PH domain. In the present study, GRK₂ PH domain was associated with PKC and down-regulated PKC activity but Btk PH domain up-regulated PKC activity as compared with GST and untreated cells.

Figure 4 Effects of the PH domain on PKC activity measured by protein kinase C Assay System. The volume was percentage of PKC activity. The data were representation of two experiments. Lanes 1, 2, 3, 4 and 5 were GST-PH domain of IRS-1, GRF/c, β -ARK1, PLC γ /n and Btk, respectively; lane 6 was the GST; lane 7 was lysate of Jurkat cells.

DISCUSSION

The GRK family is composed of six members, namely GRK 1-6. Of these, GRK₂ phosphorylates G protein-coupled receptors (GPCRs) and plays an important role in mediating homologous desensitization of GPCRs. Chuang's work showed the activity of GRK₂ was increased^[14] in a protein kinase C (PKC)-dependent manner. Further study demonstrated that PKC could directly phosphorylate GRK. This study suggested that GRK could be

activated via phosphorylation of PKC. Recent work had led to the identification of phosphorylation site at GRK₂, the study of Krasel and co-worker showed that PKC phosphorylated GRK₂ at serine 29^[15], but the detail mechanism of PKC β 1 recognizing and binding to GRK₂ remains unknown. In present study, we reported that GRK₂ could bind to PKC via its carboxyl-terminal PH domain *in vitro*, which was a fundamental event in mediating interaction between PKC and GRK₂. The present result suggested the GRK ph domain had an analogous fashion to PH domain of Btk and Itk, which could interact with protein kinase C^[6] in our previous study. The PH domain of GRK₂ is probably involved in directly binding of GRK₂ to PKC and facilitates phosphorylation and activation of GRK₂ by PKC.

Stimulation of agonist (epinephrine) on adrenergic receptor results in association of PKC β 1 with GRK₂ in Jurkat cells. GRK₂ could through its PH domain can directly bind to PKC and then be phosphorylated by PKC. But in intact cells (without stimulation of epinephrine), PKC and GRK₂ are in dissociated state. The epinephrine stimulation on adrenergic receptor may activate phospholipase C (PLC), and initiates a cascade of events. The stimulation causes PLC-mediated hydrolysis of inositol phospholipids, and results in calcium mobilization and production of second messenger diacylglycerol (DAG). The DAG and Ca⁺⁺ are activators of PKC, and cause activation of PKC^[16]. In the present study, activated PKC is likely to bind to and phosphorylate GRK₂ directly, which phosphorylates G-protein coupled receptor and results in receptor desensitization. In this signaling pathway, activation of PKC appears to be prior to receptor desensitization and is of fundamental importance in regulating the receptor desensitization.

Those PH domains from Btk, β -spectrin, dynamin and amino-terminal of AFAP-110 known directly binding to PKC share a high homology at first three β -sheets^[7]. These β -sheets form conserved structure elements and may specifically bind to PKC. Table 1 showed the residue comparison of PH domains from GRK₂ and GRK₃ with these PH domains. The PH domain of GRK₂ and GRK₃ matches that consensus well. This may form a structured base of PH domains binding to PKC.

Table 1 First three β sheets of PH domains of GRK₂ and GRK₃ are compared with other PH domain known or predicted to bind to PKC

PH domain (source)	β 1	β 2	β 3

GRK ₃	MHGMYLKL--GNPFLTQ----WQRRYFYLF--PN--RLEWRGEGES		

Consensus sequence is shown and symbols used are as in the paper of Baisden *et al.* 1 indicates aromatic residues, + indicates positively charged residues, * indicates hydrophobic residues, indicates polar residues. The sequences of GRK₂ and GRK₃ from Zheng *et al.*^[18].

The previous study revealed PKC inhibited the activity of Btk kinase via binding to Btk PH domain^[6], but the binding effect on PKC activity remains unclear. In the present study, the effects on PKC activity of Btk and GRK₂ PH domains were determined with GST. Compared with GST or control, Btk PH domain could increase PKC kinase activity, but GRK₂ PH domain inhibited PKC kinase activity. The mechanism of activation or inhibition of PKC activity might lie in the PH

domains binding to PKC regulatory domain and regulating activity of PKC kinase. Biological function of Btk PH domain inhibiting PKC activity will be laid in future investigation. The present study indicated that PKC through its binding to the PH domain of GRK and facilitates phosphorylation and activation of GRK by PKC when stimulated by epinephrine. On the other hand, GRK₂ PH domain appeared to play a negative feedback regulatory role on PKC activity. GRK₂ immediately turns off PKC kinase activity on GRK after PKC completed phosphorylation and activation of GRK.

Abstract

AIM: To propose a simple and effective method suitable for analyzing the angle and distribution of 2-dimensional collagen fiber in larger sample of small intestine and to investigate the relationship between the angles of collagen fiber and the pressure it undergoes.

METHODS: A kind of 2-dimensional visible quantitative analyzing technique was described. Digital image-processing method was utilized to determine the angle of collagen fiber in parenchyma according to the changes of area analyzed and further to investigate quantitatively the distribution of collagen fiber. A series of intestinal slice's images preprocessed by polarized light were obtained with electron microscope, and they were processed to unify each pixel. The approximate angles between collagen fibers were obtained via analyzing the images and their corresponding polarized light. The relationship between the angles of collagen fiber and the pressure it undergoes were statistically summarized.

RESULTS: The angle of collagen fiber in intestinal tissue was obtained with the quantitative analyzing method of calculating the ratio of different pixels. For the same slice, with polarized light angle's variation, the corresponding ratio of different pixels was also changed; for slices under different pressures, the biggest ratio of collagen fiber area was changed either.

CONCLUSION: This study suggests that the application of stress on the intestinal tissue will change the angle and content of collagen fiber. The method of calculating ratios of different pixel values to estimate collagen fiber angle was practical and reliable. The quantitative analysis used in the present study allows a larger area of soft tissue to be analyzed with relatively low cost and simple equipment.

INTRODUCTION

Several G.I. diseases can change the collagen fiber structure in the G.I. tract^[1-4]. The collagen fiber content and its distribution outside the cell are closely related to some diseases. For example, systemic sclerosis (scleroderma) will replace smooth muscle and deposit large amounts of collagen instead. Gastrointestinal scleroderma is a common clinical disorder; however, due to its complicated etiology, most of them are not easily diagnosed and all the patients with such disease manifested distinct collagen fiber transformations. Early collagen fiber transformations are swelling and homogenization and then become thickened, sclerosed and arranged in a close order^[5-9]. Collagen synthesis is increased especially the ratio of fine collagen fibers; at the same time, the smooth muscle fiber bundles become homogeneous, sclerosed and atrophic. There are changes occurred in the orientation of collagen fibers^[10-13]. Obstructive diseases could also change the collagen structure and content^[14-16]. In normal tissue the submucosal layer consist almost entirely of collagen, which is called the skeleton of the small intestine, and it is well known that the fibers run in a cross-cross pattern with 30 degrees angle in longitudinal direction^[17-20]. The directional distribution of collagen fibers has a very important role in studying the function and self-repair of soft tissue^[21].

The application of digital image-processing technology in medicine field has offered an accurate, simple, convenient and rapid method for the measurement and analysis of large amounts of medical images, especially for the quantitative analysis of smaller pictures, such as microscopic images. At the present time, the techniques for the quantitatively analyzing the distribution of collagen fibers consist mainly of several kinds as follows: that is, the method of quantitatively polarized light microscopy, small angle beam dispersion, image analysis and X-ray diffraction. These methods will sometimes be constrained by the image size, time cost or image connecting, and 90° orientation of template etc^[23].

The purpose of this paper is to propose a method suitable for analyzing the angle and distribution of 2-dimensional collagen fiber in larger sample and to investigate the relationship between the angles of collagen fiber and the pressure it undergoes. At the same time, this paper also offers an effective method for research of the large area collagen fiber distribution.

MATERIALS AND METHODS

Isolation of small intestine

Seven Sprague-Dawley (250-300 g body wt) rats were used in this study. They were fasted but free access to water for 24 hours before experiment. Approval of the protocol was obtained from the Danish Animal Experiment Committee. After animal was euthanized by cervical dislocation, its abdomen was opened and the small intestine was separated from the adjacent organs. An 18-cm-long segment from the middle part of small intestine was cut and excised within 2 min, then transferred to an organ bath containing oxygenated Krebs-Ringer-bicarbonate solution at pH 7.4 with 6 % Dextran and 2 mL EGTA.

Procedures

The specimen was further cut into six 3-cm-long segments. One of the six segments served as control and was fixed in 4 % formalin in no-load condition. The 5 segments left had one end ligated while the other end was connected via a tube to a fluid container for application of different pressures, which were 2, 5, 10, 15 and 20 cm H₂O respectively. Before we pressurized the intestinal segments, we placed some microbeads on surface of the middle part of the segments. Then the outlet was clamped to maintain the volume. After applying pressure for 3 minutes, a record of the whole intestine segment and the part with dots was obtained using video-camera (SONY CCD/RGB, JAPAN) to monitor the whole process (refer to Figure 1) performed under room temperature.

After the specimen was fixed in 4 % formalin for 24 hours, 1.0 cm long and 0.5 cm long transverse sections were taken from the middle part of specimen and dehydrated in a series of graded ethanol (70 %, 90 %, 95 % and 100 %) and embedded in paraffin respectively. 5 μ m serial slices were cut and stained with picrosirius red for collagen analysis and HE (hemotoxylin and eosin) for general histological observation^[22-26].

Figure 1 Slice record.

Image acquire

A series of polarized images of intestine slice was acquired by the recorder through microscope at every δ degree angle, and then stored in computer through image collecting card with TIFF format (RGB system type). The TIFF format, a very popular in use currently to reflect the details of the slice images distinctly, and the pixel values in the polarized images are suitable for the principles presented previously very well^[27-29]. Therefore we took the TIFF form to verify the method's feasibility and practicality.

In polarized light microscope, polarized light is delivered onto the sample to be analyzed and handled after being passed through two filter glasses. When the angle between optical axis of the two polarizing lens is 0 degree (that is, both of the two optical axis are parallel to the muscle direction), the blackest image area will be the part where the collagen fiber angle is 90 or 0 degree to the optical axis. Such an image area is also the part where the pixel values are minimum. Therefore, through image analysis we can find out all the area where the collagen fibers are parallel to muscle direction and thereby figure out the area ratio between the study area and the entire analysis Area (abcd). In the slice image analysis, the collagen fiber manifested as some pink striation (f) and the muscle fiber (e) some buff^[4] (refer to Figure 2).

Rotating the polarizing eyepiece while maintaining the objective lens and the experiment sample stable can make muscle fiber direction coincide with the optical axis of polarizing objective. When the polarizing eyepiece is rotated δ degree, all the areas where the collagen fiber are δ degree or $90 + \delta$ degree with the muscle fiber will present in the blackest

part^[21], in this way, their ratio to the entire analyzing area can be figured out as well.

Accordingly, we can obtain the relationship between the angle and its area ratio to the entire area. Since the collagen fiber distribution is uniform, that is, reticular in shape, its longitude and latitude lines are +30 degree and -30 degree to the muscle fiber direction. The area ratio for which is therefore the biggest, we can utilize the area ratio to reckon the collagen fiber angle.

(a) Original image

(b) Polarized image ($\delta=0$ degree)

(c) Polarized image ($\delta=5$ degree)

(d) Polarized image ($\delta=10$ degree)

Figure 2 Image processing.

Image processing

The image processing is the key part of the research, which is eventually based on the analysis of every image's pixels, namely, first to normalize the pixel value and then to use proper algorithms to obtain results. When all the data are summed up, the distribution relationship of collagen fibers can be obtained reversely through the regression curve.

Since the scope of the images recorded is so large that there can include a great deal of muscle tissue and other unrelated background (Figure 2), which should be removed by the image filter before the analysis. The area selected for analysis should be done on the original image before it was polarized.

In this study, the background noises were excluded directly with a frequency domain strengthening method because both of the edge and noise in the image correspond to the high frequency section of the image's Fourier transformation, we could weaken this part of the frequency to lessen its influence in the frequency domain^[30-33].

Data processing

For the purpose of saving much more information of each pixel, the matrix was unified. Take matrix $F(m,n)$ as the basis for further processing, the data less than the chosen threshold value were considered as the collagen fiber area in the polarized image. Figure out the pixel's number that was less than the chosen threshold value $s(j)$ ^[34,35]. And made:

$$b(j) = \frac{s(j)}{m \times n};$$

$b(j)$ was equal to the area ratio of collagen fiber and the chosen observed area in polarized image j . From this we got series of the ratio sequence, which were stored into array $Y(j)$.

RESULTS

According to the steps mentioned above, the calculation results were shown in Table 1, where the first column listed the pressures the tissue were received and the first row was the polarized light angles being rotated. We found that for the same slice, with polarized light angle's variation, its corresponding area ratio is not identical; for each tissue under different pressures, its biggest area ratio is not identical either. To obtain the smooth curve showing the relationship between the angle and the corresponding ratio, we made a nonlinear normality on the sample data^[36], the abscissa of the curve was δ 's integer multiple and the ordinate the series value in array $Y(i)$ (Figure 3).

The relationship between pressures tissue received and their corresponding fiber angle was shown in Figure 4.

The relationship between pressures tissue received and their corresponding biggest ratio was shown in Figure 5.

We tested other intestinal slice's images (of the same animal) and found that their properties above were similar by and large.

Figure 3 Relationship between angles of polarized light and their corresponding pixel ratio in series of slice images.

Figure 4 Relationship between pressures tissue received and their corresponding fiber angle.

Figure 5 Relationship between pressures tissue received and their corresponding biggest ratio.

DISCUSSION

From the data in Table 1, we found that in the same tissue sample there exist obvious alterations in the collagen area ratio

as the angles of polarized light changed; In different slice's images with different pressures, its biggest ratio was also not identical (Figure 4), and the biggest value was fairly obvious. However, it can not be determined whether the magnitude of collagen fiber angle and the fiber content are all in direct proportion with the pressure that the intestines received (Figure 4, Figure 5), because this depends some degree on the way how it receives the pressure. Using other methods to change its stress still needs to be tested in future experiments. The method of calculating ratios of different pixel values to estimate collagen fiber angle has its feasibility and reliability, which allows a larger area of soft tissue being analyzed with relatively low cost and simple equipment. The disadvantage of this method is the difficulty in determining an appropriate threshold value as well as a definite scope suitable for analyzing which have very important influence on the study results. At the same time, the less δ is to be selected, the more accurate the angle will be.

This paper has tried to acquire the collagen fiber angle of soft tissue in intestine slice through introducing a quantitative analysis method for calculating different pixel values whose validity is verified with computer program, and suggested a practical and effective method for basic research on G.I. disease.

Abstract

AIM: To determine the regulation effects of recombinant human growth hormone (rhGH) on dipeptide transporter (PepT1) in Caco-2 cells with normal culture and anoxia/reoxygenation injury.

METHODS: A human intestinal cell monolayer (Caco-2) was used as the in vitro model of human small intestine and cephalixin as the model substrate for dipeptide transporter (PepT1). Caco-2 cells grown on Transwell membrane filters were preincubated in the presence of rhGH in the culture medium for 4 d, serum was withdrawn from monolayers for 24 h before each experiment. The transport experiments of cephalixin across apical membranes were then conducted; Caco-2 cells grown on multiple well dishes (24 pore) with normal culture or anoxia/reoxygenation injury were preincubated with rhGH as above and uptake of cephalixin was then measured.

RESULTS: The transport and uptake of cephalixin across apical membranes of Caco-2 cells after preincubation with rhGH were significantly increased compared with controls ($P=0.045$, 0.0223). Also, addition of rhGH at physiological concentration (34 nM) to incubation medium greatly stimulates cephalixin uptake by anoxia/reoxygenation injured Caco-2 cells ($P=0.0116$), while the biological functions of PepT1 in injured Caco-2 cells without rhGH were markedly downregulated. Northern blot analysis showed that the level of PepT1 mRNA of rhGH-treated injured Caco-2 cells was greatly increased compared with controls.

CONCLUSION: The present results of rhGH stimulating the uptake and transport of cephalixin indicated that rhGH greatly upregulates the physiological effects of dipeptide transporters of Caco-2 cells. The alteration in the gene expression may be a mechanism of regulation of PepT1. In addition, Caco-2 cells take up cephalixin by the Proton-dependent dipeptide transporters that closely resembles the transporters present in the intestine. Caco-2 cells represent an ideal cellular model for future studies of the dipeptide transporter.

INTRODUCTION

Transport of protein in the form of small peptides (di/tripeptides) across the small intestinal wall is a major route of dietary protein absorption. The H^+ -coupled dipeptide transporter, PepT1, is known to be located in the intestine and the kidney, and plays an important role in the absorption of di/tripeptide; in addition, it mediates the intestinal absorption of β -lactam antibiotics, angiotensin-converting enzyme inhibitors, and other peptide-like drugs^[1].

To investigate the properties of the human dipeptide transporter, the human intestinal cell line Caco-2 as an in vitro model was employed. The dipeptide transporters normally found in the small intestine are present in Caco-2 cells^[2-4]. Also, Caco-2 cells spontaneously differentiate in culture to polar cells possessing microvilli and enterocytic properties^[5]. Confluent monolayers form tight junctions between cells^[5], and exhibit dome formation^[6] and electrical properties of an epithelium^[7]. These cells have been evaluated in detail as a model to study both transcellular and paracellular transport of nutrients and drugs in the gut^[8-12].

Previous studies have shown that some hormones metabolically regulate the expression of the intestinal dipeptide transporter^[13,14]. For example, as the key hormone, insulin increases the membrane population of PepT1 by increasing its translocation from a preformed cytoplasmic pool^[14]. However, little is known whether another important hormone, growth hormone (GH), also metabolically regulate the functions of PepT1. The present study was undertaken to evaluate the potential effects of recombinant human growth hormone (rhGH) for the study of the properties of the human PepT1. Especially, we observed the regulation effects of rhGH to PepT1 in Caco-2 cells which were normally cultured or anoxia/reoxygenation injured. Because dipeptide and some β -lactam antibiotics (cephalexin, cefaclor etc.) share certain structural features such as a peptide bond with an α -amino group and a terminal carboxylic acid group (as illustrated in Figure 1 for cephalixin), it is not surprising that these compounds share a common transport mechanism. Unlike dipeptides, these orally absorbed antibiotics are not hydrolyzed by intestinal peptidases. Consequently, these kinds of drugs are ideal substrates to characterize the PepT1^[15-17]. In this study, the uptake and transport of cephalixin were examined.

MATERIALS AND METHODS

Materials

Cephalixin (Figure 1) was obtained from Nanjing No.2 Pharma.Co. Ltd. rhGH was purchased from Laboratoires Serono S.A. (Switzerland). All other chemicals were purchased from Sigma (St. Louis, MO), unless specified. Cell culture

reagents were obtained from Gibco (Grand Island, NY) and culture supplies from Corning (Corning, NY) and Falcon (Lincoln Park, NJ).

Figure 1 Structure of cephalexin used in this study.

Cell culture

The human adenocarcinoma cell line Caco-2 was obtained from American Tissue Culture Collection (ATCC, Rockville, MD, U.S.A). The cells were passaged as previously described^[18]. Caco-2 cells were grown in Dulbecco's Modified Eagle's Medium supplemented with 1 % nonessential amino acids, 10 % fetal calf serum (FCS), 1 000 U^L⁻¹ penicillin, and 1 mg^L⁻¹ streptomycin (Complete DMEM). For transport Studies, Caco-2 cells were seeded on the polycarbonate filter (0.4- μ m pores, 4.71-cm² growth area) in the Transwell Cell Culture Chamber System (Costar, Cambridge, MA) at a density of 600 000 cells/filter. The cell monolayers were cultured with 1.5 and 2.6 ml of complete DMEM at the apical and the basolateral chamber, respectively. To assess the integrity of the monolayer, transepithelial electrical resistance (TEER) was monitored by measuring the transmembrane resistance. After subtracting intrinsic resistance (filter alone without cell monolayers) from the total resistance, TEER was corrected for surface area and expressed as Ω cm². Transport studies were carried out with cell monolayers that were 21-25 days old. For uptake studies, cells were seeded in the collagen-coated multiwell dishes (24 pore) with the same cell density. All the medium were replaced every day when each experiment began. Monolayers were kept at 37 °C, 5 % CO₂, and 90 % relative humidity.

Transport studies

Before the transport experiments, the culture medium was replaced every day from both sides of the monolayers, 1.5 ml pH 7.0 culture medium with 34nM rhGH were added to apical chamber of Transwell, while 2.6 ml pH 7.0 culture medium without rhGH were added to basolateral chamber. Then Caco-2 cells were cultured for 4 days. The controls were incubated with pH 7.0 culture medium both in apical side and basolateral side. All the monolayers were washed during each experiment. The apical chamber were then filled with 1.5 ml solution containing 1 mM cephalexin. Transport was examined within the time range of 0, 5, 10, 30, 60, 90, and 120 min. At the end of the incubation period, the inserts of Transwell were removed and the transport samples were obtained from the basolateral chambers. The concentrations of cephalexin of the transport samples were determined by High Performance Liquid Chromatography (HPLC, LC-10AT SHIMADU, Japan) using an isocratic solvent system described previously^[19] and the OD value was monitored at 254 nm.

Uptake studies

Using the same way as the transport experiments, the Caco-2 cells cultured in the multiwell dishes (24 pore) were cultured for 4 d with 34 nM rhGH. After washing the monolayers, the transport medium with 1 mM cephalexin was added to the pores and uptake was measured at 0, 5, 10, 30, 60, 90, and

120 min. At the end of the incubation period, cell monolayers were washed with pH 7.4 PBS to remove any extracellular cephalexin. Accumulated concentrations of cephalexin were determined by HPLC after the cells were lysed.

Anoxia-reoxygenation cells model

After Caco-2 cells were plated, media within the wells was reduced to a uniformly thin layer to reduce the diffusion distances for atmospheric gases, while maintaining cell ability. During culture, the monolayers were normally exposed to an atmosphere consisting of 95 % air and 5 % CO₂. Anoxia was produced with an atmosphere of 95 % N₂ and 5 % CO₂ for 90 min, reoxygenation was produced by restoration of the 95 % air, 5 % CO₂ for 30 min. After the period of reoxygenation, the volume of media was restored to the initial volume of 1.0 ml^[20] (Figure 2).

Figure 2 Appearance of scan electronic microscopy of Caco-2 cells. (A) Tight junction formation of normal Caco-2 cells. $\times 1\ 000$; (B) Tight junction of A/R Caco-2 cells was destroyed partially. $\times 1\ 000$.

Protein determination

Cells were lysed for 20 min or ice in 2 % Nonidet P-40, 0.2 % SDS, 1 mM dithiothreitol (DTT) in PBS, and total cellular protein was determined using Dc Protein Assay Reagent (BioRad).

Concentration dependence of cephalexin transport

To examine the kinetics of cephalexin transport by rhGH-treated Caco-2 cells, the different concentrations of cephalexin range of 20 to 80 μ g^L⁻¹ were used.

Northern blotting

Total RNAs were isolated from the Caco-2 cell fractions by extraction with acid guanidine thiocyanate-phenol-chloroform. Total RNAs were denatured by heating at 70 °C in 10 mmol^L⁻¹ 3-(N-morpholino) propanesulfonic acid (pH 7.0) containing 5 mmol^L⁻¹ sodium acetate, 1 mmol^L⁻¹ ethylenediaminetetraacetic acid (EDTA), 2.2 mol^L⁻¹ formaldehyde, and 50 % (vol/vol) formamide for 5 minutes and subjected to electrophoresis in 1.2 % agarose gel containing 2.2 mol^L⁻¹ formaldehyde. Resolved RNA was transferred to hybridization

and was performed in a solution that contains 50 % formamide, 5x sodium chloride-sodium phosphate-EDTA, 2x Denhardt's solution, and 1 % sodium dodecyl sulfate (SDS). The membranes were exposed and analyzed by Fuji BAS-2000 system. The cDNA probe was prepared from human cDNA libraries.

Antisense 5' CCGAAGCTTTCAGGAAGGAGCCTGAGAATATGAG 3'.

Statistical analysis

Data were expressed as mean \pm SE. Differences between experimental groups were assessed by analysis of Variance. *P* values of <0.05 were considered statistically significant.

RESULTS

Transepithelial cephalixin transport in Caco-2 cell with normal culture

Caco-2 cells were seeded at a high density of 600 000 cells/filter, the transport of 1 mM cephalixin across rhGH-treated Caco-2 monolayers, apical-to-basolateral, was examined at pH 6.0 in the donor and pH 7.4 in the receiver compartment. Integrity of the monolayers was monitored by TEER. The apical-to-basolateral transport of cephalixin was significantly increased compared with the controls ($P=0.0045$) (Figure 3).

Figure 3 Transport of 1 mM cephalixin in Caco-2 cells. Caco-2 cells were cultured with rhGH in apical side for 4 days. The controls were incubated with pH 7.0 culture medium without rhGH both in apical side and basolateral side. All the monolayers were washed in each experiment. The apical chambers were then filled with 1.5 ml solution containing 1 mM cephalixin. Transport was examined within the time range of 0, 5, 10, 30, 60, 90, and 120 min. At the end of the incubation period, the inserts of Transwell were removed and the transport samples were obtained from the basolateral chambers. The concentrations of cephalixin of the transport samples were determined by HPLC. The apical-to-basolateral transport of cephalixin was significantly increased compared with the controls ($P=0.0045$).

Uptake of cephalixin in Caco-2 cells with normal culture

Uptake experiments with cephalixin were performed 6-8 days after seeding and 18 h after media replacement. Cephalixin uptake was measured in the presence and absence of 34nM of rhGH. The differences were significant ($P=0.0223$), and the results were summarized in Figure 4.

Uptake of cephalixin in anoxia/reoxygenation Caco-2 cells model

Caco-2 monolayers were initially subjected to a 90-minute period of anoxia followed by a 30-minute period of reoxygenation. This was selected as optimal for the main body of the experiment on the basis of the results of our initial experiments. Consequently, the effect of the presence of rhGH on cephalixin uptake via the PepT1 of anoxia/reoxygenation

Caco-2 cells were examined (Figure 5). The present studies indicated that uptake and transport of cephalixin by the normal and anoxia/reoxygenation Caco-2 cells were significantly increased under the influence of rhGH.

Figure 4 Uptake of 1 mM cephalixin in Caco-2 cells. Caco-2 cells cultured in the multiwell dishes (24 pore) were cultured for 4 d with 34 nM rhGH. After washing the monolayers, the transport medium with 1 mM cephalixin was added to the pores and uptake was measured at 0, 5, 10, 30, 60, 90, and 120 min. At the end of the incubation period, cell monolayers were washed with pH 7.4 PBS to remove any extracellular cephalixin. Accumulated concentrations of cephalixin were determined by HPLC after the cells were lysed. The differences were significant ($P=0.0223$).

Figure 5 Uptake of 1 mM cephalixin in Caco-2 cells with anoxia/reoxygenation injury. Caco-2 monolayers were initially subjected to a 90-minute period of anoxia followed by a 30-minute period of reoxygenation. The effect of the presence of rhGH on cephalixin uptake via the PepT1 of anoxia/reoxygenation Caco-2 cells was examined. The differences were significant ($P=0.0116$).

Northern blot analysis

Northern blots of Poly (A)⁺ RNA, prepared from anoxia/reoxygenation Caco-2 cells grown either under control conditions or in medium supplemented with 34nM rhGH, were probed separately with ³²P-labelled hPepT1 and β -actin cDNAs. The studies showed that the level of mRNA in rhGH-treated Caco-2 Cells was increased 1.3-fold compared with the controls.

Concentration dependence of cephalixin transport

Transport experiments were performed across the rhGH-treated Caco-2 cells using the different concentrations of cephalixin range of 20 to 80 $\mu\text{g} \cdot \text{ml}^{-1}$. The results (Figure 6) indicated that the transport of cephalixin was increased both in rhGH-treated Caco-2 cells and Controls. However, the extent of upregulation of rhGH on the transport was greater than the controls followed the increase of the concentration of cephalixin.

Figure 6 Concentration-dependent transport of cephalalexin. The kinetics of cephalalexin transport by rhGH-treated Caco-2 cells showed that the transport level of Caco-2 cells was in accordance with the concentration of cephalalexin. The concentrations of cephalalexin range of 20 to 80 $\mu\text{g} \cdot \text{ml}^{-1}$ were used. Transport was determined at the different time-point (a, 15 min; b, 30 min; c, 45 min). The extent of upregulation of rhGH on the transport was greater than the controls followed the increase of the concentration of cephalalexin.

DISCUSSION

The nutritional importance of amino acid uptake in the form of short-chain peptides (di/tripeptides) is well known^[21]. The intraluminal products of protein digestion are predominantly small peptides^[22]. A significant fraction of the dietary amino nitrogen is absorbed as intact dipeptide rather than free amino acids. Absorption of these small peptides from the gastrointestinal (GI) tract of mammals occurs via the dipeptide transporter (PepT1). Previous studies have shown that the functions of intestine (including PepT1) were changed under the influence of many factors^[23,24]. PepT1 seems to play important roles in nutritional and pharmacological therapies; for example, it has allowed the use of small peptide as a source of nitrogen for enteral feeding and the use of oral route for delivery of peptidomimetic drugs such as β -lactam antibiotics. PepT1 was located at the brush-border membranes of the absorptive epithelial cells along the small intestine but absent in crypt and goblet cells^[25,26].

To examine the functions of PepT1, we used Caco-2 cells (the human adenocarcinoma cell line) as a unique *in vitro* intestinal model^[27]. One clear advantage of the Caco-2 cells is

that the cells stay viable throughout the transport studies. Also, a monolayer of cells may be grown on a porous support to represent an intact epithelium. Some β -lactam antibiotics (cephalexin) and dipeptides share certain structural features, and they are generally in the D-form, which allows them to escape hydrolysis by cytoplasmic peptidases. So these compounds share a common transport mechanism^[28]. In this study, we employed cephalexin as an ideal substrate.

The previous studies have shown that the insulin stimulates dipeptide transport by increasing membrane insertion of PepT1 from a preformed cytoplasmic Pool^[14], and cholera toxin decreases dipeptide transport by inhibiting the activity of PepT1 through an increase in the intracellular concentration of adenosine 3', 5'-cyclic monophosphate^[21]. It remains unclear, however, whether another key hormone, human growth hormone (hGH), also shows some significant importance. Strong evidence has demonstrated that growth hormone (GH) is an important growth factor for intestine^[28]. Complete GH depletion due to hypophysectomy caused pronounced hypoplasia of small intestinal mucosa with decreased villus height and reduced crypt cell proliferation^[29]. Simple replacement of GH can restore mucosal proliferative activity^[30]. rhGH promotes normal growth and development in the body by changing chemical activity in cells. It activates protein production in muscle cells and the release of energy from fats. rhGH significantly improves the anabolism in parenterally fed^[31]. It is typically used to stimulate growth in children with hormone deficiency, or to treat people with severe illness, burns or sepsis where destruction of human tissue and muscle occurs^[32-34]. Many of the effects of human growth hormone are brought about by the insulin-like growth factor 1 (IGF-1), which the growth hormone stimulates. IGF-1 plays an important part in growth-promoting effects of rhGH^[32]. The present studies showed that the uptake and transport of cephalalexin in Caco-2 cells were greatly increased by using of rhGH. In addition, a specific injured cell model, anoxia/reoxygenation Caco-2 cells model, was established in our present experiment. The uptake of cephalalexin in the injured Caco-2 cells was markedly decreased while the cephalalexin uptake was significantly increased in the injured Caco-2 cells with treatment of rhGH. These results indicate that the functions of PepT1 in Caco-2 cells were upregulated by rhGH. The investigation of concentration-dependent transport of cephalalexin in Caco-2 cells showed that the transport was increased both in rhGH-treated Caco-2 cells and controls. However, the upregulating extent of rhGH on the transport of cephalalexin was greater than controls following the increase of the concentration of cephalalexin. Northern blot analysis showed that the level of PepT1 mRNA of injured Caco-2 cells with rhGH treatment were increased. This result also provides novel information about the mechanism of regulation action of rhGH. It has suggested that the alteration in the gene expression may be a mechanism of regulation of PepT1.

Use of this experimental design leads to the following three questions. What is the detail mechanism of upregulating the functions of PepT1 by rhGH? How does the rhGH receptor distribute in Caco-2 cells? How does the rhGH receptor change in anoxia/reoxygenation Caco-2 cells? Clearly, the present study needs to be followed by further studies on physiology and biology of hormonal regulation of PepT1.

Abstract

AIM: To assess the feasibility and safety of radiofrequency ablation (RFA) in treatment of secondary splenomegaly and hypersplenism.

METHODS: Sixteen healthy mongrel dogs were randomly divided into two groups, group I ($n=4$) and group II ($n=12$). Congestive splenomegaly was induced by ligation of splenic vein and its collateral branches in both groups. At the end of 3rd week postoperation, RFA in spleen was performed in group II *via* laparotomy, complications of RFA were observed, CT scan was performed and the spleens were obtained. The radiofrequency (RF) thermal lesions and histopathology of spleen were examined regularly.

RESULTS: No complication or death was observed in both groups; CT revealed that the splenomegaly lasted over 2 months after ligation of splenic vein; the segmental RF lesions included hyperintense zone of coagulative necrosis and more extensive peripheral hypointense infarcted zone, the latter was called "bystander effect". The infarcted zone would be absorbed and subsequently disappeared in 4-6 weeks after RFA accompanied with shrinkage of the remnant spleen. The fundamental histopathological changes of splenic lesions caused by RF thermal energy included local coagulative necrosis, peripheral thrombotic infarction zone, subsequent tissue absorption and fibrosis in the zone of thrombotic infarction, the occlusion of vessels in remnant viable spleen, deposition of extensive fibrous protein, and disappearance of congestive splenic sinusoid - "splenic carnification". Those pathologic changes were underline of shrinkage of spleen.

CONCLUSION: It is feasible and safe to perform RFA in spleen to treat experimental splenomegaly and hypersplenism. The RFA could be safely performed clinically *via* laparotomy or laparoscopic procedure while spleen was strictly separated from surrounding organs.

INTRODUCTION

Radiofrequency ablation (RFA) was developed in 1990s and thereafter evolved rapidly as a minimally invasive technique for the treatment of primary and secondary malignant tumors in solid organs^[1-25]. The fundamental principle is that alternating electric current operated in the range of radiofrequency (460-500 kHz) can produce a focal thermal injury in living tissue, the tip of the electrode conducts the current, causing local ionic agitation and subsequent frictional heat (90-110 °C). Temperatures over 60 °C produce uniform tissue coagulative necrosis, a 2-5 cm spherical thermal injury can be produced with each ablation. The potential benefits of these techniques over conventional surgical options include tumor ablation in nonsurgical candidates with low morbidity, and being used on an outpatient basis^[1-15].

One of the most manifestations of liver cirrhosis with portal hypertension was hypersplenism secondary to splenic congestion with intrasplenic sequestration and destruction of erythrocytes, leucocytes and platelets resulting in anemia, leucopenia and thrombocytopenia^[26]. Splenectomy is a routine therapy for hypersplenism and can correct the abnormal hematologic parameters^[26,27]. However, with the awareness of the role and importance of the spleen in the immune system, splenic conservative methods have gained prominence in the treatment of benign conditions of the spleen^[27-29]. Several minimally invasive treatment modalities such as transcatheter selective splenic arterial embolization^[30], absolute alcohol or ethanolamine oleate intrasplenic injection^[31,32] have been investigated clinically, but the clinical applications were restricted due to associated complications.

In order to establish an effective therapy for hypersplenism with splenomegaly, animal model with splenomegaly was induced by ligation of splenic vein (LSV), the computerized tomographic (CT) and pathologic changes of the thermal lesions in spleen after RFA were observed, and the feasibility and safety of RFA for secondary splenomegaly and hypersplenism and its potential clinical prospective were investigated.

MATERIALS AND METHODS

Animals and experimental design

Sixteen healthy adult mongrel dogs (12 to 17 kg) were randomly divided into two groups. LSV *plus* Laparotomy were performed in Group I ($n=4$), and LSV *plus* RFA were done in Group II ($n=12$).

After fasting overnight, the animals were anesthetized generally with sodium pentobarbital (25 mg/kg) and maintained with supplemental doses of sodium pentobarbital. The great saphenous vein was cannulated for transfusion with 500 ml of acetate Ringer's solution. Midline incision was used to access the spleen, splenic veins in both groups were ligated at the confluent to portal vein, and then the main branches of splenic vein were further ligated separately at the splenic hilus in order to minimize collateral formation. The animals were cared in cages at 24 ± 2 °C and fed with standard diet and water *ad libitum* after operation. At the end of the third week, under general anesthesia again, the animals in group I were performed laparotomy only; and both laparotomy and RFA of spleen were done in group II.

Ablation procedures

RFA was performed with the RF 2000 generator system (Radio Therapeutics Corp., CA, USA), which consists of a generator generating [up to 90 W in power, a leVein monopolar array needle electrode (3.5 cm maximum array diameter), and two electrode pads (grounding pads) placed on the animal's shaved thighs. The leVein needle electrode is a 15-gauge, 15-20 cm in length insulated cannula containing 10 individual hook-shaped retractable electrode arms that deployed in situ after placement of the needle electrode in splenic parenchyma. The probe was inserted perpendicularly into the splenic parenchyma in lateral region of superior or inferior pole of spleen, and the spleen was elevated to avoid to contact with adjacent organs and skin. A 90 W monopolar radiofrequency generator (RF 2000, Radiotherapeutics) was used as the energy source. Power output was initially set at 30 W and manually titrated 10 W per 60 sec until the maximum power. Thereafter, impedance could rise with automatic power adjustment until power output was terminated. The electrode 0.5 cm retrograded in situ and above session repeated. The needle track was cauterized on needle removal.

During RFA procedure, the temperatures on the sites of thermal lesions, hilum of spleen and the tail of pancreas were measured frequently by thermosensors, and cold saline was used to lower the temperature on the hilum of spleen, and tail of pancreas. Five-hundred ml of acetate Ringer's solution and 0.8M IU of penicillin were given intravenously.

Observation of animals

The complications during RFA, such as hemorrhage, thermal injury of other organs, the appetites, eating and activities of animals, morbidity and mortality after RFA were carefully documented.

CT imaging and histopathology on splenic lesions

Splenic sizes in group I after LSV were documented with CT scans (Siemens Medical System, Germany) at 3, 6, 9 weeks after laparotomy. CT imaging (plain scan plus enhancement) performed for the dogs in group II after RFA on day 1, and at 1, 2, 4, 6 and 9 weeks after RFA to study the thermal injured lesions in spleens. Two dogs in group II were killed immediately after CT scan, and all dogs were sacrificed at the end of the 9th week. Before sacrificing the dogs, spleens were removed, specimen of liver and pancreas were harvested and fixed in 10 % formaldehyde, and routine histopathological studies were processed and examined under light microscopy.

RESULTS

Animals

The RFA procedure took 30 to 58 minutes, the temperatures on 0.5 cm in depth of thermal lesion in spleens were over 100 °C as reaching to the maximum impedance. The temperatures on the hilum of spleen were 45-50 °C, the temperatures were kept below 42 °C with iced cold saline. There was a temperature gradient rising from lateral to center of splenic hilum due to blood inflow. Thus, choosing puncture site on lateral region of superior or inferior pole of spleen could enlarge the size of thermal lesions, and approximately 40-50 % of spleen could be damaged on each episode of RFA. Minor or mild bleeding from the puncture site of spleen immediately after inserting the electrode may occur and would be stopped automatically in 5 minutes due to thermal coagulation if the electrode was kept still. The animals could well tolerate the RFA, distressing in 5 dogs due to high tension of spleen capsule caused by thermal injury was resolved after administration of tranquilizer. The dogs fasted on the day of RFA were lethargic or anorexic. All dogs were fed normally after RFA. Restlessness, vomiting

and anorexia, significant body weights change and complications of surgery such as gastrointestinal perforation, peritonitis, intra-abdominal hemorrhage, rupture of spleen or hydrothorax and death were not observed at all.

CT imaging of spleens

Splenomegaly in group I could persist over 2 months. The enhanced CT revealed that each RF thermal lesion could destroy one lobe or multiple splenic segments, and the splenic capsule was intact except small part of hilum. The ablated lesion included two zones: (a) hyperintense zone of coagulative necrosis; (b) more extensive peripheral hypointense infarcted zone - the latter was called "bystander effect". No perisplenic or splenic abscess was formed (Figure 1). The infarcted zone would be absorbed in 4 to 6 weeks after RFA, and subsequently disappeared in two months, and the size of remnant spleen shrunk significantly (Figure 2, 3).

Figure 1 Enhanced CT demonstrated multiple segmental ablated lesion at the end of 2nd week after RFA, the splenic capsule was continuous, the thermal lesion included 2 zones, namely hyperintense zone of coagulative necrosis and peripheral hypointense infarcted zone; no perisplenic or splenic abscess was seen.

Figure 2 The lesion of infarcted zone was mostly absorbed at the end of 6th week after RFA.

Figure 3 The lesion of infarcted zone was absorbed absolutely at the end of 9th week after RFA, however, the lesion of coagulative necrosis hardly altered, the remnant spleen shrunk significantly (arrow).

Figure 4 The appearance of the spleen the day after RFA, showed the lesion included the zone of solid-yellow dry necrosis (white arrow) and dark-red zone of thrombotic infarction (curve arrow), and the bright red normal spleen (black arrow); each ablation created a lesion with maximum diameter of 9 cm.

Figure 5 The lesion of infarcted zone was absorbed absolutely at the end of 9th week after RFA, however, the lesion of coagulative necrosis hardly altered (arrow).

Figure 6 Light microscopic appearance of the coagulative necrosis at the end of 2nd week after RFA, the intrasplenic hemorrhage at the probe insertion site could see (arrow), the splenic capsule thickened (HE. $\times 40$).

Figure 7 Microscopic examination at the junction of the necrotic region and infarcted region at the end of 2nd week after

RFA, massive fibroblasts and inflammatory cells aggregated, the microthrombus dissolved (HE. $\times 200$).

Figure 8 Microscopic examination of the thrombotic infarction at the end of 4th week after RFA, the microthrombus dissolved, and extensive macrophages with hemosiderin deposition presented (HE. $\times 100$).

Figure 9 Microscopic appearance of "splenic carnification" of the normal viable splenic tissue distant from ablative lesion at the end of 9th week after RFA, the tissue structure consolidated, larger vessels occluded, extensive fibrous protein deposited, and the congestive splenic sinusoid disappeared; however, the structure of splenic lymphoid nodule was intact (arrow) (HE. $\times 40$).

Figure 10 The typical appearance of poorly vascularized splenic tissue due to "splenic carnification" after RFA. The splenic sinusoid disappeared, tissue structure consolidated, granular hemosiderin deposition and sparsely neovascularized vessels (arrow) presented clearly (HE. $\times 200$).

Histopathology

Splenomegaly in gross appearance was existed in 2 months after ligation of splenic veins. The areas of ablated lesions had dot swollen dark red appearance, the spleens shrunk significantly and approached to the normal size at the end of ninth week after RFA. The macroscopic and microscopic of liver and pancreas were normal. The omentum was adherent to the ablated surface of the spleen in most cases. The appearances of cut surface of the ablated lesions matched

with the CT imaging, including the zone of soil-yellow dry necrosis and zone of thrombotic infarction (Figure 4), and the lesions became dry necrosis after the thrombotic infarction was absorbed (Figure 5). No obvious intrasplenic hemorrhage except the puncture tract was seen with microscopic examination (Figure 6). The RF energy caused focal tissue coagulative necrosis, massive vessels in the spleen were damaged thermally and occluded, consequently broad microthrombus led to the peripheral thrombotic infarction, which is called as bystander effect corresponding to the CT finding. Thrombotic infarction zone had absorbed by macrophages gradually in 4-6 weeks, where fibroblasts proliferation and local fibrosis were demonstrated. Even though some part of spleen appeared normal and viable, there had obvious thickened intima, occluded vessels, extensive fibrous protein deposition, and the absence of congestive splenic sinusoid, which we called as splenic carnification, the most important pathological basis of the shrunken spleen (Figure 7-10).

DISCUSSION

Hypersplenism is one of the common manifestations, 70-80 % patients with cirrhotic hypertension present with various degrees of splenomegaly and hypersplenism. The immune function in patients with hypersplenism would be reduced due to leucopenia, thrombocytopenia and erythropenia. Splenectomy is the traditional treatment for hypersplenism. However, patients with cirrhotic splenomegaly and hypersplenism often have many complications, which are the contraindication of splenectomy. Furthermore, endoscopic ligation or sclerosing of varices for esophageal varices bleeding due to cirrhotic portal hypertension was advocated as first line treatment in western countries, splenectomy plus devascularization are commonly abandoned^[33-38]. With the awareness of the role and importance of the spleen in the immune system, it is recommended to reserve the splenic tissue and function as much as in the treatment of benign conditions of the spleen. Thereby, new safe, effective and minimal invasive modalities should be established.

Radiofrequency ablation (RFA) technique is a safe and effective minimally invasive modality and has been clinically used in treatment of many malignant tumors and some benign tumors in solid organs^[1-25]. Until now, only two cases in treatment of colorectal and renal splenic metastasis using RFA were reported^[39, 40], no data of experimental or clinical study regarding the safety and efficacy of RFA for hypersplenism is available. The safety and effectiveness may be the cardinal considerations that impede the attempts. The limited necrotic volume identical to the lesion in liver for hepatocellular carcinoma with 3-5 cm maximal diameter could scarcely reduce the size of splenomegaly, consequently could be futile to ameliorate cytopenia for hypersplenism. However, theoretically, RFA could be used for hypersplenism due to portal hypertension: (a) spleen is a solid organ, thermal energy can cause focal tissue coagulative necrosis, and the RF heat energy has the role of electric coagulation^[39,40]; (b) certain time of RF thermal energy can lead to endothelial cells degeneration of vessels and sinus, thrombosis, and occlusion of vessels and splenic sinusoid, therefore produces effect of ablating larger lesion^[17]; (c) puncture of spleen with needle is relative safe, the morbidity rate of biopsy reported using 18-22 gauge needles for splenic lesions including splenomegaly is 0-5.2 %, without mortality^[41-43]; (d) the inflammatory reaction and neo-vascularization at the site of RFA lesion could create extensive collateral circulation between portal-cava vein systems, and reduce blood inflow to portal vein due to smaller spleen, sequentially depress the portal hypertension^[28]. Clinically, we

performed RFA for splenomegaly intraoperatively before splenectomy, only minor or mild bleeding occurred but stopped within few minutes (data not shown), and we found this procedure was practicable.

For these reasons, we carried out the study on RFA for splenomegaly and hypersplenism in canine models (the blood counts of peripheral samples in splenomegaly models also showed thrombocytopenia, erythropenia without leucopenia, which is similar to the result of Sahin *et al*^[44], and the hematologic abnormalities could be corrected by RFA; data not shown), results of preliminary study confirmed part of above presumptions.

First, RFA procedure for spleen is relative safe. Although bleeding occurred immediately following inserting of electrodes into the spleen, it ceased soon due to thermal coagulation. In order to avoid the potential risks, several important steps should be followed, the puncture site must be kept away from large vessels at hilum of spleen, the electrode should be fixed to reduce bleeding; the spleen should be elevated to avoid to contact with adjacent organs and skin; cool saline should be used on the surface of the hilum of spleen, tail of pancreas to reduce energy deposition and avoid thermal damage of pancreas. In our preliminary experiment, dog's thighs were burned due to insufficient shave of thigh and thus incomplete attachment of electrode pads; and another dog died from severe burning of internal organs, because spleen was not isolated from skin and intra-abdominal viscera. However, no morbidity and mortality occurred after procedures above in experiment were followed strictly. In addition, puncture of needle at lower pole of spleen is preferable to reduce the pulmonary complications and referred pain. If this procedure were used clinically, exposure and protection of spleen would be helpful in avoiding complications.

Second, the area of RF thermal ablated lesion is so large that compasses one lobe or multiple segments of spleen. The area of coagulative necrosis zone in spleen is similar to that of RF lesion in liver^[12,25], but the RFA in spleen also has "bystander effect" - the RF energy causes multiple segmental thrombotic infarction, enables for the management of hypersplenism effectively. The RF energy triggers occlusion of broad intrasplenic microthrombi and vessels, and absorption of area with thrombotic infarction. Even in the remaining normal splenic tissue, obvious occluded vessels, extensive fibrous protein deposition with no congestion of splenic sinusoid are still existed. The changes of "splenic carnification" are responsible for the shrinking of the remnant spleen, which could explain precisely why splenic RFA ameliorated the cytopenia.

In summary, it is feasible and safe to perform RFA in spleen to treat secondary splenomegaly and hypersplenism in a canine model, and yet its clinical application is worthy of further study. The peculiar radiological and pathological splenic changes after RFA could be used as clinical indicators for therapeutic effect and the follow-up in the therapy of hypersplenism. With the development of technique, such as RFA with the minimally invasive procedures, it would provide promising effect on selected patients with hypersplenism^[17].

Abstract

AIM: To identify new diagnostic markers and drug targets, the gene expression profiles of pancreatic cancer were compared with that of adjacent normal tissues utilizing cDNA microarray analysis.

METHODS: cDNA probes were prepared by labeling mRNA from samples of six pancreatic carcinoma tissues with Cy5-dUTP and mRNA from adjacent normal tissues with Cy3-dUTP respectively through reverse transcription. The mixed probes of each sample were then hybridized with 12 800 cDNA arrays (12 648 unique human cDNA sequences), and the fluorescent signals were scanned by ScanArray 3 000 scanner (General Scanning, Inc.). The values of Cy5-dUTP and Cy3-dUTP on each spot were analyzed and calculated by ImaGene 3.0 software (BioDiscovery, Inc.). Differentially expressed genes were screened according to the criterion that the absolute value of natural logarithm of the ratio of Cy5-dUTP to Cy3-dUTP was greater-than 0.69.

RESULTS: Among 6 samples investigated, 301 genes, which accounted for 2.38 % of genes on the microarray slides, exhibited differentially expression at least in 5. There were 166 over-expressed genes including 136 having been registered in Genbank, and 135 under-expressed genes including 79 in Genbank in cancerous tissues.

CONCLUSION: Microarray analysis may provide invaluable information on disease pathology, progression, resistance to treatment, and response to cellular microenvironments of pancreatic carcinoma and ultimately may lead to improving early diagnosis and discovering innovative therapeutic approaches for cancer.

INTRODUCTION

The morbidity of pancreatic carcinoma has taken an upward trend all over the world. In occidental countries, the morbidity of pancreatic carcinoma has increased by 3 to 7 times in nearly thirty years, and pancreatic carcinoma has become one of the ten commonest malignant tumors. In China, the morbidity was 1.16/100 000 in Shanghai in 1963, and reached on 3.80/100 000

in 1974. Then, it took the 14th place of the morbidity of the malignant tumors, and jumped to fifth in 1984. The statistical results showed that it was 5.1/100 000, which was four times higher than that of twenty years before. In some medical centers, curative resections were given to minority of patients in early stage who were highly selected, and their five-year survival of these patients might even rise to 15 to 25 percent. But generally speaking, treatment of pancreatic cancer is still a serious challenge to us. The key problem to improve the current situation of treatment is to seek novel diagnostic markers, effective adjunctive therapy and mechanism of genesis and evolution of pancreatic cancer. Hence, more and more attention has been paid to the research on molecular pathology and related genes of pancreatic cancer.

Over the past decade, many studies involving pancreatic cancer have searched for cancer-causing gene. As a result, several cancer-related genes have been identified. DPC4, p53, and p16 are the three most frequently inactivated tumor suppressor genes. Other tumor suppressor genes that are altered in pancreatic cancer include BRCA2, ALK-5, MKK4, and STK11. Mutations of K-ras oncogene are commonly seen in pancreatic cancer, with its incidence as high as 90 %. Some other cancer-related genes, such as Her-2/neu, COX-2, VEGF have also been reported to be overexpressed in pancreatic cancer. Development and progression of pancreatic cancer is a very complicated process, so it is reasonable to predict that many other genes, as yet undiscovered, might be potential tumor markers or drug targets.

Microarray is the technique that a large number of cDNAs are arranged orderly on the carrier, such as glass chip or else in high density. Data are obtained by examining the signals of fluorescence, analyzed and compared by computer software. A large number of genes can be examined simultaneously, accurately, and effectively in one experiment. In this study, we have used a high-density cDNA microarray technique to assess the gene expression profile of pancreatic carcinoma versus adjacent normal tissue. Several genes, we identified, may be involved in pancreatic tumorigenesis as well as its potential clinical biomarkers that may be used to improve early diagnosis, and to constitute potential novel therapeutic targets.

MATERIALS AND METHODS

Materials

cDNA microarray slides used in this study were fabricated in United Gene Technique, Ltd. Briefly, each slide has 12 800 spots, containing 112 genes as negative control, such as ripe U2 RNA gene (8 spots), HCV coat protein gene (8 spots), spotting solution (96 spots); and 40 housekeeping genes as positive control. Each slide has 12 648 unique human cDNA sequences. Six samples of pancreatic carcinoma were obtained from patients undergoing pancreaticoduodenectomy in department of general surgery, Changhai Hospital, the Second Military Medical University. All cases were proved pathologically as carcinoma of pancreatic head. Normal tissues as control were taken from tissue adjacent to the cutting margin of the carcinoma and proved pathologically to be free from tumor invasion. Samples were snap-frozen in liquid nitrogen within 15 to 20 minutes after resection and then stored at -80 °C.

Cy3-dUTP and Cy5-dUTP were purchased from Amersham Pharmacia Biotech, Inc. and Oligotex mRNA Midi Kit from Quagen, Inc. ScanArray 3 000 scanner was manufactured by General Scanning, Inc. ImaGene3.0 software came from BioDiscovery, Inc.

Methods

Probe preparation Total RNA isolated from pancreas tissues and normal adjacent tissues by using modified single step extraction. Briefly, frozen tissues were crushed down and homogenized in solution D and 1 % mercaptoethanol. The supernatant was then extracted by phenol: chloroform (1:1) two times, and phenol: chloroform (5:1) and NaAc (PH=4.5) once. Afterward, the supernatant was precipitated in equal volume of isopropanol at -20 °C for 1.5 hours and was precipitated in LiCl for purification. Both kinds of mRNAs were purified using Oligotex mRNA Midi Kit. The fluorescent cDNA probes were prepared by reverse transcription and then purified, according to the protocol of Schena (Schena *et al.*, 1995). The mRNA from normal tissue was labeled with Cy3- dUTP, and that from cancerous tissue with Cy5- dUTP. Then the two probes were mixed with equivalence, precipitated by ethanol, and resolved in 20 µl hybridization buffer (5×SSC + 0.4 % SDS, 50 % Formamide, 5×denhardt's solution).

Hybridization Microarray slides were pre-hybridized in hybridization buffer, which contained 0.5 mg/ml denatured clupeine DNA, at 42 °C for 6 hours. After denatured at 95 °C for 5 minutes, the probes mixture were added on the pre-hybridized slides and sealed with cover glass. After hybridizing

in HybChamber at 60 °C for 15 to 17 hours, the slides were subsequently washed in solutions of 2×SSC + 0.2 % SDS, 0.1×SSC+0.2 % SDS and 0.1×SSC respectively for 10 minutes, then dried at room temperature.

Scanning and analysis The slides were scanned by ScanArray 3 000 laser scanner at two wavelengths to obtain fluorescence intensities for both dyes (Cy3 and Cy5). The original value of each spot was normalized by the values of 40 housekeeping genes selected on the slides. The fluorescence intensities of Cy3 and Cy5 were analyzed and the ratios of Cy5 to Cy3 were calculated by ImaGene 3.0 software. The intensities of two fluorescent signals represented the quantities of two tagged probes. The ration of Cy5 to Cy3 of certain spot on the slides demonstrated that mRNA abundance of this gene expressed in cancerous tissues versus normal.

RESULTS

Verification of microarray technique system

There were 12 800 spots on each slide, including 6 170 known genes and 6 478 unknown ones. In order to monitor entire process of microarray technique system, negative and positive control genes were set on the slides. They were ripe U2 RNA gene (8 spots), HCV coat protein gene (8 spots), spotting solution (96 spots), which served as negative control; and 40 housekeeping genes as positive control. In present study, the individual result of six hybridization showed that all of positive control signals are distinct, and all of negative control signals were very low. These prove the reliability of the data.

Table 1 Over-expressed genes in pancreatic carcinoma

Accession number	Gene name	Gene function	Ratio value
U06863	Alpha 1 (III) collagen	Extracellular matrix	33.89
X91148	Microsomal triglyceride transfer protein	Microsomal triglyceride transfer	21.89
AF017986	Secreted apoptosis related protein 1 (SARP1)	Repress apoptosis	20.32
Y00755	Extracellular matrix protein BM-40	Extracellular matrix	20.23
Z74616	Alpha2 (I) collagen	Extracellular matrix	12.52
D32039	Proteoglycan PG-M(V3)	Extracellular matrix	11.90
J03607	40-kDa keratin intermediate filament precursor	Extracellular matrix	11.62
AF144103	Novel chemokine family member with altered expression in human head and neck squamous cell carcinoma	Cytokine	9.93
AF141201	Ubiquitin fusion-degradation 1 protein (UFD1)	Protease	8.29
X02761	Fibronectin (FN)	Extracellular matrix	8.01
U06863	Follistatin-related protein precursor	Nucleoprotein	6.92
M14219	Chondroitin/dermatan sulfate proteoglycan (PG40) core protein	Extracellular matrix	6.65
M17783	Glia-derived nexin (GDN)	Protease inhibitor	6.49
U59877	Low-Mr GTP-binding protein (RAB31)	Signal transduction	5.97
AF000989	Thymosin beta 4 Y isoform (TB4Y)	Thymosin isoform	5.71
L20688	GDP-dissociation inhibitor protein (Ly-GDI)	Signal transduction	5.62
X57351	1-8D gene from interferon-inducible gene	Signal transduction	5.51
U18728	Lumican	Extracellular matrix	5.15
L02326	Lambda-like gene	Immunity correlation	4.77
M14144	Vimentin	Extracellular matrix	4.64
J05633	Integrin beta-5 subunit	Cell adhesion molecule	4.42
AF070523	JWA protein	-	4.32
M27749	Immunoglobulin-related 14.1 protein	Immunity correlation	4.28
S83308	Sry-related HMG box gene (SOX5)	Transcription factor	4.16
U05875	Interferon gamma receptor accessory factor-1 (AF-1)	Immunity correlation	3.92
M17733	Thymosin beta-4	Thymosin isoform	3.89
M20259	Thymosin beta-10	Thymosin isoform	3.75
M36501	Alpha-2-macroglobulin	Protease inhibitor	3.72
AF026977	Microsomal glutathione S-transferase 3 (MGST3)	Oxidation-reduction	3.62
M14630	Prothymosin-α	Nucleoprotein	3.45

Table 2 Under-expressed genes in pancreatic carcinoma

Accession number	Gene name	Gene function	Ratio value
U96628	Nuclear antigen H731-like protein	Tumor suppressor	0.16
U72649	B-cell translocation gene 2 (BTG2)	Tumor suppressor	0.18
Y15409	Putative glucose 6-phosphate translocase	Gluconeogenesis	0.18
Z21507	Elongation factor-1-delta	Translation factor	0.20
L13463	Helix-loop-helix basic phosphoprotein (G0S8)	Cell cycle correlation	0.21
S68805	L-arginine:glycine amidinotransferase	Amino transferase	0.22
AF041474	BAF53a (BAF53a)	Chromatin reformation	0.22
X05130	Prolyl 4-hydroxylase beta subunit	Hydroxylase	0.22
AF067855	Geminin	Cell cycle correlation	0.25
D87810	Phosphomannomutase	Glycometabolism	0.25
D28540	CDC10 homologue	Cell cycle correlation	0.27
L37368	RNA-binding protein	RNA metabolism	0.27
Y00711	Lactate dehydrogenase B (LDH-B)	Dehydrogenase	0.27
M24103	Trans-golgi network glycoprotein 51 (TGN)	-	0.29
M64930	Protein phosphatase 2A beta subunit	Signal transduction	0.29
X81197	Archain	Membranin	0.31
U75686	Polyadenylate binding protein	Signal transduction	0.32
AF133659	ATP-binding cassette 7 iron transporter (ABC7)	Iron transfer	0.32
M61832	S-adenosylhomocysteine hydrolase (AHCY)	Hydrolase	0.33
Z23064	HnRNP G protein	RNA-binding protein	0.34
X85960	TRK-T3 oncogene	Oncogene	0.35
L18887	Calnexin	Calcium binding protein	0.35
J02966	Mitochondrial ADP/ADT translocator	ATP/ADP transport	0.35
X78678	Ketohexokinase	Glycometabolism	0.35
M58460	75-kD autoantigen (PM-Sc1)	Autoantigen	0.35
L12711	Transketolase (tk)	Ribose metabolism	0.35
S75311	Glycosyl phosphatidylinositol (GPI)-linked glycoprotein CD24	Signal transduction	0.35
U46838	MCM105 protein	Cell cycle correlation	0.36
Y11312	Phosphoinositide 3-kinase	Signal transduction	0.36
U83908	PDCD4 (programmed cell death 4)	Tumor suppressor	0.36

Judgement of differentially expressed genes

Hybridization of each couple of probes repeated two times. The standard of determination for differentially expressed genes was that, the absolute value of natural logarithm of the ratio of Cy5 to Cy3 was greater than 0.69, that was to say change of gene expression was above 2 times, and the signal value of either Cy3 or Cy5 needed to be greater than 600.

Genes expressed differentially

Among 6 samples investigated, 301 genes, which accounted for 2.38 % of genes on the microarray slides, exhibited differentially expression at least in 5. There were 166 over-expressed genes including 136 having been registered in Genebank, and 135 under-expressed genes including 79 in Genebank. Some of these genes, which took superior places of differentially expression, were listed in Table 1 and Table 2.

DISCUSSION

There are altogether 215 previously reported genes differently expressed in cancer tissues in our research, including urokinase plasminogen activator surface receptor (uPAR)^[1], glyceraldehyde-3-phosphate dehydrogenase (GAPDH), lumican^[2], phospholipase A2^[3], vascular cell adhesion molecule 1^[4], which have been reported to play certain role in evolution of pancreatic carcinoma. However, the relationship between the majority of these genes and development of pancreatic carcinoma has not been covered in any study up to the present. These genes are involved in various cytobiological functions, such as signal transduction, transcription and translation,

cytoskeleton, cell adhesion, extracellular matrix and matrix degradation, cell cycle and apoptosis, chromosome instability, tumor suppressor genes, enzyme, and "others". Moreover, some genes exhibit differently expression in pancreatic cancer in our study, as well as in other cancers. They are fibronectin^[5], caltractin^[6], glyceraldehyde-3-phosphate dehydrogenase (GAPDH)^[7], lipocortin II, uPAR^[8] in hepatic cancer; FN^[9], glutathione peroxidase^[10], phospholipase A2^[11], thymosin beta-10^[12], uPAR^[13], uracil DNA glycosylase^[14] in colorectal cancer; N-cadherin^[15], uPAR^[16], alpha-2-macroglobulin^[17], caltractin^[6], syntenin^[18] in gastric cancer; phospholipase A2^[19] in cholangiocarcinoma; fibronectin^[20], glutathione peroxidase^[21,22], prothymosin alpha^[23,24], thymosin beta-10^[25], uPAR^[26], caltractin^[6], GAPDH^[27], proteoglycan PG-M(V3), syntenin^[18], lumican^[28] in mammary cancer and glutathione peroxidase^[29], SPARC/osteonectin^[29], thymosin beta-10^[30], uPAR^[31] in thyroid carcinoma. These data indicated that we have obtained the same results by using cDNA microarray as by other methods. Meanwhile, these confirmed the feasibility, accuracy and effectiveness of microarray as a method to investigate the expression profiles of pancreatic cancer. On the other hand, we might get the conclusion that genesis and progression of various neoplasms have some common mechanisms. Further study on these common mechanisms might lead us go into depth the knowledge of molecular biology of cancer, and find the key to the improvement of diagnosis and treatment of cancer.

Pancreatic carcinoma is one of the most malignant tumors, and is characterized by aggressive growth behavior and high incidence rate of recurrence. During proliferation of a primary tumor or the establishment of metastatic foci, there is

continuous remodeling of the extracellular matrix including various degrees of biosynthesis, reformation and degradation. Among over-expressed genes, several genes, such as alpha1 (III) collagen, extracellular matrix protein BM-40, alpha2 (I) collagen, proteoglycan PG-M (V3), fibronectin, chondroitin/dermatan sulfate proteoglycan (PG40) core protein, lumican, vimentin, chondroitin sulfate proteoglycan versican V0 splice-variant, and versican V2 splice-variant core protein, component analysis related to extracellular matrix (ECM), take the superior places. Versican belongs to the family of large aggregating proteoglycans (PGs). In mammals, versican appears as four possible spliced variants, V₀, V₁, V₂, and V₃. It has been described that the versican-rich extracellular matrices exert an anti-adhesive effect on the cells, thus facilitating tumor cell migration and invasion. Besides decreasing cell adhesion, versican is also able to increase the cell proliferation. The study on melanoma has shown that this PG could serve as a good marker for primary malignant as well as metastatic lesion^[32]. Lumican is the member of the small leucine-rich proteoglycan (SLRP) family, whose members are known as keratocan, mimecan, decorin, biglycan, fibromodulin, epiphygan, osteoadherin, and lumican. SLRP proteins can modulate cellular behaviour, including cell migration and proliferation during embryonic development, tissue repair, and tumor growth. In breast cancer tissues, lumican mRNA is reported to be overexpressed. Furthermore, its high expression level was associated with high tumor grade, low estrogen receptor levels, and young age of patients^[28]. It is also found that lumican is not synthesized by the exocrine components of the normal pancreas, but that these cells ectopically synthesize and secrete the lumican in cancer tissues, which may play a role in pancreatic cancer cell growth^[2]. Extracellular matrix protein BM-40, an anti-adhesive protein, is proposed to modulate cell migration and vascular morphogenesis either by directly interacting with ECM proteins or by initiating a receptor-mediated signaling event. It may directly affect cell motility by inducing intracellular changes of cytoplasmic components; or indirectly promote cell migration by modulating the expression of proteolytic enzymes that degrade the ECM, such as collagenase, stromelysin and MMP-9. It may promote infiltration of tumor cells, serve as a cellular marker of invasion, and correlate to angiogenesis^[33]. Fibronectin connects with the cancer cell via its receptors, including integrins $\alpha_5\beta_1$ and $\alpha_v\beta_3$. The abilities in adhesion to fibronectin and migration increased markedly, after hepatocellular carcinoma cells were transfected with H-ras oncogene^[34]. In addition, fibronectin is the primary protein involved in the displacement of MMP-2 produced by adjacent normal cells to cancer tissues^[35]. MMP-2 can associate with the cell surface through its COOH-terminal and hemopexin-like domain via a number of mechanisms, including binding to cell-associated collagen I and IV. In our present study, we also find that collagen I and IV overexpress in cancerous tissues. This may enhance the fibronectin-induced displacement of MMP-2, and facilitates invasion of cancerous cells. Vimentin is also a component of ECM. Enhanced expression of the vimentin is associated with high degree of motility, poor differentiation and metastasis of prostate carcinoma^[36]. It has been shown that vimentin was immunohistochemically positive in basaloid squamous carcinoma of esophagus^[37]. Moreover, uPAR and cathepsin O2 are also found to be over-expressed in our study. All of these changes endow pancreatic cancer with the trait of aggressive growth, and may be potential markers of invasion.

On the other hand, recurrence to chemotherapy after resection remains a major obstacle to the cure of pancreatic cancer. It is well known that cancerous cells are surrounded by an extensive stroma of ECM at both primary and metastatic sites, which contains, among other proteins, fibronectin,

laminin and collagen IV. Adhesion of pancreatic cancer cells to these proteins confers resistance to apoptosis induced by standard chemotherapeutic agents. The study on small-cell lung cancer showed that β_1 -integrin-mediated cell adhesion to ECM proteins results in tyrosine phosphorylation, which, weaken persistent chemotherapy-induced DNA damage, prevents caspase activation and apoptosis^[38]. Alpha-tubulin^[39], lipocortin II and uracil DNA glycosylase^[14] were also found to be contributed to resistance to chemotherapy. These genes over-express in pancreatic cancer in our study, and may play the same role. It is indicated that the regulation routes of these genes may be potential targets for treatment of pancreatic carcinoma.

There are still some genes that should be mentioned. Prothymosin alpha (PTA) is a nuclear protein that is present throughout the cell cycle. It has been shown that it binds histones *in vitro* and has been proposed to affect the chromatin state. PTA is expressed in various human tumor tissues of different origins, supporting the idea that PTA expression is required for tumor growth. Recent study has shown that in breast cancer, whose tumor with low or moderate PTA level demonstrated a statistically significant decreased rate of tumor recurrence and a statistically significant increased overall survival in comparison with those whose tumor had high PTA levels. It is proposed that PTA could be used as a predictor of the potential malignancy of breast tumors that might help to identify patients at high risk of fatality^[23,24]. Fas-binding protein and secreted apoptosis related protein-1 (SARP-1) are proposed to repress apoptosis. SARP-1 may inhibit phosphorylation of liberated β -catenin and degradation by ubiquitin-protease system via Wnt signaling way. Subsequently, β -catenin accumulates in cytoplasm, and cell apoptosis is suppressed. SARP-1 thus promotes excessive proliferation and transformation. Fas-binding protein can arrest Fas-induced apoptosis. Thymosin beta-4 and Thymosin beta-10 are also up-regulated. These genes may serve as markers for measuring proliferation of pancreatic cancer cells.

There are two tumor suppressors, B-cell translocation gene 2 (BTG2) and programmed cell death 4 (PDCD4), which are down-regulated in cancer tissues. PDCD4 gene is homologous to the mouse gene (MA-3/Pdcd4/A7-1), which is associated with apoptosis and is shown to suppress tumor promoter-induced neoplastic transformation. The ORF of human PDCD4 encodes a protein of 458 aa with a predicted molecular size of 50.6 kDa. It has been demonstrated that PDCD4 protein inhibits neoplastic transformation and must be down-regulated for progression to occur^[40]. BTG2, which is induced by p53, displays an antiproliferative activity in different cell types, such as fibroblasts and PC12 cells. It is well known that the control of the cell cycle plays an essential role in cell growth and in the activation of important cellular processes, such as differentiation and apoptosis. pRb and p53 are two molecules identified as key regulators of the cell cycle. Some suggestions came from a recent report, which showed that BTG2 interacted with a protein-arginine N-methyltransferase (Prmt1) by positively modulating its activity. Prmt1, in turn, has been found to bind the interferon receptors and to be required for interferon-mediated growth inhibition. A further investigation on BTG2 demonstrated that this gene inhibited G₁/S progression in an Rb-dependent manner and that this effect was correlated with its ability to inhibit cyclin D₁ expression. Furthermore, the impairment in the ability of BTG2 to lower cyclin D₁ levels, seen in consequence of mutations of the BTG2 molecule, correlated with the extent of impairment in growth arrest^[41].

DNA replication is initiated at discrete sites on chromosomes through the coordinate action of a number of replication initiation factors. It is believed that a complex of proteins called

the origin recognition complex (ORC) associates with specific DNA sequences near origins of replication to recruit other replication initiation factors during the G₁ phase of the cell cycle. The other replication initiation factors, Cdc6p, Cdt1p, and the Mcm2-7p complex, associate with the origin sequence in an ORC-dependent reaction to form a pre-replicative complex (pre-RC). At the G₁-S transition, the activation of cyclin-dependent kinases leads to the recruitment of elongation factors, CDC45, DNA polymerases, and RPA to the pre-RCs at origins. The action of these replication elongation proteins leads to the initiation of DNA synthesis, the hallmark of S phase. Geminin interacts with Cdt1p and prevents the recruitment of the Mcm2-7p complex to origins during S, G₂, and early M phases of the cell cycle and thereby inhibits replication initiation, leading to the expectation that the protein acts as an inhibitor of cell proliferation^[42]. The research on these under-expressed genes may render invaluable information to find novel targets for the treatment of pancreatic cancer.

In summary, though some genes have been missed in present study, the genes we have identified may be important to the tumorigenesis of pancreatic cancer, and potential to serve as tumor markers or drug targets.

Abstract

AIM: To investigate TNF- α -308 and TNFB polymorphisms in acute biliary pancreatitis (ABP) and to related them to the plasma TNF- α levels.

METHODS: Genomic DNA was prepared from peripheral blood leukocytes. Genotypes and allele frequencies were determined in patients ($n=127$) and healthy controls ($n=102$) using restriction fragment length polymorphism analysis of polymerase chain reaction (PCR) products. Reading the size of digested bands from polyacrylamide gel demonstrated the two alleles TNF1 and TNF2, or the two alleles TNFB1 and TNFB2.

RESULTS: The frequencies of TNF2 polymorphism and TNFB2 polymorphism were both similar in patients with mild or severe pancreatitis, so were in pancreatitis patients and in controls. Patients with septic shock showed a significantly higher prevalence of the TNF2 than those without. No significant differences were found in the genotype distribution of TNF- α -308 and TNFB among different groups. Plasma TNF- α levels did not differ significantly in ASBP patients displaying different alleles of the TNF gene studied.

CONCLUSION: Results indicate that TNF gene polymorphisms studied play no part in determination of disease severity or susceptibility to acute biliary pancreatitis; however, TNF2 polymorphism is associated with septic shock from ASBP. Genetic factors are not important in determining plasma TNF- α levels in ASBP.

INTRODUCTION

In China and most other countries, gallstones are the most common cause of acute pancreatitis. There are reports that

gallstones account for between one third and two thirds of cases, with an average of 40 to 50 %^[1]. Acute severe pancreatitis (ASP) is a serious disease, with highly persistent morbidity and mortality. Generally speaking, the natural course of severe acute pancreatitis progresses in two phases. The first 14 days are characterized by the systemic inflammatory response syndrome resulting from the release of inflammatory mediators. The second stage, beginning approximately 2 weeks after the onset of the disease, is dominated by septic-related complications resulting from infection of pancreatic necrosis or bacteria translocation. Today, with improvements in the care of the critically ill, many patients with ASP survive over early systemic inflammatory response and enter a second phase of illness dominated by sepsis and the consequences of organ failure. More than two thirds of deaths in ASP are due to late septic organ complications^[2]. However, the susceptibility and mechanism of septic shock related to ASP are still unclear.

Tumor necrosis factor- α (TNF- α), the early cytokine to be released, is a principal mediator of immune responses to endotoxin. It can be produced in large amounts in several organs during ASP and is also believed to mediate pathophysiological changes^[3,4]. Systemic release of TNF- α is associated with septic shock and fatal outcome. TNF- α levels are increased in patients with ASP and septic shock and appear to correlate with clinical outcome.

Because of its short half-life, the value of TNF- α as a marker of susceptibility or severity for ASP is limited. The production and response of TNF- α are partly regulated at the transcription level, the role of polymorphisms of TNF promoter in determination inflammatory disease susceptibility or as a marker of severity has been the subject of intense research^[5]. There are many single nuclear polymorphisms within the TNF- α gene promoter. The TNF- α gene shows a polymorphism at position -308 in the promoter region. This polymorphism results in two allele forms, 1 in which a guanine defines the common allele TNF1 and 1 in which an adenosine defines the uncommon allele TNF2^[6]. The TNF2 allele has been associated with a variety of inflammatory disorders, including systemic lupus erythematosus, dermatitis herpetiformis, and celiac disease^[7]. Furthermore, TNF2 allele has been found to be a stronger transcription activator than the TNF1 allele^[8-12], resulting in higher TNF- α levels. Moreover, TNF2 polymorphism has been associated with morbidity and mortality of severe forms of cerebral malaria^[13], mucocutaneous leishmaniasis^[14], meningococcal disease^[15] and septic shock^[16].

A polymorphism is also found at position +252 located in the first intron of the TNF β gene, with a G in the TNFB1 allele and an A in the TNFB2 allele^[17]. In contrast to TNF- α , which is expressed mainly by macrophages, TNF β is expressed and released by lymphocytes. Genes encoding either cytokine are positioned next to each other within the cluster of human leukocyte antigen class III genes on chromosome 6. With respect to high homology and location in the genome, evolutionary studies suggest a common ancestor for both genes that duplicated during evolution. The TNFB1 allele has been associated with a higher TNF β response at both the mRNA and the protein levels^[17]. Furthermore, some studies have found

that the TNFB2 allele results in a higher TNF- α secretory capacity than the TNFB1 allele^[8], and higher plasma TNF- α levels^[18], whereas others could not confirm this observation.

The present study was focused on ABP. The aim was to investigate TNF- α -308 and TNFB polymorphisms in ABP patients, and to related the polymorphisms studied to plasma TNF- α levels.

MATERIALS AND METHODS

Subjects

127 consecutive patients with a first attack of unequivocal acute biliary pancreatitis (ABP) were prospectively considered from January 2001 to August 2002. The diagnosis of acute pancreatitis was based on clinical criteria, an increased -amylase activity (enzymatic colorimetric test) in serum and CT verification of pancreatitis. Etiology of acute pancreatitis was gallstones, in the presence of appropriate radiological of endoscopic retrograde cholangiopancreatography (ERCP) findings. Pancreatitis is classified as severe when APACHE II score is ≥ 8 ^[19] and CT severity index ≥ 4 ^[20]. Septic shock was defined according to ACCP/SCCM consensus conference criteria^[21]. The control Group came from 102 healthy volunteers. In order to be eligible for the enrollment, all of the subjects from the two groups had to be yellow Chinese Han. The exclusion criteria were defined as follows: (1) age > 75 years; (2) cardiac failure(class>III); (3) liver insufficiency (Child C); (4) White blood cell counts $<0.4 \times 10^9/L$; (5) immunosuppression; (6) there was a delay of more than 36 hours from onset of abdominal pain and hospitalization; (7) patients who had clinical, radiological, or ERCP evidence suggestive of a diagnosis of chronic pancreatitis. The study was approved by the local Ethics Committee and informed consent had been obtained from the patient or a close relative.

Measurement of plasma TNF- α concentrations

Peripheral venous plasma samples were collected (EDTA anticoagulation) from only ASBP patients at admission, centrifuged and stored at -70°C before analysis. Plasma TNF- α concentrations were measured by enzyme immunoassay kit (Quantikine HS Human TNF- α immunoassay kit, R & D Systems, Inc, Minneapolis, MN). The limit of sensitivity was 2.5 pg/mL.

TNF- α -308 G to A substitution

Each patient's DNA was extracted from whole blood using Wizard Genomic DNA Purification kit (Promega) according to the manufacture's instruction. PCR was used to amplify a 107 basepairs fragment of the TNF- α genomic sequence using primers. Upstream: 5' -AGGCAATAGGTTTGGAGGGCCAT3', downstream: 5' -TCCTCCCTGCTCCGATTCCG3' (Nanjing Bio Eng Co.Ltd.). The following PCR protocol was used: 94 $^\circ\text{C}$ for 3 minutes; 35 cycles of 94 $^\circ\text{C}$ for 45 seconds, 60 $^\circ\text{C}$ for 45 seconds, 72 $^\circ\text{C}$ for 45 seconds; 72 $^\circ\text{C}$ for 5 minutes using reagents purchased from Promega on a Gene CyclorTM (BIO-RAD, Japan). The PCR product was digested directly with 2 U NcoI restriction enzyme (Promega) at 37 $^\circ\text{C}$ for 6 hours. Digested DNA was analyzed on 5 % polyacrylamide gels. Ethidium bromide staining of the gel demonstrated the original 107 basepairs fragment (homozygous patients for allele TNF2, lacking NcoI site), three fragments of 102, 87 and 20 basepairs (heterozygous patients), or two fragments of 87 and 20 basepairs of size (homozygous patients for the allele TNF1), (Figure 1).

TNF- β NcoI polymorphism

A 782 basepairs fragment of the TNF- β genomic sequence, including the polymorphic NcoI site, was amplified using PCR.

The following nucleotide sequences were used for PCR amplification^[18]: 5' -CCGTGCTTCGTGCTTTGGACTA 3' and 5' -AGAGGGGTGGATGCTTGGGTTC3' (Nanjing Bio Eng Co.). The following PCR protocol was used: 95 $^\circ\text{C}$ for 3 minutes; 37 cycles of 95 $^\circ\text{C}$ for 1 minute, 50 $^\circ\text{C}$ for 1 minute, 72 $^\circ\text{C}$ for 1 minute; 72 $^\circ\text{C}$ for 5 minutes using reagents purchased from Promega on a Gene CyclorTM (BIO-RAD, Japan). The PCR product was digested directly with 2 U NcoI restriction enzyme (Promega) at 37 $^\circ\text{C}$ for 6 hours. Digested DNA was analyzed on 5 % polyacrylamide gels. Ethidium bromide staining of the gel demonstrated the original 782 basepairs fragment (homozygous patients for allele TNFB2), three fragments of 782, 586 and 196 basepairs (heterozygous patients), or two fragments of 586 and 196 basepairs of size (homozygous patients for the allele TNFB1), (Figure 2).

Figure 1 Lane1 and 4, TNF2 homozygote; Lane 2, TNF1/TNF2 heterozygote; Lane 3, TNF1 homozygote.

Figure 2 Lane 1 and 3, TNFB1/TNFB2 heterozygote; Lane 2, TNFB1 homozygote; Lane 4, TNFB2 homozygote.

Statistical analysis

Comparison of allelic and genotype frequencies was examined for statistical significance with chi-square test. Descriptive data of continuous variables were tested by Student's *t*-test. Plasma TNF- α levels were reported as median \pm SD. Analysis was completed by SPSS 10.0, and a 2-tailed $P < 0.05$ was considered statistically significant.

RESULTS

Characteristics of the patients

According to the selected criteria, 61 patients (36 females, males 25) with acute severe pancreatitis were studied. The mean age (\pm SD) was 54.6 ± 19 years. APACHE II, 11.5 ± 1 ; CT, 6 ± 1 . Of these, 18 had developed septic shock. The APACHE II score and CT score at the time of admission was similar in both septic shock and no septic shock patients. This study was

undertaken in selected patients with acute mild biliary pancreatitis (AMBP, $n=66$) as defined by APOCHE II score^[19] and CT severity index^[20], and matched with ASBP for age, sex, and cause of pancreatitis. Patients with AMBP had an uneventful recovery. The control group included 102 healthy volunteers, the mean age (\pm SD) was 44.5 ± 10 years. The distribution of gender was 59 females and 43 males.

Two polymorphisms of tumor necrosis factor gene

The frequency distribution of genotypes for TNF polymorphisms studied is shown in Table 1. There was no significant difference in the TNF-308 or TNFB genotype frequency distributions between patients with mild or severe disease. For the TNF-308 polymorphism, TNF2 was found in 18 (29.5 %) of patients with ASBP compared with 17 (25.8 %) of patients with AMBP ($\chi^2=0.223$, $P=0.636$). Likewise TNFB2 occurred in 42 (68.9 %) of patients with ASBP compared with 44 (66.7 %) of patients with AMBP ($\chi^2=0.147$, $P=0.702$).

Further there were no significant differences in the TNF-308 or TNFB genotype frequency distributions between patients with ABP and controls (Table 1). As to TNF2 frequency, it was found in 35 (27.6 %) of patients with ABP compared with 26 (25.5 %) of controls ($\chi^2=0.124$, $P=0.725$). Likewise TNFB2 occurred in 86 (67.7 %) of patients with ABP compared with 63 (61.8 %) of controls ($\chi^2=0.882$, $P=0.348$ respectively).

TNF2 was found in 9 (50 %) of ASBP patients who developed septic shock compared with 9 (20.1 %) of ASBP patients with no septic shock ($\chi^2=5.155$, $P=0.023$). However, TNFB2 occurred in 13 (72.2 %) of ASBP patients with septic shock compared with 29 (67.4 %) of ASBP patients with no septic shock ($\chi^2=0.135$, $P=0.713$), (Table 2).

Table 1 Comparison of TNF Genotype among different groups

	TNF-308			TNFB		
	G/G	G/A	A/A	1/1	1/2	2/2
ASBP	43 (70.5)	15 (24.6)	3 (4.9)	19 (31.1)	25 (41.0)	17 (27.9)
AMBP	49 (74.2)	14 (21.2)	3 (4.5)	22 (33.3)	26 (39.4)	18 (27.3)
	$\chi^2=0.040$, $P=0.980$			$\chi^2=0.197$, $P=0.906$		
ABP	92 (72.4)	29 (22.8)	6 (4.7)	41 (32.3)	51 (40.1)	35 (27.6)
Control	76 (74.5)	21 (20.6)	5 (4.9)	39 (38.2)	35 (34.3)	28 (27.5)
	$\chi^2=2.545$, $P=0.280$			$\chi^2=3.594$, $P=0.166$		

Note. Comparison by chi-square test. No significant differences were found in the distribution of each genotype frequency [no. (%)] between any of the two groups.

Table 2 Comparison of TNF2 frequency and TNFB2 frequency between septic shock group and no septic shock group

	Septic shock ($n=18$)	No septic shock ($n=43$)	P
TNF2	9 (44.4%)	9 (20.9%)	0.023
TNFB2	13 (72.2%)	29 (67.4%)	0.713

Patients with septic shock showed a significantly higher prevalence of the TNF2 than those without. No such association was seen in TNFB2.

Baseline concentrations of TNF- α at inclusion in ASBP

Plasma TNF- α levels at inclusion were detectable in all of the patients with ASBP and shown in Figure 3. At inclusion, among the 61 patients who were admitted for ASBP, 31 (50.8 %) had an increased concentration of TNF- α (normal value <20 pg/mL). There was no significant difference in baseline

concentrations of TNF- α , between ASBP patients who developed septic shock and ASBP patients who didn't.

Figure 3 Baseline concentrations of TNF- α at inclusion in ASBP complicated by septic shock or not. $P=0.643$. No significant differences were found in baseline TNF- α levels between septic shock group and no septic shock group.

Association of two polymorphisms of TNF gene with TNF- α levels

In ASBP patients, no association was found in baseline TNF- α levels between TNF2 carrier and TNF1 carrier (30.73 ± 23.05 vs 25.65 ± 22.63 , $P=0.430$), neither was found between TNFB2 carrier and TNFB1 carrier (25.53 ± 23.71 vs 30.73 ± 20.38 , $P=0.412$), (Figure 4 and Figure 5).

Figure 4 Comparison of TNF- α levels (pg/mL) in ASBP patients based on TNF2 allele. No significant difference was found in TNF- α levels between TNF2 carrier and TNF1 carrier.

Figure 5 Comparison of TNF- α levels (pg/mL) in ASBP patients based on TNFB2 allele. No significant difference was found in TNF- α levels between TNFB2 carrier and TNFB1 carrier.

DISCUSSION

In the study we have found no association between either TNF- α -308 or TNFB biallelic polymorphism and ASBP or ABP, and thus no evidence that these loci contribute to ASBP susceptibility

or severity. This was in line with previous study^[22, 23]. However, the distribution of TNF- α -308 polymorphisms within the ASBP patients varied, and TNF2 allele was found significantly more frequently in the septic shock patients than in no septic shock ones ($P < 0.05$). The association between the septic shock patients and TNF polymorphism was restricted to the TNF- α -308 polymorphism (TNF2 allele), no such association being seen with TNFB2. The finding of an apparent association between the TNF- α -308 polymorphism and the septic shock raises the possibility that genetic factors may play a role in controlling the onset of septic shock related to ASBP.

In our study an increased TNF- α value was documented in 50.8 % of ASBP patients at inclusion. This finding confirms two previous clinical studies in which TNF- α was documented in 29 % to 78 % of patients studied^[24, 25]. However, there was no significant difference in baseline TNF- α levels between patients who developed septic shock and patients who didn't. The result suggested that plasma baseline TNF- α level was of little value predicting whether septic shock would occur in ASP.

In sepsis and other diseases TNF polymorphisms have been associated with morbidity and mortality of severe forms^[13-16, 26]. The present study did not found an association in the distribution of either TNF2 allele frequency or TNFB2 allele frequency between ASBP patients and AMBP patients ($\chi^2 = 0.223$, $P = 0.636$ and $\chi^2 = 0.147$, $P = 0.702$ respectively). The results showed no correlation between the gene polymorphisms studied and disease severity. Comparison of TNF2 allele frequency or TNFB2 allele frequency in patients with ABP and in healthy controls suggested that these polymorphisms studied did not influence disease susceptibility ($\chi^2 = 0.124$, $P = 0.725$ and $\chi^2 = 0.882$, $P = 0.348$ respectively). However, significant difference was found in TNF2 allele frequencies between septic shock patients and non-septic shock patients ($\chi^2 = 5.155$, $P = 0.023$). Indeed, only in severe forms of cerebral malaria^[13], mucocutaneous leishmaniasis^[14], meningococcal disease^[15] and septic shock^[16], were morbidity and mortality linked with TNF2 allele or TNFB2 allele. In mild conditions, no such relationship was found between sepsis and the TNF2 allele^[27]. As to TNF- α -308 and TNFB genotype, there were no significant difference in the distribution of either type between ASBP patients and AMBP patients, neither was found between ABP patients and controls. It suggested that TNF- α -308 genotype and TNFB genotype were both not related to the susceptibility or severity of ABP.

Although polymorphisms may only be markers of other functionally significant gene polymorphism, at least one of the TNF gene polymorphisms studied is known to have functional significance. It seems that environmental factors trigger cytokine secretion, genetic factors may be important in determining levels of secretion^[28]. In vitro studies have identified that individuals may demonstrate consistent differences in leukocyte cytokine secretion^[29] and that these difference are probably genetically predetermined^[28]. In our study, plasma TNF- α concentrations of ASBP patients with TNF2 allele or TNFB2 allele were not significantly higher than that of patients without TNF2 allele or TNFB2 allele respectively. It suggested that there was no significant correlation between TNF- α concentration and TNF2 or TNFB2 allele carriage. However, many factors could influence plasma TNF- α concentrations. Of these, an important one is its relatively short half-life^[30], so we were at great risk of missing the intravascular secretion of this cytokine. Another reason for low plasma TNF- α concentrations may be the breakdown of TNF- α by enzyme released from pancreas into circulation^[31, 32]. Furthermore, this detectable level does not take into account the membrane-bound form of TNF- α . In addition, in complex biologic systems, the effect of a single gene polymorphism in determining cytokine production may be minimized through

the interaction of other factors^[33]. Maybe circulating TNF- α levels do not correspond with the TNF2 and TNFB2 polymorphisms, however, circulating TNF- α levels might be under a multifactoral regulatory process. Local TNF- α levels might be of greater importance and under more control by specific polymorphisms.

To the best of our knowledge, there have two different studies on the association of two polymorphisms of tumor necrosis factor gene with acute severe pancreatitis^[23, 35], and our results are in line with theirs. However, they both failed to study the association of two polymorphisms with septic shock due to ASBP. The finding of our study for the first time, to our knowledge, raise the possibility that TNF2 allele may play some role in the susceptibility of septic shock related to ASBP. However, the role, if any, of genetic factors in influencing the occurrence of septic shock awaits confirmation in further prospective studies. If the association between TNF2 allele and septic shock is confirmed, it would have implications not only for understanding of mechanisms of septic shock from ASBP, but also in the clinical management of patients, with the possibility that TNF2 carriers at high risk of septic shock may be identifiable early in the disease course, allowing early and aggressive therapy to be instituted. In addition, the study offers new opportunities for studying intervention with anti-TNF therapies. Determining a patient's TNF2 genotype before starting the treatment may permit the selection of a TNF2 group of high-risk patients who could benefit from treatment with anti-TNF. Such a possibility deserves further study, since an effective therapy for ASBP patients with septic shock would have important clinical and economic consequences.

In conclusion, our study demonstrated that there was no association between acute biliary pancreatitis and the two polymorphisms of tumor necrosis factor gene studied; however, TNF2 allele were associated with the susceptibility to septic shock related to acute severe biliary pancreatitis. Genetic factors are not important in determining plasma TNF- α levels in ASBP.

Abstract

AIM: Bioartificial liver is a hope of supporting liver functions in acute liver failure patients. Using polysulfon fibers, a new bioartificial liver was developed. The aim of this study was to show whether this bioartificial liver could support liver functions or not.

METHODS: Hepatocytes were procured from swine using Seglen's methods. The bioartificial liver was constructed by polysulfon bioreactor and more than 10^{10} hepatocytes. It was applied 14 times in 12 patients, who were divided into 7 cases of simultaneous HBAL and 5 cases of non-simultaneous HBAL. Each BAL treatment lasted 6 hours. The general condition of the patients and the biochemical indexes were studied.

RESULTS: After treatment with bioartificial liver, blood ammonia, prothrombin time and total bilirubin showed significant decrease. 2 days later, blood ammonia still showed improvement. within one month period, 1 case (1/7) in simultaneous group died while in non-simultaneous group 2 cases (2/5) died. The difference was significant. Mortality rate was 25 %.

CONCLUSION: The constructed bioartificial liver can support liver functions in acute liver failure. The simultaneous HBAL is better than non-simultaneous HBAL.

INTRODUCTION

Acute liver failure (ALF) is commonly seen in the mainland of China. The patients are always characterized by infection of hepatitis B. Liver cell damage is the main reason of ALF.

When the amount of normal cells decrease below its limit, liver function will deteriorate and a vicious cycle will be formed.

Liver transplantation (LT) has already been a wise choice for these patients^[1-3]. The 1 year survival rate could be improved to more than 70 % when LT is applied^[4,5]. But the donor is scarce, so it limits the wide practice of LT. Many patients exacerbated and died during the period of waiting donor liver.

Bioartificial liver (BAL) is designed to take the responsibility of supporting liver functions temporarily in acute liver failure^[6-9]. It consists of a semi-permeable membrane and living allogeneic or syngeneic liver cells. The flow of blood or plasma from the patient can exchange the substances with those cells through this membrane. The ammonia and other toxins in blood then are detoxified, as well as some useful factors are secreted into blood. Many scholars reported that BAL was effective and could be used as a bridge to LT^[8-10]. Also this technique gave the chance of spontaneous recovery of the native function because of liver cell regeneration in some cases^[8,11].

It is estimated that 1×10^9 hepatocytes are the lowest limit that are needed in BAL^[10]. Such large number of hepatocytes are very difficult to be cultured in a small bioreactor. Enlarging the volume of the bioreactor and adding a hepatocytes cell pool are both good methods to solve such problems.

Using a bioreactor made of polysulfon, we developed a bioartificial liver recently and applied it in 12 patients. The results were exciting.

MATERIALS AND METHODS

Animals

Healthy Chinese experimental miniature swine were purchased from the Animal Center of Beijing Agriculture University. On receipt, swine were kept in a temperature and humidity controlled environment (20-25 °C, humidity 50-70 %) in a 12/12 hour light/dark cycle and fed with a cereal based diet with free access to water. More than a week later, they were used to get the hepatocytes. 12 hours before procedure only free water *ad libitum* was allowed. The animals were treated in accordance with the guidelines established by Affiliated Drum Tower Hospital of Medical College of Nanjing University.

Hepatocytes preparation

Hepatocytes were isolated from the swine by in situ liver perfusion and enzymatic collagenase digestion according to the process described by Seglen^[12]. Briefly, under katamine (50 mg/kg) anesthesia, a median laparotomy and cannulation of the portal vein were performed. The inferior vena cava was ligated just above the renal vein and then was cannulated close to the heart. The liver was perfused at 4 °C and pH 7.6 with 3 000 ml Hanks solution through the portal vein. Then the liver was circularly perfused with 500 ml 0.5 % collagenase IV solution (Gibco, New York, USA) at a constant flow of 20 ml/minute. The softened liver was then excised and hepatocytes were separated from the connective liver tissue by gentle

agitation. The resulting cell suspension was filtered through 50 μm sterile metal mesh. The cells were washed three times, suspended in non serum RPMI 1640 culture medium (Sigma, Louis, USA) with 200 $\mu\text{g/L}$ hydrocortisone, 1 mg/L HGF, 10 $\mu\text{g/L}$ EGF, 20 $\mu\text{g/L}$ NGF, 100 $\mu\text{g/L}$ insulin, 4 $\mu\text{g/L}$ glucagon, 6.25 mg/L transferrin, 10 mg/L linoleic acid, 2 mmol glutamine, 0.5 g/L bovine serum albumin, 3nmol sodium selenate, 0.1 $\mu\text{g/L}$ $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, 50pM $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$, 15 mmol HEPES, 200 $\mu\text{g/L}$ cefepazone, $1 \times 10^5 \text{U/L}$ penicillin and 100 mg/L streptomycin. Cell viability was determined by the trypanum exclusion test. Only suspensions with cell viability of $\geq 95\%$ were used. Cells suspension was then stirring incubated overnight in that non serum RPMI 1640 culture medium at 37°C .

Configuration of bioartificial liver

Polysulfon bioreactor was purchased from TECA Corp. (Hongkong, China). The molecular cutoff of the membrane was 100 kD. Total fiber internal surface area was 1 620 cm^2 , external surface area was 2 060 cm^2 . Before use, the bioreactor was sterilized and rinsed by 3 000 ml normal saline. A hepatocytes reservoir, a rolling pump and a circulation cycle were designed to connect to the extra-fiber compartment of bioreactor. The aim was to ensure more than 10^{10} hepatocytes being used and enough nutrition could be provided. Then the cultured suspended cells were filled into the extra-fiber compartment of bioreactor. The rolling rate of the pump was 80 ml/minute.

Blood was removed from the patient through a double lumen catheter in superficial femoral vein at a rate of 100 ml/minute and run through a plasma separator. The separated plasma passed through a charcoal column or bilirubin absorption column and then run into the intra-fiber compartment of bioreactor in simultaneous HBAL, while in non-simultaneous HBAL the plasma run directly into the intra-fiber compartment of bioreactor. The reacted plasma were then reconstituted with red blood cells and returned to the patient via the venous cannula. (Figure 1).

Figure 1 The constructed bioartificial liver. CC: charcoal column. BAC: bilirubin absorption column.

Clinical use

12 patients, which include 9 male and 3 female, suffering from acute liver failure were adopted to this study. The age ranged

from 13 to 56. All the patients were found having hepatitis B infection (Table 1). Before the BAL supporting treatment, an evaluation of the patient's psychic state was conducted by a psychologist, and an agreement of BAL application was signed by the patient and/or his direct relatives.

The treatment regimen included simultaneous HBAL and non-simultaneous HBAL. The only difference was bilirubin absorption treatment or plasma exchange treatment being used 1 day before the bioreactor was applied in non-simultaneous HBAL while in simultaneous HBAL they were applied simultaneously. Other traditional treatments were all the same. Some liver function indexes and the one month mortality rate were used to evaluate the function of BAL.

Table 1 Clinical data of the patients

Patient No.	Sex	Age	Hepatitis B infection	Regimen of treatment	Number of treatment	Result
1	M	13	+	HBAL(CC)	1	Improved
2	M	38	+	1. HBAL(BAC) 2. BAL	1 1	Improved
3	F	34	+	HBAL(BAC)	1	Improved
4	M	55	+	HBAL(BAC)	1	Death
5	M	52	+	HBAL(BAC)	1	Improved
6	M	46	+	HBAL(BAC)	1	Improved
7	M	58	+	HBAL(BAC)	1	Improved
8	M	33	+	PE and BAL	1	Improved
9	F	50	+	PE and BAL	2	Death
10	F	52	+	HF and BAL	1	Death
11	M	40	+	HF and BAL	1	Improved
12	M	30	+	BAC and BAL	1	Improved

M: male, F: female, +: positive, HBAL: hybrid bioartificial liver, BAL: bioartificial liver, (CC): with charcoal column, (BAC): with bilirubin absorption column, PE and BAL: plasma exchange and 24 hours later BAL only, HF and BAL: hemofiltration and 24 hours later BAL only, BAC and BAL: bilirubin absorption and 24 hours later BAL only.

Statistical analysis

Mortality rate was expressed as percentage. Others were expressed as mean \pm SD. Paired T test was used (SPSS software, SPSS Inc. USA). Probability of less than 0.05 was accepted as significant.

RESULTS

In 12 patients, 14 times BAL treatments were conducted. The period of one BAL treatment lasted 6 hours. All patients experienced the procedure successfully.

3 patients died soon after the procedure and 9 were improved. The mortality rate was 25%. The criteria of improvement included improvement of general condition of the patient, persistent hepatic function improvement, improved psychic state, and recovery.

In biochemical test, ALT showed slight decrease in post-treatment period and restored to pre-treatment level 2 days later. No change in blood albumin. Blood ammonia, prothrombin time and total bilirubin indexes showed significant decrease after treatment. 2 days later, only blood ammonia still maintained significant low level (Figure 2).

In non-simultaneous HBAL, the mortality rate was 40%. While in simultaneous HBAL, the mortality rate was 14.3%. Significant difference was found comparing them (Figure 3).

Figure 2 Change of ALT, ammonia, prothrombin time, albumin and total bilirubin index in 12 patients. Compared with pre-, ammonia, prothrombin time and total bilirubin index showed significant decrease in post-. 2 days later, only ammonia showed significant lowering. pre-: pre-treatment, post-: post-treatment, 2d later: 2 days after the treatment. Paired T test was used to test the difference.

Figure 3 The mortality rate of simultaneous HBAL and non-simultaneous HBAL. Significant difference was found between this two groups ($P < 0.05$).

Typical case report: A male, aged 38 years old, was admitted for “fatigue and yellow urine for a week”. Physical examination showed yellowish face, moderate jaundice in skin and sclera, palpable liver that was 2 cm below the costal arch in right mid-clavicular line, and tenderness in right upper abdomen. Laboratory examination showed positive HBs antibody, Hbe antibody and HBc antibody, abnormal liver function. B type ultrasound examination showed image of liver injury. The diagnosis was severe acute hepatitis with hepatitis B virus infection. After admission, the patient was given conventional treatment without any improvement and ran downhill. One week later, He received a simultaneous HBAL (bilirubin absorption) treatment. Total bilirubin and prothrombin time decreased immediately. 6 days later he received another HBAL treatment because of worsening some biochemical indexes. 2 weeks after that the patient was recovered and was waiting for liver transplantation. (Table 2).

Table 2 Change of some biochemical index after the HBAL treatment

Time	ALT (U/L)	GOT (U/L)	TBI (μmol/L)	DBI (μmol/L)	TP (g/L)	ALB (g/L)	PT (s)
Admission	77.5	58.8	341.8	265.4	60.1	32.8	68.8
2 hours later	58.7	52.5	343.0	255.2	52.4	31.9	32.2
HBAL 4 hours later	66.3	69.5	345.7	280.4	52.9	31.4	40.9
(BA) 6 hours later	68.7	79.9	260.8	291.6	54.5	31.4	26.7
2 days later	80.6	68.0	423.2	336.0	70.4	37.1	20.2
Before HBAL	421.2	371.9	375.4	109.0	44.6	27.4	21.9
2 hours later	427.9	412.0	389.0	102.1	42.7	26.5	28.5
HBAL 4 hours later	431.8	411.4	373.9	99.5	43.0	26.7	28.7
6 hours later	371.0	218.0	339.8	122.1	45.6	28.8	17.4
2 days later	301.2	159.6	444.6	125.7	43.6	26.5	28.7

HBAL: hybrid bioartificial liver; BA: bilirubin absorption.

DISCUSSION

ALF is a severe disease in clinical practice with a mortality rate of 30-80 %^[1-5]. OLT is thought to be the most effective method to improve the prognosis. But it is greatly limited due to shortage of donor liver^[3,4]. HBAL is designed to take responsibility of improving the poor physical state of the patients and supporting liver function for a short time which may serve as a bridge to OLT^[6-11].

The ideal HBAL should support the patients to pass through the worst period of the course by its metabolic, synthetic, toxin and drug degradational functions. When it works, immune reactions to the living cells may be avoided^[13,14], while toxins and some useful factors might be capable to pass the membrane freely.

Construction of HBAL

The external BAL is being studied in many medical centers. Living hepatocytes are first needed in this apparatus. Human hepatocytes are the ideal choice. But the only available human livers are all used for liver transplantation. Human cell strains from some liver neoplasmas were also reported. But the danger of this application is unknown. Porcine hepatocytes are the commonest choice of many centers, because pigs are cheap and easy to get, without any ethical contradictions of killing them.

When the liver cells are procured, the membranes might be damaged by the enzymes or the mechanical factors^[15]. The damaged membrane needs 1 to 3 days for recovery^[16]. Our experience shows 1 day stirring culture of the procured hepatocytes is enough.

Enough viable hepatocytes are also important in BAL. It was estimated that 1×10^9 hepatocytes are the lowest limit^[10]. Such a large number of hepatocytes are very difficult to live and maintain its function in a small bioreactor, through which hepatocytes may exchange substance with blood. If the volume of bioreactor is enlarged greatly, hemodynamics of the patient may be disturbed. We designed a two cycles bioreactor. The first cycle was to supply the nutrition and the other one was to connect to a cell reservoir which ensured 10^{10} cells were used in this system.

The toxins in blood are sometimes harmful to living hepatocytes. To decrease this effect, mechanical filtration or absorption is used in this system. Due to long period of time to construct the system and urgent situation of the patient requiring this treatment, we designed a non-simultaneous HBAL, that used mechanical filtration or carbon absorption or bilirubin absorption or plasma exchange first, then BAL was applied the next day. The results were not satisfactory. The mortality rate was higher than the simultaneous HBAL.

Effects of HBAL

The material of the bioreactor and the characters of it are most important. Polysulfon was chosen because of its good histocompatibility with body and little toxicity. In dialysis medicine the polysulfon is already widely used as dialyzer. The molecular cut-off is another important index for the bioartificial liver. If it is large enough, cells in it may not be protected completely. Otherwise the toxins cannot be detoxified and useful factors secreted by hepatocytes cannot enter the body. The molecular cut-off we choosed was 100 kD because IgG is about 150 kD and albumin or hepatic growth factor is about 70-80 kD.

Our experiments showed that BAL could function well when applied to the patients. The ammonia, prothrombin time and total bilirubin showed significant decrease in post-treatment examination. ALT also showed a slight decrease in post-treatment study, although no significant difference was found.

Also HBAL showed a delayed reaction, 2 days after application as ammonia still showed significant decrease. We considered that this function might be due to the synthetic function of HBAL.

Abstract

AIM: To investigate and compare frequencies of serum positive cagA in patients from two separate regions of Turkey who were grouped according to the presence of peptic ulcer disease or non-ulcer dyspepsia.

METHODS: One hundred and eighty *Helicobacter pylori*-positive patients with peptic ulcer disease or non-ulcer dyspepsia were included in the study. One hundred and fourteen patients had non-ulcer dyspepsia and 66 had peptic ulcer disease (32 with gastric ulcers and/or erosions and 34 with duodenal ulcers). Each patient was tested for serum antibody to *H. pylori* cagA protein by enzyme immunoassay.

RESULTS: The total frequency of serum positive cagA in the study group was 97.2 %. The rates in the patients with peptic ulcers and in those with non-ulcer dyspepsia were 100 % and 95.6 %, respectively. These results were similar to those reported in Asian studies, but higher than those that have been noted in other studies from Turkey and Western countries.

CONCLUSION: The high rates of serum positive cagA in these patients with peptic ulcer disease and non-ulcer dyspepsia were similar to results reported in Asia. The fact that there was high serum prevalence regardless of ulcer status suggests that factors other than cagA might be responsible for ulceration or other types of severe pathology in *H. pylori*-positive individuals.

<http://www.wjgnet.com/1007-9327/9/833.htm>

INTRODUCTION

Helicobacter pylori (*H. pylori*) infection is very common, especially in developing countries; however, patients with this

infection rarely develop clinically significant conditions, such as peptic ulcer disease. This situation has prompted researchers to investigate the possible roles of host and environmental factors, and factors related to the bacterium itself in cases that show severe pathologies^[1-3]. Earlier works identified associations between *H. pylori* strains that harbor cytotoxin-associated gene A (cagA) and significant gastroduodenal pathology; however, the results of more recent studies are conflicting. In Europe, investigators have reported a significantly higher seroprevalence of cagA antigen in gastroduodenal ulcer cases than that in non-ulcer dyspepsia cases^[4,5]. In contrast, most studies from Asian countries have noted that there was no significant difference between these patient groups with respect to anti-cagA antibody positivity^[5-7]. Interpretation of these findings has been further complicated by reports from Japan and China. Some of these results differ from those of other Asian studies, and are in line with findings in Western countries^[8,9].

Turkey is geographically situated between two continents that are reported to have different cagA seroprevalence rates. Our aim in this study was to compare the frequencies of serum positive cagA in Turkish patients with peptic ulcer disease and those with non-ulcer dyspepsia.

MATERIALS AND METHODS

General data of patients

The study included 180 patients (79 males and 101 females; mean age 43.4±11.2 years old) with dyspepsia who were confirmed *H. pylori*-positive by rapid urease testing. The patients came from two Baskent University medical centers in two different Turkish cities. Ninety-nine were from the southern city of Adana, and 81 were from Ankara in central Turkey. Individuals who met at least one of the following criterias were excluded from the study: history of *H. pylori* eradication treatment; anti-secretory and/or non-steroidal anti-inflammatory drug therapy in the 4 weeks prior to the study; chronic organ failure (chronic renal, pulmonary, or liver disease); chronic alcohol intake and cigarette smoking.

Methods

Gastric specimens from the antrum and corpus of each patient from the Adana Hospital were examined with hematoxylin/eosin and Giemsa stains. For each specimen, chronic inflammation, neutrophil activity, and *H. pylori* density were scored separately, according to the updated Sydney system: 0=normal, 1=mild, 2=moderate, and 3=severe^[10]. We modified the four-point scale for histological scoring slightly in order to facilitate statistical analysis. Scores of 0-1 were categorized together as "low score" and scores of 2-3 were categorized together as "high score." The same pathologist examined all the histological sections.

Three groups were divided according to the patients' endoscopic findings: a non-ulcer dyspepsia (NUD) group ($n=114$); a duodenal ulcer (DU) group ($n=34$); and a gastric ulcer and/or erosion (GU/E) group ($n=32$).

Enzyme immunoassay (Equipar Diagnostici, Rome, Italy) was used to test for the presence of serum IgG and IgA

antibodies to *H. pylori* cagA protein. Since there is no international standard for IgG levels, this was quantitated by means of a standard curve calibrated in arbitrary units per milliliter (Uarb/mL). Serum levels above 5 Uarb/mL were considered to indicate positivity.

Statistical analysis

The unpaired Student's *T*-test and the χ^2 test were used to analyze the data, as appropriate. It was considered to be statistical significant when $P < 0.05$.

RESULTS

Of the 180 patients, 175 (97.2 %) were cagA (+). The rate serum positive cagA in the NUD group was 95.6 %, and they were 100 % in both DU and GU/E groups. The overall rate in each hospital and the group rates in each center were shown in Table 1. The NUD, DU, and GU/E groups had similar mean serum levels of IgG-type cagA antibodies (45.2 ± 40.3 Uarb/mL, 54.3 ± 42.4 Uarb/mL, and 51.2 ± 41.3 Uarb/mL, respectively; $P > 0.05$).

Table 1 The rates of serum positive cagA overall and according to endoscopic diagnosis in the patients from the two different centers

	cagA+		<i>P</i>
	Adana hospital <i>n</i> (%)	Ankara hospital <i>n</i> (%)	
Total patients	98/99 (98.9)	77/81 (95.1)	NS
NUD patients	73/74 (98.6)	36/40 (90.0)	NS
GU/E patients	12/12 (100)	20/20 (100)	NS
DU patients	13/13 (100)	21/21 (100)	NS

Denotes: NUD: Non-ulcer dyspepsia; DU: Duodenal ulcer; GU/erosion: Gastric ulcer and/or erosions.

Figure 1 The percentages of patients with high scores (moderate or severe findings) for inflammation, neutrophil activity, and *H. pylori* density in the antrum and corpus. (NUD: Non-ulcer dyspepsia; DU: Duodenal ulcer; GU/erosion: Gastric ulcer and/or erosions).

In each group, the percentages of patients with high scores for each histologic parameter were calculated. Separate calculations were made for the antrum and the corpus specimens. The results were then compared to demonstrate whether there was any difference among gastroduodenal pathologies (NUD, DU, and GU/E) with respect to severity of gastritis and *H. pylori* density in each stomach region (Figure 1). In the antrum, there were no significant differences in the group rates for chronic inflammation, neutrophil activity, and *H. pylori* density ($P > 0.05$), and all three groups had very high frequencies of high scores for chronic inflammation and *H. pylori* density. Analysis of the corpus findings showed that the DU group had a lower percentage of patients with high inflammation scores than those in the other two groups ($P < 0.05$). Also, the GU/E group had a higher percentage of patients with high *H. pylori* density scores than those in the other two groups ($P < 0.05$).

DISCUSSION

Many studies have suggested that cagA+ strains of *H. pylori* are associated with severe gastrointestinal lesions, such as severe gastritis, peptic ulcer disease, and gastric cancer^[11-13]. In infected patients, the cagA protein is translocated into epithelial cells and induces structural changes in these cells^[14,15]. A number of investigations have shown that infection with these strains leads to increased secretion of interleukin-8, which plays a pivotal role in the inflammatory response^[16,17]. Despite these findings and observations, recent studies of the frequency of cagA+ *H. pylori* strains in patients with NUD have suggested that factors other than cagA may contribute to severe gastrointestinal pathologies^[5-7].

Studies of patients with and without peptic ulcer disease in different countries, and in different regions within countries, have revealed wide variations in cagA serum prevalence in these two groups. This variation is evident if we compared the data from our study group overall (180 *H. pylori*-positive patients from health centers in central and southern Turkey) and a previously published study of patients from western Turkey^[18]. The latter report showed that the rate of serum positive cagA was significantly higher in peptic ulcer patients than that in NUD patients, whereas our results showed higher but similar rates when our patients were categorized in these two groups. When we analyzed our data of patients categorized according to hospital/city origin (Table 1), the overall rates of serum positive cagA were similar, and the corresponding rates were similar when the patients were divided into NUD, GU/E, and DU groups. These observations supported the suggestion that cagA should not be considered a universal marker for the prediction of severe gastrointestinal pathology. The reasons for, and the clinical aspects associated with this variation in serum positive cagA are not clear. Two possible reasons for the discrepancy among studies even from same country are the possible differences between commercial kits in the detection of cagA antibody in the sera of patients and variation in the prevalence of serum positive cagA strains even in areas showing geographical proximity.

In our study, we were unable to compare the severity of gastritis and *H. pylori* density in patients with cagA(+) and cagA(-) strains because almost all of the 180 patients tested positive for cagA antibodies, regardless of the endoscopic diagnosis. We performed an indirect analysis in attempt to determine whether cagA+ *H. pylori* strains were associated with severe gastritis. For this, we focused only on individuals with high histological scores, and determined the percentage of patients in each group that had high scores for chronic inflammation, neutrophil activity, and *H. pylori* density, respectively. The NUD, GU/E, and DU groups all had very high frequencies of high inflammation scores in the antrum.

However, in the corpus, the DU group had a significantly lower frequency of high inflammation scores than the other two groups. These findings suggested that cagA may have some impact on the severity of gastritis, but not on duodenal ulcer development. Previous work has shown a negative correlation between severe corpus gastritis and the presence of DU, most likely due to changes in the pattern of gastric acid secretion^[19,20]. Our findings were in line with this reported relationship.

Figura *et al* reported that most patients with NUD have both cagA(+) and cagA(-) strains of *H. pylori* simultaneously, and suggested that a particular pathological finding may be determined by the dominant strain that colonizes a particular gastric area^[21]. This may explain the conflicting results of different studies concerning the serum prevalence of cagA in NUD patients. According to this concept, a patient with anti-cagA antibody in his or her serum may clinically show NUD if the majority of the *H. pylori* organisms in the gastric mucosa are cagA(-).

There is also another possible explanation for why some patients with cagA(+) strains develop milder upper gastrointestinal pathology than those who show more severe pathology but have the same bacterial strain. The reason may be variations in genetic make-up, as a number of different cagPaI genes are required for the cagA protein to be able to enter epithelial cells. Investigation has shown that inactivation of some of these genes abolishes cagA delivery and phosphorylation^[14,22].

In conclusion, our findings reveal that the rates of cagA serum prevalence are high and similar in *H. pylori*-positive patients from two Turkish cities that are approximately half thousand of kilometers apart. These rates indicate that cagA serum prevalence in the Turkish population is close to the rates reported in Asian countries. The fact that we observed similar frequencies of cagA(+) *H. pylori* strains in all our dyspeptic patients, regardless of ulcer status, suggests that factors other than cagA may contribute to severe gastrointestinal pathology in patients with *H. pylori*.

Abstract

AIM: To explore the pathophysiologic basis for the fact that patients with digestive tract symptoms do not necessarily have gastric mucosal pathology and those without clinical symptoms do not necessarily have no gastric mucosal pathology.

METHODS: The ultrastructure, trace elements, cAMP, DNA, SOD and LPO in the gastric mucosa and its epithelial cells of 188 patients without organic lesions of heart, lung, liver, gallbladder, pancreas, kidney or intestine and basically histopathological normal persons (F) were detected synchronously by SEM, TEM, EDAX, Image analysis system RIA and ^3H -TdR Lymphocyte Transfer Test.

RESULTS: The content of Zn, Cu, cAMP and ^3H -TdR LCT in gastric mucosa and the content of Zn, Cu, DNA and LPO in gastric mucosa epithelial nuclei of each group were shown as follows: Normal control (4.1 ± 1.0 , 5.2 ± 0.8 , 15.9 ± 1.5 , 1079.7 ± 227.4 , 7.6 ± 0.4 , 58.4 ± 0.3 , 12.6 ± 2.7 , 2.6 ± 0.6); CSG without symptoms group (3.7 ± 1.2 , 5.1 ± 1.8 , 15.6 ± 0.9 , 924.5 ± 234.9 , 7.8 ± 0.3 , 58.6 ± 0.4 , 13.0 ± 3.1 , 2.9 ± 0.4); CAG without symptoms group (3.3 ± 1.0 , 4.8 ± 0.9 , 14.9 ± 0.7 , 887.7 ± 243.6 , 7.8 ± 0.3 , 58.7 ± 0.3 , 14.3 ± 2.8 , 3.1 ± 0.4); F type with symptoms group (3.5 ± 1.4 , 4.5 ± 1.0 , 15.7 ± 1.4 , 932.1 ± 244.9 , 7.9 ± 0.4 , 58.7 ± 0.5 , 13.5 ± 4.6 , 2.9 ± 0.7); CSG with symptoms group (2.8 ± 1.9 , 4.0 ± 1.5 , 14.2 ± 1.8 , 867.3 ± 240.5 , 8.1 ± 0.5 , 58.9 ± 0.5 , 15.2 ± 3.2 , 4.2 ± 0.7); CAG with symptoms group (2.0 ± 1.8 , 3.4 ± 1.5 , 13.4 ± 1.8 , 800.9 ± 221.8 , 8.6 ± 0.4 , 59.3 ± 0.5 , 16.5 ± 3.1 , 4.5 ± 0.6). The contents of Zn, Cu in mitochondria and SOD in gastric mucosa of each group were shown as follows: Normal control group (9.2 ± 0.5 , 58.3 ± 0.3 , 170.5 ± 6.1), CSG without symptoms group (8.9 ± 0.5 , 58.2 ± 0.3 , 167.2 ± 5.3), CAG without symptoms group (8.8 ± 0.4 , 57.5 ± 0.2 , 166.1 ± 4.2); F type with symptoms group (8.9 ± 0.5 , 58.0 ± 0.3 , 167.9 ± 5.7), CSG with symptoms group (8.6 ± 0.5 , 57.8 ± 0.3 , 163.3 ± 5.6); CAG with symptoms group (8.3 ± 0.4 , 57.5 ± 0.3 , 161.2 ± 4.3). There were significant differences in these cases, $P<0.05-0.001$. There were synchronous changes of gastric mucosa epithelial cellular ultrastructure. The "background lesions" (focal atrophic gastritis, focal intestinal metaplasia, micro-ulcer) in nonfocal gastric mucosa of all groups had significant differences ($P<0.05-0.001$).

CONCLUSION: Disease with symptoms, disease without symptoms, nondisease with symptoms occur on the basis

of the quantitative changes of gastric mucosa epithelial cellular ultrastructure and related bioactive substances.

INTRODUCTION

After undergoing gastroscopy with mucosal biopsy, patients with digestive tract symptoms and volunteer blood donors without any clinical symptoms were found to be of two types: those with gastric mucosa pathological changes, and others without evident pathology. In order to explore the pathophysiological basis, we detected synchronously the epithelial cell ultrastructure, trace element, cAMP, DNA, gastric mucosa SOD, serum LPO and ^3H -TdRLCT by means of histopathology, SEM, TEM with EDAX, image analysis technique, RIA and chemiluminescence method. The results were reported as follows.

MATERIALS AND METHODS

Materials

188 patients with digestive tract symptoms, had been ruled out from organic lesions of heart, lung, liver, gallbladder, pancreas, kidney or intestine by physical examination, fluoroscopy of chest, GI x-ray examination, type ultrasonography, blood biochemistry, gastroscopy with histopathological examination. According to diagnostic criteria of "the standards for the classification of chronic gastritis, gastroscopy atrophic gastritis", 68 cases were diagnosed as CSG (43 males, 25 females, average age 43, average course of disease 4a); 64 cases as CAG (37 males, 27 females, average age 47, average course of disease 6a.); 56 cases as having basically normal gastric mucosa (F group) (22 males, 34 females, average age 39, average course of disease 2a). Among 42 volunteer blood donors without any clinical symptoms, through gastroscopy and histopathological biopsy, 18 cases were diagnosed as CSG (13 males, 5 females, average age 39), 9 cases as CAG (7 males, 2 females, average age 41); 15 cases as having basically normal gastric mucosa (6 males, 9 females, average age 37) thus also referred to as normal control group (NC group).

Methods

During gastroscopy, three pieces of gastric mucosa were taken from the focal, nonfocal areas of antral region of stomach and body of stomach for histopathological examination, SEM, TEM, the determination of cAMP and SOD. Blood specimens were taken to determine LPO and ^3H -TdRLCT. For the study of gastric mucosa ultrastructure and determination of its trace elements, 501B SEM with 9100/60 EDAX were used taking three pieces of specimens from each patient and determine the weight percentage (WT%)^[1-4] of each element between the elements of gastric mucosa. Radioimmuno-assay was adopted

to detect gastric mucosa cAMP content (pmol/g)^[5], blood ³H-TdRLCT (Bq/L)^[5]. For the observation of gastric mucosa epithelial cellular ultrastructure and the determination of its trace elements, EM 430 TEM with 9100/60 EDAX^[1-4] were used. The three pieces of mucosa specimens of every patient were magnified in unison by five magnifying powers (3 600, 7 200, 14 000, 19 000, 29 000) to randomly take pictures of the panoramagram, local area and organelle and to determine the atomic number percentage (AT %) of each nuclear and mitochondrial element between the trace elements. 50 nuclei and 50 mitochondria of each patient were determined, with average WT% of each element taken as its actual WT%. For the determination of DNA in gastric mucosa epithelial nuclei, IBAS 2000 image analysis technique was used to determine IOD with gastric mucosa cell smear after Feulgen staining, taken as the relative content of nuclear DNA^[4]. Chemiluminescence method was adopted to determine the activity of SOD (u/g) in gastric mucosa^[5]. Thiobarbituric acid development process was adopted to determine serum LPO (umol/L)^[5].

Statistical method

χ^2 and *t* test.

RESULTS

Histopathological changes of gastric mucosa

In NC group and F group, there were extremely small number of mononuclear cells and lymphocytes in lamina propria of gastric mucosa, there was no abnormality in gastric gland. Therefore their gastric mucosa were defined as relatively normal. In CG gastric mucosa, in there were various degrees of infiltration of lymphocyte, plasmocyte, eosinophil and neutrophil in lamina propria, there were various degrees of degeneration necrosis, erosion and atrophy in mucosa epithelial cells. Glands decreased due to destruction and some glands had cystic dilatation. As for the inflammatory cell infiltration degree in gastric mucosa and the decrease degree of original glands (<1/3 low-grade, >1/3 <2/3 middle-degree, >2/3 heavy-grade). There was greater significant difference in CSG without symptom (CSG-woS) group, CAG without symptom (CAG-woS) group, CSG with symptom (CSG-wS) group. CAG with symptom (CAG-wS) group than in HC group and F group ($P<0.05-0.001$). There was significant difference between the first four groups ($P<0.05-0.001$, Table 1).

Ultrastructure of gastric mucosa

The relatively normal gastric mucosa had clear surface, which was divided by crisscross small groves into many lesser gastric areas, assuming convolution shape, in which there were many gastric pits (the mouths of gastric glands). The gastric pits were shaped like craters and their concave walls had round or oval epithelial cells of almost the same size (Figure 1). When magnified, the surfaces of cells were found to be rough and uneven, with short and thin microvilli as well as many semicircular cumuli, several micro processus and small fossae. The fossae were marks left by cumuli after rupture and excretion of mucus. The crater periphery projections were shaped like dykes. The gastric antrum mucosa were rough, apparently folded, the small craters were mostly groves of different lengths with deep bottoms. In low power observation, as far as gastric mucosa of chronic gastritis was concerned, the crisscross groves of the focal mucosa are shallow, the convolution structures were smooth and even, craters were deformed and of different sizes at different heights and ill-distributed; the dykes form projections that are undulating, of different width (Figure 2).

In high power observation, the focal gastric mucosa had scattering denatured, diabrotic and necrotic exfoliated epithelial cells, on it's surfaces S-shape helicobacter pylori were found (Figure 3). Massive epithelial cells were diabrotic, anabrotic and exfoliated forming micro ulcers. The ulcers spread from their centers, with adjacent cells crushed and destructed, in irregular shapes and arrangement. The epithelial cells of the crater walls were atrophic and denatured of different sizes and derangement (Figure 5), and the cells became diabrotic and necrotic and had inflammatory cell infiltration (Figure 6). The glands propria of the serious cases were shaped like grid framework structure (Figure 7). The surfaces of the epithelial cells of IM gastric mucosa were covered with a thick coating, villi were invisible, and the intercellular boundaries were not clear (Figure 8). The hollowed crateriform cells were round or polygon cavities, with ejected mucus at mouths scattering like tiny white dots. In nonfocal gastric mucosa, focal atrophic inflammatory changes, IM cell population, micro ulcers and helicobacter pylori (can be found also), they were generally referred to as "background lesion".

Comparing CSG-woS group, CAG-woS group, CSG-wS group and CAG-wS group, there were significant differences in background lesion of nonfocal gastric antrum mucosa ($P<0.05-0.001$). The incidence rate of background lesion of nonfocal gastric mucosa is especially high in CAG-wS group (Table 2).

The ultrastructure of gastric mucosa epithelial cells

The mucous cells on epithelial cell surface of relatively normal gastric mucosa were columnar epithelial cells covering endogastric surfaces and inside wall of gastric pits. Their free surfaces had short microvilli and nuclei were relatively big, at the bottoms of the cells. In cytoplasm were mucous granules of various sizes, a great deal of RERs and scattered mitochondria. The mucous neck cells were distributed over the necks of gastric glands, round or crescent shape. In the upper part of cytoplasmic nuclei, there were a great deal of secretory granules, developed Golgi's bodies, a few RERs and scattered mitochondria. On the tops of cells were a few short thick micro villi. Chief cells were distributed over the bodies and bottoms of gastric glands and their nuclei were round. In cytoplasm there are many parallel RERs, a great deal of secretory granules, well-developed Golgi's bodies and scattered mitochondria (Figure 9). The parietal cells were big and conic in shape and their conical tops turned towards gland cavities. The nuclei were in the centers of the cells. The cytosols are filled with vesicular smooth RERs (secreting hydrochloric acid), intracellular canaliculi (conveying hydrochloric acid) and many mitochondria. The endocrine cells lay between chief cells and parietal cells. They were small and their nuclei are round, at the bottoms of cellular matrixes. In cytoplasm, there are great deal of spherical endocrine granules, RERs, and a few mitochondria, Golgi's bodies lie nearby nuclei (Figure 10). The normal gastric mucosa epithelial cell nuclei were round or oval; the nuclei envelopes are slightly bending; lobulated nuclei were few; the nucleocytoplasmic ratio was less than 1; the nuclei chromatin were scattered, associated with nucleoli or distributed around the nuclei. The light bright zones between heterochromatin in the nucleoli were euchromatin; the nucleoli had high electron density without capsules (Figure 11). The normal epithelial cell mitochondria of gastric mucosa were round or oval, scattered around nuclei. The mitochondria consist of outer membrane, inner membrane, outer ventricle, inner ventricle and cristae. Crista, the inward folded inner membrane, was a hollow canal leading to outer ventricle. Some mitochondrial cristae lead directly to

cytoplasm. Cristas were generally in tabular arrangement, parallel to each other and vertical to mitochondrial long axes (Figure 12). The free surfaces of epithelial cells of CG gastric mucosa have dropped off micro villi. The intercellular space expands and cell junctions decrease; mitochondria decrease, become swollen or cristae break and had vacuolar degeneration (Figure 13). RERs dilate and were in circular arrangement. The Golgi's bodies became atrophic and had lost their typical structures; the cytoplasmic secretory granules decreased; nuclei expand or shrink; parietal cell intracytoplasmic canaliculi dilate and micro villi become short and thin or even disappear. The karyoplasmic ratio of the cells with undifferentiated nuclei and IM cells of CG gastric mucosa epithelial cells were greater than 1 and there is increase in nuclear lobulation (Figure 14), interchromatic granules, perichromatic granular density and euchromatins. The nucleoli were hypertrophic and lie close to nuclear margins (referred to as nucleolar margination). The obsolescent epithelial nuclei shrink and the nucleocyto-plasmic ratio was still less. The heterochromatins lie densely around nuclei; the electron density was low in the center of nuclei and nuclei were loop in shape (referred to as chromatic margination) (Figure 15). The shrunk nuclei were denticular, in which the electron density was moderately homogeneous and chromatin were not found (referred to as chromatic homogenization). As for the above changes, there was significant difference between NC group, CSG-woS group, CAG-woS group, F-wS group, CSG-wS group and CAG-wS group ($P<0.05-0.001$, Table 3). There were mitochondrial swelling, hypertrophy, pyknosis, hyaline degeneration as well as vacuolar degeneration in epithelial cells of CG gastric mucosa.

Deformed mitochondria were in C-shape or U-shape. There were zigzag, longitudinal, sparse, pyknosis and deranged cristae (Figure 16). There was an decrease in the number of mitochondria and their cristae. In the above changes, there is significant difference between NC group, CSG-woS group, CAG-woS group, F-wS group, CSG-wS group and CAG-wS group ($P<0.05-0.001$, Table 4).

Gastric mucosa trace elements, cAMP, SOD and blood ^3H -TdRLCT

Under the direct vision of SEM with EDAX probe that automatically detected the samples within 0.1-0.01 mm² range all the elements under 12 in atomic number and automatically calculates the weight percentage (WT%) of each element in the element series. 15 points were fixed in the three pieces of mucosa from every patient to carry out 15 detections and in every detection, 21 elements were detected to get their respective average WT% as its actual WT%. Zn and Cu were taken as index. The gastric mucosa Zn, Cu, cAMP, SOD and ^3H -TdRLCT decrease progressively in the sequence of NC group, CSG-woS group, CAG-woS group, F-wS group, CSG-wS group and CAG-wS group ($P<0.05-0.001$, Table 5).

Biochemical changes in gastric mucosa and blood serum

The quantity of nuclei DNA, Zn, Cu and serum LPO increased progressively in the sequence of NC group, CSG-woS group, CAG-woS group, F-wS group, CSG-wS group, CAG-wS group. While mitochondrial Zn, Cu, decreased progressively in the same sequence and there were significant differences between these groups ($P<0.05-0.001$, Table 6).

DISCUSSION

Compared with NC group, 188 patients with digestive tract symptoms without other organic disease and 27 patients without any clinical symptoms have a tendency of decreasing of quality in the submicrostructure of gastric mucosa epithelial cells -mitochondria. The incidence rate of karyoplasmic ratio > 1, nuclear lobulation, chromatin peripheral granule densification, hypertrophy of nucleoli, mitochondrial degeneration, and quantitative changes of nucleolar DNA, Zn, Cu and LPO increased progressively in the sequence of NC group, CSG-woS group, CAG-woS group, F-wS group, CSG-wS group and CAG-wS group. While gastric mucosa Zn, Cu, cAMP, SOD and mitochondrial Zn, Cu and the number of mitochondria and crista decreased progressively in the same sequence.

When gastric mucosa is damaged by noxious substances or ischemia, the metabolism of Zn, Cu becomes disordered with the body and thus enzyme system is disturbed. In human body, Zn is the important component and activator of over a hundred varieties of enzymes such as carbonic anhydrase, DNA polymerase, peptase, phosphatase, peroxide dismutase etc. By regulating the activity of these enzymes, it participates and regulates the metabolism of sugars, lipids, proteins, nuclei acid and vitamins, contends for mercaptan to inhibit free radical reaction. Cu participates the composition of over 30 kinds of proteins and enzymes in the body, regulates the protein metabolism and influences cellular respiration and division. When the level of Zn and Cu in the body declines, the synthesis and activity of SOD will be inhibited. Because of NADPH oxidation reduction circulation and the catalytic function of xanthine oxidase, a great deal of oxygen free radicals will be produced, far beyond the clearing ability of SOD. The excessive accumulated oxygen free radicals react in peroxidation with unsaturated fatty acid of inner and outer mitochondrial membranes and produce LPO, therefore serum LPO level will rise. The inner and outer mitochondrial membranes will accordingly be damaged, resulting in the decrease and derangement of mitochondrial cristae, the change of the ratio of mitochondrial ventricle diameter to cavity diameter and eventually the retrograde affection, the decrease of ATP production, inadequate energy supply, which in turn cause debility, structural atrophy, decrease of gastric acid secretion and even cytonecrosis. The participation of Zn and Cu dependence enzymes is essential in nuclear protein synthetic metabolism (including DNA duplication) and mitochondrial energy metabolism. When nuclear took in more Zn and Cu, the protein synthesis was brisk, nuclei division and hyperplasia were accelerated, which increased the chance of gene mutation. As the second messenger substance, cAMP regulate some vital activities in the body. Once the quantity of cyclic nucleoside phosphate in nuclei changes abnormally, pathological state will occur. The quantitative changes of cAMP result in the changes of cellular metabolism, immunity and vegetative functions. The decrease of cyclic nucleoside phosphate, especially cAMP in the body results in the inhibition of sympathetic nerve (including purinergic nerve) function, and relative hyperfunction of parasympathetic nerve function. As a result, digestive tract symptoms occur such as abdominal distention, loose stool, involuntary drooling, poor appetite, pale enlarged tongue with tooth marks. Through influencing lymphocyte metabolism, the quantitative changes of Zn and cAMP in turn influence cell respiration, differentiation and inhibit lymphocyte transformation^[4,6-13] and cause decline of ³H-TdRLCT level. As a result: (1) When gastric mucosa Zn, Cu and blood ³H-TdRLCT are nearly equal to that of NC group and gastric mucosa cAMP was markedly lower than that of

HC group, clinical phenomena as CSG-woS and CAG-woS will occur; (2) When gastric mucosa Zn, Cu and ³H-TdRLCT were markedly lower than that of NC group and gastric mucosa cAMP is nearly equal to that of NC group, the phenomenon of F type with symptoms (non-disease with symptoms) will occur; (3) When the levels of gastric mucosa Zn, Cu, cAMP and ³H-TdRLCT were all markedly lower than those of NC group, the clinical phenomena such as CSG-wS and CAG-wS will occur. The occurrences of these clinical phenomena were consistent with the change of gastric mucosa ultrastructure and histopathology, forming the pathophysiological basis in the classification of chronic gastritis. Thus it can be seen that changes of gastric mucosa epithelial cell ultrastructures and the quantitative changes of their bioactive substances are the pathophysiological bases that determines the classification of chronic gastritis with different classification has respective clinical symptoms.

Abstract

AIM: To investigate the safety, rationality and the practicality of enteral nutritional (EN) support in the postoperative patients with damaged liver function and the protective effect of EN on the gut barrier.

METHODS: 135 patients with liver function of Child B or C grade were randomly allocated to enteral nutrition group (EN, 65 cases), total parenteral nutrition group (TPN, 40 cases) and control group (CON, 30 cases). Nutritional parameters, hepatic and kidney function indexes were measured at the day before operation, 5th and 10th day after the operation respectively. Comparison was made to evaluate the efficacy of different nutritional support. Urinary concentrations of lactulose(L) and mannitol(M) were measured by pulsed electrochemical detection(HPLC-PED) and the L/M ratio calculated to evaluate their effectiveness on protection of gut barrier.

RESULTS: No significant damages in hepatic and kidney function were observed in both EN and TPN groups between pre- and postoperatively. EN group was the earliest one reaching the positive nitrogen balance after operation and with the lowest loss of body weight and there was no change in L/M ratio after the operation (0.026 ± 0.004) at the day 1 before operation, 0.030 ± 0.004 at the day 5 postoperative and 0.027 ± 0.005 at the day 10 postoperative), but the change in TPN group was significant at the day 5 postoperative (0.027 ± 0.003 vs 0.038 ± 0.009 , $P < 0.01$).

CONCLUSION: EN is a rational and effective method in patients with hepatic dysfunction after operation and has significant protection effect on the gut barrier.

INTRODUCTION

Liver is the central organ for production and utilization of nutrients and plays a key role in metabolism. In chronic liver disease severe protein-calorie malnutrition can seriously damaging the capacity of liver regeneration, however

nutritional support can improve the postoperative outcome^[1]. Parenteral nutrition (PN) has been used clinically^[2], but its limitations of the incomplete nutritional constituent^[3], catheter-related or endogenous complication^[4], metabolic complications and liver dysfunction restrict its use in hepatic damaged patients^[5]. In the mid 1980s, along with the recognition of the relevance of the gut barrier and endogenous infection^[6,7], enteral nutrition (EN) has been widely used^[8], but how does it effect on poor liver function remaining unclarified.

It is the aim of this study: (1) To investigate the safety, rationality and feasibility in performing EN in postoperative patients with poor liver function. (2) To study the influence of EN on gut barrier.

MATERIALS AND METHODS

Patients and groups

According to the later Enrolled criterion, 135 patients were enrolled and randomly divided into 3 groups: EN ($n=65$), TPN ($n=40$) and CON ($n=30$) (Table 1).

Enrolled criterion is: (1) Hospitalized adult patients from July 1998 to October 2001 with chronic liver damage requiring operative treatment; (2) The hepatic function was graded as Child B or C; (3) A patience of at least 7 days' nutritional support after the operation; (4) Except the primary disease, no other factors affecting the metabolism (5) With the agreement of the patients to join the program.

Table 1 Grouping of patients

	CON ($n=30$)			TPN($n=40$)			EN($n=65$)		
	Cases	Grade		Cases	Grade		Cases	Grade	
		B	C		B	C		B	C
PVH	13	10	3	14	8	6	21	10	11
HCC	4	2	2	11	7	4	10	5	5
CLA	1	-	1	3	1	2	8	-	8
ROBD	7	3	4	7	3	4	15	5	10
CLT	3	1	2	3	2	1	10	3	7
Others	2	1	1	2	-	2	1	-	1

PVH: Portal venous hypertension; HCC: hepatocellular carcinomar; CLA: Cholangiocarcinoma; ROBD: Reoperation of bile duct; CLT: cholelithiasis.

Reagents used

(1) 20 % and 30 % Intralipid (Beijing, Fresenius); (2) 8.5 % Novamin (Sino-swed Pharmaceutical Corp. LTD); (3) Nutrison Fibre (Nutrisia); (4) manitol (Sigma); (5) lactulose (Sigma).

Procedures

Deferent Nutrition supports were used: In TPN group, 30 cal·kg⁻¹·d⁻¹ energy and 0.16 g·kg⁻¹·d⁻¹ nitrogen were given. 1/4-1/3 nonprotein calories were provided by fat and carbohydrate. The ratio of N: nonprotein calorie=1:168. The source of nitrogen was Novamin (8.5 %) and the source of fat was from Intralipid (20 % or 30 %). Essential trace elements

and vitamins were given and the solution was given via peripheral infusion from the day 1 after the operation and lasted at least 7 days. In EN group, Nutrison Fibre was given. After 2 days of TPN, EN begun on the day 3 after the operation via the jejunostomy tube placed during the operation. On the first day, 500 ml Nutrison Fibre was given, which was increased progressively each day till 1 500 ml/d while TPN was decreased progressively till totally substituted. This was used given at least for 7 days. The temperature of Nutrison Fibre were kept at 25-30 °C and infused in 12-24 h. The rate was adjusted according to the need. In CON group, nutritional support was not performed or performed not regularly.

The sample preparation including: (1) urine sample: The patient drank the test solution, containing 2 g lactulose, 1 g mannitol in fasted condition or injected on 1 day before operation, 5th and 10th day after the operation respectively. Urine was collected for a total of 6 h and being added 0.1 ml of 10 g/L thimerosal as preservative. The total volume was recorded and 20 ml sample was stored at -20 °C until analysis by the HPLC-PED; (2) blood sample: Venous blood samples were achieved during fasting on 1 day before operation, 5th and 10th day after operation respectively for analysis.

Such Monitoring markers were measured: (1) Nutritional status marker: Transferrin (TRF), Prealbumin (PAB), Total protein (TP), Albumin (ALB), the alteration of weight (w) and circumference of upper arm (COUA) postoperatively, and accumulative nitrogen balances in the first 7 days after operation (ANE); (2) Liver and kidney function, electrolytes: Total bilirubin (TB), Direct bilirubin (DB), Albumin (ALB), Total protein (TP), Alanine aminotransferase (ALT), Aspartate aminotransferase

(AST), Creatinine (Cr), Blood urea nitrogen(BUN), Potassium (k+), Sodium (Na+), Calcium (Ca2+); (3) Gut barrier marker: Urinary ratio of lactulose and Mannitol (L/M)^[9,10].

Statistical analysis

The data was expressed as mean \pm standard error. Experimental results were analyzed by analysis of variance and *t* tests for multiple comparisons. *P*<0.05 was considered statistically significant.

RESULTS

All 135 patients, except one cirrhotic patient (CON) with portal hypertension died due to MSOF at the 26th day after operation, all completed the treatment and were discharged. In EN group, there were 32 patients complained for abdominal distention and diarrhea but disappeared by adjusting the temperature and infusion rate, given domperidone or antidiarrheal agent.

Nutritional status marker (Table 2)

In all three groups, on the 5th day postoperatively, the level of TRF, TP, and ALB declined significantly (*P*<0.05), but in EN and TPN groups, they recovered on the 10th day. Comparing with TPN, the level of TP in EN group on the 10th day was higher with significant difference (*P*<0.05). In CON group, on the 10th day PO, the level of TRF, PAB, TP and ALB were all significantly lower than these in EN and TPN groups (*P*<0.05). The W and COUA loss in CON group were significantly more than those in EN and TPN groups (*P*<0.05), and in EN group were lower than that in TPN group. Among these, EN group reached positive nitrogen balance the earliest (*P*<0.05).

*among all 3 groups, between day 1 preoperatively and day 10 postoperatively, *P*<0.01; # at day 10 postoperatively, the levels were lower in EN and TPN group than in CON group, *P*<0.05.

Liver and kidney function, electrolytes (Table 3)

After operation, the levels of TB, DB declined significantly in all three groups ($P<0.01$). Same increase could be found in patients with hepatic lobectomy, radical operation of Cholangiocarcinoma, severe portal hypertension and emergency operation, but with no statistical significance. On the 10th PO, the levels of AST and ALT were lower in EN and TPN group than those in CON group ($P<0.05$), but no difference was seen between EN and TPN group. The levels of Cr and BUN increased in EN and TPN group on the 5th day, but recovered on the 10th day. No electrolyte imbalance occurred in EN and TPN group.

Gut barrier marker (Table 4)

In EN group, the L/M ratio did not change after operation. In TPN and CON groups, they increased on the 5th day ($P<0.01$) and declined at 10th day. In both TPN and CON groups, the difference of L/M ratio between preoperation and postoperation was significant.

Table 4 Changes of L/M ratio

	1st BO	5th PO	10th PO
CON($n=30$)	0.028 \pm 0.004	0.037 \pm 0.017	0.031 \pm 0.010
TPN($n=40$)	0.027 \pm 0.003	0.038 \pm 0.009	0.030 \pm 0.006
EN($n=65$)	0.026 \pm 0.004	0.030 \pm 0.004	0.027 \pm 0.005

DISCUSSION

Present status of clinical nutritional support in patients with poor hepatic function

The liver plays a central role in nutritional homeostasis and any liver disease can lead to abnormal nutrient metabolism with the subsequent malnutrition. Severe protein-calorie malnutrition in patients with advanced liver disease can seriously undermine the capacity for liver regeneration and functional restoration. Appropriate nutritional support is helpful to these patients.

PN and EN are two major nutritional supports clinically. What has been proved is that long-term TPN may aggravate the liver damage^[11]. In recent years, there have been some advance in studies on various formulas including the branched chain amino acid (BCAA)^[13] and MCT/LCT^[14] in patients with poor hepatic function^[12], but there are still some problems: (1) How does lipid affect the nutrient metabolism; (2) What is the rational and safe dose and the suitable percentage of lipid supplied as the energy source^[15,16]; (3) The expensive cost. These problems impede the extensive use of PN which on long-term use may cause atrophy of intestinal mucosa and lead to the gut barrier dysfunction^[17]. The consequent enteric bacterial translocation would also cause endogenous infection even multiple organ failure (MOF) and death. EN is a more physiological, cheaper and has protection function on gut barrier. But when using EN^[18,19], the later three facts are inevitable: (1) The gastrointestinal tract should be intact; (2) Patient should be able to tolerate the indwelling nasogastric tube; (3) In case of hypertonic, patient may have abdominal distention, diarrhea, and sometimes nausea and vomiting and enhancement of the liver burden. There had been reported on using EN in patients with alcoholic cirrhosis and obstructive jaundice^[20,21], but in patients with worse liver function or sustain the hepatic lobectomy, radical operation of cholangiocarcinoma, severe portal hypertension with upper gastrointestinal hemorrhage, the selection of nutritional support is troublesome.

Evaluation of EN and its influence on liver function

En has been proven to be an efficient nutritional support^[22,23],

which is prefer to TPN. In this study, in both EN and PN groups, the patients' nutritional status was much better than CON group. Compare with PN groups, in weight loss and circumference of upper arm, EN group were much less and the positive nitrogen balance was reached much earlier.

Liver is the key organ in maintaining the carbohydrate, lipid and protein metabolism and the stabilization of internal environment. Also it is the site of biochemical pathways responsible for production and utilization of nutrients and other chemicals. It plays a central role in carbohydrate, lipid and nitrogen metabolism. Therefore it is not surprising that chronic liver disease has great metabolic impact. On the base of this, the impact and irritated responsiveness of the operation may aggravate the burden of liver and ultimately affect the outcome of the patients^[24-26]. On the other hand, we can suspect that if the nutrients were absorbed via liver, the liver could utilize the nutriment as the substrate to repair and rebuilt hepatic cell so as to promote its recover^[27]. Whether it is beneficial or harmful, our study have performed some useful study in finding this method for support sufficient nutriment at the same time to avoid further liver damage in such patients.

In 42/65 patients of Child C grade EN group, after EN, had their levels of ALT, AST, TB and DB declined, and their Cr and BUN did not increased. There were no signs of aggravating damage of liver and kidney. The successful use of Nutrison Fibre indicates that whether the BCAA is absolutely necessary in EN needs further study.

EN can protect the gut barrier

In patients with poor liver function, infection is a familiar complication and threat^[28]. Except for the depression of cellular immunity^[29], the bacteria translocation is the most probable reason of infection after the operation^[30]. Because of the translocation of the germ and endotoxin, the consequent systemic inflammatory reaction and sepsis and the dysfunction of renal, lung and cardiac system would even threaten the patient's life. The gut barrier plays a the major role in preventing bacteria translocation and block the subsequent malign reaction, which is the "trigger" of MSOF^[31,32]. Keeping the integrity of gut barrier is important to decrease the morbidity and mortality after operation.

In our study, the L/M probe was selected to monitor the status of gut barrier. The result showed: the L/M ratio of EN group was 0.026 \pm 0.004 in day 1 before the operation, 0.030 \pm 0.004 in day 5 postoperatively and 0.027 \pm 0.005 in day 10 postoperatively, the change was not significant, but it was markedly elevated in TPN and CON group after operation as follow. It indicated: EN could protect the gut barrier remarkably, the rational mechanisms were (1) The stimulation on the bowl wall may increase the blood perfusion^[33,34]; (2) The stimulation on the bowl wall may accelerate the secretion of pancreas and biliary duct to prevent shrinking of gut mucosa; (3) EN supplies the substrate of intestinal mucosal cell metabolism directly; (4) The fiber^[35-38] ingredient of Nutrison may also protect the gut barrier.

Clinical observation

In our study, we found through the upper jejunostomy tube placed during the operation, good nutrition support and good tolerance and good controllability are approached. The tube can be hold for at least 4 weeks. With good nursery, it can be kept fairly long, the longest one in our study is 94 days and no complications occurred.

In our study, the rate of ascites was 83.6 %, 93.3 % and 90.0 % in EN group, PN group and CON group, respectively, till discharge, the subsidence of them were 86.6 %, 61.3 % and 75 %. In EN group the ascites subsided earliest and liver function recovered faster.

The lowest rate of fever and the shortest fever time indicated that the risk of infection is low in EN. It is owed to the protection of the gut barrier.

Abstract

AIM: To determine the least invasive surgical procedure by comparing the levels of operative stress hormones, response-reactive protein (CRP) and rest energy expenditure (REE) after laparoscopic (LC) and open cholecystectomy (OC).

METHODS: Twenty-six consecutive patients with noncomplicated gallstones were randomized for LC (14) and OC (12). Plasma concentrations of somatotropin, insulin, cortisol and CRP were measured. The levels of REE were determined.

RESULTS: In the third postoperative day, the insulin levels were lower compared to that before operation ($P < 0.05$). In the first postoperative day, the levels of somatotropin and cortisol were higher in OC than those in LC. After operation the parameters of somatotropin, CRP and cortisol increased, compared to those in the preoperative period in the all patients ($P < 0.05$). In the all-postoperative days, the CRP level was higher in OC than that in LC (7.46 ± 0.02 ; 7.38 ± 0.01 , $P < 0.05$). After operation the REE level all increased in OC and LC ($P < 0.05$). In the all-postoperative days, the REE level was higher in OC than that in LC (1438.5 ± 418.5 ; 1222.3 ± 180.8 , $P < 0.05$).

CONCLUSION: LC results in less prominent stress response and smaller metabolic interference compared to open surgery. These advantages are beneficial to the restoration of stress hormones, the nitrogen balance, and the energy metabolism. However, LC can also induce acidemia and pulmonary hypoperfusion because of the pneumoperitoneum it uses during surgery.

INTRODUCTION

The superiority of laparoscopic cholecystectomy (LC) has justified its universal usage in recent years. It induces less

surgical response compared to open cholecystectomy (OC). A great many literatures had proved such an advantage^[1-4]. However, there were few studies concerning the difference between LC and OC in operative stress response and energy metabolism. In this prospective, randomized study, we compared the effects of LC and OC on body oxygen supply, metabolic hormones and response-reactive protein (CRP) levels, body energy metabolism, and acid-base balance.

MATERIALS AND METHODS

Clinical data

Twenty-six patients with uncomplicated gallstones were recruited for the study from April 2001 to Oct. 2001. They were randomized to undergo LC ($n=14$) or OC ($n=12$). The two groups of patients had comparable demographic data (Table 1). All enrolled patients were asymptomatic for at least 6 weeks prior to admission without any history of abdominal surgery. Ultrasonography was routinely performed to exclude the common bile duct stone. The patients with jaundice, severe infection, or metabolic abnormalities were also excluded in this study. Anesthesia was induced and maintained using a standard intravenous protocol in both groups. LC was undertaken by a standard 4-trochar approach with electrocautery dissection; pneumoperitoneum was established with carbon dioxide (CO₂) insufflation, and OC was performed via a sub-costal incision.

Table 1 Comparison of general conditions between the two groups

Group	Number	M/F	Median age (yrs)	Height (cm)	BW (Kg)
OC	12	3/9	45.5±12.6	161.3±7.1	61.0±3.6
LC	14	6/8	46.6±15.8	163.9±6.1	65.8±9.4

Blood samples and evaluation method

Fast venous blood was taken at 6 AM on the day prior to surgery, and days 1 and 3 postoperatively. Samples should be analyzed within 2 hours after stored *in vitro*. All hormones were quantitatively assayed. In CRP assay, rate immunonephelometry with specific protein analyzer (BN 100 Analyzer) was adopted. Growth hormones (GH) levels were determined by double-antibody RIA with reagents from Jiuding Bio-medical Co. Ltd, Tianjing. Serum cortisol and insulin analysis were both carried out by competitive RIA, using reagents from 3V Diagnostic Technique Co. Ltd. and Chinese Institute of Atomic Energy, respectively.

Energy metabolism was assessed by indirect calorimeter on the day prior to operation, and days 1 and 3 postoperatively. During analysis, patients should be reposed, with ambient temperature 18-26 °C and humidity 50-60 %. Oxygen consumption (VO₂) and CO₂ production (VCO₂) per unit time were determined at first. Then, based on the indirect calorimetry theory, REE and RQ were figured out according to the value of VO₂ and VCO₂. All energy consumption measurements were carried out using Medical Graphics Critical Care Monitor Desktop Analysis System (Medical Graphics Co.,

Minneapolis, MN). Artery and acid-base balance were assayed by automatic gas analyzer.

Statistical analysis

Data were given as means and standard error of the mean. The intergroup comparison was made using the Student's *t* test. All the statistical procedures were accomplished with SPSS 8.0. A two-tailed $P < 0.05$ was taken as significant.

RESULTS

Median surgical duration was not different between the LC (50.9±8.9 min) and OC (58.5±6.3 min) group ($P > 0.05$), while the length of hospital stay and the time to first passage of flatus were significantly shorter in LC than those in OC group (Table 2).

Table 2 Postoperative intestinal transit recovery

	OC (n=12)	LC (n=14)
Time to first passage of flatus (days)	2.8±0.4	1.5±0.3 ^a
Postoperative length of stay (days)	6.7±0.2	3.2±0.3 ^a

^a $P < 0.05$ vs OC.

Insulin levels rose significantly on the 3rd postoperative day above baseline measurements in OC group, with no intergroup difference throughout the postoperative period. GH levels elevated in both groups at all phases postoperatively. However, there was a more prominent response in patients undergoing OC. A significant intergroup difference was detected on day 1 following operation with higher values for OC than that for LC. Cortisol levels increased from baseline on both of the postoperative days in the two groups, but more remarkably in OC group. Intergroup comparison indicated that concentrations were significantly higher in patients undergoing OC on day 1, postoperatively. But on the 3rd postoperative day, cortisol concentrations were comparable in the two groups (Table 3).

Table 3 GH, Insulin, and cortisol levels before and after surgery

	Prior to surgery	1st postoperative day	3rd postoperative day
Insulin			
LC (n=14)	14.4±2.1	16.1±2.8	14.6±2.5
OC (n=12)	17.9±2.1	17.2±3.4	12.3±0.9 ^b
GH			
LC	1.0±0.2	2.7±1.0 ^{ab}	1.5±0.5 ^b
OC	1.8±0.4	5.4±2.5 ^b	2.2±0.9
Cortisol			
LC	0.46±0.01	0.56±0.11 ^{ab}	0.74±0.05 ^b
OC	0.71±0.15	1.12±0.25 ^b	0.89±0.02 ^b

^a $P < 0.05$, vs OC ^b $P < 0.05$, vs the preoperative period.

In OC groups, REE levels raised 165.3Kcal from baseline on day 1 postoperatively. The difference was significant. But on the 3rd postoperative day, it was 57.3Kcal higher than baseline only (not significant). A similar pattern was seen in the patients undergoing LC, and there was a marked increase (60.1Kcal) on day 1 but not on day 3. On both of the postoperative days, REE levels were significantly higher in OC than those in LC group. RQ fell significantly from baseline on the 1st postoperative day in both groups. There was a significant elevation of CRP concentrations from baseline

levels in both groups. However, in patients undergoing OC, the increase was more remarkable. CRP levels were significantly higher in OC than those in LC group on both of the postoperative days (Table 4).

Table 4 REE, RQ, and CRP levels before and after surgery

	Prior to surgery	1st postoperative day	3rd postoperative day
REE			
LC (n=14)	1162.2±159.6	1222.3±180.8 ^{ab}	1152.8±150.2 ^a

OC	12.37±3.55	64.50±15.20 ^b	94.25±13.43 ^b

^a $P < 0.05$, vs OC ^b $P < 0.05$, vs the preoperative period.

Artery oxygen pressure did not change remarkably after surgery in OC group, while it declined significantly on the 1st postoperative day in the LC group and returned to preoperative levels on the 3rd day. Oxygen saturation (SO₂) in blood fell significantly on the 1st postoperative day in both groups. On the 3rd day, it was much higher in LC than that in OC group. There was no significant change of PCO₂ in both groups after surgery. (Table 5) On the 3rd postoperative day, HCO₃⁻ level and BE rose significantly in LC group, and BE was significantly higher in LC than that in OC group. PH was significantly lower in LC than that in OC group on the 1st postoperative day (Table 6).

DISCUSSION

Laparoscopic cholecystectomy is becoming the choice of surgery for uncomplicated cholelithiasis because it had induced less tissue trauma response throughout the course of wound healing compared to open cholecystectomy. Surgery stimulates a series of hormonal and metabolic changes that constitute the stress response. Surgery also induces neurohormonal events that include activation of sympathetic nervous system and stimulation of hypothalamic-pituitary-adrenal axis initially. Then the adrenal cortex is activated, promoting the release of neurohormonal transmitters that would influence the intensity of postoperative pain and duration of postoperative ileus^[5-7]. ACTH, catecholamine, cortisol, and glucagon all played crucial roles in the mediation of stress response. In response to sepsis and trauma, massive catecholamine, cortisol, and glucagons are released, while serum insulin concentrations decrease relatively, and decrease of insulin levels is in correlation with the severity of the sepsis and trauma^[8-12]. In the present study, we found a marked decrease of insulin levels from baseline in OC group on the 3rd postoperative day, while the intergroup difference was not significant on either 1st or 3rd postoperative day. GH and cortisol levels increased from baseline in both groups on the 1st and 3rd postoperative day, and there was a more marked increase in OC group. On the 1st postoperative day GH and cortisol concentrations were both higher in OC than those in LC group.

The cytokines and CRP were objective markers of operative stress response as well as the mediators of host immunologic reaction. Derived from immune system or other tissues, TNF, IL-1 and IL-6 were the major mediators of the acute-phase response^[13-15]. In a recent study, Bruce and coworkers^[16] examined the changes of CRP, IL-1 Ra, IL-6, and TNF- α in LC and OC patients after surgery. A marked and persistent raise of IL-6 levels was detected from 8 hours to 7 days postoperatively in OC group, while the concentrations of CRP and albumin were comparable in the two groups. IL-1ra levels were significantly raised as early as 4 hours following incision in OC group, compared to LC group. IL-6 levels rose significantly and early (1 hour) in both groups, but there was a more prominent and prolonged response in patients undergoing OC. Significant intergroup difference of IL-6 levels was present as early as 8 hours following incision^[17-21]. In our study, we found that CRP levels rose significantly from baseline on both day 1 and day 3 after surgery in the two groups, but more prominently in OC group.

In response to the surgical trauma, the body usually presents with a hyper-metabolic state. Such a state is directly linked to the activation of sympathetic nervous system, the increase of oxygen and energy consumption, the negative nitrogen balance, and the synthesis of CRP. All surgical traumas will induce neuroendocrine activation and protein catabolism, and the nitrogen excretion is therefore increased (mainly as BUN, sometimes as SCr)^[22,23]. The amount of the increased nitrogen excretion was determined by the extent of stress, which is proportional to the intensity of injury response. Thus, the degree of metabolic restoration could be acquired using systemic nitrogen balance measurements^[8]. To our knowledge, this study is the first to assess the effect of mini-invasive surgery on body REE consumption. In the study, we observed the perioperative changes of REE levels of LC and OC groups using indirect calorimeter. As the result, REE increased significantly (165.3 Kcal) from baseline in the 1st postoperative day in OC group, while on the 3rd day the elevation was not significant (57.3 Kcal). The LC group also revealed marked increase (60.1 Kcal) in the 1st postoperative day, but not in the 3rd day. The intergroup difference of REE levels was significant (with higher levels in OC group) at all phases postoperatively. RQ decreased significantly on the 1st

postoperative day in both groups. Thus, our study revealed that LC was less invasive and induced less host stress response and metabolic disturbance compared with traditional OC and it therefore might be more beneficial to the restoration of nitrogen balance and metabolism.

During LC, pneumoperitoneum is induced by insufflation of carbon dioxide, which may be accompanied with disturbance of acid-base balance and pulmonary perfusion^[24-27]. Open surgery, on the other hand, usually results in pulmonary dysfunction. Previous studies have shown that on the 1st postoperative day, FVC and FEV1 decreased 40-70 % in patients undergoing OC, compared to 20-40 % in patients undergoing LC. There are possibly two explanations for this. One is that postoperative wound pain often causes shallow respiration, which may lead to small bronchiole closure, the pulmonary blood shunt, and hence the hyponoxia. Increased oxygen consumption after surgery may be another explanation^[28-31]. In this study, we observed that artery oxygen consumption fell significantly from baseline on day 1 and restored to preoperative levels on the day 3 postoperatively in LC patients, with no significant reduction in OC patients. SO₂ decreased significantly on the 1st postoperative day on both groups, and on the 3rd postoperative day it was higher in LC group than in OC group. Penumoperitonium could explain the reduced oxygen supply at early postoperative phases in LC patients. However, the influence of wound pain on respiration is more pronounced and permanent OC than in LC patients, this may be the reason why the intergroup difference is significant on the 3rd postoperative day. HCO₃ and BE raised significantly from baseline in OC group on the 3rd postoperative day, and BE was significantly higher in LC group than that in OC group on the day. PH levels were much lower in LC group than those in OC group on the 1st postoperative day. This is possibly because of the postoperative acidemia elicited by the retention of CO₂ during pneumoperitonium. Much attention should be paid to this change during LC.

In conclusion, LC results in less prominent stress response and metabolic interference compared to open surgery. These advantages are beneficial to the restoration of stress hormones, the nitrogen balance, and the energy metabolism. However, LC can also induce acidemia and pulmonary hypoperfusion because of the penumoperitonium it uses during surgery.

Abstract

AIM: To carry out a comparative study on ultrastructure and molecular biological changes of chronic gastritis (CG), gastric cancer (GC) and gastric precancerous lesions.

METHODS: By the use of histochemical staining, SEM with EDAX, TEM with EDAX, image analysis technique, RIA and chemiluminescence method, gastric mucosa of 168 patients were synchronously analyzed in morphology, trace elements, DNA, cAMP, SOD, ^3H -TdR LCT and serum LPO were also done.

RESULTS: The incidence of epithelial nucleoplasmic ratio >1 , lobulated nuclei, inter-chromatin aggregation of granules, nucleolar hypertrophy, and the content of DNA, Zn, Cu in nuclei and serum LPO of each group were showed as follows: normal control group (0.0, 0.0, 6.7, 0.0, 12.6 ± 2.7 , 7.6 ± 0.4 , 58.4 ± 0.3 , 2.6 ± 0.6), CSG group (5.7, 2.9, 7.4, 2.9, 15.2 ± 3.1 , 8.1 ± 0.5 , 58.9 ± 0.5 , 4.2 ± 0.7), CAG group (31.3, 29.7, 45.3, 42.2, 16.5 ± 3.1 , 8.6 ± 0.4 , 59.3 ± 0.5 , 4.5 ± 0.6), CA group (100.0, 100.0, 72.2, 50.0, 30.7 ± 8.2 , 8.8 ± 0.3 , 59.5 ± 0.4 , 6.8 ± 1.6), ATP⁺⁺ group (61.5, 38.5, 23.1, 38.5, 23.5 ± 8.9 , 8.3 ± 0.4 , 59.1 ± 0.4 , 5.1 ± 1.2), IM⁺⁺ ATP⁺⁺ group (77.8, 55.5, 33.3, 44.4, 25.1 ± 7.2 , 8.4 ± 0.5 , 59.5 ± 0.4 , 6.5 ± 1.1), IM⁺⁺⁺ ATP⁺⁺ group (100.0, 100.0, 75.0, 62.5, 28.5 ± 9.1 , 8.9 ± 0.5 , 59.7 ± 0.4 , 7.6 ± 0.7), IMII_b group (100.0, 62.5, 75.0, 50.0, 27.3 ± 10.3 , 8.6 ± 0.3 , 59.5 ± 0.4 , 6.1 ± 0.9); whereas the content of Zn, Cu in mitochondria and cAMP, SOD in gastric mucosa, and ^3H -TdR LCT of each group were shown as follows: normal control group (9.2 ± 0.5 , 58.3 ± 0.3 , 15.9 ± 1.5 , 170.5 ± 6.1 , 1079.7 ± 227.4), CSG group (8.6 ± 0.5 , 57.8 ± 0.3 , 14.6 ± 1.8 , 163.3 ± 5.6 , 867.3 ± 240.5), CAG group (8.3 ± 0.4 , 57.5 ± 0.3 , 13.4 ± 1.8 , 161.2 ± 4.3 , 800.9 ± 221.8), CA group (8.9 ± 0.4 , 57.1 ± 0.3 , 10.2 ± 3.9 , 152.2 ± 3.8 , 325.7 ± 186.8), ATP⁺⁺ group (9.1 ± 0.4 , 57.0 ± 0.3 , 12.4 ± 1.8 , 161.5 ± 3.8 , 642.9 ± 174.3), IM⁺⁺ ATP⁺⁺ group (8.6 ± 0.4 , 56.9 ± 0.3 , 12.0 ± 2.3 , 152.2 ± 2.5 , 326.3 ± 160.3), IM⁺⁺⁺ ATP⁺⁺ group (8.5 ± 0.3 , 56.8 ± 0.2 , 10.4 ± 0.9 , 147.4 ± 2.6 , 316.1 ± 170.7), IMII_b group (8.6 ± 0.3 , 56.9 ± 0.3 , 11.9 ± 1.9 , 150.0 ± 2.8 , 318.9 ± 145.8), there were significant differences between groups ($P<0.05-0.01$).

CONCLUSION: There was a significant difference between CG and GC in their ultrastructure and molecular biology. Only on the condition of changes of internal environment in combination with the harmful effect of external

environment, chronic atrophic gastritis can then develop into gastric cancer. Hence it might have similar epithelial cell ultrastructure and molecular biological changes in ATP⁺⁺, IMII_b and cancer, hence there were similar patterns of occurrence, development and transformation. Recognition of this trend might help to explore problems of prevention and cure.

INTRODUCTION

We conducted histochemical staining, detection of cAMP, SOD and DNA of gastric mucosa of 168 patients with chronic gastritis (CG) or gastric cancer (GC); SEM and TEM with EDAX were used to synchronously determine ultrastructures and trace elements and image analysis technique was used to determine nuclear DNA. ^3H -TdR LCT and serum LPO were also carried out. Following was the comparative study.

MATERIALS AND METHODS

Materials

168 patients definitely diagnosed as suffering from CSG, CAG and GC were our subjects of study. According to "The standards for the classification of chronic gastritis, for gastrofiberscopic diagnosis and for histopathological diagnosis of atrophic gastritis", gastric mucosa tissue slices underwent HE staining and AB_{PH2.5}/PAS, Hid/AB_{PH2.5} and Hid/AB_{PH2.5} histochemical staining. ATP was classified into low-grade, middle-grade and heavy-grade and IM into IM I_a, IM I_b, IM II_a, IM II_b. 68 cases were definitely diagnosed as CSG, including 43 males, 25 females, average age 43 years, average course of disease 4a, 26 cases without IM or ATP; 31 cases with concomitant or solitary IM-19 cases low-grade, 10 cases middle-grade and 2 cases heavy-grade; 9 cases with solitary ATP-8 cases low-grade, 1 case middle-grade; 2 cases with IM and concomitant ATP, IM and ATP were both middle-grade. 64 cases were definitely diagnosed as CAG, including 37 males, 27 females, average age 47 years average course of disease 6a, 3 cases without IM or ATP; 39 cases with concomitant solitary IM (17 cases low-grade, 4 cases middle-grade and 18 cases heavy-grade); 8 cases with solitary ATP (2 cases low-grade, 6 cases middle-grade.) 14 cases with IM concomitant ATP (12 cases middle-grade IM, 2 cases heavy-grade IM, 8 cases low-grade ATP, 6 cases middle-grade ATP). 36 cases were definitely diagnosed as GC, including 22 males, 14 females, average age 52 years, average course of disease, 2a, all with IM or ATP. 12 cases with solitary IM (6 cases low-grade, 3 cases middle-grade, 3 cases heavy-grade); 7 cases with solitary ATP (1 case low-grade, 6 cases middle-grade);

17 cases with IM concomitant ATP (5 cases middle-grade IM, 12 cases heavy-grade IM; 7 cases low-grade ATP, 9 cases middle-grade ATP, 1 case heavy-grade ATP). Of the 45 healthy volunteers who underwent gastroscopy and biopsy, 15 cases had basically normal gastric mucosa tissues, including 6 males 9 females, average age 37, and they were referred to as normal control (NC) group.

Methods

Under gastroscopy, three pieces of gastric mucosa were taken from the focal and nonfocal areas in antral region and body of stomach as specimens for section preparation, SEM, TEM, detection of DNA, cAMP and SOD. Blood was taken for ^3H -TdRLCT and LPO. For the observation of gastric mucosa ultrastructure and determination of its trace elements^[1-4], 501B SEM with 9100/60 EDAX was used to observe the three pieces of specimens of each patient, under the direct vision of SEM, the EDAX probe automatically detected the samples within 0.1-0.01 mm² range all the elements under 12 in atomic number and automatically calculated the weight percentage (WT%) of each element in element series. 15 points were fixed in the three pieces of mucosa of every patient to carry out 15 detections, and the average WT% of each element was taken as its actual WT%. In every detection, 21 elements such as Na, Mg, Al, Si, P, S, K, Ca, Fe, Cu, Zn, Ti, Cr etc were detected, and weight percentage (WT%) of each element between elements of gastric mucosa was calculated.

By using EM430 TEM with 9100/60 EDAX, three pieces of mucosa specimens of every patient were magnified in unison by five magnifying powers (3 600, 7 200, 14 000, 19 000, 29 000) to randomly take the pictures of the panoramagram, local area and organelle and to detect the atomic number percentage (AT%) of each nuclear and mitochondrial element between trace elements^[5-10]. After gastric mucosa cell smear was stained by Feulgen staining, IBAS 2000 image analysis technique was adopted to detect IOD, which is taken as the relative content of nuclear DNA^[7,8]. RIA was adopted to detect the content of gastric mucosa cAMP (Pmol/g); chemiluminescence method was adopted to detect the activity of SOD (u/g)^[4]. ^3H -TdRLCT. (Bq/L whole blood) was carried out; thiobarbituric acid development process was adopted to detect serum LPO (u mol/L)^[4].

Statistical method

χ^2 and t test.

RESULTS

Histopathology of gastric mucosa

Between NC group. CSG group. CAG group and CA group, there were significant differences in the incidence rate and degree of different types of IM and ATP in glands propria of gastric mucosa ($P < 0.05-0.001$, Table 1). The surface of normal gastric mucosa was isolated by crisscross small groves into many lesser gastric areas, assuming convolution shape (Figure 1). In these areas, there were many gastric pits (the mouths of gastric glands), which were shaped like craters. The concave walls had round or oval epithelial cells of almost the same size. In CSG gastric mucosa there were scattered denatured, diabrotic and necrotic exfoliated epithelial cells, on whose surface S-shape *Helicobacter pylori* (HP) were found (Figure 2). Massive epithelial cells became diabrotic, anabrotic and exfoliated forming micro ulcers. The ulcers spread out from their centers, with adjacent cells crushed, destructed in irregular shapes and arrangement. In CSG gastric mucosa, cyst was found accidentally (Figure 3), the epithelial cells of crater walls were atrophic and denatured,

of different sizes and deranged; the cells became diabrotic and necrotic and had inflammatory cell infiltration and the glands propria of the serious cases were shaped like grid framework structure (Figure 4). The surfaces of the epithelial calls of IM gastric mucosa were thickly coated, villi were invisible and the intercellular boundaries were not clear (Figure 5). SEM was not able to definitely indentify gastric mucosa ATP, but only able to distinguish whether cells were hyperplastic or not. Degeneration, hyperplasia or cellular regeneration occurred in gastric mucosa. The hyperplastic cells are of different sizes and states and the active memberanes were shaped like lesser tubercles (Figure 6, 7). The cells of gastric cancer were different sizes and shapes, deranged, characterized by obvious heteromorphic nature, conglobated and shaped like grapes or cauliflower. There were nearby or basal infiltration, destruction and ulceration of cancer cells, which have developed into ulcers.

The ultrastructure of gastric mucosa epithelial cells

The mucous cells on epithelial cell surface of relatively normal gastric mucosa were columnar epithelial cells covering endogastric surfaces and inside wall of gastric pit. Their free surfaces had short micro villi; the mucous neck cells were distributed over the necks of gastric glands, and on the tops of these cells were a few short thick micro villi. Chief cells were distributed over the bodies and bottoms of gastric glands; parietal cells were big and conic and their conical tops turned towards gland cavities; the endocrine cells lied between chief cells and parietal cells and they were small, and their nuclei are round or oval, the nuclei envelopes are slightly bent, lobulated nuclei were few, the nucleocytoplasmic ratio was less than 1.

The nuclear chromatins were scattered, or associated with nucleoli or along nuclear perimeters. The light bright zones between heterochromatins in the nucleoli are euchromatins; the nucleoli had high electron density without capsule.

Mitochondria were round or oval, scattering around nuclei. The mitochondria consisted of outer membrane, inner membrane, outer ventricle, inner ventricle and cristae. Crista, the inward folded inner membrane, was a hollow canal leading to outer ventricle. Some mitochondrial cristae directly led to cytoplasm. Cristae were generally in tabular arrangement, parallel to each other and vertical to mitochondrial long axes. In cytoplasm were many parallel rough surfaced endoplasmic reticulus (RERs), secretory granules, well-developed Golgi's bodies and scattered mitochondria. The free surfaces of epithelial cells of CG gastric mucosa had dropped micro villi; the intercellular space expanded and cell conjunctions decreased; the karyoplasmic ratio of both ill-differentiated epithelial cells and IM cells was greater than 1, and lobulated nuclei increased; nucleolar granules became thick and nucleoli expanded with irregular margins (Figure 9).

There occurred nucleolar margination (Figure 10), multinucleoli (Figure 11) and nucleolar division (Figure 12). The obsolescent epithelial nuclei shrank and the karyoplasmic ratio was still less; the heterochromatins lied densely around nuclei; the electron density was low in the center of nuclei and nuclei were loop in shape. (referred to as chromatin margination); the shrunk nuclei were denticular, in which the electron density was moderately homogeneous and chromatins were not found (referred to as chromatin homogenization). There were mitochondrial swelling, hypertrophy, pyknosis, hyaline degeneration as well as vacuolar degeneration. The deformed mitochondrias were in C-shape or U-shape. There were zigzag, longitudinal, sparse and pyknosis cristae, and deranged cristas. There was an decrease in the number of mitochondrias and their cristae. There were mitochondrial decreases in number, mitochondrial swelling, or crista fragmentation, vacuolar degeneration, and RERs in circular arrangement; the Golgi's bodies become atrophic and had lost their typical structures; the cytoplasmic incretory granules decreased. There were still greater epithelial cell changes in cancer cells of gastric cancer than in cells of gastric mucosa of chronic gastritis, intranuclear inclusion appeared (Figure 13). There was an increase in peri-chromatinic and interchromatinic granular densification (Figure 14). In euchromatins; there was a significant difference between CSG group and CAG group in nucleolar margination and nucleolar looping ($P < 0.05-0.001$, Table 2, 3); between IM II_b group, ATP⁺⁺ group, IM⁺⁺+ATP⁺⁺ group and IM⁺⁺⁺+ATP⁺⁺ group, compared with NC group, CSG group and CAG group, the difference was also significant ($P < 0.05-0.001$, Table 2, 3). There is no significant difference between IM⁺⁺⁺+ATP⁺⁺ group, IM II_b group and CA group ($P > 0.05$, Table 2, 3).

The biochemical assay in gastric mucosa and serum

The content of nuclear Zn and Cu increased progressively in the sequence of NC group, CSG group, CAG group and CA group; the content of mitochondrial Zn and Cu decreased progressively in the same sequence. There was significant differences between these groups ($P < 0.05-0.001$, Table 4). The content of Zn, Cu, cAMP and SOD in gastric mucosa decreased progressively in the same sequence; the content of DNA increased progressively in the above sequence. There were significant differences between these groups ($P < 0.05-0.001$, Table 5). The content of ³H-TdRLCT decreased in the sequence of NC group, CSG group, CAG group and CA group; content of serum LPO increased in the same sequence; there was significant difference between these groups ($P < 0.05-0.001$, Table 6). Between IMII_b group, ATP⁺⁺ group, IM⁺⁺+ATP⁺⁺ group and IM⁺⁺⁺+ATP⁺⁺ group, NC group, CSG group and CAG group, there was also significant difference ($P < 0.05-0.001$, Table 4, 5, 6). Between IM⁺⁺⁺+ATP⁺⁺ group, IM II_b group and CA group, There was no significant difference ($P > 0.05$, Table 4, 5, 6).

DISCUSSION

Chronic gastritis, CAG in particular, is generally acknowledged as precancerous state. However, not all CAGs are likely to develop into gastric cancer because there is significant difference between chronic gastritis and gastric cancer in the ultrastructure and molecular biology of gastric mucosa. In the grading and classification of IM, grading of ATP of gastric mucosa, incidence rate of epithelial karyoplasmic ratio >1, incidence rate of perichromatinic granular densification and of nucleolar hypertrophy, the number of mitochondria and cristae as well as the incidence rate of mitochondrial degeneration; as well as in the quantitative changes of nuclear DNA, Zn, Cu, cAMP, SOD and serum LPO and ³H-TdRLCT, there were significant differences between NC group, CSG group, CAG group, CA group, IM II_b group, ATP⁺⁺ group, IM⁺⁺+ATP⁺⁺ group and IM⁺⁺⁺+ATP⁺⁺ group ($P<0.05-0.0001$); There was no significant difference between IM⁺⁺⁺+ATP⁺⁺ group, IM II_b group and CA group ($P>0.05$). There are similar epithelial ultrastructures and molecular biochemical changes in ATP⁺⁺, IM II_b and CA. Consequently they should have similar law of occurrence, development and transformation, which might contribute to the exploration of prevention and treatment of the disease.

Clinically, only a few chronic gastritis patients' gastric mucosa epithelial cells are likely to develop into cancer cells, but it is essential that there should be a process which causes genetic variation of cells, the key of which is the quantitative changes of epithelial nuclear DNA. The DNA molecular is coded with nucleotide sequence fragments of special genetic codes, every fragment is a functional group, referred to as gene. The gene order has great stability. Only when intracellular cAMP declines, cytodifferentiation is disturbed. The metabolism of Zn, Cu in the body is disturbed, which in turn disturbs the enzyme system and inhibits the synthesis and activity of SOD; because of the NADPH oxidation reduction circulation and the catalytic function of xanthine oxidase, a great deal of oxygen free radicals are produced far beyond the

cleaning ability of SOD. The excessive accumulated oxygen free radicals react in lipid peroxidation with unsaturated fatty acid of inner and outer membranes of mitochondria, producing LPO. Thus level of serum LPO rises. The inner and outer membranes of mitochondria are destructed, causing decrease and derangement of mitochondrial cristae, mitochondrial degeneration decrease of adenosine triphosphate production, and inadequate energy supply of gastric mucosa epithelial cells. When nuclei take up more Zn and Cu, the protein synthesis is enhanced nuclear division and hyperplasia are accelerated; through influencing lymphocyte metabolism, the quantitative changes of Zn and cAMP in turn inhibit lymphocyte transformation and result in the decline of ³H-TdRLCT level and immunity of the organism. The above changes of intraorganism environment, only if stimulated by certain external causes such as ionizing radiation, chemical injuries, infection S-shape HP and virus, are likely to cause the change of sequences in gene group, which is referred to as gene mutation; and genetic codes change accordingly, the changed codes are transferred to heterogenous cell descendants, causing cellular differentiation disturbance and even cancerous change. Human body is an integrity organism, in which the components of tissue and cell, and the bioactive substances including trace elements, enzymes, hormones, immunity and messenger substances exist with a definite content and a definite quantitative ratio. It's important to measure the "absolute" content of each bioactive substance, but it's more important to measure quantitative ratio of each bioactive substance because it can explain the trends and laws of variation of the whole body and inner circumstance^[9,10]. These ratios in normal body keep in a state of dynamic balance within a definite range. If this balance is broken, pathological phenomena and functional disturbance will arise. The ratio fluctuation of bioactive substances higher or lower than normal value, can lead to a series of ratio variation, and then cause both a definite disease diagnosed by modern medicine and clinical expression of Chinese medical syndrome (a synthesis of symptoms without peculiarity). The composite nature of Chinese medicine treats disease through adjusting the above mentioned pathological ratio is one of it's therapeutic mechanisms. This is why Chinese medicines have multilevel, multitarget, two-way adjusting effects on human body, and how the medicines regulate pathological ratio. It's a slow process for Chinese medicines to regulate pathological ratio, so It's therapeutic effect is slow too. Measuring the "quantitative ratio" of a series of bioactive substances not only will be the research direction of medical science and biological science, but also the research kernel of the basic theory of traditional Chinese medicine^[11-13].

Abstract

AIM: To investigate the incidence of neuroendocrine (NE) cells and their hormone products in adenocarcinomas and evaluate their significance in clinical pathology and prognosis.

METHODS: By using tissue sectioning and immunocytochemistry, 356 cases of adenocarcinomas were studied to examine the presence of chromogranin and polypeptide hormones in adenocarcinoma samples from our hospital.

RESULTS: The positive rate of NE cells and hormone products was 41.5 % (54/130) and 59.3 % (32/54), respectively in large intestinal adenocarcinoma cases; 39.6 % (38/96) and 36.8 % (14/38), respectively in gastric cancer cases; 38.1 % (8/21) and 50.0 % (4/8), respectively in prostatic cancer cases; 21.0 % (17/81) and 17.6 % (3/17), respectively in breast cancer cases; 17.9 % (5/28) and 60.0 % (3/5), respectively in pancreatic cancer cases. Among carcinomas of large intestine, pancreas and breast, the highly differentiated NE cell numbers were higher than the poorly differentiated NE cell numbers; while the gastric carcinoma cases had more poorly differentiated NE cells than highly differentiated NE cells. The higher detection rate of NE cells and their hormone products, the higher 5-year survival rate among the large intestine cancer cases.

CONCLUSION: Close correlation was observed between NE cells and their hormone products with the cancer differentiations. For colorectal carcinomas, there is a close correlation of the presence of NE cells and their hormone products with the tumor staging and prognosis.

INTRODUCTION

Compared with neuroendocrine cancers, little investigation is carried out on the relationship of neuroendocrine cells and their hormone products in non- neuroendocrine cancers, especially in the common adenocarcinoma cases. By using nine different antibodies and immunocytochemistry, NE cells and their hormone products in 356 adenocarcinomas was observed with the aim of revealing the incidence and distribution of NE cells

and the correlation between the cancer differentiation with the biological behaviors was evaluated.

MATERIALS AND METHODS

Materials

All the 365 adenocarcinoma samples were got from the first affiliated hospital of Zhejiang University Medical College from 1975 to 1994. There were 96 cases of gastric cancer samples (31 samples were got from the clinical biopsy; 65 samples were got from radical operation and 22 samples had lymph nodes metastasis); there were 130 cases of large intestine cancer samples got from radical operations (110 cases had the follow-up data); there were 81 and 28 cases of breast and pancreatic cancer, respectively. The remaining 21 samples were got from prostatic cancer biopsy.

Methods

All the samples were fixed with 10 % formaldehyde with paraffin embedding and continuous sectioning at 4 μ m in thickness. Gross pathological observation was made on the HE stain slides followed by immunocytochemistry. All the samples were treated with anti-chromogranin serum for the primary screening positive cases. Further immunocytochemistry was carried out for those positive NE samples by using peptide hormone antibodies such as ST (diluted at 1:10 000, provided by the 4th Military Medical Academy) and other Dako's antibodies (somatostatin diluted at 1:300; glucagon diluted at 1:800; pancreatic polypeptide diluted at 1:800; gastrin diluted at 1:350; insulin diluted at 1:150; ACTH diluted at 1:800 and calcitonin diluted at 1:150). The immunostains were done by ABC method and coloured with AEC. The antiserum of serotonin and gastrin was used in the gastric mucosa; the pancreas tissue was used to detect the chromogranin, somatostatin, glucagon, insulin and pancreatic polypeptide; calcitonin antiserum was used in the medullary carcinoma of the thyroid gland while ACTH in the pituitary was used as the positive control. The negative control was carried out by using normal sheep serum to replace the 1st antibody. Based on the chromogranin positive NE cell numbers, all the samples were divided into three grades as the following. Negative: there was no NE cells; Positive(+): the number of NE cells was fewer than 5/mm²; Super positive (++) : the number of NE cells was over 5/mm².

Statistical analysis

The data were analysed by χ^2 test.

RESULTS

Morphology of NE cells and their incidence

Among the five common adenocarcinomas from different tissue sources, the incidence rate was 41.5 % (54/130) for the large intestinal carcinomas; 39.6 % (38/96) for the gastric carcinoma; 38.1 % (8/21) for the prostatic carcinoma; 21.0 % (17/81) for the breast cancer and 17.9 % (5/28) for the pancreatic cancers, respectively. The highest incidence was

seen in large intestinal carcinomas while the lowest in the pancreatic carcinomas. When observing the chromogranin stained slides, clear edges of NE cells and brownish granules could be seen in the cytoplasm under the microscopy. In the low differentiated carcinomas, the NE cells presented as an oval, round or irregular shape without polarizations. Abnormal structural characteristics were observed among these low differentiated NE cells, which was similar to the adjacent tumor cells; while for those highly differentiated carcinomas, the NE cells were pyramid or bar shaped with the apex pointing to the cavity of the gland. A few NE cell processes could be observed reaching the gland cavity surfaces. The distribution of NE cells were scattered or localized infiltrating all the layers with the cancer cells. NE cells could be seen in both of the primary carcinoma and the metastasis sites.

Relationship between NE cells and carcinoma differentiation

No exact correlation between NE cells and carcinoma differentiation was observed among different carcinomas. The highly differentiated NE cell incidences were 41.7 % (5/12) for the large intestinal carcinomas, 42.9 % (3/7) for the pancreas carcinomas and 32.5 % (14/43) for the breast cancers, which was much higher than that of the low differentiated carcinomas. Prostatic carcinomas had the same tendency but there was no statistical significance due to fewer case numbers. In the low differentiated gastric carcinomas, 50 % (27/54) had the positive NE cells, which was significantly higher than that of the highly differentiated carcinomas.

Distribution of hormone products of NE cells in tumors

From Table 1, the number of hormone products types was more in large intestinal and gastric carcinomas (5 types of hormone products); hormone products detected in breast cancers were the fewest (only three in 17 cases). Most of them were the tumor origin tissue hormones, but few of them were ecotopic hormones.

Relationship between positive cell of hormone products and tumor differentiation

In the large intestinal carcinomas, 9 cases were low differentiated carcinomas whose positive cell percentage of hormone products against the total NE cells was 27.0 %, which was obviously lower than that in high differentiated carcinomas (15 cases with the percentage of 43.9 %) ($\chi^2=115.9$, $P<0.01$); It was also the same in the highly differentiated large intestinal carcinomas whose percentage was lower than that in the normal mucus membrane (10 cases with the percentage of 83.1 %) ($\chi^2=212.3$, $P<0.01$) and the mucus membranes adjacent to the tumors (25 cases with the percentage of 88.7 %) ($\chi^2=168.8$, $P<0.01$). The gastric carcinoma had the similar results: the positive cell percentage of hormone products against the total

NE cells was 17.5 %. But in the positive cells of hormone products from 5 gastric sinus mucus membranes, the positive cell percentage of hormone products against the total NE cells was 78.6 % ($\chi^2=1611.8$, $P<0.01$); the samples adjacent to the gastric sinus areas had the obviously higher percentage (46.6 %, $\chi^2=266.4$, $P<0.01$). Significant difference was also observed between the percentage of the adjacent mucus membrane tissues of the tumors and the normal mucus membranes ($\chi^2=242.0$, $P<0.01$).

Ecotopic hormones and tumor differentiation

Except for the pancreatic carcinomas, ecotopic hormones were revealed in other four types of the adenocarcinomas. One of the large intestinal carcinomas cases showed gastrin positive; Six gastric carcinoma cases showed ACTH positive; Two prostatic cancer cases were glucagons positive; One breast cancer case was somatostatin positive while another breast cancer case was calcitonin positive. Except for the large intestinal and gastric carcinomas, all the other nine cases were low differentiated carcinomas among the ecotopic hormone carcinomas.

NE cells and tumor differentiation

Observed in large intestinal carcinomas, Dukes A stage accounted for 41.7 % of the NE cell (++) cases (12 cases), which was much higher than that in NE(-) group (19.7 %, 76 cases). ($\chi^2=4.668$, $P<0.05$). Among the 110 cases with following-up, the 5-year survival rate was 81.8 % in NE cell (++) group, which was obviously higher than that in the NE (+) group (45.7 %, 35 cases) ($\chi^2=4.000$, $P<0.05$) and in NE cell (-) group (42.2 %, 64 cases) ($\chi^2=4.397$, $P<0.05$).

Among the 32 hormone products positive cases with polypeptide hormones (PH), Dukes A stage cases accounted for 44.1 %, which was higher than that of NE cell positive cases with hormone products negative (36.1 %), yet no statistical difference was found between the two groups ($\chi^2=0.351$, $P>0.05$). In hormone products (+) group (17 cases), the 5-year survival rate was 70.6 %, which was higher than that of hormone products (-) group (37.9 %, 29 cases) ($\chi^2=4.148$, $P<0.05$).

DISCUSSION

The commonly used staining methods for revealing NE cells include silver staining, neuron-specific enolase (NSE), synaptophysin (SY) and chromogranin (CG) immunocytochemistry. Silver staining is the traditional staining method with less specificity and sensitivity. Although NSE, CG and SY are all the common markers, NSE has poor specificity with distributions in different tissues but is localized in the cytoplasm. CG is distributed in neuroendocrine granules. Both CG and SY are good markers and corresponding to

Table 1 Distribution of hormone productions of NE cells in tumors

Type	NE Positive Case	Serotonin Case (%)	Somatostatin Case (%)	Glucagon Case (%)	P P Case (%)	Gastrin Case (%)	Calcitonin Case (%)	ACTH Case (%)
Colorectal carcinomas	54	30(55.6)	14(25.9)	11(20.4)	5(9.3)	1(1.9)	0	0
Gastric carcinomas	38	5(13.2)	5(13.2)	5(13.2)	0	3(7.9)	0	6(15.8)
Pancreatic Carcinomas	5	1(20.0)	0	1(20.0)	2(40.0)	0	0	0
Breast Carcinomas	17	1(5.9)	1(5.9)	0	0	0	1(5.9)	0
Prostatic Carcinomas	8	4(50.0)	0	2(25.0)	0	0	0	0

respective subcellular structures. CG is a specific matrix component of endocrine granules^[1-3]. While SY is localized within small capsule membranes related to the secretion granules, whose specificity and sensitivity are less than those of CG. That's why CG is considered as a realistic marker for NE cells^[4-8]. Studies have confirmed that CG could be served as a new way of revealing NE cells and for the diagnosis of NE tumors^[9].

Our study demonstrated that NE cell numbers were closely correlated to the tumor differentiation in large intestinal, pancreatic, breast and prostatic carcinomas^[10]. The higher differentiated tumors had the higher incidence of the NE cells^[8]. That was contradicted to our gastric carcinoma observations, but corresponding to the publication reports^[11]. Further studies are needed to be conducted to reveal these differences to see if they are related to the embryology, etiology and tissue development of the tumors.

No serial report were seen about the hormone products of NE cells from the common adenocarcinomas. We observed 5 types of adenocarcinomas and found out that large intestinal and gastric carcinomas had the higher hormone products in their NE cells; but in the gastric and highly differentiated carcinomas, they had lower hormone products in NE cell than those of poor differentiated carcinomas. The hormone products were more in the large intestinal and gastric carcinomas than those in normal mucus membranes and tissues adjacent to the carcinomas. Neoplastic NE cells had lower hormone products and they were decreased with anaplasia which may be due to the fact that these cells were in immature state with lower hormone synthesis. Thus, the amount of hormone products in NE cells of the carcinomas can serve as an index for the determination of tumor differentiation and the diagnosis of benign and malignant tumors^[12-15].

Based on the study of the large intestinal carcinomas, we found that hormone products and distribution of NE cells were closely correlated to the tumor grade, clinical pathological stage of the tumor and prognosis of the patients^[16-23]. Carcinomas with NE (++) releasing PH were the early stage carcinomas. The higher 5-year survival rate may be due to the somatostatin's inhibition of the tumors^[24-29]. Zollinger-Ellison syndrome was reported in some gastric carcinoid cases^[30-32], but our study only revealed there were only different hormone products but without sign and symptoms of Zollinger-Ellison syndrome as well as other hormone signs and symptoms, which may be the fact that the hormone products produced by NE cells were not enough in the inactivated form or inactivated by the liver enzymes. Further study is required to examine whether these hormone products participate in the immune regulations of the tumor or the hormone products exert the direct effects on the tumor development and growth.

Abstract

AIM: Primary neoplasmas of the jejunum and ileum are infrequent and lack specific manifestations and inaccessibility of conventional endoscopy, so the diagnosis of these tumors are usually delayed. So far the data of primary jejunoileal neoplasmas is still scarce, especially in Chinese medical literature in English. There may be some differences among the Chinese and the westerners in jejunoileal neoplasmas.

METHODS: A retrospective analysis was made on clinical findings and pathological types.

RESULTS: Of the 60 patients with jejunal or ileal neoplasmas, the most frequent symptom was abdominal pain (57 %), followed by tarry stool (43 %) and hematochezia (10 %). Abdominal mass (40 %) was the most common finding on physical examination, followed by anemia and weight loss (35 %). 67 % of the jejunoileal neoplasms were located in the jejunum. Among the malignant neoplasmas (68 %), malignant stroma (47 %) was most common, while the benign stromoma (20 %) was the most common benign neoplasmas. Preoperatively, 40 patients (67 %) were diagnosed as small bowel neoplasmas, of which 34 were found by enteroclysis. Abdominal mass was shown by CT in 18 cases and by ultrasonography in 13. The mean duration of symptoms before diagnosis was 7 months. In 41 patients with malignant tumors, the duration of symptoms before diagnosis exceeded 12 months in 21 cases, lymphatic or distant metastases were found in 26 (63 %) cases during operation. An emergency laparotomy was performed in 4 patients (7 %) owing to intestinal obstruction or perforation.

CONCLUSION: Primary jejunoileal neoplasmas in Chinese present some difference from Westerners on clinical features and histopathologic types. Enteroclysis remains the major relevant diagnostic procedure in this study, the misdiagnostic rate is high preoperatively due to failure of detection by conventional imaging procedures such as CT and inaccessibility of routine endoscopy. For the suspected patients, combined application of aforementioned procedures may facilitate early diagnosis. The wireless capsule endoscopy may improve the diagnostic rate of jejunoileal neoplasmas in the future.

INTRODUCTION

Primary neoplasmas of jejunum and ileum, benign or malignant, are infrequent. Clinical manifestations of jejunoileal neoplasmas are nonspecific and the neoplasma-related symptoms occur late, moreover, such neoplasms are beyond the scope of conventional gastroscopy or colonoscopy. The rarity, nonspecific and inaccessibility make them liable to be overlooked, with delayed or erroneous diagnosis^[1], and are responsible for high mortality rates. So far the data on small bowel cancers are scarce^[2]. To our knowledge, there may be some differences between the Chinese and the Westerner in jejunoileal neoplasmas. Herein we reported a series of consecutive cases of primary jejunal and ileal neoplasmas in our hospital over the past 8 years, and analyzed their clinical manifestations, pathologic types and diagnostic process.

MATERIALS AND METHODS

Cases of primary jejunal and ileal neoplasmas from January 1993 to August 2001 were retrieved through the inpatient computer registry system of PLA General Hospital, Beijing. The medical records were reviewed by the authors. Cases of duodenal and metastatic small bowel tumors were excluded. A total of 60 cases of primary jejunal and ileal neoplasmas were collected. All cases underwent surgery and were confirmed by histopathology.

RESULTS

Demographic features

There were 42 males (70 %) and 18 females (30 %) with an average age of 48 years (16-77 years). The majority (51 %) of patients were over 50 years of age.

Clinical manifestations

Symptoms, signs and complications were listed in the following Table 1. Abdominal pain and tarry stool were the most common symptoms in both benign and malignant jejunoileal tumors. Abdominal mass and anemia were common findings on physical examination in both benign and malignant neoplasmas, while the weight loss was frequent in malignant ones. Complications at presentation such as intestinal obstruction and perforation were more common in malignant tumors.

Table 1 Clinical manifestations of 60 cases of jejunoileal tumors

	Benign (n)	Malignant (n)	Total
Symptoms			
Abdominal pain	8	26	34 (57%)
Tarry stool	9	17	26 (43%)
Hematochezia	2	4	6 (10%)
Signs			
Abdominal mass	9	15	24 (40%)
Anemia	6	15	21 (35%)
Weight loss	1	20	21 (35%)
Complications			
Intestinal obstruction	2	5	7 (12%)
Intestinal perforation	0	1	1

Histopathology and sites of distribution

Histopathology and sites of distribution of jejunoileal neoplasmas were summarized in Table 2. Of the 60 cases, 40 (67 %) were located in the jejunum, and 20 (33 %) in the ileum. Malignant tumors ($n=41$, 68 %) was nearly twice that of the benign ones ($n=19$, 32 %). Benign and malignant stromoma were predominant histological entities.

Table 2 Histopathology and distribution sites of 60 cases of jejunal and ileal tumors

Tumor types	Jejunum	Ileum	Total
Benign	14 (23.3%)	5 (8.3%)	19 (≈32%)
Stromoma	8	4	12 (20%)
Adenoma	2	0	2 (3.3%)
Angioleiomyoma	2	0	2 (3.3%)
Lipoma	0	1	1 (1.7%)
Lymphangioma	1	0	1 (1.7%)
Neurofibroma	1	0	1 (1.7%)
Malignant	26 (43%)	15 (25%)	41 (≈68%)
Malignant stromoma	17	11	28 (46.7%)
Adenocarcinoma	7	1	8 (13.3%)
Non-Hodgkin's lymphoma	0	2	2 (3.3%)
Carcinoid	0	1	1 (1.7%)
Neuroendocrine carcinoma	1		1 (1.7%)
Malignant histiocytosis	1	0	1 (1.7%)
Total	40(67%)	20(33%)	60 (100%)

Diagnostic procedures

Before operation, small intestinal diseases were suspected in 73 % (44/60) on admission. There were 40/60 patients (67 %) correctly diagnosed preoperatively. Among the 40 patients, 34 jejunoileal neoplasmas were correctly diagnosed by enteroclysis. Other preoperative diagnoses were made by angiography, colonoscopy, CT and Ultrasonography. Angiography was performed in 5 cases, of which 4 (80 %) of them were discovered preoperatively. One case of lymphoma of terminal ileum was detected by colonoscopy, and one jejunal tumor was diagnosed by CT scan only.

Of the 60 patients, 56 underwent CT scan, abdominal masses or intestinal wall thickening were visualized in 18 (32 %) cases, but two of them were misinterpreted as ovarian cancer, one as renal lipoma and one as intestinal tuberculosis. Ultrasonography was carried out in all 60 patients, and solid abdominal masses were demonstrated in 13 (22 %).

20 patients remained obscure diagnosis preoperatively, final diagnoses were disclosed during laparotomy. The mean duration of symptoms before diagnosis was 7 months. In 41 patients with malignant neoplasms, the duration of symptoms exceeded 12 months in 21 (52 %) cases.

Surgical findings

Of the 60 patients, three cases of intestinal obstruction and one case of intestinal perforation underwent emergency laparotomy (7 %). The rest underwent selective laparotomy (93%).

Of the 41 of malignant tumors, the masses within the intestinal walls were found in 15 without metastases; local lymph node metastasis in 12, distant and mesenteric lymph node metastasis in 9, liver metastases in 4 and urinary bladder metastasis in 1, the total rate of metastases was 63 % among the malignant tumors. lymph node metastasis was commonest in 51 % of malignant tumors.

DISCUSSION

Primary neoplasmas of jejunum and ileum are only <2 % of

the gastrointestinal malignant tumors, the incidence was 1.4 per 100 000 compared to 35.7/100 000 for colorectal and 92.9/100 000 for breast cancer^[2,3]. The jejunoileal neoplasmas are preponderant in male with a ratio of 2:1 between male and female^[3,4]. Our result showed 70 % in male and 30 % in female, similar to that reported in the literature. The patients with jejunoileal tumors were usually old people with an average age of over 50 years^[1-5], in this article, 51 % were over 50 years.

The small bowel neoplasmas located in the jejunum usually more frequent than that in ileal. In our results, the jejunal neoplasmas were twice as many as the ileal ones, higher than that reported in the literature^[4]; but the ratio of malignant and benign in small bowel tumors was concordant with those in the literature^[7]. As to the histopathologic types, the commonest pathologies of jejunoileal tumors were lymphoma, adenocarcinoma and carcinoids, followed by leiomyosarcomas, neuroendocrine tumors and other entities in Western countries^[1-7], which were significantly different from those in our study, in which the benign and malignant stromoma was predominant. In addition, some very rare tumors were seen in our investigation including angioleiomyoma, lymphangioma and malignant histiocytosis etc. The above results indicated that there were some differences between the Chinese and the Westerners in the pathologic types of jejunoileal tumors.

The clinical manifestations of jejunoileal neoplasmas were nonspecific and symptoms usually occurred late. The abdominal pain, gastrointestinal bleeding and weight loss were most frequent complaints in our patients and as well as in the other reports^[4-6], followed by nausea and/or vomiting^[4,6]. Abdominal mass and anemia were the most common physical findings in our study and related literatures^[4,6], followed by abdominal distension, muscle guarding and rigidity^[4]. The diagnosis of small bowel neoplasmas was often made when symptoms presented several months late, the median duration of symptoms before diagnosis was 7 months in our study, 3.6 and 6 months in others^[4,6]. The metastasises of jejunoileal neoplasms were common as they were usually identified late, the metastatic rate of leiomyosarcoma ranged from 24 % to 50 %, with the liver being most frequently involved^[5], distant metastasis occurred in 27 %^[2]. In our study, metastasis was found in 63 % of the malignant tumors, lymph node metastasis was the commonest (51 %) similar to that reported in the literature^[4], followed by liver metastases in 10 % of cases.

The preoperative diagnosis of primary jejunoileal neoplasmas remains difficult for clinicians owing to the nonspecific symptomatic presentation. The enteroclysis, enteroscopy and imaging methods have been used generally for small bowel diseases. Radiographic study of small bowel malignant tumors showed abnormality in 87 %^[4]. In our study, 34 cases of jejunoileal neoplasmas were diagnosed by enteroclysis. Both ultrasonography (US) and CT are also useful for detection of small bowel tumours. CT was found to detect leiomyoma and leiomyosarcoma most successfully and had the additional advantage of locating metastatic lesions^[5]. Moreover, CT offered the possibility of a preoperative staging by evaluating tumour extension through the bowel wall, involvement of lymph node and possible metastases^[8]. Other preoperative diagnoses were made through angiography, colonoscopy, CT and Ultrasonography. Angiography was performed in 5 cases, of which 4 (80 %) of small intestinal neoplasmas were discovered preoperatively. A case of lymphoma of terminal ileum was detected by colonoscopy, and one case of jejunum tumor was diagnosed by CT scan only.

Of the 60 patients, 56 underwent CT scan, abdominal masses or intestinal wall thickening were visualized in 18 (32 %), but two cases were misinterpreted as ovarian cancer, one as renal lipoma and one as intestinal tuberculosis. Ultrasonography was

carried out in all 60 patients, and the solid abdominal masses were demonstrated in 13 cases (22 %).

Final diagnoses were disclosed during laparotomy for those 20 patients whose diagnoses remained obscure preoperatively. The mean duration of symptoms before diagnosis was 7 months. In 41 patients with malignant neoplasms, the duration of symptoms exceeded 12 months in 21 cases (52 %).

Jejunum and ileum are difficult to visualize directly. Colonoscopy with retrograde ileoscopy is useful in the diagnosis of neoplasm of the terminal ileum^[4]. Enteroscopy is capable of observing most of the small intestine^[5], but it is hard for the patients to endure. Small bowel enteroclysis is still a good choice for the detection of jejunoileal neoplasms^[6], albeit a third of cases of this series may be missed in the examination. Angiography is carried out in only a small proportion of patients, though it is relatively sensitive, especially for those lesions with abundant vascularity, the expense and invasive property limit its application^[7]. Spiral CT is thought to be comparatively accurate in detecting small bowel tumors^[8], however its diagnostic accuracy is poor in this series with possible misinterpretations, probably due to lack of experience of some radiologists in this field. Despite the interference by intestinal gas, ultrasonography proves to be helpful in a fifth of cases to demonstrate thickened intestinal wall or unsuspected mass. Wireless capsule endoscopy is optimal for those patients without intestinal obstruction when it is available. Laparotomy is justified in those suspected cases as a last resort.

Thanks to a variety of investigations, the correct diagnosis is reached in the majority of patients before operation, though the delay between the onset of symptoms and the final diagnosis

is often significant. As a result, more than 60 % of patients with malignant tumors has advanced beyond the early stage of neoplasm. Recognition of this entity, with high index of suspicion, rational application of aforementioned investigation procedures, the advent of capsule endoscopy and justified early laparotomy, may facilitate the diagnosis and improve the outcome.

Abstract

AIM: To evaluate of scoring system in predicting choledocholithiasis in selective intraoperative cholangiography (IOC) during laparoscopic cholecystectomy (LC).

METHODS: The scoring system of predicting choledocholithiasis was developed during the retrospective study in 264 cases, and was tested in 184 to evaluate its predictive value in choledocholithiasis.

RESULTS: The scoring system was developed in a retrospective study of 264 cases, the statistical analyses showed the predictive factors included sex, transaminase levels, alkaline phosphatase level, bilirubin level, and common bile duct diameter on ultrasonography. The scoring system was used in 184 cases prospectively, of which, 3 of 162 (1.9 %) cases scoring <3 had choledocholithiasis, 17 of 22 (77.3 %) cases scores ≥3 had choledocholithiasis. A case of scores ≥3 or more prospectively should be considered highly intraoperative cholangiography during laparoscopic cholecystectomy.

CONCLUSION: The scoring system can predict choledocholithiasis and is helpful in selection patients for intraoperative cholangiography.

INTRODUCTION

Laparoscopic cholecystectomy (LC) has been extensively accepted since Mouret first successfully finished the procedure in 1987^[1]. Whether intraoperative cholangiogram (IOC) during LC should be applied routinely is still controversial. Thus, we develop a scoring system to predict choledocholithiasis and recommend selection of IOC during LC.

MATERIALS AND METHODS

Retrospective study

Two hundred sixty-four cases of LC from January 1996 to June

1999 were analyzed. Before operation, choledocholithiasis in cases with cholecystolithiasis was not discovered by ultrasonography (US). During operation, 54 cases of cholecystolithiasis with choledocholithiasis and 210 cases of cholecystolithiasis without choledocholithiasis were confirmed by IOC. Sex, age, history of pancreatitis, jaundice, transaminase levels, alkaline phosphatase level, bilirubin level and diameter of common bile duct (CBD) on ultrasonography were evaluated as predictors of choledocholithiasis, and scoring system of selective IOC was designed.

Prospective study

From January 2000 to June 2001, the scoring system was carried out prospectively in 184 patients undergoing LC. Following evaluation, LC and IOC were performed, then the correlation of scoring results with choledocholithiasis was studied.

RESULTS

No choledocholithiasis in 264 patients undergoing LC was discovered by ultrasonography prior to operation. During LC, IOC found choledocholithiasis in 54 patients (Table 1).

Table 1 Factors predicting choledocholithiasis in 264 patients

Factor	No of cases with choledocholithiasis (54 cases)	No of cases without choledocholithiasis (210 cases)	Percentage (%)	P
Sex				
Male	27	40	40	<0.05
Female	27	170	14	
Age				
<55ys	34	112	23	<0.05
≥55ys	20	98	17	
Pancreatitis				
Present	15	30	33	>0.05
Absent	39	180	18	
Jaundice				
Present	10	22	31	>0.05
Absent	44	188	19	
Transaminase				
Normal	31	201	13	<0.05
Elevated	23	9	72	
Alkaline phosphatase				
Normal	36	189	16	<0.05
Elevated	18	21	46	
Bilirubin				
Normal	31	205	13	<0.05
Elevated	23	5	82	
CBD diameter on US				
≤8 mm	33	204	14	<0.05
>8 mm	21	6	78	

Multivariate analysis found that independent predictors of choledocholithiasis included sex, serum level of transaminase, alkaline phosphatase, and bilirubin, and CBD diameter on US. Therefore, the scoring system in regression analysis was established (Table 2).

Table 2 Scoring system of predicting choledocholithiasis

Factor	Criteria	Score
Sex	Female	0
	Male	1
Transaminase	Normal	0
	Elevated	2
Alkaline phosphatase	Normal	0
	Elevated	2
Bilirubin	Normal	0
	Elevated	3
CBD diameter on US	≤8 mm	0
	>8 mm	3
Total		11

The scoring system was used in 184 patients undergoing LC before operation. During LC, all of the patients were performed IOC (Table 3).

Table 3 Results of scores in 184 patients before LC

	Score											
	0	1	2	3	4	5	6	7	8	9	10	11
No of patients	107	49	6	3	1	2	1	3	2	2	2	6

During LC, choledocholithiasis was found in 20 patients by IOC, the relationship between scores and choledocholithiasis was showed in Table 4.

Table 4 Relationship between scoring results and choledocholithiasis in 184 patients undergoing LC

Score	No of patients with choledocholithiasis	No of patients without choledocholithiasis	Percentage
<3	3	159	1.9
≥3 ^a	17	5	77.3

^aP<0.05 vs score of less than 3.

A significant difference in predicting value scoring 3 or more and that of less than 3 was found according to the χ^2 test. Thus, evaluation of LC patient with scoring system preoperatively would be helpful in predicting choledocholithiasis. If patient were scored more than 3, IOC should be performed during LC.

DISCUSSION

With the popularization of laparoscope, the age of micro-traumatic surgery has come and great changes have occurred in surgical operation and surgical ideology^[2]. Gallstone is one of the common primary diseases of biliary tract. LC has become a conventional method to treat patient with symptomatic gallstones. IOC is one of the accurate and safe procedure used in LC, is helpful in finding abnormality of pancreaticobiliary tract^[3], avoiding common bile duct injury^[4-8], and detecting choledocholithiasis^[9-11], thus, some recommended a routine IOC during LC^[4,5,12]. Because majority of gallstones patients do not have choledocholithiasis, IOC will increase the patient's cost

and exposure to X-ray, however, some researches found that the value of IOC were limited^[13-15], it is unnecessary to perform a routine IOC during LC. However, there are still 10-15 % of cholecystolithiasis patients who have choledocholithiasis^[16]. Preoperative ERCP and IOC may be helpful to find choledocholithiasis^[17-20].

Mahmud suggested that, some gallstones might slip into the cystic duct or the common bile duct during LC, and IOC is valuable of determining the choledocholithiasis, ERCP and EST were regarded as effective methods detecting choledocholithiasis^[21]. Edey retrospectively analyzed 31 patients with choledocholithiasis treated by EST, and ERCP showed completely cleared common bile duct, but IOC during subsequent LC revealed common duct residual stones in 8 of these 31 patients. The author suggested that even after presumed endoscopic clearance of the bile duct stone, many patients (26 %) still harbored stones in common bile duct at the time of cholecystectomy. Therefore IOC during LC was recommended even after successful ERCP^[22]. Some studies revealed that preoperative ultrasound is neither sensitive nor specific for detecting common bile duct dilatation or the presence of residual stones^[23]. Some studies assessed the use of endoscopic retrograde cholangiopancreatography (ERCP), IOC, intraoperative laparoscopic ultrasonography (IOUS)^[24-27]. Bege manifested that combined endoscopic and laparoscopic management of cholecystolithiasis and choledocholithiasis were a viable option and were optimized by endoscopic ultra-sonography^[28]. The combined procedures of endoscopic sphincterotomy and LC included one-stage treatment of cholelithiasis and choledocholithiasis, elimination of potential return to the operating room when postoperative ERCP were unsuccessful^[29,30]. Ichihara concluded that intraoperative real time cholangiograms were helpful in detecting bile duct injuries or anomalies, and unsuspected bile duct stones^[31].

We recommend that IOC during LC should be performed selectively. Digital C-arm can provide real-time imaging and obtain a clear cholangiogram easily. The protocol of selective IOC is still debatable. Snow analyzed the results of 2034 LC, and found that there were no false negative, bile duct injuries, or other complications attributable to routine IOC or selective IOC, and suggested that selective IOC were an effective method of verifying suspected choledocholithiasis and were safer and less expensive than routine IOC^[32]. Abboud performed a meta-analysis of published data to evaluate preoperative indicators of choledocholithiasis, which included cholangitis, jaundice, dilated CBD on ultrasound, hyperbilirubinemia, elevated levels of alkaline phosphatase, pancreatitis, cholecystitis, and hyperamylasemia. The results showed that these predictors could be applied as guidelines for whether to investigate for duct stones before cholecystectomy^[33]. Kim also suggested selective IOC, and the risk levels of the presence of choledocholithiasis were determined by the independent predictor including preoperative clinical, biochemical and sonographic variables^[34]. However, Koo reviewed 420 cases of elective LC, IOC was routinely performed and acted as the reference standard for the presence of choledocholithiasis, and found that there were no predictive tests that could sufficiently increase an observer's probability estimate of the presence or absence of choledocholithiasis to allow for "selective" IOC decisions^[35].

By logistic regression analysis, our studies showed that sex, transaminase levels, alkaline phosphatase level, bilirubin level and common bile duct diameter on ultrasonography were independent predictors of choledocholithiasis. A scoring system was therefore designed with a total score of 11. Our prospective studies also showed that patients scoring more than 3 were at significant risk to have choledocholithiasis, and IOC should be performed during LC.

Abstract

AIM: To review the experience on the use of endoscopic nasopancreatic drainage (ENPD) in the treatment of severe acute pancreatitis (SAP).

METHODS: Since March 1998, under the regular management of SAP with non-operative method, ENPD has been randomly used in 14 patients. The average age of the patients was 41.3 ± 15.9 (years), with 8 males and 6 females. The time from onset to admission was 32.9 ± 22.8 (hours). 8 cases were found to have gallbladder stone. The daily output of pancreatic fluid was measured. The body temperature, heart rate, WBC count, blood glucose, blood calcium, PaO_2 , blood and urine levels of amylase were detected on the fifth day and compared with their respective data on the first day. Therapeutic results and hospitalization times were recorded.

RESULTS: The time of drainage was 7.3 ± 4.0 days. The daily drainage outputs of the first five days were 236.4 ± 176.6 , 287.1 ± 164.7 , 284.6 ± 216.4 , 435.0 ± 357.8 and 377.8 ± 223.8 ml, respectively. The decreases in body temperature, heart rate, WBC counts, blood and urine levels of amylase and the increase in PaO_2 were significant on the fifth day when compared with those on the first day. Infection of pancreatic necrosis was found in one patient and controlled by anti-infectives. 6 out of 8 patients with gallbladder stone were operated during hospital stay. All patients were cured and discharged and the average hospital stay was 28.1 ± 11.6 days.

CONCLUSION: ENPD is an effective method for the drainage of pancreatic fluid and might have an important role in the treatment of SAP. Further observation, comparison and summary by this method are worthy to be considered.

INTRODUCTION

Acute pancreatitis (AP) is a common clinical emergency. For the reason of urgency of episode, severity of patient's condition, frequent complications and high mortality, extensive attention has been paid to severe acute pancreatitis (SAP) in clinical practice^[1-10]. Since August 1995, we have adopted the principle of combination therapy mainly by non-operative methods, the

therapeutic efficacy of SAP has been increased significantly and hospital stay has been shortened. Therein, the method of endoscopic naso-pancreatic drainage (ENPD) was used in 14 cases since March 1998, with significant results.

MATERIALS AND METHODS

General clinical data

A total of 14 patients were treated, with average age of 41.3 ± 15.9 (27-77) years, 8 males and 6 females. From onset of the disease to admission was 32.9 ± 22.8 (6-72) hours. In 8 cases (8/14, 57.1 %), gallbladder stone was detected by B ultrasonography or computerized tomography (CT). All patients were diagnosed as SAP in accord with the diagnostic criteria set by Surgical Pancreatic Group of the Surgical Society of Chinese Medical Association^[11,12]. Within 24 hours after hospitalization, their APACHE-II scores were ≥ 8 , Balthazar CT grades $\geq \text{II}$, and all accompanied by one or more organ dysfunction.

Routine non-operative monitoring therapy

All patients in fasting were installed with gastric tube to decompress and drain gastrointestinal fluid, and were given oxygen therapy (nasal catheter oxygen inhalation, 5 L/min), prophylactic application of antibiotics and somatostatin (14 peptide or 8 peptide). At the same time, internal homeostasis including water-electrolyte balance, acid-base balance, and the change of organ functions such as heart, lung, liver and kidney were monitored. Proper supportive therapy was given on time if necessary.

Endoscopic nasopancreatic drainage (ENPD)

After hospitalization, with the use of fiberoptic duodenoscope spectacle (Olympus TJF-30 model), nasopancreatic drainage-tube was inserted through the scope in the ward instantly after admission. The procedure was as follows: after intramuscular injection of 50 mg meperidine and 10 mg 654-2 with topical anaesthesia of throat, the endoscope was advanced to duodenum, searching for the papilla. Once found, it was observed about its shape, size, and position of the orifice. A tube was inserted into pancreatic duct for 5-10 cm through the orifice. The catheter was 1.95 m in length, 1.95 mm in outside diameter and 1.70 mm in inside diameter with 3 to 5 side holes near the distal end. If pancreatic juice could be drawn out, it indicated that insertion of the catheter was successful. The endoscope was then withdrawn and the drainage tube was guided from oral cavity to nasal cavity by a guiding catheter and fixed. Thereafter, the patency of the nasopancreatic tube was closely observed daily and was washed with gentamycin saline solution if necessary. When the abdominal symptoms and signs subsided, the tube was pulled out.

Observation index

Volume of the drainage from nasopancreatic tube was observed and recorded everyday. The body temperature, heart rate, WBC counts, blood glucose, blood calcium, PaO_2 , and blood and urine levels of amylase were surveyed on the fifth day and compared with that on the first day. The therapeutic results and the time of hospital stay were recorded.

Data processing

All data were expressed as mean \pm standard deviation, and *t*-test was used for statistical analysis.

RESULTS

Information of drainage by nasopancreatic tube

The pancreatic fluid of all patients drained out was feculent achromatic or white fluid in the first 1 to 3 days, and then turned to clear transparent pancreatic fluid. The time of nasopancreatic drainage was 7.3 ± 4.0 days. The drainage output of pancreatic fluid during the first five days was shown in Figure 1. The radiogram of naso-pancreatic catheter in a patient was shown in Figure 2.

Figure 1 The drainage output of pancreatic fluid during the first five days.

Figure 2 The radiogram of naso-pancreatic catheter in a patient.

Changes of the relevant monitoring indices

The decrease of body temperature, heart rate, WBC count, blood and urine levels of amylase and the increase of PaO_2 were significant on the fifth day when compared with that on the first day. The change of blood glucose or blood calcium had no significant difference. The details were shown in Table 1.

Table 1 Changes in several related indexes

	The first day	The fifth day

Therapeutic result of treatment and time of hospital stay

Bacterial infection of pancreatic necrosis was found in one patient and controlled after changing the anti-infectives. Cholecystectomy was performed in 6 patients with cholecystolithiasis before discharge. All patients were cured and the time of hospital stay was 28.1 ± 1.6 days.

DISCUSSION

There has been a steady increase in the incidence or the admission rate of AP^[13-15]. Generally, it is recognized that the pathogenesis of AP is correlated with the common channel of biliary and pancreatic ducts which is also called the common biliary pancreatic duct. The most common cause (60-80 %) is gallbladder stone and alcoholism^[16]. The former cause was more extensively studied than the latter. Incarceration by the calculus which enters the common channel and/or the inflammatory reaction and tissue edema caused by the passage of the calculus have often been proposed as the mechanism of AP and we name this type of AP the gallbladder stone-originated AP.

The obstruction of common biliary pancreatic duct results in the bile flowing into the pancreatic duct, activating the pancreatic enzymes and then causing the occurrence of AP. This is the classical bile reflux-common channel theory. This theory does not explain why AP happens in patients who have no calculus incarceration in or obstruction of common biliary pancreatic duct. In our group, 8 out of 14 cases, which amounted to 57.1 %, were diagnosed as having with cholecystolithiasis. But no one showed incarceration of the calculus or obstruction of common biliary pancreatic duct. We found that there was no bile mixed in the pancreatic fluid in our SAP patients with or without cholecystolithiasis, although the initial drain was feculent.

Nevertheless, the experiment of Lerch, *et al*^[17] made it clear that both pancreatic duct ligation alone and common biliary pancreatic duct ligation could cause the occurrence of AP, with pathological changes of similar severity. This result suggested that pancreatic duct obstruction, especially increase of pancreatic intraductal pressure was the main factor of the occurrence of AP. It may be the main mechanism in patients suffering from AP with or without cholecystolithiasis. Pancreatic ischaemia has an important role in the pathophysiology of AP^[18,19]. Shi and his colleagues^[20] reported that pancreatic duct obstruction was the first step causing ischaemia in AP and early decompression of the pancreatic duct prevented the early pancreatic ischaemia. The study of Choudari, *et al*^[21] proved that improving drainage of the pancreatic ductal system by endoscopic means effectively relieved the pain and reduced the number of attacks of pancreatitis in the majority of patients with hereditary pancreatitis. Aiming directly on this mechanism, we used the method of ENPD in treating SAP patients. All the patients accepted the routine non-operative therapy. Amelioration of abdominal symptoms and signs was very rapid with the drainage. Comparing with that on the first day, the decrease in body temperature, heart rate, WBC counts, blood and urine levels of amylase and the increase in PaO_2 were significant on the fifth day. Although blood glucose decreased and blood calcium increased, but they had no statistic significance. Bacterial infection of pancreatic necrosis was found only in one patient and was controlled after changing the anti-infectives. All 14 patients of this group were cured.

Studies have shown that duration of the obstruction of common biliary pancreatic duct was related directly with the severity of pancreatic necrosis and prognosis of the patient. Removal of the obstruction or decreasing the pressure on time can prevent the appearance of pancreatic necrosis or its further

development. The earlier the time of removal of the obstruction or decreasing the pressure, the better the prognosis^[16,22-24]. Beger, *et al*^[25] found that if the course of AP was longer than 3-4 days, the pancreas would necrotize irreversibly. It is important in the therapy of SAP to remove the obstruction or lower the high pressure of the pancreatic duct as early as possible. The time from onset to admission was 32.9±22.8 (6-72) hours in this group and the application of ENPD was carried out in the ward immediately after the admission. This is another important factor to get the curative effect.

This is our preliminary experience of the clinical application of ENPD in the treatment of SAP. The real value of this therapeutic modality should be further studied by strict randomised control study.

Abstract

AIM: To assess the validity of local excision for the early stage low rectal cancer as an effective treatment alternative to radical resection.

METHODS: A retrospective medical chart review was done in 47 patients with early stage low rectal carcinoma who underwent local excision from November 1980 through November 1999 at Cancer Hospital of Chinese Academy of Medical Sciences (CAMS). The patients were treated by either transanal (40 cases), trans-sacral (5 cases), or trans-vaginal (2 cases) excision of tumors and no death was related to surgery. Sixteen patients received postoperative radiotherapy.

RESULTS: T1 and T2 lesion was found in 36 (76.6 %) and 11 patients (23.4 %) respectively. The overall local tumor recurrence rate was 14.9 % (7/47), with an average recurrence time of 21 months. Among these 7 recurrent patients, there were 4 T1 and 3 T2 lesions. Microscopically, the surgical incisional margin was negative in 45 (95.7 %) and positive in 2 patients (4.3 %); Both of the later had developed local recurrence. The overall 5-year survival rate was 91.7 %, in which there were 94.4 % for T1 and 83.3 % for T2 tumors. T stage, intravessel tumor thrombosis, lymphocytic infiltration and histological grade were not found to be significant by related to the local recurrence and survival ($P>0.05$).

CONCLUSION: Local tumor excision was a safe procedure for the treatment of early stage low rectal carcinoma with minimal morbidity and mortality, which might serves as one of the primary surgical treatment methods for the disease of this kind.

INTRODUCTION

Abdominoperineal resection (APR) has traditionally been used to treat the Adenocarcinoma of the low rectum^[1-2]. In which a

permanent colostomy has to be performed, leading to the risk of complications, inconvenience of patients and even death^[3,4]. More recently, local excision has been performed with the curative intent to remove the well-differentiated lesions that are less than 3 cm in diameter and limited to the mucosa or submucosa^[5-7], which offers these patients fewer operative complications and long-term survival outcome^[8-13]. The increasing evidence based on the local tumor recurrence and survival rates supports the use of local excision as a primary treatment modality in the selected patients^[14-18].

The aim of the present study was to review our experience in the local excision of the early rectal cancers and to assess the validity of this therapeutic strategy as an effective treatment alternative to radical resection.

MATERIALS AND METHODS

Materials

Forty-seven 47 patients with early stage low rectal carcinomas were treated by local excision from November 1980 to November 1999 at the Department of General Surgical Oncology, Cancer Hospital of Chinese Academy of Medical Sciences (CAMS). They were 23 male and 24 female and with an average age 57 years (ranging from 31 to 80 years). The rectal carcinomas were located 3 to 8 cm from the anal verge (Table 1).

Table 1 Patient and treatment characteristics (n=47)

Grade	
Well differentiated	22
Moderately differentiated	23
Poorly differentiated	2
Surgical Procedure	
Transanal excision	40
Trans-sacral excision	5
Trans-vaginal excision	2

Treatment

Patients were treated by either transanal (40 cases), trans-sacral (5 cases), or trans-vaginal (2 cases) excision of tumors, in which 16 patients received postoperative radiotherapy.

Pathological diagnosis

All available pathohistological sections were reviewed by a single pathologist to assessed the depth and extent of tumor invasion, the lymphocytic infiltration, mucinous status, and the degree of tumor differentiation. The tumor was staged according to the American Joint Committee on Cancer Staging System (AJCC1996).

Statistical analysis

The end points of this study were local and distant tumor recurrence and patient survival. Obtained data were analyzed using the Statistical Package for the Social Sciences (Release 11.0, SPSS, Inc). Survival curves were estimated using the Kaplan-Meier method and were compared using the log-rank test. Significance was defined as $P < 0.05$.

RESULTS

There was no death related to surgery. The most severe complication was the fistula formation, which was necessitated to perform a temporary diverting colostomy in two patients treated with trans-sacral excision. Other complications included bleeding in 2 patients and anal stricture in one patient (Table 1).

The median tumor diameter was 2.0 cm (ranging from 0.4 to 3 cm). Thirty-six patients (76.6 %) had T1 and 11 patients (23.4 %) had T2 lesion. The resected tumors in most cases were well or moderately differentiated, poorly differentiated were only seen in two patients. For those pathological sections were available, intravessel tumor thrombosis was identified in 10 patients (21.3 %) and lymphocytic infiltration in 8 patients (17.0 %). Tumor cells appeared on the surgical incisional margin were negative in 45 patients (95.7 %) and positive in 2 cases (4.3 %).

The average time for follow-up survey was 53 months. The overall local tumor recurrence rate was 14.9 % (7 patients) with the median recurrence time of 21 months (ranging from 12 to 48 months) postoperation. Among those with local recurrence, T1 and T2 tumors were found in 4 and 3 cases respectively. Five patients had immediate reoperation (APR or anterior resection). Both of the two patients with tumor cell positive incisional margin developed local recurrence. The overall 5-year survival rate was 91.7 %, in which there were 94.4 % for T1 and 83.3 % for T2 tumors.

T stage, intravessel tumor thrombosis, lymphocytic infiltration, histological grade and mucinous differentiation were not found to be significant predictors for local tumor recurrence and survival ($P > 0.05$).

DISCUSSION

Abdominoperineal resection, the mainstay of treatment for rectal cancer nowadays, has been reported bearing a death rate of 2.3 % to 3.2 % and 30 % to 46 % postoperative complications in the patient. permanent colostomy, urinary and sexual dysfunction are common sequelae of radical proctectomy that impair seriously affecting the patient's quality of life^[1-4]. In the past, local excision was performed only if the patient was in poor medical condition or refused to have a colostomy. Recent data suggest that the combination of local excision and postoperative chemo-radiation therapy may be an option for some patients with early stage rectal cancer. Encouraging results of local treatment of early rectal cancer and the development of new diagnostic technology providing accurate preoperative staging have greatly increased the interest of surgical oncology in this therapeutic strategy^[14-19].

However, broad acceptance of local excision as the primary treatment rectal cancer has been limited by the high local tumor recurrence that was difficult to be interpreted because the

literature was dominated by retrospective analyses of heterogeneous groups of patients. Included the patients with the tumors undifferentiated and penetrating the perirectal fat, with questionable or even positive tumor cell incisional margins, or with different surgical approaches, even palliative surgery^[20,21]. Besides specific reference was not always made to the lymphatic and blood vessel invasion, and the role of salvage surgery after failed local excision has also not been clearly stated^[22-26]. Therefore, There is an almost uniform agreement at present that only the well- or moderately differentiated T1 and T2 tumors, without blood vessel or lymphatic invasion or mucinous components could be treated by local excision with curative intent.

The present study there was no death related to the surgery, postoperative mortality. Complications occurring more and with a minimal in patients treated with trans-sacral excision was the fistula that was necessitated to perform a temporary diverting colostomy in two patients. Transanal excision was associated with less morbidity than any other local excision procedures.

Our data suggested that longer follow-up was necessary to identify those who would have a relapse, as shown by the fact that the median time for the local tumor recurrence in our study was about 21 months, with a range of 12 to 48 months postoperation. Recurrence rates were 11.1 % and 27.3 % in T1 and T2 tumors, respectively, which suggested that T stage was an important factor affecting recurrence.

The fact that both of the 2 patients with tumor cell positive incisional margin developed local recurrence suggested that tumor-free incisional margin and completely tumor excision was crucial for the prevention of local tumor recurrence, which was difficult to achieve for T3 lesion because the tumor had invaded the perirectal fat or anal sphincter. Therefore, if a tumor cell negative incisional margin could not be achieved in the operation, the patient was not considered as a good candidate for the local excision^[27,28]. Statistical analysis showed that intravessel tumor thrombosis, lymphocytic infiltration, histologic grade and mucinous differentiation were not found to be the significant predictors for the local tumor recurrence and survival ($P > 0.05$).

In summary, on the basis of our retrospective data, the sphincter-preserving local excision can be used as one of the primary surgical treatment methods for the early-stage low rectal cancer with minimal morbidity and mortality.

Abstract

AIM: To investigate epidemiology and pathogenic mite
species of intestinal and urinary acariasis in individuals with
different occupations.

METHODS: A total of 1994 individuals were tested in this
study. History collection, skin prick test and pathogen
identification were conducted. The mites were isolated from
stool and urine samples by saturated saline flotation methods
and sieving following centrifugation, respectively.

RESULTS: Among the 1994 individuals examined, responses
to the skin prick test of "+++", "++", "+", "±" and "-" were
observed at frequencies of 3.96 % (79), 3.21 % (64), 2.31 %
(46), 1.25 % (25) and 89.27 % (1780), respectively. A total
number of 161 (8.07 %) individuals were shown to carry
mites, with 92 (4.61 %) positive only for stool samples, 37
(1.86 %) positive only for urine samples and 32 (1.60 %) for
both. The positive rate of mites in stool samples was 6.22 %
(124/1994), being 6.84 % (78/1140) for males and 5.39 %
(46/854) for females. No gender difference was
observed in this study ($\chi^2=1.77$, $P>0.05$). The mites from
stool samples included *Acarus siro*, *Tyrophagus putrescentiae*,
Dermatophagoides farinae, *D. pteronyssinus*, *Glycyphagus*
domesticus, *G. ornatus*, *Carpoglyphus lactis* and *Tarsonemus*
granaries. The positive rate of mites in urine samples was
3.46 % (69/1994). The positive rates for male and female
subjects were found to be 3.95 % (45/1140) and 2.81 %
(24/854) respectively, with no gender difference observed
($\chi^2=1.89$, $P>0.05$). Mites species in urine samples included
Acarus siro, *Tyrophagus putrescentiae*, *T. longior*, *Aleuroglyphus*
ovatus, *Caloglyphus berlesei*, *C. mycophagus*, *Suidasia*
nesbitti, *Lardoglyphus kono*, *Glycyphagus domesticus*,
Carpoglyphus lactis, *Lepidoglyphus destructor*,
Dermatophagoides farinae, *D. pteronyssinus*, *Euroglyphus*
magnei, *Caloglyphus hughesi*, *Tarsonemus granarus* and *T.*
hominis. The species of mites in stool and urine samples
were consistent with those separated from working
environment. A significant difference was found among the
frequencies of mite infection in individuals with different
occupations ($\chi^2=82.55$, $P<0.001$), with its frequencies in
those working in medicinal herb storehouses, those in rice
storehouse or mills, miners, railway workers, pupils and
teachers being 15.89 % (68/428), 12.96 % (53/409), 3.28 %
(18/549), 2.54 % (6/236), 5.10 % (13/255) and 2.56 % (3/
117), respectively.

CONCLUSION: The prevalence of human intestinal and
urinary acariasis was not associated with gender, and these

diseases are more frequently found in individuals working
in medicinal herb, rice storehouses or mills and other sites
with high density of mites. More attention should be paid
to the mite prevention and labor protection for these high-
risk groups.

and urinary acariasis. *World J Gastroenterol* 2003; 9(4): 874-877
<http://www.wjgnet.com/1007-9327/9/874.htm>

INTRODUCTION

Various species of mites often infest stored foodstuffs and
various drugs, and cause losses in food and drug products,
especially in humid and warm area^[1-9]. They are small creatures
of about half a millimeter in body size and creamy white in
color, proving difficult to be detected from drugs and food
products. Therefore, the incidence of various forms of human
acariasis presumably caused by the ingestion of mite-infested
food is unusually high in China^[10]. In this study we investigate
the epidemiological characteristics and pathogenic mite species
of intestinal and urinary acariasis in individuals with different
occupations in Anhui Province.

MATERIALS AND METHODS

Population

A total of 1994 subjects with the average age of 35 years (6-
63 years), 1 140 males and 854 females, were examined in this
study, including medicinal herb storehouse workers ($n=428$),
rice storehouse or mill workers ($n=409$), miners ($n=549$),
railway workers ($n=236$), pupils ($n=255$) and teachers ($n=117$).
Special attention was paid to individuals with intestinal or/
and urinary symptoms.

Methods

History collection, skin prick test and etiological examination
were carried out on the 1994 subjects.

History collection A questionnaire, administered by a nurse,
was used to collect information from each subject investigated.
Information was collected by means of in-person, telephone,
interview, including age, gender, history of present illness,
anamnesis, symptomatology (i.e. abdominal pain, diarrhea,
abdominal cramps, urethremorrhage, urodynia, cloudy urine,
frequency of micturition), onset date and duration of symptoms,
personal habits, living environmental hygiene and the date of
stool and urine sample collection.

Skin prick test Skin prick test were performed with the
concentrations of 1:100 (W/V) of the test extract. After skin
disinfection, a little of extract (about 0.01 ml) was dripped on
skin surface of right forearm flexor, then a special disinfectant
needle was used to prick into the skin through the drop of the
extract. The depth of needle in skin was limited about 0.5-1
mm and there was no bloodshed. About 5 cm apart from the
extract drop, normal saline in proximal and histamine in distalis
were used for negative and positive control solution. The mean
diameter of the wheals or areolae was measured 15-20 min
after the test. The reactions with the mean diameter up to 1.5

mm, 2 mm, 3 mm, 5 mm and 10 mm were regarded as \pm , +, ++, +++ and +++++, respectively.

The test extract was made according to NIBSC82/518 approved by World Health Organization (WHO) in 1984. The purified fraction was prepared as follows: the mites were then frozen and thawed several times after having been cultured in the initial medium for several months. A 48-hr maceration in a borate buffer (pH 8.5) was followed by centrifugation. The supernatant was neutralized and submitted to precipitation with a series of acetone. The fraction precipitated at 80 % acetone was isolated, washed and dried. This purified extract was lyophilized or stored as a solution in the presence of 50 % glycerol and 5 % phenol^[11-14].

Etiological examination All individuals were asked to provide stool and urine samples for etiological examination. Mites in stool samples were separated by saturated saline flotation methods, and the mites were identified under microscope. Each stool sample was examined for three times. Specimens containing adult or larval mites, eggs, or hypopus were considered positive.

Samples of the first urine in the morning and 24 hours' urine of all individuals were collected for separation of mites. After centrifugation and filtration with a copper sieve, they were examined under a microscope for adult or larval mites, eggs or hypopus.

Blood examination Leukocytes were also counted and sorted in 30 patients with mites detected.

Detection of mites from working environment Directcopy, waterenacopy and tullgren were used to identify mites from mill floor dust, stores of medicinal herbs including wolfberry fruit, ophiopogon root liquorice, boat-fruited sterculia seed and safflower.

Colonoscopy After defecation, the patients with mites found in their stools were examined by routine colonoscopy.

Cystoscopy After emiction, the patients with mites detected in their urine were examined by routine cystoscopy.

Statistical analysis

The positivity rates were expressed as percentages, and the statistical analysis was carried out by using χ^2 test. A probability value of less than 0.05 was considered statistically significant.

RESULTS

Skin prick test

The skin prick test was definitely positive in 189 subjects, with the results “+++”, “++”, “+”, “ \pm ” and “-” observed in 79 (3.96 %), 64 (3.21 %), 46 (2.31 %), 25 (1.25 %) and 1 780 (89.27 %), respectively among the 1994 individuals examined.

Etiological examination

Of 1994 individuals investigated, mites were detected from stool or/and urine samples in 161 (8.07 %) subjects, with the positive rates in stool, urine and in both being 4.61 % (92), 1.86 % (37) and 1.60 % (32), respectively.

The positive rate of mites in stool samples was 6.22 % (124/1 994), with that for male and female subjects being 6.84 % (78/1 140) and 5.39 % (46/854), respectively. No gender difference was found in this series ($\chi^2=1.77$, $P>0.05$). The mites from stool samples included *Acarus siro*, *Tyrophagus putrescentiae*, *Dermatophagoides farinae*, *D. pteronyssinus*, *Glycyphagus domesticus*, *G. ornatus*, *Carpoglyphus lactis* and *Tarsonemus granarius*. Among 124 cases with mites in stool samples, 54 (43.55 %) were positive for adult mites, 13 (10.48 %) for larval mites, 43 (34.68 %) for both adult and larval mites, 3 (2.42 %) for both adult mites and eggs, 6 (4.84 %) for adult and larval mites and eggs, 3 (2.42 %) for both larval mites and

eggs and 2 (1.61 %) for both hypopus and eggs. Mite concentration was also estimated, being 1-2 /cm³, 2-4 /cm³ and >5 /cm³ in 6, 30 and 88 cases, respectively.

Totally, mites were detected from urine samples at a frequency of 3.46 % (69/1 994). The positive rate for male and female subjects were 3.95 % (45/1140) and 2.81 % (24/854), respectively, with no gender difference found in this series ($\chi^2=1.89$, $P>0.05$). The mites in urine samples were separated and identified, including *Acarus siro*, *Tyrophagus putrescentiae*, *T. longior*, *Aleuroglyphus ovatus*, *Caloglyphus berlessei*, *C. mycophagus*, *Suidasia nesbitti*, *Lardoglyphus konoi*, *Glycyphagus domesticus*, *Carpoglyphus lactis*, *Lepidoglyphus destructor*, *Dermatophagoides farinae*, *D. pteronyssinus*, *Euroglyphus magnei*, *Caloglyphus hughesi*, *Tarsonemus granarius* and *T. hominis*. Among the 69 positive cases, 19 cases (27.54 %) were found to be positive for adult mites, 18 (26.09 %) for larval mites, 11 (15.94 %) both adult and larval mites, 3 (4.35 %) for adult mites and eggs, 11 (15.94 %) adult and larval mites and eggs, 6 (8.70 %) for larval mites and eggs, and 1 (1.44 %) for both hypopus and eggs. The mite concentrations were shown to be <0.5 /ml, 0.6-1 /ml, 1.1-1.5 /ml and >1.5 /ml, respectively, in 32, 25, 10 and 2 cases, reflecting the verity infectiosity of mites among different individuals.

Relationship between skin prick test and etiological examination

The results of etiological examination are correlative to skin prick test. One hundred and sixty-one of the 189 cases (85.19 %) positive skin-prick reaction were found to be positive for mites in their stool or / and urine samples. The intensities of the skin prick reaction were also found to be associated to mite concentrations in stool or / and urine samples, with the reactions “+++”, “++” and “+” corrective to 100 % (79/79), 90.63 % (58/64) and 37.50 % (24/46), respectively.

Blood examination

Leukocytes were counted and sorted in 30 cases, most of them being in the range of (5.55-10.4) $\times 10^9$ /L with the exception of 4 cases [(11.0-12.9) $\times 10^9$ /L]. The eosinophilic granulocyte count was high [(0.32-0.78) $\times 10^9$ /L]. The average value of constituent ratio of eosinophilic granulocyte was 0.09 (0.04-0.11) and was higher than the normal range ($P<0.01$).

Mites separated from working environment

The samples of mill floor dust (30 shares), stores of medicinal herbs (146 species) including wolfberry fruit, ophiopogon root liquorice, boat-fruited sterculia seed, safflower and other working environmental foodstuffs were collected and used for mites isolation. Numbers of mites per gram were shown to be 91-1862, 21-186, 0-483, 10-348, 51-712, and 311-1193, in mill floor dust, traditional Chinese medicine stores, traditional Chinese herbs including candied fruit, dry fruit, brown sugar, and expired cake. Twenty-two species, from 9 families of mites were separated and identified out of them, including *Acaridae*, *Lardoglyphidae*, *Glycyphagidae*, *Chortoglyphidae*, *Carpoglyphidae*, *Histiostomidae*, *Pyroglyphidae*, *Tarsonemus*, *Cheyletus*. The mite species isolates from working environment were shown to be similar to those from stored food staffs.

Relationship between acariasis and occupation

Of the 1994 subjects investigated, mites were detected in 68 individuals (3.41 %) working in traditional Chinese medical storehouses, and 53 rice storehouse or mill workers 53 (2.66 %), being higher than those with other occupations (Table 1).

Table 1 Prevalence of intestinal and urinary tract mite infection in individuals with different occupations

Occupations	n	Only in stool		Only in urine		Both in stool and urine		Total	
		n	%	n	%	n	%	n	%
Traditional medical storehouse workers	428	32	7.48	24	5.61	12	2.80	68	15.89 ^a
Rice storehouse or mill workers	409	28	6.85	12	2.93	13	3.18	53	12.96 ^a
Miners	549	16	2.91	0	0	2	0.36	18	3.28 ^a

Colonoscopy

Colonoscopy performs in 16 patients with mites found only in stool, showing pale intestinal wall, punctate ulcer, and exfoliated cell from intestinal wall. In addition, live mites and eggs were observed in tissues, especially in marginal zone of ulcer.

Cystoscopy

Cystoscopy was performed in the 11 patients with mites only found in urine samples, showing Pachymucosa, uroepithelial hyperplasia, lymphocyte and plasmaocyte infiltration in membrana propria and a lot of dense pink abscess in the trigone. In addition, trabecularism of inner wall of urinary bladder changed slightly, local of lateral wall was congestive, and blood capillary was also congestive and dilated. By cystoscopy, 4 adult mites were found in 3 of 11 subjects, which were identified to be *Lardoglyphus kono*, *Euroglyphus magnei*, *Tarsonemus granarus*, and neither larval mite nor egg was found.

DISCUSSION

The acaroid mite is a kind of arthropod and its geographic distribution appears to be global^[15,16]. Acaroid mites infestation is a well-known problem for stored grain, often influencing quality and hygienic condition of the grain^[1-9]. However, little is known about acariasis. Acaroid mite can survive in many environments including the storehouse, human and animal bodies. Its infestation in human can cause acariasis in several organs including the lung, intestine and urinary tract^[17-26].

In this study, mites were identified in 124 of the 1994 stool samples. The mite species observed in stool samples included *Acaridae*, *Glycyphagidae*, *Carpoglyphidae*, *Pyroglyphidae* and *Tarsonemus*, being in accordance with those found in the working places of the patients. This confirmed that mites being able to live in intestinal tract and causing intestinal acariasis were transmitted through living environment and stored foods. The respiratory infection through the polluted air may also be an alternative pathway. Eight sampling sites had been set up in a traditional Chinese medicine plant, and 13 mites had been isolated from the dust samples collected from the 640 L volume of air in the working environment of the plant. When dust with mites ingested, some of mites might go into intestine through mouth, nasal cavity or gorge. The mites living in intestinal tract may stimulate mechanically and damage intestinal tissues with its gnathosoma, chelicera, feet, and other structures^[27,28]. In addition, they may also intrude into mucous layer and deep tissues, and cause necroinflammation and ulcers^[29-33]. This has been approved in this study by colonoscopy, with spotty necrosis, petechial hemorrhage and ulcer observed. The most frequent symptoms of the intestinal acariasis were abdominal pain, diarrhea and pyohemofecia^[10, 34,45].

Urinary acariasis was caused by mites parasitizing in human urinary tract. Mite isolation from urine is essential for its

diagnosis. In the present study, 1994 individuals with different occupation were surveyed 69 patients found from their urine samples, 17 mite species were identified, with most of them being *Acaridida*. Apparently the pathogenic mites come from environment. Regarding the transmission path, the following possibilities have been proposed. First, the insects may enter the urinary tract by crawling from vulva. Second, they may enter the body through skin and reach urinary tract in some way. Third, mites in respiratory or alimentary system may enter the blood circulation, and reach kidney and urinary tract^[46-50]. Acarid in human urinary system may damage urethral epithelia, for the mites are good at digging. Furthermore, they can also invade loose connective tissue and small blood vessel in urinary tract, and caused an ulcer. Under cystoscopy, a lot of dense pink abscess were found in trigone of urinary bladder in this study.

The incidence of intestinal and urinary acariasis was shown in this study to vary greatly and was linked to occupations, being higher in individuals working in traditional Chinese medicine (16 %) and rice storehouses or mills (13 %) than in those with other occupations (2.5-8.1 %). The densities of mites in traditional Chinese medicine and rice storehouses were shown to be high. When peoples exposed to these environment for a long time, the possibility to be infected may be greater than those in environments with low densities of mites. It is important to note that some patients with acariasis have habits of having teas immersed by traditional Chinese herbs, such as *Liriope longipedicellata*, *Radix glycyrrhizae*, boat-fruited *sterculia* seed, and eating dried kern like dateplum persimmon, candied jujube and *Crataegus cuneata*. Therefore, the prevalence of acariasis was related to personal habits and densities of mites in working environment and stored foodstuffs.

Abstract

AIM: To summarize the characteristics of patients suffered from primary biliary cirrhosis associated with ulcerative colitis.

METHODS: To report a new case and review the literature.

RESULTS: There were 18 cases (including our case) of primary biliary cirrhosis complicated with ulcerative colitis reported in the literature. Compared with classical primary biliary cirrhosis, the patients were more often males and younger similar. The bowel lesions were usually mild with proctitis predominated. While ulcerative colitis was diagnosed before primary biliary cirrhosis in 13 cases, the presentation of primary biliary cirrhosis was earlier than that of ulcerative colitis in our new case reported here. The prevalence of primary biliary cirrhosis among patients of ulcerative colitis was almost 30 times higher than in general population.

CONCLUSION: Association of primary biliary cirrhosis with ulcerative colitis is rare. It should be considered in the differential diagnosis of hepatobiliary disease in patients with ulcerative colitis, and vice versa.

Xiao WB, Liu YL. Primary biliary cirrhosis and ulcerative colitis: A case report and review of literature. *World J Gastroenterol* 2003; 9(4): 878-880
<http://www.wjgnet.com/1007-9327/9/878.htm>

INTRODUCTION

A variety of hepatobiliary diseases have been described in patients with ulcerative colitis (UC). The incidence is 3-15 % with persistent abnormal liver function tests, and up to 90 % with abnormal liver histology at surgery or autopsy^[1]. These include primary sclerosing cholangitis, pericholangitis of the small bile ducts, chronic active hepatitis, cholangiocarcinoma and cirrhosis. The association of primary biliary cirrhosis (PBC) and UC has occasionally been reported^[2-4]. We hereby presented an additional case.

CASE REPORT

A 50-year-old woman was admitted to our hospital because of skin pruritus for two years. One year ago she was found to have jaundice and examined in another hospital. The results of all hepatitis virus test were negative, and she was diagnosed as cryptogenic hepatitis. Six months ago she had diarrhea 2-3

times per day. Upon physical examination icterus was evident on the skin and sclera. Hepatomegaly and splenomegaly were found. Blood routine test revealed hemoglobin 106 g/L, WBC and platelet counts normal. ESR 78 mm/h. IgM elevated to 7.73 g/L, IgA and IgG normal. Liver function tests showed ALT 81 U/L, AST 139 U/L, serum total bilirubin 223.2 umol/L, direct bilirubin 138.3 umol/L and GGT 1042 U/L. Cholesterol was 12.2 mmol/L. Immunological tests, by indirect immunofluorescence were as follows: ANA, 1:10 positive, anti-mitochondria antibody (AMA), negative, anti-LK (anti-liver and anti-kidney) microsome antibody and anti-smooth muscle antibody negative. Hepatomegaly, splenomegaly and portal hypertension were seen in abdominal computed tomography (Figure 1). No intra- and extrahepatic bile duct abnormalities were found by ERCP. Liver biopsy disclosed an increased portal infiltration consisting of lymphocytes, plasmacytes, and scattered eosinophils with fibrosis and pseudolobulation. Two portal areas had hyperplastic ductule. The findings were compatible with PBC stage 3-4 (Figure 2). Colonoscopy showed up to 20 cm continuous lesions of the mucosa with numerous ulcers and adherent mucopurulent exudate (Figure 3). Histological examination demonstrated loss of goblet cells, neutrophilic microabscesses in the crypts, and infiltration with mononuclear cells and plasma cells in the lamina propria (Figure 4). Ulcerative colitis limited to rectosigmoid was diagnosed. Ursodeoxycholic acid (UDCA) was prescribed. One month later serum bilirubin and liver function tests returned to normal. But diarrhea persisted and sulfasalazine was given. The bowel symptoms were then relieved.

Table 1 Review of patients of PBC associated with UC^a

Refer-ences	Patient	Sex	Age (yr)	Comorbidity	AMA (titer)
3	1	F	65	Pancolitis, chronic pancreatitis	1/64
4	2	F	20	Proctitis	Strongly
4	3	M	22	Proctitis	1/160
4	4	M	44	Proctitis	1/320
4	5	F	28	Left-side colitis	1/200
5	6	F	49	Proctitis, chronic myelocytic leukemia	Positive
6	7	F	45	Proctitis, chronic pancreatitis	Positive
7	8	M	40	Left-side colitis	1/160
8	9	F	48	Pancolitis, renal cell carcinoma	1/160
9	10	M	58	Proctitis	1/160
9	11	F	68	Proctitis	1/160
10	12	F	43	Pancolitis	>1/160
11	13	M	61	Proctitis	Positive
Present	14	F	50	Proctitis	Negative

^aFour cases with incomplete data were not shown here.

Figure 1 Abdominal CT disclosed hepatomegaly, splenomegaly and portal hypertension.

Figure 2 Liver biopsy revealed portal infiltration of lymphocytes, plasmacytes, and scattered eosinophils with fibrosis and pseudolobule (H&E, 10×10).

Figure 3 Colonoscopy showed continuous mucosal ulceration.

Figure 4 Histological examination demonstrated neutrophilic microabscesses in the crypts (H&E, 10×20).

DISCUSSION

Hepatobiliary diseases are commonly found in association with UC. Primary sclerosing cholangitis (PSC) involved the large bile ducts is the most common associated hepatopathy, affecting 2.4-7.5 % of UC patients. PBC is another autoimmune hepatobiliary disease similar to PSC. The typical features include skin pruritus, with hyperbilirubinemia, increased IgM levels and hypercholesterolemia. AMA is present in about 95 % of patients, that is in about 5 % AMA is negative. Cholangiogram is normal. Granulomatous inflammation of the periportal areas is a typical finding. The clinical manifestation and histologic features of our patient were compatible with PBC, although AMA was negative.

PBC associated with UC is rare. There were 18 cases (including our case) reported in the literature. In 4 cases from Sweden and Taiwan data were incomplete. In the remaining 14 patients, their presentations were different from that of typical PBC without UC (Table 1). It is well known that PBC usually affects middle-aged women. The sex ratio is 10:1 (women to men), and the mean age at diagnosis was 57.5 years. It is quite obvious that these figures differ in the patients of table 1. The sex ratio was low (2:1) and the mean age was younger similar to that of UC. In addition, UC was mild and limited with proctitis predominating. Only 3 of 12 patients had pancolitis. Similarly, UC associated with PSC tends to be mild, but usually involving the whole bowel.

The prevalence of PBC in Europe is about 15/100 000. In a cohort of 412 cases of UC, 2 cases of PBC were diagnosed estimating the prevalence of PBC among these patients 485/100 1 000, almost 30 times higher as compared with the general population^[2]. It is believed that both PBC and UC are autoimmune disease, and have similar pathogenesis. Associated autoimmune conditions are frequent in both PBC and UC. PBC and UC may be an additional example of a true association between syndromes of autoimmune etiology. But the detail remains to be clarified. In 13 out of the 14 patients UC were diagnosed many years before the diagnosis of PBC. Symptoms of PBC usually presented during the active stage of UC. In other words, PBC runs a course depending the activity of UC. So most authors considered PBC as the extraintestinal (hepatobiliary) manifestation of UC. But in our case it is clear that the presentation of PBC is earlier than that of UC. We believe that UC also could be regarded as extrahepatic manifestation of PBC.

Treatment of these patients presents some difficulties. Prednisolone, which is indicated for the treatment of the active stage of UC, might lead to extensive osteoporosis in PBC. But as mentioned above, UC associated with PBC is usually mild, so sulfasalazine is the first choice. If the presentation of PBC is evident, UDCA could be added.

In conclusion the reported association between UC and PBC is rare, and it has not yet been established whether it occurs coincidentally or is due to a common immunogenetic basis. PBC should be considered in the differential diagnosis of hepatobiliary disease in patients with UC, and vice versa. Liver biopsy and serum AMA are two diagnostic criteria that clearly distinguish PBC from PSC.

Abstract

The congenital H-type fistula between the anorectum and genital tract besides a normal anus is a rare entity in the spectrum of anorectal anomalies. We described a girl with an anovestibular H-type fistula and left vulvar abscess. A 40-day-old girl presented symptoms after her parents noted the presence of stool at the vestibulum. On the physical examination, anus was in normal location and size, and had normal sphincter tone. A vestibular opening was seen in the midline just below of the hymen. A fistulous communication was found between the vestibular opening and the anus, just above the dentate line. There was a vulvar abscess which had a left lateral vulvar drainage opening 15 mm left lateral to the perineum. After the management of local inflammation and abscess, the patient was operated for primary repair of the fistula. A protective colostomy wasn't performed prior the operation. A profuse diarrhea started after 5 hours of postoperation. After the diarrhea, a recurrent fistula was occurred on the second postoperative day. A divided sigmoid colostomy was performed. 2 months later, and anterior sagittal anorectoplasty was reconstructed and colostomy was closed 1 month later. Various surgical techniques with or without protective colostomy have been described for double termination repair. But there is no consensus regarding surgical management of double termination.

INTRODUCTION

The congenital H-type fistula between the anorectum and genital tract without anal atresia is a rare entity in the spectrum of anorectal anomalies. This type of anomaly has been termed as "double termination" of the alimentary tract in girls^[1-3]. Most of the fistulas localized between the anorectum and vestibule of the vagina, and this type anomaly was described as Perineal Canal^[1,2,4-6]. We described a 40-day-old girl with a congenital anovestibular H-type fistula complicated with a vulvar abscess.

CASE REPORT

A 40-day-old girl referred to our university medical center with a passage of stool through vestibulum as well as through the normal anal passage from birth. She had been swelling and tenderness on her left vulvar region for one week. On the physical examination, anus was at the normal location and size,

and it had normal sphincter tone. A vestibular opening was found in the midline just below of the hymen. With insertion of an 8 Fr catheter through the vestibular opening, a fistulous communication was detected between the vestibule of the vagina and the anus at the dentate line. Nearly 3 mm to the left side of this opening, there was a second opening about 3 mm in diameter. A metal sound was inserted through this opening and it was found that it had a subcutaneous continuity with a vulvar abscess. This abscess was detected to drain through a cutaneous opening 15 mm lateral to the perineum (Figure 1). No associated anomaly was detected.

Figure 1 8 Fr catheter was placed in the perineal canal and metal sound was passed through vestibular and cutaneous openings of the abscess.

After the management of local inflammation and abscess, the patient was operated for primary repair of the fistula. The bowel preparation was performed with saline enemas. A protective colostomy was not performed either prior or during the definitive operation. We used the technique of anterior sagittal anorectoplasty described by Kulshrestha *et al.* in 1998^[1]. At the operation, a metal sound was passed through the fistula from the vestibule of the vagina into the anal canal in the lithotomy position. Then the perineal body that remained over the sound vertically was incised. This incision included skin, subcutaneous tissue, a few fibers of external sphincter muscle, wall of the fistulous tract and anal canal mucosa. The mucosa of the opened fistulous tract was dissected off the underlying muscle. Then, perineal reconstruction was performed by stitching the vestibule, perineal body, sphincter muscle and the anorectum with interrupted 4/0 PDS sutures. Perineal skin was closed with 4/0 Prolene. Five hours following the transfer of the patient to the ward, a profuse diarrhea started resulting in 16 defecations on the first postoperative day. Unfortunately, this caused a partial breakdown of the wound on the second postoperative day, which caused the recurrence of the fistula. And the divided sigmoid colostomy was performed.

Two months later, we operated with the same technique and this attempt was successful. One month following the repair of the fistula, we closed her colostomy and started a rectal dilatation program. Her first year postoperative follow-up was uneventful.

DISCUSSION

The incidence of double termination among female anorectal malformations ranged between 4-14 % in different Asian series^[1,5-8]. On the basis of Wingspread classification, these H-type fistulas were divided into three groups according to their level. Low type double termination included cases in which the fistula was lying between the anal canal and the vestibule and this was named as "perineal canal". In the intermediate type, communication was found between the rectum and the vestibule. High type of double termination consisted of a fistula between the rectum and the vagina^[1]. Our case had a low type double termination and an abscess which was detected in her vulvar region complicated her anomaly. When we reviewed the cases reported in the literature, we found out that Rintala *et al.* reported vulvar abscess formation in three girls with double termination^[2]. In another report by Brem *et al.* abscess formation was claimed to be secondary to the infection in either a congenital blind-ending sinus or an existing fistula leading to additional openings^[9].

On the other hand, high type of vestibular fistula demands a more specific operation and it may be named as vestibulorectal pull-through procedure. Without protective colostomy, this type of repair is reported to have a fairly high recurrence rate^[7]. Various surgical techniques have been described for low-type double termination repair. These techniques were utilized either with or without protective colostomy in different series. Chatterjee described a simple perineal procedure without colostomy and with good results^[3]. Tsuchida *et al* did not use diversion during definitive procedure they named as "pull-through of the anterior wall of the rectum" in 3 of his 7 cases with perineal canal. Their results were satisfactory for both diverted and non-diverted cases. However, they were not as successful as above with their cases managed with another different simple repair technique and without diversion^[5]. Kulshrestha *et al.* described anterior sagittal anorectoplasty in 1998 as a surgical technique for all types of double termination without colostomy and without no complications^[1]. This series which were the most recent and had a successful outcome for the repair of perineal canal directed us to prefer this technique in our series. Furthermore,

avoiding a colostomy in using this technique was another major factor for our selection.

Unfortunately, our case's fistula recurred. This may have resulted not from insufficiency of the technique, but from some factors that did not take place in Kulshrestha's series. A major reason for breakdown of the repair may be due to the unexpected and unwanted profuse diarrhea of the patient that started after 5 hours of the post-operation. The sufficiency of the technique may be thought of when one thinks that in the redo operation, it was proved to be a good result.

In conclusion, it is believed that definitive repair can be performed without protective colostomy when no abscess formation is present in the vulvar region. If an abscess is detected, it should be well managed before the operation.

Abstract

We reported a case of 79-year old woman with known large bowel diverticulosis presenting with small bowel obstruction due to stone impaction - found on plain abdominal X-ray. Contrast studies demonstrated small bowel diverticulosis. At laparotomy, the gall bladder was normal with no stones and no abnormal communication with small bowel - excluding the possibility of a gallstone ileus. Analysis of the stone revealed a composition of bile pigments and calcium oxalate. This was a rare case of small bowel obstruction due to enterolith formation - made distinctive by calcification (previously unreported in the proximal small bowel).

Hayee B, Khan HN, Al-Mishlab T, McPartlin JF. A case of enterolith small bowel obstruction and jejunal diverticulosis. *World J Gastroenterol* 2003; 9(4): 883-884

<http://www.wjgnet.com/1007-9327/9/883.htm>

INTRODUCTION

Diverticulosis of the small bowel (excluding Meckel's) is uncommon - being found in less than 5 % of post-mortem examinations, although the prevalence increases with age^[1]. The condition can be complicated by diverticulitis, haemorrhage or perforation^[2,3]. Small bowel obstruction due to an enterolith formed and extruded from a diverticulum is a rare complication^[4-6].

Enteroliths form in small bowel diverticula either *de novo* or around a central nidus such as a fruit stone or undigested vegetable matter (the latter is termed a bezoar). The usual composition of true enteroliths is choleic acid^[7] - an end product of bile salt metabolism - postulated to form as a result of acidic pH shift within a small bowel diverticulum. Radiological diagnosis of such stones is rare, unless calcified (which usually occurs only in the more alkaline ileum)^[7]. Diagnosis is therefore made at laparotomy with the presence of the stone, diverticula and the finding of a normal gall bladder (excluding a gallstone ileus). It is unclear how stones are extruded from small bowel diverticula lacking a muscular coat, but larger stones will be extruded and pass distally to cause obstruction - an enterolith ileus.

CASE REPORT

A 79-year-old lady presented with a two-day history of vomiting and central, colicky abdominal pain. She had been constipated prior to this episode and had taken senna with only a little effect on the previous day. She had a known history of

sigmoid diverticular disease and had been admitted only once previously for suspected diverticulitis. She appeared dehydrated with fever of 37.6 degrees. Her abdomen was distended but soft with some central and left-sided tenderness. Bowel sounds were heard and digital rectal examination was unremarkable. Blood tests revealed a white cell count of $21.6 \times 10^9/L$ without other abnormality. A plain abdominal film demonstrated opacity on the left side (Figure 1) and a gastrografen study revealed numerous small bowel diverticula of varying sizes. The opacity now was presumed to be a stone, was noted within the small bowel (Figure 2).

Figure 1 Radio-opaque stone was clearly seen in the plain abdominal radiograph (arrow).

Figure 2 Contrast study (105 mins) demonstrated multiple jejunal diverticula and minimal passage of barium beyond the mid-jejunum. Stone was still visible (arrow).

At laparotomy, the presence of large jejunal diverticula was confirmed and the stone was found impacted in the mid-

jejunum. The gall bladder appeared normal without stones. The stone approximately 3×4 cm and weighing 10.60 g appeared greyish and hard which was removed via a small enterotomy close to it. The patient made a good recovery from operation, delayed only by post-operative nausea. Analysis of the stone revealed a composition of bile pigments and calcium oxalate.

DISCUSSION

We reported the first case of proximal small bowel obstruction due to a calcified enterolith. It is postulated that diverticulas provide the more acidic environment necessary for choleic acid precipitation and stone formation^[7]. However calcification cannot occur without an alkaline pH shift, which normally occurs in the ileum. Our case confirmed calcification occurring in the proximal small bowel which made this theory less definitive but facilitated the diagnosis.

The consensus management of enterolith ileus at laparotomy is to first attempt manual lysis of the stone without enterotomy and to milk the smaller parts into the colon where they are passed through rectum^[8]. If this is proved to be impossible or inappropriate, the stone is removed through an enterotomy which is made in a less edematous segment of proximal small bowel.

The rarity of enterolith small bowel obstruction is well recognised with the condition occurring in conjunction with

cases of diverticulosis. However the diagnosis should be considered in patients presenting with clinical features of small bowel obstruction without evidence of previous abdominal surgery or incarcerated hernia.

Abstract

AIM: To explore the properties of hypervariable region 1 (HVR1) in the envelope 2 gene of hepatitis C virus by analyzing the reactivity of HVR1 fusion proteins from different Chinese HCV strains with sera of patients with chronic hepatitis C and by comparing their reactivity between interferon therapy responders and non-responders.

METHODS: Gene fragments of HVR1 of four HCV strains (three genotype 1b and one genotype 2a) were amplified from pGEMT-E2 plasmids and sub-cloned into pQE40 vectors respectively to construct recombinant expression plasmids which expressed HVR1 fused downstream to DHFR in *Escherichia coli* strain TG1. The purified DHFR-HVR1 proteins were then used to detect the anti-HVR1 antibodies in 70 serum samples of patients with chronic hepatitis C.

RESULTS: Four DHFR- HVR1 fusion proteins were successfully expressed in *E. coli* (320-800 µg fusion proteins per 100 ml culture). Each fusion protein (SH1b, BJ1b, SD1b and SD2a) reacted with 72.8 % (51/70), 60 % (42/70), 48.6 % (34/70), and 58.6 % (41/70) of the anti-HCV positive patients' sera respectively by ELISA. 57.1 % (4/7) of non responders reacted with all four HVR1 fusion proteins, while only 15.3 % (2/13) of responders reacted with all of them. The O.D. values of sera from IFN therapy responders were significantly higher than those of non responders ($P < 0.05$).

CONCLUSION: The selected HVR1 fusion proteins expressed in *E. coli* can broadly react with HCV-infected patients' sera. The intensity and/or quality of the immune response against HCV may be a critical factor determining the response to interferon treatment. With the evolution of virus strains, anti-HVR1 antibodies can not neutralize all the quasispecies. A polyvalent and high immunogenic vaccine comprising a mixture of several HVR1 sequences that cover the reactivity of most HCV isolates may be useful.

Zhang XX, Zhang SY, Liu J, Lu ZM, Wang Y. Expression of hepatitis C virus hypervariable region 1 and its clinical significance. *World J Gastroenterol* 2003; 9(5): 1003-1007
<http://www.wjgnet.com/1007-9327/9/1003.htm>

INTRODUCTION

Hepatitis C virus (HCV) is the major etiologic agent of blood transfusion-associated and sporadic non-A non-B hepatitis worldwide. About 70 % of the infections become chronic, among which a significant proportion eventually develops cirrhosis and hepatocellular carcinoma. Despite recent success after the combination therapy with Interferon- α and ribavirin^[1-3], about 60 % of patients still fail to respond. Thus, the development of HCV vaccine is especially important, but it remains an urgent challenge due to the high mutation rate of HCV.

Multiple lines of evidence indicate that one of the principal neutralization determinants corresponds to the hypervariable region 1 (HVR1), which is located in the amino-terminus of E2 of HCV (nt1150-1230). Zibert *et al*^[4] found that an early appearance of antibodies directed to HVR1 is associated with acute self-limiting infection of HCV, while the persistence of HVR1 antibodies is associated with chronic HCV infection. Antibodies against HVR1 have been shown to block adsorption to susceptible cells *in vitro*^[5,6]. Animal antibodies raised against this region have provided effective prophylaxis in chimpanzee challenge experiments^[7-9], but attempts to develop a HVR1 vaccine against HCV were hampered by the frequent mutations of HVR1. Although anti-HVR1 antibodies react with HVR1 proteins specifically, a single fraction of antibodies has potentiality to react with more than one HVR1 protein sharing a similar amino acid sequence^[10]. These findings suggest that HVR1 may play an important role in the prevention of HCV infection.

Our previous study^[11] analyzed the variability of HCV envelope region in 12 dominant strains from different cities of China and predicted the immunogenicity with computer programs, demonstrating that genotypes and epidemic areas should be considered when identifying the cross-reactive epitopes for vaccine design. In this study, we selected four HCV strains of two genotypes from three regions (Shanghai, Beijing and Shandong) of China according to the results of the variant analysis and immunogenicity prediction of the envelope region in Chinese HCV strains. The gene fragments of HVR1 were amplified from four corresponding pGEMT-E2 plasmids and sub-cloned into pQE 40 vectors respectively to construct four recombinant prokaryotic expression plasmids that can express HVR1 as fusion proteins with DHFR. The purified DHFR- HVR1 proteins were then used to detect the anti-HVR1 antibodies in sera of patients with chronic hepatitis C to further explore their antigenicity and analyze the different reactivity between IFN therapy responders and non-responders.

MATERIALS AND METHODS

Patients

Fifty HCV-infected patients were studied, who were all anti-HCV positive by commercial anti-HCV assays (third generation of enzyme-linked immunosorbent assay [ELISA], Abbott, North Chicago, IL). Of these, 20 patients received interferon (IFN) therapy, Roferon (Roche, Switzerland), 3 million units three times a week for 6 months. 13 patients who showed negativity of serum HCV RNA and normalization of

alanine aminotransferase (ALT) level after cessation of IFN were considered as responders, while the other 7 patients who remained HCV RNA positive and/or presented fluctuation of ALT were designed non responders (Table 1). Quantitation of serum HCV RNA was performed using commercial kit from Fu Hua Gene Company, Shanghai. Informed consent was obtained from all the patients, and study protocol was approved by the committee on human ethics. 20 healthy blood donors who were anti-HCV negative were also analyzed as negative control.

Table 1 Characteristics of chronic hepatitis C patients treated with IFN- α

	Responders	Non responders
Number	13	7
Age (Yr)	41	40
Sex (F/M)	5/8	2/5
Known duration of infection (Yr)	10.6	9.9
Baseline ALT (IU/ml)	185	126 ($P=0.1660$)
Baseline viral load (copies/ml)	4.37×10^6	2.92×10^6 ($P=0.6908$)

Methods

Construction of recombinant expression plasmids Part of E2/NS1 regions was cloned from sera of the patients and sequenced as described before^[11]. From these plasmids pGEMT-E2, DNA fragments containing HVR1 (nt1150-1233, aa384-411) were amplified by PCR. The primers for HCV strain Shanghai 1b (SH1b), sense: nt1150-1161, 5' TTAGATCTGCAACCTACACG3', anti-sense: nt1225-1233, 5' CCCAAGCTTAGATTTTCTG3'; the primers for strain Beijing 1b (BJ1b), sense: nt1150-1161, 5' TTAGATCTGGCACCTATACG3', anti-sense: same as SH1b; the primers for strain Shandong 1b (SD1b), sense: nt1150-1159, 5' TTAGATCTGAGACCCGTG3', anti-sense: same as SH1b, and the primers for Shandong 2a (SD2a), sense: nt1150-1159, 5' TTAGATCTAGCACCCACG 3', anti-sense: nt1225-1233, 5' CCCAAGCTTAGATGTTCTG3'. The PCR products were purified and ligated into the Hind III, Bgl II sites of the expression vector pQE40 which allows fusion of HVR1 encoding sequences downstream to the murine dihydrofolate reductase (DHFR) with a N-terminal 6 \times His tag.

The recombinant plasmids were identified by digestion with Hind III and Bgl II. The inserts were then sequenced to ensure that the DNA encoded the authentic HCV sequence. The identified plasmids were named as pQE40-HVR1-SH1b, BJ1b, SD1b and SD2a respectively.

Expression and purification of the fusion proteins The recombinant plasmids and pQE40 vector were transformed to E.coli strain TG1.DHFR-HVR1 fusion proteins were expressed by induction with 1 mmol/l isopropyl- β -D-thiogalactotyranside (IPTG) in 100 ml of LB/ampicillin media cultured at 37 °C with vigorous shaking. After 6 h of induction, cells were harvested by centrifugation at 4 °C and 5 000 g for 30 min.

Harvested cells were re-suspended in 10 ml of 8M urea/20mM β -ME/PBS pH8.0, and cell disruption was performed using an ultrasound sonication method. After centrifugation at 20 000 g and 4 °C for 30 min, the supernatant was saved for purification on Ni²⁺-nitrilotriacetate (NTA)-agarose (Qiagen) according to manufacture's instructions at room temperatures. Denatured crude extract was allowed to bind to Ni²⁺-NTA-agarose pre-equilibrated in 8M urea/20mM β -ME/PBS pH8.0 for 2 h. The gel matrix were then washed with the same solution pH6.3 and gel-bound proteins were eluted with that of pH4.3.

The purified fusion proteins were run on 12 % sodium

dodecyl sulfate -polyacrylamide gel electrophoresis (SDS-PAGE) for identification. For protein visualization and quantification, gels were stained with Coomassie brilliant blue (Sigma). The purity and yield of recombinant proteins were calculated from densitometric scanning results by comparing with known quantity of BSA (Bio-Rad) run on the same gel.

ELISA The plates were coated with four purified fusion proteins respectively or combined at of 0.2 μ g/well for 1 hour at 37 °C and then overnight at 4 °C in carbonate buffer pH 9.5. After blocking with 1 % BSA for 1 hour at 37 °C, sera were dispensed in wells at a dilution of 1:20 and incubated for 45 min at 37 °C, followed by washing. HRP conjugated goat anti-human IgG (Sino-American Biological Company) diluted 1:8 000 was then added and plates were incubated for 45 min at 37 °C. After washing, the color was developed using TMB according to standard procedures, and the optical density values were measured at 450nm (OD₄₅₀) in automatic photometer (Wellsan K3, Labsystem Company).

Statistical analysis

The results were analyzed by the *t* test. In all analyses, a *P* value less than 0.05 was considered statistically significant.

RESULTS

Construction of the recombinant plasmids

Four recombinant plasmids expressing HVR1 fused with DHFR were constructed as described in methods. Obtained clones were digested with Hind III and Bgl II, 95bp fragments of HVR1 coding sequences could be detected from each of them (Figure 1). Automatic sequencing confirmed that the inserted HVR1 fragments corresponded to reported data (Figure 2). The reading frames of the recombinant plasmids were correct.

Figure 2B Deduced amino acid sequence of the HVR1 fragments in pQE40-HVR1. Sequences are shown with a single-letter amino acid code where residue is different from the consensus sequence of genotype 1b defined by Hattori *et al.*, and with a dash where residue is identical.

Expression and purification of the fusion proteins

The proteins expressed in transformed *E. coli* were analyzed by SDS-PAGE. The fusion proteins migrated as an approximately 28 kDa band, approximately 3 kDa larger than DHFR (Figure 3A), in accordance with the fusion of 28 aa HVR1. Figure 3B shows the SDS-PAGE result of four purified fusion proteins and DHFR. The concentrations estimated by BSA grades are 0.4–1.0 µg/µl, so about 320–800 µg of purified protein can be obtained from every 100 ml of bacteria culture.

Detection of anti-HVR1 Ab in HCV infected patients' sera

Anti-HVR1 antibodies were detected in 70 serum samples from 50 patients with chronic hepatitis C (sera were tested before and after IFN therapy for 20 patients) using the four DHFR-HVR1 fusion proteins respectively. None of the healthy blood donors, who were anti-HCV negative, was anti-HVR1 positive. Anti-HCV seronegative healthy donors had mean OD₄₅₀ value of 0.06. Sera were scored positive showing OD value >0.2 (cut off = 3 time mean neg + 10 %) in at least two experiments.

Each fusion protein (SH1b, BJ1b, SD1b and SD2a) reacted with 72.8 % (51/70), 60 % (42/70), 48.6 % (34/70), and 58.6 % (41/70) of the anti-HCV positive patients respectively. SH1b was the most broadly reactive fusion protein. 91.4 % (64/70) of the tested sera reacted positively with one or more fusion proteins, and among these, 89.1 % (57/64) can react with more than one fusion proteins, 20.3 % (13/64) samples of these sera were shown to react with all four fusion proteins.

The reactivity of sera was compared between responders and non-responders in 20 patients who received interferon therapy (Table 2). The reactive rates of sera with the four fusion proteins were higher in non-responders than in responders before interferon therapy, but there was no statistical significance. 57.1 % (4/7) of non-responders reacted with all four DHFR-HVR1 fusion proteins, while only 15.3 % (2/13) of responders react with all of them (Figure 4). With the three fusion proteins (SH1b, BJ1b and SD2a), the ODs of the serum reactivity of the non-responders were higher than those of responders, and the difference had statistical significances for the four mixed proteins between the two groups of patients ($P < 0.05$) (Figure 5).

Figure 4 The serum of hepatitis C patients reacted with different numbers of HVR1 fusion proteins. A shows that the sera of IFN responders reacted with 0–4 kinds of HVR1 sequence; B shows that the sera of IFN non-responders reacted with 1–4 kinds of HVR1 sequence.

Figure 5 The OD values of 40 HCV-infected patients' sera reacted with the four HVR1 fusion proteins respectively or totally, which were compared between R (IFN-responders) and NR

(IFN-non responders). For the mixed fusion proteins, the values (OD/CUT OFF) of the responders' sera were significantly higher than those of non-responders ($P=0.0358$).

Table 2 The serum reactive rates of chronic hepatitis C patients with the four HVR1 fusion proteins before IFN therapy

Proteins	Responders(13)	Non responders(7)	Total(20)
SH1b	69.2 % (9/13)	85.7 % (6/7)	75 % (15/20)
BJ1b	53.8 % (7/13)	57.1 % (4/7)	55 % (11/20)
SD1b	30.8 % (4/13)	71.4 % (5/7)	45 % (9/20)
SD2a	69.2 % (9/13)	71.4 % (5/7)	70 % (14/20)
MIX	69.2 % (9/13)	71.4 % (5/7)	70 % (14/20)

DISCUSSION

Antibodies against HVR1 of the main envelope protein of HCV are hypothesized to be neutralizing, but frequent mutation in HVR1 is driven by the host's humoral immune response^[12] and is a major mechanism of viral persistence by escaping host immune recognition^[13,14]. The relationship between the severity of liver diseases and the molecular evolution of HCV during chronic infection remains unclear and controversial^[15]. HVR1 has the potential to provide a viral antigen for vaccine development, and the cross-reactivity of HVR1 sequences is an essential consideration in the development of a broadly protective vaccine to prevent HCV infection. Cerino *et al*^[16] reported that the appearance of anti-HVR1 is earlier than anti-E2, and the early appearance of anti-HVR1 antibodies may be predictive of the later clearance of HCV. It has also been found that HVR1 sequences could induce anti-HVR1 antibodies capable of reacting with many HVR1 sequences in vitro other than the original immunogen sequence^[17]. It might be the conserved sub-regions in HVR1 sequences that determined the observed immunological cross-reactivity, by which it may eventually be possible to develop a polyvalent vaccine using a mixture of several HVR1 sequences that cover the reactivity of most HCV isolates.

Synthetic HVR1 peptides have been used in many studies, but this method is too expensive to be used widely. Hattori *et al*^[10] successfully expressed HVR1 (aa383-410) as fusion proteins with GST (about 32kDa) in *E.coli* DH5 α , and each fusion protein reacted with 36.1 % to 59.3 % of HCV infected patients' sera. Others reported different reactivity of chronic hepatitis C patients' sera with HVR1 proteins from 15 % to 67 %^[18,19]. In this study, we selected four HCV strains of two genotypes from our previous reported clones (SH1b, BJ1b, SD1b and SD2a), because the HVR1 fragments in these four strains was predicted to have higher hydrophilicity and possess 2-3 immunogenic epitopes in each of them^[11]. We used pQE40 vector to express HVR1 fused with DHFR in *E.coli*. pQE40 is constructed for expression of N-terminally 6 \times his-tagged DHFR-fusion proteins and is recommended for expression of poorly expressed proteins or short peptides. DHFR could enhance both stability and antigenicity of the fusion protein, while DHFR itself displays little immunogenicity^[20].

The reactivity of the fusion proteins with HCV-infected patients' sera, especially SH1b was higher than most reports. We selected the HVR1 sequences according to computer prediction. The reason that the selected HVR1 sequence reacted with a considerable proportion of HCV-infected patients' sera may be that cross-reactive antibodies react with the different HVR1 proteins through common epitopes, as suggested by Scarselli *et al*^[21]. It might also be the consequence of exposure to multiple strains of HCV.

HCV genotype and the baseline level of viremia have been pointed out as the most important predictive factors of responsiveness to IFN therapy^[22]. However, several studies

suggested that other factors, such as the heterogeneity of virus population^[23] and replication in PBMC^[24], might also influence the effectiveness of therapy. Like most RNA viruses, HCV circulates in the human host as a complex population of different but closely related viral variants, commonly referred to as quasispecies^[25]. It has been suggested that a reduction in genetic diversity leading to an increasingly homogeneous viral population in the envelope genes, and especially in the HVR1 of the E2 gene, is likely to be the result of a more successful and balanced cellular and humoral immune response^[26], which can be observed in IFN therapy responders with viral clearance^[27,28]. It was also reported that the broad reactivity of serum anti-HVR1 antibodies correlated with viral loads and response to IFN in genotype-1b-infected patients^[10]. But Del porto *et al*^[29] found that the frequency of anti-HVR1 T cell response was significantly higher in patients who recovered after IFN therapy than that in those who did not, while no difference in the anti-HVR1 antibody reactivities were detected. In our study, the reactive rates of the four HVR1 fusion proteins with patients' sera were higher in non-responders than those in responders, although there was no statistical difference, which might be due to insufficient number of patients. Meanwhile, 57.1 % (4/7) of non responders reacted with all four HVR1 fusion proteins, while only 15.3 % (2/13) of responders reacted with all of them. These facts suggested that the genetic diversity of HCV was greater in non responders than that in responders. The broad cross-reactivity of anti-HVR1 anti-bodies causes the inefficiency of neutralizing activity as proposed by the theory of "viral antigenic sin"^[21,30]. According to this theory, after the exposure to the first immunodominant and cross-reactive virus strain, patients produce not a new antibody to the second related virus strain, but an antibody to the original antigen, which is inefficient to neutralize the new variant. The findings that the serum reactive rates with the four HVR1 fusion proteins were higher in non responders than in responders may be interpreted by this theory. On the other hand, the O.D. values of anti-HVR1 antibodies were higher in responders than those in non responders. This reflected the immune status of these patients and implied that the pre-therapy immune response is a major factor determining eventual virus elimination as suggested by others^[31,32].

In conclusion, the selected HVR1 fusion proteins expressed in *E. coli* can broadly react with HCV-infected patients' sera. The intensity and/or quality of the immune response against HCV could be a critical factor determining the response to treatment. With the evolution of virus strains, anti-HVR1 antibodies could not neutralize all the quasispecies. A polyvalent and high immunogenic vaccine combining a mixture of several HVR1 sequences that cover the reactivity of most HCV isolates might be useful.

Abstract

AIM: To investigate the anti-virus infection activity of internal ribosome entry site (IRES) specific inhibitor RNA (IRNA).

METHODS: IRNA eukaryotic vector pcRz-IRNA or miRNA eukaryotic vector pcRz-miRNA was transfected into human hepatocarcinoma cells (HHCC), then selected with neomycin G418 for 4 to 8 weeks, and then infected with polio virus vaccinas line. The cytopathogenesis effect was investigated and the cell extract was collected. At last the polio virus titer of different cells was determined by plaque assay.

RESULTS: Constitutive expression of IRNA was not detrimental to cell growth. HCV IRES-mediated cap-independent translation was markedly inhibited in cells constitutively expressing IRNA compared to control hepatoma cells. However, cap-dependent translation was not significantly affected in these cell line. Additionally, HHCC cells constitutively expressing IRNA became refractory to infection of polio virus.

CONCLUSION: IRES specific IRNA can inhibit HCV IRES mediated translation and poliovirus replication.

INTRODUCTION

IRES is one of the key structures of some virus such as poliovirus and hepatitis C virus. The structure stability and integrality of IRES are crucial for the virus life cycle^[1-8]. IRNA is one IRES specific yeast small RNA. We constructed the human hepatoma cells constitutively expressing the IRNA. Using polio vaccine virus infected the cells, we demonstrated that the cells expressing IRNA became refractory to infection of poliovirus.

MATERIALS AND METHODS

Materials

Human hepatocarcinoma cell (HHCC) was grown in

RPMI1640 medium supplemented with 100 mL/L newborn calf serum. PV I tennate vaccinas line (Third Department of vaccinia, Chinese Drug and Bioproduct Identified Agent) was amplified in Hep2 cells, and the virus titer was calculated by plaque assay.

Methods

Plasmid construction By using subcloning methods, the IRNA and miRNA sequence were cloned into the pcDNA3 vector, yielding pcRz-IRNA and pcRz-miRNA which introduced the ribozyme sequence over the both sites of IRNA and miRNA to generate the correct site of IRNA and miRNA. In summary, by using PCR methods the sequences of target RNA were generated from pGRz-IRNA or pGRz-miRNA which were constructed by our laboratory. Then the PCR product was cloning into the *Bam*HI-*Apa*I sites of the pcDNA3 vector.

Construction of HHCCs expressing IRNA or miRNA Plasmids pcRz-IRNA and pcRz-miRNA were transfected into HHCC cells respectively by using Lipofectamine 2000 reagent (Gibco) and screened for neomycin resistance with 300 µg of G418 (Invitrogen) per milliliter for 4 weeks. The antibiotic-resistant cell clones were harvested and further screened by dilution titer. The control cells were also prepared by using similar method using plasmid pcDNA3.

Detection of IRNA/miRNA in the cells IRNA or miRNA expression in the cells was measured by isolating total RNA from these cells and the IRNA or miRNA were detected by reverse transcriptase (RT)-mediated PCR (RT-PCR) by using IRNA or miRNA specific oligonucleotide primers. 1 to 2 µg of total RNA isolated from the IRNA or miRNA expressing cells, and 2 µg total RNA from HHCC control cells were reversely transcribed by murine leukemia virus RT using random hexamer primers in a 20 µl reaction mixture according to the TaKaRa RNA PCR kit protocol. 20pmol of each primer (corresponding to 5' nt 1 to 20 and 3' nt 1 to 20 of the IRNA or miRNA sequence) was used to amplify the 60-nt fragment in a 100 µl PCR reaction. The cycling parameters were as follows: denaturation, 95 °C for 1 min; annealing, 65 °C for 1 min; extension, 72 °C for 1 min, total extension, 72 °C for 10 mins; a total of 50 cycles. Twenty microliters of each reaction product were loaded onto 20 g/L gel and visualized by ethidium bromide staining.

Detection of cell protein levels by laser confocal microscopy Monolayers of HHCCs were plated on cover glass and fixed with pure ethanol for 10 mins. Monoclonal antibody of β-actin was properly diluted and covered on the glass with HHCC cells for 1 h at 37 °C, and then the glass was washed with PBS 3 times (10 mins each). Then FITC labeled second antibody was covered on the glass at 37 °C for 1 h and the glass was washed with PBS 3 times again. At last the cells were examined by using the laser confocal microscopy.

Plaque assay Plaque assay were performed as described below. HHCCs (10⁶ cells) were infected with PV I tennate line, and after 72 h, cytopathic effect was observed and cell extracts were prepared. Two hundred microliters of cell extracts was used to further infect Hep2 cells (5×10⁶ cells in 60

millimeter diameter plates). After 3 days of inoculation at 37 °C, the plaques were developed by staining with 10 g/L crystal violet.

Mobility shift electrophoresis assay Fifty micrograms of rabbit reticulocyte lysate (RRL) was preincubated at 30 °C for 10 mins with 4 µg of poly (dI-dC) (Pharmacia) in a 15 µl reaction mixture containing 5 mmol/L HEPES (N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid) (pH 7.5), 25 mmol/L KCl₂, 2 mmol/L MgCl₂, 38g/L glycerol, and 2 mmol/L dithiothreitol. For competition experiments, 25 to 50-fold excess of unlabeled competitor RNAs were added to the reaction mixture and incubated for 10 min at 30 °C. Finally, 5 to 10 fmol of labeled RNA probes were added to respective reaction mixture and incubation was continued for another 30 min at 30 °C. The nonspecific RNA used in competition assay was the sequence of the polylinker region of the pGEM 3Z vector (Promega). Three microliters of gel loading dye was added to the reaction mixture to a final concentration of 100 g/L glyceol and 2 g/L each of bromophenol blue and xylene cyanol. RNA-protein complexes were then analyzed on a 40 g/L polyacrylamide gel (39:1 ratio of acrylamide: bis) in a 0.5×TBE.

RESULTS

Construction of hepatoma cells expressing IRNA or miRNA constitutionally

To determine the long-term effect of expression of IRNA in HHCC cells, the cells constitutionally expressing IRNA were generated by using a pcDNA-based vector as described in Material and Methods. In order to obtain the correct and stable both sides of the expressed IRNA, the ribozyme sequences were introduced into the both sides of the IRNA and miRNA. The IRNA or miRNA was examined by RT-PCR using appropriate primers. As can be seen in Figure 1, IRNA and miRNA was expressed stably in the cloning cells.

Figure 1 Detection IRNA or miRNA in the total RNA of HHCCs which constitutionally expressing IRNA or miRNA. 1: DNA Marker DL2000; 2 and 3: RT-PCR of cell lines expressing IRNA; 4: RT-PCR of cell lines expressing miRNA; 5 and 6: PCR of cell lines expressing IRNA or miRNA.

Effect of long-term IRNA expression on cellular protein expression

To determine whether constitutionally expressing of IRNA interfered with cellular protein translation, levels of cellular protein β -actin was determined by laser confocal microscopy. As can be seen in Figure 2A and 2B, no differences were detected in the overall expression of the cellular protein between HHCC (control) and IRNA-expressing cells (11.74 ± 6.52 vs 10.06 ± 5.75 , $P > 0.05$).

Inhibition of long-term expressing IRNA on HCV IRES mediated translation

To test the inhibitor activity of long-term expressing IRNA on

HCV IRES mediated translation, the control cells (HHCC) and cells expressing IRNA or miRNA were transiently cotransfected with pCMVNCRLuc and pSV40/ β -Gal. Additionally, in order to exclude the nonspecific effect of nonspecific small RNA on the protein translation, the cells expressing pcDNA3 were cotransfected with pCMVNCRLuc and pSV40/ β -Gal as well. Cell extracts were used to measure both luciferase and β -Gal activities. The results were plotted as percent of control after normalizing for β -Gal activity and protein concentration. Maximum inhibition of luciferase expression was 80 % in the cells expressing IRNA compared to the control, but no differences were observed in the cells expressing miRNA and pcDNA3.

To determine the effect of long-term expressing IRNA on cap-dependent translation, the cells were transfected with pcDNA-luc. As seen in Figure 3, no significant inhibition of cap-dependent translation from the pcDNA-luc construct was observed in cells expressing IRNA compared to the control cells.

Figure 3 The effect of long-term expressing IRNA on cap-independent and cap-dependent protein translation.

Hepatoma cells constitutionally expressing IRNA are refractory to infection by a PV tenuate virus

To determine the inhibit effect of IRNA on IRES mediated protein translation during virus infection, the pcRz-IRNA and pcRz-mIRNA cells were infected with a vaccinia PV. After infection with PV, the cells were stained and the cytopathic effects were observed and we found that the pcRz-mIRNA cells and control cells were appeared marked cytopathic effect compared to the cells prior to the infection, but the cells expressing IRNA were almost totally protected from the cytopathic effect of PV (Figure 4). Following the infection,

cell extracts were prepared from infected cells which were then used to further infect Hep2 monolayer cells. Plaques characteristic of PV were apparent in Hep2 cells infected with cell extract from control hepatoma cells and pcRz-mIRNA cells (Figure 5A, B). Evidently viral replication was drastically affected in the cels expressing IRNA (Figure 5D).

To rule out the possibility that the nonspecific small RNA expressing cells affected the viral replication, the pcDNA3 cells were infected under the same condition. As can be seen in the Figure 4C and Figure 5C, the PV replication was not affected in the pcDNA3 cells.

Figure 6 IRNA forms a gel-retarded complex which is inhibited by 5' UTR of HCV RNA. 32 P-labeled IRNA was incubated with RRL extract in the absence (lane 2) or presence of an unlabeled 25- or 50-fold molar excess of IRNA (lane 3 and lane 4, respectively) or 5' UTR (lane 5) or of a 50-fold molar excess of

nonspecific RNA (lane 6). Protein- RNA complexes were analyzed on a nondenaturing gel. In lane 1, RRL extract was not added. FP: free probe; C: complexes.

IRNA forms a gel-retarded complex that is inhibited by UTR

In order to study the mechanism of IRNA inhibitor activity on IRES mediated protein translation, 32 P-body-labeled IRNA probe was prepared and mixed with RRL extract, and the resulting RNA-protein complexes were analyzed by nondenaturing polyacrylamide gel electrophoresis. As shown in Figure 6, lane 2, a single complexes (denoted C).

DISCUSSION

IRES-dependent protein translation mechanism was first discovered in picornavirus, including PV, rhinovirus and hepatitis A virus, as well as certain flavivirus, such as hepatitis C virus^[9-12]. Although there is very little sequence homology between these different IRES elements, structural similarity do appear to exist. In fact for keeping the activity of IRES, it is more important to maintain the secondary structure than to maintain the integrality of certain genome sequences^[1-3,7,8]. IRES is the key structure for some virus RNA replication, so it has been the target for antiviral infection^[13-20]. We have constructed the self-cleavage plasmid of IRNA, and affirmed that IRNA can inhibit IRES-dependent protein translation both *in vivo* and *in vitro*^[21]. In order to further confirm the long-term expressing IRNA effect on cellular protein and virus protein translation, we cloned the HHCCs expressing IRNA, and confirmed that long-term expressing IRNA could inhibit IRES mediated protein translation significantly compared to the control cells and mIRNA expressing cells. Das and his collaborates prepared the a number of human hepatoma (Huh-7) cell lines expressing IRNA by using the similar methods. They found that HCV IRES-mediated cap-independent translation was markedly inhibited in cells constitutively expressing IRNA compared to control hepatoma cells^[22].

Additionally, We have shown here that the long-term expression of IRNA did not affect the overall translation of cellular protein as shown by laser confocal microscopy. This was surprising since some cellular mRNAs such as the immunoglobulin heavy-chain-binding protein, mouse androgen receptor, and *Drosophila* antennapedia mRNAs has been shown to use IRES-mediated translation. It is possible that cellular mRNAs having IRES elements are also translated in a cap-dependent manner, as almost all mRNAs synthesized *in vivo* are capped. Das and his collaborates also confirmed that the constitutive expression of IRNA was not detrimental to cell growth^[22].

Recent studies on picornavirus-IRES-mediated translation have demonstrated that cellular *trans*-acting proteins distinct from canonical translation initiation factors play an important role in IRES-mediated translation. These proteins bind to the IRES and presumably help to facilitate the binding of ribosomes to the IRES. Some of the *trans*-acting proteins have been identified as the La autoantigen, polypyrimidine tract-binding (PTB) protein, glyceraldehydes 3-phosphate dehydrogenase (GAPDH). The La polypeptide binds to both PV and HCV IRES elements and stimulates IRES-mediated translation. Similarly, the PTB protein interacts with HCV and other picornavirus IRES sequences and stimulated viral 5' UTR mediated translation^[23-25]. Because HCV IRES and PV IRES bind the similar cellular protein, and we lack effective HCV culture system *in vitro*, we studied the long-term expressing IRNA blocking viral replication ability by using PV infection *in vitro*. Our results demonstrated that long-term expressing IRNA blocks the PV replication effectively. Das and his collaborates constructed PV-HCV chimera in which PV IRES

was replaced by the HCV IRES. They demonstrated that Huh-7 cells constitutively expressing IRNA became refractory to infection by the PV-HCV chimera, but the replication of a PV-encephalomyocarditis virus (ECMV) chimera containing the ECMV IRES element was not affected significantly in the IRNA-producing cell line^[22].

At low multiplicities of infection of the virus, cells expressing IRNA showed significant resistance to virus infection compared to control cells. This could be due to inhibition of primary translation of the input viral RNA in cells expressing IRNA. Multiple rounds of replication and reinfection of control cells, but not of IRNA-expressing cells, resulting in an amplified effect seen in the plaque assay was shown in Figure 5. At higher multiplicities of infections, the virus titer was approximately 10-fold lower in IRNA cells compared to control cells. This could be due to one or more of the following reasons: (1) the level of IRNA expression was relatively low in the cell line; (2) the viral 5' UTR, which competed with IRNA for binding of relevant protein factors, has significantly higher affinity for these proteins than IRNA; (3) the amount of IRNA in the cytoplasm was low compared to the total amount of expressed IRNA; and finally (4) all of the IRNA molecules in the cell line might not have been properly folded to assume the right secondary structure required for its translation-inhibitory activity.

Theoretically, IRNA could inhibit IRES-mediated translation by two possible mechanisms. It could bind to some sequences in the UTR as antisense RNA or it could bind protein factors necessary for the internal entry of ribosome, thus inhibiting IRES-dependent translation. The possibility that the IRNA acted by binding protein factors required for IRES-mediated translation was plausible for the following reasons. First, purified RNA was not complementary to 5' UTR sequences nor did it hybridize with virus 5' UTR. Secondly, inhibition of the translation of PV RNA could be overcome by the addition of increasing concentrations of HeLa extract but not of PV RNA or 5' UTR sequence. In fact, in order to identify the mechanism of IRNA inhibitor activity, several laboratories by using the UV-crossing linking methods and Gel retardation methods studied the mechanism respectively. They found that IRNA specifically binds proteins which interact with RNA secondary structures within the virus 5' UTR presumably involved in internal initiation. Furthermore, they demonstrated that purified IRNA specifically competed with virus RNA structures within the 5' UTR which bind a cellular protein with an approximate molecular mass of 52 KD, 57KD. Then they determined that p52 protein appears to be identical to human La autoantigen and the binding of the La autoantigen to the HCV IRES element was specifically and efficiently competed by IRNA. The data present here (Figure 6) also suggested that the IRNA inhibit viral IRES mediated protein translation through binding specific cellular factors^[22, 26-31]. Additionally, Das and his collaborator determined the secondary structure of IRNA and founded that both a stem and a loop formed by intramolecular folding of IRNA were important for inhibition of viral IRES mediated translation. Venkatesan had also predicted the secondary structure of the IRNA and its complementary RNA (cIRNA) using bioinformatics MFOLD by energy minimal principle and further determined the structure using enzyme methods and chemical modification methods. They found that IRNA and cIRNA have not only same secondary structure but also similar inhibitor activity on PV IRES mediated protein translation^[31]. Our laboratory have also modeled the secondary structure of IRNA and cIRNA and got the similar results to the Venkatesan (data reported in other file).

In summary, we could get the conclusion that (1) IRNA expressing cells could significantly anti polio virus infection; (2) IRNA long-term expression has no significant affect on

cellular protein translation; (3) IRNA expressing cells significantly inhibit the HCV IRES mediated protein translation.

Abstract

AIM: To study the relationship between the radiological anatomy and the dynamics on bile duct sphincter in bile draining and regulatory effect of gallbladder.

METHODS: Sixteen healthy dogs weighing 18 kg to 25 kg were divided randomly into control group and experimental group (cholecystectomy group). Cineradiography, manometry with perfusion, to effect of endogenous cholecystokinin and change of ultrastructure were employed.

RESULTS: According to finding of the choledochography and manometry, in control group the intraluminal basal pressure of cephalic cyclic smooth muscle of choledochal sphincter cCS was 9.0 ± 2.0 mmHg and that of middle oblique smooth muscle of choledochal sphincter (mOS) was 16.8 ± 0.5 mmHg, the intraluminal basal pressure of cCS segment was obviously lower than that of mOS ($P < 0.01$) in the interval period of bile draining, but significant difference of intraluminal basal pressure of the mOS segment was not found between the interval period of bile draining (16.8 ± 0.5 mmHg) and the bile flowing period (15.9 ± 0.9 mmHg) ($P > 0.05$). The motility of cCS was mainly characterized by rhythmically concentric contraction, just as motility of cCS bile juice was pumped into the mOS segment in control group. And motility of mOS segment showed mainly diastolic and systolic activity of autonomically longitudinal peristalsis. There was spasmodic state in cCS and mOS segment and reaction to endogenous cholecystokinin was debased after cholecystectomy. The change of ultrastructure of cCS portion showed mainly that the myofilaments of cell line in derangement and mitochondria is swelling.

CONCLUSION: During fasting, the cCS portion has a function as similar cardiac "pump" and it is main primary power source in bile draining, and mOS segment serves mainly as secondary power in bile draining. The existence of the intact gallbladder is one of the important factors in guaranteeing the functional coordination between the cCS and mOS of bile duct sphincter. There is dysfunction in the cCS and mOS with cholecystectomy.

INTRODUCTION

The sphincter of Oddi regulates both bile and pancreatic juice flowing into the duodenum, and one of important feature is that the time of bile draining was delayed when the sphincter of Oddi dysfunction in postcholecystectomy. Obviously, this is relative to the abnormal dynamic change of choledochal sphincter in bile draining^[1-7]. But the mechanism of sphincter of Oddi dysfunction remains speculative^[8-19]. Up to now there was no report the relationship between the abnormal changes of bile draining and the functional anatomy of choledochal sphincter.

At the opening site of terminal bile duct there was a bundle of cyclic smooth muscles. Afterwards Ruger Oddi reported his results that this sphincter played a "valve"-like role in bile and pancreatic juice output. This bundle of muscles encysted the ampulla of Vater at the confluence of bile duct and pancreatic duct, thus was called ampulla sphincter or sphincter of Oddi. Boyden EA and Eichhorn EP, however, had also confirmed that, situated at the cephalic side of ampulla of Vater, in bile duct and in pancreatic duct there were two bundles of sphincter respectively which were independent to each other. The independent bile duct sphincter showed its own remarkable structural features that there was cyclic smooth muscle at the cephalic side portion, it was called cephalic cyclic segment of choledochal sphincter (cCS), and there was oblique and longitudinal smooth muscle following the cCS portion, it was called middle oblique smooth muscle segment of choledochal sphincter (mOS) because it was between in the cCS and classical SO. According to the above mentioned anatomical data, it seems that up to now the anatomical structures of sphincters involved in the studies of the function of sphincter of Oddi should include cCS, mOS and SO, which are referred to as the sphincter of Oddi. Obviously it is significantly different in concept and range from the classical sphincter of Oddi suggested by Ruger Oddi earlier. Based on the analysis of the anatomical characteristics, cCS and mOS are considered as the chief constitutive part of bile duct sphincter, thus it is suggested that the physiological role of cCS and mOS in regulating the bile flow is different from that of the classical sphincter of Oddi in this semi-enclosed hydrostatic system. In order to this objective, the methods of cholangiography, pressure measurement by perfusion, and microscopic observation were employed in this research primarily to observe the radiological anatomy of cCS and mOS, before and or after cholecystectomy, the morphologic features during bile draining, and the histological changes of cCS and mOS. The functional features of Ccs, mOS and its role in bile draining were investigated to find out the regulatory factors that affected the function of cCS and mOS.

MATERIALS AND METHODS

Experimental instruments and animal model

Unicameral manometry Teflon catheter with an 0.8 mm internal diameter and 1.7 mm outer diameter (Cook Co, USA), PT-16M pressure sensor (external pressure transducer, Shanghai, China), RM-6200C polygraph recorder (Chengdu, China), WZ-50 trace perfusion apparatus (Zhejiang, China) were used to

record pressures. Sixteen healthy hybrid dogs (Weighing 18–25 kg) raised in Shaanxi were randomly classified as control group and experimental group. The cholecystectomy were undertaken under they had received intraperitoneal injection with amobarbital, then they were fed for 4–6 weeks in experimental dogs.

Manometry and cholangiography

Anaesthesia was introduced with ketamine (100 mg/h). The operation was performed through thorax-abdomen-combined incision while autonomous respirator was being used to control animals' respiration. The cystic ducts of the experimental dogs were ligated. A vertical incision was then made on the proximal choledochus in order to insert the manometry catheter. Cholangiography was performed with 30 % meglumine diatrizoate injected through the manometry catheter (based on the calibration of developing in secondary branch of intrahepatic bile duct), and the bile excretion at portion of bile duct sphincter was recorded by cineradiography at the rate of 25 width/Sec. The intraluminal pressures at the portion of cCS and mOS were measured after the completion of contrast radiography.

The catheter that had been inserted into bile duct was introduced into duodenum again and measured the pressures in duodenal lumen. The manometric catheter system (the compliance of this system was low) was infused with 0.85 % NaCl solution at a flow rate of 25 ml/h, while the velocity of recording paper was 60 mm/min. The curves of changes in intraluminal pressures in the duodenum, the mOS and cCS portion of the bile duct sphincter were recorded respectively for 5 min. The intraluminal pressure in the duodenum was calibrated as zero basal level of pressure. In addition, a Teflon catheter was inserted into the stoma opening of stomach wall, with its top being placed in duodenal lumen for next experiment.

Observational parameters

Manometric parameters The numbers of the mOS segment contraction per min were regarded as the mOS contractile frequency (mOSCF). The difference between the diastolic pressure at the mOS portion and the duodenal intraluminal pressure was considered as the mOS basal pressure (mOSBP), and the difference between the contractile wave peak and its diastolic period intraluminal pressure as the mOS contractile amplitude (mOSCA). The difference between the cCS and the duodenal intraluminal pressure was classified as the cCS basal pressure (cCSBP).

Maximal inner diameter of bile duct and contrast draining time The maximal inner diameter of bile duct during cholangiography period was referred as the maximal inner diameter of choledochus, which was corrected by the magnification of contrast duct diameter. The biliary draining time (BDT) was referred as the time between the period when contrast medium completely filled the extrahepatic bile duct and the period when it completely disappeared. And the time in which biliary flows in choledochus was between the period when the bile duct sphincter began to drain bile and the period when it stopped draining bile. The time interval between the two biliary draining times was regarded as the interval of biliary draining.

Pathological examination

The intact choledochal sphincter segment of bile duct was fixed with 2.5 % glutaral, then with 1 % osmium acid, and finally embedded with epoxy resin after dehydration with 95 % alcohol. The ultra-thin section of the sample was sliced and stained with plumbum acid citrate. Then the observation was

done under JEM-2000EX electromicroscope. Two dogs were involved in both the control and experimental groups.

Statistical analysis

The “*t*” test was used to evaluate the results. A *P* value less than or equal to 0.05 was regarded as significant.

RESULTS

The diameter of bile duct

The maximal diameter of bile duct was 3.5–4.5 mm in controls, and that of experimental group was 4.7–7.5 mm, the average diameter of bile duct was 6.1 ± 1.3 mm in experimental group in 46 days and 58 days. There was significant difference between the control and the experimental group ($P < 0.01$). There were no stones and obstruction in the dilatants bile duct.

The contrast results in the control group

During interval period of bile draining, the mOS was in a state of shutting up, thus the terminal end of cCS portion shaped like “pestle”, while the distal end of bile duct showed a cyclic notch which was the radiological marker of the initial part of cCS. With the concentric contraction of cCS segment, the bile was pumped into the mOS segment. The mOS segment appeared to be a narrow, slender lumen. An uneven caliber could be seen in peristalsis contraction, and at the same time the bile was squeezed into the duodenum (Figure 1). 10 min after 20 ml of 33.3 % MgSO_4 was injected through the catheter placed in duodenum, there was no significant change in the shape of cCS segment, but while the mOS lumen was significantly dilated in 3 fold, compared with that before the injection, there was no significant contraction and peristalsis in the mOS segment.

Figure 1 During bile draining in control group. It was showed that the mOS portion was in a peristaltic movement (↑→▲), and the narrow distal segment (▲→▲) was portion of the mOS and SO segment of bile duct. Between the end of choledochus and the cCS portion was demarcated by notch (↑).

Image in the experimental group

During the bile draining period, between the distal end of bile duct, and cCS portion, there was a remarkable notch which appeared to be in a “infundibulum” shape at the cCS portion in connection with mOS segment. There was no significant contraction in the form of the spastic cCS segment and no significant peristaltic movement of the mOS segment, and lumen of the mOS segment appeared to be a narrow lumen as a “thin line”, to last until the bile draining period ended (Figure 2). 10 min after the bile duct was injected with 20 ml of 33.3 % MgSO_4 through the intestinal tract, and significant change did not demonstrated in the diameter of cCS part and the diameter of mOS segment.

Figure 2 In experimental group of bile drainage. During bile draining the remarkable notch to keep up still in between the choledochus and the cCS portion, and it appeared to be in an "infundibulum" shape at the cCS portion and there was no significant contraction in the form of spastic cCS portion of bile duct and no significant peristelsis movement and there appeared to be a narrow lumen as a "thin line", to last until the bile draining period ended at the mOS segment. Infusion of 33.3% MgSO₄ after, no significant change was seen in the diameter of cCS partion (↑→▲) and mOS segment (▲→▲) of bile duct.

Manometric results

The pressure of cCS and mOS segments in the control and experimental groups (Table 1).

Table 1 The pressures of cCS and mOS segments before MgSO₄ infusion in interval period of bile draining (mmHg)

Group	cCSBP	mOSBP
Control (n=7)	9.0±2.0 ^a	16.8±0.5 ^b
Study (n=7)	14.0±2.0	14.7±0.7

^aP<0.01, t=6.195; ^bP<0.05, t=2.717. vs the study group.

It is indicated that the cCSBP of control and experimental groups were lower than the mOSBP, which suggested that there was a retrograde pressure gradient between cCS and mOS segments in interval period of the bile draining. Although mOSBP in the study group was lower than that in the controls before infused MgSO₄, but the pressures of cCS segment in the study group were significantly higher than those in the controls (P<0.05), suggesting that the cCS and the mOS segment was in state of spastic contraction in the study group. **The pressure of mOS in the control** Manometric results and reaction of mOS to 33.3 % MgSO₄ infusion in the control group (Table 2) and pressure curve of mOS (Figure 3,4).

Table 2 The manometric results of mOS segment before and after MgSO₄ infusion in the controls ($\bar{x}\pm s$)

	mOSBP (mmHg)	mOSCA (mmHg)	mOSCF (No/min)	BDT (min)
Before Infusion (n=7)	16.8±0.5	21.9±0.9	15.2±0.7	17.1±0.9
After Infusion (n=7)	15.7±0.9 ^a	15.1±2.1 ^b	11.4±0.3 ^c	10.8±1.1 ^d

^aP<0.05, t=2.651; ^bP<0.01, t=7.344; ^cP<0.01, t=35.155; ^dP<0.01, t=33.375. vs before MgSO₄ infusion.

It is showed that the high-pressure zone of the sphincters of bile duct was mainly located at mOS segment, and the resistance and contractile frequencies of mOS were significantly reduced by endogenous cholecystokinin (CCK) while the intact gallbladder remained. (Table 2 and Figures 3,4).

In addition, it was founded, that there was no significantly different between the mOSBP in interval period of bile draining (16.8±0.07 mmHg), and the mOSBP in bile draining period (15.9±0.7 mmHg) in control group (P>0.05).

Manometric results and reaction of mOS segment to MgSO₄ infusion in the experimental group The pressure curves and the changes in pressures of mOS segment before and after MgSO₄ infusion are shown in Table 3 and Figures 5,6.

Table 3 The manometric results of mOS segment before and after MgSO₄ infusion in the study group ($\bar{x}\pm s$)

	mOSBP (mmHg)	mOSCA (mmHg)	mOSCF (No/min)	BDT (min)
Before Infusion (n=7)	14.7±0.7	14.2±1.3	15.9±0.7	27.0±3.4
After Infusion (n=7)	14.3±1.3	14.0±1.4	15.1±0.7	26.3±2.3

There were no significant differences in each parameter before and after infusion in the experimental group (P>0.05). This indicated that the sensitivity of mOS segment to endogenous CCK decreased after cholecystectomy, and that the diastolic and systolic movements of mOS segment were damaged, resulting in the elevation of resistance in bile draining. (Figures 5,6).

Figure 3 Pressure curves of the cCS and mOS portion and duodenum in control group. There is high pressure zone and rythmical contractile movement was appeared in the mOS portion of bile duct and pressure of the cCS portion of bile duct is lower than pressure of the mOS and the SO portion of bile duct.

Figure 4 Reaction to the injection of 33.3 % MgSO₄ in control group. 10 min after 20 ml of 33.3 % MgSO₄ was injected through the catheter placed in duodenum, the pressure of mOS segment of bile duct is decreased, compared that before the injection, and unregular pressure curves was appeared in the mOS segment of bile duct.

Figure 5 A pressure curves before MgSO₄ solution infusion in

the study group. Signs of the pressure curves is similar to the control group in the mOS segment of bile duct.

Figure 6 A pressure curves after MgSO_4 solution infusion in the study group. Signs of the pressure curves is similar to the pressure curves before MgSO_4 solution infusion.

Microscopic results of histopathology of the cCS portion

The results of the transection of cCS portion in the controls are showed in Figure 7.

The results of the transection of cCS portion in the study group: The light microscope results showed no the degeneration of muscular fibers of cCS, mOS portion and infiltration of inflammatory cells. Under the electromicroscope, the changes of smooth muscular cells are showed in Figure 8.

Figure 7 The figure is a transection of cCS portion of bile duct in the control group. It is showed that the smooth muscular cell membrane (\uparrow) was flat, the myofilament and dense body appeared to be longitudinal arrangement in parallel to the long axis of smooth muscular cell and the dense body like spindles (\blacktriangle). The structure of the mitochondrion was normal, which evenly distributed itself among the cytoplasm.

Figure 8 The figures is a transection of cCS portion of bile duct in experimental group. Under the electromicroscope the cell membrane twisted like billows, and the myofilament density was not even, shaping like “whirl”. The dense body showed derangement and various shapes (\uparrow). The mitochondrions clustered at the end of the nucleus, and vacuolation (\blacktriangle) was seen.

DISCUSSION

Evaluation of infused catheter manometry as a method of functional analysis of bile duct sphincter

The manometry with ERCP, which began in 1970s, has been widely used in functional evaluation and experimental studies of bile duct sphincter^[20,21]. Based on the manifestation of manometry, Venu and Sherman suggested that the lesions of bile duct sphincter could be classified as functional and structural lesions. It is reported that the functional disturbances of bile duct sphincter are further classified in four types^[22-26]: sphincter spasm, high-frequency contraction, abnormally directory contraction and abnormal response to CCK based on the results of manometry. Combined with the observations of clinically therapeutic effect, it is now generally accepted that the directory manometry with infused catheter is a golden criterion in evaluating the function of bile duct sphincter.

Dodds firstly reported the manometry of inner pressure of esophagus. He believed that the accuracy of infused manometry with catheter was negatively correlated with the compliance of catheter, but positively with the speed of infused fluid. In order to increase the accuracy of manometry, the catheter used must be characterized with less elasticity and thick wall. As far as the speed of infused fluid is concerned, Some people believed that it was suitable to have a speed of 0.25-0.6 ml/min^[27-29]. The physical character of catheter and the speed of infused fluid employed in this study meet the above criteria, and manometric results obtained can objectively reflect the characteristic changes in pressures of CS segment in dogs.

The anatomical and functional study of CS

Eichhorn and Barraya confirmed in their study on the bile duct sphincter in dogs that there were successively from cephalic to distal ends of bile duct sphincter the cyclic sphincter (cCS), oblique and longitudinal sphincter (mOS) and classic SO (a strong cyclic sphincter encysting the terminal opening of bile duct). There is no anatomical definite boundary between the classic SO and mOS, but their arrangements show the remarkable differences. Because the anatomical structure and distributive position of the cCS and mOS segments are different from classical SO, there would be differences in their functions. Up to now, however, there has been no report on the functional features of the cCS and mOS segments.

The bile is a kind of important digestive fluid in the digestion of fatty substances. Dodds reported that 75 % bile secreted by liver is stored in the gallbladder, then being drained into the duodenum after alternating with the bile which already remains in the gallbladder, and the rest of it (25 %) directly flows into the duodenum through the bile duct sphincter. Eating causes the gallbladder contracting and results a large quantity of bile draining into duodenum to digest food within a short time. Only a small quantity of bile from the duct is directly drained into duodenum through the bile duct sphincter during the fasting period. Obviously, they are two different processes in bile draining. Only when the function of bile duct sphincter remains intact and coordinative, two different processes of bile draining can be successfully completed.

Nowadays there are arguments about the mechanism of bile duct sphincter in bile draining^[30-37]. Tooouli believed that the intramural type of choledochal sphincter, only plays a role of a “valve” in bile draining. Some people reported that the SO takes an active part in bile draining, and the power in bile draining comes from the spontaneous peristalsis contraction of bile duct sphincter. Scott, however, explained that the SO acts as a power source in bile draining while SO contracts moderately, and as a “valve” while contracting strongly. But our research results have confirmed that during fasting the lumen of mOS segment is not uniform in caliber. It can be

determined based on the study on the physiological function of smooth muscle that peristalsis-like diastolic and systolic motions are apparently not the patterns of characteristic manifestation of motions of cCS segment. Compared and analyzed with the manometric results, the peristaltic motility can only originate from the high-pressure area of bile duct sphincter, where the mOS segment of bile duct locates. It is further demonstrated by the manometric results in this study that cCS segment is a low-pressure lumen (9.0 ± 2.0 mmHg), than that the pressure are of the mOS segment (16.8 ± 0.5 mmHg), during the interval period of bile draining, and there is apparently a retrograde pressure gradient between cCS portion and mOS segment. It is apparent that the existing of high-pressure area in mOS segment is beneficial for preventing from the reflux of duodenal fluid, and even at the bile draining period the pressure in mOS segment does not decrease significantly, obviously, it is that the retrograde pressure gradient between the cCS segment and the mOS segment form the resistance in bile draining. But it is showed by cholangiography that cCS segment reveals concentric contraction in bile draining in the controls when fasting period, and its luminal volume reduces, resulting in the bile being “pressed” into mOS segment. With the peristaltic contraction of mOS segment, the bile filled in mOS segment ejects like “squeezed milk” into the duodenum. Obviously in order to overcome the resistance in bile draining cCS segmen should play a role of similar cardiac “pump” in the process of changing the retrograde pressure gradient, that prevented reflux of duodenal juice, into a positive pressure gradient during bile draining. It is just because of the different roles of cCS and mOS segments play in bile draining, that the bile duct sphincter takes not only a part in inhibiting the reflux of duodenal fluid as a “valve”, but also a part in regulating the stability of pressure in bile duct.

Effect of gallbladder to the movement of cCS and mOS segments

It is suggested that the functional coordination of cCS portion and mOS segment is closely related to whether the gallbladder is intact or not. It is showed by cholangiography that cCS segment has apparently dilative and contractile functions, while the peristaltic motion exists in the mOS segment that appears to be in a functional high pressure zone during the process of bile draining in the controls. But in the experimental group, cCS and mOS segments are constantly, and the notch remains still at the inferior extremity of bile duct and the lumen of mOS segment appears narrow like a “line”. After infusion with MgSO_4 , the notch at the inferior extremity of bile duct doesn't disappear, and the “line”-shaped narrow lumen of the mOS segment shows neither significant dilation nor apparent peristaltic motion, and it showed that the cCS and the mOS segment are in the state of spasm. Grace has also confirmed that there was a decline of the sensitivity of the bile duct sphincter to the endogenous CCK after cholecystectomy. Tokunaga and his men has discovered that, with a concentration of $1 \mu\text{mol} \cdot \text{L}^{-1}$, 0.11 ± 0.03 gm of CCK-8 is needed to relax the cyclic muscle stripe of bile duct sphincter, but with the same concentration, only 0.02 ± 0.01 gm of CCK-8 can relax the mOS segment. It seems to suggest from the above results that mOS segment is very sensitive to CCK-8 than that of the cCS, and its functional regulation is closely related to the content of endogenous cholecystokinin. In this study the results obtained from the choledochography confirm that Tokunaga Y's viewpoint is right. Our results indicate that the functional regulation between the cCS and mOS segment is manifested in intact gallbladder. Further, our results showed that there is a significant change in spatial structure of smooth muscle cells

of bile duct sphincter: the morphological manifestation of which is that the cell membrane is like billows, and myofilaments line in derangement and twist like “whirlpool”. The form and size of the attachment points of corresponding myofilaments-dense bodies, are different and lose their behaviors of normal fusiform arrangement in parallel to the long axis of cells. There have been no reports about its pathological significance. If the changes are considered, this change in spatial structure of cytoskeleton may be related to the strong contraction and dragging of the myofilaments. The spastic state of cCS segment and the reduced range of concentric contraction, furthermore, will unavoidably result in decreasing in its bile draining volume. Although the basal pressure in mOS segment during bile draining somewhat decreases, the resistance produced by mOS segment in bile draining cannot be completely overcome by the motility obtained from contraction of cCS segment in bile draining, this may mostly be the important cause that the bile cannot drain smoothly from the bile duct and the time for emptying the contrast medium is elongated in the experimental group. The direct result is that the bile flow slows down and the relative stasis exists, and the bile duct is dilated.

Abstract

AIM: To investigate the chemo preventive effects of vanadium on rat colorectal carcinogenesis induced by 1,2-dimethylhydrazine (DMH).

METHODS: Male Sprague-Dawley Rats were randomly divided into four groups. Rats in Group A received saline vehicle alone for 16 weeks. Rats in Group B were given DMH injection once a week intraperitoneally for 16 weeks; rats in Group C, with the same DMH treatment as in the Group B, but received 0.5-ppm vanadium in the form ammonium monovanadate *ad libitum* in drinking water. Rats in the Group D received vanadium alone as in the Group C without DMH injection.

RESULTS: Aberrant crypt foci (ACF) were formed in animals in DMH-treated groups at the end of week 16. Compared to DMH group, vanadium treated group had less ACF ($P < 0.001$). At the end of week 32, all rats in DMH group developed large intestinal tumors. Rats treated with vanadium contained significantly few colonic adenomas and carcinomas ($P < 0.05$) compared to rats administered DMH only. In addition, a significant reduction ($P < 0.05$) in colon tumor burden (sum of tumor sizes per animal) was also evident in animals of Group C when compared to those in rats of carcinogen control Group B. The results also showed that vanadium significantly lowered PCNA index in ACF ($P < 0.005$). Furthermore, vanadium supplementation also elevated liver GST and Cyt P-450 activities ($P < 0.001$ and $P < 0.02$, respectively).

CONCLUSION: Vanadium in the form of ammonium monovanadate supplemented in drinking water *ad libitum* has been found to be highly effective in reducing tumor incidence and preneoplastic foci on DMH-induced colorectal carcinogenesis. These findings suggest that vanadium administration can suppress colon carcinogenesis in rats.

INTRODUCTION

Colon cancer is one of the most common malignancies in many regions of the world^[1]. The idea that this cancer might be a root cause for chemoprevention stems from epidemiological evidence that some factors in the diet may play important roles in its development, where others may reduce the risk^[2,3]. Experimental Colon carcinogenesis is a multistep process involving three distinct stages, initiation, that alters the molecular message of a normal cell, followed by promotion and progression that ultimately ends up with a phenotypically altered "transformed cell"^[4]. In animal studies, treated with a carcinogen, such as, 1,2 dimethylhydrazine (DMH), methylnitrosurea, N-methyl-N'-nitro-N-nitrosoguanidine will induce colon tumors in experimental animals particularly in rodents^[5,6]. Colon carcinogenesis models using DMH or the related azoxymethane, with putative preneoplastic aberrant crypt foci (ACF) as end-point marker lesions have been used to assess the influence of modulatory factors^[7,8].

ACF are readily discernible 'preadenomatous' morphological putative lesions within the colonic mucosa of rodents and even in cancer patients that may contribute to the stepwise progression to colon cancer^[9-11]. The formation and growth of ACF are associated with the induction of colon tumors in rats and are influenced by exposure to chemopreventive agents^[12,13]. Natural compounds that inhibit ACF induced colon carcinogenesis have proved to be protective against colon cancer in rodents^[14].

Besides the DMH-target tissue colon, the liver was preferentially selected for assaying the biotransformation and detoxification pattern^[15,16]. Many chemical changes of the liver are detectable prior to the onset of secondary pathological and nutritional changes associated with conditions such as neoplasia. The pathological alterations in the liver often act as an indicator of overall damage caused by a carcinogen since liver enzymes provide more sensitive indicators of pathogenesis than blood^[17]. Efficient inactivation of both xenobiotics and endogenous toxins result in the preservation of cellular integrity and inhibition of cytotoxic events, which lead to several diseases including cancer^[18]. Glutathione S-transferases (GST) are a family of multifunctional proteins, which act as binding proteins and also as enzymes in various detoxification processes^[19-21]. GSTs have been acknowledged as preneoplastic and neoplastic markers^[22]. Cytochrome P-450s, also known as mixed function oxidases having a very broad range of substrate specificity in both exogenous and endogenous including drugs, chemical carcinogens and xenobiotics^[23,24] carry out biotransformation and reduction. Aberration in epithelial colonic crypt cell proliferation leads to hyperplasia with higher risk of colon cancers both in humans and experimental animal models^[25]. Assessment of PCNA expression as an indicator of colonic crypt cell proliferation is suggested as a putative intermediate marker of colon cancer risk^[26].

Vanadium, an element of complex chemistry is of considerable scientific and biological interest nowadays, because of its diverse physiological properties with narrow thresholds between essential and toxic doses^[27]. Various studies from our laboratory have established vanadium for the very first time to be a novel biological regulator in assessing the

physiological and biochemical state of animals in a dose related manner in the detoxification of a number of xenobiotics, including electrophilic chemical carcinogens. Vanadium is observed to be capable of exhibiting some unique beneficial effects particularly, its anticarcinogenic potential under a very low dose^[28-30] without any adverse toxicity. Our laboratory has documented a number of works involving vanadium as a potential antineoplastic agent in rat liver carcinogenesis. Furthermore, this element has shown to be able to inhibit chromosomal and molecular damages by abating the generation of DNA single stranded-breaks and thereby maintaining the genomic integrity^[31]. Thus, there are good reasons to suspect that this micronutrient vanadium may be considered as a potential cancer chemopreventive agent.

In the present study, we had focused on the inhibitory effect of vanadium against the early stages of neoplastic transformation in a defined DMH-induced rat colon carcinogenesis model, since no reports from any other laboratories have documented the same, by morphometric evaluation of the ACF in colonic mucosa and colonic tumors in terms of tumor incidence, colon tumor multiplicity and tumor burden along with histological typings. Furthermore, the chemopreventive efficacy of the trace element was also investigated on certain hepatic drug metabolizing and phase II detoxifying enzyme activity patterns e.g. on liver glutathione S-transferase [GST] and Cytochrome P-450 [Cyt P-450] activities. Finally, PCNA expression as an indicator of cellular proliferation was carried out to correlate the morphometric and enzymological parameters with the protein expression to establish the possible antineoplastic potential of the said element at the cellular level.

MATERIALS AND METHODS

Animals

40 Male Sprague Dawley rats (3-4 weeks old) weighing 80-100 grams were purchased from Indian Institute of Chemical Biology (CSIR), Kolkata (Calcutta), India and quarantined for a week. They were housed 10 per cage under controlled conditions of a 12:12 hour light and dark cycle at $28 \pm 3^\circ\text{C}$. All rats were maintained on a semi purified basal diet (Lipton, Calcutta, India) and water *ad libitum*. All rats received human care according to the criteria outlined in the "Guide for the Care and Use of Laboratory Animals" prepared by the National Academy of Sciences and published by the National Institutes of Health (NIH publication 86-23, revised 1985). Body weights were recorded every 2 weeks.

Chemicals

1, 2 Dimethylhydrazine (DMH) and Vanadium as Ammonium monovanadate was purchased from E. Merck Ltd, Bombay, India.

Experimental protocols

Rats were randomly assigned into experimental and control groups. Group A: animals constituted the normal untreated controls and received saline vehicle intraperitoneally, once a week, throughout the entire course of experimental study, till 32 weeks. Group B: comprised of carcinogen control animals. 1,2 DMH was administered intraperitoneally at a dose of 20-mg/kg-body weight, once a week in 0.9 % NaCl solution (pH 7.2) for a total period of 16 weeks. Group C: included the experimental animals, which received both DMH and Vanadium treatment. Vanadium as ammonium monovanadate at a dose of 0.5-ppm was administered *ad libitum* through drinking water while DMH was injected in the same dose mentioned earlier for Group A animals. Vanadium treatment

was initiated simultaneously with the DMH injection (termed day 0). Group D: animals were vanadium controls and received vanadium alone as ammonium monovanadate at a dose of 0.5 ppm *ad libitum* through drinking water. They were not subjected to any DMH injection.

Interim sacrifice was performed at 16 weeks from the day of initiation in order to evaluate the preventive efficacy of vanadium in the initial stages of carcinogenesis in terms of histology and ACF studies. The terminal sacrifice was carried out at end of 32nd week as shown in Figure 1. All animals were fasted overnight before termination and sacrifice under light ether anesthesia. The length of the colon was recorded.

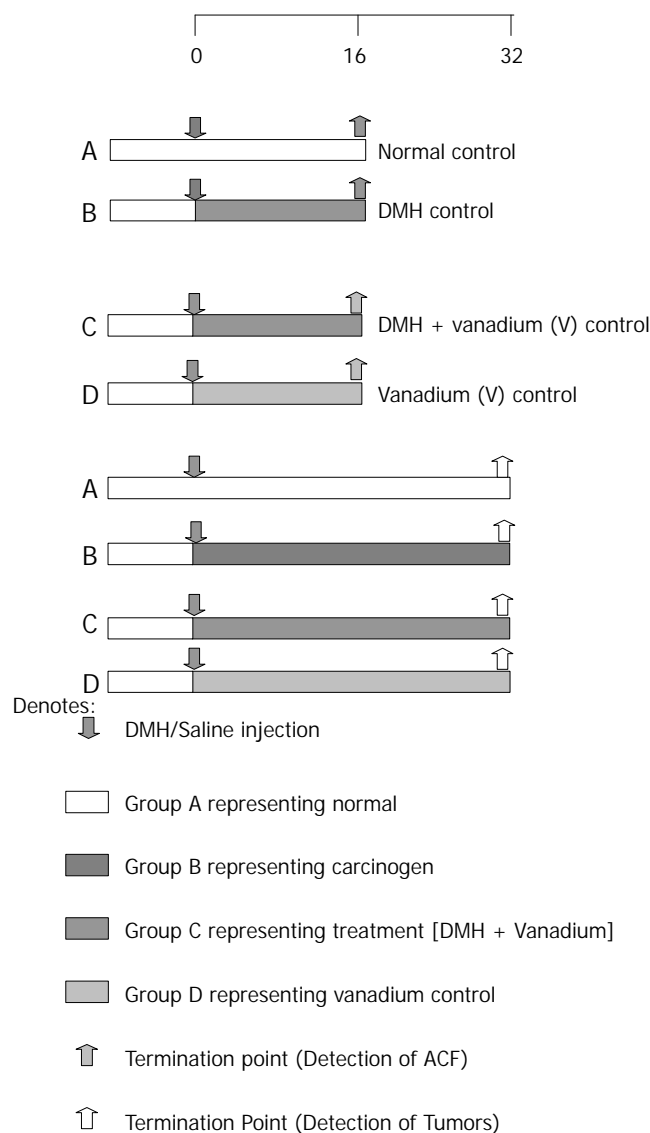

Figure 1 Grouping and different time point of the experiment.

Histological evaluation and ACF assay

The method of Bird^[32] was used to stain and highlight ACF. The number of ACF was evaluated in the 0.3 % methylene blue stained colon. ACF was scored under a light microscope with 40 times magnification to transilluminate the colon. Only ACF meeting the criteria given by McLellan and Bird were chosen. These included crypts of increased size with a thicker and deeply stained epithelial lining and increased pericryptal zone compared with normal crypts.

Morphometric evaluation

After the terminal sacrifice at 32 weeks, colons were excised from the rats, blotted dry, cut open longitudinally and the inner

surface was examined whether there were visible macroscopic lesions (neoplastic tumors). Tumors were easily discernable in the inflamed sections of the colon. The number and size of the tumors were noted for tumor incidence, multiplicity and burden studies. Tumors were classified as adenomas/carcinomas based on the evidence of invasion through the muscularis mucosa. Those with clear-cut invasion were considered to be carcinomas while the rest were classified as adenomas^[33]. The three main axes of each macroscopic tumor from rats were measured using a vernier caliper with 0.1 mm graduation. Preneoplastic lesions were not included in tumor counts.

Assay of GST and Cyt P-450 activities

To determine whether vanadium could modify liver GST and Cyt P-450 activities, livers were excised immediately from all rats necropsy. The livers were perfused with saline to remove blood and minced into small pieces. Aliquots from minced livers were processed to obtain the cytosolic fraction as described^[34]. The activities of GST with 1,2-dichloro-4-nitrobenzene (DCNB) as substrates, and Cyt P-450 assay was determined as described^[35-37]. All assays were performed with UV-Visible Spectrophotometer (Jasco V-530). One unit of enzyme activity was the amount of enzyme catalyzing the conversion of 1 μ mol of substrate to produce per min at 25 °C. Cytosolic protein concentrations were determined by the method of Lowry *et al*^[38] using bovine serum albumin as the standard.

Immunohistochemistry of proliferating cell nuclear antigen (PCNA)

Immunohistochemical staining for PCNA was performed by the avidin-biotin complex method (Sigma). Tissue sections were deparaffinized with xylene, hydrated through a graded ethanol series, immersed in 0.3 % hydrogen peroxide in absolute methanol for 30 minutes at room temperature to block endogenous peroxidase activity and then washed in phosphate-buffered saline (pH 7.2). Following incubation with normal rabbit serum at room temperature for 10 minutes to block background staining, the sections were incubated with an anti-PCNA antibody (mouse monoclonal PC 10; Sigma, USA; a 1:100 dilution) for 12 hours in a humidified chamber at room temperature. They were then reacted with 3,3'-diaminobenzidine and counterstained with Harris' hematoxylin. For determination of PCNA-positive index, 10 full-length crypts (aberrant crypts, normal-appearing crypts or normal crypts) of each colon were examined. The number of PCNA positively stained nuclei in each crypt column was recorded. The PCNA positive index (number of positive stained nuclei X 100/total number of nuclei counted) was then calculated.

Statistical analysis

The statistical analysis for morphometric studies between different groups was performed by Fischer's exact probability test for tumor incidence. Student's *t* test was used to analyzed the tumor multiplicity and tumor burden.

RESULTS

Food and water intake

No appreciable change in food consumption was observed among different groups of rats. The daily food and water intakes were measured with a measuring cylinder and it was found that rats took on an average of 8-10 ml of water/day per rat.

Mortality

All animals survived during the entire course of the experiment.

Body weight of rats

Figure 2 showed the body weight of the rats in different groups sacrificed on the 32nd weeks following the first DMH injection. DMH treatment did not appreciably decrease rat body weight when compared with saline treatment, for first few weeks but by the end of the experimental study at 32nd weeks, differences between normal and carcinogen control Group A were statistically significant ($P < 0.05$). In Group C, animals undergoing treatment with vanadium, maintained near normal body weights. Animals in vanadium control Group D displayed body weights close to those in normal Group B.

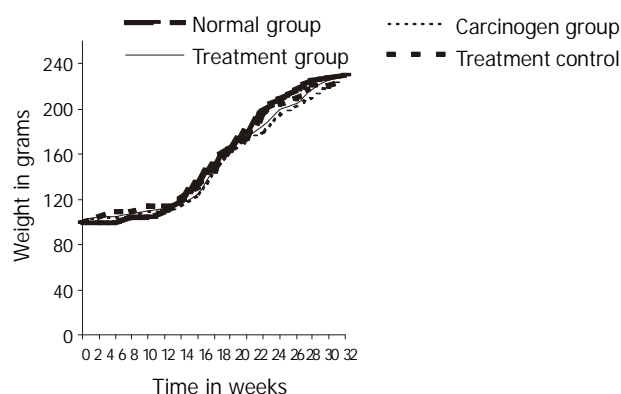

Figure 2 Depicts the body weights of different group of animals.

Aberrant crypt assay

The effect of vanadium on the growth and development of ACF, induced by DMH, in rats was given in Table 1. There was a remarkable decrease in the incidence of aberrant crypts, expressed in terms of percentage, from 100 % in carcinogen group B to 66.07 % in vanadium treatment Group C in early stages of colon carcinogenesis. The average yield of aberrant crypts for the carcinogen group was 112 ± 3.2 ACF/Colon and the range was 90-115 ACF/Colon. For the vanadium treatment Group C, this was significantly reduced ($P < 0.001$ when compared with Group B) to a mean value of 38 ± 3.1 and ranged between 15-40 ACF/Colon. There were no observable foci witnessed in rats of Group D which had administration of vanadium alone *ad libitum* throughout the experiment.

Table 1 Chemopreventive efficacy of vanadium on DMH-induced ACF in Sprague Dawley rats

Group	Number of rats/Group	Number of ACF per rat colon (mean \pm SE)	Inhibition (%)
Normal Control A	10	-	-
DMH Control B	10	112 ± 3.2	-
DMH + V C	10	38 ± 3.1^a	66.07
V Control D	10	-	-

^a $P < 0.001$ vs DMH-only group B by Student's *t* test.

Histology

Tissue sections of Group A displayed normal colonic architecture with no signs of apparent abnormality (Figure 3.1 a,b). In the Carcinogen group B, well-differentiated signs of neoplasia were evident. Nuclei were enlarged and hyperchromatic with mitosis. Simultaneously, there was a loss in nuclear polarity. Connective tissues showed edema and swelling of endothelial cells (Figure 3.2 a,b). In the vanadium treatment Group C, histology revealed no loss of nuclear polarity. Tubules were well formed while crypts lie parallel

to each other. The size and shape of the cells were uniform. Occasionally, hyper chromatic nucleus was evident. However, connective tissue invasion was not seen. No oedema or infiltration of polymorph nuclear leucocytes was sighted (Figure 3.3 a,b). There were no signs of neoplasia or toxicity observed in Group D rats administered with vanadium supplementation (Figure 4.3 a,b).

Colonic tumor analysis

Administration of ammonium monovanadate at the dose of 0.5 ppm, *ad libitum* through drinking water for each animal, brought about a significant reduction of tumor incidence in DMH-induced colon carcinogenesis (Table 2). In the carcinogen Group B, tumor incidence was 100 % (Figure 4.

1 a,b). It dropped to a significant 60 % in the vanadium treated Group C ($P<0.01$ when compared to DMH control group B by Fischer's exact probability test) (Figure 4.2 a,b). The average number of tumor (classified as adenomas, carcinomas) per tumor bearing rat was also considered in the study. Rats treated with vanadium in Group C contained significantly few colonic adenomas and carcinomas ($P<0.05$ by Student's *t* test) compared to rats administered with DMH only (Table 2). In addition, a significant reduction ($P<0.05$) in colon tumor burden (sum of tumor sizes per animal) was also evident in Group C when compared to those in carcinogen control Group B. The results were statistically significant (Table 3). There were no marked changes observed in Group D (Figure 4.3 a,b).

Liver GST and CYT P-450 activities

Liver GST and Cyt P-450 activities at the end of the study were shown in Table 4. DMH treatment in Group B significantly elevated liver GST (*P*<0.05) and Cyt P-450 (*P*<0.001) activities using CDNB as a substrate when compared with those of Group A. GST activities in Group C was significantly greater than those in Group B (*P*<0.02) and Cyt P-450 activities in Group C was also significantly greater than those in Group B (*P*<0.001).

Table 4 Liver GST and Cyt P-450 activities (mean ± SE, *n*=10)

Group	Cyt P-450 activity (mU/mg protein)	GST-CDNB (mU/mg protein)
A Normal Control	0.62±0.06	0.83±0.10
B DMH-Control	0.20±0.03 ^d	0.45±0.03 ^a
C DMH + V	0.41±0.01 ^e	1.98±0.09 ^f
D V-Control	0.47±0.05	0.90±0.19

DISCUSSION

Variable inhibitory effects of vanadium on the incidence of preneoplastic lesions (ACF) were observed during different phases of colorectal carcinogenesis. The finding of the histological and morphometric study clearly supports that trace element vanadium holds a promising anticancer potential with respect to colon carcinogenesis^[39]. The results suggest that chemically induced carcinogenesis in the rat colon follows a distinct pathway where histogenesis obeys the ACF-adenoma-carcinoma sequence in the mid and distal colon and the ACF are an intermediate stage only existed in better-differentiated tumors. A linear relationship between AC formation and colon tumor induction for the same group of laboratory animals could also be established.

As there is strong correlation between ACF formation and colon carcinogenesis, the observation amply imply that supplementation by 0.5-ppm vanadium under the conditions of the experiment, can greatly affect the post initiation stages of colon carcinogenesis by altering the efficacy at which DMH can initiate foci appearance. Increased mitotic activity, which have been proposed as a biomarker of the early stages of colon cancer^[40] was observed in most of the ACF induced by DMH administration alone. Treatment with vanadium greatly restored normalcy in the colonic epithelial cells. The ability of vanadium to reduce the number of ACF per colon also indicates that the anti-carcinogenic potential of vanadium could be mediated through an enhanced repair or remodeling of preneoplastic lesions^[41].

In our observation, we have studied vanadium mediated inhibition of the tumor multiplicity coupled with tumor burden as a percentage of the colonic length. This observation is of interest if one considers that there was no major difference in body weights among the normal rats and rats in Group C. This is particularly important because nutritional deprivation causing body weight loss may parallel a decrease in tumor burden^[42]. The variation in weight gain among the different groups under experiment, thus, do not seem to be significant when evaluating possible causes for the observed differences in the induction of AC or tumors.

Treatment of rats with drinking water supplemented with vanadium for 16 and 32 weeks not only decreased the number of preneoplastic foci but also caused a decrement in the tumor incidence/tumor multiplicity with a concomitant reduction in tumor burden as a percentage of colonic length. This strongly suggests the potentiality of vanadium in inhibiting/slowing tumorigenesis in the rat colon.

Phase II enzymes help to inhibit the formation of electrophiles and catalyze their conversion to inactivate conjugates making them more water soluble and readily excretable from the cell. It is the cellular balance between the Phase I activating enzymes and Phase II detoxifying enzymes that contribute to one's risk of developing cancer^[43]. GSTs catalyze the reaction of the compounds with thiol group of GSH, thus neutralize their electrophilic sites and render the product more water soluble^[44]. 1, 2-DMH is a colon specific procarcinogen that is metabolically activated to the active carcinogen in the liver through a sequential radical generating mechanism^[45] implying a need for detoxification through antioxidant as well as biotransformation mechanism. Cellular GSH by itself or together with GST can function as a non-critical nucleophile for conjugation reactions and play an important role in the inactivation of electrophilic compounds^[46]. Therefore, an elevation of GSH level indicates an increase in the systemic ability to detoxify electrophilic compounds including carcinogens. Data from several laboratories continue to suggest a relationship between decreased GST expression and an increased risk for cancer^[47-49]. The decrease may be associated further with interference of protein synthesis and accumulation of electrophilic metabolites. Increased GST level towards normal value clearly indicates that the tumor genesis burden

is not high, at the same time shows that vanadium is a good protective agent against DMH induced colon carcinogenesis.

Preliminary studies from our laboratory^[50,51] have shown that under a certain optimum dose of 0.5 ppm, the trace element could lead to stable induction of GST activity without any apparent signs of toxicity. A probable mechanistic explanation could be increased transcription of GST gene and/or allosteric modification of the enzyme. Alternatively, this increase in GST activity by vanadium can be viewed as the host cellular response in boosting up the GSH-related conjugation system against the possible free radical mediated stress.

In the present study, we also report that vanadium functions as an anticarcinogen by altering the activity of Cyt P-450 related enzyme. Vanadium might have induced the Cyt P-450 level due to its property as a heavy metal. Since the dose used is non-toxic^[52], it is having a positive action on inhibiting tumor promotion. The induction of Cyt P-450 may also be due to alteration of the ATP/ADP ratio by the inhibition of oxidative phosphorylation thereby increasing the NADPH content rapidly for the mixed function oxidase system to act. Alternatively, vanadium may elevate the Cyt P-450 level by regulating the transcriptional activation of the P-450 gene^[53]. Considering the relative persistence of oxidative damage, antioxidant defense and biotransformation alterations, we could predict that the biochemical markers measured in the liver may well be a prognostic marker of the distant neoplasm of the colon, even at the early stages of preneoplasia at 16 weeks.

Finally, PCNA-labeling index, an intermediate biomarker of carcinogenesis, was decreased in DMH-treated ACF by supplementation of vanadium in the drinking water. Cell proliferation plays an important role in multistage carcinogenesis with multiple genetic changes^[54]. PCNA is an auxiliary protein of the DNA polymerase delta, reaching an expression peak during the S-phase of the cell cycle and playing an important role in cellular proliferation^[55]. PCNA has been used as an intermediate biomarker in chemoprevention of colorectal cancer^[56]. Zheng *et al*^[57] observed that Vitamin A significantly decreased PCNA in the AOM-induced colorectal cancer animal model. Thus, the inhibitory effect of vanadium may be due, in part, to modification of cell proliferation through the above mechanisms.

One of the predominating factors which often limit the therapeutic efficacy of many antineoplastic elements and their complexes is their considerable toxic side effects associated with hepato and nephrotoxicity. However in the present study, supplementing vanadium at 0.5 ppm have shown no clinical signs of toxicity such as decrease in food and water intake, retarded growth or eventual death.

In conclusion, the results of this study suggest that daily supplementation of 0.5 ppm vanadium in the form of ammonium monovanadate in the drinking water has a positive beneficial effect against chemically induced colonic preneoplastic progression in rats induced by DMH, which provides an effective dietary chemopreventive approach to disease management. However, other definitive bioassay including protein expression and documentation of specific molecular markers is now being planned in our laboratory to establish the surrogate end-point biomarker in vanadium-mediated cancer chemoprevention.

Abstract

AIM: To investigate the regulatory effect of electroacupuncture (EA) at Zusanli (ST36) on tumor necrosis factor- α (TNF- α) in rats with ulcerative colitis (UC), and further elucidate the therapeutic mechanism of EA on UC.

METHODS: Thirty-two male Sprague-Dawley (SD) rats were randomly divided into four groups ($n=8$): normal control group, UC control group, UC+ST36 group and UC+non-acupoint group. A solution containing ethanol and 2,4,6-trinitrobenzenesulfonic acid (TNBS) was instilled into the distal colon in the rat (at a dose of 100 mg/kg) to set up UC rat model. Rats in wakefulness state of UC+ST36 group were stimulated at ST36 by EA once a day, while those of UC+non-acupoint group were done at 0.5 cm beside ST36. After 10 d treatment, all rats were sacrificed simultaneously. Colon mucosal inflammation and damage were assessed by measuring colon mass, morphologic damage score, colonic myeloperoxidase enzyme (MPO) activity, serum TNF- α and colonic TNF- α mRNA level. Morphologic damage score was examined under stereomicroscope. Colonic MPO activity was measured by spectrophotometer method. Serum TNF- α concentration was determined by radioimmunoassay (RIA). Colonic TNF- α mRNA expression level was analyzed by semiquantitative reverse transcription polymerase chain reaction (RT-PCR).

RESULTS: Ratio of colonic mass/body mass (m_c/m_b) and activity of colonic MPO ($\mu\text{kat/g}$ tissue) markedly increased (8.5 ± 2.6 vs 2.5 ± 0.4 ; 145 ± 25 vs 24 ± 8 , $P<0.01$ vs normal control group). Compared with normal control rats, serum TNF- α and colonic TNF- α mRNA level in UC control group were increased 2.5 fold ($2\,278\pm170$ vs 894 ± 248 , $P<0.01$) and 4.3 fold (0.98 ± 0.11 vs 0.23 ± 0.11 , $P<0.01$) respectively. After EA at ST36, m_c/m_b and MPO activity were reduced significantly (5.3 ± 2.0 vs 8.5 ± 2.6 ; 104 ± 36 vs 145 ± 25 , $P<0.01$, 0.05) compared with those of UC control group. Serum TNF- α and colonic TNF- α mRNA level were inhibited by EA stimulation at ST36 ($P<0.01$). The inhibitory rate was 16 % and 44 % respectively. Morphologic damage score was also increased markedly in rat with UC ($P<0.01$), whereas it was decreased by EA at ST36 ($P<0.05$). There was no significant difference between UC control group and UC+EA at non-acupoint

($P>0.05$). Furthermore, these parameters were highly correlated with each other ($P<0.01$).

CONCLUSION: Serum TNF- α concentration and colonic TNF- α mRNA expression level are increased significantly in UC rats in correlation with the severity of disease. It indicates that TNF- α is closely involved in the immune abnormalities and inflammatory responses in UC. EA at ST36 has therapeutic effect on UC by downregulating serum TNF- α and colonic TNF- α mRNA expression. High levels of TNF- α and its corresponding mRNA expression seem to be implicated in the pathogenesis of UC.

INTRODUCTION

The incidence of ulcerative colitis (UC) has become higher in China^[1]. It is characterized by intestinal inflammation and ulceration^[22-26]. Its pathogenesis has not been elucidated yet. A number of clinical and experimental studies, however, have suggested that imbalance between proinflammatory cytokines and anti-inflammatory cytokines is involved in the pathogenesis of UC^[5,6]. High levels of proinflammatory cytokines (interleukin-1 β , interleukin-6, interleukin-8 and TNF- α) in the intestinal mucosa are thought to be the pivotal factors in the pathogenesis of intestinal inflammation and ulceration in UC. These proinflammatory cytokines concentrations and their corresponding mRNA expression levels elevated significantly in colonic mucosa, perfusion fluids, spleen and serum of UC patients. It has been suggested that TNF- α may be an important mediator involved in the initiation and perpetuation of intestinal inflammation in UC. TNF- α can cause inflammation directly, and indirectly by inducing the production of other proinflammatory cytokines.

Nearly all drug treatments for UC have many side effects, which limit patients' acceptance. Acupuncture is characteristic technique of traditional oriental medicine. It has been accepted by patients for its better clinical therapeutic effects and fewer side effects on many diseases including UC. Recent studies have demonstrated that acupuncture has immunoregulatory role. It can modulate the production and expression of many cytokines. But the therapeutic mechanism of acupuncture on UC is still uncertain. As an important acupoint, ST36 is not only for disorders of the lower limbs, but also for the whole digestive system, even with certain effect on immunity. The effect of EA at ST36 on UC has rarely been reported yet.

In this study, we induced UC in rats and stimulated them with EA at ST36 (Zusanli). The aim of this study was to assess the effect of EA stimulation at ST36 on UC, further investigate its role of regulating TNF- α , explain the therapeutic mechanism of EA on UC and provide new thought to acupuncture and moxibustion.

MATERIALS AND METHODS

Materials

Male SD rats weighed 220 ± 20 g were purchased from Experimental Animal Research Center, Fourth Military Medical University. The rats were housed in an air-conditioned animal room at 25 ± 2 °C and 60 % humidity with food and water available ad libitum, and drinking water was changed every day. Hadecyltrimethylammonium bromide (HATB) was purchased from Xizhong Chemical Co (Beijing, China). TNBS was purchased from Sigma Chemical Co (St.Louis, MO). TNF- α RIA kit was purchased from Dongya Biotechnology (Beijing, China). Access RT-PCR System Kit was obtained from Promega (Madison, WI). TRIzol Reagents were purchased from Gibco BRL (Gercy-Pontoise, France).

Induction of ulcerative colitis

The rats were randomized into 4 groups (8 rats for each group): normal control group, UC control group, UC+ EA at ST36 group and UC+ non-acupoint group. Rats were fast for 24 hours. Being gently anesthetized by ether, a rubber catheter (OD, 2 mm) was inserted through anus into its colon whose length in the lumen was 8 cm proximally. TNBS dissolved in 300 mL ethanol was instilled into the lumen of the colon through the rubber catheter at the dose of 100 mg/kg^[28,29]. Rats of normal control group were treated by 90 mL/L NaCl solution at the same dose.

EA stimulation

Rats in wakefulness state of UC+ST36 group were stimulated at ST36 (bilateral) which lies just 0.5 cm below fibular head of hinder leg in rat, while those of UC+non-acupoint group were done at 0.5 cm beside ST36^[33,35,40]. These rats were immobilized in special cages, and then were stimulated by the intermittent pulse with 2Hz frequency, 4mA intensity for 30 minutes once a day and 10 times in all. Rats in other two groups were immobilized in the same way with sham acupuncture stimulation.

Preparation of the samples

All rats were weighed after 10 d treatment. Serum was separated from blood drawn from carotid and then stored at -20 °C until analysis. All rats were sacrificed simultaneously. The colon was taken from the region, which was 8 cm proximal to the anus. Along its mesenteric border, the colon was opened and gently rinsed out of its contents with an iced NaCl solution 90 mL/L. The colon was then placed flat, with mucosal surface upwards, on a plate chilled at 4 °C. The colon was immediately examined under a stereomicroscope and any visible damage was scored on a 0-5 scale by two independent observers blinded to the treatment^[28]. There was a highly significant linear correlation between the scores assigned by the two observers ($r=0.98$, $P<0.001$). The colon tissue was weighed after being dried on a filter paper. Three tissue samples (1 mm³) were excised from affected region of each colon and then were fixed in 40 g/L glutaraldehyde for electro microscopic examination. The remaining colon was stored at -70 °C.

Colonic MPO activity assay

The distal 6 cm segment of the colon was homogenized in 5 mL/L HTAB in 20 mmol/L phosphate buffer (pH=6.0, 50 mg of tissue/mL). Homogenates were sonicated and centrifuged for 15 min (15 000 r/min). The supernatant was assayed for MPO activity by using a spectrophotometer, and 0.1 mL of supernatant was mixed with 2.9 mL of 20 mmol/L phosphate buffer (pH=6.0) containing 20 mmol/L guaiacol and 5 mL/L hydrogen peroxide. The changes in absorbance at 460 nm were measured with an Uvikon 860 spectrophotometer (Kontron

Instrument, St. Quentin, France). MPO activity was expressed as $\mu\text{kat/g}$. One $\mu\text{kat/g}$ was defined as that degrading 1 μmol of peroxides per second at 25 °C for 1 g of tissue.

Measurement of serum TNF- α concentration by TNF- α RIA kit

Measurement of TNF- α mRNA expression in colonic tissue

Total RNA of 100 mg colonic tissue was purified by TRIzol Reagents. Reverse transcription (RT) was performed in a final volume of 50 μL containing nuclease-free water, AMV/tfl 5 \times reaction buffer, dNTP mix (10 mM each dNTP), 50 pmol specific primers, 25 mmol/L MgSO₄, 5Mu/L AMV Reverse Transcriptase, 5Mu/L tfl DNA Polymerase and 1 μg RNA. cDNA was synthesized by incubating the solution for 50 minutes at 48 °C and heating them for 2 minutes at 94 °C. Then 45 cycles of PCR were performed in a thermal cycler, using the following conditions: denaturation, 30 seconds at 94 °C; annealing, 1 minute at 55 °C for TNF- α and 57 °C for β -actin; and extension, 2 minutes at 68 °C. At the end of the 45 cycles, further extension was continued for 7 minutes at 68 °C. The primers were TNF- α sense, 5'-AGAACTCCAGGCGGTGTCT-3'; TNF- α antisense, 5'-TCCCTCAGGGGTGCTTCTAG-3' (484bp); β -actin sense, 5'-AACCTAAGGCCAACCGTGAAAAG-3'; β -actin antisense, 5'-GCTCGAAGTCTAGGCAACATA-3' (343bp). Amplification of β -actin was used for the determination of TNF- α mRNA expression level. 10 μL aliquots of the synthesized PCR products were separated by electrophoresis on a 22 g/L agarose gel and analyzed by Gel-Pro version 3.1 software (Media Cybernetics). The ratio of arbitrary unit (AU, $D_{\text{area}} \cdot D_{\text{density}}$) of TNF- α over β -actin was used for expressing the relative level of mRNA expression.

Statistical analysis

The results are expressed as mean \pm SEM. All data were analyzed by using ANOVA. P values <0.05 were considered significant. All statistical calculations were performed using the SPSS for windows version 10.0 software package.

RESULTS

Effect of EA on colonic morphology of UC rats

The levels of colonic tissue damage score and m_c/m_B of rats in UC control group were increased significantly compared with those of normal control group ($P<0.01$). In comparison with those of UC control group, EA at ST36 made them decreased markedly ($P<0.01$). EA stimulation at non-acupoint had few effects on these two parameters ($P>0.05$, Table 1, Figure 1).

Table 1 Effect of EA on colonic tissue damage score

Group	n_A	n_B	P
1 2	8	8	0.000
1 3	8	8	0.000
1 4	8	8	0.000
2 3	8	8	0.006
2 4	8	8	1.000
3 4	8	8	0.040

1: Normal control; 2: UC Control; 3: UC+EA at ST36; 4: UC+EA at non-acupoint. These classifications are qualified for all figures.

Histological ultrastructure of colonic tissue was assessed by electron microscopy. Colonic ultrastructure manifestations of rats in UC control group and those in UC+non-acupoint group were similar: exiguous goblet cells, scanty microvilli, dilatations of endoplasmic reticula, mitochondria swelling

and rounding, with loss of cristae and many inflammatory cells infiltration. While in UC+EA at ST36 group, the results of colonic electron microscopy were more microvilli with well organized appearance, more goblet cells filled with numerous mucous drop in colonic mucosa and only slight mitochondria swelling compared with those of UC control group (Figure 2-4).

Figure 1 Effect of EA on m_c/m_b . ^a $P<0.05$, ^b $P<0.01$ vs normal control; ^d $P<0.01$, ^f $P>0.05$ vs UC control; ^e $P<0.05$ vs UC+EA at non-acupoint.

Figure 2 Colonic ultrastructure of UC control group: A, goblet cells, microvilli, endoplasmic reticula and mitochondria (TEM×10 000); B, inflammatory cells (TEM×2 500).

Figure 3 Colonic ultrastructure of UC+EA at ST36 group: A, goblet cells (TEM×4 000); B microvilli and mitochondria (TEM×8 000).

Figure 4 Colonic ultrastructure of EA+non-acupoint group: A, goblet cells, microvilli and mitochondria (TEM×8 000); B, endoplasmic reticula and mitochondria (TEM×10 000).

Figure 5 Effect of EA on colonic MPO activity. ^b $P<0.01$ vs normal control; ^c $P<0.05$, ^f $P>0.05$ vs UC control; ^e $P<0.05$ vs UC+EA at non-acupoint.

Effect of EA on colonic MPO activity

Colonic MPO activity of rats in UC control group was significant higher than that in normal control group (145 ± 25

vs 24 ± 8 , $P < 0.01$). After EA stimulation at ST36, colonic MPO activity became lower than that in UC control group (104 ± 36 vs 145 ± 25 , $P < 0.05$). There was no significant difference between UC control group and UC+non-acupoint group (142 ± 45 vs 145 ± 25 , $P > 0.05$, Figure 5).

Effect of EA on the production and expression of TNF- α

Compared with normal control rats, serum TNF- α concentration and colonic TNF- α mRNA expression level increased 2.5 fold ($2\,278 \pm 170$ vs 894 ± 248 , $P < 0.01$) and 4.3 fold (0.98 ± 0.11 vs 0.23 ± 0.11 , $P < 0.01$). Serum TNF- α and colonic TNF- α mRNA expression were inhibited by EA stimulation at ST36. The inhibitory rate was 16 % ($1\,913 \pm 232$ vs $2\,278 \pm 170$, $P < 0.01$) and 44 % (0.55 ± 0.13 vs 0.98 ± 0.11 , $P < 0.01$), respectively. While the production of serum TNF- α and the level of TNF- α mRNA expression were not affected by EA stimulation at non-acupoint ($2\,183 \pm 209$ vs $2\,278 \pm 170$, 0.92 ± 0.17 vs 0.98 ± 0.11 , $P > 0.05$, Figure 6, 7).

Figure 6 Effect of EA on TNF- α mRNA expression. A: Representative pictures of RT-PCR. Lane 1, 4, 7, 9: β -actin. Lane 2, 3, 6, 8: TNF- α . Lane 5, 10: DNA Marker (DL2000). B: Relative level of TNF- α mRNA expression. ^b $P < 0.01$ vs normal control; ^d $P < 0.01$, ^f $P > 0.05$ vs UC control; ^g $P < 0.01$ vs UC+EA at non-acupoint.

Figure 7 Effect of EA on serum TNF- α concentration. ^b $P < 0.01$ vs normal control; ^d $P < 0.01$, ^f $P > 0.05$ vs UC control; ^e $P < 0.05$ vs UC+EA at non-acupoint.

Correlation among parameters quantified above

There were significant correlations between serum TNF- α concentration and colonic MPO activity ($r = 0.815$, $P < 0.01$), serum TNF- α and damage scores ($r = 0.877$, $P < 0.01$), serum TNF- α and m_c/m_b ($r = 0.691$, $P < 0.01$). colonic TNF- α mRNA expression level was highly correlated with colonic MPO activity ($r = 0.791$, $P < 0.01$), damage scores ($r = 0.827$, $P < 0.01$), and m_c/m_b ($r = 0.686$, $P < 0.01$). The correlation matrix is shown in Table 2.

Table 2 Correlations among the parameters (r)

Parameters	TNF- α	TNF- α mRNA	m_c/m_b	MPO	Damage scores
TNF- α	1	0.814	0.691	0.815	0.877
TNF- α mRNA		1	0.686	0.791	0.827
m_c/m_b			1	0.759	0.770
MPO				1	0.902
Damage scores					1

DISCUSSION

UC is a non-specific inflammatory bowel disease. Many factors including infection, environment and immune abnormality may involve in the pathogenesis of UC, in which abnormal immunoregulation plays an important role^[2-4]. There is strong evidence that inflammatory immunoregulation in the intestinal mucosa is characterized by increased concentrations of proinflammatory cytokines with apparent inability to adequately downregulate immune activation. UC showed significantly increased mRNA expression of interleukin-1 β (IL-1 β), interleukin-6 (IL-6), interleukin-8 (IL-8) and TNF- α in large numbers of cells throughout the inflamed intestine but also in some macroscopically unaffected tissue specimens. Elevated concentrations of proinflammatory cytokines were also found in serum, colonic mucosa, spleen and colorectal perfusion fluids in UC^[7-12]. There is significant correlation between the production of these cytokines and the activity of UC. The increased production of proinflammatory cytokines is thought to be a pivotal factor in the pathogenesis of UC. It is accepted that TNF- α may be particularly important for inducing and sustaining intestinal inflammation in UC. It is known from many studies that TNF- α is expressed in human gastrointestinal mucosa, and that the expression is strongly enhanced in the inflammatory course of UC. TNF- α production in the gut has been attributed to monocytes, macrophages, natural killer cells, T lymphocytes and mast cells. TNF- α is known to induce the synthesis of IL-6 and IL-8. TNF- α and IL-1 β induce each other. The effects of IL-1 β and TNF- α appear synergistic. These cytokines regulate many nuclear factor kappaB inducible genes that control expression of other cytokines, cell adhesion molecules, immunoregulatory molecules, and proinflammatory mediators^[13]. Enhanced production of TNF- α and IL-1 β may induce some key enzymes of the inflammation cascade and neutrophils chemotaxis. TNF- α can also induce more production of nitric oxide (NO) and inducible nitric oxide synthase (iNOS), which further promotes inflammation than IL-1 β ^[14-20]. High levels of proinflammatory cytokines in the mucosa lead to the excessive production of matrix degrading enzymes by gut fibroblasts, loss of mucosa integrity and ulceration^[21].

MPO is an enzyme found predominantly in the azurophilic granules of polymorphonuclear neutrophils (PMN) and has been used as a quantitative index of inflammation in several tissues, including intestine. PMN are the most abundant cell type in intestinal lesions in UC. PMN carry the capacity to secrete increased amounts of TNF- α and IL-1 β in active UC

and infectious colitis. Neutrophils may be important contributors to the initiation and perpetuation of mucosa inflammation^[27].

Quantitative indexes of inflammation (damage scores, colon mass and MPO activity) were elevated significantly in UC^[22-26]. This study showed that in UC control group, erosion and ulceration induced by TNBS were so particularly severe in rectum and even extended to the proximal colon that damage scores and colon mass were increased markedly, neutrophil infiltration was characteristically present in the lesions and surrounding mucosa, MPO activity at lesions sites was increased, serum TNF- α concentration and colonic TNF- α mRNA expression level elevated significantly compared with those of normal control rats. All these parameters correlated significantly with each other. So TNF- α is a key inflammatory mediator in the pathogenesis of UC.

Based on recent studies, several new therapeutic strategies are currently tested in clinical practice including inhibitors of proinflammatory cytokines (TNF- α , IL-12) and their receptors (TNF- α , IL-6R), in which anti-TNF- α has been impressive. These new therapeutic strategies have demonstrated efficacy in refractory UC patients. But there are still many problems to solve including the best way of therapy and side effects before they are formally applied to UC patients. Other potent medications with side effects limit patients' acceptance. While the advantages of acupuncture treatment for UC have been obvious^[39].

Acupuncture is one of the most important part of traditional Chinese medicine (TCM) which possesses a unique theoretical systems, rich clinical experience and excellent clinical effects. TCM theory says: inharmony between Qi and blood, and imbalance between Yin and Yang can lead to disease. EA at acupoint is able to stimulate meridians to transport Qi and blood, regulate Yin and Yang keeping the functions and activities of all parts of the body in harmony and balance relatively.

As an important acupoint in TCM, ST36 is the lower He-(Sea) point. This point has a tonifying function. It is an important point for health maintenance and disorder of stomach and abdomen. Recent studies have shown that EA stimulation at ST36 may regulate nerve-endocrine-immune network by influencing the production and expression of neurotransmitters, hormones and cytokines^[30-37]. EA stimulation at ST36 significantly restores brain-derived neurotrophic factor (BDNF) mRNA expression declined by emergency^[38]. EA stimulation at ST36 improves the immune function by inducing interleukin-2 (IL-2) and interferon-gamma (IFN- γ) production of spleen lymphocytes in traumatized rats. ST36 stimulated by EA can also inhibit abnormal IL-1 increment induced by trauma and even disease. Li *et al*^[40] found that high levels of serum IL-1 β , IL-6, TNF- α and NO induced by lipopolysaccharide in rats were decreased significantly by EA stimulation at ST36.

Acupuncture at acupoints such as Tianshu(ST25), Guanyuan (Ren4) has a marked curative effects with few side ones on UC, and therefore was readily acceptable to the patients^[39]. But its therapeutic mechanism is still unclear. There are only a few studies on its corresponding theory. Some studies showed that EA stimulation at Qihai(RN6) and Tianshu(ST25) may downregulate the expression of proinflammatory cytokines mRNA (IL-1 β mRNA, IL-6 mRNA) and iNOS mRNA of spleen and colon in UC rats, whereas it could upregulate IL-1 α mRNA expression. It is reported that acupuncture stimulation at acupoint reduces the excessive production of TNF- α positive cells of colonic mucosa in rats with UC. The study of effect of EA stimulation at ST36 on UC has rarely been reported yet.

This study showed that in UC+EA at ST36 group, lesion formation was inhibited grossly and microscopically,

neutrophil infiltration and MPO activity in and around lesions were lessened, serum TNF- α concentration and colonic TNF- α mRNA expression level were decreased significantly. These results suggest that EA stimulation at ST36 can inhibit effectively inflammation cascade in UC. But these parameters were not restored to normal levels by EA stimulation at ST36 without being accompanied by other acupoint.

In summary, this study showed EA stimulation at ST36 has therapeutic effect on UC by reducing serum TNF- α concentration and colonic TNF- α mRNA expression level, decreasing colonic MPO activity and alleviating colonic inflammation damage. Its therapeutic mechanism is attributed to its downregulation effect on TNF- α , which is a key proinflammatory cytokine. It is still unknown whether EA can keep the balance between proinflammatory cytokines and anti-inflammatory cytokines by upregulating the key anti-inflammatory cytokines (IL-4, IL-10, IL-13) when it downregulates proinflammatory cytokines. Its mechanism of regulating cytokines needs further study.

Abstract

AIM: To determine whether serum leptin level and the leptin receptor (OB-R) expression in the basolateral amygdala (BLA) change following conditioned taste aversion (CTA) formation.

METHODS: The serum leptin concentration was measured by rat leptin RIA kit, long and short forms of leptin receptor (OB-Rb and OB-Ra) mRNA in the brain sections were examined by in situ hybridization (ISH) and the expression of OB-R was assessed by immunohistochemistry ABC method with a highly specific goat anti-OB-R antibody.

RESULTS: The level of serum leptin didn't show significant difference between CTA and control group. Comparing with the control group, the CTA group had an increase on count of OB-R immunohistochemistry positive-stained cells in the BLA (127 ± 12 vs 48 ± 9 per 1 mm^2). The OB-Rb mRNA expression level enhanced by 11.9 % in the BLA, while OB-Ra mRNA level increased by 7.4 % on the choroid plexus in CTA group. So BLA was supposed to be a region where interactions between gustatory and vagal signals take place.

CONCLUSION: BLA is one of the sites, which are responsible for CTA formation in the brain. Leptin and OB-R maybe involved in neuronal communication for CTA. So leptin and its receptors probably take part in CTA and integration of autonomic and exteroceptive information.

INTRODUCTION

Conditioned taste aversion (CTA) is a protective reflex by which an animal learns to discriminate and to reject potentially harmful substances by their flavor. When the consumption of novel flavored food is followed by internal malaise, animals

avoid ingesting the food on subsequent presentations^[1,2]. The anatomical substrates responsible for CTA learning have been well established^[3]. But the neurotransmitters involved in neuronal communication for CTA are not yet well known.

Leptin has been discovered since 1994 by Zhang *et al* (*Nature* 1994; 372:425-431) as the product of the *ob* gene. Leptin (OB protein) is produced primarily by adipose tissue and secreted into the bloodstream, then delivered to the brain. In the brain some specific receptors of leptin have been characterized, especially in hypothalamic nuclei where express neuropeptides and neurotransmitters that were involved in the long-term regulation of food intake and metabolism rate^[4-7], therefore, leptin serves as a unique feedback signal system to submit information regarding to adipose tissue energy store into the central nervous system^[8]. As leptin level growth coincidence with adiposity increment in rodents and mankind, it is proposed to act as a negative feedback 'adipostatic signal' to brain centers and control energy homeostasis, prevent from obesity in time of nutritional abundance^[9].

In recent years leptin receptor has been found to be expressed in the amygdala^[10], especially in the basolateral amygdala (BLA)^[11]. The interest in amygdala which acts as a regulator of weight and intake behavior has also been warming up. Amygdala is one of critical centers to regulate weight and ingestive behavior. Robust increases in body weight and food intake has been observed in rats with lesions of the BLA and posterodorsal amygdala (PDA) (*Brain Res* 1996;740:193-200). In addition to food intake alteration, lesions (electrolytic and excitotoxic) in the amygdala have also been known to disrupt the formation of conditioned taste aversion (CTA), particularly lesions placed in the BLA^[12-15]. The sense of taste lies in the interface between the external and internal of milieu and participates in control of motivational processes which guide dietary selection. The amygdala plays an important role in the initiation and guidance of autonomic and exteroceptive information^[16].

The present study was undertaken to further investigate possible changes of the leptin receptor expression accompanied with learning and maintaining of CTA.

MATERIALS AND METHODS

Animals

Twenty healthy adult male Sprague-Dawley rats, weighing 200-250 g, were used in all experiments. Every rat was housed at one cage in a temperature-controlled room (18-24 °C) on a 12 h light/dark cycle and allowed food (rodent chow) and water ad libitum for 3 days. All rats were randomly grouped into 2 groups. Each group consisted of 10 rats.

Behavior experiment

Rats were water-deprived for 24 h prior to test day. At 08:30 to 09:00 from day 1 to 5, the rats were trained to drink distilled water for 30 min in the home cages. At the same time on day 6, each rat in test group received an ip injection of 0.15 mol/L LiCl (2 % body weight) as an unconditioned stimulus (US) soon after 30 min of free access to 1 g/L (0.005 mol/L) sodium

saccharin instead of water as a conditioned stimulus (CS). Rats in control group received an ip injection of an equivalent volume of 0.15 mol/L NaCl. From day 7 to 9, all rats have accessed to distilled water for 30 min. On day 10, the rats were presented with 1 g/L saccharin for 30 min. The volumes of intake of the CS were recorded on day 6 and 10.

Sample collection

Rats were anaesthetized with urethane (1.2 g/kg, ip). Then the tail was cut, the whole blood glucose level was measured by One Touch Brand blood glucose meter (Lifescan inc, USA). Then opened thorax and 2 mL blood was drawn from the aorta and put into dry tube allowing to clot for 1 h. Serum was separated by centrifugation (2 000 r/min) for 20 min. Then the rats were perfused via the ascending aorta with 300 ml of 8.5 g/L saline (room temperature) followed by 300 mL of paraformaldehyde (PFA, 4 g/L, pH 7.4). Brains were dissected out and then post-fixed in the same fixative for 3 hours at 4 °C. After being paraffin embedded, three series of sections were cut coronally at a thickness of 5 µm, thaw-mounted on poly-L-lysine-coated glass slides and stored at -70 °C. One of the series was used for immunohistochemical staining, another for ISH. The remaining series of sections were stained with hematoxylin-eosin.

The assay of serum leptin

Serum leptin and insulin were measured by radioimmunoassay (RIA) (rat leptin RIA kit, rat insulin RIA kit, Linco Research, St, Louis, MO). The lower limits of sensitivity of the assay are 0.5 µg/L and 0.1 µg/L.

Immunohistochemistry

Endogenous peroxidase activity was blocked with 0.01 mol/L PB containing 0.3 mL/L hydrogen peroxide. Then the sections were heated to 92 °C in citric acid (pH 6.0). After that the sections were rinsed with 0.01 mol/L phosphate-buffered saline (PBS), incubated with 15 mL/L blocking serum in PBS for 1 h. The sections were incubated at 4 °C for 40 h with goat polyclonal antiserum against leptin receptor (antiserum Sc-1834 with dilution at 1:100, Santa-Cruz Biotechnology, CA, USA). After incubation, the sections were immunostained by the avidin-biotin complex method (goat ABC staining system, Sc-2023, Santa-Cruz Biotechnology, CA, USA). The sections were mounted on slide glasses, dried and dehydrated in a graded ethanol series, and covered with balata.

To verify the specificity of staining, some sections were incubated with non-immune serum instead of the primary antiserum, or with the primary antiserum without the second antiserum to serve as a negative control. No LR-IR was observed in the negative control tissue.

In situ hybridization

Prior to hybridization, the sections were deparaffinized, incubated at 37 °C in 2 mg/L of proteinase K for 25 min. Post fixation was performed in a PFA solution and the sections were treated with 2 mol/L HCl. The specific oligonucleotide probes are 5' -GGC TCC AGA AGA AGA CCA AAT ATC (Nucleotide number 2 712-2 738 of Genbank sequence D84500) for OB-Rb and 5' -CAA GCA TGG GCT GCA GTG ACA TTA GAG (Nucleotide number 671-697 of Genbank sequence D84550) for OB-Ra. The probe was terminally labeled with digoxigenin-dUTP (Dig Oligonucleotide Tailing Kit, Cat No.1417231, Roche, Germany) and tested by Dig nucleic acid detection kit (1175041, Roche, Germany). Its concentration was 100 nmol/L. Probe was prepared in a solution containing 500 g/L formamide, 0.3 mol/L NaCl, 10 mmol/L Tris, 1 g/L ssDNA, 1×Denhardt's solution, and 100 g/L dextran

sulfate, then they were hybridized to sections at 50 °C for 16-18 h. After hybridization, the slides were washed sequentially in 2× saline-sodium citrate (SSC) for 30 min followed by rinses in 1×SSC, 0.5×SSC. Then they were incubated with phosphatase-labeled anti-digoxigenin antibody (1:400) at 37 °C for 2 h. Staining was performed with a freshly prepared substrate solution of Nitro Blue Tetrazolium and 5-bromo-4-chloro-3-indolyl phosphate. Then the sections were restained by methyl green.

To assess the specificity of labelling, control sections were co-incubated with a 100-fold excess of unlabelled probe in addition to the corresponding DIG-labelled probe. No labelling above background was detected in those sections.

Quantification and data analysis

On the basis of volumes of following two test days, we calculated a CTA index as an indicator of the strength of CTA formation. The larger this index, the stronger the acquisition of CTA: CTA index=1-(total saccharin intake on day 10/total saccharin intake on day 6).

Some sections were photographed. Then expression of leptin receptor immunoreactivity was quantified by counting positive-stained cells in BLA of five adjacent brain sections. All films of ISH were analyzed by using a computer-assisted image analysis system, multi-analyst, connected to a GS 690 Imaging Densitometer (Bio-Rad, USA). Quantification of mRNA expression levels was obtained by measuring the average density of each region in five adjacent brain sections. All data are shown as the $\bar{x} \pm s_x$ for groups based on eight rats in each group. Analysis was performed by SPSS software. Unpaired, two tailed *t*-test and Anova comparison test were used with *P*<0.05 be considered as sufficient to reject no difference hypothesis.

RESULTS

There were no significant differences of weight, glucose level, serum leptin and serum insulin level (Compared with control rats, *P*>0.05) between test and control groups (Table 1).

Table 1 Comparison of weight, glucose level, serum leptin and insulin between test and control groups ($\bar{x} \pm s$)

Group	<i>n</i>	Weight (g)	Glucose	Leptin (µg/L)	Insulin(µg/L)
CTA	8	227.2±11.7	6.2±0.8	2.2±0.4	1.2±0.4
Control	9	226.3±10.2	6.4±1.2	2.1±0.4	1.4±0.5

Many neuronal cell bodies and dendritic processes in the amygdala expressed leptin receptor immunoreactivity (LR-IR). The expressed immunoreactivity was quantified by counting positive-stained cells. Compared with the control group, the expression of leptin receptor was increased by 166.7 % in BLA. The average number of LR-IR positive cell was 127±12 vs 48±9 per 1 mm² (*t*=12.67, *P*=0.000). LR-IR was mainly found in the membrane of cells in the control group. In CTA rats, it was shown that LR-IR mostly deposited in cytoplasm and membrane. That is to say, LR-IR immigrated into cells after CTA leaning (Figure 1).

By means of CTA learning, rats displayed a significant difference at the level of OB-Rb mRNA expression in the BLA. Compared with the control group, the levels of OB-Rb mRNA increased by + 11.9 % (116.5±10.8 vs 104.3±10.9). The level of OB-Ra mRNA on the choroid plexus also rose up by 7.4 % (114.2±12.0 vs 106.1±13.8 (Figure 2, 3)). After CTA learning, the expression of both OB-Rb mRNA in the BLA and Ob-Ra mRNA on the choroid plexus have significantly enhanced.

Figure 1 LR-IR positive cells in BLA of rats. A: CTA group; B: control group.

Figure 2 OB-Rb mRNA expression in BLA of rats. A: CTA group; B: control group.

Figure 3 OB-Ra mRNA expression on choroid plexus of rats. A: CTA group; B: control group.

DISCUSSION

BLA and CTA

Many researches have observed deficits in the CTA paradigm after functional disruption of the BLA, which included electrolytic lesions, ibotenic acid lesions^[17-20]. The amygdala has long been believed to be associated with the control of emotions, motivation, and hedonic tone^[21,22]. The amygdala receives information from various sensory modalities via the neocortex and directly from the thalamus, brain stem and plays an important role in ingestive behaviors. In rodents, the amygdala is one of the major recipients of gustatory projections to forebrain. The nucleus tractus solitarius (NTS) in the medulla receives taste information from peripheral taste nerves and sends gustatory information to the pontine parabrachial nucleus (PBN). Gustatory neurons in the PBN pass through two parallel ascending paths, one path goes to thalamocortical axis and the other directly goes to the amygdala^[23]. Gustatory and visceral information from the PBN may travel through the insular cortex or the thalamus, ultimately reaching the BLA. All these appear to be the routes relevant to CTA^[2]. On the basis of the typical CTA paradigm in which ingestion of a taste solution is paired with an ip injection of LiCl as an illness-inducing agent, CTA can be thought in a simple framework of association learning between taste information via the taste nerves and general

visceral information via the vagus nerve.

So BLA has been characterized as a region where presents of the internal and external worlds overlap, and it permits the animal to assess physiological needs in relation to the external resources, which are available to fulfill. As a result, the amygdala plays a critical role in the initiation and guidance of feeding, on which relies an integration of autonomic and exteroceptive information. Nishijo's study suggested that the activity of the amygdaloid neurons was altered when animals must modulate ingestive behavior by learning a new stimulus associated with food and being exposed to stress. The amygdala may not contribute to gustatory processing by precise discrimination, but by imparting hedonic appreciation and emotional significance to the taste experience, and by mediating the effects of conditional and of physiological needs on taste perception^[24].

Leptin and CTA

Leptin is a hormone believed to control appetite and regulate body weight via receptors^[25]. The leptin receptor is widely distributed in the brain, including hypothalamus^[26], pituitary^[27] and amygdala^[10]. These observations suggest that leptin maybe involved not only in the control of energy expenditure, but also in other neuroendocrine functions^[28,29]. The expression of OB-

Rb and OB-Ra mRNA increased following by CTA formation indicate that leptin and its receptors may take part in CTA learning and interactions between gustatory and vagal signals.

To date, six different alternatively spliced isoforms have been identified, referred to as OB-Ra-f (*Nature* 1996;379:632-635). They are classified by the length of intracellular domains of the receptors. The long form of the receptor, OB-Rb is taken as the main functional receptor, which is capable of signaling, and is thus able to mediate the biological effects of leptin^[30]. Short forms, especially OB-Ra may play a role not only in transport but also in clearance or as a source of soluble receptor (*J Biol Chem* 1997; 272:6093-6096). The leptin receptor on the choroid plexus plays an important role in transporting plasma leptin into the brain^[31].

In the present study, although the level of serum leptin has not changed, strong expression of OB-R protein and OB-Rb mRNA has been found in the BLA and OB-Ra mRNA level increasing on the choroid plexus after CTA formation. All these results suggest that leptin receptor may participate in the formation of CTA. After CTA formation, LR-IR was expressed in the cytoplasm and the membrane of cells. It can be predicted that the function or activity of leptin receptor maybe change in the formation and maintenance of CTA.

Leptin is well known for its regulation of food intake and body weight. It also acts as a sweet-sensing suppressor. After i.p. injection of recombinant leptin, the sucrose and saccharin responses decreased parallelly along with the serum leptin level increased^[4]. So leptin and its receptors possibly act as a mediate factor between feeding and taste. It maybe a sweet-sensing modulator that takes part in regulation of food intake. But in the present immunohistochemistry staining, the primary antibody reacts with all isoforms, including the long and short forms of receptors. Thus the antiserum could not discriminate the isoforms. Further studies are necessary to clarify the functional significance of OB-R isoforms of different aspects in taste aversion learning.

In summary, we have discovered (1) Expression of OB-Rb mRNA and OB-R protein were increased by means of CTA learning in the BLA; (2) OB-Ra mRNA levels enhanced followed by CTA formation on the choroid plexus; (3) LR-IR immigrated into cells after CTA formation.

ACKNOWLEDGEMENT

Mrs. Song and Mr. Lai for their technical assistance.

Abstract

AIM: To investigate changes of tumor necrosis factor- α (TNF- α) and TNFR-I expression in vital organs and their significance in the pathogenesis of multiple organ damage associated with endogenous endotoxin following major burns.

METHODS: Wistar rats subjected to a 35 % full-thickness scald injury were sacrificed at 12 h, 24 h, 48 h, and 72 h postburn, respectively. Meanwhile, eight rats were taken as normal controls. Tissue samples from liver, spleen, kidney, lung and intestine were collected to assay tissue endotoxin levels and measure TNF- α and TNFR-I expression. In addition, blood samples were obtained for the determination of organ function parameters.

RESULTS: Endotoxin levels in liver, spleen and lung increased markedly after thermal injury, with the highest level in liver. The gene expression of TNF- α in liver, lung and kidney was up-regulated after thermal injury, while the TNFR-I mRNA expression in liver, lung, kidney and intestine was shown decreased throughout the observation period. Thus, the mRNA expression ratio of TNF- α to TNFR-I was significantly increased postburn, particularly in pulmonary tissue (67-fold). In addition, the significant correlations between the expression of TNFR-I or the expression ratio of TNF- α /TNFR mRNA in liver tissue and serum aspartate aminotransferase levels were noted ($P < 0.05-0.01$). Similar results were also obtained between pulmonary TNF- α mRNA expression and myeloperoxidase activities ($P < 0.01$), whereas there was a highly negative correlation between levels of renal TNFR-I mRNA expression and serum creatinine.

CONCLUSION: Burn injury could result in the translocation of gut-derived endotoxin that was mainly distributed in the liver, spleen and lung. The translocated endotoxin then made the expression of TNF- α and TNFR-I mRNA up-regulated and down-regulated respectively in various organs, which might be involved in the pathogenesis of multiple organ damage following burns.

INTRODUCTION

Gram-negative bacterial sepsis with resulting multiple organ dysfunction syndrome (MODS) and death continues to be a major problem in critical surgical patients. Lipopolysaccharide (LPS), an integral component of the gram-negative bacterial cell membrane, is responsible for many, if not all, of the toxic effects that occur during gram-negative sepsis. Both experimental and clinical data recently implicated that gut-derived bacteria or endotoxin translocation might play a role in the development of sepsis and multiple organ damage in critically ill patients, especially after trauma, thermal injury, hemorrhagic shock and major elective surgical procedure^[1-3]. It has also become clear that endotoxin initiates an inflammatory cytokine and mediator cascade, and these mediators, in turn, act on additional target cells to produce an array of pro-inflammatory cytokines leading to cardiovascular shock, MODS, or even death^[4-7]. Among these inflammatory mediators, tumor necrosis factor- α (TNF- α) in particular occupies a pivotal role in the pathogenesis of inflammation, cachexia, septic shock and tissue injury.

TNF- α exerts its pleiotropic effect by interacting with two high affinity receptors termed TNFR-I (55 kilodaltons) and TNFR-II (75 kilodaltons) on a variety of cells^[8]. Both TNFRs also exist in soluble forms^[9]. The soluble TNFRs (sTNFRs) are produced by proteolytic cleavage of the extracellular domain of TNFRs. The biological role of sTNFR appears to be dose-dependent. For instance, at low concentrations, sTNFRs stabilize the trimeric structure of TNF- α , thereby slowing its spontaneous decay of bioactivity, and augmenting the long-term effects of TNF- α by providing a reservoir of bioactive TNF- α that is slowly released. When more quantities of sTNFRs are present, however, they reduce the bioactivity of TNF- α by competing for TNF- α binding with cell-associated receptors. These above regulatory processes may modulate TNF- α activity in response to inflammation. In this regard, to obtain a complete view of the *in vivo* pathophysiologic roles of TNF- α , one should further study the regulation of TNF- α /TNFR and the balance between them. Since most of the known cellular TNF- α responses occur through TNFR-I, we investigated the expression changes of TNF- α and TNFR-I in vital organs, and their significance in the pathogenesis of multiple organ damage associated with endogenous endotoxin following major burns.

MATERIALS AND METHODS

Animals and thermal injury

Male Wistar rats (weight range 250-300 g), purchased from the Laboratory Animal Center, Beijing, China, were used for the study. The animals were housed in separate cages in a temperature-controlled room with alternating 12-h light-dark cycles, and were allowed to acclimatize for at least 7 days

before being used. All animals had free access to water, but were fasted overnight prior to the experiment. After the rats were anesthetized by the intraperitoneal (i.p.) injection of pentobarbital sodium (40 mg/kg), their dorsal hair was shaved and a 35 % of total body surface area with full-thickness burn was inflicted by immersion of the dorsal skin in a 100 °C water bath for 12 s. All animals received Ringer's solution (50 ml/kg) administered i.p. after burn injury for resuscitation, and the burn wounds were treated with an antibacterial agent everyday as a prophylactic measure against wound infection. All experimental manipulations were undertaken in accordance with the National Institute of Health Guide for the Care and Use of Laboratory Animals, and with the approval of the Scientific Investigation Board of the Burns Institute, Postgraduate Medical College, Beijing.

Experimental design

A total of 46 animals were sacrificed at each of following time points: 12 h, 24 h, 48 h and 72 h postburn. Meanwhile, eight rats were taken as normal controls. Under anesthesia, systemic blood samples were obtained. Then tissue specimens were taken from mesenteric lymph nodes (MLNs), liver, spleen, kidneys, lungs, and intestine.

Bacterial translocation

The MLNs, spleen, liver, kidney, lung and subeschar tissues were removed aseptically in this order. Each organ sample was weighed, homogenized in 2 ml of sterile saline under aseptic conditions, and 100 μ l of the homogenate were plated on Chinese blue agar and 5 % sheep blood agar. After 48 h of aerobic incubation at 37 °C, all agar plates were examined for growth. The number of viable microorganisms per gram of organ tissue was calculated, and the obtained organisms were identified by standard bacteriological techniques.

Tissue endotoxin measurement

Tissue specimens from liver, spleen, kidneys and lungs were aseptically removed, and were homogenized in 3-fold volume pyrogen-free saline on ice. The homogenate was stored at -20 °C until analyzed. The tissue endotoxin levels were measured by the chromogenic Limulus Amebocyte Lysate (LAL) assay with the procedure based on the LS-1 kit (Seikagaku Corp., Tokyo, Japan) protocol modified by perchloric acid (PCA) treatment of samples to remove nonspecific activators or inhibitors of the lysate^[10]. Briefly, 150 μ l of 0.32 M PCA were added to 75 μ l of homogenate in an ice bath, and the mixture was incubated at 37 °C for 20 min. After centrifuged (Kubota Corp., Japan) at 3 000 rpm for 15 min, the supernatant was neutralized with an equal volume of 0.18 N NaOH. Then, 100 μ l of the supernatant was incubated for 18 min at 37 °C with 50 μ l of amebocyte lysate. Chromogenic substrate then was added, and after 3 min of further incubation, the reaction was stopped. The amount of *p*-nitroaniline (pNA) released from the substrate was determined, after diazo-coupling, by the absorbance of the solution at 545 nm (Beckman Corp. U.S.). The endotoxin concentration expressed as endotoxin units per gram of organ tissue was calculated from a standard curve derived from the assay of a standard endotoxin (Lot EC-5, endotoxin unit (EU) = 100 pg of U.S. standard endotoxin). The detection limit with this method was 0.01 EU/ml.

RNA extraction and reverse-transcription-polymerase chain reaction

Tissue samples from liver, lungs, kidneys and intestine were stored in liquid nitrogen until analysis. Extraction of total tissue RNA was performed with guanidine isothiocyanate according to the method by Chomczynski and Sacchi^[11]. First-strand

cDNA was synthesized using oligo-dT primer and the AMV reverse transcriptase (Promega Corp., Madison, WI). In brief, 2 μ g of total RNA was reversely transcribed by adding 20 μ l of a master mixed with 1 U/ μ l RNase inhibitor, 0.025 μ g of random hexamers, 5 mmol/L MgCl₂, 1 \times reverse transcriptase buffer, 1 mmol/L of dNTP mixture, and 0.7 U/ml AMV reverse transcriptase (final concentrations indicated). Samples were incubated at 42 °C for 60 min.

For the cDNA amplification, the PCR with hot start technique was used, in which *Taq* polymerase was added to each tube at 88 °C with Thermal Cycler (Perkin-Elmer Corp., U.S.). The PCR mixture contained a final concentration of 0.2 μ mol/L specific primers for TNF- α and TNFR-I (from Beijing Medical University), 1 \times PCR buffer, 1.5 mmol/L MgCl₂, 0.2 mmol/L of each dNTP and 0.5 U/25 μ l *Taq* polymerase (Promega Corp., Madison, WI). After a 5-min initial melting step at 97 °C, the PCR with 28 to 32 cycles was carried out [94 °C 1 min for denaturation; 58 °C (TNF- α) or 63 °C (TNFR-I) 1 min for annealing; and 72 °C 1 min for extension]. The final cycle was followed by a 10-min soak at 72 °C. The sequences of primer pairs, and predicted sizes of the amplified PCR fragments were shown in Table 1. The house keeping gene β -actin was used as internal controls for standardization of PCR product^[14].

Table 1 Primer sequences used for polymerase chain reaction (PCR)

Target gene	Oligonucleotide primers	Size of PCR production, bp	Ref.
TNF- α	5'-AGA ACT CCA GGC GGT GTC TCT G-3'	415	8
	5'-GT GGC AAA TCG GCT GAC GGT GT-3'		
TNFR	5'-CC ATC TGC TGC ACC AAG TGC CA-3'	347	9
	5'-AA TCC TCG GTG GCA GTT ACA CA-3'		

PCR products and molecular weight markers were subjected to electrophoresis and visualized by means of ethidium bromide staining. The cycle number of each study was chosen in a linear range to avoid the plateau effect. The gel then was photographed, and the negative scanned with a densitometer (Pharmacia Corp., Sweden). Final data were expressed as a ratio of the band of interest to the unregulated control (β -actin).

Tumor necrosis factor- α protein analysis

Liver, lung, kidney and intestine tissues were respectively homogenized in 9-fold volume 0.01 mmol/L sodium phosphate buffer, pH 7.2 in an ice bath, and centrifuged (Haerus Corp., Germany) for 20 min at 1 400 rpm, 4 °C. The supernatant was stored at -20 °C until analysis. TNF- α concentration was determined by a commercially available protocol (rat tumor necrosis factor ELISA test kit; Endogen Corp., U.S.). In brief, aliquots of freshly diluted standard concentrations of recombinant rat TNF- α or samples were incubated in duplicate on ELISA plates. ELISA wells were then sequentially exposed to biotinylated antibody, streptavidin-HRP, and finally TMB substrate. The reaction was terminated using stop solution. The sample absorbance was detected at 450 nm with a plate reader (Denley Corp., England) and the TNF- α concentrations were determined by the reading of the standard curve. The sample protein was measured by the method of Bradford^[15], and the detected tissue TNF- α was finally expressed as pg/mg protein.

Myeloperoxidase assay

Lung tissue was homogenized in a 9-fold volume of 20 mmol/L potassium phosphate buffer, pH 7.4, and centrifuged (Hitachi Corp., Japan) for 30 min at 35 000 rpm, 4 °C^[16]. The pellet was

resuspended in 1 ml of 50 mmol/L potassium phosphate buffer, pH 6.0, containing 0.5 mg/dl hexadecyltrimethylammonium bromide and frozen overnight at -70°C . Then, the samples were thawed, sonicated for 90 s at full power, incubated in a 60°C water bath for 2 h, and centrifuged for 10 min at 35 000 rpm, 4°C . 0.1 ml of supernatant, was added to 2.9 ml of 50 mmol/L potassium phosphate buffer, pH 6.0, containing 0.167 mg/ml o-dianisidine and 0.0005 hydrogen peroxide. The sample absorbance was measured at 460 nm visible light (A_{460}) for 2 min (Beckman Corp., U.S.). Myeloperoxidase (MPO) activity per gram wet lung (gwl) was calculated by the following formula: Myeloperoxidase activity (units/gwl) = $(\Delta A_{460}) \times (13.5) / \text{lung weight (g)}$, where ΔA_{460} was the changes in absorbance at 460 nm from 30 to 90 s after the initiation of the reaction. The coefficient 13.5 was empirically determined such that 1 unit MPO activity was the amount of enzyme that would reduce 1mmole peroxide/min.

Diamine oxidase activity measurement

The small intestines were removed and stored in liquid nitrogen before analysis. For measurement of intestinal diamine oxidase (DAO) activity, the small intestine was homogenized in a threefold volume of ice-cold phosphate buffer (0.1M, pH 7.2) and centrifuged (Haerus Corp., Germany) for 30 min at 10 000 rpm, 4°C . After the resulting upper layer was discarded, the supernatant left was used as the source of the enzyme. DAO activity was assayed according to the modified method^[17]. The assay mixture contained 3 ml of phosphate buffer (0.2 M, pH 7.2); 0.1 ml (4 μg) of horseradish peroxidase solution (Shanghai Biochemistry Institute, China), 0.1 ml of o-dianisidine (Sigma Chemical, St. Louis, MO) methanol solution (500 μg), 0.5 ml of intestinal homogenate or freshly diluted DAO standard, and 0.1 ml of substrate (cadaverine dihydrochloride from Sigma Chemical, St. Louis, MO) solution (175 μg), which was incubated for 30 min at 37°C . Then, the absorbance was measured at 436 nm (Beckman Corp. Germany), and the DAO activity was read on the standard curve. Sample protein was measured as described previously^[15]. The intestinal DAO activity was calculated by the following formula: DAO activity (units/mg protein) = DAO activity $\times (60) / \text{protein concentration}$.

Organ function parameters measurement

Systemic blood samples were collected and serum was prepared by centrifugation for 10 min at 2 000 rpm. Then, the samples were stored at -20°C until analysis. Serum aminoleucine transferase (ALT), aspartate aminotransferase (AST), MB isoenzyme of creatine kinase (CK-MB) and creatinine (Cr) levels were determined with a biochemical autoanalyzer (Model 7170; Hitachi Ltd., Japan).

Statistical analysis

Statistical analyses were done by using the statistical package SAS 6.04, and the data were expressed as the mean \pm SEM. Statistical evaluation of the continuous data were performed by one-way analysis of variance (ANOVA), following by either Dunnett's *t* test or Kruskal-Wallis test for inter-group comparisons. Correlations between variables were tested by Spearman's correlation coefficients. The level of significance was considered to be $P < 0.05$.

RESULTS

Bacterial translocation and endotoxin levels in tissues

Microbiologic cultures from subeschar tissues were all negative throughout the observation period, while the bacterial translocation was significantly increased at various

time points after severe burns ($P < 0.05$), which was predominantly detected in MLNs (the incidence was 30.0 %) with the higher cultured bacterial number than that in other organs (control: negative, postburn: $4.748 \pm 0.313 \log_{10}\text{CFU/g}$). The translocating organisms were predominantly *E. coli*, but *Klebsiella spp.* and *Enterococcus* species were also identified. Meanwhile, the endotoxin levels in liver, spleen and lungs were significantly elevated at 12 h postburn, with the liver highest (control: $1.388 \pm 0.312 \text{ EU/g}$, 12 h postburn: $17.337 \pm 3.687 \text{ EU/g}$, $P < 0.01$). Endotoxin levels in liver and spleen then fell quickly, and elevated again at 48 h ($2.805 \pm 0.306 \text{ EU/g}$ in liver, $2.623 \pm 0.321 \text{ EU/g}$ in spleen, $P < 0.01$ compared with the controls). On the other hand, endotoxin levels in lungs maintained a high level till 72 h (control: $4.510 \pm 1.139 \text{ EU/g}$, 72 h postburn: $6.938 \pm 1.715 \text{ EU/g}$). There was no significant difference in endotoxin levels in kidneys at any time point postburn.

Expression of TNF- α and TNFR-I in Tissues

The expressions of TNF- α mRNA in tissues (liver, lungs, kidneys and intestine) were examined by RT-PCR as shown in Figure 1, which revealed a constitutively lower level in the control animals and a marked increase in burned subjects. The expression of TNF- α mRNA in liver was increased to a maximum at 12 h postburn (control: 0.020 ± 0.013 , 12 h postburn: 0.140 ± 0.032 , $P < 0.05$) and decreased thereafter (Figure 1A), whereas that in the kidneys and lungs peaked at 48 h postburn with the increased expression by 10-fold and 8-fold respectively (Figure 1B), among which the pulmonary mRNA expression maintained at a higher level up to 72 h postburn ($P < 0.05$ compared with the controls). However, there was a trend of lower expression of TNF- α mRNA in intestine (Figure 1B).

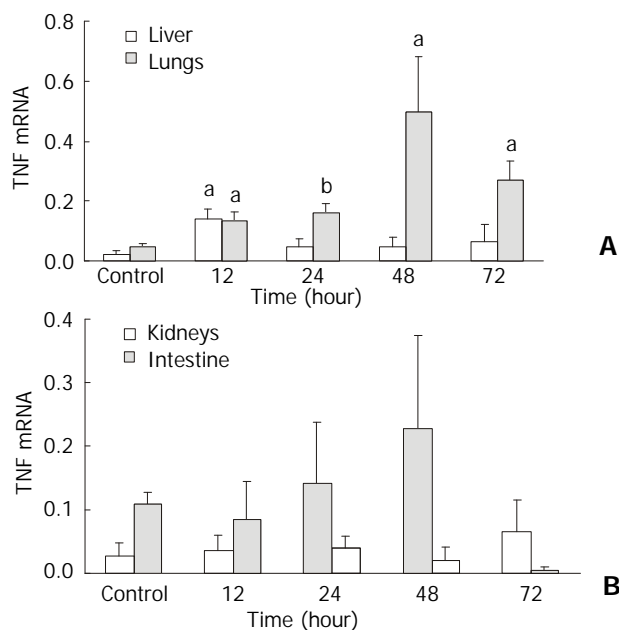

Figure 1 Semiquantitative analysis of tumor necrosis factor- α (TNF- α) mRNA in various organs after thermal injury. Values are reported as the ratio of TNF- α to β -actin signals. ^a $P < 0.05$ and ^b $P < 0.01$ as compared to the control values.

Tissue TNF- α protein assayed by ELISA exhibited higher levels in both liver and intestine (Figure 2, A and B), with the former that was increased by 25 % at 72 h postburn compared with control values, and the latter that peaked at 48 h postburn (control: $45.723 \pm 1.133 \text{ pg/mg protein}$, 48 h postburn: $80.448 \pm 14.018 \text{ pg/mg protein}$, $P < 0.05$) and maintained at a higher levels until 72 h postburn ($61.357 \pm 4.902 \text{ pg/mg protein}$).

However, there was no significant difference in TNF- α levels in lungs at each time point postburn compared with the controls. So was TNF- α levels in kidneys.

TNFR-I mRNA expression in vital organs by RT-PCR was shown in Figure 3, in which abundant expression was observed in the control animals, with the highest level in the liver (1.029 \pm 0.215). After burn injury, however, TNFR mRNA expression in liver, kidneys and lungs was shown to reduce dramatically, with the lowest levels at 24-48 h postburn (26.1-46.7 % of the control values). Though increased gradually thereafter, TNFR mRNA levels in these organs were shown lower than the control values at 72 h after thermal injury. A remarkable decrease in intestinal TNFR mRNA expression was also noted (17.3 % of the control values, $P<0.05$) and maintained throughout the observation period.

Figure 2 TNF- α protein levels in various organs after thermal injury. Values are reported as pg/mg protein. ^a $P<0.05$ as compared to the control values.

Figure 3 Semiquantitative analysis of tumor necrosis factor- α receptor-I (TNFR-I) mRNA in observed organs after thermal injury. Values are reported as the ratio of TNFR-I to β -actin signals. ^a $P<0.05$ as compared to the control values.

The ratio of TNF- α to TNFR-I mRNA (T/R ratio) in various organs was investigated in the present study as shown in Figure 4, which revealed that T/R ratio in these organs was significantly increased postburn, particularly in pulmonary tissue that was 67-fold of control values at 48 h after burn injury. T/R ratios in liver and kidneys reached at their maximums between 24 and 48 h ($P<0.05-0.01$), whereas the elevated ratio in lungs and intestine existed till 72 h postburn.

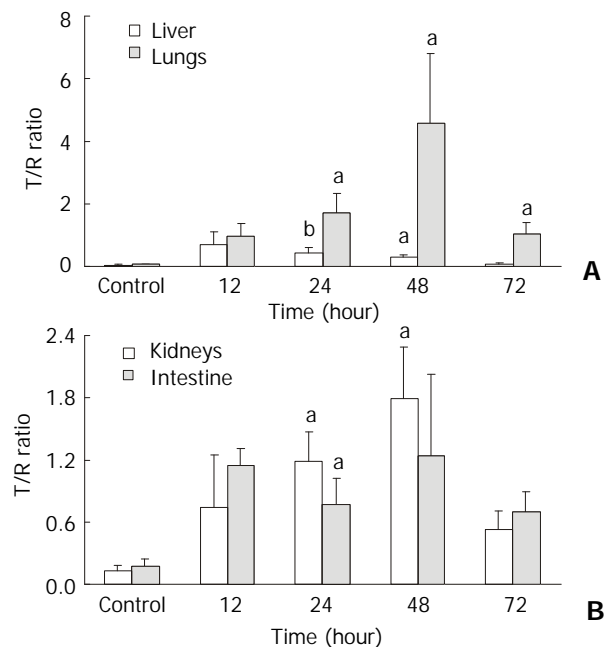

Figure 4 mRNA expression ratio of tumor necrosis factor- α to TNFR-I (T/R ratio) in observed organs after thermal injury. ^a $P<0.05$ and ^b $P<0.01$ as compared to the control values.

Organ function parameters

Serum ALT and AST levels markedly increased after scald injury, reaching a maximum between 12 and 24 h (4-5 folds of control values, $P<0.01$ compared with the controls), and remaining higher than control levels at 72 h postburn ($P<0.05-0.01$). Similarly, levels of serum CK-MB increased rapidly postburn, peaking at 12 h (control: 1 193.875 \pm 195.427 U/L, 12 h postburn: 3 626.100 \pm 410.073 U/L, $P<0.01$), and then decreasing gradually to baseline. However, serum Cr levels were not significantly different between normal and burned animals. There was a negative correlation between hepatic TNFR mRNA and serum AST levels ($r=-0.3930$, $P=0.0121$). Similar results were also obtained between renal TNFR mRNA and serum Cr levels ($r=-0.9295$, $P=0.0001$). In addition, it was noted significant correlation between T/R ratio in liver tissues and serum AST levels ($r=0.4409$, $P=0.0056$).

MPO and DAO activities

The pulmonary MPO activity that stood for the neutrophil sequestration was markedly increased after burns with the peaking at 12 h and elevating till 72 h postburn. The mucosal DAO activity, which might serve as a useful marker of intestinal injury, tended to be decreased at each time point postburn. It was noted that there was a significant correlation between pulmonary TNF- α mRNA levels and MPO activities ($r=0.4289$, $P=0.0091$), but there wasn't between intestinal TNF- α mRNA levels and DAO activities, as well as between MPO or DAO activities and TNFR mRNA in lungs and intestine ($P>0.05$).

DISCUSSION

The role of endotoxin in the pathogenesis of septic shock and

organ failure has been well established. It is almost an opinion in unison that LPS initiates a cytokine cascade, and among these cytokines TNF- α is recognized as the pivotal one to evoke systemic responses to sepsis and injury^[18]. Most of our current knowledge on the *in vivo* induction and regulation of TNF- α has been attained by measurement of serum cytokine levels. To date, only a few studies have addressed the gene regulation of the tissue-specific cytokines *in vivo*. In the current study, we investigated mRNA of TNF- α as well as its receptor and TNF- α protein expression in vital organs following severe burns. It was found that thermal injury induced a marked increase in mRNA of TNF- α . Hepatic TNF- α mRNA expression increased early and transiently with a peak at 12 h, whereas sustained elevation of TNF- α gene expression was observed in kidneys and lungs. Especially in the latter, the highest induced levels of TNF- α mRNA were found, suggesting a possible role for TNF- α in mediating pulmonary damage, which is commonly encountered in sepsis.

The investigations of Furse *et al.* have shown that TNF- α mRNA levels were increased in monocytes of trauma patients, and an increased amount of TNF- α protein was produced^[19]. In the present study, we attempt to determine the association between TNF- α mRNA expression and TNF- α protein production by comparing their respective time course of exhibition. Recent studies document that cytokines exert their primary effects in a paracrine fashion at the local tissue level^[20]. Andrejko *et al.* reported that the changes in TNF- α -dependent hepatic gene expression accompanied an animal model of the systemic inflammatory response syndrome correlated with intrahepatic, and not plasma concentrations of TNF- α ^[21]. Since circulating levels of cytokines may not appreciably reflect their true biological activity in the affected tissues^[22], we determined tissue TNF- α protein expression in various organs instead of plasma levels of TNF- α . To our surprise, the results revealed that the changes in TNF- α protein did not correlate temporally with increased expression of TNF- α mRNA in vital organs. To explain the discrepancy, we offer the following possibilities. Firstly, TNF- α is short-lived in plasma^[23]. There was a transient rise in TNF- α after the injection of *E. coli* or endotoxin, and TNF- α became undetectable by 4-6 h^[24]. Therefore it is likely that the TNF- α response is too transient to be detected. Secondly, shed soluble TNF- α receptors may interfere with TNF- α activity in immunoassay^[25]. Finally, despite of transcriptional control, TNF- α production is also regulated posttranscriptionally^[26]. Thus, TNF- α protein concentration is a cesspool of complex interactions regarding binding and release from cell membranes, magnitude and kinetics of the soluble receptors and natural cytokine antagonists, and rates of catabolisms. Account of the aforementioned interfering factors, we suggest that determination of TNF- α mRNA expression may be more reliable to reflect the kinetics of cytokine at the local tissue level.

A large body of clinical and experimental evidence suggests that gut-derived endotoxemia following trauma, burns and circulatory shock could result in TNF- α production, which may play a key role in mediating subsequent septic response and systemic tissue injury^[27-29]. In burn injury, however, the causative effect of locally accumulated endotoxin on TNF- α mRNA expression in various organs is still not completely understood. In the present study, it was found that endotoxin levels in the liver, spleen and lung rose markedly after thermal injury, peaking at 12 h. Endotoxin levels in liver and spleen then lowered gradually, while pulmonary endotoxin levels maintained a high level till 72 h. The temporal relationship between the kinetic changes of TNF- α mRNA and that of endotoxin levels in the visceral organs, as observed in the present study, suggests that endotoxin originated from the gastrointestinal tract appears to be one of the most potential

triggers for TNF- α gene expression. Hadjimines *et al.* demonstrated that TNF- α mRNA in peritoneal exudated macrophages of mice rose fourfold after intraperitoneal administration of endotoxin^[30]. Similarly, cecal ligation and puncture was shown to induce a rapid increase in hepatic and pulmonary TNF- α mRNA by 3 h, remaining high for 18 h^[31]. These findings are consistent with our data suggesting that endotoxin can induce TNF- α gene expression in various tissues.

Monocytes have been demonstrated to be major producers of the elevated TNF- α seen post-trauma. In the model used here, hepatic macrophages appear to be the principal cellular source of TNF- α , as the Kupffer cell population within the liver is the largest fixed tissue macrophage population in the body. Recent study had shown that Kupffer cells were the major source of TNF- α in culture supernatants of hepatic perfusate mononuclear cells from ethanol-consuming rats injected LPS^[32,33]. Additionally, blood monocytes, pulmonary macrophages and peritoneal macrophages were also possibly involved in TNF- α formation^[30, 34-36], since endotoxin distributing to lung and spleen was evident after burns in the present study. Unexpectedly, correlation analysis between tissue endotoxin concentrations and TNF- α mRNA levels did not reveal any significant correlation. From that, endotoxin translocation originated from the gut may serve purely as an initial trigger. Moreover, although endotoxin translocation occur following severe burns, endotoxin may not be the sole agent responsible for the subsequent induction of cytokine, whereas a variety of factors, such as hypoxemia, shock, and necrosis tissues, may be also involved in cytokine production^[37].

The majority of human cells express high-affinity receptors that mediated the biological activities of TNF- α . The potent regulatory abilities of TNF- α are transduced by two distinct cell surface receptors, namely 55 kd (TNFR-I) and 75 kd (TNFR-II) relative molecule mass^[38]. In inflammation, the receptors activate both unique and synergistic responses. Studies of TNFR knockout mice have established that TNFR-I plays a predominant role in LPS-induced inflammatory diseases and mediate the lethal effects of endotoxin^[39-41]. Furthermore, mice lacking TNFR-I showed resistance to endotoxin challenge^[42]. Therefore, we attempted to observe the mRNA expression of this receptor in vital organs. It was found that although normal tissue expressed TNFR mRNA abundantly, with the highest level in liver, TNFR mRNA expression in various organs plummeted after burn injury. Previous study has shown that loss of monocyte surface TNFRs is an early event in the response to endotoxemia^[43]. The nadir of this response occurred 2 h after endotoxin administration, and the monocyte surface TNFR levels then returned to baseline within 6 h after endotoxin challenge. These results indicate that monocyte surface TNFR levels rapidly decrease in response to an inflammatory stimulus *in vivo* and also rapidly normalize when the stimulus is no longer present. Thus, the significant and sustained decrease in TNFR mRNA levels observed in present study may represent an ongoing condition of systemic inflammation. Our findings are consistent with the recent observations of Calvano *et al.*, who reported a significant and sustained (up to 4 days) decrease in monocyte surface TNFR levels in non-surviving patients with sepsis^[44]. On the other hand, the extracellular domains of the TNFR apparently are shed from the cell surface in response to many of the same inflammatory stimuli that are known to induce TNF- α production^[25]. Our data may thus imply that a dual deregulation in TNFR reflects decreased expression of TNFR on the cell surface concomitant to decreased cell shedding of TNFR.

The shedding of TNFR and resultant acute decrease in the number of TNFR on the cell surface may serve to transiently desensitize cells, thereby providing a mechanism for inhibition of TNF- α activity. This process may have additional

significance, as released soluble receptors (sTNFR) may inhibit TNF- α bioactivity by binding to the molecule and preventing ligand binding to the cellular TNFR. *In vitro* studies demonstrated that sTNFR in critical ill patients and in experimental endotoxemia are sufficient to neutralize the bioactivity associated with TNF- α concentrations observed in mild inflammation, whereas such levels are inadequate to neutralize the cytotoxicity associated with TNF- α levels seen in overwhelming or lethal sepsis^[45]. Thus, imbalance of TNF- α to TNFR may reflect more than one dysfunction in monocyte TNF- α production and regulation, which may contribute to overwhelming activation of the inflammation cascade.

Pellegrini *et al.* reported that monocyte membrane associated TNF- α (mTNF- α) elevated and TNFR shedding decreased in trauma patients^[46]. There was a correlation between increased mTNF- α and decreased TNFR shedding to increased MODS score, but this lacked specificity. However, when mTNF- α and TNFR are assessed as the mTNF- α /TNFR ratio, an increased ratio correlated with higher specificity to development of organ failure. In this paper, we investigated for the first time the ratio of TNF- α to TNFR mRNA (T/R ratio) in various tissues. Our results revealed that tissue T/R ratio was significantly increased postburn. It is impressive that the magnitude of T/R ratio elevation was much higher than TNF- α (10-60 folds in T/R ratios *vs.* 8-10 folds in TNF- α). Combined with the persistently elevated levels found in tissues, this suggests that T/R ratio would better reflect the inflammatory status than TNF- α or TNFR alone. Moreover, it was noted that T/R ratio in liver tissue and serum AST level were significantly correlated, suggesting that this kind of cytokine regulation appears to be in sufficient in counteracting overwhelming sepsis, and the imbalance of TNF- α to TNFR might be involved in liver dysfunction. Hence, assessment of T/R ratio might provide a more sensitive indicator of organ damage or even outcome.

In this study, it was found that significant correlation between T/R ratio in liver tissues and serum AST levels. Similar results were also obtained between pulmonary TNF- α mRNA and MPO activities, whereas there were highly negative correlations between hepatic TNFR mRNA and serum AST levels, and between renal TNFR mRNA and serum Cr levels, suggesting imbalance of TNF- α to TNFR might be involved in the development of multiple organ damage following burns. Since TNF- α has been shown to be a pivotal cytokine of sepsis and MODS induced by endotoxin translocation post-trauma, we have evaluated the protective effect of anti- TNF- α monoclonal antibody (MoAb) for vital organs following intestinal ischemia-reperfusion or thermal injury. In rat intestinal ischemia-reperfusion model, prophylactic treatment with anti-TNF- α MoAb resulted in striking decreases in systemic TNF- α levels, and associated with such a neutralization effect were amelioration of hypotension and distant organ injury, including liver, kidneys, and lungs, as well as significant improvement in survival^[47-49]. Similarly, early treatment with anti- TNF- α MoAb could attenuate endotoxemia-mediated multiple organ damage resulting from severe burns, which might be associated with the down-regulation effects of tissue lipopolysaccharide binding protein (LBP) gene expression by use of MoAb^[50]. Moreover, a recent series of investigations have shown that recombinant sTNFR protected animals from death caused by endotoxin and gram-negative bacteria, and these promising experimental results prompted large scale randomized clinical trials^[51]. Additionally, TNFR-deficient mice were resistant to endotoxin shock and sepsis induced by cecal ligation and puncture^[42, 52]. Thus, appropriate use of agents to interrupt the chains of cytokine cascade might provide more balanced cytokine response, which may be beneficial to the host.

In summary, the present study demonstrated that burn injury *per se* could result in gut-derived endotoxin translocation that was mainly to the liver, spleen and lungs. The translocated endotoxin might be responsible at least in part, for the up-regulating of TNF- α and down-regulating of TNFR-I mRNA expression in these organs. The expression imbalance between TNF- α and TNFR might play a part in the development of multiple organ damage following burns.

Abstract

AIM: To prove that neurons in the different structures of the brainstem that express tyrosine hydroxylase (TH) are involved in the transmission and modulation of visceral or somatic nociceptive information in rat.

METHODS: Immunohistochemical double-staining method was used to co-localize TH and Fos expression in neurons of the rat brainstem in visceral or subcutaneous noxious stimulation models.

RESULTS: Neurons co-expressing TH/Fos were observed in lateral reticular nucleus (LRT), rostroventrolateral reticular nucleus (RVL), solitary tract nucleus (SOL), locus coeruleus (LC), A5, A7 neuronal groups and ventrolateral subdivision of the periaqueductal gray (vPAG) in both models. But the proportion and number of the double-labeled neurons responding to the two noxious stimuli were significantly different in the LRT, RVL and LC nuclei. The proportion and number of the TH/Fos double-labeled neurons in the visceral pain model were smaller than that in the subcutaneous pain model. However, in the case of SOL, they were similar in the two models.

CONCLUSION: Differences of Fos expression in TH immunoreactive neurons in animals after visceral and somatic noxious stimulation indicate that the mechanisms of the transmission and modulation of visceral nociceptive information in the brainstem may be different from that of somatic nociceptive information.

INTRODUCTION

Tyrosine hydroxylase (TH) is a catecholamine (including

noradrenaline, adrenaline and dopamine) synthesis enzyme. In the brainstem, except that substantia nigra (SN) TH is mainly involved in the locomotive modulation, TH immunoreactive (TH-ir) neurons are mainly located in the lateral reticular nucleus (LRT), rostroventrolateral reticular nucleus (RVL), solitary tract nucleus (SOL), locus coeruleus (LC), A5, A7 neuronal groups and ventrolateral subdivision of the midbrain periaqueductal gray (vPAG). All these regions, except for RVL and SOL, are regarded as the origins of the descending inhibitory system, which uses predominantly noradrenaline (NA) and 5-hydroxytryptamine (5-HT) as neurotransmitters^[1, 2]. Morphological evidence has shown that these nuclei directly or indirectly project to the superficial laminae of the spinal and medullary dorsal horns and SOL, forming intrinsic circuits that modulate the visceral and peripheral nociceptive message transmission^[1]. Electrophysiological results proved that NTS, VLM, PBL, and vPAG were involved in visceral message transmission and modulation and electrical stimulation of vPAG depressed visceral message transmission^[3-6]. RVL is mainly associated with cardiovascular regulation^[7] and projects to spinal autonomic nuclei^[8], while SOL is mainly involved in the visceral nociceptive message transmission, convergence and cardiovascular reflection^[9, 10].

c-fos proto-oncogene is expressed within the neurons following voltage-gated calcium entry into the cell^[11, 12]. Fos protein, which is encoded by *c-fos*, has been regarded as a third messenger molecule which coupled the short term extracellular signals with the long term alteration in cell function after neurons were excited^[13, 14]. Mapping studies have shown that noxious stimulation could induce Fos expression in the central neuronal system and visceral organs^[15-21]. Thus, Fos is usually used as a marker to indicate the activation of neurons^[22].

It is well known that the brainstem noradrenergic (NAergic) system plays an important role in the process of antinociception and that the mechanism of visceral noxious message modulation is different from those of somatic noxious message modulation^[23]. It is reasonable for us to propose that the location of Fos expression, under the effects of different noxious stimuli in the structures of brainstem, which express TH, could be diverse. In order to prove this hypothesis, we studied the expression pattern of Fos induced by visceral or subcutaneous noxious stimuli as well as the co-localization of Fos and TH protein expression using an immunohistochemical double-staining method.

MATERIALS AND METHODS

Materials

Experiments were carried out using 40 Sprague-Dawley male rats (weighing 200-250 g). The rats were kept in a dark facility for 24 hours before the experiment, and then randomly divided into two experimental groups and two control groups (for each group, *n*=10). All procedures described below were approved by the Committee for Animal Care and Usage for Research

and Education from the Fourth Military Medical University (Xi' an, P. R. China).

Methods

All rats were anesthetized by being placed into a transparent glass container with methoxyflurane gas. After anesthesia, 2 mL of 100 mL/L formalin or 2 mL distilled water was perfused into the oesophagus and stomach through a fine plastic tube, or 0.1 mL of 100 mL/L formalin or 0.1 mL distilled water was injected subcutaneously into the left forepaw in the rats of experimental or control groups respectively. Then the animals were put back into the cages and 2 hours later, all rats were anesthetized with sodium pentobarbital intraperitoneally (60 mg/kg) were intracardially perfused with 100 mL of saline followed by 500 mL of 4 % paraformaldehyde in 0.1 mol/L phosphate buffer (PB, pH 7.4). The brainstems were immediately removed, placed into the same fresh fixative for 4 hours (4 °C), and saturated with a solution of 300 g/L sucrose in 0.1 mol/L PB (pH 7.4) overnight at 4 °C. Thirty- μ m thick serial frontal sections were cut on a cryostat and serially collected into 5 dishes separately. Then all sections were washed with 0.01 mol/L phosphate-buffered saline (PBS, pH 7.4).

The first section was initially incubated overnight at room temperature with rabbit antisera against Fos (1:1 000 dilution; Santa Cruz, USA) in 0.01 mol/L PBS containing 50 mL/L normal horse serum, 3 g/L Triton X-100, 0.05 g/L NaN₃ and 5 g/L carrageenan (PBS-NHS). Secondly, the sections were incubated with goat anti-rabbit IgG (1:100 dilution; Cappel, USA) in PBS-NHS for 3 hours, and followed by rabbit peroxidase anti-peroxidase (PAP) complex (1:200 dilution; Polysciences, USA) in PBS for 1 hour. Finally, Fos-immunoreactive (Fos-ir) neurons were visualized by incubated the sections with 0.05 mol/L Tris-HCl buffer (pH 7.6) containing 0.4 g/L diaminobenzidine tetrahydrochloride (DAB) (Dojin, Japan), 0.03 mL/L H₂O₂ and 0.4 g/L Ni(NH₄)₂SO₄ for 30-40 minutes.

The second section was incubated at room temperature with mouse antisera against TH (1:3 000 dilution; Chemicon, USA) overnight, followed by biotinylated horse anti-mouse IgG (1:100 dilution; Vector, USA) for 3 hours, and then with ABC (avidin-biotin peroxidase complex) Elite kit (1:50 dilution; Vector) for 1 hour. Finally, TH-immunoreactive (TH-ir) neurons were visualized by incubated the sections with 0.05 mol/L Tris-HCl buffer (pH 7.6) containing 0.4 g/L DAB, 0.03 mL/L H₂O₂ and 0.4 g/L Ni(NH₄)₂SO₄ for 30-40 minutes.

The third section was incubated overnight at room temperature with a mixture of rabbit anti-Fos and mouse anti-TH, followed by goat anti-rabbit IgG or biotinylated horse anti-mouse IgG for 3 hours, and then with rabbit PAP for 1 hour. The sections were firstly reacted with 0.05 mol/L Tris-HCl buffer (pH 7.6) containing 0.4 g/L DAB, 0.03 mL/L H₂O₂ and 0.4 g/L Ni(NH₄)₂SO₄ for 30-40 minutes to intensify DAB-based reaction to Fos-ir neurons. Then the reacted sections were washed three times in PBS for 30 minutes and incubated with ABC Elite kit for 1 hour, and finally reacted in the same reaction solution without Ni(NH₄)₂SO₄ for 30-40 minutes to detect TH-ir neurons and TH/Fos double-labeled neurons. The number of TH-ir neurons, Fos-ir neurons, and TH/Fos double-labeled neurons was counted from the sections from the third section of each rat. The distribution of the immunohistochemically stained neurons in two animals in each model was charted with the aid of a camera and one rat was used to represent each experimental group.

A mixture of normal rabbit serum and normal mouse serum was used to replace rabbit anti-Fos and mouse anti-TH antisera to incubate the fourth section. The subsequent staining procedures were the same as those used for the third section.

All the sections were washed and mounted onto gelatin-coated glass slides and examined with light microscope (BH-2; Olympus, Japan).

The fifth section was mounted onto gelatin-coated slides and processed for Nissl staining.

Statistical analysis

Values were expressed as $\bar{x} \pm s$. Statistical differences between means of TH/Fos double-labeled neurons were determined by Student's *t* test. The difference in proportion of TH/Fos double-labeled neurons to Fos-ir neurons was analyzed by Crosstab's test. A *P* < 0.05 is considered to be significant.

RESULTS

On the first, second, and third sections from the experimental groups, three kinds of immunocytochemically positive neurons were identified in the nuclei of the brainstem: Fos-ir neurons, TH-ir neurons and TH/Fos double-labeled neurons. The cellular nuclei of the Fos-ir neurons were dark with oval or round shape, leaving their cytoplasm unstained. In contrast to Fos-ir neurons, TH-ir neurons showed brownish cytoplasm and dendrites with unstained nuclei. Scattered among those Fos- and TH-ir neurons, some neurons with dark nuclei and brownish cytoplasm exhibiting the co-localization of Fos and TH in the neurons were also observed.

On the first sections of experimental groups, Fos-ir neurons were mainly located in the caudal subnucleus of the spinal trigeminal nucleus (Sp5C), lateral reticular nucleus (LRT), rostroventrolateral reticular nucleus (RVL), nucleus solitary tract (SOL), nucleus raphe obscurus (ROb), nucleus raphe pallidus (RPa), paramedian raphe nucleus (PMN), lateral paragigantocellular nucleus (LPGi), alpha part of gigantocellular reticular nucleus (G_{ia}), nucleus raphe magnus (NRM), locus coeruleus (LC), parabrachial nuclear complex (PBNC), nucleus raphe pontis (RPn), dorsal raphe nucleus (DR), ventrolateral subregion of the midbrain periaqueductal gray (vIPAG), and median raphe nucleus (MnR) (Figure 1, 2). Fos-ir neurons in these nuclei of the subcutaneous noxious stimulation group was somewhat more than that in the visceral noxious stimulation group, but in the SOL, the number of the Fos-ir neurons in both visceral and subcutaneous noxious stimulations was similar between the experiment groups (Table 1). On the sections of the control groups, only a few Fos-ir neuronal cell bodies were observed in the superficial part of the Sp5C or SOL.

Table 1 The number and distribution of the immunopositive neurons in the brainstem

Nuclei	TH		Fos		TH/Fos	
	Visc	Sub	Visc	Sub	Visc	Sub
SOL	203±13	214±17	254±31	99±7	60±5	54±5
LRT and RVL	42±15	252±24	57±7	151±13 ^a	31±4	90±10 ^a
LC	328±26	330±25	42±6	103±12 ^a	26±3	72±9 ^a

Data are shown as ($\bar{x} \pm s$) ^a*P* < 0.05 Sub vs Visc. Visc: visceral noxious stimulation; Sub: subcutaneous noxious stimulation; TH: TH-ir neurons; Fos: Fos-ir neurons; TH/Fos: TH/Fos double-labeled neurons.

On the second sections of both experimental and control groups, the distribution of TH-ir neuronal cell bodies were mainly in LRT, RVL, SOL, A4, A5, LC, A7, vIPAG and substantia nigra (SN) (Figures 1 and 2). There was no remarkable difference in the number and distribution of TH-ir neurons between the experimental and control groups.

Immunohistochemical staining of the third sections from experimental groups showed, except that TH-ir and Fos-ir neurons were the same as that seen on the first and second sections of the experimental groups, TH/Fos double-labeled

neurons were mainly distributed in the LRT, RVL, SOL, A5, LC, A7 and vlPAG in both visceral (Figures 1, 3a, 3a', 3c, 3c', 3e and 3e') and subcutaneous (Figures 2, 3b, 3b', 3d, 3d', 3f and 3f') pain models. In LRT, RVL, A5, A7, LC, and vlPAG, the proportion and number of TH/Fos double-labeled neurons in visceral pain model were less than those in subcutaneous pain model (Table 1). It is interesting to note that in the SOL,

TH/Fos double-labeled neurons in both visceral and subcutaneous pain models were similar (Table 1). TH/Fos double-labeled neurons, with medium to large (20–35 μ m) fusiform, oval, multipolar shaped neuronal cellular bodies, were observed.

In the brainstem, there was no expression of Fos and/or TH in the neurons from the fourth dish of both the groups.

Figure 1 Drawing of the brainstem areas showing the distribution of TH, Fos and TH/Fos immunoreactive neurons after visceral noxious stimulation. Each ■ represents three TH-ir neurons. Each ○ represents five Fos-ir neurons. Each ▲ represents one TH/Fos double-labeled neuron. Abbreviations: 12: hypoglossal nuclei; 7n: facial nerve or its root; icp: inferior cerebellar peduncle; PAG: the midbrain periaqueductal gray; Pn: pontine nuclei; py: pyramidal tract; pyx: pyramidal decussation; scp: superior cerebellar peduncle; sol: solitary trace; SOL: solitary trace nuclei; sp5: spinal trigeminal tract; Sp5: spinal trigeminal nuclei.

Figure 2 Drawing of the brainstem areas showing the distribution of TH (■), Fos (○) and TH/Fos (▲) immunoreactive neurons after subcutaneous noxious stimulation on the left forepaw. The ratios for each marker to present the number of TH, Fos and TH/Fos immunoreactive neurons and the abbreviations are the same as Figure 1.

Figure 3 Photomicrographs showing the distribution and morphological characteristics of TH-ir neurons (arrowheads), Fos-ir neurons (arrows) and TH/Fos double-labeled neurons (double arrowheads) in SOL (a, a' and b, b'), RVL (c, c' and d, d') and LC (e, e' and f, f'). a, a', c, c' and e, e' were taken from visceral noxious stimulating rats, while b, b', d, d' and f, f' were taken from subcutaneous noxious stimulating rats, respectively. a, b, c, d, e and f are lower magnification photomicrograph (original magnification ×100). a', b', c', d', e' and f' are higher magnification photomicrograph (original magnification ×1 000) of the rectangle in a, b, c, d, e and f, respectively. Abbreviations: 4V: the fourth ventricle. cc: central canal. LC: locus coeruleus. LRT: lateral reticular nucleus. RVL: rostromedial ventral lateral nucleus. sol: solitary tract. SOL: solitary tract nucleus.

DISCUSSION

TH is a critical enzyme for the synthesis of catecholamine. NA is thought to be one of the two neurotransmitters in descending inhibitory system, which can exert potent supraspinal control of nociceptive information *via* various pathways^[24, 25]. In the brainstem, the descending inhibitory system is mainly composed of LRT, LC, vIPAG, rostral ventral ventromedial medulla and its surrounding reticular nuclei and other brainstem raphe nuclei^[1]. NA can inhibit either excitatory transmitters (glutamate, substance P, *etc.*) released from primary afferent terminals or the EPSCs produced by primary afferent fibers *via* postsynaptic G-protein^[23, 26]. Intrathecal injection of naloxone could reverse the NA-produced antinociception at the spinal level^[27], indicating the involvement of endogenous opiate peptides in the antinociceptive effects of the NA. LRT and LC including NAergic neurons project to SOL and are thought to be involved in visceral nociceptive message modulation and antinociception, which is proved by the electrophysiological experiments^[28, 29]. These results suggest that NA is an important neurotransmitter for the control of the nociceptive transmission in the central nervous system. In RVL and SOL, the neurons containing TH receive nociceptive message and produce somatic-visceral or viscera-somatic reflection^[7, 10], which do not belong to the descending inhibitory system. There exist many diseases with pain in visceral organs, and therapeutic methods for visceral pain are similar to those for somatic pain^[30-34]. But it is not clear whether the neurons containing NA play different roles in different pain models. In order to clarify the functional roles of the NAergic neurons in the visceral and somatic pain models, we observed the expression pattern of both Fos and TH in which Fos protein was used as a marker to indicate TH-ir neurons activation using an immunohistochemical double-staining method.

In the present study, we observed TH/Fos double-labeled neurons in the LRT, RVL, SOL, A5, LC, A7 and vIPAG and then compared the distribution, number and proportion of TH-ir neurons related to visceral and somatic noxious stimuli. Our results suggested that visceral and subcutaneous nociceptive inputs triggered similar TH immunoreactive in neurons in the brainstem, and indicated that these nuclei in the brainstem were involved in both visceral and subcutaneous nociceptive message convergence and modulation. Our results also indicated that the mechanisms involved could be different. As we know neither the factors resulting in *c-fos* expression nor the consequences of Fos protein expression, caution must be taken in interpreting these data. It might not be the case that all labeled neurons are nociceptive; on the other hand, the absence of Fos in these neurons does not exclude that these neurons are nociceptive since some nociceptive neurons might not be activated by the experimental conditions used. Nevertheless, this method allows us to monitor the response of a large number of neurons to noxious stimulation in awaken animals, which complements to the electrophysiological tests on anesthetized animals.

It is accepted that anesthesia is effective in triggering Fos expression in many brain regions, such as descending inhibitory system, RVL and SOL. More Fos-ir neurons were found in the experiment groups than those in the control groups. Based on these phenomena, we suggest that in addition to anesthetic effect, the noxious stimuli might be one of the inducing factors of Fos expression.

In LRT and RVL, there were fewer TH/Fos double-labeled neurons in visceral pain model than those in subcutaneous pain model. Both visceral and subcutaneous noxious stimuli can induce Fos expression in TH-ir neurons of LRT and RVL, indicating the occurrence of nociceptive neurons in this area. As this area is known to be crucial for vasomotor functions^[28, 35],

and connected with SOL^[36], NAergic neurons in this region are probably involved in eliciting the neurovegetative reaction induced by pain and producing somatic-visceral reflection.

Several evidences have suggested that the LC played a significant role in the descending inhibitory system^[1, 4]. TH/Fos double-labeled neurons were observed in the LC in both visceral and subcutaneous noxious stimuli models. This indicates the induction of NAergic neuronal activation in the LC in both models. The localization of these neurons is correspondent with the functional data implicating a role of LC in antinociception^[29]. Therefore, we suggest that NAergic neurons in the LC probably receive the visceral nociceptive convergence and probably mediate the behavioral and physiological characteristics of visceral pain as well. The difference in the proportion and number of TH/Fos double-labeled neurons in visceral and subcutaneous pain models shows that NAergic neurons in LRT, RVL and LC may be mainly involved in somatic nociceptive message transmission and modulation.

SOL, which receives most of the visceral primary terminations from the majority of organs in the neck, chest and abdomen, is closely related to visceral nociceptive message transmission and convergence and pain-induced sensory-cardiovascular reflection^[2, 4, 37]. Neurons in the SOL also projected to lateral parabrachial nucleus (LPB)^[36]. These results provide anatomical evidence for physiological data, confirms the involvement of this nucleus in nociceptive transmission. In addition, our data proved that TH/Fos double-labeled neurons were mainly located in the middle portion of SOL in both models, but TH/Fos double-labeled neurons in the subcutaneous nociceptive model were more rostral than those in the visceral nociceptive model. These results indicate that TH/Fos double-labeled neurons are distributed topographically in two pain models and the mechanism that the NAergic neurons in SOL are involved in transmission and modulation of nociceptive information in visceral pain models is different from that in subcutaneous pain models.

Abstract

AIM: To compare the effects of Roux-en-Y and jejunum interposition reconstruction procedures after total gastrectomy on intestinal motility.

METHODS: Fifty male Sprague-Dawley rats were randomly divided into 5 groups: the control group (C), the laparotomy group (L), the jejunal transection group (JT) where the jejunum was transected 10 cm distal from the Treitz ligament and anastomosed, the Roux-en-Y group (RY) and the jejunal interposition group (JI) after total gastrectomy. To evaluate intestinal transit, the animals were given 0.1 ml Evans Blue solution through an orogastric tube. The rats were executed by CO₂ inhalation 30 minutes later and the intestinal transit was determined as the distance between the site of esophageojejunal anastomosis and the most distal site of small intestine colored with blue.

RESULTS: One month after operation, the body weight of rats among JI and RY were almost identical (274.6 ± 9.5 vs 270.4 ± 10.6 , $P > 0.05$), but were significantly lighter than those of JT and L group. Four months after the operation, the body weight in the JI group increased compared to the preoperative level (345.2 ± 15.7 g vs 299.5 ± 8.3 g, $P < 0.01$). However, the body weight of RY group decreased compared to preoperative (255.1 ± 11.3 g vs 295.0 ± 12.0 g, $P < 0.01$). The difference was more significant at six months postoperative. Small bowel transit time in RY was slower than that in JI group and C group ($P < 0.01$).

CONCLUSION: Changes of body weight and intestinal motility in JI group are less influenced than in RY group.

INTRODUCTION

Total gastrectomy is one of the popular operative procedures for gastric malignancy, but there still are debates on the recommended method of gastrointestinal reconstruction after total gastrectomy. The choice of suitable method is crucial to

the patients' quality of life. To a great extent, surgeons choose the reconstruction methods according to personal experiences. We compared the prognosis of the different reconstruction methods and explored their effects on gastrointestinal motility in rats.

MATERIALS AND METHODS

Animal and grouping

Fifty male Sprague-Dawley rats (weight 280-310 g) were randomly divided into 5 groups, each of which contained 10 subjects. Five groups included controlled group (C), laparotomy group (L), jejunal transection group (JT) receiving transection of jejunum at 10 cm distal to the Treitz ligament and anastomosis in situ in each rat, jejunal interposition group (JI) receiving jejunal interposition with the segment of 5 cm length after total gastrectomy, and esophageojejunal Roux-en-Y anastomosis group (RY). All rats in RY underwent anastomosis of esophagus and jejunum after total gastrectomy with the R-Y loop of 10 cm. Rats resumed to normal diet on day 3 post-surgery.

Methods

Body weight of each rat was measured before operation and 1, 4, 6 months after operation, respectively. After fasting for 12 hours (free access to water), rat underwent corresponding operation. After six months, weight and the time of intestinal transition were recorded. Each rat was given 0.1 ml Evans Blue solution (50 mg/ml, Sigma, St Louis, USA) through orogastric tube to stomach directly or esophageojejunal junction in the JI and RY groups.

Statistic analysis

Statistical analysis was performed with statistical software SPSS 10.0. The results were expressed as mean \pm SD and comparisons among groups were performed by Student's *t* Test, ANOVA test and *q* test. All tests were two sided. *P* values < 0.01 were considered significant.

RESULTS

Body weight

No significant difference in body weight of rats before operation was detected among L, JT, JI and RY group, though the weight of C group was significantly lower than other groups ($P < 0.01$) (Table 1); One month after operation ($F > F_{(0.01, 49)}$, $P < 0.01$), body weight in L and JT was significantly higher than that in JI and RY, while no significant differences between L and JT group, as well as between RY and JI ($P > 0.01$) were not observed; At fourth month postoperatively, weight in C, L and JT group were similar, while these of JI and RY were significantly lower than those in other groups. Furthermore, the weight of RY was much lower than that of JI ($P < 0.01$); At 6 months after operation, rats in group C, L and JT gained weight significantly ($P < 0.01$). Although the weight of rats in group JI was not as much as that of group C, L and JT ($P < 0.01$), it still increased significantly compared to preoperative weight

(385.0±21.2 g vs 299.5±8.3, $P<0.01$). Nevertheless, the rats in group RY lost weight compared to preoperative weight (247.7±13.4 g vs 295.0±12.0 g, $P<0.01$), and they were significantly lighter than those of other groups at 6 months after operation, including JI group ($P<0.01$).

Transit time of intestine

Transit time of intestine (TTI) was 24.8±10.3 cm/30 min in group RY, which was significantly longer than that of group C (54.7±6.7 cm/30 min) ($P<0.01$). No significant differences in TTI were found among group JI, JT, L and C (Table 2).

Table 1 Weight of rats pre-and postoperative (g)

	C	L	JT	JI	RY
Preoperative	249.5±10.4	297.5±11.1	294.7±11.9	299.5±8.3	295.0±12.0
Postoperative 1 month	287.4±12.3	320.4±9.3	322.3±10.6	274.6±9.5	270.4±10.6
Postoperative 4 month	368.3±13.5	381.7±15.5	384.0±19.3	345.2±15.7	255.1±11.3
Postoperative 6 month	430.0±30.9	453.0±32.2	457.0±29.8	385.0±21.3	247.7±13.4

Table 2 Postoperative TTI of rats

Group	Postoperative TTI
C	54.6±6.7

Figure 1 Body weight of rats before and after operation.

DISCUSSION

Since Karl Schlatter first successfully performed total gastrectomy in 1897, it has been mainly indicated for Zollinger-Ellison syndrome and for potentially curable gastric carcinoma^[1]. Formerly, it was quite common to apply esophagus-jejunum anastomosis after total gastrectomy. Although this procedure has merit of simple, the operative complication of reflux esophagitis restricts its application^[2]. To avoid the complication, many surgeons adopt Roux-en-Y anastomosis of esophagus and jejunum to reconstruct digestive tract. At first, the results were quite promising; later, many patients complained about fullness, abdominal pain, nausea, even food vomiting. Many studies indicated that the gastrointestinal motility of patients underwent Roux-en-Y anastomosis of esophagus and jejunum was obviously weakened. Such symptoms were nominated as "Roux stasis syndrome"^[3-5]. Nowadays, many researches advocate jejunal pouch with Roux-en-Y reconstruction as a modified method^[6].

Recently, some researchers advocate gastric substitution by interposition of jejunum. As the procedure is more accordant with physiology, it can eliminate the shortcomings of Roux-en-Y esophagojejunostomy induced by chyme bypass of duodenum^[7, 8]. Moreover, interposition of jejunum makes preparatory assimilation possible by mixing of chyme with bile and pancreatic fluid in duodenum. Also, such procedure has fewer disturbances on gastrointestinal motility. Our results indicated that the rats in group JI gained weight six months after operation and had similar gastrointestinal motility as control group, which means the nutrition and growth of rats were not impaired. But Miholic J measured the emptying of gastric substitute after total gastrectomy and compared the differences between jejunal interposition and Roux-y esophagojejunostomy and contended that the concept of a gastric substitute pouch was not supported^[9].

Our study illuminated that the rats lost weight in group RY and group JI at one month after total gastrectomy, but rats in group C, L and JT steadily gained weight during the same time. At four months after operation, the growth curves of group RY and group JI were markedly different. After initial fall in weight of 8 % in the gastrectomized rats (274.6±9.5 vs 299.5±8.3), a sizable rise was observed in the rats of group JI. As for RY group, the rats constantly lost weight till 6 month after gastrectomy. Our results revealed that procedure of jejunal interposition may affect the nutrition status of rats and the effect may last less than four month, which was consistent with results of other researches^[10, 11]. But rats among RY group still lost weight at six month after operation, and it indicated the Roux-en-Y esophagojejunostomy might influence the nutrition status of rats for at least 6 months, much longer than jejunal interposition. So it seems that the jejunal interposition is superior to Roux-en-Y esophagojejunostomy after total gastrectomy.

Rats in RY group revealed delayed transit time of intestine at six months after the operation, just as Pellegrini reported^[12], which also supports that gastrointestinal motility was impaired after Roux-en-Y esophagojejunostomy. Meanwhile, rats in group C, L, JT and JI revealed similar intestinal transit time, which was significantly different from that in group RY. The result was consistent with the growth curve of body weight of rats (Figure 1). Thus slowed intestinal transit may be one main etiological factor in postgastrectomy malnutrition. But some studies did not found abnormal intestinal transit after total gastrectomy^[13], more conclusive research is required.

Although no significant differences in TTI in other 4 groups were observed at six months after operation, previous study has revealed that different operative procedure and anesthesia do affect the gastrointestinal motility^[14]. Although we did not measure the TTI soon after operation, our results showed that TTI could resume to preoperative level after several months for some surgical procedures. In addition to abdominal operation, prior study indicated that gastric emptying was markedly delayed after cardiac surgery^[15]. Some researchers advocate that motilin may be one of possible reason for such changes^[16], which is a widely distributed neuropeptide and has been located in digestive tract and brain^[17]. Specific receptor of motilin has been isolated and located on chromosome^[18], and is proved at mucosa^[19]. And new neuropeptide has been identified and proved to be related with gastrointestinal activity^[20].

In conclusion, the procedure of jejunal interposition has fewer disturbances on intestinal transit than Roux-en-Y, and the gastrointestinal motility and nutrition status of rats of group JI are much better than those of rats of group RY.

Abstract

AIM: To investigate the expression of immunoglobulin gene SNC73 in malignant tumors and non-cancerous normal tissues.

METHODS: Expression level of SNC73 in tumors and non-cancerous tissues from the same patient was determined by reverse transcription polymerase chain reaction and enzyme-linked immunosorbent assay (RT-PCR-ELISA) in 90 cases of malignant tumors, including colorectal cancer, gastric cancer, breast cancer, lung cancer and liver cancer. Analysis on the correlation of SNC73 expression with sex, age, site, grade of differentiation, depth of invasion, and metastases in colorectal cancer patients was made.

RESULTS: Expression level of SNC73 in non-cancerous colorectal mucosa and colorectal cancerous tissues was 1.234 ± 0.842 and 0.737 ± 0.731 , respectively ($P < 0.01$), with the mean ratio of 7.134 ± 14.092 (range, 0.36-59.54). Expression of SNC73 showed no significant difference among gastric cancer, breast cancer, lung cancer and liver cancer when compared with non-cancerous tissues ($P > 0.05$). No correlation was found between SNC73 expression level and various clinicopathological factors, including sex, age, site, grade of differentiation, depth of invasion and metastases of CRC patients.

CONCLUSION: Down-regulation of SNC73 expression may be a relatively specific phenomenon in colorectal cancer. SNC73 is a potential genetic marker for the carcinogenesis of colorectal cancer. The relationship of SNC73 expression and carcinogenesis of colorectal cancer merits further study.

INTRODUCTION

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths in developed western countries^[1]. A series of

molecular changes are involved in colorectal carcinogenesis, including activation of oncogenes, inactivation and/or mutational changes of tumor suppressor genes, microsatellite instability, and so on^[2-10]. Fearon *et al* proposed a genetic model of colorectal tumorigenesis^[11]. However, despite the tremendous efforts that have been made, there are still many problems unsolved for the model of CRC due to the complexity of carcinogenesis. The early detection and new therapeutic target of CRC have yet to be found. Modern medicine proves that almost all diseases arise from gene function change, which is mainly reflected by the differential gene expression^[12]. Hopefully the identification and characterization of genes expressed differently in tumor tissues and normal mucosa will shed light on the mechanisms of CRC and provide useful molecular markers for screening, diagnosis, prognosis and therapeutic monitoring.

To explore new molecular events that are related to carcinogenesis of CRC, Cancer Institute of Zhejiang University constructed CRC negative-associated cDNA libraries by subtractive hybridization^[13-17]. Subtractive hybridization between cDNA of normal mucosal tissues and mRNA of CRC tissues was performed and a total of 46 cDNA clones that were expressed in normal mucosal tissues but were either expressed at a significantly reduced level or not expressed at all in cancerous tissues were isolated. SNC73 is one of the 46 CRC negative-associated complement DNA (cDNA) clones. Northern blot, reverse transcription-polymerase chain reaction (RT-PCR), in situ hybridization, and in situ PCR confirmed expression of SNC73 in normal epithelial cells and several non-hematopoietic cancer cell strains^[17]. The aim of this study was to confirm the negative association between CRC and SNC73 expression and to examine whether such association also exists in other tumors. In the present study, expression level of SNC73 in 90 cases of malignant tumors (31 cases colorectal cancer, 24 cases gastric cancer, 15 cases breast cancer, 11 cases lung cancer and 9 cases liver cancer) and non-cancerous tissues from the same patient was determined by RT-PCR-ELISA.

MATERIALS AND METHODS

Tissue sample preparation

Fresh samples of surgically resected cancer and its non-cancerous tissues were obtained from the same patient at the Second Affiliated Hospital of Zhejiang University Medical College, and were immediately frozen in liquid nitrogen until used. Several paired specimens were collected for replication. The total RNA was extracted with Trizol reagent (Gibco BRL, USA). RNA integrity was checked on 1 % formaldehyde agarose gel. RNA samples were accepted only when the ratio between absorbance optical density values at 260 nm and at 280 nm was higher than 1.65.

RT-PCR (DIG Labeling)

RNA samples were reverse transcribed with AMV reverse transcriptase (Promega Co.). The primers were labeled with biotin for following immobilization by streptavidin coated microtiter plate modules. The primer for SNC73 was designed

based on its cDNA sequence according to previous study. The sequence is 5' biotin-AAA CAC ATT CCG GCC CGA G 3' and 5' biotin-AGC GGT CGA TGG TCT TCT G 3'. The sequence of primer for β -actin is 5' biotin-TCG ACA ACG GCT CCG GCA 3' and 5' biotin-CGT ACA TGG CTG GGG TGT 3'. RT-PCR was carried out to amplify the mRNA of SNC73 and β -actin. The PCR products were labeled with digoxigenin (dig) by using mixture of dATP, dCTP, dGTP, dTTP and DIG-dUTP in reaction mixture during the amplification process. PCR reaction mixture contained 15.7 μ l sterile water, 2.5 μ l PCR buffer (10 \times conc., with $MgCl_2$), 2.5 μ l 2 mM PCR DIG labeling mix, 2 μ l 10 mM primers mixture, 0.3 μ l Taq DNA polymerase and 2 μ l template cDNA. The cycling program was denaturation of the template 94 $^{\circ}C$ for 3 min, 22 cycles of amplification: 94 $^{\circ}C$ for 10 s (denaturation), 58 $^{\circ}C$ for 20 s (hybridization), 72 $^{\circ}C$ for 30 s (elongation) and elongation (72 $^{\circ}C$) for 5 min was added after last cycle to ensure the completion of the reaction. PCR products quality was confirmed by electrophoresis in 1 % agarose gel stained with ethidium bromide.

PCR ELISA (DIG Detection)

DIG detection of PCR ELISA was carried out using a modification of the assay protocol according to reagent kit (Boehringer Mannheim Co., German). DIG labelled PCR products were immobilized by incubating appropriate dilutions of amplification reaction at 55 $^{\circ}C$ for 3 h. The solution was discarded and each well was washed 5 times with washing solution. The strips were incubated with anti-digoxigenin peroxidase conjugate at 37 $^{\circ}C$ for 30 min. The solution was discarded and each well was washed 5 times again with washing solution. The colorimetric substrate ABTS was added and

incubated at 37 $^{\circ}C$ for 30 min. Absorbance was read in an ELISA-reader at 405 nm. The absorbance optical density values at 405 nm (A_{405}) represented the relative concentrations of PCR products. The results were normalized by the absorbance optical density values of β -actin, which was used as an endogenous standard because of its equal expression in various tissues. This would correct the variation in product abundance due to differences in the efficiencies of individual RT-PCR reaction.

Statistical analysis

The expression level of SNC73 in both cancerous tissues and non-cancerous tissues was interpreted as the ratio of its OD value relative to that of β -actin. SNC73 expression level in various cancerous tissues and non-cancerous tissues and the ratio of non-cancerous tissues to cancerous tissues were calculated. All results were expressed as means \pm SD. Statistical differences between means of various cancerous tissues and non-cancerous tissues were determined by Wilcoxon nonparametric test (2-related samples). The differences were considered significant at $P < 0.05$.

To get more information about the down-regulation of SNC73, which may be helpful to determine its characteristics, we investigated the relationship between SNC73 expression level and various clinicopathological factors of CRC patients. All CRC patients were grouped according to sex, age, site, grade of differentiation, depth of invasion and metastases (including lymph node metastases and distant metastases). The same functions as those used between various cancerous tissues and non-cancerous tissues were applied among different groups. Statistical differences of means among different groups were determined by analysis of variance. The differences were considered significant at $P < 0.05$.

Table 1 SNC73 expression level in human cancerous tissues and non-cancerous tissues (Mean \pm SD). The expression level of SNC73 in both cancerous tissues and non-cancerous tissues was expressed as the ratio of its OD value relative to that of β -actin. ($\bar{x} \pm s$)

Tumor	n	SNC73 expression level		Non-cancerous tissues / Cancerous tissues
		Non-cancerous tissues	Cancerous tissues	
CRC	31	1.234 \pm 0.842	0.737 \pm 0.731 ^a	7.134 \pm 14.092

	Negative	9	1.257 \pm 0.682	0.977 \pm 1.144	8.263 \pm 19.334

RESULTS

Expression of SNC73 was significantly down-regulated in CRC compared with non-cancerous colorectal mucosa from the same patient. Expression level of SNC73 in normal colorectal mucosa and colorectal cancerous tissues was 1.234 ± 0.842 and 0.737 ± 0.731 , respectively ($P < 0.01$), with the mean ratio between them of 7.134 ± 14.092 (range, 0.36-59.54). Among 31 cases of CRC, cancerous tissues of 24 cases (77.4 %) expressed lower level SNC73 as compared with non-cancerous colorectal mucosa from the same patient. Study on the expression of SNC73 in other kinds of carcinomas revealed that no differential expression of SNC73 was found in gastric cancer, breast cancer, lung cancer and liver cancer as compared with non-cancerous tissues from the same patient ($P > 0.05$, Table 1).

Further analysis on the relationship between SNC73 expression level and various clinicopathological factors of CRC patients revealed that no correlation was found between SNC73 expression level and various clinicopathological factors, including sex, age, site, grade of differentiation, depth of invasion and metastases of CRC patients ($P > 0.05$, Table 2).

DISCUSSION

RT-PCR-ELISA allows convenient and sensitive detection of PCR products. The sensitivity of the PCR ELISA is in general about one hundredfold higher than conventional analysis of the PCR products in ethidium bromide stained agarose gels^[18-20]. The high sensitivity makes detection of low or unknown expression level of genes closer to the real status. The whole process of RT-PCR-ELISA takes no more than ten hours, and a group of samples can be detected at the same time. These are the reasons why this method was used to get a relative estimates about expression levels of SNC73 in different human carcinomas in this study.

SNC73 is one of the 46 cDNA clones of CRC negative-associated cDNA libraries constructed by Cancer Institute of Zhejiang University by subtractive hybridization technique. Sequence analysis revealed that full-length cDNA of SNC73 is 1651bp. Open reading frame analysis showed SNC73 encodes one immunoglobulin (Ig) heavy chain molecule with 384 amino acids, with its constant region identical to that of IgA1. The predicted structure of SNC73 had no apparent difference from other matured IgA molecules that serve in the immune system. Northern Blot, RT-PCR, in situ hybridization and in situ PCR confirmed expression of SNC73 in normal epithelial cells of colorectal mucosa and several non-hematopoietic cancer cell strains^[17]. There are several reports about Ig and Ig-like genes expressed in non-hematopoietic cell lines^[21-30], and Ig gene rearrangement was confirmed in the epithelial malignant cells^[24]. These findings raise the possibility that immunoglobulin genes, whose expression is generally considered to be restricted to lymphocytes-origin cells, can be expressed by non-lymphoid cells. Maybe some factors during de-differentiation of cells activated the rearrangement of Ig genes in malignant cells, but it remains to be explored how Ig genes undergo rearrangement in epithelial cells.

Expression level of SNC73 in CRC and non-cancerous mucosa had been determined by the method of RT-PCR-imaging, Northern-blot and in situ hybridization. The present study confirmed the initial findings that CRC expresses lower level SNC73 than non-cancerous mucosa^[17,30]. Expression level of SNC73 in other human cancerous tissues and non-cancerous tissues was also determined. No significantly different expression was found in gastric cancer, lung cancer, breast cancer and liver cancer compared with non-cancerous tissues from the same patient. This is the first semi-quantitative analysis about SNC73 expression in different human cancers. In this study the number of cases of breast cancer, lung cancer

and liver cancer was small, and more cases are needed to draw a conclusion. Interestingly, beyond our expectation, gastric cancer, which also originates from gastrointestinal tract, expressed no significantly different level of SNC73 compared with normal gastric mucosa. Conclusion drawn from the results of this study suggests that down-regulation of SNC73 expression may be a relatively specific phenomenon in CRC, and SNC73 may serve as a potential genetic marker for carcinogenesis of CRC. Further study on expression of SNC73 in tissues of different pathological status, such as adenoma, dysplastic mucosa and para-cancerous tissues, may provide clearer conclusion^[31].

The relation between SNC73 and carcinogenesis of CRC remains to be explored. Carcinogenesis of tumor is closely related to immunological surveillance of host. Previous study proved the significance of immune responses to mucosal carcinogens in carcinogenesis^[32]. Recently, Ig molecules or Ig-like proteins have been reported to influence the development of tumor directly or through interaction with oncogenes or tumor suppressor genes^[24,33,34]. So the relationship between Ig and carcinogenesis of tumor should be further explored besides the conventional humoral immunity. These clues implicate some role of SNC73 in carcinogenesis of CRC. SNC73 encoded protein can be assumed to be an immune molecule secreted by normal epithelial cells, together with Ig secreted by plasma cells, participating in local anti-tumor activity. The protein affects carcinogenesis of CRC through the similar influence on adhesion or signal transduction to other Ig superfamily components or interaction with some oncogenes or tumor suppressor genes is also possible. Further study on the mechanisms of down-regulation of SNC73 in CRC and the biological function of SNC73 will provide important clues for determining its role in screening, diagnosis, prognosis and therapy of CRC. The relationship of SNC73 expression and carcinogenesis of colorectal cancer merits further study.

Abstract

AIM: The present study was aimed to investigate the developmental patterns of growth hormone receptor (GHr) and somatostatin (SS) mRNA expression in porcine gastric tissue and its relationship with gastric growth and gastric functional development.

METHODS: Erhualian and Large White boars were selected randomly and sampled at birth (D0), 3, 20, 30, 90, 120 and 180 days of age respectively, meanwhile the bodyweight and gastric weight were recorded. The single tube semi-quantitative RT-PCR was applied in this experiment to investigate the developmental patterns of gastric GHr and SS mRNA expression, the correlations between the patterns of mRNA expression and the relative gastric weight (ratio of gastric weight to bodyweight) and the pepsin contents in gastric mucous membrane were analyzed. In order to further elucidate the effect of GH on gastric function, the primary cultures of gastric fundic mucosal cells were treated with 2 ng/ml, 20 ng/ml and 200 ng/ml of rpGH for 18 hrs respectively, and the pepsin contents in culture medium were measured.

RESULTS: The expression of GHr mRNA was high at birth, followed by a significant decrease at 3 days of age (D3) in both breeds. In Large White boars, the expression of GHr mRNA reached a peak at D90 and remained a plateau afterward. In Erhualian pigs, however, a slight yet significant increase occurred at D30 reaching a level that was kept constant thereafter. From birth to D30, the expression of GHr mRNA in gastric tissue was higher in Erhualian boars than that in Large White boars, but from D90 to D180, the higher expression of GHr mRNA was found in Large White boars. The gastric GHr mRNA expression was significantly correlated with the relative gastric weight ($r=0.541$, $P<0.05$) and pepsin content in gastric mucosa ($r=0.625$, $P<0.05$) respectively.

The gastric SS mRNA expression was high at birth (Erhualian 1.59, Large White 0.80), but dropped significantly at D3 (Erhualian 0.95, Large White 0.19, $P<0.05$), a stepwise increase was followed thereafter until a peak at D30 (Erhualian 1.71, Large White 0.95). In general, Erhualian pigs expressed higher levels of SS mRNA in gastric tissue as compared with Large White pigs at the same age ($P<0.05$). No significant correlations between SS mRNA and relative gastric weight or pepsin content were found.

In vitro, 2 ng/ml of rpGH elicited significant increase in pepsin secretion from primary cultures of gastric mucosal cells ($P<0.05$), and no responses were observed at 20 ng/ml and 200 ng/ml.

CONCLUSION: The results suggested that: 1, GHr and SS mRNA in porcine stomach are expressed according to strain specific developmental patterns; 2, GH acts directly at the gastric tissue and regulates the structural and functional growth of stomach.

INTRODUCTION

The growth hormone (GH) regulates numerous cellular functions by direct binding to its receptors (growth hormone receptor, GHr) in many different tissues, such as liver, muscle, lymph and adipose tissue, etc. It has been reported that GHr was expressed in the stomach of rat^[1,2], rabbit^[3] and human^[4], respectively, suggesting that stomach is the target organ of GH.

Somatostatin (SS) is a typical brain-gut-peptide, and it is expressed both in the brain and gastrointestinal system. Hypothalamic SS serves as an inhibitory factor to regulate GH secretion from anterior pituitary^[5], while gastric SS works to inhibit the secretion of pepsin, gastric acid, as well as gastrin, hence plays an important role in the regulation of gastric function^[6].

The retardation of gastric functional development, such as insufficient gastric acid and pepsin secretion, results in dyspepsia, diarrhea, poor growth and even death in newborn piglets. It is postulated that GH and gastric SS might be involved in the regulation of porcine stomach development, but no much data available to date. Therefore, the present study employed two breeds of pig with different genetic backgrounds, Large White and Erhualian pigs, as animal model to investigate the developmental patterns of growth hormone receptor (GHr) and somatostatin (SS) mRNA expression in porcine gastric tissue. The correlation between the patterns of GHr and SS mRNA expression and the gastric growth as well as the gastric functional development were analyzed. In addition, an *in vitro* cell culture trial was conducted to study the effect of GH on gastric pepsin secretion.

MATERIALS AND METHODS

Animals and Sampling

Eight litters newborn purebred piglets respectively from 2nd or 3rd farrowing Large White and Erhualian sows were kept for experiment, and water and feed were available ad libitum. The diet was formulated according to the requirement of each breed. Large White piglets weaned at D30 of age, while Erhualian piglets at D45. Erhualian boars ($n=4$) and Large White boars ($n=4$) were selected randomly and sacrificed at birth, 3, 20, 30, 90, 120 and 180 days of age respectively, meanwhile the bodyweight and gastric weight were recorded.

The fundic tissue were sampled and frozen in liquid nitrogen immediately, then stored at -70 °C. The fundic mucosa were taken and stored at -20 °C.

Pepsin detection

One gram fundic mucosa was homogenized with 3 ml 0.85 % NaCl, then the homogenate was centrifuged at 4 °C for 30 min at 5 000 rpm. The supernatant was collected for pepsin activity analysis according to the procedure modified by Robinson (1972), using hemoglobin as the substrate. Since hemoglobin was diluted with hydrochloric acid ($pH=1.6$), at such acidic condition, all pepsinogen were activated, so the gastric pepsin activity measured accounted for the total pepsin content of gastric mucosa. The protein content in the same supernatant of the homogenate was measured for normalizing the pepsin content as follows:

$$\text{Gastric mucosa pepsin activity (U/g)} = \frac{\text{Pepsin (U)/homogenate liquid (ml)}}{\text{Protein (g)/homogenate liquid (ml)}}$$

Semi-quantitative RT-PCR

Total RNA was isolated from porcine gastric tissue using guanidinium thiocyanate-phenol-chloroform one-step method. RNA was reverse transcribed into cDNA with random hexamer primers. An RT⁻ control tube containing all RT reagents except reverse transcriptase was included to monitor genomic DNA contamination.

The primers for GHr were designed according to the cDNA sequence published on Gene Bank (X54429): sense, 5' - ctcgatattgatgacctga-3', and anti-sense, 5' - gatgagtgtagtcagttcca-3', and the predicted PCR product was 341bp. SS primers were achieved according to the code region of porcine genomic DNA (Gene Bank, U36385): sense, 5' - AGCTGCTGTCTGAACCCAAC-3', and anti-sense, 5' - GAAATTCTTGCAGCCAGCTT-3'. Classic 18S rRNA internal standards (Ambion Inc. USA) was used to adjust the variation in pipetting and amplification.

PCR conditions were optimized for both GHr and SS. The reaction volume for GHr was 50 µl, including 5 µl 10×PCR buffer, 1.3 mmol/L MgCl₂, 10 mmol/L dNTP, 0.66 mmol/L GHr sense and anti-sense primer, 2 µl 18S primer pair, 2 µl 18S competitor, 2 µl RT product, 1.0 U Tag DNA polymerase (Promega, Shanghai). Amplification conditions included: denaturation at 94 °C for 5 min, denaturation at 94 °C for 30 sec, annealing at 52 °C for 1 min, extension at 72 °C for 1 min, total in 32 cycles, finally an additional extension step at 72 °C for 5 min was done. The SS PCR reaction mix contained 5 µl 10×PCR buffer, 1.5 mmol/L MgCl₂, 10 mmol/L dNTP, 1 mmol/L SS sense and anti-sense primer, 2 µl 18S primer pair, 2 µl 18S competitor, 2 µl RT product, and 1.0 U Tag DNA polymerase (Promega, Shanghai). Total volume was 50 µl. Amplification conditions included: denaturation at 94 °C for 5 min; denaturation at 94 °C for 30 sec, annealing at 55 °C for 30 sec; denaturation at 72 °C for 1 min, total in 32 cycles, finally it was finished by an extension step at 72 °C for 5 min. All samples were amplified in the same PCR run together with quality and contamination controls on GeneAmp PCR system 9600 (Perkin Elmer, U.S.A.).

Twenty µl PCR products were separated through 2 % agarose gel electrophoresis. The band intensities were analyzed by Kodak ID Electrophoresis Documentation and Analysis System 120 (Kodak Photo Film Co., Ltd., U.S.). The ratio of target gene intensity to 18S intensity was used to represent the abundance of GHr and SS mRNA expression.

Cell culture

Animal and reagent Four Landrace X Large White crossbred gilts at the age of D35 were used in this trial. HEPES and DMEM/F-12 were products of Hyclone, collagenase type I

was bought from Sigma and the fetal bovine serum was purchased from Hangzhou Sijiqing Company, China.

Sample and culture Piglets were sacrificed and the fundic mucosa was isolated. The tissue was washed in Hank's solution thoroughly and dipped in Hank's solution containing 500 U/ml of antibiotics for 30 min. Then the fundic mucosa were dispersed by 600 U/ml of collagenase I at 37 °C for 2 hrs, filtrated and centrifuged (1 000 r/min, 5 min). Thereafter cells at the density of 1×10^5 per cm² were cultured (37 °C, 5 % CO₂) in DEME/F-12 supplemented with 10 % fetal bovine serum, 5 mM HEPES buffer, and 100 U/ml antibiotics. After 24 hrs, the culture medium was refreshed by new medium containing 2 ng/ml, 20 ng/ml and 200 ng/ml GH respectively. The GH challenge lasted for 18 hrs before the medium were collected for pepsin analysis.

Statistical analysis

All data were analyzed by SPSS10. Significant difference analysis were conducted by *t*-test, one-way ANOVA and LSD. The correlation between the GHr, SS mRNA expression and the relative gastric weight, as well as the gastric mucosa pepsin content were determined.

RESULTS

Gastric growth

As shown in Figure 2, the gastric growth rate is low before weaning both in Large White and Erhualian pigs, especially during the period from D3 to D20. Highest growth rate is seen between D30 and D90. From D90 onwards, the gastric weight of Large White Boars keeps increase while that of Erhualian boars maintains a plateau, which results in a higher gastric growth rate in Large White boars than that of Erhualian boars. Compared to the body weight changes shown in Figure 1, the stomach weight changes display different patterns, which is more obvious in Erhualian pigs. Figure 3 shows the developmental pattern of relative gastric weight, it seems that the gastric growth lags behind the body growth during the period from D20 to D30.

Figure 1 The developmental patterns of body weight in Erhualian and Large White boars.

Figure 2 The developmental patterns of gastric weight in Erhualian and Large White boars.

Figure 3 The developmental patterns of the relative gastric weight in Erhualian and Large White boars.

Developmental changes of pepsin contents in gastric mucosa

From birth to D30, no notable variation was found in gastric pepsin content in Large White boars, but after D30, the gastric pepsin content increased significantly ($P < 0.05$) and kept constant thereafter (Figure 4). However in Erhualian pigs, the gastric pepsin content was high at birth, but dropped significantly at D3 and D20 ($P < 0.05$). A significant up-regulation occurred at D30 for gastric pepsin content until a peak level was reached at D120.

Figure 4 The developmental patterns of the pepsin activity (U/g protein) of fundic mucosa in Letters a and b for Erhualian boars, letters c and d and g for Large White boars, letter e and f for the different breeds at same ages, different letters differ significantly $P < 0.05$.

Developmental changes of gastric GHr mRNA expression

Figure 6 shows the expression patterns of GHr mRNA in gastric tissue. The GHr mRNA was high at birth, but dropped dramatically at D3 in both breeds. In both breeds of pigs, the expression of GHr mRNA increased from D30 but followed different patterns thereafter. In Large White pigs, the GHr mRNA expression continued to increase till D90 when a plateau was reached. While in Erhualian pigs, the gastric GHr mRNA expression went up in a much lesser extent and reached a much lower plateau earlier at D30. As the result, the expression of GHr mRNA in gastric tissue was higher in Erhualian boars than that in Large White boars in earlier stages from birth to D30, whereas the opposite was true in later stages from D90 to D180. The statistic analysis revealed that the gastric GHr mRNA expression was positively correlated with the relative gastric weight ($r = 0.541$, $P < 0.05$) and the pepsin content in gastric mucosa ($r = 0.625$, $P < 0.05$), respectively.

RT-PCR product for gastric GHr mRNA in Erhualian and Large White boars. (M is marker pUC19, E0-E180 represents Erhualian boars at day 0-180 respectively, and L0-L180 represents Large White boars at day 0-180 respectively).

Figure 6 The developmental pattern of GHr mRNA expression in stomach of Erhualian and Large Letters a and b for Erhualian boars, letters c and d and g for Large White boars, letter e and f for the different breeds at same ages, different letters differ significantly $P < 0.05$.

The developmental changes of porcine gastric SS mRNA expression

The gastric SS mRNA expression followed a similar pattern in two breeds of pigs (Figure 8). The SS mRNA expression was high at birth, but significantly decreased at D3 ($P < 0.05$), soon after a stepwise increase was found reaching a peak at D30 in both breeds of pigs. In general, Erhualian pigs expressed higher levels of SS mRNA in gastric tissue as compared with Large White pigs at the same age in early stages ($P < 0.05$) but this difference diminished in later stages at D120 and D180. No clear correlation was found between gastric SS mRNA expression and relative gastric weight or pepsin content in gastric mucosa.

Figure 7 Representative agarose gel electrophoresis photo of RT-PCR product for gastric SS mRNA in Erhualian and Large White boars. (M is marker pUC19, E0-E180 represents Erhualian boars at day 0-180 respectively, and L0-L180 represents Large White boars at day 0-180 respectively).

Figure 8 The developmental pattern of SS mRNA expression in stomach of Erhualian and Large Letters a and b for Erhualian boars, letters c and d for Large White boars, letter e and f for the different breeds at same ages, different letters differ significantly $P < 0.05$.

The effect of GH on pepsin secretion in vitro

As shown in Figure 9, 2 ng/ml of rpGH significantly stimulated

pepsin secretion ($P < 0.05$), but 20 and 200 ng/ml of GH failed to show any influence in terms of pepsin secretion *in vitro*.

Figure 9 Effects of rpGH on the pepsin secretion from gastric mucous cells *in vitro* (a indicating significant difference between different treatment, $P < 0.05$).

DISCUSSION

The effects of GH on growth can be mediated via: (1) binding to the hepatic GHr to stimulate the IGF-1 secretion from liver into circulation, in which IGF-1 then works in an endocrine manner to promote the growth of target organs, (2) directly binding to GHr in extra-hepatic tissues to induce IGF-1 expression, in which IGF-1 works in both endocrine and paracrine manner to stimulate target tissue development, (3) directly binding to the GHr of extra-hepatic tissues to regulate the development of target organs^[7]. It was reported by Lobie *et al.* (1992) that bGH (bovine GH) administration significantly increased rat gastric weight, relative gastric weight, as well as the height of mucosa^[2]. There are evidences for the localization of GHr mRNA expression in the gastric mucous membrane of rat, rabbit, human^[1-4]. Using semi-quantitative RT-PCR, the present experiment proved the expression of GHr mRNA in stomach of both Large White and Erhualian pigs. Furthermore, the gastric GHr mRNA expressed in an age-dependent manner which is positively correlated to relative gastric weight. This positive correlation implies that GH may directly act on stomach to regulate its growth. However, from birth to D3, the expression of gastric GHr significantly decreased, but the stomach was in a rapid growth period, it may be contributed by maternal influences through colostrum. Xu (1996) reviewed that there are high concentrations of hormones and growth-promoting peptides, such as insulin, cortisol, epidermal growth factor (EGF) and insulin-like growth factor I (IGF-I) in the maternal colostrums and there are evidences that colostrum-borne EGF and IGF-I play a role in postnatal stomach development^[8]. Many researches have proved that IGF-1 can stimulate gastric mucosal cell proliferation^[9-12]. Coerper *et al.* (2001) reported that IGF-1 at low dose of 0.4 mg/kg BW and 4 mg/kg BW significantly stimulated gastric cell proliferation and ulcer healing^[13]. However, it is not clear whether the maternal growth factors in colostrum contribute to the down regulation of gastric GHr mRNA expression at 3 days of age.

The GH actions are tissue-specific, which depends on the sensitivities of target tissues to GH stimulation. The tissue sensitivity depends upon the abundance of GHr^[14]. Studies of Ilkbahar. (1995)^[15], Klempt *et al.* (1993)^[16], Schnoebelen-Combes *et al.* (1996)^[17] and Peng *et al.* (1998)^[18] on mice, sheep and pigs, proved that the developmental patterns of GHr mRNA expression varied among different tissues, species and breeds. Our results also showed that the developmental patterns of GHr expression in stomach differ from that in liver, spleen and muscle. This tissue-specific GHr expression may account for the different functions and regulatory mechanisms of GH in different tissues or organs.

Our results also showed that the expression of GHr mRNA in gastric tissues was higher in Erhualian boars in early stages from birth to D30, but from D90 to D180, the higher expression of GHr mRNA was found in Large White boars. This result was in accordance with the differences in stomach growth between the two breeds of pigs. The present results suggest that GH play an important role in the regulation of gastric growth through the GHr expressed in stomach.

The significant correlation between gastric GHr mRNA expression and the pepsin content in mucous membrane provided an important hint that GH may be involved in the regulation of gastric function apart from its role in gastric growth. To date, however, controversy results have been published in this regard. Drago *et al.* (1997) proved that GH stimulated the gastric acid secretion in rats but failed to restore the decreased peptic activity in hypophysectomized rats^[19]. On the contrary, however, GH did restore peptic activity in hypophysectomized dog^[11,2]. In order to clarify the effect of GH on pepsin secretion from gastric mucosa membrane, we performed an *in vitro* trial in primary cell culture and found that 2 ng/ml of GH significant elevated pepsin secretion ($P < 0.05$), but 20 ng/ml and 200 ng/ml of GH did not show significant effect on pepsin secretion compared with the control. The results suggest that GH is indeed involved in the regulation of pepsin secretion in a dose-related manner.

It is well known that gastric SS located in D-cell of autrum and fundus is a key player in the gastric function regulation. SS inhibits gastric acid, pepsin, and gastrin secretion via both paracrine and endocrine pathways^[21]. It was reported that SS inhibits gastrin secretion by down-regulating the gastrin mRNA expression. Sheep immunized against SS boosted gastric acid and gastrin secretion^[6]. *In vitro* studies proved that SS antisera significantly increased gastric acid release from perfused stomach of rat, mouse and pig^[22].

There have been some publications on the ontogeny of gastric SS. Yee *et al.* (1996) concluded that, in the fetal rabbit stomach, the expression of gastrin and somatostatin may regulate the onset of acid secretion from parietal cells^[23]. Read *et al.* (1992) found that in ovine, the developmental pattern of gastric SS mRNA was on the contrary to that patterns of gastrin mRNA and H⁺/K⁺-ATPase mRNA. It was proposed that the gastrin, H⁺/K⁺-ATPase and SS work in synergy to initiate gastric acid secretion^[24]. In present experiment, the developmental changes of gastric SS expression negatively correlated with the changes in gastric acid secretion in general. The gastric SS mRNA decreased significantly from birth to D3, which coincided with the increase in gastric acid secretion in the same period^[20]. Before weaning, the inhibition of gastric acid secretion agreed with the up-regulation of gastric SS expression. Our results confirmed that SS is the inhibiting factor for gastric acid secretion. Gastric SS inhibits both gastric acid and gastrin secretion, and it has negative effect on pepsin secretion as well^[25]. We found in present experiment significant differences in the expression of gastric SS mRNA between two breeds of pigs, which was negatively correlated with the pepsin content in fundic mucosa during the sucking period. However, the correlation between gastric SS mRNA expression and pepsin content was low, suggesting that the gastric SS is not the major regulator of pepsin secretion.

In conclusion, GH and gastric SS play important roles in the regulation of porcine stomach development and gastric functions, but the interaction between GH and gastric SS is still unclear. Drago *et al.* (1997) reported that the stimulation of GH on gastric acid secretion may be related to GH down-regulating gastric SS secretion^[19]. Our unpublished data indicated that GH mRNA expression in the pituitary of Large White pigs was higher than that of Erhualian pigs. It might be presumed that the lower expression of gastric SS mRNA in

Large White pigs was resulted from, to some extent, the higher expression of GH in pituitary. However, the positive correlation between gastric SS and GHr mRNA expression over the period of investigation did not support this presumption. The complex interactions between GH and gastric SS are still to be illuminated.

Abstract

AIM: To observe dynamic of different chemical elements in stomach tissue during fetal development.

METHODS: To determine contents of the 21 chemical elements in each stomach samples from fetus aging four to ten months. The content values were compared to those from adult tissue samples, and the values for each month group were also analyzed for dynamic changes.

RESULTS: Three representations were found regarding the relationship between contents of the elements and ages of the fetus, including the positive correlative (K), reversely correlative (Na, Ca, P, Al, Cu, Zn, Fe, Mn, Cr, Sr, Li, Cd, Ba, Se) and irrelevant groups (Mg, Co, Ni, V, Pb, Ti).

CONCLUSION: The chemical elements' contents in stomach tissues were found to change dynamically with the stomach weights. The age-dependent representations for different chemical elements during the prenatal development may be of some significance for assessing development of fetal stomach and some chemical elements. The data may be helpful for the nutritional balance of fetus and mothers during prenatal development and even the perinatal stages.

INTRODUCTION

Embryonic stomach develops from the caudal side of foregut, and then the primitive stomach expands towards abdomen. With its enlargement, a 90 degrees clockwise rotation occurs around its major axis, giving the rise to the shape similar to the adult stomach. During the prenatal development, stomach is one of the fast growing organs, and all nutritious elements for the growth are supplied by mother through the placenta. The stomach is mainly for digestion of food and absorption of

nutrients, so its development and functional maturation after birth is important for its adaptability to the changing nutrient intaking way. In this article, we reported the dynamics contents of 21 chemical elements in gastric tissues during the development of fetal stomach.

MATERIALS AND METHODS

Materials

The fetuses were 4-10 months old (every 4 weeks are one month), all begin from countryside of Henan Province. Those gland 10 months old were obtained through unexpected abortion and those with shorter pregnancies were collected after the induced abortion. No case of the abortion could be attributed to environmental pollution, or their maternal health or nutrition problems. The stomach was taken from the fetus, using redistilled water, and then dried in an oven at 70-80 °C. The samples were crushed into powder and kept in the desiccator for use. Stainless steel scalpel and Teflon scissors were used during the sample processing, and contamination was avoided in the whole course.

Methods

Se was measured using the method of 2,3 - di-aminonaphthalene fluorescence, with a fluorescence spectrometer (Model MPF-4, Hitachi). The other elements were detected using the method of ICP-AES^[1], with a sequential plasma emission spectrometer (ICP-2070 Barid Company's Model). All reagents employed were of commercial reagent-grade quality. Quality control was carried out by national first grade references including ox liver powder (ESA-1) and the pork (GBW08552). Statistical computations were conducted using the soft package SPSS 10.0.

Analysis data of adult

All data of adults were taken from the literature^[2], covering reference parameters from the 100 persons (68 men, 32 women, 31.3 ± 1.0 years old) 4 provinces in South and Northern China. The original values, presumed to contain 71.6 % of water, were converts into those by dry weight.

RESULTS

Contents of constant elements in fetal stomach

Table 1 showed the contents of six constant elements of stomach of fetus aging 4-10 month, with that of K increasing with age, the values of Na, Ca, P, and Al were found to decrease with the fetus age, but the change for Mg was not significant. Contents of K, Na, Ca, P, Al and Mg in stomach tissues from fetus 10 month-old were 112.4 %, 60.6 %, 53.3 %, 78.0 %, 44.3 %, 86.1 % respectively of those from fetus 4 month-old. This indicates that the gastric tissues at embryo stages, contain more K than those at later pregnancy, and that Na, Ca, P, Al and Mg are higher in the embryonic stomach. In addition, K, Na, Ca and Mg contents were higher in the fetal stomach than in the adult samples.

Contents of essential elements in fetal stomach

Table 2 showed the contents of ten essential elements of stomach of fetus at the ages of 4-10 months. A tendency of age-dependent reduction was observed for all of 10 trace

elements, with the changes of Cu, Zn, Fe, Mn, Cr, Se and being more pronounced, and Cu, Zn, Fe, Mn, Cr, Sr, Se, Co, Ni, V contents in fetal stomach age of 10 month were 67.5 %, 38.8 %, 69.8 %, 78.0 %, 54.6 %, 95.8 %, 72.7 %, 99.0 %,

Ti	0.347 0.154(6)	0.567 0.298(19)	0.474 0.275(14)	0.497 0.286(9)	0.543 0.353(7)	0.533 0.385(6)	0.419 0.290(5)	

41.3 % and 46.3 % respectively of that of 4 month. This indicates that the embryonic stomachs contain more essential elements than the fetal stomach. In comparison to the adult tissues, the gastric samples from fetuses aging 10 months contain more Cu, Zn, Fe and Co, less Cr and Ni, but the Mn content was similar. There were no analytical datum of Se, Sr, V in stomach of China Reference Person.

Contents of harmful elements in fetal stomach and comparison with those in adult

Table 3 showed the contents of five harmful elements of stomach of fetus ageing 4-10 months. Except Ti, other elements reduced with the fetal development. Li, Cd, Ba, Pb and Ti contents in fetal stomach at the age of 10 month were 54.2 %, 30.5 %, 27.8 %, 78.2 % and 120.7 % respectively of those at the age of 4 month. In comparison to the published data for the adult group^[2], the stomach tissue in fetuses at the age of 10 month contained less Cd and more Pb.

Change regulation of contents of chemical elements in Fetus' stomach and its significance

Table 4 showed the stomach weights of fetuses from 4 to 10 months. The data in agreement with those reported elsewhere^[3]. The stomach weight was positively correlative the age ($r=0.961$, $P=0.001$). Table 5 showed the relation between contents of 21 elements and the age of fetus, with both parameters positively correlative for K, negatively correlative for 14 elements and statistically independent for the remaining elements.

Table 4 Stomach weights of fetus aging from 4 to 10 months

Month-age	4	5	6	7	8	9	10
Weight (gram)	0.35 0.12(6)	0.94 0.45(19)	1.73 0.64(14)	3.17 0.74(9)	4.20 1.19(7)	5.41 0.76(6)	8.93 2.10(5)

DISCUSSION

Embryo's development is a special stage in human life. It can be divided into the embryo, fetus and neonate stage. There are respective characteristics during each stage. Main character of fetus is that embryo differentiates into different organs for

fetal development and storage for material and energy. Neonate characteristic is the adaptation of outer-environment of womb, and fetal metabolism changes from anabolism to catabolism. These characters are extremely easy to be interfered by environment, different dangers happen in different stages, and this is one of reasons that changes happen in the later stage of fetus appear after birth^[4]. At present, there is very deficient knowledge to the variety of the chemical elements and understanding of their physiological function in the special changes that happen in the stage of fetus, it is helpful to solve these problems through dynamic observation of chemical elements of fetal tissues.

In this article, the correlation analysis between chemical elements in stomach and fetal age indicates that elements that are positively correlative with age in per gram stomach tissue increases with the development of the stomach, and elements' contents in fetus are lower than neonate; 14 elements that are reversely correlative with age in per gram stomach tissue reduce notably with the development of the stomach, and the elements contents in fetus are higher than neonate; 6 elements that are statistically independent with age in stomach of fetus may be basically unanimous of those of neonate. These results may be of some significance for studying the relation between elements and stomach development and physiological function.

In eleven essential elements that have datum of "China reference person", there are eight elements' contents of stomach of fetus higher than those of adult. For example, Ca of fetus stomach is 5.8 times of the adult's, Cu is 6.5 times, Fe is 3.8 times, and Zn is 1.7 times. It is well known that Ca, Cu, Fe, Zn are the elements that are easy to be lack and affect on the organs' development, cause a lot of physiology biochemical pathological changes and health problems in neonate, infant and children^[5-9], the character that there are higher contents in the stage of fetus not only reflects the material' storage function of fetus, but also reveals the regulation of "adaptation to outer-environment of womb" after birth. The contaminative trace elements' contents are remarkably lower than adult (Cr, Ni), such as Cr content in stomach of adult is 12.2 times of that of fetus, this indicates that the increase of this kind of elements' contents in adult is closely related with environment^[2]. Harmful elements like Cd and Pb, their contents decrease with the increase of age, for example, the contents of Cd of stomach of fetus 10 month age is 30.45 % of that of fetus 4 month age, and the content of Pb of children over 7 is 37.5 % that of the neonate, which indicates that the content of Cd, Pb doesn't bring harm to fetus, and the accumulations of Cd, Pb in body of children result from environmental pollution, bad living and sanitary custom *et al*^[8, 10-20], this can consult for environmental monitoring.

Our series study of 21 elements contents' dynamics in other tissues of fetus (liver, kidney, brain, heart, lung, spleen), the same to stomach, majority of 21 elements' contents in per gram tissue remarkably reduce with the fetal age, the decreasing rate is especially large before birth. This common character of elements' change in different tissues indicates the sensitivities to these elements deficiency in the stage of neonate and infant, if the supply of this kind of elements from mother-environmental system is insufficient, it may bring nutritional lack of this kind of elements. Intervene experiment shows that it will take good effects on fetus and infant development with this kind of elements supplement singly to pregnant women^[21-25], however, supplement with Ca, Fe, Zn jointly to pregnant women, the mean values of the weight and height of their baby at birth are largest than other groups, this indicates that Ca, Fe, Zn supplement to pregnant woman is benefit for fetus and infant development^[26-28]. Our study not only provides basis for adjusting and controlling nutrition of neonate, infant and pregnant and breast-feeding

woman, at the same time, furthermore can offer physiological foundation for focus viewpoint that some diseases of adult originate from fetus^[29-32].

Abstract

AIM: To study the mechanism and the preventive role of 1, 25-dihydroxyvitamin D₃ in acute rejection following orthotopic liver transplantation.

METHODS: Rats were randomly divided as donors or recipients for orthotopic liver allotransplantation model. Four groups were designed in the study, Group I: syngenic control (Wistar to Wistar); Group II: acute rejection (SD to Wistar); Group III: acute rejection treated with cyclosporine A, and Group IV: acute rejection treated with 1,25-(OH)₂D₃. Liver function, rejection activity index and mRNA of IFN- γ , IL-10 intragraft in recipients were measured on day 1, 5, 7, 15, 30 posttransplant for assessing graft function, severity of acute rejection and immune state of recipients.

RESULTS: Survival time of recipients in Group IV was significantly prolonged (4/6 recipients survived for over 100 days. vs Group II, $P < 0.001$; vs Group III, $P > 0.05$). After treatment with 1,25-(OH)₂D₃, mean value of all the assay tested on each experimental time was compared, liver function in group IV was significantly improved (AST 127 ± 41 U/L- 360 ± 104 U/L, BIL 13 ± 5 mmol/L- 38 ± 11 mmol/L; vs Group II, $P < 0.05$; vs Group III, $P > 0.05$). Rejection activity index was significantly decreased ($0.3.3 \pm 1.6$; vs Group II, $P < 0.05$; vs Group III, $P > 0.05$). Level of hepatic IFN- γ mRNA in group IV was decreased, while level of hepatic IL-10 mRNA was increased (vs Group II, $P < 0.05$; vs Group III, $P > 0.05$).

CONCLUSION: Our results indicated that 1,25-(OH)₂D₃ induced the secretion of cytokine toward to Th2 type, which would alleviate acute rejection, protect liver function and prolong survival of recipient after orthotopic liver transplantation.

INTRODUCTION

1,25-dihydroxyvitamin D₃ (1,25-(OH)₂D₃), the functional metabolite of vitamin D, is a key regulator of calcium and

phosphorus^[1], has important immunomodulatory action^[2,3], and was demonstrated to be able to prevent graft from acute rejection after transplantation of heart and renal, and prolong the survival of graft significantly^[4-7]. In previous study, we demonstrated that 1,25-(OH)₂D₃ played important role in preventing the rejection of allograft after liver transplantation. The kinetic characteristic of 1,25-dihydroxyvitamin D₃ on liver allograft viability and rejection after liver transplantation was explored in present study with orthotopic rat liver transplantation model. Furthermore, expression of IFN and IL-10 was determined to examine the immunomodulatory effect of 1,25-dihydroxyvitamin D₃.

MATERIALS AND METHODS

Animals, surgical procedure and experimental groups

Male Sprague-Dawley (SD) and Wistar rats (200-250 g, purchased from Shanghai Animal Center, Academy of Science, Shanghai) were selected randomly as transplant donors or recipients. Under ether inhalation, orthotopic rat liver transplantation was performed according to Kamada's two-cuff technique^[8]. Four experimental groups were designed in this study, Group I: syngenic control (Wistar-to-Wistar); Group II: acute rejection (SD-to-Wistar); Group III: acute rejection treated with cyclosporine A 3.0 mg·kg⁻¹·d⁻¹ intramuscularly, from day 0 to 13 posttransplant (SD-to-Wistar+CsA); Group IV: acute rejection treated with 1,25-(OH)₂D₃ 1.0 μ g·kg⁻¹·d⁻¹ intraperitoneally, from day 0 to day 13 posttransplant (SD-to-Wistar+1,25-(OH)₂D₃). Recipient animals had an experimental diet containing 0.47 % calcium 7 days before transplantation; only recipients in Group IV received experimental diet for 15 days following transplantation.

Sample harvesting

On day 1, 5, 7, 15, and 30 posttransplant, three rats were selected from each group for sample harvesting. Serum calcium levels were measured to study the effect of 1,25-(OH)₂D₃ on calcium metabolism. Serum aspartate aminotransferase (AST) and total bilirubin (BIL) were measured to study the effect of 1,25-(OH)₂D₃ on liver functions. Liver allografts were taken for histology and cytokine determination. Another 6 rats in each group were bred for observing survival time. Rocaltrol®, 1,25-dihydroxyvitamin D₃ product of Roche Pharma, and Sandimmune®, Cyclosporine A product of Novartis Pharma were used in this study.

Histopathologic examination

Grafted liver samples were fixed in 10 % buffered formalin and embed in paraffin. Five-micrometer-thick sections were affixed on slides, deparaffinized, and stained with hematoxylin and eosin. Morphologic change of graft was observed and severity of acute rejection was assessed with Rejection Activity Index according to Banff 97 working classification of hepatic allograft pathology^[9].

Cytokine reverse transcription-polymerase chain reaction

Primer sequences and reaction conditions The sequences of primers, synthesized by Bioengine-ering Corp at Shanghai

are as follow, IFN- γ sense primer 5' -ACT GCC AAG GCA CAC TCA TT-3', antisense primer 5' -AGG TGC GAT TCG ATG ACA CT-3' (size 235bp); IL-10 sense primer 5' -TGC TCT TAC TGG CTG GAG TG-3', IL-10 antisense primer 5' -GTC GCA GCT GTA TCC AGA GG-3' (size 345bp). β -actin sense primer, 5' -TCG TAC CAC TGG CAT TGT GA-3', β -actin antisense primer, 5' -TCC TGC TTG CTG ATC CAC AT-3' (size 645bp). Amplification were performed using an initial denaturation step of 95 °C for 2 minutes, followed by 32 cycles consisting of 94 °C for 45 seconds, 56 °C for 45 seconds and 72 °C for 45 seconds. The final extension step was one cycle at 72 °C for 10 minutes.

RT-PCR Total RNA was prepared from grafted liver with TRIzol Reagent (Gibco, BRL) according to the manufacturer's recommendations. For cDNA synthesis, 4 μ g total RNA was reverse transcribed with MuLV (MBI, Fermentas) reverse transcriptase according to the manufacturer's recommendations. Two microliters from the resulting cDNA solution were then amplified in a volume of 25 μ l PCR buffer using specific oligonucleotides under the conditions aforementioned. Reaction products were run on a 1.5 % agarose gel for 20-30 min at 100 V, and visualized with ethidium bromide under UV light. Relative expression of cytokines was defined as optical density ratio (cytokine/ β -actin) analyzed by Kodak science scanning system.

Statistics

All data were expressed as mean values and standard deviations and analyzed using SPSS software (version 10.0 for windows). Difference in mean value between the groups was tested by Independent-Samples *t* test. Differences in pathological Rejection Activity Index score between the groups were tested with the Mann-Whitney U nonparametric test. Recipient's survival was estimated with the Kaplan-Mier product limit estimator. Statistically significance was defined at $P < 0.05$.

RESULTS

Survival of recipient posttransplantation

All the recipients in Group I survived for over 100 days; all the recipients in Group II died at day 7 to day 19 posttransplantation and median survival time was 12.3 ± 4.0 days. Five out of 6 recipients in Group III, and 4 out of 6 recipients in Group IV survived for long term. Difference between Group IV and II was statistically significant, but not for that between group IV and III. Kaplan-Mier Survival Curve was showed in Figure 1.

Figure 1 Effect of 1,25-(OH) $_2$ D $_3$ on survival of rat recipients of an orthotopic liver allograft (Kaplan-Meier Survival Curve). When Group III was compared with Group II: $P = 0.0005$. When Group IV was compared with Group II: $P = 0.0005$. When Group IV was compared with Group III: $P = 0.70$.

Effect of 1,25-(OH) $_2$ D $_3$ on serum calcium and liver function

An obvious limitation to the use of vitamin D $_3$ derivatives in transplantation was hypercalcemia. Serum calcium in Group I

on day 7 posttransplant was defined as basal value. If value was not significant in comparison with basal value, no significant effect of 1,25-(OH) $_2$ D $_3$ or CsA on calcium metabolism was considered (Table 1). Level of AST and BIL in Group I increased slightly within 7 days posttransplant and then gradually restored to normal after 7 days posttransplant. In Group II, liver function deteriorated dramatically on day 5 posttransplant, and levels of bilirubin and AST increased steadily until the death of recipients. In contrast, administration of either CsA or 1,25-(OH) $_2$ D $_3$ prevented deterioration of the graft function during the first 30 days after transplantation. The average values of AST were 146 ± 33 U/L- 241 ± 107 U/L, and BIL 17 ± 6 mmol/L- 25 ± 9 mmol/L in Group III, while mean level of AST, BIL in Group IV posttransplant was 127 ± 41 U/L- 360 ± 104 U/L and 13 ± 5 mmol/L- 38 ± 11 mmol/L, respectively. Difference of these values between Group II and IV was statistically significant while difference between group III and IV was not (Figure 2).

Table 1 Serum calcium assessment (mmol/L, $\bar{x} \pm s$)^a

Group	Time posttransplant (d)		
	7	15	30
I	2.29 ± 0.13	2.16 ± 0.05	2.22 ± 0.16
II	2.34 ± 0.04		
III	2.25 ± 0.11	2.32 ± 0.07	2.12 ± 0.09
IV	2.60 ± 0.31	2.47 ± 0.27	2.33 ± 0.31

a: Serum calcium of Group I on 7 d posttransplant was supposed as basal values, each value was not significant in comparison with basal values ($P > 0.05$).

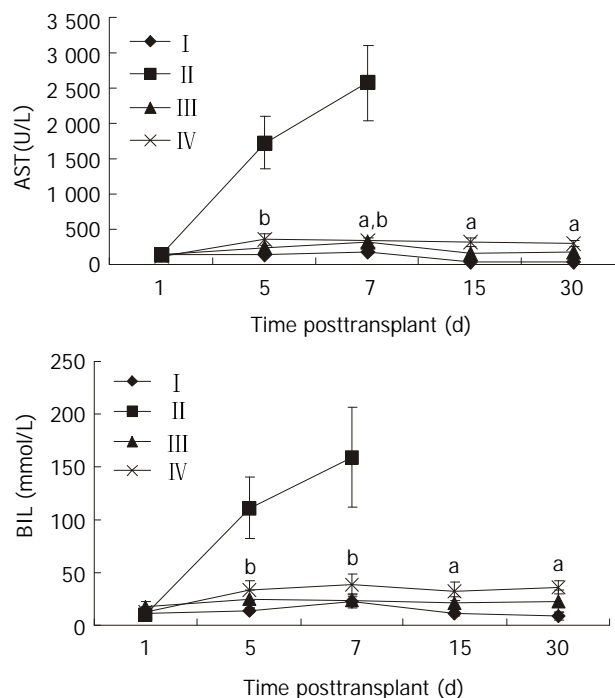

Figure 2 Effect of 1,25-(OH) $_2$ D $_3$ on graft function ($\bar{x} \pm s$). ^a $P < 0.05$, vs Group I; ^b $P < 0.05$, vs Group II.

Histological assessment of graft rejection

In Group I no signs of rejection were found all the time, on day 5 posttransplant, minimal inflammation on portal area was found, average RAI score was 0.3 ± 0.6 . On all other experimental times, RAI score was 0; In group II, a few lymphocytes infiltrated in portal area with minimal vein endothelialitis on day 1 posttransplant. Lymphocytes infiltrated

in portal area obviously with degeneration of hepatic parenchyma in all cases on day 5 posttransplant with average RAI 8.3 ± 1.1 . Marked mononuclear infiltration, severe vein subendothelialitis with bridging hepatocellular necrosis can be found on day 7 posttransplant with average RAI 8.7 ± 0.6 . Rejection reaction was greatly inhibited in Group III due to the immunosuppressive effect of CsA. No evidence of rejection was found on day 1 and day 5 posttransplant. But both inflammatory infiltration and endothelialitis can be found on day 7 with RAI at 2.3 ± 0.6 was evaluated. Infiltration in portal area and bile duct hyperplasia in some cases were detected on day 15 and day 30 posttransplant. As for Group IV, RAI was 0 on day 1 posttransplant. On day 5 posttransplant, RAI was 2.3 ± 0.6 . Inflammatory was mild. Vein subendothelial tissue and bile duct were cuffed by lymphocytic infiltrate occasionally. Necrosis of hepatocytes was not detected. On day 7 and 15, mild to moderate portal inflammatory was continuously mild to moderate. Various degree endothelialitis or hepatocyte necrosis existed in some cases. On day 30 posttransplant, mild to moderate portal infiltrate was still existed. Mild bile duct hyperplasia was found in 2/3 cases. RAI in Group IV was lower than in Group II significantly ($P < 0.05$) on each time point. In comparison with Group III, RAI in group IV was slightly higher without any significance ($P > 0.05$) on each time point (Figure 3).

Figure 3 Effect of $1,25-(\text{OH})_2\text{D}_3$ on Rejection Activity Index (RAI). ($\bar{x} \pm s$). ^a $P < 0.05$, vs Group I; ^b $P < 0.05$ vs Group II.

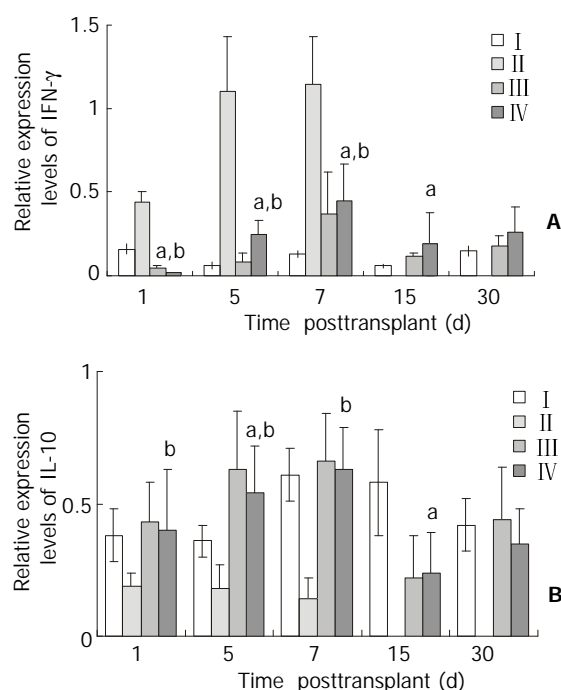

Figure 4 Effect of $1,25-(\text{OH})_2\text{D}_3$ on IFN- γ and IL-10 gene transcription ($\bar{x} \pm s$, analyzed by RT-PCR). ^a $P < 0.05$, vs Group I; ^b $P < 0.05$ vs Group II.

Effect of $1,25-(\text{OH})_2\text{D}_3$ on IFN- γ mRNA and IL-10 mRNA

On each defined time posttransplant, the expression of IFN- γ mRNA intra-graft was little in Group I and strong in Group II. After administration of CsA, the expressed level of IFN- γ mRNA decreased significantly ($P < 0.05$, vs Group II). After treatment with $1,25-(\text{OH})_2\text{D}_3$ $1.0 \mu\text{g} \cdot \text{kg}^{-1} \cdot \text{d}^{-1}$, the expressed level of IFN- γ mRNA decreased significantly ($P < 0.05$, vs Group I; $P > 0.05$, vs Group III).

In contrast, expression of IL-10 mRNA intra-graft was strong and obvious in Group, but very weak in Group II. The expression level increased significantly ($P < 0.05$, vs Group II) after treatment with CsA. As for Group IV, the expression level increased markedly ($P < 0.05$, vs Group II; $P > 0.05$, vs Group III) (Figure 4).

DISCUSSION

As a newly recognized hormone, $1,25-(\text{OH})_2\text{D}_3$ has immune activity *in vitro* and its role in organ transplantation has been highlighted last decade. For instance, MC1288, a analogue of $1,25-(\text{OH})_2\text{D}_3$, could prolong survival of cardiac and small-bowel allografts in rats^[4]. $1,25-(\text{OH})_2\text{D}_3$ was demonstrated to inhibit neonatal as well as vascularized heart transplantation rejection much effectively than a high-dose CsA regimen^[5]. However, no effect was observed in graft survival in a neonatal nonvascularized murine heart transplantation model in another report^[10]; Jordan *et al.*^[11] reported a marginal effect of vitamin D on rat cardiac allograft survival. In all cases, significant toxicity of hypercalcemia was observed. In our study, we showed that $1,25-(\text{OH})_2\text{D}_3$ can effectively inhibit acute rejection following liver transplantation, and prolong recipients' survival markedly. Our study also showed that hypercalcemic effect of $1,25-(\text{OH})_2\text{D}_3$ can be mitigated by a low-calcium diet. The major differences between these studies were the administrative route of $1,25-(\text{OH})_2\text{D}_3$. It was given every other day intraperitoneally in previous study. Since the half-life of $1,25-(\text{OH})_2\text{D}_3$ is few hours^[1], the administration of this compound every other day would not be sufficient. Furthermore, several studies used various analogues of vitamin D such as KH1060, MC1288. These analogues had varied side effect of hypercalcemia by changing its stereochemistry at C-20^[12-14], and allowed to take higher dosage of this agents and thus increased its immune effect in therapy.

In present study, it has been confirmed that the beneficial of $1,25-(\text{OH})_2\text{D}_3$ on survival was due to a marked inhibition of rejection and amelioration of graft function. At the cellular level, $1,25-(\text{OH})_2\text{D}_3$ interferes with function of antigen-presenting cells by decreasing MHC class II expression, and blocks mitogen stimulated T-cell proliferation^[15-17]. As a result, $1,25-(\text{OH})_2\text{D}_3$ reduces the immunogenicity of allograft and the cytotoxicity of CTL, prevents the allograft from immune attack. In present study, the allografts of rats that did not receive $1,25-(\text{OH})_2\text{D}_3$ demonstrated moderate to severe acute rejection. Marked lymphocytic infiltration, severe bile duct injury, subendothelialitis and hepatic necrosis were observed. The RAI score and bilirubin concentration, AST activity increased continuously until the death of recipients. In contrast, allografts of rats receiving $1,25-(\text{OH})_2\text{D}_3$ showed significant improvement. Lymphocytic infiltration intra-graft and hepatocellular necrosis were mild, and the rejection activity was inhibited. On each time point observed, the differences in values of RAI, BIL and AST between Group III and IV were not significant statistically. It suggested that the effect of $1,25-(\text{OH})_2\text{D}_3$ and CsA in protecting graft function was equal.

Some studies^[18-21] showed that in allografting Th1 cells launched rejection by priming the cytotoxicity of CTL and delayed-type hypersensitivity reaction through cytokine, and Th2 cells induced allografts tolerance by receding the activity

of Th1 cells through cytokine. 1,25-(OH)₂D₃ interacted with a nuclear receptor (VDR). In nuclear, VDR combined with RXR to form a heterodimer, then bound to the target gene. Once 1, 25-(OH)₂D₃ combined with the VDR, DNA bending occurs. Ultimately it affected the RNA polymerase activity for either stimulation or suppression of transcription^[22-24]. The present study has demonstrated that 1,25-(OH)₂D₃ can inhibit transcription of IFN- γ , and stimulate transcription of IL-10. Thus, our results provide further evidence that a high IL-10 and low IFN- γ expression state may protect allografts^[25,26]. It was manifested *in vitro* that 1,25-(OH)₂D₃ could inhibit interleukin 12^[27] which was produced by myelomonocytic cells and played a pivotal role in the development of Th1 cells, as well as inhibition the excretion of cytokine such as IFN- γ ^[28,29] and IL-2^[30,31]. In the other hand, 1,25-(OH)₂D₃ can directly stimulate Th2 cells to excrete cytokine such as IL-4, IL-5 and IL-10^[32-34]. The effect of vitamin D3 on cytokine may shift the immune response from the Th1 pathway, which leads to allograft rejection to the Th2 pathway, which can induce allograft tolerance.

In kinetic surveillance, some common characteristic can be found in all groups. In isograft, variation of each index was relatively gentle. The allografts of rats that did not take 1,25-(OH)₂D₃ demonstrated a obvious tidemark of rejection on day 5 posttransplant. In Group III and IV, the rejection reaction was inhibited markedly due to the immunosuppressive effect of 1,25-(OH)₂D₃ and CsA. The kinetic in the two groups and IFN- γ mRNA and RAI were similar, that is, the severe rejection reaction appeared on day 7 posttransplant, meanwhile expression of IL-10 mRNA and liver function were very low. Previous studies^[35,36] showed that high immunoresponses occurred day 3 to day 5 posttransplantation and thus called a transient "rejection crisis". It may be due to the strong immunosuppressive effect of 1,25-(OH)₂D₃ and CSA that rejection crisis phase in Group III and IV was postponed. Interesting, although majority of recipients in group III and IV survived for long-term, all of grafts in these two groups were demonstrated various degree of rejection activity. Further studies^[37,38] have confirmed that majority of this rejection was self-limited, and it could resolve spontaneously by day 50 posttransplant without immunosuppressive agents.

In conclusion, our study proved that 1,25-(OH)₂D₃ could effectively modulate the cytokine net, induce TH1/TH2 shifting, and thus postpone the "rejection crisis", inhibit the acute rejection and protect the graft function.

Abstract

AIM: To study the modulating effect of GdCl₃ and Angelica Sinensis polysaccharides (ASP) on differentially expressed genes in liver of hepatic immunological mice by cDNA microarray.

METHODS: Hepatic immunological injury was induced by lipopolysaccharide (LPS ip, 0.2 mg·kg⁻¹) in bacillus calmetteguerin (BCG ip, 1 mg·kg⁻¹) primed mice; A single dose of 20 mg·kg⁻¹ GdCl₃ was simultaneously pretreated and 30 mg·kg⁻¹ ASP (ig, qd×7 d) was administrated when the BCG+LPS was primed. The mice were sacrificed at the end of the 7th day after ip LPS for 6 h and the liver was removed quickly. The PCR products of 512 genes were spotted onto a chemical material-coated glass plate in array. The DNAs were fixed to the glass plate after series of treatments. The total RNAs were isolated from the liver tissue, and were purified to mRNAs by Oligotex. Both mRNAs from the normal liver tissue and the liver tissue from the mice with hepatic immunological injury or that pretreated with GdCl₃ or ASP were reversely transcribed to cDNAs with the incorporation of fluorescent dUTP to prepare the hybridization probes. The mixed probes were hybridized to the cDNA microarray. After high-stringent washing, the cDNA microarray was scanned for fluorescent signals and showed differences between the two tissues.

RESULTS: Among the 512 target genes, 18 differed in liver tissue of hepatic immunological injury mice, and 6 differed in those pretreated by ASP, 7 differed in those pretreated by GdCl₃.

CONCLUSION: cDNA microarray technique is effective in screening the differentially expressed genes between two different kinds of tissue. Further analysis of those obtained genes will be helpful to understand the molecular mechanism of hepatic immunological injury and to study the intervention of drug. Both ASP and GdCl₃ can decrease the number of the differentially expressed genes in liver tissue of mice with hepatic immunological injury.

INTRODUCTION

The advanced technique of DNA microarray makes it possible to monitor the expression of ten out of thousand genes simultaneously in one hybridization experiment^[1,2]. The past year has demonstrated the versatility of microarrays for the analysis of whole model-organism genomes and has seen the development of chips to measure the expression of 40 000 human genes. Microarray technology has also become considerably more robust and sensitive^[3]. The technology of microarrays has advanced from reverse Northern blots on filters detected using radioactive probes to a highly technical field involving miniaturized synthesis, multi-color fluorescent labeling, and database management. Recently, whole genome has been analyzed^[4,5]. Microarray analyses typically follow the steps of gene selection, microarray synthesis, sample preparation, array hybridization, detection, and data analysis with appropriate controls required for each. Functional genomics is the study of gene function through the parallel expression measurements of genomes, most commonly using the technologies of microarrays and serial analysis of gene expression. Microarray could use in some other field also, such as, basic research of drug and target discovery, biomarker determination, pharmacology, toxicogenomics, target selectivity, development of prognostic tests and disease-subclass determination^[6]. In this experiment, the DNA segments were spotted on a slide with high density. Then cDNA retro-transcribed from mRNA derived from normal or pathological tissues, which were labeled with Cy3 and Cy5 fluorescence, hybridized with the microarray slide^[7]. Through this technique, detection of differentially expressed genes and the construction of differential gene expression profiles are greatly facilitated. The BioDoor 512DNA microarray was used for investigating the changes of gene expression in liver tissue of hepatic immunological mice and studying the effective mechanisms of ASP and GdCl₃, which might give important health benefits to understanding, diagnosing and treating the liver injury.

MATERIALS AND METHODS

Animals and treatments

Hepatic immunological injury was induced by lipopolysaccharide (LPS ip, 0.2 mg·kg⁻¹) in bacillus calmetteguerin (BCG ip, 1 mg·kg⁻¹) primed mice (Model); A single dose of 20 mg·kg⁻¹ GdCl₃ was pretreated simultaneously (Model+GdCl₃) and 30 mg·kg⁻¹ ASP (Model+ASP, ig, qd×7 d) was administrated when the BCG+LPS was primed. The mice were sacrificed at the end of the 7th day after ip LPS for 6 h and the liver was collected for analysis of cDNA microarray.

Construction of microarrays^[4]

The BioDoor 512 microarray consisted of a total of 512 novel or known genes (provided by United Gene Holdings, Ltd). These genes were amplified through PCR using universal primers and then purified; the purity of PCR production was dissolved in 3×SSC solution, and these target genes were spotted on silylated slides (Tele Chem, Inc.) by Cartesian 7 500 Spotting Robotics (Cartesian, Inc.). After spotting, the slides were hydrated (2 h), dried (0.5 h) at room temperature, UV cross-linked (65 mJ/cm), and then treated with 0.2 % SDS (10 min). The slides were dried again and ready for use.

Probe preparation^[4]

The method of total RNA extraction was modified from the original single step extraction with Trizol agent. The liver tissue stored in liquid nitrogen were ground completely into tiny granules in 100 mm ceramic mortar (RNase free) and homogenized in Trizol. The pellet of total RNA was dissolved with Milli-Q H₂O. The mRNAs were purified using Oligotex mRNA Midi Kit (Qiagen, Inc.). The fluorescent cDNA probes were prepared through reverse transcription and then purified (referring to the protocol of Mark. Schena.). The probes from normal tissues were labeled with Cy3-dUTP, those from the pathological tissues were with Cy5-dUTP.

Hybridization and washing^[4]

The probes were mixed and precipitated by ethanol, and resolved in 20 µl hybridization solution (5×SSC + 0.4 % SDS +50 % formamide + 5×denhardt's solution). Chip was prehybridized with Hyb sol +3 µl denatured salmon sperm DNA at 42 °C for 6 h. After denaturing at 95 °C for 5 min, the probe mixture was added on the prehybridized chip and covered with glass. The chips were incubated at 42 °C for 15-17 h. The slide was then washed in solutions of 2×SSC + 0.2 % SDS,

0.1×SSC+ 0.2 % SDS and 0.1×SSC at 60 °C, respectively for 10 min each, then dried at room temperature.

Detection and analysis^[4]

The chip was scanned by ScanArray 5000 laser scanner (General Scanning, Inc) at 2 wavelengths. The acquired image was analyzed by ImaGene 3.0 software (BioDiscovery, Inc.). The intensity of each spot at the 2 wavelengths represented the quantity of Cy3-dUTP and Cy5-dUTP, respectively. The ratio of Cy3 to Cy5 was calculated. The two overall intensity was normalized by a coefficient according to the ratios of the located 40 housekeeping genes.

RESULTS***Differentially expressed gene in liver tissues between mice with or without hepatic immunological injury***

Total 18 differentially expressed genes that might be associated with hepatic immunological injury were selected from microarray. 4 genes showed up-regulation and 14 genes showed down-regulation (Table1, Figures 1 and 2).

Differentially expressed gene in liver tissues between mice with hepatic immunological injury and those pretreated by GdCl₃

6 differentially expressed genes associated with the effect of GdCl₃ on hepatic immunological injury were selected from the microarray. 1 gene showed up-regulation and 5 genes showed down-regulation (Table 2, Figures 1 and 2).

Differentially expressed gene in liver tissues between mice with hepatic immunological injury and those pretreated by ASP

7 differentially expressed genes associated with the effect of ASP on hepatic immunological injury were selected from the microarray. 1 gene showed up-regulation and 6 genes showed down-regulation (Table3, Figures 1 and 2).

DISCUSSION

Hepatic immunological injury is a result of altering multiple genes expression. cDNA microarray method can simultaneously determine a number of genes altered in the different pathological and physiological status, so gene chip is a useful tool for studying the target cause of disease and the effect of drug^[10]. The DNA microarray hybridization applications reviewed include the important areas of gene expression analysis and genotyping for point mutations, single nucleotide polymorphisms (SNPs), and short tandem repeats (STRs)^[11,12]. In addition to the many molecular biological and genomic research uses, systems for pharmacogenomic research and drug discovery^[13,14], infectious and genetic disease and cancer diagnostics, and forensic and genetic identification purposes^[15-17]. Additionally, microarray technology being developed and applied to new areas of proteomic and cellular analysis are reviewed^[18,19]. Now, microarray has been developed many kinds, such as, protein microarray, GEM microarray, tissue microarray, they also have different kinds uses^[20-22].

The present study showed that 18 differentially expressed genes that might be associated with hepatic immunological injury were found, 4 genes showed up-regulation and 14 genes showed down-regulation. These genes expression could recover to normal level by GdCl₃ except the HIV-1 Nef interacting protein (Nip7-1) mRNA (Hsu83843). And by ASP except the HIV-1 Nef interacting protein (Nip7-1) mRNA (Hsu83843), sterol carrier protein X/sterol carrier protein 2 Mrna (Humsnp2a), and H.sapiens hug mRNA for uracil DNA glycosylase (Hsngmna).

Furthermore, cDNA or uracil-DNA glycosylase, serine kinase mRNA, encoding the c-myc oncogene expression (Hsmycl) showed down-regulation in the mice pretreated with GdCl₃. In this study we find that using GdCl₃ and ASP to pretreat mice with hepatic immunological liver both would cause down-regulation of Hsung and Hsngmna. Hsung and Hsngmna both related to encoding uracil-DNA glycosylase. In humans, uracil appears in DNA at the rate of several hundred bases per cell each day as a result of misincorporation of deoxyuridine (dU) or deamination of cytosine. The human UNG-gene at position 12q24.1 encodes nuclear (UNG2) and mitochondrial (UNG1) two forms of uracil-DNA glycosylase^[23]. Repair of uracil-DNA is a base-excision pathway initiated by a uracil-DNA glycosylase (UDG) enzyme of which have four families^[24]. The most efficient and well characterized of these uracil-DNA glycosylases is UDG which releases uracil from DNA, restores the correct DNA sequence, excises U from single- or double-stranded DNA and is associated with DNA replication forks^[25,26]. Uracil DNA glycosylase (UDG) and DNA polymerase beta (beta pol) are the two enzymes of base excision repair (BER)^[10]. Krokan *et al* propose that BER is important both in the prevention of cancer and for preserving the integrity of germ cell DNA during evolution^[23]. But Kvaløy *et al* find mutations affecting the function of human UNG gene are seemingly infrequent in human tumor cell lines^[26,27]. So we infer down-regulation of these genes may affect cell proliferation, and GdCl₃ and ASP protect liver depend on this mechanism in some degree. Although ornithine aminotransferase mRNA (Humoat) also showed down-regulation, its expression showed a little improvement (Cy5/Cy3 increased from 0.290 to 0.454). Ataxin-2 Mrna (Hsu70323) expression showed up-regulation in the mice pretreated with GdCl₃. As for the mice pretreated with ASP, Humoat expression also showed some improvement (Cy5/Cy3 increased from 0.290 to 0.421). TNF alpha can cause liver cell apoptosis through the TNF-alpha receptor or Fas/CD95, which is expressed by liver cells. The TNF-alpha induced expression of the nuclear oncogene c-myc in intact hepatocytes has been

studied^[28]. The expression of Hsmycl is down-regulation, which may be the reason of preventing hepatic cell from apoptosis. The liver plays a central role in nitrogen metabolism. Nitrogen enters the liver as free ammonia and as amino acids of which glutamine and alanine are the most important precursors. Detoxification of ammonia to urea involves deamination and transamination. Half of the extra NH₃ removed by the liver was, apparently, utilized by periportal glutamate dehydrogenase and aspartate aminotransferase for sequential glutamate and aspartate synthesis and converted to urea as the 2-amino moiety of aspartate^[29]. Ornithine aminotransferase is the most important enzyme to metabolize free ammonia and amino acids. The gene exists as a single copy in the malarial genome and is located on chromosomes 6/7/8^[30]. Ornithine-delta-aminotransferase (OAT) (EC 2.6.1.13) is a pyridoxal-5' phosphate dependent mitochondrial matrix enzyme. It controls the L-ornithine (Orn) level in tissues by catalysing the transfer of the delta-amino group of Orn to 2-oxoglutarate. The products of this reaction are L-glutamate-gamma-semialdehyde and L-glutamate^[31]. Boon L proves that high protein diet would cause ornithine aminotransferase increased^[32]. NOX significantly reduced serum levels of ornithine carbamoyltransferase and aspartate aminotransferase as hepatic injury^[33]. The present study showed ornithine aminotransferase mRNA (Humoat) showed down-regulation, but its expression showed a little improvement (Cy5/Cy3 increased from 0.290 to 0.454) and (Cy5/Cy3 increased from 0.290 to 0.421) with GdCl₃ and ASP. So we think ornithine aminotransferase is important aspect in hepatic injury. Protective effect of GdCl₃ and ASP on the hepatic immunological injury depends on regulating the expression of ornithine aminotransferase. While the heparin-binding growth factor receptor (HBGF-R-alpha-a2) mRNA (humhbgfb) expression showed down-regulation and neuroleukin mRNA (Humnlk) expression showed up-regulation in the mice. Neuroleukin (NLK) is a multifunctional protein, involved in neuronal growth, glucose metabolism, cell motility, and differentiation. Neuroleukin (NLK), autocrine motility factor (AMF) and phosphohexose isomerase (PHI) have been identified same structure, so they have many kinds on functions and expressed in many tissues and organs, such as, brain, bone, liver, etc. NLK could mediate leukemia cell^[34]. Romagnoli *et al* show that the block of NLK commits PC12 cells to caspase-dependent apoptosis, and suggest a general protective role of NLK in the control of cell death in neuronal cells^[35]. NLK may be modulating inflammation and is probably involved in protecting CN and the cerebellums against apoptosis^[36]. When ASP pretreat mice with hepatic immunological injury, the expression of Humnlk up-regulation may show ASP prevent cell apoptosis. It remains to be demonstrated whether the altered genes are target of protective effect of GdCl₃ or ASP on the immunological liver injury, and further analysis the function of these genes is needed.

Abstract

AIM: Allo-cell transplant rejection and autoimmune responses were associated with the presence of class II major histocompatibility complex (MHC II) molecules on cells. This paper studied the effect of Ribonuclease P (RNase P) against CIITA, which was a major regulator of MHCII molecules, on repressing the expression of MHCII molecules on hepatocyte.

METHODS: M1-RNA is the catalytic RNA subunit of RNase P from *Escherichia coli*. It were constructed that M1-RNA with guide sequences (GS) recognizing the 452, 3408 site of CIITA by PCR from *pTK117* plasmid, then were cloned into the *EcoRI/BglII* or *EcoRI/SalI* site of vector *psNAV* (*psNAV*-M1-452-GS, *psNAV*-M1-3408-GS) respectively. The target mould plate (3176-3560) of CIITA was obtained from Raji cell by RT-PCR, and then inserted into the *XhoI/EcoRI* of *pGEM-7zf(+)* plasmid (*pGEM*-3176). These recombinant plasmids were screened out by sequence analysis. *psNAV*-M1-452-GS, *psNAV*-M1-3408-GS and its target RNA *pGEM*-3176 were transcribed and then mixed up and incubated *in vitro*. It showed that M1-3408-GS could exclusively cleave target RNA that formed a base pair with the GS. Stable transfectants of hepatocyte cell line with *psNAV*-M1-3408-GS were tested for expression of class II MHC through FCM, for mRNA abundance of MHCII, Ii and CIITA by RT-PCR, for the level of IL-2 mRNA on T cell by mixed lymphocyte reaction.

RESULTS: When induced with recombinant human interferon-gamma (*IFN-γ*), the expression of HLA-DR, -DP, -DQ on *psNAV*-M1-3408-GS⁺ hepatocyte was reduced 83.27 %, 88.93 %, 58.82 % respectively, the mRNA contents of CIITA, HLA-DR, -DP, -DQ and Ii decreased significantly. While T cell expressed less IL-2 mRNA in the case of *psNAV*-M1-3408-GS⁺ hepatocyte.

CONCLUSION: The Ribonuclease P against CIITA-M1-

3408-GS could effectively induce antigen-specific tolerance through cleaving CIITA. These results provided insight into the future application of M1-3408-GS as a new nucleic acid drug against allo-transplantation rejection and autoimmune diseases.

INTRODUCTION

The donor shortage has become the major restriction on liver transplantation with the increasing demands for it^[1]. Now people are trying to produce artificial liver with hepatocytes and various biological materials^[2,3], but are faced with the challenge of rejection in allo-hepatocyte transplantation^[4]. Allo-transplant rejection, was associated with the presence of class II major histocompatibility complex (MHCII) on the tissues and organs^[5,6]. MHCII played a critical role in the induction of immune responses by presenting fragments of alloantigenic peptides to CD4⁺ T lymphocytes, then resulting in the activation of CD8⁺ T lymphocytes. So it was more important for compatibility of MHCII in allo-transplantation. Moreover, the abnormal expression of MHCII molecules was associated with autoimmune disease too^[7-9]. There are codominance and multiple allele for MHCII molecules which lead to their complicated polymorphism, so it is difficult to repress every MHCII molecules expression directly. MHC class II transactivator (CIITA) was the major rate-limiting factor for both constitutive and inducible MHCII expression., and with rare exceptions, its expression parallels to that of MHCII transcripts^[10-12]. There was no rejection in allo-skin graft^[5] or prolonged survival time in allo-cardiac graft^[13] of CIITA(-/-) according to the latest investigation.

Ribozymes included hammerhead-, hairpin-, Ribonuclease P (RNase P), *et al.* M1-RNA was the catalytic RNA subunit of RNase P from *Escherichia coli*. RNase P was a ribonucleoprotein complex that catalyzed the hydrolysis reaction by removing a 5' leader sequence from tRNA precursors^[14]. Hammerhead ribozymes required presence of specific nucleotide sequences in the target RNA to be cut^[15,16], and these requirements could not always be fulfilled. M1-RNA could be used as a tool to cleave any specific mRNA sequence simply by the 3' terminal addition to the ribozyme sequence of a so-called guide sequence (GS) complementary to the target mRNA, that formed a base-pair with it and left a 5' -ACCAC-3' unpaired stretch needed for the M1-GS RNA to recognize and cleave this artificially created substrate (Figure 1B). Thus, M1-GS RNA, apart from some requirements to improve its cleavage efficiency, could be specifically directed to cut any mRNA sequences. This study represents, to our knowledge, the first gene therapy approach that makes use of the catalytic activity of M1-RNA for allo-cell transplant rejection in hepatic tissue engineering and the autoimmune diseases.

MATERIALS AND METHODS

Plasmids

PTK117, a *pUC19* derivative in which the DNA sequence coding for *E. coli* M1RNA is under the control of the T7 RNA polymerase promoter, was provided by Dr Chen BB^[14]. *pGEM-7zf(+)* vector was purchased from Shanghai BioEngineering Company, adeno-associated virus vector (*psNAV*) was provided by Dr Lu HZ.

Enzymes and chemicals

T4 DNA ligase and restriction endonucleases *EcoRI*, *Sall*, *BglII*, *XhoI* were purchased from MBI; mouse anti-human isotype control (IgG2a)-FITC, HLA-DR (IgG2a, k), -DQ (IgG2a, k) monoclonal antibody and recombinant human IFN- γ were obtained from PharMingen, mouse anti-HLA-DP (IgG2b, BRA-FB6) from CYMBUS, GENETICIN (G418) from GIBCO. TRIZOL^R from GIBCOBRL, TITANIUM^R one-step RT-PCR kit from Clontech.

Cell culture

Cell line used included L-02 cell line (from human fetal liver) and Raji cell line (human B lymphoma), all purchased from Cell Bank of Shanghai Academy of Science. Cells were maintained in RPMI1640 (GIBCOBRL) medium supplemented with 15 % fetal calf serum (HyClone).

In vitro cleavage of anti-CIITA RNaseP

RNaseP construction The M1-RNA with the anti-CIITA-directed GS (M1-452-GS or M1-3408-GS) were constructed by the polymerase chain reaction (PCR) with the gene for M1-RNA as found in plasmid *PTK117* as a template. The 5' primer, OliT7: 5'-gcggaattcTAATACGACTCACTATAG-3', annealing with the T7 promoter and providing a 5' *EcoRI* site for cloning. The 3' primers contained the appropriate GS and were Oli3408: 5'-acgcgtcgacGTGGTGCAGCTCGCTGATTACGCCAAGC-3' and Oli452: 5'-gaagatctGTGGTTCTTCCAGGACTGCCAAGCTTGC-3'. The 3' proximal sequences of 15 nucleotides in Oli3408 and 11 nucleotides in Oli452 served as primers for the PCR with the *PTK117* sequence. The lowercase sequences, the underlined sequences, and the black ones corresponded, respectively, to the *Sall* in Oli3408 or *BglII* in Oli452, the ACCAC-3' sequence, and the GS. The two different PCR products were obtained according to the instructions of 2 \times HiFi Master PCR kit (Shanghai Bioengineering Company), and cloned into *psNAV* (*psNAV*-M1-3408-GS, *psNAV*-M1-452-GS), then completely sequenced to exclude any mutation during the PCR reaction.

Construction of artificial substrate The CIITA (3176-3560) mould mRNA was obtained from Raji cell line by RT-PCR, according to instructions of TRIZOL^R and TITANIUM^R one-step RT-PCR kit. The 5' primer: 5'-ccgctcgagAGCTGAAGTCCTTGGAA-3', The 3' primers: 5'-gcggaattcGAACATGCCTGTCCAGAGC-3'. The RT-PCR product, containing 384 nucleotides spanning at the point of 3408, was cloned into the *XhoI/EcoRI* site of *pGEM-7zf(+)* (*pGEM*-3176).

Assays for cleavage by M1-GS RNA^[16] Plasmid *pGM*-3176 was linearized with *EcoRI*, *psNAV*-M1-3408-GS and *psNAV*-M1-452-GS were linearized with *BglII*, then purified by EndoFree^R Plasmid Maxi kit (QIAGEN), and transcribed in vitro from the *pGEM-7zf* or M1-RNA T7 promoter in the presence of [³²P]-GTP, with Ribomax large scale RNA production system-T7 (Promega), then transcribed ribozyme and substrate RNA were phenol chloroform extracted and precipitated with ethanol, and their integrity was checked by either acrylamide/urea or agarose electrophoresis. RNaseP

RNA and uniformly labeled substrates were incubated for 4 h at 50 °C in 25 mM Tris HCl(pH7.5), 50 mM MgCl₂, 50 mM NH₄Cl buffer in a final reaction volume of 20 μ l. Reactions were stopped by the addition of 6 μ l of a solution containing 95 % formamide, 20 mM EDTA, 0.05 % bromophenol blue, and 0.05 % xylene cyanol FF boiled for 5 min and chilled on ice. The reaction products were analyzed on 10 % polyacrylamide/8 mol/L urea gels (Figure 1C).

5' UCUUCCAGGACUCCAGCUGGAGGGCCUGAGCAAGGACA3'

B

In vitro transcribed mould plate RNA of unrelated CIITA

Cleavage point (452)

In vitro transcribed mould plate RNA of *pGEM*-3176 in CIITA

Cleavage point (3408)

C

Figure 1 Cleavage of CIITA substrate by M1-GS RNA *in vitro* (A): The mould plate RNA of CIITA *pGM*-3176 (3176-3560) include the cutting point of only M1-3408-GS, not M1-452-GS. (B): Schematic representation of targeting the CIITA mRNA by M1-RNA: GS encoding 12 or 11 nucleotides complementary to CIITA was covalently linked to the 3' end of M1-452-GS or M1-3408-GS. So M1-452-GS and M1-3408-GS specifically cut CIITA on the site of 452 and 3408 respectively. (C): Sequence-specific cleavage of *pGM*-3176 substrate by M1-3408-GS: autoradiograph of transcripts of M1-452-GS (lane 1), M1-3408-GS (lane 2) and *pGM*-3176 (lane 3), and *pGM*-3176 substrate was incubated either with M1-3408-GS (lane 4), or with M1-452-GS (lane 5). So only M1-3408-GS (not M1-452-GS) could cleave *pGM*-3176.

Cell transfection through nanometer vector

Hepatocytes were transfected with 0.4 μ g *psNAV*-M1-3408-GS by nanometer vector. According to Effectene (QIAGEN) kit's instructions, seeded 2.5 \times 10⁵ cells/well the day before transfection. The cell number seeded should produce 40-80 % confluence on the day of transfection. *psNAV*-M1-3408-GS were diluted in 100 μ l EC buffer, mixed with Enhancer 3.2 μ l, incubating 2-4 min at RT, then adding Effectene 10 μ l, at RT 7-8 min, mixed with 600 μ l medium containing serum and antibiotics, and immediately transferred the total volume to the above cells in the 6-well plate.

The expression of MHCII antigens on hepatocyte by FCM

Hepatocytes were collected and washed with 1.5 g/L MPBS buffer (10 g/L BSA and 1 g/L NaN₃) once at the density of $1 \times 10^6/\text{ml}$, adding IgG2a, HLA-DR, DP, DQ 10 μl respectively, incubating at 4 °C for 30 min, detecting the expression of MHCII molecules by Flow cytometry (COULTER, EPICSXL).

RNA analysis

RT-PCR was done according to the instructions of TRIZOL^R and TITANIUM^R one-step RT-PCR kit. In a total 50 μl volume, 50 °C 1 h, 94 °C 5 min, 94 °C 30 s, 65 °C 30 s, 68 °C 1 min, 30 cycles, 72 °C extending 7 min. Primers sequences (synthesized by Shanghai Bioengineering Company) referred to Table 1.

Mixed lymphocyte reaction (MLR)

It were incubated at 37 °C, 5 % CO₂ (keeping away light) after adding mitocin-C (25 $\mu\text{g}/\text{ml}$, Sigma) into IFN- γ induced psNAV-M1-3408-GS⁺ hepatocyte ($1 \times 10^7/\text{ml}$), and washed with RPMI1640 twice, plated at a density of $1 \times 10^6/\text{well}$ as stimulating cells. Then added peripheral blood mono-nucleated cells (PBMNC, 1×10^6) from healthy donors into above stimulating cells. The level of IL-2 mRNA from PBMNC after 48 h incubation was Detected through RT-PCR^[17].

RESULTS

The expression of MHCII molecules on hepatocyte

Hepatocyte without IFN- γ induction The expression of HLA-DR, DP, DQ on hepatocyte was low, (0.14 \pm 0.04) %, (26.76 \pm 5.26) %, (2.12 \pm 0.56) % respectively.

Hepatocyte after IFN- γ induction The expression of HLA-DR, DP, DQ on hepatocyte with IFN- γ (40 ng/ml) induction for 3 d increased significantly, (18.68 \pm 2.94) %, (41.78 \pm 4.90) %, (4.78 \pm 1.26) % respectively.

Rnase P down-modulating MHCII expression on hepatocyte

The expression of MHCII on psNAV-M1-3408-GS⁺ hepatocyte after the induction of IFN- γ (40 ng/ml) for 3 d was repressed. Compared with void-vector⁺ hepatocyte, the expression of HLA-DR, DP, and DQ on psNAV-M1-3408-GS⁺ hepatocyte was inhibited 83.27 %, 88.93 %, and 58.82 % respectively.

The expression of MHCII, Ii and CIITA mRNA through RT-PCR detection

The induction of MHCII, Ii and CIITA mRNA on psNAV-M1-3408-GS⁺ hepatocyte was detected through RT-PCR (Figure 2). Compared with void vector, the amount of MHCII and Ii mRNA of psNAV-M1-3408-GS⁺ hepatocyte was significantly down-modulated, the CIITA mRNA was down-modulated 71 %.

Figure 2 Comparison of CIITA, MHCII mRNA abundance of psNAV-M1-3408-GS⁺ hepatocyte with void vector⁺ following IFN- γ induction. The total RNA of psNAV-M1-3408-GS⁺ (p3408-H) or void vector⁺ (p-H) hepatocyte after IFN- γ (30 ng/ml, 3 d) induction was both extracted, then RT-PCR. 1: HLA-DR (335bp); 2: HLA-DP (197bp); 3: HLA-DQ (153bp); 4: Ii (714bp); 5: β -actin (310bp); 6: CIITA (410bp); 7: 100bp DNA Ladder.

Hepatocyte inducing mixed lymphocyte reaction

The excretion of IL-2 from PBMNC stimulated by psNAV-M1-3408-GS⁺ hepatocyte after the induction of IFN- γ for 3 d referred to Figure 3. Void-vector⁺ hepatocyte could induce PBMNC high amount of IL-2 mRNA, but negative control and psNAV-M1-3408-GS⁺ hepatocyte could hardly induce the excretion of IL-2 mRNA from PBMNC.

Figure 3 The secretion of IL-2 mRNA from PBMNC through RT-PCR. M: 100bp DNA ladder; 1: Negative control; 2: The IL-2 from PBMNC stimulated by psNAV-M1-3408-GS⁺ hepatocyte after IFN- γ induction; 3: The IL-2 from PBMNC stimulated by void vector control after IFN- γ induction.

DISCUSSION

In allo-cell transplantation or autoimmune diseases, some cytokines such as IFN- γ , induced some low/non MHCII antigen expressing cells to express these molecules highly^[18,19]. We selected IFN- γ to induce hepatocyte for 3 days, the expression

of HLA-DR, DP, DQ antigens increased exactly, while the expression of HLA-DP was most apparent.

CIITA regulated the transcription of MHCII gene by interacting with the trans-acting factors such as RFX, X2BP and NFY. The expression of CIITA paralleled to that of MHCII molecules and appeared only in the MHCII-positive cells^[10,11]. In the hepatocyte detected by us, the expression of CIITA was consistent with that of MHCII molecules: without IFN- γ induction, all hepatocytes didn't express MHCII molecules and CIITA gene; following IFN- γ induction, these cells expressed MHCII molecules and CIITA gene simultaneously; in the case of anti-CIITA psNAV-M1-3408-GS positive hepatocytes, the induced MHCII expression on their surface was nearly completely lost, and their CIITA mRNA detected by RT-PCR was also defect, perhaps the latter was the direct reason that MHCII expression didn't react to IFN- γ induction. This view was coincidence with that of Luder *et al*^[18,20]: TOXO plasma gondi parasite lowered the MHCII expression by inhibiting its induced CIITA expression. Moreover, HMG-CoA reductase inhibitors, cyclosporine and phosphatidylethanolamine-linked hyaluronic acid (HYPE) could completely repress MHCII expression of human microvascular endothelial cells by reducing its induced CIITA mRNA contents *ex vitro*^[19,21-23].

Gene blocking techniques were mainly made up of anti-sense oligonucleotide, anti-sense RNA, ribozyme and RNA interference (RNAi), and so on. Anti-sense oligonucleotide referred to a small fragment of single-strand deoxyribonucleic acid (14-23 bases) synthesized artificially, which could hybridize with target DNA or mRNA. However, there were still some problems of stability and efficiency of entering cell *in vivo* about it. Anti-sense RNA, ribozyme and RNAi all took action on target mRNA, namely anti-sense complementation, cutting and interference respectively. The novel RNAi technique was the double-strand RNA connected by anti-sense RNA and sense RNA in essence, and was more efficient than single anti-sense RNA^[24,25]. The mechanism of which was still not clear and might be related to activating ribonuclease to degrade target mRNA. But when it is larger than 30bp, the action of it was not specific^[24]. Compared with above-mentioned gene blocking techniques, ribozyme not only sealed mRNA, but also cut mRNA with specificity. Moreover, ribozyme could be used repeatedly, so it had higher efficiency. Both hammerhead ribozyme and hairpin ribozyme require GUC sequence to identify in target sequence. However, RnaseP was not limited to this and could aim at any site in the target sequence, so it had wider selective range^[14]. There was no report on RnaseP yet at home. According to human RNA sequences published in the NCBI Gene Bank, our experiment selected 452, 3408 site in the CIITA gene as target sites of M1-RNA after eliminating the possibility of their homology. PST and LRR regions initiated by 452, 3408 site were very essential to the transcription activation of CIITA. Moreover, the secondary structure around them was relatively simple and accessible. The GS of M1-3408-GS and M1-452-GS were programmed as 11 and 12 nucleotides respectively, to fit for the combination with their own substrate, the disconnection of cutting products with the ribozyme, and the specificity of the ribozyme. The 5'-terminal of M1-RNA had a TAATA box (T7 promoter), and M1-RNA was cloned into the psNAV vector (without T7 promoter), then the transcription was gone on owing to T7 promoter in the ribozyme itself. This could avoid supplementary sequence of the psNAV vector and objectively reflect the cutting activity of the Rnase P. The result of our experiment revealed the expected cutting stripes in the electrophoresis of cutting products of M1-3408-GS and CIITA mould plate *ex vitro*.

The reason why our experiment used nanometer-vector to mediate the transfection of M1-RNA into hepatocyte was that

nanometer had the advantages of both virus vector and non-virus vector^[26,27]. For instance, adenovirus vector^[28,29] or retroviral vectors^[30] could cause too strong immunological reaction of body to fit for the study of inhibiting the immunological rejection in our experiment; Especially, nanometer-vector could mediate exogenous gene to integrate into the chromosome DNA of host cell so that the long-term and stable expression of transgene could be obtained. In our experiment using the novel nanometer vector Effectene to transfect human hepatocyte, the rate was about 11 %, and it could rise to 60-80 % after the screening with G418 for 1 wk. Nanometer vector, however, has just begun to be used in the field of gene therapy. So far, internationally, there has no report on it used in the gene therapy of clinical or pre-clinical study.

Moreover, hepatocytes induced by IFN- γ could stimulate the secretion of IL-2 mRNA from exogenous T cell, while psNAV-M1-3408-GS⁺ hepatocyte after IFN- γ induction lost this ability. Therefore, M1-3408-GS inhibited CIITA mRNA and thus the family of MHCII molecules regulated by CIITA, then down-regulated the ability of stimulating mixed lymphocyte reaction. In conclusion, our research will have important theoretical and practical meaning on the study of transplantation immune in the whole hepatocyte tissue engineering and the therapy of autoimmune diseases.

Abstract

AIM: To explore the effect of the classical lay open technique or fistulotomy with the radio frequency surgical device in the treatment of fistula in anus.

METHODS: In our study, the conventional 'lay open' technique, or 'fistulotomy' was performed by employing the radio frequency surgical device as an alternative to the traditional knife and scissors. In a span of 18 months starting from July 1999 to December 2000, 210 cases with fistula in anus of varied types were operated in our nursing home exclusively applying the radio frequency device.

RESULTS: The results of the study were not only encouraging but also were satisfactory. A follow up of the operated patients with radio frequency surgery over a period of 15 months, i.e. from December 2000 to March 2002 was summarized as below: (a) average time taken by the patient to resume routine - 7 days; (b) none of the patient had any interference with the continence; (c) the wounds were found healed within an average time of 47 days; (d) delayed wound healing was noticed only in 7 patients; (e) recurrence/ failure rate was reduced to as low as 1.5 percent.

CONCLUSION: This technique has been found superior to the conventional fistulotomy in the sense that the time taken for the whole procedure is reduced to almost half, chances of bleeding are reduced to a minimum and the use of suture material is dispensed with. The procedure can safely be called a "Sutureless fistulotomy".

INTRODUCTION

Fistula in anus is defined as an abnormal communication lined by granulation tissue between the anal canal and the exterior i.e. the skin, which causes a chronic inflammatory response.

Etiology

The most common cause is secondary to an anorectal abscess. These abscesses either have been treated inadequately, or have bursts spontaneously. Abscess is commonly formed secondary to infection of an anal gland (cryptoglandular hypothesis of Eisenhammer)^[1]. Other causes are as follows: (a) Secondary to inflammatory bowel disease- Crohn's or Ulcerative

proctocolitis; (b) Secondary to introduction of a foreign body e.g. probing of an abscess or a low fistula; (c) Associated with anal fissure, i.e. post fissure fistula; (d) Rectum cancer especially the colloid carcinoma.

Causes of multiple fistulae include T.B, Crohn's disease, ulcerative proctocolitis, lymphogranuloma inguinale, bilharziasis, hidradenitis suppurativa, etc.

Clinical features

History Patients had the history of seropurulent discharge, persistent pruritus and discomfort in the surrounding skin^[2]. Patients feel pain if the fistula tract is blocked for accumulation of secretions under pressure.

Inspection The external opening can usually be seen as an elevation of granulation tissue often active with purulent discharge. The number and location of external openings and the relationships to the anal canal provide a clue as to the internal origin. According to Goodsall's rule, if the opening is anterior to a transverse anal line (coronal plane), the internal opening will be in a direct radial line to the nearest crypt. If the opening is posterior to the coronal line, the internal opening will usually be in a posterior midline crypt, and the tract will be curved^[3]. Exceptions to Goodsall's rule include anterior openings that are more than 3 cm far from the anal margin and multiple openings. In these situations, the internal opening is more likely to be located in one of the posterior crypts. Other clinical conditions can simulate the appearance of a fistula, including hidradenitis suppurativa, pilonidal sinus, and Bartholin's gland abscess or sinus^[4].

Palpation Palpation may reveal an indurated cord beneath the skin in the direction of the internal opening^[5]. Digital anal palpation may reveal a suspicious scarred or retracted crypt. Further internal palpation may reveal posterior or lateral induration, indicating fistulas deep in the postanal space or horseshoe fistulas. Digital rectal examination also provides assessment of sphincter tone and voluntary squeeze pressure, which may indicate the need for preoperative manometry.

Anoscopy It may aid in identifying the internal opening in the anal canal. Massaging the tract may produce a bead of pus at the dentate line. Proctosigmoidoscopy may exclude a proximal internal opening, inflammatory bowel disease, or neoplasia. Colonoscopy is appropriate if the diagnosis of Crohn's disease is suspected based on a history of recurrent or multiple fistulas or if examination is suggestive of inflammatory bowel disease. A small-bowel series also may be appropriate for patients with recurrent or multiple fistulas.

Fistulography This may have a role in evaluation of recurrent fistula, particularly when the prior surgical procedure has failed to identify the internal opening. The external opening is cannulated with a small caliber feeding tube, and contrast material is gently injected into the tract. X-ray images are then taken in the anteroposterior, oblique, and lateral positions. Complications are rare, and limiting the volume and pressure of contrast injection can minimize patient discomfort. Accuracy rates have been reported to range from 16 to 48 percent, with a false-positivity rate of 10 %^[6].

Classification There are four main types described: (1)

Transphincteric low; (2) Transphincteric high; (3) Supralevator; and (4) Intersphincteric. However, numerous variations of each can occur^[7].

Treatment The classical lay open technique is still the most favoured procedure^[8]. Slitting the complete tract from the external to internal opening is the basis of the traditional fistulotomy. Tissues around the external openings and internal opening are excised along with a small margin of tissue lining the tract and the wound is kept open for healing by secondary intention.

The traditional approach is as follows^[9]. Preoperative cleansing enema is given. The patient is kept in lithotomic position. Anesthesia: general or regional block is OK. The procedures were as follows: Digital palpation- the tract is felt as nodule or cord. Proctoscopy- a hypertrophied anal papilla may be the point of internal opening. Probing- It is done with delicate hand either retrograde (preferred) or antegrade. Methylene blue dye or milk with hydrogen peroxide is injected from the external opening to locate the direction and path of the tract^[10].

A director probe is inserted inside the fistula. Tract is cut along probe. Edges of wounds were trimmed and 1-3 mm of tissue margins was removed. The excised tract is sent for histopathological examination.

This conventional procedure encounters a lot of bleeding from the cut surfaces needing multiple ligatures to tie the bleeding vessels. At times, certain raw areas, which cannot be tied individually, may need under-running also. Due to all these hindrances, the whole procedure becomes somewhat messy and time consuming.

MATERIALS AND METHODS

In our study, the radio frequency surgical device was used instead of the surgical knife and scissors. The device is called as the *Ellman Dual Frequency 4MHz* unit from Ellman International, Hewlett, N.Y.

In a span of 18 months starting from July 1999 to December 2000, 210 cases with fistula in anus of varied types have been operated in our nursing home exclusively employing the aforesaid radio frequency surgery device. There were 187 males and 23 females. The mean age was 37 years old (age range: from 22 to 63 years old). The mean duration of the disease was 19 months (ranging from 4 months to 11 years). Seventeen patients had an operation for fistula once before and they had a recurrence.

Radio frequency surgery is a technique for cutting and coagulating the tissues using a high frequency alternate current. It is a method of coagulating the tissues, which occurs because of heat produced by the tissue resistance to the passage of high frequency wave. The heat makes the intracellular water boil, increasing the cell inner pressure to the point of breaking it from inside to outside explosion^[11]. This phenomenon is called as cellular volatilization. The principle of radio frequency wave surgery is using high frequency radio waves at 4.0 MHz, which delivers low temperature through RF micro-fiber electrodes and is similar to the frequency of marine band radio frequencies. The tissue serves as the resistance instead of the electrode; hence, there is no heating of the RF micro-fiber electrode. Instead, the intracellular tissue water provides the resistance and vaporizes without causing the heat and damage seen in electro surgery. This tissue vaporization also results in significant hemostasis without actually burning the tissue. In addition, there is no danger of shocking or burning the patient. Most important is the fact that there is controlled and minimal lateral tissue damage with the 4.0 MHz high frequency, low temperature radio frequency wave surgery^[12].

The unit is provided with a handle to which different

electrodes can be attached as per the requirement of the procedure. A ball electrode meant for coagulation, a needle electrode to incise the fistula tract and round loop electrode to shave the surrounding infected tissue has been used in our procedure.

All the patients under study were given to understand the use of the new technique to be employed in the procedure and were clearly explained the potential drawbacks like relapses and need for repetition that may follow. The patients were allowed an option to choose between the conventional method and the radio frequency technique. An informed consent was obtained from them before subjecting them to this new technique.

Exclusion criteria of the study

Only low fistulas having opening below the anus rectal ring were included for study. High trans sphincteric fistulas with or without high blind tract, suprasphincteric, extrasphincteric, and horseshoe fistulas as well as fistulas associated with inflammatory bowel disease were excluded from the study.

Radio frequency surgical fistulotomy procedures

The steps in the fistulotomy^[13] were the same as described above with the following modifications. (1) Injection of methylene blue dye with hydrogen peroxide. (2) Director probe inserted in the fistula. (3) To begin with, the skin overlying the probe, which is in the fistula tract, was coagulated by moving the ball electrode over its complete length. This reduced the amount of bleeding when the tract is slit opened. (4) The track was cut open along the probe with the help of the needle electrode that was kept in cutting and coagulation mode. This reduced the bleeding while cutting and the dissection became smooth without a drag on the tissues. (5) The bleeding edges were caught in the hemostat and were coagulated with the ball electrode kept in coagulation mode. This avoided need of suturing or under running of the bleeding points and raw areas. (6) The edges along with the surrounding infected, fibrotic tissues were shaved with the loop electrode on cut and coagulation mode. As cutting and coagulation worked simultaneously, the brisk bleeding often encountered in the conventional knife and scissor dissection was avoided. (7) At this stage, we used an accessory called the suction coagulator. This was an accessory supplied with the radio frequency surgical device. This helped in removing the ooze of blood from the raw area while the bleeding points are being coagulated. The use of this additional tool eliminated frequent mopping of the operative field while coagulating the bleeding point, as both could be done simultaneously.

Apart from the main procedure of fistulotomy, this radio frequency surgical device could also be used in coagulating associated skin tags, and internal pile masses if present.

Postoperative care

This consisted of dressing the wound twice a day after warm sitz bath. The wound could be covered with sanitary napkin, which helped in mopping up the discharge and kept the wound dry. The patient was required to stay in the hospital for a day or two. Time off work was between 5-7 days after which patient could resume his routine.

Comparative study

Encouraged by the outcome of the radio frequency fistulotomy, we carried out a separate study. This study was to compare the efficacy of radio frequency surgical fistulotomy over the conventional one. One hundred patients of low anal fistula treated by the classical 'lay open' technique were examined. Fifty patients were operated by conventional method, while

fifty were operated by radio frequency fistulotomy.

RESULTS

Failure occur mainly due to premature union of the skin edges, failure to excise the internal opening, failure to locate an extra tract, failure to detect a cavity leading upwards from the main tract, presence of foreign bodies and poor post fistulotomy wound care^[14]. In our study, the failure rate was as low as 1.5 %.

Follow up findings

A follow up of the operated patients of fistulotomy with radio frequency surgery over a period of 15 months, i.e. from December 2000 to March 2002 was as follows. None of patients lost during the follow up of 9 days. Average time taken for complete wound healing was 47 days. Average time taken by the patient to resume routine was 7 days. Delayed wound healing happened in 7 patients (took about 80-90 days for complete healing). It was observed that the fistula wounds which were close to the midline, i.e., near 12 or 6' O clock positions when the patient was in lithotomic position took longer time to heal than wounds at other places. The reason possibly could be an excess of stress on the wounds in that situation due to proximity with joints.

Four patients had a premature closure of the proximal wound while the distal remained unhealed. In case of these patients, the healed edges of the proximal wound were slit opened with needle electrode under local anaesthesia. One of them thereafter had an uneventful healing, while the wound remained unhealed in the remaining three.

The remaining three patients continued to have discharge from a small wound left behind, which despite repeated attempts of refreshing the edges remained unresolved. So, they were labeled as cases of 'failure of wound healing', rather than of recurrence. Out of these three patients, one patient was from the series of those seventeen patients who came with a recurrence after conventional procedure in the past.

None of these patients had any interference with the continence, anal stenosis, or mucosal prolapse^[15].

The data of follow up findings was shown in Figure 1.

Follow up findings after radio surgical fistulotomy

Figure 1 Follow up findings after radio frequency fistulotomy.

Complications

No major complications were encountered. Few minor ones were discussed as follows. Deep dissection may cause more scarring and longer time for healing. Excessive power of the unit can cause more smoke and charring. Either accidental burns on the part of the patient or operator due to unintended activation of hand piece has been noted. Development of edema in the surrounding tissue would occur, if power was too high. Excessive discharge from the open wound was found in few patients. This usually happened when the tissues at the base were coagulated in excess.

Results of Comparative study

The comparative data of events observed after conventional and radio frequency surgical fistulotomy were shown in Table 1 and Figure 2.

Table 1 Comparative data of events after conventional and RF fistulotomy

Events observed	Conventional fistulotomy (n=50)	Radio frequency surgical fistulotomy (n=50)
Average time of procedure	37 minutes	22 minutes
Average bleeding during procedure	134 ml	47 ml
Need of Suture material	100 %	8 %
Post operative pain	9 days	5 days
Hospital Stay [Mean]	56 hrs	37 hrs
Recurrence/Failure of Treatment	6 %	2 %
Time off work	11 days	7 days
Mean healing time	64 days	47 days
Impairment of continence	12 % for flatus	4 % for flatus

Figure 2 Comparative findings of the results of radio frequency and conventional fistulotomy.

DISCUSSION

Radio frequency surgery, not to be confused with electro surgery, diathermy, spark-gap circuitry, or electrocautery, uses a very high frequency radio frequency wave. Unlike electrocautery or diathermy, the electrode remains cold^[16]. This is possible because of use of very high frequency current of 4 MHz, as compared to 0.5 to 1.5 MHz used in the electrocautery. As contrast to true cautery, which causes damage similar to 3rd degree burns, the tissue damage that does occur is very superficial and is comparable to that which occurs with Lasers. Histologically, it has been shown that tissue damage with radio frequency surgery is actually less than with a conventional scalpel and equals cold scalpel^[17]. Radio frequency surgery creates minimal collateral heat damage in the tissue resulting in rapid healing and leaves no ugly scar. Biopsies performed of the skin tissue indicate a maximum thickness of heat-denatured collagen to be 75 micrometer. This is equal to or even better than carbon dioxide laser used for cutting^[18].

Rapidity of treatment, a nearly bloodless field, minimal postoperative pain, and rapid healing are but few advantages of radio frequency surgery. Once proper technique is established, a scar by this method of treatment is often less pronounced than those produced by other surgical techniques. Excising too deeply increases the likelihood of scars^[19].

Precautions to be taken

Removing a lesion on someone who is on aspirin or anticoagulant therapy may be accompanied by increased bleeding.

The unit should not be used in presence of flammable or

explosive liquids or gases. The surgeon must also remember to deactivate the hand piece whenever the electrodes are changed^[20].

As with all radio frequency surgery machines, smoke is produced, this needs to be attended to avoid the unpleasant smell of burning. This could be achieved by employing a vacuum extractor with the help of the assistant^[21].

The various techniques used for treating fistula^[22] are fistulectomy, fistulotomy, fistulotomy with marsupialisation^[23] of fistula, curettage of fistula and placement of flaps of mucosa or skin, placement of medicated Setons, insertion of antibiotic beads, and injection of commercial or autologous fibrin glue^[24]. Out of these options available to the surgeon, majorities of them still rely on the classical lay open technique (fistulotomy) as the gold standard of treatment in over 90 % of anal fistula cases^[25].

Patients' satisfaction after the surgical treatment for fistula-in-anus is associated with recurrence of the fistula, the development of anal incontinence, and the effects of anal incontinence on patient lifestyle^[26]. The radio frequency surgical technique of fistulotomy has been found more acceptable than the conventional fistulotomy in the sense that the time taken for the whole procedure is reduced to half, bleeding is reduced to a minimum and the use of suture material is dispensed with. None of the patients in our study had any interference with the continence and the recurrence rate was as low as 1.5 %.

If compared to electrocautery or laser, the active electrode does not heat up, so there is minimal or no heat generated to the surgical site. This allows the surgeon to work in direct proximity of the functional tissues that needs to be preserved^[27].

CONCLUSION

This technique has been found superior to the conventional and can safely be called a "sutureless fistulotomy".

Abstract

AIM: To introduce our latest innovation on technical manipulation of laparoscopic splenectomy.

METHODS: Under general anesthesia and carbon dioxide (CO₂) pneumoperitoneum, 86 cases of laparoscopic splenectomy (LS) were performed. The patients were placed in three different operative positions: 7 cases in the lithotomic position, 31 cases in the right recumbent position and 48 cases in the right lateral position. An ultrasonic scissors was used to dissect the pancreaticosplenic ligament, the splenocolic ligament, lienorenal ligament and the lienophrenic ligament, respectively. Lastly, the gastrosplenic ligament and short gastric vessels were dissected. The splenic artery and vein were resected at splenic hilum with Endo-GIA. The impact of different operative positions, spleen size and other events during the operation were studied.

RESULTS: The laparoscopic splenectomy was successfully performed on all 86 patients from August 1997 to August 2002. No operative complications, such as peritoneal cavity infection, massive bleeding after operation and adjacent organs injured were observed. There was no death related to the operation. The study showed that different operative positions could significantly influence the manipulation of LS. The right lateral position had more advantages than the lithotomic position and the right recumbent position in LS.

CONCLUSION: Most cases of LS could be accomplished successfully when patients are placed in the right lateral position. The right lateral position has more advantages than the conventional supine approach by providing a more direct view of the splenic hilum as well as other important anatomies. Regardless of operation positions, the major axis of spleen exceeding 15 cm by B-ultrasound in vitro will surely increase the difficulties of LS and therefore prolong the duration of operation. LS is a safe and feasible modality for splenectomy.

INTRODUCTION

Endoscopic surgery has continued to gain popularity in almost

all fields of general surgery. Since the first case of LS described by Delaitre and his colleagues^[1] in 1991, more and more LS have been reported in the world^[2-13]. LS has been proven to be a safe modality and become now the first choice of treatment for most patients requiring a splenectomy^[14-20]. LS will be the best choice in laparoscopic surgery followed by the laparoscopic cholecystectomy^[21,22]. However, we noticed that some anatomical and technical factors could significantly influence the outcome of LS. We herein report our latest results of 86 cases with LS.

MATERIALS AND METHODS

Patients

From August 1997 to August 2002, there were 86 patients with various splenic disorders shown in Table 1 received LS. There were thirty-five males and fifty-one females, with the mean age of 41 years (range 16-71). The platelet count (PLT) of 47 patients, in this study, with immune thrombocytopenic purpura (ITP) ranged 12-77×10⁹/L. The major axis of spleen by B-ultrasound in vitro preoperatively were less than 12 cm in fifty-four cases, 12-15 cm in twenty-one cases, 15-20 cm in eight cases and more than 20 cm in three cases. The patient with the largest spleen (23 cm) in this study was a case who suffered from portal hypertension, hypersplenism disease. Accessory spleen was detected in 6 cases with the size of 8 mm to 20 mm. The same surgeon performed all LSs.

Table 1 Diagnosis of 86 Patients in this study

Diagnosis	Cases (percentage %)
Hematologic disorders	
ITP	47 (54.7 %)
Hereditary spherocytosis (HS)	7 (8.1 %)
Autoimmune hemolytic anemia	4 (4.7 %)
Aplastic anemia (AA)	3 (3.5 %)
Hodgkin's lymphoma	3 (3.5 %)
Systemic lupus erythematosus (SLE)	2 (2.3 %)
Other disorders	
Hypersplenism	12 (13.9 %)
Multiple splenic cysts	3 (3.5 %)
Splenic tuberculosis	3 (3.5 %)
Splenic hemangioma	2 (2.3 %)
Total	86 (100 %)

Preoperative managements

Patients with non-hematologic disorders were similar to those receiving traditional open splenectomy in preoperative management. Patients with ITP received an oral administration of prednisone 30-40 mg twice a day and high doses of immunoglobulin G (400 mg/kg per day) 3-5 days for at least one week prior to the operation to raise the platelet count to a mean value of 80 (range 14-110)×10⁹/L. Intravenous administration of prophylactic antibiotics and hydrocortisone 200-300 mg were needed immediately before operation. Prednisone should be given continuously after the operation and reduced in dose gradually according to clinical situations.

Operative technique

All patients received the general anesthesia and were placed in three different operative positions: 7 cases in the lithotomic position, 31 cases in the right recumbent position and 48 cases in the right lateral position. In the right recumbent position and the lateral position, three trocars were usually used to perform the LS (Figure 1). Once all ports were placed, a 30° telescope was introduced through the 10 mm trocar into the peritoneal cavity. Ultrasonic scissors were used to dissect the pancreaticosplenic ligament, splenocolic ligament, lienorenal ligament and lienophrenic ligament, respectively. Lastly, the gastrosplenic ligament and short gastric vessels were dissected. The splenic artery and vein were resected at splenic hilum with Endo-GIA staplers (Autosuture CO; USA), which enabled safe vascular operation for larger vessels. Finally, the spleen was extracted in a plastic or nylon bag through a port wound which enlarged to about 3 cm.

Figure 1 Trocar placement for laparoscopic splenectomy in the lateral position. Three trocars are required.

RESULTS

No postoperative complications or mortality occurred in any patients with LS. All patients were hemodynamically stable during the perioperative period.

Eighty-six cases underwent a successful LS with a mean operating time of 110 minutes (range 50-270 minutes) except one case with extensive dense adhesion around the spleen due to severe perisplenitis, for whom it took nearly six hours to accomplish the operation. The situations of patients with operating time over 120 minutes were: the initial five cases of our patients being conducted LS and eleven cases with spleen major axis exceeding 15 cm. The case with 23 cm in major axis of spleen took 270 minutes to finish the LS. Blood loss was estimated between 50-800 ml during operation in all patients. Three cases received intraoperative transfusion of 400 ml red blood cell. Fifty-two of eighty-six cases (60.5 %) needed to place the drainage tube in lienalis recess postoperatively, which was removed within three days (1 to 3 days). The total amount of draining fluids was less than 100 ml (range 15-100 ml). Recovery of bowel movement occurred within an average of twenty-two (range 18-50) hours after LS. Patients were discharged from hospital in three to six days postoperatively. For patients with ITP, a positive immediate response to splenectomy was defined as a PLT more than $100 \times 10^9/L$ after surgery, which maintained without therapy. In 39 of the 47 patients with ITP, the effective rate of LS was 82.9 % (39/47).

DISCUSSION

Splenectomy for those patients with hereditary spherocytosis (HS) was initially described by Sutherland and Burghard in 1910. With the advancement of laparoscopic instruments and surgeon's experience, minimally invasive approach has been used extensively in many surgical procedures including splenectomy. Now LS has been recognized as a safe and effective treatment for hematologic disorders and other splenic diseases^[23-26]. However, the spleen is fragile and is located deeply in the left upper quadrant, and the abdominal organs like stomach, omentum, and pancreas tail obscure the splenic hilum. Operators are faced with a great deal of difficulty and risk when dealing with LS.

Since the initial reports, early experience has been gained in patients with immune thrombocytopenic purpura and other splenic disorders in a number of centers. In all these early reports, patients received LS either in the supine or the lithotomic position, and laparoscope was placed through a port near the umbilicus. In our seven early LS cases, the patients were placed in the lithotomic position too. This position, however, may take exposure and dissection suboptimal, or even cumbersome. In the lithotomic position, the laparoscope is usually inserted through the trocar near the umbilicus, when peri-splenic adhesion or splenomegaly, causes trouble to expose and dissect the peri-splenic ligaments, such as lienorenal ligament and lienophrenic ligament. Also, this position is very difficult for surgeons to expose posterior-dorsal vessels of spleen clearly and retract spleen to the medial abdomen against its gravity, when attempted to dissect the superior splenic ligaments. For these reasons, we made the rest LS patients lie in the right recumbent position or the right lateral position. We found that the abdominal organs like stomach, omentum and colon all went to the right by their gravity, dorsal side of spleen was exposed satisfactorily, and the peri-splenic ligaments are dissected easily in these two positions. In our experience, it is easy to dissect ligaments, to mobilize spleen and to place the stapler without any tension when using the right lateral approach. The procedure we used can also reduce operating time and avoid spleen or capsule fractures. In this study, there was no massive intraoperative bleeding, and no injury to great splenic vessels was observed.

Splenomegaly was initially considered as a contraindication of laparoscopic splenectomy^[27-32]. With the advancement of laparoscopic technology, LS of enlarged spleen has been performed successfully with laparoscopy^[33-38]. However, the difficulty in conducting LS on splenomegaly is certainly greater than that on the spleen with normal size. As operative area is stuffed with enlarged spleen, the peri-splenic ligaments is relative shorter, and the splenic hilum is deeply hidden in the enlarged spleen, the manipulation of LS becomes very difficult. It is hard to dissect the dorsal and upper pole ligaments of spleen in this situation. A tear of splenic capsule and splenic pedicle hemorrhage can often occur. It is a common cause to alter LS to open splenectomy in splenomegaly. In our study, we found that the right lateral approach is particularly suitable for patients with splenomegaly. Surgeons easily manipulate in right lateral position by taking advantage of gravity of spleen to expose the retroperitoneal attachments and to dissection even in the presence of dense diaphragmatic adhesions. The right lateral position offers a better laparoscopic view and space for manipulation than other positions. Moreover, only three trocars are typically required, and splenic pedicle exposition can be performed easily with less risk of capsular disruption. In fact, we have used this position in all LS cases regardless of the size of spleen since 2000^[39,40]. However, the disadvantage of the right lateral position is lack of wide visual field, which presents the possibility of missing the accessory spleen not

located in the neighborhood of splenic hilum. In addition, the distance between costal margin and iliac crest is rather short in some patients with obesity being placed in the right lateral position, which may cause difficulty for laparoscopic manipulation.

After exploring the abdominal cavity, the lower pole ligament of spleen and splenocolic ligament should be dissected firstly. Then, lienorenal ligament and lienophrenic ligament were dissected in order. The gastrosplenic ligament should be dissected after dealing with all peri-splenic ligaments, because these ligaments, especially lienophrenic ligament, create a narrow area between stomach and spleen. When the peri-splenic ligaments are dissected, the spleen will be turned down easily, the space between stomach and spleen will be enlarged, and the gastrosplenic ligament as well as short gastric vessels can be transected by ultrasonic scissors^[41,42] or titanium clips. Following this procedure, the injury to stomach or the tear of upper pole of spleen can be avoided when dissecting the upper part of gastrosplenic ligament. At last, the splenic artery and vein are isolated and divided by endoscopic vascular staplers. Individual ligation of splenic vessels requires dissecting the artery and vein of splenic hilum, which may increase the risk of damage to the tail of pancreas and hilum vessels. The high success rate in our group may be related to the operative position we adopted which provides a nice exposure of hilum of the spleen, so that it is certain for endoscopic vascular stapler to cross the entire splenic hilar vessels completely. By the way, the application of stapling instrument is safer than other manners when dealing with the splenic hilum vessels.

Perisplenitis may lead to contraction of ligaments and adhesion of the spleen to the adjacent organs, which increases the difficulty of manipulation and the risk of operation. The adhesion and peri-splenic ligaments should be dissected with ultrasonic scissors carefully in order to avoid possible capsular being torn or great vessels broken, which will result in uncontrollable bleeding. Once the splenic hilum is exposed clearly, transection procedure should be taken before handling the upper pole of spleen. This procedure is very important for the enlarged spleen, which usually has autoinfection leading to inflammatory adhesions to the diaphragm and omentum. To mobilize all the peri-splenic ligaments before transecting the splenic hilum for patients with splenomegaly, it will take the branch for the root and easily lead to uncontrollable bleeding. In one of our cases, the operation took nearly six hours on the patient who suffered from severe perisplenitis and extensive dense adhesion around the spleen. Another two cases received intraoperative transfusion of 400 ml red blood cell, in which the possible causes of bleeding were considered as massively enlarged spleen (more than 20 cm), severe extensive dense adhesion and in the lithotomic position. Although more and more reports defined LS as a safe and easy operation in massive splenomegaly^[43-47], we thought the major axis of spleen exceeding 15 cm will surely raise the difficulty and risk in LS.

For patient with hematology disorders, accessory spleen often results in unfavorable therapeutic outcome or recurrence of primary disease^[48]. It is reported that the incidence of accessory spleens are 10 % to 30 % in patients with hematologic diseases^[49-55]. In this series, we found six patients (12.8 %) with accessory spleen. The "cure" rates of the patients with ITP in our group are approximately 83 %, showing a good response to LS. However, it is considered that the period of follow-up was short in our study. So far there has been no data available of long-term cure rates of ITP by means of LS. The long-term follow-up is needed to answer this question. Notably, in a comparative study, the rate of discovery of accessory spleens was 3 times higher in open splenectomy than that in laparoscopic splenectomy^[56]. The observation showed the need

for a systematic search, in various sites such as splenic hilum, tail of pancreas, splenocolic and gastrosplenic ligaments, and the greater omentum, for accessory spleens during laparoscopic splenectomy.

Laparoscopic surgery has more advantages for improving postoperative course. The majority of our patients started to drink water eight hours after the operation. And the hospitalization ranged from three to six days.

In conclusion, laparoscopic splenectomy for patients with hematologic disorders and some other splenic diseases is technically safe and feasible. It is believe that it is easy to conduct laparoscopic splenectomy in the right lateral position. While in case of splenomegaly, the right lateral position provides better visualization than the lithotomic position and the right recumbent position. The lateral position offers many advantages than the conventional supine approach as it provides a more direct view of the splenic hilum by using the gravity of spleen to expose important anatomy. Regardless of the operative position, the major axis of spleen exceeding 15 cm by B-ultrasound in vitro surely increases the difficulty of LS and therefore prolongs the duration of operation.

Abstract

AIM: To develop a technique of combined endoscopic sclerotherapy and ligation (ESL) in which both techniques of endoscopic sclerotherapy (ES) and endoscopic variceal ligation (EVL) can be optimally used.

METHODS: ESL was performed in 10 patients (age 46.4 ± 7.9 ; 9 males, 1 female) with cirrhosis of liver using sclerotherapy needle and Speedband, Superview multiple band ligater (Boston Scientific, Microvasive, Watertown, MA). A single band was placed 5-10 cm proximal to the gastro-esophageal junction over each varix from proximal to distal margin, followed by intravariceal injection of 1.5 % ethoxysclerol (4 ml each) 2 to 3 cm proximal to the gastroesophageal junction on the ligated varices distal to deployed band. EVL was then performed at the injection site. Similarly other varices were also injected and ligated from distal to proximally. In the subsequent sessions, ES alone was performed to sclerose small varices at the gastroesophageal junction.

RESULTS: ESL was successfully performed in all patients. A median of 3 (ESL 1, ES 2) sessions (ranged 1-4) were required to eradicate the varices in 9 (90 %) of 10 patients. Recurrence of varices without bleed was seen in 1 patient during a mean follow-up of 10.3 months (ranged 6-15). Two patients died of liver failure. None died of variceal bleeding. None of the patients had procedure related complications.

CONCLUSION: ESL may be useful in the fast eradication of esophageal varices. However, randomised controlled trials are required to find out its relative efficacy and impact on variceal recurrence in comparison to ES or EVL.

INTRODUCTION

Endoscopic sclerotherapy (ES) and endoscopic variceal ligation (EVL) are well-established nonsurgical procedures for the secondary prevention of bleeding from esophageal varices. EVL, developed by Stiegmann *et al*^[1], has been

shown to have lesser complications and also require fewer endoscopy sessions to obliterate esophageal varices^[2]. However, EVL is associated with higher variceal recurrence rate in the long term^[3-7]. High recurrence rates following EVL could be related to inability to further ligate varices once they became small and had no effect on perforating veins and paraesophageal collaterals^[8-10]. The presence of paraesophageal varices predicts the recurrence of esophageal varices and recurrent bleeding^[8-10]. The mechanisms of ES and EVL in achieving variceal sclerosis are quite different. The effect induced by EVL is localized to the submucosa, whereas the chemical effect of ES is deeper, i.e. on perforating veins and paraesophageal collaterals^[8-10]. We have proposed a new technique of combined endoscopic sclerotherapy and ligation (ESL) in which both techniques of ES and EVL can be optimally utilized to achieve rapid eradication and decreased recurrence of esophageal varices^[11]. In this pilot study, we reported our initial experience with this new technique of ESL.

MATERIALS AND METHODS

Patients

Ten patients (mean age 46.4 ± 7.9 years, ranged 38-60; 9 males, 1 female) with cirrhosis of liver and upper gastrointestinal bleeding underwent ESL for variceal eradication. None of the patients was actively bleeding. The diagnosis of cirrhosis was based on clinical, biochemical and ultrasound findings. All patients had a patent splenoportovenous axis on Doppler ultrasound. The etiology of cirrhosis was related to alcohol in 6 patients, hepatitis B virus in 2, autoimmune hepatitis in 1 and cryptogenic in 1. One patient was in Child's grade A, 3 in Child's grade B and 6 patients were in Child's grade C. All patients received first session of ESL followed by ES alone with 1.5 % ethoxysclerol every 2 to 3 weeks.

Methods

ESL was performed with the Olympus EVIS GIF-Type 100 or OES GIF-XQ20 forward-viewing fiberoptic endoscope and Superview, a multiple band ligator device (Boston Scientific Co., Watertown, MA, USA) and a locally fabricated sclerotherapy needle with an outer diameter of 1.8 mm^[12]. The scope was loaded with multiple band ligator devices according to manufacturer's instructions. A small nick with a sharp, pointed blade was made in the plastic covering near the trip wire of the handle unit for the introduction of the sclerotherapy needle (Figure 1). The sclerotherapy needle was thus passed through the working channel of the scope and could be brought out distally through the cylinder of the ligating unit for ES (Figure 2). The scope was loaded with multiple band ligator device containing 5 or 8 bands, then it was introduced into the esophagus and a single band was applied 5 -10 cm proximal to the gastroesophageal junction over the varix starting from proximal to distal margin (Figure 3). This was followed by intravariceal injection of 1.5 % ethoxysclerol (4 ml each) 2 to 3 cm proximal to gastroesophageal junction on the ligated varices distal to the deployed bands. The sclerotherapy needle

was removed and EVL was then performed at the injection site. Similarly, other varices were also injected and ligated from distal to proximal margin. The scope was then removed after ensuring complete hemostasis.

Figure 3 ESL using Speedband, Superview multiple band ligator (Boston Scientific Co., Watertown, MA) and sclerotherapy needle. (a) EVL at least 5 cm or more proximal to gastroesophageal junction, (b) sclerotherapy 2 to 3 cm proximal to gastroesophageal junction on the same varix, (c) EVL on the injection site (arrow) and (d) proximal (large arrow) and distal (small arrow) EVL on the same varix.

Figure 1 Handle unit with trip wire and scope fastener. Injector was passed along the trip wire after making a small nick in the plastic covering (arrow) with a sharp blade.

Figure 2 Endoscope loaded with the ligating unit at its distal end. An injector was coming out from the cylinder of the ligating device through the working channel of the scope.

There was marked reduction in the size of esophageal varices after the ESL; therefore in the subsequent treatment sessions, ES alone was performed with 1.5 % ethoxysclerol to eradicate the remaining varices by intravariceal injection method every 2 to 3 weeks. The patients were then followed-up every 3 to 4 months.

RESULTS

All results were showed in Table 1. Eight patients had large esophageal varices (grade 3 or 4) and 2 patients had small (grade 2) varices. Each patient received 1 session of ESL as described. Esophageal varices were eradicated in 9 (90 %) patients. Marked reduction in variceal size was found following ESL in all patients on the first follow-up of ES session after 2 to 3 weeks. One patient need not require ES as the varices were completely eradicated after the first session of ESL. Three patients each required 1 and 2 sessions of ES with 1.5 % ethoxysclerol, respectively and two patients required 3 ES sessions for complete eradication of esophageal varices. Thus, eradication of varices was achieved in a median of 3 (ESL 1, ESL 2) sessions (range 1-4). None of the patient had procedure-related complications. None of them underwent a “second look” endoscopy after the therapy for evaluation of any symptoms. Large liner superficial ulcers were seen in 3 patients on the first follow-up endoscopy after 2 weeks, which healed uneventfully with marked reduction in variceal size. None of the patient received β -blockers.

Nine patients, in whom variceal eradication was achieved, were followed-up for a mean of 10.3 months (range 6-15). Small (grade 2) esophageal varices recurred in 1 (11.1 %) patient without variceal bleeding. ES was carried out to eradicate the varices again. Two patients died of liver failure. While 1 patient died before the varices could be eradicated,

another died during follow-up for 9 months after the eradication of varices. None of the patient died of variceal bleeding.

One patient had large fundal varices with cherry red spots. This patient received undiluted 2.5 ml of intravariceal injection of n-butyl-2-cyanoacrylate into the fundal varices in 2 sessions. Fundal varices disappeared following extrusions of cyanoacrylate cast 3 months later. Mild portal hypertensive gastropathy was present in 1 patient before the eradication of esophageal varices and in 3 patients after the eradication of varices.

Table 1 Endoscopic parameters

Grade of esophageal varices	Number of patients
Grade 3 or 4	8
Grade 2	2
ESL sessions	1
Follow-up ES sessions (median, range)	2(0-3)
Total ESL + ES sessions (median, range)	3(1-4)
Gastric varices	
Before eradication of esophageal varices ^a	1
After eradication of esophageal varices	0
Portal hypertensive gastropathy	
Before	1
After	3
Death ^b	2

^aThe patient received n-butyl-2-cyanoacrylate for large gastric (fundal) varices, ^bLiver failure.

DISCUSSION

We successfully performed this new technique in all patients with cirrhosis of liver, thus showing its efficacy in a clinical setting. Large paraesophageal collaterals on endosonography predict recurrence of esophageal varices^[10,13]. We have earlier shown that the ES has an effect on the perforating veins and paraesophageal collaterals as evidenced by reduction in their number and size, while no effect could be demonstrated on these venous structures with EVL^[7,8]. In order to reduce the early recurrence of the varices, the present technique aimed at augmenting the effect of sclerosant on perforating veins and on paraesophageal collaterals, while at the same time maintaining the efficacy of EVL to quickly obliterate the esophageal varices.

In this technique, proximal ligation of varices with a band not only interrupts the cephalic variceal blood flow but also divert it into the paraesophageal collaterals via perforating veins, thereby, augmenting the effect of sclerosant on the perforating veins and paraesophageal collaterals or feeders. The effect of this technique may be similar to the technique of ESL used by Umehara *et al*^[4], or the technique of ES used by Takase *et al*^[14] where the effect of sclerosant on feeder vessels of the varices could be increased by interrupting variceal blood flow by inflating the proximal balloon affixed to endoscope. In both the techniques, fluoroscopy was used to confirm the opacification of feeders with sclerosant and contrast mixture. However, our technique was simple and did not require fluoroscopy thereby reducing the radiation exposure to the patient. This method had another advantage. The effectiveness of ES also depended on the time that sclerosant remained in contact with endothelial cells in blood vessels^[15]. Proximal ligation of varices in this technique thus increased the effectiveness of sclerosant by increasing the contact time with endothelial cells. After the ES, a band was placed either on the injection site or distal to it, to achieve complete hemostasis

and the optimal effect of EVL. The endoscopist however must be careful while negotiating the scope beyond the proximally ligated varices. We did not experience the displacement of proximally deployed band.

If the effect of EVL and ES in this technique is additive then the variceal eradication rate should be higher, the varices should be eradicated in fewer sessions and the recurrence of the varices should be low. In this pilot study, complete eradication of esophageal varices was achieved in 9 (90 %) patients in a median of 3 (ESL1, ES2) sessions (range 1-4), while our previous experience with ES alone showed that 6.8±4.9 (mean ± SD) sessions were required to obliterate varices in 45 % of patients with cirrhosis of liver^[16]. Recurrence of esophageal varices in our previous experience was 25.9 %^[16]. These results comparing with historical control, indicate that the present technique of ESL is not only effective in reducing the number of sessions for eradication of esophageal varices but also in achieving eradication of varices in a higher proportion of patients. However, prospective, multi-center randomised trials are required to substantiate these results as well as to observe the impact on variceal recurrence with this technique.

ES was done easily without any complication as the injector could be passed though the working channel of the scope. We, however, observed large linear superficial ulcers over the varices on follow-up endoscopy. This finding is not unexpected as the effect of sclerosant is increased by the interruption of the variceal blood flow proximally by a band. These ulcers were superficial and healed without any complication, and were associated with eradication or marked reduction in the variceal size.

In conclusion, our new technique of ESL may be useful in the fast eradication and in achieving lower recurrence of esophageal varices. It, however, requires further randomised controlled trials with EVL or ES to find out its efficacy and impact on the variceal recurrence.

Abstract

AIM: To explore the effects of COX-2 gene in the proliferative activity induced by bile from anomalous pancreaticobiliary ductal union (APBDU) on human cholangiocarcinoma cell line.

METHODS: Bile sample from APBDU and normal bile sample were used for this study. The proliferative effect of bile was measured by methabenzthiazuron (MTT) assay; COX-2 mRNA was examined by semi-quantitative reverse transcription polymerase chain reaction (RT-PCR). Cell cycle was analyzed by flow cytometry (FCM), and the PGE₂ levels in the supernatant of cultured cholangiocarcinoma cells were quantitated by enzyme-linked immunoabsorbent assay (ELISA).

RESULTS: Bile from APBDU can significantly promote the proliferation of human cholangiocarcinoma QBC939 cells compared with normal bile ($P=0.005$) and up-regulated remarkably their COX-2 mRNA expression ($P=0.004$). The proliferative activity of APBDU bile can be abolished by addition of cyclooxygenase-2 specific inhibitor celecoxib.

CONCLUSION: Bile from APBDU can promote the proliferation of human cholangiocarcinoma QBC939 cells via COX-2 pathway.

INTRODUCTION

It is well known that APBDU is associated with choledochal cyst^[1-9]. Recently, a frequent association of biliary tract carcinoma and APBDU without choledochal cyst is well recognized, but its underlying mechanism is unclarified. For the purpose of resolving these mechanism we used the APBDU bile to act directly on the QBC939 cells to determine the effects of bile from APBDU on the cholangiocarcinoma cells growth.

MATERIALS AND METHODS

Materials

Bile samples collection and treatment: APBDU bile was obtained from the common bile duct of a patient (male, 39) with polypoid lesion of the gallbladder who underwent cholecystectomy in the Department of Surgery, Tongji hospital, Wuhan, China. Preoperative MRCP revealed the length of the pancreaticobiliary common channel was 19 mm with absence of dilation of the common bile duct, the pancreatic duct merged with the bile duct (P-B type) and the pancreaticobiliary ductal union was located proximal to the narrow distal segment, which represented the sphincter of Oddi, APBDU was diagnosed by intraoperative cholangiography concordant with the MRCP diagnosis. Normal control bile was obtained from the common bile duct of another patient (male, 41) with gastric cancer and a normal hepatobiliary tract. Both patients had not taken any nonsteroidal anti-inflammatory drugs, antibiotics or anti-tumor drugs before the operation. Bile samples were sterile and filtered (0.22 μ m, Millipore) twice immediately and stored at -80 °C. PBS (pH7.2) was used as negative control. Human extrahepatic cholangiocarcinoma cell line QBC939 was gifted by professor Wang (Third Military Medical University, China)^[10], the cells were maintained as monolayers in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10 % fetal bovine serum (FBS, Gibco, USA.), 100 units/ml penicillin and 100 mg/ml streptomycin in a humidified atmosphere of 95 % air and 5 % CO₂ at 37 °C. PGE₂ ELISA detection kit was purchased from Jingmei Biotech Co., Wuhan, China. Celecoxib was provided by Dr. Mei (Wuhan University, China)^[11]. Stock solution was prepared in dimethylsulfoxide (DMSO) and stored at -20 °C. In all experiments the final concentration of DMSO in the medium was ≤ 0.1 %.

Methods

Cytotoxicity pretesting Cytotoxicity pretesting was taken with each of the gradient in diluted bile sample to determine the concentration of experimental bile samples. Our results showed that 1 % bile (10 μ L bile/mL medium) was not cytotoxic to QBC939 cells.

MTT assay The proliferating status of human cholangiocarcinoma cells QBC939 was determined by MTT assay. Cholangiocarcinoma cells were seeded at a density of 1×10^4 cells per well in flat-bottomed 96-well microplates. 12 h after incubation, the cells were treated with 1 % bile with or without 20 μ mol/L celecoxib. After 72 h incubation, 20 μ L MTT (5 g/L) was added to each well and cultured for 4 h. Upon removal of the supernatant, added DMSO 150 μ L and shook for 5 min until the crystals were dissolved. OD490nm value was measured by enzyme-linked immunoabsorbent assay. The negative control well was used as zero point of absorbance. Each assay was performed three times in triplicate.

ELISA The PGE₂ levels in the supernatant of the cultured human cholangiocarcinoma cells QBC939 were quantitated

by ELISA. Cells were seeded into 24-well microplates (4.0×10^5 /well) and allowed to adhere overnight. The cells were then incubated in presence 1 % bile with or without 20 $\mu\text{mol/L}$ celecoxib for 48 h. The supernatants were aspirated and centrifuged to prepare for the detection of PGE_2 . 0.5 mL supernatant was added into 1 N HCl 0.1 mL and centrifuged for 10 min at room temperature; then 1.2 N NaOH 0.1 mL was used to neutralize the acidified samples. Standard solution (200 μL /well) or activated samples were added into the microplates. Then the steps were proceeded as instructed. The value of OD of each well was determined at 450nm. The supernatants were harvested in triplicate and the experiment was performed three times.

Flow cytometric analysis Human cholangiocarcinoma cells QBC939 were trypsinized and plated in 6-well culture dishes in presence of 1 % APBDU bile or 1 % normal bile. After 24 h, the cells were harvested, centrifuged at low speed and fixed in 70 % ethanol. After overnight incubation at 4 °C, the cells were stained with 50 $\mu\text{g/ml}$ propidium iodide in presence of RNasin A (10 $\mu\text{g/ml}$) and 0.1 % Triton X-100 and determined by flow cytometer.

RT-PCR QBC939 cells were cultured in presence of 1 % APBDU bile, 1 % normal bile or 1 % PBS for 3 d. The total RNA was prepared from subconfluent cultures with RNA-SOLV reagent (Omega) according to the manufacture' instruction. The primers were designed to amplify a fragment of COX-2 cDNA based on the reported sequence for human COX-2. To normalize the amount of input RNA, RT-PCR was performed with primers for the constitutively expressed β -actin gene. The COX-2 primers were 5' - ACAATGCTGACTATGGCTAC-3' (sense) and 5' - AACTGATGCGTGAAGTGCTG-3' (antisense), giving rise to a 238 base pair polymerase chain reaction production. The β -actin primers were 5' -GTGCGTGACATTAAGGAG-3' (sense) and 5' -CTAAGTCATAGTCCGCCT-3' (antisense), giving rise to a 520 base pair polymerase chain reaction production. The first strand cDNA synthesis and the subsequent PCR were performed with RNA PCR kit (AMV) using a programmed temperature control system set for 30 cycles of denaturation at 94 °C for 45 s, annealing at 58 °C for 30 s, and extension at 72 °C for 60 s. 10 μL reaction mixture was electrophoresed on a 1.5 % agarose gel, and the PCR products were visualized by ethidium bromide staining and quantified by an ImageQuant software. COX-2 mRNA expression level was determined by COX-2/ β -actin protein.

Statistical analysis

The data were expressed as $\bar{x} \pm s$. Student's *t*-test was used for statistical analysis. $P < 0.05$ indicated significant difference.

RESULTS

Assay of COX-2 activity

PGE_2 levels in the supernatant released by the cultured human cholangiocarcinoma cells QBC939 determined the COX-2 activity. The concentrations of PGE_2 in culture medium of QBC939 cells treated with 1 % APBDU bile or 1 % normal bile with or without 20 $\mu\text{mol/L}$ celecoxib for 48 h were quantitated by ELISA. APBDU bile could induce the release of PGE_2 in QBC939 cells: the PGE_2 level was higher significantly ($P=0.004$) in APBDU bile group (187.1 ± 14.0 ng/well) as compared with that in normal bile group (139.4 ± 15.3 ng/well). Celecoxib could suppress PGE_2 production of the QBC939 cells, the PGE_2 concentration was (65.2 ± 10.6) ng/well and (57.0 ± 9.8) ng/well in APBDU bile group and normal bile group respectively when pre-treated with 20 $\mu\text{mol/L}$ celecoxib, there was no statistical difference between the two group ($P=0.09$).

Effects of bile on the proliferation activity of QBC939

QBC939 cells were incubated in 1 % bile with or without 20 $\mu\text{mol/L}$ celecoxib, and the cells density was measured by MTT assay. APBDU bile could significantly promote the proliferation of QBC939 cells as compared with normal bile ($P=0.005$), and the proliferative effect of APBDU bile could be abolished by addition of 20 $\mu\text{mol/L}$ celecoxib ($P=0.103$, Table 1).

Table 1 Effects of bile on the growth of QBC939 with or without celecoxib

Group	OD ₄₉₀	P	+CE OD ₄₉₀	P
A	0.82±0.19	^b $P=0.008$, ^d $P=0.005$	0.33±0.14	^b $P=0.297$, ^d $P=0.103$
B	0.47±0.14	^b $P=0.398$	0.26±0.07	^b $P=0.052$
C	0.43±0.10		0.24±0.09	

QBC939 cells were incubated in 1 % APBDU bile (A), 1 % normal bile (B) or 1 % PBS (C) with or without 20 $\mu\text{mol/L}$ celecoxib (+CE), and the cells density (OD_{490nm}) was measured by using MTT assay. Data were expressed as $\bar{x} \pm s$, b vs C, d vs B.

Flow cytometric analysis of proliferative index of QBC939 cells

The QBC939 cells proliferative index (PI) increased significantly ($P=0.003$) after treatment with 1 % APBDU bile (60.59 ± 4.06) as compared with that of the normal bile (28.69 ± 1.79 , Figure 2), $\text{PI} = (\text{S} + \text{G}_2/\text{M}) \times 100\%$.

Figure 1 Expression of COX-2 mRNA, β -actin served as control. M: DL2,000 marker; 1: normal bile; 2 and 4: APBDU; 3: PBS.

Figure 2 Representative data of cell cycle from QBC939 cells in the presence of 1 % APBDU bile ($\text{S} + \text{G}_2/\text{M} = 65.12\%$) or 1 % normal bile ($\text{S} + \text{G}_2/\text{M} = 30.47\%$) for 24 h was analyzed by flow cytometry.

Expression level of COX-2 mRNA

APBDU bile could markedly ($P=0.004$) up-regulate the COX-2 mRNA expression of QBC939 cells (Figure 1, Ttable 2).

Table 2 Expression level of COX-2 mRNA

Group	n	COX-2/ β -actin	t	P
A	6	0.4322 \pm 0.0448	^b t=11.556, ^d t=5.010	^b P<0.001, ^d P=0.004
B	6	0.2267 \pm 0.0638	^b t=1.820	^b P=0.128
C	6	0.1367 \pm 0.0653		

COX-2 mRNA expression level was determined by COX-2/ β -actin protein. Data were expressed as $\bar{x}\pm s$, b vs C (PBS), d vs B (normal bile), A: APBDU.

DISCUSSION

A frequent association of biliary tract carcinoma and APBDU is well recognized^[12-19], especially in the undilated type APBDU^[20, 21]. Mori^[7] had reported that among 698 patients subjected to endoscopic retrograde cholangiopancreatography, APBDU was found in 6 patients (0.9 %). 4 of these 6 patients had no associated congenital choledochal cyst, and two patients had advanced gallbladder cancer. The remaining 2 patients had no associated carcinoma of the biliary tract. They further studied 28 such APBDU without choledochal cyst cases. The clinicopathological data showed that the thickness of the gallbladder wall was visualized in 26/28 (92.9 %) patients. Some researchers^[20-22] had reported that patients with adenomyomatosis (a presumed premalignant lesion of the gallbladder) were frequently associated with the undilated type APBDU. Tanno^[23] reported 15/24 (63 %) of APBDU patients had epithelial hyperplasia of the gallbladder, the incidence of which was significantly higher in the gallbladders of undilated type APBDU patients (91 %) than that in dilated type patients (38 %). Ki-67 labeling index was significantly higher in hyperplastic mucosa than that in the control gallbladder mucosa. 2/9 (22 %) high grade hyperplasia cases had K-ras mutations. Their results suggested that hyperplasia of the gallbladder mucosa in APBDU patients was an early change. Cell kinetic studies of gallbladder epithelial cells by Yang^[24] had shown the Ki-67 labeling index, PCNA labeling index and BrdU labeling index of the noncancerous mucosa in patients with APBDU and/or gallbladder carcinoma were significantly higher than those in patients without APBDU and gallbladder carcinoma.

Increase of the secondary and free bile acid concentrations is considered a risk factor for biliary carcinogenesis in APBDU patients. Sugiyama^[25] had suggested that elevation of the lysolecithin (LL) in the bile was one of the factors for development of biliary tract carcinoma in patients with APBDU: the LL in the phospholipid produced from lecithin by activated phospholipase A₂ in the refluxed pancreatic juice, was significantly elevated in the APBDU group. Yoon^[26] also indicated that bile acids induced both EGFR phosphorylation and enhanced COX-2 protein expression. EGFR was activated by bile acids to induce COX-2 expression by a MAPK cascade. The induction of COX-2 might participate in the genesis and progression of cholangiocarcinoma.

In an effort to delineate the underlying mechanism of the carcinogenesis in APBDU and the effects of COX-2 gene in the proliferative activity induced by APBDU bile, we used the bile from APBDU to see the direct effect on the human cholangiocarcinoma QBC939 cells *in vitro* to determine the effect of APBDU bile on the growth of human cholangiocarcinoma cells. Our data show that APBDU bile could significantly promote the proliferation of human cholangiocarcinoma QBC939 cells and up-regulated remarkably their COX-2 mRNA expression, and the proliferative activity of APBDU bile could be abolished by adding cyclooxygenase-2 specific inhibitor celecoxib. Our

study indicated that APBDU bile promoted the proliferation of human cholangiocarcinoma QBC939 cells via COX-2 pathway.

Substantial evidences have shown that COX-2 is important in carcinogenesis^[27-33]. Celecoxib as a new COX-2 selective inhibitor has shown its safety and efficiency in human and animals. Several studies have demonstrated that celecoxib has significant efficacy in animal models: Celecoxib inhibited intestinal tumor multiplicity up to 71 % as compared with controls in the Min mouse model, and inhibited colorectal tumor burden in the rat azoxymethane (AOM) model^[34-36]. Recently celecoxib has been approved by the FDA to reduce the number of adenomatous colorectal polyps in patients with familial adenomatous polyposis (FAP). Our data suggested that celecoxib as a chemopreventive and chemotherapeutic agent might be effective in cholangiocarcinoma and could be used as a chemopreventive strategy in the people of high-risk conditions for the development of cholangiocarcinoma such as APBDU. Our study demonstrated that the QBC939 cells proliferative index increased significantly after treated with APBDU bile for 24 h. These data suggested that APBDU bile could affect the QBC939 cell proliferation cycle.

In conclusion, APBDU bile can promote the proliferative activity of human cholangiocarcinoma QBC939 cells and the effect is via COX-2 pathway.

Abstract

AIM: To evaluate the clinical, radiological and microbiological properties of abdominal tuberculosis (TB) and to discuss methods needed to get the diagnosis.

METHODS: Thirty-one patients diagnosed as abdominal TB between March 1998 and December 2001 at the Gastroenterology Department of Kartal State Hospital, Istanbul, Turkey were evaluated prospectively. Complete physical examination, medical and family history, blood count erythrocyte sedimentation rate, routine biochemical tests, Mantoux skin test, chest X-ray and abdominal ultrasonography (USG) were performed in all cases, whereas microbiological examination of ascites, upper gastrointestinal endoscopy, colonoscopy or barium enema, abdominal tomography, mediastinoscopy, laparoscopy or laparotomy were done when needed.

RESULTS: The median age of patients (14 females, 17 males) was 34.2 years (range 15-65 years). The most frequent symptoms were abdominal pain and weight loss. Eleven patients had active pulmonary TB. The most common abdominal USG findings were ascites and hepatomegaly. Ascitic fluid analysis performed in 13 patients was found to be exudative and acid resistant bacilli were present in smear and cultured only in one patient with BacTec (3.2 %). Upper gastrointestinal endoscopy yielded nonspecific findings in 16 patients. Colonoscopy performed in 20 patients showed ulcers in 9 (45 %), nodules in 2 (10 %) and, stricture, polypoid lesions, granulomatous findings in terminal ileum and rectal fistula each in one patient (5 %). Laparoscopy on 4 patients showed dilated bowel loops, thickening in the mesentery, multiple ulcers and tubercles on the peritoneum. Patients with abdominal TB were divided into three groups according to the type of involvement. Fifteen patients (48 %) had intestinal TB, 11 patients (35.2 %) had tuberculous peritonitis and 5 (16.8 %) tuberculous lymphadenitis. The diagnosis of abdominal TB was confirmed microbiologically in 5 (16 %) and histopathologically in 19 patients (60.8 %). The remaining nine patients (28.8 %) had been diagnosed by a positive response to antituberculous treatment.

CONCLUSION: Neither clinical signs, laboratory, radiological and endoscopic methods nor bacteriological and histopathological findings provide a gold standard by themselves in the diagnosis of abdominal TB. However, an algorithm of these diagnostic methods leads to considerably higher precision in the diagnosis of this insidious disease

which primarily necessitate a clinical awareness of this serious health problem.

INTRODUCTION

Tuberculosis (TB) was a prevalent infection even in Ancient Greek and Egypt. The disease could be taken under control only after the advent of antimicrobial therapy in 1946. However, it has started to resurge worldwide in the last 10 years, due to HIV epidemic and to primary resistance to first-line drugs. One-third of the world population is under the risk of acquiring TB according to WHO and more than 30 million deaths had been expected due to TB in the nineties especially in Africa and Asia^[1]. Not surprisingly, there is also an increase in the percentage of patients with atypical presentations and atypical extra-pulmonary forms of TB. Extra-pulmonary organ involvement of TB is estimated as 10-15 % of patients not infected with HIV whereas the frequency is about 50-70 % in patients infected with HIV^[2].

Abdominal TB is one of the most prevalent forms of extra-pulmonary disease. Gastrointestinal involvement had been reported to be 55-90 % in patients with active pulmonary TB before the advent of specific anti-TB treatment. But it was regressed to 25 % after the development of specific drugs^[3]. The abdominal form of TB has an insidious course like any other chronic infectious disease without any specific laboratory, radiological or clinical findings. Due to this non-specificity there are great difficulties in its diagnosis. Various methods of investigation had been reported as the gold standard of diagnosis in earlier studies; however there are great difficulties in clinical practice. As a result, the diagnosis of abdominal TB is still a challenge to the physician. In the present prospective study, we analyzed the clinical, laboratory, radiologic, endoscopic and microbiological features of abdominal TB patients in order to evaluate the diagnostic value of various methods and to define the correct tool of diagnosis.

MATERIALS AND METHODS

Thirty-one patients were diagnosed as abdominal TB in Gastroenterology Department of Kartal State Hospital-Istanbul, between March 1998 and December 2001. On admission, every patient had a complete physical examination, medical and family history, blood count and erythrocyte sedimentation rate (ESR), routine biochemical tests, Mantoux skin test, chest X-ray and abdominal ultrasonography (USG). After these basic investigations, an algorithm of diagnostic evaluation was applied according to the presence of certain symptoms, namely, ascites, upper gastrointestinal symptoms, chronic or bloody diarrhea, change in bowel habits, malabsorption, and additional suspicious lesions in other body parts. If present, ascites was taken for direct examination and culture for *Mycobacterium tuberculosis*. Patients complaining of dyspepsia, abdominal pain, vomiting, upper gastrointestinal bleeding or gastric

distention had an upper gastrointestinal endoscopy. 3 to 4 gastric biopsies were routinely taken from corpus and antrum during the endoscopy and the specimens were investigated for mycobacterium tuberculosis or the presence of granulomas. If the patient had symptoms suggestive of intestinal TB like chronic diarrhea, bloody stools or change in bowel habit, stool was examined for bacilli and culture for mycobacterium tuberculosis was done. Then, colonoscopy, or in patients with problems of performing colonoscopy, barium enema was performed. Eight to ten biopsies were taken for histopathologic and microbiological examinations if any lesions were found present during colonoscopy. Signs of small bowel involvement like malabsorption were evaluated with small bowel series. Any abnormality of abdominal organs, lymph nodes, mesentery and peritoneum seen on abdominal USG examination was evaluated by abdominal CT. Otherwise routine abdominal CT was not done. If necessary for any additional suspected lesions, mediastinoscopy, laparoscopy or laparotomy was also performed. In the presence of any pathological findings, multiple biopsies were taken and sent for bacteriological and histopathological investigations. A microbiological diagnosis was attempted in all cases. However, in some of the patients where no microbiological diagnosis could be met despite every effort, the histopathological finding of typical caseating granulomas was accepted as a definite evidence of TB. In patients where none of the diagnosis was available and clinical suspicion of abdominal TB was high, a therapeutic trial of anti-TB treatment with four agents (Rifampicin, Ethambutol, Isoniazid and Morphozinamide) was started, and response to treatment was evaluated after three months.

We treated all patients with the standard four-drug regimens (streptomycin or ethambutol, rifampin, pyrazinamide, isoniazid) for 9 months and the patients were reevaluated again at the end of this time. If there was no resolution of symptoms and Mycobacterium tuberculosis was still present in any specimen, an additional 9-months of treatment was given.

RESULTS

Thirty-one patients with abdominal TB (14 females, 17 males) with a median age of 34.2 years (range 15-65 years) were diagnosed in 5 years. A past medical history of pulmonary TB was obtained in 6 patients (19.2 %) and of bone TB in 2 patients (6.4 %). There was a family history of TB (in the first-degree relatives of index patient) in 8 (25.6 %). The mean duration of symptoms showed great variation among the patients (range 1 month-11 years).

The presenting symptoms and signs were summarized in Table 1. Abdominal pain and weight loss appeared to be the most frequent symptoms among these.

Laboratory investigations revealed anemia in 22 (70.4 %), elevated ESR in 20 (64 %), and hypoalbuminaemia in 15 (48 %) patients as the most prominent features. Other findings were leucocytosis in 2 (6.4 %), positive CRP in 5 (16 %), elevated transaminases in 7 patients (22.4 %). Of these 7 patients, 2 were chronic HBV carriers, 1 was immune to HBV and 1 was anti-HCV positive. In 4 patients (12.8 %), all laboratory examinations were within normal limits.

Mantoux skin test was found positive in 6 (19.2 %) of the patients. There was ascites in 13 (41.6 %). Ascitic fluid analysis performed in those patients was found to be exudative in character and only in one patient acid-fast bacilli (ARB) were present in smear and cultured only in one patient with BacTec (3.2 %).

In 11 patients (35.2 %), chest X-ray showed lesions compatible with active pulmonary TB, like fibrocavitary lesions, effusions, or lymphadenopathies. Thorax CT was carried out on these patients and lung lesions such as pleural

involvement, lymphadenopathy or nodular infiltration were present in all of them. Thorax CT did not provide additional data in comparison to chest X-ray.

Abdominal USG was performed on all patients except in five because of technical problems due to recent operations. USG findings of 26 patients were summarized in Table 2. Abdominal CT was performed on 22 of these patients who presented with abnormal findings in USG. Ascites in 8 (36.3 %), thickening of mesentery in 5 (22.7 %), abdominal lymphadenopathy in 3 (13.6 %), omental pathology in 3 (13.6 %) and lymphadenopathy in liver hilum, cholelithiasis, destruction in sacral bone, ovary cyst and splenomegaly each for one (4.5 %) occasions had been observed as the most important CT findings among these patients. Only 3 patients (13.6 %) presented with completely normal CT examination.

Table 1 Presenting symptoms (*may be more than one in each patient*) and signs and their frequency in patients (n=32)

Symptoms and signs	Number of patients	Percentage (%)
Abdominal pain	16	51.2
Weight loss	16	51.2
Ascites	12	38.4
Diarrhea	10	32
Cough and sputum	6	19.2
Vomiting and nausea	5	16
Fever	4	12.8
Perforation	3	9.6
Bone pain	2	6.4
Night sweats	2	6.4
Urinary symptoms	1	3.2
Mass in the lower quadrant	1	3.2
Cervical pain	1	3.2
Evisceration following laparotomy	1	3.2
Incidental	1	3.2
Operation because of brid ileus	1	3.2

Table 2 Abdominal ultrasonographic findings (*may be more than one in each patient*) and their frequency in the patients (n=26)

Abdominal USG findings	Number of patients	Percentage (%)
Normal	4	17.2
Ascites	14	53.2
Hepatomegaly	4	17.2
Thickening	3	11.4
Atrophic	2	7.6
Abdominal	2	7.6
Hepatosteatosi	2	7.6
Splenomegaly	1	3.8
Pericardial	1	3.8
LAP	1	3.8
Calcifications	1	3.8

Small bowel follow-up was done on seven patients and the bowel was significantly shortened due to extensive resection because of perforation in one of them. Barium enema was performed on two, and there was irregularity and ulcers in the bowel wall of one patient's.

Upper gastrointestinal endoscopy was performed in 17 patients and showed nonspecific findings in 16. In every case, gastric biopsies were taken but no acid-resistant bacilli (ARB) or granulomas were identified in tissue sections.

Colonoscopy was performed in 20 patients. There was no abnormality in 8 patients (40 %). Ulcers in 9 (45 %), nodules in 2 (10 %) and, stricture, polypoid lesions, granulomatous

findings in terminal ileum and rectal fistula each in one (5 %), occasions were found in these patients.

Laparoscopy was performed on 4 patients and there were positive findings in all of them. Dilated bowel loops, thickening in the mesentery, multiple ulcers and tubercles on the peritoneum, each for once, were observed in these patients. Peritoneal biopsies confirmed the diagnosis of tuberculosis in three of these patients. In the fourth patient, a peritoneal biopsy could not be taken because of high bleeding risk due to a very long prothrombin time.

Mediastinoscopy in one patient, and fine needle aspiration biopsy of the lymphadenopathy in liver hilum in another one were performed to confirm the diagnosis. In only 2 patients of the whole series, the diagnosis was clarified by biopsies taken in an operation under general anesthesia (one was operated because of bulging cervical disc and the other because of intestinal obstruction).

Patients with abdominal TB were divided into three groups according to the type of involvement. 15 patients (48 %) had intestinal TB, 11 patients (35.2 %) tuberculous peritonitis and 5 (16.8 %) tuberculous lymphadenitis.

It was able to confirm the diagnosis of abdominal tuberculosis microbiologically in 5 patients (16 %). Two of these patients were diagnosed by positive ARB smears of sputum, 1 with ARB in enterocutaneous fistula discharge, 1 with ARB in ascitic fluid, and 1 with ARB in biopsy material. Two patients were found positive in BacTec, but none of these patients had positive culture on Löwenstein medium. Nineteen patients (60.8 %) were diagnosed histopathologically and the diagnosis in the remaining nine patients (28.8 %) have been reached by a positive response to antituberculous treatment. In 2 patients, there were both, histopathologic and microbiologic diagnosis of tuberculosis.

Twenty-eight patients were symptom-free after 9 months of treatment. Furthermore, no pathological findings were observed in the next follow-up visits after six months. In the remaining 3 patients, the disease had a complicated course and although antituberculous treatment with four agents (streptomycin or ethambutol, rifampin, pyrazinamide, isoniazid) was begun, mammarian abscess developed in one of them, osteomyelitis and enterocutaneous fistula in the second patient, and incisional enterocutaneous fistula in the last patient.

DISCUSSION

Abdominal TB is again on the rise all over the world with the resurgence of multidrug resistant TB and with AIDS pandemic. It is also an increasing health problem because of the immigrants from underdeveloped countries where it is more common. However, this topic is still restricted within a few paragraphs in the textbooks and the current knowledge of abdominal TB has to be updated. Sensitivity of various methods have already been speculated in previous studies without any serious conclusion. In the present study we aimed to investigate the relative reliability of these tools in the diagnosis of abdominal TB which has an exceptionally insidious course. As shown in the present study, the clinical and laboratory features of abdominal TB are nonspecific and lead to the suspicion of only a chronic infectious disease.

Three diagnostic stages have been evaluated in the diagnosis of abdominal TB. The first two stages, clinical evaluation of the patient and the radiologic examination, give indirect evidence of the disease. The third stage includes the invasive techniques to achieve direct evidence. However, the diagnosis of TB has its own difficulties that these evidences generally come out to be relatively direct in practice.

The vague character of symptoms has been previously defined in many studies^[4,5] and the radiographic presentation of this disease which frequently mimics many other conditions

has already been described^[6,7]. The combination of mesenteric thickening of 15 mm with associated mesenteric lymphadenopathy has been stated as a prominent sonographic finding in abdominal TB^[8,9] which could not be confirmed in our study. We found rather nonspecific findings in abdominal ultrasonography such as ascites and hepatomegaly. However, CT features of abdominal TB have been reported to be of value in the diagnosis^[10] and the ability to differentiate TB peritonitis from malignant diseases of the peritoneum could be increased by combining some CT findings^[11]. The same is true for this study; we had a positive finding in 88 % of the patients in abdominal CT. The results obtained on CT scans are comparable to USG findings in the literature^[4]. Thus abdominal CT findings appear to provide more objective data about the disease than other radiological methods.

The invasive diagnostic tools have the very real advantage of examining the lesion itself either macroscopically or microscopically. However, even these direct methods have their own drawbacks in clinical practice.

Colonoscopic findings of abdominal TB are problematic because of segmentary involvement of the disease^[12] and because of low yield of granulomas as a result of submucosal disease. In a study of Singh and associates^[13], granulomas were seen in 44 % of the patients, and 19 % of them had caseation. We could find colonoscopic abnormalities in 60 % of the patients and confirm TB histopathologically. However, colonoscopy is still mandatory to obtain tissue for culturing the agent which is very important for the diagnosis of intestinal TB.

The sensitivity of endoscopic biopsy ranges between 30 and 80 % and Bhargawa *et al*^[14] suggested obtaining 8 to 10 biopsies for histology and 3 to 4 specimens for culture.

In patients with palpable abdominal masses, direct fine needle aspiration cytology can also be applied^[5]. This method is not feasible in any of our patients because we could not palpate these masses in any of them.

Laparoscopic pattern and biopsies obtained from the peritoneum have been reported to be more helpful and that this finding could be used even for treating patients with abdominal TB without any histopathologic or bacteriologic confirmation^[15]. In the present study, laparoscopy was performed in 4 patients and confirmed the diagnosis histopathologically in 3 and macroscopically in one patient. Thus, it appeared to be a highly sensitive diagnostic tool in all selected patients. In a study of Lisehora *et al*^[16], even mini laparotomy was reported as the most sensitive and specific diagnostic procedure in abdominal TB.

The diagnosis of abdominal TB classically requires microbiological and culture confirmation of mycobacterium tuberculosis, whereas, the diagnosis can be established histopathologically in many studies^[4,15]. Also in the current study, the diagnosis could be reached histopathologically in 60.8 % of the patients. If the isolation of Mycobacterium tuberculosis is accepted as “sine qua non” for this infectious disease according to the postulates of Koch, histopathological diagnosis can not be regarded as standard. However, microbiological isolation of the agent is very rare for patients with abdominal TB. It has remained under 50 % in all the reported series. Isolation of bacilli in endoscopic biopsy materials has been postulated as even to be zero^[12,13]. It is known that Mycobacterium tuberculosis can be occasionally isolated in stool of persons with healthy conditions. Therefore special decontamination techniques and BacTec technology must be used for culture of this agent^[17]. Interestingly, we could not be able to confirm the existence of Mycobacterium tuberculosis in any of our patients using Löwenstein medium that was said to be the ideal culture medium for this bacterium. Even in patients who were ARB positive in direct smear, culture in Löwenstein was not positive; but we had culture positivity in

two patients with BacTec technique. In a case report of Anand and associates^[17], PCR was used on endoscopic biopsy specimens obtained from a patient with chronic diarrhea and the result was found positive.

The isolation of *Mycobacterium tuberculosis* with BacTec or PCR are promising methods for the future but even these methods appear to be far from ideal since it is not enough for the treatment of the disease because of the lack of culture. We think that we have to refine our isolation procedures for the bacterium and in every case of extrapulmonary TB, not only histopathological but also microbiological confirmation should still be sought in order to break the vicious circle of multidrug resistancy.

A past history of pulmonary TB or a family history of TB is quite frequent in patients with abdominal TB^[19] which is also the case in our study. It is known that patients with multidrug resistant organisms acquire the organisms through multiple ineffective courses of treatment with various drugs^[20]. Thus, it can be concluded that most of the cases with abdominal TB have a primary resistance to conventional chemotherapy.

The isolation of mycobacterium tuberculosis is also essential for susceptibility tests which are now performed on every patient with pulmonary TB because of the high incidence of multidrug resistance (it has increased from 2 % to 9 % in the past three decades)^[20].

Based upon our clinical observation with abdominal TB, we can stress on these patient with high resistance because of the long course of the disease and because of frequency of complications. If a better way of isolating the organism cannot be found and if the resistance cannot be detected before starting with the antituberculous treatment, the increase of new TB cases will be inevitable. The problem of mutant strains could also be expected in the future. It is known that two different mutant strains can coexist in the same patient which further complicates the resistance problem. Although the molecular fingerprinting of mycobacterium tuberculosis may help to solve these problems in some extent^[21], these facts should be taken into consideration for future directions in the diagnosis and treatment of abdominal TB.

CONCLUSION

Neither clinical signs, laboratory, radiological and endoscopic methods nor bacteriological and histopathological findings provide a gold standard by themselves in the diagnosis of abdominal TB. However, an algorithm of these diagnostic methods leads to considerably higher precision in the diagnosis of this insidious disease which primarily necessitate a clinical awareness of this serious health problem.

Abstract

AIM: To analyze factors predisposing to the infections associated with severe acute pancreatitis (SAP) and to work out ways for its prevention.

METHODS: Total 208 cases of SAP treated in this hospital from Jan. 1980 to Dec. 2001 were retrospectively analyzed.

RESULTS: Statistical difference in the incidence of the aforementioned infections was found between the following pairs: between the groups of bloody or non-bloody ascites, paralytic ileus lasting shorter or longer than 5 days, Ranson scores lower or higher than 5, hematocrit lower or higher than 45 %, CT Balthazar scores lower or higher than 7 and between 1980.1-1992.6 or 1992.7-2001.12 admissions ($\chi^2 > 3.84$, $P < 0.05$), while no statistical difference was established between the groups of biliogenic and non - biliogenic pancreatitis, serum amylase < 200 U/L and ≥ 200 U/L, serum calcium < 2 mmol/L and ≥ 2 mmol/L or groups of total parenteral nutrition shorter or longer than 7 days ($\chi^2 < 3.84$, $P > 0.05$).

CONCLUSION: Occurrence of infection in patients with SAP is closely related with bloody ascites, paralytic ileus ≥ 5 days, Ranson scores ≥ 5 , hematocrit ≥ 45 % and CT Balthazar Scores ≥ 7 , but not with pathogens, serum calcium and total parenteral nutrition (TPN). Comprehensive prevention of pancreatic infection and practice of individualized therapy contribute to reducing the incidence of infection.

INTRODUCTION

Severe acute pancreatitis (SAP) characterized by atrocious progression, multi-complications and unquenchable mortality rate is a very dangerous acute abdomen^[1-3]. SAP progresses in two consecutive stages: the earlier stage marked by serious physiological disorder and the later stage presenting with necrosis and infection. The earlier-stage mortality mainly caused by hypovolaemia, shock, adult respiratory distress syndromes (ARDS) and cardiac or renal insufficiency has been

remarkably lowered as a result of the improvement on intensive care for severe diseases in recent years, however the later-stage mortality as a consequence of pancreatic or peri- pancreatic infections and their complications is still above 50 %^[4-6]. Though the primary choice for pancreatic infection was surgery, surgical intervention can not obviously bring down the formidable mortality, thus rendering it extremely valuable to study the predisposing factors and to work out ways for effective prevention.

MATERIALS AND METHODS

Clinical data

Total 208 SAP cases treated in this hospital since Jan. 1980 to Dec. 2001 were selected, which consisted of 112 males and 96 females with an average age of 49 ranging from 18 to 82 years old. All the patients were diagnosed by clinical presentations, biochemical findings and CT scanning on pancreas according to the universal standard for SAP diagnosis in China. Among these 208 cases, 68 were diagnosed as secondary pancreatic infection and the other 114 non-infections. 94 cases admitted between Jan. 1980 and June. 1992 underwent operations in the earlier stage, while the other 114 cases between July 1992 and Dec. 2001 were treated by the principle of "Individualized therapy", which, with emphasis on conservative management in the earlier stage, exploited comprehensive individualized treatments to prevent secondary pancreatic infection. Preventive measures include: (1) volume supplementation, shock correction and protection against multiple organ dysfunction syndrome (MODS); (2) improving pancreatic micro-circulation; (3) decontamination of intestinal tract to facilitate the recovery of gastrointestinal function; (4) preventive prescription of antibiotics; (5) nutritional support; (6) peritoneal lavage or drainage in case of retention with a great amount of exudates in the abdominal cavity. The criteria for diagnosis of pancreatic infection are: (1) body temperature continuously ≥ 38.5 °C, white blood cell count (WBC) $\geq 20 \times 10^9/L$ and signs of peritoneal irritation in more than 2 quadrants; (2) air bubbles in necrotic tissue of the pancreas by enhanced CT scanning; (3) bacteria found by culture or smear examination on fine needle aspirate.

Statistical analysis

All the data was analyzed by chi-square test.

RESULTS

Analysis of factors inducing pancreatic infection

Table 1 shows that statistical difference existed between the groups of bloody and non-bloody ascites, paralytic ileus lasting shorter or longer than 5 days, Ranson scores lower or higher than 5, hematocrit lower or higher than 45 %, CT Balthazar scores lower or higher than 7 and between 1980.1-1992.6 or 1992.7-2001.12 admissions ($\chi^2 > 3.84$, $P < 0.05$), while no statistical difference was found between the groups of biliogenic and non - biliogenic pancreatitis, serum amylase < 200 U/L and ≥ 200 U/L, serum calcium < 2 mmol/L and

≥ 2 mmol/L or groups of total parenteral nutrition shorter or longer than 7 days ($\chi^2 < 3.84$, $P > 0.05$).

Table 1 Factors predisposing to infections associated with SAP

Factors	Total cases	Incidence of infections			P values

DISCUSSION

More than 80 % of mortality in SAP is related with infection, mainly the secondary infection in the tissues^[7-9]. Secondary pancreatic infections including infective pancreatic necrosis, pancreatic abscess and infective pancreatic pseudocyst are responsible for more than 90 % of systematic infections and predispose to acute injury of gastric mucosa, hemorrhage in the abdominal cavity, fistula of digestive tract and multiple organ failure. Baron *et al* deemed that the morbidity of secondary infection was 30-70 %^[10], while a morbidity of 32.7 % was demonstrated in this study. The mechanisms of secondary infection have not been fully elucidated yet. Gastrointestinal paralysis and edema of the intestinal mucosa caused by pancreatic enzymes and many other bioactive and toxic substances released in the acute stage give rise to disorder and translocation of bacterial clusters as well as atrophy of the intestinal mucosa lack of stimulus from food as a result of long-term (more than 1 week) gastric decompression. TPN impairs the mononuclear phagocytic system and thus weakens the intestinal immunity, which in turn promotes intestinal bacteria translocation making secondary infection inevitable^[11-13]. In our experience the main cause of mortality in the later stage of SAP (after 2 weeks) was pancreatic infection or multiple organ

system failure (MOSF). To prevent secondary pancreatic infection is essential to reducing the mortality of SAP. Therefore it is of chief importance to understand the factors related to pancreatic infection before any prevention is undertaken against it^[14,15].

Our data did not indicate obvious relationship between the incidence of secondary infection and etiology of pancreatitis, serum amylase, serum calcium and TPN. Biliogenic pancreatitis is generally considered as a high risk factor to pancreatic infection, since it is always accompanied by biliary tract infection. However such consequence is not confirmed by our data, which may be that the secondary infection of SAP is mainly entero-genic. Whether TPN increases the incidence of secondary infection is still controversial^[16-18], but there is an evidence that long-term central venous catheter deposit, tedious intubating manipulation and improper nursing of catheter lead to certain catheter-related infections, which are proved to give priority to G⁻ bacteria, whereas in our study, to G⁺ bacteria instead. Accordingly, it may be concluded that TPN has no marked relationship with infections caused by intestinal bacteria translocation.

According to our data, bloody ascites, paralytic ileus ≥ 5 days, Ranson scores ≥ 5 , hematocrit ≥ 45 % and CT Balthazar scores ≥ 7 predispose to secondary pancreatic infection. Great amount of bloody ascites indicating severe hemorrhage and necrosis of the pancreas and dissemination of inflammatory mediators throughout the abdominal cavity can not be absorbed in most cases if not timely eliminated, and it acts as an important initiator giving rise to or worsening the ongoing intra-peritoneal infection. The relationship between pancreatic infection and the extent of pancreatic or peri-pancreatic necrosis graded by CT Balthazar scoring has been confirmed by many investigations^[19,20], but intestinal malfunction as an initiative to bacteria translocation and pancreatic infection has been ignored although the latter two are being investigated more deeply, producing the concept of preventive prescription of intra-intestinal antibiotics in view of pancreatic infection. Recently, some traditional Chinese medical doctors, who have achieved prominent efficacy using prescriptions emphasized on Tungli (an acupoint) and purgation, found the earlier the intestinal malfunction corrected, the lower the incidence of secondary pancreatic infection in the later stage was, otherwise the high incidence of both MOSF in the earlier stage and secondary pancreatic infection in the later stage persists. Ranson's grading system as a standard to evaluate the severity of acute pancreatitis and to determine its prognosis went into practice in 1974 and has been proved efficient ever since by both domestic and foreign researchers. In our study, the coincidence of secondary infection with the Ranson's score of SAP was established.

Recently, some scholars pointed out that pachyhememia poses threat in the earlier stage of SAP, as Hayakawa demonstrated that apparent reduction of circulation volume and pachyhememia existed in patients with SAP and suggested hemoglobin >150 g/L as a preliminary indicator to pachyhememia^[21]. Baillargeon's study demonstrated that pachyhememia with hematocrit ≥ 47 % at admission or HCT staying high in 24 hours after admission points to SAP and helps evaluate the extent of pancreatic necrosis and predict the onset of MOSF^[22,23]. In this study, hematocrit was obtained in the earlier stage of SAP before any intervention, which precisely reflected the extent of pachyhememia. Our data further demonstrated that pachyhememia is closely related with secondary infection of SAP, but the mechanism was unknown. We deem it may be that the exudation of large amount of plasma from circulation into the third space through the capillary bed with enhanced permeability by activated pancreatic enzymes and other vaso-active substances produced by SAP results in systemic

pachyemia, elevated HCT count and deteriorated pancreatic micro-circulation and eventually leads to pancreatic infection. We also found that the incidence of pancreatic infection in the group admitted in 1992-07/2001-12 was significantly lower than that in the group of 1980-01/1992-06 admission. The reasons were: (1) application of "individualized therapy" on SAP; (2) adoption of comprehensive prevention against secondary pancreatic infection. The patients admitted during 1980-01/1992-06 underwent operations in the earlier stage, which as a matter of fact, not only aggravated the instability of circulation in the earlier stage or even caused shock rather than reduced the incidence of MOSF, but also destroyed the integrity of the pancreas, hampered its self-healing process, gave rise to further ischemia and necrosis after the operation and rendered it a site vulnerable to bacteria translocation increasing the incidence of pancreatic infection.

While in recent years, as to the patients admitted in 1992-07/2001-12 "Individualized therapy" was adopted, which with emphasis on conservative management in the earlier stage employs comprehensive individualized treatments to prevent secondary pancreatic infection and alternates to surgical operations if failed. Comprehensive preventions include: (1) blood volume supplementation, shock correction and especially preventions against multi-organ low perfusion injury and MOSF in the earlier stage of SAP. Ischemia and anoxia are responsible for pancreatic necrosis, damage to gastrointestinal mucosal barrier, bacteria translocation and even malfunction of the heart, the kidneys or the lungs; (2) to improve the microcirculation: by decreasing the fragility of RBC and lowering blood viscosity, the combined administration of Dextran, Saliva miltorrhiza, Ca^{2+} -blocker and large dosages of dexamethason maintains hyperdynamic circulation, which is efficient in oxygen transportation. Therefore, pancreatic and systemic micro-circulation is protected and intracellular Ca^{2+} overload prevented, resulting in alleviated necrosis of the pancreatic acinar, suppression of various inflammatory mediators and lowered incidence of micro-thrombocytosis; (3) intestinal decontamination to facilitate the recovery of gastrointestinal function: traditional Chinese cathartic herbs including castor oil and magnesium sulfate were early administrated to achieve decontamination, which not only decrease the population of intestinal bacteria but also promote gastrointestinal peristalsis eliminating "dead cavities". Translocation of intestinal bacteria as the principal cause of secondary infection is thus constrained. Moreover, physical therapy targeted at the gastrointestinal tract is helpful for the recovery of its function; (4) preventive administration of antibiotics: the antibiotics against G⁻ bacilli especially those capable of passing through the blood-pancreas barrier such as third generation cephalosporin, imipenem, tinidazole, etc are effective, while other antibiotics such as first generation cephalosporin, ampicillin, amikacin, etc have been proved ineffective thus improper for prescription^[24,25]. (5) nutritional support: enough energy should be supplemented by means of EN (enteral nutrition) or TPN (total parenteral nutrition) to stop self burning, potentiate resistance against infection and accelerate tissue healing^[26]. Recent study shows that pure TPN reduces the production of saliva, gastric juice, intestinal juice and bile, which are essential to the integrity of gastrointestinal barrier and function. Though a necessary part of the therapeutic planning, single application of TPN can not reverse hypercatabolism in the earlier stage but together with fasting, enhances the permeability of the intestinal mucosa. It is suggested that TPN should give way to EN when the digestive tract restore the ability to bear food load; (6) peritoneal lavage and drainage of effusion^[27]: Beger argued that severe intra-peritoneal hyperbaric status might lead to the death of patients with SAP^[28,29]. When large amount of ascites develops in SAP

patients, active peritoneal lavage or ultrasonic B or CT guided drainage through a small abdominal incision should be employed to eliminate activated inflammatory mediators and toxic peritoneal exudates, so that toxin intake and intra-peritoneal hyperbaric status can be alleviated. By these measures certain cases, on which conservative treatment is ineffective, avoid the operations aimed at establishing peri-pancreatic drainage in the earlier stage and the incidence of secondary pancreatic infection is thus reduced.

Abstract

AIM: To determine the prevalence of nonalcoholic fatty liver in a specific population in Shanghai by an epidemiological survey, and to analyze risk factors of fatty liver.

METHODS: Total 4009 administrative officers who denied regular alcohol drinking participated in the survey, and underwent physical examination and laboratory tests. The important parameters were body mass index (BMI), waist hip circumferences ratio (WHR) and levels of serum lipids. Diagnosis of fatty liver was based on established real-time ultrasonographic criteria, the presence of an ultrasonographic pattern consistent with "bright liver", with evident ultrasonographic contrast between hepatic and renal parenchyma, vessel blurring, and narrowing of the lumen of the hepatic veins. Analysis of data was performed through SPSS for Windows statistical package.

RESULTS: The overall prevalence of fatty liver was 12.9 %, 15.8 % in males and 7.5 % in females, and the prevalence of fatty liver in males younger than 50 years old, was significantly higher (13.3 %) than that of in females (2.7 %). But the difference between the sexes became less significant in people older than 50 years (19.1 % vs 18.1 %). The prevalence of fatty liver was increased with age; this was markedly presented in females younger than 50 years. Multiple variant regression analysis demonstrated that the prevalence of fatty liver was positively correlated to several risk factors, including male, aging (>50yr), hyperlipidemia, impaired glucose tolerance/diabetes mellitus, hypertension and overweight/obesity.

CONCLUSION: There is a high prevalence of nonalcoholic fatty liver among certain population in Shanghai, to which overweight and hyperlipidemia are closely relevant.

INTRODUCTION

Fatty liver has increasingly been recognized as an important

and common form of chronic liver disease over the past 20 years^[1]. Fatty liver consists the intrahepatic accumulation of lipids. It is the commonest liver disease, accounting for abnormal liver function tests in the majority of asymptomatic subjects^[2]. Although generally unprogressive, fatty liver is an important precursor to the development of fibrosis in aetiologically diverse conditions such as hepatitis C, and alcoholic and nonalcoholic liver disease^[3]. Furthermore, it has the potential to lead to end-stage liver failure^[4] via steatohepatitis from lipid peroxidation, even in the nonalcohol drinker, an entity that is being studied with growing interest in the affluent society^[5]. Fatty liver is an increasingly common problem worldwide and has been reported in Japan^[6,7], Australia^[8], America^[4,9], Europe^[10,11], and the Middle East^[12], although geographic variations in prevalence are evident. Along with the steady improvement of living level and wide use of ultrasonography, the number of patients with diagnosis of fatty liver is increasing in China recently. The objective of this study was to determine the prevalence of fatty liver in a specific population in Shanghai by epidemiological survey, and analysis of its risk factors.

MATERIALS AND METHODS

Study participants (demographics)

A total of 4375 administrative officers, who took part in annual regular physical examination from September 1 to November 30 in 1999 (in Renji Hospital and Central Hospital of Putuo District in Shanghai) were recruited. Complete laboratory data were obtained from 4009 participants, who denied regular alcohol drinking and included in this study. 2583 were males and 1426 females. The mean age of participants was 46±14 years with ranged was 20-81 years.

Methods of examination

For each participant, an extensive medical history was obtained that included alcohol intake, history of chronic liver disease in first-degree relatives; a detailed history of viral hepatitis, gallstone disease and drug abuse; previous diagnosis of diabetes, hypertension and coronary heart disease.

Each participant also underwent a detailed physical examination, including of measurement of body weight, height, waist and hip circumferences. The body mass index (BMI) was calculated as: body weight in kg/(height in meter)². The waist hip circumferences ratio (WHR) was calculated by dividing waist girth (halfway between the lower costal margin and the iliac crest in the mid expiratory phase of breathing while the subject was standing) by hip girth (maximum circumference around the buttocks) previously measured while the subject was wearing light underwear.

Laboratory tests included routine blood and urine analysis, serum alanine aminotransferase (ALT), total cholesterol (Tch), triglycerine (TG), low-density lipoprotein cholesterol (LDL-Ch), high-density-lipoprotein cholesterol (HDL-Ch), plasma glucose levels, hepatitis B surface antigen (HBsAg), routine chest fluorography, electrocardiography and optic fundus examination.

Ultrasonographic examination of liver and gallbladder was performed by two experienced ultrasonographers, using the Simens Sonoline-SI450 unit with 3.5MHz probe. Fatty liver was defined as the presence of an ultrasonographic pattern consistent with “bright liver,” with evident ultrasonographic contrast between hepatic and renal parenchyma, vessel blurring, and narrowing of the lumen of the hepatic veins in the absence of findings suggestive of chronic liver disease^[13,14].

Statistical analysis

All statistical analysis was processed by Clinical Epidemiological Network in Zhongshan Hospital, Fudan University with Software SPSS. Statistical analysis was performed by using the SPSS statistical package, version 7.1(SPSS, Inc.). The following tests were applied, unpaired Student's *t*-test, chi-squared test with Fisher's exact test, analysis of variance, and logistic regression analysis (LRA). Rejection of the null hypothesis was set at $P < 0.05$. Analysis of data was performed through SPSS for Windows statistical package.

RESULTS

Body-mass index (BMI)

The mean BMI was 22.93 ± 2.82 . Among them 31.6 % had BMI > 24 , which were considered as overweight, 53.3 % had BMI between 20-24; and 15.1 % had BMI < 20 .

Waist-hip-circumference ratio (WHR)

The mean value of WHR was 0.83 ± 0.06 . Among them 2.78 % had WHR > 0.94 , 21.1 % had WHR between 0.88-0.94 and 76.2 % had WHR < 0.88 .

Blood lipids

The mean TG was 115.9 ± 84.6 mg/dl (1.31 ± 0.95 mmol/L), TCh 189.0 ± 56.7 mg/dl (4.89 ± 1.47 mmol/L). Among them 627 had hypertriglycerinemia only; 282 participants had hypercholesterolemia only and 256 participants had mixed hyperlipidemia. Thus, the prevalence of hyperlipidemia among participants was 28.9 %. Each patient was classified into the following four previously defined hyperlipidemia phenotypes according to 12-hr fasting plasma lipid levels: hypertriglyceremia (≥ 150 mg/dl, 1.7 mmol/L), hypercholesterinemia (≥ 220 mg/dl, 5.7 mmol/L), mixed hyperlipidemia and normal blood lipids.

Blood glucose, liver function and HB_sAg

Among participants 86 (2.2 %) suffered from impaired glucose tolerance, 93 (2.3 %) had diabetes mellitus (DM); 59 (1.5 %) suffered from increased ALT, and 257 (6.4 %) were HB_sAg positive.

Fatty liver and cholelithiasis

Fatty liver was detected with ultrasound examination in 516 participants (12.9 %); cholesterol crystal in gallbladder was detected in 54 persons (1.3 %), Gallstone or cholecystectomy was noted in 358 participants (8.9 %).

Influence of sex and aging on parameters

In this study, the mean age of male participants (47.3 ± 14.7 years) was older than the female participants (43.4 ± 23.5 years, $P < 0.01$). BMI, WHR, serum level of TG and glucose in male group was significantly higher than those in female group. Levels of serum TCh and LDL -Ch were similar in both groups (Table 1).

As presented in Table 2, there are more participants with increased ALT, positive HB_sAg and arteriosclerosis of optic fundus in male group. Prevalence of DM, coronary artery disease, hypertension and fatty liver are significantly higher

in male group than those in female group; but the prevalence of cholelithiasis is similar in both groups.

Table 3 shows sex and age related change of hyperlipidemia. In participants younger than 50 years old, more cases of hypertriglycerinemia are detected, whereas participants older than 50 years older, prevalence of hypercholesterolemia increase significantly, especially in females. In whole group the prevalence of three hyperlipidemia types increase significantly with aging.

Among females younger than 50 years old, the prevalence of hyperlipidemia is lower than that among males. After 50 years of age this prevalence was significantly higher than in males.

As in showed the Table 4, the prevalence of fatty liver increased with aging, which is markedly presented in females younger than 50 years. The prevalence of fatty liver in males younger than 50 years is significantly higher (13.3 %) than that in females (2.7 %). In participants older than 50 years, no significant difference of prevalence of fatty liver is noted between males and females (19.1 % vs 18.1 %).

Table 1 Obesity indices and lipid parameters in males and females

Parameters	Male	Female	P value
BMI	23.5 ± 2.7	21.5 ± 2.6	< 0.001
WHR	0.86 ± 0.05	0.79 ± 0.06	< 0.001
TG(mg/dl)	126.3 ± 87.7	97.2 ± 75.2	< 0.001
TCh(mg/dl)	188.8 ± 56.7	189.3 ± 56.6	> 0.05
HDL-Ch(mg/dl)	81.4 ± 75.4	84.4 ± 57.0	> 0.05
LDL-Ch(mg/dl)	143.1 ± 166.0	133.5 ± 153.7	> 0.05

Table 2 Difference of prevalences of several diseases in males and females

Diseases	Male%	Female%	P value
Abnormal ALT	2.1	0.35	< 0.001
Positive HB _s Ag	7.3	4.8	< 0.001
Arteriosclerosis of optic fundus	13.4	6.3	< 0.001
Diabetes mellitus	5.1	3.3	< 0.001

	Total	484	27.4	27.4	12.0	55.4

Table 4 Prevalence of fatty liver in groups of different sex and ages

Age(years)	Sex	Number	Fatty liver n%
<30	Males	314	11 (6.4)
	Females	257	2 (1.6)
	Total	571	13 (2.3)
30-50	Males	1202	190 (20.7)
	Females	726	25 (5.4)
	Total	1928	215 (11.2)
51-64	Males	702	125 (17.9)
	Females	324	57 (19.7)
	Total	1026	182 (17.7)
≥65	Males	365	83 (22.7)
	Females	119	23 (19.3)
	Total	484	106 (21.9)

In this survey 516 patients (12.9 %) with fatty liver were detected by ultrasonography. The age, BMI, WHR, levels of serum TG and TCh of patients with fatty liver were significantly higher than participants without fatty liver (3493 persons). The details were presented in Table 5. The results of monovariant regression analysis of relation between prevalence of fatty liver and other factors was presented in Table 6. Prevalence of fatty liver was associated with several parameters, including sex, BMI, and WHR.

Stepwise logistic multivariant regression analysis of relationship between prevalence of fatty liver and other parameters demonstrated that 9 parameters were closely related with prevalence of fatty liver. As presented in order of importance, these were WHR, increased ALT, BMI, and hypertension, DM and impaired glucose tolerance, hyperlipidemia, male sex and arteriosclerosis of optic fundus.

Table 5 Obesity indices and lipid parameters in groups with and without fatty liver

	Age (years)	BMI (kg/m ²)	WHR	TG (mg/dl)	TCh (mg/dl)
Group without fatty liver	44.6±14.3	22.2±2.4	0.8±0.1	105.0±78.4	186.2±59.5
Group with fatty liver	52.3±13.0	26.0±2.4	0.9±0.1	168.6±93.4	202.2±37.7

DISCUSSION

The natural history of fatty liver ranges from asymptomatic indolent to end stage liver disease. Diagnosis of nonalcoholic fatty liver (NAFL) and nonalcoholic steatohepatitis (NASH) may involve ultrasonography, liver biopsy and recognition of related condition^[1]. Fatty liver is a common disease of liver without specific clinical features and lack of confirmatory laboratory tests^[15-17]. In patients undergoing liver biopsy, the prevalence of NAFL ranges between 15 % and 39 %^[18]. This wide range in the prevalence of NAFL is probably related to differences in the study design. Because patients undergoing liver biopsy were highly selected, these data might not reflect the true prevalence of NAFL in the general population. Therefore, current best estimates make the prevalence of NAFL approximately 20 % and of NASH 2-3 % in the general population^[18].

While it could be argued that in the absence of histology this figure may not reflect the true prevalence of fatty infiltration, previous studies in which ultrasound findings were compared to histologic results indicate that the overall sensitivity and specificity of ultrasound examinations for the diagnosis of fatty liver are approximately 80-95 % and 90-95 % respectively^[13,19-21]. In the present study, the prevalence of NAFL was 15.8 % in males and 7.5 % in females according to ultrasonic criteria of diagnosis for fatty liver.

This study was limited in survey of the administrative officers in two districts of Shanghai. Nevertheless, these participants were representatives of the health status of administrative officers. In comparison with general population, participants of this study had better living condition and less physical exercises. The results of this study showed higher prevalence of hyperlipidemia and fatty liver in participants than those in general population in Shanghai.

Several authors suggested that fatty liver should be included in "metabolic syndrome"^[2,14,22]. Evidence for this hypothesis derives, in our opinion, from epidemiology, metabolism, and experimental pathology. The results of this survey showed that overweight was detected in 31.6 % of participants and hyperlipidemia in 28.8 %, and the prevalence of fatty liver was 12.9 %. The prevalence of DM, hypertension and coronary heart disease was 4.5 %, 12.8 % and 3.1 % respectively, suggesting that overweight and associated diseases are becoming common diseases among administrative officers in Shanghai.

Hyperlipidemia is considered as a risk factor for fatty infiltration of the liver^[23,24]. The pathogenesis of nonalcoholic steatohepatitis is poorly understood, but lipid peroxidation and oxidative stress are the leading culprits^[16, 25]. Diabetes and hypertriglyceridemia were the two states predictive of fatty liver that is consistent with the presence of insulin resistance^[23]. NAFL correlates significantly with both anthropometrical data BMI, WHR and with abdominal fat^[26]. In clinical practice BMI over

24 used as diagnostic criteria for overweight in China.

In this study, both monovariant and multivariant regression analysis demonstrated a close correlation between BMI and fatty liver. High WHR suggests increased abdominal fatty tissue, which is a strong predictive factor for DM and other metabolism abnormalities^[27-30]. Increased WHR is considered as the most important risk factor for fatty liver. The development of fatty liver may be a result of transportation of the abnormal fatty tissue into the liver^[23,31,32]. BMI was found to be an independent predictor of fatty liver in either sex^[33]. Both monovariant and multi variant regression analysis revealed that hypertension is correlated with fatty liver. The relation between fatty liver and impaired glucose tolerance, DM and hyperlipidemia has been well established^[34-43], and was confirmed again in this study. Fatty liver could be gender-related^[33]. The results of this study showed that in male participants younger than 50 years old, the prevalence of three types of hyperlipidemia and fatty liver were markedly higher than those in females. In participants older than 50 years old the prevalence were similar in males and females. This result suggested that female hormones might have favorable effects on lipid metabolism in liver. Monovariant analysis showed that many factors were correlated with prevalence of fatty liver. However, logistic multivariant regression analysis demonstrated that only nine parameters were closely correlated with fatty liver.

In majority of patients with fatty liver, the hepatic function is normal, therefore determination of ALT can not reflect the content of fat retention in liver^[7,44]. Results of this study showed negative correlation between positive HB_sAg and fatty liver, which might explain that chronic hepatitis B infection would not induce the development of fatty liver. The sensibility by liver function tests to detect fatty liver was inferior to that of BMI^[7]. But hepatitis C may be linked to hepatic steatosis^[45-47].

This epidemiological survey demonstrated that fatty liver is a common disease among administrative officers in Shanghai. Overweight, hyperlipidemia, and DM are high risk factors for fatty liver. It is clear that NAFL is a chronic liver disease with the potential for progression to cirrhosis and to cause liver-related death^[48,50]. Although ultrasonography provides the prevalence of NAFL, it can not delineate the different histologic form of NAFL^[18]. If it is clinically indicated, a liver biopsy to assess the degree of inflammation and fibrosis should be performed during follow-up^[10]. To reduce the incidence of fatty liver, comprehensive measures are necessary^[32,51-53].

Abstract

AIM: To compare the efficiency of different plasmids as DNA vectors by cloning three HBsAg-encoded genes into two eukaryotic expression vectors, pRc/CMV and pSG5UTPL/Flag, and to express HBsAg S, MS, and LS proteins in SP2/0 cells, and to establish monoclonal SP2/0 cell strains that are capable of expressing S or S2S proteins stably.

METHODS: Segments of S, preS2-S, preS1-preS2-S genes of Hepatitis B virus were amplified by routine PCR and preS1-S fragment was amplified by Over-Lap Extension PCR. The amplified segments were cleaved with restricted endonuclease Hind III/Not I followed by ligation with pRc/CMV, or BamHI/EcoR I followed by ligation with pSG5UTPL/Flag. After the plasmid vectors were cleaved with the correspond enzymes, the amplified segments were inserted into pRc/CMV or pSG5UTPL/Flag plasmid vectors with T4 DNA ligase. KOZAK sequence was added before the initial ATG code of each fragment using specific primer. The inserted segments in the recombinant plasmids were sequenced after subcloning. BALB/c mice myeloma cells (SP2/0 cell line) were transfected with the recombinant plasmids. The expressions of the different recombinants were compared by Western-blot, using a monoclonal anti-HBs antibody as the primary antibody and peroxidase-labeled multi-linker as the secondary. Stable SP2/0-pRc/CMV-S or SP2/0-pRc/CMV-MS clones were established through clone screening with G418.

RESULTS: Fragments with anticipated size were harvested after PCR. After recombination and screening, the sequences of the inserted segments in the recombinants were confirmed to be S, preS2S, preS1-preS2S and preS1S encoding genes, determined by sequencing. The results of Western-blot hybridization were positive for the anticipated proteins. Among them, pRc/CMV-S or pRc/CMV-MS demonstrated the highest expressing their respective antigen.

CONCLUSION: Eight recombinant plasmids expressing S,

M, L or preS1S proteins are obtained. For hepatitis surface antigen expression in eukaryotic cells, the vector pRc/CMV is superior to pSG5UTPL/Flag, and pRc/CMV-S and pRc/CMV-MS are the most efficient in the pRc/CMV clones. SP2/0 cells stably expressing HBsAg are established, and may be used as target cells for evaluating the CTL activity of a DNA vaccine in vitro.

INTRODUCTION

Hepatitis B virus (HBV) infection is epidemic worldwide^[1-3]. Unfortunately, there are no satisfactory drugs to cure HBV-related diseases, and the only way to control the epidemic is through vaccination^[4-6]. Great efforts have been made to develop more successful vaccines than those currently available to prevent or to treat HBV infection. The newest approach is genetic immunization. This involves the transfer of a viral gene into host somatic cells by a plasmid vector, with subsequent endogenous production and intracellular processing of the virus' structural proteins into small peptides. The processed peptides eventually induce a broad-based immune response^[7-11]. Hepatitis B virus surface antigen consists of S (S, small surface), MS (medium surface, S+preS₂), and LS (large surface, S+preS₁+preS₂) HBsAg molecules. We have reported that DNA vaccine expressing HBsAg S molecule induced humoral and cellular immune responses against HBsAg^[12,13]. Because the preS antigen is necessary for HBV to penetrate the cell membrane of the host, vaccines containing the preS antigen are more effective. Hence, we constructed a series of plasmids encoding small (S), medium (M), or large (L) envelope proteins of HBsAg utilizing different promoters. In addition, the expression levels of these recombinant plasmids were evaluated, in order to choose a better vector for designing future DNA vaccines.

MATERIALS AND METHODS

Gene fragments expressing S, MS, LS, and preS1S proteins

Plasmid pBHB₄ (containing the *adr* subtype of HBV genome DNA) was used as a template to amplify S, preS₂ and preS₁ fragments. The following primers were used: the forward primers: SF (nt 28-41), 5' - GCG AAT TCT AGC TTA TCG ATC ACC ATG GAG AAC ACA AC, complementary to the S gene; S₂F (nt 3077-3090), 5' - GCG AAT TCA AGC TTA TCG ATC ACC ATG CAG TGG AAC ACA TC, complementary to the preS₂ gene; and S₁F (nt 2179-2733), 5' - GCG AAT TCA AGC TTA TCG ATC ACC ATG GGA GGT TGG TC, complementary to the preS₁ gene. The same reverse primer was used for all reactions: SR (nt 705-693): GCG CGG CCG CTT AGG ATC CAA TCG ATA CCC AA. The primers contain a flanking sequence having endonuclease enzyme sequence

for the convenience of clone manipulation.

To obtain a unique fragment containing the S and preS₁ gene, overlap extension PCR was used. The forward primer (S₁-SF) is complementary to the beginning of the S gene and to the end of preS₁ gene, while the reverse primer (S-S₁R) is complementary to the end of the preS₁ gene and the beginning of the S gene (Figure 1). Using pBHB₄ as a template, and the S₁-SF/SR and S₁F/S-S₁R primers, the resultant PCR product contained the 3' end of preS₁ gene followed by the complete S gene sequences that the two PCR fragments contained complementary ends. When these fragments were consequently used as templates and S₁F/SR primers, only the preS₁-S was amplified.

Recombinant plasmids construction

The PCR fragments and plasmid vector pRc/CMV (containing the CMV promoter, Invitrogen, USA) were cleaved by HindIII/NotI (Bio-Lab, USA), while the PCR fragments and plasmid vector pSG5UTPL/Flag (containing SV40 promoter) were cleaved by BamHI/EcoR I (Bio-Lab, USA). The cleaved products were ligated using T₄ DNA ligase. *E.coli* XLBlue1 was transformed using the ligated products and screened for the positive clones containing the inserted fragments, which was performed by colony-PCR techniques. The positive colonies were amplified, extracted, purified, and identified by endo-nuclease cleavage. The sequences of the inserted fragments were confirmed by sequencing with Nucleic Acid Auto-Analysis (TYPE 373A).

Transient expression in vitro

The extracted recombinant plasmids were purified by CsCl/ethidium bromide equilibrium centrifugation. SP2/0 cells (myeloma cells from inbred BALB/c mice) were transfected with purified plasmids by an amended calcium chloride method as described elsewhere^[14]. Two days later, the cells were collected in LAC buffer (20 mmol·L⁻¹ Hepes pH 7.9, 400 mmol·L⁻¹ NaCl, 1 mmol·L⁻¹ EDTA, 9 mmol·L⁻¹ CHAPS, 250 ml·L⁻¹ glycerol) containing 1/200V 0.5 mol·L⁻¹ DTT, 2.5 mmol·L⁻¹ EDTA, 5 g·L⁻¹ Apotinine, 5 g·L⁻¹ Leupetine and 0.2 mol·L⁻¹ PMSF, and lysed by sonication (Ubra-Cell, Sonics & Materials, USA). Supernatants were collected and analyzed as follows: proteins were separated by 120 g·L⁻¹ SDS-polyacrylamide gel, electrophoresis, and transferred to PVDF membranes (Millipore, USA), followed by blocking for 2 h in PBS containing 50 g·L⁻¹ nonfat dry-milk at room temperature. To detect HBsAg, the membranes were first incubated with mono-clone anti-HBs antibody (BioGenex, USA) at 1:1 000 dilution and conjugated antibodies were detected with horseradish peroxidase-labeled multi-linker antibodies (BioGenex, USA) at a dilution of 1:300. The blots were visualized by chemiluminescence reactions (Luminol and Iodophenol, Fluka).

Long-term transfected cell strains

After the transient in vitro expression, the plasmids demonstrating a high level of expression were chosen to permanently transfect SP2/0 cells. After 2 d of transfection, fresh cultural medium containing 200 mg·L⁻¹ G418 (at this concentration, there were no viable SP2/0 cells after 2 w in preliminary studies) was added in order to grow the cells under

G418 pressure. The media was refreshed every 3 to 5 d. 2w later, cells forming colonies were chosen using a light microscope, and subcultured under G418 pressure. After 30 generations, the DNA was extracted following the protocols described elsewhere^[15] and detected the HBV S gene by dot-blot hybridization (Dig-probe of HBV S was prepared in our laboratory, Dig-labeling Kit from Roche Company). HBsAg in the culture media and supernatant of cell lyses were detected by ELISA (Kits from SABCO), HBsAg in the cells by immunochemistry. Presence of the plasmid was detected by *in situ* hybridization with the corresponding probe (labeled in our laboratory, Dig-label kit from Roche Company). The cells containing the HBV S gene and the HBsAg were chosen as long-term expression cell strains and stored in liquid nitrogen for further use as the target cells for evaluation of CTL activity after DNA immunization.

RESULTS

Construction of recombinant plasmids

DNA fragments of 0.72kb, 0.88kb, and 1.24kb were generated by PCR methods (pBHB₄ template and SF/SR, S₂F/SR, S₁F/SR primers). The length of these fragments corresponded to the length of S, MS, and LS genes. When the PCR product primed by S₁F/S-S₁R and S₁-SF/SR was used as templates (overlap extension PCR), a 1.02kb DNA fragment, equal to the length of preS₁S was obtained. After cleavage by Hind III/Not I, S, MS, LS and preS₁S genes were inserted into a multiple cloning site downstream of the CMV promoter in pRc/CMV, while the fragments cleaved by Bam HI/EcoR I were inserted into multiple cloning site downstream of the SV40 promoter in pSG5UTPL/Flag. *E.Coli*. XLBlue1 cells were transformed separately with the series 8 recombinant plasmids, and cultured in LB containing ampicillin. PCR was performed on colonies, and 0.72kb, 0.88kb, 1.24kb, and 1.02kb fragments were obtained. When these PCR products were cleaved by restriction enzymes Hind III/Not I (pRc/CMV as vector) or Bam HI/EcoRI (pSG5UTPL/Flag as vector), the anticipated DNA bands were obtained. We have constructed CMV promoter controlled recombinant plasmids: pCMV-S, pCMV-MS, pCMV-LS, pCMV-S₁S; and SV40 promoter controlled recombinant plasmids: pSG5Flag-S, pSG5Flag-MS, pSG5Flag-LS, pSG5Flag-S₁S. KOZAK sequences (CACC) were placed before the initiation code of all recombinant plasmids to enhance the efficiency of protein expression. The sequences of the inserted fragments of all 8 plasmids were identical to HBV-S, MS, LS and preS₁S genes, confirmed by following sequencing.

Transient expression

After SP2/0 cells were transfected with recombinant plasmids above, the supernatants of lysed cells were run on SDS-PAGE and Western-Blot, all were positive for the anticipated bands, while the SP2/0 cells not transfected with the recombinants were negative for any HBsAg antigen. Among them, pRc/CMV-S and pRc/CMV-S₂S demonstrated the highest expression.

Construction of long-term expression cell strains

pRc/CMV-S and pRc/CMV-S₂S were used to transfect SP2/0 cells. The transfected cells grew in clusters under the selection pressure of G418. After 2 mo, 10 strains of SP2/0-pRc/CMV-S and 16 strains of SP2/0-pRc/CMV-S₂S continued to grow well in G418-containing medium, while SP2/0 cells not transfected with recombinant plasmid died within 2 wk. Of the G418 resistant monoclonal cells, 3 strains of SP2/0-pRc/CMV-S and 4 strains of SP2/0-pRc/CMV-S₂S were positive for HBsAg in the supernatants of sonicated cells. The HBsAg was detected by ELISA. They were also positive for the protein

bands when detected by Western-Blot. Cytosolic HBsAg was detected by immunochemistry. The 7 cell strains above were also positive for pRc/CMV-S or pRc/CMV-S₂S when detected by *in situ* hybridization.

DISCUSSION

DNA immunization involves the recombination of the genes of interest with the selected eukaryotic expression plasmid/vector and the transfer of the recombinant plasmid into muscle or skin cells of the host, with a subsequent induction of specific immune responses^[16-20]. DNA immunization is attractive for its advantages over traditional vaccines, and is discussed in elsewhere^[21-24]. We have reported that HBV DNA vaccine NV-HB/s could express HBsAg in muscle cells after injecting into mouse muscle, followed by the induction of an immune response, including the switchover of anti-HBs production in peripheral blood^[12,13].

HBsAg-encoded genes include S, preS₁, and preS₂. All the proteins expressed by these genes are antigenic. The elicited response is strongest with preS₁ and preS₂. The titer of preS antibody in rabbits immunized with preS protein is 400 times greater than that of S antibody in rabbits immunized with S protein. In addition, some mice are non-responsive to S protein of HBV, which is determined by an allele of H₂ gene. Vaccines containing HBV preS₁ and/or preS₂ antigen may alter this inherited non-responsive state, inducing anti-HBs in mice which were previously immunized with vaccines only containing S. Moreover, preS proteins are necessary in order for HBV to infect hepatocytes. preS₁ protein can bind hepatocytes specifically while preS₂ can bind hepatocytes through PHSA (polymerase human serum albumin). Because of the importance of HBV preS proteins, we constructed plasmids, which can be used for DNA vaccines containing the preS₁ and/or preS₂ genes. Several plasmids were constructed by different promoters in order to compare their expression proficiency. All these recombinant plasmids demonstrated expression in SP2/0 cells, while the vector pRc/CMV was the most effective, with the highest expression demonstrated as pRc/CMV-S and pRc/CMV-S₂S. pRc/CMV-S and pRc/CMV-S₂S may be used as good candidates for DNA immunization. Their efficacy in inducing immune responses is still in experimental process.

Long-term expression cell strains transfected with pRc/CMV-S or pRc/CMV-S₂S were established in our experiment through selection with G418 more than 30 generations. The cell lines SP2/0-pRc/CMV-S and SP2/0-pRc/CMV-S₂S can express HBsAg S protein or S₂S protein effectively and may be used as target cells for CTL test in the study of DNA immunization for HBV in the near future.

ACKNOWLEDGEMENTS

We are grateful to Prof. Senshi Murukami, Kanazawa University in Japan, for generous gift of plasmid pBHB4 and plasmid vector pSG5UTPL. The authors thank Kathleen N from Biomolecular Science Center of University of Central Florida for her reviewing of the manuscript.

Abstract

AIM: To assess the accuracy of three-dimensional contrast-enhanced magnetic resonance angiography (3D CE MRA) in evaluation of the portal vein involvement in patients with hepatic tumors.

METHODS: 3D CE MRA was performed in 62 patients with hepatic tumors to assess the patency of the main, right and left portal veins before hepatic surgery. A total of 186 veins were examined for encasement, occlusion and tumor thrombosis. The results of 3D CE MRA diagnosis were then correlated with the surgical-pathological and intra-operative sonographic findings.

RESULTS: 3D CE MRA correctly detected 48 of 49 involved and 135 of 137 noninvolved portal veins with the sensitivity of 98 %, specificity of 99 %, positive predictive value of 96 % and negative predictive value of 99 %.

CONCLUSION: 3D CE MRA is accurate in evaluation of the portal vein involvement in patients with hepatic tumors.

http://www.wjgnet.com/1007-9327/9/1114.htm

INTRODUCTION

Evaluation of the patency of the portal vein (PV) is essential before surgical resection of hepatic tumors. There are advantages and limitations to the conventional methods for PV imaging. Ultrasound (US) is noninvasive and relatively inexpensive, but it is operator dependent and may not be successful when the acoustic window is restricted^[1,2]. Contrast-enhanced computed tomography (CT) is readily available and can demonstrate the PV, but it uses ionizing radiation and requires intravenous administration of a large amount of iodinated contrast medium with the risk of nephrotoxicity and possible allergic reaction^[2-5]. X-ray portography is the standard technique for evaluation of the PV due to its superb spatial resolution^[2], but it is invasive, uncomfortable and, like CT,

involves radiation and use of iodinated contrast medium. Occasionally, opacity of the PV is poor by intra-arterial portography in patients with portal hypertension^[2,6,7]. The disadvantages of x-ray portography also include high cost, requirement for operator expertise and associated complications such as hemorrhage and aortic dissection^[8]. Non-enhanced magnetic resonance angiography (MRA) with time-of-flight (TOF) and phase-contrast (PC) techniques is another means for non-invasive demonstration of the PV. However, it is limited by long acquisition time, motion and flow artifacts and saturation effects^[1,9-13].

Three-dimensional contrast-enhanced MRA (3D CE MRA) is a recently developed, non-invasive and fast and easy to perform technique which is suited for evaluation of the portal venous system^[14-21]. With this technique, the imaging of the PV is accomplished in a single breath hold. It requires only a peripheral venous injection of a small amount of gadolinium, which is much safer than iodine-based contrast media. Using gadolinium to shorten the T1 value of the blood, it overcomes flow artifacts and saturation effects in TOF and PC. Moreover, it involves no radiation. 3D CE MRA has been frequently used in our hospital in patients with liver tumors for the preoperative diagnosis of the patency of the portal venous system. The goal of this study was to evaluate the accuracy of this technique for the assessment of the PV involvement in hepatic tumors.

MATERIALS AND METHODS

Patients

Sixty-two consecutive patients who required evaluation of their portal venous system before surgical resection of hepatic tumors were recruited. They consisted of 56 men and 6 women ranging in age from 26 to 78 years (mean age 54 years) and were diagnosed clinically as hepatocellular carcinoma (55 patients), hepatic metastasis (4 patients), hemangioma (1 patient), hepatic adenoma (1 patient) and right adrenal carcinoma with liver involvement (1 patient).

MR examinations

MR scans were performed using a 1.5T MR imager (Signa, General Electric Medical Systems, Milwaukee, WI, USA) and a body coil. After images located were acquired, a breath-hold T1-weighted fast multiplanar spoiled gradient-echo (FMPSPGR) sequence (repetition time/echo time, 150/4.2 ms; flip angle, 90°; field of view, 360 mm; matrix, 128×256; 18 slices of 7.0 mm thickness each; gap, 3.0 mm; one signal acquired) and a respiratory-triggered T2-weighted fast spin-echo sequence (repetition time/echo time, 2800-4200/80 ms; echo train length 8-12, field of view, 360 mm; matrix, 128×256; 18 slices of 7.0 mm thickness each; gap, 3.0 mm; 2 signals acquired) were performed in the liver. For 3D CE MRA, a breath-hold 3D fast spoiled gradient-echo sequence (repetition time/echo time, 5.2-10.2/1.2-1.9 ms; flip angle, 30° or 45°; field of view, 360-480 mm; matrix, 128×256; imaging volume, 75-168 mm; number of partitions, 24-30; one signal acquired; and acquisition time, 19-28 s) was used.

With T1-weighted and T2-weighted images as references the imaging volume of 3D CE MRA was acquired in a coronal plane to cover the main PV and its left and right intrahepatic branches. The imaging volume was determined by a radiologist depending on each patient's liver size and ability of breathholding. A gadolinium chelate called gadopentetate-dimeglumine (Magnevist; Schering AG, Berlin, Germany) was used as a contrast medium for all examinations, with a concentration of 0.15 mmol per kg body weight. The contrast medium was injected by an experienced MR technician through an antecubital vein at an injection rate of approximately 3 ml/s. Acquisition was commenced immediately after the injection and repeated three times with a 6-second delay between each acquisition to allow patient breathing. The second acquisition coincided with portal venous phase, while the first acquisition was the arterial phase and the third acquisition was the equilibrium phase. Source images of portal venous phase were reviewed first. These images were then reconstructed on a workstation (Advantage Windows Workstation, General Electric Medical Systems, Milwaukee, WI) to produce projectional images like x-ray portography. Both maximum intensity projection and multiplanar reconstruction techniques were performed and reviewed.

Image analysis

The patency of the main PV and intrahepatic left and right PV including their anterior and posterior branches on 3D CE MRA were assessed by two radiologists who were unaware of the patient's clinical status. A consensus reading between them was reached in every case. The PV involvement was considered to be present if the veins were encased, occluded and thrombosed. Encasement was diagnosed when the PV was surrounded by a tumor and showed mural irregularity or had an indistinct wall or irregular lumen narrowing. The PV was considered to be occluded if the lumen was obstructed, interrupted or not visualized due to tumor invasion. Tumor thrombosis was diagnosed when the PV was widened with linear, nodular or irregular filling defect.

Surgery was performed 1-20 days (mean, 6 days) after the MR imaging. Tumor location and portal venous status were recorded by the surgeon in the surgical report for each case. In 12 of 49 patients who underwent hepatic resection, tumor

thrombi were removed from the stump and/or main trunk of the PV during the operation. In 13 patients whose tumors were found to be unresectable at surgery, intra-operative US was performed to demonstrate the PV. In these unresectable cases, small amount of tumor tissue was taken for pathological examination and 3 of them had tumor thrombi removed from the main PV. The results of 3D CE MRA for assessment of the PV involvement were compared with the surgeon's findings. Sensitivity, specificity, positive and negative predictive values of 3D CE MRA were calculated using surgical-pathologic and intra-operative US findings as the references. All cases with false positive and negative diagnosis were further analyzed to determine the cause of the error.

RESULTS

All 3D CE MRA examinations were performed successfully. The main PV and intrahepatic left PV and right PV including their anterior and posterior branches were shown well without diagnostic difficulty in each case.

Forty-nine of 186 PVs were found to be involved at surgery. Encasement was present in 7 veins, occlusion in 13 veins and tumor thrombosis in 29 veins (Figures 1-3). The site and type of the PV involvement were summarized in Table 1. The remaining 137 PVs were normal. 3D CE MRA correctly depicted 48 of 49 (98 %) involved PVs and 135 of 137 (99 %) noninvolved PVs with an overall sensitivity of 98 %, specificity of 99 %, positive predictive value of 96 %, and negative predictive value of 99 % for the evaluation of all PVs including the main, left and right PVs. The accuracy in examination of the patency of the main PV reached 100 %. The relationship between 3D CE MRA for each of the PVs and the surgical findings is shown in Table 2. Use of 3D CE MRA resulted in two false positive interpretations involving the left PV (Figure 4) and one false negative interpretation involving the right PV (Figure 5). The two false positive diagnoses were made in which the left PVs were interpreted as occluded at 3D CE MRA, whereas at surgery they were found to be compressed but not invaded by tumors in left lobes. For the false negative diagnosis, the right PV was diagnosed as normal by 3D CE MRA, but surgical-pathologic examination revealed that the right posterior PV was thrombosed with tumor.

Table 1 Surgical-pathologic findings of portal vein involvement

	Type of involvement				
	Total involved	Encasement	Occlusion	Tumor thrombosis	Normal
Main PV	12	0	0	12	50
Left PV	18	3	8	7	44
Right PV	19	4	5	10	43
Total	49	7	13	29	137

Note: Data are number of cases. PV is portal vein.

Table 2 Relationship between 3-dimensional contrast-enhanced MR angiography diagnosis of portal vein involvement and surgical-pathologic findings

	True positive	True negative	False negative	False positive	Sensitivity (%)	Specificity (%)	Positive predictive (%)	Negative predictive (%)
Main PV	12	50	0	0	100	100	100	100
Left PV	18	42	0	2	100	95	90	100
Right PV	18	43	1	0	95	100	100	98
Total	48	135	1	2	98	99	96	99

Note: Data are number of cases except otherwise indicated. PV is portal vein.

Figure 1 A patient with hepatocellular carcinoma in the right lobe. (A) Source image of 3-dimensional contrast-enhanced MR angiography demonstrates a hypointense tumor in the right lobe (arrow). (B) Multiplanar reconstruction of 3-dimensional contrast-enhanced MR angiography shows widened main and right portal vein with filling defects (arrow). (C) The patient underwent tumor resection and removal of tumor thrombi in the portal vein. Histopathology (HE $\times 40$) reveals tumor thrombus in the portal vein (arrow).

Figure 3 A patient with hepatocellular carcinoma in the left lobe. 3-dimensional contrast-enhanced MR angiography demonstrates occluded left portal vein and irregular filling defect in the main portal vein (arrow). The right portal vein is normal.

Figure 2 A patient with hepatocellular carcinoma in the right lobe. (A) 3-dimensional contrast-enhanced MR angiography depicts a nodular filling defect in the right portal vein (arrow). (B) After partial right hepatic resection and removal of the tumor thrombi, the right portal vein is shown patent (arrow).

Figure 4 A patient with hepatocellular carcinoma in the left lobe (arrow). The left portal vein is not visualized and interpreted as occlusion by the tumor.

Figure 5 A patient with hepatocellular carcinoma in the right lobe (thick arrow). The normal right anterior portal vein (thin arrow) is misinterpreted as the right portal vein. But at surgery, the right posterior portal vein was involved by the tumor.

DISCUSSION

Hepatocellular carcinoma often invades the portal venous system^[22]. Once this system is involved, the prognosis and quality of life of the patients become extremely poor as a result of increased portal pressure, intrahepatic spread of the tumor, and deteriorated liver function^[22-24]. Traditionally, involvement of the main PV or the bifurcation of the PV is the indications of the unresectability. However, with the advances in surgical technique for hepatic resection, the survival of these patients can be prolonged by combination of hepatic resection, removal of tumor thrombi in the PV and post-operative transarterial embolization^[23]. The removal of tumor thrombi in the main PV can relieve portal hypertension, lower the risk of variceal bleeding and partially restore the liver function. Accordingly, prior to the appropriate surgical or interventional planning to be made, it is crucial to determine whether the portal venous system is patent or invaded and the site and the extent of the invasion.

In our results, 3D CE MRA was 98 % sensitive and 99 % specific in the diagnosis of the involvement of the main PV and its intrahepatic branches. The accuracy in depicting main PV involvement was 100 %. A minor compromise of positive predictive value (96 %) of 3D CE MRA was due to the false positive diagnosis for evaluation of the left PV. However, for the main and right PV, the positive predictive value reached 100 %. Using a technique similar to ours, Kreft *et al*^[25] reported a sensitivity and specificity of 100 % and 98 % for identifying PV thrombosis in 36 patients.

US is currently the screening technique for the PV. Tessler *et al*^[26] evaluated the main PV with color Doppler US in 215 patients and showed 9 of them with PV thrombosis. The sensitivity was 89 %, specificity was 92 %, negative predictive value was 98 %, and positive predictive value was 62 %. Bach *et al*^[27] found that color Doppler US had a sensitivity of 93 %, specificity of 99 %, positive predictive value of 97 % and negative predictive value of 98 % for evaluation of the main, left and right PV in 63 patients with hepatic tumors. In a recent study by Marshall *et al*^[28], microbubble contrast-enhanced color Doppler US was used to improve the visualization of the PV, but the accuracy was only 87 % for diagnosis of PV thrombosis in 15 patients. CT during arterial portography (CTAP) is also frequently employed to assess the portal venous system. According to Bach's study^[27], it gave a sensitivity of 90 %, specificity of 99 %, positive predictive value of 95 % and negative predictive value of 97 % for evaluation of the PV involvement. Compared with the findings using US or CTAP, our study showed that 3D CE MRA was more accurate in demonstration of the PV involvement by hepatic tumors, especially regarding its higher sensitivity. Although US is the first-choice imaging modality, it is observer dependent and sometimes hampered by patient's habitus and presence of bowel gas, ascites and heterogenous cirrhotic liver. When venous flow in patent PV was slow or stagnant, a PV thrombosis might be misdiagnosed. Similarly, false negative results might occur when flow was detected in a collateral vein and it was erroneously thought to be a patent main PV, which was actually thrombosed^[2,26-28]. Thus, 3D CE MRA should be a useful noninvasive alternative when the visualization of the PV on US was inadequate or when the involvement was suspected clinically but the US diagnosis was indeterminate. In comparison to CTAP, 3D CE MRA is readily acceptable by patients owing to its noninvasive nature, the lack of allergic reaction to iodine and the lack of radiation. With a higher sensitivity and equal specificity, 3D CE MRA can replace CTAP for evaluation of the PV.

Nevertheless, the two false positive results of 3D CE MRA in demonstration of the patency of the left PV indicate that the assessment of the left PV could be compromised by the

presence of large masses in left lobes. These masses caused substantial compression of the left PV. When collapsed, the left PV was underfilled with contrast medium injected from a peripheral vein and hardly distinguishable from the surrounding enhanced tumor. Therefore, 3D CE MRA had limitation in distinguishing compression of the small-caliber left PV from occlusion by tumor, which might adversely affect the surgical or interventional treatment options.

As for one false negative diagnosis occurred on the right PV, an anatomic variation of the PV found at surgery was thought to be the reason. In that case, the main PV trifurcated directly into the left and right anterior and right posterior PV at the porta hepatis. Although the right posterior PV was invaded by tumor, the right anterior PV was normal. On 3D CE MRA, we erroneously interpreted the normal right anterior PV as the right PV. In studies by Atri and Akgul *et al*^[29,30], variation of the intrahepatic PV branching was common and trifurcation of the main PV could occur in 10.8 % and 12.3 % of patients respectively. As a result, the images of 3D CE MRA must be interpreted meticulously, with an understanding of the vascular anatomy and variation, and also with attention to the other potential sources of error noted above.

In summary, 3D CE MRA is an excellent noninvasive alternative to US for imaging the portal venous system. It is highly accurate in the evaluation of the PV involvement by hepatic tumors and is able to provide valuable information before surgery and interventional treatment for liver tumors.

Abstract

AIM: To construct a recombinant strain which highly expresses catalase of *Helicobacter pylori* (*H. pylori*) and assay the activity of *H. pylori* catalase.

METHODS: The catalase DNA was amplified from *H. pylori* chromosomal DNA with PCR techniques and inserted into the prokaryotic expression vector pET-22b (+), and then was transformed into the BL21 (DE3) *E. coli* strain which expressed catalase recombinant protein. The activity of *H. pylori* catalase was assayed by the Beers&Sizers.

RESULTS: DNA sequence analysis showed that the sequence of catalase DNA was the same as GenBank's research. The catalase recombinant protein amounted to 24.4 % of the total bacterial protein after induced with IPTG for 3 hours at 37 °C and the activity of *H. pylori* catalase was high in the BL21 (DE3) *E. coli* strain.

CONCLUSION: A clone expressing high activity *H. pylori* catalase is obtained, laying a good foundation for further studies.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a bacillus first isolated from human gastric antral epithelium in 1982. It is recognized as a human-specific gastric pathogen that colonizes the stomachs of at least half of the world population^[1,2]. *H. pylori* infection is the major cause of chronic gastritis and peptic ulcer^[3-13], and is also closely related to adenocarcinoma of stomach and mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma^[14-32]. This organism was recently categorized as a class I carcinoma by the World Health Organization^[33], and direct evidence of carcinogenesis was recently demonstrated in an animal model^[34-36]. In addition, seroepidemiologic studies indicate that *H. pylori* infection is also associated with the occurrence of circulatory, respiratory and alimentary (except stomach and duodenum) system diseases and autoimmune diseases^[37-41]. With discoveries that

H. pylori may play an important role in many diseases, *H. pylori* is being studied thoroughly, especially the mechanism of escaping from host killing and clearing. Because of only escaping from host killing and clearing, *H. pylori* can locate in body steadily and cause diseases. The effect of catalase is emphasized increasingly in escaping from killing of host's free radical and sustaining the balance of self-oxygen metabolism. No study in expressing high activity *H. pylori* catalase had been reported in China and abroad. In this study, PCR technology was performed to obtain catalase gene, and construct expressing vectors. The sequence analysis and activity detection were performed in order to obtain the clone, effective expression and activity evaluation of catalase gene, thus laying a good foundation for further studying the associated functions.

MATERIALS AND METHODS

Plasmids and strains and growth conditions

Plasmid pET-22b (+) was obtained from Novagen. *Escherichia coli* (*E. coli*) DH5 α (Biodev) was used as a host for recombinant DNA manipulation, *E. coli* BL21 (DE3) was used for expression of the catalase gene. *H. pylori* was stored in this lab. *E. coli* was grown in Luria-Bertani medium containing 100 mg of ampicillin liter⁻¹.

Recombinant DNA techniques

All restriction enzyme digestions, ligations and other common DNA manipulations, unless otherwise stated, were performed by standard procedures. The genome of *H. pylori* was prepared from the cells collected from the colonies on the agar plate. The gene of *H. pylori* catalase was amplified from the genome of *H. pylori* by PCR (Techne PROGENE) using the primers cat1 (5' -TG GCC ATG GAT GTT AAT AAA GAT GTG AAA C-3') as upstream primer and cat2 (5' -AG TGC GGC CGC CTT TTT CTT TTT TGT GTG-3') as downstream primer as described in the literature^[42]. Cat1 and cat2 contained *Nco* I and *Not* I sites, respectively. The PCR product was recovered from agarose gel, digested with *Nco* I and *Not* I, and inserted into the *Nco* I and *Not* I restriction fragment of the expression vector pET-22b(+) using T4 DNA ligase. The resulting plasmid pET-CAT was transformed into competent *E. coli* BL21 (DE3) cells using ampicillin resistance for selection. The insert was confirmed using *Xho* I digestion to check for a 1.5-kb increase in size and *Nco* I and *Not* I digestion to show a 1.5-kb fragment.

Microbiological manipulations

Strain BL21 (DE3) BL21 (DE3) containing pET-22b(+)-CAT, was incubated overnight at 37 °C while shaking in 5 ml LB with 100 μ g/mL ampicillin. Fifty mL LB was inoculated and the cells grew until the optical density at 600nm reached 0.4-0.6. Isopropyl- β -D-thiogalactopyranoside (IPTG) was added to a final concentration of 1mM.

Enzyme assay

Catalase activity was assayed according to the modified method of Aebi. The assay was performed in a reaction mixture (1 ml) containing 10mM H₂O₂ in 50mM potassium phosphate buffer (pH 7.0, buffer B) at 30 °C. The rate of disappearance of H₂O₂ was measured spectrophotometrically at 240nm using a

Shimadzu UV-3000 spectrophotometer (Kyoto). One unit of catalase activity was defined as the amount of enzyme that decomposed 1 μmol H_2O_2 per minute under the assay conditions.

Preparation of cell fractionation

E. coli cells from a 50 mL growth 5 h after induction were harvested by centrifugation at $12\,000\times g$ for 10 min and the pellet was resuspended in 1 mL 30 mM Tris buffer (pH8.0) containing 1 mmol/L EDTA (pH8.0), 20 % sucrose. The suspension was put on ice for 10 min, then centrifuged for 10 min at $12\,000\times g$, and the resulting supernatant contained proteins from the periplasm. The resulting pellet was resuspended in 5 mL 50 mM Tris buffer (pH8.0) containing 2 mM EDTA, 0.1 mg/mL lysozyme and 1 % Triton X-100. The suspension was incubated at 30 °C for 20 min and then sonicated on ice until it became clarified. The lysate was centrifuged at $12\,000\times g$ for 15 min at 4 °C, and the resulting supernatant contained proteins from the cytoplasm, while pelleted proteins were derived from inclusion bodies.

Optimization of expression

Induction of glycolate oxidase expression as a function of the concentration of IPTG: Seven flasks each with 50 mL medium containing 100 $\mu\text{g/mL}$ ampicillin were inoculated with BL21 (DE3) carrying plasmid pET-CAT. At OD_{600} of 0.6, expression of CAT was induced with IPTG, of which the concentrations were 0, 0.1, 0.2, 0.4, 0.6, 0.8, 1.0 mM, respectively. After 5 hours the cells were harvested, crude extracts were compared by SDS-gel electrophoresis. CAT activity of the cells was determined as described above.

Induction of glycolate oxidase expression as a function of cell density: Three flasks each with 50 mL medium containing 100 $\mu\text{g/mL}$ ampicillin were inoculated with BL21 (DE3) carrying plasmid pET-CAT. At OD_{600} of 0.4, 0.6 and 1.0, respectively, expression of CAT was induced with IPTG (final concentration 0.2 mM). After 5 hours cells were harvested, crude extracts were compared and CAT activity was determined as described above.

RESULTS

Cloning of *H. pylori* catalase gene

The *H. pylori* catalase gene was amplified by PCR using the *H. pylori* genome as the template and cloned into plasmid pET-22b(+). The recombinant plasmids pET-CAT were all digested by Xho I, and by Nco I and Not I simultaneously, then digestive products were visualized on 10 g $\cdot\text{L}^{-1}$ agarose gel electrophoreses (Figure 1). It demonstrated that recombinant plasmid contained the objective gene. The DNA sequencing proved that the entire sequence of the gene was consistent with the results reported before^[42].

Figure 1 Agarose gel electrophoresis of PCR products and plasmid pET-CAT digested with restriction enzymes. Lane 1: DNA marker; Lane 2: PCR product; Lane 3: pET-22b (+)/ Xho I; Lane 4: pET-CAT/ Xho I; Lane 5: pET-CAT/NcoI+NotI.

Expression of *H. pylori* catalase in *E. coli*

Following recombinant vector transformed into BL21 *E. coli* strains, recombinant *E. coli* strains expressing catalase were obtained. The expressed protein amounted to 24.4 % of the total bacterial protein after induced with IPTG for 3 h at 37 °C. Its molecular mass was M_r 58 000 by 100 g/L SDS-PAGE gel analysis. After preparation of cell fractionation, the expressed protein amounted to 11.5 % of the bacterial periplasm protein, 14.9 % of the bacterial sonicate supernatant and 58.1 % of the bacterial inclusion body (Figure 2).

Figure 2 SDS-PAGE analysis of catalase recombinant protein expressed in BL21 (DE3). Lane 1: Molecular weight marker (20, 30, 43, 67, 94) $\times 10^3$; Lane 2: BL21 (pET-CAT) cells before induction; Lane 3: BL21 (pET-CAT) cells after 3 h induction with IPTG; Lane 4: BL21 (pET-CAT) cells periplasm protein after 3 h induction with IPTG; Lane 5: sonicate supernatant of BL21 (pET-CAT) cells after 3 h induction with IPTG; Lane 6: inclusion body of BL21 (pET-CAT) cells after 3 h induction with IPTG; Lane 7: control strain BL21 (pET) before induction; Lane 8: control strain BL21 (pET) after 3 h induction with IPTG.

Optimization of expression

An important factor that might affect the expression is the concentration of the inducer. Since IPTG is a rather costly component we decided to investigate the dependency of the expression system on the IPTG concentration. We found that in the range of 0.1-1 mM final concentration of IPTG, the expression level was independent of the inducer concentration, and the catalase activity of the whole cells was from 633.6 U/mg cells (dry weight) to 660.1 U/mg cells (dry weight). The data are shown in Table 1.

Table 1 Induction of glycolate oxidase expression at different IPTG concentrations

IPTG concentration (mM)	0.1	0.2	0.4	0.6	0.8	1.0
Activity (U/mg cells (dry weight))	638.5	653.6	660.1	642.3	646.7	631.2

In order to further optimize the conditions for expression we induced the bacterial cultures at various cell densities. The expression was the highest at $\text{OD}_{600}=0.6$, and at the same time the activity was also optimal at $\text{OD}_{600}=0.6$, (Table 2).

Table 2 Induction of *H. pylori* catalase expression at different cell densities

Induction at OD_{600}	Activity (U/mg cells (dry weight))
0.4	603.2
0.6	661.2
1.0	584.1

DISCUSSION

For a long time, people had presumed that transferring poisonous oxygen metabolite into nonpoisonous water,

sustaining self-metabolite equilibrium and protecting *H. pylori* from the killing of neutrophilic leukocyte were the main functions of *H. pylori* catalase^[43]. However, Bauerfeind *et al.* found that *H. pylori* catalase accounts only for 1.5 %, while urease accounts for 10 % of thallus' s gross protein at pH 6 or 7. The activity of urease could not be detected at pH 5. On the other hand, the activity of catalase is still sustained at pH 3. This finding indicated that catalase may play a more important role than urease when *H. pylori* survives in an acid environment^[44]. In addition, recent studies found that catalase may play an important role in preventing *H. pylori* from bacillus to coccus^[45-47].

Most interestingly, Radcliff *et al.* have suggested that the protective rate of natural catalase can reach 80 %, while that of recombinant catalase can reach 90 %, based on their animal experiments, which indicated that catalase is a new antigen for the preparation of *H. pylori* vaccine^[42].

Overall, further studies on catalase are essential, in order to understand the effect of catalase on *H. pylori* mechanism of causing disease, as well as immune prevention and treatment. In this study, *H. pylori* catalase gene was cloned and inserted into fused cloning strain, which was demonstrated by catalase activity. An important experimental basis for further studies on mechanism of catalase causing disease, and immune protective effects has been laid.

Plasmid pET-22b(+) was a secretion vector and the foreign protein was transported into periplasm directed by the signal peptide Pel B. Soluble and functional expression of catalase was achieved by secreting the recombinant protein to periplasm, which provided an environment favorable for the folding of this protein. These may explain why the cloning strain has the high activity. The high activity of the cloning strain may provide better measures to treat diseases caused by free radicals, such as sequela radiotherapy on neoplasm, all kinds of phlogosis, several kinds of dermatosis, second perfusion in open cardiac operation and so on.

Abstract

AIM: To investigate the effects of antireflux treatment on bronchial hyper-responsiveness and lung function in asthmatic patients with gastroesophageal reflux disease (GERD).

METHODS: Thirty asthmatic patients with GERD were randomly divided into two groups (group A and group B). Patients in group A ($n=15$) only received asthma medication including inhaled salbutamol 200 μg four times a day and budesonide 400 μg twice a day for 6 weeks. Patients in Group B ($n=15$) received the same medication as group A, and also antireflux therapy including oral omeprazole 20 mg once a day and domperidone 10 mg three times a day for 6 weeks. Pulmonary function tests and histamine bronchoprovocation test were performed before and after the study.

RESULTS: There was no significant difference in the baseline values of pulmonary function and histamine $\text{PC}_{20\text{-FEV}_1}$ between the two groups. At the end of the study, the mean values for VC, VC%, FVC, FVC%, FEV₁, FEV₁%, PEF, PEF%, $\text{PC}_{20\text{-FEV}_1}$ were all significantly improved in group B, compared with group A.

CONCLUSION: Antireflux therapy may improve pulmonary function and inhibit bronchial hyper-responsiveness in asthmatic patients with GERD.

INTRODUCTION

Bronchial asthma is likely to be associated with gastroesophageal reflux disease (GERD). Bronchial hyper-responsiveness is one of the characteristics of asthma.

Numerous observations have suggested that GERD may be causally related to the reactive airways condition, and may at least be a trigger causing airways to react^[1-4]. Our study was carried out to determine the effects of antireflux treatment on bronchial hyper-responsiveness and lung function in asthmatic patients with GERD.

MATERIALS AND METHODS

Thirty asthmatic patients with GERD were included in our study. All patients were recruited in the Second Affiliated Hospital Sun Yat-Sen University from December 2000 to December 2001. The diagnosis of asthma was established according to the Global Initiative for Asthma issued by the National Heart, Lung, and Blood Institute. The presence of GERD was determined in accordance with below standards^[5]: typical clinical symptom of GERD such as postprandial chest pain and sour regurgitation, signs of erosive esophagitis shown by barium esophagogram and/or lower esophageal erosions shown by endoscopic examination and mucosal biopsy.

The patients were randomly divided into two groups. Group A included 15 patients (7 men, 8 women; range of age 23-60 years, mean 34.9 ± 19.2 years), with duration of asthma ranging from 1-19 years (mean 8.2 ± 6.3 years). Group B included 15 patients (6 men, 9 women; range of age 20-65 years, mean 35.6 ± 17.4 years), with duration of asthma ranging from 1-25 years (mean 7.8 ± 6.1 years). There was no significant difference in age, sex, and duration of asthma between these two groups.

Patients in group A only received asthma medication which included inhaled salbutamol 200 μg four times a day and budesonide 400 μg twice a day for 6 weeks. Patients in Group B received the same medication as group A, and also antireflux therapy which included oral omeprazole 20 mg once a day and domperidone 10 mg three times a day for 6 weeks. Pulmonary function tests and histamine bronchoprovocation test were performed before and at the end of the medications.

Pulmonary function tests included vital capacity (VC), forced vital capacity (FVC), forced expiratory volume at the first second (FEV₁), and the peak expiratory flow rate (PEF), and the percentage of the above parameters over the predicted values (i.e. VC%; FVC%; FEV₁% and PEF%). Bronchial hyper-responsiveness was detected by histamine bronchoprovocation test (HIT). Briefly, the patients were asked to orderly inhale a series of histamine solutions with increasing concentrations ranging from 0.03, 0.06, 0.12, 0.24, 0.48, 1, 2, 4 to 8 g/L for two minutes with an interval of 5 minutes. Every 30 seconds and 90 seconds after each inhalation, FEV₁ was detected. The test was stopped when FEV₁ fell by 20 % from baseline value. Histamine- $\text{PC}_{20\text{-FEV}_1}$, the concentration of histamine required to produce a 20 % fall from baseline in FEV₁, calculated from Cockcroft formula^[6], represented the degree of bronchial responsiveness. Pulmonary function tests and inhaled histamine bronchoprovocation test were performed with the Spiroanalyzer ST-300, Fukuda Sangyo, Japan.

Statistical analysis

The differences of mean values \pm SD were determined by *t* test. The distribution of frequency of histamine PC_{20-FEV1} was skewed distribution. When the values were expressed as geometric mean, it became a normal distribution. A *P* value of < 0.05 was considered statistically significant.

RESULTS

There was no significant difference in the baseline values of pulmonary function and histamine PC_{20-FEV1} between the two groups. At the end of the study, the mean values for VC, VC%, FVC, FVC%, FEV₁, FEV₁%, PEF, PEF%, PC_{20-FEV1} did not change significantly in group A, while in group B the mean values for VC, VC%, FVC, FVC%, FEV₁, FEV₁%, PEF, PEF%, PC_{20-FEV1} all significantly increased. Also, at the end of the study, the mean values for above indices were all significantly higher in group B than in group A. The changes in pulmonary function and bronchial responsiveness were showed in Table 1.

Table 1 Changes in pulmonary function and bronchial responsiveness in asthmatic patients with GERD (mean values \pm SD)

Index	Group A n=15		Group B n=15	
	Before therapy	After therapy	Before therapy	After therapy
VC(L)	2.9 \pm 0.4	2.7 \pm 0.9	2.8 \pm 0.7	3.7 \pm 0.7 ^{ab}
VC%	86.3 \pm 14.6	85.9 \pm 1.9	84.9 \pm 18.9	111.2 \pm 13.6 ^{ab}
FVC(L)	2.9 \pm 0.6	2.7 \pm 0.8	2.8 \pm 0.4	3.6 \pm 0.9 ^{ab}
FVC%	88.4 \pm 19.2	85.1 \pm 23.6	86.3 \pm 21.7	102.6 \pm 16.1 ^{ab}
FEV ₁ (L)	2.3 \pm 0.9	2.4 \pm 0.6	2.2 \pm 0.8	2.8 \pm 0.5 ^{ab}
FEV ₁ %	76.8 \pm 11.6	77.5 \pm 16.3	75.6 \pm 14.5	84.6 \pm 12.7 ^{ab}
PEF(L/S)	4.4 \pm 1.5	4.8 \pm 1.7	4.6 \pm 1.2	5.9 \pm 1.6 ^{ab}
PEF%	74.8 \pm 19.6	75.1 \pm 16.3	70.5 \pm 20.4	85.1 \pm 23.1 ^{ab}
PC _{20-FEV1} (g/L)	0.31 \pm 0.11	0.28 \pm 0.16	0.33 \pm 0.14	0.84 \pm 0.22 ^{ab}

^a*P*<0.05 vs. group A after therapy, the *t* values were 2.34, 2.59, 2.31, 2.55, 2.49, 2.26, 2.63, 2.22, and 2.68, respectively. ^b*P*<0.01 vs. group B before therapy, the *t* values were 3.93, 4.16, 3.87, 4.04, 3.95, 3.62, 4.46, 3.98, and 4.33, respectively.

DISCUSSION

It has been indicated that there is a causal relationship between asthma and GERD: asthma may cause or precipitate GERD and vice versa, and so much as a vicious cycle^[11-13]. On one hand, asthma may be the cause of GERD in some patients. Prolonged period of cough, wheezing and greater respiratory muscle effort in asthma increase abdominal pressure, and facilitate the movement of gastric secretions towards the lower esophageal sphincter (LES). Moreover, the diaphragm's contribution to sphincter tone is decreased in asthma. Furthermore, bronchodilator therapies (both beta-agonists and theophylline) appear to reduce LES pressure^[7]. It has become clear that the pressure gradient across the LES is increased in asthma, which promotes the development of GERD.

On the other hand, GERD may cause or facilitate asthma. Mechanisms of bronchospasm inspired by reflux include^[8,9]: (1) acid in the inflamed esophagus may stimulate exposed acid sensitive receptors which act through vagal afferents to the airways to cause an increase in bronchial hyper-responsiveness which leads to bronchoconstriction; (2) microaspiration, with stimulation of upper-airway vagal receptor, causes bronchoconstriction; and (3) microaspiration of gastric contents into the lung results into exudative mucosal reaction.

GERD has been found to occur in 30-80 % of asthmatic

patients. Kiljander *et al* found that the prevalence of GERD in asthmatic patients is 53 %^[11]. Dal Negro *et al* reported that GERD was found in 78.9 % of atopic asthmatic patients^[12]. Sontag *et al* demonstrated that more than 80 % of asthmatic patients had abnormal GERD^[13]. A number of authors have suggested that some factors may be associated with an increased risk for the development of GERD in asthmatic patients, and thus further diagnostic tests should be proposed to evaluate the presence of GERD in such patients. These factors include^[10]: (1) asthma of adult onset; (2) asthmatic symptoms that are largely or predominantly nocturnal; (3) large meals, which might cause or worsen cough and wheezing; (4) asthma of non-smokers; (5) sour dietary and drinks that can cause cough and wheezing; (6) non-allergic (it may be changed to no allergen identified); (7) responders to antacid therapy; and (8) steroid resistant asthma.

Many diagnostic tests have been used to prove the presence of GERD, including barium esophagogram, endoscopic examination and mucosal biopsy, measurement of the LES pressure, esophageal acid perfusion tests, gastroesophageal scintiscan, and twenty-four-hour esophageal PH monitoring.

In 1985, Barish *et al* established a series of procedures to determine the prevalence of GERD in asthmatic patients^[5] including barium esophagogram, endoscopic examination, mucosal biopsy and measurement of the LES pressure. It was suggested that GERD be definitely diagnosed if there are two positive results from above examinations. Otherwise, ambulatory 24-hour esophageal PH monitoring can be used as the gold standard to determine the prevalence of GERD^[14,15]. However, Barish *et al* emphasized that this test should only be used in cases with diagnostic difficulties because of long time of catheter inserting or shortage of equipment^[5]. David *et al* established that in patients with predominant reflux symptoms and supportive evidence from endoscopy, the diagnosis of GERD was straightforward^[10]. Allescher *et al* suggested that in patients with persistent reflux problems and erosive reflux esophagitis indicated by endoscopy, the diagnosis of GERD was certain^[17]. Hollenz *et al* also proposed that gastroesophageal reflux was diagnosed when endoscopy revealed typical esophageal lesions^[16]. In some uncertain cases, 24-hour pH monitoring can be used to verify and objectify an acid gastroesophageal reflux^[17].

All the thirty cases in our study had classic symptoms of GERD and positive signs by both barium esophagogram and endoscopic examination. Therefore, the presence of GERD is certain.

A variety of different treatments aiming at the improvement of reflux symptoms have been used in adult asthmatic patients with GERD. Most investigators^[10,18] have suggested the three-step procedures. The first step includes elevation of the head of the beds 15-20 cm, no eating or drinking for three hours before sleeping, avoidance of large meals, weight loss, restricted consumption of caffeine, alcohol, spicy foods and chocolate and no smoking. The second step consists of medical management including antacids, H₂-receptor antagonists, proton pump inhibitors, pro-kinetic agents and cytoprotective agents. The third step consists of surgical management. In asthmatic patients with GERD, many studies have indicated that medical antireflux therapy can improve the symptoms of asthma. Harding *et al* reported improvements in both symptoms and pulmonary function in asthmatic patients with GERD after antireflux therapy^[19]. Levin *et al* demonstrated that omeprazole improved PEF and quality of life in asthmatic patients with GERD^[20]. Teichtahl *et al* found that omeprazole therapy significantly increased evening PEF in asthmatic patients with GERD^[21]. Meier *et al* indicated that medical antireflux therapy by omeprazole might predispose to improve respiratory function in asthmatics with GERD^[22]. Our observation also

demonstrated that antireflux medications could make an obvious favor in the improvement of pulmonary function and inhibition of bronchial hyper-responsiveness in asthmatic patients with GERD. These results provide strong evidence that GERD can precipitate asthma. Therefore, in such subset of patients, elimination of GERD may be proven to be especially beneficial.

In patients with GERD, esophageal acid exposure is reduced by up to 80 % with H₂-receptor antagonists and up to 95 % with proton pump inhibitors^[10]. So, proton pump inhibitors are superior to H₂-receptor antagonists. In addition, pro-kinetic agents also decrease GERD by improving gastric emptying.

In conclusion, our observations indicate that antireflux therapy by proton pump inhibitors and pro-kinetic agents is beneficial to asthmatic patients with GERD.

Abstract

AIM: To study the eradication rate of *Helicobacter pylori* (*Hp*) in a group of type 2 diabetes and compared it with an age and sex matched *non-diabetic* group.

METHODS: 40 diabetic patients (21 females, 19 males; 56±7 years) and 40 *non-diabetic* dyspeptic patients (20 females, 20 males; 54±9 years) were evaluated. Diabetic patients with dyspeptic complaints were referred for upper gastrointestinal endoscopies; 2 corpus and 2 antral gastric biopsy specimens were performed on each patient. Patients with positive *Hp* results on histopathological examination comprised the study group. *Non-diabetic* dyspeptic patients seen at the Gastroenterology Outpatient Clinic and with the same biopsy and treatment protocol formed the control group. A triple therapy with amoxicillin (1 g b.i.d), clarithromycin (500 mg b.i.d) and omeprazole (20 mg b.i.d.) was given to both groups for 10 days. Cure was defined as the absence of *Hp* infection assessed by corpus and antrum biopsies in control upper gastrointestinal endoscopies performed 6 weeks after completing the antimicrobial therapy.

RESULTS: The eradication rate was 50 % in the diabetic group versus 85 % in the *non-diabetic* control group ($P<0.001$).

CONCLUSION: Type 2 diabetic patients showed a significantly lower eradication rate than controls which may be due to changes in microvasculature of the stomach and to frequent antibiotic usage because of recurrent bacterial infections with the development of resistant strains.

INTRODUCTION

Helicobacter pylori (*Hp*) is the most prevalent infection all over the world and has been considered as the causative agent of many gastrointestinal diseases^[1,2]. Type 2 diabetes mellitus can present with many protean gastrointestinal symptoms and *Hp* can play a role in this context^[3,4].

Although a number of studies has been performed on the association of *Hp* and diabetes mellitus, the results have been

controversial. In a large study performed by Xia *et al.*, the seroprevalance of *Hp* infection was not statistically different in patients with diabetes mellitus and *non-diabetic* controls^[5]. In earlier studies, the prevalence of *Hp* was reported to be 62 % versus 21%, but according to Xia *et al.*, the prevalence of *Hp* should be corrected for age and gender and there are no differences if an adjustment has been done for these variables^[6].

The literature is even scarce about treatment regimens of *Hp* infection in diabetes mellitus. We also know that the eradication of *Hp* shows great differences between different ethnic groups and in patients with some chronic conditions^[1,7]. Therefore we proposed that the eradication rate of *Hp* may be also different in type 2 diabetics in comparison to *non-diabetic* controls and we planned a prospective study to elucidate the eradication rate of *Hp* infection in type 2 diabetic subjects.

MATERIALS AND METHODS

Patients

Diabetic patients with dyspeptic complaints from Diabetes Outpatient Clinic were referred for upper gastrointestinal endoscopies in the Gastroenterology Department. Upper gastrointestinal endoscopies were performed in a standard fashion with a videoendoscope (Pentax G-2940, Japan) by the same endoscopist. Endoscopic findings were noted and *Hp* infection was assessed using 2 gastric antrum and 2 gastric corpus biopsy specimens, which were evaluated with the rapid urease test and the pathological examination (Haematoxylin-Eosin staining and Giemsa if the first stain was negative). Only patients with positive results for *Hp* in pathological specimens were included in the study. The study population consisted of 40 patients with type 2 diabetic (21 females and 19 males; mean age 56±7 years) and 40 *non-diabetic* dyspeptic patients as a control group from Gastroenterology Outpatient Clinic (20 females and 20 males; mean age 54±9 years) matched for sex and age (Table 1). All patients had detailed information about the study and written informed consent.

Table 1 Characteristics of the patients in diabetic and control groups

	Diabetics	Control	P
n (F/M)	40 (21/19)	63 (25/40)	>0.05
Age (y)	56±7	54±9	>0.05
Diabetes duration (y)	7.2±5	-	
HbA1c (%)	7.4±1.3	-	

Methods

At enrolment and at the end of the treatment, each patient completed a dyspepsia questionnaire proposed by Buckley *et al.*, which had been slightly modified^[8]. A triple therapy with amoxicillin (1 g b.i.d), clarithromycin (500 mg b.i.d) and omeprazole (20 mg b.i.d) was given for 10 days. After 10 days, the patients received 20 mg omeprazole for 5 weeks if a gastric or duodenal ulcer was identified in the initial endoscopy or 40 mg of famotidin if there was gastritis. Cure was defined as the

absence of *Hp* infection assessed by corpus and antrum biopsies in control upper gastrointestinal endoscopies performed 6 weeks after completing the antimicrobial therapy. Endoscopic findings were evaluated again in control endoscopy and compared with initial endoscopic findings. Any side effects due to the treatment were reported.

During the same study period, dyspeptic patients seen at the Gastroenterology Outpatient Clinic were taken as the control group if there was no history of type 2 diabetes, and their fasting plasma glucose levels were in normal limits (between 80-110 mg/dl) and pathological *Hp* positivity was found in gastric antrum and corpus specimens. The same triple therapy and a control upper gastrointestinal endoscopy after 6 weeks were also applied to the control group.

Statistical analysis

Results were expressed as means \pm SEM. Statistically significant differences between groups were assessed using either Student *t* test, Fischer's exact test or ANOVA test, as appropriate. $P < 0.05$ was considered to be significant.

RESULTS

All enrolled patients completed the study. *Hp* was eradicated in 50 % (20/40) type 2 diabetic patients and in 85 % (34/40) *non-diabetic* dyspeptic patients. The eradication rate was significantly lower in diabetics in comparison to the controls ($P < 0.05$).

There were no side effects in both groups, which led to discontinuation of the treatment.

At baseline, type 2 diabetic patients infected with *Hp* showed a high prevalence of gastrointestinal symptoms. There was a statistically significant decrease in epigastric pain, nausea and belching after *Hp* eradication treatment (Table 2).

Table 2 Prevalence of gastrointestinal symptoms in type 2 diabetic patients before and after the treatment

	Before (%)	After (%)	<i>P</i>
Epigastric pain	75 (30/40)	30 (12/40)	<0.05
Bloating	68 (27/40)	43 (17/40)	NS
Pyrosis	63 (25/40)	38 (15/40)	NS
Nausea	55 (22/40)	23 (9/40)	<0.05
Belching	63 (25/40)	30 (12/40)	<0.05
Early satiety	30 (12/40)	20 (8/40)	NS

Denotes: NS=not significant

Age, duration of the diabetes and Haemoglobin A1c levels were not significantly different between the diabetics in whose *Hp* was eradicated and whose *Hp* was not eradicated (Table 3).

Table 3 Comparison of demographic data of diabetic patients in whom *Hp* was eradicated and *Hp* was not eradicated

	<i>Hp</i> (+) at control endoscopy	<i>Hp</i> (-) at control endoscopy	<i>P</i>
Female sex (%)	53	47	>0.05
Age (y)	56.2 \pm 8	55.8 \pm 8	>0.05
Diabetes duration (y)	7.3 \pm 5	7.2 \pm 5	>0.05
HbA1c (%)	7.2 \pm 1.2	7.2 \pm 1.2	>0.05

DISCUSSION

Hp infection is responsible for up to 90 % of upper gastrointestinal diseases and is linked to the development of

gastric carcinoma, MALT associated lymphoma and has to be eradicated whenever it's possible^[9,10].

Standard triple therapy (Omeprazole, Clarithromycin and Amoxicillin) has been shown to be highly effective in the eradication of *Hp* in *non-diabetic* subjects in many previous studies (91 %)^[11,12]. In our control group, we found an eradication rate of 85 %, which was compatible with the results in the literature.

Many authors have extensively explored the relationship between *Hp* and diabetes mellitus. There has been controversial results in previous studies but in a larger, well-designed study of Xia *et al.*, there was no difference of the seroprevalence of *Hp* infection between patients with diabetes mellitus and *non-diabetic* controls^[5]. But there were no studies which explored the efficacy of anti *Hp* protocols in type 2 diabetics, whereas in a study of Gasbarrini *et al.* in type 1 diabetics, the *Hp* eradication rate was 65 % in comparison to 92 % in controls^[13]. In another study performed on type 1 diabetics, the eradication rate was 62 % with different triple antibiotic regimens and this could be increased by quadruple regimen to 88 %^[14]. In the present study performed on type 2 diabetics, a much lower eradication rate of *Hp* (50 %) was found. Histopathological examination was used in this study for the detection of pre and post treatment *Hp* and as the gold standard, it was more reliable and reproducible than the ¹³C urea breath test, which has been used in the studies by Gasbarrini *et al.*^[13,14].

Immunosuppression in diabetes might predispose to the low eradication rate of *Hp* infection but other mechanisms may also explain the low eradication rate of *Hp* in type 2 diabetics. Type 2 diabetics are more susceptible to many bacterial and mycotic infections, which may lead to frequent use of antibiotics, and to the development of resistance^[15-18].

Due to absorption problems in gastric mucosa, the extent of antibiotic absorption may be less^[19]. This study showed a high rate of pathological endoscopic findings in type 2 diabetics, which may lead to disorders in gastrointestinal motility and to insufficient absorption of the drugs. Autonomic neuropathy has also been accused as a culprit. But studies in the literature suggested that there was no correlation between *Hp* positivity and delay in gastric emptying.

A standard 10 days triple therapy with conventional antibiotics seems not to be warranted in diabetics. Due to problems of absorption and motility, alternative regimens with longer duration seem to be necessary for a higher eradication rate. In particular, if we take into consideration that gastrointestinal symptoms, which are quite frequent in diabetics, are significantly improving when it is possible to eradicate *Hp*, we should try to eradicate *Hp* in diabetic subjects. But this is a new area of research and the larger prospective studies with different anti *Hp* regimens for type 2 diabetics are needed.

Abstract

AIM: To determine predictive factors for postoperative dysphagia after laparoscopic myotomy for achalasia.

METHODS: Logistic regression was used to investigate the possible association between the response (postoperative dysphagia, with two levels: none/mild and moderate/severe) and several plausible predictive factors.

RESULTS: Eight patients experienced severe or moderate postoperative dysphagia. The logistic regression revealed that only the severity of preoperative dysphagia (with four levels: mild, moderate, severe, and liquid) was a marginally significant ($P=0.0575$) predictive factor for postoperative dysphagia.

CONCLUSION: The severity of postoperative dysphagia is strongly associated with preoperative dysphagia. Preoperative symptomatology can significantly impact patient outcome.

INTRODUCTION

Results of laparoscopic Heller myotomy are as effective as traditional surgery and have the additional advantages of a shorter hospital stay and less discomfort^[1,2]. Although the early results of mini-invasive surgery for achalasia appear satisfactory in general, postmyotomy dysphagia remains a problem^[3,4]. Most reports do not describe the cause of postoperative dysphagia although its incidence is quantified.

Aperistalsis, incomplete relaxation of the lower esophageal sphincter, exposure of the esophageal mucosa to reflux material, incomplete myotomy and a too tight or a distorted Dor fundoplication can result in dysphagia. In addition, operation-related trauma such as perforation, edema, vagal nerve injury and fibrosis may cause dysphagia. For further improvement of laparoscopic Heller myotomy, additional factors affecting results should be determined for postmyotomy dysphagia is not rare. This study was conducted to investigate the causes of persistent symptomatology and to assist in predicting poor results of laparoscopic surgery for achalasia.

MATERIALS AND METHODS

Patients

36 patients (18 females and 18 males) who underwent laparoscopic Heller myotomy and fundoplication were investigated retrospectively. All patients underwent a preoperative barium swallow, esophagogastrosopy and manometry to establish the diagnosis of achalasia.

Manometry

Lower esophageal sphincter (LES) manometry was performed utilizing the station pull-through method and the esophageal body study was completed using 10 wet swallows with the distal tip of the manometry catheter located 3 cm above the upper border of the LES.

Surgical procedures

Two surgeons performed these procedures at the same institution. Myotomy was performed in all cases from approximately 4 cm above the esophagogastric junction to 2 cm distal to the gastroesophageal junction. Methods used to establish the location of the esophagogastric junction included identifying an outward tapering of the stomach, a change in the thickness of muscularis, the angle of the circular muscles and observation with intraoperative esophagoscopy in selected cases. Either an anterior or posterior fundoplication was performed in conjunction with the Heller myotomy, according to the surgeon's preference.

Grouping

The response variable, postoperative dysphagia, was classified into 2 categories according to the severity: severe or moderate dysphagia (Group A), and mild or no dysphagia (Group B). A category of "severe dysphagia" represented debilitating dysphagia requiring therapeutic intervention; "moderate dysphagia" represented frequent but not requiring intervention, "mild dysphagia" represented occasional symptoms not requiring therapy and "no dysphagia" represented absence of symptoms.

Parameters

Fourteen predictive factors for postoperative dysphagia as the response / dependent variables were evaluated. These included age, weight, preoperative symptom duration, LES pressure, abdominal and overall length of the LES, relaxation of the LES, contraction pressure of the esophageal body, percentage of simultaneous contractions, preoperative pneumatic dilation, the type of fundoplication, severity of preoperative dysphagia (*D*), heartburn (*HB*) and regurgitation (*R*). Factors *D*, *HB* and *R* were numerically ranked by an independent observer according to their severity, as 1-4 for mild through liquid dysphagia, 0-3 and 0-3, respectively. Preoperative forceful dilation and the type of fundoplication were categorized as binary (0-1) variables.

Statistical analysis

Since our response variable was binary, we had chosen the logistic regression approach and expressed the logarithm of the odds ratio for the response as a linear function of the

explanatory variables, i.e. we had fitted a model of the form:

$$\text{Log} \left(\frac{P}{1-P} \right) = \beta_0 + \beta_1 \times \text{Age} + \dots + \beta_{12} \times D + \beta_{13} \times HB + \beta_{14} \times R \quad \{\text{I}\}$$

Where P was the probability of poor outcome (moderate/severe postoperative dysphagia) and $1-p$ is the probability of favorable outcome (none/mild postoperative dysphagia). We used the statistical package SAS® 8.0 to implement the maximum likelihood estimation of the coefficients of the above equation. As a result, the final model included only one predictive factor.

RESULTS

Six patients experienced severe dysphagia after the operation and required interventional treatment. A 43 year-old female complaining of severe postoperative dysphagia and weight loss underwent repeat laparoscopic myotomy which was completed uneventfully 16 months after the primary myotomy. Only dense adhesions of the anterior esophagus were found.

Five patients underwent endoscopic dilatation 1 to 18 months after the primary operation. Two patients required two balloon dilatations while the remaining 3 patients underwent Hurst Maloney bouginage.

Two additional patients complained of moderate postoperative dysphagia. Their dysphagia lasted several months but improved without further intervention. Seven of the 8 patients with postoperative severe or moderate dysphagia experienced no complications. One patient had gastric stasis requiring 9 days of hospitalization.

As a result of the logistic regression analysis (equation {I}), only preoperative dysphagia, D , was marginally significant ($P=0.0575$); all the rest had P -values larger than 0.20 and were not significant. Thus, the final model involves only one predictive factor, D :

$$\text{Log} \left(\frac{P}{1-P} \right) = \beta_0 + \beta_{11} \times D \quad \{\text{II}\}$$

where $\beta_0 = -2.7953$, $\beta_{11} = 0.9366$. Therefore, the odds ratio increased as D increased, and as a result of {II} the odds in favor of having moderate/severe postoperative dysphagia for somebody with mild preoperative dysphagia were approximately 39.2 % of that for somebody with moderate preoperative dysphagia. Similarly, the chance of somebody with moderate preoperative dysphagia to have moderate/severe postoperative dysphagia was 39.2 % of that for somebody with severe preoperative dysphagia and, finally, somebody with severe preoperative dysphagia had only 39.2% of that chance for somebody with moderate preoperative dysphagia. The last number was derived by first exponentiating 0.9366 which gave 2.551, and then finding its reciprocal, 0.392.

What we could derive from {II} was the fact that there existed a positive association between the probability of poor outcome (severe or moderate postoperative dysphagia) and the explanatory variable, the severity of preoperative dysphagia, D . The fact that we obtained only marginal significance ($P=0.0575$) was apparently due to the small sample size. Should the sample size be increased, the result would have been statistically significant at a level 0.05.

DISCUSSION

The objective of this study was to clarify causes for postoperative dysphagia after laparoscopic Heller myotomy for achalasia.

The severity of preoperative dysphagia is marginally significant with a P value of 0.0575 and was positively

associated with postoperative dysphagia. Numerous articles on laparoscopic Heller myotomy have been published since the first case report^[5]. However, none have specifically addressed the cause of failed myotomy. Some studies were instructive in surgical technique and others are simply case reports^[6,7].

The type of fundoplication and the extent of myotomy onto the gastric wall are extremely important for this operation^[8,9]. A previous report has shown that patients undergoing anterior fundoplication in conjunction with myotomy were more likely to experience postmyotomy dysphagia or heartburn than those undergoing posterior fundoplication^[9]. Posterior fundoplication is considered effective because it is capable of keeping the edges of myotomy apart^[10].

We demonstrated a positive association between the probability of poor outcome and the severity of preoperative dysphagia. Why does the severity of preoperative dysphagia make the outcome poor? Preoperative manometry showed that patients with the more severe preoperative dysphagia did not always have higher LES pressure or poor relaxation of the LES. There also was no evidence of poorer esophageal peristalsis (all patients were 100 % dysfunctional).

Patients with short-term dysphagia (5 to 6 months) were included in the analysis because they presented a significant problem for the clinician. Early postoperative dysphagia (< 2 months) was well tolerated by the patient. More prolonged difficulty required explanation. The degree of preoperative dysphagia could be explained preoperatively as a postoperative risk factor and would assist in reducing patient anxiety and expectations.

The length of myotomy is believed to be a critical technical feature of the operation. The extent of the gastric myotomy appears to play a key role in prevention of dysphagia. Some surgeons prefer to extend the myotomy 1 cm beyond gastroesophageal junction^[11,12], while others recommend 2 cm or longer^[9,13]. Generally, a shorter gastric myotomy is performed in conjunction with the transthoracic or thoracoscopic approach. On the other hand, longer myotomy is usually performed with concomitant fundoplication with open transabdominal or laparoscopic approach^[14,15]. The former operation is prone to gastroesophageal reflux disease as documented by pH monitoring^[10,16]. Several authors have demonstrated the necessity of fundoplication. They have shown that patients undergoing myotomy without fundoplication have a higher chance of experiencing postoperative gastroesophageal reflux^[17,18]. Mattioli *et al.* has clearly shown in a prospective study that a significantly better long-term outcome results from a transabdominal long cardiomyotomy plus anterior fundoplication as compared to transabdominal long myotomy alone or a transthoracic short cardiomyotomy^[18].

Abstract

AIM: The study was initiated to evaluate the reactogenicity and immunogenicity of a recombinant hepatitis B vaccine in age group >40 years and to study the response of a single booster dose in primary non-responders to the hepatitis B vaccination.

METHODS: A total of 102 volunteers without markers of hepatitis B infection (negative for HBsAg, anti-HBc antibody, HBeAg and anti-HBs antibody) received 20 µg of recombinant HB vaccine intramuscularly at 0, 1, and 6 months. Anti HBs titers were evaluated by a quantitative Elisa kit at 90 and 210 days. A booster dose of 20 µg HB vaccine was given after 6 months of the 3rd vaccine dose to the 15 non-responders and anti-HBs titers were measured after 1 month.

RESULTS: Seroprotection (anti-HBs GMT³ 10 IU/L) was achieved in 85.3 % (87/102) volunteers. The mean GMT titers of the vaccine responders was 136.1 IU/L. Of the seroprotected individuals, there were 32.4 % (33/102) hyporesponders (anti-HBs titers <10-99 mIU/ml) and 52.9 % (54/102) were responders (anti-HBs titers >100 IU/L). All the non-responders (15/15) responded to a single dose of the booster dose of recombinant HB vaccine and their mean anti-HBs antibody titers were more than 100.5 mIU/ml after the booster dose.

CONCLUSION: Recombinant hepatitis B vaccine offers good seroprotection in the age group >40 years and has a good safety profile. A single booster dose after 6 months in primary non-responders leads to good seroprotective anti-HBs antibody titers. However, larger population based studies are needed to evaluate the role of a booster dose in selected group of non-responders and whether such an approach will be cost effective.

INTRODUCTION

Hepatitis B infection is a major public health problem worldwide due to its long-term sequelae which include chronic

hepatitis, cirrhosis and hepatocellular carcinoma. The situation is grim in developing countries like India, where blood bank infrastructure is non-existent outside the major metropolitan cities and safe blood handling practice standards are low. India comes under intermediate zone of HBV prevalence, and with a carrier rate of 4.7 %^[1,2] has a estimated 42 million carriers, next only to China. Hepatitis B vaccination has been one of the success stories of the 20th century and has been extensively used in a wide range of groups throughout the world. Hepatitis B vaccination programmes have successfully reduced the prevalence of hepatitis B, e.g. in Taiwan, where universal HB vaccination^[3] has led to a significant reduction of hepatitis B prevalence and incidence of hepatocellular carcinoma in children. The immunogenicity, efficiency and safety profile of hepatitis B vaccine has been well established. More than 90 % seroconversion has been achieved in adult populations consistently^[4-7]. The safety profile of the recombinant vaccine has been very good^[8]. No response to hepatitis B vaccination is increased among certain risk groups like smokers, diabetes, chronic renal failure patients, elderly obese individuals. It is important to predict vaccine non-responders as they are susceptible to break through hepatitis B infection^[9]. The study was designed to evaluate the immunogenicity and reactogenicity and safety profile of a recombinant hepatitis B vaccine in subjects above the age of 40 yr and to study the response of a single booster dose in primary non-responders to hepatitis B vaccination.

MATERIALS AND METHODS

Volunteer selection

The study was conducted in L. N. Hospital, New Delhi over the period of one year (1996-1997). A total of 147 healthy volunteers (volunteers were attendants of the patients attending the medical OPD services) in the age group more than 40 yrs out of 387 healthy persons who were none obese and non-smokers attending the medical outpatient services consented to be included in the study. All of these volunteers were tested for markers of HBV infection. All the subjects were screened by the serological tests including HBsAg (Ranbaxy Diagnostics, India) and anti-HBc (Melotec, Spain) using commercially available ELISA kits. 102 volunteers who were negative for all the serological markers of hepatitis B infection, completed the hepatitis B vaccination programme.

HBV vaccination and sample collection

In a total of 102 volunteers after their informed consent, 20 mg of recombinant DNA hepatitis B vaccine (EnivacHB, Panacea Biotech) was administered intramuscularly at a dosing schedule of 0, 1 and 6 months. Five dropped out after the first vaccine dose themselves, hence 102 volunteers received all the three doses of HBV vaccination. Serum samples for anti-HBs antibody titres were determined at 90 and 210 days. Anti-HBs antibodies were done using a commercially available quantitative ELISA kit (AUSAB-EIA, Abbot Labs, USA).

Protection with hepatitis B vaccination is considered to be achieved when concentration of anti-HBs antibody titers is more than 10 IU/L. A non-response was defined as mean anti-HBs antibody titers below 10 IU/L, low responders were those with titers between 10-99 IU/L, and those with anti-HBs titers more than 100 IU/L^[13-26] were responders. A high response was on with titers more than 1 000 IU/L.

Booster schedule

All the non- responders (15/15) received an additional booster dose (20 µg) at 6 months after the third vaccination dose (12 months from the first vaccine dose) and the anti-HBs titers were measured after one month of booster dose.

Statistical analysis

Statistical analysis was done using Chi-square test and Student's test.

RESULTS

A total of 102 subjects were enrolled in the study. The mean age of the study group was 44.6±5.6 yr. with male: female ratio of 1.9:1. At day 90, after administration of two doses of recombinant vaccine 87.3 % (89/102) subjects achieved seroprotective levels of anti-HBs. At day 210 after administration of the third dose of recombinant vaccine 87/102 (85.3 %) subjects achieved seroprotective levels of anti-HBs. The mean anti-HBs titres achieved after the third dose of vaccine in the responders was 136.1 IU/L. The age distribution of mean anti-HBs levels achieved after the third dose of vaccine are given in Table 1. The peak anti-HBs levels achieved are lower in patients with increasing age. Further more, 13.3 % (11/83) subjects in the age group 40-49 years did not achieve seroprotective levels. Whereas ¼(25 %) subjects in the age group >60 years did not respond but the difference was not statistically significant. Also the number of high responders (anti-HBs levels >1 000 IU/L) was not significantly higher in the age group 40-49 years as compared to the age group 50-59 years [85.7 % (18/21) in the age group 40-49 years and 14.3 % (3/21) in the age group 50-59 years]. The mean age of 15 non- responders was 46.4±6.9 yr which was, however, not statistically different from the mean age of responders. 11.9 % (8/67) males were non- responders whereas 20 % (7/35) females were non- responders but the difference was not statistically significant.

All the non- responders, who were given an additional booster dose of 20 µg recombinant vaccine, responded and this achieved seroprotective levels.

Table 1 Age distribution of (GMT) anti-HBs titers

	Age (years)			Total
	40 - 49	50 - 59	> 60	
Male	52 (76.5%)	13 (19.1%)	3 (4.4%)	68
Mean GMT	136.0	105.9	107.5	
Female	30 (91.1%)	2 (5.8%)	1 (2.9%)	33
Mean GMT	145.4	177.6	41.56	

DISCUSSION

Risk factors that have been associated with non-response to hepatitis B vaccine include increasing age, male gender, obesity, history of smoking, administration of vaccine in buttock rather than deltoid^[4,8,10-13], diabetes and chronic renal failure^[14,15]. In many of the non-responders not explained by the above risk factors, certain HLA types have been found to

be associated with non response^[16-19]. The relationship of hepatitis B vaccination response with age is controversial. Our study suggests that seroconversion in age group >40 years is 85.7 %, which is considered high compared to most other studies^[20,21] where a seroconversion rate of around 60 % has been reported. However, as all the above studies, we too found a decreasing seroconversion rate with increasing age (Table 1). Our study suggests that 85.7 % of the high responders (mean titers >1 000 IU/L) occurred in the relatively younger age groups. These findings favor the hypothesis that increasing age decreases seroprotective antibody formation after vaccination. This finding is of clinical importance as non-responders who do not develop protective antibody level remain susceptible to break-through hepatitis B infection. Although no comparative Indian study of HBV vaccine in elderly is available, reports in adults show a 90-100 % seroconversion rate for 20 µg recombinant HBV vaccine administered intramuscularly^[22] not different from Western rates. For management of non-responders, there are no exact guidelines. Most unresponsive subjects are not absolute non-responders, since it has been shown that most of them can develop protective anti-HBsAg titers after a fourth or fifth dose of vaccination^[23-25]. Most studies in literature have found a variable response rate of 40-60 %^[28-30] to booster dose vaccination among nonresponders. Our study suggests a 100 % seroprotection rate after a single booster dose that is higher than most reports in the literature. One of the reasons for higher rate of seroprotection in our study compared to other reports in literature could be: (i) volunteers had received the booster dose after 6 months from the last vaccine dose and (ii) The selection of non-obese and non-smoking volunteers. If further such reports of 100 % seroprotection are available from other centers as well, an additional vaccine dose among the older populations could be recommended routinely after evaluation of cost effectiveness of such a strategy. There were no major side effects and relatively few minor side effects viz pain at injection site, fever etc. in 36/102 (35.3 %) of the cases. To conclude, the study suggests that the recombinant HBV vaccine is highly immunogenic with good safel profile among the age group >40 yr and a single booster dose is effective in non-responders. Further larger population based studies need to be undertaken to confirm our findings.

ACKNOWLEDGEMENT

We wish to thank Sanjay Singh and Abhijit Kumar of Panacea Biotech for extending co-operation and providing us the vaccine for the clinical trial.

Abstract

The limits of medicine have not yet been reached. Numerous human illnesses initially thought to be incurable are reversible under unique and unpredictable individual circumstances. This paper, and the preceding companion publication, describes instances of the successful treatment of patients previously labeled as untreatable, including instances of severe ulcerative colitis and Crohn's disease.

<http://www.wjgnet.com/1007-9327/9/885.htm>

“We simply cannot predict what will happen to every given patient.”

—James S. Goodwin and Jean M. Goodwin - 1987

The recent (2002) social visit with a former, now healthy patient, first seen 54 years earlier, prompted the review of my 1960 paper entitled “The Treatment of the Untreatable Patient”^[1]. In that publication, I described the improvement and recovery of a group of patients, some with organic disease (cancer, inflammatory bowel disease, and septicemia) and some with emotionally-related disorders who responded to sustained nutritional aid and emotionally supportive therapy after having been evaluated elsewhere as “medically untreatable.”

My former patient, R.K., had immigrated with his parents to the USA from Germany in 1938. Now age 66, and in good health, he was first seen by me in 1948 when he was 12 years old. He had been diagnosed at two major medical centers as having severe ulcerative colitis, “untreatable medically”, and “requiring a total colectomy and ileostomy”. His parents then had brought him to the University of Chicago for admission to my hospital service. Physical examination revealed a pale, undernourished boy, obviously sick. Diagnostic studies confirmed the presence of severe idiopathic ulcerative colitis involving the entire colon. Laboratory tests documented the presence of a severe iron-deficiency anemia and a lowered serum albumin of 2.8 grams (normal 4.0 grams).

In the 1940s and 1950s, it was possible at the University of Chicago Medical Center, and very helpful, to keep seriously ill patients in the hospital for extended periods of time, and R. K. remained for approximately three months. Therapy initially included blood transfusions, nutritional support, and sulfonamides. Supportive psychotherapy, emphasizing

personal improvement and ultimate recovery, was provided for the patient. The patient's parents were informed daily as to progress and provided daily encouragement. In an ambience of optimism, expectations of success, and the involvement of an enthusiastic and caring hospital staff, the patient began to improve. Steroids, immunosuppressive compounds, and biological agents, of course, were not yet available. After the anemia had been corrected with several blood transfusions and the serum albumin had been restored to normal, with infusions of human albumin, the diarrhea, rectal bleeding and the abdominal discomfort gradually diminished. His appetite improved and he began to gain weight. When he returned home after three months in the hospital, he also had increased in height. At home, the improvement continued without interruption. After six months, and in the absence of any symptoms, all medications and dietary limitations were discontinued. At age 21, he was 6' 2" tall and weighed 190 lbs. He has remained well ever since. He married and raised a family of three children and 8 grandchildren, all healthy. Today, he continues in excellent health and is a successful businessman. In retrospect, R.K. and his colon were not “medically untreatable” initially, but rather difficult to treat. What was the therapeutic difference? It was probably the sustained therapy, the optimistic approach, and the strong nutritional and psychosocial personal support. The patient himself includes the interest, skill and unwavering optimism of his physician.

While less common than hoped for, such instances of recovery from ulcerative colitis are not rare, as described in earlier papers^[2,3]. In a second recent experience, A. T., first seen by me in 1952, with severe ulcerative colitis, had developed the disease in 1951; the treatment included nutritional and emotional support supplemented with injections of ACTH. The colitis recurred intermittently until 1959, when the patient “changed his life style” and “totally eliminated stress from his life”. The diagnosis of “multiple polypoid defects” on barium examination performed elsewhere, in 1991 had led to a recommendation of colectomy; but follow-up examinations found no evidence of colonic polyps. Expert colonoscopy was performed in April 2000 at the University of Chicago, and except for a mild “vascular distortion”, was unremarkable; colonic biopsies were negative for dysplasia. The patient has remained free of symptoms since 1960, now continuing for more than 40 years. Living in Hawaii, he organized and became president of a successful chemical company. In this patient also, the explanation for the apparent recovery from ulcerative colitis remains unclear: although “the avoidance of stress,” may be a contributing factor. Noteworthy in both patients with ulcerative colitis, therapy had emphasized nutritional and psychological support. In each instance, IBD improvement had coincided with personal achievement; issues rarely emphasized in today's world of molecules and genes. Biologic therapy, cytokine inhibition and gene transfer are exciting treatment possibilities for the future; but until these complex measures are realized, and perhaps irregardless of their availability, treatment of inflammatory bowel disease should continue to emphasize detailed attention to the nutritional and personal needs of the patient.

The word “untreatable” does not appear in Webster's dictionary; the Random House Dictionary of the English language, the American Heritage dictionary, nor in Roget's

Thesaurus. Webster's Medical Desk dictionary blandly defines untreatable as "not susceptible to medical treatment". Medicine has never fully accepted Hippocrates' observation^[4], "... for it is impossible to make all the sick well . . .", and has made remarkable progress in reducing the ranks of the "untreatable". Indeed, as the Goodwins^[5] have indicated: "Twentieth Century Medicine can be seen as a systematic denial of the impossible." Nevertheless, uncertainty in the course of human disease, and in its prognosis has characterized Medicine, throughout history as reviewed by J. Barondess^[6] and by R. Fox^[7].

The designation "untreatability" in medicine is both arbitrary and absolute. It may be a relative term, reflecting non-cooperation of the patient or an inadequate therapeutic approach, rather than the illness itself. Occasionally, "untreatability" is the inappropriate label for an initially erroneous diagnosis, as illustrated in the following patient, first described in 1960. A.J., a 62-year old photo-engraver, in 1940, had developed severe pain in the epigastrium and in the back with nausea, vomiting, and weight loss. Surgery at another hospital demonstrated an "inoperable carcinoma of the pancreas," and the abdomen was closed. The patient then was referred to the University of Chicago for possible chordotomy to relieve the intractable pain. Here, the pain and vomiting continued. The alert hospital resident noted the vomitus as clear, watery-appearing, fluid; and having learned earlier that gastric acid secretion is a watery appearing fluid; he tested the vomitus with Töpfer's reagent, and indeed identified the fluid as gastric secretion containing hydrochloric acid. The intragastric instillation of hydrochloric acid reproduced the pain and vomiting, and gastric aspiration, removing the acid secretion, relieved the pain. X-rays demonstrated a huge duodenal ulcer crater. Large amounts of calcium carbonate hourly, day and night, atropine sulphate, and frequent gastric aspirations were required to diminish the pain and heal the ulcer, events consistent with duodenal ulcer, penetrating into the pancreas, causing pancreatitis. The surgeon presumably had misinterpreted the inflammatory thickening of the pancreas as neoplasm. In August 1941, an appendectomy was performed for acute appendicitis; and confirmed the absence of carcinoma. Ulcer recurrences necessitated a supradiaphragmatic vagotomy; and gastroenterostomy in June 1944, with complete recovery. He later succumbed to a heart attack 35 years after the initial erroneous diagnosis of pancreatic carcinoma.

At times, the determined patient provides the vital spark, transforming an apparently hopeless situation into one of renewed hope and improved health. A striking example, cited in the 1960 paper, is that of a man, then 53 years old, with a history of alcoholism, cirrhosis of the liver and malnutrition, who was hospitalized with ascites and thrombophlebitis of superficial veins in the abdominal wall. X-rays revealed not only esophageal varices, but also a linitis plastica-type carcinoma of the stomach. When he became confused, the situation appeared hopeless indeed. It seemed only humane to grant the patient's plea for simply orange juice and coffee. Astonishingly, instead of deteriorating, he improved. The thrombophlebitis subsided; the ascites gradually diminished, and in several weeks the patient returned home. Additional history revealed that he had swallowed lye during childhood, causing the gastric deformity simulating neoplasm. The patient survived for many years thereafter; and occasionally revisited us to demonstrate his continuing viability. The hepatic disease eventually became "untreatable", and he died following a massive hemorrhage from esophageal varices; but had he been untreatable initially?

Patients with emotional difficulties and associated gastrointestinal symptoms may be especially challenging, because of the difficulty in fully understanding emotionally generated symptoms^[8,9] prematurely prompting the label of

"untreatability". This important problem has been reviewed recently^[10]. Useful therapy includes the exclusion of structural disease and evaluation of the life situation of the patient, a reassuring explanation of the physiologic basis of the symptoms, avoiding criticism, and sustained supportive therapy^[11]. Medication alone often does not suffice in these circumstances, and the art of medicine is as necessary as its science. Indeed, hope, faith and trust, together with sustained therapeutic effort salvage more sick people than many physicians realize^[12,13]. H.G. Wolff^[14] has pointed out that "hope, like faith and purpose in life, is medicinal".

The significant beneficial impact of religious beliefs in some patients with chronic illness also has been documented^[15]. The treatment of such patients, often is prolonged, and demanding; but the satisfaction following successful therapy is one of the rewarding personal experiences in the practice of medicine. An example of this type of "medical untreatability", noted in the 1960 paper, is that of M.V., then a 50 year-old man, who repeatedly sought treatment for digestive symptoms, including a bitter taste, belching, flatulence, constipation and diarrhea, abdominal pain, and fatigue; diagnosed as an irritable bowel. Many laboratory and diagnostic studies were normal; and many consultations with physicians in other areas of medicine did not reveal additional problems. Psychiatric evaluation of the patient included the following: "... a passive, inhibited male. . . his hypochondriacal expressions are at once expressions of his primary concern with himself and defenses against object relationships (which are threatening because of their homosexual character . . .) . . . Psychotherapy could be of little value and is not indicated in the present circumstances". However, the patient was regularly employed. In time he became involved in the affairs of his community and was recognized for this activity. The many medical visits undoubtedly provided him with a measure of support, though the continuing need for reassurance reflected limited acquired understanding of his situation. The patient was perhaps "untreatable" in that his basic emotional difficulty was not fully resolved. However, he was relatively treatable in that, with support, reassurance, and personal attention, he was able to function as a useful citizen. Since then, modern research has documented significant biological and physiologic relationships between mind and body^[3,16,17] and has provided a scientific basis for the understanding and management of emotionally associated gastrointestinal symptomatology.

The limits of medicine, as these clinical experiences illustrate, are by no means rigid or irreversible. While much has been learned about human illness and its molecular nature, there is much more knowledge yet to be acquired about individual human illness^[18], its neurological, immunological and genetic dimensions. Hopefully, as expressed by Barondess^[6], "... through continued research and technologic innovation, fueled by curiosity and personal drive, by institutional agendas and by the insightful and compassionate physician in the service of human needs", additional progress can be anticipated in the successful management of the "untreatable patient."

Abstract

AIM: To understand the response of human *REV3* gene to gastric cancer inducing carcinogen *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG) and its role in human mutagenesis.

METHODS: The response of the human *REV3* gene to MNNG was measured in human 293 cells and FL cells by RT-PCR. By using antisense technology, mutation analysis at *HPRT* locus (on which lesion-targeted mutation usually occurs) was conducted in human transgenic cell line FL-*REV3*⁻ by 8-azaguanine screening, and mutation occurred on undamaged DNA template was detected by using a shuttle plasmid pZ189 as the probe in human transgenic cell lines 293-*REV3*⁻ and FL-*REV3*⁻. The blockage effect of *REV3* was measured by combination of reverse transcription-polymerase chain reaction to detect the expression of antisense *REV3* RNA and Western blotting to detect the *REV3* protein level.

RESULTS: The human *REV3* gene was significantly activated by MNNG treatment, as indicated by the upregulation of *REV3* gene expression at the transcriptional level in MNNG-treated human cells, with significant increase of *REV3* expression level by 0.38 fold, 0.33 fold and 0.27 fold respectively at 6 h, 12 h and 24 h in MNNG-treated 293 cells ($P<0.05$); and to 0.77 fold and 0.65 fold at 12 h and 24 h respectively in MNNG-treated FL cells ($P<0.05$). In transgenic cell line (in which *REV3* was blocked by antisense *REV3* RNA), high level of antisense *REV3* RNA was detected, with a decreased level of *REV3* protein. MNNG treatment significantly increased the mutation frequencies on undamaged DNA template (untargeted mutation), and also at *HPRT* locus (lesion-targeted mutation). However, when *REV3* gene was blocked by antisense *REV3* RNA, the MNNG-induced mutation frequency on undamaged DNA templates was significantly decreased by 3.8 fold ($P<0.05$) and 5.8 fold ($P<0.01$) respectively both in MNNG-pretreated transgenic 293 cells and FL cells in which *REV3* was blocked by antisense RNA, and almost recovered to their spontaneous mutation levels.

The spontaneous *HPRT* mutation was disappeared in *REV3*-disrupted cells, and induced mutation frequency at *HPRT* locus significantly decreased from 8.66×10^{-6} in FL cells to 0.14×10^{-6} in transgenic cells as well ($P<0.01$).

CONCLUSION: The expression of the human *REV3* can be upregulated at the transcriptional level in response to MNNG. The human *REV3* gene plays a role not only in lesion-targeted DNA mutagenesis, but also in mutagenesis on undamaged DNA templates that is called untargeted mutation.

INTRODUCTION

It has long been known that exposure to certain chemicals is associated with the development of specific human cancers, which is largely the outcome of interaction between environmental agents and genetic susceptibility. Examples include the associations between amine dyes and bladder cancer, benzene and leukemia, aflatoxin and hepatocellular carcinoma, and tobacco smoke and lung cancer^[1-5]. Recent studies have also revealed that tobacco smoke significantly increases the risks for oral^[6, 7], esophageal^[3-5, 8], bladder^[9-12], pancreas^[11], gastric^[13] and colorectal cancers^[14]. In addition, men who have a history of chronic indigestion or gastroduodenal ulcer have substantially higher mortality rates associated with concurrent cigarette smoking^[13].

Tobacco smoke consists of many chemicals. One important substance found in tobacco smoke is chemical carcinogen *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG), a direct acting carcinogen, that targets the cellular DNA and induces severe genotoxic stress to the cell that can result in various DNA damages^[15]. Epidemiologic studies have suggested an etiological role for *N*-nitroso compounds from dietary sources in the development of gastric and colorectal cancer in humans^[16, 17], and animal experiments have shown that MNNG induces gastric cancer^[18-21] and colorectal cancer^[22, 23]. Obviously, the link between DNA damages and MNNG induced cancers is closely related to mutagenesis. To ensure normal growth control and accuracy in DNA replication, cells have developed a variety of responses to stress, such as DNA repair, cell cycle checkpoints, DNA damage avoidance, or in extreme cases, apoptosis^[24]. In addition, cells have also evolved a sophisticated lesion bypass system (also called translation synthesis, or TLS) to repair the damaged DNA, resulting in DNA damage lesion-targeted mutation. However, mutation can also occur on undamaged DNA template, which is designated untargeted mutation (UTM), which has been described in SOS-induced mutagenesis in *E. coli*^[25]. It has been known that untargeted and targeted mutations caused by SOS response in *E. coli* both are resulted from the inhibition of DNA polymerase functions

that normally maintain fidelity and the involvement of DNA polymerases with low fidelity, which include DNA pol IV (dinB), pol V (UmuD' 2C) and other factors^[26-30]. In eukaryote, it has been found that up to 40 % of cycl-91 revertants induced by ultraviolet (UV) is untargeted using mating experiments with excision deficient strains of *Saccharomyces cerevisiae*^[31], and that stress response induced by DNA damaging agents (8-methoxy-psoralen or UV) leads to specific and delayed UTM in mouse T-lymphoma cells^[32]. Previous studies in our laboratory also shown that low concentration MNNG induces UTM in mammalian cells^[33]. Currently, it has been known that specialized DNA polymerases are responsible for DNA damage lesion-targeted mutation in eukaryote. However, it is not clear which factor can be activated and involved in UTM on undamaged DNA templates.

The human *REV3* gene, encoding the catalytic subunit REV3 of human pol ζ , has been received intensive attention in recent years^[34]. *REV3* gene is thought to be the major component of error-prone TLS pathway^[34, 35], although a number of other polymerases might also be involved in this process^[36]. It is responsible for most of spontaneous and UV-induced mutation in yeast and humans, as well as somatic hypermutation in humans^[34, 35, 37-43, 44-47]. The expression of *REV3* appears to be elevated at the transcriptional level in some tumor cell lines^[48]. However, the response of *REV3* gene to gastric cancer inducing carcinogen MNNG and its role in MNNG-induced mutagenesis are still not clear. In order to understand the relationship between the human *REV3* gene and the etiology of gastric cancer and colorectal cancer in humans, the response of *REV3* to MNNG and its role in MNNG-induced mutagenesis, including both lesion-targeted and untargeted mutation, were explored.

MATERIALS AND METHODS

Cell culture and treatment

Human 293 cells were grown in DMEM (Dulbecco's Modified Eagle Medium, Gibco) containing 10 % fetal bovine serum (Gibco), 200 units/ml penicillin, 100 μ g/ml streptomycin and 200 μ g/ml kanamycin. Human FL cells were grown in MEM (Minimum Essential Medium, Gibco), containing 10 % newborn calf serum (Gibco), 200 units/ml penicillin, 100 μ g/ml streptomycin and 200 μ g/ml kanamycin. Transgenic cell line 293-*REV3*^[49] and FL-*REV3*⁻ (unpublished data) were established in this laboratory by transfecting 293 cells and FL cells with pM-RS⁻ plasmid^[50] that can express anti *REV3* RNA when induced by dexamethasone (dex). 293-M and FL-M cell line were established by transfecting 293 cells and FL cells with the control vector pMAM neo-amp⁻ alone. These transgenic cell lines were grown in MEM containing 200 mg/ml of G418 (geneticin, Gibco). For MNNG treatment, cells were exposed to 0.2 μ M of MNNG (Sigma, dimethyl sulfoxide (DMSO) as solvent) in serum-free DMEM (for 293 cells) or MEM (for FL cells) for 2.5 h, and then MNNG was removed and replaced with fresh medium. DMSO treated cells were used as control.

Response of human *REV3* to MNNG

The response of the human *REV3* gene to MNNG was measured at the transcriptional level by using reverse transcription-polymerase chain reaction (RT-PCR) with *ARF1* (encoding ADP-ribosylation factor 1) as the internal control. RNA from 2×10^6 293 or FL cells was extracted at different time point using TRIzol agent (Gibco) after 0.2 μ M MNNG treatment, followed by the first-strand cDNAs synthesis with 3 μ g of RNA using M-MuLV reverse transcriptase (MBI fermentas) and random hexamer primer. After exponential

phase selection, PCR was performed with the appropriate cycles: 5 min pre-denaturation at 95 $^{\circ}$ C, 30 sec denaturation at 94 $^{\circ}$ C, 30 sec annealing at 59 $^{\circ}$ C, 1 min extension at 72 $^{\circ}$ C, and an additional 10 min extension at 72 $^{\circ}$ C. PCR primers: *REV3*, 5' -TGT CCA AGG CAC CAT ATC TC-3' (sense), 5' -TGC TAC ACG TGG TAC TAC TG-3' (antisense); *ARF1*, 5' -GAA CAT CTT CGC CAA CCT CTT C-3' (sense), 5' -ACA GCC AGT CCA GTC CTT CAT A-3' (antisense). The sizes of the expected products are 635bp for *REV3* and 515bp for *ARF1*. Ratios of OD_{REV3}/OD_{ARF1} representing *REV3* transcript level were calculated.

Identification of the antisense blocking effect on *REV3* function in transgenic cells

The antisense blocking effect on *REV3* function was analyzed by detecting the expression of antisense *REV3* fragment with RT-PCR and the *REV3* protein level with Western blotting. RNA was extracted from transgenic cells, which could express antisense *REV3* fragment after 10 μ M dex treatment for 3 days. 0.1 μ g RNA from 1 μ g RNA sample digested by 1 unit DNaseI (Gibco) was reverse transcribed using the *REV3* specific sense primer (5' -AAG GCC AGC ATA CAA GAC-3'). For the positive control (with no dex treatment), a random hexamer primer was used as the reverse transcription. Each cDNAs sample was amplified with the specific primers: 5' -GCC AAG GAA TAC AGA GGA AGT-3' (sense), 5' -CCA GCT GAA GAC ATC AAT ACC-3' (antisense). The PCR cycling parameter is as following: 5 min pre-denaturation at 94 $^{\circ}$ C, 30 cycles of 30 sec denaturation at 94 $^{\circ}$ C, 30 sec annealing at 59 $^{\circ}$ C, and 1 min extension at 72 $^{\circ}$ C. Amplifications were completed by an additional 8 min extension at 72 $^{\circ}$ C. For Western blotting, the nuclear protein were extracted from the cell strains as described before^[24]. Each nuclear extract (30 μ g) was used for Western blotting, and the Ku70 protein was used as the loading control.

Detection of mutation at *HPRT* locus^[51]

2×10^5 cells of the FL, FL-M or FL-*REV3*⁻ were seeded in 100 ml culture flasks, respectively. After 1 day incubation, the media were replaced with HAT medium (Gibco) for 24 h and HT medium (Gibco) for the next 48 h to remove the pre-existed *HPRT* cells in the population, then the cells were induced with 10 μ M dex for another 48 h. After treatment with 0.2 μ M MNNG or DMSO for 2.5 h, the medium was removed and replaced with a fresh medium containing 10 μ M dex for an additional 24 h incubation. Cells reaching approximately 80 % confluent were subcultured three or four times, with a consistent density at 10^6 cells/flask. Then 200 cells were transferred to a 9-cm plate (5 plates total) for 15 days to count the relative cloning efficiency. In the meantime, 2×10^5 cells were seeded in 100 ml culture flask (5 flasks total). After 24 h, the medium was replaced with fresh one containing 5 μ g/ml 8-azaguanine (Gibco). Cells were then maintained for 30 days, with the medium changed every 3 days. After washing with 0.9 % NaCl, the clones were fixed with ethanol: acetic acid (3:1), stained with 1 % methylene blue, and the number counted. The mutation frequency was calculated as following:

Mutation frequency = (number of mutant clones/ 10^6 cells) \times (1/relative cloning efficiency).

Statistical analysis was performed according to the method described by Kastenbaum and Bowman^[52].

Detection of untargeted mutation on shuttle plasmid pZ189

The detection of untargeted mutation was performed as described (Figure 1)^[33].

Figure 1 The detection system of untargeted mutation occurring on undamaged DNA template. Cells were pretreated by MNNG, and then intact and undamaged shuttle plasmid pZ189 was transfected into cells after removing MNNG. After replication for 48 h in cells, replicated pZ189 plasmid was rescued and then transformed to host bacterial MBM7070 to screen pZ189 mutants.

RESULTS

Response of human mutator *REV3* to MNNG

It was found that PCR with 31 cycles for 293 cells and 28 cycles for FL cells ensured the exponential amplification of *REV3* and *ARF1* within the same tube (data not shown). The expression of *REV3* was upregulated at the transcriptional level in both 293 cells and FL cells after MNNG treatment. In MNNG-treated 293 cells, the level of *REV3* expression was significantly increased by 0.38 fold at 6 h, 0.33 fold at 12 h and 0.27 fold at 24 h, when compared with the control ($P < 0.05$, Figure 2). Similarly, the transcriptional level of *REV3* was also significantly increased by 0.77 fold at 12 h and 0.65 fold at 24 h in MNNG-treated FL cells, when compared with the control (all $P < 0.05$, Figure 2). The data suggest that the human mutator *REV3* gene was activated by low concentration MNNG treatment and could be regulated at the transcriptional level.

Figure 2 The response of the human *REV3* to MNNG at different time points. The response of *REV3* to MNNG was measured in human 293 cells and FL cells at the transcriptional level by using RT-PCR. ^a $P < 0.05$, compared with the control.

Identification of the antisense blocking effect on *REV3* function in transgenic cells

An expected high level of 297bp antisense RNA to C-terminal of *REV3* was detected in transgenic cells by RT-PCR (Figure

3). In addition, the results of Western blotting showed that the *REV3* protein level was obviously reduced in transgenic cells (Figure 4). Therefore, it was indicated that the function of *REV3* protein was partially blocked by antisense *REV3* fragment in transgenic cells.

Figure 3 Detection of antisense *REV3* RNA fragment expressed in 293-*REV3* cells using RT-PCR. A, 100bp DNA ladder; B, RT-PCR result in Dex-treated 293-*REV3* cells; C, RT-PCR result in 293-*REV3* cells (Dex-free); D, a positive control.

Western analysis showing the level of expression of *REV3* protein in nuclear extracts from *REV3* antisense-expressing transfectant FL-*REV3* and its parental strain FL. Ku-70 was used as the loading control.

Decreased formation of MNNG induced *HPRT* mutants in transgenic cells

HPRT locus is traditionally used as a genetic marker for genome instability. Normally the spontaneous mutation frequency at *HPRT* locus was quite low. In the present study, we observed that the spontaneous mutation frequency was 2.87×10^{-6} in FL cells, and 4×10^{-6} in FL-M cells. Interestingly, in FL-*REV3* cells, no spontaneous mutants were observed. This observation led to the speculation that *REV3* may be involved in the process of spontaneous mutagenesis.

Previous studies found that MNNG could induce *HPRT* mutation in human cells^[53]. It would be of interest to know if MNNG had the same effect on FL and the derived FL-M and FL-*REV3* cells. As shown in Table 1, we observed that MNNG treatment significantly elevated the mutation frequency from 2.87×10^{-6} to 8.66×10^{-6} at *HPRT* locus in FL cells. Similarly, the mutation frequency was also increased in FL-M cells by MNNG treatment from 4×10^{-6} to 18.75×10^{-6} . On the other hand, the induced mutation frequency was only 0.14×10^{-6} cells in FL-*REV3* cells, which was significantly lower than that of the spontaneous mutation frequency in FL cells (Table 1).

Decreased untargeted mutation frequency on undamaged plasmid transfected into MNNG pretreated transgenic cells

Intact and undamaged shuttle plasmid pZ189 DNA was introduced into MNNG pretreated human cells. Progeny plasmids were harvested 48 h after transfection, and used to transform MBM7070. White and light blue colonies were picked and the frequency of *supF tRNA* mutants was scored. As shown in Table 2, the spontaneous mutation frequencies were at comparable level between each cell lines. Untargeted mutation on undamaged DNA templates was increasingly

Table 1 Detection of the spontaneous and induced mutation frequency at *HPRT* locus in FL, FL-M and FL-REV3⁻ cells

Cell line	MNNG (0.3 μ M)	Antisense block of <i>REV3</i>	No. of mutants per 10 ⁶ cells selected	Mutation frequency (10 ⁻⁶)

a, c χ test *P*<0.05 and 0.01 respectively as compared with spontaneous mutation frequency; b, d χ test *P*<0.05 and 0.01 as compared with induced mutation frequency in 293-REV3⁻ and FL-REV3⁻ cells respectively.

induced in MNNG-pretreated 293, 293-M, FL and FL-M cells, with the mutation frequencies occurred in these cells being 4.5-5.8-fold higher than those in control groups. However, the untargeted mutation frequencies significantly decreased by 3.8 fold (from 7.37 \times 10⁻⁴ to 1.52 \times 10⁻⁴, *P*<0.05) and 5.8 fold (from 27.4 \times 10⁻⁴ to 4.0 \times 10⁻⁴, *P*<0.01) respectively in MNNG-pretreated transgenic 293 cells and FL cells in which *REV3* was blocked by antisense RNA, and the mutation frequencies were almost similar to their spontaneous mutation levels.

DISCUSSION

The interconnections between environment and human health have been increasingly recognized. With the increasing cases of environmental cancer in the world range, especially in developing countries, investigation on the potential biomarkers for environmental risk assay or new targets for gene therapy is an emergent task to prevent and control the carcinogenesis. In China, the incidence of gastric cardia cancer has greatly increased in the past 2-3 decades, and dietary habits might be one of the risk factors for the cardia carcinogenesis among Chinese population^[54]. Recently, it was found that COX-2 may contribute to progression of tumor in human gastric adenocarcinoma^[55]. However, it has become clear that the induction of carcinogenesis is a complex multi-step process involving a series of genetic and epigenetic changes. For example, the induction of colon cancer requires alterations in at least three tumor-suppressor genes (*MCC*, *DCC*, and *p53*) and activation of the oncogene *K-ras*^[56-58]. The genetic changes mainly occur in initiation, malignant conversion and progression stages in the development of malignant tumors^[59]. DNA damaging agents can induce lesions in DNA template, causing the block on DNA replication fork. However, it also leads to the activation of several TLS DNA polymerases, especially the activation of pol ζ , to restart the replication process by replacing the normal replication polymerases and finally result in lesion-targeted mutation^[40, 42, 60]. On the other hand, UV-light or chemical carcinogen can induce the UTM on undamaged DNA templates^[31-33].

It was interesting to find that human *REV3* gene, which

encodes the catalytic subunit of TLS polymerase ζ , was activated by the carcinogen MNNG that can induce gastric and colorectal cancer. Our computational analysis indicated that transcriptional factor binding sites for CREB, AP-1 and NF- κ B were found in the promoter region of *REV3* (data not shown). Previous studies in our laboratory have shown that MNNG treatment activates CREB^[61], AP-1 and NF- κ B (unpublished data) in mammalian cells as early epigenetic events, which indicates that *REV3* could be activated by MNNG via the activation of specific transcriptional factors in advance.

Mutation at *HPRT* locus can be used as an indicator to reflect the degree of genome instability^[62]. It has been recognized that *HPRT* mutants are generated directly by DNA damage^[62, 63], i. e., the mutation spectrum belongs to lesion-targeted mutation. In human fibroblasts, the number of UV-induced *HPRT* mutants is significantly increased, whereas, the mutation is remarkably depressed in the human cells that express high levels of *REV3* antisense RNA^[47]. In this study, our data showed that the spontaneous mutation of *HPRT* locus in human cells was dependent on the function of *REV3*, since mutation at *HPRT* locus was eliminated in cells expressing antisense *REV3* (Table 1). On the other hand, *REV3* gene was also involved in MNNG-induced *HPRT* mutation, like in UV-induced mutation^[47], as the antisense block of *REV3* function significantly decreased the MNNG-induced mutation frequency. It is also possible that other factors might be involved in MNNG-induced *HPRT* mutagenesis, for example, the function of human *REV1* gene is required for mutagenesis at *HPRT* locus induced by UV light^[64].

Interestingly, our data further indicated that human *REV3* gene also played a role in mutation genesis occurred on undamaged DNA templates. Unlike the role of *REV3* in lesion-targeted mutation, the spontaneous mutagenesis in *SupF tRNA* gene in pZ189 replicated in human cells was *REV3*-independent, i.e., the antisense block of *REV3* has no effect on the spontaneous mutations (Table 2). It was suggested that most of the spontaneous mutation occurring in such an experimental system are due to the deletion damage induced by the shear force during transfection. Different mechanisms are involved in repairing the base damage and deletion damage,

in the later case no evidence was presented of *REV3* dependent. In this study, however, we proved that MNNG-induced mutation on undamaged DNA templates was *REV3*-dependent (Table 2). To date, we still do not know whether there are other factors involved in untargeted mutation in addition to the human *REV3* gene. Taken together, these data strongly suggest that human *REV3* gene is capable of inducing mammalian genome instability, and this mutator gene could be a potential target for gastric and colorectal cancer prevention and gene therapy.

Abstract

AIM: To investigate the expression level of ZNRD1 gene in gastric cancer cells SGC7901 and gastric cancer MDR (multidrug resistant) cells SGC7901/VCR, and to observe the drug sensitizing and proliferation effect of ZNRD1 antisense nucleic acid transduction on SGC7901/VCR cells.

METHODS: Amplification of sequences encoding ZNRD1 from SGC7901/VCR cDNA by PCR. The levels of ZNRD1 mRNA expression were demonstrated using semiquantitative reverse transcription polymerase chain reaction (RT-PCR). Eukaryotic expression vector pcDNA3.1-anti ZNRD1 was constructed and transfected into SGC7901/VCR cells by lipofectamine. Immunochemical method was used to detect the expression of protein in SGC7901/VCR cells and transfectants. The cell cycle alteration and the intracellular adriamycin (ADM) accumulation were observed by FACS. Growth curve and drug sensitization of cells for vincristine (VCR) were analyzed with MTT assay.

RESULTS: We cloned the open reading frame of full-length ZNRD1. The expression of ZNRD1 showed higher in SGC7901/VCR than in SGC7901 cells. The antisense ZNRD1 drug-resistant clones were selected after gene transfection. Immunochemical results showed that the expression level of ZNRD1 protein was lower in anti ZNRD1-SGC7901/VCR cells than that in non-transfectants. Comparing to SGC7901/VCR and pcDNA3.1-SGC7901/VCR, anti ZNRD1-SGC7901/VCR showed gradually accumulated in G₁ phase, with a concomitant decrease of cell population in S phase. FACS also suggested intracellular ADM accumulation increased 2fold in SGC7901/VCR cells after transfected with antisense ZNRD1. MTT assay showed that transfectants cells proliferation was lagged and more sensitive to VCR than non-transfectants.

CONCLUSION: ZNRD1 gene displayed highly expression in VCR resistant gastric cancer cells. Expression of ZNRD1 protein was effectively blocked in anti ZNRD1-SGC7901/VCR cells by gene transfection. ZNRD1 antisense nucleic acid transfection sensitized drug resistant gastric cancer cells to VCR, increased ADM accumulation and inhibited the cells proliferation. ZNRD1 antisense RNA transduction could reverse the MDR of human drug-resistant gastric cancer cell SGC7901/VCR to a degree.

INTRODUCTION

Chemotherapy is one of the major methods in tumor treatment, but it often does not work due to MDR. In previous studies, we examined the expression of ZNRD1 is higher in VCR-resistant (SGC7901/VCR) cells than in parental cells SGC7901 by Subtractive Hybridization. The purpose of this study was to investigate the expression and effect of ZNRD1. We transfected ZNRD1 antisense nucleic acid, which is a Homo sapiens transcription-associated zinc ribbon protein, into VCR-resistant gastric cancer cells, and observed the expression of target protein in transfectants and the sensitivity of transfectants to chemotherapeutic agents in order to find the ground for reversing gastric cancer MDR.

MATERIALS AND METHODS

Material

Gastric cancer cell line SGC7901, VCR-resistant gastric cancer SGC7901/VCR cells, DH5 α bacterial strain and rat anti human ZNRD1 polyclonal antibody were kept in our department. The expression vector pcDNA3.1⁺ was from our department. EcoRV, Xba I, BamHI, cloning vector pUCm-T and T4 DNA ligase were purchased from Takara; MTT, DEPC from Sigma. TRIZOL, M-MuLV RT enzyme, Taq DNA polymerase, DMEM, Lipofectamine and G418 were products of Gibco BRL, and Primer from Sangon, Shanghai. Avidin biotin peroxidase complex (ABC) kit was obtained from Vector. VCR from Shanghai Hualian Pharmaceutical Co. Ltd, and ADM from Meiji Pharmaceutical Co. Ltd.

Methods

Cell culture The MDR subline SGC7901/VCR was developed by exposing the parental SGC7901 cells to stepwise increasing concentrations of anticancer drugs VCR. All cells were cultivated in DMEM supplemented with 10 % heat-inactivated fetal bovine serum at 37 °C in 5 % CO₂ atmosphere. Medium for SGC7901/VCR cells was further supplemented with VCR (1.0 μ g/ml). Before use in experiments, SGC7901/VCR cells were cultured in drug-free medium for 2 weeks. Cell stocks were cultivated in these conditions until nearly confluent and subcultured at 1:20 dilution or plated for experiments.

RT-PCR of ZNRD1 Total cellular RNA was extracted from SGC7901 and SGC7901/VCR cells using TRIZOL reagent, cDNA was transcribed from mRNA by RT-PCR. Total RNA (5 μ g) and random primer (2 μ g) in DEPC water were denatured at 65 °C for 15 min, then 4 μ L 5 \times reverse transcriptase buffer, 3 μ L 10 mmol \cdot L⁻¹ dNTP, 1 μ L M-MuLV reverse transcriptase (200 U) and DEPC water were added to have the total volume of 20 μ L. The reaction was performed at 25 °C for 10 min, then 42 °C for 1 hour, and 70 °C for 10 min to inactivate the reverse transcriptase. PCR was performed in a 50 μ L reaction mixture

containing 2 μ L reactant, 2.5 U *Taq* DNA polymerase, deoxynucleoside triphosphates (0.2 mM each), and 1.5 mM $MgCl_2$. The sense primer (5'-ccaactccctcctcagaccgcg-3') and antisense primer (5'-cctgggcaaatatacagtc-3') designed according to the DNA sequence of ZNRD1 (GenBank accession no. AF024617). The PCR consisted of initial denaturation at 94 °C for 5 min, followed by 30 reaction cycles (50 s at 94 °C and 60 °C, and 30 s at 70 °C) and a final cycle at 72 °C for 10 min. The β_2 -microglobulin was used to internal standard. The amplified fragments were detected by agarose gel electrophoresis.

Construction of recombinant pUCm-T-ZNRD1 and sequencing of ZNRD1 The PCR product of about 434 bp was isolated and ligated with pUCm-T vector by T4 DNA ligase. *E. Coli* DH5 α was transformed with the resulted recombinants pUCm-T-ZNRD1 and the positive bacteria colonies were screened by ampicillin resistant and blue-white screening with X-gal and IPTG. The cDNA of ZNRD1 cloned in pUCm-T was sequenced by the dideoxynucleotide termination procedure of Sanger.

Construction and identification of antisense nucleic acid The ZNRD1 cDNA was generated by digestion of pUCm-T-ZNRD1 plasmid with EcoRV and BamHI restriction enzyme site. Under T4 DNA ligase, cDNA fragment was inserted in the reverse orientation into the pcDNA3.1⁺ expression vector that was linearized with the same enzymes. The recombinant plasmid was identified through enzyme digestion and agarose gel electrophoresis.

Gene transfection and selection The pcDNA3.1-anti ZNRD1 (1 μ g) diluted in 100 μ L DMEM was mixed with 2 μ L lipofectamine, and placed at room temperature for 10 min. The mixture was then transfected into 1×10^5 SGC7901/VCR cells. After 24 h incubation at 37 °C, the culture was rinsed and re-fed with fresh growth medium. After transfection 48 h, the culture was split and then selected in the culture medium containing the neomycin analogue G418 (400 mg/L). At the same time, pcDNA3.1⁺ vector that lacked target genes transfected cells and non-transfectants served as negative controls.

Immunocytochemistry The expression of ZNRD1 was detected by immunocytochemical staining with the ABC kit. Cells were seeded in glass slides in DMEM at 37 °C for further 24 h, slides were washed with phosphate-buffered saline (PBS) for 3-5 min, then fixed in cold acetone for 5 min; 50 mL L^{-1} H_2O_2 was added and incubated at room temperature for 10-15 min then added 3 g L^{-1} TritonX-100 for another 15 min. The rabbit-anti-human polyclonal antibody ZNRD1 and normal rabbit serum were used at dilution of 1:100, and incubated at 4 °C overnight; Biotinylated goat anti-rabbit IgG was added and incubated at 37 °C for 1 h, then incubated with avidin DH-Biotinylated peroxidase for 45 min. Finally, color was developed by immersion of the sections in a peroxidase substrate solution DAB.

Cell cycle Cells were harvested, washed with PBS twice and fixed with ethanol at 4 °C overnight. Fixed cells were washed twice with PBS and stained with propidium iodide. The fluorescence intensity of propidium iodide-stained nuclei was determined by flow cytometric analysis.

Adriamycin accumulation According to described previously^[1], cells were cultured in 6-well culture plates at 37 °C for 48 h, ADM was added to the final concentration of 5 mg L^{-1} . After further culture for 1 h, PBS was used as negative controls. Cells were harvested and suspended in cold PBS; intracellular adriamycin fluorescence intensity was determined by flow cytometric analysis with the stimulative and acceptant wave length at 488 nm and 575 nm, respectively.

Growth curve Exponentially growing cells (10^3) were trypsinized and inoculated in 96-well plates. The cells were allowed to attach overnight and then incubated for eight days. Cell number and viability were determined by MTT cytotoxic assay. The cells in three wells were supplemented with 20 μ L MTT solution (5 g/L) every day. After 4 h, culture media were discarded followed by

addition of 150 μ L DMSO to melt crystal. The absorbance (A) was measured at 490nm using a microplate reader.

Drug sensitivity assay Dose-survival curves defining the sensitivity of SGC7901/VCR, pcDNA3.1-SGC7901/VCR and anti ZNRD1-SGC7901/VCR transfectants to VCR was obtained using MTT cytotoxic assay. Cells (10^3 - 10^4) diluted with 200 μ L 10 % DMEM were seeded into 96 well plates, after culturing for 12 h, added VCR (0.05, 0.5, 5 and 50 μ g/mL) according to the clinically established plasma peak concentration. Three days later, the absorbance (A) was measured as previously described above. The percentage of viable cells was calculated as follow: (A of experimental group / A of control group) $\times 100$ %. The IC_{50} was obtained by Nosa soft.

Statistical analysis

Student's *t* test was used to assess statistical significance of differences. If $P < 0.05$, the difference was considered significant.

RESULTS

Semiquantitative RT-PCR

To examine ZNRD1 gene expression in MDR subline SGC7901/VCR and SGC7901 cell line with Semiquantitative RT-PCR. Two fragments were amplified, ZNRD1 cDNA (434bp) and endogenous control gene β_2 -microglobulin (118bp). It is revealed significantly higher ZNRD1 expression in SGC7901/VCR than in SGC7901 cell line (Figure 1).

Figure 1 Semiquantitative RT-PCR for ZNRD1 and β_2 -microglobulin. M: Marker (DL2000); Lane 1,3: SGC7901 cells; 2,4: SGC7901/VCR cells.

Construction of recombinants

The recombinant of pUCm-T-ZNRD1 was constructed with the human ZNRD1 inserted into the cloning site of vector pUCm-T. Selection and identification of the recombinant was carried out by EcoRV/XbaI endonuclease digestion and agarose electrophoresis (Figure 2). The cloned DNA segments in selected recombinants were sequenced completely. According to the results of DNA sequencing, the cDNA in a selected recombinant was identical to the DNA sequence of ZNRD1 (GenBank accession no. AF024617) in the reading frame.

Figure 2 Electrophoresis of PCR product and pUCm-T-ZNRD1 digested with enzymes. Lane 1: PCR product; Lane 2,3: Marker (200bp); Lane 4: recombinant of pUCm-T-ZNRD1 cleaved by EcoRV and XbaI; Lane 5: recombinant of pUCm-T-ZNRD1.

Construction of eukaryotic expression vector

The EcoRV/BamHI fragment containing the complete ZNRD1 cDNA was subcloned into the pcDNA3.1⁺ expression vector. Selection and identification of the recombinants were carried out by EcoRV/BamHI endonuclease digestion and agarose electrophoresis (Figure 3). The pcDNA3.1⁺ vector carrying the neomycin-resistance gene for the selection of transfected cells.

Figure 3 Electrophoresis identification of pcDNA3.1-anti ZNRD1. Lane 1: pcDNA3.1-anti ZNRD1/EcoRV+BamHI; Lane 2: pcDNA3.1-anti ZNRD1; Lane 3: Marker (200bp).

Establishment of transfectants

When transfected cells were cultured selectively by G418 for 4-5 weeks, resistant clones formed gradually. In contrast, all nontransfectants died two weeks after G418 selection. Resistant clones were further incubated in the presence of low dose G418 for 40-50 days. We got resistant clones, anti ZNRD1-SGC7901/VCR cells.

Expression of ZNRD1

We detected ZNRD1 protein expression in transfectants by immunocytochemistry. All cells had positive staining, staining on anti ZNRD1-SGC7901/VCR cells was weaker than that on SGC7901/VCR, ZNRD1 protein was expressed mostly in the nucleus (Figure 4).

Figure 4 Detection of ZNRD1 expression in cells by immunocytochemical staining. ×200. A: SGC7901/VCR; B: anti ZNRD1-SGC7901/VCR.

Adriamycin accumulation

The effects of ZNRD1 antisense nucleic acid on ADM accumulation in SGC7901/VCR cells were determined by flow cytometric analysis. When cells were cultured in drug-DMEM, intracellular drug concentration would increase and finally stabilized at the highest plateau value, which was called adriamycin accumulation. The fluorescence intensity of SGC7901/VCR, pcDNA3.1-SGC7901/VCR and anti ZNRD1-SGC7901/VCR cells, mean fluorescence of 10^4 cells, is 3.68, 5.70, and 7.24 respectively. The intracellular ADR accumulation marked increase 2fold.

Inhibition of cell proliferation by ZNRD1 antisense nucleic acid

Cell cycle When transfected SGC7901/VCR cells with ZNRD1 antisense nucleic acid, the cell cycle obtained by FCM was as shown in Table 1. The anti ZNRD1-SGC7901/VCR cells gradually accumulated in G₁ phase, with a concomitant decrease of cell population in S phase.

Table 1 Cell cycle distribution of three kinds of cell lines (Number fraction)

Cell line	G1	G2	S	G1/G2
SGC7901/VCR	0.572	0.111	0.317	1.900
pcDNA3.1-SGC7901/VCR	0.652	0.091	0.256	1.887
Anti ZNRD1-SGC7901/VCR	0.744	0.118	0.138	1.881

Growth curves The cells viability were daily measured by MTT proliferation analysis. The growth curve showed that cell growth was suppressed after transfected with ZNRD1 antisense nucleic acid (Figure 5).

Figure 5 Growth curve of cells.

Drug sensitivity assay

The IC₅₀ of SGC7901/VCR, pcDNA3.1-SGC7901/VCR and anti ZNRD1-SGC7901/VCR cells treated with VCR is 50.51 ± 0.3 , 42.68 ± 0.79 , 10.87 ± 0.25 ($\mu\text{g/mL}$), respectively. The anti ZNRD1-SGC7901/VCR cells were more sensitive to VCR ($P < 0.01$).

DISCUSSION

Multidrug resistance (MDR), the principal mechanism by which many cancers develop resistance to chemotherapeutic drugs, is a major factor in the failure of many forms of chemotherapy. There are several ways for cancer cells to develop resistance or defense mechanisms against cytotoxic drugs^[2-4]. Several molecules have been found to confer MDR phenotype of tumor cells, such as P-gp, MRP, LRP, BCRP, GSH/GSH, TopoII, apoptosis associated proteins and anti-apoptosis proteins. We found the MDR markers are differently over-expressed and no coexpression exists in gastric cancer, MGr1-Ag was a novel MDR protein^[5-7]. However, these

molecules could not interpret completely how tumor cells develop MDR. The key to the clinical use of reversal agents therefore lies in searching for agents with low toxicity and high reversal activity. For gene therapy has very low toxicity, it might therefore be suitable for clinical use.

SGC7901/VCR is a vincristine-resistant SGC7901 cell line, and it overexpresses P-gp and is cross-resistant to several anti-cancer drugs. In previous studies, we have identified that 54 cDNA fragments were preferentially expressed in SGC 7901/VCR cells by DD-PCR^[8]. We isolated differentially expressed genes from drug-resistant human gastric adenocarcinoma cell lines using a polymerase chain reaction-based subtractive hybridization technique, and the expression of ZNRD1 is higher in SGC7901/VCR cells than in parental cells SGC7901^[9]. ZNRD1 is a new zinc ribbon gene that cloned from the human MHC class I region, named the gene ZNRD1 for zinc ribbon domain-containing 1 protein^[10]. Alignment with genomic DNA demonstrates that this gene spans 3.6 kb and consists of four exons and three introns. The full-length cDNA contains an open reading frame of 378 bp. Within the putative polypeptide of 126 amino acids, two zinc-ribbon domains were identified: Cx2Cx15Cx2C at the N-terminal and Cx2Cx24Cx2C at the C-terminal. The C-terminal domain is actually folded as three β -sheets stabilized by a zinc ion instead of finger like helices, compared to TFIIS zinc ribbon folds, they fit each other very well. The conserved amino acid sequence, CxRCx6Yx3QxRSADEx2TxFxCx2C is highly homologous to the yeast RNA polymerase A subunit 9 and transcription-associated proteins.

Transcriptional initiation and elongation provide control points in gene expression. The highly conserved eukaryotic transcriptional elongation factor TFIIS helps overcome elongation barriers and enhances proofreading by RNA polymerase II (RNAPII). The nucleic acid binding domain of TFIIS contains a Cys4 Zn⁽²⁺⁾-binding site with no homology to previously characterized Cys4, Cys6, or Cys2-His2 Zn fingers. Its solution structure exhibits a novel three-stranded antiparallel beta-sheet (designated the Zn ribbon), extends the repertoire of Zn-mediated peptide architectures and highlights the growing recognition of the beta-sheet as a motif of nucleic-acid recognition. The TFIIS functions may be modulated by the Zn ribbon domain through interactions with nucleic acids in the elongation complex. The RNAPII contain a Zn ribbon, in as much as the polymerase's 15-kDa subunit contains a sequence that aligns well with the TFIIS Zn ribbon sequence, including a similarly placed pair of acidic residues. It has demonstrated that TFIIS Zn ribbon is critical for stimulation of both elongation and RNA cleavage activities of RNAPII. Eukaryotic RNA polymerase II subunit 9 (RPB9) contains Zn ribbon motifs homologous to TFIIS; it regulates start-site selection and elongational arrest. RNAPII lacking the Rpb9 subunit uses alternate transcription initiation sites *in vitro* and *in vivo* and is unable to respond to the transcription elongation factor TFIIS *in vitro*. Alanine substitutions in the C-terminal zinc ribbon domain of Rpb9, like amino acid substitutions in the homologous part of TFIIS, completely eliminated elongation activity. It has show that RPB9 has a synthetic phenotype with the TFIIS gene^[11].

DNA primases are enzymes whose continual activity is required at the DNA replication fork. They catalyze the synthesis of short RNA molecules used as primers for DNA polymerases. All DNA primases contain a metal binding site, which is composed of four conserved Cys or His residues that could potentially coordinate zinc^[12]. Motif IV in the small subunit contains four cysteines that could form a zinc ribbon motif as a member of the zinc ribbon subfamily of zinc binding motifs.

The ability to selectively regulate the expression of genes

implicated in cancer could have important ramifications for both basic research and for therapy. Using peptide combinatorial libraries expressed in yeast, Bartsevich^[13] has screened for a novel zinc finger proteins that selectively bind to an overlapping EGR1/SP1/WT1 regulatory site in the promoter of the MDR1 multidrug resistance gene. The novel proteins were only moderately effective in blocking transcription by simple masking of the target site. However, when coupled to mammalian transactivator or repressor domains, they could selectively modulate the expression of reporter genes having promoters containing the MDR1 target site. Moreover, they could also regulate transcription of the chromosomal MDR1 gene. These studies potentially provide a novel alternative approach to the control of multidrug resistance. They also provide important insights into strategies for developing selective regulators of gene expression.

Thus, zinc ribbon is related to transcription and DNA replication, and the construction is same to zinc finger. It may regulate the expression of genes to control MDR.

Semiquantitative RT-PCR analysis is a sensitive and specific method; it is revealed that the RNA expression levels of ZNRD1 were significantly higher in SGC7901/VCR cells than that in SGC7901 cells. We transduced ZNRD1 antisense RNA into SGC7901/VCR cells, then found that intrinsic ZNRD1 protein was decreased, and transfected cells were more sensitive to VCR and cell growth was suppressed, the cell cycle was notably changed, the G1 phase cells were gradually increased, with a concomitant decrease of cell population in S phase, these observations suggest that ZNRD1 antisense RNA may be involved in the action of the G1 checkpoint and inhibition of DNA replication. ADR can emit fluorescence; its intensity represents its accumulation, which was markedly enhanced in transfectants. The results suggested that the formation of MDR in SGC7901/VCR cells was associated with over expression of ZNRD1. Because gastric cancer is common in China and some areas in the world^[14-33], these results may be important for further study.

Abstract

AIM: The expressive balance between matrix metalloproteinase-9 (MMP-9) and its tissue inhibitor of metalloproteinase-1 (TIMP-1) plays a critical role in maintaining the degradation and synthesis of extracellular matrix. Loss of such balance is associated with invasion and metastasis of tumors. This study aimed to determine the expression of MMP-9 and TIMP-1 in gastric carcinoma, and the association of the expressive imbalance between MMP-9 and TIMP-1 with the invasion and metastasis and prognosis of gastric carcinoma.

METHODS: We used immunohistochemistry to determine the expressions of MMP-9, TIMP-1 and proliferating cell nuclear antigen Ki-67 in the gastric specimens taken from 256 patients with primary gastric carcinoma. The patients were followed-up for up to 96 months.

RESULTS: No association between the expression of MMP-9 and TIMP-1 and patients' sex and age, tumor size and location of gastric carcinoma was observed. The incidence of the positive expression of MMP-9 in cases with tumors invasion to muscularis propria and visceral peritoneum (70.13 % and 69.09 %, respectively) was significantly higher than that in cases with tumor invasion only to lamina propria or submucosa (42.50 %, $P=0.0162$). The positive correlation between MMP-9 expression and the depth of tumor invasion was observed (Pearson correlation coefficient=0.2129, $P=0.016$). Along with the increase of the metastatic station of lymph nodes, the incidence of the MMP-9 expression was increased by degrees; a positive correlation between them was observed (Pearson correlation coefficient=0.2910, $P=0.0001$). There was also a significant correlation between MMP-9 expression and the TNM stage in gastric carcinoma (Pearson correlation coefficient=0.3027, $P<0.0001$). The incidence of MMP-9 expression in stage II and III/IV (75.00 % and 76.15 %, respectively) was significantly higher than those in stage I (46.15 %, $P<0.0001$). A negative correlation between TIMP-1 immunoreactivity and the depth of invasion, status of lymph node metastasis and TNM stage was observed (Pearson correlation coefficient = -0.1688, -0.3556

and -0.3004, $P=0.023$, <0.0001 and <0.0001 , respectively). Four types of co-expression of MMP-9 and TIMP-1 were observed; i.e. MMP-9 positive but TIMP-1 negative ($n=115$), both positive ($n=52$), both negative ($n=62$) and MMP-9 negative but TIMP-1 positive ($n=27$). The frequency of serosal invasiveness was significant higher in patients with MMP-9 but without TIMP-1 expression than those with other types of the co-expression ($P=0.0303$). The incidence of lymph node metastasis was highest in patients with MMP-9 but without TIMP-1 expression, and lowest in those with TIMP-1 but without MMP-9 expression ($P<0.0001$). The survival rate in patients with MMP-9 but without TIMP-1 expression was lower than that in those with TIMP-1 but without MMP-9 expression ($P=0.0014$).

CONCLUSION: Our results in gastric carcinoma demonstrated a significant positive association of MMP-9 over-expression with proliferation of tumor cells, the depth of invasiveness, lymph node metastasis and TNM stage, suggesting MMP-9 can serve as a molecular marker of tumor invasion and metastasis. We also demonstrate a significant negative relationship of TIMP-1 expression with the depth of invasiveness and lymph node metastasis, which provide a new idea in the tumor biological and genetic treatment. The interaction between MMP-9 and TIMP-1 in the processes of tumor invasion and metastasis is that MMP-9 mainly promotes tumor invasion and metastasis and TIMP-1 inhibits functions of MMP-9. The imbalance between MMP-9 and TIMP-1 expression may suggest the occurrence of tumor invasion and metastasis, predict poor prognosis. For patients with imbalanced MMP-9 and TIMP-1 expression, the optimal treatment scheme needs to be selected.

INTRODUCTION

The malignant behavior of tumor cells mainly depends on the capability of invasion and metastasis of cancer cells. After the components of the extracellular matrix (ECM) are degraded, tumor cells invade the surrounding tissue and the vascular or lymphatic vessels to form metastatic colonies at distant sites. Matrix metalloproteinase-9 (MMP-9) can degrade the main components of the ECM, type IV and V collagen and gelatin^[1-6], thus, its activities are closely related to the ability of the invasiveness and metastasis of tumor cells^[7,8]. Increased expression of matrix metalloproteinases (MMPs) renders the tumor cells capable of digesting essential tissue barriers especially basement membranes lining the blood vessels, thereby promoting the cells' motility. By forming a 1:1 complex with MMP-9 and inhibiting its enzymatic activity^[2,9,10], tissue

inhibitor of metalloproteinase-1 (TIMP-1) plays negative role in the invasion and metastasis of tumor cells^[11]. Therefore, attentions have been paid to the role of MMP-9 and TIMP-1 in the progress of tumor, and it has been reported that the expression of MMP-9 and TIMP-1 was correlated^[12], but the relationship of their expressive imbalance to the invasion and metastasis in gastric carcinoma was rarely reported. In the present study, we study the expressive pattern of MMP-9 and TIMP-1 in 256 patients with primary gastric carcinoma by immunohistochemistry, as well as the relationship of their expressive imbalance to invasion and lymph node metastasis and prognosis of gastric carcinoma. We demonstrated that the expressive imbalance of MMP-9 and TIMP-1 was significantly associated with the invasion and metastasis of gastric carcinoma.

MATERIALS AND METHODS

Materials

Two hundred fifty-six patients who underwent a surgery for the primary gastric carcinoma at the First Affiliated Hospital of Fujian Medical University, between 1991 and 1999, and had sufficient clinical materials were selected for this study. These patients comprised 186 males and 70 females. The median age was 60 with a range from 23 to 84 years. All studied patients had not been accepted for radiation therapy and chemotherapy before the operation. The histological findings, lymph node metastasis and TNM stage were evaluated based on World Health Organization Classification of Tumors^[13,14]. Follow-up information was available for 167 patients.

Methods

The specimens were fixed in formalin and embedded in paraffin wax, sliced serial step sections of 4 μ m thickness and stained by hematoxylin-eosin.

Immunohistochemistry

Paraffin sections (4 μ m thick) were immunostained with anti-mouse monoclonal antibodies for MMP-9 (GE-213, 1:10, NeoMarkers), TIMP-1 (102D1, 1:10, NeoMarkers) and Ki-67 (MB67, Ready, NeoMarkers) by the peroxidase-conjugated streptavidin complex method. Sections were deparaffinized and heated in a microwave oven for 10 min to retrieve the antigens. They were immersed in 3 % hydrogen peroxide in 100 % methanol for 10 min to block the endogenous peroxidase activity. After incubated in normal horse serum for 20 min, the tissue sections were incubated with the primary antibodies for 120 min at room temperature. The sections were incubated with biotinylated rabbit anti-mouse immunoglobulins G for 20 min and then treated with peroxidase-conjugated streptavidin for 20 min. The sections were immersed into DAB solution. The slides were counterstained with haematoxylin solution, dehydrated and mounted. Between steps, the slides were washed three times with phosphate buffered saline (PBS). As a negative control, PBS was used instead of the primary antibody.

Two independent observers without knowledge of the clinical outcomes evaluated the degree of immunohistochemical staining. All sections for which the two observers disagreed were re-evaluated until there was a complete agreement on the classification.

Immunohistochemical analyses of MMP-9, TIMP-1 and Ki-67 labeling index

Figures 1 and 2 show a positive expression of MMP-9 and TIMP-1, respectively. They were expressed within the cell membrane and/or cytoplasm. The intensity of staining in cell membrane and cytoplasm and the percentage of immunoreactive cells to total tumor cells were evaluated. The intensity of staining was graded as 0, when staining not greater

than negative control, 1, for light staining, and 2, for heavy staining. Immunoreactivity was scored according to the percentage of immunoreactive cells over total tumor cells counted as 0, if <5 % cells were stained; 1 if 5-25 % cells were immunoreactive, 2 if 26-50 % cells were immunoreactive and 3 if >50 % cells were immunoreactive. The expression of MMP-9 and TIMP-1 was finally defined according to the score obtained from the grade of intensity multiplied by the score of cell immunoreactivity, i.e. negative (-, score 0-1), positive (+, score 2-3), and strong positive (++, score 4 or above).

The positive expression of Ki-67 staining was in the nuclei of the carcinoma cells. Ki-67 labeling index was defined as the ratio of immunoreactive cells over 1 000 tumor cells counted labeling.

Statistical analysis

The χ^2 analysis was used for univariable categorical analysis. The relationship of the expressive imbalance between MMP-9 and TIMP-1 to the postoperative survival was tested for prognostic significance in gastric carcinoma specific survival using Kaplan-Meier survival curves and the log-rank test. All statistical analysis was performed using the SPSS 6.0 statistical software program. A value of $P < 0.05$ was considered statistically significant.

RESULTS

Relationship between MMP-9 expression and the clinical pathological parameters of gastric carcinoma

MMP-9 was mainly expressed within the cytoplasm and cytoplasmic membranes of the gastric carcinoma cells (Figure 1). Among 256 primary gastric carcinomas, the incidence of a positive expression of MMP-9 in carcinoma cells was 65.23 % (167/256), with the incidence of strong immunoreactivity of 13.67 % (35/256). No significant correlations between the expression of MMP-9 and sex, age, location and size of tumors were observed. As shown in Table 1, the incidence of the positive expression of MMP-9 in cases whose tumors invaded to muscularis propria and visceral peritoneum (70.13 % and 69.09 %, respectively) were significantly higher than those whose tumors only invaded to lamina propria or submucosa (42.50 %, $P = 0.0162$). A significant correlation between MMP-9 expression and the depth of tumor invasion was observed (Pearson correlation coefficient = 0.2129, $P = 0.016$). Along with the increase of the metastatic station of lymph nodes, the incidence of the MMP-9 expression was increased by degrees; a positive correlation between them was observed (Pearson correlation coefficient = 0.2910, $P = 0.0001$). We also demonstrated a significant correlation between MMP-9 expression and the TNM stage of gastric carcinoma (Pearson correlation coefficient = 0.3027, $P < 0.0001$), the incidence of MMP-9 expression was significantly higher in stage II and III/IV (75.00 % and 76.15 %, respectively) than in stage I (46.15 %, $P < 0.0001$, Table 1).

Relationship between TIMP-1 expression and the clinical pathological parameter in gastric carcinoma

A total of 79 (30.89 %) patients had positive immunohistochemical staining for TIMP-1 in the cytoplasm and cytoplasmic membrane of the gastric carcinoma cells, with the strong positive staining only five (1.95 %) cases (Figure 2). No statistical correlation between TIMP-1 immunoreactivity and sex, age, location and tumor size was observed. There were significant negative correlations between TIMP-1 immunoreactivity and the depth of invasion, status of lymph node metastasis and TNM stage (Pearson correlation coefficient = -0.1688, -0.3556 and -0.3004, $P = 0.023$, < 0.0001 and < 0.0001 , respectively, Table 1).

Figure 1 MMP-9 (matrix metalloproteinase-9) strongly positive staining. Membrane or cytoplasm of gastric cancer cells was stained brown. (SP method $\times 400$).

Figure 2 TIMP-1 (tissue inhibitor of metalloproteinase-1) strongly positive staining. Membrane or cytoplasm of gastric cancer cells was stained brown. (SP method. $\times 400$).

Relationship between MMP-9 and TIMP-1 expression and Ki-67 labeling index

As shown in Table 1, the higher the expression of MMP-9 in gastric carcinoma, the higher the Ki-67 labeling indexes in tumor cells ($F=6.7013$, $P=0.0015$). There was no significant difference in Ki-67 labeling index between the positive group and negative group of TIMP-1 expression in gastric carcinoma ($F=3.4474$, $P>0.05$).

Relationship of the expressive imbalance between MMP-9 and TIMP-1 to the invasiveness and metastasis of gastric carcinoma

According to the expression of MMP-9 and TIMP-1 in gastric carcinoma tissues, four patterns of co-expression were observed: 1, MMP-9 positive but TIMP-1 negative, or MMP-9 expression greater than TIMP-1 expression, $n=115$ (44.92 %); 2, MMP-9 and TIMP-1 both positive, $n=52$ (20.13 %); 3, MMP-9 and TIMP-1 both negative, $n=62$ (24.22 %); 4, MMP-9 negative but TIMP-1 positive, or TIMP-1 expression greater than MMP-9 expression, $n=27$ (10.55 %). Whereas patterns 2 and 3 of the co-expression of MMP-9 and TIMP-1 were defined as balanced, the co-expression patterns in 1 and 4 were defined as imbalanced. The frequency of the serosa invasiveness in patients with the co-expression pattern 1 was significant higher than those with other patterns ($P=0.0303$). Similarly, the incidence of lymph node metastasis was highest in patients with the co-expression pattern 1 and lowest in those with the pattern 4 ($P<0.0001$, Table 2).

Relationship of the expression of MMP-9 and TIMP-1 to the postoperative survival of patients with gastric carcinoma

Follow-up (6-97 months) information was available for 167 patients with gastric carcinoma. The postoperative survival rate appeared to decrease in patients with MMP-9 expression compared with those without MMP-9 expression, and in patients without TIMP-1 expression compared with those with TIMP-1 expression, although their difference was not statistically significant ($P>0.05$). However, the correlation between the expressive imbalance of MMP-9 and TIMP-1 and the postoperative survival was demonstrated. The survival rate was significantly decreased in patients with the co-expression pattern 1 compared with those with the co-expression pattern 4 ($P=0.0014$, Table 3, Figure 3).

DISCUSSION

Expression of MMP-9 and invasiveness, metastasis and prognosis of gastric carcinoma

Degradation of extracellular matrix (ECM) and basement membranes by the tumor cells is a critical step in the processes of tumor invasion and metastasis. MMP-9 is one member of the matrix metalloproteinase families, and characterized by substrate high-specificity and capable of degrading several components of ECM, including type IV collagen molecules which form the major component of the basement membrane.

Increased levels of MMP-9 have been implicated in the invasive potential of tumors^[11-4]. There was a trend towards a higher proportion of active MMP-9 with an increasing grade of breast carcinoma, endometrial carcinoma, colorectal carcinoma, papillary thyroid carcinoma and squamous cell carcinoma of the head and neck^[15-19]. In this study, we observed positive expression of MMP-9 in 65.23 % of patients with gastric carcinoma, but no association of the expression of MMP-9 with sex, age, tumor size and location. These results were similar to the results reported by Murray *et al*^[12] and Hou *et al*^[20]. In contrast to the Murray's and Hou's study, we also demonstrated there was a significant correlation between MMP-9 expression and proliferation of tumor cells, the depth of invasiveness, lymph node metastasis and TNM stage of gastric carcinoma. Pereda *et al* also found that high levels of matrix metalloproteinases promoted the proliferation of pituitary adenomas cells^[21]. Kabashima *et al* reported that MMP-9 expression correlated with lymph node metastasis in intramucosal gastric carcinoma^[22]. Torri *et al* reported that preoperative plasma MMP-9 concentration correlated closely with severity of T, N and M classification, and stage^[23]. These results suggest that over-expression of MMP-9 plays an important role in the progress of gastric carcinoma, and MMP-9 protein may be served as a marker for invasiveness and metastasis of gastric carcinoma. We also noticed that MMP-9 expression increased dramatically in advanced tumors compared with early tumors, whereas there was no such difference between different stages of the advanced tumors. These results suggested that MMP-9 expression might play an important role in the early progress of gastric carcinoma. Sier *et al* reported that the expression and activation of MMP-9 in tumor tissues were of prognostic significance for poor overall survival of the patients with gastric carcinoma, independent of the major clinicopathological parameters^[8,24]. Although there was a decreasing trend of survival in the patients with MMP-9 expression compared with those without the expression, the difference was no significant. Maatta *et al* reported the similarly results in hepatocellular carcinoma and pancreatic adenocarcinoma^[25]. The relation of MMP-9 to the prognosis of gastric carcinoma still needs to be further investigated.

Expression of TIMP-1 and invasiveness, metastasis and prognosis of gastric carcinoma

During the process of invasiveness and metastasis of tumors, the secretion and activation of metalloproteinases (MMPs) is not sufficient to degrade ECM components, as its enzymatic activity can be inhibited by a family of endogenous inhibitors, the tissue inhibitors of metalloproteinase (TIMPs). TIMP-1, a 28.5 kDa glycoprotein, is the first member of the TIMP family, and known to form a complex of 1:1 stoichiometry with activated collagenase, stromelysin and MMP-9 to inhibit their activities. Watanabe *et al* found that the transfection of the complete human TIMP-1 cDNA into highly metastatic human gastric carcinoma cell line KKLS notably decreased the formation of liver metastases when transplanted into nude mice^[11]. It is suggested that TIMP-1 is a negative regulators in the process of tumor metastasis. The expression of TIMP-1 in gastric carcinoma has not been widely examined so far. In our study, a negative association between TIMP-1 expression and invasiveness and metastasis and TNM stage was observed, but there was no association between TIMP-1 expression and sex, age, tumor size and location in gastric carcinoma. These results were opposite to the results reported by Mimori *et al* that the expression of TIMP-1 mRNA in the biopsy samples from human gastric carcinoma tissues (T) was higher than in the biopsy samples from the corresponding normal tissues (N), and a higher T/N ratio of TIMP-1 mRNA correlated with lately advanced stage and poor prognosis of human gastric

carcinoma^[26]. Other studies also showed that the increased TIMP-1 expression correlated with poor prognosis variables, including shortened survival, in patients with renal cell carcinoma and lung cancer^[8,27]. Several studies have shown that TIMP-1 possesses two activities, i.e. inhibitory activity of metalloproteinases, and growth promoting function^[2,28]. Our findings suggest that, TIMP-1 in the progress of human gastric carcinoma functions mainly as an inhibitor of metalloproteinases, subsequently blocking the invasiveness and metastasis of tumor cells. Our findings may offer a new idea in the biological and genetic treatment for gastric carcinoma^[29-34]. In our study, the survival rate of patients with TIMP-1 expression was higher than those without TIMP-1 expression, although difference was not significant. Further studies are needed to determine whether or not TIMP-1 expression alone can serve as a marker predicting the prognosis of patients with gastric cancer.

Imbalance between expression of MMP-9 and TIMP-1 in the invasiveness, metastasis and prognosis of gastric carcinoma

Under physiological conditions the expression of MMPs and TIMPs is highly coordinated at the level of gene expression, and this balanced expression guarantees normal tissue structure and organ function, and prevents both excessive ECM deposition and increased ECM degradation. As some factors in malignant tumors contributes to the over-expression of MMPs without matched TIMP expression, and thus, this balance was broken, thereby, the ECM was degraded and the cancer metastasis was occurred. By contraries, over-expression of TIMPs can prevent the degradation of ECM and inhibit the cancer invasion and metastasis. TIMP-1 can bind to the catalytic domain of MMP-9 in a 1:1 stoichiometry to form complex, so inhibiting the enzymatic activity of MMP-9^[2,9,10]. Murray *et al* revealed the correlation between the expression of MMP-9 and the expression of TIMP-1 in gastric carcinoma^[12,27,35]. However, observation concerning the association of imbalance between the expression of MMP-9 and TIMP-1 with invasion and metastasis in gastric carcinoma has rarely been published. We found that the tumor invasion and metastasis was more frequent in the cases with positive expression of MMP-9. However, the extents of invasion and metastasis in gastric carcinoma significantly decreased if the TIMP-1 was also expressed in these cases at the same time. This suggests that MMP-9 mainly exert functions of promoting cancer invasion and metastasis, while TIMP-1 independently exerts the inhibiting function for cancer invasion and metastasis during the processes of the invasion and metastasis of gastric carcinoma. We also found that the incidence of visceral peritoneum invasion and lymph node metastasis was the highest in the cases with MMP-9 expression but without TIMP-1 expression, whereas, the incidence of lymph node metastasis in the cases with the TIMP-1 expression but without MMP-9 expression was the lowest, with the modest incidence in cases with balanced expression of MMP-9 and TIMP-1. These findings strongly support the hypothesis the expressive imbalance between MMP-9 and TIMP-1 is an important factor in tumor invasion and metastasis. In brief, altered balance of expression between MMP-9 and TIMP-1 plays a central role in progression of gastric carcinoma. According to our follow-up information, we found, for the first time, that although MMP-9 or TIMP-1 alone may not serve as an indicator for patient prognosis, there is a significant association of the expressive imbalance between MMP-9 and TIMP-1 with the postoperative survival of patients with gastric carcinoma. Our data suggest that patients with over-expression of MMP-9 and no expression of TIMP-1 have more aggressive tumor progression and a lower survival rate.

In conclusion, our results indicate a significant positive association between MMP-9 expression and proliferation of tumor cells, the depth of invasiveness, lymph node metastasis

and TNM stage of gastric carcinoma, suggesting MMP-9 can serve as a molecular marker of tumor invasion and metastasis. Our results also demonstrate a significant negative association of TIMP-1 expression with the depth of invasiveness and lymph node metastasis, which provides a new idea in tumor biological and genetic treatment. The interaction between MMP-9 and TIMP-1 in the processes of tumor invasion and metastasis is that MMP-9 mainly promotes tumor invasion and metastasis whereas TIMP-1 inhibits the functions of MMP-9. Imbalance between MMP-9 and TIMP-1 expression may predict the occurrence of tumor invasion and metastasis and poor prognosis. For these patients with imbalanced MMP-9 and TIMP-1 expression, the optimal treatment scheme needs to be selected.

Abstract

AIM: To investigate the relationship between inactivation of p16 gene and gastric carcinoma, and the mechanism of inactivation of p16 gene in gastric carcinogenesis.

METHODS: 40 fresh tumor tissue specimens were taken from primary gastric cancer patients. Expression of P16 protein was detected by immunohistochemical method. Deletion and point mutation of p16 gene were analyzed by polymerase chain reaction (PCR) and DNA sequencing, respectively.

RESULTS: The frequency of loss of P16 protein expression in the gastric cancer tissue, adjacent nontumor tissue, and distal normal tissue was 77.5 % (31/40), 55.0 % (22/40), and 17.5 % (7/40), respectively ($P < 0.005$). Homozygous deletion of exon 1 and exon 3 was observed in two and three cases, respectively, giving an overall frequency of homozygous deletion of 12.5 %. All five cases had diffuse type gastric carcinoma. No p16 gene point mutation was detected.

CONCLUSION: These findings suggest a close correlation between inactivation of p16 gene and gastric carcinoma. Further investigations are needed to testify the mechanism of inactivation of p16 gene in gastric carcinogenesis.

INTRODUCTION

Gastric carcinoma (GC) is common in China^[1-19]. From 1991 to 2000, 18,029 inpatients with malignant tumor had been treated in the Affiliated Yijishan Hospital of Wannan Medical College. 2,859 cases were GC sufferers, which accounted for 16 % of the total inpatients and ranked the first in malignant tumor. The statistical data showed that GC was one of the commonest tumors in South Anhui province. Therefore, it

would have clinical significance to explore the pathogenesis of gastric carcinogenesis.

Early in 1994, Kamb *et al*^[20] and Norobi *et al*^[21] reported their studies on p16 gene simultaneously but independently. p16 gene is located in chromosome 9p21, consisting of 2 introns and 3 exons. Exon 1 contains a region of 126 bp, while exon 2 contains a region of 307 bp, and exon 3 contains a region of 11 bp. In recent years, studies have revealed homozygous deletion and mutation of p16 gene, predominantly in exon 2, in various malignant tumor, suggesting that p16 gene is a multiple tumor suppressor 1 (MTS1)^[20-33].

The mechanism of p16 gene in gastric carcinogenesis remains unidentified. Some studies have suggested that p16 gene alteration in GC presents itself in different mechanism from other tumors. The alteration is infrequent in exon 2, but exists predominantly in exon 1 and 3^[34-36]. In this study, using polymerase chain reaction (PCR), DNA sequencing analysis and an immunohistochemical method, the fresh tumor specimens of 40 GC patients were examined for homozygous deletion, point mutation of p16 gene and expression of P16 protein to verify the relationship between p16 gene alteration and GC.

MATERIALS AND METHODS

Gastric carcinoma specimens

Under sterile conditions, fresh tumor specimens and their adjacent non-tumor (≤ 3 cm away from the tumor) and distal (≥ 5 cm away from the tumor) normal appearing tissues were obtained in the course of surgery from 40 patients with primary GC at the Affiliated Yijishan Hospital of Wannan Medical College. None of the patients had received either chemotherapy or radiotherapy prior to surgery. All of the primary tumors were pathologically confirmed to be GC cases, among which there were 26 males and 14 females. The age ranged from 31 to 68 (mean 55.4) years old. 14 cases had intestinal type and 26 cases diffuse type by histopathological typing. 12 cases had well-differentiated and 28 cases poorly differentiated.

DNA extraction

Approximately 50 mg tissue of GC was abraded with routine methods and digested with proteinase K. DNA was extracted by means of the routine phenol-chloroform method. The purity and concentration of extracted DNA were detected with ultraviolet spectrophotometer (Daojin Company, UV-2201 type). The extracted DNA was stored at 4 °C until use.

Polymerase chain reaction

The three exons of p16 gene were amplified by employing 3 pairs of primers. The primers 1 and 3 were synthesized by Shanghai Boya Company, and the primer 2 by Saer Biotechnology Company of Shanghai Cell Biology Institution. The sequence of primers and the length of PCR products were listed in Table 1.

PCR was performed in 50 μ L reaction volume containing 0.2 μ g DNA template, 2 U Taq DNA polymerase (Shanghai Sangon

Company), 10 pmol/L each pair of primers, 0.2 mmol/L dNTP, 1.5 mmol/L MgCl₂, 5 μ L 10 \times buffer. PCR reaction was carried out in a thermal cycle machine (Perkin-Elmer, 480 type) for an initial 5 min denaturation step at 98 $^{\circ}$ C. After Taq DNA polymerase was added, the thermal cycle followed. The reaction conditions consisted of denaturation at 94 $^{\circ}$ C for 45 s, annealing at 58 $^{\circ}$ C for 50 s for exon 1, 56 $^{\circ}$ C for 60 s for exon 2, 52 $^{\circ}$ C for 50 s for exon 3, extension at 72 $^{\circ}$ C for 60 s, on completion of 35 cycles, at last extension at 72 $^{\circ}$ C for 5 min. 10 μ L of PCR product was loaded into the gel, and a 100 bp DNA ladder was used as a marker. The PCR products were electrophoresed at voltage of 100 V on 2 % agarose gel for 30 min and visualized under UV illumination using an ethidium bromide stain. The results were photographed by a digital camera.

Table 1 The primer sequence of the p16 gene

Exon	Sequence of the primer	Product of PCR (bp)	Temperature for annealing ($^{\circ}$ C)
1S	5' TCTGCGGAGAGGGGAGAGCAG 3'	280	58
1A	5' GCGCTACCTGATTCCAATTC 3'		
2S	5' TTCCTTCCGTCATGCCGG 3'	394	56
2A	5' GTACAAATCTCAGATCATCAGTCCTC 3'		
3S	5' GGATGTTCCACACATCTTTG 3'	189	52
3A	5' ATGAAACTACGAAAGCGGG 3'		

S: sense; A: antisense.

DNA sequencing analysis

The GC specimens that produced amplified product were reamplified by PCR. PCR was performed in 100 μ L reaction volume. The products were purified using Spin PCRapid Purification kit (Promage Company), and then together with PCR primers were sequenced (dideoxy chain termination) by an ABI Prism 377 DNA sequencer (Perkin-Elmer Company) in Shanghai Sangon Company.

Immunohistochemistry

The sections were deparaffined, boiled and retrieved in citric acid buffer for 10 min. Then, the immunohistochemical streptavidin-in-peroxidase (SP) method was used according to the specification of SP kit. The known positive sections were used as a positive control. Phosphatic buffer solution (PBS) replacing the primary antibody was used as a negative control in every experiment. Mouse-anti-human P16 (ZJ11) and SP kit were products of Fuzhou Maixin Biotechnology Company.

RESULTS

Deletion and mutation of p16 gene

Of 40 GC specimens in PCR products, exon 1 and exon 3 were not detected in 2 cases and 3 cases, respectively. But all of specimens were detected the PCR product of exon 2. These findings indicate that homozygous deletion of p16 gene exon 1 and exon 3 exist in GC (Figure 1, 2, 3). The frequency of deletion of p16 gene was 12.5 % (5/40). All five cases with p16 gene deletion had poorly differentiated were all diffuse type GC, with staging of PT₃N₂M₀, as assessed by pathological section analysis.

Amongst the 35 GC cases in whom p16 deletion was not detected, 10 cases were randomly selected for DNA sequencing. No point mutation was detected in these GC specimens when compared with the normal p16 gene cDNA sequence^[37].

Figure 2 The PCR products of p16 gene exon 2. M: marker 100 bp. ladder; Line 1-11: gastric carcinoma.

Figure 3 The PCR products of p16 gene exon 3. M: marker 100 bp. ladder; Line 1-11: gastric carcinoma; Line 1-3: homozygous deletion.

Expression of P16 protein

Expression of P16 protein in GC tissues, adjacent nontumor tissue (≤ 3 cm) and distal normal tissue (≥ 5 cm) were summarized in Table 2 and Figure 4, 5, 6. Using χ^2 test, the value of χ^2 was 29.40, $P < 0.005$, which has significant difference. These data revealed a strong correlation between inactivation of p16 gene and gastric carcinogenesis.

Table 2 P16 protein expression at GC

Hisological types	n	Positive	Negative	The frequency of P16 protein expression loss (%)
Gastric carcinoma	40	9	31	77.5
Adjacent nontumor tissue (≤ 3 cm)	40	18	22	55.0
Distal normal tissue (≥ 5 cm)	40	33	7	17.5

DISCUSSION

Fission of tumor cells undergoes a regular cell cycle as normal cells do, which is commonly divided into G1, S, G2, and M phase. When a cell goes into the cell cycle, the cell depends on activation of cyclin dependent kinase (CDK). Only combined with a cyclin, can CDK be activated, and inhibited when it combines with a series of proteins. These proteins known as cyclin dependent kinase inhibitors are a group of small molecular proteins that are involved in the negative regulation of the cell cycle. Alteration of these proteins results in uncontrollable cell proliferation and thus carcinogenesis. P16 protein is one of these proteins so that mutation and deletion of p16 gene lead to uncontrollable cell proliferation, and then carcinogenesis^[1, 20, 21, 37-40]. The relationship between alteration of p16 gene and carcinogenesis of various tumors has been verified^[1, 20-36, 41].

In this study, homozygous deletion of exon 1 and exon 3 was observed, respectively, in 2 cases and 3 cases with poorly

differentiated diffuse type GC amongst 40 samples. The frequency of deletion was 12.5 %. Our results showed that alteration in p16 gene was highly associated with poorly differentiated GC, which is almost identical to the observations by Lu *et al.*^[34] and Lee *et al.*^[35]. Therefore, it is suggested that alteration of p16 gene is associated with the differentiation degree and metastasis of GC. In contrast, Wu *et al.*^[36] reported that deletion of p16 gene was frequently encountered in the intestinal type, with a lower frequency in the diffuse type. Furthermore, He *et al.*^[41] reported that there was homozygous deletion of p16 gene exon 2 in GC, with a frequency of 20.0 %. Our finding does not tally with above observation^[34-36]. We randomly selected 10 of the 35 GC cases without p16 gene deletion for DNA sequencing, no point mutation was detected. The results reveal that point mutation of p16 gene is rare in gastric carcinogenesis. It coincides with previous findings^[34-36, 41].

In human primary GC, deletion and point mutation of p16 gene are infrequent, but loss of expression of P16 protein is common. Some studies have found^[1, 35, 40-42] that the frequency of loss of P16 protein expression ranges from 52 % to 90 %. Our results agree with these studies. We found that the frequency of loss of expression of P16 protein was 77.5 %. It had statistically significant difference with adjacent non-tumor tissue (55.0 %) and distal normal appearing tissue (17.5 %) ($P < 0.005$). These results suggest that inactivation of p16 gene is strongly associated with gastric carcinogenesis, however, deletion and point mutation of p16 gene are not the major mechanism of p16 inactivation in GC.

The methylation-specific PCR (MSP) method established by Herman *et al.*^[43] in 1996 has significantly promoted the research on the interrelationship between hypermethylation and gene silencing. Subsequent studies have revealed high frequency of hypermethylation in p16 gene 5' promotor regions in various tumors, with frequency ranging from 60 % to 89 %^[44-48]. Inactivation of p16 gene correlates with hypermethylation of 5' promotor regions CpG island in GC. Some studies have found that hypermethylation in the promotor regions CpG island is an important mechanism for p16 gene inactivation in GC, whereas deletion and point mutation of the gene are rarely seen^[49-56]. The CpG island hypermethylation occurred early in multistep gastric carcinogenesis tends to accumulate along the process^[55]. P16 gene with methylated promotor regions would reexpress P16 protein when it is treated with 5-aza-2'-deoxycytidine which demethylates^[35] or when the inducers of hypermethylation are eliminated^[57, 58]. The effect mechanism of p16 gene is to inhibit cell cycle directly, and it is easy to perform gene targeting or protein modification because p16 gene is small. Therefore, it is needed to further investigate the relationship between p16 gene inactivation and gastric carcinogenesis, and the mechanism of p16 gene inactivation, since it is of significant clinical implications in early diagnosis, therapy and prognosis.

Abstract

AIM: To investigate the expression of TFF2 and *Helicobacter pylori* infection in carcinogenesis of gastric mucosa.

METHODS: The expression of TFF2 was immunohistochemically analyzed in paraffin-embedded samples from 119 patients with endoscopic biopsy and subtotal gastrectomy specimens of gastric mucosal lesions, including 16 cases of chronic superficial gastritis (CSG), 20 chronic atrophic gastritis (CAG), 35 intestinal metaplasia (IM), 23 gastric epithelial dysplasia (GED) and 25 gastric carcinoma (CA), and *Helicobacter pylori* infection was detected by Warthin-Starry staining.

RESULTS: 1: TFF2 was located in the cytoplasm of gastric mucous neck cell. The expression of TFF2 was 100 %, 100 %, 0, 56.5 % and 0 in CSGs, CAGs, IMs, GEDs and CAs, respectively. 2: The value of TFF2 positive cell density in CSG with *Helicobacter pylori* infection was higher than that without *Helicobacter pylori* infection. (52.89 ± 7.27 vs 46.49 ± 13.04 , $P > 0.05$); But the value of TFF2 positive cell density in CAG and GED with *Helicobacter pylori* infection was significantly lower than that without *Helicobacter pylori* infection (18.17 ± 4.09 vs 37.93 ± 13.80 , $P < 0.01$ and 14.44 ± 9.32 vs 24.84 ± 10.22 , $P < 0.05$).

CONCLUSION: Increase of TFF2 expression in CSG is perhaps associated with the protective mechanism after gastric mucosal injury. Decrease of TFF2 expression in CAG possibly attributes to the decrease in the number of gastric gland cell expressing TFF2. Re-expression of TFF2 in gastric epithelial dysplasia implies that TFF2 possibly contributes to the initiation of gastric carcinoma. The effect of *Helicobacter pylori* on the expression of TFF2 depends on the status of gastric mucosa.

INTRODUCTION

Trefoil factor family 2 (TFF2), also known as spasmodic polypeptide (SP), is one of three known mammalian trefoil peptides. Trefoil peptides are small (7-12 kDa) protease-

resistant proteins secreted by the gastrointestinal mucosa in a lineage-specific manner. While expressed and secreted preferentially by gastric mucous neck cell^[1,2], TFF2 is upregulated in diverse pathological conditions of gastrointestinal tract, which involves regeneration and restitution of epithelial lineage during the epithelial cell injury, mucosal protection and healing of ulcer^[3-5]. However, the relationship between TFF2 expression and gastric carcinoma is still not fully elucidated. In the present study, we evaluated the expression of TFF2 and *Helicobacter pylori* infection in a series of gastric mucosal lesions. The aim of this study was in two aspect: to characterize the expression pattern of TFF2 on carcinogenesis of gastric mucosa; and to study the relationship between the expression of TFF2 and *Helicobacter pylori* infection.

MATERIALS AND METHODS

Tissue material

The gastric mucosal lesions of all 119 patients who had undergone surgical resection or endoscopic biopsy in the Renmin Hospital of Wuhan University from March 2001 to March 2002 were studied. There were 16 cases of chronic superficial gastritis (CSG), 20 chronic atrophic gastritis (CAG), 35 intestinal metaplasia (IM), 23 gastric epithelial dysplasia (GED) and 25 gastric carcinoma (CA). Tissue fragments were fixed in 10 % formaldehyde and embedded in paraffin. Serial sections of 4 μ m were stained with haematoxylin and eosin (HE), Warthin-Starry and by immunohistochemistry.

Immunohistochemistry of TFF2 protein

A modification of the streptavidin-peroxidase method was applied to immunohistochemistry and with 3, 3'-diaminobenzidine (DAB) as the chromogen (Ultrasensitive SP Kit, DAB, FuZhou Maixin Biotechnology Co). Sections was incubated for one hour at 37 °C with monoclonal antibody against human TFF2 (hSP, diluted 1:35, Novocastra Laboratories Ltd). All batches of staining included positive control. Negative control was performed by replacing the primary mAbs with Tris buffer solution (TBS). The value of positive cell density was determined by image analysis system of HPIAS2000.

Warthin-Starry staining

Histological examination with Warthin-Starry staining technique was used for *Helicobacter pylori* infection diagnosis in all cases, and was identified as positive brown-black or black staining of *Helicobacter pylori*.

Scoring of immunoreactivity

Immunoreactivity were scored according to the presence of immunoreactive cells: -, none or rate positive cells (<5 %); +, 5-25 %; ++, 25-75 %; +++, >75 %.

Statistical analysis

All results are expressed as means plus or minus SD unless otherwise stated, and analyzed by software of SPSS 10.00.

The statistical significance of difference was evaluated with the Student's *t* test. A *P* value of less than 0.05 was considered statistically significant.

RESULTS

Expression pattern of TFF2 protein in carcinogenesis of gastric mucosa

TFF2 protein was located in the cytoplasm of gastric epithelial cells and gastric gland mucous neck cells by immunohistochemistry, and positive cells were stained brown-yellow. TFF2 protein was expressed in all the chronic superficial gastritis and chronic atrophic gastritis (Figure 1-2), but the scoring of TFF2 staining was higher in chronic superficial gastritis than in that chronic atrophic gastritis. The expression of TFF2 was partly detected (56.5 %) in the gastric epithelial dysplasia (Figure 3). There was no expression of TFF2 in the intestinal metaplasia and gastric carcinoma. (Figure 4-5) (Table 1).

The relationship between the expression of TFF2 and *Helicobacter pylori* infection

The positive rate of *Helicobacter pylori* was 53.8 % (64/119) in our cases. The value of TFF2 positive cell density in chronic superficial gastritis with *Helicobacter pylori* infection was higher than that without *Helicobacter pylori* infection (52.89 ± 7.27 vs 46.49 ± 13.04 , $P > 0.05$), but the difference was not statistically significant; While the value of that in chronic atrophic gastritis and dysplasia with *Helicobacter pylori* infection was significantly lower than that without *Helicobacter pylori* infection (18.17 ± 4.09 vs 37.93 ± 13.80 , $P < 0.01$ and 14.44 ± 9.32 vs 24.84 ± 10.22 , $P < 0.05$), and the difference was statistically significant (Table 2).

DISCUSSION

We undertook the present study in order to characterize the pattern of TFF2 protein expression in carcinogenesis of gastric mucosa. In conformity with data in the literature^[2], immunohistochemical expression of TFF2 was not observed at the surface epithelium, although expression of the corresponding mRNA was previously detected by *in situ* hybridization^[2]. We observed, as did others, the expression of TFF2^[2,6] in the mucous cells of the antrum, the chief cells of the body and neck zone cells.

In this study, we have clarified the expression pattern of TFF2 protein in carcinogenesis of gastric mucosa. In chronic superficial gastritis and atrophic gastritis, the high expression of TFF2 was observed in all cases. As a cytoprotective factor, TFF2 protein was induced as a result of gastric mucosal injury. Our results confirmed an important cytoprotective and restitutive role for TFF2. The mechanism of protective and healing effect of TFF2 on the gastric mucosa is still not fully elucidated. *In vitro*, TFF2 stimulated cell migration^[7]. It has recently been shown that hTFF decreased proton permeation through interacting with mucus *in vivo* and *in vitro*^[8], and oral TFF2 binds to the mucus layer of the stomach^[9], which accelerates the gastric ulcer healing in rat. Further, we also discovered that the scores of TFF2 staining were higher in chronic superficial gastritis than that in chronic atrophic gastritis, which might attribute to the decrease in the number of mucous neck cell expressing TFF2 in chronic atrophic gastritis. There was no expression of TFF2 protein in intestinal metaplasia and gastric carcinoma, but TFF2 protein was observed in surrounding tissues of intestinal metaplasia and gastric carcinoma, which suggested the expression of TFF2 could be associated with the phenotype of gastric epithelial cell differentiation. Although it had been reported by Machado *et al*^[10], the expression of TFF2 was observed in 10 (10.4 %) of 96 cases of gastric carcinomas.

Furthermore, we also found that there were 13 out of 20 cases with re-expression of TFF2 in gastric epithelial dysplasia. It was well known that dysplasia is a precancerous lesion of stomach, and TFF2 could contribute to the initiation of gastric carcinoma. In 1999, Schemidt *et al*^[11] found the SPEM (SP-expressing metaplasia) lineage was detected in 91 % of gastric carcinoma, typically located in mucosa adjacent to the carcinoma or areas of dysphasia. And others studies^[12] also discovered that SPEM was identified in 88 % of the surrounding mucosa in the remnant cancers, as well as 61 % of the follow-up biopsies. In the malignant resections, 67 % of the surface dysplasia displayed SP positive cells. All findings implicated a strong association of the SPEM lineage with gastric carcinoma. At present, no confirmed relationship could be found between TFF2 and carcinoma^[11-19]. However, Farrell *et al*^[20] generated a model of TFF2-deficient mice, and suggested a physiologic role of TFF2 in promoting mucosal healing through the stimulation of proliferation and downregulation of gastric

acid secretion. In other words, increased TFF2 expression and secretion could contribute directly to gastric cancer risk not only through stimulation of proliferation, but also through inhibition of acid secretion. Meanwhile, our results and others^[11] showed there was loss of TFF2 in all gastric carcinoma cases. Therefore, it is impossible that TFF2 expression plays an important role in the progression of gastric carcinoma. Whether TFF2 can directly or indirectly contribute to carcinogenesis of gastric mucosa will be required for further studies.

Gastric carcinoma is the most common tumor in gastrointestinal tract^[21-32], more and more studies suggested that *Helicobacter pylori* infection was significantly associated with gastric carcinoma and was a high risk factor for gastric carcinoma^[33-52]. It has been reported that an increase in the number of mucous neck cells expressing TFF2 has been observed in both *Helicobacter* infected human patients^[12] and *Helicobacter*-infected mice with both preneoplastic^[53] and neoplastic^[54] changes of the gastric mucosa. In all of these findings, it was likely that *Helicobacter pylori* infection would contribute to the expression of TFF2 by promoting the proliferation of gastric mucosal cell, which would be a mechanism of *Helicobacter pylori* contributing to carcinogenesis of gastric mucosa. Then, we examined retrospectively the *Helicobacter pylori* infection of all cases by Warthin-Starry staining, and found that the value of TFF2 positive cell density was higher in chronic superficial gastritis with *Helicobacter pylori* infection than that without, which suggested that TFF2 was induced in the early stage of *Helicobacter pylori* infection. Nevertheless, its value was significantly lower in chronic atrophic gastritis and dysplasia with *Helicobacter pylori* infection than that without. We inferred that low expression of TFF2 was associated with a decrease in the number of gastric mucosal cell as result of *Helicobacter pylori* infection. As a result, the effect of *Helicobacter pylori* on the expression of TFF2 could depend on the status of gastric mucosa.

In conclusion, early-stage or short-term upregulation of TFF2 appears to be helpful in healing of gastric mucosa, but prolonged upregulation may in fact contribute to carcinogenesis. Further studies will be needed to define the role of TFF2 in *Helicobacter pylori*-associated chronic gastritis and gastric carcinoma.

Abstract

AIM: To evaluate the potential role of Nimesulide, a selective COX-2 inhibitor, in proliferation and apoptosis of gastric adenocarcinoma cells SGC7901.

METHODS: Cell counts and MTT assay were used to quantify the influence of Nimesulide in the proliferation of SGC7901 cells. Transmission electron microscopy and flow cytometry were used to observe the induction of Nimesulide the apoptosis of SGC7901 cells and influence in the distribution of cell cycle. The expression of P27^{kip1} protein was observed by immunocytochemical staining.

RESULTS: SGC-7901 Cells treated with Nimesulide at various concentrations exhibited a profound dose- and time-dependent reduction in the proliferation rate over the 72 h test period. The highest survival rate of the cells was 78.7 %, but the lowest being 22.7 %. Nimesulide induced apoptosis of the cells in a dose-dependent and non-linear manner and increased the proportion of cells in the G₀/G₁ phase and decreased the proportion in the S and G₂/M phase of the cell cycle. Meanwhile, Nimesulide could up-regulate the expression of P27^{kip1} protein.

CONCLUSION: The induction of apoptosis and cell cycle arrest are both anti-proliferative responses that likely contribute to the antineoplastic action of nimesulide on SGC-7901 cells. The up-regulation of P27^{kip1} gene may contribute to the accumulation of these cells in the G₀/G₁ phase following treatment with Nimesulide. Selective COX-2 inhibitor may be a new channel of the chemoprevention and chemotherapy for gastric carcinoma.

INTRODUCTION

Nonsteroidal anti-inflammatory drugs (NSAIDs) are among the most commonly used medications. Recently, numerous studies have shown that NSAIDs can reduce the risk of

colorectal cancer. The mechanism of action of NSAIDs is principally due to the inhibition of cyclooxygenase (COX). COX exists in two isozyme forms: COX-1 is a constitutive form of the enzyme, and COX-2, a cytokine-inducible form of the enzyme. Enhanced COX-2 expression was observed in esophageal, gastric, colorectal, liver, lung, prostate, the head and neck cancers^[1-10]. These findings suggest that COX-2 may play an important role in carcinogenesis. It is thought that inhibition of COX-2 activity by NSAIDs as the antineoplastic mechanism of this class of drugs and gastrointestinal complications of using NSAIDs attribute to the inhibition of COX-1. For this reason, development of selective COX-2 inhibitors was promoted. Current, studies on the relationship between COX-2 and NSAIDs with neoplasm focused on the studies of colorectal carcinomas^[11-15]. Gastric carcinoma is the most common malignancy and the first leading cause of cancer deaths in our country, its pathogenesis is not completely understood and treatment for advanced tumors are relatively poor^[16-21]. Therefore, an increased understanding of pathogenesis of gastric carcinoma and developing effective treatment approaches are very important. Prophylaxis and treatment of NSAIDs for gastric carcinoma are emphasized. Epidemiological studies show that NSAIDs can also reduce the incidence rate and mortality from gastric carcinoma. Nimesulide, a selective COX-2 inhibitor, was found to be between 5 and 16 fold selective that for COX-2^[22]. However, effects of Nimesulide on the growth of gastric carcinoma cells have not been studied.

In this study, we have tested the effects of Nimesulide in proliferation, apoptosis and distribution of cell cycle of SGC-7901 gastric adenocarcinoma cells. In order to seek theoretical evidences for chemoprevention action of selective COX-2 inhibitor on gastric carcinoma.

MATERIALS AND METHODS

Cell culture

Human gastric adenocarcinoma cell line SGC-7901, purchased from Shanghai Insititute of Cell Biology, Chinese Academy of Sciences, was routinely maintained in RPMI 1640 containing 10 % fetal bovine serum (FBS), 100 U· ml⁻¹ penicillin, 100 U· ml⁻¹ streptomycin at 37 °C in a humidified atmosphere containing 5 % CO₂.

Cell viability assay

SGC-7901 cells were plated at 3×10⁴ cells/well in 24 well plates for 24 h. At day 0, the medium was changed, incubations were continued without or with increasing concentrations of Nimesulide (50, 100, 200, 400 μmol· L⁻¹) for 72 h. For the time course experiments, cells were incubated with or without Nimesulide and harvested at various intervals. Dead cells were removed by gentle washing with PBS, and the number of living cells after treatment was counted by a hemocytometer.

MTT assay

Cells were seeded at a density of 4×10³ per well in 96-well plates in RPMI-1640 containing 10 % FBS. After 24 h, fresh

medium was added, containing Nimesulide at concentrations of 0 to 400 $\mu\text{mol} \cdot \text{L}^{-1}$. During 72 h incubation, MTT assay was performed every 24 h. Twenty μl of stock MTT (5 $\text{mg} \cdot \text{ml}^{-1}$) was added to each well, and the cells were further incubated at 37 °C for 4 h. The supernatant was removed and 150 μl DMSO was added to each well. A ELISA reader measured the absorbance at a wavelength of 570nm.

Transmission electron microscopy

SGC-7901 cells were treated with Nimesulide at various concentrations for 72 h. Then the cells were centrifuged and fixed in glutaraldehyde for observation of transmission electron microscopy.

Flow cytometry

SGC-7901 cells were treated with Nimesulide at a concentration of 0 to 400 $\mu\text{mol} \cdot \text{L}^{-1}$ for 72 h. Cells were digested by 2.5 $\text{g} \cdot \text{L}^{-1}$ trypsin, washed by 0.01M PBS, fixed by cold alcohol at 4 °C and dyed with PI (propidium iodide), and then were analyzed by flow cytometry.

Immunocytochemistry

SGC-7901 cells were added to 24-well plates with cover glass-slides at 3×10^4 cells/well, after being incubated with Nimesulide at the different concentrations of 0 to 400 $\mu\text{mol} \cdot \text{L}^{-1}$ for 72 h and fixed in 95 % alcohol. After washing in 0.01M PBS, the cells were incubated in 0.5 % H_2O_2 solution to inactive endogenous peroxidase, nonspecific binding was blocked with normal goat serum at room temperature for ten minutes. The cells were incubated with anti-P27kip1 protein monoclonal antibody (impromptu type, Zhong Shan Co) 2 h at 37 °C. Immunocytochemical staining for P27kip1 was performed using SP technique according to SP immunostain kit instructions (Zhong Shan Co). PBS was used as substitutes of protein antibody for negative controls. The positive signal of immunocytochemical staining showed brown particles, and distributed in the cytoplasm or nuclei. The absorbance value (A value) of positive cells was detected by image analysis software. The mean value under five random fields was regarded as the relative quantity of P27^{kip1} protein expression.

Statistical analysis

Data were presented as $\bar{x} \pm s$. Statistical analysis of the data was performed using the Student's *t* test, $P < 0.05$ was considered statistically significant.

RESULTS

Effect of Nimesulide on cell growth

Cell counts The number of viable cells following incubation with either Nimesulide or control medium, is shown in Figure 1. This figure demonstrates that control SGC-7901 cells entered a line growth and increased by approximately 7-fold within 72 h. Compared with control cultures, cultures treated with Nimesulide displayed a dose-dependent reduction of viable cell number in their proliferation rate over the 72 h test period. At 200 $\mu\text{mol} \cdot \text{L}^{-1}$ and 400 $\mu\text{mol} \cdot \text{L}^{-1}$, Nimesulide strongly inhibited the proliferation of these cells. At 400 $\mu\text{mol} \cdot \text{L}^{-1}$, the proliferation curve was flat over the entire 72 h.

MTT assay In order to further investigate the growth inhibition of Nimesulide on SGC-7901 cells, cell growth was determined by MTT assay. The result was similar to cell counts. The survival rate of the control groups is regarded as 100 %, and the survival rate of Nimesulide group is expressed as the % absorbance for treated wells/controls. As shown in Figure 2, the highest survival rate of the cells was 78.7 %, but the lowest was 22.7 %.

Figure 1 Effects of various concentration of nimesulide on the proliferation of SGC7901 cells for different time periods analysing by cell counts ($n=3$).

Figure 2 Effects of nimesulide on SGC-7901 cells analyzing the cell survival using the MTT assay.

Figure 3 (A) control group: Microvilli of SGC7901 cells were enrichment, nucleus was large and round, chromatin was disperse, nucleolus was distinct. TEM $\times 6000$. (B) Treated with nimesulide at the concentration of 400 $\mu\text{mol/L}$ for 72 h: Disappearance of microvilli, margination of nuclear chromatin, the organelle swelled up and physallization. TEM $\times 8000$.

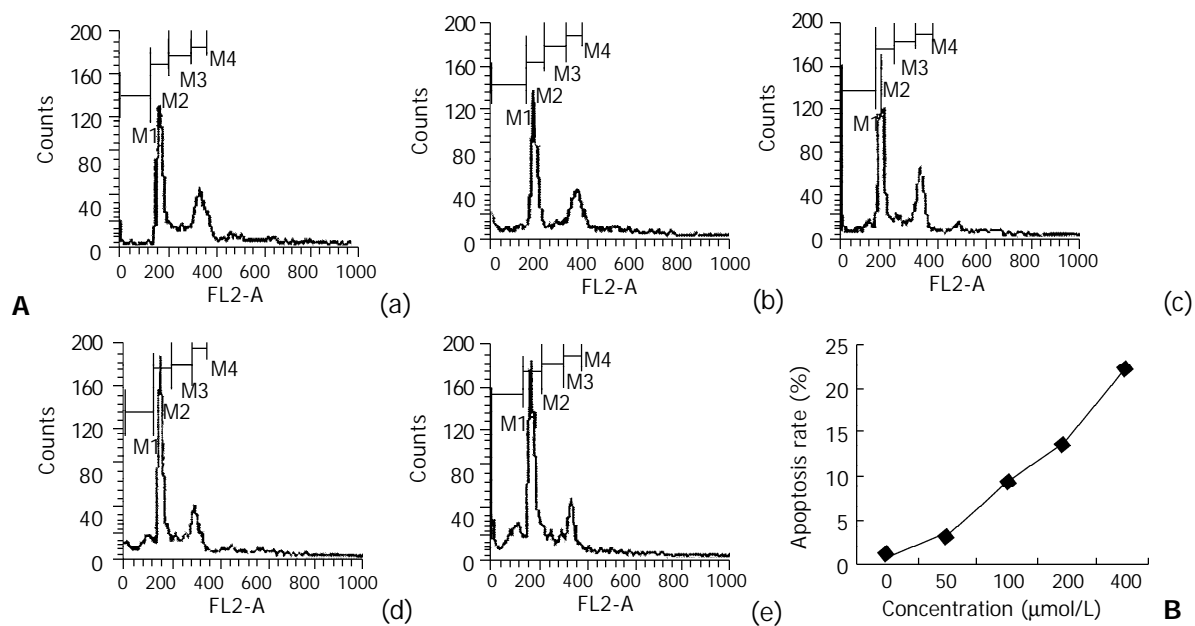

Figure 4 The results of flow cytometry analysis of SGC7901 cells treated with nimesulide for 72 h and their DNA content was determined by flow cytometry. A: DNA histogram: (a) control, (b) 50 μmol/L nimesulide, (c) 100 μmol/L nimesulide, (d) 200 μmol/L nimesulide, (e) 400 μmol/L nimesulide. B: The apoptosis percentage of nimesulide-treated SGC7901 cells.

Apoptosis of SGC-7901 cells induced by nimesulide

The TEM images of the normal SGC-7901 cells: Microvilli of SGC7901 cells were abundant, nucleus was large and round, chromatin was disperse, and nucleolus was distinct. After treated with various concentrations of nimesulide for 72 h, disappearance of microvilli, margination and condensation of nuclear chromatin, nuclear shrinkage, the swollen organelle and cytoplasmic blebbing with maintenance of the integrity of the cell membrane (Figure 3). SGC-7901 cells were treated with various concentrations of nimesulide for 72 h, DNA content of cells was measured by PI staining and flow cytometry analysis was made to detect apoptotic cells. The apoptotic cells can be observed on a DNA histogram as subdiploid or pre-G₁ peak, which was especially remarkable at the 400 μmol·L⁻¹ concentration, and the percentage of apoptotic cells increased to 22.02±1.27 % of the total cell population. Nimesulide induced apoptosis of the cells in a dose-dependent and non-linear manner (Figure 4).

Effect of Nimesulide on cell cycle phase distribution

We assessed the effect of Nimesulide in cell cycle phase distribution of SGC-7901 cells using flow cytometry analysis. The SGC-7901 cells incubated for 72 h in control or nimesulide medium is shown in Table 1. After 72 h treatment, Nimesulide caused a dose-dependent alteration in the cell cycle distribution of SGC-7901 cells, it increased the proportion of cells in the G₀/G₁ phase and decreased the proportion in the S and G₂/M phases of the cell cycle.

Table 1 Effect of Nimesulide in cell cycle progression of gastric cancer cells ($\bar{x} \pm s$)

Concentration (μmol/L)	Percentage of cell cycle (%)		
	G ₀ /G ₁	S	G ₂ /M
0	48.24±2.12	23.51±1.75	28.10±2.17

Expression of P27^{kip1} protein

Before treatment with Nimesulide, the expression of P27^{kip1} protein was mainly located in the cytoplasm of SGC-7901 cells. After Incubated with different concentrations of Nimesulide for 72 h, P27^{kip1} immunoreactivity in cytoplasm was significantly increased, meanwhile nucleus exhibited positive staining. Compared with controls, absorbance value of P27^{kip1} positive cells was increased after Nimesulide treatment (Figures 5-6).

Figure 5 (A) Positive staining of P27^{kip1} protein was mainly in cytoplasm of SGC-7901 cells before treated with nimesulide. (B) Strong positive staining of P27^{kip1} protein was in cytoplasm and in nuclei of SGC-7901 cells after treated with nimesulide at the concentration of 400 μmol/L. SP×200.

DISCUSSION

Accumulating evidence indicates that NSAIDs can lower the incidence of colorectal carcinomas. The anti-neoplastic property of NSAIDs has been shown in epidemiological studies with human, clinical studies of the human disease familial adenomatous polyposis (FAP) and in experimental carcinogenesis studies with animals^[23-26]. NSAIDs may be active on epithelial cancer other than colon cancer, such as esophageal^[27], pancreas^[28], lung^[29] and breast cancer^[30]. However, long-term uses of non-selective NSAIDs can lead to gastrointestinal toxicity from sustained inhibition COX-1. With the recent development of highly selective COX-2 inhibitors, an evaluation of the effectiveness of these agents in chemoprevention of cancer would be very important. Several selective COX-2 inhibitors have been tested for their possible utility as chemopreventive agents in colon cancer^[31,32]. However, studies on the role of selective COX-2 inhibitor in human gastric cancer are limited.

There are a lot of sensitive tests of anti-tumor medicine *in vitro*. However, each test method has its merits and weak points. So we detected growth inhibitive effect of Nimesulide on SGC-7901 gastric cancer cells by two methods of cell counts and MTT assay. We found that Nimesulide has anti-proliferative effect on cultured SGC-7901 gastric cancer cells *in vitro* in a dose- and time-dependent manner. Our findings that Nimesulide have profound anti-proliferative effects on SGC-7901 gastric adenocarcinoma cells are in agreement with previous studies demonstrating that many of the selective COX-2 inhibitors inhibit the proliferation of tumor cell line^[33-35].

A number of studies have shown that NSAIDs have an effect of growth inhibition of cancer cells, but the mechanism of the antineoplastic effect of NSAIDs is unknown. These theoretically could be related to the changes of the dynamics of cell proliferation. This hypothesis is supported by the work of Bayer *et al*, who demonstrated that indomethacin reversibly inhibits the proliferation of human fibroblasts and rat hepatoma cells and arrests them in the G₁ phase of cell cycle^[36]. An explanation for the antineoplastic properties of NSAIDs was first suggested by Adolphie, who reported that certain NSAIDs were capable of inhibiting the proliferation of cultured HeLa cells by causing cell cycle arrest^[37]. Since NSAIDs may inhibit proliferation of non-gastric cancer cells and change the distribution of cell cycle, we guess that it may have the similar effects on gastric cancer cells. We further studied the effects of Nimesulide on cell cycle of SGC-7901 gastric cancer cells *in vitro*.

We found that Nimesulide can result in changes in cell cycle distribution of SGC-7901 cells. There is an increase in the proportion of cells in G₀/G₁ and a relative decrease in the percentage of cells in S phase and G₂/M. Shiff found^[38] that NSAIDs caused colon cancer cells to accumulate in the G₀/G₁

phase of cell cycle. This effect was produced by influencing signaling pathways in these cells that control the levels and activity of certain cdk proteins. Goldberg *et al*^[39] found that the G₀/G₁ block induced by sulindac and sulindac sulfide in HT-29 cells was associated with an initial rise, followed by an abrupt decrease in P34^{cdk2}, an increase in P21^{WAF/cip1}, and a reduction in mutant p53. We can speculate reasonably that Nimesulide may increase the fraction of cells with G₀/G₁ DNA content by arresting them in the G₁ or G₀ phase of the cell cycle through an effect on the molecular components that regulate cell cycle transitions.

The cell cycle is a complex process, regulated by many factors, which can be divided into three groups: cyclins; cyclin-dependent kinases(CDK); and CDK inhibitors(CDKI). p27^{Kip1} is a member of the Cip1/Kip1 family of CDKI and is a potential tumor suppressor gene. It possessed the ability to inhibit several cyclin-Cdk complexes *in vitro* but seem to target preferentially those containing Cdk2, which control progression through G₁, and inhibit the G₁/S transition^[40,41]. Before treatment with Nimesulide, the expression of P27^{kip1} protein mainly was located in the cytoplasm of SGC-7901 cells. After treated with Nimesulide, P27^{kip1} immunoreactivity in cytoplasm was significantly increased, meanwhile nucleus exhibited positive staining. Interestingly, there was a change in subcellular localization of P27^{kip1} protein expression. Singh's studies suggested that the nuclear location of p27 was essential for its growth-inhibiting function^[42]. So, the result of nuclear localization of P27^{kip1} protein after Nimesulide treatment indicates the anti-proliferation of Nimesulide. We found that Nimesulide could increase the proportion of SGC-7901 cells at G₀/G₁ phase and reduce the cells at S and G₂/M phase. P27^{kip1} is generally associated with the G₁ checkpoint. In our study, overexpression of P27^{kip1} may be associated with the accumulation of cells at G₀/G₁ phase after Nimesulide treatment.

It is also possible that mechanisms responsible for the anti-proliferative effects of the NSAIDs on cultured cells are multifactorial. Apoptotic cell death is another mechanism that could contribute to reduced cell growth. Additional recent reports have demonstrated that NSAIDs induced apoptosis in different tumor cells^[43-48]. It is also conceivable that apoptosis might occur in the human gastric cancer cells in response to Nimesulide. To evaluate the antiproliferative mechanisms of Nimesulide, we tested the apoptosis of SGC-7901 cells induced by Nimesulide. Evidence that apoptosis was induced by Nimesulide was based on the detection of morphological changes of apoptosis and a sub-diploid peak of DNA content on flow cytometry analysis. The results showed Nimesulide also induced apoptosis in SGC-7901 cells at concentrations that affected their proliferation. Thus, apoptosis may be one of the mechanisms responsible for the inhibition of cell growth in Nimesulide-treated SGC-7901 cells. The intracellular molecular events involved in the role of COX-2 inhibitors in the induction of apoptosis are still by far unknown. It might be associated with the changes of expression of bcl-2^[49] and c-myc^[50].

In summary, we conclude that selective COX-2 inhibitor Nimesulide, has anti-proliferative effects in cultured SGC-7901 gastric cancer cells *in vitro*. The up-regulation of P27^{kip1} gene may contribute to the accumulation of these cells in the G₀/G₁ phase following treatment with Nimesulide. The induction of apoptosis and cell cycle arrest are both anti-proliferative responses that likely contribute to the inhibition of SGC-7901 cell proliferation treated with Nimesulide. The selective COX-2 inhibitor Nimesulide, may be useful as a novel approach to the treatment of gastric carcinoma without undesirable side effects.

Abstract

AIM: To study the abnormal cytokeratin (CK) expression, emergence of CK19 with or without CK7, in liver parenchymal cells and the role of laminin (LN), a basement membrane protein, in this process.

METHODS: Six hepatocellular carcinoma (HCC) cell lines were examined for different CKs, LN and its receptor by immunocytochemistry and Western blotting. Double immunofluorescent reaction, laser-scanning confocal microscopy and an *in vitro* induction procedure were used to demonstrate the role of LN in regulating CK19 expression in these cells.

RESULTS: Immunoreactivities for CK8, CK18, CK7 and the receptor for LN were observed in all the six HCC cell lines examined. However, CK19 was merely found in four of the six cell lines, and was in any case associated with LN expression. Laser-scanning confocal microscopy demonstrated the concomitant presence of these two molecules in most of the positive cells. In the two HCC cell lines, originally negative for CK19, addition of LN to the culture medium resulted in an induction of CK19 in a dose-dependent manner. Both the artificially induced and the intrinsic production of CK19 were completely blocked by an antibody to LN.

CONCLUSION: LN can induce expression of CK19 in HCC cells *in vitro*, providing direct evidence for our hypothesis that the abnormal hepatocytic CK19 expression *in situ* is due to pathologic LN deposition.

INTRODUCTION

Cytokeratins (CKs) constitute the cytoskeleton of intermediate

filament type in most epithelial cells. They consist of at least 20 members, designated CK1 to CK20 according to their molecular weights and isoelectric points^[1,2]. Each type of epithelial cell has a rather stable CK composition, termed CK pattern, which has been used in identification of different epithelial tissues and their neoplasms^[1-3]. In normal adult liver, hepatocytes contain only CK18 and CK8 ("hepatocytic" CKs), while the epithelial cells lining the human biliary tree additionally express CK19 and CK7 ("bile duct type" CKs). This difference has been traced back to the early stage of morphogenesis of intrahepatic bile ducts both in rat^[4-6] and in man^[7]. It was believed that the characteristic adult CK pattern of each cell type is maintained in various liver diseases including neoplasia (reviewed by Moll *et al*^[1] and Cooper *et al*^[3]). However, CK19 expression, with or without appearance of CK7, has been observed under many pathologic conditions including human hepatocellular carcinoma (HCC)^[8,9], chronic hepatitis and cirrhosis caused by alcoholism^[10-12], cholestasis^[10,12], hepatitis B virus (HBV) infection^[13] and exposure of rats to carbon tetrachloride^[14,15], butter yellow, and local frostbite injury caused by liquid nitrogen^[16] (for more literatures see Van Eyken *et al*^[17] and Fu *et al*^[18]).

The additional expression of CK19 in liver parenchymal cells has been considered a phenotypic change involved in three common pathologic processes, namely 1) remodeling of the liver parenchyma or cirrhotic nodules (destruction of the limiting plate), 2) the capillarization of hepatic sinusoids, and 3) ductular (oval) cell proliferation^[16]. However, little is known about the molecular mechanism resulting in CK19 expression under these conditions.

The hepatocytes in normal liver are characterized by the absence of a basement membrane (BM)^[5,15,16,19-23] and simplicity of their CK composition^[1,17,18]. All the three pathologic processes mentioned above are associated with an increase in production of laminin (LN), a BM glycoprotein, and its deposition within the involved sinusoids to form an LN-positive BM^[15,16,24-27]. The abnormal deposition of LN was postulated to be a common cause for CK19 expression in liver parenchymal cells^[15,16]. In the present study, we provide direct evidence for this hypothesis in human HCC cell lines using laser-scanning confocal microscopy (LSCM), Western blotting, and an *in vitro* assay for the induction of CK19.

MATERIALS AND METHODS

Cell lines and cell culture

Six well characterized and intensively used human HCC cell lines, including HepG2^[28], Hep3B^[29], HCC-9724^[30,31], HHCC (kindly supplied by Dr. Xian-Hui Wang), HCC-9204^[32,33], and SMMC7721^[9,34-38], were examined in this study. The cells were cultured in RPMI1640 medium (Gibco BRL, Life Technologies Inc, Gaithersburg, MD, USA) containing 100 mL/L newborn calf serum (Biotech Shaanxi, Xi'an, China), 10⁵ u/L penicillin, 10⁵ u/L streptomycin and 2 g/L glutamine at 37 °C in the air containing 50 mL/L CO₂. After two to three days, the cell monolayers growing on coverslips were taken out from the 12-well plastic flasks, rinsed in 10 mmol/L, pH 7.4 phosphate-buffered saline (PBS) for 2 min and fixed for 10 min in the

methanol/acetone (1:1 in volume) solution precooled at 4 °C. After being washed with PBS for three times, 5 min each, the cell monolayers were ready for the immunostaining as detailed below.

Immunocytochemical reactions

The cell monolayers fixed on coverslips were treated in 800 mL/L methanol solution containing 3 mL/L H₂O₂ to block the endogenous peroxidase, washed with PBS for three times. After pretreatment with 100 mL/L bovine serum in PBS, separate incubation with monoclonal antibodies to the following proteins was conducted overnight at 4 °C: CK8 (M0631, Dako A/S, Copenhagen, Denmark; 1:40), CK18 (M7010, Dako; 1:40), CK7 (M7018, Dako; 1:40), CK19 (M0772, Dako; 1:75), LN (M0638, Dako; 1:25) and LN receptor (MAB0273, Clone MLUC5, Maxim Biol Fuzhou, China; 1:30). The antigen-antibody conjugation *in situ* was demonstrated by consecutive incubation with biotinylated anti-mouse/rabbit IgG and streptavidin-labeled peroxidase (S-P) using an Ultrasensitive™ S-P kit (KIT-9730, Maxim Bio Fuzhou). Finally, the immunoreactions were visualized by incubation in a 3,3'-diaminobenzidine-H₂O₂ solution for 10 min, and the monolayers were slightly counterstained with hematoxylin. Normal mouse and rabbit IgG of the same concentrations were used to substitute for the mouse monoclonal and rabbit polyclonal antibodies, respectively, as negative controls.
