Double immunofluorescence reactions for LN and CK19 and LSCM

After blocking with 30 mL/L bovine serum in PBS, the cell monolayers were incubated with an antibody mixture (1:1) of mouse monoclonal anti-CK19 (1:75) and rabbit polyclonal anti-LN (Z0097, Dako; 1:38). The reactions were demonstrated by incubation with an antibody mixture (1:1) of the fluorescein isothiocyanate (FITC)-labeled goat anti-mouse IgG (Dako; 1:15) and tetramethylrhodamine isothiocyanate (TRITC)-labeled swine anti-rabbit IgG (Dako; 1:30), and observed under a laser-scanning confocal microscope (Zeis 100) equipped with the Biorad MRC-1024 system. The FITC- and TRITC-labeled signals were visualized at 488 nm and 568 nm, respectively, as their emission wavelength.

Western blotting analysis

Sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis (PAGE) and Western blotting were carried out as described previously^[39]. Briefly, five cell lines, including HHCC, HCC-9204, HepG2, HCC-9724 and SMMC7721, were cultured in the RPMI1640 medium supplemented with newborn calf serum (100 mL/L). Cells were harvested by digestion with trypsin. For all cell lines examined, 10⁷ cells were used for each protein extraction. The cells were washed in precooled PBS for two times, 5 min each, and then extracted with 1 mL of a Tris-HCl solution (50 mmol/L, pH 8.0) containing 150 mmol/L NaCl, 100 mg/L Nonidet P-40, 50 mg/L Sodium deoxycholate, 10 mg/L SDS, 2 mg/L pepstatin, 2 mg/L leupeptin and 100 mg/L phenylmethylsulfonyl fluoride. After centrifugation at 2 000 r/min for 2 min, the supernatant was collected. Lysates of the cell lines, 10 µL for each, were loaded on to a 100-g/L SDS-polyacrylamide gel. Proteins were resolved through electrophoresis at 150 V using a miniVE vertical unit (Hoefer Pharmacia Biotech Inc, San Francisco, CA) and transferred onto a nitrocellulose membrane (Biotech Shaanxi) by using the same unit according to the instructions of the manufacturer. After the blocking with 1 mL/L bovine serum albumin in PBS for 2 h, the blots were incubated overnight at 4 °C separately with monoclonal antibodies to CK18 (1:600), CK7 (1:600) and CK19 (1:750). The reactions were demonstrated by incubation with alkaline phosphatase (AP)-labeled anti-mouse IgG (Dako; 1:2 000) and visualized

by incubating the filters in 5-bromo-4-chloro-3-indolyl phosphate (BCIP)/nitro blue tetrazolium (NBT) solution for 10 min.

Induction of CK19 expression by exogenous LN and its blocking test

Two HCC cell lines, HHCC and HCC-9724, did not produce LN and were negative for CK19 when growing in the ordinary complete medium (see below). They were transferred into the medium containing LN at concentrations ranging from 2.5 mg/L to 60 mg/L. The LN preparation, isolated and purified from mouse Engelbreth-Holm-Swarm tumor, was supplied by Department of Cell Biology, Health Science Center, Peking University. Sterilized PBS of the same volume was used to substitute for LN as a negative control for the assay. After growing for 60 h, the coverslips with cell monolayers within each well were taken out and immunostained for CK19 using the S-P kit as described above.

In order to show specificity of the induction role of exogenous LN, a blocking test was carried out using the cell line, HHCC. The cells were transferred into the complete RPMI1640 medium supplemented with LN (20 mg/L), and then divided into three groups. In one group, the rabbit polyclonal anti-LN IgG, with its concentrations ranging from 20 mg/L to 0.002 mg/L, was added into the LN-containing medium. The two remaining groups, in which normal rabbit IgG at corresponding concentrations or sterilized PBS of the same volume, respectively, were added to the medium, served as negative controls.

Inhibition test of the CK19 expression associated with intrinsic LN

In order to elucidate the mechanism of CK19 expression in HCC cells with intrinsic production of LN (see below), SMMC7721 cells were cultured in the ordinary medium without addition of LN, and divided into three groups. As for the blocking test in HHCC, the rabbit anti-LN IgG was added to the culture medium at corresponding concentrations, and normal rabbit IgG or sterilized PBS, respectively, were used for negative controls.

Statistical analyses

Intensities of the immunoreaction in single cells were graded into negative (-), weakly positive (+), moderately positive (2+) and strongly positive (3+) as described previously^[15,40]. For assessment of expression levels of the antigens tested, ten high-power microscopical fields were determined randomly in different samples, all cells within these areas were counted, and their immunoreactions were evaluated.

In each cell lines immunoreactivities for the antigens detected were graded into negative (-, reaction being absent or too weak to be identified from background), weak (+, definite reaction visible but weak in its intensity or smaller in number of immunoreactive cells) and strong (2+, brown or darker brown reaction in up to half of cells). Statistical computations were conducted using the software package SLPM^[41]. The semiquantitative data obtained were analyzed by Karl-Pearson and Krushal-Wallis tests. The *P* value below 0.05 was regarded as statistical significance.

RESULTS

Expression of CKs, LN and its receptor in different HCC cell lines

Immunoreactivities for CK18 and CK8 were observed by the immunoperoxidase reaction in cytoplasm of all the six HCC cell lines examined (Table 1). CK7-immunoreactivity was also found in all of these cell lines (Figure 1 A, B), but its intensity varied markedly, being stronger in SMMC7721 and HCC-

9204, and weaker in the others. CK19 and LN expression correlated well, both being present in the cell lines SMMC7721, HepG2 (Figure 1 C, E), Hep3B and HCC-9204, but undetectable in the cell lines HHCC and HCC-9724 (Figure 1 D, F). All of these cell lines were positive for the LN receptor, its immunoreactivity being localized at and beneath the cytoplasmic membrane (Figure 1 G, H).

Expression of CK18 and CK7 was also demonstrated by Western blotting in cell lines SMMC7721, HepG2, HCC-9204, HCC-9724 and HHCC, as shown in Figure 2 A to E, respectively. However, CK19 was only identified in the former three cell lines (Figure 2 A-C), and not in the latter two (Figure 2 D, E).

Table 1 Expression of CKs, LN and its receptor in six HCC cell lines in culture

Antigens	SMMC7721	Hep3B	HCC-9204	HepG2	HHCC	HCC-9724
CK8	++	++	++	++	++	++
CK18	++	++	++	++	++	++
CK7	++	+	++	+	+	+
CK19	+	+	+	+	-	-
LN	+	+	+	+	-	-
LN receptor	+	+	+	+	+	+

Figure 1 Expression of CK7 (A, B), CK19 (C, D), LN (E, F) and its receptor (LN-R, the reactivity denoted by arrows; G, H) in the representative HCC cell lines, HepG2 (A, C, E, G) and HCC-9724 (B, D, F, H). Both CK19 and LN present in HepG2 (C and E) and absent in HCC-9724 (D and F). S-P reaction, slightly counterstained with hematoxylin. $\times 250$.

Figure 2 Western blotting for CK18, CK7 and CK19 using the intermediate filament cytoskeleton extracts from HCC cell lines SMMC7721 (A), HCC-9204 (B), HepG2 (C), HHCC (D) and HCC-9724 (E). Immunoreactions were demonstrated by AP-labeled anti-mouse IgG and visualized in a BCIP/NBT solution. The right lanes show molecular weight standards (MWS) visualized by staining with Coomassie R250, with three indicated by the short bars (from top to bottom, M_r 62 000, M_r 47 500 and M_r 32 500, respectively).

Figure 3 Double immunofluorescence reaction for LN (TRITC-labeled, red) and CK19 (FITC-labeled, green) in HCC cell lines HepG2 (A-C) and HCC-9724 (D-F) under a laser-scanning confocal microscope. Definite signals for LN and CK19, frequently coexisting within cytoplasmic compartment (orange), were found only in the cell line HepG2. $\times 400$.

Figure 4 Induction test using the HCC cell line HCC-9724. Cells were inoculated in RPMI1640 medium containing LN at concentrations of 2.5 (A), 5 (B), 10 (C), 20 (D), 40 (E) and 60 mg/L (F), respectively. CK19 expression was found in cells incubated with LN starting at a concentration of 10 mg/L (C), and increasing with LN concentrations (D-F). S-P reaction, slightly counterstained with hematoxylin. $\times 250$.

Concomitant emergence of CK19 and LN as demonstrated by LSCM

CK19 and LN were labeled by double immunofluorescence staining in the same five cell lines showing these proteins on Western blots. The reactions were examined by LSCM, the results being similar to those obtained by the S-P procedure (Table 1). The concomitant occurrence of CK19 and LN was observed in the positive cell lines SMMC7721, HepG2 and HCC-9204, the majority of the positive cells expressing both elements with close correlation of the intensities of the immunoreactivities (Figure 3 A-C). In the cell lines HHCC and HCC-9724, both reactions were negative, showing only some faint background staining (Figure 3 D-F).

Induction of CK 19 expression by addition of LN to the medium

The data described above verified the link between the aberrant expression of CK19 in liver parenchymal cells and abnormal LN deposition. However, more direct evidence is needed to unequivocally establish the role of LN for the induction of abnormal CK19 expression. For this reason, an induction test was carried out in two HCC cell lines, HHCC and HCC-9724. Growing of both cell lines in the medium containing LN resulted in the appearance of CK19 when the concentration of

LN reached 10 mg/L (Figure 4). The expression level of CK19 was found to increase along with concentration of LN in the medium (Figure 5). In the control group, addition of the same volume of sterilized PBS to the medium did not give rise to any CK19-positive cell.

Blocking of LN-induced CK19 expression by LN antibody

If LN added to culture medium is indeed responsible for the emergence of CK19 expression in the LN-negative cell lines as described above, the effect should be blocked, or at least be partially inhibited, by the addition of LN antibody. This assay was performed using the cell line HHCC. The cells, being negative for both LN and CK19 when growing in ordinary medium, were found to express CK19 with the presence of exogenous LN in the medium (20 mg/L). Its levels in HHCC cells growing in the medium containing different amounts of rabbit anti-LN IgG were assessed. CK19 became undetectable in the cells when the final concentration of LN antibody reached 0.2 mg/L in the LN-containing medium (Figure 6A), while addition of the same amount of normal rabbit IgG or sterilized PBS did not inhibit the expression of CK19 (Figure 6B). These data prove that exogenous LN can induce CK19 expression in HCC cells growing *in vitro*.

Figure 5 Induction of CK19 expression in HCC cell lines, HHCC (A) and HCC-9724 (B), by LN. Concentrations of LN in culture medium ranging from 2.5 mg/L to 60 mg/L. Numbers of cells expressing CK19 were presented in percentages, and the expression levels indicated by column colors (white, +; gray, 2+; black, 3+). ^a $P < 0.05$ (compared to group on the left).

Figure 6 Blocking test of the CK19 expression in HHCC cells induced by exogenous LN. A. CK19 expression completely blocked with concentration of the polyclonal anti-LN up to 0.2 mg/L in the LN-conditioned medium (20 mg/L). B. Addition of the same amount of normal rabbit IgG having no effect on the CK19 expression. Numbers of cells expressing CK19 presented in percentages, and CK19 expression levels indicated by column colors (white, +; gray, 2+; black, 3+). ^a $P < 0.05$ (compared to group on the left).

For the HHCC cells whose CK19 expression was completely inhibited by LN antibody, CK19 reappeared when cells were transferred back to the medium containing LN (20 mg/L) and cultured for 14 d. This demonstrates that the inhibition effect by LN antibody is reversible.

The antibody inhibition test was also conducted in the HCC cell line SMMC7721, whose endogenous production of LN has been described above and whose expression of CK19 has been observed when growing in the ordinary medium. Levels of CK19 expression in the cells growing in the medium containing different amounts of rabbit anti-LN IgG were assessed. CK19 became undetectable in the cells when the final concentration of rabbit anti-LN IgG reached 0.02 mg/L in the medium (Figure 7A), while addition of the same amount of normal rabbit IgG or sterilized PBS did not exert this effect (Figure 7B). Similarly, CK19-immunoreactivity reappeared when the cells were transferred to the medium without LN antibody and cultured for 14 d. These data demonstrate that endogenous LN is also responsible for maintaining CK19 expression in HCC cells growing *in vitro*.

Figure 7 Blocking test of the CK19 expression in SMMC7721 cells associated with endogenous LN. A. CK19 expression completely blocked with concentration of the polyclonal anti-LN up to 0.02 mg/L in the ordinary medium. B. Addition of the same amount of normal rabbit IgG having no effect on the CK19 expression. Numbers of cells expressing CK19 were presented in percentages, and CK19 expression levels indicated by column colors (white, +; gray, 2+; black, 3+). ^a $P < 0.05$ (compared to group on the left).

DISCUSSION

The data obtained in this and other groups during last decade have demonstrated that the CK expression in hepatocytes^[10-16,40] and hepatocytic neoplasms^[8,9] is not so stable as considered before^[17,18]. The expression of CK18 and CK8, the “hepatocytic” CKs, may change greatly in some phenotypically altered hepatocytes^[42]. Moreover, expression of CK19, with or without CK7, has been observed in parenchymal cells in some liver diseases, indicating that hepatocytes can also express the so-called “bile duct type” CKs under certain pathological conditions^[17,18]. The abnormal CK19 expression is found in

chronic hepatitis, cholestasis and cirrhosis^[10-15], as well as in some HCCs^[8,9] and HCC cell lines^[9,35,43], and has been considered an adaptive reaction to some alterations of the local microenvironment^[15,16,18]. This change has been linked to three common pathologic processes including remodeling of the parenchyma in livers with chronic hepatitis or cirrhosis, capillarization of hepatic sinusoids and ductular (oval) cell proliferation^[16]. The ductular (oval) cells are frequently seen in rodent liver under some pathological conditions which suppress regeneration of the parenchymal cells^[16,44,45] (for more references see a review by Vessey and de la Hall^[46]). Cells with similar morphologic and immunohistochemical phenotypes have also been described in human livers with chronic hepatitis^[13,47-50]. In addition, some of the small epithelial liver cells, identified in human livers with chronic hepatitis or cirrhosis and possibly involved in reparative regeneration of liver parenchyma^[40] and progression of the preneoplastic foci of altered hepatocytes^[42,51], were also shown to express CK19^[40,52]. It seems to be true that these CK19-positive cells correspond to a subpopulation of small hepatocytes, being phenotypically intermediate between ductular (oval) cells and typical hepatocytes^[40,52]. Considering the frequent abnormal CK19 expression in extrafocal parenchyma in livers with progressive diseases and in HCC cells^[8-15,35,43], occurrence of CK19-immunoreactivity in some small-cell preneoplastic foci, as recently observed by Libbrecht *et al.*^[52], fails to provide any unequivocal evidence for their speculation that ductular (oval) cells give rise to the small-cell foci, and does not argue against the hepatocytic origin of hepatic preneoplastic foci as demonstrated in both rodents^[53-55] and man^[42,51,56].

Apparently, the frequent occurrence of CK19 expression reflects the complexity in the differentiation of hepatic epithelial cells, and implies great difficulties in using these "bile duct type" CKs for the differential diagnosis between hepatocellular and cholangiocellular neoplasms^[9]. Moreover, its mode of origin has not been fully established. Several lines of indirect evidence have related the aberrant CK19 expression, at least partially, to ductular metaplasia of hepatocytes and glandular differentiation of HCC cells, and indicated its association with abnormal deposition of LN. It has been shown that the morphogenesis of intrahepatic bile ducts in fetal liver, which is characterized by the occurrence of CK19 expression^[4,7], is linked to the deposition of LN around portal vein branches^[5]. Secondly, all of the three pathologic processes related to the CK19 expression as discussed above were associated with an abnormal deposition of LN within the hepatic sinusoids involved^[15,16,18-27], the patterns of histological distribution of these two immunohistochemical reactions being largely correlated with each other^[15,16,27]. Thirdly, both CK19 expression and LN production were also found in some hepatocytes in primary culture and in some HCC cell lines growing *in vitro*^[9,18,35,43,57], and a coexpression of these two molecules has been noted under these conditions^[35,43,58]. The recent data from Blaheta *et al.*^[59] and Nishikawa *et al.*^[60] proved that fetal hepatocytes growing in culture differentiated in response to some extracellular extracts, containing collagen types I and IV, fibronectin, LN and many other extracellular matrix components. The differentiation was reflected by changes in their CK composition^[59-62]. However, these data failed to demonstrate which of the extracellular elements was responsible for the effect.

In this study, the immunocytochemical and Western blotting data proved the concomitant occurrence of LN and CK19 in four of the six HCC cell lines examined, both elements were colocalized in most of the positive cells as demonstrated by LSCM. The data strongly, though still indirectly, suggest a role of LN for the induction of CK19 expression in liver parenchymal cells.

Our induction assay was conducted in two HCC cell lines, HHCC and HCC-9724, which did not produce LN and were negative for CK19 when growing in ordinary medium. CK19 expression emerged with a certain amount of LN added to the culture medium. The effect was found to be dose-dependent, and was completely blocked by a polyclonal antibody against LN. The blocking test was also done with the HCC cell line SMMC7721, which was found to produce LN itself and was positive for CK19 as observed previously^[35,43]. LN antibody added to the medium completely inhibited the CK19 expression. These data clearly demonstrate that LN, either of exogenous origin or produced intrinsically, can induce the expression of CK19 in HCC cells *in vitro*.

Based on results from this and previous studies, we believe that LN, being frequently deposited in hepatic sinusoids as a common response to various kinds of liver injury, is one of the key molecules causing the abnormal CK19 expression. It has been noted that LN is able to induce the hepatocytes to express its receptor, a type of integrin molecules. The receptor takes part in the regulation of cellular differentiation and replication^[61-64]. Immunoreactivity for LN receptor was also observed in all the six HCC cell lines examined in this study. In addition, the successful blocking of the induction effect of intrinsically produced LN by anti-LN IgG molecules added to the medium, as well as the reversibility of this reaction, indicate that a receptor-mediated pathway is needed for LN to exert its effect. Therefore, we suggest that LN induce CK19 expression in hepatocytes and HCC cells through its receptors located on the surface of their cytoplasmic membrane.

In summary, this study provided direct evidence for an essential role of LN in the induction of CK19 expression in liver parenchymal cells, and established abnormal LN deposition as a key causative factor for the development of aberrant expression of CK19. This will be helpful for the further understanding of differentiation and transformation of liver cells, as well as for evaluating CK19 immunohistochemistry in differential diagnosis of hepatocellular and cholangiocellular carcinomas.

Abstract

AIM: To study the effect of arsenic trioxide (As_2O_3) on rat experimental hepatocarcinoma and its renal cytotoxicity.

METHODS: The hepatocarcinoma model was established by diethylnitrosamine perfusion in stomach of 120 Wistar rats, and the treatment began at the end of 20 weeks. Before the treatment, the rat models were randomly divided into 5 groups. In the treatment groups, three doses of As_2O_3 were injected into rat abdominal cavity, the total time of drug administration was 4 weeks. Cisplatin control or the blank group was injected into abdominal cavity with equal amount of cisplatin or saline at the same time, respectively. On the 7th, 14th and 28th day after the treatment, the hepatocarcinoma nodules were obtained and the morphologic changes of hepatocarcinoma cells were observed under light and electron microscopes; Immunohistochemistry (S-P methods) was employed to detect the expression of bcl-2, bax and PCNA in hepatocarcinoma tissues; flow cytometry (TUNEL assay) was used to detect the apoptosis of liver cancer cells and the change of cytokinetics. On the 28th day, the kidneys were obtained and their histologic changes were observed under light microscope, and immunohistochemistry (SP stain) was also employed to detect the expression of bcl-2 and PCNA. Cisplatin and saline solution were used as the control.

RESULTS: As_2O_3 could induce the apoptosis of rat liver cancer cells and exhibited typical morphologic changes. The incidence of apoptosis of hepatocarcinoma cells was elevated ($P=0.001$). The elevation was the most higher in the group of middle-dose of As_2O_3 ($1 \text{ mg} \cdot \text{kg}^{-1}$), significantly higher than that of the other arsenic groups and the controls ($P=0.001$). Large dose of As_2O_3 ($5 \text{ mg} \cdot \text{kg}^{-1}$) was able to arise the incidence of apoptosis, but also produced a large amount of necrosis and inflammatory reaction. Middle dose of As_2O_3 dramatically increased the cell number in G2/M phase ($P=0.0001$), and apoptosis happened apparently. The expression of bcl-2 and bax was related to the dose of As_2O_3 . With the up-regulation of apoptotic incidence, the ratio of bcl-2/bax decreased. But the incidence of apoptosis was not the highest status and the ratio of bcl-2/bax was at the lowest when the highest-dose of As_2O_3 was used. There was significant difference among the PCNA indexes (PCNA L1) of the five groups. Of them, three arsenic groups all showed decrease of different degrees, and this down-

regulation was most obvious in group A. There was significant difference among the three groups ($P=0.016$). Under the light microscope, the rat kidney in the cisplatin group exhibited tubular epithelium swelling and degeneration, protein casts in collecting tubules; While all arsenic groups didn't show the significant changes ($P=0.013$). In the arsenic groups, the expression of bcl-2 in the renal tubular epithelium was increased ($P=0.005$), no obvious changes happened to PCNA L1. But in the group of cisplatin, the PCNA L1 increased significantly ($P=0.001$).

CONCLUSION: As_2O_3 can induce apoptosis of rat hepatocellular carcinoma cells. And there is optimum dose; too high dose will induce the cytotoxic effect, while certain dose of As_2O_3 is able to block the cell cycle at G2/M phase. As_2O_3 had the most remarkable influence on G2/M cells, and it can also induce apoptosis to cells at other phases. As_2O_3 can restrain the proliferation of rat hepatocellular carcinoma cells, in a dose-time dependent manner. Compared with cisplatin, As_2O_3 didn't show obvious renal toxicity, which was related to the increasing expression of bcl-2 in renal tubular epithelium, the inhibition of apoptosis and the anti-oxidation effects.

INTRODUCTION

Primary hepatocellular carcinoma has been found to be one of the most common malignancies worldwide. In the recent years, the diagnosis rate of early hepatocellular carcinoma has increased and the curative effect of surgery resection also improved. However, most of the early hepatocellular carcinoma is subclinical, once it is symptomatic, it is mainly in its middle or later stage. As the update statistic indicates, hepatocellular carcinoma ranked the second cause of cancer mortality since 1990s in China^[1]. Presently, what challenges us most is the mid-or-late stage hepatocarcinoma, unresectable hepatocarcinoma, high postoperative reoccurrence and high metastasis. Thus efficient nonsurgical methods are urgent^[2,31-36].

Recently, it has been reported that arsenic (mainly arsenic trioxide, As_2O_3) in the treatment of leukemia has obvious curative effect through inducing tumor cell apoptosis^[3,4]. But whether arsenic chemist can be used in the treatment of other malignancy such as hepatocellular carcinoma is still under the exploration. The blockage of apoptosis plays a more important role not only in the cause of malignancy but also in the out of control of proliferation. Thus in the two strategies of tumor treatment: inhabiting tumor cells' proliferation and inducing their apoptosis, the later seems to be more preferable^[5-7]. Our study is to establish a rat hepatocellular carcinoma model with the treatment of As_2O_3 , then observe the apoptosis and proliferation of hepatocellular carcinoma cells and influence of it on the cell cycle, as well as the possibly noxious side effect on kidney of As_2O_3 .

MATERIALS AND METHODS

Materials

Arsenic trioxide (As_2O_3 Sigma) was dissolved by PBS and diluted to 0.2 % (m/m), kept under 4 °C. Diethylnitrosamine (DEN Sigma) was diluted to 1 % (v/v) by water solution. Cisplatin (Qilu Pharmaceutical Department) was diluted to 0.08 % (m/m) by injection solution. There were also keg reagents as follows: murine monoclonal antibody against human Bcl-2 (1:50, SANTA CRUZ) and murine monoclonal antibody Bax (1:70, SANTA CRUZ) and murine monoclonal antibody against rat proliferation cell nuclear antigen (PCNA) (1:100, Zhongshan Biotech Ltd, Beijing); Histostain™-Plus Immunohistochemical reagent box (Zymed), DAB stain kit (Zhongshan Biotech Ltd, Beijing) APO-BRDU™ apoptosis quantitative test reagent box (Becton Dickinson).

FACS Vantage flow cytometry (Becton Dickinson), H600-4 transmission electron microscope (HITACHI) were used in this study.

Animal model, grouping and treatment

120 Wistar rats (60 males and 60 females, 6 weeks old) were supplied by the Fourth Institute of Military Medical Academy of Science. According to the method in the reference^[8], the hepatocarcinoma model was established by DEN perfusion in stomach, and the treatment began at the end of 20 weeks. Before the treatment, the rat models were randomly divided into 5 groups. There were no difference in the number, sex and weight among the 5 groups. Group A: high-dose of As_2O_3 ($5 \text{ mg} \cdot \text{kg}^{-1}$), group B: middle-dose of As_2O_3 ($1 \text{ mg} \cdot \text{kg}^{-1}$), group C: low-dose of As_2O_3 ($0.2 \text{ mg} \cdot \text{kg}^{-1}$), group D: cisplatin control ($2 \text{ mg} \cdot \text{kg}^{-1}$), group E: blank control (saline solution).

In the treatment groups, three doses of As_2O_3 were injected into rat abdominal cavity, once a day, after two weeks, it is changed to twice a week, and the total time of drug administration was 4 weeks. Cisplatin control or the blank group was injected into abdominal cavity with equal amount of cisplatin or saline at the same time, respectively.

The choice of the dose of As_2O_3 was based on the curative dose on human leukemia ($10 \text{ mg} \cdot \text{d}^{-1}$)^[4], obtained by calculating the ratio of equal effective dose of body surface area between the human and rat. The dose of cisplatin was chosen according to the reference^[9].

Methods

Sample preparation After the treatment, all rats were operated to obtain the liver nodules through 3 operations under anesthesia of sodium pentobarbital (abdominal cavity injection, $40\text{--}50 \text{ mg} \cdot \text{kg}^{-1}$) on the 7th, 14th and 28th day, respectively. The specimens with the formation of carcinoma proved by pathologic examination were chosen as experimental objects. At the last operation, the rats' kidneys were obtained at the same time and the rats were killed.

The hepatocellular carcinoma nodules were divided into three parts along the center, one part (about 0.2 mg, fresh tissue) was made into monocyte suspending solution, used in the detection of flow cytometry; one part was fixed in 10 % formaldehyde, embedded in paraffin with 4 μm successive section and HE staining. The pathologic changes of cancer nodules were observed under light microscope or by immunohistochemistry (IHC). The third part was processed into thin slice (<1 mm) and immediately immersed into 2.5 % glutaraldehyde phosphoric buffer. The embedded sections were made using the common electron microscope specimens. The ultrastructure of the hepatocellular carcinoma cells was observed under the transmission electron microscope^[37].

Flow cytometry analysis The FACS Vantage flow cytometry was employed with the 5w argon laser as emission resource, and the wavelength of emission light was 488 nm. The variation

coefficient (CV) of the machine was regulated as < 4 % using chicken blood erythrocytes fixed by glutaraldehyde. 1×10^4 cells were analyzed and the data was analyzed using MODifit LT software. Referring to the kit protocol, PI stain was used to label the cellular DNA to analyze cell cycle TdT to catalyze dUTP combined with external bromides (Br-dUTP) ligated to the 3' -OH terminal end of DNA fragments, then it was combined with anti- Br-dUTP mono-antibody labeled by FITC, and then the intensity of fluorescence of FITC was detected through the flow cytometry to estimate the number of DNA breakage points to qualitatively examine the cell apoptosis. The occurrence of apoptosis in different phases was analyzed combining with the staining result of PI.

Histology analysis The paraffin-embedded rat hepatocellular carcinoma tissues after 7 days of treatment were successively cut into 4 μm sections and the HIC (SP stain) was employed to detect the expression of bcl-2, bax and PCNA. The successive 4 μm sections were obtained from the paraffin-embedded rat hepatocellular carcinoma tissues after 28 days of treatment and stained with HE. And the histomorphologic change was observed under light microscope. IHC (SP stain) was used to detect the expression of bcl-2 and PCNA. PCNA labeling index (LI) = PCNA positive cells number / 500 (using % to denote).

Statistical analysis

All the data were processed by statistical software SPSS10.0. The total VAR difference of each group was analyzed by Bartlett test. If it was the same, then analyzed by the one way ANOVA or student *t* test, otherwise by Kruskal-Wallis *H* test, or Mann Whitney *U* test which as for the multi-sample comparison; to the quantity material analysis, χ^2 test was used (test standard: two-side $\alpha=0.05$).

RESULTS

On 7th, 14th, 28th day after the treatment, the hepatocarcinoma nodules of the rats (No. 65, 43, 34) were collected respectively (proved by pathology). The other rats were repelled out of the experiment due to the absence of carcinoma nodules. The kidneys of hepatocarcinoma rats were obtained on the 28th day after the treatment.

Morphologic change

Macroscopic observation The liver was yellow or pale with dramatically increase of the volume and weight. The liver grew as multi-nodular mass. The nodules were of variable size ranging from 3 mm to 3.5 cm. Some nodules were hemorrhagic. The liver was firm in texture, pale on section and with necrosis. Some nodules were dark red on section accompanied by the hemorrhagic necrosis (more obviously seen in Group A and D than in the others).

Light microscopic observation Hepatocarcinoma cells were arrayed in column or gland-like, most commonly presented middle- or highly- differentiated status, few were poorly differentiated status. In some specimens, the hepatocarcinoma cells showed patched or focal necrosis with red-stained non-structural materials. The nucleic chromatin disappeared, prominently seen in group A and D. The necrosis region and portal tracts were infiltrated by inflammatory cells with vascular dilation and hyperemia. Group B, C and E mainly exhibited point necrosis, slight inflammatory reaction in portal tracts, and vascular dilation was less obvious than the former groups. In the treated groups, some hepatocarcinoma cells presented apoptotic features, cell membrane was shrunken but intact, chromatin was condensed and accumulated at side or broken up forming nucleic bodies in different sizes within cells, without inflammatory cells invasion, seen more commonly in group A, B and D. Under microscope, group D (4/7) exhibited relatively extensive renal tubular epithelium cloudy swelling

and degeneration. Protein casts was formed in the collecting tubules (4/7), there were no casts formed in group A, B, C and E (0/6, 0/6, 0/8, 0/7) without or occasionally tubular epithelium swelling and denaturalization. There was significant difference among the five groups ($\chi^2=12.69$, $P=0.013$).

Electron microscope observation The chromatin was accumulated at the side of the nucleic membranes which was condensed. The nucleic shape was irregular and the surface of nucleic membrane was rough. The nucleus was broken but encapsulated by intact membrane, containing intact organelles and apoptotic bodies.

Flow cytometry analysis of hepatocarcinoma cells

Tumor cell apoptotic rate in each group and influence of treatment time On the 7th, 14th, 28th day of treatment, there was significant difference of tumor cell apoptotic rate presents among each group ($P=0.001$). Compared with group E, apoptotic rate of group A, B, C, D all increased evidently, especially that of group B ($P=0.000$). The apoptotic rate of Group B depended on time, firstly it was increased then decreased ($P=0.004$), but there was no significant difference between them on the 14th day and 28th day ($P=0.224$). The relationship of apoptosis and treatment time between group A and group C was almost the same (Table 1).

Table 1 Relationship between tumor cells apoptotic rate in each group and treatment time ($\bar{x}\pm s$)

Specimen	7days	14days	28days
Group A	18.30 \pm 3.43 ^a	20.16 \pm 5.31 ^a	16.92 \pm 4.03 ^a
Group B	40.99 \pm 5.89 ^b	51.59 \pm 7.67 ^b	47.49 \pm 3.23 ^b
Group C	11.80 \pm 7.02	12.24 \pm 4.41 ^a	10.77 \pm 3.45 ^a
Group D	22.41 \pm 7.09 ^a	17.31 \pm 6.16 ^a	13.88 \pm 3.83 ^a
Group E	7.66 \pm 2.23	6.72 \pm 2.31	6.30 \pm 1.15

^a $P<0.05$, vs group E; ^b $P<0.001$, vs group E.

Compared with group E, apoptotic rate of G₀/G₁, G₂/M phase cell in group B was significantly increased ($P<0.05$), especial that of G₂/M phase cell ($P=0.001$). Cell apoptosis presented during the whole cell cycle in group A, C, D, without distinct specificity (Table 2). In group B, apoptotic rate of G₀/G₁ phase cell is lower than that of G₂/M phase cell, but the number

of apoptotic cells at G₀/G₁ phase still accounted for a rather large proportion of the whole apoptotic cells.

Tumor cell cycle changes in each group (Table 3)

The tumor cells apoptotic distribution at G₀/G₁, G₂/M phase in each group Compared with group E, on the 7th, 14th, 28th day after the treatment, the percentage of G₀/G₁ phase cells in group A was increased significantly ($P=0.001$), while that in group D was significantly decreased ($P=0.001$), and no statistical difference in group B, C ($P>0.05$); the percentage of S phase cell in group A, B, C was reduced ($P=0.001$); while that of G₂/M phase cell in group B, C, D was increased ($P=0.001$).

Immunohistochemical analysis

Immunohistochemical result of hepatocarcinoma tissue

Among the 65-rat hepatocarcinoma tissue obtained after the treatment for 7 days, bc1-2 expressed positively in 57 of them. The intensity of bc1-2 positive expression was evidently differed among the 5 groups (chi-square test, $P=0.034$), it was lower expressed in group A, B, C, especial group B, which was significantly lower than that in the controls. Among the 65 specimens, 54 of them presented positive expression of bax. The intensity and rate of positive expression had significant difference among the 5 groups (chi-square test, $P=0.022$ and $P=0.006$). It was significantly higher in group A, B, C than that in the controls, whereas there was no statistical difference among the former. PCNA was expressed positively in 63 specimen, with significant difference among the 5 groups (Kruskal-Wallis test, $P=0.001$). Compared with group E, PCNA LI expression was down regulated in group A, B, C, and D, especially in group A.

Immunohistochemical analyzing of renal tissue There was no significant difference in the expression of bcl-2 among the 5 groups, but among different positions. In group D and E, bc1-2 was positively expressed commonly in stroma cells without significant difference among the 5 groups. But in the renal tubular epithelium its positive expression was obviously enhanced ($\chi^2=14.93$, $P=0.005$) (Figure 1, 2). PCNA LI was significantly different (Kruskal-Wallis test, $P=0.001$). Compared to group E, PCNA LI expression was increased evidently (Mann-Whitney, $P=0.001$), without significant difference between Group A, B, C. Expression of PCNA LI renal tubular epithelium and stroma cells had significant difference among the 5 groups; while that of stroma cells, cortex-

Figure 4 PCNA expression in renal cortex tubular cells in medium dose in arsenic group epithelium (SP, ×400).

DISCUSSION

At present, the pathogenesis and progression of tumor are thought to relate to cellular abnormal proliferation^[16, 37, 39], and as well as the abnormal apoptosis^[19, 41]. Exploring the origination and development of tumor from the viewpoint of apoptosis may elucidate the pathogenesis of tumor and helpfully open a new way to the therapy of tumor.

Studies indicated that As_2O_3 was able to induce hepatocarcinoma cells apoptosis^[41-44], and to inhibit the growth of transplanted hepatocarcinoma of nude mice^[11-14]. However, there is no report on the effect of chemocarcinogen on hepatocarcinoma *in vitro*. The result in this study revealed that As_2O_3 could induce the apoptosis of hepatic carcinoma cells and inhibited the proliferation of carcinoma cells after treatment of hepatocarcinoma induced by DEN in rat. There was no apparent damage to the renal, especially to the tubular epithelial cells. Different dosages of arsenic had different effects on the apoptosis, showing a problem of an optimum dose. As for the morphologic changes, it was assumed that two death mechanisms worked at the same time when the arsenic dose was too high. Though it could induce the apoptosis in certain degree, it could also produce cellular toxic phenomena^[17-23], leading to necrosis and inflammation of carcinoma cells, and kill the normal cells. While too low dose had weak cytotoxicity, it couldn't take effect in spite of the ability to induce apoptosis of carcinoma cells. Moderate dose could induce the apoptosis of amount of cancer cells, but produce obvious cytotoxic effect^[41-45].

Apoptosis has a close relationship with cell cycle. Among the current anti-cancer drugs, whether the cellular cycle-specific drugs or the non-specific ones, both of them have the first-class kinetics, which is that they cannot kill all of the tumor cells but some proportion of them. Studies showed that some carcinoma cell lines, such as human hepatocarcinoma^[14, 22], stomach cancer and pancreatic cancer and so on^[36], may show blockage of G₂/M phase after treated with As_2O_3 *in vitro*. While in human mammary carcinoma cell line, cell cycle was blocked at different phases with different dose of As_2O_3 . The results in this study indicated that As_2O_3 could induce the change of cell cycle in rat. The prominent feature was that middle-dose of As_2O_3 would lead to G₂/M blockage and large-dose of As_2O_3 would lead to G₀/G₁ blockage. It was thought that different dose of As_2O_3 held different influence on cell cycle of rat carcinoma cells and they correspondingly maybe had different end of cell cycle blockage. This study showed that with middle-dose of As_2O_3 , the cells at G₂/M phase had very high incidence of apoptosis, while the rate of apoptosis was low at G₁ and S phase, presenting very strong cell cycle-specific manner. However, at the same time, in spite of the low incidence of apoptosis at G₁ and S phase, at both of them, especially at G₁ phase, the proportion of apoptotic cells to total apoptotic cells couldn't be ignored. In the high- or low- dose of arsenic group, apoptosis didn't present the highest sensitivity at some phase. The above results suggested that arsenic may belong to a kind of non-typical cell cycle-specific drugs, and would get better therapy effect after combination with other cell cycle-specific drugs.

PCNA is an assistant protein of DNA polymerase, directly participating in the DNA replication during the cell proliferation. PCNA is lowly expressed in rest cells, and gets its peak at G₁ late phase and S phase, and then significantly descends at G₂/M phase. The content and expression degree of PCNA reflect the activity of cellular proliferation, which is a main biologic index of cellular proliferation. The present study showed that PCNA LI of the rat hepatocarcinoma cells was decreased to different level after the treatment of As_2O_3 . Different dosages of As_2O_3 resulted in different degree of

reduction of PCNA LI. The higher dose resulted in more significant reduction, proving that there did exist certain dose effect relationship in the inhibition of proliferation of As_2O_3 on hepatocarcinoma cells.

Cisplatin is one of the most effective chemotherapy drugs on hepatocarcinoma at present, but the serious renal-toxicity limits its use. Under microscope the renal toxicity of cisplatin manifests acute denaturalization tubular epithelium, necrosis, interstitial edema and tubular dilation. Our study showed these changes were showed in the cisplatin group (4/7) while no significant changes happened in the As_2O_3 group.

Studies showed that the renal toxicity had close relation with its oxidized damage to tubules. Bcl-2 is an apoptosis inhibitor and a strong anti-oxidant^[18-21]. With the action of cisplatin, the expression of bcl-2 was strikingly decreased in the renal tubular epithelium. Preliminary treatment with some medicines (Midkine, uranyl acetate) can increase the expression of bcl-2 and decrease the apoptosis resulting from cisplatin, and subsequently on low its damage on tubules^[9,19]. In this study, after administration of As_2O_3 , the expression of bcl-2 in renal tubular epithelium was increased, while PCNA LI was not significantly changed. It was supposed that with the effect of As_2O_3 , expression of apoptosis repression gene bcl-2 was increased, resulting in the inhibition of apoptosis, meanwhile, the anti-oxidated effect of bcl-2 was able to counteract possible oxidated damage, therefore it didn't have obvious toxic side effect on renal tubular epithelium.

In conclusion, this study indicated that As_2O_3 could induce apoptosis of rat hepatocarcinoma cells. And there exists optimization dose, too high dose will cause the cytotoxic effect, while proper dose of As_2O_3 is able to block the cell cycle at G2/M phase. As_2O_3 had the most remarkable influence on cells at G2/M phase, and it can also induce apoptosis to the cells at other phases. As_2O_3 can restrain the proliferation of rat hepatocarcinoma cells, presenting a dose-time relationship. Compared with cisplatin, As_2O_3 didn't show obvious renal toxicity which maybe was related to the increase of expression of bcl-2 in renal tubular epithelium, the inhibition of apoptosis and its anti-oxidation effects^[45].

Abstract

AIM: To compare the effect of nimesulide or/and 5-fluorouracil (5-FU) on tumor growth inhibition and apoptosis in mice with the implanted hepatoma and to observe their possible interactions.

METHODS: The inhibitory effects on tumor growth was evaluated by inhibition rate. Apoptosis was assessed by the ultrastructural, flow cytometry features and the DNA ladder demonstrated by agarose gel electrophoresis. PGE₂ level was determined by radioimmunoassay. Expression levels of c-jun, c-fos and p53 were evaluated by western blotting.

RESULTS: Nimesulide or 5-FU alone inhibited the growth of hepatoma, while a synergistic effect was observed for a combined use of both. More pronounced morphologic changes for tumor cell apoptosis and the DNA ladder were found for the latter treatment. Expression levels of c-jun and p53 were found to be elevated for the tumors from mice treated with nimesulide and 5-FU comparing to those with either of them, but a reduced PGE₂ level was observed only for the treatment with nimesulide. No change was detected on c-fos expression.

CONCLUSION: Nimesulide and 5-FU appear to have synergistic effects for the growth inhibition and apoptosis induction. Both were found to be overexpressed in p53 and c-jun proteins, rather than that of c-fos, associations with the resulted apoptosis.

INTRODUCTION

5-Fluorouracil (5-FU) is widely used in the chemotherapies

for many malignancies including gastrointestinal, breast and head and neck cancers. Its intravenous or intra-arterial delivery was often used as a monotherapy or in combination with other chemotherapeutic agents. It can cause DNA damage and induces apoptosis in some cancers^[1-3]. Further works are being done to potentiate 5-FU cytotoxicity by improving the dosing schedule and biochemical modulation of 5-FU. However, one of the major hindrances for its clinical application is the development of resistance by neoplastic cells, being innate or acquired for 5-FU^[4]. 5-FU, therefore is often used in combination with other anti-cancer therapies in the treatment of solid tumors. Experimental have indicated that pre-exposure of MCF-7 breast cancer cells to paclitaxel followed by 5-FU was preferable^[5].

During the last 20 years, accumulating data have shown an anti-proliferative effect of non-steroidal anti-inflammatory drugs (NSAIDs) in a variety of malignant cell lines^[6-12]. PGs and their synthesizing enzyme COX-2 was suggested to be involved in carcinogenesis^[13]. Reducing the COX-2 and PGE₂ expression proved to be an alteration approach to inhibit tumor growth. Some selective COX-2 inhibitors may be of the therapeutic significance. Nimesulide, a sulfonanilide class COX-2 inhibitor, can bind specifically to the large catalytic moiety of COX-2, with much less adverse effects on the gastrointestinal tract compared to the non-specific NSAIDs^[14]. In our previous studies, nimesulide was found to reduce the COX-2 and PGE₂ levels in association with the resulted apoptosis in mice implanted Hepatoma. In the present study a synergistic effect was observed for nimesulide and 5-FU on the growth and apoptosis of mouse hepatoma, and its possible molecular mechanism(s) was also investigated.

MATERIALS AND METHODS

Drugs and reagents

5-FU was purchased from Dongrui Pharmaceutical Co (Jiangsu, China). Nimesulide and other chemicals were purchased from Sigma Chemical Co (St. Louis, MO, USA) and suspended in PBS (pH 7.2). Monoclonal anti-mouse antibodies were supplied from Santa Cruz.

Animals and tumor model

Kunming breed mice, with their body weights ranging from 18 g to 22 g, were used. Subcutaneous inoculation was conducted in the flank with 1×10⁷/ml mouse hepatoma cell line HepA^[15]. The mice were bred on standard mouse chow and tap water under standard conditions. Nimesulide was given ig daily in a volume of 0.2 ml. 5-FU was injected ip every three days. Mice were randomly separated into five groups, 10 mice each: vehicle control, nimesulide 20 mg/kg, 5-FU 10 mg/kg, 5-FU 20 mg/kg, and nimesulide 20 mg/kg plus 5-FU 10 mg/kg. Throughout the experimentation period, food and water was available to animals *ad libitum*. After 21d test period animals were killed by cervical dislocation. Tumor was weighed, and fixed or minced using a mortar and pestle.

Tumor inhibition rate

Tumor growth was evaluated by the inhibition rate as assessed

by the formula: $IR = (1 - T/C) \times 100\%$. IR represents inhibition rate, T and C indicate the mean tumor weights in the treatment and control groups, respectively.

Morphological analysis of apoptosis

Morphological changes indicative of apoptosis were detected by electron microscopy (EM). Briefly, dissected tumor samples were fixed with 20 ml/L glutaraldehyde in PBS for 1 h. After being washed with buffer for 3 times, the samples were post-fixed in OsO_4 in cacodylate buffer for 1 h. Subsequently, the samples were dehydrated in ethanol and embedded in epoxy resin (Agar 100). Thin sections (70nm) were stained in uranyl acetate and Reynolds lead citrate and viewed at 75 kV in an electron microscope (JEM-100CX 11/T).

Flow cytometry

Cell suspension was fixed in ice-cold 70 % ethanol in PBS, and stored at $-20^\circ C$. Prior to analysis, the cells were washed and resuspended in PBS and incubated with RNase I 1 g/L and propidium iodide 20 mg/mL at $37^\circ C$ for 30 min. The analysis of samples was performed using a flow cytometer.

DNA ladder visualization

Pulverized tumors were lysed with 150 μ l hypotonic lysis buffer (10 mmol/L EDTA, 0.5 % Triton X-100 in 1 mmol/L Tris-HCl, pH7.4) for 15 min on ice and were precipitated with 2.5 % polyethyleneglycol and 1 mol/L NaCl for 15 min at 4 %. After centrifugation at 16 000 g for 10 min at room temperature, the supernatant was incubated in the presence of proteinase K (0.3 g/L) at $37^\circ C$ for one hour and precipitated with isopropanol at $-20^\circ C$. After centrifugation, each pellet was dissolved in 10 μ l of Tris-EDTA (pH7.6) and electrophoresed on a 1.5 % agarose gel containing ethidium bromide 2 mg/mL. DNA fragments were visualized by ultraviolet transillumination.

Detection of prostaglandin E2 (PGE₂) by radioimmunoassay (RIA)

The amounts of immunoreactive PGE₂ in samples of solid tumor from mice were determined by RIA using a kit (Institute of Blood, Suzhou Medical university, China) following to the manufacturer's instructions. Briefly, to each polypropylene RIA tube, 100 μ l of anti-PGE₂, ^{125}I -PGE₂, and PGE₂ or a sample were added. Immune complexes were precipitated 24 h later with 1 ml of polyethylene glycol solution, and the radioactivity in the precipitate was determined by a gamma counter. There was no nonspecific interference of the assay by the components of the sample. Assays were carried out in triplicate and the mean and standard deviations were obtained.

Western blotting for c-jun, c-fos, and p53

Samples were extracted with a lysis buffer (1 % Triton-100, 50 mM NaCl, 50 mM NaF, 20 mM Tris pH 7.4, 1 mM EDTA, 1 mM EGTA, 1 mM sodium vanadate, 0.2 mM phenylmethylsulfonyl fluoride, and 0.5 % Nonidet P-40). The cell lysates, 60 mg each, were solubilized in sample buffer by boiling for 5 min, and then subjected to 10 % SDS-PAGE. The resolved proteins were electrotransferred onto a nitrocellulose filter. The filter was incubated consecutively with a primary antibody and with peroxidase-conjugated anti-mouse immunoglobulin G (IgG). The reactions were visualized using the ECL detection system.

Statistical analysis

Results are expressed as $\bar{x} \pm s$. Statistical analysis of the results was performed using the student's *t*-test. $P < 0.05$ was considered statistically significant.

RESULTS

Tumor inhibition rate

Administrated nimesulide and 5-FU suppressed tumor growth of the implanted hepatoma. The growth inhibitory rate was about 30 % after treatment with nimesulide (20 mg/kg). Application of 5-FU (20 mg/kg) also resulted in a marked inhibitory effect on the growth of the implanted tumors, while no significant effect was observed with the lower dose (10 mg/kg). It showed a greater inhibitory effect with a combined use of nimesulide and 5-FU than with either of them (Table 1).

Table 1 Effect of nimesulide and 5-FU on tumor inhibition in mouse implanted hepatomas ($n=10$, $\bar{x} \pm s$)

Group	X1	R1	X2	R2
Control	3.67 ± 1.7	-	3.69 ± 1.6	-
Nimesulide 20mg/kg	2.59 ± 0.9^c	30%	2.56 ± 0.9^c	31%
5-FU 10mg/kg	2.63 ± 0.9^c	28%	2.61 ± 1.0^c	29%
5-FU 20mg/kg	1.11 ± 0.6^{ab}	70%	1.01 ± 0.6^{ab}	73%
Nimesulide 20mg/kg +5-FU 10mg/kg	0.43 ± 0.2^a	88%	0.49 ± 0.2^a	87%

^a $P < 0.01$ vs control, ^b $P < 0.05$, ^c $P < 0.01$ vs nimesulide+5-FU. X1: the first mean tumor weights; R1: the first mean inhibition rates; X2: the second mean tumor weights; R2: the second mean inhibition rates.

Effect of nimesulide and 5-FU on apoptosis in HepA cells

The tumor growth-inhibiting effect was found to be associated with apoptosis as demonstrated by EM, and characterized by cell shrinkage and blebbing, condensation of unclear chromatin and nuclear fragment (Figure 1). Administration of 20 mg/kg of nimesulide or 20 mg/kg of 5-FU alone resulted in slight increases in apoptotic cell numbers, whereas the combined use of 20 mg/kg of nimesulide and 10 mg/kg of 5-FU caused markedly increased number of apoptotic cells.

Figure 1 Electro micrographs of nimesulide plus 5-FU treated mice hepatoma. A, control; B, nimesulide plus 5-FU.

Agarose gel electrophoresis showed DNA ladder in the hepatoma tissue 21 d after the treatment. Compared to those caused by nimesulide or 5-FU alone, the DNA ladder appeared more pronounced for the combined treatment with 5-FU (10 mg/kg) and nimesulide. (Figure 2).

Figure 2 DNA ladder pattern of hepatoma tissues as demonstrated by agarose gel 1.5 % electrophoresis. M, DNA markers; lanes 0–3, control, nimesulide 20 mg/kg, 5-FU 20 mg/kg, nimesulide 20 mg/kg +5-FU 10 mg/kg.

The pro-apoptotic effect of nimesulide was further confirmed by flow cytometry. After treatment with nimesulide and/or 5-FU for 21 d, the profiles of the DNA histograms were different from control (Figure 3). With 5-FU and nimesulide administered, a striking SubG₁ peak was found and the apoptotic index increased from (4.3±1.5) % to (72.0±2.5) % (Table 2).

Table 2 Apoptotic indices of nimesulide and 5-FU in mouse hepatoma tissues after the treatment with determined by FCM. $n=3$, $\bar{x}\pm s$

	Control	Nimesulide (20 mg/kg)	5-FU (20 mg/kg)	Nimesulide (20 mg/kg)+ 5-FU (10 mg/kg)
Apoptotic Index	4.3±1.5	29.0±2.6 ^{ac}	49.0±2.0 ^{ac}	72.0±2.5 ^a

^a $P<0.01$ vs control; ^c $P<0.01$ vs nimesulide +5-FU.

Figure 3 Data of flow cytometry of mouse hepatoma without any treatment as a control (A), or following 21 d treatment with nimesulide 20 mg/kg (B), 5-FU 20 mg/kg (C) and nimesulide 20 mg/kg+5-FU 10 mg/kg (D). The sub-G₁ peak to the left of the G₁ peak represents apoptotic cells.

Expression of PGE₂

The PGE₂ contents of the implanted hepatoma tissue was 636.67±17.9 ng/ml after treatment with 20 mg/kg of 5-FU, being at the same level as in the control group. However, it was significantly reduced with nimesulide administered, alone or combined with 5-FU (10 mg/kg) (Figure 4). Apparently, the mechanisms for the growth inhibition by nimesulide and 5-FU may be different, the former being associated with, and the latter independent of, PGE₂ content in tumor tissue.

Figure 4 Effect of Nimesulide and 5-FU on PGE₂ content in mouse hepatoma. Each column is the mean ± SD of the sample. 1-4, control, nimesulide 20 mg/kg, 5-FU 20 mg/kg, and nimesulide 20 mg/kg+5-FU 10 mg/kg. $n=3$. $\bar{x}\pm s$. ^a $P<0.01$ vs control, ^c $P<0.01$ vs nimesulide+5-FU.

Effect on c-jun, c-fos, and p53 expressions

Western blotting showed that nimesulide or 5-FU induced expression of c-jun and p53 in mouse hepatoma. Treatment with nimesulide plus 5-FU resulted in up regulation of the expression of these genes, while it was not for the c-fos expression. Treatment with 5-FU, 20 mg/kg in dose, also gave rise to expression of c-jun and p53. However, the effect of the combined application of nimesulide and a low dose of 5-FU (10 mg/kg) was more pronounced compared to those of 5-FU or nimesulide alone (Figure 5).

Figure 5 Effect of nimesulide and 5-FU on expression of c-fos, c-jun, and p53 in mouse hepatoma. 0-3, control, nimesulide 20 mg/kg, 5-FU 20 mg/kg, nimesulide 10 mg/kg+5-fu 10 mg/kg. The β-actin was used as an intrinsic reference molecule.

DISCUSSION

Previous observations showed that indomethacin, a non-selective COX inhibitor, improved hematopoietic recovery following 5-FU. 5-FU toxicity, determined as loss of colony-forming ability, increased with its dose, and indomethacin caused a generalized alleviation of 5-FU toxicity, but only if given concurrently with 5-FU^[16]. By the subsequent treatment with interferon γ, indomethacin, and phenylbutyrate in human

colon carcinoma cells, the recurrence of colon carcinomas, occurring frequently between cycles of 5-FU treatment, can be prevented or at least effectively retarded^[17].

The present study demonstrated that both nimesulide and 5-FU can inhibit the tumor growth and induce apoptosis, the combination of nimesulide and 5-FU being more effective compared to that of 5-FU or nimesulide alone. Apparently, apoptosis may be associated with the growth-inhibiting effect of 5-FU combined with nimesulide, and a synergistic effect was observed for these two agents. As demonstrated in this report, 5-FU (20 mg/kg) or nimesulide alone stimulated c-jun and p53 expression in hepatoma at a low level, this effect being greatly enhanced its combination with nimesulide.

The mechanism involved in growth inhibition and cell apoptosis by combination nimesulide with 5-FU treatment remains obscure. The ultimate outcome of tumor treatment with anti-cancer agents is the effect of many intrinsic and extrinsic factors, functioning independently or cooperatively^[18-20]. In the present study the possible role of c-fos and c-jun protein on tumor growth and apoptosis was evaluated^[21]. The well-characterized substrate of JNK is c-Jun, a component of the AP-1 transcription factor^[22,23]. Expression of c-jun was repeatedly shown to be involved in apoptosis induction and growth inhibition of many anti-cancer agents. In the present study, the level of c-jun was up-regulated by the treatment with nimesulide or 5-FU alone, and that with nimesulide plus 5-FU were even more effective. No significant change was observed in the c-fos levels in tumors after treatment with nimesulide or 5-FU alone, or their combined use, indicating that the anti-cancer effects on mouse hepatoma were associated with c-jun rather than c-fos.

The tumor suppressor gene, p53, is a key component in regulating cell cycle progression^[24]. Strikingly, many apoptotic stimuli are known to be p53-dependent^[25-30]. For example, p53 is required for the bleomycin-induced cerebellar granule cell death, following c-jun protein overexpression^[31]. MIF, a local proinflammatory cytokine, is capable of functionally inactivating p53. The observation provides a mechanistic link between inflammation and cancer^[32]. Moreover it is well known that selective COX-2 inhibitors have anti-inflammation and anti-cancer effects through inhibition COX-2. The elevated p53 level in mouse hepatoma treated with nimesulide alone or plus 5-FU may be due to inhibit COX-2 and PGE₂ level. Furthermore 5-FU induces cell apoptosis in a p53-dependent way^[33]. Our results raise the possibility that p53 is required for c-jun-dependent apoptosis induced by nimesulide or/and 5-FU treatment. It is possible that theses two drugs increase p53 expression though different intracellular pathway for activating cell death processes.

In conclusion, a synergistic effect was observed between nimesulide and 5-FU on apoptosis in murine hepatoma, indicating its potential application in the management of human hepatocellular carcinomas.

Abstract

AIM: To probe the pathological biological characteristics of hepatocellular carcinoma (HCC) by the ultrasound-guided aspiration biopsy and assess the clinical application value of this method.

METHODS: The biopsy and DNA analysis by flow cytometry (FCM) were taken in 46 cases with HCC nodules, including 26 cases and 20 cases with nodules ≤ 3 cm and > 3 cm in diameters respectively, and 12 cases with intrahepatic benign hyperplastic nodules. They were taken in 22 cases of 46 cases with HCC before and after the therapy. Fine-needles and automatic histological incised biopsy needles were used. The fresh biopsy tissue was produced into the single cell suspension, which was sent for DNA detection and ratio analysis of cell period. The ratio of each DNA period of cell proliferation of each group was calculated and compared with each other. The DNA aneuploid (AN) and apoptosis cell peak were observed and their percentages were calculated.

RESULTS: The ratios of S and G₂/M periods of DNA, which reflect cell hyperproliferation, in the group with HCC tumors > 3 cm in diameter were markedly higher than those of the group with HCC nodules ≤ 3 cm in diameter and the group with the benign hyperplastic nodules ($P < 0.01$ except A:B of S period, $P < 0.05$). The ratios of the middle group were also apparently higher than those of the latter group ($P < 0.01$). The ratio of DNA AN of 46 cases with HCC nodules was 34.8 % (16/46). None of the cases with the intrahepatic hyperplastic nodules appeared AN. The DNA AN appeared more apparently with the growth of the tumors. The AN ratio of the group with tumors > 3 cm in diameter was 55 % (11/20), markedly higher than that of the group with tumors ≤ 3 cm in diameter which was 19.2 % (5/26) ($P < 0.01$). The FCM DNA analysis of 22 specimens of hepatic carcinoma tissue before therapy showed that the aneuploid peaks appeared in 5 cases (22.7 %). The ratio of G₁ period rose after therapy while the S period and G₂/M ratios fell ($P < 0.01$). The aneuploid peak disappeared in the 5 cases after the therapy, while the apoptosis peaks in 12 cases (54.5 %) appeared.

CONCLUSION: Addition to supply the information of the pathological morphology of the tumor, the ultrasound-guided fine-needle aspiration tissue could be sent for FCM DNA

analysis to comprehend its pathological biological characteristics. This can not only provide the clinic the reliable information about the occurrence, development, diagnosis, curative effect and prognosis of tumors but also supply biological information for clinic to choose therapeutic schemes.

INTRODUCTION

Recently, with the wide use of flow cytometry (FCM) in clinic, it becomes possible to make pathological diagnosis develop from qualitative analysis of the morphology to quantitative analysis^[1-5]. The study of DNA analysis of the biological characteristics of hepatocellular carcinoma (HCC) model and hepatectomy specimens of man HCC has greatly developed^[6-18]. But the study of DNA analysis of the pathological biological characteristics of HCC specimens acquired from the ultrasound-guided aspiration biopsy has been rarely reported^[15,19]. In our study, the ultrasound-guided aspiration biopsy and the FCM DNA analysis were taken in 46 cases with HCC, including 22 cases with HCC before and after the therapy and 12 cases with intrahepatic benign hyperplastic nodules (IBHN) in order to probe the biological characteristics of HCC and assessed the clinical application value of this research.

MATERIALS AND METHODS

Subjects

Forty-six cases with HCC, including 26 cases and 20 cases with nodules 3 cm and > 3 cm in diameters respectively, consisted of 39 males and 7 females. The mean age was 53.7 years (range, 29-72). Twenty-two of 46 cases taking ultrasound-guided interventional therapy included 16 males and 6 females. Twelve cases with IBHN comprised 7 males and 5 females and the average age was 47.5 years (range, 27-58). The diagnosis was established by cytopathological and / or histological examinations.

Instruments and methods

The apparatuses were Aloka-650 and 1700 with 3.5-MHz probe. All cases took aspiration biopsy with 22G PTC needles. Twenty-two cases with HCC took percutaneous ethanol or other anti-tumor drug injection therapy for 5-8 times after biopsy, then took aspiration biopsy once again. The 18G automatic histological incised biopsy needle (produced by C.R. Bard, Inc, American) was used if the specimen taken by the fine needle aspiration was unsatisfactory. The amount of platelet of the patient must be $> 60 \times 10^9/L$ and the mobility of thrombogen of the cases must be > 50 %. The process of fine-needle aspiration biopsy was as follows. The point of puncture

in the skin was determined by ultrasonography. Then sterilization, drape and local paralysis were done. The fine needle punctured through the point into the focus. The needle was twitched up and down in the focus. At the same time, the negative pressure was kept in the syringe. The needle was taken out when the tissue and / or tissue with blood were seen in the syringe. The aspirated material was divided into three parts. One part was smeared on glass slides for pathological examination. The second part was placed in 10 % formalin or electron microscope (EM) liquid for electron microscopy. The last part was placed in 10 ml physiological saline for cytometric DNA analysis. The process of puncture of automatic histological incised biopsy was similar to that of fine-needle aspiration biopsy. The needle punctured to the periphery of the mass, ejected and excised the tumor tissue, then was extracted quickly. The sample was 19.0 mm in length and 1.0 mm in diameter.

The examination method of FCM

The FACScan (B.D. company, America) was adopted. At first, the fresh biopsy tissue was produced into the single cell suspension^[1]. Then it was stained by PI for DNA analysis. DNA content was measured and the ratio of each DNA period of cell proliferation was analyzed. The ratio of each DNA period, the percentage of the DNA aneuploid (AN) and the percentage of apoptosis cell peak were observed.

Statistical analysis

The average value and standard deviation of the percentage of the ratio of cell proliferation and DNA AN stem-line of each group were calculated respectively. The student-*t* test or student-*t'* test was used to test whether the mean of each group was different from each other. A difference was regarded as significance if $P < 0.05$.

RESULTS

Table 1 showed the ratio of each DNA period of cell proliferation of each group. Statistical analysis showed that the ratio of S and G₂/M periods of DNA, which reflect cell hyperproliferation, in the group with HCC tumors >3 cm in diameter were markedly higher than those of the group with nodules ≤3 cm in diameter and the group with the benign hyperplastic nodules ($P < 0.01$ except A:B of S period, $P < 0.05$). The ratios of the middle group were also apparently higher than those of the latter group ($P < 0.01$). The apparent characteristics were that the DNA of IBHN was steadily in G₁ period, which means the nonproliferation diploid (2c) state (Figure 1). While the DNA of HCC cell stayed in unstable division stage and appeared the cell hyperproliferation state (Figure 2) with the development of foci.

Table 1 The ratios of cell proliferation of HCC in different diameter and benign hyperplastic nodules (% , $\bar{x} \pm s$)

Characteristics of foci	Number of cases	DNA analysis of each period		
		G ₁ period	S period	G ₂ /M period
The group with HCC >3 cm (A)	20	40.3±6.8	43.5±7.4	16.2±1.7
The group with HCC ≤3 cm (B)	26	57.7±5.8	30.4±5.2	11.9±1.1
The group with IBHN (C)	12	94.8±0.7	2.6±0.5	2.6±0.4

G₁ period A:B A:C B:C $P < 0.01$; S period A:B $P < 0.05$, S period B:C A:C $P < 0.01$; G₂/M period A:B B:C A:C $P < 0.01$.

Figure 1 DNA analysis of aspiration biopsy tissues acquired from intrahepatic benign hyperplastic nodules showed steady diploid (2C) peak that stayed in G₁ period (single red peak).

Figure 2 DNA analysis of aspiration biopsy tissues acquired from HCC nodules showed S period of hyperproliferation (the peak with oblique lines) and G₂/M period (the second red peak).

The statistical materials also showed that the ratio of DNA AN stem-line of 46 cases with HCC nodules was 34.8 % (16/46) (Figure 3). While none of cases with IBHN appeared AN stem-line. The DNA appeared AN more apparently with the growth of the tumors. The AN ratio of the group with tumors >3 cm in diameter was 55 % (11/20), markedly higher than that of the group with tumors ≤3 cm in diameter which was 19.20 % (5/26) ($P < 0.01$).

Figure 3 DNA analysis of HCC nodules showed aneuploid (AN) peak (the orange peak).

The pathological results of 22 cases among 46 cases with HCC after the ultrasound-guided percutaneous interventional therapy showed that the tumor cells appeared pyknosis and necrosis in various degrees. The Table 2 showed the results of FCM DNA analysis of the aspiration tissue. The ratio of G₁ period which reflects cell steady state rose apparently after therapy ($P < 0.01$). While the ratios of S period and G₂/M period

which reflect cell hyperproliferation fell ($P<0.01$). After therapy the AN peaks disappeared in 5 cases which appeared before therapy and the apoptosis peaks appeared in 12 cases (54.5 %) (Figure 4) which was consistent with the cell pyknosis and dark nuclear staining showed by the histopathologic examination and the typical apoptosis cell or/and apoptosis body showed by the electron microscopy (Figure 5).

Figure 4 DNA analysis of HCC nodules showed hyperproliferation state before therapy (left) and apoptosis peak after therapy (the blue peak).

Figure 5 The same cases as those in figure.4 appeared typical apoptosis cells and apoptosis bodies after therapy.

Table 2 Cell proliferative ratios of 22 cases with HCC before and after ultrasound-guided interventional therapy (% , $\bar{x} \pm s$)

Time of detect	Each period of cell proliferation (%)		
	G ₁ period	S period	G ₂ /M period
Before therapy(a)	52.6 \pm 7.2	37.5 \pm 8.1	9.9 \pm 1.9
After therapy(b)	94.7 \pm 4.1	3.7 \pm 2.5	1.6 \pm 0.5

a:b of each period $P<0.01$.

DISCUSSION

The application value of cytopathological and histological examinations using ultrasound-guided aspiration biopsy has been affirmed in clinic^[20-22]. There are also many scholars using many immunological methods to study the biological characteristics of hepatic tumors^[23-45]. But the study of DNA detection of intrahepatic tumor tissue by ultrasound-guided fine-needle aspiration or incising biopsy^[15,19] is rarely reported. On the basis of comparative study between ultrasound-guided fine-needle and heavy-needle biopsy, we made pathomorphological examination of HCC nodules that were different in diameter, HCC nodules before and after therapy as well as benign hyperplastic nodules by ultrasound-guided

puncturing biopsy. At the same time^[46-48], the fresh biopsy tissue was produced into the single cell suspension which was sent for FCM DNA detection and ratio analysis of cell period. The changing process of cell proliferation was observed. Through the study of biological characteristics of hepatic carcinoma and pathological comparison of hepatic carcinoma tissue before and after the therapy, we probed the application value of DNA analysis in assessment of the therapeutic efficacy and prognosis.

It is determined by the biological behavior of the cell itself that the normal tissue, reactive tissue and benign tumor all have normal diploid DNA. Like most other malignant tumors, HCC appears polyploid DNA, especially AN DNA. AN has become a reliable cytobiological signs of human malignant tumors^[49]. On the other side, like other malignant tumors, the occurrence and development pattern of HCC also relate to a biological behavior that changes from a relative steady benign state in the early period to a high proliferative malignant state^[3,4,7,50]. The study of HCC model of animal shows that, acted by the carcinogen the animal based on the hepatic cirrhosis appears the proliferation group of new born hepatocytes with diploid DNA stem-line which has highly proliferative activity and the potential ability of malignant tendency. That is the cytological basis of carcinogenesis later. The continuous changes of DNA stem-line in the process of occurrence and development of HCC form the characteristics of the various biological dynamic mechanism from early relative benign state to markedly malignant state of high proliferation. The course of DNA stem-line changing from 2C to AN is an important pathobiological sign. So the study of biological characteristics of HCC has the important clinical practical value for early diagnosis, selection of therapeutic schemes and judgment of prognosis of HCC. In our study, DNA analysis of HCC tissue by ultrasound-guided puncturing aspiration biopsy was made before and after therapy. The ratio of each period in cell period showed that the ratios of synthesis phase (S period) and mitosis phase (G₂/M period) which reflect high proliferation of HCC group were apparently higher than those of benign hyperplastic group ($P<0.01$) and that the ratios of S and G₂/M period apparently rose with the growth of the tumors. As we all know, DNA, as the material basis of heredity of biotic bodies, is mainly located in chromosome of nucleus. The degree of maturation is closely relative to DNA content. The cell in non-proliferative state is characterized by 2C DNA stem-line. The DNA content increases multiply when cells enter division stage and DNA changes into AN stem-line. With the increasing of malignant degree of cell, the structure and amount of chromosome are more abnormal and the phenomena of changing into high proliferative state and AN is more remarkable. On the basis of the studies of animal HCC model and hepatectomic human HCC sample, Cong MW regards that the smaller HCC <3 cm in diameter is mainly characterized by diploid DNA stem-line which indicates relatively slow growth, lower malignant degree, tumors mostly having capsules, foci limiting, lower distant metastasis rate and lower occurring rates of thrombosis and satellite foci of tumor^[3,4]. All these are the pathological basis of conducting radical operation. Our material also shows that 34.8 % of 46 cases with HCC appeared AN. The ratio of AN of the group with tumor >3 cm in diameter reached 55.0 % (11/20), markedly higher than that of the group with tumor \leq 3 cm in diameter which was 19.2 % (5/26) ($P<0.01$). None of the cases with IBHN appeared AN. It is worth mentioning that, with the growth of tumor, the DNA gradually changes from low proliferation to AN stem-line at certain extent, which reflects that pathobiological characteristics is in relation to the size of tumor nodules. But it is not consistent thoroughly. In our study, the diameter of a small HCC nodule was only 1.1 cm, yet the DNA analysis characterized it by typical AN stem-

line (Figure 3).

Many scholars have made the researches in the relationship between the ploidy type and the prognosis of many tumors including HCC by FCM DNA analysis^[51-55]. But the study of DNA analysis by ultrasound-guided fine-needle biopsy to assess the therapeutic efficacy has been rarely reported^[56]. In our study, DNA analysis of tumor biopsy tissue shows that the AN stem-line which appeared before therapy disappeared after the ultrasound-guided interventional therapy with the cancer cell being killed. The ratios of S and G₂/M periods all fell obviously ($P < 0.01$) and 54.5 % cases appeared physiological death process which was different from common necrosis, in another word, appeared apoptosis peak before G₀-G₁ period. All these changes were consistent with what had been seen in pathological examination. DNA content rose multiply and the cell appeared polyploid when the cell entered division stage. In pathological state, especially for cancer cells, the structure and amount of chromosome became abnormal and the phenomenon of polyploid and/or AN became more remarkable. Summarily, the content and periods of DNA decreased and increased with dying and recurring of the cancer cell^[2,5,57]. The materials also show that DNA analysis could supply reliable biological information and objective quantification index.

This study shows that besides providing pathomorphological information of cytology and histology, the tissues acquired by ultrasound-guided puncturing biopsy could also be sent for FCM DNA analysis to comprehend the biological characteristics of tumors. So this method attains the objective of "one needle, three uses" and provides valuable clinical basis for diagnosis, therapeutic efficacy and prognosis assessment of tumors and is worth further studying.

Abstract

AIM: To investigate gap junctional intercellular communication (GJIC) in hepatocellular carcinoma cell lines, and signal transduction mechanism of gap junction genes connexin32(cx32), connexin43(cx43) in human hepatocarcinogenesis.

METHODS: Scraped loading and dye transfer (SLDT) was employed with Lucifer Yellow (LY) to detect GJIC function in hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal control liver cell line QZG. After Fluo-3AM loading, laser scanning confocal microscope (LSCM) was used to measure concentrations of intracellular calcium $[Ca^{2+}]_i$ in the cells. The phosphorylation on tyrosine of connexin proteins was examined by immunoblot.

RESULTS: SLDT showed that ability of GJIC function was higher in QZG cell than that in HHCC and SMMC-7721 cell lines. By laser scanning confocal microscopy, concentrations of intracellular free calcium $[Ca^{2+}]_i$ was much higher in QZG cell line (108.37 nmol/L) than those in HHCC (35.13 nmol/L) and SMMC-7721 (47.08 nmol/L) cells. Western blot suggested that only QZG cells had unphosphorylated tyrosine in Cx32 protein of 32 ku and Cx43 protein of 43 ku; SMMC-7721 cells showed phosphorylated tyrosine Cx43 protein.

CONCLUSION: The results indicated that carcinogenesis and development of human hepatocellular carcinoma related with the abnormal expression of cx genes and disorder of its signal transduction pathway, such as decrease of $[Ca^{2+}]_i$, post-translation phosphorylation on tyrosine of Cx proteins which led to a dramatic disruption of GJIC.

INTRODUCTION

Hepatocellular carcinoma has been one of the most common malignant threatening human health^[1-9], and much higher incidences of human hepatocellular carcinoma (HCC) are observed recently^[10-18]. Gap junctional intercellular communication (GJIC) is performed by intercellular hemichannels^[19], which are formed by six basic protein subunits named connexin (Cx) expressed in neighboring cells^[20]. Six connexins form around a central pore^[21], through which adjacent cells can exchange low weight molecules of information and energy directly^[22]. At least 16 members of connexin super gene family have been identified, which are divided into two groups according to amino acid sequence. GJIC mediated via gap junctions plays important roles in tissue homeostasis, embryonic development as well as carcinogenesis^[23-25]. The mechanisms of carcinogenesis may be related with the block of GJIC of homologous and heterologous communication between tumor cells and surrounding normal cells^[26].

Connexin32 (Cx32) and connexin43 (Cx43) are the major kinds of gap junction proteins expressing in hepatocytes^[18]. Our works showed that expressions of Cx32, Cx43 proteins decreased in hepatocellular carcinoma tissues and cell lines whereas increased in normal tissues and cell lines^[19-21], but cx32 mRNA and cx43 mRNA kept a high level in both hepatocellular carcinoma and normal liver cells lines described previously^[22,23]. It suggested that the mechanism involved in abnormal processes in post-translation or signal transduction is worthy of discussing^[24].

MATERIALS AND METHODS

Cell culture

Hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal hepatocyte cell line QZG, were kindly provided by professor Chen in 863 Project Group in Fourth Military Medical University. The cells were cultured in RPMI 1640 medium (Gibco BRL, USA), supplemented with 10 mL/L fetal bovine serum (Gibco BRL, USA), incubated in a humidified atmosphere which contains 950 mL/L air and 5 mL/L CO₂ at 37 °C.

Scrape loading dye transfer (SLDT)

Functions of gap junctional intercellular communication (GJIC) in adjacent cells were assessed by scrape loading dye transfer (SLDT) with fluorescent dye Lucifer Yellow (LY, Sigma, USA). The cultures were rinsed three times with serum free RPMI 1640 medium, several scrapes were made on the monolayer using a surgical scalpel, cells were exposed to 100 g/L LY in 0.33 mol/L LiCl, incubated for 3 min, and rinsed by serum free RPMI 1640 medium for several times to remove any background fluorescence. The GJIC function in adjacent cells revealed by LY dye transfer could be detected under fluorescent microscope (Nikon UFX-II, Japan).

Concentration of intracellular calcium ($[Ca^{2+}]_i$) measured by laser scanning confocal microscopy (LSCM)

Digested by trypsin and collected, HHCC, SMMC-7721 and QZG cells were loaded by 100 nmol/L special fluorescent dye

indicator of calcium Fluo-3 AM (Sigma, USA) in serum free RPMI-1640 medium, 37 °C for 90 min, rinsed by Ca²⁺ free D-Hank's for three times. MRC-1024 laser scanning confocal microscope imaging system (Bio-Rad, USA) was used to obtain the images determining the location and intensity of intracellular Ca²⁺ in various cell lines.

MRC-1024 laser scanning confocal microscope imaging system consists of a laser scanning system intermediate optics and a detector controlled by lasership software (Bio-Rad, USA). Images were obtained by Zesis 100 microscope and images of interest were saved to a 512×512 pixel, Zoom was 4.0. Besides analysis of location of Ca²⁺, quantities of intracellular concentration [Ca²⁺]_i were counted with formation below: $[Ca^{2+}]_i = kd \times (F - F_{min}) / (F_{max} - F)$, $kd = 400$ nmol/L.

Immunoblot analysis of phosphorylation on tyrosine

Western blot was performed to analyses the phosphorylation on tyrosine. Cells were rinsed with cold 0.01 mol/L PBS containing 5 mmol/L EDTA, 10 mmol/L NaF and 1 mmol/L PMSF on ice for 20 min, harvested by scraping in the same solution, and centrifuged at 13 000 r/min at 4 °C for 30 min. Pellets were rinsed dissolved in 20 g/L SDS. Concentrations of proteins were measured by the Bio-Rad DC protein assay (Bio-Rad, USA).

20 ug protein of various cells in equal amounts of 2×SDS denatured at 100 °C for 4 min. 100 g/L SDS-PAGE vertical electrophoretically Min-PROTEAN II (Bio-Rad, USA) was used at 80V for 30 min and 120V for 60 min. Mini Trans-Blot transferred proteins form gel to NC membranes (Hybond, USA) by transferring electrophoretically (Bio-Rad, USA) at 100V 350 mA 4 °C for 2 h.

Normal serum blocked NC membranes at room temperature for 2 h. Cx32 and Cx43 protein bands were detected using a mouse monoclonal anti-Cx32 antibody (1:2 000, Zymed, USA), a mouse monoclonal anti-Cx43 antibody (1:2 000, Zymed, USA). Phosphorylations on tyrosine were detected by special anti- phosphorylation tyrosine mAb 4G10 (1:2 000, CA, USA) at room temperature for 2 h. NC membranes were washed by TBST for 10 min for several times, incubated with a biotin-streptavidin alkaline phosphatase conjugated secondary IgG (1:32, Johnson, USA) at room temperature for 2 h and washed by TBST for 10 min for several times again. The enhanced chemiluminescence (ECL) detection kit (Amersham, UK) was employed to detect immunoblot signal.

RESULTS

Gap junctional intercellular communication of various cells

After stained with special fluorescent dye Lucifer Yellow (LY), function of gap junctional intercellular communication were detected by scrape loading and dye transfer (SLDT). Molecular weight of LY is below 1 000 u that can pass via gap junction smoothly. Normal liver cell line QZG showed stronger intensity and amount yellow fluorescent among neighboring cells, whereas hepatocellular carcinoma cells HHCC and SMMC-7721 showed much slight fluorescent staining limited among adjacent cells.

Analysis of concentrations and location of intracellular Ca²⁺ ([Ca²⁺]_i) LSCM was used to determine intracellular Ca²⁺ in cultured cells after being loaded with special indicator of Ca²⁺ Fluo-3 AM. The results showed that intensity of Ca²⁺ was much higher with a very bright and higher peak signal of Ca²⁺ in QZG cells. Intracellular concentration of Ca²⁺ in QZG cells was 108.37 nmol/L. In HHCC and SMMC-7721 cells peak signals of Ca²⁺ were lower. [Ca²⁺]_i in HHCC cell decreased to 35.13 nmol/L, SMMC-7721 cells also had lower peak Ca²⁺ and its [Ca²⁺]_i decreased to 47.08 nmol/L as shown in Figure 1-3.

Figure 1 Special indicator Fluo-3 AM was loading at 37 °C for 90 min in hepatocarcinoma cell lines in order to examine localization and concentration of intracellular calcium in MRC-1024 laser scanning confocal microscope imaging system. (A). In normal hepatocyte cell line QZG, stronger signal of calcium with lower peak released. (B). Concentration of intracellular calcium in HHCC was 108.37 nmol/L.

Figure 2 Special indicator Fluo-3 AM was loading at 37 °C for 90 min in hepatocarcinoma cell lines in order to examine local-

ization and concentration of intracellular calcium in MRC-1024 laser scanning confocal microscope imaging system. (A). In hepatocarcinoma cell line HHCC, slight signal of calcium with lower peak was observed. (B). Concentration of intracellular calcium in HHCC was 35.13 nmol/L.

Figure 3 Special indicator Fluo-3 AM was loading at 37 °C for 90 min in hepatocarcinoma cell lines in order to examine localization and concentration of intracellular calcium in MRC-1024 laser scanning confocal microscope imaging system. (A). Loading by Fluo-3 AM, dark signal of calcium and lower peak was also absent in hepatocarcinoma cell line SMMC-7721. (B). Concentration of intracellular calcium was 47.08 nmol/L.

Phosphorylation on tyrosine of Cx32, Cx43 proteins

The expressions of Cx32, Cx43 proteins were assessed using western blot analysis with anti-Cx32 mAb, anti-Cx43 mAb. We also verified the phosphorylation on tyrosine using western blot analysis with anti-phosphorylated tyrosine mAb 4G10.

Western blot showed that major bands at 32 ku, 44 ku in a blot is unphosphorylated tyrosine in QZG cells. It recognized a band at 32 ku phosphorylated tyrosine Cx32 protein and phosphorylated tyrosine Cx43 protein of 43 ku in SMMC-7721 cells. No evidence of phosphorylated tyrosine at 32 ku of Cx32 and 44 ku of Cx43 proteins were detected in HHCC cells.

These results conform that the mouse monoclonal antibody selectively binds phosphorylated tyrosine Cx43 proteins was corresponding decrease of concentrations of calcium and block of gap junctional intercellular communication in same hepatocellular carcinoma cell lines as shown in Figure 4A-D.

Figure 4 Western blot analysis of phosphorylation on tyrosine of Cx32, Cx43 proteins in various cells lines. Cells were harvested and lysed, equal amount of cell lysates were resolved of SDS-PAGE, transferred to NC membranes, and then probed with anti-phosphorylation tyrosine mAb 4G10. (A). Expressions of Cx32 proteins in cell lines with special anti-Cx32 mAb. Cx32 showed high immunoblot signal only in normal hepatocyte cell line QZG with very slight signal in hepatocarcinoma cell lines HHCC, SMMC-7721. (B). Expressions of Cx43 proteins in cell lines with special anti-Cx43 mAb. Cx43 appeared in both QZG and SMMC-7721 cells but no in HHCC. (C). Phosphorylation on tyrosine of Cx43 with special anti-phosphorylation tyrosine 4G10, unphosphorylation appeared in QZG cells even they showed high level expression of Cx32, Cx43. (D). Phosphorylated tyrosine of Cx43 protein was detected in SMMC-7721 cells.

DISCUSSION

Gap junctions are channels between neighboring cells, which allow small molecules, and ions (mass molecules are below 1 000 u) to pass through directly. Normal hepatocytes express high quantities of connexin32, connexin43 as the major gap junction forming proteins^[20,27]. As described previously, immunohistochemical analysis showed gap junctional proteins Cx32, Cx43 frequently decreased in hepatocellular carcinoma tissues and cell lines^[28-31]. But by in situ hybridization (ISH), cx32 mRNA, cx43 mRNA in hepatocellular carcinoma tissues and cell lines showed same strong positive rates and density without significant difference^[32,33]. The aberrant location of Cx32 and Cx43 proteins might be responsible for hepatocarcinogenesis^[34], the mechanism might be defect of cx genes in post-translational processing^[35].

In various neoplasm, including hepatocellular carcinoma cells often express less connexin, but the mechanisms are unknown. It suggested that decrease of expression and lacking of function of Cx32, Cx43 might keep close relationship with liver hepatocarcinogenesis. Disruption of GJIC activity could contribute to the multi-step, multi-mechanism process of carcinogenesis^[36]. Most tumors demonstrate a reduction between either homologous and heterologous gap junctional intercellular communication (GJIC). GJIC was assessed by transfer of the fluorescent dye Lucifer Yellow (LY) after scrape loading dye transfer (SLDT) in hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver cell line QZG. Molecular mass of LY is below 1 000 u, which can pass via gap

junction smoothly^[37]. Our results showed that QZG had high ability of GJIC function than that in HHCC and SMMC-7721 cell lines, which were almost blocked.

Presumably down-regulation of GJIC activity would lead to the removal of growth inhibitory signaling. It was hypothesized that an initiated cell would be growth suppressed by being coupled by gap junctions to surrounding normal cells. Disturbance of GJIC facilitate cells to escape from intercellular signals involved regulations on proliferation, differentiation and apoptosis. Many factors, tumor-promoting chemicals^[38] and oncogenes influence signal transduction in the initiated and surrounding normal cells, which would cause the down-regulation of GJIC. Many kinds of tumor promoting agents have been shown to decrease expressions of gap junction proteins or block GJIC associated with hepatocarcinogenesis^[39]. H-ras, v-myc also cooperate malignancy^[40]. Connexin genes might belong to the group of tumor suppressor genes.

Our results suggested that multiple mechanisms likely contributed to block of GJIC, including decrease of expressions of gap junction proteins and abnormal pathway of signal transduction including decreased level of intracellular Ca^{2+} , phosphorylation on tyrosine and other potential mechanisms. In different tissues molecules smaller than approximately 1 000 u may pass through gap junctions which implies that the most common second messengers cAMP, inositol-1,4,5-trisphosphate (IP₃) and intracellular free calcium ions Ca^{2+} can be transferred. The mechanisms of intracellular calcium signaling are currently being investigated. Mechanisms during hepatocarcinogenesis are related to multiple pathophysiological processes including decreased in intracellular Ca^{2+} . Calcium signals might be an important mechanism for controlling and synchronizing physiology. With intact gap junctional coupling, calcium in connected hepatocytes can communicate directly through gap junctions.

Whereas, gap junctional permeability and conductance affected by the calcium concentrations spikes in hepatocytes, a reduction of junctional conductance by calcium concentrations has been observed in hepatoma cells^[42,43]. In our study, after special indicator of calcium Fluo-3AM loading, LSCM was used to measure concentrations of intracellular calcium [Ca^{2+}]_i in hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver cell line QZG. Concentrations of intracellular calcium [Ca^{2+}]_i was much higher in QZG (108.37 nmol/L) cell line than that in HHCC (35.13 nmol/L) and SMMC-7721 (47.08 nmol/L) cell lines. QZG cells showed much higher calcium peaks than HHCC, SMMC-7721 cells which was associated with disruption of GJIC in these cell lines. Decreased level of intracellular Ca^{2+} contributed to conduction abnormalities of GJIC which immediate loss of calcium fluxes and influence the calcium dynamics in hepatocellular carcinoma cell lines.

Gap junctions are modulated by a multi-step molecular components and signaling pathway. Our observations also suggested that disruption of GJIC in hepatoma cells was associated with multiple distinct steps such as phosphorylation on tyrosine of Cx32, Cx43 proteins^[43]. Cx contains phosphorylations sites for several protein kinases including protein kinase C (PKC) and mitogen-activated protein kinase (MAPK) which are involved in Cx phosphorylation leading to the closure of GJIC^[44,45]. Disruption of GJIC requires Cx43 phosphorylation and interaction with other cellular factors. Phosphorylation of Cx proteins has been postulated to be a critical regulatory element for gap junctional communication^[46]. In our study, western blot suggested that only QZG cells had unphosphorylated tyrosine in Cx32 protein at 32ku and Cx43 protein at 43ku; SMMC-7721 cells had phosphorylated tyrosine Cx43 proteins. Change in the amount and distribution of phosphorylated and nonphosphorylated isoforms of Cx32 and

Cx43 were measured by immunoblot using isoform-specific antibodies anti-Cx32 mAb, anti-Cx43 mAb. Dramatic decreases in gap junctional communication and loss of phosphorylation on tyrosine^[47]. It indicated post-translation phosphorylation on tyrosine of Cx proteins, which associated with a dramatic disruption of GJIC^[48]. Functional recovery was associated with increased levels of unphosphorylated Cx43.

As above all, disruption of GJIC in hepatocellular carcinoma cells could also be achieved by multi-mechanisms. We could make conclusions that the establishment and permanent of functional gap junctions were regulated by transcriptions as well as post-translational controls including reduce of concentrations of intracellular calcium and phosphorylation on tyrosine of connexin proteins even the biological consequences of specific changes in Cx proteins phosphorylation are not understood in detail. The decrease of Cx proteins or the disorder of signal transduction of cx genes might keep close relationships with hepatocellular carcinoma.

Abstract

AIM: To explore the anti-tumor immunity against CT26 colon tumor of the microencapsulated cells modified with murine interleukine-12 (mIL-12) gene.

METHODS: Mouse fibroblasts (NIH3T3) were stably transfected to express mIL-12 using expression plasmids carrying mIL-12 gene (p35 and p40), and NIH3T3-mIL-12 cells were encapsulated in alginate microcapsules for long-term delivery of mIL-12. mIL-12 released from the microencapsulated NIH3T3-mIL-12 cells was confirmed using ELISA assay. Transplantation of the microencapsulated NIH3T3-mIL-12 cells was performed in the tumor-bearing mice with CT26 cells. The anti-tumor responses and the anti-tumor activities of the microencapsulated NIH3T3-mIL-12 cells were evaluated.

RESULTS: Microencapsulated NIH3T3-mIL-12 cells could release mIL-12 continuously and stably for a long time. After the microencapsulated NIH3T3-mIL-12 cells were transplanted subcutaneously into the tumor-bearing mice for 21 d, the serum concentrations of mIL-12, mIL-2 and mIFN- γ , the cytotoxicity of the CTL from the splenocytes and the NK activity in the treatment group were significantly higher than those in the controls. Moreover, mIL-12 released from the microencapsulated NIH3T3-mIL-12 cells resulted in a significant inhibition of tumor proliferation and a prolonged survival of tumor-bearing mice.

CONCLUSION: The microencapsulated NIH3T3-mIL-12 cells have a significant therapeutic effect on the experimental colon tumor by activating anti-tumor immune responses *in vivo*. Microencapsulated and genetically engineered cells may be an extremely versatile tool for tumor gene therapy.

INTRODUCTION

Alginate microcapsules have been used extensively for different applications, particularly for the encapsulation of pancreatic islet cells and insulin delivery^[1]. This method has

also been used for the encapsulation of cells that release growth hormone, β -endorphin, endostatin and other agents for gene therapy^[2-5]. The alginate membranes allow the free exchange of nutrients and oxygen between the implanted cells, and could prevent the escape and elimination of encapsulated cells. More important, this approach provides a prolonged sustained delivery of recombinant protein produced by the cells, thus maintaining high levels of the agent.

In recent years, interleukine-12 (IL-12) has received considerable interest in cancer biologic therapy. *In vivo* IL-12 was found to have a potent antitumor efficacy in a variety of murine tumor models^[6,7]. Local or systemic treatment with recombinant IL-12 protein (rIL-12) was shown to inhibit the growth of established subcutaneous tumor and tumor metastasis^[8-10]. However, systemic administration of rIL-12 caused severe dose-dependent toxicity and led to an interruption of the first human trial^[11]. In contrast, the local transfer of cytokine genes as a means for gene therapy could circumvent such systemic toxicity and provide effective and persistent local cytokine levels for immune cells activation^[12-15]. Some studies using an *ex vivo* IL-12 gene therapy yielded encouraging results, showing that murine fibroblasts or tumor cells transduced *in vitro* with IL-12 cDNA, using a retroviral vector, were able to induce antitumor immune responses in the absence of apparent toxicities^[16]. This strategy, however, has many obstacles precluding successful clinical application: e.g. autologous somatic cells or tumor cells are difficult to culture and transfect, and selection for transfected cells requires prolonged culture and the attendant costs of these process are expensive. To avoid these potential disadvantages, an alternative approach to obtain prolonged local cytokine secretion is adopted to use microencapsulated engineered cells to secrete IL-12.

In the present study, NIH3T3 cells engineered to continuously secrete high levels of mIL-12 were encapsulated with alginate. The ability of this system to secrete biologically active mIL-12 capable of inhibiting the tumor growth of a murine colon carcinoma xenograft in the mouse was investigated.

MATERIALS AND METHODS

Mice and cell lines

Male BALB/C mice aged between 6 and 8 weeks were purchased from Joint Ventures Sipper BK Experimental Animal Company (Shanghai, China) and housed in a specific pathogen-free condition for all experiments. Mouse fibroblasts (NIH3T3) and the murine colon adenocarcinoma cell line (CT26) were donated by the Institute of Immunology, Zhejiang University (Hangzhou, China). Cells were cultured in RPMI-1640 medium (GIBCO-BRL, Gaithersburg, MD, USA) supplemented with 10 % heat-inactivated fetal calf serum (FCS; HyClon, Logan, UT, USA), 2 mM glutamine, penicillin 100 U/ml, and streptomycin 100 μ g/ml.

Expression plasmids and transfection of NIH3T3 cells

Murine p35 and p40 subunits of mIL-12 were subcloned into pcDNA3.1 plasmids containing a cytomegalovirus (CMV) immediate-early enhancer promoter and a G418 selected gene.

NIH3T3 cells were stably transfected with these expression plasmids using LF2000™ (Ivotrogen, Life Technologies, USA). To obtain stably transfected clones (NIH3T3-mIL-12), transfected cells were grown in G418 containing medium (400 g/L, Ivotrogen, Life Technologies, USA) for 14 days, and resistant clones were propagated separately. With subsequent determination of mIL-12 expression by ELISA kit (R&D systems, Inc., USA).

Microencapsulation of NIH3T3-mIL-12

NIH3T3-mIL-12 cells were encapsulated within microspheres composed of Ba²⁺-alginate. Briefly, cells were resuspended in sodium alginate-saline (1.5 % wt/vol, purified by Syringe Driven Filter Unit) (Sigma, St Louis, MO, USA) to a final ratio of 0.5×10^9 cells/L of alginate. The suspension was sprayed through an air jet-head droplet-forming apparatus, into a solution of 4.9 % Barium chloride (pH 7.4, Sigma), where they were allowed to gel for 10 min, washed three times with PBS, then cultured in the conditioned medium described above. The number of cells encapsulated and the viability of the cells in the microcapsules were evaluated weekly using a modified MTT assay.

In vitro release of mIL-12 from encapsulated NIH3T3-mIL-12 cells

Microencapsulated NIH3T3-mIL-12 cells were suspended in the conditioned medium described above at a density of 2×10^5 cells/well. The medium was collected every 2 hrs. and assayed for mIL-12 using ELISA assay (Endogen, Woburn, MA, USA). Medium from NIH3T3-mIL-12 monolayer cells was used as a positive control.

Murine studies

The BALB/C mice were inoculated subcutaneously in the right-behind armpit with CT26 cells (2×10^5 tumor cells/injection). Mice were randomly divided into four groups of twenty each. Group 1 received a single subcutaneous injection of microcapsules containing NIH3T3-mIL-12 cells within 0.5 cm apart from the area where CT26 cells were inoculated (1×10^5 encapsulated cells/animal); Group 2 RPMI-1640 (control), Group 3 microcapsules containing NIH3T3 (1×10^5 cells), and Group 4 RPMI injected at the same region of mice. The length and width of the tumor mass were measured with calipers every other day after tumor inoculation. Tumor size was expressed as $1/2$ (length + width). Twenty-one days after tumor inoculation, ten mice taken randomly from each group were sacrificed, and spleen was resected, and blood was collected from the mice eyeballs. The rest ten mice in each group were observed for their survival period until 60 days after injection.

Cytotoxic assay of CTL and NK cells

Spleen cells derived from each group of experimental mice were unstimulated or were stimulated with irradiated CT26 cells (1×10^5) for 7 days *in vitro* and processed for the NK or cytotoxic T lymphocyte (CTL) assay, respectively. The NK activity and CTL activity were determined by lactate dehydrogenase (LDH) release assay with Non-Radioactive Cytotoxicity Assay kit (Promega, Madison, WI, USA). The target cells (YAC-1 cells for the NK assay, and CT26 cells for the CTL assay) were washed three times with RPMI 1640 medium containing $50 \text{ ml} \cdot \text{L}^{-1}$ FCS to remove adherent LDH derived from lysed cells. The cell suspension was diluted with RPMI 1640 medium containing $50 \text{ ml} \cdot \text{L}^{-1}$ FCS to give a final concentration of 1×10^8 cells/L; and $100 \mu\text{L}$ target cell suspension and $100 \mu\text{L}$ different ratios of effector cells were pipetted together into the wells of a round-bottomed microtiter plate. Suspensions containing exclusively effector cells, target cells,

or culture medium, respectively, served as controls to estimate the LDH background. The plates were incubated for 4 hrs in a humidified $50 \text{ ml} \cdot \text{L}^{-1} \text{CO}_2$ atmosphere at 37°C . After incubation, they were centrifuged for 10 min. Then $100 \mu\text{L}$ of the supernatant from each well was transferred to the corresponding well of enzymatic assay plate. Fifty μL reconstituted substrate mix (containing lactate and NAD^+) was added to each well. The plate was covered and incubated at room temperature (protected from light). Thirty minutes later, $50 \mu\text{L}$ stop solution was added to each well. The reaction was measured in an ELISA reader at a wavelength of 490 nm. Calculations were carried out according to the following formula: percent specific lysis = $100 \times (\text{mean experimental cpm} - \text{mean spontaneous cpm}) / (\text{mean maximum cpm} - \text{mean spontaneous cpm})$.

Determination of serum cytokine production

Blood samples were collected from the mice 21 days after tumor inoculation. Stored serum were separated from the whole blood and frozen at -70°C until analyzed for cytokine production. mIL-2, mIL-12, mIL-4, mIL-10 and mIFN- γ were measured using a standard sandwich ELISA technique with corresponding kits purchased from Endogen (Woburn, MA, USA).

Statistical analysis

Data were expressed as mean \pm SD. Statistical analysis was performed using the *t* test and log-rank test (for survival analysis). The difference was considered statistically significant when the *P* value was less than 0.05. The SPSS software package version 10.0 was used for statistical calculation.

RESULTS

In vitro expression and release of mIL-12 from encapsulated cells

NIH3T3 cells were transfected with a mIL-12 expression vector and clonal populations of stably transfected NIH3T3 cells were obtained (NIH3T3-mIL-12). The microcapsules have an average diameter of $0.45 \text{ mm} \pm 0.05 \text{ mm}$ (Figure 1). Both encapsulated and nonencapsulated NIH3T3-mIL-12 cells were cultured *in vitro*, and the conditioned medium was collected every week for six weeks. The encapsulated cells were viable in culture as determined by MTT assay. ELISA method was used to determine mIL-12 in the medium collected at all time points. The average concentration of mIL-12 secreted by 2×10^5 cultured encapsulated NIH3T3-mIL-12 cells or nonencapsulated NIH3T3-mIL-12 cells were $5.12 \mu\text{g} \cdot \text{L}^{-1}$ and $5.45 \mu\text{g} \cdot \text{L}^{-1}$ for every 24hrs, and the optimal expression up to 46.8 and 48.2 ng of mIL-12 per 24 hrs per 10^5 cells, respectively. These results indicate that mIL-12 protein could release freely from the microencapsulated NIH3T3-mIL-12 cells.

Figure 1 NIH3T3-mIL-12 cells-loaded microcapsules (average capsule diameter $450 \mu\text{m}$).

Increased NK activity after delivery of microencapsulated NIH3T3-mIL-12 cells

Twenty-one days after treatment of tumor-bearing mice with various injections, the splenocytes were used in cytolytic assay against YAC-1 cells at effector:target (E:T) ratios at 20:1, 40:1, 80:1. As shown in Figure 2, NK activity in mice treated with NIH3T3-mIL-12 cells capsule increased significantly when compared with the mice treated with NIH3T3-mIL-12 cells, NIH3T3 cells capsule or RPMI-1640 ($P<0.01$). These data suggested that nonspecific immunity was enhanced significantly by the local delivery of IL-12 with NIH3T3-mIL-12 cells capsule.

Figure 2 NK activity induced by various treatment. $\bar{x} \pm s$, $n=10$, ^b $P<0.01$ for the group treated with NIH3T3-mIL-12 cells capsule versus other three counterpart groups, respectively.

Potent CTL activity induced by delivery of microencapsulated NIH3T3-mIL-12 cells

The splenocytes collected from various groups were restimulated *in vitro* with inactivated CT26 tumor cells for CTL induction. As shown in Figure 3, the mice treated with NIH3T3-mIL-12 cells capsule exhibited a CT26 colon carcinoma-specific CTL response that was higher than that of mice treated with NIH3T3-mIL-12 cells, NIH3T3 cells capsule or RPMI-1640 ($P<0.01$). It suggested that CTL activity against tumor was induced significantly by the local delivery of IL-12 with NIH3T3-mIL-12 cells capsule.

Figure 3 CTL activity against CT26 induced by various treatment. $\bar{x} \pm s$, $n=10$, ^b $P<0.01$ for the group treated with NIH3T3-mIL-12 cells capsule versus other three counterpart groups, respectively.

Serum cytokine production

Twenty-one days after the microencapsulated NIH3T3-mIL-12 cells were injected into the tumor-bearing mice, blood was collected for analysis of serum mIL-12, mIL-2, mIFN- γ and mIL-4, mIL-10. The serum average concentrations of mIL-12, mIL-2 and mIFN- γ in the group treated with

microencapsulated NIH3T3-mIL-12 cells were 542 ± 48 , 176 ± 25 and 982 ± 112 ng \cdot L⁻¹, respectively, which were significantly higher as compared with the counterpart control groups ($P<0.01$), but the serum concentrations of mIL-4 and mIL-10 were lowered significantly compared to the controls ($P<0.01$). The results of the studies are shown in Figure 4.

Figure 4 Cytokines levels in serum after various treatment in the tumor-bearing model. $\bar{x} \pm s$, $n=10$, ^b $P<0.01$ for the group treated with NIH3T3-mIL-12 cells capsule versus other three counterpart groups, respectively.

Figure 5 Inhibition of tumor growth by microencapsulated NIH3T3-mIL-12. Two days after tumor inoculation, mice were injected sc with NIH3T3-mIL-12 cells capsule (▲), NIH3T3-mIL-12 cells (△), NIH3T3 cells capsule (●) or RPMI-1640 (○). $\bar{x} \pm s$, $n=20$, ^a $P<0.05$ for the group treated with NIH3T3-mIL-12 cells capsule versus other three counterpart groups respectively.

Figure 6 Survival time after various treatment in the tumor-bearing model. Two days after tumor inoculation, mice were injected sc with RPMI-1640 (○), NIH3T3 cells capsule (●), NIH3T3-mIL-12 cells (△) and NIH3T3-mIL-12 cells capsule (▲), respectively. Ten tumor-bearing mice ($n=10$) in each group were observed for their survival time. All surviving mice were monitored for at least 60 d. ^a $P<0.05$, compared with other three counterpart groups, respectively.

Effects of encapsulated NIH3T3-mIL-12 cells on subcutaneous tumor xenografts

The subcutaneous tumor size was calculated as follows: tumor size = (maximum diameter + vertical diameter)/2. The growth of tumor xenografts was significantly inhibited by a single dose of microcapsules containing NIH3T3-mIL-12 cells when compared with both control groups ($P < 0.05$) (Figure 5).

Survival time after delivery of microencapsulated NIH3T3-mIL-12 cells in the tumor-bearing model

When treated mice were observed up to 60 days after implantation of CT26 tumor, the mice survival time of the group treated with microencapsulated NIH3T3-mIL-12 cells was longer than other counterpart control groups ($P < 0.05$) (Figure 6).

DISCUSSION

Encapsulation of living cells in a protective, biocompatible, and semipermeable polymeric membrane has been proven to be an effective method for immunoprotection of desired cells, regardless of the type recipient involved (allograft, xenograft)^[17]. Alginate microcapsules have been applied for various purposes, and the molecular cutoff of alginate microcapsule membrane was 75 kDa^[18], so the IL-12 protein (a molecular weight of 70 kDa) could pass through the membrane. In the present study, we observed that mIL-12 protein could release freely from the microencapsulated NIH3T3-mIL-12 cells. Twenty-one days after the microencapsulated NIH3T3-mIL-12 cells were transplanted subcutaneously into the tumor-bearing mice, both the NK and CTL activities were significantly enhanced, and the mice serum average concentrations of mIL-12, mIL-2 and mIFN- γ were upregulated, but the mIL-4 and mIL-10 were downregulated in the treated group as compared with those of other control groups. In tumor bearing mice, Th1 cytokine production (IL-2, IFN- γ) is suppressed and Th2 cytokine production (IL-4, IL-10) was increased, as compared with those of normal mice. The administration of microencapsulated NIH3T3-mIL-12 cells to tumor bearing mice transferred the balance of Th1/Th2 cell responses from Th2 dominant state to the Th1 dominant state. These findings are consistent with the results of previous studies showing that production of IFN- γ , NK cell activation, CTL differentiation, and Th1 differentiation were the main mechanisms of antitumor activity of IL-12^[19].

The present study developed an alternative approach for local long-term delivery of mIL-12 by a single administration of alginate microcapsules containing cells secreting mIL-12. Using this system, the microencapsulated engineered cells could supply the appropriate doses of effective mIL-12 protein in a paracrine fashion to induce potent anti-tumor immune response and constituted an efficacious therapy in mouse colon models. This system differs from other cytokine gene therapy models, which utilize engineered autologous somatic cells^[20,21], tumor cells^[22-24] or intratumoral injection of adenovirus expressing cytokine^[25,26]. Considering the difficulties of prolonged culture and transduction of human autologous somatic cells or primary tumor cells for each patient, and in contrast, the ready availability of microencapsulated cells, the use of microencapsulated engineered cells for prolonged cytokine administration is an attractive alternate method for clinical application of gene therapy. With respect to the finding that local secretion of IL-12 at the site of tumor might induce an immune response against poorly immunogenic tumor without severe toxicities that were often observed with systemic administration, this system has significant advantages for initiating studies of the prolonged delivery effect of IL-12 with

microencapsulated engineered cells on tumor growth.

The transplantation of the microencapsulated NIH3T3-mIL-12 cells could lead to prolonged, homogeneous expression of mIL-12 and continuous stimulation of TILs, with tumor-specific immunity ultimately being established. Such immunity is advantageous because it could result in continued destruction of tumor cells even after expression of mIL-12 had declined^[27]. Moreover, no side effects of IL-12 were noticed in treated mice, which is in contrast to the results of trials using recombinant IL-12 protein, where severe toxicity (e.g. fur ruffling or lethargy) was often observed with systemic administration. This is probably because mIL-12 mainly restricted to the vicinity of tumors, a prolonged appropriate blood concentration of cytokines could stimulate an antitumor immune response without causing excessive systemic inflammatory and immunoreaction^[28]. Thus this approach should be a better-tolerated and safer strategy than systemic administration of recombinant IL-12 protein. In this study, by treatment of a single dose of microcapsules containing NIH3T3-mIL-12 cells, the growth of tumor xenografts was significantly inhibited and the mice survival time was significantly prolonged. This result also showed that the approach for local and sustained release of interleukin 12 could induces both innate and adaptive antitumor immune responses resulting in significant growth suppression and metastases of tumor^[29-31].

It should also be emphasized that controlling the amount of encapsulated cells makes an appropriate concentration of IL-12 obtainable. Preliminary *in vitro* test for IL-12 expression revealed that the microencapsulated NIH3T3-mIL-12 cells secreted up to 468 ng of mIL-12 per 24hrs per 10^6 cells. This result indicates that using an optimized amount of encapsulated cells may lead to more powerful antitumor effects and less side effects. Furthermore, using this approach, the antitumor effects of IL-12 may be augmented by combination with other therapeutic genes (e.g., genes encoding other cytokines and apoptotic genes), which is probably necessary in destruction and prevention of recurrence of not only primary tumors, but also metastases^[32].

Colorectal carcinomas are generally not very sensitive to the established chemotherapeutic agents and most patients with colorectal carcinoma will die from distant metastases that are not detectable at the initiation of treatment, the alternative antitumor therapy approaches, such as biotherapy, are necessary for the patients suffering from colorectal cancer^[33-35]. This study show that microencapsulated engineered cells could supply appropriate doses of effective mIL-12 protein locally to induce potent anti-tumor immune response and constitute an efficacious therapy in mouse colon models. Investigation of optimal combinations of genes used with encapsulated cells has the potential to contribute to a successful anticancer gene therapy for colon cancer.

ACKNOWLEDGEMENTS

We could like to thank Professor LH Zhang and Dr. HP Yao for their encouragement and Mr. M Zhu for technical assistance.

Abstract

AIM: To determine the association of *hOGG1* (8-oxoguanine glycosylase I, *OGG1*) polymorphism of Ser326Cys substitution with colon cancer risk and possible interaction with known environmental risk factors.

METHODS: A case-control study with 125 colon cancer cases and 247 controls was conducted.

RESULTS: There was no major difference in Ser326Cys genotype distribution between cases and controls. The meat intake tended to increase the odds ratio for colon cancer with an OR of 1.72 (95 % confidence interval; CI=1.12-2.76). Such tendency was more prominent in Cys/Cys carriers (OR=4.31, 95 % CI=1.64-11.48), but meat intake was not a significant risk factor for colon cancer in Ser/Ser or Ser/Cys carriers. The OR for colon cancer was elevated with marginal significance in smokers who were Cys/Cys carriers (OR=2.75, 95 % CI=1.07-7.53) but not in Ser/Ser or Ser/Cys carriers.

CONCLUSION: These results suggest that the *hOGG1* Ser326Cys polymorphism is probably not a major contributor to individual colon cancer susceptibility overall, but the Cys/Cys genotype may alter the impact of some environmental factors on colon cancer development.

INTRODUCTION

Reactive oxygen species are formed continuously in living cells through both endogenous and exogenous processes. The reaction of reactive oxygen species results in various forms of both cellular and DNA damage^[1]. Oxidative damage to DNA is thought to cause mutations, which in turn can activate oncogenes or inactivate tumor suppressor genes and may finally lead to carcinogenesis^[2-4]. 7,8-Dihydro-8-oxoguanine

(8oxoG) is one of the most important lesions produced in DNA by oxygen radical forming agents. Due to its mispairing with deoxyadenosine, it causes mutagenic transversion of G:C to T:A *in vitro* and *in vivo*^[5,6]. The *hOGG1* gene encodes a DNA glycosylase/AP-lyase that catalyzes the removal of 8oxoG adducts as part of the base excision repair pathway. The *hOGG1* gene is expressed as multiple alternatively-spliced isoforms with only the 1 α -form containing a nuclear localization signal^[7,8]. Previous studies have revealed the presence of several polymorphisms at the *hOGG1* locus. A C/G polymorphism at position of 1245 in the 1 α -specific exon 7 of the *hOGG1* gene results in an amino acid substitution from serine to cysteine in codon 326^[9]. Although no difference in catalytic activity was observed between Ser326 and Cys326 variants in some studies^[10,11], the *hOGG1* protein encoded by the Ser326 allele exhibited substantially higher activities than the Cys326 variants in an *in vitro* *Escherichia coli* complementation activities assay^[9].

Several studies have suggested that Cys326 type allele is associated with increased risk for lung^[12], esophageal^[13] and a subset of stomach cancer^[14]. The possible causal relationship between oxygen free radicals and cancer development has been reported mainly in organs under a high burden of oxygen free radicals, including the lung and oro-laryngeal cancer associated with smoking history. Among the smokers, the Cys/Cys carriers who are supposed to have decreased capability in coping with the oxidative DNA damage tended to be more susceptible to lung cancer than the Ser/Ser or Ser/Cys carriers. The colon may be continuously exposed to the attack of oxygen free radicals. The relatively high concentrations of iron in feces, together with the ability of bile pigments to act as iron chelators that support Fenton chemistry, may very well permit efficient hydroxyl radical (-OH) generation from superoxide and hydrogen peroxide produced by bacterial metabolism^[15]. The abundant free radical generation in colon supports the free radical related colon carcinogenesis.

We previously demonstrated that the impact of genetic defect on carcinogenesis is modulated by an environmental risk factor in hereditary nonpolyposis colorectal cancer patients^[16]. In addition, we tried to delineate the relationship between *hOGG1* enzyme activity and the allele type harbored in Ser326Cys polymorphism *in vivo*^[17]. However, any clear conclusion was not made despite of possible relevance. The available information makes it plausible to hypothesize that the Ser326Cys polymorphism may alter colon cancer risk, particularly in association with the environmental risk factors. We will conduct a case control study to examine the hypothesis.

MATERIALS AND METHODS

Study populations and sample processing

Case subjects consisted of 125 patients operated with primary colorectal cancer. All the patients agreed to participate in this study and consented. Community-based controls consisted of subjects who were visited the health-screening center of Ilsan-Paik hospital. At this center, screenings of common cancers as

well as evaluation on the general status of health were performed. All control subjects were recruited after an initial verbal screening to determine whether they had no previous diagnosis of cancer, and none of the controls recruited into this study were diagnosed with any form of cancer after screening. The eligible pool of control subjects was restricted to those individuals of the same age (± 5 years) and sex as case subjects. The controls pair-matched into a 2 to 1 ratio in terms of those cases studied. Ninety-five percent of the control subjects ($n=247$) consented. A trained interviewer conducted in-person interviews. Information was collected on life-long smoking, alcohol consumption, diet habits, physical activity and family history of colorectal cancer.

Genotypic assays

The genotypes of *hOGG1* alleles were determined by a polymerase chain reaction - restriction endonuclease length polymorphism (PCR-RELP) analysis. Briefly, a 251 bp fragment was amplified by PCR in a 25 μ L reaction volume that contained 50 ng of genomic DNA, 10 mmol/L Tris-HCl, 50 mmol/L KCl, 1 mmol/L MgCl₂, 0.2 mmol/L of each dNTP, 10 pmol of the *hOGG1* sense (*hOGG1F*; 5'-AGTGGATTCTCATTGCCTTCG-3', corresponding to nucleotide 8 919 through 8 939 of *hOGG1* intron 6 DNA sequences; Genbank accession #HSA131341) and antisense (*hOGG1R*; 5'-GGTGCTTGGGGAATTTCTTT-3', corresponding to nucleotide 9 150 through 9 169 of *hOGG1* exon 7 sequences) primers and 2 units of Taq DNA polymerase. Cycling conditions were as follows: initial denaturation at 94 °C for 5 min following 30 cycles of denaturation at 94 °C for 30 sec, annealing at 57 °C for 30 and elongation at 72 °C for 40. Ten μ L of each PCR sample was digested with 2 units of Fsp4HI (Bioneer, Taejeon, Korea) at 37 °C for 12 h and resolved on 30 g/L agarose gels to detect differences in RFLP patterns.

Statistical analysis

The association between the *hOGG1* polymorphism and colorectal cancer risk was estimated by the odds ratio (OR), using the unconditional logistic regression model. We calculated not only crude ORs, but also values adjusted for age, sex, drinking habits, smoking and diet habits to control the effect of potential confounding environmental factors. Because the Ser/Ser genotype was thought to have the highest effective enzymatic activity, we used this genotype as reference for colorectal cancer risk. Thus, the ORs for the Ser/Cys and Cys/Cys types relative to the Ser/Ser were calculated. The ORs for the Cys/Cys type versus other types combined were also calculated because only the Cys/Cys type could potentially influence the individual repair activity. Statistical differences of the categorical comparison and the probability of the Hardy-Weinberg equilibrium were tested using χ^2 test.

RESULTS

The mean age of the case and control groups were 57.2 and 56.1 years, respectively, and the case and control groups consisted of 36.5 % and 37.2 % females, respectively. There were no significant statistical differences in age and gender between the case and control groups.

Three banding patterns were observed depending on the genotypes; a single 251 bp band corresponding to the Ser326/Ser326 genotype, a 251, 153 and 98 bp bands that corresponded to the Ser326/Cys326 genotype, and 153 and 98 bp bands corresponding to the Cys326/Cys326 genotype (Figure 1A). The specificity of the amplification products was verified by sequencing (Figure 1B).

Figure 1 A: The representative PCR-RFLP analysis of *hOGG1* Ser326Cys polymorphism. Lane 1, 5, undigested PCR-amplified product observed in homozygous Ser326 carriers; Lane 2, Fsp4HI-digested PCR product from subject with heterozygous *hOGG1* genotype; Lane 3, 4, Fsp4HI-digested PCR product from subject with homozygous Cys326 genotype. B: DNA sequence histogram revealing the indicated sequence changes (underlined). In the 2nd histogram, both the cytosine (blue line) and guanine (black line) are observed in the codon 326 site (marked as N), indicating the heterozygous genotype.

The allelic frequency was not significantly different between cases and controls, slightly more homozygous Cys326 alleles were found in the case group than that in the controls (Table 1). The prevalence of the *hOGG1* Ser/Cys polymorphism followed the Hardy-Weinberg equilibrium.

Table 1 Odds ratios for colon cancer according to the genotypes of *hOGG1* Ser326Cys polymorphism

	Number (%)		OR (95% CI)	P for trend
	Controls	Cases		
Ser / Ser	52 (21.1)	24 (19.2)	1.00	P=0.871
Ser / Cys	131 (53.0)	66 (52.8)	1.09 (0.60-2.00)	
Cys / Cys	64 (25.9)	35 (28.0)	1.18 (0.60-2.35)	
Total	247 (100)	125 (100)		

To examine the relationship between the *hOGG1* genotype and colon cancer risk in the presence of selected environmental risk factors, study subjects were stratified by *hOGG1* genotype and several known colon cancer risk factors. Table 2 represented the frequency distribution of the *hOGG1* genotype stratified with the risk factors and ORs with

a 95 % confidence interval (95 % CI) for colon cancer cases compared with controls. None of the risk factors analyzed in the present study significantly elevated the ORs for colon cancer in the total number of subjects studied. Only frequent meat intake increased the OR with marginal statistical significance.

Denotes: Ca/Co=Cases/Controls.

In the subgroup analysis with reference to the Ser326Cys polymorphism, the smoking habit did not increase the ORs for colon cancer in Ser/Ser or Ser/Cys carriers. In contrast, a near-significant increase in risk was observed for smokers with the Cys/Cys genotype (OR=2.75, 95 % CI=1.07-7.53). Meat intake was associated with increased colon cancer incidence with borderline significance among the total number of subjects (OR=1.72, 95 % CI=1.12-2.76). The OR for colon cancer with frequent meat intake was further increased in the Cys/Cys subgroup (OR=4.31, 95 % CI=1.64-11.48), while the OR was not increased in Ser/Ser or Ser/Cys carriers. Except for the meat intake factor, the intake of selected foods including alcohol, vegetable and soybean products did not alter the ORs for colon cancer neither in the entire group of subjects studied nor in the Cys/Cys subgroup. No significant alteration in the OR for colon cancer according to the extent of physical activity was observed in either genotype carriers.

Because the presence of colon cancer in relatives, particularly in 1st or 2nd degree relatives, has been known to be associated with colon cancer risk and because the genetic polymorphism could be one of the possible causes, changing patterns of OR for colon cancer according to the *hOGG1* Ser326Cys polymorphism when there was at least one colon cancer patient within a family were investigated. Although the risk was increased with the presence of colon cancer within a family among the total number of subjects studied, there was no apparent increase in the OR among subjects with Cys/Cys genotype.

DISCUSSION

It is theoretically possible that the incidence of cancer differs depending on the genotypes of *hOGG1* Ser326Cys polymorphism. This view is supported by the difference in DNA repairing capability depending on the allele type^[9] and increase of the incidence of cancer in certain organs in Cys326 allele carriers^[12,13,18].

Colon is the most susceptible organ for cancer development in hereditary non-polyposis colorectal cancer (HNPCC), where the DNA mismatch repair activity is defective^[19]. As the role of defects in DNA mismatches repair process in colon carcinogenesis is very clear, attention has also recently focused on the possible role of alternative DNA repair pathways such as base excision repair in colon cancer formation.

In the present investigation, however, the *hOGG1* Ser326Cys polymorphism did not alter the overall odds ratios for colon cancers despite of the theoretical relevancies. Subgroup analysis revealed an increased tendency of ORs with smoking habit or frequent meat intaking in Cys/Cys carriers although the statistical significance of the former factor is marginal.

The intake of meat and animal fat was almost consistently associated with the increased risk of large-bowel cancer in the previous studies^[20-22]. It was suggested that the abundant fecal iron after red meat intake, together with the ability of bile pigments to act as iron chelators, supports the superoxide-driven Fenton reaction^[15]. Meanwhile, excessive fat ingestion increases the concentrations of bile acids in the colon. The increased fatty acids and secondary bile acids in the colonic

lumen, which acts as cytotoxic surfactants, can damage colonic epithelial cells and thus induce a compensatory hyperproliferation of crypt cells^[23]. In addition, the high intake of polyunsaturated fatty acid induces peroxidative reaction with plasma low-density lipoproteins, which in turn generate free radicals. Meat is a major source of dietary animal fat. Thus, the question is still unresolved whether the association of meat with colorectal cancer seen in some epidemiologic investigations reflects the effect of fat, or meat in general, or just particular types of meat. One prospective study showed that red meat, but not the chicken or fish could be an independent risk factor for colon cancer^[24]. The result of the present investigation together with a literature review consists with the suggestion that oxidative damage after meat intake may play a role in colon carcinogenesis and that the role may be more pronounced in Cys/Cys carriers, who have a lower activity in terms of repair of DNA.

Some discussion is required on the credibility of the answer concerning the meat intake habit. The dietary environment has been rapidly changing in Korea in accordance with economic development. Meat consumption per capita has increased more than 3 times during the past 3 decades^[25]. A possible problem under this circumstance is that the answers on the questionnaire might be more influenced by recent dietary habits rather than lifelong ones, although we tried to reduce such problems to a minimum during the interview.

Among the various lifestyle factors, tobacco smoking might provide the strongest oxygen radical generating environment. An array of studies demonstrated the increased oxidative DNA damage in smokers compared to non-smokers^[26,27]. The carcinogenic role of tobacco in association with the oxygen free radical seems clear in airway tract tissues. Recent studies showed that an increased risk of squamous type lung cancer, orolaryngeal cancer in smokers, was particularly found in homozygous Cys 326 gene carriers. In general, the biologic role of tobacco smoke as an etiology of cancer in the gastrointestinal tract might be less prominent than that in the airway tract. Tobacco smoking history is often inconsistent with the incidence of colorectal cancers although it shows a near consistent positive relationship with the presence of colorectal adenomas^[28,29]. The previous studies, which investigated the effect of smoking in gastric cancer development in connection with the Ser326Cys polymorphism, showed only a weak association^[14]. In the present study, the OR for colon cancer among smokers tended to be higher in Cys/Cys carriers than that in Ser/Ser and Ser/Cys carriers, the interaction being of borderline statistical significance. The result of present findings suggested that the oxygen free radical generated from tobacco smoke might be involved in colon carcinogenesis although the role is probably limited.

The role of oxidative DNA damage in alcohol-related carcinogenesis is still controversial. Alcohol consumption was associated with increased DNA damage or induction of 8oxoG in some studies^[30,31] in contrast, but not in others^[32,33]. The present study showed that alcohol intake did not increase the risk of colon cancer even in Cys/Cys carriers. It suggested that the role of alcohol consumption in colon cancer formation, particularly in association with the 8oxoG adduct induction, was limited. The other factors including vegetable or soybean product intake, physical exercise and family history of colon cancer did not increase OR for colon cancer in the total number of subjects studied as well as in Cys/Cys carriers. Thus, it was difficult to interpret whether these factors play a role during colon carcinogenesis, particularly in interaction with the *hOGG1* Ser326Cys polymorphism.

In summary, the *hOGG1* Ser/Cys polymorphism does not significantly alter the overall risk of colon cancer. The Cys type allele, however, may exert an impact on colon

carcinogenesis through an interaction with certain environmental factors such as smoking or meat consumption. There are lines of complex biologic factors involved in colon carcinogenesis. The present study suggests the possibility that an inter-individual difference in DNA repair capacity can be one such factor, however, the influence of such a role is believed to be limited. Further studies with a large number of subjects are warranted to better assess the role of *hOGG1* polymorphism in colon carcinogenesis.

Abstract

AIM: To perform a review of patients with colorectal cancer to a community hospital and to compare the risk-adjusted survival between patients managed in general surgical units versus a colorectal unit.

METHODS: The study evaluated all patients with colorectal cancer referred to either general surgical units or a colorectal unit from 1/1996 to 6/2001. These results were compared to a historical control group treated within general surgical units at the same hospital from 1/1989 to 12/1994. A Kaplan-Meier survival analysis compared the overall survivals (all-cause mortality) between the groups. A Cox proportional hazards model was used to determine the influence of a number of independent variables on survival. These variables included age, ASA score, disease stage, emergency surgery, adjuvant chemotherapy and/or radiotherapy, disease location, and surgical unit.

RESULTS: There were 974 patients involved in this study. There were no significant differences in the demographic details for the three groups. Patients in the colorectal group were more likely to have rectal cancer and Stage I cancers, and less likely to have Stage II cancers. Patients treated in the colorectal group had a significantly higher overall 5-year survival when compared with the general surgical group and the historical control group (56 % versus 45 % and 40 % respectively, $P < 0.01$). Survival regression analysis identified age, ASA score, disease stage, adjuvant chemotherapy, and treatment in a colorectal unit (Hazards ratio: 0.67; 95 % CI: 0.53 to 0.84, $P = 0.0005$), as significant independent predictors of survival.

CONCLUSION: The results suggest that there may be a survival advantage for patients with colon and rectal cancers being treated within a specialist colorectal surgical unit.

INTRODUCTION

The question of who should be performing surgery on patients with colorectal cancer has important implications for both specialist colorectal surgeons and general surgeons. This is

because it impacts on not only patient management, but also surgical training and the provision of surgical services in regional areas.

A significant volume of literature has been devoted to try and define if sub-specialization benefits patients with colorectal cancer^[1-3]. However, there is currently little convincing evidence that specialist colorectal surgeons can achieve superior results when compared to general surgeons. The Australian NHMRC guidelines for the management of colorectal cancer^[4] address only the issue of who should perform elective rectal cancer surgery. It states rather enigmatically that “*such surgery should be performed by surgeons who have undergone a period of special exposure to this form of surgery and who have satisfactory experience in the surgical management of rectal cancer*”.

The aim of this study was to determine if there was a risk-adjusted survival advantage for patients with colorectal cancer being treated within a specialist colorectal surgical unit when compared to general surgical units.

MATERIALS AND METHODS

The colorectal service was established at Fremantle Hospital in 1996 with the appointment of a single surgeon who had received accredited training in colorectal surgery. The management of these patients was standardized through the use of treatment pathways, and protocols for the use of adjuvant chemo and/or radiotherapy. All patients referred to the service with a histologically proven colorectal cancer were prospectively entered into a designated colorectal computer database (Filemaker Pro 3.0 and 5.0, Claris) managed by the service. The three general surgical units at the hospital comprised of 10 different general surgeons who were employed by the hospital over the study period. All patients referred to these units with a histologically proven colorectal cancer were prospectively entered into the general surgical database managed through the Department of Surgery. A medical student group crosschecked these database entries with the patients' medical records and pathological records to accurately determine tumour stage, use of adjuvant therapy, and whether the operation was an emergency. These data were validated by the author. The study period was from 1/1/1996 to 1/6/2001. Patients presenting with recurrent colorectal cancers for management were included in the analysis.

The historical control group consisted of a cohort of patients with colorectal cancer who had been managed at Fremantle Hospital from 1/1989 to 12/1994 by a group of 8 general surgeons. This group of 475 patients had previously been part of a retrospective analysis performed in 1996 by the author, and the results published in 1997^[5]. In view of the retrospective nature of the data collection, some areas of information were not collected as accurately as in the present prospective trial. In particular, the information required to calculate cancer free survivals was not available. This control group was chosen because it predated the widespread acceptance and use of adjuvant chemotherapy and radiotherapy at Fremantle Hospital. All the endpoints were defined prior to the collection of data.

The surgical procedure was termed curative if there was macroscopic removal of all the tumour and histological assessment showed there to be clear margins. A palliative procedure was where the surgeon had left tumour remaining following surgery, or where no attempt had been made to remove the tumour. Histological assessment of the resected specimen was required to adequately determine this. A positive surgical margin was defined as the presence of tumour within 1 mm of the resection line.

Primary was defined as the first presentation with a colorectal neoplasia, or if a second presentation, where the tumour occurred in a metachronous location. The rectum was defined as commencing in the area where the taenia coli of the sigmoid colon coalesce into a uniform outer longitudinal muscular wall. At colonoscopy, it included the area up to 18 cm from the anal verge. An emergency procedure was where a patient underwent urgent surgery (i.e. within 24 hours of admission) without recourse to the normal pre-operative work up which includes colonoscopy and bowel preparation (including presentations with acute obstruction, perforation, and massive bleeding). The American Society of Anaesthesia score (ASA score) was used as a general measure of patient well-being. The TNM staging system was used in this study. For those patients who received pre-operative radiotherapy to their rectal cancers, and where there had been complete resolution of the primary tumour, the staging was based upon the pre-treatment endoanal ultrasound and CT scan.

In the colorectal group, adjuvant chemotherapy was offered to all patients with Stage III colon cancers and a selected group of Stage II colon cancers if there was evidence of poor prognostic markers (i.e. poorly differentiated, lymphovascular invasion) or if they were of young age (<50 years). Adjuvant preoperative radiotherapy was offered to patients with rectal cancers if the lesion was - (1) less than or equal to 12 cm from the anal verge, (2) fixed in position, (3) mobile lesions if found on endorectal ultrasound to be T3 or T4 in staging, (4) no associated metastatic disease found on abdominal CT scan. The general surgeons did not maintain guidelines for the use of adjuvant chemo/radio therapy. There was minimal use of adjuvant therapy in the historical control group.

The three data sets (a. colorectal group, b. general surgeon group, c. historical group) were then linked to the Mortality Registry of the Health Department of Western Australia. This enabled cross checking of the date of death of patients, and the survival curves were calculated from this information.

Statistical analysis

The mean, standard deviation, and range were used as descriptive statistics. Survival was calculated using the Kaplan-Meier product-limit estimate of survival. The survival time was calculated from the time of initial surgery (or if no surgery was performed, from initial consultation) to either death or 1-12-2002. The survival analysis was an overall analysis and included patients dying - (1) in the 30 day postoperative period, (2) from colorectal cancer, or (3) from unrelated causes (e.g. myocardial infarct). Patients presenting with recurrent cancer were included in the survival analysis. Comparisons of the overall (all-cause mortality) survival data were made between the study groups using the log rank test and the Breslow-Gehan-Wilcoxon test. The latter test was chosen because it could give greater weight to times with more observations in the risk set, and was therefore less sensitive than the log rank test to late events when few subjects remained in the study. The Chi-square test was used in comparisons of nominal data.

A Cox proportional hazards model (Statview 5.0, SAS Institute Inc.) was then applied to identify those factors associated with the improved survival of patients with

colorectal cancer. The variables which were evaluated were: (1) patients age, (2) stage of disease, (3) location - colon versus rectum, (4) surgical timing - elective versus emergency, (5) surgical management group - colorectal group and the general surgical group versus the historical control group, (6) use of adjuvant chemotherapy, (7) use of adjuvant radiotherapy (8) ASA score. Those factors identified on univariate analysis as significant predictors of survival were then included in a forward multiple linear regression analysis (Statview 5.0, SAS Institute Inc.). Significance was defined as the probability of a type I error of less than 5 %.

RESULTS

There were 974 patients involved in this study. The basic demographic data for the study groups was detailed in Table 1. The only significant differences noted were that patients in the colorectal group were more likely to have a rectal cancer, and those patients in the colorectal group and general surgical groups were more likely to have an ASA score of 3 or 4 when compared with the controls. The mean follow up time in the colorectal group was shorter than that in the general surgical group. This was because the rate of referrals was increasing in the former and declining in the latter. For example, the general surgical group managed only 11 colorectal cancers during 2000.

Table 1 Basic demographic data for the study groups of patients with colorectal cancer

	Colorectal group	General surgical group	Historical group
Number	362	137	475
Mean age-years	69 (±12)	70 (±11)	69 (±13)
Age range-years	29 to 93	38 to 93	32 to 95
Sex ration M:F	1.3:1	1.4:1	1.4:1
ASA score of 3 or 4	40 %	39 %	22 %
Elective vs emergency procedures	319 vs 43 (88% vs 12%)	112 vs 25 (78% vs 18%)	394 vs 81 (79% vs 17%)
Curative vs palliative pesections	264 vs 80 (73 % vs 22%)	101 vs 23 (74 % vs 17%)	366 vs 85 (77 % vs 18%)
No surgery	18 (5%)	13 (9%)	24 (5%)
Colon cancer	170 (47%) ^a	90 (66%)	314 (66%)
Rectal cancer	192 (53%) ^b	47 (34%)	161 (34%)
Adjuvant chemotherapy	116 (32%) ^c	19 (14%)	17 (4%)
Adjuvant radiotherapy	65 (18%) ^d	9 (7%)	14 (4%)
Mean follow-up-years	2.75 (±1.2) ^e	4.5 (±1.4)	5.1 (±4.5)
Max follow-up-years	6.8	6.9	13.9

a,b,c,d,e,f $P < 0.05$ vs the other two group.

The information for staging for both colon and rectal cancers for the three groups was presented in Table 2. Patients in the colorectal group were significantly more likely to have a stage I cancer, and had significantly fewer stage II cancers, when compared with the other two groups. There was also a significant difference between the two groups in the use of adjuvant chemotherapy for patients who were less than 75 years of age and who had stage III colorectal cancers. For this group of patients, the percentage receiving adjuvant therapy was 89 % in the colorectal group, versus 41 % in the general surgery group, and 5.8 % in the historical group. For patients with stage II colorectal cancer, adjuvant chemotherapy was administered to 11 % of patients in the colorectal group, and no patients in the general surgery or historical groups. No patients with stage I cancer received adjuvant chemotherapy in either group.

Table 2 Staging information for colorectal cancers for the study groups

Stage	Colorectal group number (%)	General surgical group number (%)	Historical group number (%)
Stage I	81 (22 %) ^a	9 (7 %)	57 (12 %)
Stage II	95 (26 %) ^b	53 (39 %)	159 (33 %)
Stage III	91 (25 %)	41 (30 %)	146 (31 %)
Stage IV	91 (25 %)	29 (21 %)	106 (22 %)
Stage unknown	4 (1 %)	4 (3 %)	7 (2 %)

^{a,b} $P < 0.05$ vs the other two group with the Chi-square test.

A comparison of the survival between the study groups found that patients in the colorectal group had a significantly higher overall 5 year survival when compared with the general surgical group and historical groups (56 % versus 45 % and 40 % respectively, $P < 0.0001$). The survivals for the various study groups based on the tumour stage were presented in Table 3. Patients in the colorectal group who had either Stage I or Stage III cancers were noted to have significantly higher survivals when compared to the other two groups.

Table 3 A comparison of the overall 5 year survival based on stage for the study groups

Stage	Colorectal group	General surgical group	Historical group
I	90 % ^a	67 %	72 %
II	62 %	57 %	58 %
III	60 % ^b	46 %	34 %
IV (2 year survivals)	22 %	21 %	19 %

^{a,b} $P < 0.05$ vs the other two group.

In the uni-variate analysis, those factors that were found to be significant predictors of overall survival were: age, ASA score, emergency surgery, and stage of disease, adjuvant chemotherapy, adjuvant radiotherapy, and the surgical unit the patients were managed in. These independent variables were then entered into a multiple logistic regression analysis (Table 4) that identified: age, ASA score, stage of disease, the use of adjuvant chemotherapy, and management in the colorectal surgical group as significant independent predictors of survival. The comparisons for the surgical groups were made against the historical control group, with the general surgical group showing no improvement in survival when compared with the controls.

Table 4 Cox survival regression analysis of independent predictors of the overall survival in the 974 patients with colorectal cancer

Independent variables	<i>P</i>	Hazard ratio	95% Confidence interval
Age	0.15	1.011	1.002-1.020
ASA score	<0.0001	1.477	1.29-1.69
Adjuvant chemotherapy	0.047	0.634	0.405-0.993
Stage I	<0.0001	0.211	0.107-0.418
Stage II	0.003	0.397	0.214-0.738
Stage III	0.19	0.665	0.358-1.237
Stage IV	0.009	2.27	1.229-4.186
Colorectal surgical unit vs control	0.0005	0.667	0.531-0.837

DISCUSSION

The results of this study suggest that there was a survival advantage for patients with colorectal cancer being managed within a specialist colorectal surgical unit at a community based teaching hospital. These improvements in survival appear to be independent of other known predictors of survival that include stage of disease at presentation, emergency procedures, and the use of adjuvant chemotherapy. It remains to be determined as to why these differences exist. Do they simply reflect a higher surgical case load, or are they a result of improved surgical technique, better utilization of adjuvant therapy, or even standardized care through the use of treatment pathways?

There are a number of difficulties in designing a study to determine if there is a survival advantage in patients with colorectal cancer being managed by different groups of surgeons. A review of the surgical literature will show that rarely have clinical trials been conducted which compared the performance of different groups of surgeons. The logistics of trying to randomize patients into such a trial are very difficult. In this study, we have attempted to compare the risk adjusted survival of patients managed in general surgical units with those in a colorectal unit, and have compared these results with a well studied control group to see if there have been any improvements. Evaluating risk-adjusted survival in large cohorts of patients using historical controls is one recognized technique for addressing this issue. Clearly there were significant differences between the groups, with those patients in the colorectal group more likely to have Stage I disease and rectal cancers and with a trend towards fewer emergency procedures. However, the multivariate analysis is designed to account for these differences, and to include those factors that have been identified as independent predictors of survival. The individual surgeon was not included as an independent risk factor in this study because the majority of the general surgeons performed less than 20 cases during the study period. Such a small number makes it difficult to assess an individual surgeon's performance.

There have been a number of reports in the literature detailing wide variations in outcomes between surgeons managing patients with malignant disease^[1-3]. An important aspect to this variation appears to be case loads^[6-8]. In both patients with breast cancer^[6], oesophageal cancer^[7] and rectal cancer^[1], surgeons managing higher numbers of patients seem to gain improved results. A comprehensive review of the relationship between volume of surgical procedures and outcome has recently been published^[9,10]. This review assessed 88 studies and found that 77 % of the trials demonstrated a positive relationship between volume of work and reduced mortality, with the other 23 % of studies showing no relationship. None of the studies demonstrated a negative relationship.

The question of whether a surgeon who is sub-specialized in colorectal surgery can achieve improved results remains an unresolved issue. Porter *et al.*^[11], in their study on factors which influenced survival and local recurrence rates in patients treated for rectal cancer, found that surgeons who were trained in colorectal cancer had significantly improved survivals and reduced local recurrence rates when compared to general surgeons performing less than 21 procedures over the eight year study period. Nonetheless, their results were not significantly better than when compared to general surgeons performing greater than 21 procedures in the study period. Yet again this study focuses on rectal cancer and ignores colonic cancers. It remains to be determined whether these improvements relate to factors such as accuracy of tumour excision, minimizing tissue trauma, reduced incidence of septic

complications (which may influence cancer survival)^[11], and even possible to reduced blood loss and transfusion requirements.

In conclusion, there appears to be a survival advantage for patients with colorectal cancer being managed within a specialized colorectal unit. However, it remains to be determined which aspects of the management in such a unit are the most important determinates in this improvement in out-come.

Abstract

AIM: To evaluate the therapeutic efficiency of Tumor Necrosis Factor-related Apoptosis-inducing Ligand (TRAIL) gene on human colorectal cancer cell line HT29.

METHODS: Human embryonal kidney cells transformed by introducing sheared fragments of Ad5 DNA (293 cell) were used for amplification of adenoviral vectors: Ad/GT-TRAIL, Ad/GT-Bax, Ad/GT-LacZ and Ad/PGK-GV16. Human colorectal cancer cell line HT29 was transfected with binary adenovirus-mediated TRAIL gene. Bax gene was used as positive control, LacZ gene was used as the vector control, and cells treated with PBS only were used as a mock control. The morphological changes, cell growth and apoptosis were measured by reversmicroscope, MTT method and flow cytometry.

RESULTS: All adenoviral vectors titer determined by optical absorbency at A260nm were 1×10^{10} viral particle/ml(vp/ml). Obviously morphological changes of HT29 cells were observed when infected with Ad/GT-TRAIL, and these changes were much more obviously when Ad/PGK-GV16 was coinfectd. The cell suppression percentage and the percentage of apoptotic cells were 52.5 % and 16.5 % respectively when infected with Ad/GT-TRAIL alone, while combining with Ad/PGK-GV16, the growth of HT29 was suppressed by 85.2 % and the percentage of apoptotic cells was 35.9 %. It showed a significantly enhanced therapeutic efficiency with binary system ($P < 0.05$).

CONCLUSION: A binary adenoviral vector system provides an effective approach to amplify viral vectors that express potentially toxic gene, TRAIL. Ad/GT-TRAIL showed a significantly enhanced therapeutic efficiency for HT29 when coinfectd with Ad/PGK-GV16. Ad/GT-TRAIL could induce apoptosis of HT29 and inhibit its growth.

INTRODUCTION

Tumor necrosis factor-related apoptosis-inducing ligand, is also called Apo-2L, a new member of TNF family. It was first identified through a search of an expressed sequence tag (EST) database using a conserved sequence contained in many TNF family members. TRAIL is a type II transmembrane protein whose extracellular region forms a soluble molecule on cleavage. Both membrane-bound TRAIL and soluble TRAIL rapidly induce apoptosis in a wide variety of tumorigenic cells via interaction with the death receptors DR4 and DR5. However, unlike its relatives, TNF and CD95L, TRAIL appears to induce apoptosis only in tumorigenic or transformed or virus infected cells and not in normal cells. Because of its selective cellular toxicity, TRAIL may act as a safe agent for tumor gene therapy^[1,2]. In our experiment, human colorectal cancer cell line HT29 was transfected with binary adenovirus-mediated TRAIL gene. Bax gene was used as positive control, LacZ gene was used as the vector control, and cells treated with PBS only were used as a mock control. To evaluate the therapeutic efficiency of TRAIL on human colorectal cancer cell line HT29, reversmicroscope, MTT method and flow cytometry were used.

MATERIALS AND METHODS

Materials

Adenoviral vectors and cell lines: Ad/GT-TRAIL, Ad/GT-Bax, Ad/GT-LacZ and Ad/PGK-GV16 were presented by Dr. Bingliang Fang (Department of Thoracic and Cardiovascular surgery, The University of Texas M.D.Anderson Cancer center). Human embryonal kidney cells transformed by introducing sheared fragments of Ad5 DNA (293 cell) was maintained in our laboratory (Clinical research institute of Sir Run Run Shaw Hospital, Zhejiang University). Human colorectal cancer cell line HT29, a kind gift from Dr. Junhui Cui (Medical School, Zhejiang University).

Methods

Construction, amplification and titration of adenoviruses^[3]

Adenoviral vectors Ad/GT-Bax, Ad/GT-LacZ and Ad/PGK-GV16 were constructed as described previously^[14]. Ad/GT-TRAIL, an adenoviral vector expressing TRAIL, was also constructed. Briefly, a cDNA containing the entire coding sequence of human TRAIL was inserted into an expression cassette driven by a GT promoter to generate shuttle plasmid pAd/GT-TRAIL. This shuttle plasmid was then cotransfected into 293 cells along with a 35-kb ClaI fragment from adenovirus type 5. Then, recombinant vector Ad/GT-TRAIL was generated by homologous recombination and plaque-purified. To produce large quantities of the virus, when 293 cells (transformed primary human embryonal kidney cells) are grown to 60-70 % confluency on 75 cm² bottle, the media were changed using RPMI1640 supplemented with 10 % FBS and antibiotics. Purified virus is added to the bottles at a multiplicity of infection (MOI) of 100:1. Every 15 min gently rock the bottles to redistribute the liquid over the entire bottle, and rotate the bottles to allow for even distribution of the viral

suspension. After one hour incubation, add 15 ml fresh media to each bottle. Incubate the bottles in a 37 °C, 5 % CO₂ incubator for 48-72 h, harvest the cells when a complete cytopathic effect (CPE) is evident (95-100 % cells rounded with 10-20 % floating). The cells should be lifted off the bottle by gently pipetting medium over them and collect cells into 50 ml centrifuge tubes. Centrifuge in a clinical centrifuge at room temperature for 3-4 min at 1 500 rpm. The supernatant may be placed directly at -70 °C for further infection. The cell pellet may also be placed directly at -70 °C until ready for purification. After three cycles of freeze-thaw the cell pellets, remove the cellular debris by centrifuging in a clinical centrifuge at 2 500 rpm for 5 min. The titer determined by the absorbency of the dissociated virus at A260 nm (one A260 nm unit=10¹² viral particles/ml) was used in this study. All of the viral preparations were found to be free of the E1+ adenovirus by PCR assay and endotoxin by testing with a Limulus ameocyte lysate endotoxin detection kit.

MTT assay of cell growth

Cell growth was measured by MTT methods. Cells were seeded onto 96-well plates at a density of 10⁴ in 100 µl of medium per well. When HT29 cells were grown to 80 % confluency, PBS, Ad/GT-LacZ, Ad/GT-Bax, Ad/GT-TRAIL, Ad/GT-LacZ+Ad/PGK-GV16 (1:1), Ad/GT-Bax+Ad/PGK-GV16 (1:1), Ad/GT-TRAIL+Ad/PGK-GV16 (1:1) were added respectively. The optimal MOI was determined by infecting HT29 cell with Ad/GT-LacZ+Ad/PGK-GV16 (1:1) and assessing the expression of β-galactosidase via X-gal staining. The MOI that resulted in >85 % of cells being stained blue were used in this experiment. The MOI was 1 000 particles for HT29 cells. Unless otherwise specified, Bax was used as positive control, LacZ was used as the vector control, and cells treated with PBS only were used as a mock control. At 0, 1 d, 3 d and 5 d, cells were incubated with 0.5 % MTT for 4 hours. The medium was then removed and 150 µl DMSO solution was added, followed by incubation at 37 °C for another 4 hours. The absorbance of the reaction solution at 490 nm was measured. These data were used to make growth curves. The cell suppression percentage=(1-absorbance of experimental group/absorbance of control group)×100 %.

Assay of apoptosis (FCM)

HT29 cells were seeded onto 6-well plates at a density of 4×10⁶ in 2.5 ml of medium per well. The cells were given the same treatment as we did in the MTT assay. The MOI was 1 000, reverse microscope was used to watch the morphological changes. Cells were harvested by trypsinization at 5 d after treatment, then FCM analysis for cell surface molecules was performed using Annexin V Kit (Immunotech, Annexin-FITC), according to the following procedure: wash cells twice with cold PBS, resuspend cells in 1×Binding Buffer at a concentration of 1×10⁶cells/ml, transfer 100 µl to a 5 ml culture tube, add 5 µl Annexin V-FITC and 10 µlPI, gently vortex the tube and incubate for 15 min at room temperature in the dark, add 400 µl 1×Binding Buffer to each tube, analyze by flow cytometry as soon as possible (within one hour). PI/Annexin V-negative cells were regarded as living cells; PI-positive/Annexin-negative cells were regarded as injured ones; PI-negative/Annexin V-positive cells were regarded as early apoptotic cells; PI/Annexin V-positive cells were regarded as late apoptotic or secondary necrotic ones.

Statistical analysis

Differences among the treatment groups were assessed by paired *t*-test using SPSS10.0 statistical software. *P*<0.05 indicates significant difference.

RESULTS

Titers of recombinant adenovirus

All adenoviral vectors titer determined by optical absorbency at A260nm were 1×10¹⁰ viral particle/ml(vp/ml).

Morphological changes of recombinant adenovirus on HT29 cell

When HT29 were transfected with Ad/GT-TRAIL, Ad/GT-Bax, obviously morphological changes of HT29 were found. These changes were found to be much more early and obviously when Ad/PGK-GV16 was cultured together. Over 80 % of the cells showed signs of cytopathology, and became rounded and detached. However, when HT29 were transfected with Ad/GT-LacZ, Ad/GT-LacZ+Ad/PGK-GV16, no significant morphological changes were found, the cells remained in monolayers with normal morphology.

Cell growth inhibition of recombinant adenovirus on HT29 cell

Cell viability was measured by MTT assay as showed in Figure 1 and Figure 2. Cultured with Ad/GT-TRAIL, Ad/GT-Bax, Ad/GT-LacZ, the cell growth of HT29 was inhibited by 52.5 %, 30.3 % and 10.5 % respectively (Table 1). When Ad/PGK-GV16 was added, the cell growth inhibition rates were 85.2 %, 61.5 % and 12.1 % respectively (Table 2). There were significant difference between TRAIL, Bax and LacZ, and PBS treatment, Ad/GT-TRAIL and Ad/GT-TRAIL+ Ad/PGK-GV16, Ad/GT-Bax and Ad/GT-Bax+ Ad/PGK-GV16 (*P*<0.05). There were also shown significant difference between TRAIL and Bax treatment when combined with Ad/PGK-GV16. The result showed TRAIL was more efficient to inhibit cell growth than Bax on HT29.

Table 1 Cell growth inhibition of recombinant adenovirus on HT29 cell

Group	OD ($\bar{x}\pm s$)	Cell growth inhibition rates (%)
Ad/GT-TRAIL	0.57±0.12 ^{ac}	52.5
Ad/GT-Bax	0.84±0.08 ^a	30.3
Ad/GT-LacZ	1.07±0.13	10.5
PBS	1.20±0.17	0.0

^a*P*<0.05, vs LacZ, PBS groups; ^c*P*<0.05, vs Bax group.

Table 2 Cell growth inhibition of recombinant adenovirus on HT29 cell when combined with Ad/PGK-GV16

Group	OD ($\bar{x}\pm s$)	Cell growth inhibition rates (%)
Ad/GT-TRAIL+Ad/PGK-GV16	0.18±0.03 ^{ac}	85.2
Ad/GT-Bax +Ad/PGK-GV16	0.46±0.09 ^a	61.5
Ad/GT-LacZ +Ad/PGK-GV16	1.05±0.07	12.1
PBS	1.20±0.17	0.0

^a*P*<0.05, vs LacZ, PBS groups; ^c*P*<0.01, vs Bax group.

Apoptosis detected by flow cytometry

Apoptosis was detected by flow cytometry (Figure 3). The percentage of apoptotic cells treated with Ad/GT-TRAIL, Ad/GT-Bax, Ad/GT-LacZ and PBS (120 h after treatment) were 16.5 %, 14.7 %, 7.45 %, and 6.15 % respectively (Table 3). There were significant difference between Ad/GT-TRAIL, Ad/GT-Bax and Ad/GT-LacZ, PBS group (*P*<0.05). When combined with Ad/PGK-GV16, the percentage of apoptotic cells were significantly increased (*P*<0.05), 35.9 %, 29.0 % and 11.2 % respectively (Table 4). There were no significant difference between Ad/GT-TRAIL and Ad/GT-Bax treatment,

but there were significant difference between Ad/GT-TRAIL+Ad/PGK-GV16, Ad/GT-Bax+Ad/PGK-GV16 and Ad/GT-LacZ+Ad/PGK-GV16, PBS treatment ($P<0.01$).

Table 3 The percentage of apoptotic cells of recombinant adenovirus on HT29 cell after 5 d treatment

Group	The percentage of apoptotic cells (% , $\bar{x}\pm s$)
Ad/GT-TRAIL	16.50 \pm 1.13 ^a
Ad/GT-Bax	14.70 \pm 0.46 ^a
Ad/GT-LacZ	7.45 \pm 0.75
PBS	6.15 \pm 0.23

^a $P<0.05$, compared with LacZ, PBS groups.

Table 4 The percentage of apoptotic cells of recombinant adenovirus on HT29 cell when combined with Ad/PGK-GV16 after 5 d treatment

Group	The percentage of apoptotic cells (% , $\bar{x}\pm s$)
Ad/GT-TRAIL+Ad/PGK-GV16	35.90 \pm 1.32 ^a
Ad/GT-Bax+Ad/PGK-GV16	29.00 \pm 1.66 ^a
Ad/GT-LacZ+Ad/PGK-GV16	11.23 \pm 1.14
PBS	6.15 \pm 0.23

^a $P<0.01$, compared with LacZ, PBS groups.

DISCUSSION

Colorectal cancer is one of the malignant tumors that threaten human life severely. The main treatments of colorectal cancer are surgical resection, chemotherapy and radiotherapy. Because of local recurrence and metastasis, the 5-year survival rate after surgical resection is about 50 %. Gene therapy is a new method of introducing genetic material into cells developed in modern medicine and molecular biology. It is certain that occurrence of colorectal cancer is the result of interaction between hereditary and environmental factors, research on colorectal gene therapy has been undertaken in recent years, including suicide gene therapy (HSV-TK/GCV system, CD/5-FC system), tumor suppressor gene, immunogene therapy and anti-VEGF gene therapy. The idea of them is to induce apoptosis of tumor cells^[4-9].

Tumor necrosis factor-related apoptosis-inducing ligand (TRAIL), which is a new member of the TNF family, showed a promising result for tumor gene therapy because of its selective cytotoxic effect. TRAIL is present on many normal cell surfaces. It appears to induce apoptosis only in tumorigenic or transformed cells or virus infected cells but not in normal cells^[10,11]. It has five receptors: DR4^[12], DR5^[13], DcR1^[14], DcR2^[15], OPG^[16] (Osteoprotegerin). Both member-bound TRAIL and soluble TRAIL induce apoptosis rapidly via interaction with death receptors DR4, DR5. DcR1, with no death domain and DcR2, with a truncated death domain are not capable of inducing apoptosis, however by competing for TRAIL, they are capable of inhibiting TRAIL-induced apoptosis, thereby protecting normal cells from the cytotoxic effect^[17,18]. In addition, it is important for tumor gene therapy that TRAIL may elicit bystander effects either through interaction of surface TRAIL molecules with receptors on neighboring cells or through the action of soluble TRAIL from the TRAIL-expressing cells^[19].

Recent studies showed that TRAIL induced apoptosis in a wide variety of tumor cell lines, both *in vitro* and *in vivo*. Because of the TRAIL gene's high apoptotic activity and its toxic effect on packaging 293 cells, constructing an adenoviral vector that can express TRAIL remain to be a problem. In this study, we constructed adenoviral vectors expressing the human TRAIL gene using a binary vector system that allows expression of a highly apoptotic gene. Briefly, the TRAIL gene's promoter was replaced by GT, a synthetic promoter consisting of five GAL4-binding sites and a TATA box, which has very low transcriptional activity *in vitro* and *in vivo* when placed in an adenoviral backbone. Moreover, the transgene activity can be substantially induced *in vitro* and *in vivo* by administering this construct along with an adenoviral vector (Ad/PGK-GV16) expressing a GT transactivator, namely, the GAL4-VP16 fusion protein^[20]. This means TRAIL protein expression could be induced by coinfecting target cells with Ad/GT-TRAIL and Ad/PGK-GV16. One potential problem that may arise in using this system is that not all the target cells may be transduced by both the transgene-expressing and transactivator-expressing vector. Our early study showed *in vitro* transduction of H1299 cells with Ad/CMV-LacZ or Ad/GT-LacZ+Ad/PGK-GV16 (1:1) at the same MOI showed equivalent blue cells by X-gal staining, which suggested that transduction efficiency may not be hampered by using two vectors. The binary adenoviral vector system was effective for expressing high levels of the proapoptotic gene, it was also confirmed in Bax gene study^[21]. Here Bax gene was used as positive control. The results showed Ad/GT-TRAIL and Ad/GT-Bax were able to induce apoptosis of HT29 and inhibit its growth. When combined with Ad/PGK-GV16, the effects were enhanced significantly, it was testified again that the binary adenoviral vector system was simple and effective for

expressing high levels of the proapoptotic gene. This method may provide an alternative approach for colorectal cancer biotherapy. Our result also provides experimental evidences for preclinical research on colorectal cancer gene therapy. There are several advantages using adenoviral vector: high transduction efficiency; high expression of report gene; high viral titer; simpler to construct recombinant virus; insert size up to 8kb. Direct intratumoral injection of recombinant adenoviral vector can induce tumor cell apoptosis, suppress tumor progression and even ablate the tumor with TRAIL gene's antitumor and bystander effect. Recent studies showed that repeated i.v. injection of recombinant and biologically active TRAIL induced tumor cell apoptosis, suppressed tumor progression, and improved survival in mice bearing colorectal cancer model (DLD-1), with no detectable toxicity^[19]. Whereas toxic effects of TRAIL on human hepatocytes *in vitro* were observed, concern must be raised about the potential toxicity of TRAIL, especially when administered systemically. A non-tagged, soluble, native-sequence form of TRAIL (amino acids 114-281) failed to induce hepatotoxicity in cynomolgus monkeys^[10]. A recombinant, soluble version of the ligand fused to a trimerizing leucine zipper (amino acids 95-281) also lacked hepatotoxicity in mice^[11]. More recently, a polyhistidine-tagged recombinant soluble form of TRAIL (amino acids 114-281) was reported to induce apoptosis in cultured human hepatocytes^[22]. Although the recent report of hepatocyte death after treatment with TRAIL *in vitro* must be taken seriously, it is important that the limitations of the model system used in these experiments are also understood^[23]. Fortunately, further research showed that the proapoptotic activity of the TRAIL gene is mainly elicited via membrane-bound TRAIL, and soluble factors contribute little to antitumor and bystander effect. The possible explanation is that the effects of the soluble TRAIL may be dose-dependent, conformation-dependent. It has been reported that only the trimerized recombinant TRAIL is the most effective. With direct intratumoral injection of TRAIL, the release of soluble TRAIL from such TRAIL-expressing tumor cells is not substantial enough to cause liver damage, and toxicity may be reduced by vector-targeting strategies. TRAIL has a strong bystander effect, but our preliminary data showed the bystander effect was mediated by the membrane-bound TRAIL, and it was cell-contact dependent. Therefore, efficient delivery of the TRAIL gene into as many cancer cells as possible is still an important goal in treating cancer patients.

Although our data showed TRAIL and Bax gene can significantly inhibit the growth of HT29, the percentage of apoptotic cell are not very high. It has been shown that different kinds of tumors, even different cell lines of the same tumor have different sensitivity to TRAIL, which had relation to level of FLIP, low expression or mutation or loss of DR4 gene, activation or not of NF- κ B, overexpression of Bcl-2, etc. However with the addition of chemotherapeutic agent or immunoregulator^[24-26], TRAIL-resistant tumor cells recovered its sensitivity to TRAIL. For examples, addition of actinomycin D to TRAIL-resistant melanomas resulted in decreased intracellular concentrations of FLIP, which correlated with their acquisition of TRAIL sensitivity^[27]. The same results were found, when treated with Doxorubicin or 5-Fu to induce apoptosis of breast cancer, Doxorubicin or Camptothecin to human hepatocellular carcinoma dramatically augmented TRAIL-induced cytotoxicity^[28]. In experiment of the antitumor activity of recombinant TRAIL on mice bearing human colon carcinoma, Gliniak^[29] found that these tumors displayed a differential sensitivity to TRAIL *in vivo* that paralleled their susceptibility to TRAIL-induced apoptosis *in vitro*. It demonstrated that TRAIL alone was a potent antitumor agent *in vivo*, and its activity could be significantly enhanced in

combination with the chemotherapeutic agent CPT-11. However, one of these reports also mentioned that normal cells could be sensitized to TRAIL-induced apoptosis^[30]. This suggests that such a combination treatment may also increase toxicity. Nevertheless such an increase in toxicity in response to this combination therapy may be avoided if TRAIL expression can be limited locally to tumors. With the combination of TRAIL and chemotherapy, the dose of chemotherapeutic agent could be reduced, and thus decreased the side effects of chemotherapy. In order to explore a more effective approach to deliver TRAIL gene for colorectal treatment, or to evaluate the effect of TRAIL gene on liver metastasis (through liver metastasis models of human colorectal carcinoma established in nude mice)^[31], further research on it is necessary.

Abstract

AIM: To discuss the rationality of extended radical resection (ERR) and to guide the surgical treatment of rectal cancer.

METHODS: Total 211 patients who underwent ERR from 1981 to 1987 (follow-up rate of 94.8 %) were selected to study the patterns of lymphatic metastasis and therapeutic effect. The control group was made of 293 patients with rectal cancer who underwent conventional radical resection (CRR) and its follow-up rate was 98.5 %. The lymph node specimens, obtained by the triple-approach lymph node resection during the radical resection of rectal cancer, were studied by conventional pathological method. The extended radical resection, guided by the patterns of lymphatic metastasis, was applied in the clinical practice.

RESULTS: The incidence of lymphatic metastasis in Chinese patients with advanced rectal cancer was 43.6 %, and that of the upper 2nd and 3rd groups and the lateral group was 14.2 %, 10.9 % and 11 % respectively. The 5, 10-year-survival rates of the ERR were 68.0 % and 47.0 %, respectively, which were much higher than those of the conventional radical resection (42.9 % and 25.3 %).

CONCLUSION: The ERR for rectal cancer removes all the lymph nodes, prevents possible metastasis and finally improves the survival rate.

INTRODUCTION

Early in 1970s, the opinion for extended radical resection (ERR) of rectal cancer, which was suggested by some Japanese scholars, caused great controversy among the scholars who majored in colorectal cancer all over the world. In 1980s, to study the rationality of surgical treatment for Chinese rectal cancer, our hospital first got the patterns of lymphatic metastasis in Chinese rectal cancer with studying rectal normal lymphatic drainage and lymphatic metastasis of rectal cancer. And the EER, guided by the patterns of lymphatic metastasis, has been applied in our hospital for about 20 years. These caused a lot of controversy as well. Here, the patterns of

lymphatic metastasis in rectal cancer and therapeutic effect of ERR are reviewed and analyzed, then the scholar's doubts are discussed.

MATERIALS AND METHODS

Materials

All cases of advanced rectal cancer were received and treated in our hospital. 211 cases used to study the patterns of lymphatic metastasis and therapeutic effect were chosen within the patients who underwent ERR (include all upper and lateral lymph nodes cleaning) from 1981 to 1987 (follow-up rate of 94.8 %). The control group was made of 293 cases that underwent conventional radical resection (CRR) and its follow-up rate was 98.5 %. Between two groups, there was no significant difference in the clinical data such as location, pathological type, degree of infiltration, lymphatic metastasis and so on.

Methods

During operation, the upper lymph nodes were resected from the root of inferior mesenteric artery. The periaorta lymph nodes were cleaned partially. Then the lymph nodes around common, internal and external iliac arteries were resected, as well as those of obturator foramen. The inferior mesenteric artery or superior rectal artery and middle rectal artery was ligated and cut off at the root. And the rectal lateral ligament was cut off along the pelvic wall. In the Miles operation, the levator muscle of anus was cut off along the pelvic wall as well. And the connective tissue in the ischioanal fossa should be cleaned.

These lymph nodes included those of perirectum, superior rectal artery, inferior mesenteric artery and its root, middle rectal artery, and external iliac artery, common iliac artery, obturator, aorta, inferior vena cava and deep inguinal.

The lymph nodes were collected by touch and modified transparent methods. Both the nodes and the primary locus were analyzed by conventional pathological method. The survival rate of both groups was compared by direct method.

RESULTS

The patterns of lymphatic metastasis

Total 6894 lymph nodes were collected among 211 patients who underwent the extended radical resection, 32.7 nodes per patient in average. There were 92 cases (43.6 %) and 616 nodes (8.9 %) with metastasis. The metastasis rate of upper 2nd and 3rd group was respectively 14.2 % and 10.9 %. 16 cases of rectal cancer below the peritoneum reflex had lateral metastasis (11 %). The metastasis rate of the cases with $>1/2$ rectal circumference involved was 53.7 %, and that with $<1/2$ circumference involved was 26.7 % ($P<0.01$). The metastasis rate of the cases with serosal invasion was 63.5 %, and that of muscular invasion was 26.0 % ($P<0.01$). The metastasis rate of the cases with invasive type was 58.9 %, local type 32.3 % ($P<0.01$). Poorly differentiated and mucinous adenocarcinoma had a metastasis rate of 68.6%, well and moderately differentiated ones 31.8 % ($P<0.01$), invasive type of growth 70.0 %, and expanding type of growth 22.9 % ($P<0.01$). (Tables 1-5).

Table 1 Relationship between lymphatic metastasis and invasive rate

Circumference	<i>n</i>	Lymphatic metastasis (-)	Lymphatic metastasis (+)	Positive rate (%)

^e*P*<0.01, vs. expanding type.**Table 6** Survival rate of extend radical resection (ERR) and conventional radical resection (CRR)

	<i>n</i> ₁	5-year-survival rate	<i>n</i> ₂	10-year-survival rate
Dukes A				
CRR	54/103	52.4 %	16/55	29.1 %
ERR	63/73	86.3 %	5/9	55.69 %
Dukes B				
CRR	32/71	45.1 %	12/43	27.9 %
ERR	28/47	59.5 %	1/3	33.3 %
Dukes C				
CRR	38/115	33.0 %	12/60	20.0 %
ERR	52/91	57.1 %	2/12	40.0 %
Total				
CRR	124/289	42.9 %	40/158	25.3 %
ERR	136/200	68.0 %	8/17	47.0 %

The therapeutic effect of the ERR

Table 6 shows that the 5- and 10-year-survival rate of patients with advanced rectal cancer who underwent ERR (68.0 % and 47.0 %) is obvious higher than that of patients with CRR (42.9 % and 25.3 %), *P*<0.05.

DISCUSSION

The lymphatic drainage of rectum and the patterns of lymphatic metastasis of rectal cancer

The research on anatomy of rectum^[1,16,19,36] had played an important role in operation of rectal cancer. Numbers of researches have showed that there are three routes of lymphatic drainage. The upper way drains the lymph of the whole anorectum, the lateral one drains that of the anal canal and the rectum below the level of peritoneal reflection, and inferior one only drains that of the anal canal^[1]. Then this result of the anatomic research has been used to guide the operations in clinical practice^[2-6, 17, 20, 23, 28,37]. Early in 1980s, our hospital first began to study the principle of lymphatic metastasis in Chinese patients with rectal cancer and showed that lymphatic metastasis followed the normal lymphatic drainage^[6, 27].

The ERR

According to the patterns, we concluded that ERR could be used for advanced rectal cancer. During cleaning of lymphatic tissue, the upper level of the cleaning should reach the root of inferior mesenteric artery, or 10 % lymphatic metastasis would have been left. For the rectal cancer beneath the level of peritoneal reflection, the lateral cleaning with internal iliac artery and obturator nodes should be carried out, or else another 10 % would have been left.

The indications for EER should be fitful. The advanced rectal cancer with no transperitoneal and distant metastasis and the one with the local invasion but resectable would be preferred. The patients must have no serious disease and could endure the surgical operation and the anaesthesia. The ERR cleaned all the upper, lateral and partial lower lymphatic tissue with potential metastasis, and thus improve the survival rate^[7, 8, 26].

The influence of EER to the immune function

For the extended radical resection, the experts in the field of rectal cancer wondered whether the cleaning of the lymphatic tissue affected the immune function of the patients. So we carried out the comparative study of the immune function, which included the "E" wreath test and the IgA, IgG, IgE determination before operation and after operation. And the results showed that the ERR have no negative influence of the immune reaction.

The problem about how to clean all the nodes with metastasis and maintain the normal ones

It was not always correct to judge whether it metastasize or not with nude eyes. That is to say, we could not confirm the Dukes stage of the rectal cancer during the operation. The misdiagnosis rate is about 25 %. The lymphatic micrometastasis^[30-32] of rectal cancer, that was a new challenge for judging the lymphatic metastasis, was investigated by Silva^[25] and Sterk *et al*^[35] using lymphoscintigraphy and lymphangiography^[34], but there is still controversy^[34]. Still now, there is no effective method to judge whether lymphatic metastasis took place in one lymph node during the operation yet^[38].

Key points of studying the principle of lymphatic metastasis

In the European scholar's studies, the metastasis rate was not so high and that of lateral way was only 2 %. But the Japanese scholars showed that the metastasis rate was 10-20 %. There

was a significant difference between them. So we thought the following conditions should be important to study the patterns of lymphatic metastasis: 1. The quantity of lymphatic nodes resected during the operation must be enough to study. 2. All the nodes should be checked out by use of correct methods. 3. The careful pathological examination should be carried out.

Whether ERR would cause more bleeding and trauma

According to our statistics, the average quantity of blood transfusion in ERR was 760 ml, and that of conventional radical resection was 700 ml. There was no significant difference between them. The common damages in rectal operation included the injuries of ureter, sacral venous plexus and pelvis autonomic nerve. During the operation, the ureters were dissociated for about 20 cm, and then the resection of lymphatic nodes was carried out directly in sight. In our study, the ureter-injury rate in the extended resection was 1.4 % (3/211), and that in the conventional radical resection was 1.7 % (5/289). There was no significant difference between the both groups. The ischemia and necrosis caused by insufficient ureter dissociation never took place in our study. To avoid the injury of sacral venous plexus, we should get familiar with the anatomy of pelvis and operate directly in sight.

Early in 1980s, Japanese experts made lots of researches on preventing these complications^[9,10,18,33]. We also began to carry out the ERR with pelvis autonomic nerve reservation from 1988. And the rate of post-operative bladder and sex dysfunction was effectively reduced. The western scholars such as Mass *et al*^[24] and Di Matteo *et al*^[29] had drawn the similar conclusions. So we ensured that the functional ERR should be one of the most satisfactory operations for advanced rectal cancer.

The relationship between the functional ERR and the total mesenteric excision (TME)

TME^[11-13] was recently paid attention to by the scholars^[15,21,22,26] all over the world. Japanese experts^[14,26] divided the cleaning of perirectal connective tissue into three regions, A, B and C, and TME was similar to A region only^[14]. Our opinion is that TME should be one portion of the functional preserved EER. Early in 1980s, when ERR was established, we mentioned that total perirectal connective tissue should be resected along the lateral wall of pelvis, so did in Miles operation. In low anterior resection (LAR) operation, the perirectal connective tissue should be resected at least beneath the lower transect of the rectum. Therefore we believe that a throughout ERR should include TME.

Abstract

AIM: To identify the role of survivin in colorectal carcinogenesis and the relationship between Survivin and histological differentiation grade of colorectal carcinoma.

METHODS: Immunohistochemical staining of survivin by using the monoclonal antibody was performed by the standard streptavidin-peroxidase (SP) technique for the 188 paraffin sections which included 30 normal colorectal mucosas, 41 adenomas with low grade dysplasia, 30 adenomas with high grade dysplasia, and 87 colorectal carcinomas which were classified as high, middle and low differentiated subgroups which included 33, 28, 26 cases respectively.

RESULTS: Expression of survivin was observed in the cytoplasm of adenoma with dysplasia and colorectal carcinoma cells. No immunoreactivity of survivin was seen in normal mucosas. The positive rate of survivin increased in the transition from normal mucosas to adenomas with low grade dysplasia to high grade dysplasia/ carcinomas (0.0 %, 31.7 %, 56.7 % and 63.2% respectively). But the difference between high grade dysplasia and carcinomas had no statistical significance. Positive rate was not related to histological differentiation grade of colorectal carcinoma. Moreover, there was no correlation between histological differentiation grade of colorectal carcinoma and immunoreactive intensity of survivin.

CONCLUSION: The expression of survivin is the essential event in the early stage of colorectal carcinogenesis and plays an important role in the transition sequence and it is not related to histological differentiation grade of colorectal carcinoma. It thus may provide a new diagnostic and therapeutic target in colorectal cancer.

INTRODUCTION

Disturbance of apoptosis is thought to be very important in neoplastic transformation and progression. Several tumor

suppressor genes and oncogenes, such as p53 and the bcl-2 family, are involved in regulation of cell apoptosis, which were thoroughly studied^[1-12]. Moreover, a gene family of inhibitor of apoptosis (IAP) has been identified recently. Survivin, a novel member of IAP family, directly inhibits caspase-3 and -7 activity^[13] or conjugates caspase-9^[14], and regulates the cell cycle in the G2/M phase by interact with spindle microtubules^[15]. Survivin shows markedly different tissue expression compared with other IAPs. It is present during embryonic and fetal development, but is downregulated in normal adult tissues. However, it becomes re-expressed in a variety of cancers^[16-20]. The unique feature makes it attractive as a target for cancer therapy^[21]. In this study, we sought to investigate the expression of survivin in normal colorectal mucosas, adenomas with low grade dysplasia, adenomas with high grade dysplasia, and colorectal carcinomas by immunohistochemical staining method in order to identify the role of survivin in colorectal carcinogenesis and the relationship between survivin and histological differentiation grade of colorectal carcinoma.

MATERIALS AND METHODS

Tissue samples

Tissue specimens used for this study were obtained from 188 patients which were resected surgically or endoscopically at the 2nd Hospital Affiliated to China Medical University from 1998 to 2002. There were 105 males and 83 females, and the mean age of the patients was 56.2 years. Materials were composed of 30 cases of normal colorectal mucosas, 41 cases of adenomas with low grade dysplasia, 30 cases of adenomas with high grade dysplasia, and 87 cases of colorectal carcinomas, their mean ages were 52.3, 55.4, 57.9 and 57.4 respectively. According to histological differentiation grade, 87 cases of colorectal carcinoma were classified to high, middle and low differentiated subgroups which included 33, 28, 26 cases and the mean ages were 62.0, 57.9, and 51.1 respectively. The patients had received neither chemotherapy nor radiation therapy before tumor resection.

Methods

Routinely processed formalin fixed, paraffin embedded, serial sections of 5 µm were prepared from the cut surface of blocks at the maximum cross-section. For morphologic analysis, tissue sections were routinely stained with hematoxylin and eosin. At least 2 experienced pathologists studied the sections. The immunohisto- chemical staining for survivin antigen was carried out by the standard streptavidin /peroxidase (SP) technique. Briefly, before labeling with primary antibody, paraffin sections were dewaxed, and then incubated with 30 ml/L hydrogen peroxide for 10 minutes, and antigen retrieval was performed by boiling in EDTA (0.01M, pH7.4). The sections were cooled and washed in PBS. Nonspecific reactions were blocked by incubating the sections in a solution containing normal serum. The sections were incubated with a primary antibody overnight at 4 °C. The anti-survivin antibody was sc-8806 antibody (Sant Cruz Biotechnology, Inc) at a 1:50 dilution. Rinsed with PBS, then the sections were incubated for 30 minutes at 37 °C with biotinylated

secondary antibody and streptavidin conjugated to horseradish peroxidase, respectively. After three rinses with PBS, the sections were incubated with diaminobenzidine substrate, then rinsed with distilled water and counterstained with hematoxylin.

Scoring criteria

The mean percentage of positive cells for the expression of survivin was determined in at least 5 areas at 400-fold magnification, and cases with less than 10 % positively stained cells were defined as negative. Cases with 10 to 29 % positively stained cells were defined as “+”, 30 to 59 % as “++”, and 60 % or more than 60 % as “+++”. These scorings were performed in a blinded fashion.

Statistical analysis

The difference and correlation were analyzed by χ^2 test. A value of $P < 0.05$ was considered statistically significant.

RESULTS

By immunohistochemical staining, we examined the expression of survivin in adenoma-carcinoma sequence. Representative results were shown in Figure 1. The expression of survivin was observed in the cytoplasm of the benign and malignant tumor cells, whereas not in normal tissues. As shown in Table 1, the positive rate for survivin expression increased gradually from normal colorectal mucosas to adenomas with low grade dysplasia, adenomas with high grade dysplasia, and carcinomas. The expression rates were 0.0 %, 31.7 %, 56.7 %, and 63.2 % respectively. Analyzed by χ^2 test, there were significant differences in the expressions of survivin between the normal mucosas group and any one of the other groups, between adenomas with low grade dysplasia and carcinomas, and between adenomas with low grade dysplasia and adenomas with high grade dysplasia ($P < 0.05$), while there were no significant differences between adenomas with high grade dysplasia and carcinomas ($\chi^2 = 0.40$, $0.5 < P < 0.75$).

Figure 1 Immunohistochemical staining of survivin in adenoma-carcinoma sequence. The expression of survivin was observed in the cytoplasm of the benign and malignant tumor cells, whereas not in normal tissues. N: normal tissue. D: adenoma with dysplasia; C: carcinoma; 1: $\times 200$ fold; 2: $\times 400$ fold.

Table 1 Expression of survivin in the colorectal carcinogenesis

Lesion	n	Expression intensity				Expression rate %
		-	+	++	+++	
Normal mucosas	30	30	0	0	0	0.0
Adenomas with low grade dysplasia	41	28	7	5	0	31.7
Adenomas with high grade dysplasia	30	13	3	7	7	56.7
Carcinomas	87	32	8	20	27	63.2

To study the relationship between survivin and histological differentiation grade of colorectal carcinoma, 87 cases of colorectal carcinoma were classified to high, middle and low differentiated subgroups. The results were shown in Table 2. Analyzed by χ^2 test, there were no significant differences in the expressions of survivin among the subgroups ($P>0.90$). Moreover, there was no relationship between the differentiation grade of colorectal carcinoma and the expression intensity ($P>0.75$).

Table 2 Correlation between the differentiation grade of colorectal carcinoma and the expression intensity of survivin

Lesion	n	Expression intensity				Expression rate %
		-	+	++	+++	
High differentiation	33	12	3	10	8	63.6
Middle differentiation	28	11	2	4	11	60.7
Low differentiation	26	9	3	6	8	65.4
Total	87	32	8	20	27	63.2

DISCUSSION

The development of colorectal carcinoma proceeds through a series of genetic changes involving the activation of oncogenes and loss of tumor suppressor genes. During this process, a disturbance in the balance between cell proliferation and apoptosis may underlie neoplastic development. Previous investigations have well studied the role of p53 and bcl-2 family^[1-12]. The IAPs is a widely expressed gene family of apoptosis inhibitors. Survivin, a novel and structurally unique member of the IAP gene family, is the strongest apoptosis inhibitor. A characteristic finding of survivin is that it is expressed during embryonic and fetal development but not in normal adult differentiated tissues, and prominently reexpressed in the most common human carcinomas. The mechanism is unclear. In this study, we aimed to identify the role of survivin in colorectal carcinogenesis and the relationship between survivin and histological differentiation grade of colorectal carcinoma.

In our study, we demonstrated that survivin was not expressed in normal colorectal mucosas, which coincided with previous reports. The expression of survivin was localized in the cytoplasm of the adenoma and carcinoma cells, and the positive rate for survivin expression increased gradually from normal colorectal mucosas to adenomas with low grade dysplasia, adenomas with high grade dysplasia, and to carcinomas. The expression rates were 0.0 %, 31.7 %, 56.7 % and 63.2 % respectively. Analyzed by χ^2 test, there were significant differences in the expressions of survivin between the normal mucosa group and any one of the other groups ($P<0.05$), between adenomas with low grade dysplasia and carcinomas ($P<0.05$), and between adenomas with low grade dysplasia and adenomas with high grade dysplasia, while there were no significant differences between adenomas with high

grade dysplasia and carcinomas. We analyze the adenomas with high grade dysplasia and the carcinoma groups. The positive rates of them were 56.7 % and 63.2 % respectively, and the total number of cases were 30 and 87 respectively, then, the value of χ^2 was 0.40 and P was more than 0.5 but less than 0.75. Thus, we consider that there is no difference between them. This result has not been analyzed by other studies, but it coincides with the clinical practice that the treatment of adenomas with high grade dysplasia is similar to that of the carcinomas.

To study the relationship between survivin and histological differentiation grade of colorectal carcinoma, 87 cases of colorectal carcinoma were classified to high, middle and low differentiated subgroups. The number of cases were 33, 28, and 26 respectively, and the positive rates were 63.6 %, 60.7 % and 65.4 % respectively. Analyzed by χ^2 test, there was no significant difference in the expressions of survivin among the subgroups ($P>0.90$). Moreover, there was no relationship between the differentiation grade of colorectal carcinoma and the expression intensity ($P>0.75$). These results conflict with those of Wang Mei *et al*^[22], who thought the expression of survivin was related to the tumor histological grade in cervical carcinoma. These may be due to the different tissue origin. There was no significant difference in the expressions of survivin among the different grade of colorectal carcinoma, which makes it possible to use survivin as a tumor-specific target for therapy or diagnosis. That is, no matter what historical grade the colorectal carcinoma is, the cancer can be diagnosed by detecting survivin and be treated by targeting survivin. Meanwhile, the normal cells will not be killed because survivin is not expressed in normal cells. Survivin is an attractive candidate for cancer therapy. Therefore, our study gives some directions to diagnose and treat colorectal cancer. Whether the expression of survivin can predict prognosis in cancer or not is still under discussion^[23-36].

Survivin, a novel mammalian IAP molecule, has interested scholars for its unique developmentally regulated expression and mechanism. There are still many problems to be solved, such as the molecular mechanism for its selective expression, the details about its anti-apoptosis, and so on. The targeting therapy is just beginning. Therefore, it is worthy to be further studied to settle a firm basis of tumor diagnosis and therapy.

Abstract

AIM: To characterize the host response to hepatitis B virus (HBV) infection in human hepatocytes transplanted into immunocompetent rodent rats tolerized by, and transplanted with primary human hepatocytes.

METHODS: One week after the transplantation, rats were inoculated with HBV, and viral gene expression, replication, and host response was monitored.

RESULTS: HBV DNA was detectable in serum for at least 60 days. HBsAg levels rose steadily for 3 weeks post-inoculation and then plateaued at a level of about 0.6 pg/ml. HBV RNA was also found in liver at levels that remained constant through the time course. Immunofluorescence revealed clusters of hepatocytes that stained positive for HBcAg. The presence of HBV covalently closed circular DNA (cccDNA) in liver was demonstrated using nuclease digestion of single-stranded DNA followed by PCR. Serum ALT levels rose and reached a peak level of 180 IU/L on day 18, but remained elevated for 60 days. Histology revealed a progressive predominantly mononuclear lobular hepatitis.

CONCLUSION: These data indicate that human hepatocytes transplanted into rats rendered tolerant to these cells, when infected by HBV, results in biochemical as well as histological evidence of hepatitis that accompanies viral gene expression, and DNA replication.

INTRODUCTION

It has been shown recently that primary human hepatocytes can be transplanted into rats and infected with human hepatitis

B virus^[1]. This was accomplished by rendering normal rats tolerant to human hepatocytes by intrafetal injection of primary hepatocytes. The rats were then transplanted with the same batches of cells, and then infected by inoculation of those animals with purified HBV. This resulted in production of HBV antigens. The current studies were performed to evaluate the effects of this infection on the host liver.

MATERIALS AND METHODS

Animals

Pregnant Sprague-Dawley rats, 250 to 300 g of body weight (Charles River Co., Inc., Wilmington, MA) were maintained on 12 hour light-dark cycles, and fed *ad lib* with standard rat chow in the Center for Laboratory Animal Care at the University of Connecticut Health Center. All animal procedures were approved by Institutional Animal Care and Use Committee and conformed to USDA and NIH animal usage guidelines.

Cells

Human hepatocytes were obtained from Clonetics Corp (Walkersville, MD). HepG2 2.2.15^[2] cells, a transformed human liver cell line that constitutively produces infectious HBV, were grown in Dulbecco Modified Eagle's medium (DMEM) with 10 % fetal bovine serum (FBS) and antibiotics.

Intrafetal intraperitoneal injections of human hepatocytes

Rats were rendered tolerant to human hepatocytes by intrafetal injection of those cells as described previously^[1]. In brief, at 15 to 17 days of gestation, groups of pregnant rats were anesthetized by intramuscular injections of ketamine (40 mg/kg body weight) and xylazine (5 mg/kg body weight) as described previously^[3]. Laparotomies were performed under sterile conditions; gravid uteri were exposed, and transilluminated by a high intensity lamp (Fiber-lite MI-150, Dolan-Jenner Industries, Lawrence, MA). Human hepatocytes, 1×10⁵ cells in 10 µl PBS, were injected through the uterine wall into the peritoneal cavities of rat fetuses using a sterile 200 µl Hamilton syringe with a 28 gauge beveled point needle (Hamilton Inc., Reno, NV).

Cell transplantation

Within 24 hours of birth, newborn rats were placed on ice for 2-5 min, and 2×10⁶ human hepatocytes in 200 µl PBS were injected into the spleen by sterile Hamilton syringe.

Sample collection

Peripheral blood samples were drawn from tail veins, spun, and serum stored at -20 °C. Liver samples were collected either by sacrificing animals or by performing partial hepatectomies. Samples were fresh frozen in liquid nitrogen, and stored at -80 °C.

HBV inoculation of rats

One week following human hepatocyte transplantation, tolerized rats were inoculated with 10⁵ HBV particles in 100

μl TEN (0.02 M Tris-HCl, pH 7.5, 1 mM EDTA, 0.15 M NaCl) buffer by intrasplenic injection. Controls consisted of tolerized neonatal rats from the same litter that did not receive human hepatocyte transplantation, but were also inoculated identically with HBV, as well as tolerized rats from the same litter that transplanted with human hepatocytes, but no HBV, and tolerized rats from the same litter with saline injection only.

Detection and quantitation of HBsAg in serum

Levels of HBsAg in rat serum were measured as a function of time after inoculation using an enzyme-linked immunoassay kit for HBV surface antigen (Abbott Labs) according to the manufacturer's protocol. Antigen was quantitated using a spectrophotometer at 492 nm. Assays were done in triplicate, and the results expressed as means \pm S.D. in units of pg/ml serum.

Detection and time course of HBV DNA in serum

To detect circulating virus, HBV DNA was extracted from 30 μl of rat serum, incubated with 100 μg/ml proteinase K in 0.05 M Tris-HCl, pH 8.0, 0.1 M EDTA and 0.5 % SDS, overnight at 55 °C. DNA was purified by phenol-chloroform extraction^[4]. An antisense primer 5' - ATCTTCTGCGACGCGCGATGGAGATC-3' and a sense primer 5' - CTCTGCTGGGGGAATTGATGACTCTAGC-3' were used to generate an expected 355 bp fragment of adw HBV genome spanning nt 2079-2434. One third of total cDNA was mixed with 100 pmol of amplification primers, and 2.5 U Taq polymerase, and amplified by 1 cycle of 94 °C for 3 min; 38 cycles of 94 °C for 1 min, 55 °C for 1 min, 72 °C for 1 min; and the final elongation reaction at 72 °C for 5 min. The PCR products were analyzed on 1.0 % agarose gels in Tris-borate-acetate buffer and visualized by ethidium bromide staining.

Detection and time course of HBV RNA levels in rat liver

Total liver RNA was extracted from 100 mg liver samples from rats tolerized only, rats tolerized and transplanted with human hepatocytes, rats tolerized and transplanted with human hepatocytes followed by HBV inoculation. Samples obtained at 1, 6 and 14 weeks following HBV inoculation were homogenized in a guanidinium isothiocyanate solution^[5]. RNA concentrations were determined by spectrophotometric measurement, and samples either used immediately or stored at -80 °C. In some experiments, total RNA was passed through an oligo-dT cellulose column and poly A(+) RNA isolated^[6]. 10 μg total RNA or 1 μg poly A(+) RNA was reverse transcribed using reverse transcriptase (Gibco/BRL Life Technologies) with random primers. One third of the reverse transcriptase reaction sample was used for PCR generation of a 355 bp fragment using the same primers as mentioned above. One third of total RNA was mixed with 100 pmol of amplification primers, and 2.5 U Taq polymerase, and amplified for 1 cycle at 95 °C for 5 min; 38 cycles at 95 °C for 5 min, 55 °C for 1 min, 72 °C for 1 min; and the final elongation reaction at 72 °C for 5 min. The PCR products were analyzed on 1.0 % agarose gels in Tris-borate-acetate buffer and visualized by ethidium bromide staining.

Detection of HBcAg in rat liver

Immunohistochemical staining was performed as described previously^[1]. In brief, frozen rat liver tissue slides were immersed in acetone for 2 min at 25 °C and washed with PBS (pH 7.4). Endogenous peroxidase activity was blocked by incubation in a solution containing hydrogen peroxide (Sigma) and methanol for 20 min at 25 °C. Slides were washed with PBS (pH 7.4), and non-specific activity was blocked by incubation in PBS (pH 7.4) and 1 % BSA (Sigma) for 10 min

at 25 °C. Primary antibody, rabbit anti-HBV core (Sigma), was diluted 1:1 000 in PBS (pH 7.4) and 1 % BSA and slides were incubated with primary antibody for 3 hrs at 25 °C. Washes were performed using PBS (pH 7.4) and 1 % BSA with 1 % Tween-20 (Sigma). Secondary antibody, rhodamine conjugated anti-rabbit IgG (Jackson ImmunoResearch Lab., West Grove, Pa), was diluted 1:200 in PBS (pH 7.4) and 1 % BSA. Slides were incubated for 1 hour at 25 °C and washed with PBS and 1 % BSA with 1 % Tween-20, and finally washed in PBS (pH 7.4). Slides were sealed and immunofluorescence visualized using a Zeiss Scanning laser confocal microscope (Model LSM-410).

Detection of HBV cccDNA in rat liver

Low molecular weight DNA was isolated using fractionation as described by Yeh, *et al.*^[7] and originally by Hirt^[8]. 5 μg of extracted DNA were subjected to the following conditions: (a) no treatment or (b) digestion with 0.1 unit of Mung Bean nuclease (New England Biolabs, Beverly, MA) in 50 mM sodium acetate (pH 5.0), 30 mM NaCl, 1 mM ZnCl₂ at 25 °C for 5 min and inactivation at 70 °C for 15 min. Samples were then mixed with 100 pmol primers in 1×PCR buffer (Invitrogen, Carlsbad, CA), 500 mM MgCl₂, 100 mM dNTPs, and 2.5 U Taq DNA polymerase (Invitrogen). The cycler was programmed for 5 min at 95 °C, 2 min at 55 °C, 38 cycles of 1 min at 95 °C, 1 min at 55 °C, 1 min at 72 °C with a final cycle of 5 min at 72 °C. Samples were analyzed on a 1 % agarose gel stained with ethidium bromide. The primers used were: a 21-mer sense strand (5' AGGCTGTAGGCACAAATTGGT 3') and a 20-mer antisense strand (5' GTATGGTGAGGTGAGCAATG 3') spanning 1 780 to 2 060 of the adwR2 HBV genome which generates a predicted 280 bp fragment after PCR.

Serum aminotransferase assays

To detect possible liver damage following inoculation of HBV, 10 μl aliquots of rat serum were assayed for ALT spectrophotometrically using kits (Sigma) as instructed by the manufacturer. All assays were performed in triplicate and results expressed as means \pm S.D. in units of IU/L.

Liver histology

Liver specimens were fixed in formalin, and stained with hematoxylin and eosin to evaluate liver architecture, and cellular reaction, and examined in a blinded fashion.

RESULTS

Time course of HBV DNA and HBsAg in serum

Figure 1 showed the results of assays of serum for HBsAg and HBV DNA as a function of time after inoculation of HBV into rats tolerized and transplanted with human hepatocytes cells. Surface antigen levels were detectable at a level of 0.2 pg/ml on day 1, declined slightly by day 4, but increased to a maximum of 0.7 pg/ml by day 21. There was no significant change in levels thereafter as the levels plateaued through day 60. Serum HBV DNA was detected on day 7, and remained positive on up to day 70 of post-inoculation. These data confirmed the results from our previous study^[1], and were presented here to show the dynamics of the parameters in a single figure.

HBV mRNA is present in livers from transplanted and HBV inoculated rats

To be certain that the HBsAg detected in serum was actually produced in the liver, and not simply remnants of injected virus, the presence of viral messenger (poly A(+) RNA) was sought in liver by RT-PCR as a function of time after inoculation.

Figure 2 showed that, as expected, neither normal untreated rat liver, lane 2, nor Huh7, a transformed human liver cell line, lane 3, produced any signal corresponding to the expected 355 bp fragment from amplification of HBV RNA in the core-polymerase reading frames. As a positive control, RNA from HepG2 2.2.15 cells which constitutively produced infectious HBV particles, lane 4, did produce a band of the predicted size. Livers from rats tolerized and transplanted with human hepatocytes and subsequently inoculated with HBV, also produced a band at 355 bp when assayed after one week, lane 5. This signal remained detectable at week 6, lane 6, and through week 14, lane 7.

Figure 1 Composite time course of HBsAg, HBV DNA in serum. Levels of HBsAg in rat serum were measured as a function of time after inoculation using an enzyme-linked immunoassay kit as described in Materials and Methods. Assays were done in triplicate, and the results expressed as means \pm S.D. in units of pg/ml serum. HBV DNA was extracted from rat serum, and amplified with primers spanning nt 2 079-2 434 of the adw HBV genome. Upper panel, serum positive for HBV DNA. Lower panel, HBsAg levels.

Figure 2 Detection and time course of HBV RNA in liver. Poly A(+) RNA from livers were isolated, reverse transcribed and amplified by PCR as described in Materials and Methods to generate a 355 bp fragment. Lane 1, molecular size markers; lane 2, normal untreated rat liver; lane 3, Huh7 human liver cell line; lane 4, HepG2 2.2.15 cells which constitutively produce infectious HBV particles. Livers from rats after tolerization and transplantation with human hepatocytes and subsequent inoculation with HBV after 1 week, lane 5; 6 weeks, lane 6, and 14 weeks, lane 7.

HBcAg was detectable in HBV infected rats

To obtain evidence of HBV replication, the presence of HBcAg was sought by immunofluorescence. Figure 3 showed a representative immunofluorescence pattern from the liver of a rat tolerized and transplanted with human hepatocytes, and subsequently inoculated with HBV. Clumps of cells can be seen with cytoplasmic staining for HbcAg, Figure 3A. In contrast, livers from rats without transplantation, but inoculated with the same amount of HBV as the rat in Figure 3A had no staining, Figure 3B, indicating that the observed staining in

Figure 3A could not have been due to uptake or artifact from the input injected virus. Similarly, control untreated rats in Figure 3C had no HBcAg staining confirming that the observed results in Figure 3A were not due to non-specific cross reactivity to a rat antigen.

Figure 3 Detection of HBcAg in livers of rats transplanted and inoculated with HBV. Livers were removed 14 weeks after inoculation with HBV, incubated with anti-HbcAb and rhodamine-conjugated secondary antibody as described in Materials and Methods. Figure 3A, a rat tolerized, transplanted, and inoculated with HBV; Figure 3B a rat tolerized and inoculated, but not transplanted; Figure 3C, an untreated rat.

HBV cccDNA is detectable in HBV infected rat liver

Further evidence supporting HBV replication was obtained from assays for HBV covalently closed circular DNA (cccDNA). In these experiments, Mung Bean nuclease, a DNA nuclease with a cleavage preference for single-stranded DNA was used to distinguish partially double stranded viral DNA from completely double stranded cccDNA. At low concentrations of enzyme, the partially double-stranded region DNA of the virus should be digested, and only cccDNA should survive exposure to the nuclease. In Figure 4, lane 2 showed that media from HepG2 2.2.15 cells known to secrete intact virus into the medium, produced after amplification, a band corresponding to an expected size of 280 nt. However, lane 3 showed that when first digested with Mung nuclease, and then amplified, no signal could be produced even with 5 times the amount of DNA sample from media compared to lane 2. DNA

extracted from cell layers of HepG2 2.2.15 cells produced a smear when amplified as shown in lane 4. However, prior exposure to Mung nuclease yielded a surviving band at 280 nt indicating that Mung nuclease resistant DNA was present in the low molecular weight extracts of the cell layers. Lane 6 showed that DNA extracted from livers of rats tolerized, transplanted and inoculated with HBV also generated a smear in the absence of nuclease. However, lane 7 showed that even after prior exposure to Mung nuclease, a 280 nt band spanning the partially double stranded region in the virus was still evident, supporting the presence of cccDNA in that rat liver. In contrast, DNA from rats without transplantation, but inoculated with the same amount of HBV DNA failed to generate any signal with, lane 9, or without nuclease, lane 8, indicating the signal detected in lane 7 was not due to an artifact of input viral DNA. Similarly, liver from untreated rats failed to generate the 280 nt band either with or without nuclease digestion, lanes 11, and 10 respectively, indicating that the observed band in lane 7 was not due to nonspecific amplification of host rat sequences.

Figure 4 Detection of HBV cccDNA in liver. Low molecular weight DNA was extracted from liver, digested with Mung Bean nuclease or amplified by PCR without nuclease digestion as described in Materials and Methods. Lane 1, molecular weight markers; lane 2, 5 μ g DNA from HepG2 2.2.15 cell media (containing partially double stranded viral DNA); lane 3, 25 μ g DNA from HepG2 2.2.15 cell media plus 0.1 U Mung Bean nuclease pretreatment; lane 4, 5 μ g DNA from HepG2 2.2.15 cell layer; lane 5, 5 μ g DNA from HepG2 2.2.15 cell layer plus 0.1 U nuclease pretreatment; lane 6, 5 μ g liver DNA from a tolerized, transplanted and HBV inoculated rat; lane 7, 5 μ g liver DNA from a tolerized, transplanted and HBV inoculated rat; plus 0.1 U nuclease; lane 8, 5 μ g liver DNA from a non-transplanted rat inoculated with HBV; lane 9, 5 μ g liver DNA from a non-transplanted rat inoculated with HBV plus 0.1 U nuclease; lane 10, 5 μ g DNA from an untreated rat; lane 11, 5 μ g DNA from an untreated rat plus 0.1 U nuclease; lanes 1 and 12, molecular size markers.

Figure 5 Time course of ALT. To detect possible liver damage following inoculation of HBV, aliquots of rat serum, 10 μ L, were assayed for ALT spectrophotometrically as described in Mate-

rials and methods. All assays were performed in triplicate and results expressed as means \pm S.D. in units of IU/L. Rats tolerized transplanted and inoculated with HBV, open triangles; rats inoculated with HBV, had a slight increase in ALT on the first day, solid squares; rats transplanted, but not inoculated with HBV, open squares.

Figure 6 Histological examination. Liver specimens were obtained at various time points after inoculation with HBV, fixed in formalin and stained with hematoxylin and eosin as described in Materials and Methods. Figure 6A, 1 week; Figure 6B, 6 weeks, Figure 6C, 14 weeks.

HBV infection results in biochemical evidence of liver damage

To determine whether HBV inoculation was associated with liver damage, serum alanine aminotransferase (ALT) activities were measured as a function of time after inoculation. Figure 5 showed that in animals that were transplanted with human hepatocytes, and inoculated with HBV, ALT levels rose from normal levels of 20 IU/L on the first day to a peak of 180 IU/L on day 18, and remained significantly above normal throughout the study with a value of 160 IU/L on day 60. In contrast, rats which were not transplanted, but were inoculated with HBV, had a slight increase in ALT on the first day, but returned to normal levels throughout the course. Rats that were transplanted, but not inoculated with HBV, had no increases in ALT levels at any time.

Histology confirms an immune response following HBV inoculation

To determine whether the biochemical abnormalities were associated with any pathological evidence of liver damage, livers were examined histologically as a function of time after HBV inoculation. Figure 6A showed no significant abnormalities at one week after inoculation. However, by the sixth week, Figure 6B, there was moderate inflammation characterized by lymphocytic and neutrophilic infiltration of the lobules, Kupffer cell hyperplasia, and mild portal inflammation. Figure 6C showed that at 14 weeks of post-inoculation, the inflammation was maintained, with characteristics similar to that seen in Figure 6B: moderate lobular hepatitis with lymphocytic and neutrophilic infiltration in the lobules and portal inflammation. There were no significant differences in fibrosis among any of the samples. Control livers from rats transplanted, but not inoculated with HBV, or rats not transplanted, but were inoculated with HBV failed to show any inflammation (data not shown). These data taken together with the ALT measurements indicated that inoculation of HBV into rats transplanted with human hepatocytes was associated not only with viral replication, but also liver damage mediated at least in part by a host immune response.

DISCUSSION

The developing immune system in the fetus allows a unique opportunity for the induction of tolerance to specific cells without generalized suppression of the immune system. *In utero* injection of donor cells directly into the peritoneal cavities of fetuses during gestation has been shown previously to result in a donor-specific tolerance^[9-11].

Chimeric liver models have been described previously, but in immunocompromised hosts. For example, normal adult woodchuck hepatocytes were transplanted into uPA/RAG2 knock out mice via intrasplenic injection. These cells eventually reconstituted 90 % of those mouse livers^[12]. Similarly, immortalized primary human hepatocytes have been transplanted into RAG-2 knock out mice^[13]. Primary human hepatocytes transplanted under the kidney capsule of SCID/NOD mice were shown to be susceptible to HBV infection^[14, 15]. Recently, primary human hepatocytes were transplanted into SCID-Alb-uPA mice and shown to be susceptible to hepatitis C viral infection^[16]. The results demonstrate that when transplanted into immunocompromised hosts, human hepatocytes can not only survive, but also maintain susceptibility to human hepatitis viruses. Our current data on infection and HBV replication confirmed this observation, and further indicated that general immune deficiency or suppression was not required, and intrafetal tolerization was sufficient to prevent rejection. As the mouse models described above were immunodeficient, no inflammatory response was observed as expected, in contrast to our results.

The sustained elevated levels of serum HBsAg, liver HBV RNA and serum ALT levels through 60 days of observation were not characteristics of an acute infection. Given that the viral inoculations were performed shortly (two week) after birth, the situation may be analogous to perinatal HBV infections in man. In these cases, the frequency of progression to chronic infection is extremely high, unlike the situation in adults^[17]. Some data suggest that the viral load of the inoculum is predictive of the outcome of the infection in neonates^[18]. Therefore, the development of chronicity in our model may be dependent on, and possibly controlled by the amount of virus in the inoculations.

While susceptibility of transplanted human hepatocytes to

HBV was not totally unexpected, the development of liver damage was. It is generally accepted that the majority of the liver damage by human hepatitis B viral infection in man is due to the host immune response. However, in the case of our model, because of the mismatch between host rat immunocytes and human hepatocyte MHC, no significant recognition or interaction between HBV antigens and immune cells was anticipated. Thus, the finding of evidence of hepatitis was surprising. However, non-specific immune-mediated toxicity has been described in other systems^[19]. The mechanism of the response observed in the present study is unknown, and is presently under investigation.

Nevertheless, the model system in its present form may be useful in the evaluation of new antiviral agents for efficacy, including those with immunostimulatory properties that can only be assessed in the presence of a functional immune system. Eventually, models such as this might also permit evaluation of hepatocyte toxicity of agents as well.

Abstract

AIM: Clinical therapy and prognosis in HCV infections are not good, and mix-infections with different HCV genotypes or quasiespecies and mix-infections with HCV plus other hepatitis viruses are important concerns worldwide. The present report describes the sequence diversity and genotyping of the 5' NCR of HCV isolates from hepatitis patients mix-infected with different HCV genotypes or variants, and the conditions of mix-infections with HCV plus other hepatitis viruses, providing important diagnostic and prognostic information for more effective treatment of HCV infections.

METHODS: The 5' non-coding region (5' NCR) of HCV was isolated from the patients sera and sequenced, and sequence variability and genotypes of HCV were defined by nucleotide sequence alignment and phylogenetic analysis, and the patients mix-infected with HCV plus other hepatitis viruses were analyzed. The conditions and clinical significance of mix-infections with HCV plus other hepatitis viruses were further studied.

RESULTS: Twenty-four out of 43 patients with chronic hepatitis C were defined as mix-infected with different genotypes of HCV. Among these 24 patients, 9 were mix-infected with genotype 1 and 3, 7 with different variants of genotype 1, 2 with different variants of genotype 2, 6 with different variants of genotype 3. No patients were found mix-infected with genotype 1 and 2 or with genotype 2 and 3. The clinical virological analysis of 60 patients mix-infected with HCV plus other hepatitis viruses showed that 45.0 % of the patients were mix-infected with HCV plus HAV, 61.7 % with HCV plus HBV, 6.7 % with HCV plus HDV/HBV, 8.4 % with HCV plus HEV, 3.3 % with HCV plus HGV. Infections with HCV plus other hepatitis viruses may exacerbate the pathological lesion of the liver.

CONCLUSION: The findings in the present study imply

that mix-infections with different HCV genotypes and mix-infections with HCV plus other hepatitis viruses were relatively high in Yunnan, China, providing important diagnostic and prognostic information for more effective treatment of HCV infections.

INTRODUCTION

Hepatitis C virus (HCV) is the major causative agent of non-A, non-B posttransfusional hepatitis, possessing a positive-stranded RNA genome of 9.4 kb^[1]. Since the discovery of HCV, investigations showed that HCV genome has great diversity, proposing that HCV isolates be classified into different groups (genotypes) or subtypes. HCV sequence diversity observed among isolates relevant to the process of viral evolution as it occurred during the history of human populations^[2]; therefore, it has been largely exploited to classify viral variants showing different epidemiological and pathogenic features^[3]. Conversely genetic diversity within individuals is more pertinent to the long-term adaptation of the virus to the host and reflect the dynamics of viral population and the selective mechanisms operating during the course of the infection^[4], formation of persistent and chronic infections^[5,6].

Clinic therapy and prognosis in HCV infections are not good. More than 50 % of individuals exposed to HCV develop chronic infection, and of those individuals chronically infected, approximately 20 % to 30 % will develop liver cirrhosis and/or hepatocellular carcinoma when followed a twenty to thirty years^[5,7]. For those results, in addition to HCV infection, mix-infection (co-infection or super-infection) with HCV plus other hepatitis viruses might have important significance in these situations. It was previously believed that some of the individuals with hepatitis C might in fact be mix-infected by HCV plus other hepatitis viruses. In such cases, HCV viremia clearance might be observed after clinical treatment directed to HCV infection, but the serum ALT level be not normalized or only transiently decreased. Mix-infection with HCV plus other hepatitis viruses is an important concern worthy further investigation.

The present report described the sequence diversity and genotyping of the 5' NCR of HCV isolates from hepatitis patients mix-infected with different HCV genotypes or variants, and the conditions of mix-infections with HCV plus other hepatitis viruses in Yunnan, China.

MATERIALS AND METHODS

Subjects

The cases described in this study are all Chinese patients in Yunnan province clinically diagnosed with liver diseases mix-infected with different HCV genotypes or variants, or with

HCV plus other hepatitis viruses. The serum specimens were collected from the patients for virological tests.

Sequencing and genotyping of HCV genome

HCV-RNA extraction HCV-RNA was extracted from the sera of patients with hepatitis C by the guanidinium lysis and phenol-chloroform method described previously^[8]. The HCV RNA extract from 450 µl of serum was finally dissolved in 45 µl of distilled water.

HCV PCR HCV-positive serum specimens were obtained from patients with hepatitis infected by HCV, and the details of RT-PCR method used to generate the double-stranded cDNA fragment have been described elsewhere^[8], with some modification. Briefly, 45 µl of RNA was extracted from 450 µl of serum as described previously, and the antisense primer AS-1 (5' -GTGCACGGTCTACGAGACCT-3') derived from the 5' NCR was used in a reverse transcriptase reaction to generate a cDNA copy of the antisense strand. Synthesis of HCV cDNA was performed from 2 µl of RNA extract, mixed with 13 µl of pre-RT buffer (50 mM Tris-HCl, 50 mM KCl, 10 mM MgCl₂, 0.5 mM spermidine, 10 mM DTT, 1.25 mM of the four dNTPs [Promega Biological Products Ltd., Shanghai, China] and 150 ng of the AS-1). After heat treated for 30 s at 92 °C and quick chilling, the above mix was added with 5 µl of RT buffer containing 20 u of RNasin and 10 u AMV reverse transcriptase (Promega, Shanghai, China) and then incubated for 1 hr at 42 °C.

Twenty microliters of cDNA from each reverse transcriptase reaction was used as a template for the first subsequent PCR in a DNA Thermal Cycler (Perkin-Elmer/Cetus, CA., USA). The first PCR was performed in a reaction volume of 100 µl containing 10 mM Tris-HCl (pH9.0), 50 mM KCl, 25 mM MgCl₂, 0.1 % Triton x-100, 5 mM of each dNTPs, 5 u Taq DNA polymerase [Promega], 150 ng of primers AS-1 and S-1 (5' -GCCATGGCGTTAGTATGAGT-3') and 20 µl of cDNA. The PCR was performed for 30 cycles at 94 °C for 45 s, 56 °C for 45 s and 72 °C for 45 s.

Cloning and sequencing One µl aliquot of the first PCR product (comprising nucleotides -240 to -22) was used as a template for the second of PCR amplification, using a new pair of primers AS-2 (5' -CGGGGAGCTCGCAAGCACCTAT-3'), S-2 (5' -GTCGTGGTACCTCCAGGACC-3'). The conditions of the second PCR reaction were the same as described above, except the primers AS-2 and S-2 which induced restriction endonuclease sites (underlined) Kpn I (GGTACC) and Sac I (GAGCTC) on the 5' - and 3' -end of the PCR product. The second PCR product (comprising nucleotides -220 to -47) was then cut with enzymes Kpn I/Sac I and inserted into pBluescript II K/S +/- (pBS) cloning vector by standard procedures. Clones were sequenced by the dideoxy chain termination method with phage T7 DNA polymerase (⁷SequencingTM, Pharmacia Biotech Inc. USA) (Figure 1). To minimize sequencing errors due to sequencing reaction and electrophoresis artifacts, all the clones were sequenced in both directions.

Sequence analysis To make a comparative analysis with reported sequences, sequences of the 5' NCR were compared with the consensus sequence of HCV-1^[9]. Genalign was used for sequence alignments and comparison (Intelligenetics). A phylogenetic tree for HCV was constructed by the previously described method^[10]. Briefly, evolutionary distance (i.e. those corrected for multiple substitution) between pairs of sequences were estimated using the DNADIST program in the PHYLIP package^[11]. Phylogenetic analysis was carried out using the programs DNADIST, NEIGHBOR and DRAWTREE in the PHYLIP package^[11].

Seral and virological tests

Anti-HAV detection Serum anti-HAV IgM was examined with an ELISA kit (Beijing Science & Health Clinic

Diagnostics Company, Beijing) as described in the manual.

HBV detection HBV infection markers including HBsAg, anti-HBs, anti-HBc, HBeAg were examined with ELISA kits (Beijing Biochemical & Immunological Reagent Company, Beijing). HBV-DNA was examined by PCR. The patients positive for at least two of the above markers were considered HBV-infected cases.

HCV detection Serum anti-HCV was examined with a second generation ELISA kit (AxSYM, Abbott Laboratories Diagnostics Division, USA) and the 5' NCR of HCV genome was examined by reverse transcription PCR (RT-PCR) as described previously^[8]. The patients positive for both anti-HCV and HCV-RNA were considered HCV-infected cases.

Anti-HDV detection Serum anti-HDV was examined with an ELISA kit (Beijing Science & Health Clinic Diagnostics Company, Beijing).

Anti-HEV detection Anti-HEV IgM was examined with an ELISA kit (Genelab Diagnostics PTE LTD, Singapore).

Anti-HGV detection HGV-RNA was examined by RT-PCR with HGV specific primers^[12].

Serum ALT detection Serum ALT was examined by Rate's method.

Statistical analysis

Statistical analysis was performed using the Mann Witney test and Fisher's exact test^[13].

Nucleotide sequence accession numbers

The nucleotide sequence data reported in this study have been deposited in the Genbank and EMBL Databases under the following accession numbers: AJ388314 to AJ388391. Genbank accession numbers of the previously reported sequences cited in this study are HCV1 (1a), M62321; HCVJ (1b), D90208; HC-J6 (2a), D00944; HC-J8(2b), D10988; NE92 (2d), X78862; Eb1 (3a), D10114; HCV-TR (3b), D11433; NE048 (3c), D16612; NE125 (3f), D16614; IND1751 (3g), X91421; T983 (2c), Ref. 14.

RESULTS

Mix-infections with different HCV genotypes or variants and sequence diversity

Forty-three serum samples from HCV antibody-positive patients with chronic hepatitis were analyzed by RT-PCR. The alignment of the DNA sequences (Figure 1 and 2) showed that 24 patients were mix-infected with different HCV genotypes or variants. Among these 24 patients, 9 were mix-infected with genotype 1 and 3 (Figure 1), 7 with different variants of genotype 1, 2 with variants of genotype 2, and 6 with variants of genotype 3 (Figure 2). There were no patients mix-infected with genotype 1 and 2 or mix-infected with genotype 2 and 3. Phylogenetic analysis with DNADIST (Figure 3 and 4) clearly demonstrated these results.

Nineteen isolates were cloned from the nine patients mix-infected with genotype 1 and 3 (Figure 1). Of them only 2 isolates (YS233-3 and YS245-3) were found possessing the sequence completely identical to the previously reported genotype 1b (HCVJ)^[15]. Two isolates (YS203-3 and YS232-2) possessed high sequence homology with genotype 1b. The remaining sequences were quite different from the existing (classified) genotypes reported previously.

Fourteen isolates were cloned from the seven individuals mix-infected with different variants of genotype 1, and only 2 isolates (YS246-2 and YS248-1) were found possessing the sequences completely identical to HCVJ (1b). Four isolates were cloned from the two patients mix-infected with different variants of genotype 2, and only one (R4-1) was found possessing sequence quite similar to T983 (genotype 2c)^[14].

Figure 1 Alignment of DNA sequence of the 5' NCR of HCV isolated from the patients mix-infected with genotypes 1 and 3 mix-infected patients. Comparison of nucleotide sequences in the 5' NCR from Chinese patients (YS-, R-) with previously published HCV sequences. Nucleotide numbering corresponds to that described for the prototype HCV1^[9]. Dashes indicate identity with sequence of HCV1 (top line). Nucleotide substitutions are indicated. Numbers in parentheses indicates the genotype of that sequence. Source of published sequences referred to Materials and Methods.

(continued)

Figure 2 Alignment of DNA sequence of the 5' NCR of HCV isolated from the patients mix-infected with different variants of the same genotype. Comparison of nucleotide sequences in the 5' NCR from Chinese patients (YS-, R-) with previously published HCV sequences. Patients were presumably divided in three groups, as shown in the left column. Nucleotide numbering corresponds to that described for the prototype HCV1^[9]. Dashes indicate identity with sequence of HCV1 (top line). Nucleotide substitutions are indicated. Numbers in parentheses indicates the genotype of that sequence. Source of published sequences referred to Materials and Methods.

Figure 3 Phylogenetic tree constructed with Chinese (YS-, R-) and previously reported sequences, based on nucleotide (nt) identity of 5' NCR sequence (nt -220 to -47). Dendrogram shows 19 Chinese isolates distributed within 2 major genotypes (genotypes 1 and 3). Source of published sequences referred to Materials and Methods.

Figure 4 Phylogenetic tree constructed with Chinese (YS-, R-) and previously reported sequences, based on nucleotide (nt) identity of 5' NCR sequence (nt -220 to -47). Dendrogram shows 34 different Chinese isolates distributed within 3 major genotypes, 14 isolates in genotype 1, 4 in genotype 2, and 16 in genotype 3. Source of published sequences referred to materials and Methods.

Variation in the HCV 5' NCR sequences

Fifty one isolates were obtained from the 24 mix-infected patients, and only 5 isolates were found possessing the sequences completely identical to the known HCVJ (genotype 1b), the remaining possess high variability from the known genotypes. On the other side, isolates cloned from different individuals might possess the completely identical sequences, such as YS233-3 and YS245-3 (Figure 1); YS203-5, YS215-1, YS243-1, R19-2 (Figure 1), YS201-4 and YS250-3 (Figure 2); YS233-2 (Figure 1) and YS250-1 (Figure 2); YS239-1 (Figure 1) and YS252-7 (Figure 2).

The sequence analyzing found that out of 51 isolates, 29 (57 %) possessed a G at nucleotide position -61, in place of the

“T” that was present in all previously reported sequences. Of them, 14 were in genotype 1, 2 in genotype 2, 13 in genotype 3.

Clinic virus detection

In order to detect the conditions of mix-infection with HCV plus other hepatitis viruses, HAV, HBV, HDV, HEV and/or HGV infection markers were detected in 82 patients HCV chronically infected. The results showed that 60 patients were mix-infected with HCV plus other hepatitis viruses. The incidence was very high. Among these cases, 30.0 % (18/60) were mix-infected with HCV plus HAV, 46.7 % (28/60) with HCV plus HBV, 18.3 % (11/60) with HCV plus other two or three hepatitis viruses (Table 1). The individuals mix-infected

HCV ⁺ +HBV ⁺	34.6 (18-71) [970/28]	741 (30-2745) [20748/28]	35.7 (18-53) [678/19]	610.4 (30-1905) [11598/19]	32.4 (19-71) [292/9]	1016.7 (35-2745) [9150/9]
HCV ⁺ +other hepatitis viruses	29.3 (14-64) [439/15]	1266.5 (49-4160) [18998/15]	27.6 (14-54) [276/10]	1090.4 (49-3800) [10904/10]	32.6 (16-64) [163/5]	1618.8 (345-4160) [8094/5]
Total	30.7 (4-71) [2429/79]	803.2 (20-4160) [71354/79]	30.7 (6-57) [1472/48]	799.5 (21-3800) [38375/48]	30.9 (4-71) [95/31]	1100.5 (35-4160) [33014/30]

*Patients were divided into different groups: HCV-infected group (HCV⁺), HCV plus HAV mix-infected group (HCV⁺+HAV⁺), HCV plus HBV mix-infected group (HCV⁺+HBV⁺), and, HCV plus other hepatitis viruses mix-infected group (HCV⁺+other viruses). Refer to table 1.

Table 4 Mean ages and ALT levels of patients mix-infected with HCV plus HAV and other hepatitis viruses and with HCV plus HBV and other hepatitis viruses

Group	Total		Male		Female	
	Age (years)	ALT (U/L)	Age (years)	ALT (U/L)	Age (years)	ALT (U/L)
HCV ⁺ +HAV ⁺	26.9 (14-64) [242/9]	1521.9 (233-4160) [13697/9]	21.6 (14-41) [108/5]	1552.6 (233-3800) [7763/5]	33.5 (16-64) [134/4]	1483.5 (345-4160) [5934/4]
HCV ⁺ +HBV ⁺	34.3 (26-64) [309/9]	771.8 (49-2680) [6406/9]	31.8 (26-50) [191/6]	772 (49-2680) [4632/6]	39.3 (54-64) [118/3]	591.3 (234-1429) [1774/3]

with HCV plus HDV were all infected with HBV. Among these HCV infected patients, the positive rates of HAV, HBV, HDV, HEV and HGV were 45.0 %, 61.2 %, 6.7 %, 8.3 % and 3.3 %, respectively (Table 2).

Ages and serum ALT

The ages and serum ALT levels in different group patients were showed in Table 3.

The mean age of individuals infected singly with HCV was 35.9 years old, older than those mix-infected with HCV plus other hepatitis viruses. The mean age of the patients mix-infected with HCV plus HAV was 18.9 years old, which was significantly younger than that (35.9 years) singly infected with HCV ($P<0.001$), mix-infected with HCV plus HBV (34.6 %) ($P<0.001$) or mix-infected with HCV plus other one or more viruses (29.3 years) ($P<0.001$). The serum ALT level of the patients mix-infected with HCV plus HAV was 1 253.4 U/L, which was significantly higher than that (577.7 U/L) singly infected with HCV ($P<0.001$) or than that (741 U/L) mix-infected with HCV plus HBV ($P<0.05$) (Table 3). The mean age of the patients mix-infected with HCV plus HAV was significantly younger than that mix-infected with HCV plus HBV ($P<0.001$), no matter whether they were mix-infected with other hepatitis viruses or not (Table 3 and 4).

There were no significant differences in mean ages or in mean ALT levels between two sex individuals within different groups.

DISCUSSION

Conditions and features of different genotype HCV mix-infections

High variability of HCV genome appears not only in its highly variable region (HVR) of E2 protein, but also in the most highly conserved 5' NCR. The 5' NCR is the first generation of direct sequencing tests which provide complete sequence information to characterize HCV genotypes^[8,14]. However, the previously reported sequence comparisons between isolates were mainly cloned from the same individuals and focused on HVR of E2 or C protein region^[6,16-18], and largely within the same genotype. Isolates of HCV genome cloned from the same individual could belong to the same genotype^[16] or the different genotype^[19]. The previous report showed that HVR1 of HCV variation had an adaptive significance and was associated with favorable features of liver disease^[6] and the 5' NCR did so as showed in the present study. The findings in the present study showed that mix-infections within the same individual with different HCV genotypes or variants commonly existed, and mix-infection with genotype 1 plus genotype 3 were only found in the present study up to now in China. No genotype 1/2 or genotype 2/3 mix-infected cases were found in the present study. Different HCV genotypes or variants existed within the same individual. Most of the viral sequences found in the present study had high diversity from previously reported, implying that HCV genotypes in China had specific geographic distributions and epidemiological features.

Considerable sequence diversity exists both among isolates from unrelated individuals and within the same individual, implying that the virus is not a single molecular species, but as a variable population of closely related or unrelated genomes, according to the model of the viral genotypes or quasispecies. The pathogenetic mechanisms responsible for persistent HCV infection and progressive liver disease are largely unclear; nonetheless, variant genotypes or quasispecies presence was thought favorable to escaping from immune surveillance, leading to chronicity. In fact, the immune response failed to eradicate HCV infection and did not confer protection^[20],

despite the continuous presence of antibodies^[21-23] and cytotoxic T-cell^[24,25]. This phenomenon is likely to result in the continuous selection of new variants.

The previous reports showed that different HCV genotypes had different clinical pathological features and had different response to interferon therapy, while very few reports described clinical pathologic implications of mix-infection with different genotypes or variants. This is worthy to further study.

Clinical implications of mix-infections with HCV plus other hepatitis viruses

A considerable number of HCV/HA V or HCV/HB V mix-infections were observed in this study. Among the studied cases, only 26.8 % (22/82) of the patients were singly infected with HCV. The results showed that the mean age was lower and the mean ALT level was higher in the patients mix-infected with HCV plus other hepatitis virus than in the patients singly infected with HCV. These findings implied mix-infection with HCV plus other hepatitis virus might exacerbate pathological lesion of the liver, accelerating the progress of liver disease. Affections by HAV super-infection were most significant.

HCV infection has become an important public health problem worldwide including China^[26], and mix-infections among the patients with liver diseases with HCV plus other hepatitis viruses in China seems to be also a common problem. There were a lot of investigations about infections with only single HCV or other hepatitis viruses, but only few involved in mix-infections with HCV plus HAV^[27], HCV plus HBV^[28-31], HCV plus HDV^[28,32], or HCV plus HGV^[12,28,33-35], with high incidence rate has been reported in China. While there were no investigations involved the cases mix-infected with HCV plus so many hepatitis viruses with clinical features in China and even abroad. The findings in the present study showed that patients might get mix-infections with HCV plus one, two or three other hepatitis viruses. The positive rate in the patients mix-infected with HCV plus HBV was very high, implying that mix-infection with HCV plus HBV have great significance in diagnosis and treatment of HCV infected patients. Besides, mix-infection with HCV plus HIV would not be another ignorable public health problem in China today, especially in blood donors and drug abusers^[26,36,37]. The preliminary results obtained in the present study would provide important diagnostic and prognostic information for more effective treatment of HCV infections. In order to get better insight in the whole conditions of mix-infection of different hepatitis viruses more investigations are still necessary.

ACKNOWLEDGEMENT

We are indebted to Professor Francisco E. Baralle (International Centre for Genetic Engineering and Biotechnology, ICGEB) for his technical assistance in the present study, careful reading of the manuscript and for helpful discussions. This study was supported by research grants from ICGEB Collaborative Research Program (CRP/CHN96-05) and from China Yunnan Provincial Science & Technology Commission International Collaborative Research Program (97C009).

Abstract

AIM: To assess the prevalence of hepatitis B and C serological markers in a population of refugees living in Athens.

METHODS: One hundred and thirty refugees (81 males and 49 females, mean age \pm SD: 31.7 \pm 8 years) were included in the study. The hepatitis B virus surface antigen (HBsAg), the hepatitis B virus core antibody (anti-HBc) and the hepatitis C virus antibody (anti-HCV) were detected using a third-generation immunoassay.

RESULTS: Twenty individuals (15.4 %) were HBsAg positive and 69 (53.1 %) were anti-HBc positive. The prevalence of HBsAg and anti-HBc was higher among refugees from Albania and Asia (statistical significant difference, $P < 0.008$ and $P < 0.001$ respectively). The prevalence of these markers was found irrelevant to age or sex. Anti-HCV was detected in the serum of 3 individuals (2.3 %). No differences among age, sex or ethnicity regarding anti-HCV prevalence were found.

CONCLUSION: It can be concluded that refugees living in Athens are an immigrant population characterized by a high incidence of HBV infection. The prevalence of HBV markers is higher among refugees from Albania and Asia. It is therefore believed that the adherence to general precautions and the initiation of HBV vaccination programs will be necessary in the future, especially in these communities. Although the prevalence of HCV infection seems to be relatively low, extended epidemiological surveys are needed to provide valid results.

INTRODUCTION

During the last decade, refugees from countries with an increased prevalence of infectious diseases, (i.e. viral hepatitis, AIDS and tuberculosis) have settled in Greece. The crowded living conditions and the avoidance of well-organized places of sheltering, due to the fear of deportation or expulsion, characterize immigrant populations and facilitate the spread of these diseases^[1].

Assessing the prevalence of viral hepatitis among refugees

is necessary in order to plan health control measures regarding primary and secondary prevention and prophylaxis for the entire population^[2,3]. Both prevention and prophylaxis are of great importance for public health, as chronic viral hepatitis remains the main etiology for the development of hepatocellular carcinoma, in our country^[4] and worldwide^[5-7]. In Greece, previous studies on Albanian refugees showed a high prevalence of hepatitis B^[8,9]. However, data regarding refugees of other nationalities is limited. Moreover, insufficient information is available on the prevalence of hepatitis C.

The aim of this study was to assess the prevalence of hepatitis B and C serological markers in a population of refugees of various nationalities, living in Athens.

MATERIALS AND METHODS

Materials

The study involved all refugees referred to the outpatient clinic of our Department for a health certificate, during a six-month period. A total of 130 refugees (81 men and 49 women), aged between 18 and 69 years (mean age \pm SD: 31.7 \pm 8 years old), were studied. The local ethics committee approved the study and signed informed consent was obtained from each participant.

Methods

All subjects were interviewed by means of a structured questionnaire for general demographic details (age, sex, ethnic origin) and risk factors for hepatitis B and C infections (blood transfusions, intravenous drug use, tattoos). Thereafter, 10 ml of blood was obtained by venesection and the serum was separated by centrifugation. Each serum sample was coded and stored at -20 °C. The hepatitis B virus surface antigen (HBsAg), the hepatitis B virus core antibody (anti-HBc) and the hepatitis C virus antibody (anti-HCV) were detected by a third-generation enzyme-linked immunosorbent assay (ELISA, ABBOTT, EIA-3). This immunoassay method was used according to the instructions of the manufacturer.

Statistical analysis

Results were expressed as mean \pm SD. A Chi - squared (χ^2) test with Yate's correction was used to detect differences between groups and predictive indices. χ^2 -analysis was performed using the SPSS program (version 9.0, SPSS Inc., IL, USA). $P < 0.05$ were considered statistically significant.

RESULTS

Albanian refugees represented the higher proportion (59 %) in our study population. Refugees from eastern European countries (the former USSR, Poland, Bulgaria and Romania), Asia and Africa, were also examined. The mean age did not differ among the various ethnic groups. Male sex was prominent in Albanian (67 %) and Asian (100 %) refugees. The demographic characteristics of the 130 subjects were shown analytically in Table 1.

Twenty individuals (15.4 %) were HBsAg positive and 69 (53.1 %) were anti-HBc positive. Table 2 showed the distribution of hepatitis B markers according to sex. The

prevalence of HBsAg and anti-HBc was higher in men than that in women but the difference was not statistically significant ($P=0.23$ and $P=0.14$ respectively). Finally, the mean age did not differ significantly between seropositive and seronegative for these markers groups [HBsAg (+): 31.8 ± 6 years, HBsAg (-): 32.7 ± 7 years, $P=0.66$; and anti-HBc (+): 30.9 ± 7 years, anti-HBc (-): 32.8 ± 6 years, $P=0.23$].

A total of 3 individuals (2.3 %), two men (aged 32 and 34) and one woman aged 33 were anti-HCV positive. No differences in age ($P=0.71$) and sex ($P=0.87$) regarding anti-HCV prevalence were found.

Table 3 showed the distribution of hepatitis B and C serological markers according to ethnicity. The prevalence of HBsAg and anti-HBc was higher among refugees from Albania and Asia (statistically significant difference, $P<0.008$ and $P<0.001$, respectively). Although a high prevalence of hepatitis C infection (12.5 %) characterized African refugees, no statistically significant difference among the various groups ($P=0.76$) was found.

Table 1 Demographic characteristics of refugees

Ethnicity	n (%)	Sex (M/F)	Age (mean \pm SD)
Albania	76 (59)	51/25	31.8 \pm 8.5
East europe	35 (27)	15/20	32.5 \pm 10.2
Asia	11 (8.5)	11/0	31.4 \pm 6.2
Africa	8 (6.2)	4/4	31.1 \pm 6.7
Total	130	81/49	31.7 \pm 8.5

Table 2 Distribution of hepatitis B serological markers according to sex

Sex	n	HBsAg(+)	Anti-HBc(+)	HBsAg, anti-HBc(-)
Males	81	15 (18.5 %)	47 (58 %)	19 (23.5 %)
Females	49	5 (10.2 %)	22 (45 %)	22 (44.8 %)
Total	130	20 (15.4 %)	69 (53.1 %)	41 (31.5 %)

Table 3 Distribution of hepatitis B and C serological markers according to ethnicity

Ethnicity	n	HBsAg(+)	Anti-HBc(+)	Anti-HCV(+)
Albania	76	17 (22.4 %) ^a	54 (71 %) ^a	1 (1.3 %)
E Europe	35	0 (0)	8 (23 %)	1 (2.8 %)
Asia	11	3 (27.3 %) ^b	5 (45 %) ^b	0 (0)
Africa	8	0 (0)	2 (25 %)	1 (12.5 %)
Total	130	20 (13.4 %)	69 (53.1 %)	3 (2.3 %)

^a $P<0.008$, ^b $P<0.001$.

DISCUSSION

Hepatitis B and C are widespread infectious diseases representing major health problems. The worldwide seroprevalence of HBsAg and anti-HCV is estimated to be 5 % and 1 %, respectively. However, marked geographic variation exists. Local factors, such as the ethnic composition of the population, influence the prevalence of these infections in a particular community^[2,3]. It is well known that refugees constitute a special social group in a geographical area. They often live under conditions that facilitate the spread of infectious diseases. Moreover, the prevalence of chronic infections among them depends on the endemicity of these diseases in the country of origin. In the present study, the prevalence of hepatitis B and C serological markers among

refugees of various nationalities living in Athens was evaluated. Greece has been traditionally considered as a region of intermediate endemicity for HBV infection and estimated prevalence rates for HBsAg and anti-HBc were 3 % and 30-40 %, respectively^[10]. Recent information regarding the seroprevalence of these markers in the Greek population is not available. However, in recent studies, blood donors and recruits in the army had an HBsAg positivity below 1 %, possibly indicating a shift towards lower endemicity in Greece^[11]. In the population of our study, the prevalence of HBsAg and anti-HBc was extremely high (15.4 % and 53.1 %, respectively), similar to that reported in countries of high endemicity for HBV infection. In Greece, the reported HBsAg prevalence even in high-risk groups for HBV infection, such as HIV-patients (13.3 %)^[12] and drug addicts (6.9 %)^[13,14], is lower than that observed in our population. Higher HBsAg prevalence (17.2 %) has been reported only in Kurdish of a refugee camp in Athens, a social group characterized by particularly unhealthy living conditions^[15].

An increased prevalence of hepatitis B serological markers has been reported in previous studies concerning Albanian refugees in Greece and Italy^[8,9,16,17]. Our results confirm that Albanian refugees have a high seroprevalence of HBV markers, which possibly reflects the high endemicity of HBV infection in Albania. It is also suggested that Asian refugees should be considered as another group with high prevalence of chronic HBV infection. If a larger epidemiological research confirms our results, then future preventive intervention could be conducted for those communities of refugees that are at highest risk.

The prevalence of anti-HCV in the population of refugees was relatively low (2.3 %) and no differences among various nationalities were found. A previous study among Albanian refugees in northwestern Greece showed anti-HCV seroprevalence of 1.75 %^[8]. To our knowledge, the present study is the first concerning refugees living in Athens. In Greece, several reports have shown the important role of HCV in the development of cirrhosis and hepatocellular cancer^[18,19]. However, most of the epidemiological research for the prevalence of hepatitis C concerns specific population groups, such as blood donors, medical staff, and chronic alcoholics^[20-22]. Recently, a random community-based study of the general population in the Greek Island of Zakynthos showed lower prevalence of hepatitis C (1.25 %) compared to our results^[23]. However, this difference is slight. Therefore, refugees living in Athens cannot be considered as a potential reservoir of HCV infection for the indigenous population.

It is concluded that refugees living in Athens are characterized by a high prevalence of HBV infection. The seroprevalence of HBV markers is higher among refugees from Albania and Asia. We, therefore, believe that the adherence to general precautions and an effort to improve living conditions will be necessary in the future, especially in these communities. The initiation of HBV vaccination programs is also needed. Although the prevalence of HCV infection seems to be relatively low among refugees living in Athens, extended epidemiological surveys are needed to provide valid results.

Abstract

AIM: To investigate the expression of recombinant HBsAg (rHBsAg) in transgenic cherry tomatillo in order to explore the feasibility of producing HBV oral vaccine with cherry tomatillo by animal immune tests.

METHODS: The recombinant plant expression vector containing HBsAg gene was constructed. Mediated with *Agrobacterium tumefaciens*, HBsAg gene was transferred into cotyledons of cherry tomatillo. Transformed cherry tomatillos were obtained through hygromycin delay-selection. Integrated DNA in transgenic cherry tomatillo was confirmed by hygromycin resistance selection, Gus detection, polymerase chain reaction (PCR) and dot blotting analysis. Antigenicity of rHBsAg was examined by ELISA and the immunogenicity of rHBsAg derived from transgenic cherry tomatillo tissues was confirmed by oral feed of transformed tissues to BALB/c mice primed with commercial HBV vaccines. Specific antibody titers in mice's serum were examined by ELISA every week.

RESULTS: By far, 10 positive lines of transgenic cherry tomatillos containing HBsAg gene were obtained. Among different organs of the same transgenic cherry tomatillo, level of rHBsAg expressed in leaves was the highest with the yield up to 300ng/g fresh weight. And the rHBsAg expression level in fruits was about 10 ng/g fresh weight. In animal immune tests, oral delivery with transgenic tissues to mice primed with commercial vaccine instead of naive mice resulted in significant immune response.

CONCLUSION: The result of this animal immune test indicated the rHBsAg derived from transgenic cherry tomatillo possessed normal immunogenicity. This work demonstrated the feasibility to generate oral immunogenic rHBsAg in transgenic cherry tomatillo, and would provide some experimental approach for the production of low-cost oral vaccines using transgenic cherry tomatillo in large scale.

INTRODUCTION

Hepatitis B virus infection is one of the most widespread viral infections of humans, especially in China. HBV DNA were found in most of newborns of HBsAg positive mothers^[1]. HBV vaccines have prevented numerous infections. However, administration of vaccine intramuscularly causes some pain, it is not accepted widely, especially in children. In recent years, a novel production system of vaccines- "edible vaccines" or "oral vaccines" is developed. Oral vaccines can serve multiple immunization priorities, including simplicity of use, increase in compliance (as a result of increased comfort of delivery), enhanced immune responses at mucosal sites, and stimulation of humoral immunity^[2-5].

The use of transgenic vegetables and fruits for the expression and delivery of recombinant protein antigens as edible vaccines has become an attractive topic for plant molecular biologists. Plants are potential source of antigen protein that is not dependent upon process technology to ensure protein folding and particle assembly. In addition, a plant-based antigen protein expression system makes possible the testing of an oral immunization strategy by simply feeding the plant tissues. So far, the production of oral vaccines in transgenic plant has focus on viral and bacterial subunit antigen, including *E.coli* heat-labile enterotoxin B subunit (LT-B)^[6-12], cholera toxin B subunit (CT-B)^[13,14], hepatitis B surface antigen (HBsAg)^[15-21], Norwalk virus capsid protein (NVCP)^[22,23], rabies virus glycoprotein^[24], etc. The results of oral immune tests in human bodies with transgenic potato and lettuce expressing rHBsAg have been reported, and the special antibody was detected in serum of the volunteers who were given edible tissues of transgenic plant^[25]. As we know, potato and lettuce could not be eaten in raw in certain population. But cooking process would destroy the target protein and affect its immunogenicity. So the plant acceptor should not only be easy to handle in genetic constructs, but also be able to be consumed in raw. In our study, we chose cherry tomatillo as the plant system for producing recombinant antigen.

Tomatillo, *Physalis ixocarpa* Brot. is grown in Mexico annually. It is a good source of vitamin C. The flesh of tomatillo is solid and seedy. And the pulp is glutinous, a little sweeter than tomato, and the flavor is somewhat similar to green apple. It is a key ingredient of many Mexican recipes, raw or cooked. Ripe fruits can be eaten raw, in sandwiches and salads. As an important commercial vegetable crop in the diets of Mexicans and Central Americans, tomatillo has been known by more and more researchers. The aim of this study that chose tomatillo as the plant acceptor was to investigate the feasibility of producing HBV oral vaccine with transgenic cherry tomatillo.

MATERIALS AND METHODS

Materials

Plant materials Cherry tomatillo (*Physalis ixocarpa* Brot.). The seeds were obtained from Xiamen ITG Seed IMP&EXP CO., LTD.

Bacteria and plasmids *Agrobacterium tumefaciens* strain EHA105, was kindly provided by Prof. Zhang Qi-fa, Huazhong Agricultural University. p1301HBs, recombinant mini Ti

plasmid of the binary expression vector (containing hygromycin-resistant gene, kanamycin-resistant gene, Gus gene and HBsAg-S gene), was constructed in our lab^[20,21].

Animals in immune tests BALB/c mice aged 4-6 weeks were purchased from the Center of Cancer Research, Xiamen University.

Methods

Construction of plant expression vector A 0.8 kb DNA fragment containing HBsAg-S gene was obtained by a PCR-based assembly from patient's serum and inserted into pBPF Ω 7 between the constitutively-expressed cauliflower mosaic virus (CaMV) 35S promoter and Nos terminator at the Xho I/EcoR I site by substituting the Ω gene to form pBHBs, then the 2.4 kb DNA fragment containing the HBsAg-S gene, the CaMV35S promoter and the nos terminator was cleaved with PstI from pBHBs and ligated into the binary plant vector pCAMBIA1301 (containing hygromycin-resistant gene, kanamycin-resistant gene, Gus gene) digested by Pst I to give the resulting plasmid, p1301HBs (Figure 1).

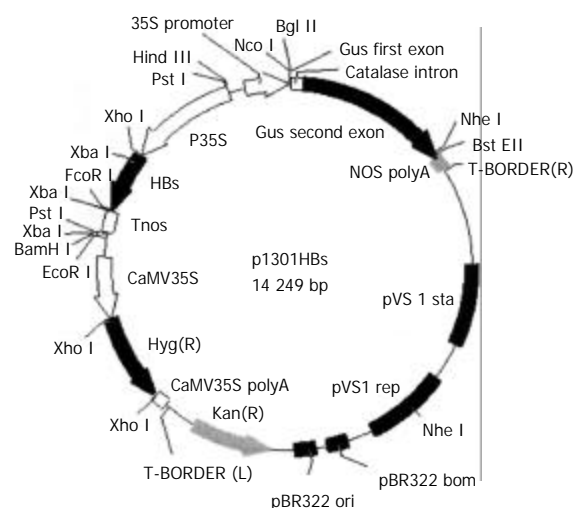

Figure 1 Plasmid p1301HBs.

Plant transformation and regeneration p1301HBs was introduced into *Agrobacterium tumefaciens* strain EHA105 directly by the freeze-thaw method with slight modifications. Subsequently, *Agrobacterium tumefaciens* carrying p1301HBs was used to transform cherry tomatillo cotyledons disks. Ten-days post germination cotyledons were excised from *in vitro*-germinated seedlings, and co-cultivated for 48-72 h with an overnight-grown culture of *Agrobacterium tumefaciens* carrying p1301HBs on a shooting medium containing 2 mg/l 6-benzyladenine (6-BA) and 0.2 mg/l indole-3-acetic acid (IAA). Cotyledons were then rinsed with sterilized water added 500 mg/l cefotaxime to kill the *A. tumefaciens* on the surface of explants, blotted dry on a sterilized paper towel, and placed onto a shooting medium added 500 mg/l cefotaxime for recovery. After seven days' recovery period, the explants were transferred to a shooting medium added 300 mg/l cefotaxime and 25 mg/l hygromycin to select transgenic progeny. About eight weeks later, hygromycin-resistant shoot regenerants were removed to a rooting medium containing 0.2 mg/l IAA and 25 mg/l hygromycin. Rooted plantlets were acclimatized and transferred to a greenhouse for fruiting.

Analysis of transgenic plants

Detection of expression activity of reporter gene-Gus gene Histochemical quantification of Gus activity was performed.

Different tissues were cut from transgenic plantlets and immersed into Gus reaction buffer (889 mg/l X-Gluc, 100 mg/l chloramphenicol, 50 mM NaH₂PO₄, 1 % Triton-X100, 20 % methanol, pH 7.0-8.0). After incubation at 37 °C for 24 h, the tissues were bleached with absolute alcohol, then observed and photographed under the dissecting microscope. Tissues from non-transformed cherry tomatillo were used as negative control.

PCR amplification of plant genomic DNA Transgenic plants were checked for the presence of target gene in leaf tissue using PCR and dot-blot analysis. Genomic DNA samples extracted from leaves of regenerated cherry tomatillos plants by the CTAB method^[26] were used as templates in PCR reactions using the following primers: forward primer 5' - ATGGAGAACACAACATC-3'; reverse primer 5' - GGATCCTTTTTCGGAAGCCCA-3', such that amplification would yield a PCR product of 480 bps. The DNA was denatured at 94 °C for 10 min. Forty cycles of PCR were performed at: 94 °C for 50 sec, 45 °C for 45 sec, 72 °C for 50 sec; followed by a 72 °C incubation for 7 min. A positive control (p1301HBs) and a negative control (DNA from non-transformed tomatillo leaves) were included in this experiment. Analysis of PCR products was carried out by loading samples onto a 1.2 % agarose gel containing ethidium bromide (EB), followed by electrophoresis and visualization via ultraviolet transillumination. A molecular weight standard (DL-2000, Takara) was used.

Dot blotting The denatured genomic DNA samples were loaded onto a nitrocellulose membrane (Millipore). A positive control (p1301HBs) and a negative control (DNA from non-transformed tomatillo leaves) were included in this experiment. Pre-hybridization was followed by DNA hybridization using a DIG-labelled probe generated from the same 480 bps fragment that was amplified from p1301HBs. Pre-hybridization and hybridization conditions were both at 42 °C. After washing procedure, the membrane was incubated with alkaline phosphatase-conjugated anti-DIG antibody for 2 h at room temperature. The membrane was finally soaked in the color solution at room temperature for up to 4 h in the dark, and the reaction was stopped by rinsing the membrane in distilled water when satisfactory color was observed.

ELISA Different organs of Cherry tomatillo were harvested, frozen in liquid N₂, and ground to a fine power. The power was suspended in extraction buffer (50 mM Tris-HCl, 0.029 % NaN₃, pH9.5) at room temperature overnight. The slurry was then centrifuged at 12 000 rpm for 10 min at 4 °C, and supernatants were tested for HBsAg by ELISA (Double Antibody sandwich-ELISA Kit, provided by Beijing Wantai Biological Medicine Co.) following the corresponding protocol. Total soluble protein was quantified using Molecular Biology Assistant (MBA2000, Perkin-Elmer Co.).

Immunization of animals

Oral primary immunization Two four-week-old BALB/c mice were fed 20 g transgenic tomatillo tissues (containing the equivalent of approximate 1 µg HBsAg) every day. Two control mice were fed wild-type tomatillo tissues. After four weeks, two groups of mice were all boosted parenterally with a subimmunogenic dose (containing 0.5 µg HBsAg) of commercial vaccine (Chuangchun Institute of Biological Products).

Oral booster immunization Four four-week-old BALB/c mice were administered parenterally with commercial vaccine (containing 2 µg HBsAg) as primary immunization. Once the serum antibody levels of the mice decreased apparently, three mice were fed transgenic cherry tomato tissues (20 g/day, containing the equivalent of approximately 1 µg HBsAg) and negative control one was fed wild-type tomatillo tissues.

Antibody assays Mice sera were collected once every week and evaluated for anti-HBsAg-specific antibodies using a

commercially available enzyme immunoassay (EIA) diagnostic kit (Double Antigen sandwich-ELISA Kit, Beijing Wantai Biological Medicine Co.).

RESULTS

Transformation and regeneration of cherry tomatillo

The plasmid for expression of HBsAg in plants (p1301HBs, Figure 1) was introduced into *Agrobacterium tumefaciens* and used in transformation experiments. Hygromycin incorporated

into tissue culture media allowed for selection of transformed callus tissue from which shoots and thereafter mature cherry tomatillo plants were regenerated over a period of about 2-3 months. Ten independent hygromycin-resistant lines of transgenic plants were generated finally. Some lines grew poorly in tissue culture. Such effects could result from insertional mutagenesis. Four lines appearing similar in morphology to wild-type plants were transferred to a greenhouse for fruiting (Figure 2). And F1 progeny of one line was obtained.

Figure 2 Transgenic cherry tomatillo. A, Transgenic plant in tissue culture; B, Transgenic plant in greenhouse; C, Green transgenic fruits; D, Ripe transgenic fruits.

Figure 3 Analysis of Gus activity in transformed cherry tomatillo tissues. A, Leaf of transformed cherry tomatillo; B, Leaf of non-transformed cherry tomatillo; C, Fruit of transformed cherry tomatillo; D, Fruit of non-transformed cherry tomatillo.

Detection of expression activity of reporter gene (*Gus*)

The transformed plants, containing *Gus* gene as the report gene, were tested for the *Gus* activity (Figure 3). The results demonstrated that *Gus* gene was stably integrated into nuclear chromosomal DNA of tomatillo and different organs all presented a remarkably high *Gus* activity.

PCR screening for the presence of HBsAg gene

To verify that these plants contained the target gene, genomic DNA extracted from young leaves was subjected to PCR amplification and the PCR products were electrophoresed through agarose. Samples containing the target gene were identified by the presence of an amplified product of 480 bp, representing a fragment of the HBsAg-S coding sequence in p1301HBs. The results obtained demonstrated the presence of an amplified product of the expected size in all the hygromycin-resistant plants tested, which was absent in non-transformed plants (Figure 4 A).

Analysis of genomic DNA by dot blotting

To further confirm that HBsAg coding gene was stably integrated into nuclear chromosomal DNA of transgenic cherry tomatillo, genomic DNA was analyzed by dot blotting, which showed that all the transgenic samples had the same hybridization signals as the positive control (p1301HBs) (Figure 4 B).

Figure 4 Identification of HBsAg gene in transgenic cherry tomatillo by PCR (A) and dot blot (B). A1, DNA marker; A2, Positive Control; A3, Non-transformed plants; A4-9, Transformed plants. B1-6, Transformed plants; B7, Non-transformed plants; B8, Positive control.

Immunological detection and quantification of rHBsAg in transgenic tomatillo

Plants positive in PCR and dot blotting were further tested by ELISA to detect and quantitatively analyze the target protein. The rHBsAg levels in different organs from a representative one of several tactile lines are presented in Table 1. The results indicated that the expression levels of rHBsAg varied among different organs of the same plant. Apparently, the amount of rHBsAg produced in leaf was much higher than any of the other organs. rHBsAg protein levels in fruit and stem were in a similar range. However, rHBsAg/TSP (total soluble protein) value of fruit was somewhat higher than that of leaf. No

significant variation was observed among the rHBsAg/TSP values of the same kind of organs in different individuals reproduced from the same line, but striking difference in the absolute expression levels of rHBsAg was observed and the level of TSP in leaves of the plantlets in tissue culture was significantly lower than that in leaves of the plants in greenhouse. The difference might be due to growth condition of these plants.

The rHBsAg levels in leaves of tissue-cultured plantlets of four different lines were shown in Table 2. ELISA analysis demonstrated that rHBsAg was expressed in these different lines ranging from 21 to 90 nag/g fresh weight.

Table 1 Expression of HBsAg in different organs and different plants of same line

Plant No.	Organ	Total soluble protein (mg/g fresh weight)	Content of HBsAg (nag/g fresh weight)	HBsAg/TSP (1/1000 000)
1#	Leaf	31.6	300	9
	Stem	5.8	15	3
	Fruit	0.7	7	10
2#	Leaf	30.0	240	8
	Stem	5.0	9	2
	Fruit	0.6	6	10
3#	Leaf	27.3	210	8
	Stem	3.6	7	2
	Fruit	0.6	6	10
4#	Leaf	11.3	90	8
	Stem	2.6	5	2
CK	Leaf	28.4	-	-
	Stem	4.7	-	-
	Fruit	0.6	-	-

Note: 1#, 2#, 3#, 4# were different plants of same transgenic cherry tomatillo line; 1#, 2#, 3# were transferred to soil in the greenhouse; 4# was still in tissue culture; CK was a non-transformed plant growing in the greenhouse.

Table 2 Expressed target protein

Line No.	Total soluble protein (mg/g fresh weight)	Content of HBsAg (ng/g fresh weight)	HBsAg/TSP (1/1000 000)
1#	16.0	45	3
2#	15.5	24	2
3#	12.6	21	2
4#	13.1	90	7
CK	13.7	-	-

Note: 1#, 2#, 3# and 4# were four different lines of transgenic cherry tomatillo with normal phenotype, and these materials were all leaves of transgenic plants in the condition of tissue culture; CK was leaf of a non-transformed tomatillo in tissue culture.

Oral immunogenicity of rHBsAg derived from transgenic tomatillo in mice

The immunogenicity of plant-derived rHBsAg was tested by oral immunizing BALB/c mice with transgenic tissues from plant line with highest production of rHBsAg. Then vaccinated mice were bled weekly, and the sera were assessed for the presence of specific antibodies by ELISA.

Oral primary immunization

Oral immunization of two naive mice by feeding transgenic tissues did not evoke primary antibody within four weeks. Then mice in two groups were both injected with a subimmunogenic dose (0.5 µg HBsAg) of commercial HBV vaccine via an

intramuscularly route as booster. However, none of the mice developed measurable specific serum antibodies in the following examination. There was no significant difference between serum antibody titers of the mice primed with transgenic tissues and those of the control mice in this experiment (Figure 5).

Figure 5 Serum antibody response elicited by oral prime with transgenic cherry tomatillo. A,B: Mice were fed non-transformed tissues until week 4, then boosted with a subimmunogenic dose of commercial vaccine; C,D: Mice were fed transformed tissues until week 4, then boosted parenterally with a subimmunogenic dose of commercial vaccine.

Oral booster immunization

After a single dose (2 μ g HBsAg) of commercial vaccine as priming, titers of serum antibody in mice rose sharply in response to antigen initially and then declined. Three mice primed were orally immunized with tissues of the transgenic tomatillo tissues as booster, and elicited an immediate high-level recall antibody response within the following 3-5 weeks. Antibody titers in serum were augmented significantly. In comparison, one negative control mouse fed with wild type tomatillo tissues did not show any booster response. Serum titers of antibody remained same (Figure 6).

We concluded that immune memory cells were established in mice following parenteral immunization of commercial vaccine and a recall response was elicited by oral delivery of HBsAg in transgenic tissues.

Our results showed that tomatillo-derived rHBsAg had same immunogenicity as commercial vaccine in stimulating production of HBsAg-specific antibodies in animal. The present experiment was limited by the total amount of plant tissues that mice ingested in 24 h and the amount of rHBsAg produced in the transgenic tissues. Absence of expected anti-HBsAg response in the oral priming study might be due to inadequate immunization schedule, such as low doses of antigen, or low sensitivity of the detection system and interference of plant material with development of an immune response. In contrast, active immune response to orally administrated antigens in parenterally primed animals might be due to altered antigen processing in favoring of active antibody production rather than oral immunotolerance.

DISCUSSION

Oral vaccination using transgenic plants is a viable approach to the development of a novel HBV vaccine. Availability of the vaccine in an edible form as a fruit or vegetable would enhance vaccination coverage by providing an inexpensive, easy to deliver and relatively heat-stable package for distribution. Such a vaccine would have the potential to enable rates of vaccination to reach the targets required for global eradication.

In this study a new foreign breed of cherry tomatillo was used as the vector of producing transgenic plant vaccine. Through the research of transforming HBsAg gene into

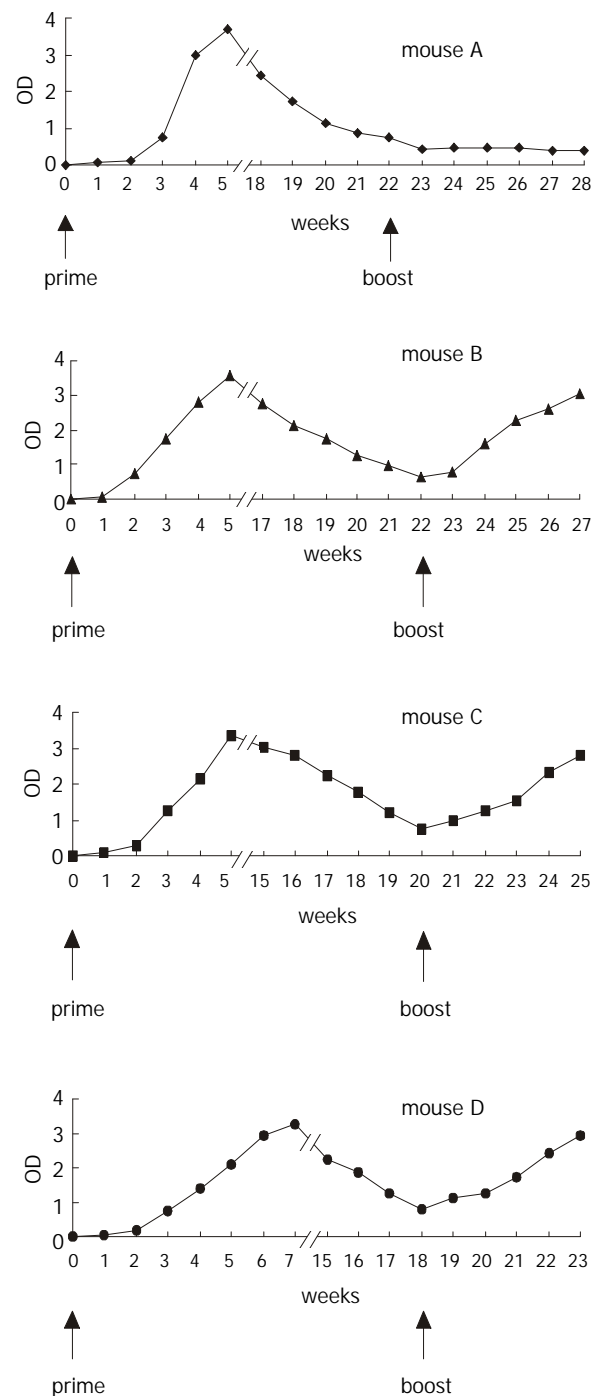

Figure 6 Serum antibody response elicited by oral boost with transgenic cherry tomatillo. A: Mouse was primed parenterally with 2 μ g commercial rHBsAg, and when its serum antibody level descends to OD<1.0, mouse was fed with untransformed tissues; B,C,D: Mice were primed parenterally with 2 μ g yeast-derived rHBsAg, and when their serum antibody levels descend to OD<1.0, mice were fed with transformed tissues as boost.

tomatillo, a high efficient transformation system of tomatillo was produced, and the recombinant protein from transgenic plants possessed good immunogenicity. The work demonstrated the feasibility of expressing the oral immunogenic rHBsAg in transgenic tomatillo, and provided some theoretic and experimental directions for the production oral vaccines using transgenic tomatillo in large scale.

Transgenic plants expressing recombinant antigens have been developed successfully since it was first described by Mason *et al.* A corollary of this research is the goal of developing subunit vaccines that are produced in edible plant

products, such that the plant-derived vaccine can be ingested directly without prior purification or processing. It appears to be a very promising alternative to other methods for expressing recombinant protein. Nevertheless, a number of questions and challenges still remain to be solved. And its main disadvantage is low yields of antigen expressed. To our knowledge, in most cases at present expression levels of vaccine proteins in transgenic plants are lower than 0.1 %. We encountered the same problem in the study. Although plant-derived rHBsAg had good immunogenicity, the maximal level of rHBsAg in transgenic tomatillos was inadequate for use practically.

Bioencapsulation of the recombinant antigen within plant cells may protect it from degradation by gastrointestinal proteinases and allow important epitopes to be recognized. It may result in greater stability of the antigen in the stomach, effectively increasing the amount of antigen available for uptake in the gut. However, foreign antigens expressed in edible plant tissues for use as oral vaccines also will consist of impure mixtures with numerous other plant proteins. The stability of such a protein in the gut is unknown yet, but high protein levels and localization in the cell wall should ensure that at least some of the antigen will be delivered to the intestine. To address these possibilities, we need edible plant tissues that produce higher levels of rHBsAg, and thus our further studies will focus on increasing the accumulation of rHBsAg in transgenic tomatillos.

Over the past decade increasing endeavors have been directed towards how to augment expression levels of foreign genes in transgenic plants. Some modifications of expression vectors have been successfully assayed to have the function to lead to increased levels of expression of the recombinant genes, including the use of stronger promoters^[15], plant-optimized synthetic genes^[8], plant-derived leader sequences, signal peptides which can target the protein for retention in intercellular compartments^[7,10,27], the fruit-specific expressed promoter^[28,29], and the chloroplast expression system^[30] etc.

Although this study was not yet complete, we could demonstrate that plant-derived rHBsAg was active as an oral immunogen and cherry tomatillo might be a potential source of vaccines for direct application. Transgenic tomatillos could induce specific immune response depending on the route of administration and immune status of the animal. In our hands, oral immunization solely by feeding transgenic tissues was not effective. Activation of the immune system by a primary immunization via a parenteral route followed by booster via the oral route resulted in significant antibody responses. The results showed that the administration of edible vaccines in primed instead of naive subjects revealed a more sensitive test system and higher probability of success. The mechanisms underlying the increased responsiveness of parenterally primed animals to orally delivered antigens are not clear yet. Further research is required to optimize this approach and to identify the underlying mechanisms. Combinations of parenteral and oral delivery may eventually prove to be most efficient, and in this regard, the present study provides a platform for ongoing and future investigations.

In conclusion, more and more attentions have been paid to the study on oral vaccine using transgenic plants in the recent years, and many great achievements have been attained in this field. However, there is a long way to go before practical use of oral vaccine. Many problems still need to be solved, such as how to improve the accumulation of target protein in edible tissues of transgenic plant, how to enlarge the production scale of plant oral vaccine, how to properly determine the suitable delivery method and dosage of plant oral vaccine.

Abstract

Severe acute respiratory syndrome (SARS) is an infectious atypical pneumonia that has recently been recognized in the patients in 32 countries and regions. This brief review summarizes some of the initial etiologic findings, pathological description, and its lesions of digestive system caused by SARS virus. It is an attempt to draw gastroenterologists and hepatologists' attention to this fatal illness, especially when it manifests itself initially as digestive symptoms.

INTRODUCTION

In November 2002, a so-called atypical pneumonia with unknown etiology appeared in Guangdong Province, China, followed by reports from Hong Kong, Vietnam, Singapore, Canada and Beijing of severe febrile respiratory illness that spread to household members and health care workers^[1-6,23-26]. This disease was designated "severe acute respiratory syndrome (SARS)" later by the World Health Organization (WHO) and global efforts to understand the cause of this illness and prevent its spread were instituted in March 2003. Many cases could be linked through chains of transmission to a health care worker from Guangdong Province, China, who visited Hong Kong, where he was hospitalized with SARS and died. Till May 19, 2003, a cumulative total of 7 864 SARS cases were reported to WHO from 29 countries; 643 deaths (case-fatality proportion: 8.2 %) have been reported, in which most cases occurred in China (7291 cases)^[7]. The incubation period for the disease is usually 2 to 7 days. Infection is characterized by fever, non-productive cough, and shortness of breath, and the presence of minimal auscultatory findings with consolidation on chest radiographs. Lymphopenia, leucopenia, thrombocytopenia, and elevated liver enzymes and creatinine kinase may also present in most cases.

In response to this outbreak, WHO coordinated an international collaboration that included clinical, epidemiologic, and laboratory investigation, and initiated efforts to control the spread of SARS. Rapid research progress has been made in last three months. This brief review is to focus on the etiologic and pathologic findings with an emphasis on the known lesions in the liver and intestine.

ETIOLOGICAL FINDINGS

The isolation of a novel coronavirus was obtained from the respiratory secretions of patients with SARS and subsequently demonstrating this virus or a serologic response to this virus, points to a possible etiologic association with SARS^[5,6,17,20,22,27]. The discovery of this new virus occurred through a broad-based and multidisciplinary effort by clinical, epidemiologic, and laboratory investigators.

Researchers around the world have sequenced the genetic codes of SARS virus, and are searching for clues to the virus' s origins, behavior, and future. Science is set to publish online a paper analyzing the genome from the BCCA Genome Sciences Center in Vancouver, as well as one from the Centers for Disease Control and Prevention (CDC) in Atlanta (www.sciencemag.org/feature/data/sars). Now that sequencing technology has become cheap and widely available, almost every country or area affected by SARS is sequencing its own version, including Hong Kong, Singapore and China^[8-10]. The viruses themselves are something of an oddity. With a genome of the complete -29 700 nucleotides, coronaviruses are relative giants, and they have a complex two-step replication mechanism. Many RNA virus genomes contain a single, large gene that is translated by the host' s cellular machinery to produce all viral proteins. Coronaviruses, instead, can have up to 10 separate genes. Most ribosomes translate the biggest one of these, called replicase, which by itself is twice the size of many other RNA viral genomes. The replicase gene produces a series of enzymes that use the rest of the genome as a template to produce a set of smaller, overlapping messenger RNA molecules, which are then translated into the so-called structural proteins - the building blocks of new viral particles. Most coronaviruses cause either a respiratory or an enteric disease, and some do both. But the differences among these types can be small. In 1999, for instance, a team led by Luí s Enjuanes of the Autonomous University of Madrid, Spain, showed that just two point mutations can change a mostly enteric virus that can kill piglets into a nondeadly one that excels at the respiratory route but replicates poorly in the gut^[11].

Researchers have grouped coronaviruses into three categories based on cross-reactivity of antibodies backed up by genetic data; the two previously known human viruses fell into different groups. Investigators have hoped that the genome sequence of the new virus would help pinpoint its origins. But a first glance at the data has yielded few clues. The new coronavirus does not fit into any of the clusters but is a new one by itself. Phylogenetic analysis of the predicted viral proteins indicates that the virus does not closely resemble any of the three previously known groups of coronaviruses. The genome sequence will aid in the diagnosis of SARS virus infection in humans and potential animal hosts (using PCR and immunological tests), in the development of antivirals (including neutralizing antibodies), and in the identification of putative epitopes for vaccine development.

PATHOLOGICAL CHANGES IN THE LUNG

Pathological studies of patients who died of SARS from Guangdong, Hongkong, Beijing and Singapore showed diffuse

alveolar damage (DAD) in the lung as the most notable feature^[5,6,12,15,21]. In those individuals with severe disease resulting in death, scattered type II pneumocytes showed marked cytologic changes including multinucleation, cytomegaly, nucleomegaly, clearing of nuclear chromatin, and prominent nucleoli. Although these changes were severe, they were within the spectrum of epithelial changes seen in other cases of DAD. Definite viral inclusions were not always found in the cytoplasm of epithelial cells. Nicholis *et al*^[12] found that DAD was common but not universal. Morphologic changes identified were bronchial epithelial denudation, loss of cilia, and squamous metaplasia. Other findings included focal intraalveolar hemorrhage, hemophagocytosis, necrotic inflammatory debris in small airways, organizing pneumonia or secondary bacterial pneumonia.

DAD is a pattern of acute lung injury characterized, in the acute phase, by hyaline membranes, interstitial and intraalveolar edema, patchy type II pneumocyte hyperplasia, microthrombi, and scant interstitial infiltrates of mononuclear cells. The acute phase forms a continuum with the proliferative or organizing phase in which proliferation of interstitial fibroblasts and prominent type II pneumocyte hyperplasia are the histologic hallmarks. In addition to DAD, the autopsy cases showed acute bronchopneumonia and variable intravascular thrombosis, all of which are common as terminal events. Biopsy material from milder cases or earlier in the course of illness may better define the initial lesion in SARS.

Multinucleated syncytial cells were identified in the alveolar spaces in a few patients. These cells contained abundant vacuolated cytoplasm with cleaved and convoluted nuclei, which show either CD68 or cytokeratin positive. No obvious intranuclear or intracytoplasmic viral inclusions were identified, and electron-microscopical examination of a limited number of these syncytial cells revealed no coronavirus particles. No definitive immunostaining was identified in tissues from a patient with SARS, with the use of a battery of immunohistochemical stains reactive with coronavirus from antigenic groups I, II, and III. In addition, no staining of patient tissues was identified with the use of immunohistochemical stains for influenza viruses A and B, adenoviruses, Hendra and Nipah viruses, metapneumoviruses, respiratory syncytial virus, measles virus, *Mycoplasma pneumoniae*, and *Chlamydia pneumoniae*^[14].

Evaluation of Vero E6 cells infected with coronavirus isolated from a patient with SARS revealed viral cytopathic effect that included occasional multinucleated syncytial cells but no obvious viral inclusions. Immunohistochemical assays with various antibodies reactive with coronavirus from antigenic group I, including human coronavirus 229E, feline infectious peritonitis virus 1, and porcine transmissible gastroenteritis virus, and with an immune serum specimen from a patient with SARS demonstrated strong cytoplasmic and membranous staining of infected cells. No staining was identified with any of several monoclonal or polyclonal antibodies reactive with coronavirus in antigenic group II (human coronavirus OC43, bovine coronavirus, and mouse coronavirus) or group III (turkey coronavirus and infectious bronchitis virus). Electron-microscopical examination of a bronchoalveolar-lavage specimen from one patient revealed many coronavirus-infected cells^[14].

Ksiazek and colleagues^[5] noticed that the primary histopathological lesions are consistent with a nonspecific acute response to lung injury that can be caused by infections, trauma, drugs, or toxic chemicals. The multinucleated syncytial cells without viral inclusions seen in the lungs of two patients, however, are suggestive of a number of viral infections including measles and parainfluenzavirus, respiratory syncytial virus, and Nipah virus infection. Multinucleated syncytial cells

associated with some human coronavirus infections have occasionally been observed in cell culture, but most often in cell cultures inoculated with animal coronaviruses. To detect this novel coronavirus antigen, the investigators used an extensive panel of antibodies against coronaviruses that are representative of the three antigenic groups, including several group 1 antiserum specimens that reacted against Urbani SARS-associated coronavirus infected tissue-culture material. A possible explanation for the failure of this antiserum to react with antigens in these patients on immunohistochemical analysis is that the host immune response has cleared the virus from these tissues. The tissues were available late in the course of the illness, 14 to 20 days after its onset. For many viral respiratory infections, viral antigens and nucleic acids are cleared within two weeks after the onset of disease.

Electron microscopic examination showed that virus-like particles with 100-150 nm in diameter were found in cytoplasm and dilated reticular endoplasm of the infected alveolar epithelial cells and endothelial cells^[5,15-17]. Other agents, such as paramyxovirus, metapneumovirus and chlamydia, were also identified in the pulmonary tissues^[16,22]. It could be that the coronavirus may by itself produce the disease but it may also open the door for other viruses, or nonviruses, to aggravate the disease.

The pathogenesis of this disorder remains to be determined. However, the mechanism of acute lung injury could involve direct damage by the virus to the alveolar wall by targeting either endothelial cells or epithelial cells. Alternatively, the virus could infect inflammatory cells with the injury mediated through cytokines, interleukins, or tumor necrosis factor-alpha. It is also possible that the tissue damage in SARS is not directly related to viral infection in tissues but is a secondary effect of cytokines or other factors induced by viral infection proximal to but not within the lung tissue. In influenza infections, viral antigens are seen predominantly in respiratory epithelium of large airways and are only rarely identified in pulmonary parenchyma, despite concomitant and occasionally severe interstitial pneumonitis.

LESIONS IN DIGESTIVE ORGANS

As previously described, most coronaviruses cause either a respiratory or an enteric disease, which is also transmitted by the faecal-oral route. During this outbreak of SARS, symptoms of gastrointestinal tract in the patients were noticed. Many investigators^[13,19,24] found that gastrointestinal symptoms are not uncommon at presentation, including diarrhea (19-50 percent), nausea and vomiting (19.6 percent), and abdominal pain (13 percent) manifested in SARS patients.

As many as 66 % of the patients in the Amoy Garden SARS outbreak in Hong Kong also had diarrhea, contributing to a significant virus load being discharged in the sewerage, which caused 361 cases of SARS^[3]. During hospitalization, some patients were present with mildly elevated aminotransferase levels (indicating liver damage), or developed dysfunction of the liver at the later stage of the disease. Some patients presented with severe acute abdominal pain requiring exploratory laparotomy. All these patients developed typical SARS. These clinical findings suggest that SARS virus does involve the digestive system, especially the epithelial cells of intestinal mucosa.

Pathologic evaluation of the fatal cases showed that, except the lung changes, hepatocytes underwent fatty degeneration, cloudy swelling, apoptosis and dot necrosis, with Kupffer cell proliferation and portal infiltrates of lymphocytes^[15,16]. There were regional hemorrhages, vascular congestion and lymphocytic infiltration in gastrointestinal walls of the patient. Suckling mice inoculated with SARS-infected samples also

demonstrated hepatocytic lesions, including swelling, vacuolar and hydropic degenerations, focal cellular condensation and necrosis. But no coronavirus-like particles were found in hepatocytes.

Epidemiologic investigation also showed that the virus could survive in stools for at least two days and in diarrhoeal stools, which has a higher pH, for up to four days. It can also survive on plastic surfaces for up to 48 hours, but it is not yet known how big a dose of the virus is required to cause infection^[18].

According to the experience of Prince of Wales Hospital in Hong Kong^[20], where SARS outbreak happened, the difficulty of making a firm diagnosis until chest radiographic changes appear has important implications for health-care personnel and for surveillance. Three major reasons for spread of infection to health-care workers are: failure to apply isolation precautions to cases not yet identified as SARS, breaches of procedure, and inadequate precautions. Every patient must now be assumed to have SARS, which has major long-term implications for the health-care system. Another reason for spread among health-care workers is infected workers continuing to work despite symptoms, such as mild fever. Such individuals must now cease working. However, staying at home can also have disastrous consequences for exposed family members. Potential cases therefore require early isolation from both workplace and household. Extreme measures are required to protect health-care workers, who account for about 20 % of cases. Therefore, gastroenterologists and hepatologists should pay more attention when contacting the patients.

SARS has been appropriately elicited because current knowledge regarding the transmission of this disease is rapidly evolving and clinicians must provide patient care while dealing with a degree of uncertainty. The Centers for Disease Control and Prevention have published and regularly update logical recommendations for preventing the spread of the causative agent. The causative organism appears to spread predominantly by contact and droplets and may spread by airborne routes as well. The use of N-95 masks, gowns, double gloves, hand hygiene, and eye protection seem well advised and appear to have substantially curtailed spread within hospitals.

Global efforts have described this new syndrome with dramatic speed, and identified and sequenced the apparent etiologic agents. With expedited efforts to develop a specific diagnostic test, effective infection-control techniques, and to develop effective therapies and vaccines for SARS-associated coronavirus, and to create a true global health network, there is much reason for optimism. To be prepared for that challenge, health care professionals must not forsake their patients, the research community must help provide answers to the unanswered questions, and health care leadership must take the knowledge from that research to rapidly implement whatever strategies necessary to better combat this newly emerging infectious disease^[28].

Abstract

It has been proved that severe acute respiratory syndrome (SARS) is caused by SARS-associated coronavirus, a novel coronavirus. SARS originated in Guangdong Province, the People's Republic of China at the end of 2002. At present, it has spread to more than 33 countries or regions all over the world and affected 8 360 people and killed 764 by May 31, 2003. Identification of the SARS causative agent and development of a diagnostic test are important. Detecting disease in its early stage, understanding its pathways of transmission and implementing specific prevention measures for the disease are dependent upon swift progress. Due to the efforts of the WHO-led network of laboratories testing for SARS, tests for the novel coronavirus have been developed with unprecedented speed. The genome sequence reveals that this coronavirus is only moderately related to other known coronaviruses. WHO established the definitions of suspected and confirmed and probable cases. But the laboratory tests and definitions are limited. Until now, the primary measures included isolation, ribavirin and corticosteroid therapy, mechanical ventilation, etc. Other therapies such as convalescent plasma are being explored. It is necessary to find more effective therapy. There still are many problems to be solved in the course of conquering SARS.

INTRODUCTION

On 12 March 2003, the World Health Organization (WHO) issued a global alert on the atypical pneumonia, also called severe acute respiratory syndrome (SARS), after reports from the Department of Health of Hong Kong of an outbreak of pneumonia in one of its public hospitals. At about the same time, WHO received reports of the syndrome from China, Singapore, Vietnam, Thailand, Indonesia, Taiwan, and the Philippines, as well as from countries in other continents including Canada, the United States, and Germany. The disease

originated in Guangdong Province at the end of 2002 and has affected 8 360 people and killed 764 by May 31, 2003. Dr. Carlo Urbani reported the disease first in a Vietnam French Hospital of Hanoi^[1]. WHO took prompt measures to avoid wider spread of SARS according to his alarm. It has been proved that a novel coronavirus is associated with SARS (SARS-CoV), and that this virus plays an etiologic role in SARS^[2-9]. Because of the death of Dr. Carlo Urbani (46 years old, an expert of infectious diseases, Italian) from SARS, Ksiazek and his colleagues proposed that their first isolate be named the Urbani strain of SARS-associated coronavirus.

On 17 March 2003, WHO called upon 11 laboratories in 9 countries to join a collaborative multi-center research project on SARS diagnosis. This network took advantage of modern communication technologies to share outcomes of investigation of clinical samples from SARS cases in real time. Clinicians from China, Hong Kong and the USA introduced their own experience of treatment on SARS. Scientists have made great progress in the clinical diagnosis and treatment of SARS. However, there are still many difficulties and problems to be solved in the course of conquering SARS.

DIAGNOSIS

Identification of SARS causative agent and development of a diagnostic test are of paramount importance. Detecting disease in its early stage, understanding its pathways of transmission and implementing disease specific prevention measures are dependent upon swift progress and results in aetiological and diagnostic research.

Clinical presentations

Booth *et al*^[10] reported that features of the clinical examination most commonly found in the patients at admission were self-reported fever (99 %), documented elevated temperature (85 %), nonproductive cough (69 %), myalgia (49 %), and dyspnea (42 %). The reports from Zhong^[11] and Chan-Yeung *et al*^[12] were similar to this.

Laboratory tests

Due to the efforts of the WHO-led international multi-center collaborative network of laboratory testing for SARS, tests for the novel coronavirus have been developed with unprecedented speed^[13].

Early in the course of the disease, the absolute lymphocyte count is often decreased. Overall white blood cell counts are generally normal or decreased. At the peak of the respiratory illness, approximately 50 % of patients have leukopenia and thrombocytopenia or low platelet counts within normal range. Early in the respiratory phase, elevated creatine phosphokinase levels (as high as 3 000 IU/L) and hepatic transaminases (two to six times of the upper limits of normal) have been noted. In the majority of patients, renal function is normal. Common laboratory features include elevated lactate dehydrogenase (87 %), hypocalcemia (60 %), and lymphopenia (54 %). Only 2 % of patients have rhinorrhea^[10] (Tables 1 and 2).

Table 1 Earliest symptoms of SARS^a

Symptom	No. (%) of patients (n=144)
Fever (n=106)	
Alone	33(23)
With prodrome	33(23)
With prodrome and cough or dyspnea	16(11)
With cough or dyspnea	15(11)
With other combinations	9(6)
Prodrome alone	19(13)
Cough or dyspnea alone	13(9)
Symptom reported first	
Prodrome	74(52)
Fever	106(74)
Cough or dyspnea	51(35)
Diarrhea	9(6)

^aProdrome includes headache, malaise, or myalgia.

Table 2 Laboratory features of SARS at admission and during hospitalization

	At admission		During hospitalization ^a	
	Median (IQR)	No./Total(%) Abnormal ^b	Median (IQR)	No./Total(%) Abnormal ^b
Lymphocytes, /μL	900 (700-1300)	104/122 (85)	500 (400-800)	106/120 (88)
Lactate dehydrogenase, U/L	396 (219-629)	86/99 (87)	630 (363-1156)	115/123 (94)
Creatine kinase, U/L	157 (70-310)	43/109 (39)	370 (208-959)	64/118 (54)
Potassium, mEq/L	3.7 (3.4-4.0)	36/137 (26)	3.2 (2.9-3.4)	60/140 (43)
Calcium, mg/dL ^c	8.52 (8.2-9.16)	53/89 (60)	8.1 (7.76)	71/101 (70)
Magnesium, mg/dL	1.94 (1.7-2.19)	12/68 (18)	1.43 (0.97-1.51)	55/96 (57)
Phosphorus, mg/dL	3.10 (2.76-3.69)	17/64 (27)	2.17 (1.83-2.48)	41/78 (53)

Abbreviations: IQR, interquartile range; SI conversions: To convert calcium to mmol/L, multiply by 0.25. To convert magnesium to mmol/L, multiply by 0.411. To convert phosphorus to mmol/L, multiply by 0.323. ^aThe most abnormal value recorded used. ^bDefined as lymphocytes <1 500/μL; lactate dehydrogenase >190 U/L; creatine kinase >240 U/L for men and >190 U/L for women; potassium <3.5 mEq/L; calcium <8.8 mg/dL; magnesium <1.70 mg/dL; phosphate <2.79 mg/dL. ^cCalcium values have been corrected for serum albumin.

Radiographic findings of SARS

Wong *et al*^[14] found that initial chest radiographs were abnormal in 108 of 138 (78.3 %) patients and showed air-space opacity. Lower lung zone (70 of 108, 64.8 %) and right lung (82 of 108, 75.9 %) were more preferably involved. In most patients, peripheral lung involvement was more common (81 of 108, 75.0 %). Unifocal involvement (59 of 108, 54.6 %) was more frequent than multifocal or bilateral involvement.

Molecular test (PCR)

Sequencing of the about 30000-base genome of the SARS-associated coronavirus has completed^[15-21]. The genome sequence revealed that this coronavirus was only moderately related to other known coronaviruses, including two human coronaviruses, HCoV-OC43 and HCoV-229E. A valid positive PCR result indicated that there was genetic material (RNA) from the SARS-CoV in the sample. However, it does not mean the virus present is infectious, or that it is present in a large

enough quantity to infect another person. Negative PCR results do not exclude SARS. Besides the possibility of obtaining false-negative test results, specimens may not have been collected at a time when the virus or its genetic material was present.

The SARS-CoV-specific RNA can be detected in various clinical specimens such as blood, stool, respiratory secretions or body tissues by PCR. A number of PCR protocols developed by members of the WHO laboratory network are available on a WHO website^[22].

Despite their high sensitivity, the existing PCR tests cannot rule out the presence of the SARS virus in patients on account of possible false negative results. On the other hand, contamination of samples in laboratories may lead to false positive results.

SARS-CoV isolation

The presence of the infectious virus can be detected by inoculating suitable cell cultures (e.g. Vero cells) with patient's specimens (such as respiratory secretions, blood or stool) and propagating the virus *in vitro*. Once isolated, the virus must be identified as SARS-CoV using further tests. Cell culture is a very demanding test, but is currently (with the exception of animal trials) the only means to show the existence of a live virus. Positive cell culture results indicate the presence of live SARS-CoV in the sample. Negative cell culture results do not exclude SARS.

Antibody detection

Various methods provide a means for the detection of antibodies produced in response to infection with SARS-CoV. Different types of antibodies (IgM or IgG) appear and change in level during the course of infection. They can be undetectable in the early stages of infection. IgG usually remains detectable after resolution of the illness. It was reported that IgG would reach peak value 60 days after obvious symptoms and then keep it, while IgM would reach peak value on day 14 after onset of apparent symptoms. Enzyme-linked immunosorbent assay (ELISA), immunofluorescence assay (IFA), neutralisation test are being developed, but are not yet commercially available.

WHO CASE DEFINITION^[23]

The definitions of suspected and confirmed and probable case according to the WHO Case Definition are as follows:

Suspect case

A person presenting after 1 November 2002, with history of: high fever (>38 °C) and cough or breathing difficulty, and one or more of the following exposures during the 10 days prior to onset of symptoms: (1) close contact, with a person who is a suspect or probable case of SARS; (2) history of travel, to an area with recent local transmission of SARS; (3) residing in an area with recent local transmission of SARS. Close contact means having cared for, lived with, or had direct contact with respiratory secretions or body fluids of a suspect or probable case of SARS.

A person with an unexplained acute respiratory illness resulting in death after 1 November 2002, but on whom no autopsy has been performed, and one or more of the following exposures during the 10 days prior to onset of symptoms: (1) close contact with a person who is a suspect or probable case of SARS; (2) history of travel to an area with recent local transmission of SARS, and (3) residing in an area with recent local transmission of SARS.

Probable case

(1) A suspect case with radiographic evidence of infiltrates

consistent with pneumonia or respiratory distress syndrome (RDS) on chest X-ray (CXR). (2) A suspect case of SARS that is positive for SARS coronavirus by one or more assays. See Use of laboratory methods for SARS diagnosis. (3) A suspect case with autopsy findings consistent with the pathology of RDS without an identifiable cause.

Exclusion criteria

A case should be excluded if an alternative diagnosis can fully explain their illness.

Reclassification of cases

As SARS is currently a diagnosis of exclusion, the status of a reported case may change over time. A patient should always be managed as clinically appropriate, regardless of their case status. (1) A case initially classified as suspect or probable, for whom an alternative diagnosis can fully explain the illness, should be discarded after carefully considering the possibility of co-infection. (2) A suspect case who, after investigation, fulfils the probable case definition should be reclassified as "probable". (3) A suspect case with a normal CXR should be treated, as deemed appropriate, and monitored for 7 days. Those cases in whom recovery is inadequate should be re-evaluated by CXR. (4) Those suspect cases in whom recovery is adequate but whose illness cannot be fully explained by an alternative diagnosis should remain as "suspect". (5) A suspect case who died, on whom no autopsy was conducted, should remain classified as "suspect". However, if this case is identified as being part of a chain transmission of SARS, the case should be reclassified as "probable". (6) If an autopsy was conducted and no pathological evidence of RDS was found, the case should be "discarded".

The surveillance period began on 1 November 2002 to capture cases of atypical pneumonia in China now recognized as SARS. International transmission of SARS was first reported in March 2003 for cases with onset in February 2003. The Centers for Disease Control and Prevention have added laboratory criteria for evidence of infection with SARS-CoV to the interim surveillance case definition^[24]. Using the new laboratory criteria, a SARS case is laboratorily confirmed if one of the following is met: detection of the SARS-CoV antibody by indirect fluorescent antibody (IFA) or enzyme-linked immunosorbent assay (ELISA), isolation of SARS-CoV in tissue culture, detection of SARS-CoV RNA by reverse transcriptase-polymerase chain reaction (RT-PCR), which must be confirmed by a second PCR test. Negative laboratory results for PCR, viral culture, or antibody tests obtained within 21 days of illness do not rule out SARS-CoV infection. In these cases, an antibody test of a specimen obtained more than 21 days after the onset of illness is needed to determine infection. Unless PCR confirms the initial suspicion of SARS infection, the diagnosis of SARS is based on the clinical findings of an atypical pneumonia not attributed to any other cause as well as a history of exposure to a suspect or probable case of SARS, or to their respiratory secretions or other body fluids. The initial diagnostic testing for suspected SARS patients should include chest radiography, pulse oximetry, blood cultures, sputum Gram stain and culture, and testing for viral respiratory pathogens, obviously influenza A and B and respiratory syncytial virus. A specimen for *Legionella* and pneumococcal urinary antigen testing should also be considered.

Clinicians should save any available clinical specimens (respiratory, blood, and serum) for additional testing until a specific diagnosis is made. Acute and convalescent (greater than 21 days after the onset of symptoms) serum samples should be collected from each patient who meets the definition criteria for SARS. Specific instructions for collecting specimens from suspected SARS patients are available on the Internet.

In the early stages, SARS may be hard to differentiate from other viral infections, and diagnostic delays may contribute to the spread of the epidemic. Nevertheless, until standardized reagents for virus and antibody detection become available and methods have been adequately tested, the diagnosis of SARS remains based on clinical and epidemiological findings. The revised case definition for the first time includes laboratory results: a suspected case of SARS, that is positive for SARS-CoV in one or more assays, should be reclassified as a probable case. At present there are no defined criteria for SARS-CoV test results to confirm or reject the diagnosis of SARS.

Positive laboratory test results for other known agents that are able to cause atypical pneumonia such as *Legionella pneumophila*, influenza and parainfluenza viruses, *Mycoplasma pneumoniae* etc. may serve as exclusion criteria; according to the case definition, a case should be excluded if an alternative diagnosis can fully explain the illness. However, the possibility of dual infection must not be ruled out completely. According to our clinical experience and correlative papers, we think that exact diagnosis of a confirmed case must need a history of close contact and persistent symptoms (fever or influenza-like symptom). To observe the chest x-ray of patient continuously is also necessary.

TREATMENT

From initial clinical experience, SARS can develop in stages, including acute constitutional symptoms, acute viral pneumonitis, acute lung injury, and even acute respiratory distress syndrome, evolving over 1 to 2 weeks. Initial infection followed by a hyperactive immune response appears to underlie the severe manifestations of SARS. Therefore, corticosteroids can be used to dampen excessive lung damage due to an inflammatory response.

Ribavirin and glucocorticoid therapy

A series of 31 patients with probable SARS were treated according to a treatment protocol consisting of antibacterials and a combination of ribavirin and methylprednisolone in Hong Kong^[25]. One patient recovered by antibacterial treatment alone, 17 showed rapid and sustained responses, and 13 achieved improvements with step-up or pulsed methylprednisolone. Four patients required short periods of non-invasive ventilation. No patient required intubation or mechanical ventilation. There was no mortality or treatment morbidity in this series. The following is the standard protocol.

Antibacterial treatment

- (1) Levofloxacin 500 mg once daily intravenously or orally;
- (2) Or clarithromycin 500 mg twice daily orally plus coamoxiclav (amoxicillin and clavulanic acid), 375 mg three times daily orally if patient is <18 years old, pregnant, or suspected to have tuberculosis.

Ribavirin and methylprednisolone

Combination treatment with ribavirin and methylprednisolone when: (1) Extensive or bilateral chest radiographic involvement; (2) Or persistent chest radiographic involvement and persistent high fever for 2 days; (3) Or clinical, chest radiographic, or laboratory findings suggestive of worsening; (4) Or oxygen saturation <95 % in room air.

Standard corticosteroid regimen for 21 days

- (1) Methylprednisolone 1 mg/kg every 8 h (3 mg/kg daily) intravenously for 5 days;
- (2) Then methylprednisolone 1 mg/kg every 12 h (2 mg/kg daily) intravenously for 5 days;
- (3) Then prednisolone 0.5 mg/kg twice daily (1 mg/kg daily) orally

for 5 days; (4) Then prednisolone 0.5 mg/kg daily orally for 3 days; (5) Then prednisolone 0.25 mg/kg daily orally for 3 days; (6) Then off.

Ribavirin regimen for 10-14 days

(1) Ribavirin 400 mg every 8 h (1 200 mg daily) intravenously for at least 3 days (or until condition becomes stable); (2) Then ribavirin 1 200 mg twice daily (2 400 mg daily) orally.

Pulsed methylprednisolone

(1) Give pulsed methylprednisolone if clinical condition, chest radiograph, or oxygen saturation worsens (at least two of these), and lymphopenia persists; (2) Give methylprednisolone 500 mg twice daily intravenously for 2 days, then back to standard corticosteroid regimen.

Mechanical ventilation

Traditional approaches to mechanical ventilation use tidal volumes of 10 to 15 ml per kilogram of body weight and may cause stretch-induced lung injury in patients with acute lung injury and the acute respiratory distress syndrome. The Acute Respiratory Distress Syndrome Network therefore conducted a trial. The mean tidal volumes on days 1 to 3 were 6.2 ± 0.8 and 11.8 ± 0.8 ml per kilogram of predicted body weight. They found that in patients with acute lung injury and acute respiratory distress syndrome, mechanical ventilation with a lower tidal volume than traditionally used resulted in decreased mortality and increased number of days without ventilator use^[26-29].

Cordingley *et al*^[30] suggests that reduced mortality may be achieved by using a strategy that aims at preventing overdistension of the lungs. There is no clinical evidence to support the use of specific FiO_2 thresholds, but it is common clinical practice to decrease FiO_2 below 0.6 as quickly as possible. SaO_2 values of around 90 % are commonly accepted. PaCO_2 is allowed to rise during lung protective volume and pressure limited ventilation. PaCO_2 levels of 2-3 times 3 normal seem to be well tolerated for prolonged periods. Renal compensation for respiratory acidosis occurs over several days. Many clinicians infuse sodium bicarbonate slowly if arterial pH falls below 7.20, Set PEEP at a relatively high level such as 15 cm H_2O in patients with ARDS. It is common practice during pressure control ventilation to increase the I:E ratio to 1:1 or 2:1 (inverse ratio ventilation) with close monitoring of intrinsic PEEP and haemodynamics.

Other therapies being studied

At present, serum therapy is being studied for SARS patients. 40 patients were divided into two groups in the Medical College of Hong Kong Chinese University. One group was treated with convalescent plasma and another group not. The effect was obviously different among two groups after one month, the therapy group died no patients while another group 3 patients, but it needs more clinical trial to be proved. In their opinion, to use convalescent plasma within earlier two weeks will shorten the in-hospital period and fever time and reduce mortality. Serum therapy was used to dying patients and aged patients with other severe or chronic disease and pregnant women.

As to another trial in Hong Kong^[31], treatment of a SARS patient followed by 200 ml convalescent plasma donated by SARS patients in their convalescent phase. No adverse reaction occurred after administration of convalescent plasma. The fever subsided, chest X-ray showed further resolution of basal lung infiltrates, and she made an uneventful recovery. Although no probable SARS case has been ascribed to transmission by labile blood products or blood derivatives, there is a theoretical risk

of transmission of the SARS virus through transfusion of labile blood products, since low viraemia has been detected up to approximately 10 days after the onset of symptoms from probable SARS patients^[32].

Moller *et al*^[33] reported that bovine surfactant therapy in severe ARDS improved oxygenation immediately after administration. This improvement was sustained only in the subgroup of patients without pneumonia but with an initial $\text{PaO}_2/\text{FIO}_2$ ratio higher than 65. The SARS studies on antisense oligonucleotide drug, polypeptide, and vaccine will benefit the treatment of this disease.

It has been proved that a novel coronavirus is the cause of SARS with strong infectivity. Up to now, we have only understood the preliminary pathogenesis and epidemiology of SARS. After all SARS is a disease seen never before in human. To control and defend human being from this disease, further studies are needed, such as: (1) origin, mutation, life cycle, transmission pathways of SARS-CoV; (2) the mechanisms of SARS-CoV replicating and coming into the host cell; (3) pathogenesis of acute lung injury and abnormal immune response; (4) rapid diagnosis and vaccine, and (5) effective medicine such as inhibitory polypeptide. With rapid progress in the basic studies of the disease all over the world, more effective drugs and treatment measures will be discovered in the days to come and SARS will be put under complete control by mankind soon.

Abstract

Tumor angiogenesis is the proliferation of a network of blood vessels that penetrates into cancerous growths, supplying nutrients and oxygen and removing waste products. The process of angiogenesis plays an important role in many physiological and pathological conditions. Solid tumors depend on angiogenesis for growth and metastasis in a hostile environment. In the prevascular phase, the tumor is rarely larger than 2 to 3 mm³ and may contain a million or more cells. Up to this size, tumor cells can obtain the necessary oxygen and nutrient supplies required for growth and survival by simple passive diffusion. The properties of tumors to release and induce several angiogenic and anti-angiogenic factors which play crucial roles in regulating endothelial cell (EC) proliferation, migration, apoptosis or survival, cell-cell and cell-matrix adhesion through different intracellular signaling are thought to be the essential mechanisms during tumor-induced angiogenesis. Tumor angiogenesis actually starts with tumor cells releasing molecules that send signals to surrounding normal host tissue. This signaling activates certain genes in the host tissue that, in turn, make proteins to encourage growth of new blood vessels. In this review, we focus the mechanisms of tumor-induced angiogenesis, with an emphasis on the regulatory role of several angiogenic and anti-angiogenic agents during the angiogenic process in tumors. Advances in understanding the mechanisms of tumor angiogenesis have led to the development of several most effective anti-angiogenic and anti-metastatic therapeutic agents and also have provided several techniques for the regulation of cancer's angiogenic switch. The suggestion is made that standard cytotoxic chemotherapy and angiogenesis inhibitors used in combination may produce complementary therapeutic benefits in the treatment of cancer.

MECHANISM OF ANGIOGENESIS

Angiogenesis is a complex multi-step process involving extensive interplay between cells, soluble factors, and extracellular matrix (ECM) components. Four distinct sequential steps in angiogenesis include: (1) degradation of basement membrane by proteases; (2) migration of endothelial cells (ECs) into the interstitial space and sprouting; (3) ECs

proliferation at the migrating tip; (4) lumen formation, generation of new basement membrane with the recruitment of pericyte, formation of anastomoses and finally blood flow^[1]. The angiogenic response in the microvasculature is associated with changes in cellular adhesive interactions between adjacent ECs, pericytes and surrounding ECM. In the process of active neovascularization, activated ECs reorganize their cytoskeleton, express cell surface adhesion molecules such as integrins and selectins, secrete proteolytic enzymes, and remodel their adjacent ECM. These events are followed by the formation of capillary buds. Autocrine and/or paracrine angiogenic factors must be present to induce EC migration, proliferation, elongation, orientation and differentiation leading to the re-establishment of the basement membrane, lumen formation and anastomosis with other new or pre-existing vessels, eventually leading to the formation of intact microvessels.

CANCER'S ANGIOGENIC SWITCH

Angiogenic phenotype serves the development of malignant tumor at multiple stages. Tumor cells may overexpress one or more of the positive regulators of angiogenesis, may mobilize an angiogenic protein from the ECM, may recruit host cells such as macrophages (which produce their own angiogenic proteins), or may engage in a combination of these processes. Tumor angiogenesis is mediated by tumor-secreted angiogenic growth factors that interact with their surface receptors expressed on ECs. The most commonly found angiogenic growth factors such as VEGF and bFGF, when encounter ECs, they bind to the tyrosine kinase receptors on ECs membrane. Binding leads to dimerization of the receptors and activation of autophosphorylation of tyrosines on the receptor surface and thereby initiates the several signaling proteins (including PI3-kinase, Src, Grb2/m-SOS-1 (a nucleotide exchange factor for Ras) and signal transducers and activators of transcriptions (STATs) each of which contains src-homology-2 (SH-2) domains^[2]. Binding of the SH-2 regions of these proteins to the phosphotyrosines on the receptor tyrosine kinases (RTKs) activates several pathways that are crucial for triggering the cell cycle machinery. The most well studied pathway passes through the GTP-binding protein Ras and activates the mitogen activated protein kinase (MAPK) cascade and subsequently transcription factors in the nucleus^[2]. Up-regulation of an angiogenic factor is not sufficient in itself for a tumor cell to become angiogenic, however, certain negative regulators or inhibitors of vessel growth may need to be down-regulated^[3]. If there is a preponderance of angiogenic factors in the local milieu, the neovasculature may persist as capillaries, or differentiate into mature venules or arterioles. If instead, the local milieu changes such that there is a preponderance of angiostatic factors, the neovessels can regress. The angiostatic factors that mediate regression can do so either by inducing apoptosis or cell cycle arrest of ECs. Thus, the switch to the angiogenic phenotype is regulated by a change in the local equilibrium between positive and negative regulators of the growth of microvessels^[1,3].

FACTORS INVOLVED IN TUMOR ANGIOGENESIS

Vascular endothelial growth factor and receptors

Vascular endothelial growth factor (VEGF), also known as

vascular permeability factor (VPF), is a heparin-binding angiogenic growth factor, and is highly expressed in various types of tumors. It may increase ECs permeability by enhancing the activity of vesicular-vacuolar organelles, clustered vesicles in ECs lining small vessels that facilitate transport of metabolites between luminal and abluminal plasma membranes^[4]. Alternatively, VEGF may enhance permeability through mitogen-activated protein (MAP) kinase signal transduction cascade by loosening adhering junctions between ECs in a monolayer via rearrangement of cadherin/catenin complexes^[5,6]. In addition, recent studies have shown that VEGF enhances ECs permeability by activating PKB/Akt, endothelial nitric-oxide synthase (eNOS), and MAP kinase dependent pathways using human umbilical vein endothelial cell^[7] (Figure 1). Increased vascular permeability may allow the extravasation of plasma proteins and formation of ECM favorable to endothelial and stromal cell migration.

Figure 1 The triggering mechanism in tumor angiogenesis: inactivated tumor suppressor genes/activated oncogenes versus hypoxia.

VEGF is an EC specific mitogen. VEGF, after binding to its high affinity receptors (Flt-1/VEGFR-1, Flk-1/KDR/VEGFR-2), promotes the formation of the second messenger via hydrolysis of inositol, thus induces the autophosphorylation of the receptors in the presence of heparin-like molecules, and open phosphatidylinositol metabolic signal transduction pathways, activates MAP kinases in EC and thereby VEGF exerts its mitogenic effect by promoting EC proliferation^[8,9].

VEGF induces a balanced system of proteolysis that can remodel ECM components necessary for angiogenesis. VEGF stimulates EC production of urokinase-like plasminogen activator (uPA), tissue type plasminogen activator (tPA) and plasminogen activator inhibitor-1 (PAI-1)^[10,11], proteolytic enzymes, tissue factors, and interstitial collagenase^[12]. Plasminogen activators activate plasminogen to plasmin, which can break down ECM components. In addition to remodeling the basement membrane, uPA bound to uPAR also mediates intracellular signal transduction in ECs. Tang *et al.* have demonstrated that uPAR occupancy on ECs results in the phosphorylation of focal adhesion proteins and the activation

of MAP kinase^[13] through which uPA influences EC migration and proliferation (Figure 2).

Moreover, VEGF has been shown to exhibit its angiogenic effect by inducing expression of the $\alpha_1\beta_1$, $\alpha_2\beta_1$ and $\alpha_v\beta_3$ integrins, which promote cell migration, proliferation and matrix reorganization (Figure 2), and $\alpha_1\beta_1$, $\alpha_2\beta_1$ and $\alpha_v\beta_3$ antagonists may prove effective on inhibiting VEGF-driven angiogenesis associated with cancers and other pathologies through apoptosis^[14,15]. VEGF, in addition to a very specific mitogen for vascular EC, is a potent pro-survival factor for ECs in newly formed immature vessels. Several endothelial survival factors (VEGF, angiopoietin-1 and $\alpha_v\beta_3$) suppress p53, p21, p16 and p27, and proapoptotic protein Bax, whereas they variably activate the survival PI3K/Akt, p42/44 MAP kinases, bcl-2, A1 and survivin pathways^[16-20] (Figure 2). It was reported that p42/p44 MAP kinases promoted VEGF expression by activating its transcription via recruitment of the AP-2/Sp1 (activator protein-2) complex on the proximal region (-88/-66) of the VEGF promoter and by direct phosphorylation of hypoxia-inducible factor 1 alpha (HIF-1 alpha)^[21]. Pharmacological inhibition of PI3K or transfection with a dominant-negative Akt mutant abolished the antiapoptotic effect of VEGF on ECs. In addition to the PI3K/Akt pathway, ras-dependent signaling pathways might also play an important role at least for VEGF signaling. Thus, H-rasV12G down-regulation leads to profound tumor regression, which is initially characterized by massive apoptosis of tumor- and host-derived ECs^[22]. Therefore, apoptosis induction is resistant to enforced VEGF expression, suggesting that VEGF requires an intact Ras-dependent signaling pathway to mediate its apoptosis inhibitory effect^[22]. And also, VEGF via the KDR/Flt-1 receptor induces enhanced expression of the serine-threonine protein kinase Akt^[19], a downstream target of PI3-kinase, which potentially blocks apoptosis by interfering with various apoptosis signaling pathways^[23,24], promotes EC migration^[25], and enhances the expression of the hypoxia-inducible factor (HIF), which is known to stimulate VEGF expression^[26], suggesting a potent proangiogenic effect^[27,28]. These findings have identified the VEGFR2 and the PI3K/Akt signal transduction pathway as crucial elements in promoting EC survival induced by VEGF. The downstream effector pathways mediating the antiapoptotic VEGF effect include Akt-dependent activation of the endothelial nitric oxide synthase (NOS)^[29,30], resulting in an enhanced endothelial NO synthesis, which, in turn promotes EC survival (Figure 2). Gupta *et al.* demonstrated that the VEGF-induced activation of the MAPK/extracellular signal-regulated kinase (ERK) pathway and inhibition of the stress-activated protein kinase/c-Jun amino-terminal kinase pathway is also implicated in the antiapoptotic effect mediated by VEGF^[31] (Figure 2). Interestingly, the activation of the PI3K/Akt pathway mediates not only the antiapoptotic effect but also the migratory effect of VEGF on ECs via Akt-dependent phosphorylation and activation of eNOS^[32] (Figure 2).

The expression of VEGF mRNA is highest in hypoxic tumor cells adjacent to necrotic areas. Hypoxia-induced transcription of VEGF mRNA is apparently mediated, at least in part, by the binding of hypoxia-inducible factor 1 (HIF-1) to an HIF-1 binding site located in the VEGF promoter, and by the activation of a stress inducible PI3K/Akt pathway^[26,33]. In fact, progressive growth of tumor creates ongoing hypoxia, which up-regulates several pro-angiogenic compounds including VEGF, bFGF, IL-8, TNF- α , TGF- β etc. These compounds, via several mechanisms such as increase of vessel hyperpermeability, release of plasma proteins, induction of proteases, fibrin formation, EC proliferation, migration etc, promote angiogenesis and fibrinolysis resulting in continued tumor growth and dysfunctional vasculature, which further positively feedback to create continuing hypoxia inside tumors (Figure 1).

Fibroblast growth factors

Fibroblast growth factors (FGFs) and their receptors are overexpressed in various types of cancers, and are important tumor angiogenic and ECs survival factors. Pardo *et al.* reported that bFGF induced expression of the antiapoptotic proteins bcl-XL and bcl-2 via the MEK/ERK signaling pathway^[34] (Figure 2). Expression of VEGF mRNA in the tumor is increased by bFGF overexpression, and the bFGF-induced tumor development is significantly inhibited by treatment with KDR/Flk-1 neutralizing monoclonal antibody (mAb), which suggests that bFGF synergistically augments VEGF-mediated hepatocellular carcinoma development and angiogenesis, at least in part, by induction of VEGF through KDR/Flk-1^[35]. In addition, bFGF induces an increase of VEGF mRNA in vascular smooth muscle cells^[36] and an increase in VEGF receptors in microvascular ECs^[37]. aFGF and bFGF are mitogenic for ECs and stimulate ECs migration as well as ECs production of plasminogen activator (PA) and collagenase that are capable of degrading basement membrane^[38] (Figure 2). FGFs are responsible for production of ECM and release of matrix metalloproteinases (MMPs) for selective degradation and organization of ECM^[39] (Figure 2).

Binding of FGFs to their high affinity receptors causes the activation of the intrinsic tyrosine kinase and a cascade of events, leading eventually to the induction of immediate early gene transcription, and to cell proliferation. FGFs receptors dimerize upon ligand binding, and transphosphorylate at tyrosine residue. Angiogenic growth factors, like bFGF and VEGF165, require interaction with heparin sulfate (HS) in order to induce a proliferative signal through tyrosine kinase receptors. Binding of bFGF to high affinity cell surface receptor sites can be modulated by heparin-mimicking compounds (i. e. RG-13577) that can modulate abnormal bFGF signaling by disrupting bFGF mediated autocrine loop, compete with heparin sulfate (HS) on binding to bFGF, bind the growth factor, and prevent receptor binding and/or dimerization^[40], and by proteolytic enzymes (e.g. MMP-2) that cleave the ectodomain of the receptor. These effects are associated with profound inhibition of bFGF mediated signal transduction (tyrosine phosphorylation) and proliferation of vascular ECs^[40]. Spontaneous migration of ECs is inhibited by neutralizing antibodies to bFGF, suggesting an autocrine of bFGF synthesized and released by the ECs themselves^[38]. A dominant-negative receptor, which, when co-expressed with

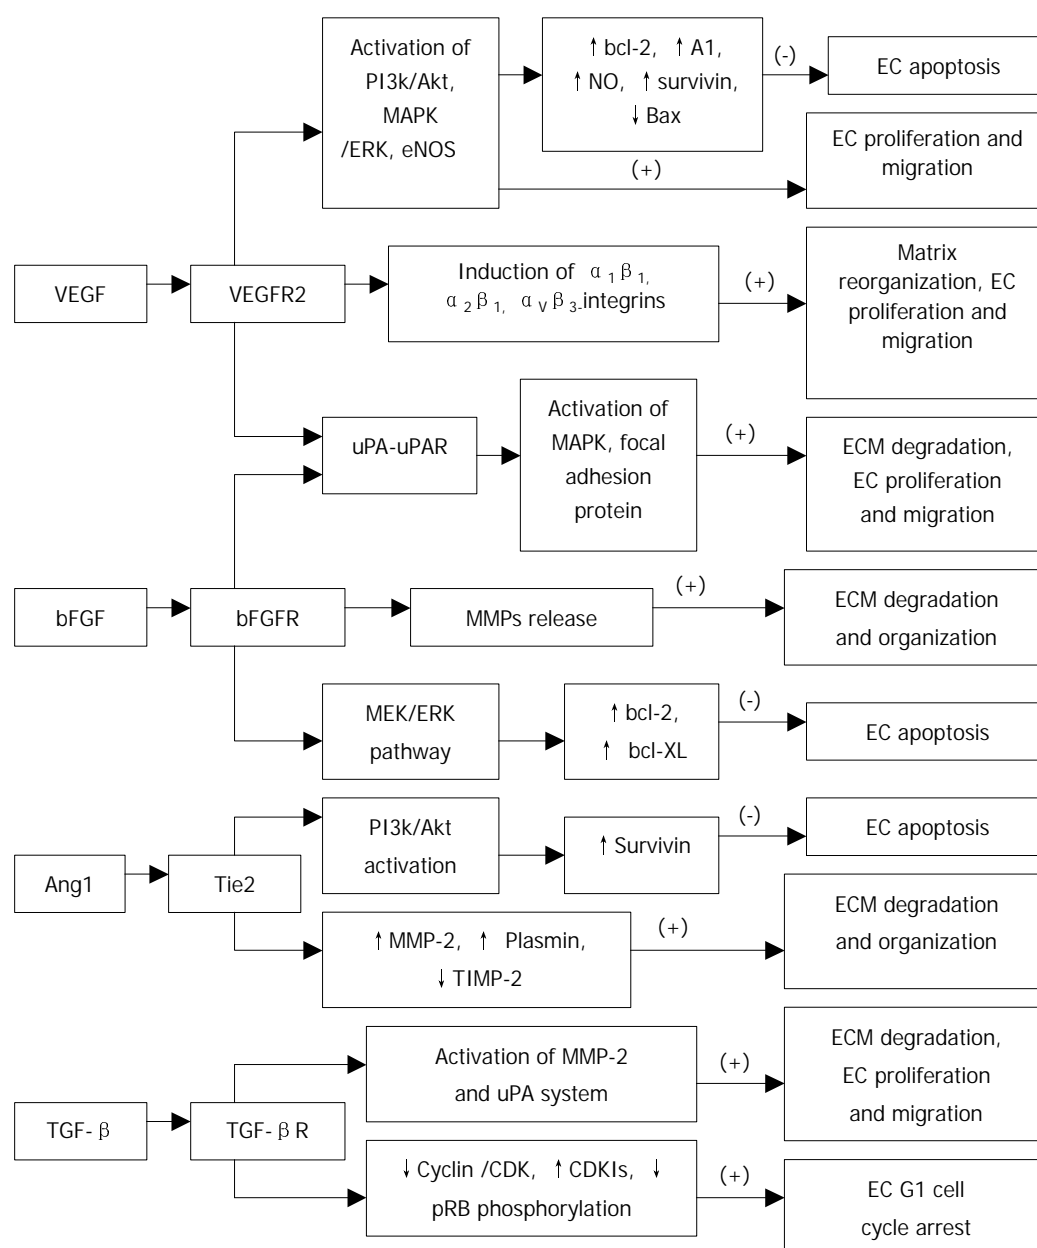

Figure 2 Mechanism of angiogenesis by angiogenic factors.

FGF receptors (FGFRs), can block the activation and signal transduction. In addition, the ligand-specific targeting of toxin to tumor cells expressing FGFRs and the compounds that bind and inactivate FGF ligands, can block ECs proliferation.

Angiopoietins and tie receptors

It has been proposed that angiopoietin-1 (Ang1) and angiopoietin-2 (Ang2) are pro-angiogenic and anti-angiogenic owing to their respective agonist and antagonist signaling action through the Tie2 receptor^[41]. Lobov *et al.* have demonstrated that *in vivo*, in the presence of endogenous VEGF-A, Ang2 promotes a rapid increase in capillary diameter, remodeling of the basal lamina, proliferation and migration of ECs, and stimulates sprouting of new blood vessels^[41]. By contrast, Ang2 promotes ECs death and vessel regression if the activity of endogenous VEGF is inhibited^[41]. It was reported that Ang1 induced phosphorylation of Tie2 and the p85 subunit of PI 3'-kinase and increased PI 3'-kinase activity in a dose-dependent manner, suggesting that the Tie2 receptor, PI 3'-kinase, and Akt are crucial elements in signal transduction pathway leading to EC survival induced by the paracrine activity of Ang1^[42] (Figure 2). Alternatively, Ang1 prevents EC apoptosis via Akt/survivin pathway by activating a critical survival messenger, Akt, and by up-regulating a broad spectrum apoptosis inhibitor, survivin^[43, 44] (Figure 2), but has no effect on the expression of bcl-2 and XIAP^[44]. Moreover, Ang1-induced migratory effect might be mediated through PI 3'-kinase activity dependent tyrosine phosphorylation of p125^{FAK}, which plays a key role in regulating dynamic changes in actin cytoskeleton organization during EC migration^[45]. Increased plasmin and MMP-2 secretion, and suppressed TIMP-2 secretion by Ang1 from ECs are also important determinants for inducing ECs sprouting^[45] (Figure 2). In contrast, the PI 3'-kinase inhibitors have been found to inhibit Ang1-stimulated tyrosine phosphorylation of p125^{FAK}, and secretion of MMP-2 and plasmin from ECs and migration^[45]. Ang2 blocks Ang1-mediated Tie2 autophosphorylation in ECs and acts as a check point on Ang1/Tie2-mediated angiogenesis to prevent excessive branching and sprouting of blood vessels by promoting destabilization of blood vessels.

Transforming growth factor- β

Transforming growth factor- β s (TGF- β s) are multifunctional polypeptides that regulate cell growth and differentiation, ECM deposition, cellular adhesion properties, angiogenesis and immune functions. TGF- β 1 acts through the TGF- β type I and type II receptors to activate intracellular mediators, such as Smad proteins, the p38 MAPK, and the ERK pathway^[46]. TGF- β 1 mRNA levels by activin receptor-like kinase 5 (ALK5) independent of p38 MAPK activation^[46]. In contrast, TGF- β 1 induction of fibronectin (FN) mRNA requires p38 MAPK activity^[46]. TGF- β 1 induction of PAI-1 and TSP-1 mRNA uses at least ALK5 and possibly the p38 MAPK pathway^[46]. TGF- β secreted by most cultured cells is in biologically inactive form, and cannot bind TGF- β receptors; the latent TGF- β is activated by proteases such as plasmin and cathepsin D, low pH, chaotropic agents such as urea, and heat^[47, 48]. Several studies suggested that VEGF increases plasminogen activator (PA) activity in vascular ECs^[11] and that plasmin is able to activate latent TGF- β ₁^[49, 50] which decreases Flk-1 expression and thereby negatively regulates the VEGF/Flk-1 signal transduction pathway in EC^[51], raise the possibility that a complex self-regulating mechanism of VEGF signal transduction may exist during angiogenesis^[50]. However, immunohistochemical study has shown that TGF- β 1 might be associated with tumor progression by indirectly stimulating angiogenesis through the up-regulation of VEGF expression in gastric carcinoma^[52]. In addition, TGF- β 1 inhibits the

generation of the anti-angiogenic molecule angiostatin by human pancreatic cancer cells in a time- and dose-dependent manner, and this effect is mediated through modulation of the plasminogen/plasmin system^[53].

TGF- β not only inhibits the activity and expression of cyclins and CDKs but also induces the cyclin-dependent kinase inhibitors (CDKIs) p15, p27 and p15, which bind to the cyclin/CDKs, preventing phosphorylation of pRB and thereby arresting most epithelial cells (including ECs) at late G1 phase^[54] (Figure 2). The effects of TGF- β 1 on endothelial tube formation may be mediated through a net antiproteolytic activity by modulating uPA and PAI levels^[55]. Ellenrieder *et al.* reported that TGF- β treatment of PANC-1 and IMIM-PC1 cells resulted in strong up-regulation of expression and activity of both matrix metalloproteinase-2 (MMP-2) and the uPA system, and treatment with MMP inhibitors or inhibitors of the uPA system caused significant reduction of TGF- β -induced invasiveness in both cell lines suggesting that TGF- β acts in an autocrine manner to induce tumor cell invasion, which is mediated by MMP-2 and the uPA system^[56] (Figure 2). Furthermore, TGF- β indirectly stimulates angiogenesis by the recruitment of inflammatory mediators that secrete angiogenic factors. Thus, TGF- β regulates vascular remodeling through its pleiotropic effects on different cell types.

Interleukin-8 and matrix metalloproteinase-2

Up-regulation of MMP activity, favoring proteolytic degradation of the basement membrane and ECM, has been linked to tumor growth and metastasis, as well as tumor-associated angiogenesis. IL-8 mRNA is up-regulated in neoplastic tissues, such as non-small cell lung cancer^[57] and that its expression correlates with the extent of neovascularization, tumor progression and survival. And also, MMP-2 mRNA level is increased in tumor cells transfected with IL-8, but VEGF and bFGF mRNA levels are unchanged^[58, 59] suggesting that IL-8-induced MMP-2 production is a major mechanism by which tumor cells induce angiogenesis. IL-8 can also be up-regulated by hypoxia, suggesting that the environment plays a major role in regulating IL-8 expression and metastasis^[58]. MMPs induce tumor angiogenesis by degrading ECM and thereby release angiogenic mitogens that have been shown to be stored within the matrix. In addition, MMP-2 and MMP-3 are able to release soluble FGF receptor 1 (FGFR1)^[60] and soluble 12-kDa immunoreactive and mitogenic heparin-binding epidermal growth factor (HB-EGF)^[61], respectively. MMP-2 has been shown to directly modulate melanoma cell adhesion, spreading on ECM and invasion^[62], and an inhibitor of MMP-2 significantly inhibits growth and neovascularization of tumors implanted into chick chorioallantoic membrane (CAM) by preventing MMP-2 binding to $\alpha v \beta_3$ and blocking cell surface collagenolytic activity^[63]. Furthermore, MMP-9, as well as MMP-2 proteolytically cleave and activate latent TGF- β , and promote tumor invasion and angiogenesis^[64].

Oncogene and tumor suppressor genes

Oncogenes are found to be activated and tumor suppressor genes are found to be inactivated in tumor, and hence promote tumor growth and angiogenesis through different mechanisms (Figure 1). It has been shown that VEGF is introduced by K- or H-ras mutant gene, v-src and v-raf in transformed fibroblast and ECs. Other angiogenic factors such as VEGF, TNF- α , TGF- β have been shown to be up-regulated by mutant ras^[65]. These effect may be mediated through a ras-raf-MAP kinase signal transduction pathway (Figure 1), which results in activation of promoter regions of genes of angiogenic growth factors^[66]. Moreover, expression of ras, either constitutive or transient, potentiated the induction of VEGF by hypoxia^[67].

p53 is an important suppressor gene, which inhibits the angiogenic process by inducing thrombospondin-1, down-regulating VEGF and NOS and, in addition, down-regulating hypoxia-induced angiogenesis, either inducing apoptosis or enhancing anti-angiogenic factors^[68]. A transient transfection of mutated p53 results in up-regulation of VEGF mRNA in NIH3T3 cells^[69]. In contrast, adenovirus-mediated wild-type p53 overexpression down-regulates CD40-induced VEGF expression and transmigration in human multiple myeloma cells expressing mutant p53^[70]. And, we have previously demonstrated that the expression of Flt-1 receptor is significantly correlated with p53 mutation gene, not obviously with ras mutation gene in pancreatic carcinoma cells, which suggest that wild type p53, after mutation, might lose the suppressive function to the expression of Flt-1 receptor, thus results in neovascularization of pancreatic neoplasm and promotes the growth of tumor cells, whereas ras mutation may take part in neovascularization through other approaches. Recombinant wild type p53 represses bFGF mRNA translation in rabbit reticulocyte lysate, in a dose- dependent manner via blocking translation initiation by preventing 80S ribosome formation on an mRNA bearing the bFGF mRNA leader sequence^[71]. Moreover, adenoviral vector-mediated wild type p53 transduction results in tumor regression, at least in part, via anti-angiogenesis mediated by the down-modulation of FGF binding protein, a secreted protein required for the activation of angiogenic factor bFGF^[72]. In addition, wild type p53 gene transfer significantly reduces cell invasiveness *in vitro* via a decrease in the secreted levels of MMP-2 in mutated p53 human melanoma cell lines^[73]. Biologically, p53 acts at a G1/S check point, postponing DNA replication after certain cell stress, such as DNA damage^[74], and also induces the apoptotic pathway of cell death^[75].

THE ANGIOGENIC INHIBITORS

Mechanism of angiogenesis inhibitors

Leading anti-angiogenic targets that have been identified are^[76, 77]: (1) inhibition of the growth factors that promote endothelial proliferation; (2) inhibition of the proteases required for ECs to penetrate basement membrane and form new blood vessels; (3) disruption of specific intracellular signal transduction pathway; (4) induction of EC apoptosis or inhibition of EC survival; (5) inhibition of endothelial bone marrow precursor cells; and (6) inhibition of $\alpha v \beta_3$ -integrin-vitronectin interaction that is pivotal in mediating ECs adhesion to ECM during neovascularization^[77].

Inhibitors of angiogenic growth-factors and their receptors

One broad class of angiogenesis inhibitors is made up of drugs that target growth factors such as bFGF and VEGF. The factors tend to bind to heparin, a property that may trap them within the ECM and may thereby govern their bioavailability. Hence, the early generation of drugs is heparin-like (e.g. Pentosan polysulfate), especially with regard to carrying multiple negative charges that promote growth factor binding. However, receptor targeting agents can impede tumor growth and metastasis by interfering, at specific growth-factor receptors, such as those for FGFs and VEGF, with the transduction of angiogenic stimuli into intracellular responses. In these pathways, the receptors are transmembrane tyrosine kinases, in which ligand binding to an extracellular domain induces autophosphorylation of an intracellular kinase domain. Each kinase then functions as an activator of downstream signals. To disrupt such a sequence, a drug may compete for receptor binding and prevent tyrosine kinase autophosphorylation. Inhibitors of VEGF family include: (1) anti-VEGF mAb^[78]: directly neutralizes VEGF proteins, and inhibits biological

activities of VEGF; (2) soluble VEGF receptors: specifically bind to VEGF, indirectly block the function of VEGF with receptors; (3) inhibitors of VEGF receptors^[79]: bind to VEGF receptors and block their functions with VEGF; (4) inhibitors of VEGF signal transduction: interfere a series of signal transduction pathways by blocking autophosphorylation of VEGF receptors; (5) VEGF antisense^[80]: is a specific nucleotide sequence, which binds to VEGF mRNA and thereby interferes VEGF mRNA translation and VEGF protein formation. A recent study has shown that the VEGFR2 DNzyme can cleave its substrate efficiently in a concentration- and time-dependent manner, inhibit the proliferation of EC with a concomitant reduction of VEGFR2 mRNA, and inhibit tumor growth *in vivo*^[81].

Endogenous angiogenesis inhibitors

More than 40 endogenous angiogenesis inhibitors have been characterized, and they are divided into 4 major groups: interferons (IFNs), proteolytic fragments, interleukins (ILs), and tissue inhibitors of metalloproteinases (TIMPs)^[82].

Interferons The interferons (INF- α , - β , and - γ) are members of a family of secreted glycoproteins, which have direct or indirect inhibitory effect on tumor angiogenesis and growth. IFN- α/β have been reported to down-regulate the expression of pro-angiogenic factor MMP-9 mRNA and protein in different cancers^[83-86]. Also, IFN- α/β down-regulate IL-8 expression in bladder cancer^[83-84]. Several studies demonstrated that the administration of optimal biological dose of IFN- α/β decreased the expression of bFGF mRNA and protein and microvessel density in the tumors and, in addition, induced EC apoptosis^[83-85, 87]. Sasamura *et al.* demonstrated that IFN- γ had mild inhibitory effects on VEGF mRNA and bFGF mRNA expression, whereas IFN- α did not significantly decrease the level of either VEGF mRNA or bFGF mRNA in renal cell carcinoma^[88]. However, some studies demonstrated that IFN- α/β treatment did not cause the reduction of bFGF and VEGF levels in serum from patients with carcinoid tumours^[89] and leukemia^[86]. Thus, anti-angiogenic effect of IFNs treatment might be mediated by the regulation of different angiogenic factors in different tumors in dose- and time-dependent manner. Moreover, IFN- γ is presumed to induce its anti-angiogenic effects through the secretion of IFN- γ -inducible protein 10 (IP-10) and monokine induced by IFN- γ ^[90]. Finally, IFNs have antitumor properties, which may be mediated through a direct cytotoxic effect on tumor cells, augmentation of immunogenicity of tumor by up-regulation of major histocompatibility (MHC) classes *I and II* and tumor associated antigens, and/or activation of macrophages, T lymphocytes and natural killer cells^[89].

Interleukins It was reported that interleukins (ILs) having a Glu-Leu-Arg (ELR) motif at the NH₂ terminus, such as IL-8, enhance angiogenesis, and those that lack this sequence, such as IL-4, inhibit it^[91]. IL-4 inhibits *in vivo* neovascularization induced by bFGF in the rat cornea and blocks the migration of microvascular ECs toward bFGF *in vitro*^[92]. However, it has been shown that IL-1 α , a representative cytokine of activated macrophages, induces angiogenesis through the enhanced expression of various angiogenic factors such as VEGF, IL-8, and bFGF^[93]. And also, IL-6 was found to counteract the apoptotic effect mediated by wild type p53^[75]. Several studies have reported that IL-12 suppresses the expression of VEGF mRNA^[94, 95], bFGF^[94] and MMP-9 mRNA^[94]. Additionally, IL-12 was found to stimulate mRNA expression of IFN- γ and its inducible anti-angiogenic chemokine IFN- γ -inducible protein (IP-10) in ECs cultured with IL-12^[95]. IL-12 significantly promotes apoptosis and inhibits proliferation rate of human tumors and extensive necrosis in the murine, and thereby reducing tumor vessel density^[95]. Furthermore, the *in vivo* inhibition of neovascularization in IL-10-secreting tumors

might be mediated by the ability of IL-10 to down-regulate the synthesis of VEGF, IL-1 β , TNF- α , IL-6, and MMP-9 in tumor-associated macrophages^[96]. And also, IL-10 inhibits tumor metastasis through a natural killer (NK) cell-dependent mechanism^[96].

Tissue inhibitors of metalloproteinases Remodeled ECM components comprise a scaffold upon which ECs can adhere, migrate, and form tubes, and deposition of these components forms the basal lamina that ensheaths endothelial and mural cells. *In vitro* migration of ECs through gelatin is significantly inhibited by overexpressed TIMP-1^[97]. Murphy *et al.* reported that TIMP-2, but not TIMP-1, inhibited bFGF-induced EC proliferation^[98]. TIMP-2 is able to inhibit soluble FGFR1 released by MMP-2^[60]. Transfection of the highly metastatic B6F10 murine melanoma cell line with TIMP-2 cDNA showed the reduced levels of blood vessel formation and diminished induction of EC migration and invasion^[99]. Studies have shown that the overexpression of TIMP-3 induces the apoptotic cell death of a number of cancer cell lines and rat vascular smooth muscle cells through the stabilization of TNF- α receptors on the cell surface, perhaps by inhibiting a receptor shedding metalloproteinase^[100, 101]. Furthermore, anti-angiogenic and antitumor effects of TIMP-3 appear to be mediated, in part, by decreased expression of vascular endothelial (VE)-cadherin by ECs in the presence of TIMP-3 in an *in vitro* assay and in TIMP-3-overexpressing tumors^[102]. Finally, TIMP-1, TIMP-2, TIMP-3 and TIMP-4 inhibit neovascularization by inhibiting MMP-1, MMP-2, and MMP-9 induced breakdown of surrounding matrix^[103]. Thus, the multiple effects of TIMPs on both endothelial and tumor cells migration render MMPs attractive targets for tumor therapy.

Proteolytic fragments Most of these fragments are derived from ECM components, such as collagen or fibronectin, or from enzymes such as plasminogen and MMP-2 that remodel ECM. Perhaps the most characterized inhibitors in this class are angiostatin and endostatin.

Angiostatin The anti-angiogenic effect of angiostatin, a 38-kDa internal fragment of plasminogen, may be mediated, at least in part, by their ability to down-regulate VEGF expression within the tumor^[104]. Angiostatin inhibits hepatocyte growth factor (HGF)-induced phosphorylation of c-met, Akt, and ERK1/2, and thereby exerts its anti-angiogenic effect via disruption of HGF/c-met signaling^[105]. Intraperitoneal administration of angiostatin potentially inhibits the neovascularization and metastasis formation in mice observed after a primary tumor has been removed^[106]. It has been shown that binding of angiostatin to the α/β -subunits of plasma membrane-localized ATP synthase may suppress endothelial-surface ATP metabolism and thereby mediates its anti-angiogenic effects and the down-regulation of EC proliferation and migration^[107, 108] (Figure 3). Further, adenoviral mediated angiostatin gene transfer selectively inhibits EC proliferation and disrupts the G₂/M transition induced by M-phase-promoting factors, and that ECs show a significant mitosis arrest that is correlated with the down-regulation of the M-phase phosphoproteins^[109]. Other studies have shown that angiostatin treatment significantly increases the apoptosis of EC and tumor cells, and decreases density of tumor blood vessels^[109-111]. Angiostatin was found to produce a transient increase in ceramide that correlates with actin stress fiber reorganization, detachment and death^[112] and, in addition, treatment with angiostatin or ceramide resulted in the activation of RhoA, an important effector of cytoskeletal structure^[112] (Figure 3). Angiostatin can selectively regulate the expression of E-selectin and thereby inhibits the proliferation of ECs.

Endostatin It is a 20-kDa fragment of type XVIII collagen that has been identified as a factor produced by hemangioendothelioma cells that inhibits ECs proliferation,

angiogenesis and tumor growth. The mechanisms by which endostatin inhibits VEGF-induced proliferation and migration of ECs are (Figure 3): First, endostatin blocks the VEGF-induced tyrosine phosphorylation of KDR/Flk-1 in ECs^[113]. Second, endostatin suppresses the VEGF-induced activation of ERK, p38 MAPK, and p125^{FAK}, which are downstream events of the KDR/Flk-1 signaling and are involved in the mitogenic and motogenic activities of VEGF in ECs^[113]. Third, endostatin inhibits the binding of VEGF to ECs and to its cell surface receptor, KDR/Flk-1^[113]. Finally, endostatin directly binds to KDR/Flk-1 but not to VEGF^[113]. Endostatin was found to exhibit its anti-migratory effect by reducing VEGF-induced phosphorylation of endothelial NOS (eNOS)^[114] (Figure 3). Rehn *et al.* demonstrated that soluble endostatin was capable of binding to α_v - and α_5 -integrins, thereby inhibiting the integrin functions, such as EC migration^[115] (Figure 3). In addition, endostatin may exert its antiproliferative and anti-angiogenic effects by competing with bFGF for binding to cell surface heparan sulphate proteoglycans, which could disrupt the mitogenic growth factor signaling^[116]. Endostatin induces a significant decrease in EC proliferation in the basal state and after stimulation by neuropeptide Y and bombesin^[117]. Endostatin potentially inhibits both the extracellular activation of proMMP-2 by inhibition of membrane-type 1 MMP (MT1-MMP) and the catalytic activity of MMP-2 and thereby can block the invasiveness of ECs and tumor cells^[118]. The proapoptotic activity of endostatin appears to be mediated via tyrosine kinase signaling^[119] and reduction of antiapoptotic proteins bcl-2 and bcl-XL without affecting the level of the proapoptotic Bax protein^[120] (Figure 3). Furthermore, the Shb adaptor protein has been suggested to be involved in the mediation of the apoptotic signaling of endostatin^[119] (Figure 3).

Somatostatin and its analogs

Somatostatin (SS) and its analogs inhibit the proliferation of somatostatin receptors (SSTRs) positive endocrine neoplasm. The antiproliferative action of SS is signaled via five specific G-protein coupled receptors (SSTR1-SSTR5), which initiate pertussis toxin sensitive-G protein dependent, and tyrosine phosphatase mediated cell growth arrest or apoptosis according to receptor subtypes and target cells. It has been shown that activation of SSTR1, 2, 4, and 5 induce G1 cell cycle arrest through the ability of SS to maintain high levels of CDKIs p27^(Kip1) and p21, and inactivate cyclin E-CDK2 complexes, thus leading to hypophosphorylation of pRb^[121, 122] (Figure 3). Moreover, somatostatin-mediated growth inhibition of normal and cancer pancreatic acinar cells is triggered via an inhibition of PI3-kinase signaling pathway^[123]. SS may directly stimulate tumor apoptosis via sstr3-dependent G protein signaling, causing the induction of suppressor gene p53 and proapoptotic protein Bax^[124] (Figure 3). Our recent investigation reported that the low expression or loss of SSTR2 gene was more negatively correlated with the over-expression of p53 and ras mutation genes, which might take part in the angiogenesis of pancreatic neoplasm, whereas there was no significant relationship between SSTR2 and DPC4 (deleted in pancreatic cancer, locus 4), which suggested that there was different regulatory pathway in neovascularization of pancreatic neoplasm. Albini *et al.* provided evidence that SS inhibits Kaposi sarcoma associated angiogenesis by inhibiting both EC proliferation and invasion, and also by inhibiting migration of monocytes, which are important mediators of the angiogenic cascade, and are able to produce survival factors that, in turn, activate ECs^[125]. In addition, SS induces a significant decrease in basal and stimulates EC proliferation in HUVEC, and also decreases number of capillaries^[117]. CAM model study showed that unlabeled SS analogs inhibited angiogenesis, which was

proportional to the ability of the analogs to inhibit growth hormone (GH) production^[126].

It is defined that SSTR subtypes are responsible for the specific post-receptor signal transduction mechanisms involved in octreotide's inhibition of angiogenesis^[126]. The intracellular signal transduction mechanisms involved in this angiogenic inhibition include the G^α_i-binding protein, cAMP, and calcium^[127]. Further, SS and its analogs induce their biologic effects by interacting with specific receptors that are coupled to a variety of signal transduction pathways involving adenylate cyclase, guanylate cyclase, ionic conductance channels, phospholipase C-β, phospholipase A₂, and tyrosine phosphatase and protein dephosphorylation and thereby regulate cell growth^[128, 129]. The best characterized pathway involves the inhibition of adenylate cyclase, leading to a reduction in intracellular cAMP levels. Antiproliferative effects that are mediated through SSTR1 and SSTR2, involve the stimulation of tyrosin phosphatases, however SSTR5 appears to be coupled to inositol phospholipid/calcium pathway^[130]. Mentlein *et al.* reported that cultivated cells from solid human gliomas of different stages and glioma cell lines secreted variable amounts of VEGF, which was reduced between 25 and 80 % of control levels depending on the glioma by co-incubation with SS or

SSTR2-selective agonists (octreotide and L-054 522) in dose-dependent manner^[131]. Growth factor-induced (EGF, bFGF) VEGF synthesis could also be suppressed to <50 % by co-incubation with SS or SSTR2-selective agonists, which was less pronounced in hypoxia-induced VEGF synthesis^[131]. And also, SS and octreotide diminished the proliferative activity of cultured murine ECs HECa10 *vs.* controls; however, SS and octreotide did not change the release of VEGF into supernatants of 24-h or 72-h EC cultures^[132]. A recent study has demonstrated that SS 14 can reduce bFGF-induced corneal angiogenesis^[133].

In summary, the mechanisms of action of tumor growth inhibition by SS and its analogs are^[134]: (1) inhibition of the secretion of hormones, such as GH, insulin and/or gastrointestinal hormones; (2) direct or indirect (via GH) inhibition of IGF-1 and/or other growth factors that exert a stimulatory effect on tumor growth. On the other hand, SS analogs can selectively stimulate the formation of IGF-binding protein 1, and thereby interfering with IGF-1 action at the receptor level; (3) inhibition of angiogenesis through different mechanisms; (4) direct antimitotic effects of growth factors, which act on tyrosine kinase receptors such as EGF and FGF, via SSTRs on the tumor cells; (5) modulation of immunological activity.

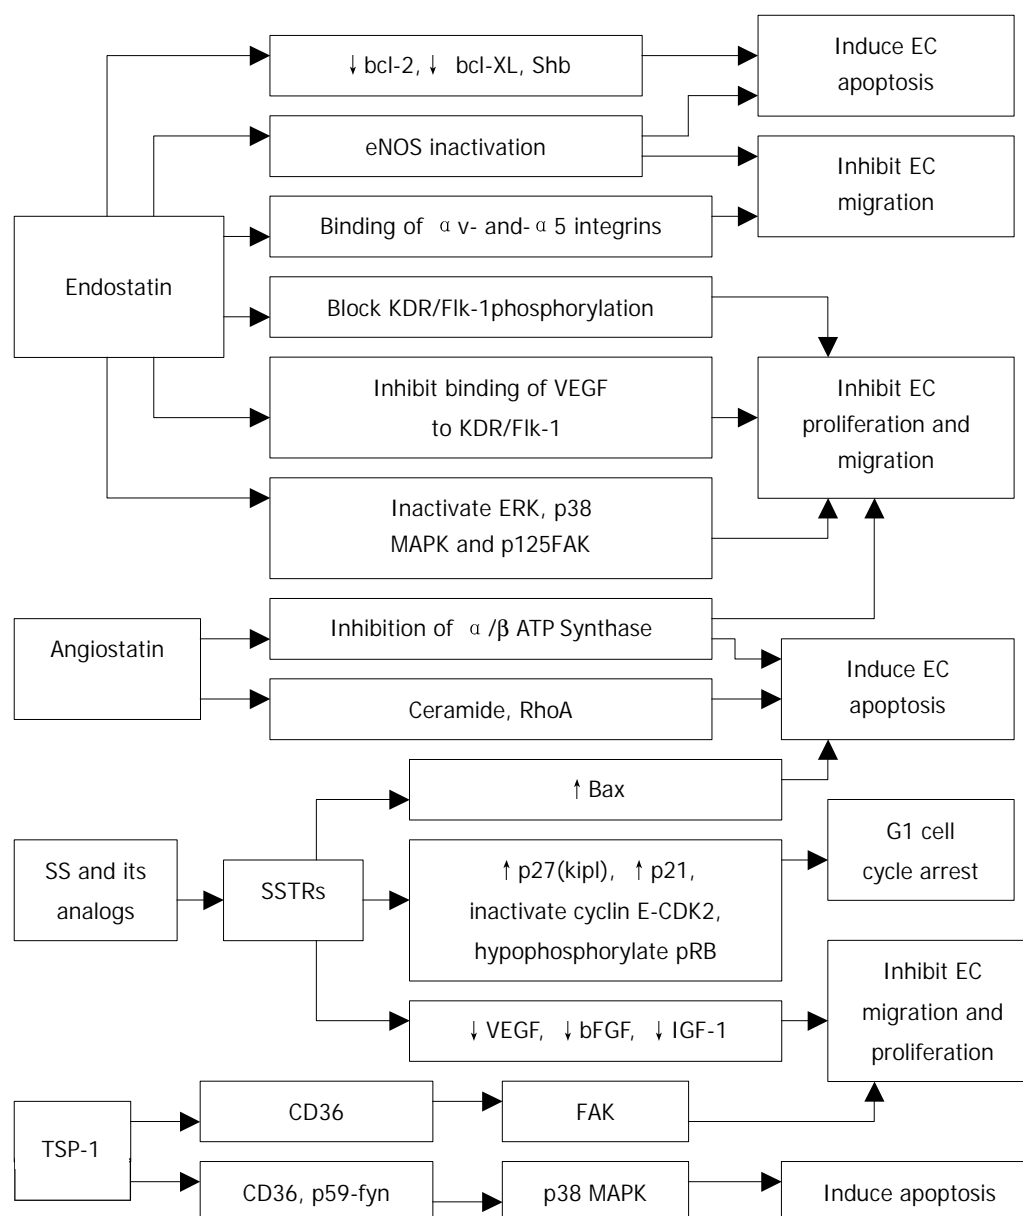

Figure 3 Proposed effector pathways of angiogenic inhibitors.

Thrombospondin-1

Thrombospondin-1 (TSP-1) is a naturally occurring inhibitor of angiogenesis that limits vessel density in normal tissues and curtails tumor growth. TSP-1 exerts its anti-angiogenic activity via binding to the CD36 receptor by triggering an apoptotic signaling pathway^[135]. Binding of TSP-1 to CD36 receptor leads to the recruitment of the Src-related kinase, p59-fyn, and to activation of p38 MAPK. The activation of the p38 MAPK has been shown to be p59-fyn-dependent and to require a caspase-3-like proteolytic activity^[135]. Furthermore, activated p38 MAPK leads to the activation of caspase-3 and to apoptosis^[135] (Figure 3). Interestingly, the apoptotic effect of TSP-1 is restricted to ECs activated to take part in the angiogenic process and not in quiescent vessels^[135]. TSP-1 acts through CD36 to modulate the activity of focal adhesion kinase (FAK) and thus inhibits EC migration and proliferation^[136] (Figure 3). TSP-1 can effectively inhibit chemotaxis *in vitro* and neovascularization *in vivo*, induced by several angiogenic stimuli. These include protein that acts via tyrosine kinase receptors (VEGF, bFGF, aFGF, PDGF), via G proteins (IL-8), via serine/threonine kinase receptors (TGF- β), and also lipids (PGE-1)^[137, 138].

SUMMARY AND CONCLUSION

Developmental status and evaluation of anti-angiogenic therapy in human clinical trials

Angiogenesis is a complex process that depends on the coordination of many different activities in several cell types. The angiogenic response in the microvasculature is associated with changes in cellular adhesive interactions between adjacent ECs, pericytes, fibroblasts, and immune mediators express many different cytokines and growth factors that react with other cells or ECM components to affect ECs migration, proliferation, tube formation, and vessel stabilization. As one or more of the positive regulators of angiogenesis are up-regulated, and simultaneously, certain negative regulators of angiogenesis are down-regulated, tumors become angiogenic. Interestingly, different angiogenic regulators, sometimes, function through the same mechanism and a single angiogenic regulator, sometimes, functions through different mechanisms. Hence, the anti-angiogenic therapy can be realized through the regulation of 'angiogenic switch' by interfering with different mechanisms.

Anti-angiogenic agents, if administered before a tumor develops or becomes vascular supply dependent, would therefore theoretically act similarly to a vaccine in preventing tumor development, not just tumor growth. However, it is notable that anti-angiogenic therapy represents a treatment, not a cure, for cancer. A cure for cancer can be realized only by targeting the agents and mechanisms that cause normal cells to become tumorigenic. The anti-angiogenic therapy of cancer, nonetheless, represents a highly effective strategy for destroying tumors because fundamental requirement of tumor growth is dependent on a blood supply. Unlike standard chemotherapy that targets tumor cells and other proliferating cells, angiogenesis inhibitors target dividing ECs that have been recruited into the tumor bed. For example, certain tubulin-binding agents such as combretastin A-4, exhibit a selective toxicity for proliferating ECs *in vitro* and causing a vascular collapse in tumor models *in vivo* via apoptosis and the subsequent death of much larger numbers of tumor cells^[139]. Thus, specific anti-angiogenic therapy has little or no toxicities such as gastrointestinal symptoms and myelosuppression that are characteristic of standard chemotherapeutic regimens, does not require that the therapeutic agent enter any tumor cells nor cross the blood brain barrier, controls tumor growth independently of growth fraction or tumor cell heterogeneity or even tumor cell type, and does not induce acquired drug resistance^[140]. Further, since normal vasculature in the adult is

quiescent, the appropriate use of selective angiogenic inhibitors may be expected to confer a degree of specificity that is not obtainable with the nonspecific modalities of chemotherapy and radiation therapy and to allow for relatively nontoxic, long-term treatment of tumors.

Because anti-angiogenic agents are expected to be cytostatic rather than cytotoxic, they may be particularly effective in combination with cytotoxic agents, even used in advanced cases of pancreatic, colon, and hormone-refractory prostate cancer, thereby targeting not only DNA synthesis and cell division but also the biologic behavior of tumor cells. The following guidelines are suggested to improve the therapeutic efficacy of endogenous angiogenesis inhibitors in clinical trials: (1) after surgery or radiotherapy to prevent recurrence of distant metastases; (2) combinatorial therapies, for example, in combination with conventional chemotherapy, radiotherapy and vaccine therapy or immunotherapy, and also, in combination with several angiogenesis inhibitors rather than a single inhibitor; (3) targeting therapy. Angiogenesis inhibitors may be specifically targeted to the disease locus at high concentrations rather than be widely distributed in the entire body; (4) gene therapy, several advantages including prolonged therapy, low doses of DNA molecules, and less frequent injections may be achieved by anti-angiogenic gene therapy with endogenous angiogenesis inhibitors; (5) more potent angiogenesis inhibitors should be discovered; (6) prolonged half-lives. Slow-release of angiogenesis inhibitors in the body reaches a steady-state level in the circulation.

Remarkably diverse groups of anti-angiogenic drugs are currently undergoing evaluation in phase I, II or III clinical trials. However, there are still some difficulties associated with the clinical evaluation of these drugs efficacy. In the experimental animal model, tumors can be removed and examined for therapeutic efficacy such as changes in the extent of vascularization, vascular structure, EC viability or apoptosis, as well as for markers of angiogenic activity, e.g. VEGF expression. But in the clinical situation, taking serial biopsies of metastatic tumors may not be a particularly practical or desirable approach. For this, reliable surrogate markers of tumor angiogenesis in serum or urine, and non-invasive strategy may be necessary. Several studies have successfully used various non-invasive medical imaging strategies (e.g. MRI, Doppler ultrasound) to monitor changes in tumor blood flow, vascular structure and permeability^[141-143]. Indeed, there are considerable research efforts underway in this field. In addition, there are obvious concerns about delayed toxicity associated with long-term anti-angiogenic therapy, and physiological angiogenesis affected by anti-angiogenic drugs such as wound healing in a cancer patient, reproductive angiogenesis (e.g. corpus luteum development in adult females, development of the vasculature in developing embryos), in neonates and children. In this concern, a potentially significant development in the near future could be the use of genomics based technologies to uncover a large number of highly (or even totally) specific molecular markers for the activated ECs of newly formed blood vessels.

In the near future, the outcome of ongoing clinical trials will give us more insights into the potential of anti-angiogenic approaches to treat cancer.

Abstract

Gastric cardia adenocarcinoma (GCA) is an under-studied subject. The pathogenesis, molecular changes in the early stage of carcinogenesis and related risk factors have not been well characterized. There is evidence, however, that GCA differs from cancer of the rest of the stomach in terms of natural history and histopathogenesis. Adenocarcinomas of the lower esophagus, esophagogastric junction (EGJ) and gastric cardia have been given much attention because of their increasing incidences in the past decades, which is in striking contrast with the steady decrease in distal stomach adenocarcinoma. In China, epidemiologically, GCA shares very similar geographic distribution with esophageal squamous cell carcinoma (SCC), especially in Linzhou (formerly Linxian County), Henan Province, North China, the highest incidence area of esophageal SCC in the world. Historically, both GCA and SCC in these areas were referred to as esophageal cancer (EC) by the public because of the common syndrome of dysphagia. In Western countries, Barrett's esophagus is very common and has been considered as an important precancerous lesion of adenocarcinoma at EGJ. Because of the low incidence of Barrett's esophagus in China, it is unlikely to be an important factor in early stage of EGJ adenocarcinoma development. However, Z line up-growth into lower esophagus may be one of the characteristic changes in these areas in early stage of GCA development. Whether intestinal metaplasia (IM) is a premalignant lesion for GCA is still not clear. Higher frequency of IM observed at adjacent GCA tissues in Henan suggests the possibility of IM as a precancerous lesion for GCA in these areas. Molecular information on GCA, especially in early stage, is very limited. The accumulated data about the changes of tumor suppressor gene, such as p53 mutation, and oncogeny, such as C-erbB2, especially the similar alterations in GCA and SCC in the same patient, indicated that there might be some similar risk factors,

such as nitrosamine, involved in both GCA and SCC in Henan population. The present observations also suggest that GCA should be considered as a distinct entity.

INTRODUCTION

Adenocarcinomas of the gastric cardia are currently classified as gastric cancers^[1,2]. However, recent studies have suggested that these tumors have distinct epidemiological and biological characteristics^[3,4]. In the last two decades, the incidence of primary adenocarcinomas of the lower esophagus, esophagogastric junction (EGJ) and adenocarcinomas of the gastric cardia has increased dramatically in North America and Western European countries^[3-6]. In contrast, the incidence of adenocarcinoma of the distal stomach has decreased steadily in recent years.

In China, adenocarcinomas of the gastric cardia have unique epidemiological features distinguishing these tumors from the adenocarcinomas of the distal stomach. Linzhou (formerly Linzhou County), the region with the highest incidence rate of esophageal cancer in the world, also has a high incidence of adenocarcinoma of the gastric cardia. However, the incidence of adenocarcinoma arising from the distal stomach is very low in this area. Therefore, previously, adenocarcinomas arising from the EGJ (gastric cardia) were referred to as esophageal cancers, because they shared similar clinical symptoms such as dysphagia. As most of the adenocarcinomas arising from the cardia are diagnosed at an advanced stage, it is very difficult to accurately define whether these tumors have a primary esophageal or gastric origin. Therefore, adenocarcinomas of the EGJ (gastric cardia) are now generally referred to as gastric cardia adenocarcinomas (GCA). With the exception of Barrett's esophagus (a well documented premalignant lesion of esophageal adenocarcinoma in Caucasians)^[7,8], the role of other risk factors, such as *H. pylori* infection, diet, alcohol and tobacco exposure, still remains unclear.

Most studies of esophageal carcinoma in Linzhou have evaluated only esophageal squamous cell carcinoma (SCC). Few have studied adenocarcinoma (AC) of the gastric cardia, particularly as a separate pathological entity in China. In this review, recent epidemiological, histopathological and molecular biological advances were summarized to provide clues about the risk factors and the molecular carcinogenesis of adenocarcinomas of the lower esophagus, and EGJ (gastric cardia).

EPIDEMIOLOGY OF ADENOCARCINOMA OF THE GASTRIC CARDIA

GCA shares several common features with the adenocarcinoma arising from the distal esophagus: a lower mean age of

presentation, a higher incidence in the Caucasian population, a higher male to female ratio, and similar risk factors^[4, 9]. Epidemiological studies have demonstrated that smoking, alcohol consumption, increased body mass index (reflecting obesity), and lower socioeconomic status are risk factors for adenocarcinomas of both the distal esophagus and gastric cardia^[10-12]. In Linzhou, China, adenocarcinoma of the gastric cardia was previously classified as esophageal cancer by the local registry for the past several decades, primarily because of comparable clinical features and similarity in therapy. Reviewing hospital records of patients with dysphagia, our research group reported that while approximately 60 percent of patients were found to have a diagnosis of SCC, the remaining 40 percent were found to have adenocarcinomas of the lower esophagus or gastric cardia^[13]. A case-control study performed on the patients with presumed distal esophageal or gastric cardia cancer in Linzhou found that one third of all these tumors was adenocarcinomas of the gastric cardia^[14]. While there is considerable evidence implicating that dietary factors, including certain nutrient deficiencies and consumption of nitrosamine-contaminated food, and drinking water are associated with the development of SCC^[15-18], it is not clear whether adenocarcinomas of the gastric cardia share the same risk factors in this high-incidence area in China.

DIAGNOSTIC CRITERIA FOR ADENOCARCINOMA OF THE GASTRIC CARDIA

It is generally difficult to distinguish where cardia adenocarcinomas originate, as most tumors present in advanced stage at diagnosis, often involving both esophagus and stomach. Imprecise clinical and pathological definitions of adenocarcinomas of the lower esophagus, EGJ or gastric cardia may be the reason underlying inconsistencies between different studies. An adenocarcinoma is considered to be of cardia origin when the epicenter of the tumor is at the esophagogastric junction, or within 2 cm distally^[19]. Strict clinicopathologic criteria have been used also to define primary esophageal adenocarcinomas^[20]. A new classification for adenocarcinomas of the esophagogastric junction was proposed at a recent conference of the International Gastric Cancer Association (IGCA) and the International Society for Diseases of the Esophagus (ISDE). Adenocarcinomas of the cardia has been defined as tumors that have their centres within 5 cm of the anatomic esophagogastric junction. Three distinct tumor entities (Type I, II and III) have been proposed^[21].

RELEVANT PATHOLOGICAL CONDITIONS OF ADENOCARCINOMA OF THE GASTRIC CARDIA

Barrett's esophagus

Barrett's esophagus is the condition in which columnar epithelium replaces the squamous epithelium that normally lines the distal esophagus^[22]. The endoscopic appearance is characteristic, with a salmon-pink color and velvety texture. This upward extension may be circumferential, or limited to finger-like projections, or even islands of columnar epithelium that only involve part of the distal esophageal wall^[23]. In healthy individuals, the squamo-columnar junction (SCJ) does not always correspond with the anatomic EGJ. The juxtaposition of pale squamous epithelium and reddish columnar epithelium forms a visible line called the Z line, or the SCJ. The EGJ is the most proximate part of gastric folds. The Z line and gastroesophageal junction often coincide. When the Z line is located above the EGJ, there is a columnar lined segment of esophagus. Barrett's esophagus is diagnosed endoscopically if columnar mucosa extending greater than 3 cm above the EGJ, or by histologic finding of intestinal metaplasia

(specialized mucosa) existing at any level of the tubular esophagus^[22].

The pathogenesis of Barrett's esophagus is still unclear. Most Barrett's esophagus develops from approximately 10 % of persons who have chronic gastroesophageal reflux^[24]. In addition to gastroesophageal reflux diseases (GERD), Barrett's esophagus is associated with several other esophageal disorders, such as hiatal hernia^[25], and occasionally familial groupings are reported^[26-28].

The significance of Barrett's esophagus is its association with the development of esophageal malignancy^[29,30]. Patients with Barrett's esophagus have (by conservative estimates) a 30- to 40-fold higher risk of developing esophageal adenocarcinoma than those without^[23]. Since the diagnostic criteria for Barrett's esophagus now include the histological finding of intestinal metaplasia, a columnar-lined esophagus less than 3 cm in length is now recognized as short-segment Barrett's esophagus (SSBE), in contrast to the traditional long-segment Barrett's esophagus (LSBE)^[31]. The risk of malignancy in SSBE still needs to be determined^[32].

In China, Barrett's esophagus used to be regarded as a rare condition, and consequently has not been studied in detail. However, based on an endoscopic survey performed by our research group in the high-risk population in Linzhou, Barrett's esophagus was detected with a frequency of 0.7 % (3/402); not as rare as it was considered previously^[33]. It has been identified that there is an apparent change of Z line upgrowth among symptom free subjects in the high-incidence area for esophageal cancer in Henan Province. Z line upgrowth is related with epithelial cell hyperproliferation both in gastric cardia and lower segment of esophagus. These results suggest that Z line upgrowth may be one of the characteristic changes, or precancerous lesions related with EGJ carcinogenesis in the high-risk population for GCA in Henan^[11]. Further characterizing Barrett's Esophagus, Z line upgrowth, and esophageal and gastric reflux esophagitis in this population may provide new insights into understanding of cardia carcinogenesis^[34].

Intestinal metaplasia

Since the diagnostic criteria for Barrett's esophagus based on endoscopy are arbitrary, recent definitions of Barrett's esophagus have included the histologic finding of intestinal metaplasia, regardless of the length of the columnar-lined esophagus^[35]. Histologically, three types of columnar epithelium have been observed in Barrett's esophagus: gastric fundic type, junctional type and specialized intestinal metaplasia (IM). Based on the mucin content of the columnar and goblet cells, intestinal metaplasia is histopathologically divided into three types: the complete form (Type I), in which the columnar cells are absorptive and contain neutral mucins, and the two incomplete forms, in which the columnar cells are partly secretory and contain acidic sialomucins (Type II) or sulphomucins (Type III)^[36,37]. Type I is the predominant form of intestinal metaplasia found in the stomach, including both benign and malignant conditions. Type III is the least common form in the stomach, but the one most strongly associated with gastric cancer^[38]. The incomplete form of intestinal metaplasia also termed specialized columnar epithelium (SCE), is the histological mark of Barrett's esophagus^[39].

IM is also associated with GERD, and the frequency of IM is increased with the extension of columnar lining in the esophagus^[40]. However, gastritis rather than GERD seems to be a risk factor of cardiac intestinal metaplasia^[41]. While complete intestinal metaplasia is a manifestation of multifocal atrophic gastritis, the incomplete form may result from carditis and GERD^[42].

It has been hypothesized that Barrett's adenocarcinoma follows the metaplasia-dysplasia-adenocarcinoma sequence (MCS)^[43]. Whether intestinal metaplasia is a premalignant lesion for adenocarcinoma of the gastric cardia is still not clear^[44]. Several studies showed that dysplasia was infrequently observed in EGJ or gastric cardia with intestinal metaplasia^[42, 44, 45]. These suggest that intestinal metaplasia at the EGJ or gastric cardia is not a high-risk precursor lesion for adenocarcinoma. However, progression from intestinal metaplasia at the EGJ or gastric cardia to dysplasia still requires further characterization^[46].

Examination of the adjacent gastric cardia cancer tissue by our research group showed that IM was frequently observed in as high as 20 % of the specimens^[47]. In contrast, only 0.7 % symptom-free subjects in Linzhou were identified with IM in gastric cardia biopsies^[33]. Goblet cell was invariably identified on HE stained specimen. Half of the IM lesion was found to have dysplasia. These suggest that IM may be a precursor of gastric cardia adenocarcinoma in Henan, which is not consistent with that in Western countries. The reason is not clear. Standard histologic evaluation fails to reliably differentiate between IM in the esophagus and IM in native cardiac mucosa. Further characterization for subtypes of IM with biohistochemistry and immunohistochemistry will provide important evidence for elucidating the significance of IM in gastric cardia carcinogenesis.

Chronic carditis: *H. pylori* infection or gastroesophageal reflux disease

IM in the distal stomach is usually a consequence of chronic inflammation, mainly caused by *H. pylori* infection^[48], while the intestinal metaplasia of Barrett's esophagus has been demonstrated to be associated with GERD^[49]. Furthermore, recent studies suggested that gastric infection with *H. pylori* might protect the esophagus from developing of reflux esophagitis and Barrett's esophagus^[50-54]. It is reasonable to hypothesize that intestinal metaplasia at the gastric cardia may develop as a consequence of chronic inflammation due to either GERD or infection. Several recent studies have focused on the relative contribution of *H. pylori* infection and GERD to gastric carditis, however, results have been inconsistent, to date^[55-58]. One possible reason may be related to the use of different histopathologic criteria for identification of the gastric cardia. A study of 33 consecutive autopsies in children showed that the length of cardiac epithelium ranged from 1 to 4 mm, with a mean extent of 1.8 mm^[59]. Ormsby expanded the study to 223 adult autopsies, finding that the mean extent of cardiac epithelium in patients aged <18, 19-50, and >50 years was 1.7, 2.6, and 3.3 mm, respectively^[60]. Such a narrow range makes accurate sampling extremely difficult. Therefore, biopsies from the gastric cardia may have two origins: esophagus or stomach.

MOLECULAR BASIS FOR ADENOCARCINOMA OF GASTRIC CARDIA

The pathogenesis of carcinoma has been demonstrated to be a progressive, multi-step process, manifested as an uncontrolled cell cycle and abnormal proliferation. The molecular basis of human cancer has been investigated widely in the recent two decades, and has implicated deregulation of tumor suppressor genes, activation of oncogenes, and aberrant expression of growth factors. Different genetic alterations have been observed between the two different histologic sub-types of esophageal cancer. Meanwhile, molecular evidence is also accumulating to support the hypothesis that adenocarcinomas of the gastric cardia are distinct from adenocarcinomas of the esophagus and stomach.

Loss of heterozygosity (LOH)

LOH has been demonstrated to play an important role in tumorigenesis, and to be frequently associated with the loss of tumor suppressor gene function. LOH was initially observed at several tumor suppressor gene loci (17p, 13q, 5q, 18q and 9p for p53, Rb, APC, MSH2, DCC and p16, E-cadherin, 19p, respectively) in human esophageal and gastric cancer^[61-67]. At present, LOH has been used to localize putative tumor suppressor genes. LOH has also been reported at 1p, 3p, 4q, 9q, 11p and 17q in esophageal adenocarcinomas^[68, 69]. Allelic loss of the tumor suppressor gene p73 on 1p is frequently observed in neuroblastoma^[70, 71], and hMLH-1, a mismatch repair gene associated with hereditary non-polyposis colorectal cancer, is located on 3q21^[72]. The tylosis esophageal cancer (TOC) gene, initially reported in families with autosomal dominant tylosis families who developed esophageal cancer, has been located on chromosome 17q25. Allelic loss at this region has been implicated in both sporadic SCC and Barrett's adenocarcinoma^[73]. BCRA1, associated with susceptibility to breast and ovarian cancer, is located on 17q^[74]. Using comparative genomic hybridization (CGH), deletion of a specific region at 14q31-32.1 occurred significantly more frequently in Barrett's adenocarcinomas in the distal esophagus than in gastric cardia cancers, suggesting genetic divergence in this group of closely related cancers^[75]. Allelotype analysis performed on 38 gastric cardia adenocarcinomas even differentiated this allelic imbalance between the intestinal-type and diffuse-type adenocarcinomas, and a higher frequency of allelic imbalance on chromosome 16q was detected in the diffuse-type adenocarcinomas^[76].

Dysfunction of tumor suppressor genes

Tumor suppressor gene p53 P53 is located on chromosome 17p13, encoding a phosphoprotein with a molecular weight of 53kd. Abnormalities in p53 gene function cause uncontrolled cell cycles and abnormal cell proliferation. P53 mutations are the most frequent genetic alterations found in human cancers^[77]. Over 90 percent of p53 mutations are observed in exons 5-8, which is the highly conserved region for DNA binding. Comparison of p53 mutations in premalignant (basal cell hypertrophy, BCH; dysplasia, DYS; carcinoma *in situ*, CIS) esophageal tissues matched with corresponding invasive SCC tumor tissues, showed similar p53 mutations in DYS, CIS and tumors^[78]. Similar studies with Barrett's adenocarcinoma showed that p53 mutations in Barrett's epithelia (metaplasia, non-dysplastic) did not necessarily correspond to the matched adenocarcinoma^[20]. The high coincident alterations for P53 in SCC and GCA from the same patient indicate the possibility of similar molecular mechanisms, which provides important molecular basis and etiological clue for similar geographic distribution and risk factors in SCC and GCA^[79, 80]. These results suggest that some p53 mutations may have a selective tumorigenic advantage during tumor progression. And some findings suggest p53, bcl-2 and caspase-3 may play an important role in the induction of apoptosis in AGS cells^[81]. In the course of the formation of gastric carcinoma, proliferation of gastric mucosa can be greatly increased by *H. pylori* infection, which can strengthen the expression of mutated p53 gene^[82]. Less aggressive mutations may increase the genetic instability of Barrett's mucosa, promoting abnormal cellular proliferation, but as they are incapable of transformation independently, additional molecular or epigenetic events are required for tumorigenesis.

About 90 percent of p53 mutations are located within the DNA binding domain (exons 5 to 8). They may occur either at the binding surface or at the hydrophobic core, disrupting the structure for DNA binding. P53 mutations do not distribute in a random manner through the whole encoding region. Several

“hot spot” mutations have been located such as codon 175, 176, 245, 248, 249, 273 and 282 in all the human cancers^[83], implying that there may be a general pathway for the pathogenesis of tumors with a high percentage of p53 mutations. However, mutation sites also appear to be organ specific and cell-dependent. In esophageal adenocarcinomas, p53 mutations occur most frequently at codon 175 (9 %), 248 (16 %) and 273 (16 %), which are also hot spot mutations for all human cancers recorded, while mutations at codon 248 and 273 are much less frequently observed, even though the mutation at codon 175 accounts for 8 % in SCC. Relatively high frequencies of p53 mutations at codons 193, 194, 195 and 270 are unique in comparison to other human cancers^[77].

P53 mutations may result from endogenous processes or exogenous carcinogens^[84], and the spectrum of mutations may be indicative of specific carcinogenic mechanisms. Mutation profiles of p53 also help to identify the DNA damage arising from environmental carcinogens. Approximately 31 % of p53 mutations occur at the A:T base pairs in the SCC, which are usually caused by exogenous carcinogenic compounds. But in esophageal adenocarcinoma, p53 mutations have a very high frequency of transition at the CpG dinucleotides. This alteration is thought to result from spontaneous deamination of 5-methylcytosine, suggesting a defective DNA mismatch repair^[77, 85]. Differences in p53 mutation spectra between SCC and esophageal adenocarcinoma are consistent with the results of epidemiological studies, suggesting that SCC and esophageal adenocarcinoma have different etiology.

Adenocarcinomas of gastric cardia share similar epidemiological and histological features to esophageal adenocarcinomas in North America and some European countries. Gleeson *et al.*^[86] compared the p53 abnormalities in adenocarcinoma of the distal esophagus and gastric cardia, and reported that p53 mutations were detected in 70 % and 63 % of adenocarcinoma of esophagus and gastric cardia, respectively. 85 % of the p53 mutations in esophageal adenocarcinoma occurred as G:C→A:T transitions, with 69 % at the CpG dinucleotides. Similar p53 mutations were observed in adenocarcinoma of the gastric cardia, in which 82 % were base transitions with 55 % occurring at the CpG dinucleotides. One study from Linzhou based on the p53 gene mutation analysis identified 6 mutations among 14 adenocarcinomas of the gastric cardia, 3 of which were G to T transversions, a mutation that is rarely observed in Barrett's adenocarcinoma^[87]. Further investigation and comparison of mutation analysis of p53 gene between SCC and adenocarcinoma of the gastric cardia in this population are needed so to provide more insights into the etiology of both SCC and adenocarcinomas of esophagus and the gastric cardia.

p53 gene family Recently, discovery of p53 homologues such as p73 and p63 suggests a more complex pathway. p73 and p63, similar to p53, may result in transactivation, DNA binding and oligomerization domains^[88], capable of activating the transcription of p53-responsive genes and inducing apoptosis^[89-91]. p73 is located on chromosome 1p36, a region that is frequently deleted in neuroblastoma^[73, 74], but unlike p53, p73 mutations have been detected infrequently in other types of tumor, including esophageal and gastric carcinoma^[92-100]. Silencing of p73 gene due to hypermethylation at its promoter region was observed in a subset of lymphoblastic leukaemia and Burkett's lymphoma^[101, 102], but increased level of mRNA was more commonly observed in other tumors^[95, 103-105]. p73 is characterized by loss of imprinting (LOI), resulting in monoallelic expression in normal tissues. It has been observed that p73 is overexpressed in several tumors, which is thought to be due to the switching from monoallelic to biallelic expression^[93, 95]. Meanwhile, p73 isoforms, caused by alternative splicing, have been observed in rare types of brain

tumors, suggesting tissue-specificity in the regulation of p73 gene transcription^[106]. However, the precise function of p73 isoforms in tumor development is still unclear. Specific mutations of p73 or p63 causing amino acid substitutions are not identified. Neither p53, p73 nor p63 is related to prognosis. p73 and p63 have rarely been found to be mutated in gastric carcinomas, but both proteins are expressed in only a subset of tumors. The status of these p53 homologues is discordant among all patients with multiple simultaneous gastric carcinomas. The increased expression of p63 (TAp63 and black triangleNp63) in less well-differentiated gastric carcinomas may indicate that p63 can act to promote neoplastic growth in the gastric epithelium^[107]. In 15 SCC samples from Henan, no p73 mutations were found in exons 4-7, but a high frequency of LOI and LOH was observed in these samples. The SCC samples with p53 defects were significantly correlated with those, which had elevated expression of p73. These results suggest that increased expression of p73, including that by LOI, could be a partial compensatory mechanism for defective p53^[100].

The p63 gene also encodes multiple isoforms through alternative splicing with different abilities to transactivate p53-responsive genes. However, p63 is more closely related to p73 than to p53, and p63 mutations have been rarely observed in human tumors^[108, 109]. The predominant isoform of p63, lacking in an acidic N-terminus corresponding to the transactivation domain of p53, has been detected in many kinds of epithelial tissue. This truncated protein may act as a dominant-negative agents toward transactivation by p53^[110]. Up to date, p63 has not been studied in esophageal adenocarcinoma or adenocarcinomas of the cardia.

Rb gene One study compared LOH with the expression of Rb gene in SCC, finding that 90 % of the tumor samples containing LOH showed low or no Rb expression, while only 20 % of those without LOH had altered expression of Rb, suggesting LOH is the principal molecular alteration of Rb in SCC^[111]. Recent studies of SCC cell lines demonstrated that the hypophosphorylated Rb protein was also associated with G2 arrest^[112]. Besides inhibition of the cell cycle progression, Rb protein appears to have other distinct mechanisms to suppress cellular proliferation^[113]. In the gastric carcinogenesis, *H. pylori* might cause severe imbalance of proliferation and apoptosis in the precancerous lesions (IMIII and DysIII) first, leading to p53-Rb tumor-suppressor system mutation and telomerase reactivation, and finally causing gastric cancer^[114]. Wang *et al.*^[115] suggested the alteration of Rb protein might play a role in the early stages of gastric cardia carcinogenesis.

p16INK4a, p15INK4b and p14ARF LOH of p16INK4a has been detected with high frequencies in both SCC (65 %) and esophageal adenocarcinoma (69 %)^[116]. Several studies have demonstrated that hypermethylation of the promoter region of p16INK4a is the main mechanism causing gene silencing rather than point mutation, which rarely occurs in esophageal carcinomas^[116-119]. Distinct from p16INK4a, p15INK4b, which inhibits the cell growth in response to extracellular stimuli such as TGF- β ^[120], is more frequently deleted, at a frequency of 40 %^[118]. Though p16INK4a regulates cell cycle through inhibiting the phosphorylation of Rb protein, p14ARF is closely associated with p53 by attenuating mdm2-mediated degradation of p53^[121, 122]. Similar to p15INK4b, p14ARF is also deleted frequently in SCC, losing its function to protect p53 from ubiquitin-dependent degradation^[123].

Abnormalities of oncogenes Point mutation, amplification, rearrangement and overexpression are the most frequent mechanisms for oncogene activation. Amplification of cyclinD1, HER-2/neu(c-erbB2), c-myc, c-ras, Int-2/hst-1 and c-erbB (EGFR) has been observed in gastric and esophageal carcinomas^[124-130]. The amplification of c-erbB2 was followed

by overexpression in the same gastric adenocarcinoma tissue^[125,129]. No amplification of c-erbB2 was detected in SCC. Amplification of oncogenes that encode growth factor receptors is more commonly found in adenocarcinomas. Int-2 and hst-1, encoding FGF-3 and FGR-4 respectively, are located at chromosome 11q13 with the oncogene cyclinD1. Coamplification of int-2 and hst-1 was observed at a frequency of 28-47 % in primary esophageal carcinomas and much higher in metastatic tumors, suggesting an association with tumor progression and distal metastasis^[131, 132]. CyclinD1, a cell cycle protein, facilitates cell cycle progression from G1 to S phase through combining with CDK4. Both the amplification and overexpression of cyclinD1 were detected in esophageal carcinomas^[133, 134]. Abnormal expression of cyclin E and p27 may be one of the important molecular changes in the early stage of esophageal carcinogenesis, and the high-expression of cyclin E and low-expression of p27 may be one of the mechanisms driving the mild lesion towards carcinogenesis^[135]. In contrast to other gastrointestinal tumors, the ras oncogene is rarely mutated in human esophageal adenocarcinoma^[127]. However, overexpression of ras and ras-regulated genes (osteopontin, cathepsin L) has been reported in 58 % of primary esophageal adenocarcinomas^[136].

DIFFERENCES BETWEEN ADENOCARCINOMAS OF LOWER ESOPHAGUS, GASTRIC CARDIA AND SUBCARDIAC STOMACH

Though adenocarcinomas of the lower esophagus and gastric cardia share similar epidemiological characteristics, new clinicopathologic classifications have established criteria to differentiate these two entities. Taniere^[137] compared molecular markers in esophageal adenocarcinomas with those in adenocarcinomas of the gastric cardia. The male to female ratio and p53 mutation frequency were higher in esophageal adenocarcinomas, while mdm2 amplification was more frequent in the adenocarcinomas of the gastric cardia. Patterns of cytokeratin immunostaining were also different between these two tumors. Flejou^[138] performed a study to compare p53 protein expression immunohistochemically between esophageal and gastric carcinomas, and reported a higher prevalence of p53 protein overexpression was found in esophageal and cardiac adenocarcinomas compared with gastric antral adenocarcinoma. This was confirmed by an additional study, which reported p53 mutation rates in adenocarcinomas of distal stomach were significantly lower than those in adenocarcinomas of esophagus and gastric cardia^[139]. These results suggest that adenocarcinoma of the gastric cardia may be a distinct entity from adenocarcinoma of the distal stomach.

Comparison between gastric cardia adenocarcinoma and esophageal squamous cell carcinoma, with special reference to Linzhou

Because of the highly concurrent incidence of gastric cardia adenocarcinoma and esophageal squamous cell carcinoma in Linzhou^[140], it is highly desirable to characterize the molecular differences between these tumors of different histological types to explore the possible clues related with etiological risk factors. However, useful information concerning this topic is very limited. In Linzhou, it is not uncommon clinically to identify patients with both gastric cardia adenocarcinoma and esophageal squamous cell carcinoma^[141], which is the most common pattern of multiple primary malignant neoplasm (MPN) with an incidence of 0.4-2.5 %^[142]. Recent studies from Wang's laboratory showed that there was a highly consistent positive immunostaining rate for p53 in SCC and GCA from the same patient (60 %, 12/25 vs 40 %, 10/25)^[79] similar results were observed for PCNA. p53 mutation analysis in patients with either SCC or GCA from Linzhou indicated that G:C to

A:T transition was the most frequent mutation pattern both in SCC and GCA. The consistency of P53 gene mutation was as high as 64 %^[143]. G to A mutation pattern may be resulted from DNA methylation induced by nitrosamine^[141]. These results are of important value in explaining the similar geographic distribution of SCC and GCA in this area. Protein file analysis also showed similar expression pattern in SCC and GCA, such as PTEN^[144], c-erbB-2 and c-myc^[145], MUC1^[146], CYP1A1 and 2E1^[147], MUC3^[148], mEH^[149], GSTM1, GSTT1 and GSTP^[150], EGFR^[151], etc from the samples in Linzhou.

CONCLUSION

In summary, the incidence of adenocarcinomas arising from the distal esophagus, EGJ and gastric cardia is increasing at a dramatic rate in North America and Europe. It is suggested that adenocarcinomas of the esophagus develop in a metaplasia-dysplasia-carcinoma sequence. Whether adenocarcinomas of the gastric cardia follow the same pattern needs further study. Although both esophageal squamous cell carcinomas and adenocarcinomas of the gastric cardia have a high incidence in the same high-risk population in Linzhou, little information is available on the molecular and etiological differences between these two tumor types. Metaplasia is a frequent finding in the gastric cardia, but its significance in the development of adenocarcinoma of the gastric cardia is not clear. *H.pylori* infection, a main factor causing atrophy of the mucosa of distal stomach, also leads to chronic inflammation of the gastric cardia. Though *H.pylori* has been classified as a Type I carcinogen, the role it plays in gastric cardia carcinogenesis remains unclear. To study adenocarcinoma of the gastric cardia in China, researchers are beginning to evaluate epidemiological, histopathologic and molecular characteristics of the tumor.

Abstract

Information about the mechanisms that generate mutations in eukaryotes is likely to be useful for understanding human health concerns, such as genotoxicity and cancer. Eukaryotic mutagenesis is largely the outcome of attacks by endogenous and environmental agents. Except for DNA repair, cell cycle checkpoints and DNA damage avoidance, cells have also evolved DNA damage tolerance mechanism, by which lesion-targeted mutation might occur in the genome during replication by specific DNA polymerases to bypass the lesions (translesion DNA synthesis, TLS), or mutation on undamaged DNA templates (untargeted mutation) might be induced. DNA polymerase ζ (pol ζ), which was found firstly in budding yeast *Saccharomyces cerevisiae* and consists of catalytic subunit scRev3 and stimulating subunit scRev7, has received more attention in recent years. Pol ζ is a member of DNA polymerase δ subfamily, which belongs to DNA polymerase B family, and exists in almost all eukaryotes. Human homolog of the scRev3 gene is located in chromosome region 6q21, and the mouse equivalent maps to chromosome 10, distal to the c-myc gene and close to the Macs gene. Alternative splicing, upstream out-of frame ATG can be found in yeast scRev3, mouse and human homologs. Furthermore, the sequence from 253-323 immediate upstream of the AUG initiator codon has the potential to form a stem-loop hairpin secondary structure in REV3 mRNA, suggesting that human REV3 protein may be expressed at low levels in human cells under normal growth conditions. The functional domain analysis showed that yeast Rev3-980 tyrosine in conserved region II is at the polymerase active site. Human REV3 amino acid residues 1 776-2 195 provide a REV7 binding domain, and REV7 amino acid residues 1-211 provide a bind domain for REV1, REV3 and REV7 itself. More interestingly, REV7 interacts with hMAD2 and therefore might function in the cell cycle control by affecting the activation of APC (anaphase promoting complex). Currently it has been known that pol ζ is involved in most spontaneous mutation, lesion-targeted mutation via TLS, chemical carcinogen induced untargeted mutation and somatic hypermutation of antibody genes in mammalian. In TLS pathway, pol ζ acts as a "mismatch extender" with combination of other DNA polymerases, such as pol ι . Unlike in yeast, it was found that pol ζ also functioned in mouse embryonic development more recently. It was hypothesized that the roles of pol ζ in TLS and cell cycle control might contribute to mouse embryonic lethality.

INTRODUCTION

The increase of environmental cancer has been received intensive attention in recent years^[1-6]. An arresting example is that tobacco smoke significantly increases the risks for oral^[7,8], esophageal^[3,6,9,10], bladder^[11-14], pancreas^[13], gastric^[15] and colorectal cancers^[16]. To understand the relationship between environmental agents and cancer is a noteworthy hotspot, by which it is possible to establish a system to prevent and control environmental cancers.

Information about the mechanisms that generate mutations in eukaryotes is likely to be useful for understanding human health concerns, such as genotoxicity and cancer. Eukaryotic mutagenesis is largely the outcome of attacks by endogenous and environmental agents. However, the cells have evolved sophisticated systems in response to DNA damage, including DNA repair and cell cycle checkpoints. Even when DNA repair systems and cell cycle checkpoints are fully functional, some damage can still persist in the genome during replication under circumstances such as: (i) when cells sustain significant DNA damage; (ii) when a particular damage is poorly repaired; or (iii) when some genomic regions are inefficiently repaired. DNA damage frequently blocks replication. Such blockage can be overcome by error-free or error-prone translesion DNA synthesis (TLS) bypass, employing specialized DNA polymerases and proteins for promoting continuous nascent strand extension at forks blocked by the presence of unrepaired DNA damage at the cost of increasing mutation frequency^[17]. Alternatively, mutation can be avoided by DNA damage avoidance^[18], or occur on undamaged DNA template and lead to untargeted mutation via damage tolerance^[19].

DNA polymerase ζ (pol ζ), consisting of catalytic subunit scRev3 and stimulating scRev7 in budding yeast *Saccharomyces cerevisiae*, has received more attention in recent years. It is thought to be the major component of error-prone TLS pathway^[20-24], although a number of other polymerases might be involved in this process^[25]. In *Saccharomyces cerevisiae*, TLS pathway pasting many types of DNA damage in yeast depends on the activities of pol ζ and Rev1p, which is a major source of DNA-damage-induced substitutions and frameshifts and of spontaneous mutations^[21,22,26-30]. It has been speculated and demonstrated later that human pol ζ plays a major role in UV-induced mutagenesis and somatic hypermutation in antibody genes^[31-34]. More recently, it was found that human pol ζ was also involved in mammalian untargeted mutagenesis, and the expression of human mutator REV3 could be upregulated at transcriptional level in response to chemical carcinogen *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG)^[35], which could induce gastric cancer^[36-39] and colorectal cancer^[40,41]. Evidences also suggested that pol ζ was concerned with cell cycle control and early

embryonic development^[42-45]. The aim of this paper was to review the structural and functional features of pol ζ , and its roles in mutagenesis and embryonic development as well.

PROPERTIES OF STRUCTURE AND FUNCTION DOMAIN OF POL ζ

In the budding yeast *Saccharomyces cerevisiae*, the scRev3-scRev7 complex is the sixth eukaryotic DNA polymerase to be described, and is therefore called DNA polymerase ζ ^[22]. The catalytic subunit Rev3 is a member of family B DNA polymerases, which contains six conserved motifs^[46, 47]. Mutation analysis *in vivo* and the X-ray crystal structures of family B polymerases reveal that yeast scRev3-980 tyrosine in conserved region II is at the polymerase active site^[48]. Investigation suggests that homologues of the yeast scRev3 gene are found in almost all eukaryotes, including *Arabidopsis thaliana*, *Drosophila melanogaster*, *Schizosaccharomyces pombe*, mouse and specifically humans^[30, 31, 49-53].

Human homolog of the *Saccharomyces cerevisiae* scRev3 gene is located on chromosome region 6q21, and the mouse equivalent maps to chromosome 10, distal to the *c-myc* gene, and close to the *Macs* gene^[50, 52]. The full-length cDNA of human REV3 consists of 10 919 nucleotides, with a putative open reading frame of 9 390 bp^[31, 50, 51]. Human REV3 gene contains 33 exons in about 200 kb of genomic DNA, in which an additional exon, alternative splicing event and an upstream out-of frame ATG have been demonstrated^[31, 50]. The same alternative splicing has also been observed in mouse, with a 128bp exon inserted between nt +139 and +140 in approximately 50 % of the transcripts^[52]. An upstream out-of-frame ATG with an ORF that terminates within the main ORF is also found in the yeast gene^[21], suggesting that it may be evolutionally conserved in all pol ζ genes. The sequence context of the upstream gene performs a similar function to that of its yeast counterpart. Interestingly, three stretches of sequences, GGCAGTGGCGGC, AGGGGAGGGGGC, and GCCGCCGCCGCTGC, are duplicated in the 5' untranslated region constituting 323 nucleotides. Furthermore, the sequence from 253-323 immediate upstream of the AUG initiator codon has the potential to form a stem-loop hairpin secondary structure in REV3 mRNA^[51]. Such primary structural features and the secondary structure in the 5' untranslated region are expected to reduce the translational efficiency of the message, suggesting that human REV3 protein may be expressed at low levels in human cells under normal growth conditions.

The predicted homologous proteins in human and mouse are a little over twice the length of the yeast scRev3 protein (1 504 residues), i.e., 3 130 amino acids with an expected mass of 353 kDa and a calculated *pI* of 8.7 in human, and 3 122 amino acids in mouse respectively. The homologous proteins of yeast scRev3 are highly conserved^[31, 51, 52]: (i) in the N-terminal part, the overall homology between yeast scRev3/*Drosophila* DmRev3, yeast scRev3/human REV3 and *Drosophila* DmRev3/human REV3 amounts to respectively 33.3 %, 35.0 % and 50.5 % identical amino acids. (ii) in a region of 850 residues at the carboxyl terminus, the overall homology between yeast scRev3/human REV3 amounts to 39 % identical amino acids, and (iii) in a 55-residue region in the middle of both scRev3 and REV3 proteins, with 29 % identity. But little similarity can be found in the intervening regions^[31].

The carboxyl terminus region of yeast Rev3 homologue proteins in human, mouse and *Drosophila* contains the six conserved sequence motifs characterized by DNA polymerases in the right order, including the canonical hexapeptide motifs within regions 1 and 2, YGDTDS and SLYPSI, which are found jointly only in type B DNA polymerases^[46, 47]. Further alignment shows that pol ζ is a member of DNA polymerase δ

family with two specifically conserved motifs ζ I and ζ II in pol ζ , and in the N-terminal part, a conserved glycine repeat motif (G-x4-G-x2-G-x8-G-x3-YFY) in pol δ is also present in the homologues which have been implicated in nucleotide binding^[51]. Outside the six DNA polymerase motifs in the C-terminal, both yeast scRev3 and human REV3 proteins contain a putative zinc finger DNA binding region, and the location of this putative zinc finger is also highly conserved from yeast to humans^[51]. Such structural features are consistent with the notion that the C-terminal region of scRev3 homologue serves as the catalytic domain during nucleotide polymerization, while its N-terminal region may provide sites for protein-protein interactions with other factors such as a putative yeast scRev7 homologue during translesional DNA synthesis.

However, the existence of a much larger nonhomologous or species-specific region in the expected human protein suggests that pol ζ may perform a wider range of functions in the higher eukaryotes. In *Saccharomyces cerevisiae*, it was found that LexA-scRev3 and Gal4-scRev7 fusions interacted with each other^[22]. More recently, studies showed that human REV3 amino acid residues 1 776-2 195 provided a REV7 binding domain, and REV7 amino acid residues 1-211 provided a bind domain for REV1, REV3 and REV7 itself^[54, 55]. REV7, the stimulating subunit of pol ζ which is located on chromosome 1p36, displays 23 % identity and 53 % similarity with scRev7, as well as 23 % identity and 54 % similarity with the human mitotic checkpoint protein hMAD2. And yeast two-hybrid assay suggests that REV7 may interact with hMAD2 but not with hMAD1^[54]. It is possible that REV3, REV7, and hMAD2 might be capable of forming a stable triprotein complex.

CHARACTERISTICS AND ROLES OF POL ζ INVOLVED IN EUKARYOTIC MUTAGENESIS

DNA damage induced elevation of mutations during the course of translesion replication is likely to be an important contributory cause in the development of many cancers^[27]. With *in vitro* and *in vivo* investigation, it has been clear that pol ζ plays a role in an error-prone way. Yeast pol ζ can bypass T-T cyclobutane dimer, but not (6-4) T-T photoproduct and abasic site, inserting an incorrect nucleotide with relatively low efficiency *in vitro* (f_{inc} values range from 4.1×10^{-3} to 1.9×10^{-5})^[22, 56]. When combined with REV1 (transfers a dCMP residue from dCTP to the 3' end of a DNA primer in a template-dependent reaction opposite abasic site), pol ι (inserts a deoxynucleotide opposite the (6-4) T-T photoproduct and abasic site) or pol η (bypasses T-T cyclobutane dimer with relative high accuracy and efficiency), pol ζ can bypass all three types of lesions with more efficiency (f_{ext} values range from 10^{-1} to 10^{-2}) at elongating from a mismatched terminus, which develops the TLS two-step model (Figure 1)^[56-58].

Mutation caused by TLS is usually designated targeted mutation. However, mutation can also occur on undamaged DNA template and therefore is called untargeted mutation (UTM), which has been described in SOS-induced mutagenesis in *E. coli*^[59]. It has been known that untargeted and targeted mutations caused by SOS response in *E. coli* both result from the inhibition of DNA polymerase functions that normally maintain fidelity and the involvement of DNA polymerases with low fidelity, which include DNA pol III, pol IV (dinB), pol V (UmuD' 2C) and other factors (RecA*, β -sliding clamp, γ -clamp loading complex and single-stranded binding protein)^[60-64]. Using mating experiments with excision deficient strains of *Saccharomyces cerevisiae*, Lawrence and Christensen found that up to 40 % of cycl-91 revertants induced by UV were untargeted, showing that a reduction in fidelity of DNA replication^[65]. In mouse T-lymphoma cells, stress response induced by DNA damage agents (8-methoxy-psoralen or UVA)

leads to specific, delayed and untargeted mutations^[66]. It has been found that low concentration *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG), a carcinogen which can induce gastric cancer, could induce mammalian UTM^[19]. However, it is not clear which factor capable of inhibiting fidelity can be induced or activated. More recently, it was found that pol ζ might be involved in the mammalian UTM induced by MNNG. The transcriptional level of *REV3* gene is upregulated when human cells are treated by low concentration MNNG. Furthermore, human cells, in which the function of pol ζ is inhibited by antisense *REV3* RNA, display characteristics of both anti UTM and targeted mutation^[35].

Pol ζ also functions in somatic hypermutation^[33,34]. Accumulation of somatic mutations in the V(H) genes of memory B cells from transgenic mice which express antisense RNA to a portion of mouse *REV3* is decreased, particularly among those that generate amino acid replacements enhancing the affinity of the B cell receptor to the hapten^[33]. In addition, inhibition of the mouse mRev3 by specific phosphorothioate-modified oligonucleotides impairs Ig and bcl-6 hypermutation and UV damage-induced DNA mutagenesis, without affecting cell cycle or viability^[34].

Figure 1 TLS two-step model in human cells. (1) The main replicase in humans, pol δ , has difficulty in replicating through *cis-syn* T-T cyclobutane dimmer and (6-4) T-T photoproduct. This recruits specialized polymerases such as pol η , pol ι to insert or misinsert deoxynucleotides, and then pol ζ functions as a mismatch extender. (2) Opposite the abasic site, pol ι or REV1 inserts a deoxynucleotide, and bypass of this lesion occurs when combined with pol ζ .

ROLE OF POL ζ IN MAMMALIAN EMBRYONIC DEVELOPMENT

In *Saccharomyces cerevisiae*, pol ζ is not essential for cell viability, as indicated by the fact that haploids carrying a complete deletion of *Rev3* are viable^[21]. Besides, human fibroblast cells expressing high levels of an *REV3* antisense RNA fragment grow normally^[31]. However, recent evidences have shown that pol ζ is essential for cell viability during embryonic development in mammals (Table 1)^[43-45, 67].

Table 1 Characteristics of *mRev3*^{-/-} embryo

Size	Reduced at day 10.5
Viability	Usually aborted around day 12.5
Inner cell mass (ICM)	Diminished expansion
Haematopoietic cells	No haematopoietic cells developed other than erythrocytes
Morphogenesis of embryo	1. Abnormalities in the development and maintenance of embryonic mesoderm 2. Predominant disorder and lack of integrity mainly in mesenchymal tissues, including heart and large blood vessels

It has been realized that numerous DNA lesions caused by unavoidable oxidative and hydrolytic processes are constantly formed in genomes^[68]. Double-strand breaks can form when DNA replication forks encounter nicked templates, and these stalled replication forks must be reactivated by replication or repair. Unlike cells in adult tissues or in culture, which have mechanisms to cease division or DNA replication temporarily in order to allow accurate and specific DNA repair enzymes to act before proceeding through the cell cycle, embryonic development adheres to a strict temporal program that requires rapid cell division. Under such conditions, enzymes that can rapidly bypass DNA lesions may be expected to be particularly important, and an intolerable load of damaged DNA in critical embryonic or extra-embryonic cells would then lead to death. On the other hand, the proliferating cells in the embryo might gradually accumulate DNA damage and ES cells may be a special case of a cell type primed to undergo apoptosis after accumulated low levels of DNA damage^[69]. During the developmental stage of the mRev3-defective mouse embryos before embryonic death, the embryos are still able to propagate rapidly and differentiate through many cell divisions.

It is noteworthy that mouse *mRev3* is most highly expressed in mesodermal tissues and embryonic death coincides with the period of more widely distributed *mRev3l* expression. High-level expression of mouse *mRev3* is developmentally regulated during embryogenesis, occurring first in early somatogenesis and then in other mesodermal tissues up to at least 11.5 days *post coitum*^[45]. This differential expression seems likely to account for the predominant disorder and lack of integrity found mainly in mesenchymal tissues. Lack of proper development of the heart and large blood vessels might in itself be the immediate cause of death. Also, as mouse *mRev3* is normally expressed within extraembryonic membranes, the absence of functional mRev3 in mouse *mRev3*^{-/-} embryos could be the cause of the pericardial sac edema, yolk sac fragility and weak attachment to the decidual implantation site. Yolk-sac malfunction can induce osmotic imbalance, leading to edema, whereas delayed and/or suboptimal chorioallantoic fusion can result in an implantation defect. Defects of the chorioallantoic placenta or yolk sac are a common cause of murine lethality *in utero* and could contribute to the embryonic lethality of mouse *mRev3* disruption. Therefore, ES cells may have a special need for the activity of pol ζ if certain types of DNA damage accumulate within them, and bypass of specific types of DNA lesions by pol ζ is essential for cell viability during embryonic development in mammals.

However, it is also possible that mouse mRev3 has an additional unknown function. In view of the fact that yeast scRev7 shares a region of homology, termed the HORMA (Hop1p, Rev7p and Mad2) domain with Mad2, which associates with unattached kinetochores and functions in the spindle assembly mitotic checkpoint^[71]. Mad2, Rev3 and Rev7 proteins might therefore have the potential to interact *in vitro*. It has been demonstrated that human REV7 may interact with hMAD2^[54]. Interestingly, the tumor suppressor p33^{ING1}, which has recently been demonstrated to have no synergistic effect with p53 in camptothecin-induced cell death in melanoma cells^[72], strongly associates with mRev3 protein in a two-hybrid assay^[30]. It was observed that mouse *mRev3*^{-/-} embryonic death occurred in a p53-independent pathway indicating mRev3 functions with no direct or indirect interaction with p53^[67]. Furthermore, it has been found that *Saccharomyces cerevisiae* lacking Snm1, scRev3 or Rad51 have a normal S-phase but arrest permanently in G₂ after cisplatin treatment^[42]. Therefore, pol ζ can play a central role in apoptosis, cell proliferation, and the control of cell cycle by protein-protein interaction, and thus affect the embryonic development.

Abstract

AIM: To investigate the putative role of human papillomavirus (HPV) infection in the carcinogenesis of esophageal squamous cell carcinoma in China.

METHODS: Twenty-three esophageal squamous cell carcinoma samples and the distal normal epithelium from Shanxi Province, and 25 more esophageal squamous cell carcinoma samples from Anyang city, two areas with a high incidence of esophageal cancer in China, were detected for the existence of HPV-16 DNA by PCR, mRNA *in situ* hybridization (ISH) and immunohistochemistry (IHC) targeting HPV-16 E6 gene.

RESULTS: There were approximately 64 % (31/48) patients having HPV-16 DNA in tumor samples, among them nearly two-thirds (19/31) samples were detected with mRNA expression of HPV-16 E6. However, in the normal esophageal epithelium from cancer patients, the DNA and mRNA of HPV-16 were found with much less rate: 34.7 % (8/23) and 26.1 % (6/23) respectively. In addition, at protein level detected by IHC assay, 27.1 % (13/48) tumor samples had virus oncoprotein E6 expression, while only one case of normal epithelium was found positive.

CONCLUSION: HPV infection, especially type 16, should be considered as a risk factor for esophageal malignancies in China.

INTRODUCTION

Esophageal squamous cell carcinoma (ESCC) is one of the leading causes among Chinese cancer mortality, and the

incidence is mainly aggregated in North China, from which Henan and Shanxi Provinces are two high-incidence areas. The distinct geographical distribution suggests a dominant role of environmental factors in the etiology of this disease. Furthermore, other risk factors have been speculated, such as nutrition imbalance (lack or absence of vitamins and minerals), improper life style (cigarette smoking and consumption of pickled food), exposure to nitrosamines, during the carcinogenesis of ESCC in China^[1-2]. Nevertheless, the real causes and the mechanism of ESCC have not been elucidated yet.

Human papillomavirus (HPV) as one kind of important tumor-related virus has been firmly recognized in cervical cancer. But its oncogenic role in other tumors is still disputed^[3-5]. As to its role in ESCC, it was firstly suggested by Syrjanen 20 years ago, when he found the HPV infection in ESCC by pathological observation^[6]. Since then, many reports regarding this topic have been published, but the HPV infection rate in ESCC varied from zero to 67 %^[7,8], depending on the specimens obtained from low- or high-risk area around the world and the methods used in each study^[9-12]. In our previous study, we found that the prevalence of HPV-16 E6 and E7 genes in high incidence area was higher than that in low incidence area, detected by means of PCR and ISH, from the samples of balloon cytologic examination in Anyang area of China^[13]. In order to confirm and further investigate the prevalence of HPV infection in ESCC, the tumor samples and the distal normal epithelia from Shanxi Province, another high incidence region in China, with the tumor samples from Anyang city together, were tested for the existence of HPV-16 DNA.

Based on our previous data^[13], in this study, we focused on the HPV-16 E6 gene, a major viral oncogene of high-risk HPV type. In addition to detecting its DNA and mRNA by using PCR and ISH, the E6 protein expression was simultaneously analyzed by IHC for all the samples. Furthermore the status of HPV-16 infection was compared between tumor samples and their adjacent "normal" esophageal epithelium.

MATERIALS AND METHODS

Clinical samples

A total of 48 primary esophageal carcinoma specimens and 23 normal samples were obtained. Among them, 25 cases were from Anyang City Cancer Hospital and 23 from Shanxi Province Cancer Hospital. Distal end of the 23 surgical samples was pathologically diagnosed as normal esophageal mucous in morphology. Both areas are high incidence region of ESCC in China. The group included 36 males and 12 females with an average age of 57.4 years.

All the samples were esophageal squamous cell carcinomas. None of the patients had radical therapy or chemotherapy before surgery. The paraffin-embedded, formaldehyde fixed samples were cut into 5 μ m slides continuously, one for H&E staining and others for DNA extraction, immunohistochemistry and ISH analysis.

DNA extraction and PCR

The methods were as described previously^[13]. Briefly, 5-10

slides were deparaffinized in xylene and graded alcohol, then the lysis buffer (300 mmol/l NaCl; 50 mmol/l Tris·HCl pH 8.0; 0.2 % SDS) was added into the tube with proteinase K (200 mg/l), and the solution was incubated at 55 °C overnight until it became clear. Then DNA was extracted using phenol/chloroform, precipitated with cold alcohol, and dissolved in ion-free water and the concentration was determined from its optical density. Quality of the extracted DNA was tested by PCR with β -actin primer: 5' GGC GGC ACC ACC ATG TAC CCT 3' and 5' AGG GGC CGG ACT CGT CAT ACT 3'. The usable DNA went through PCR amplification using primer: 5' -CAAGCAACAGTTACTGCGA-3' and 5' -CAACAAG-ACATACATCGACC-3' targeting HPV-16 E6 gene under conditions at 94 °C denaturing for 1 min, at 60 °C annealing for 1 min, and at 72 °C prolonging for 1 min with 30 cycles.

The PCR product was about 321 bp. The plasmid containing full of length of HPV-16 genome as template was the positive control, and the water as template was the negative control.

In situ hybridization assay

HPV-16 E6 gene by PCR from the plasmid containing full length of HPV-16 was obtained and cloned into PGEM-T easy vector (Promega). After Sal I digestion, a digoxin-labelled E6 probe was made via *in vitro* transcription with the kit (Roche, No, 1175025).

The slides were deparaffinized and hydrated in xylene and graded ethanol continuously, then were treated with 0.2 mol/L HCl for 10 min at room temperature, followed by digestion with proteinase K 100 mg/l at 37 °C for 15 min. Twenty-five to fifty ng probe was added into hybridization solution (50 % formamide, 4×SSC, 5 % dextran sulfate, 5×Denhardt's solution and 200 g/l denatured salmon sperm DNA), then the solution containing E6 probe was dropped on the slides. The hybridization reaction was completed overnight in wet-chamber at 42 °C. After this, the slides were washed by 2×SSC, 1×SSC orderly twice, 30 min each time. The anti-digoxin antibody conjugated with alkaline phosphatase was added to the samples for 30 min at 37 °C. The purple-blue ISH signals were developed by adding substrate NBT/BCIP (Roche, No, 1175041) on the slides. The slides were incubated with hybridizing solution without E6 probe as negative control, and the cervical cancer biopsies were used as positive control.

Immunohistochemical staining for HPV-16 E6

The sections were deparaffinized in xylene and hydrated in graded ethanol continuously. Then the sections were covered with 3 % hydrogen peroxide in PBS to block the endogenous peroxidase activity for 10 min. The sections were pre-treated in citrate buffer (0.01 M, pH=6.0) under microwave heating for 20 min to retrieve the antigen. Normal goat serum was added to the slides for 30 min at room temperature. After that, the sections were incubated overnight at 4 °C with mouse monoclonal primary antibody against HPV-16 E6 (Santa Cruz, sc-460#), while the negative control was incubated with PBS instead of primary antibody under the same conditions. After the slides were washed three times in PBS for 5 min each, the biotinylated goat anti-mouse secondary antibody was added for 30 min followed by the avidin-biotinylated peroxidase complex for another 30 min at room temperature. After being washed with PBS, the slides were stained with DAB, and then counterstained in haematoxylin. The cervical cancer biopsies were used as positive control.

Evaluation of ISH and IHC results

If more than 10 % of epithelial cells in one slide showed

the positive signals, the case was regarded as positive. And the data were calculated by χ^2 -test. $P < 0.05$ was regarded as significant.

RESULTS

PCR analysis

All the extracted DNA samples showed good quality of DNA after PCR with β -actin primer. After PCR amplification using HPV-16 E6 specific primer, HPV infection was found in tumor patients from both regions, with an infection rate of 80 % in Anyang, and 47.8 % in Shanxi Province (Figure 1 and Table 1).

Furthermore, we detected the positive rate of 34.7 % of HPV-16 DNA in the morphologically normal epithelium adjacent to tumor tissue. But comparing the positive rate of cancer and normal samples, the difference of HPV infection in DNA level was significant (Table 1).

ISH and IHC assays

To identify whether HPV-16 infection can definitely cause mRNA transcription and protein expression of E6 oncogene, we further detected these two levels by ISH and IHC.

Using digoxin-labelled HPV-16 E6 specific cRNA probe, a total of 19 samples showed positive ISH signals in the cytoplasm of cancer cells. Among them, only 2 had nuclear positive signals (Figure 1). And 6 samples from adjacent normal esophageal epithelium were positive for HPV-16.

Among 48 cancer samples from both regions, 13 had HPV-16 E6 protein expression, while only one normal epithelium sample showed IHC positive signals. The difference between cancer and normal epithelia was significant ($P < 0.05$, Table 1).

The immunohistochemistry dark-brown signals scattered in the infected cancer cells, was similar to those mentioned before^[14] (Figure 2).

Table 1 HPV-16 infection rate detected by PCR, ISH and IHC in normal and tumor esophageal epithelium from two high-incidence regions in China

Samples	Region	n	PCR	ISH	IHC
Normal	Shanxi	23	8(34.7%) ^a	6(26.1%)	1(4.3%) ^a
Tumor	Shanxi	23	11(47.8%)	6(26.1%)	5(21.7%)
	Anyang	25	20(80.0%)	13(52.0%)	8(32.0%)
Total		48	31(64.6%)	19(39.6%)	13(27.1%)

^a $P < 0.05$, from PCR and IHC data, HPV infection rate in normal esophageal epithelium was distinctly different from those in esophageal cancer samples.

Figure 1 PCR results of Chinese esophageal cancer samples using HPV-16 E6 specific primer. Lane 1,2 were the positive and negative control; Lane 4,5,7 were the positive samples; Lane 3,6 were the negative samples; Lane 8 was 100 bp ladder.

Figure 2 ISH and IHC results of tumor samples targeting HPV-16 E6 gene. A, the positive purple-blue ISH signal is mainly located in the cytoplasm of esophageal cancer cell. $\times 200$; B, the positive purple-blue ISH signal is mainly located in the nuclear of the carcinoma cell. $\times 100$; C, note the dark-brown IHC signals located mainly in the cytoplasm of cancer cell. SP methods, haematoxylin counterstained $\times 200$.

DISCUSSION

HPV infection of the esophagus was first suggested by Syrjanen in 1982, who found that 40 % of the esophageal specimens with squamous cell carcinoma presented histological changes identical to those of condylomatous lesions in or around these carcinomas, and demonstrated the presence of HPV antigen in one case of esophageal squamous cell papilloma using immunohistochemistry. This finding was subsequently confirmed by others who demonstrated HPV antigens as well as HPV DNA in benign and malignant esophageal lesions^[15-19]. But the infection rate reported in the literature varied largely, such as in India, one of Asian high ESCC regions, the detection rate could reach as high as 67 %^[8], while in some Western countries such as France^[20], Slovenia^[21], Sweden^[22], Belgium^[23] and Finland^[24], the HPV infection rate is close to zero. Based on our previous study^[13], and after carefully reviewing the literature, we share the opinion with others^[21,25] that HPV infection plays a much more significant role in ESCC in those regions of the world with a high prevalence of disease than in areas with a moderate or low risk^[26-28].

Besides the influence of geographic, environmental and

racial differences, the sensitivity of the detection techniques and the different methodologies should not be ignored for the variation around the world. For example, consensus L1 primers were frequently used as the proper PCR primers for its ability to detect a wide spectrum of HPV types^[12,26,29]. But during virus integration into the host genome, L1 and L2 were often lost. Therefore, the detection using consensus primers against the L1 gene would likely lead to a low rate. This has been demonstrated clearly by our previous and other studies^[13,25].

HPV type 16 has been most commonly implicated in ESCC, and in addition, it is known that the E6 amplification system is retained during viral integration into the host genome^[25]. In this study, we used specific primer targeting E6 gene of HPV-16 as before^[13]. The presence of HPV-16 DNA was found in 65 % tumor patients from Anyang city and Shanxi Province, two high-incidence regions in ESCC in China. Furthermore, E6 mRNA expression of HPV-16 was detected in nearly two-thirds samples among those viral DNA positive patients, while the positive rate of E6 protein expression not found as high as that of mRNA, but still in more than 40 % (13/31) tumor samples, the E6 protein could be detected by IHC when HPV-16 infection occurred among those patients. From this study, it is demonstrated that HPV-16 infection of esophageal epithelium is very common within ESCC patients from Anyang city, and this observation is truly the same as within those from Shanxi Province.

Comparing the status of HPV-16 infection between some adjacent "normal" esophageal epithelium and their tumor samples, the most significant difference was E6 expression at protein level, rather than DNA and mRNA level between them (Table 1). Therefore, it is confirmed that not only existence of the viral DNA, but also the expression of E6 gene may play an important role in the carcinogenesis of ESCC in those high incidence regions.

It is well known that HPV oncogenes expressed in cervical cancer cells are involved in their transformation and immortalization, and are required for the progression towards malignancy^[30-35]. In cervical cancer, the knowledge has been firmly established that HPV infection could interfere normal cell cycles by degrading tumor suppressor protein P53 and Rb and cause host genomic instability through its DNA integrating host genome randomly and increasing centrosome number. As for the exact function of HPV infection during the carcinogenesis of ESCC, it is still unclear. But in recent years, more evidences suggested the possible mechanism of high-risk HPV in transforming esophageal epithelial cells, such as induction of HPV on the activity of telomerase^[36], interaction of E6 with P53^[37] the association of HPV-16 E6 with nuclear matrix^[38] and others^[39-40].

In conclusion, from our previous study and this study, as well as others, HPV infection should be considered as a risk factor for ESCC, at least in high incidence area in China, and in order to further explore the role of viral DNA infection during the carcinogenesis of ESCC, more works are needed in the future.

Abstract

AIM: To study the mechanisms responsible for inactivation of a novel esophageal cancer related gene 4 (ECRG4) in esophageal squamous cell carcinoma (ESCC).

METHODS: A pair of primers was designed to amplify a 220 bp fragment, which contains 16 CpG sites in the core promoter region of the *ECRG 4* gene. PCR products of bisulfite-modified CpG islands were analyzed by denaturing high-performance liquid chromatography (DHPLC), which were confirmed by DNA sequencing. The methylation status of *ECRG 4* promoter in 20 cases of esophageal cancer and the adjacent normal tissues, 5 human tumor cell lines (esophageal cancer cell line-NEC, EC109, EC9706; gastric cancer cell line- GLC; human embryo kidney cell line-Hek293) and 2 normal esophagus tissues were detected. The expression level of the *ECRG 4* gene in these samples was examined by RT-PCR.

RESULTS: The expression level of *ECRG 4* gene was varied. Of 20 esophageal cancer tissues, nine were unexpressed, six were lowly expressed and five were highly expressed compared with the adjacent tissues and the 2 normal esophageal epithelia. In addition, 4 out of the 5 human cell lines were also unexpressed. A high frequency of methylation was revealed in 12 (8 unexpressed and 4 lowly expressed) of the 15 (80 %) downregulated cancer tissues and 3 of the 4 unexpressed cell lines. No methylation peak was observed in the two highly expressed normal esophageal epithelia and the methylation frequency was low (3/20) among the 20 cases in the highly expressed adjacent tissues. The methylation status of the samples was consistent with the result of DNA sequencing.

CONCLUSION: These results indicate that the inactivation of *ECRG 4* gene by hypermethylation is a frequent molecular event in ESCC and may be involved in the carcinogenesis of this cancer.

INTRODUCTION

Esophageal cancer (EC) is one of the most common malignant tumors in the world. Previous studies have shown several genetic abnormalities including amplification of *c-myc*, *int-2* and *Hst*, mutation and/or deletion of *p53* and *Rb* in human EC and EC cell lines^[1,2]. However, the genetic events leading to the development of EC are not clear yet. In recent years, many studies of EC focused on the clone and identification of novel EC-related genes, which might play an important role in the carcinogenesis and development of esophageal cancer^[3-5].

Recently, we have cloned and identified a novel tumor candidate suppressor gene, *ECRG 4* (Genbank Accession NO. AF 325503), from human normal esophageal epithelium^[6,7]. The *ECRG 4* gene located in chromosome 2q14.1-14.3 contains 4 exons, spans about 13 kb and has a full-length cDNA of 772 bp. Analysis by bioinformatics has shown that the protein coded by *ECRG 4* shows a 31 % homology with mouse IgG V region. The results of SAGE and RT-PCR detection have demonstrated the *ECRG 4* gene is expressed in adult esophageal epithelium but is downregulated in esophageal squamous cell carcinoma (ESCC) and tumor cell lines. These findings suggest that the *ECRG 4* gene might be involved in the development of ESCC, but the mechanism inactivating it remains to be determined.

According to the result of the sequence analysis in *ECRG 4* gene, we found that there were CpG islands in the promoter region, exon 1 and part of intron 1 of the gene. Many tumor suppressor genes are downregulated by promoter methylation during the development and progression of cancer, and hypermethylation of gene-promoter regions is being revealed as one of the most frequent mechanisms in loss of gene function, thus detection of CpG methylation is important to understand the gene regulation of cancer^[8,9]. It has been reported that the expression of some tumor suppressor genes, such as *p16^{INK4a}*, *p16^{INK4b}*, *FHIT* and *E-cadherin* are commonly downregulated by CpG island hypermethylation in ESCC^[10-13]. However, the reason for reducing expression of *ECRG 4* in ESCC is unknown.

In order to determine the mechanism involved in the downregulation of *ECRG 4* in ESCC, we have examined the methylation status of the 5' CpG island in promoter region of the *ECRG 4* gene in 5 human cell lines, which include 3 esophageal cancer cell lines, 2 normal esophageal epithelia and 20 cases with ESCC and adjacent tissues. The methylation status of the cell lines and tissues were compared with the expression of the *ECRG 4* gene in the same samples by RT-PCR respectively.

MATERIALS AND METHODS

Cell lines and tissue samples

Five cell lines, including 3 esophageal cancer cell line-NEC,

EC109 and EC9706; 1 gastric cancer cell line- GLC and 1 human embryo kidney cell line-Hek293 were used in this study. All cell lines were routinely cultured in 1640 medium (Gibco) supplemented with 10 % fetal bovine serum (Hyclone) at 37 °C with 5 % CO₂. 20 pairs of ESCC and corresponding tissues adjacent to the tumors were obtained from surgically removed specimens of individual patients who underwent an operation at the Cancer Hospital in Linxian County which has the highest age-adjusted mortality rate of this cancer. Two normal esophageal epithelia were collected from healthy individuals by biopsy. All the samples were frozen at -70 °C before RNA and DNA were extracted with standard method as described previously^[14].

Bisulfite treatment of DNA

Genomic DNA was treated with sodium bisulfite as described by Herman *et al*^[15]. Briefly, 1 g DNA was denatured by adding freshly prepared NaOH with the final concentration 0.3 M for 15 min in a 37 °C water bath. The denatured DNA was then diluted in 30 µl freshly prepared 10 mM hydroquinone (Sigma) and 520 µl freshly prepared 3 M sodium bisulfite (Sigma) at pH 5.0. The DNA was incubated at 50 °C for 16 h and subsequently purified by the Wizard DNA Clean-Up System Kit (A7280; Promega).

20 µg of human placenta genomic DNA was incubated for 24 h with 20 units of *SssI* (New England Biolabs) as described in the instruction manual and the methylated DNA was treated by bisulfite and purified by the Wizard DNA Clean-Up System Kit (A7280; Promega) as described above.

Design of primers and SsPCR condition

Primers were designed according to the CpG island of the sense strand of the *ECRG 4* gene. The strand-specific primers for the treated CpG island were used to amplify a 220 bp fragment containing 16 CpG sites and 4 cis-acting elements, and they were: 5'-AGTGGGGGA GTT AAG GAG ATA TT-3' (forward), and 5'-CCC CTA AAC TCC AAA ACC AA-3' (reverse). PCR was performed in a GeneAmp 2400 thermocycler (Perkin-Elmer, Norwalk, CT) with a 25 µl reaction mixture containing about 100 ng DNA, 1.6 µmol each primer, 400 µmol each dNTPs, 1.25 U LA Taq with 1× LA reaction buffer (TaKaRa). Thermal cycles were: at 94 °C for 2 min, then 40 cycles at 94 °C for 30 sec, at 52 °C for 30 sec, at 72 °C for 1 min and 30 sec followed by extension at 72 °C for 7 min. The PCR products were detected in 1.5 % agarose gels.

Analysis for methylation by DHPLC

The ssPCR products of *ECRG 4* were introduced into the mobile phase at an injection volume of 5 µl by the autosampler on a WAVE DNA Fragment Analysis System (Transgenomic) identical to that described by Deng *et al*^[16]. Non-denaturing analysis was conducted at 48 °C and partially denaturing analysis was conducted at 56 °C, which was predicted by

WAVEMaker.

The ssPCR product from the *SssI* and bisulfite treated human placenta genomic DNA was the positive control of the experiment.

DNA cloning and sequencing

The PCR products amplified with primers specific either for the methylated or for the unmethylated DNA were purified and cloned into the pMD18-T Easy Vector (Promega) and sequenced on an ABI 377 automated sequencer (Applied Biosystems) by using M13 primers.

RT-PCR detection

Total RNA was isolated from cells and tissues using Trizol reagent (Invitrogen). Reverse transcription was carried out with the SuperScript TM First-Strand Synthesis System (Invitrogen). Approximately 3 µg total RNA was used in each reverse transcription reaction and the final volume was 20 µl. The ORF of *ECRG 4* gene was amplified using the primers 5'-GGT TCT CCC TCG CAG CAC CT-3' (forward), and 5'-CAG CGT GTG GCA AGT CAT GGT TAG T-3' (reverse). PCR was performed in a GeneAmp 2400 thermocycler (Perkin-Elmer, Norwalk, CT) with a 25 µl reaction mixture containing 1 µl reverse transcription products, 200 pmol each primer, 200 µmol each dNTPs, 1.5 mM Mg²⁺, 2.0 U PLATINUM pfx DNA polymerase with 1×reaction buffer (Promega). Thermal cycles were: at 95 °C for 2 min, then 30 cycles at 95 °C for 30 sec, at 62 °C for 30 sec, at 72 °C for 1 min followed by extension at 72 °C for 7 min. The β-actin transcripts in each sample were also amplified as internal controls to normalize the amount of *ECRG 4* specific products.

RESULTS

The promoter hypermethylation in *ECRG 4* gene

Based on the flanking DNA sequences of the *ECRG 4*-core promoter region, PCR primers were designed to amplify a 220 bp fragment containing the 16 CpG sites (Figure 1). Using the ssPCR-specific primers, a 220 bp product was successfully obtained from each bisulfite-treated sample, which was detected by 1.5 % agarose gels and DHPLC size analysis, and the specific band (Figure 2) and the single chromatogram peak (Figure 3) were obtained respectively. The agarose gel detection and the size analysis on DHPLC all indicating the quality and quantity of the ssPCR products were high and the products could be used in the methylation analysis on DHPLC. Figure 4a shows the detection of methylated and unmethylated CpG islands in ssPCR products by DHPLC. Compared with the peak of positive control from the *SssI* treated human fetal DNA, the methylated and unmethylated samples could be easily discerned. The different proportion of methylated peak represented the different methylation levels in different samples. To confirm the reliability of the ssPCR products of

Figure 1 The sequence of *ECRG 4* fragment for bisulfite-DHPLC analysis. The fragment contains 4 cis-acting elements and 16 CpG sites in shadow. The 5' and 3' primers are in the frames of the two ends of the fragment respectively.

the *ECRG4* promoter region, either the methylated or the unmethylated DNA was cloned and sequenced (Figure 5). The cytosines in the CpG sites of methylated ssPCR products remained unchanged, but the cytosines of unmethylated products were converted to thymines. The promoter methylation of *ECRG4* gene in esophageal tissues is shown in Table 1. A high frequency of methylation was observed in 12 cancer tissues, 3 tumor adjacent tissues and 3 cell lines (EC 9706, EC 109 and GLC). No methylation peak was obtained in the two normal esophageal epithelia, the other tumor and adjacent tissues and the two cell lines (NEC and Hek293).

Figure 4 (a) The methylation detection of ssPCR products at 56 °C on DHPLC. The methylation peak was emphasized by the arrow. PC was the product from the *SssI* treated human placenta genomic DNA. 1, 2, 3, 4; the same samples as Figure 2. **(b)** The expression level of *ECRG4* by RT-PCR using the primer set flanking the ORF of the gene in the same samples was detected on DHPLC. The β -Actin gene was amplified as internal control. M; 1 kb DNA Ladder Marker. 1, 2, 3, 4; the same samples as Figure 2.

The expression level of *ECRG4* gene was different, and a high frequency of methylation was revealed in 12 (8 unexpressed and 4 lowly expressed) of the 15 (80 %) cancer tissues and the 3 of the 4 unexpressed cell lines. No methylation peak was observed in the two highly expressed normal esophageal epithelia and the methylation frequency was low (3/20) among the 20 cases in the highly expressed adjacent tissues.

Expression of *ECRG4* gene related to methylation

The expression level of the *ECRG4* gene in the tissues and cell lines was examined by RT-PCR (Figure 4b). Out of 20 esophageal cancer tissues, nine were unexpressed, six were lowly expressed and five were highly expressed compared with the adjacent tissues and the 2 normal esophageal epithelia. In addition, 4 out of the 5 human cell lines were also unexpressed. The methylation was observed in 12 (8 unexpressed and 4 lowly expressed) of the 15 (80.0 %) cancer tissues and the 3 unexpressed cell lines (Table 1 and Table 2). Among the normal tissues corresponding to the 12-methylation cancer tissues, nine were highly expressed and unmethylated; three were lowly expressed or unexpressed and methylated (Table 1). No methylation peak was obtained in the highly expressed samples, including the two normal esophageal epithelia, the cell line Hek293 and the other tumor and adjacent tissues. The results demonstrated that the expression of *ECRG4* was downregulated by CpG island hypermethylation in human esophageal squamous cell carcinoma.

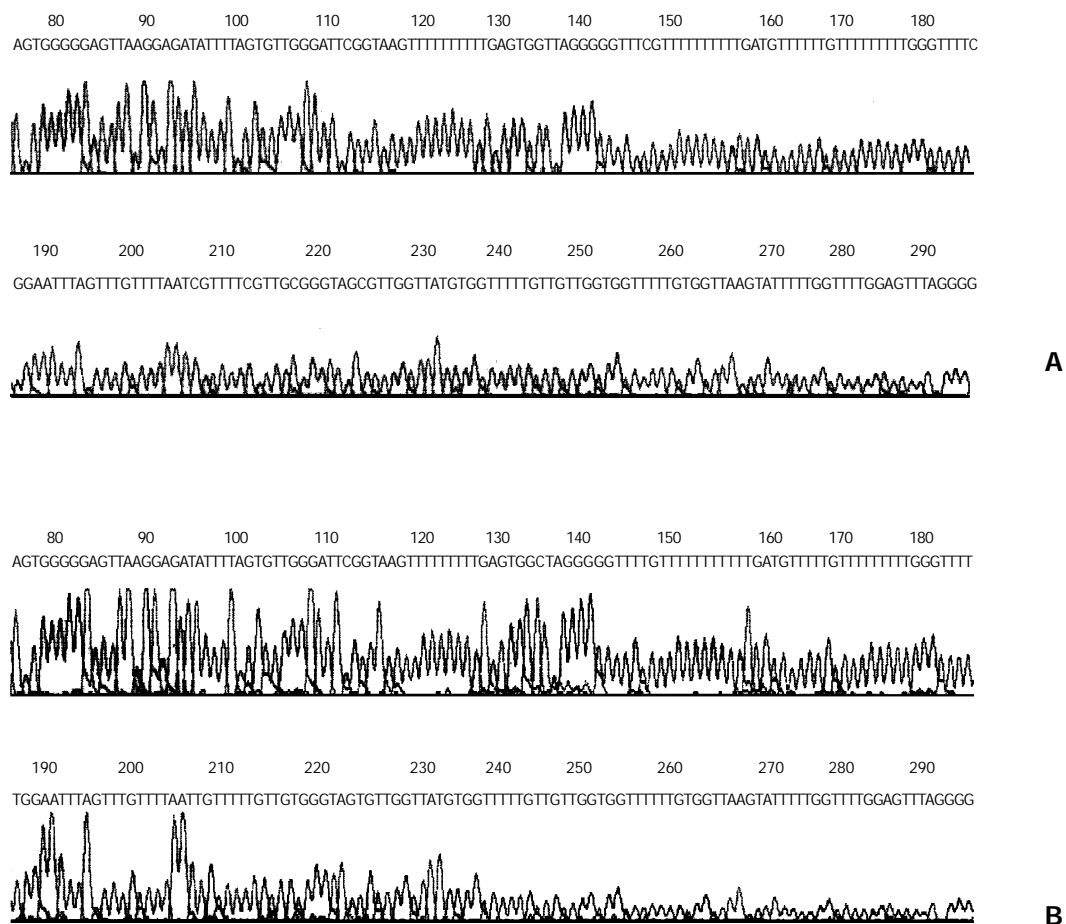

Figure 5 Sequencing of ssPCR products of the *ECRG4* gene promoter region. All cytosines in CpG dinucleotides in the methylated *ECRG4* remain as cytosines, indicating methylation (A), while all cytosines in unmethylated *ECRG4* have been converted to thymidines, indicating unmethylation (B).

DISCUSSION

We used a high-throughout methylation assay, bisulfite-DHPLC assay to examine the methylation status of the *ECRG 4* gene promoter in ESCC. The results demonstrated for the first time that downregulated expression of *ECRG 4* in ESCC was associated with CpG island methylation in the core promoter region of the gene. These findings suggest that inactivation by the promoter hypermethylation of *ECRG 4* is a common molecular event in ESCC and it may be involved in the development of this cancer, since this epigenetic change of the *ECRG 4* gene was not found in the normal epithelium and immortalizing cell line Hek293. Eads *et al* reported that DNA hypermethylation was an early epigenetic alteration in the multistep progression of the esophageal adenocarcinoma, because they found that the premalignant tissue was significantly more methylated than the normal tissue^[17]. Then, we can speculate that the inactivation by hypermethylation of *ECRG 4* might be an early event in the progression of ESCC carcinogenesis.

Because of the extent of methylation at various CpG sites of most genes, especially a novel identified gene is unknown, it is hard to design good MSP primers or MethyLight probes for methylated templates, which require full methylation at all CpG sites in their mating region^[15,18]. However, the ssPCR for bisulfite-modified templates are not influenced by the extent of methylation of CpGs, because no CpG site exists in the primer sequence and the primer for modified DNA can amplify both methylated and unmethylated templates. Deng *et al* had compared the bisulfite-DHPLC with other methylation detection method, and demonstrated the bisulfite-DHPLC assay could be used to detect methylation in homoallelic and heteroallelic CpG islands in cell lines and tissues rapidly and

reliably^[16]. In the present study, we also confirmed the reliability of bisulfite-DHPLC assay by DNA sequencing.

Abnormal hypermethylation of CpG islands associated with tumor suppressor genes can lead to repression of gene expression and contribute significantly to tumorigenesis of many kinds of tumors, such as esophageal cancer, gastric cancer, lung cancer, breast cancer and cervical cancer^[19-23]. Furthermore, each tumor type has a characteristic set of genes with an increased propensity to become methylated, and an individual tumor within a single patient has a unique epigenetic fingerprint^[24]. Determining tumor-type specific and patient-specific fingerprints may provide biomarkers that can be used in diagnosis, such as cancer detection, cancer chemoprediction and prognostics^[25, 26]. The recent study has been repleted with the examples of hypermethylation of CpG islands in the promoter region of more than 40 lung cancer related genes to analyse methylation patterns of multiple genes. They want to obtain complex DNA methylation signatures, which can provide a useful and highly specific tool for lung cancer diagnosis^[27].

The promoter hypermethylation of the ESCC-related genes such as, *p16^{INK4a}*, *p15^{INK4b}*, *hMLH1*, *E-cadherin*, *Chfr* and HLA class I genes, has been shown to be a common epigenetic event in this cancer and the studies of these genes suggest that hypermethylation of key genes may be used in combination with other molecular changes, such as *p53* mutation, in the development of biomarkers for predicting the risk for ESCC^[28-30]. Our present study extended the findings of methylation signature in ESCC, and the methylation in more ESCC-related genes was studied, better understanding of the mechanisms underlying tumor progression in this cancer was

obtained, so that improved diagnosis and therapy can be facilitated.

In summary, our study demonstrated that aberrant methylation of CpG islands in the core promoter of the *ECRG 4* gene was a frequent molecular event in ESCC and proved for the first time that loss or lower expression of *ECRG 4* was associated with *ECRG 4* CpG island methylation. These results indicate that the inactivation of *ECRG 4* gene by hypermethylation in ESCC may be involved in the carcinogenesis of the cancer.

Abstract

AIM: To study the relationship between the expression profiles of a plant-associated human cancer antigen and carcinogenesis of esophagus and its significance.

METHODS: We analyzed expression of a plant-associated human cancer antigen in biopsy specimens of normal ($n=29$), mildly hyperplastic ($n=29$), mildly ($n=30$), moderately ($n=27$) and severely dysplastic ($n=29$) and malignant esophageal ($n=30$) tissues by immunohistochemistry.

RESULTS: The plant-associated human cancer antigen was mainly confined to the cytoplasm and showed diffuse type of staining. Positive staining was absent or weak in normal (0/30) and mildly hyperplastic tissue samples (2/29), while strong staining was observed in severe dysplasia (23/29) and carcinoma *in situ* (24/30). There was significant difference of its expression between normal mucosa and severely dysplastic tissues ($P<0.001$) or carcinoma *in situ* ($P<0.001$). Significant difference was also observed between mild dysplasia and severe dysplasia ($P<0.001$) or carcinoma *in situ* ($P<0.001$). An overall trend toward increased staining intensity with increasing grade of dysplasia was found. There was a linear correlation between grade of lesions and staining intensity ($r=0.794$, $P<0.001$). Samples from esophageal cancer showed no higher levels of expression than those in severely dysplastic lesions ($P>0.05$).

CONCLUSION: The abnormal expression of this plant-associated human cancer antigen in esophageal lesions is a frequent and early finding in the normal-dysplasia-carcinoma sequence in esophageal carcinogenesis. It might contribute to the carcinogenesis of esophageal cancer. The abnormal expression of this plant-associated human cancer antigen in esophageal lesion tissues may serve as a potential new biomarker for early identification of esophageal cancer.

INTRODUCTION

Despite three decades of progress in cancer treatment, esophageal cancer remains a significant health problem worldwide with a very low 5-year survival rate and a rapid increase in its incidence^[1-4]. Esophageal squamous cell carcinoma is believed to develop progressively through a dysplasia-carcinoma sequence^[5,6]. The evolution of sequential histological changes from normal to dysplasia and carcinoma *in situ* suggests that specific biomarkers may be expressed at different points in the evolution of esophageal carcinoma^[7]. Therefore, research directed toward the discovery of new biomarkers that can aid in the early detection of esophageal neoplasm has been intensified in recent years.

In the 1990s, Dr. Zhen-Hai Zheng separated and identified a glycoprotein (molecular weight: 46 kilo-dalton) from a lower plant. Early experiments demonstrated its stimulatory activity on the growth of esophageal cancer cells. Recently the differential stimulatory effects of this plant antigen on isolated lymphocytes from patients with dysplasia or breast cancer have been confirmed. Their experiments also suggested that this plant antigen might have an associated counterpart cancer antigen in human.

In this research, we aimed to study the relationship between expression profiles of this human cancer antigen and carcinogenesis of esophagus and its significance.

MATERIALS AND METHODS

Tissue specimens

Biopsy specimens were obtained from the Cancer Hospital (Chinese Academy of Medical Sciences) in Beijing. These samples were taken from patients with morphologically normal ($n=29$), mildly hyperplastic ($n=29$) esophageal mucosa, mildly ($n=30$), moderately ($n=27$) or severely ($n=29$) dysplastic lesions, or squamous carcinomas *in situ* ($n=30$). All samples were routinely fixed in 10 % buffered formalin, embedded in paraffin, and cut into 4 μ m sections. Samples were selected based on the pathological diagnosis and reviewed by a pathologist to ensure the correct diagnosis.

Reagents

SP-ABC kit was purchased from Beijing Zhong Shan Biotechnology Co. Ltd. Rabbit polyclonal antibody anti-plant antigen was kindly provided by professor Zhen-Hai Zheng, diluted to 2×10^{-2} g \cdot L⁻¹ before use.

Immunohistochemistry

The immunohistochemical localization of the plant-associated human cancer antigen was performed using a modified ABC technique^[8]. Briefly, tissue sections were deparaffinized in xylene and rehydrated in a series of ethanol solutions (100-50 %). The sections were then microwaved for 15 min to restore antigens in 0.01M citric acid solutions. The endogenous peroxidase activity was blocked by incubation in a 3 % hydrogen peroxide solution for 20 min at 23 °C. This was followed by preincubation with 1.5 % normal sheep serum to minimize nonspecific binding of the second antibody. The

sections were incubated at 4 °C overnight with rabbit polyclonal antibody anti-plant protein. After being washed three times in PBS, the sections were incubated with biotinylated sheep anti-rabbit IgG for 20 min at 37 °C and were washed three times in PBS. Sections were then incubated with streptavidin-peroxidase for 20 min at 37 °C, followed by 2 min staining with DAB-H₂O₂ solution and nuclear counterstained with hematoxylin. For negative controls, the rabbit anti-plant protein polyclonal antibody was replaced by normal rabbit serum.

Review and scoring of the section

The stained sections were reviewed and scored independently by two investigators using an Olympus microscope. The intensity of staining was graded on a scale of 0 to 3 as follows: 0 meaning the amounts of positive cells were less than 10 %; 1, weak positive, the amounts of positive cells were more than 10 %, but less than 30 %; 2, positive, the amounts of positive cells were more than 30 % but less than 50 %; and 3, strong positive, the amounts of positive cells were more than 50 %^[9]. The grading for each section used for data analysis was the highest intensity seen on the section.

Statistical analysis

The mean values of the staining intensity for different grades of diseases were compared by analysis of variance. Linear regression analysis was done to evaluate the linear correlation between lesion severity and staining intensity. Statistical analysis was made using Fisher's exact test to determine the

association between normal or dysplastic tissues and tumors. *P* values were generated using SPSS 10.0 for Windows. Statistical significance was accepted at the *P*<0.05 level.

RESULTS

Our finding suggested that the plant-associated human cancer antigen was mainly confined to the cytoplasm and showed diffuse type of staining, enormous nuclear staining could also be observed in severe dysplastic and carcinoma *in situ* tissue samples. Only background staining was observed in basal layers underlying epithelium. Staining was absent to weak in normal and mildly hyperplastic tissue samples (Figure 1-6). Positive staining was absent to weak in normal (0/30) and mildly hyperplastic tissue samples (2/29), while high positive rate was observed in severe dysplasia (23/29) and carcinoma *in situ* (24/30).

There was significant difference of its expression between normal mucosa and severely dysplastic tissues (*P*<0.001) or esophageal cancer (*P*<0.001). Significant difference was also observed between mild dysplasia and severe dysplasia (*P*<0.001) or esophageal cancer (*P*<0.001) (Table 1). Samples from esophageal cancer showed no higher levels of its expression than seen in severely dysplastic lesions (*P*>0.05). An overall trend toward increased staining intensity with increasing grade of dysplasia was found. There was a linear correlation between grade of lesion and staining intensity (*r*=0.794, *P*<0.001) (Table 2).

DISCUSSION

We have evaluated esophageal mucosal expression of the plant-associated human cancer antigen in a variety of normal, precancerous or malignant esophageal tissue specimens. Esophageal biopsy specimens with normal histology or low-grade dysplasia did not express significant levels of this human cancer antigen. Its intensive expression was observed in high-grade dysplastic and malignant lesions. There was an overall trend toward increased staining intensity with increasing grade of dysplasia, and the largest difference was observed between mild and severe dysplastic lesions, suggesting that its up-regulation of expression may be involved in esophageal carcinogenesis. Since esophageal carcinogenesis is a multi-stage process, early detection is very crucial^[10,11]. This human cancer antigen might be a useful diagnostic marker for advanced dysplasia and could serve as a useful target for biological treatment and for bio-prevention in high-risk patients diagnosed having dysplasia or esophageal carcinoma.

In this report, we also studied the expression distribution of this human cancer antigen in abnormal human sections. Although this antigen was mainly expressed in cytoplasm, enormous nuclear staining could also be observed in severely dysplastic and malignant tissue samples. Combined with previous conclusions, our finding suggested that this protein might be involved in signal transduction pathway or cell cycle control. Its intracellular translocation from cytoplasm to nuclei might play an important role in the transition from low-grade dysplasia to severe lesions and neoplasm. The mechanism of action of this cancer antigen in esophageal carcinogenesis still awaits further studies.

The ability to identify the plant-associated human cancer antigen in esophageal biopsy specimens from patients with dysplasia may provide a useful method for early detection, identification of high-risk patients, monitoring response to therapy. Further studies are needed to separate and identify this protein and its encoding gene in order to fully understand the regulatory mechanism underlying its aberrant expression and its role in esophageal carcinogenesis.

Abstract

AIM: To investigate the correlation between ezrin expression and invasive phenotype formation in malignantly transformed esophageal epithelial cells.

METHODS: The experimental cell line employed in the present study was originated from the progressive induction of a human embryonic esophageal epithelial cell line (SHEE) by the E6E7 genes of human papillomavirus (HPV) type 18. The cells at the 35th passage after induction called SHEEIMM were in a state of immortalized phase and used as the control, while that of the 85th passage denominated as SHEEMT represented the status of cells that were malignantly transformed. The expression changes of ezrin and its mRNA in both cell passages were respectively analyzed by RT-PCR and Western blot. Invasive phenotype was assessed *in vivo* by inoculating these cells into the severe combined immunodeficient (SCID) mice via subcutaneous and intraperitoneal injection, and *in vitro* by inoculating them on the surface of the amnion membranes, which then was determined by light microscopy and scanning electron microscopy.

RESULTS: Upregulated expression of ezrin protein and its mRNA was observed in SHEEMT compared with that in SHEEIMM cells. The SHEEMT cells inoculated in SCID mice were observed forming tumor masses in both visceral organs and soft tissues in a period of 40 days with a special propensity to invading mesentery and pancreas, but did not exhibit hepatic metastases. Pathologically, these tumor cells harboring larger nucleus, nucleolus and less cytoplasm could infiltrate and destroy adjacent tissues. In the *in vitro* study, the inoculated SHEEMT cells could grow in cluster on the amniotic epithelial surface and intrude into the amniotic stroma. In contrast, unrestricted growth and invasiveness were not found in SHEEIMM cells in both *in vivo* and *in vitro* experiment.

CONCLUSION: The upregulated ezrin expression is one of the important factors that are possibly associated with the

invasive phenotype formation in malignantly transformed esophageal epithelial cells.

INTRODUCTION

It has been well known that cancer cells can invade and destroy surrounding tissues by their disseminative potency. This acquired malignant property is believed recently to be determined by the abnormal changes of expression patterns of certain genes such as c-met, urokinase type plasminogen activator receptor or ezrin and so on^[1-9]. Therefore, the correlation between the invasive phenotype of tumor cells and the aberrant expression of these genes has become a focus of attention by the worldwide oncologists.

Induced by E₆E₇ genes of human papilloma virus (HPV) type 18, we have established both kinds of immortalized and malignantly transformed cells from a human embryonic esophageal epithelial cell line (SHEE)^[10]. At early passages after induction, the cell did not display any abnormal growth ability in soft agar and nude mice^[11-13]. At the 20th passage, the cell was noted to be immortalized with the appearance of telomerase^[14, 15]. At the 30th passage, the cell manifested as a phenotype of biphasic differentiation^[16]. While cultivated over 60 passages, the cell exhibited atypical morphological changes and chromosomal alterations that were suspected to be a kind of premalignant transformation^[17]. Over 85 passages, the cell was observed having harbored a property of malignant transformation shown by its unrestricted growth in the nude mice and invasion to the surrounding tissues^[18, 19]. Obviously, this process of malignant transformation of SHEE cells induced by E₆E₇ genes of HPV type 18 possesses a progressive and stepwise characteristic, which is no doubt a good cell model suitable for the study of correlations between abnormal gene expression and corresponding malignant phenotype formation in tumorigenesis.

Differential display analysis of RNA samples isolated from the SHEEIMM and SHEEMT cells has been performed in our previous study. There were 15 up-regulated and 6 down-regulated genes being identified by the cDNA microarray method (Data to be published), in which ezrin was one of the up-regulated genes that have been found existed in certain diseases and tumors. Being a membrane-cytoskeleton linker, ezrin protein is located in cytoplasm and is rich in microvilli and cell surface structures with the function involved in the formation of microvilli and intercellular junctions, as well as the cell motility and invasive behavior of malignant tumors^[20-28]. Up to the present, however, there have been few reports concerned about how the ezrin expressed in the malignant transformation of esophageal epithelial cells and what was its relation to the invasiveness formation of tumor cells, which are of both theoretical and practical importance in the

investigation of cancerogenesis. Thus, our present study was conducted to identify the correlation between the ezrin gene expression and invasive phenotype formation in malignantly transformed esophageal epithelial cells.

MATERIALS AND METHODS

Cell lines and cell culture

The experimental cells came from our laboratory, and were established by the progressive induction of SHEE cell line with the E6E7 genes of HPV type 18. The 35th, 85th passages of induced cells were employed in the present study. The cells at the 35th passage called SHEEIMM were in a state of immortalized phase, while that of the 85th passage denominated as SHEEMT represented the status of cells that were malignantly transformed. Both passages of cells were continuously cultivated in flasks with medium 199 (GIBCO) supplemented by 10 % fetal bovine serum (FBS), 100 U·ml⁻¹ penicillin and 100 U·ml⁻¹ streptomycin at 37 °C in a humidified atmosphere containing 5 % of CO₂.

RT-PCR

Total RNA was extracted from SHEEIMM and SHEEMT cells using the Trizol reagent (Invitrogen). The first-strand cDNA synthesis was performed with 1 µg total RNA and carried out at 42 °C for 1 h followed by at 95 °C for 5 min and at 0-5 °C for 5 min according to protocol of reverse transcription system (Promega). The synthesized cDNA was diluted to 100 µl with TE and stored at -20 °C until use. In the following experiment, 5 µl of cDNA was amplified in a 25 µl PCR reaction volume with Advantage 2 PCR Kit (CLONTECH). Both of the ezrin primer 5' CGGGCGCTCTAAGGGTTCT3' (sense), 5' TGCCTTTGCAAAGCTTTTATTTCA3' (antisense) and GAPDH primer 5' GAAGGTGAAGGTCGGAGTC 3' (sense), 5' GAAGATGGTGATGGGATTTC 3' (antisense) were synthesized by Genecore Company (Shanghai). After prepared by routine procedures, PCR products were visualized by electrophoresis on 1 % agarose gel stained with ethidium bromide and quantitated with Gelworks 1D Intermediate software (version 3.51, Kodak).

Western blot

Western blot was used to detect ezrin protein expressed by experimental cells. Confluent cells of 3 flasks were washed three times with ice-cold PBS and then lysed in buffer containing 50 mM Tris-HCl (pH 8.0), 150 mM NaCl, 100 µg·ml⁻¹ phenyl-methyl-sulfonyl fluoride (PMSF) and 1 % Triton X-100 for 30 min on ice. After removal of cell debris by centrifugation at 12 000 g for 5 min, 50 µl of supernatant was boiled for 5 min in the sample buffer and separated by 10 % SDS-PAGE, which was then transferred onto the nitrocellulose membrane (Pall Corporation). After non-specific reactivity was blocked by 5 % fat-free milk in TBST (10 mM Tris-HCl, pH 7.5, 150 mM NaCl, 0.05 % Tween 20) for 1 h at room temperature, the membrane was incubated in turn with monoclonal antibody of mouse against human ezrin p81 (Maixin-Bio) and anti-mouse IgG-HRP antibody. Reactive protein was finally detected by ECL chemiluminescence system (Santa Cruz).

Oncogenesis and invasive potency of SHEE in vivo

SCID mice (C.B-17/IcrJ-scid nu/nu) were from Animal Laboratory Center, Chinese Academy of Medical Sciences. For the determination of their oncogenesis and invasive potency, SHEEIMM and SHEEMT cells were cultured in flasks with fresh medium to reconstitute their surface protein. After digested and washed twice with PBS, they were counted and

resuspended in PBS solution (10×10⁶·ml⁻¹) until use. Then SCID mice were anesthetized with 7 % chloralhydrate followed by intraperitoneal and subcutaneous inoculation with the both passages of cells. That is, 2×10⁶ SHEEMT or SHEEIMM cells in 0.2 ml PBS were injected into the peritoneal cavity in 5 mice and into the right axilla of the same number of animals. Instead, the control mice were injected only with 0.2 ml of PBS. The experimental animals were checked daily and all were killed on after day 40 inoculation by an overdose of anesthetic. Tissues from tumor mass, mesentery, pancreas and gastrointestinal tract were sampled and prepared with the routine method to produce thin paraffin sections (5 µm) stained by hematoxylin and eosin for the assessment of tumor invasion.

Invasive potency of SHEE in vitro

Tumor cell invasion *in vitro* was assessed by using a fresh fetal amnion, which was cultured in 199 medium supplemented with 10 % FBS. In the experiment, a piece of amnion and 50 000 SHEEIMM or SHEEMT cells were in turn added to one well of a 24-well plate and incubated together for 24 h and 72 h, and then were washed for several times with PBS. Then the samples, including the piece of amnion and cells adhering to it, were fixed with 2.5 % glutaraldehyde and post-fixed with 2 % osmium tetroxide. After full dehydration with gradient concentrations of ethanol, the samples were adhered to an aluminium stub and sprayed plating with gold for 3 minutes (EIKD, IB-3, Hitachi), which were further examined by Hitachi H300 electron microscope with the attachment of scanning apparatus.

RESULTS

Expressive alterations of ezrin and its mRNA

The ezrin mRNA detected by electrophoresis on 1 % agarose gel was shown as a band of 3 032 bp segment, whose expression was observed to be significantly up-regulated in SHEEMT by RT-PCR assay compared with that expressed in SHEEIMM cells as displayed in Figure 1. The same difference was also noted in the expression of ezrin protein between both of the cell passages (Figure 2).

Figure 1 RT-PCR assay of ezrin mRNA. The expression of ezrin mRNA was significantly increased in SHEEMT compared with that in SHEEIMM cells. A. Ezrin; B. GAPDH: a. Marker; b. SHEEIMM; c. SHEEMT.

Figure 2 Western blot analysis of ezrin protein expression. The ezrin protein was exhibited as a band of 81-kDa segment, whose expression was up-regulated in SHEEMT compared with that in SHEEIMM cells. Lane a: SHEEIMM; lane b: SHEEMT.

Figure 3 The inoculated SHEEMT cells (arrow) invaded into the parenchyma of pancreas (P) (HE, ×200).

Figure 4 Tumor formation in subcutaneous tissue inoculated with SHEEMT cells (C), the latter was also shown to invade and destroy nearby muscle fibers (M). (HE, ×200).

Figure 5 The invasiveness of inoculated SHEEMT cells on amniotic epithelium was demonstrated by scanning electron microscopy. A. A cluster of SHEEMT cells (T) grew on the amniotic epithelial surface (bar, 5 μ); B. On the cutting surface, SHEEMT cells (T) were observed invading into the amnion stroma (bar, 50 μ).

Oncogenesis and invasiveness in SCID mice

After inoculated into the SCID mice, SHEEMT cells were noted growing rapidly and forming tumor masses in 40 days. In peritoneal cavity, tumors were observed occurring on the mesentery, pancreas, urinary cyst, sub-diaphragm etc. with a special propensity for invading mesentery and pancreas, but did not exhibit any signs of hepatic metastases. Histological examination revealed that these tumor cells did not only grow on the organ surface, but also invade into adjacent tissues (Figure 3). In the subcutaneous tissue of the right axilla, tumor mass was observed macroscopically forming on the thoracic wall and penetrating into the thoracic cavity. Pathologically, these tumor cells harboring larger nucleus, nucleolus and less cytoplasm could infiltrate and destroy adjacent muscular fibers (Figure 4). Once transplanted, tumors could keep be passed to other SCID mice. In contrast, SHEEIMM cells were not found to form tumors in inoculated tissue by gross examination.

Invasive potency in vitro

After inoculated on the amnion, SHEEMT cells were shown growing in cluster on the epithelial surface with the formation of pseudopod that intruded into the gap between intercellular junctions (Figure 5A). On the cutting surface, SHEEMT cells were observed invading into the amnion stroma (Figure 5B). It was not found that the inoculated SHEEIMM cells could adhere to or colonize on the amniotic epithelium.

DISCUSSION

Invasive potency is one of the most important features of malignant tumors and is involved in a critical cascade of events such as extracellular matrix degradation, cell migration and colonization in the assaulted tissue. The invasive phenotype formation of malignant cells requires up-regulated expression of certain adhesive molecules, enzymes and related genes responsible for the interaction between cancer cells and extracellular matrix^[29]. Several co-factors have been reported to be involved in the process of invasion and metastasis^[30-32] besides ezrin that has been considered as an important molecule contributing to the malignantly transformation of cells. In addition to combining with adhesion molecules such as E-cadherin and catenin implicated in cell-cell and cell-matrix adhesion^[33], ezrin plays a critical role in the determination of invasiveness of cancer cells^[34].

In the present study, we investigated the expression of ezrin and its mRNA in a malignantly transformed esophageal epithelial cell line SHEEMT and further demonstrated its unrestricted growth and invasive potency in both *in vivo* and *in vitro* circumstances. The experimental results revealed that the expression of ezrin protein and its mRNA was significantly upregulated in SHEEMT compared with that in SHEEIMM cells. The SHEEMT cells inoculated to SCID mice could form tumor masses in both visceral organs and soft tissues in a period of 40 days. Pathologically, these tumor cells harboring larger nucleus, nucleolus and less cytoplasm could infiltrate and destroy adjacent tissues. In the *in vitro* study, the inoculated SHEEMT cells could grow in cluster on the amniotic epithelial surface and intrude into the amniotic stroma. In contrast, unrestricted growth and invasive property were not found in the SHEEIMM cells that were used as the control in both *in vivo* and *in vitro* experiments. As to our knowledge, this is one of the few reports concerned about how the ezrin gene expresses and what is its relation to the invasiveness formation in malignantly transformed esophageal epithelial cells.

New technology in molecular medicine allows global descriptions of complex expression patterns of genes responsible for the malignant properties of tumors^[35-38]. With the two representative passages of cells described above, we

have defined the profile of genes involved in the invasiveness of tumor cells using a sensitive cDNA microarray in a previous study. We found that increased expression of ezrin protein in SHEMT cells was in accordance with their acquisition of the invasive potency^[39]. Based on these observations, we therefore speculated that ezrin might be an important candidate of genes in charge of the invasive behaviors of malignant transformed esophageal epithelial cells, as reported in lymphoma and astrocytic tumors^[40, 41]. However, recent work in this field has also focused on the identification of ezrin-binding molecules, including CD₄₄, CD₄₃, intercellular adhesion molecule^[42-44] and syndecan-2^[45]. Moreover, modulation of the ERM protein ezrin by Merlin and NF-2 has been reported in other literatures^[46-48]. In the meanwhile, we have demonstrated that following expression of MMP₂ and MMP₉, highly invasive potency was developed in SHEMT cells (Data to be published). All these suggest the invasiveness of tumor cells is determined by multiple genes and co-factors with complicated cellular signal pathways. Therefore, future works are necessitated to demonstrate more exactly the roles of ezrin and related molecules in the formation of invasive potency of cancer cells by the gene knockout technique and other powerful tools.

Abstract

AIM: In order to detect risk factors for esophageal cancer, a national research program was carried out during the Eighth Five-Year Plan (from 1991 to 1995).

METHODS: Cixian County and Chichen County in Hebei Province were selected as the index and the control for the study fields with higher or lower incidence of esophagus cancer in China, respectively. In these areas, we investigated the pollution of three nitrogenous compounds in well water for drinking and the use of nitrogen fertilizer in farming.

RESULTS: In well water, nitrate nitrogen, nitrite nitrogen and ammonia nitrogen were 8.77 mg/L, 0.014 mg/L and 0.009 mg/L in Cixian County in 1993, respectively. They were significantly higher than their levels (3.84 mg/L, 0.004 mg/L and 0.004 mg/L) in Chichen County ($P < 0.01$, $t = 6.281$, $t = 3.784$, $t = 3.775$). There was a trend that the nitrogenous compounds in well water increased from 1993 to 1996. The amount of nitrogen fertilizer used in farming was 787.6 kg per hectare land in Cixian County in 1991, significantly higher than 186 kg per hectare in Chichen County ($t = 9.603$, $P < 0.001$).

CONCLUSION: These investigations indicate that the pollution of nitrogenous compounds in well water for drinking is closely related to the use of nitrogen fertilizer in farming, and there is a significantly positive correlation between the level of three nitrogenous compounds in well water and the mortality of esophageal cancer (correlation coefficient = 0.5992). We suggest that improvement of well system for drinking water quality should be an effective measure for esophageal cancer prevention and control in rural areas.

INTRODUCTION

It is well known that the chief causes of most cancers are environmental, dietary and lifestyle factors. In China, there is a special area around the Taihang Mountain with the highest incidence of esophageal cancer. Esophageal cancer has been studied in this rural area for a long time^[1-3]. These studies indicate some relationship between local environmental factors and esophageal cancer^[4-8]. Among these, nitrogenous compounds in well water for drinking is considered as a possible risk factor for esophageal cancer because of its close relationship with local people's life^[7,8]. In this rural area, well is the main water source for drinking. It is polluted usually by nitrogenous compounds. In order to identify the effect of nitrogenous compound pollution on esophageal cancer, we designed a 2×2 cross-sectional study for factor analysis during the Eighth Five-Year Plan (from 1991 to 1995). The research program for investigating the relationship between drinking water pollution and esophageal cancer was carried out. It also included a step of improvement in well water quality and pollution control.

MATERIALS AND METHODS

Study fields

According to mortality, two counties from Hebei Province were selected for the present study fields, Cixian County as index and Chichen County as control, respectively. From 1974 to 1976, the mortality per 100 000 of esophageal cancer standardized by Chinese population in Cixian County and in Chichen County was 147.7 and 8.3 in male, and 79.33 and 2.8 in female, respectively. Cixian County is located at the southern part of Hebei Province and the eastern foot of the Taihang Mountain. There are 354 villages under 35 local town governments in Cixian County. It covers an area of 1 015 Km² and has a population of 580 000.

Well registration

Before the investigation, a team for the program was organized. The investigators and other work staff were trained based on the program guideline. From the end of 1991 to the beginning of 1992, we completed registration of the wells located in 101 villages (9 towns) in Cixian County and made well file. The registered items of well file included (1) position, (2) type, (3) depth, (4) enclosing wall, (5) wall structure, (6) pipeline, (7) pollution source within 10 meter distance, (8) served population, and (9) served time. According to the well registration, we started a consecutive monitor on the pollution of three nitrogenous compounds (nitrate nitrogen, nitrite nitrogen and ammonia nitrogen) in the selected wells. Meanwhile, we investigated the amount of nitrogen fertilizer used in farming per year in the study fields.

Nitrogenous compounds examination

The level of ammonia nitrogen in water was analyzed by Nessler's reagent method. The amount of nitrate nitrogen and of nitrite nitrogen was tested in terms of Cadmium column

reduction method. The water samples were collected according to the routine method^[9-12].

Statistical analysis

Statistical analysis was performed by *t* test, and linear correlation was used for analysis on the relationship between three nitrogenous compounds and mortality of esophageal cancer. Two-tailed *P* value of less than 0.05 was defined as statistically significant.

RESULTS

Among 9 towns in Cixian County, there were three types of well served for drinking water, manual-pump well, motor-pump well and non-pump well. Non-pump well was main type, about 554 were built in these areas. This type of well had a big opening mouth without pipe, enclosing wall and cover. Recently, some new motor-pump wells were built. They were 200 meter in depth with brick wall. These old and new wells provided drinking water for 130 952 people. In the control areas, 1/3 of wells was about 8 meters and 2/3 was less than 40 meters in depth. The depth of water varied with season. The served time of wells was different. The oldest one, for example, the Longwangmiao Well of the Xiguanglu Village of the Guanglu Town had a history of 300 years, and the new one was only 2 years.

The pollution of nitrogenous compounds in drinking water was a big health problem. We found that 41.2 % of the motor-pump wells and 88.5 % of non-pump wells existed pollution sources within 10 meter distance, for example, excrement and urine from the residents and animals, and pollution sources increased year by year. The monitoring data from the sampled wells showed that nitrate nitrogen, nitrite nitrogen and ammonia nitrogen in Cixian County were significantly higher than those in Chichen County ($P < 0.01$), and the pollution increased gradually from 1993 to 1996 (Table 1). They were 20.6 %, 50.5 % and 33.3 % higher than the state permissive level, respectively. The amount of nitrogen fertilizer used in Cixian County's farming was significantly higher than in Chichen County ($P < 0.01$), and there was an increasing trend (Table 2). The time trend of three nitrogen compounds in relation to the use of nitrogen fertilizer is shown in Figure 1, Figure 2 and Figure 3 for Cixian County and Chichen County, respectively.

DISCUSSION

It has been proven in animal experiments that nitrosamine compounds (NOC) are a kind of strong carcinogen and can

cause tumor in different animal tissues and organs^[13-21]. The epidemiological investigation has also demonstrated an increased risk of human gastric cancer with food intake polluted by nitrosamine compounds^[22,23]. Nitrate and nitrite are precursors of NOC^[24,25].

If well water contains a large amount of three nitrogenous compounds, and serve as main water source, there may be two harmful effects on local people's health. One is that three nitrogenous compounds would accumulate in plants and in crops^[25-29]. Usually, nitrate is easily reduced to nitrite, and then it is synthesized into NOC. The other harmful effect is that local people and livestock or poultry would have an increased intake of three nitrogenous compounds through the drinking water^[30-32]. These nitrogenous compounds with ammonia can be changed to a strong carcinogen, NOC, in stomach since its pH value is 1-3 from gastric acid^[33].

The present investigation showed that the pollution of three nitrogenous compounds in the index area with high risk of esophageal cancer was significantly higher than that in the control area ($P<0.01$). The mortality ratio between Cixian County and Chichen County was 17.9 (147.7 per 100 000 / 8.3 per 100 000) in male, and 28.5 (79.3/2.8) in female in the period of 1974 through 1976. There was a positive correlation between the nitrate nitrogen, nitrite nitrogen in well water and mortality of esophageal cancer in the study fields. The present findings indicate that heavy pollution of nitrogenous compounds in drinking water in the index area is a possible risk factor for esophageal cancer.

There were two possible pollution sources of nitrogenous compounds for well in the investigated fields, living garbage or excrement and farming nitrogen fertilizer. In comparison of the two counties, we found that the amount of nitrogen fertilizer used in farming in Cixian County was significantly higher than that in Chichen County, and the pollution of nitrate nitrogen and nitrite nitrogen in well water had a similar trend (Figure 1 and Figure 2). It can be understood that the nitrate nitrogen and nitrite nitrogen in well water come mainly from the pollution of farming nitrogen fertilizer. The amount of ammonia nitrogen in well has not a regular change. Its pollution to the drinking water is possibly resulted from the excrement of local people and animals other than farming nitrogen fertilizer.

Based on these evidences, well water pollution control of three nitrogenous compounds will be one of the important measures for the primary prevention of esophageal cancer in the higher risk areas. The study revealed that water quality improvement had a beneficial effect on gastric cancer prevention^[34]. At the beginning of the Ninth Five-Year Plan (1996-2000), a program for improvement of water supply system in the index area was started. Initial effect was observed (Table 3). There was a significant decline of three nitrogenous compounds in well water after several years' pollution control. These findings indicate that the program for improvement in water supply system is successful for pollution control. Whether pollution control of nitrogenous compounds contributes to incidence decline of esophageal cancer in the higher risk area, needs further study and more evidence.

Table 3 Three nitrogenous compounds (mg/L) in well water before and after well reconstruction

No. of well	Nitrate nitrogen		Nitrite nitrogen		Ammonia nitrogen	
	Before	After	Before	After	Before	After
12#	14.9621	8.0097	0.0077	0.0033	0.0131	0.0048
14#	8.9890	1.9099	0.0208	0.0067	0.0127	0.0053
29#	18.4929	0.0000	0.2929	0.0100	0.0459	0.0087

12#, 14#, 29# are the number of the sampled well.

Based on the presently investigated results, measures for pollution prevention and control in the areas with high risk of esophageal cancer should include: (1) The first measure is to improve the health consciousness of local people on drinking water, and to develop the type of deep well with pipeline. (2) The second is to focus on the environmental hygiene surrounding the well. It includes garbage control near water source, and sanitary management of excrement and urine. (3) The third is to establish and to improve the system management of water source, and to supply clean water with pipeline. (4) The fourth is to build high quality lavatory and to prevent its pollution to well water. (5) The fifth is to encourage local farmers to use rational formula fertilization in order to decrease effectively organic nitrogen pollution in the environment.

Abstract

AIM: To develop an oral DNA vaccine against gastric cancer and evaluate its efficacy in mice.

METHODS: The genes of the MG7-Ag mimotope and a universal Th epitope (Pan-DR epitope, PADRE) were included in the PCR primers. By PCR, the fusion gene of the two epitopes was amplified. The fusion gene was confirmed by sequencing and was then cloned into pcDNA3.1(+) plasmid. The pcDNA3.1(+)-MG7/PADRE was used to transfect an attenuated *Salmonella typhimurium*. C57BL/6 mice were orally immunized with 1×10^8 cfu *Salmonella* transfectants. *Salmonella* harboring the empty pcDNA3.1(+) plasmid and phosphate buffer saline (PBS) were used as negative controls. At the 6th week, serum titer of MG7-Ag specific antibody was detected by ELISA. At the 8th week cellular immunity was detected by an unprimed proliferation test of the spleenocytes by using a [3 H]-thymidine incorporation assay. Ehrlich ascites carcinoma cells expressing MG7-Ag were used as a model in tumor challenge assay to evaluate the protective effect of the vaccine.

RESULTS: Serum titer of antibody against MG7-Ag was significantly higher in mice immunized with the vaccine than that in control groups (0.841 vs 0.347, $P < 0.01$; 0.841 vs 0.298, $P < 0.01$), while *in vitro* unprimed proliferation assay of the spleenocytes showed no statistical difference between those three groups. Two weeks after tumor challenge, 2 in 7 immunized mice were tumor free, while all the mice in the control groups showed tumor formation.

CONCLUSION: Oral DNA vaccine against the MG7-Ag mimotope of gastric cancer is immunogenic. It can induce significant humoral immunity against tumor in mice, and the vaccine has partially protective effects.

INTRODUCTION

Gastric cancer is the most common malignant tumor in China and the second most common malignancy around the world. Conventional intervention measures such as operation and chemotherapy work poorly in treating gastric cancer. And with few tumor-specific antigens identified, there are few effective vaccines developed to combat gastric cancer. MG7-Ag, discovered by our institute, is a kind of gastric cancer-specific tumor-associated antigen. Detecting the serum anti-MG7-Ag antibody serves as a preliminary test in the diagnosis for gastric cancer and could be used for the surveillance of relapse and the appraisal of treatment efficacy^[1]. MG7-Ag can be used as an indicator for high risk of malignant change in stomach mucosa dysplasia^[2]. Primary study showed that MG7-Ag could elicit significant specific immune response against gastric cancer, suggesting that it could be an excellent target for cancer vaccine development. However, due to its unknown identity, it is much difficult to isolate and purify MG7-Ag from tumor tissues. Recently, we have identified the mimotopes of MG7-Ag by screening the phage display library, and the mimotopes could mimic the primary antigen efficiently, as shown by *in vitro* and *in vivo* assays^[3,4]. We reported here for the first time the development of an oral DNA vaccine by using the MG7-Ag mimotope of gastric cancer.

MATERIALS AND METHODS

Plasmids and bacteria

The plasmid pcDNA3.1(+) was purchased from Invitrogen Corporation. And the pEGFP plasmid containing the enhanced green fluorescence protein (EGFP) gene was purchased from Clontech Corporation. Attenuated *Salmonella typhimurium* SL3261 strain was used as the oral vector to develop the vaccine.

Construction of eukaryotic expression vector of MG7-Ag mimotope fused with a helper T cell epitope PADRE

Two pairs of PCR primers (P_{1.1}, P_{1.2} and P_{2.1}, P_{2.2}) were designed by using Primer Premiere 5.0 software. The sense primers (P_{1.1} and P_{2.1}) were both 5'-CGATGTACGGGCCAGATA TACGCG-3', corresponding to the 209-232 bp sequence of pcDNA3.1(+). Reverse primer P_{1.2} was 5'-ACTTCCTC CTCCTTTGTATGCACA TGAGGTTTCATGGTGGCAA GCTTCCTACCGCCCATTTGCGT, corresponding to the reverse complementary sequence of 768-785 bp sequence of pcDNA3.1(+), Hind III digestion site, Kozak sequence, and the sequence of the MG7-Ag mimotope. Reverse primer P_{2.2} was 5'-TTAAGCAGCAGCTTTAAGTGTCCAAGCAGCCAC AAATTTAGCACTTCCTCCTCCTTTTGTATGCA-3', corresponding to the reverse complementary sequence of the MG7-Ag mimotope and the universal Th epitope PADRE. Two PCR reactions were performed to incorporate the mimotope and the PADRE into a fragment of pcDNA3.1(+) plasmid. In this case, the pcDNA3.1 fragment was used as a carrier to facilitate further manipulations. For the first PCR reaction, template was plasmid pcDNA3.1(+), and primers were P_{1.1} and P_{1.2}. By using the product of the first PCR as template, a second PCR was performed with primers P_{2.1} and P_{2.2} to incorporate

the PADRE epitope into the yielding fragment. The final PCR product was visualized by agarose electrophoresis and was then cloned into pUCm-T vector and sequenced on ABI PRISM™ 377 sequencer. Then, the PCR product was subcloned into pcDNA3.1(+) vector from the pUCm-T vector. By restrictive enzyme digestion with *Hind* III, the non-relevant plasmid fragment was removed from the final recombinant vector pcDNA3.1(+)-MG7/PADRE. The vector was sequenced to confirm the proper encoding sequence.

Construction of oral DNA vaccine and in vitro experiment using attenuated *Salmonella typhimurium* as the oral DNA vector

To get the oral DNA vaccine, the pcDNA3.1(+)-MG7/PADRE vector was transduced into the attenuated *Salmonella typhimurium* SL3261 by electroporation (2.5 kV, 25 μ F, 200 Ω , pulse time 0.0326S). Plasmid in the *Salmonella* transfectant was extracted and used as template, and PCR was performed by using primer P_{1.1} and primer P_{2.2} to verify the successful transfection. The PCR product underwent agarose electrophoresis for visualization. An *in vitro* experiment was performed by using the SL3261 strain as the oral vector of DNA vaccine according to reference^[5]. Briefly, eukaryotic expression vector of the enhanced green fluorescence protein was transduced into the attenuated *Salmonella typhimurium* SL3261. The transfectants were coincubated with murine peritoneal macrophage at 37 °C for 30 min. SL3261 harboring the empty pcDNA3.1(+) plasmid was used as negative control. Gentamycin was added into the culture media to kill the extracellular bacteria. Four hours later, tetracycline was added to kill the intracellular bacteria. The infected macrophages were cultured for 48 hours, and were then examined by flow cytometry (FCM) for the expression of green fluorescence protein.

Immunization of the mice and immune response examination

Thirty-five female 4-week-aged C57BL/6J mice weighing 15-20g were used in the immunization assay. They were randomly divided into 3 groups, which were orally given the PBS solution (10 mice, PBS control), the attenuated *Salmonella* SL3261 harboring the empty pcDNA3.1(+) plasmid (10 mice, empty control) or the oral DNA vaccine SL3261 strain harboring the pcDNA3.1(+)-MG7/PADRE (15 mice, immunization group).

Before immunization, all the mice were starved overnight and pre-administered with 100 μ L 10 g/L NaHCO₃ solution. Each time, 100 μ L PBS (pH7.6) was given to the mice in PBS control group, and 1×10^8 *Salmonella typhimurium* were given to the mice in the empty control and immunization group. PBS and *Salmonella typhimurium* were given to the mice by orogastric inoculation. Immunization was repeated every two weeks. At the 6th week after the first immunization, sera from the mice (5 mice from each group) were prepared and 1:80 diluted. By coating KATO III cells expressing the MG7-Ag on the plates, a cellular ELISA was performed to detect the antibody against MG7-Ag. At the 8th week, the splenocyte suspension was prepared, and an unprimed proliferation test of the splenocytes was performed by a [³H]-thymidine incorporation assay^[6] with a few modifications. Briefly, splenocyte suspension of the mice from three groups was prepared. 1×10^6 cells were plated into each well of 96-well plate. Into each well, 1×10^5 mytocin C-pretreated autologous antigen-presenting cells (APC) were added. The cells were incubated with 50 μ g/ml synthetic MG7-Ag mimotope peptide for 4 hours. The cells were washed and cultured for 3 days. Then cells were incubated for 6 hours with 74MBq/L of [³H]thymidine. The plates were harvested, and the proliferative response of the splenocytes was examined by measuring the β counts of the cells. To further investigate the efficacy of the oral DNA vaccine, the tumor challenge assay was performed. Ehrlich ascites carcinoma cells (EAC) were immunostained with MG7 antibody to verify the presence of the MG7-Ag. Then 1×10^7 EAC cells were injected into the abdominal cavity of the mice in each group. The number of tumor-bearing mice and the survival rate of each group were observed.

RESULTS

Construction of the oral DNA vaccine

By PCR, MG7-Ag mimotope and PADRE were fused together and incorporated into a fragment of the pcDNA3.1(+) (Figure 1). The proper coding of the epitopes was confirmed by sequencing (Figure 2). The PCR product was subcloned into pcDNA3.1(+). And by *Hind* III digestion, the fragment of the pcDNA3.1 in the PCR product was removed (Figure 3).

Figure 1 Incorporation of the epitope gene into the pcDNA3.1 fragment by PCR: A product of 620bp was amplified by the first PCR (a), and a fragment of 660bp was amplified by the second PCR (b).

Figure 2 *Hind* III digestion of the recombinant plasmid after subcloning the PCR product into pcDNA3.1(+) from the pUCm-T vector: A fragment of 660bp was released (c), which corresponded to the size of the carrier fragment.

Figure 4 PCR identification of the pcDNA3.1(+)-MG7/PADRE plasmid harbored by the *Salmonella typhimurium* SL3261: By PCR, a fragment of 800bp was amplified (d), suggesting the existence of epitope genes and removal of carrier fragment.

Figure 3 Sequencing of PCR product (partial sequence): By PCR, the two epitopes were fused together and incorporated into a pcDNA3.1 fragment. The amino acid sequence of KPHVHTKGGGS corresponded to the sequence of MG7-Ag mimotope. AKFVAAWTLKAAZ corresponds to the sequence of universal Th epitope PADRE.

The pcDNA3.1(+)-MG7/PADRE was transduced into the attenuated *Salmonella typhimurium* SL3261 by electroporation. Plasmid from the transfectant was extracted and used as template. By PCR, it was verified that the plasmid harbored by the SL3261 transfectant was pcDNA3.1(+)-MG7/PADRE (Figure 4).

In vitro assay using *Salmonella typhimurium* as oral DNA vaccine vector

Forty-eight hours after infection with *Salmonella typhimurium*, fluorescence intensity of macrophages infected by the *Salmonella* harbouring the pcDNA3.1(+)-EGFP was 0.927 and the percentage of fluorescent cells was 40.6 %, which was significantly higher than that of the control (0.345 $P<0.01$ and 3.8 % $P<0.01$ respectively). Our result showed that pcDNA3.1(+)-EGFP plasmid was transferred into the macrophages from the bacteria and was expressed by the macrophages, suggesting that the SL3261 strain could be used as the oral DNA vaccine vector.

Immune response induced by the oral DNA vaccine

No diarrhea was seen in the mice given the *Salmonella typhimurium* harbouring either the vaccine DNA or the empty pcDNA3.1(+) vector. And no *Salmonella* infection-associated death occurred in the end of the experiments. Six weeks after the first immunization, serum titre of the antibody against MG7-Ag was significantly increased in the vaccine-immunized mice, while no significant titre of MG7 antibody was detected in the control groups. There was a significant difference between the vaccine-immunized group and the control groups ($P<0.05$), while no difference was detected between the two control groups ($P<0.05$, Table 1). *In vitro* unprimed proliferation assay of the splenocytes showed no statistical difference between those three groups (Table 2), suggesting no significant cellular immunity was elicited.

Table 1 Cellular ELISA detection of antibody in the immune serum (OD_{450} , $\bar{X}\pm s$)

Group	OD_{450}
PBS control	0.298 ± 0.017
Empty vector control	0.347 ± 0.062
Vaccination group	0.841 ± 0.136

Paired Student *t*-test was used to investigate the difference between two groups.

Table 2 *In vitro* unprimed assay of splenocytes (Radiation count/min cpm $\bar{X}\pm s$)

Group	Radiation count (cpm)
PBS control	2981 ± 389.8
Empty vector control	3158 ± 416.7
Vaccination group	2896 ± 335.4

Paired student *t*-test was used to investigate the difference between two groups.

By immunohistochemical staining, it was found that MG7-Ag was expressed in the EAC cells, both on the membrane and in the cytoplasm (Figure 5), indicating that the EAC cells can be used to challenge the mice to investigate the protective ability of the oral DNA vaccine. Two weeks after the challenge, all the mice in the control groups developed neoplastic ascites, which was confirmed by microscopic observation of the cells in ascites. However, 2 in the 7 vaccinated mice were tumor free. All the mice in the control group died 4 weeks after the

primary challenge, while the tumor-free mice in the immunization group survived 8 weeks after the challenge with no signs of tumor formation. Our results suggested that the oral DNA vaccine was partially protective.

Figure 5 Immunohistochemical staining of the Ehrlich ascites carcinoma cells (EAC): Positive signal was seen in the cytoplasm and membrane of the EAC cells (A). When stained with a negative control monoclonal antibody (anti-E-tag antibody), the EAC cells showed no positive staining (B).

DISCUSSION

Attenuated strains of *Salmonella typhimurium* have been widely used as vehicles for delivery and expression of vaccine antigens. Attenuated *Salmonella typhimurium* strains expressing antigens from bacteria, viruses and parasites have been proved efficient as well as safe in combating respective pathogens^[7]. Due to mutations in their genome, attenuated *Salmonella typhimurium* lost their pathogenicity but remained to be invasive. When used as the oral vehicle, they can invade the M cells and the intestinal epithelial cells and penetrate the mucosal barrier of the intestine. Subsequently, they can be uptaken by the macrophages and dendritic cells (DC) in the lamina propria and the Peyer's patch. The intracellular bacteria would not undergo lysis in the lysosomes immediately but survive for a period of time due to unknown reasons. The intracellular bacteria could provide a reservoir of antigen, so these features of the *Salmonella typhimurium* strains make them an excellent vehicle of oral vaccines. The use of attenuated *Salmonella typhimurium* as oral DNA vaccine carrier was first reported by Darji and his colleagues^[8]. They found that when used as the carrier of DNA vaccines, the *Salmonella* could deliver the eukaryotic vector to the host cells through the unknown mechanism and the eukaryotic vector could be expressed by the host cells. Further study by Paglia *et al* suggested that attenuated *Salmonella typhimurium* could deliver the eukaryotic vector to the dendritic cells in the spleen^[9]. Other studies suggested the expression of eukaryotic vectors in dendritic cells in the mesenteric nodes and Peyer's patch was detected early after inoculation^[10-12]. Oral DNA vaccines developed by using *Salmonella typhimurium* as carrier

can provide a context similar to intracellular bacteria infection and render the body danger signals. Besides, the DC cells are excellent antigen presenting cells and have high expression of costimulatory molecules. So it is not surprising that the oral DNA vaccines can evoke significant immune response, especially CTL response^[5, 11, 13, 14]. In this study, we used an attenuated *Salmonella typhimurium* strain SL3261 (*S. typhimurium* WARY hisG46 aroA del407 Fusaricres etc, R+M+), which genotype is much the same as SL7207. We found that it could also act as the carrier of DNA vaccine, which was safe to mice.

CD4+ T cells (T helper cells, Th) play important roles in modulating immune response: They can facilitate the activation of CTL cells by cross-priming, produce various cytokines for the activation of T and B cells, upregulate the costimulatory molecules on APC cells and enhance their ability of antigen processing and presenting. In order to enhance the efficacy of the DNA vaccine, we fused the MG7-Ag mimotope with a universal T helper cell epitope PADRE, which was developed by Alexander *et al*^[15]. They introduced the anchoring motif of MHC molecules into the polyalanine backbone and found that the PADRE could bind to most of the human HLA-DR alleles and certain mouse class II alleles and elicit strong CD4+ T cell response; the epitopes were approximately 1000 times more powerful than natural T cell epitopes. PADRE has been used as the adjuvant for various epitopes including B cell epitope, CTL epitope and carbohydrate epitope and was proved to be efficient in enhancing the immunogenicity of these epitopes. Ishioka *et al*^[16] developed a minigene vaccine by including PADRE in tandem with multiple CTL epitopes with no spacer between them, and found that though the affinity of the CTL epitopes varied much, PADRE could still provide adjuvant effects on the induction of strong CTL response. Their study suggested that spacers were not necessarily needed in designing the multi-epitope minigene DNA vaccines. Therefore we fused the PADRE directly with the mimotope gene. To guarantee the efficient expression of the minigene, we included a Kozak sequence to right upstream the ATG initiation codon of the fusion gene. Kozak sequence is a specific sequence for the recognition and initiation of the transcription for the eukaryotic ribosome. The study suggested that Kozak sequence was necessary for correct and efficient expression of minigene vaccine^[17].

MG7-Ag of gastric cancer was discovered by our institute, and we found that the immunogenicity of the MG7-Ag was located in the carbohydrate chain of the glycoprotein. Due to its unknown identity, MG7-Ag is hard to be isolated from tumor tissue. Our institute has successfully identified the anti-MG-Ag antibodies using phage display method^[18,19]. Thus we identified the mimic peptides of MG7-Ag by screening the phage display peptide library with the MG7 antibody and then used it as the target for vaccine development. DNA vaccine of mimotope was first reported by Kieber-Emmons *et al*^[20], and the feasibility to develop DNA vaccine of mimotopes was further confirmed by Lesinski *et al*^[21]. In both studies, the DNA vaccine of mimotope induced strong humoral immune response. And in the former study, no significant CTL response was elicited. As shown by Monzavi-Karbassi *et al*, the mimic peptides could induce carbohydrate antigen reactive T cell response^[22]. Therefore, absence of significant specific T cell response in Kieber-Emmons' study and our study might be due to the immunogen type of the primary antigen. However, the oral DNA vaccine developed by us was shown to be partially protective as shown by the tumor challenge assay though no significant difference was seen in the ³H-Tdr incorporation assay. The inconsistency between the results of tumor challenge assay and the ³H-Tdr incorporation assay might be due to the following reasons: (1) The inaccuracy of

the ³H-Tdr incorporation assay in determining the T cell response. More accurate methods include ⁵¹Cr-releasing assay and ELISPOT. Moreover in our study, we did not purify CD8+ T cells for ³H-Tdr incorporation assay. The existence of other types of cells might affect the results. (2) The sample included in the tumor challenge assay was too small. Much larger samples would be needed to further confirm the protective effect of the oral DNA vaccine.

Due to its various mechanisms of multi-drug resistance, gastric cancer often responds poorly to chemotherapy^[23, 24]. Cancer vaccines have been proved a powerful adjuvant intervention in gastric cancer management. Study showed that gastric cancer antigens could induce specific immune response^[25]. We reported here the first attempt to develop an oral DNA vaccine against gastric cancer antigen mimotope. The oral DNA vaccine against MG7-Ag mimotope is immunogenic. It can induce significant immune response against gastric cancer and may be partially protective in mice. Our results verified the feasibility to develop oral DNA vaccine of mimotopes and efficacy as well as safety of *Salmonella typhimurium* as oral DNA vaccine carriers.

Abstract

AIM: To identify the gene that may predispose to human gastric cancer and to analyze its expression in gastric cancer and non-tumorous gastric mucosa.

METHODS: Cancer, para-tumor, and non-tumor gastric tissues were studied for gene expression profile using fluorescent differential display reverse transcription polymerase chain reaction (DDRT-PCR). The differentially expressed bands of interest were analyzed by cloning, Northern blotting, and sequencing. The sequencing results were compared with the GenBank database for homology and conserved domain analysis. *In situ* hybridization with DIG-labeled cRNA probes was used to detect the expression of gene in paraffin embedded gastric adenocarcinoma and non-cancerous tissues.

RESULTS: A gene expressed higher in tumor and para-tumor tissues than in their non-tumor counterparts of all 7 tested gastric adenocarcinoma patients was identified by means of DDRT-PCR analysis. It was named *GCRG213* (gastric cancer related gene 213). Northern blot confirmed the differential expression. *GCRG213* (GenBank No. AY053451) consisted of 1094 base pairs with an open reading frame (ORF) which encoded 142 amino acids. The deduced amino acid sequence contained a putative conserved domain, apurinic/apyrimidinic endonuclease (APE). *In situ* hybridization analysis showed that *GCRG213* was expressed higher in gastric cancer tissues than in their corresponding non-tumor ones. Precancerous lesions of gastric adenocarcinoma showed a high *GCRG213* expression, too. No difference of the expression patterns was found between the early and advanced gastric cancer.

CONCLUSION: A gene named *GCRG213* was identified in human gastric adenocarcinoma. It encoded an APE-like protein which was probably a new member of the APE family. *GCRG213* was over-expressed not only in gastric cancer, but also in its precancerous lesions. The role of *GCRG213* expression in carcinogenesis needs further study.

INTRODUCTION

Gastric cancer is the second most common cause of cancer-related deaths in the world. It is widely accepted that genetic alterations play an important role in the pathogenesis of gastric cancer^[1,2]. The expression of oncogenes such as c-met, c-myc, ras, c-erbB-2^[3-5], the inactivation of tumor-suppressor genes, such as p53, p16, Rb, DCC, APC^[6-12], and the abnormal transcription of genes related to metastasis, such as nm23, CD44, and E-cadherin^[12,13], have been reported in patients with gastric adenocarcinoma. Recent data showed that cancer related genes such as COX-2^[14,15], survivin^[16,17], metallothionein II and RUNX3, etc.^[18-22] were also expressed abnormally in gastric cancer. With the development of molecular biology techniques, such as cDNA array and differential display reverse transcription polymerase chain reaction (DDRT-PCR), some novel genes or cDNA fragments closely related to the development of human gastric cancer were identified recently^[23-32]. However, the genetic factors in human gastric cancer and their mechanisms of carcinogenesis remain uncertain and deserve further study. We, therefore, used DDRT-PCR to screen the human intestinal-type gastric adenocarcinoma and its precursor lesions for the differential expression of gastric cancer related genes (GCRGs).

In our previous reports, we described a cDNA fragment which was upregulated in human gastric cancer tissues. Two subclones, *GCRG213* and *GCRG224*, were subsequently identified. *GCRG224* was overexpressed in almost all gastric mucosal epithelia but only in a small portion of gastric cancer and precancerous lesions^[33]. In this study, we investigated the subclone, *GCRG213* and found that it was a gene encoding an apurinic/apyrimidinic endonuclease (APE)-like protein. *GCRG213* was overexpressed in gastric cancer and in its precancerous lesions.

MATERIALS AND METHODS

Patients and tissue acquisition

Fresh primary intestinal-type gastric adenocarcinoma, para-tumor tissues and non-cancerous gastric mucosal tissues were collected from 7 patients (male: 4, female: 3; mean age: 51±18 years old) during surgical operation for the differential display analyses of genes. The para-tumor tissues were collected at 1.0 cm away from the tumor mass. Three other sets of fresh gastric adenocarcinoma and non-cancerous gastric tissues were used for Northern blot analysis. Specimens of paraffin embedded gastric adenocarcinoma (male: 21, female: 11; mean age 57±8 years old) and their corresponding noncancerous tissues were collected for *in situ* hybridization analysis. Of the 32 cases of gastric adenocarcinoma, 15 cases were early gastric cancer while the other 17 cases were advanced carcinoma. The diagnosis of cancer was confirmed through histological findings.

Differential display, cloning and sequencing

Total RNA was extracted from tissues using TRIzol reagent (Life Technologies, Inc., Rockville, Maryland) according to the instructions of the manufacturer. The fluorescent differential display was performed as previously described^[34]. The primers used in the assay were T₁₂GG vs. ARP-8: 5' TGGTAAAGGG3'

(Genomx Corporation, Foster City, CA). The intensity of differentially expressed bands was quantified by Image Quant software (Molecular Dynamics, Sunnyvale, CA). The differentially expressed cDNA fragments were sub-cloned and sequenced as described previously^[33]. The sequenced cDNA was analyzed via the BLAST program for matches in the GenBank database^[35], and DNASIS software (Hitachi Software Engineering America Ltd., San Bruno, CA) was used for bioinformatic analysis.

Northern blot analysis

Dig Northern Starter Kit (Roche Diagnostic Corporation, Indianapolis, IN) was used. The procedure of hybridization was performed according to the manufacturer's protocol. Anti-sense cRNA probe labeled with digoxigenin was generated from a digested cDNA insert by means of *in vitro* transcription. Digoxigenin labeled sense cRNA probe was used as a negative control. The hybridization signals were visualized with chemiluminescence which is recorded on X-ray films. The exposure time was 10 minutes.

In situ hybridization

All specimens were fixed in 10 % neutral buffered formalin and embedded in paraffin. A series of 5 µm thick sections were cut for analysis. *In situ* hybridization (ISH) was performed as previously described^[36,37] using anti-sense cRNA probe labeled with digoxigenin. Briefly, the slides were dried at 40 °C overnight, dewaxed, rehydrated and pretreated with DEPC-treated PBS containing Triton X-100. The sections were then permeabilized with 20 µg/ml RNase-free proteinase K (Merck, Darmstadt, Germany) for 20 min, incubated at 37 °C for at least 20 min with prehybridization buffer. Each section was overlaid with 30 µl of hybridization buffer containing 10 ng of digoxigenin-labeled cRNA probe and incubated at 42 °C

overnight. The positive signal for GCRG213 mRNA was finally detected by using NBT/BCIP as substrate. Sense cRNA probes were used as negative control. The presentation of blue staining in cytoplasm was considered positive. The positive staining of cytoplasm was semi-quantified as Grade ± barely detectable light blue, Grade 1+: diffuse light blue, Grade 2+: blue staining, and Grade 3+: dark blue. More than 100 non-tumor or tumor cells were quantified in each measurement, and more than one measurement was required to confirm the diagnosis. Consequent slides with H&E staining were then reviewed to compare the histological patterns to the staining patterns in the ISH preparations.

Informed consents

The study protocol was approved by the Institutional Review Board of the hospital under the guidelines of the 1975 Declaration of Helsinki. Written informed consents were obtained from patients.

RESULTS

Identification of a human gastric cancer related gene

One differentially expressed cDNA band named W2 was found to be more abundant in the tumor and paratumor samples in all tested patients. W2 was sub-cloned into a pGEM-T easy vector, and confirmed by EcoR I digestion. Two subclones, *GCRG213* and *GCRG224*, were subsequently identified^[33]. Sequencing results showed that *GCRG213* consisted of 1094 base pairs with an open reading frame (ORF) which encoded 142 amino acids with an estimated molecular weight of 16.4 kDa (Figure 1). This nucleotide sequence data were submitted to GenBank with accession No. AY053451. BLASTN analysis revealed that *GCRG213* shared 88 % homology with human

Figure 1 Sequence of the human *GCRG213* cDNA. The DNA sequence encoding the predicted start (ATG) and stop (TGA) codons is bolded and underlined. Three possible polyadenylation signals (AATAAA) are in italics. The protein encoded by the open reading frame is indicated in the single-letter code below the DNA sequence.

retrotransposable LINE-1 element LRE2. Through conserved domain database search in GenBank, a putative conserved domain, apurinic/aprimidinic endonuclease1 (APE), was detected in the deduced amino acid sequence of *GCRG213*-

ORF, it shared 61.0 % alignment with the C-terminal region of APE conserved domain (Figure 2). Northern blot analysis showed that *GCRG213* was over-expressed in tumor tissues than in their non-tumor counterparts (Figure 3).

Figure 2 NCBI conserved domain search results. A: *GCRG213* ORF produced significant alignments with gnl | Pfam | pfam 01260 AP_endonuclease1, AP endonuclease family 1; CD-length =250 residues, only 61.0 % aligned; Score=88.2 bits (217), Expect=3e-19. B: Human APE protein produced significant alignments with gnl | Pfam | pfam01260 AP_endonuclease1, AP endonuclease family 1; CD-length=250 residues, 100.0 % aligned. Score=161 bits (407), Expect=1e-40. *GCRG213*-ORF contained residues such as Y171, D210, N212, D308 and H309 (arrowed) that are important for the endonuclease activity of APE.

Figure 4 *In situ* hybridization analysis of *GCRG213* in formalin-fixed, paraffin-embedded tissues with a digoxigenin-labeled anti-sense probe, NBT/BCIP was used as alkaline phosphatase substrates, the expression appeared as cytoplasmic staining (blue precipitates). (A) gastric adenocarcinoma invading into the muscle layer showed grade 2+ ~ 3+ staining, (B) gastric IM epithelium showed grade 2+ ~ 3+ staining, (C) normal gastric glands showed grade ± ~ + staining, (D) negative control. Magnification was 10×10.

Figure 3 Northern blot analysis of *GCRG213* in human gastric tissues. *GCRG213* showed higher expression in tumor tissues than in non-tumorous ones. The expression of β -actin served as an internal control. N: non-tumorous tissue; T: tumor; 1-3: patient number.

In situ hybridization

GCRG213 expression was analyzed at the mRNA level using *in situ* hybridization. The hybridization signal appeared as a blue color in cytoplasm.

Both the early and advanced gastric cancer tissues were stained grade 2+ ~ 3+. Eight of the 17 cases of advanced adenocarcinoma showed an invasion of cancer into the muscle layer, with all eight cases showing grade 3+ staining in the invading tumor cells (Figure 4A). Dysplasia tissues at the para-tumor region were found in 22 patients. 15/22 dysplasia tissues showed grade 2+ ~ 3+ staining of *GCRG213* expression while the rest showed grade 1+ staining. Nineteen patients had intestinal metaplasia (IM) epithelia at the para-tumor tissue. 9/19 IM showed grade 2+ ~ 3+ staining, the rest showed non-staining to grade 1+ staining (Figure 4B). All normal gastric glands showed grade \pm ~ + staining (Figure 4C).

DISCUSSION

In the present study, we used differential display to study the gene expression profile of human gastric cancer. One cDNA fragment, named by us as gastric cancer related gene 213 (*GCRG213*), was up-regulated in the gastric adenocarcinoma tissues of all 7 tested patients. Northern blot analysis confirmed the differential expression of *GCRG213*. As for the consistent up-regulation in gastric cancer tissues, further studies are necessary to confirm the role of *GCRG213* and its expression pattern in tumors.

The nucleotide sequence of *GCRG213* shared 88 % homology with human retrotransposable LINE1 element LRE2. LINE-1 elements are very ancient, they constitute 20 % or more of some mammalian genomes and presumably play a role in the evolution, structure, and function of mammalian genomes. LINE-1 elements contain regulatory signals and encode two proteins: one is an RNA-binding protein and the other is an APE-like enzyme which has both endonuclease and reverse transcriptase activities^[38,39]. BLASTP analysis in this study showed that the deduced amino acid sequence of *GCRG213*-ORF shared 84 % homology with the N terminal of LINE-1 ORF2 where the repair nuclease domain of APE exists.

We proposed that *GCRG213*-ORF be a new APE-like protein based on the following facts. First, APE conserved domain could be detected in *GCRG213*-ORF and the latter shared homology with the C terminal of human APE protein which is of particular relevance to the endonuclease function of APE. Furthermore, *GCRG213*-ORF also contains residues proposed to be important to the endonuclease activity of APE (Y171, D210, N212, D308 and H309)^[40-42].

AP endonucleases have been divided into two families based on their amino acid sequence identity to either exonuclease III or Endo IV. Typically, the exonuclease III family of endonucleases accounts for approximately 95 % of

the repair activity in the organism. In mammals, the predominant AP endonuclease is APE (also called HAP1 or APEX), an enzyme that belongs to the ExoIII family^[42]. Human APE plays an important role in the base excision repair machinery of eukaryotic cells^[40]. The DNA repair activity of APE resides in the C-terminal region^[41].

Many mechanisms such as hydrolysis of purine or pyrimidine, ionizing radiation, UV irradiation, and N-glycosylases may act on endogenous apurinic/aprimidinic sites to modify DNA bases^[40-43]. Unrepaired apurinic/aprimidinic sites result in mutations during DNA replication. Apart from its DNA repair function, APE exhibits as Redox-factor-1 which is important for the activation of transcription factors, such as activator protein 1, p53 and nuclear factor kappa B. APE also regulates the transactivation and pro-apoptotic functions of p53^[41]. Therefore, a role of APE in human tumorigenesis has been suggested.

APE protein is expressed in a wide range of human cells. Through immunohistochemistry detection, APE can be mainly localized in nucleus or cytoplasm or both^[44] depending on the cell type. Elevated expression of APE has been reported in a number of tumors such as prostate, ovarian, cervical, colorectal and germ cell tumors, malignant gliomas, whereas the cellular localization (nuclear/cytoplasmic ratio) differs in some neoplasia (colorectal carcinomas, epithelial ovarian cancers, primary breast carcinomas and thyroid carcinomas)^[45-54]. In breast cancer, APE protein expression correlates with lymph node status and angiogenesis^[51] while in head-and-neck cancer, nuclear expression of APE is associated with its resistance to chemoradiotherapy and poor outcome^[55]. In this study, *GCRG213* overexpressed in gastric intestinal metaplasia and dysplasia of the stomach as well as early and advanced gastric adenocarcinoma. The patterns of *GCRG213* expression in cancerous tissue of the early gastric cancer did not differ significantly from those in the advanced gastric carcinoma. Thus, the *GCRG213* expression appears "early" in the stage of gastric adenocarcinoma. This expression pattern is consistent with that of APE in cervical, prostate, colorectal cancer and their premalignant lesions^[45-47] reported.

There are two immediate implications of these findings of elevated *GCRG213* expression in cancers. First, if the expression of *GCRG213* could be modulated downward to, or below normal levels in the cancer cells, there may be an effect on the progression of the cancer or, the cells may become more sensitive to chemotherapeutic treatment. The latter presumes that the increase in AP endonuclease activity result in increased DNA repair activity, protecting more cancer cells against base damage than normal cells.

In conclusion, a gene, *GCRG213*, overexpressed in tumors was identified in this study. Because of the similarity of the expression pattern in tumors between APE and *GCRG213*, as well as the 61 % alignment between the amino acid sequences of *GCRG213*-ORF and APE conserved domain, it is likely that *GCRG213*-ORF is a new member of the APE family. A greater understanding of alterations in the function of *GCRG213* in human cancers may explore its epidemiological and therapeutic significance.

ACKNOWLEDGEMENTS

The authors would like to thank Dr. Sien-Sing Yang, the Cathay General Hospital, Taipei, Taiwan and Timothy K Lee, Ph.D., FDA, U.S.A. for their comments.

Abstract

AIM: To evaluate mutant p53 gene in primary hepatocellular carcinoma and to investigate the correlation between it and the recurrence of hepatocellular carcinoma.

METHODS: Mutations of p53 gene were examined using anti-human p53 monoclonal antibody and immunohistochemical staining in 79 resected hepatocellular carcinomas. The correlations among variables of p53 positivity and invasiveness, disease free interval and survival were studied. In addition, in those who developed recurrence, the correlation among p53 positivity, clinical features and post-recurrence survival were also studied.

RESULTS: Of these 79 cases, 64 (81 %) had p53 mutation. Those patients with mutant p53 positivity had significantly more tumor recurrence (76.6 % vs 40.0 %, $P=0.0107$). However, the COX proportional hazards model showed that p53 overexpression had only weak correlations with recurrence free interval and survival time ($P=0.088$ and 0.081), which was probably related to the short duration of follow-up. The invasiveness variables may be predictors of HCC recurrence. On univariate analysis, more patients with mutant p53 positivity had vascular permeation [78.1 vs 40.0 %, $P=0.0088$, O.R. (odds ratio) =5.3], grade II-IV differentiation (98.4 vs 80.0 %, $P=0.0203$, O.R. =15.7), no complete capsule (82.8 vs 53.3 %, $P=0.0346$, O.R. =4.2) and daughter nodules (60.9 vs. 33.3 %, $P=0.0527$, O.R. =3.1) than patients with negative p53 staining. On multivariate analysis, only vascular permeation and grade of differentiation remained significant ($P=0.042$ and 0.012). There was no statistically significant correlation between the status of p53 in the primary lesion and the clinical features of recurrent hepatocellular carcinomas examined, including extrahepatic metastasis ($P=0.1103$) and the number of recurrent tumors ($P=1.000$) except for disease over more than one segment in the extent of recurrent tumors ($P=0.0043$). The post-recurrence median survival was lower in patients in whom p53 mutation had been detected in the primary lesion with a weak significance (3.42 months vs 11.0 months, $P=0.051$).

CONCLUSION: Our findings suggest that p53 mutation

correlates significantly with invasiveness including vascular permeation, grade of cellular differentiation, incomplete capsule and multinodular lesions. Hepatocellular carcinomas with p53 mutations had more tumor recurrence and p53 mutation may also influence disease recurrence interval and survival time. Hepatocellular carcinomas with p53 mutations recur more extensively with a shorter survival. Therefore, p53 mutation in the primary lesion is useful as an indicator of the biological behavior of recurrent hepatocellular carcinomas.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common types of malignant tumors that carry a poor prognosis. During the last 10 years, efforts have been made worldwide toward earlier detection and safer surgical resection of HCC. However, despite these recent diagnostic and therapeutic advances, postoperative recurrence is still common^[1-4]. How to predict recurrence before resection is a challenging problem for surgeons. Certain characteristics related to HCC recurrence have been reported widely and variably in the literatures^[1-11]. Risk factors which have been mentioned include vascular permeation, absence of capsule, presence of daughter nodules, histological grade of tumor differentiation, tumor size, associated cirrhosis, hepatitis B virus (HBV) infection, hepatitis C virus (HCV) infection, daughter nodules, and adequate section margin, etc.

The cellular wild-type p53 gene on chromosome 17p is an established tumor suppressor gene^[12-14]. It regulates the cell cycle of DNA repair and synthesis, and also programmed cell death. Once it is mutated, loss of normal function leads to the evolution of neoplasm. Moreover, the speed of tumor growth and invasion may also be enhanced. When mutated, this gene may have transforming properties and can be stained immunohistochemically^[15-21]. Its prognostic significance in some types of human cancer has been reported. The relationship between hepatocellular carcinoma (HCC) and overexpression of the mutant p53 gene have been studied in different countries^[15-32]. The results are varied. In addition, mutation of the p53 gene was emphasized in advanced but not in early hepatocellular carcinoma^[33,34]. However, the correlation between the clinical significance of such p53 mutations and the clinical recurrence of HCC has rarely been clarified.

In this study, we did immunohistochemical staining to investigate the overexpression of p53 protein in HCC in a series of patients. The correlation of the clinical and pathological variables of HCC, recurrence of HCC and the biological behaviors of the mutant p53 gene were studied. The goal of this study was to elucidate the possible role of p53 mutations in the prediction of recurrent HCCs.

MATERIALS AND METHODS

Patients

One hundred patients with HCC who underwent hepatectomy at Mackay Memorial Hospital, between January 1993 and December 1997 whose tissue specimens (formalin fixed, paraffin wax embedded) were histopathologically found to have no degeneration or necrosis were selected for this study. Clinical details were available from medical records of all patients. Seventy-nine patients entered this study and twenty-one cases were excluded for the following reasons: (1) immediate operative mortality, (2) failure to obtain p53 results due to severe, extensive tumor necrosis, some of which probably resulted from preoperative transcatheter hepatic arterial chemoembolization (TACE), (3) incomplete follow-up, and (4) causes of death not related to liver disease. The mean age of patients was 52.4 ± 16.6 years (range 16-82) with a male to female ratio of 2:1 (52:27). All received curative resections. The surgical operations included major resections (15 partial lobectomies, 31 lobectomies and 9 extended lobectomies) and minor resections (19 segmentectomies, 3 subsegmentectomies and 2 wedge resections). After resection, all patients were followed up at our out-patient-clinic receiving regular clinical assessment, periodic abdominal ultrasonography (every 2 to 3 months during the first 5 years, then every 4 to 6 months thereafter) to detect tumor recurrence, serum alpha-fetoprotein (AFP) and liver biochemistry (every 2 months during the first 2 years, then every 4 months during the following 3 years, and every 6 months thereafter). Abdominal computed tomography was also done (every 6 months during the first year, then every year).

Methods

Five-micron-thick formalin-fixed and paraffin embedded sections were cut, deparaffinized and rehydrated with graded alcohol and xylene. Endogenous peroxidase was blocked using 3 % H_2O_2 for 5 minutes, followed by a brief wash in Tris buffer, pH 7.2. Sections were rehydrated and heated in citrate buffer, pH 6.0, in a microwave oven at 500 watts for 10 minutes to retrieve the antigen. The tissues were stained with a monoclonal mouse anti-human p53 antibody (DAKO-p53, clone DO-7, Dako Corp, Carpinteria, Calif. U.S.A.) and a labeled streptavidin-biotin staining kit (DAKO LSAB kit, alkaline phosphatase system 40). They were incubated with the antibody at a dilution of 1:100 (in Tris-HCl buffer) for one hour at room temperature. The peroxidase reaction used 3,3'-diaminobenzidine tetrahydrochloride as chromogen and the slides were counterstained with hematoxylin. Two independent, blinded observers evaluated all tissue sections. Only nuclear staining was regarded as positive. Cases were scored as negative when no cell was stained even at a concentration as high as 1:10 in a triplicate study. A known colon adenocarcinoma with diffuse p53 nuclear accumulation was stained in parallel as the positive control. For negative controls, we used buffer instead of the specific primary antibody.

We used light microscopy to search for the highest concentration of reactive staining nuclei in each p53 staining section and counted 1 000 cells from the most aggressive area of the tumor to represent the tumor's behavior and reduce count variability. Specific staining was identified by the presence of a red reaction product in the nuclei and was graded as negative (0), slight (+), moderate (++), or strong (+++) immunostaining, with the distribution as diffuse or focal. The percentage of nuclei immunostained was estimated and was scored without knowledge of the grade of tumor differentiation.

The differences of p53 overexpression in diverse clinicopathologic parameters were evaluated. Parameters included the presence of associated liver cirrhosis (confirmed

from the operative findings and also from the pathological examination of the specimen), HBV surface antigen (HBsAg), hepatitis C virus (HCV) infection (antibody to HCV, anti-HCV), Child-Pugh classification of liver reserve, serum alpha fetoprotein (AFP) titer, tumor size (<3 cm, 3-10 cm, >10 cm), cell differentiation grade (Edmondson and Steiner grade I vs II-IV), encapsulation (complete, infiltration by HCC or absent), vascular permeation (including vascular invasion and/or tumor thrombi within the portal vein or hepatic vein), and presence of daughter nodules (Table 1). The time lapse between the postoperation till the detection of recurrence is defined as the recurrence free interval. During the follow-up (median 3 years, range 2 to 5 years), 55 patients had tumor recurrence (48 intrahepatic, and 7 both intrahepatic and extrahepatic) and 43 patients died. We also correlated the p53 overexpression with the outcomes. In these 55 patients with recurrence, the correlation between p53 mutation of the primary lesion (presence or absence) and recurrence was studied. The following prognostic factors after recurrence were also analyzed: extrahepatic metastasis (presence or absence), the number (solitary or multiple) and the extent of recurrent tumors (affecting more than or less than one segment), treatment for recurrent tumor (surgical or nonsurgical treatment), and survival time after recurrence.

Table 1 Characteristics of 79 patients with HCC

Characteristics	n (%)
Age (years, mean \pm S.D.)	52.4 \pm 16.6
Male	52 (65.8)
Liver cirrhosis	57 (72.2)
Child class A:B	55:24 (70:30)
Tumor size small (<3 cm): median (3-10 cm): large (>10 cm)	24:25:30 (30.4:31.6:38.0)
HBsAg (+)	60 (75.9)
Anti-HCV (+)	41 (51.9)
AFP: normal: >1000ng/ml	30:20(38.0:25.3)
Edmondson grade: I:II:III:IV	4:30:42:3(5.1:38.0:53.2:3.8)
Capsule: absent: incomplete: complete	54:7:18(68.4:8.9:22.8)
Vascular permeation	56 (70.9)
Daughter nodules	44 (55.7)
Resection, major: minor	55:24 (69.6:30.4)

Notes: HCC: hepatocellular carcinoma; HBsAg: hepatitis B surface antigen; Anti-HCV: antibody to hepatitis C virus; AFP: alpha-fetoprotein; Edmondson grade: Edmondson-Steiner grade of cellular differentiation.

Statistical analysis

The data were tested with statistical programs (BMDP), Student's *t*-test or Mann-Whitney test for continuous variables, chi-square test or Fisher's exact test for categorical variables, and logistic regression and COX proportional hazards model for multivariate analysis. *P* value<0.05 was defined as statistically and significantly different.

RESULTS

Among the 79 patients, 64 (81 %) patients had a p53-positive result. Among the 64 patients with immunopositivity, 29 patients (45 %) had moderate (++) immunostaining and 3 patients (4.7 %) had strong (+++++) immunostaining. The correlations between a positive oncoprotein p53 and patient characteristics are shown in Table 2. Age, gender, positivity of HBsAg or Anti-HCV, levels of AFP, liver cirrhosis, Child-Pugh class A or B, and size of the HCC showed no statistically

significant difference between p53 positive and negative groups. From univariate analysis, a significant correlation was found between p53 over-expression and vascular permeation (78.1 vs 40.0 %, $P=0.0088$, odds ratio (O.R.)=5.357), grade of differentiation (Edmondson-Steiner grade I vs. II to IV, 98.4 vs 80.0 %, $P=0.0203$, O.R.=15.750), complete capsule vs infiltration or absent capsule (82.8 vs 53.3 %, $P=0.0346$, O.R.=4.200), and presence of daughter nodules (60.9 vs 33.3 %, $P=0.0527$, O.R.=3.120) (Table 2). From multivariate analysis, only vascular permeation and grade of differentiation remained significant ($P=0.042$ and 0.012 , respectively).

Table 2 Comparison of characteristics between p53 positive and negative groups

Characteristics	P53 Positive (n=64)	P53 Negative (n=15)	P (UV)
Age (years)	52.8	48.3	n.s.
Male	65.6 %	66.7 %	n.s.
Liver cirrhosis	76.6 %	53.3 %	n.s.
Child class A	68.8 %	73.3 %	n.s.
Tumor ≤ 3 cm	34.4 %	13.3 %	n.s.
>10 cm	35.9 %	40.0 %	n.s.
HBsAg (+)	78.1 %	66.7 %	n.s.
Anti-HCV (+)	53.1 %	46.6 %	n.s.
AFP <20 ng/mL	37.5 %	40.0 %	n.s.
>1 000 ng/mL	21.9 %	40.0 %	n.s.
Edmondson grade I ^a	1.6 %	20.0 %	0.0203
Capsule complete	17.2 %	46.7 %	0.0346
Daughter nodules	60.9 %	33.3 %	0.0527
Vascular permeation ^b	78.1 %	40.0 %	0.0088

Notes: P (UV): The P value by univariate analysis; In multivariate analysis, the significant variables of ^a and ^b: P values were 0.0120 and 0.0420 respectively; HBsAg: hepatitis B surface antigen; Anti-HCV: antibody to hepatitis C virus; AFP: alpha-fetoprotein; Edmondson grade: Edmondson-Steiner grade of cellular differentiation; n.s.: no statistical significance; O.R.: odds ratio.

Table 3 shows that patients with p53 positivity had more tumor recurrence (76.6 % vs 40.0 %, $P=0.0107$) and more death (59.4 % vs 33.3 %, $P=0.0683$). After analysis with the COX proportional hazards model, p53 overexpression had only a weak correlation with recurrence free interval and survival time ($P=0.088$ and 0.081). Factors influencing HCC recurrence and time lapse to recurrence were vascular permeation ($P=0.0002$, O.R.=5.36), complete capsule ($P=0.0160$, O.R.=3.10), and p53 positivity ($P=0.088$, O.R.=2.29) (Table 4). The significant variables affecting death resulting from recurrence included vascular permeation ($P<0.0001$, O.R.=8.35) and p53 positivity ($P=0.081$, O.R.=2.38).

Table 3 Correlation of p53 with the outcome of patients with HCC

Outcome	p53 positive (n=64)	p53 negative (n=15)	P value
Morbidity of surgery (%)	6.3	6.7	n.s.
Recurrence (%) (number)	76.6 (49)	40.0 (6)	0.0107
Death ^a (%)	59.4	33.3	0.0683
Recurrence free interval (median, months)	8.3	39.1	0.0880
Duration of survival (median, months)	11.8	41.9	0.0810

Notes: n.s.: no statistical significance; Death^a: patients died of recurrence.

Table 4 Factors influencing tumor recurrence and death of patients in multivariate analysis

Variables	P	O.R.
Recurrence		
Vascular permeation	0.0002	5.36
Complete capsule	0.0160	3.10
p53 positivity	0.0880	2.29
Death		
Vascular permeation	<0.0001	8.35
p53 positivity	0.0810	2.38

Note: O.R: odds ratio.

In 55 patients with recurrent HCCs, there was no statistically significant correlation between the status of mutant p53 positivity in the primary lesion and the treatment for recurrent tumors, and the clinical features of recurrent HCCs examined, i.e. the existence of extrahepatic metastasis ($P=0.113$), and the number of recurrent tumors ($P=1.000$), except for the extent of recurrent tumors over one hepatic segment ($P=0.0043$). The median survival after recurrence was shorter (3.42 months vs 11 months) in those with p53 mutation with a weak significance ($P=0.051$) (Table 5).

Table 5 Correlation between the clinical features of recurrent hepatocellular carcinoma and the presence of a p53 mutation in the primary lesion

The clinical features	P53 Positive (n=49)	P53 Negative (n=6)	P
Extrahepatic metastasis (number) (%)	24 (49.0)	3 (50.0)	0.1130
Multiple-recurrent tumors (number) (%)	34 (69.4)	4 (66.7)	1.0000
Extent of recurrent tumors:	34 (69.4)	5 (83.3)	0.0043

Surgery (number) (%)	0	1 ^a (16.7)	n.s.
Non-surgical ^b (number) (%)	20 (40.8)	3 (50.0)	
No treatment (number) (%)	29 (59.2)	2 (33.3)	

Notes: n.s.: no statistical significant; ^a: A 55 year old man had a resection of segment II and III; ^b: The Non-surgical treatments included transcatheter arterial chemoembolization and percutaneous ethanol injection.

DISCUSSION

P53 gene mutation has been identified in over half of human tumors, including HCC, and is the most common genetic abnormality in human cancers^[13, 17, 20, 25, 34-42]. Its inactivation by mutation is thought to be a fundamentally important step in carcinogenesis. In addition, the correlation among p53 gene alteration and diagnosis, assessment of tumor progression, recurrence, or cancer prognosis has been investigated and reported^[24,28,33]. Recently, Nagao *et al*^[43] and Saegusa *et al*^[44] found p53 overexpression to be strongly associated with proliferation activity of HCC cells by immunohistochemical studies. Lowe *et al.* demonstrated that a few point mutations on p53 which thus inactivated the gene produced treatment-resistant tumors^[45, 46]. They suggested p53 status was an important determinant of tumor response to therapy. This indicates that recurrent HCCs with p53 mutation therefore either have a high proliferation rate or are resistant to treatment. Our results supported theirs from a clinical point of view, and also suggested that the high malignant potential was caused by the

p53 mutation. The positive rate of the mutant p53 gene in our HCC patients was 81 %. A wide range in the incidence of p53 mutations from 0 to over 70 % has been reported, with a lower frequency than in other types of cancer, except for special populations in China and Africa. Factors related to the wide variation in positivity may include different thresholds of positivity adopted, different anti-p53 antibodies used, geographical variations and differences in the molecular mechanisms of hepatocarcinogenesis, such as aflatoxin exposure. Some authors have raised a question of whether p53 protein over-expression can represent p53 gene mutation in neoplasms^[47]. Hall mentioned a very close correlation between p53 expression and mutations of the p53 gene and found that most antibodies gave the same results^[48]. The high recurrence rate after resection is one of the main factors in the poor outcome for HCC patients^[1-6, 10, 11]. Tumor recurrence limits the long-term survival. However, tumor recurrence is well correlated with tumor invasiveness. Tumor invasiveness may be determined from vascular permeation, the grade of cell differentiation, infiltration or absence of capsule and presence of daughter lesion. According to our study, they are also all compatible with oncoprotein p53 positivity. In our study, p53 protein over-expression correlated well with tumor recurrence ($P=0.0107$). To analyze the factors relating to HCC recurrence and death, vascular invasion, complete capsule, and p53 positivity correlated well with recurrence and only vascular permeation and p53 positivity correlated with death. A weak association with both recurrence free interval and duration of survival with mutation of the p53 gene was found. The weak correlation may be attributed to the short duration of follow-up (2 to 5 years, median 3 years) in this study.

Vascular permeation indicating tumor invasiveness, consists of either tumor invasion of the hepatic vein, portal vein and/or hepatic artery, or tumor thrombi within the vessels. It may be detected preoperatively by ultrasonography, arteriography or portography, intraoperative ultrasonography or direct observation, or postoperative pathological examination of surgical specimens. Vascular permeation is the most consistent significant prognostic factor of postoperative tumor recurrence^[10]. In our univariate analysis, the positive p53 status was significantly related to vascular permeation and in the COX model, patients with vascular permeation had significantly shorter recurrence free intervals and survival periods.

Whether the grade of differentiation of HCC is a determinant of recurrence after resection has been debated for a long time. The association of grade of anaplasia (Edmondson-Steiner's classification) with p53 positivity also varied in reports^[28,49,50]. In our series, less overexpression of p53 and less recurrence were found in patients with well differentiated tumors (Edmondson-Steiner's grade I) than in those with grade II to IV tumors. The histological differentiation of the HCCs in this study correlated with p53 mutations, and the incidence of p53 mutations increased with increased dedifferentiation. Our findings were consistent with previous reports showing p53 mutation to be associated with the progression of HCC as a late event in hepatocarcinogenesis^[33, 34].

The exact mechanism of capsular formation is not known. A tumor capsule may act as a barricade preventing the spread of cancer cells and has a positive role in the prognosis of HCC. The invaded capsule was regarded as incomplete in our series. We found the overexpression rate of p53 was similar in patients with no capsule and incomplete capsule (87.1 % vs 85.7 %), but was significantly lower in those with a complete capsule (17.2 %, $P=0.0346$) (Table 2). Other authors had different findings^[23,24,49,50]. Multifocal HCCs are also a controversial issue. Some consider them an early metastasis via the portal vein, but some consider them multicentric. The former is a

poor prognostic factor but the latter might not be^[51]. Without the aid of molecular biology, it is difficult to differentiate daughter nodules, intrahepatic metastatic nodules and multicentric HCC. In the present study, we selected daughter nodules as intrahepatic metastasis according to the criteria of the Liver Cancer Study Group of Japan in order to assess the clinical outcome after recurrence. As for the evaluation of prognosis after recurrence, Ikeda *et al.*^[1] reported that the most significant factor affecting the survival time of patients with intrahepatic recurrence was the number of tumor nodules at the time of recurrence. Those with daughter nodules showed a higher mutant p53 positive rate than the group with solitary HCC ($P=0.0527$). This might suggest that most daughter nodules favor intrahepatic metastasis.

Tumor size has been emphasized as one of the significant prognostic factors^[2-5] because vascular invasion and daughter lesions may increasingly develop as the tumor grows. In our study, no significant correlation between p53 positivity and tumor size was found. In addition, tumor size also had no significant correlation with histological grade, vascular invasion, recurrence free interval or survival in our patients. From our experience, some large HCCs may be the result of expansive growth and may have slow intraportal or distant spread.

The implications of our results, nevertheless, are that the immunohistochemical detection of p53 is a valuable tool for prediction of recurrence in patients after resection or for identifying subgroups of patients who may be at higher risk. There is some discrepancy between our results and the findings of previous studies on the role of p53 expression in determining the prognosis of patients with HCC. These discrepancies, however, might reflect important variables of selection, such as number of patients, histological type of tumors, tumor stage, period of follow-up, and type of antibody used. All the patients entering our study had received curative resections.

Prognosis after recurrence in relation to p53 mutations in the primary lesion is rarely reported in the literatures. Our findings suggest that HCCs with p53 mutations have a higher malignant potential. Matsuda *et al.*^[52] found that the postrecurrence survival of patients with repeat surgery was better than that of patients who were treated conservatively. However, from our study, the type of treatment for recurrent HCCs did not affect the postrecurrent survival because the choice of treatment was closely related to the number and extent of recurrent tumors and the liver function of the remnant. The majority of our patients had diffused multiple recurrent nodules over the liver remnant. Repeat surgery was undertaken on only one patient. In our study, the postrecurrent survival was weakly lower ($P=0.051$) in patients with p53 mutations in their primary lesion than in those without them.

We thus consider the status of p53 mutations in the primary lesion to be useful as a predictor affecting both the recurrence after resection and the prognosis after recurrence, even before the pathologic findings of recurrent HCCs are known. Therefore, it is important in the follow-up of patients after resection of HCCs. In conclusion, patients with p53 mutations have a worse prognosis than patients without such mutations, including survival after recurrence. Therefore, p53 mutation in the primary lesion is considered useful as an indicator of the biological behavior of recurrent HCCs.

Abstract

AIM: To investigate the relationship between transcatheter arterial embolization (TAE) and pulmonary metastasis in subjects with hepatocellular carcinoma (HCC).

METHODS: A total of 287 patients with HCC followed up for more than 1 week were included. 102 patients underwent transcatheter arterial embolization (TAE group) and 185 received conservative treatment (control group). The patients' chest x-rays and chest CT scans were examined for pulmonary metastasis.

RESULTS: Patients with TAE had a median survival of 19.3 months while that of the control group was only 10.0 months ($P < 0.05$). Pulmonary metastasis occurred in 14 (13.7 %) patients in the TAE group and 14 (7.6 %) patients in the control group, there was no significant difference ($P > 0.05$). The 1-year, 2-year and 5-year cumulative incidence of pulmonary metastasis was 11.8 %, 17.6 % and 24.0 % in the TAE group and 7.0 %, 13.0 % and 21.7 % in the control group, respectively ($P > 0.05$). On the univariate analysis, tumor size, abnormal serum alanine aminotransferase levels and heterogeneity on sonography were significantly associated with pulmonary metastasis. However, on the multivariate analysis, only tumor size was significantly predictive of pulmonary metastasis.

CONCLUSION: TAE is effective on prolonging survival of patients with HCC. It does not significantly increase the risk of pulmonary metastasis. Tumor size is the only significant predictive factor associated with lung metastasis.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common cancer in Taiwan and certain other parts of the world where hepatitis B virus infection is hyperendemic^[1]. HCC has a dismal overall prognosis, with 94 % of affected individuals dying of the disease^[2]. Treatment leading to long-term survival generally includes resection or ablative therapy for small or localized

hepatic tumors^[3-6]. Unfortunately, patients with HCC are usually diagnosed at a late stage when few can be treated with surgical resection. Factors indicating unresectability are (1) large or multicentric liver tumors, (2) the presence of metastatic disease, and (3) insufficient functional hepatic reserve^[3]. Therapies other than surgical resection include systemic or infusional chemotherapy, hepatic artery ligation or embolization, and radiolabeled antibodies^[7]. Transcatheter arterial embolization (TAE) has been performed for the treatment of unresectable HCC^[8,9] and has been shown to be able to prolong survival^[7, 10-11]. One study found survival of post-TAE to be comparable to that of post-hepatectomy^[12].

However, it has been suggested that TAE-induced necrosis might result in hematogenous dissemination from the primary tumor^[13]. The lung is the most common site of extrahepatic metastasis in HCC^[14]. A higher incidence of pulmonary metastasis following TAE in patients with HCC has been reported. However, the subjects who developed lung metastasis in that series were followed for a longer period than those without metastasis^[15]. We designed this case control study to evaluate the risk of pulmonary metastasis in patients with HCC following TAE, taking into account duration of follow up.

MATERIALS AND METHODS

Patients

Patients with HCC diagnosed from January 1996 to December 1999 at our hospital were included in this study. Diagnosis of HCC was based on high serum alpha-fetoprotein (AFP) values, ultrasonography, computed tomography (CT), and angiographic findings with or without needle biopsy or aspiration cytological examination. Patients who had pulmonary metastasis before or within 1 week after admission or who died within 1 week after admission were excluded, as were those eligible for surgical resection or percutaneous ethanol injection. There were 102 patients receiving TAE treatment during the study period. We selected another 185 patients with HCC who had refused either TAE or chemotherapy as a control group.

Methods

TAE was performed with lipiodol mixed with gelatin particles at an interval of 12 to 16 weeks. All patients were followed until death or December 31, 2000. Chest x-rays were taken at each admission or every 3 months in the outpatient clinic. Multiple nodules in the lung fields on chest x-ray and chest CT scans were diagnosed as pulmonary metastasis. Liver ultrasonography was performed every 3 months. Tumor size and sonographic patterns were recorded. Tumors with both hyper-echoic and hypo-echoic patterns were classified as heterogeneous. The presence of portal vein thrombosis was evaluated with a combination of ultrasonography, angiography and CT. Tumor stage was assessed according to the staging system described by Okuda *et al*^[16].

Statistical analysis

Statistical analysis was performed using the χ^2 test to compare

differences between groups. Results were given as the mean \pm standard deviation. Comparisons between group means were performed using Student's *t* test. Survival time was calculated from the time of cancer diagnosis until death or December 31, 2000. The time from the date of the diagnosis of cancer to the date of pulmonary metastasis or December 31, 2000 was calculated for analysis of cumulative incidence of pulmonary metastasis. The cumulative probability of survival and the cumulative incidence of pulmonary metastasis were calculated using the Kaplan-Meier method, and the difference between groups was compared using the log-rank test^[16]. Univariate and multivariate analyses using Cox proportional hazard models were performed to evaluate clinical parameters associated with pulmonary metastasis and calculate odds ratios (OR). The parameters included in the analysis were age, sex, serum albumin levels, bilirubin levels, AST and ALT values, AFP value, presence of cirrhosis, presence of ascites, presence of encephalopathy, Child scores, tumor size, sonographic pattern, uni- or multifocal tumor, presence of tumor halo, presence of portal vein thrombosis, stage of the disease, and TAE therapy. Significant parameters in the univariate analyses were analyzed with multivariate analysis. The level of significance was set at $P < 0.05$.

RESULTS

Demographic and clinical characteristics, liver function tests, and tumor characteristics did not differ significantly between the TAE and control groups (Table 1). Patients who had received TAE had a median survival time of 19.3 months compared with only 10.0 months for controls. The 6 month, one-year and two-year survival rate was 83 %, 59.1 % and 47.5 % respectively, in the TAE group, and 66.8 %, 43.7 % and 25.7 %, respectively, in the control group ($P < 0.001$, Figure 1). Pulmonary metastasis developed in 14 (13.7 %) patients in the TAE group and 14 (7.6 %) patients in the control group ($P > 0.05$). There was no significant difference in the cumulative incidence of pulmonary metastasis between these two groups. The 1-year, 2-year, 3-year, and 5-year cumulative incidence of pulmonary metastasis was 11.8 %, 17.6 %, 17.6 % and 24 % in the TAE group, 7 %, 13 %, 21.7 % and 21.7 % in the control group, respectively ($P > 0.05$, Figure 2).

Table 1 Clinical characteristics of patients with hepatocellular carcinoma

Parameters	TAE group (n=102)	Control group (n=185)	P
Male (%)	75 (74.3%)	148 (80%)	NS
Age (years)*	56.7 \pm 10.5	56.8 \pm 13.7	NS
Albumin (g/dl)*	3.51 \pm 0.57	3.40 \pm 0.61	NS
Bilirubin (mg/dl)*	2.02 \pm 7.17	1.30 \pm 1.25	NS
ALT (IU/ml)*	68.4 \pm 63.6	63.0 \pm 57.1	NS
Prolonged Prothrombin time*	1.38 \pm 1.25	1.48 \pm 1.11	NS
Encephalopathy (%)	6 (5.9%)	14 (7.6%)	NS
Cirrhosis (%)	76 (74.5%)	121 (65.4%)	NS
Ascites (%)	14 (13.7%)	32 (17.3%)	NS
Multicentric tumors (%)	19 (18.6%)	39 (21.1%)	NS
Heterogeneous echopattern (%)	34 (33.4%)	72 (39.1%)	NS
Encapsulated tumors (%)	49 (48.0%)	76 (41.1%)	NS
PV thrombosis (%)	23 (22.5%)	58 (31.4%)	NS
Large tumor size (%)	56 (54.9%)	103 (55.7%)	NS

Data expressed as means \pm standard deviation, comparison with unpaired Student's *t* test. NS=not significant.

Figure 1 Survival curves of patients with HCC treated with TAE and untreated controls.

Figure 2 Cumulative incidence of pulmonary metastasis in patients with HCC treated with TAE or untreated controls.

On the univariate analysis using the Cox proportional hazard model, tumor size (OR 2.34), abnormal serum ALT levels (OR 1.94) and heterogeneous sonographic pattern (OR 2.08) were significantly associated with the risk of pulmonary metastasis. However, on multivariate analysis only tumor size was significantly predictive of pulmonary metastasis (OR 2.24, 95 % CI 1.37 to 6.45).

DISCUSSION

It is believed that manipulation of tumor with TAE will increase the risk of hematogenous metastasis due to an increase in activity of serum type IV collagen-degrading enzyme^[17], or a decrease in activity of the tumor invasion-inhibiting factor^[18]. The disruption of tissue architecture resulting from ischemic necrosis after the TAE treatment may facilitate the dissemination of neoplastic cells^[19]. The incidence of extrahepatic recurrence of HCC is increased in patients who receive preoperative TAE treatment compared to those who undergo surgery alone^[20]. However, in our study, the incidence of pulmonary metastasis after the TAE therapy was not significantly increased. TAE patients also experienced longer survival and were followed longer than untreated controls (Figure 1). The 1-year, 2-year, 3-year and 5-year cumulative incidence of lung metastasis did not differ between the two groups.

The overall incidence of pulmonary metastasis in our series was 7.2 %, lower than that from an autopsy series of HCC reported in Japan^[21]. There may be several reasons for this discrepancy. We excluded patients with obvious pulmonary metastasis within 1 month after the diagnosis of cancer, although we could not exclude the presence of micro-metastasis. Our diagnosis of metastatic disease was based on

multi-nodular lesions on the chest x-ray and confirmed by chest CT. Most of our patients with metastasis had lesions larger than 3 mm on the chest film. Peters reported that pulmonary metastasis larger than 1 cm in size was rare and that, in 55 % of cases, lung metastasis was only recognizable microscopically^[22]. We would expect the actual incidence of pulmonary metastasis in our series to be more than 10 %, but this could not be documented, in part because autopsy is not well accepted in Taiwan. However, as both TAE and control groups initially included patients without clinically detectable metastasis, we believe that our results are still valid, as the subjects were similar at baseline.

It has been reported in an autopsy study that the HCC tumor size and invasion of the portal vein were associated with pulmonary metastasis^[21]. In another study of patients with long survival, the same association was found, with the coexistence of pulmonary metastasis, a large tumor size and portal vein invasion being the final event leading to death^[23]. In our series, on univariate analysis only large tumor size, a heterogeneous echo pattern, or abnormal alanine aminotransferase levels were associated with an increased incidence of pulmonary metastasis.

When HCC is small, the sonographic pattern is homogeneous and hypo-echoic. Most small hepatomas progress from hypoechoic to heterogeneous hyperechoic patterns when they grow larger^[24]. In general, small hepatomas without necrosis are hypoechoic; medium-sized tumors have a hypoechoic periphery and a hyperechoic center. The hypoechoic periphery corresponds to viable tumor and the hyperechoic core corresponds to central coagulation necrosis. Large tumors with extensive necrosis have an irregular mixed-echo pattern^[25]. A significant correlation between the incidence of metastasis and extent of necrosis in the primary tumor has been reported^[26]. The heterogeneous sonographic pattern of the tumor therefore implies later stage disease with more potential of extrahepatic metastasis. The serum alanine aminotransferase level correlates with hepatocellular damage. Tumor necrosis releases alanine aminotransferase enzymes into the blood flow. These observations likely explain our finding of an association on the univariate analysis between these factors and pulmonary metastasis. The fact that tumor size was the only independent predictor of metastasis on the multivariate analysis is thus understandable, as large tumors are almost invariably heterogeneous on sonography and associated with abnormal alanine aminotransferase levels.

Unfortunately, about 80 % of all our patients with HCC were not treated (data not shown). The reasons for lack of specific treatment in the control group varied. Most of them did not have regular serum AFP screening or sonographic examination and some already had late-stage HCC with a poor general condition and were thus too unwell for any specific treatment. Some did not trust Western medicine and tried Chinese herbal medicine instead. Only 20 % of our patients with HCC received treatment, 21 % undergoing surgical resection or percutaneous ethanol injection and 75 % of them being treated with TAE. More frequent sonographic screening of patients at high risk for HCC is important for earlier detection of smaller tumors.

In conclusion, TAE therapy is effective on prolonging survival of some patients with HCC. In our series, TAE did not increase the incidence of pulmonary metastasis. The larger the tumor, the higher the risk for pulmonary metastasis.

Abstract

AIM: To examine the survival patterns and determinants of primary liver cancer in a geographically defined Chinese population.

METHODS: Primary liver cancer cases ($n=13\ 685$) diagnosed between 1981 and 2000 were identified by the Tianjin Cancer Registry. Age-adjusted and age-specific incidence rates were examined in both males and females. Proportional hazards (Cox) regression was utilized to explore the effects of time of diagnosis, sex, age, occupation, residence, and hospital of diagnosis on survival.

RESULTS: Crude and age-adjusted incidence rates in the study period were: 27.4/100 000 and 26.3/100 000 in males; and 11.5/100 000 and 10.4/100 000 in females, respectively. Cox regression analyses indicated that there was a significant improvement in survival rates over time. Industrial workers and older people had relatively poor survival rates. The hospital in which the liver cancer was diagnosed was a statistically significant predictor of survival; patients diagnosed in city hospitals were more likely to have better survival than those diagnosed in community/district hospitals.

CONCLUSION: Patients diagnosed in recent years appeared to have a better outcome than those diagnosed in early times. There were also significant survival disparities with respect to occupation and hospital of diagnosis, which suggest that socioeconomic status may play an important role in determining prognosis.

INTRODUCTION

Liver cancer is a fairly common malignancy world wide^[1-5], especially in developing countries^[6-9]. In China, primary liver cancer is the third and fourth most common cancer in men and women with the age-adjusted incidence rates of 28.2/100 000 and 9.8/100 000 respectively in Shanghai^[10]. Population-based

survival data on cancer are indispensable in providing real, unbiased, average outcome of cancer patients. While liver cancer is a major cause of cancer-related mortality in China, little is known about its survival patterns over time. The objective of this study was two-fold: (1) to examine a specific hypothesis regarding the survival patterns of liver cancer in the studied urban Chinese population; (2) to examine the factors affecting such survival patterns. The objectives were achieved by analysing the data from the Tianjin Cancer Registry. The Tianjin Cancer Registry Centre is one of the members of the International Agency for Research on Cancer (IARC) of the World Health Organization. The cancer incidence data from Tianjin have been included in IARC official publications: "Cancer Incidence in Five Continents" since 1981. As Tianjin Cancer Registry is one of the few internationally accredited cancer registries in China, the results have important implications.

MATERIALS AND METHODS

Data

Tianjin, the third largest city in China, has a population about 10 million, of which about 98 % belongs to the Han ethnic group. The Tianjin Cancer Registry was established in 1978 and became operational in 1981^[11-13]. While the registry covers the whole city, data from six urban districts, which include approximately 4-million people, have been computerized and evaluated here. A city by-law requires that all physicians are responsible for filling out a report form for each new diagnosis of cancer. Practically, the task of cancer reporting is delegated to the medical record unit at each hospital. Thus, cancer cases are normally reported when patients are discharged from or die in the hospital. Information collected on the cancer reporting card includes name, sex, current age or date of birth, address, reporting hospital or medical institute, date (month and year) of diagnosis, four digit ICD-9 codes, and occupation. The Centre for Disease Control in Tianjin performs an annual quality control examination in at least 20 randomly selected hospitals in Tianjin to ensure that each hospital meets the standard cancer case reporting protocol. The evaluation results are used as part of the overall hospital report card, which is further used for hospital excellence ranking. A monetary incentive is offered for each cancer case reported, which is normally paid to the medical record unit rather than to individual physicians. Patients from other parts of China or those without permanent residence in Tianjin are not reflected in the current registry data.

All death certificates, which are the second source of cancer registration, are registered both at the district public health unit (DPHU) and the local police station. The DPHU routinely reviews all death certificates and identifies deaths, which are directly or indirectly caused by cancers. All cancer cases identified through death certificates are checked against the existing database at the Tianjin Cancer Institute for possible double or multiple reporting. In this study, we included all primary liver cancer patients (ICD-9 codes 155.1, 155.2). Numbers in each age-sex specific population for the six urban districts were obtained from the Tianjin Police Head Office,

which enumerates the Tianjin urban population based on people's unique resident cards.

Analyses

Univariate and bivariate descriptive analyses were performed prior to multivariate analyses. Proportional hazards regression (Cox model)^[14-20] was used to examine the effects of various factors on survival time for the study population. The proportional hazards model can be expressed as:

$$h(t; X) = h_0(t) \exp(\mathbf{b}' X)$$

where $h(t; X)$ is the hazard function of T at time t given a regression vector X ; h_0 is the unspecified baseline hazard function. The SAS PROC PHREG procedure was used to examine the specified survival model. The time variable (in days) was defined as the interval between the date of diagnosis and date of death. The covariates included in the survival analyses were age, sex, occupation, year of diagnosis, and residence. To best capture the impact of age on survival time, we explored different ways to categorize it in our regression models. As the incidence rates of liver cancer are very low in children, in our final model, we used ages 0-19 years as one group (baseline) and 10-year intervals thereafter to get stable estimates for the regression coefficients. Treating age categories as dummy variables in the model did not result in a better goodness of fit than simply introducing age as an ordered categorical variable with one degree of freedom.

Residence was introduced as a binary variable. As Hexi district is generally regarded as the best neighbourhood in Tianjin, it was used as a reference group and coded as "0". Other districts were coded as "1" and compared to Hexi district. Self-reported occupations were collapsed into 4-broad mutually exclusive categories: professionals and managers (such as teachers, medical doctors), service industry workers (such as

salespeople), industry workers, and others. The professional and manager group was treated as the reference category. Year of diagnosis was treated as single year in Poisson regression and grouped into four categories in Cox regression analysis: 1981-1985 (reference category), 1986-1990, 1991-1995, and 1996-2000. Hospital of diagnosis was dichotomized to community/district hospitals (reference category) and city hospitals. Community hospitals normally provide walk-in service in their districts but do not provide surgical operations. District hospitals provide in-patient service and day-surgery operations in their districts. City general hospitals and speciality hospitals, which normally have advanced technology and research programs, provide a wide range of service to all Tianjin residents referred by community or district hospitals and sometimes patients from other parts of China.

RESULTS

In total, 13 685 cancer cases were identified during the study period (1981-2000) and 70.6 % occurred in males. The mean age at diagnosis for the study population was 62.2 years (61.3 and 64.3 years for males and females, respectively) with a median survival time of 151 days. As shown in Table 1, diagnosis based on death certificate only (DCO) was less than 1 %. Most cancer cases were reported from city (75.1 %) or district hospitals (15.5 %) and most cases were diagnosed based on either medical imaging (60.6 %) or histology (28.4 %). While there are few gender differences with respect to the age at diagnosis and types of hospitals of diagnosis, males were more likely than females to be administrators or professionals.

The crude and age-adjusted incidence rates for the entire study period were 27.4/100 000 and 26.3/100 000 respectively for males. The corresponding rates were 11.5/100 000 and 10.4/100 000 for females.

Table 1 Characteristics of liver cancer cases diagnosed during 1981 to 2000, Tianjin, China

Variable	Category	Male		Female		Total	
		<i>n</i>	%	<i>n</i>	%	<i>n</i>	%
Sex	Male	-	-	-	-	9666	70.63
	Female	-	-	-	-	4019	29.37
Age	0-19	19	0.20	18	0.45	37	0.27
	20-29	64	0.66	24	0.60	88	0.64
	30-39	360	3.72	119	2.96	479	3.50
	40-49	1118	11.57	284	7.07	1402	10.24
	50-59	2443	25.27	728	18.11	3171	23.17
	60-69	3155	32.64	1395	34.71	4550	33.25
	70-79	2009	20.78	1129	28.09	3138	22.93
	80+	498	5.15	322	8.1	820	5.99
Type of diagnosis	Clinical only	981	10.15	473	11.77	1454	10.62
	Medical imaging only	5934	61.39	2353	58.55	8287	60.56
	Histology at local site	2710	28.04	1176	29.26	3886	28.40
	Surgical examination or autopsy	14	0.14	8	0.20	22	0.16
	Death certificate only	1	0.01	1	0.02	2	0.01
Occupation	Unknown	26	0.27	8	0.20	34	0.25
	Professionals and administrators	3193	33.03	390	9.7	3583	26.18
	Service industry workers	1220	12.62	334	8.31	1554	11.36
	Industry workers	3937	40.73	989	24.61	4926	36.00
	All others	1316	13.62	2306	57.38	3622	26.46
Type of reporting hospital	City general or specified hospitals	7306	75.58	2968	73.85	10274	75.07
	District general hospital	1495	15.47	624	15.53	2119	15.48
	Community hospital	865	8.95	427	10.62	1292	9.44

Table 2 displays the results from the proportional hazard regression analyses. Older age and female gender were associated with poor survival rates, with relative risks of 1.06 (95 % CI: 1.01, 1.11) and 1.08 (95 % CI: 1.05, 1.09) respectively. Hospital of diagnosis was a statistically significant predictor of survival time. Patients diagnosed in city hospitals tended to live longer than those diagnosed in district or community hospitals, with relative risk of death of 0.76 (95 % CI: 0.73, 0.79). The results showed that period of diagnosis was a statistically significant predictor of patients' survival time. Patients diagnosed in more recent years were likely to live longer than those diagnosed in earlier years with a relative risk of 0.85 (95 % CI: 0.83, 0.86) for every 5-year increment.

Table 2 Proportional hazards analyses of liver cancer diagnosed between 1981 and 2000 in Tianjin urban districts

Variable	Category	Relative risk	95 % CI
Sex	Male	1	
	Female	1.06	1.01, 1.11
Age	0-19	1	
	Every 10-years increase	1.08	1.05, 1.09
Period of diagnosis	1981-1985	1	
	Every 5-years increase	0.85	0.83, 0.86
Residence	Hexi District (advantaged)	1	
	Other districts	1.02	0.97, 1.08
Occupation	Administrators	1	
	Service industry workers	1.06	0.99, 1.13
	Industry workers	1.08	1.03, 1.13
	All others	0.97	0.91, 1.02
Hospital	District or community hospitals	1	
	City general or speciality hospitals	0.76	0.73, 0.79

DISCUSSION

In this study, we described the survival patterns for primary liver cancer in a Chinese urban population over the last 20 years. To the best of our knowledge, this was the first study of its kind ever reported from China. Given the inconsistencies in the literature regarding liver cancer incidence trends^[21-26] and survival patterns^[27-32], this study provides another piece of useful information for this disease. As Tianjin has a first-class cancer treatment centre and facilities, patients from other parts of China often seek treatment in Tianjin. It is relatively uncommon that Tianjin residents travel to other parts of China for treatment. There is no conceivable reason that this pattern had changed during the study period. Moreover, regardless of where a Tianjin patient gets treated, his/her cancer status would eventually be reflected in the death certificates, which are one source of our cancer registration data.

Based on clinical patients in Qidong, which has the highest liver cancer incidence rates in China, Chen *et al*^[31] reported that females had a more favourable prognosis than males. In this study, we found that females had slightly poor survival rate than males. As the magnitude of the reported survival difference was small, the results were unlikely to be conclusive. Nevertheless, the discrepancy between the two studies may be related to the differences in study population, such as, clinical setting versus population based or rural (Qidong) versus urban (Tianjin). The last four decades have seen a significant improvement in liver cancer treatment in China^[33]. While the current study only had a span of 20 years, the improvement in survival was apparent. The changes may be explained by improvements in liver cancer clinical management in this city. For example, unpublished data indicate the proportion of liver cancer patients who undergo surgery for their condition has

increased substantially in Tianjin.

This study has several limitations. First, we only included urban residents and were unable to compare the differences between rural and urban populations. Since China is a vast country with significant variations in economic conditions, the reported results may only be applicable to urban Chinese residents. Second, as the Tianjin Cancer Registry only records cancer related deaths (direct and indirect), it is possible that liver cancer patients who died from other causes, such as traffic accidents, were not reflected in our data bases. As a result, the observed survival time as reflected in the cancer registry data, might have been inflated. However, given that liver cancer is a fast progressive condition and a dominant majority of liver cancer patients die from it or its complications, it is unlikely that the problem related to non-liver cancer deaths would have altered the observed survival patterns greatly. Furthermore, since the possible artificially better survival caused by omission of non-liver cancer deaths would have been more in evidence for patients diagnosed in early periods, the true survival advantage for the patients diagnosed in recent years could be even greater. Third, we did not have information on cancer stage and treatment and were unable to estimate their impact on the observed survival pattern. It was possible that some of the observed survival advantage in later periods could be attributed to the cancer stage shift over time. Thus, studies on the changes in cancer stage and treatment over time are needed to address these questions.

ACKNOWLEDGEMENTS

Tianjin Cancer Registry is jointly funded by the Tianjin Health Bureau and the Tianjin Cancer Institute. All computations were prepared at Tianjin Cancer Institute and the responsibility for the use and interpretation of these data is entirely that of the authors. The authors thank the International Agency for Research on Cancer (IARC) for their technological support. We are grateful to Dr. Qi-Long Yi, University of Toronto, for his statistical advice.

Abstract

AIM: To investigate the expression of fragile histidine triad (FHIT) gene protein, Fhit, which is recently thought to be a candidate tumor suppressor. Abnormal expression of fragile histidine triad has been found in a variety of human cancers, but little is known about its expression in human hepatocellular carcinogenesis and evolution.

METHODS: Sections of 83 primary human hepatocellular carcinoma with corresponding para-neoplastic liver tissue and 10 normal liver tissue were evaluated immunohistochemically for Fhit protein expression.

RESULTS: All normal liver tissue and para-neoplastic liver tissue showed a strong expression of Fhit, whereas 50 of 83 (65.0 %) carcinomas showed a marked loss or absence of Fhit expression. The differences of Fhit expression between carcinoma and normal or para-neoplastic liver tissue were highly significant ($P=0.000$). The proportion of carcinomas with reduced Fhit expression showed an increasing trend (a) with decreasing differentiation or higher histological grade ($P=0.219$); (b) in tumors with higher clinical stage III and IV (91.3 %, $P=0.000$), compared with tumors with lower stage I and II (27.6 %); and (c) in cancers with bigger tumor size (>50 mm) (75.0 %, $P=0.017$), compared with smaller tumor size (≤ 50 mm).

CONCLUSION: FHIT inactivation seems to be both an early and a later event, associated with carcinogenesis and progression to more aggressive hepatocellular carcinomas. Thus, evaluation of Fhit expression by immunohistochemistry in hepatocellular carcinoma may provide important diagnostic and prognostic information in clinical application.

INTRODUCTION

Fragile histidine triad gene (FHIT) has been cloned and mapped to chromosomal region 3p14.2^[1]. It spans the t(3:8) +(p14.2;q24) translocation breakpoint found in familial renal cell carcinoma and encompasses the most common human fragile site, FRA3B^[2,3]. Alterations of FHIT and its expression have been found in primary tumors and cell lines of the lung^[4,5],

breast^[6-8], head and neck^[9], esophageal^[10-12], stomach^[13-15], colon and rectum^[16-18], pancreas^[19], kidney^[20,21], cervix^[22-25], and hepatocellular carcinomas^[26-30]. Allelic deletion of FHIT and abnormal expression of Fhit protein (Fhit) in lung cancer are associated with smoking history and poor prognosis^[31,32]. The finding of decreased expression of Fhit in 93 % of precancerous lesions of the lung suggests that this gene may be used as a molecular marker for early diagnosis and prognosis of lung cancers^[32]. However, there are only a few reports that evaluated FHIT in hepatocellular carcinoma in a small number of cases so far^[30] and further investigation of Fhit protein expression during hepatocellular carcinogenesis is required. Liver cancer, like lung cancer, is thought to be induced by carcinogens such as major viral and environmental risk factors. Therefore, it is imperative to determine whether FHIT plays a role in the development of hepatocellular carcinoma which has been ranked the second in cancer mortality in China since 1990s and is increasing in the rate of its incidence among males in many countries. In this study, 10 normal liver tissues and 83 hepatocellular carcinomas with their corresponding para-neoplastic liver tissues were examined for Fhit expression by immunohistochemistry. It was found that the expression of Fhit was altered in a high proportion of hepatocellular carcinomas and the loss of Fhit expression was associated with more advanced stage of the tumor.

MATERIALS AND METHODS

Specimens

Paraffin embedded sections of 83 hepatocellular carcinomas with corresponding para-neoplastic tissues and 10 normal liver tissues as controls were obtained from the Department of Pathology, Chinese People's Liberation Army General Hospital. The patients included 71 men and 12 women with the mean age of 52 ± 9.67 years (range 10-76 years). Of these patients, 15 were at grade I, 39 at grade II and 29 at grade III according to histological grading; and 4 were at stage I, 33 at stage II, 46 at stage III and 4 at stage IV according to clinical staging of UICC. In terms of size, 44 tumors were bigger than and 39 were equal to or smaller than 50 mm in diameter.

Immunohistochemical determination of Fhit

All specimens were fixed in 10 % buffered formalin and embedded in paraffin. Paraffin blocks were sectioned into 4- μ m thickness and the sections were mounted onto APES-coated glass slides. The slides were deparaffinized in xylene twice for 10 minutes, rehydrated through graded ethanol to distilled water, incubated for 30 minutes with 3 % hydrogen peroxidase-methanol to inhibit endogenous peroxidase activity, and heated in 0.01M citrate buffer (pH 6.0) in a microwave oven for 5 minutes at 100 °C for antigen retrieval. After cooled down at room temperature for 30 minutes, the slides were blocked for 15 minutes in PBS containing 10 % normal goat serum, incubated at 4 °C overnight in a humidified chamber with rabbit polyclonal antibody to human Fhit (Zymed Laboratories Inc., South San Francisco, CA) at 1:200 dilution in blocking solution. The sections were then rinsed in PBS and incubated

for 30 minutes with biotinylated secondary antibody (Histostain-SP, Zymed), rinsed again in PBS and incubated for 30 minutes in streptavidin-HRP (Histostain-SP, Zymed). 3, 3'-Diaminobenzidine was used as the chromogen. Slides were counterstained for 3 minutes with hematoxylin solution. Normal liver tissue was used as the positive control for each lesion, whereas the primary antibody was replaced by normal rabbit serum IgG with a similar dilution or PBS for the negative control.

Evaluation of score

Both the extent and intensity of immunostaining were considered when scoring Fhit protein expression according to Hao *et al*^[18]. The intensity of positive staining was scored as 0, negative; 1, weak; 2, moderate; 3, strong as in normal liver. The extent of positive staining was scored as 0, <5%; 1, >5-25%; 2, >25-50%; 3, >50-75%; 4, >75% of the hepatocytes in the respective lesions. The final score was determined by multiplying the intensity score and the extent score, yielding a range from 0 to 12. Scores 9-12 were defined as preserved or strong staining (++), 5-8 as weak staining (+) and 0-4 as markedly reduced or negative expression (-).

Statistical analysis

Fisher's exact test (two sided) and Pearson Chi square's test for trends in proportions were used to assess the associations between Fhit expression and pathological indices. A $P < 0.05$ was considered statistically significant.

RESULTS

Fhit expression in normal, para-neoplastic tissue and carcinoma

Fhit was strongly expressed in the cytoplasm of hepatocytes in all 10 normal liver and 83 para-neoplastic tissues (Figure 1A). Some stromal cells, such as lymphocytes, plasma cells and macrophages, also expressed Fhit in both nucleus and cytoplasm. The expression of Fhit was strong in 33, weak in 21 and negative in 29 hepatocellular carcinomas (Table 1). The carcinomas with markedly reduced or loss of Fhit expression were observed in 50 (65.2%) cases, whereas those with expression of Fhit equal to normal liver were observed in 33 (34.8%) cases. In cases with reduced expression of Fhit, both the extent and intensity of Fhit staining were reduced markedly (Figure 1B).

Normal liver tissue ^b	10	0	0	10

^b $P=0.000$, vs hepatocellular carcinomas.

Relationship between Fhit expression and histological grade, clinical stage and tumor size

The percentage of carcinomas with reduced expression of Fhit increased from 46.7% (7 of 15) in well-differentiated cancers (grade I) to 53.8% (21 of 39) in moderately differentiated cancers (grade II) and to 75.8% (22 of 29) in poorly differentiated cancers (grade III), although this association of increased histological grade of tumors with decreased Fhit expression was not statistically significant ($P > 0.05$, Table 2). Nevertheless, the decrease in expression of Fhit was

significantly associated with more advanced clinical stage of the tumors. Whereas 21.6% (8 of 37) stage I and II cases showed reduced expression of Fhit, the percentage of stage III and IV cases with reduced expression of Fhit increased to 91.3% (42 of 46) ($P=0.000$, Table 2). In addition, the carcinomas with reduced expression of Fhit protein were found in 75% (33 of 44) of tumors greater than 50 mm in diameter, compared with 43.6% (17 of 39) of tumors 50 mm or smaller in diameter ($P=0.017$).

DISCUSSION

Fhit protein is expressed in most types of normal human tissues but has been found to be frequently reduced or lost in a variety of human tumors due to alterations in its gene transcription or gene deletion^[1]. It has thus been suggested that FHIT gene is a candidate tumor suppressor gene for multiple carcinomas. Fhit,

the FHIT gene protein, is a member of histidine triad family and the mechanism of its suppression on tumor cells remains obscure^[1-3]. The following possible mechanisms have been considered as a tumor suppressor^[33]: First, the tumor-suppressing function of Fhit might be to catabolize ApppA (Ap₃A) or related substrates. Ap₃A is an analogue of ATP, which can provide phosphates as a substrate to raise the activity of protein kinase. Loss of Fhit protein may lead to the loss of Ap₃A hydrolase activity and the resulting elevated levels of Ap₃A or similar compounds may enhance the transductive signals of growth, thus contribute to carcinogenesis. Second, the activity of Fhit on mRNA cap analogs raises the possibility that failure of a decapping function might be tumorigenic, however, the properties of Fhit are quite different from those of enzymes known to decap mRNA, making this an unlikely mechanism. Third, the tumor-suppressing function of Fhit might be signaling by Fhit-substrate complexes or compounds as an active form of Fhit, which may be more important than its role of hydrolase. Fourth, Fhit might have a nucleotide-independent role as a tumor suppressor^[33].

Yuan *et al.*^[30] found that 4 of 9 cell lines and 5 of 10 primary hepatocellular carcinomas did not express Fhit protein or only expressed reduced levels of Fhit. Consistent with their results, we found that 50 of 83 (65.2 %) primary hepatocellular carcinomas showed markedly reduced or loss of expression of Fhit, suggesting that loss of Fhit protein might be related to the carcinogenesis of hepatocytes. Furthermore, decreasing expression of Fhit protein with higher histological grading, and more significantly with advanced clinical stages (stage III and IV) of primary tumors and bigger tumor size (>50 mm in diameter) suggests that loss of Fhit expression is strongly associated with the development and progression of hepatocellular carcinoma. Similar association between loss of FHIT function and the stage, grade and poor prognosis of tumors has been noted in lung cancer^[4-5], colorectal carcinoma^[18] and advanced breast cancer^[8].

In summary, expression of Fhit is reduced or lost in a significant proportion of hepatocellular carcinomas and especially in more advanced stages of primary tumors. Thus, detection of Fhit protein expression by immunohistochemistry in hepatocellular lesions may provide important diagnostic and prognostic information in practical clinical application.

Abstract

AIM: To investigate whether troglitazone (TGZ), the peroxisome proliferator-activated receptor (PPAR) gamma ligand, can induce apoptosis and inhibit cell proliferation in human liver cancer cell line HepG2 and to explore the molecular mechanisms.

METHODS: [3-(4,5)-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide (MTT), [^3H] Thymidine incorporation, Hoechst33258 staining, DNA ladder, enzyme-linked immunosorbent assay (ELISA), RT-PCR, Northern and Western blotting analyses were employed to investigate the effect of TGZ on HepG2 cells and related molecular mechanisms.

RESULTS: TGZ was found to inhibit the growth of HepG2 cells and to induce apoptosis. During the process, the expression of COX-2 mRNA and protein and Bcl-2 protein was down-regulated, while that of Bax and Bak proteins was up-regulated, and the activity of caspase-3 was elevated. Furthermore, the level of PGE $_2$ was decreased transiently after 12 h of treatment with 30 μM troglitazone.

CONCLUSION: TGZ inhibits cell proliferation and induces apoptosis in HepG2 cells, which may be associated with the activation of caspase-3-like proteases, down-regulation of the expression of COX-2 mRNA and protein, Bcl-2 protein, the elevation of PGE $_2$ levels, and up-regulation of the expressions of Bax and Bak proteins.

INTRODUCTION

Peroxisome proliferator-activated receptors (PPARs) are transcription factors belonging to the nuclear receptor gene family. PPARs bind to specific response elements as heterodimers with the retinoid X receptor and activate

transcription in response to a variety of endogenous and exogenous ligands, including some polyunsaturated fatty acids, arachidonic acid metabolites, and some anti-diabetic drugs and non-steroidal anti-inflammatory drugs^[1-6]. Recently, PPARs subfamily has been defined as PPAR α , PPAR β and PPAR γ . Three PPAR isoforms differ in their tissue distribution and ligand specificity. PPAR α is predominantly expressed in tissues exhibiting high catabolic rate of fatty acids, whereas PPAR β expression is ubiquitous, and its physiological role is not clear. PPAR γ is expressed predominantly in adipose tissue, the adrenal gland, spleen, large colon and the immune system. Several lines of evidence indicate that PPAR γ plays an important role in regulating adipocyte differentiation and glucose homeostasis. Both PPAR α and PPAR γ have been shown to be involved in anti-inflammatory reactions mediated by arachidonic acid metabolites. PPAR α binds to, and is activated by leukotriene B $_4$, and its level is regulated at the transcriptional level by anti-inflammatory glucocorticoids^[7-15]. PPAR γ is activated by prostaglandin D $_2$ metabolite 15-deoxy- $\Delta^{12,14}$ prostaglandin J $_2$ (15 d-PGJ $_2$) and synthetic anti-diabetic thiazolidinedione drugs, resulting in down-regulation of the expression of pro-inflammatory genes and inhibition of tumor cell growth^[16,17].

Cyclooxygenase (COX) is a rate-limiting enzyme, catalyzing the initial step in biosynthesis of prostaglandins (PGs) from arachidonic acid^[18,19]. COX is encoded by two separate genes, COX-1 and COX-2, both of which participate in formation of a variety of eicosanoids including PGD $_2$, PGE $_2$, PGI $_2$, PGF $_{2\alpha}$, and thromboxane A. COX-1 is expressed constitutionally in most tissues and has been proposed to be a house-keeping gene, which is involved in cytoprotection of gastric mucosa, vasodilation in kidney, and control of platelet aggregation. In contrast, COX-2 is an inducible immediate-early gene that is upregulated by various stimuli including mitogens, cytokines, growth factors, and tumor promoters. Previous studies have demonstrated that COX-2 expression is aberrantly increased in (various) human epithelial cancers in colorectum, esophagus, stomach, lung, and bladder^[20-39]. These findings suggest that up-regulation of COX-2 may be a common mechanism in epithelial carcinogenesis. Recently, PPAR γ ligands was found to suppress COX-2 expression in fetal hepatocytes^[40] and in macrophage-like differentiated U937 cells^[41]. However, other authors reported that 15d-PGJ $_2$ induced the expression of COX-2 in immortalized epithelial^[42] and colorectal cancer cells^[43]. The mechanisms for the different regulation of COX-2 expression by PPAR γ ligands remain to be elucidated. In the present study, we wanted to investigate the effect of PPAR γ activation on cell growth and apoptosis, and to investigate underlying mechanism in regard to the expression of COX-2 and Bcl-2 members in HepG2 cells.

MATERIALS AND METHODS

Cell culture

Human liver cancer cell line HepG2 was provided by the American Type Culture Collection. Cells were grown in RPMI-1640 medium supplemented with 15 % new born bovine serum, penicillin G (100 kU \cdot L $^{-1}$) and kanamycin (0.1g/L) at 37 $^{\circ}\text{C}$ in

the 5 % CO₂ incubator. Cells were grown on 96-well plates for MTT assay, [³H] thymidine incorporation and DNA fragmentation enzyme-linked immunosorbent assay (ELISA). For the experiment, cells were grown in fresh serum-free medium, incubated for 6 hours, and treated with experimental reagents.

MTT cell viability assay

Cell growth was assessed by a modified MTT assay. About 2×10⁵ cells/well were plated in 96-well microtiter plates and incubated overnight. Cells were then treated with troglitazone for 48 h in various concentrations. Then 10 μ l stock MTT (0.5 g/L) was added to each well, and the cells were further incubated at 37 °C for 4 h. After supernatant was removed, 100 μ l of 0.04 M HCl in isopropanol was added to each well to solubilize the formazan products. The absorbance at the wavelength of 570 nm was measured by a micro-ELISA reader. The negative control well contained medium only. The ratios of the absorbance of treated cells relative to those of the control wells were calculated and expressed as percentage of growth inhibition.

[³H] thymidine incorporation

Cells were planted in 96-well plates and grown for 24 h after being starved by growing in the serum-free medium for 48 h. Then, they were treated with troglitazone for 48 h and labeled with 5 μ Ci of [³H] thymidine for 4 h. Radioactivity was detected using a Beckman LS 5000TD counter, after the reaction was washed and stopped with 5 % trichloro acetic acid and the cells solubilized in 0.5 % of 0.25 N sodium hydroxide. Each experiment was done in quadruplicates and repeated at least three times.

Hoechst 33258 staining

Cells were fixed with 4 % formaldehyde in phosphate-buffered saline (PBS) for 10 min, stained by Hoechst 33258 (10 mg/L) for 1 hour, and subjected to fluorescence microscopy. After treatment with troglitazone, morphologic changes, including reduction in cell size and nuclear chromatin condensation, were observed.

DNA ladder demonstration

After induction of apoptosis, cells (7×10⁶/sample, both attached and detached cells) were lysed with 150 μ l hypotonic lysis buffer (edetic acid 10 mM, 0.5 % Triton X-100, Tris-HCl, pH7.4) for 15 min on ice and were precipitated with 2.5 % polyethylene glycol and 1 M NaCl for 15 min at 4 °C. After centrifugation at 16 000×g for 10 min at room temperature, the supernatant was treated with proteinase K (0.3 g/L) at 37 °C for 1 h and precipitated with isopropanol at -20 °C. After centrifugation, each pellet was dissolved in 10 μ l of Tris-EDTA (pH 7.6) and electrophoresed on a 1.5 % agarose gel containing ethidium bromide. DNA ladder pattern was identified under ultraviolet light.

Detection of DNA fragmentation

HepG2 cells were grown in 96-well plates. The cells were incubated with various dose of troglitazone for 48 h. DNA fragmentation was detected using an enzyme-linked immunosorbent assay (ELISA) kit (Roche). This assay was based on a quantitative sandwich enzyme-immunoassay directed against cytoplasmic histone-associated DNA fragments. Briefly, the cells were incubated in 200 μ l of lysis buffer. After centrifugation, 20 μ l of the supernatant was reacted overnight at 4 °C in streptavidin-coated wells with 80 μ l of biotinylated anti-histone antibody and peroxidase-conjugated anti-DNA antibody. After washing, the immunocomplex-bound peroxidase

was probed with 2,2'-azino-di[3-ethylbenzthiazoline sulfonate] for spectrophotometric detection at 405 nm.

TUNEL reaction

TUNEL reaction was done using apoptosis detection system (Cayman). Cells were fixed overnight at 4 °C with 4 % paraformaldehyde in PBS. The samples were washed three times with PBS and permeabilized by 0.2 % Triton X-100 in PBS for 15 min on ice. After washed twice, cells were equilibrated at room temperature for 15 to 30 min in equilibration buffer (potassium cacodylate 200 mM, dithiothreitol 0.2 mM, bovine serum albumin 0.25 g/L, and cobalt chloride 2.5 mM in 25 mM Tris-HCl, pH 6.6), and then incubated in a solution containing 5 μ M fluorescein-12-dUTP, 10 μ M dATP, 100 μ M edetic acid, and terminal deoxynucleotidyl transferase at 37 °C for 1.5 h in a dark chamber. The tailing reaction was terminated by 2×standard saline citrate (SSC). The samples were washed three times with PBS and analyzed by fluorescence microscopy. At least 1000 cells were counted, and the percentage of TUNEL-positive cells was determined.

RNA isolation and northern blotting

After incubation with different doses of troglitazone for 6 h, cells were washed with RPMI. Total RNA was extracted from adherent cells using Rneasy Mini kits (Sigma) as described previously^[37]. 30 mg of total RNA from each sample was separated on agarose/formaldehyde gels and transferred to nylon membranes. The membrane was hybridized with probes for COX-2 and for GAPDH as a reference.

RT-PCR for COX-2

Total RNA was extracted from cells using TRIzolTM (Sigma). COX-2 and beta-actin mRNA were detected by polymerase-chain-reaction following reverse transcription- (RT-PCR) as described^[37]. Primers for beta-actin were: sense 5' -ATCTGGCACCACACCTTCTACAATGAGCTGCG-3', antisense 5' -CGTCATACTCCTGCTTGCTGATCCACATCTGC-3'.

Western blotting analysis

The cells were lysed in a lysis buffer (hepes 25 mM, Triton X-100 1.5 %, sodium deoxycholate 1 %, SDS 0.1 %, NaCl 0.5 M, edetic acid 5 mM, NaF 50 mM, sodium vanadate 0.1 mM, phenylmethylsulfonyl fluoride (PMSF) 1 mM and leupeptin 0.1 g/L, pH7.8) at 4 °C with sonication. The lysates were centrifuged at 15 000 g for 15 min and the concentration of the protein in each lysate was determined with Coomassie brilliant blue G-250. Loading buffer (42 mM Tris-HCl, containing 10 % glycerol, 2.3 % SDS, 5 % 2-mercaptoethanol and 0.002 % bromophenol blue) was then added to each lysate, which was subsequently boiled for 3 min and then electrophoresed on a SDS-polyacrylamide gel. Proteins were transferred onto a nitrocellulose filter and incubated separately with the antibodies against Bcl-2, Bax, Bak, Bcl-x_L and COX-2, and then labeled with peroxidase-conjugated secondary antibodies. The reactions were visualized using the enhanced chemiluminescence reagent (Sigma). The results were approved by repeating the reactions 2 times.

Evaluation of PGE2 production

To determine the levels of PGE2, HepG2 cells were treated with different concentrations of troglitazone for 24 h. The quantity of PGE2 in supernatants was immediately determined with the PGE2 Enzyme Immunoassay kit (Cayman Chemical) according to the manufacturer's instructions. Data were recorded using a Dynatech MR50000 microplate reader and normalized to micrograms of protein.

Assessment of caspase-3 activity

Caspase-3 activity was evaluated using a caspase assay kit following instructions of the manufacturer. In brief, caspase-3 fluorogenic substrate (Ac-DEVD-AMC or Ac-IETD-AMC) was incubated with JTE522-treated cell for 1 h at 37 °C, then AMC released from Ac-DEVD-AMC or Ac-IETD-AMC was detected using a fluorometric plate reader with an excitation wavelength of 380nm and an emission wavelength of 420-460nm.

Statistical analysis

Data were presented as the mean \pm standard error, unless otherwise indicated. Multiple comparisons were examined for significant differences using analysis of variance, followed by individual comparisons with the Bonferroni post-test. Comparisons between two groups were made with the Student *t* test. $P < 0.05$ was considered significant.

RESULTS

Effects of PPAR γ activation on cell proliferation and cell viability

HepG2 cells were incubated with various doses of troglitazone for 48 h. MTT assay showed that troglitazone significantly inhibited cell viability. The inhibition was dependent on dose of troglitazone administered (Figure 1A). Application of troglitazone also resulted in a reduction of [3 H] thymidine uptake in a dose-dependent manner (Figure 1B).

Figure 1 Effect of TGZ on growth of HepG2 cells. HepG2 cells were incubated with various concentrations of TGZ for 48 h: (A) MTT assay; (B) [3 H] thymidine uptake assay. The value was represented as mean \pm SEM ($n=3$). $^bP < 0.01$ versus corresponding control group.

Influence of PPAR γ activation on apoptosis

Effect of PPAR γ activation on apoptosis was assessed by staining with Hoechst 33258, TUNEL reaction, DNA fragmentation demonstration on an agarose gel and by ELISA. The initiating effect of PPAR γ activation on apoptosis was confirmed in HepG2 cell, the morphologic changes included reduction in cell size and nuclear chromatin condensation visualized by Hoechst 33258 staining. The apoptotic index was also increased by treatment with different concentration of troglitazone from

3.2 \pm 1.2 % to 53 \pm 2.6 %. Agarose gel electrophoresis showed DNA ladder pattern in the exposed HepG2 cells (Figure 2). The PPAR γ pathway-induced apoptosis was further demonstrated in quantitative measurement of cytoplasmic histone-associated DNA fragment by ELISA. As shown in Figure 3, troglitazone induced significant increase in DNA fragmentation in a dose-dependent manner.

Figure 2 DNA ladder pattern formation in HepG2 cells after treatment with TGZ. Cells were treated with TGZ for 48 h and the formation of oligonucleosomal fragments was determined by 1.5 % agarose gel electrophoresis: M) DNA markers; 1) control; 2) 10 μM TGZ; 3) 30 μM TGZ.

Figure 3 DNA fragmentation by ELISA assay, as measured by absorbance (OD 450 values). HepG2 cells cultured for 48 h in the presence of TGZ resulted in dose dependent DNA fragmentation. $^aP < 0.05$, $^bP < 0.01$ compared to respective control.

Down-regulation of COX-2 associated with the PPAR γ activation

The fact that the COX-2 promoter contains a PPRE indicates that COX-2 might be one of the downstream targets of the PPAR γ pathway. In the present study, COX-2 expression was observed in HepG2 cells treated with vehicle or 30 μM troglitazone. After 6, 12, 24 and 48 h of the treatment, cells were harvested. COX-2 mRNA was analysed by RT-PCR (4A) and Northern blotting (4B), and its translation product was demonstrated by Western blotting (4C). As shown in Figure 4, no significant change was detected during the first 6 h of treatment when compared with the control. After treatment with 30 μM troglitazone for 12 h, the expression of COX-2 was inhibited.

Effects of PPAR γ activation on expression levels of Bcl-2, Bcl-x_L, Bax and Bak

To further elucidate the mechanisms of troglitazone-induced apoptosis in HepG2 cells, we assessed the involvement of bcl-2 family proteins in the process by Western blotting. Expression of Bax protein was up-regulated 6 h after 20 μM troglitazone treatment and remained elevated to 24 h. Expression level of Bak protein was also elevated 12 h after the treatment with 30 μM troglitazone and declined at 48 h. On the contrary, Bcl-2

protein expression was down-regulated at 6 h and undetectable at 24 h. No significant change was observed in the expression of bcl-x_L protein (Figure 5).

Figure 4 Effect of TGZ on the expression of COX-2 mRNA and protein in human liver cancer cell line HepG2 cells: (A) RT-PCR; (B) Northern blot; (C): Western blot.

Figure 5 Effects of TGZ on the levels of bcl-2, bcl-x_L, bax and bak proteins in HepG2 cells at indicated time.

Effects of PPAR γ activation on PGE₂ production

The levels of PGE₂ in vehicle controls were always high throughout the culture. When HepG2 cells were treated with 30 μ M troglitazone, PGE₂ concentration decreased transiently at 12 h (Figure 6).

Figure 6 Effect of TGZ on the production of PGE₂. The value was represented as mean \pm SEM ($n=3$). ^b $P<0.01$ compared to respective control.

Change in caspase-3 activity associated with PPAR γ activation

In consideration of frequent involvement of caspases activation in apoptosis, caspase-3 activity was assessed in HepG2 cell, treated with 20 μ M troglitazone. As shown in Figure 7, the caspase-3 activity increased with the treatment, the reaction was time-dependent.

Figure 7 Effect of TGZ on the activity of caspase-3. The value was represented as mean \pm SEM ($n=3$).

DISCUSSION

Potent effects of PPAR γ on cell proliferation and cell cycling have been described. PPAR γ ligands can trigger cell cycle arrest in NIH3T3 cells and HIB-1B cells^[44]. PPAR γ ligands can also induce terminal differentiation and withdrawal of human liposarcoma cells from the cell cycle^[45]. Importantly, PPAR γ ligands have been found to slow down the progression of advanced liposarcoma in humans^[46]. Given the expression of PPAR γ in nonadipose tissues, the effect of PPAR γ on human breast cancer, gastric cancer, prostate cancer, colon cancer and transitional cell, bladder cancer have been explored. Treatment of cultured breast cancer cells with troglitazone results in cell growth arrest and promotes differentiation^[47]. Troglitazone has also been shown to inhibit tumor growth and induce apoptosis in human breast cancer cells *in vitro* and in BNX mice. Moreover, another PPAR γ ligand, GW7845, has been shown to decrease tumor incidence, tumor growth and tumor burden I, the NMU induced mammary carcinoma^[48]. These data suggest that PPAR γ ligands may be used as novel, nontoxic and selective chemotherapeutic agents for human breast cancers. In the present study, our results have shown that activation of PPAR γ by troglitazone inhibits cell growth and induces apoptosis in human liver cancer HepG2 cells. We confirmed that the induction of apoptosis was mediated through down-regulation of COX-2 and Bcl-2 expression, and up-regulation of Bax and Bak expression. The down-regulation of COX-2 was coincident with down-regulation of the production of PGE₂. The activity of Caspase-3 was increased after treatment with 30 μ M PPAR γ ligand troglitazone in a time-dependent manner.

Meade *et al.* have demonstrated that COX-2 expression is enhanced by peroxisome proliferators, including some fatty acids, PGs and NSAIDs, as well as the prototypical peroxisome proliferator WY-14, 643, in mammary and colonic epithelial cells, presumably through PPAR α ^[49]. Yang *et al.* showed that activation of PPAR pathway by ciglitazone induced apoptosis and inhibition of COX-2 expression in human colon cancer cells HT-29^[50], but the result was not approved in an observation by Lefebvre *et al.*^[51]. Our data showed that PPAR γ activation inhibited the expression of COX-2. The discrepancy may be caused by different cell types used in these groups.

Overexpression of COX-2 plays important roles in cell adhesion, apoptosis and angiogenesis. Numerous epidemiological studies suggest that use of nonsteroidal anti-inflammatory drugs

(NSAIDs) decreases the incidence of gastrointestinal cancers and COX-2 is recognized as a major target of NSAIDs^[52-64]. Inhibition of COX-2 by NSAIDs or COX-2 specific inhibitors causes cell death in cancer cells, indicating that COX-2 may be used as an important molecular target for prevention and therapy in gastrointestinal cancers^[65-70]. The mechanism of COX-2 expression remains unclear. Subbaramaiah and colleagues have shown that PPAR γ can inhibit COX-2 expression.

In the present study, the levels of PGE₂ were decreased in a time-dependent manner after the treatment with 30 μ M troglitazone, and were correlated with the change in COX-2 expression. This is in agreement with previous observations in other cell lines^[71-73]. Thus, excessively synthesized PGE₂ mediated by overexpression of COX-2 is believed to play an important role in neoplasia formation. Inhibition of COX-2 activity may at least partly explain the chemopreventative effect of activated PPAR pathway in human liver cancer.

Apoptosis is characterized by a series of distinct morphological and biochemical changes. Several apoptosis-related genes have been found. One group of apoptosis regulatory genes is the Bcl-2 family^[74-79]. Of these genes, Bcl-2, Bcl-x_L are antiapoptotic, whereas Bax, Bcl-x_s, Bak, Bad and Bik are proapoptotic. In this study, overexpression of Bax and Bak, and suppression of the expression of Bcl-2 were found during the apoptosis induced by PPAR γ activation. These data confirm the role of these proteins in troglitazone-induced apoptosis in HepG2 cells. In addition, the activity of caspase-3 was also found to be elevated during the apoptotic process induced by PPAR γ activation.

In summary, we have shown that activation of PPAR γ by troglitazone induces apoptosis in HepG2 cells through down-regulation of the expression of COX-2 and bcl-2, up-regulation of bax and bak, and activation of caspase-3. Consistent with other potential chemopreventive agents in human liver cancer model, we believe that COX-2, bak, bax, bcl-2 and caspase-3 play some roles in the process of PPAR γ activation-induced apoptosis. These serve as potential targets for future drugs or therapies for prevention and treatment of liver cancer.

Abstract

AIM: To clarify the association of vascular endothelial growth factor (VEGF) and microvascular density (MVD) expression with the angiogenesis and prognosis of colorectal cancer.

METHODS: A total of 97 cases of colorectal carcinomas were examined by immunohistochemical staining (SP method), using anti-VEGF and anti-factor CD34⁺ monoclonal antibodies.

RESULTS: VEGF positive staining was obtained in 68 out of 97 cases (70.1 %), and observed mainly in the cytoplasm of tumor cells, and also frequently in stromal cells. VEGF expression was more intense in poorly differentiated adenocarcinoma in comparison with others, but there was no significant correlation between VEGF expression and age, sex and stage. A significant correlation was found between the MVD and grades, and there was no significant relationship between the MVD and age, sex, and stage. The MVD in the VEGF positive group (68 cases) was higher than that in the negative group. Upon multivariate analysis, the significant variables were stage, tumor grade and MVD; VEGF expression was not an independent prognostic factor.

CONCLUSION: The expression of VEGF has a significant correlation with MVD; MVD expression has prognostic value but VEGF has not in colon cancer.

INTRODUCTION

Angiogenesis is an essential process required for the growth and metastatic ability of solid tumors^[1]. Some studies demonstrated that an increase in microvascular density (MVD) was found to be closely associated with the expression of vascular endothelial growth factor (VEGF), and that MVD and VEGF expression had a prognostic value in predicting metastasis of various malignant solid tumors^[2,3]. Several studies have noted that the level of VEGF expression, a strong angiogenic factor, correlates with neovascularity and tumor progression in human breast and brain cancers and experimental tumor models^[4,5]. In this study, we investigated

the correlation of the VEGF and MVD in the tumor tissue of patients with colon cancer.

MATERIALS AND METHODS

Patients and tumor specimens

Tumor specimens from 97 patients resected for colorectal cancers, from the Second Affiliated Hospital of Zhejiang University (Hangzhou, China) from March 1993 to September 1995 were assessed. The age of the patients ranged from 36 to 74 years; 58 were male and 39 were female; average age, male 57.5 years old, female 61.5 years old. The patients were staged according to operation and pathological findings with UICC TNM classification: 9 (9.3 %) in stage I, 38 (39.2 %) in stage II, 32 (32.9 %) in stage III, and 18 (18.6) in stage IV.

Immunohistochemistry

Specimens were fixed in a 10 % formaldehyde solution and embedded in paraffin. Sections, 5 μ m thick, were cut and mounted on glass slides. Immunohistochemical staining was performed using the avidin-biotin method. Staining for VEGF was performed using an anti-VEGF monoclonal antibody (MAb) (Calbiochem, Cambridge, UK). Staining for vascular endothelial cells was performed using an anti-CD34 MAb (DAKO, Copenhagen, Denmark). Briefly, formalin-fixed, paraffin-embedded 5 μ m tissue sections were deparaffinised with xylene, dehydrated in ethanol and incubated with 3 % hydrogen peroxidase for 5 min. After washed with phosphate-buffered saline (PBS), tissue sections were incubated in 10 % normal bovine serum for 20 min, followed by an overnight incubation with anti-VEGF (1:50) antibody or anti-CD34 antibody (1:50). Biotinylated goat antimouse and antirabbit immunoglobulins were used as secondary antibodies. Peroxidase-conjugated avidin was used as a dilution of 1:500. Finally, 0.02 % diaminobenzidine and 1 % hydrogen peroxide in PBS were used as the substrate. Normal mouse IgG diluted to an equivalent protein concentration was used as a control in place of the primary antibody. Counterstaining was performed with haematoxylin.

Any single brown-stained cell that indicates an endothelial cell stained with CD34 was counted as a single vessel. Branching structures were counted as a single vessel, unless there was a break in the continuity of the structure. The stained sections were screened at 5 times magnification, to identify the areas of highest vascular density. After the area of highest neovascularization was identified, individual vessel counts were performed at $\times 200$ magnification.

Evaluation of VEGF expression

For the evaluation of VEGF expression, immunostaining was classified in two groups, corresponding to the percentage of immunoreactive cells; the cut-off point to distinguish low from high VEGF expression was 25 % of positive carcinoma cells.

Statistical analysis

Statistical comparisons for significance were made with the Student's *t* test and χ^2 test. Multivariate analysis was performed

using the Cox's regression multiple hazard model. $P<0.05$ was considered statistically significant.

RESULTS

VEGF expression

Positive staining was obtained in 68 out of 97 cases (70.1 %) and a typical immunohistochemical staining is shown in Figure 1. VEGF immunoreactivity was observed mainly in the cytoplasm of tumor cells, and also frequently in stromal cells. The distribution of VEGF-staining was not continuous in the whole slide of the specimen. VEGF expression was more intense in poorly differentiated adenocarcinoma in comparison with other tumors ($P=0.014$), but there was no significant correlation between VEGF expression and age, sex and stage (Table 1).

Figure 1 VEGF expression in colorectal cancer specimen. VEGF immunoreactivity was observed mainly in the cytoplasm of tumor cells, and also frequently in stromal cells.

Table 1 Relationship between clinicopathologic factors and VEGF expression ($n=97$)

Variables	<i>n</i> (%)	VEGF expression		<i>P</i> value
		+ <i>n</i> (%)	- <i>n</i> (%)	
Age				
<45 years	36	26(72.2)	10(27.8)	
>45 years	61	42(68.8)	19(31.2)	
Sex

IV	18	11(61.5)	7(38.5)	

$P<0.05$ vs Well differentiated group.

Microvascular density (MVD)

Any single brown-stained cell that indicates an endothelial cell stained with CD34 was counted as a single vessel (Figure 2). The median MVD was 187.6 ± 17.3 . A significant correlation was found between the MVD and different grade (0.028), and there was no significant relationship between the MVD and age, sex, and stage (Table 2).

Figure 2 Microvascular density in colorectal cancer specimen. The single brown-stained cell indicates an endothelial cell that was stained for the presence of CD34.

Table 2 Relationship between clinicopathologic factors and MVD ($n=97$)

Variables	<i>n</i>	MVD		<i>P</i> value
		high MVD	low MVD	
Age				
<45 years	36	20(55.6)	16(44.4)	
>45 years	61	33(54.3)	28(45.7)	
Sex

Table 3 Relationship between MVD and VEGF expression

Variable	MVD	<i>P</i> value
VEGF (+)	213.4±12.8	
Expression (-)	138.7±19.4	0.027

$P<0.05$ vs VEGF (-) group.

Table 4 Multivariate analysis of overall survival by Cox proportional hazards model

Variable	Categories	Hazard ratio	SEM	<i>P</i> value
Age	>45 years versus <45 years	1.877	0.3796	
Sex	Male versus female	1.216	0.4071	
Differentiation	Poor versus others	2.361	0.2438	0.0217
Stage	I, II versus III, IV	2.973	0.1976	0.0012
VEGF	(+) versus (-)	1.164	0.3874	
MVD	>187.6 versus <187.6	2.526	0.2126	0.0314

$P<0.05$ vs Stage I, II group.

Association between VEGF expression and MVD

The MVD in the VEGF positive group was 213.4 ± 12.8 , and that in the negative group was 138.7 ± 19.4 . MVD in the VEGF

positive group was higher than that in the negative group ($P=0.027$) (Table 3).

Multivariate analysis

Upon multivariate analysis of all patients, the significant variables were stage, tumor grade and MVD. Age, sex, VEGF expression were not independent prognostic factors (Table 4).

DISCUSSION

Microvasculature is important in cancer growth and metastasis because it is involved in the transport of various nutrients to the tumor cells^[1,2]. In this process of tumor growth and angiogenesis numerous angiogenic factors are involved. In recent years several of these factors have been identified^[3-6]. One of the most important regulators of angiogenesis is VEGF. It induces the vascular stroma not only as a direct endothelial cell mitogen, but also as a potent mediator of microvessel permeability. This ability of VEGF to induce fenestrations on microvessels has been demonstrated in experimental tumors^[7,8].

The VEGF is overexpressed in a variety of benign tissues and malignant human tumors. The expression of VEGF suggests that it plays a role in luminal secretion by increasing local vascular permeability^[9]. In neuroendocrine tumors the high levels of VEGF expression could indicate a role for VEGF in the release of gastrointestinal hormones through the regulation of baseline permeability of the normal microcirculation^[10]. The high level of VEGF expression in some malignant tumors, such as breast cancer, non-small cell lung cancer, bladder cancer and gastric cancer, is a characteristic feature of these tumors. Several studies have demonstrated that high microvessel density is a useful indicator for poor prognosis in these cancers^[11-15].

CD34 antigen is expressed on immature human haematopoietic precursor cells and is progressively lost during maturation^[16,17]. In normal resting tissues, anti-CD34 antibodies are predominantly reacted with the luminal endothelial membrane, whereas the abluminal membrane is negative or only weakly positive. In contrast, significant staining of the endothelial abluminal microprocesses (EAM) has been found in tumor stroma^[18]. It has been shown that CD34 is a marker for EAM during angiogenesis and the antigenicity of CD34 is preserved by freezing, or ethanol, and formalin fixation^[19].

Microvessel density (MVD) and expression of VEGF act as a highly specific inducer of angiogenesis. Strong VEGF expression and high MVD are considered important parameters of tumor angiogenesis and related to poor survival probability in vulvar cancer patients^[20,21]. In primary breast cancer, MVD and VEGF serve as a parameter for determining tumor biological, metastatic potential and prognosis^[22]. VEGF is highly related to angiogenesis of gastric carcinoma and promotes growth, invasion and metastasis of gastric carcinoma, VEGF expression and MVD are predictors for the biological behavior of gastric carcinoma^[21,23]. In primary liver cancer, besides tumor stage, satellite nodules and portal vein embolus, the MVD and VEGF expressions are also of prognostic significance^[24]. Intense VEGF staining was found in the majority of advanced primary SCCs, lymph node metastases, and human SCCs in severe combined immunodeficient mice, where no dysplasia, CIS, or early SCCs showed intense immunostaining. Suggesting a role for VEGF in both clinical and experimental HNSCC^[25,26]. By univariate analysis, VEGF expression and MVD in the biopsy specimens were significant predictors of bladder cancer recurrence. By multivariate analysis, only VEGF expression was an independent prognostic factor^[27]. The metastatic potency of NPC tissue and the prognosis of the patients with NPC could be estimated by measuring MVD and the expression of VEGF in NPC tissue^[28].

Previously it was demonstrated that in prostate tumors, angiogenesis measured as microvessel density (MVD) was associated with tumor stage as well as WHO grade and was an independent predictor of clinical outcome. Vascular endothelial growth factor (VEGF) is a major inducer of angiogenesis^[29]. The relationship between VEGF expression and MVD in ovarian carcinoma suggests that in conjunction with the established clinicopathologic prognostic parameters of ovarian carcinoma, VEGF expression may enhance the predictability of patients at high risk for tumor progression who are potential candidates for further aggressive therapy^[30]. But MVD in synovial sarcomas did not correlate with prognosis or VEGF expression, angiogenesis in synovial sarcoma might be controlled by angiogenesis activators other than VEGF^[31]. In patients with invasive cervical cancer VEGF expression has no prognostic value in contrast with the MVD^[32].

In this study, we found positive VEGF staining was obtained in 68 out of 97 cases (70.1 %), VEGF immunoactivity was observed mainly in the cytoplasm of tumor cells, and also frequently in stromal cells. VEGF expression was more intense in poorly differentiated adenocarcinoma in comparison with other tumors, but there was no significant correlation between VEGF expression and age, sex and stage. A significant correlation was found between the MVD and different grade, and there was no significant relationship between the MVD and age, sex, and stage. MVD in the VEGF positive group was higher than that in the negative group. Upon multivariate analysis, the significant variables were stage, tumor grade and MVD; VEGF expression was not an independent prognostic factor. We conclude that MVD but not VEGF expression has prognostic value in colon cancer.

Abstract

AIM: To investigate the effects of KAI1/CD82 on biological behavior of colorectal carcinoma cells.

METHODS: KAI1 cDNA was transfected into highly malignant colorectal carcinoma cell line, LoVo, which had low level of endogenous KAI1 expression, and established stable transfectant clones with high KAI1/CD82 expression. The cell-cell adhesion, cell aggregation, cell-matrix adhesion and cell invasion assay were performed to determine whether KAI1 transfectant could have an effect on proliferation, adhesion and tumor metastasis in comparison with the control transfectant cells.

RESULTS: KAI1 expression did not alter *in vitro* cell proliferation. But the KAI1 transfectant cells exhibited significantly increased homotypic cell-cell adhesion and cell aggregation in comparison with the control transfectant cells ($P < 0.05$). Furthermore, KAI1 expression significantly suppressed the cell adhesion to extracellular matrix components and *in vitro* cell invasion in KAI1-transfected LoVo cells. The data indicated that KAI1 expression significantly suppressed the metastatic potential of KAI1-transfected LoVo cells.

CONCLUSION: Our results suggest that KAI1 might function as a negative regulator of colorectal carcinoma metastasis.

INTRODUCTION

KAI1, a newly identified metastatic suppressor gene for prostatic cancer, is located on human chromosome 11p11.2. It was originally isolated by Dong in 1995^[1,2]. KAI1 mRNA, is ubiquitously expressed with abundant expression in the surface

epithelium of the major epithelial tissues, including prostate, breast, bladder, and gastrointestinal tract^[3,4]. Its protein product, CD82, belongs to TM4SF (transmembrane four superfamily) or TST (tetra span transmembrane) superfamily, many of which, including KAI1, are CD antigens present on the surface of leukocytes^[5,6]. Four hydrophobic transmembrane domains and one large extracellular hydrophilic domain containing 3 potential N-glycosylation sites are thought to function in cell-cell and cell-matrix interactions. At least three TM4SF members are implicated in metastasis, including CD9/MRP-1, CD63/ME491, and CD82/KAI1^[7]. KAI1 and other TM4SF members have been demonstrated to bind to each other, integrins, and E-cadherin, and other surface molecules to relay extracellular signals to signal transduction pathways that are important in cellular adhesion, invasive motility, and metastasis suppression^[8-10].

The role of KAI1 in tumor progression may not be limited to prostatic cancer. It was reported to be important in preventing the development of metastases in a wide variety of human tumor types, including several cancers such as cervical^[11], breast^[12], pancreatic^[13], esophageal^[14], and ovarian cancer^[15]. Therefore, we transfected KAI1 plasmid into highly malignant colorectal carcinoma cell line, LoVo, and examined cell proliferation, adhesion and invasion. The aim of this study was to determine whether KAI1 could suppress the invasive or metastatic ability of colorectal carcinoma cells.

MATERIALS AND METHODS

Cell lines and culture conditions

LoVo cell line was derived from human colon adenocarcinoma established from the metastatic nodule resected from a 56-year-old Caucasian man with colon adenocarcinoma in 1972. ECV304 cell line was derived from human umbilical cord transformed endothelium. Both cell lines were cultured in RPMI-1640 medium supplemented with 10 % heat-inactivated fetal bovine serum (FBS) and 100 U/ml penicillin/streptomycin. All cells were grown in 5 % CO₂ humidified atmosphere at 37 °C, and harvested for analysis at 80-90 % confluency.

Transfection and selection of the expressing cells

pCMV-KAI1 plasmid was a generous gift from Carl Barrett. 1.6 kb KAI1 cDNA inserting at *salI* sites was inserted into the *xhoI* site of pCMV-neo-*xhoI* vector to construct pCMV-KAI1. This plasmid was transfected into LoVo cell using the cationic polymer transfection reagent (jetPEI transfection reagent was purchased from Dakewe Biotechnology Company). The transfection proposal was as follows: the cells were plated at 6-well plate 1d before the transfection. 3 µg pCMV-KAI1 plasmid was diluted to 100 µl 150 mM NaCl and 6 µl jetPEI solution was diluted to 100 µl 150 mM NaCl. 100 µl jetPEI solution was added to the 100 µl DNA solution and vortex the solution immediately. Then the mixture was added drop-wise onto the serum containing medium in each well after incubated for 30 min at room temperature. After incubated for 48 h at 37 °C, 5 % CO₂ in a humidified atmosphere, the transfectants named LoVo-KAI1 were isolated by growing them in G418-containing medium (700 µg/ml) and G418-resistant clones

were established in two weeks. The pCMV-neo (purchased from Stratagene Company) vector alone was also transfected into LoVo cells to generate neo transfected control clones, designated as LoVo-neo.

In situ hybridization (ISH) assay

To prepare digoxigenin-labeled KAI1-DNA probes for *in situ* hybridization, PCR amplification was performed with a forward primer 5'-AGTCCTCCCTGCTGCTGTGTG-3' and reverse primer 5'-TCAGTCAGGTGGGCAAGAGG-3' and a 1 030 bp KAI1 fragment was achieved^[16]. The probes were labeled by Dig DNA Labeling and detecting Kit (purchased from Roche Company). Blot hybridization of Dig-labeled probe showed the labeling efficiency. ISH was performed according to the description of the enhanced sensitive ISH detection kit (purchased from Boster Biotechnology Company). Briefly, the cells that were incubated in cover slip for 24 hour and fixed with 95 % ethanol were washed with PBS (phosphate-buffered saline) three times. The endogenous peroxidases were blocked by incubating with 0.5 % H₂O₂ for 30 min at room temperature. The cells were subsequently treated for 10 min with triton X-100 and for 40 s with 3 % pepsin. At 37 °C the cells were prehybridized for 3 h and hybridized overnight. The final concentrations of the labeled probes were 150 pg/μl. After hybridization, excess probe was removed by washing in 2×SSC, 0.5×SSC, 0.2×SSC respectively. The cells were incubated with an antidigoxigenin antibody conjugated biotin for 120 min at room temperature and then added strept-avidin biotin complex for 30 min. For color reaction, diaminobenzidine (DAB) was used. If the ISH signals were present, the cytoplasm would be full of brown granules. The control was LoVo-neo cell group.

Immunohistochemistry (IHC) assay

The fixed cells were subjected to immunostaining by using an ultrasensitive S-P technique (Maixin Biotechnology Company). Endogenous peroxidases were blocked by incubating with 0.5 % H₂O₂ for 30 min at room temperature. The cells were subsequently treated for 10 min with triton X-100 and for 40 s with 3 % pepsin. The cells were incubated for 30 min at 37 °C with normal nonimmune serum before incubation at 4 °C with specific monoclonal KAI1-antibody (BD Pharmingen Technical Company) used at a dilution of 1:100 overnight. The cells were then treated with biotin-conjugated second antibody before adding streptavidin-peroxidase. For color reaction, diaminobenzidine was used. If the IHC signals were present, the cytoplasm and membrane were stained brown. The control was LoVo-neo cell group.

Growth curve

LoVo-KAI1 Cells were prepared by trypsinization. The cells were resuspended at a concentration of 10⁴ cells/ml in RPMI 1640 10 % FCS and then 100 μl aliquots were dispensed into 96 well microtiter plates. The cells were incubated for 1,2,3,4,5,6 day respectively and MTT assay was performed by adding 20 μl MTT (5 mg/ml) for 4 h. When the MTT incubation was completed, the supernatants were removed. 150 μl dimethyl sulfoxide (DMSO) was added to each well. The A value of each well was measured with a microplate reader at 570 nm 15 min later. All experiments were performed in triplicate. The control was LoVo-neo cell group.

Cell-cell adhesion assay

Cell-cell adhesion assays were performed using 96-well plates. The cells were cultured in 96-well plates and in confluence without vacant space. Other homotypic cells were harvested with 0.25 % trypsin and resuspended to a density of 10⁵ cells/ml in RPMI-1640 without FCS. Then the cells of 100 μl were

added into each well with already cultured homotypic cells and recovered for 60 min, 90 min at 37 °C. Non-adherent cells were collected by gentle washing with PBS and the washed cells were counted. The number of cell-cell adhesion was calculated using the following formula: The number of cell-cell adhesion = total number of added cells - the number of cells being washed. The experiments were performed in triplicate and repeated three times. The control was LoVo-neo cell group.

Cell-cell aggregation assay^[17]

12-well plate was coated with 1 % agar. And then single cell suspension (10⁵/ml) was washed by PBS three time after the cells were detached from the culture flasks with 0.25 % trypsin. The cells (1 ml) were added to 12-well plate and incubated at 37 °C with rotary shaking (70 r/min) for 5 h. The number of single cell was counted by haemocytometer. The cell-cell aggregation rate was then measured as ((total number of cells - single cells)/(total number of cells)) × 100 %.

Cell-matrix adhesion^[18]

96-well plates were incubated with 75 μl fibronectin (50 μg/ml) for 45 min and blocked with BSA (10 mg/ml). The cells were harvested as described for cell-cell adhesion assay. The cells (10⁵ cells/ml) of 100 μl were added to each well and allowed to attach 2 h at 37 °C. After washed with PBS twice to withdraw the non-adherent cells, 20 μl MTT was added for 4 h and 200 μl DMSO was added as above. The value of each well was measured with a microplate reader at 570 nm 15 min later. The experiments were performed in triplicate. The control was LoVo-neo cell group.

In vitro invasion assay

This assay was based on the principle of Boyden chamber^[19]. The top and bottom of Boyden chamber (Corning Company) were separated by polycarbonate filter with 8 μm pore size. The top chamber was prepared by coating the filter with 50 μg of diluted matrigel and incubated for 30 min. The bottom chamber was prepared with 5 % FBS as a chemoattractant. After 24 h, 48 h incubation, the noninvasive cells were removed with a cotton swab. The cells that had migrated through the membrane and stuck to the lower surface of the membrane were fixed with methanol and stained with hematoxylin. For quantification, the cells were counted under a microscope in five predetermined fields at ×200. The control was LoVo-neo cell group.

Monolayer cells invasion assay

ECV304 cells were cultured in cover slip and confluence without vacant space. LoVo-KAI1 cells were harvested with 0.25 % trypsin and resuspended to a density of 10⁵ cells/ml in RPMI-1640 with 2 % FBS and 10⁵ cells were added to the surface of ECV304 cells. After interaction for 24 h, the cells were washed with PBS and fixed immediately with 95 % ethanol. The cells that had migrated through the ECV304 cells and grown under ECV304 cells were counted. For quantification, the cells were counted under a microscope in five random fields at ×200. The experiments were performed in triplicate and the control was LoVo-neo cell group.

Statistical analysis

The comparison was made using Student *t*-test with a single contrast of LoVo-neo. The *P* value <0.05 was considered to be significant.

RESULTS

Transfection of KAI1 cDNA and selection of stable clones

To clarify whether KAI1 could suppress colorectal cancer

invasion and metastasis, we transfected KAI1 full-length cDNA into colorectal carcinoma LoVo cell lines. An expression vector was transfected as a negative control. After transfection and G418 selection for two weeks, 10 of each growing clone were picked and screened to confirm the transgene by *in situ* hybridization and immunohistochemistry. The probes for ISH were about 1 000 bp. (Figure 1). The blot hybridization was used to evaluate the efficiency of Dig-labeling probe (Figure 2). KAI1 mRNA expression in LoVo-KAI1 cell was located in the cytoplasm by *in situ* hybridization. LoVo-KAI1 cells were full of brown granules, but the LoVo-neo cells were negative (Figure 3). KAI1 protein expression was detected by immunohistochemistry and located in the cytoplasm and membrane. LoVo-KAI1 cells displayed positive immunostaining and LoVo-neo cells displayed negative staining (Figure 4). The results suggested that KAI1 was expressed in mRNA and protein level.

Figure 1 1 % gelose electrophoretogram of the product of PCR (1 030 bp). M: PCR marker; 1: PCR product.

Figure 2 Blot hybridization of Dig-labeled probe to show the labeling efficiency. Column 1: Dig-labeling probe; Column 2: standard control (unit: pg/ μ l).

Growth curve

Growth curve showed LoVo-KAI1 cells and LoVo-neo cells existing no difference in proliferation ability (Figure 5). The result demonstrated that KAI1 gene had no effect on cell proliferation ability.

Cell-cell adhesion assay

After interaction of homotypic cells in 60 min and 90 min, cell-cell adhesion was analyzed (Figure 6). These data suggested KAI1 gene could increase adhesion of homotypic cells.

Cell-cell aggregation assay

Aggregation observed in the LoVo-KAI1 cells was very different from that of the LoVo-neo cells. The LoVo-KAI1 cells formed large multicellular aggregates containing many cells, whereas the aggregates formed by LoVo-neo cells were much smaller and rarely contained more than a few cells (Figure 7). The number of LoVo-KAI1 cells aggregation (64.8 ± 4.4) was much larger than that of LoVo-neo cells (58.6 ± 3.5) ($P < 0.05$).

Figure 3 Expression of KAI1 in LoVo-KAI1 cell and LoVo-neo cell by *in situ* hybridization. The left picture: Expression of LoVo-KAI1 cells ($\times 400$) showed that the positive expression (brown granule) located in cytoplasm. The right picture: Expression of LoVo-neo cells ($\times 400$) was negative.

Figure 4 Expression of CD82 in LoVo-KAI1 cells and LoVo-neo cells by immunohistochemistry. The left picture: Detection of LoVo-KAI1 cells ($\times 400$) was positive, the cytoplasm and the membrane were stained brown. The right picture: Detection of LoVo-neo cells ($\times 400$) was negative.

Cell-matrix adhesion assay

All LoVo-neo cells attached to fibronectin and the surface of fibronectin appeared the phenomena of degradation while most LoVo-KAI1 cells attached to fibronectin and no degradation occurred. MTT assay showed OD_{570} in LoVo-KAI1 cells was 0.164 ± 0.011 and OD_{570} in LoVo-neo cells was 0.499 ± 0.023 . Attachment of LoVo-neo cells to fibronectin were demonstrated to be much higher compared to attachment of LoVo-KAI1 cells ($P < 0.01$).

In vitro invasion assay

An *in vitro* cell invasion assay was performed based on the principle of the Boyden chamber assay. The matrigel matrix served as a reconstituted basement membrane *in vitro*. The number of cells migrating through the Matrigel matrix was counted and the result was presented in Figure 8, 9. The LoVo-KAI1 cells showed significantly reduced invasiveness as compared with LoVo-neo cells ($P < 0.01$). These data indicated that the enhanced expression of KAI1 in LoVo-KAI1 cells was associated with reduced invasive ability.

Monolayer cells invasion assay

After cultured for 24 h, some tumor cells had invaded the ECV304 cells and migrated through the monolayer cells of ECV304. The invasive number of LoVo-KAI1 cells was 6.33 ± 1.74 and that of LoVo-neo was 17.67 ± 4.73 . The invasive ability of the LoVo-KAI1 cells was significantly reduced compared with that of the LoVo-neo cells ($P < 0.05$).

Figure 5 Growth curve of LoVo-KAI1 and LoVo-neo ($P < 0.05$).

Figure 6 Adhesion of homotypic cells: The cell-cell adhesion ability in LoVo-KAI1 cells was significantly increased as compared with that of LoVo-neo cells ($P < 0.01$).

DISCUSSION

Loss of the function of metastasis suppressor genes is an important step in the progression of a tumor type. KAI1 is thought to be one of such metastasis suppressor genes because it has been shown to suppress the ability of human prostatic cancer cells to metastasize when the tumor is transplanted into nude mice^[1] and because KAI1 mRNA expression is reduced in advanced pancreatic cancer^[20], it enables the pancreatic cancer cells to spread to lymph nodes and distant organs. Furthermore, transfer of the KAI1 gene into mammary cancer cells has been shown to lead to suppression of their metastatic potential, whereas their primary tumor growth is not affected.

In our previous studies, KAI1 gene expression at protein level was inversely correlated with the metastatic potential of some established colorectal carcinoma cell lines. Maurer *et al* also demonstrated that the progression of colorectal cancer was associated with decreased expression of KAI1^[21]. To further elucidate the effect of KAI1 on colorectal carcinoma cell behavior, we transfected KAI1 cDNA into highly malignant colon adenocarcinoma cell lines, LoVo, which have low level of endogenous KAI1 expression. Consistent with the studies of prostatic cancer^[2], breast cancer^[12] cells by Dong and Yang, our data also indicated that KAI1 expression did not alter *in vitro* cell proliferation.

To determine if KAI1 expression was reflected in changes of intercellular adhesion, we used cell-cell adhesion assay and cell-cell aggregation assay. We found KAI1 could increase homotypic cells adhesion and the transfectants formed large multicellular aggregates than non-transfected cells. In terms of cell-matrix, our results showed that KAI1 could reduce the transfectants adhesion to fibronectin as compared with the controls. Member of the TM4SF family of proteins associated with each other and specific integrins^[22], suggesting that they might be involved in cell-cell and cell-matrix interactions. Current thinking suggests that these interactions are involved in the formation of multiprotein complexes within the cell membrane that include cell surface receptors, specific integrins and TM4SF proteins. Consequently, a reduced expression of TM4SF proteins might reasonably be expected to have profound effects on cell-cell and cell-matrix interactions. An important avenue of further investigation will be to determine precisely the functions and location of TM4SF-integrin complexes. In this context, Berditchevski^[23] has recently provided evidence that TM4SF can modulate integrin signaling and point to a mechanism by which TM4SF proteins regulate cell adhesion.

Our data showed KAI1 could decrease invasive ability in

the transfected cells to a reconstituted basement membrane and endothelium compared to the controls. And there is also accumulated evidence that KAI1 is involved in the reduction of invasive tumor cells. Imai demonstrated that decreased KAI1 gene expression might be associated with increased invasive ability of oral squamous cell carcinoma^[24]. Takaoka's study also suggested that reduced KAI1 gene expression might contribute to the invasiveness and metastatic ability of colon cancer cells^[25]. How does reduced TM4SF expression cause changes of invasive ability in tumor cells? It was hypothesized that tetraspanins might be implicated in the assembly of integrin-containing signaling complexes, thus modulating the function of integrin receptors in cell migration^[26]. Sugiura's results indicated that integrin-tetraspanin protein complexes played an important role in regulating protrusive activity of the tumor cells and contributed to ECM-induced production of MMP-2, and as a consequence, the invasive ability of cells^[27].

Our *in vitro* study are consistent with *in vivo* observations that reduced KAI1 expression is associated with invasive human colorectal carcinoma. Muneyuki and Lombardi found that KAI1 expression was closely correlated with clinicopathological factors for colorectal cancers and appeared to be a useful prognostic marker^[28-30].

KAI1 has been extensively studied for its involvement in the progression of different human cancers. The mechanism of down-regulation is also analyzed although it exists much debate. Mashimo recently found a putative p53 consensus-binding site within the promoter region of KAI1 and demonstrated that the loss of p53 function, which is commonly observed in many types of cancer, leads to the down-regulation of KAI1 gene, which may result in the progression of metastasis^[31]. But Uzawa's data suggest that the down-regulation of KAI1 is not associated with either mutation, allelic loss, methylation of the promoter, or p53 regulation^[32]. Our previous study also demonstrated that mutation of KAI1 gene, methylation of CpG islands and abnormality of p53 were not related to low expression of KAI1.

Our results demonstrated a significantly increased adhesion to homotypic cells and decreased adhesion to extracellular matrix components and lower level of invasiveness. In conclusion, KAI1 has a close relationship with tumor adhesion and invasion and the effect of KAI1 appears to be directly targeted on tumor metastasis. Through our studies, we wish colorectal carcinoma cells would be more homotypic adhesion, less adhesive to matrix, less invasive^[33] that are necessary for metastasis.

Abstract

AIM: Cyclooxygenase-2 is involved in a variety of important cellular functions, including cell growth and differentiation, cancer cell motility and invasion, angiogenesis and immune function. However, the role of cyclooxygenase-2 as an angiogenic factor in colorectal cancer tissue is still unclear. We investigated the relationship between cyclooxygenase-2 and angiogenesis by analyzing the expression of cyclooxygenase-2 in colorectal cancer tissue, as well as its association with vascular endothelial growth factor (VEGF) and microvascular density (MVD).

METHODS: The expression of cyclooxygenase-2, VEGF, as well as MVD was detected in 128 cases of colorectal cancer by immunohistochemical staining. The relationship between the cyclooxygenase-2 and VEGF expression and MVD was evaluated. Our objective was to determine the effect of cyclooxygenase-2 on the angiogenesis of colorectal cancer tissue.

RESULTS: Among 128 cases of colorectal cancer, 87 were positive for cyclooxygenase-2 (67.9 %), and 49 for VEGF (38.3 %), respectively. The microvessel counts ranged from 23 to 142, with a mean of 51.7 (standard deviation, 19.8). The expression of cyclooxygenase-2 was correlated significantly with the depth of invasion, stage of disease, metastasis (lymph node and liver), VEGF expression and MVD. Patients in T3-T4, stage III-IV and with metastasis had much higher expression of cyclooxygenase-2 than patients in T1-T2, stage I-II and without metastasis ($P < 0.05$). The positive expression rate of VEGF (81.6 %) in the cyclooxygenase-2 positive group was higher than that in the cyclooxygenase-2 negative group (18.4 %, $P < 0.05$). Also, the microvessel count (56 ± 16) in cyclooxygenase-2 positive group was significantly higher than that in cyclooxygenase-2 negative group (43 ± 12 , $P < 0.05$). The microvessel count in tumors with positive cyclooxygenase-2 and VEGF was the highest (60 ± 18 , 41-142, $P < 0.05$), whereas that in tumors with negative cyclooxygenase-2 and VEGF was the lowest (39 ± 16 , 23-68, $P < 0.05$).

CONCLUSION: Cyclooxygenase-2 may be associated with tumor progression by modulating the angiogenesis in colorectal cancer tissue and used as a possible biomarker.

INTRODUCTION

Angiogenesis has been postulated to play an important role in the development of malignant tumors^[1-5]. Increased vascularity may allow not only an increase in tumor growth but also a greater chance of hematogenous tumor embolization^[6]. An association between poor prognosis and increase in microvascular density (MVD) of tumor has been reported in certain tumors^[7-10]. This neoangiogenesis depends on the production of angiogenic factors by tumor cells and normal cells^[11-15].

Cyclooxygenase (COX) is a key enzyme in prostaglandin biosynthesis^[16]. Two COX isoforms, COX-1 and COX-2, have been identified. COX-1 is constitutively expressed and involved in general cell functions, whereas COX-2 is an inducible enzyme that is up-regulated in response to various stimuli, including growth factors and mitogens^[17-22]. An enhanced expression of COX-2 has been found in many tumors, such as the lung, the breast, the esophagus and colon cancer^[23-26]. Recent studies have demonstrated that COX-2 could affect carcinogenesis via several different mechanisms^[27-35]. COX-2 has been also reported to induce angiogenesis^[36-39]. COX-2 may be related to development of colorectal cancer, however, its association with angiogenesis in colorectal cancer tissue still remains unclear. To determine the role of COX-2 expression in angiogenesis of colorectal cancer, we examined the VEGF and MVD in colorectal cancer tissue, and then compared the findings with the expression of COX-2 protein.

MATERIALS AND METHODS

Patients

A total of 128 cases of colorectal adenocarcinoma patients who had undergone surgical resection in the Affiliated Zhongnan Hospital of Wuhan University (Wuhan, China) from January 1999 to September 2002 were included. COX-2, VEGF immunohistochemical staining and MVD counting were performed. There were 73 men and 55 women, and their age ranged from 23 to 74 years (means, 56 ± 11 years). Among the 128 patients, 26 were well differentiated adenocarcinoma, 57 moderately differentiated adenocarcinoma and 45 poorly differentiated adenocarcinoma. According to Duke's staging criteria, 37 cases were stage I, 41 stage II, 39 stage III and 11 stage IV.

Methods

Immunohistochemistry: All the tissue specimens were fixed in 100 mL \cdot L⁻¹ neutral formalin and embedded in paraffin. Five- μ m thick sections were dewaxed in xylene and dehydrated in ethanol. Tissue sections were washed three times in 0.05 mol \cdot L⁻¹ PBS, and incubated in endogenous peroxidase blocking solution. Non-specific antibody binding was blocked by pretreatment with PBS containing 5 g \cdot L⁻¹ bovin serum albumin. Sections were then rinsed in PBS and incubated overnight at 4 °C with diluted anti-COX-2, anti-VEGF and anti-CD34 antibodies. The steps were performed using immunostain kit according to the manufacturer's

instructions. PBS was used as substitutes of antibody for negative control. The sections were examined under light microscope. Anti-VEGF polyclonal antibody and anti-CD34 monoclonal antibody were purchased from Bosden Co. (Wuhan, China). Anti-COX-2 polyclonal antibody was purchased from Santa Cruz Co. (USA). S-P detection kit was purchased from Fuzhou Maixin Co. (Fuzhou, China). Anti-COX-2 polyclonal antibody was diluted to 1:75. Anti-VEGF polyclonal antibody and anti-CD34 monoclonal antibody were impromptu type.

Results: Positive evaluation for COX-2 was performed according to the following scoring system^[16]: staining intensity was graded as weak (1), moderate (2), or strong (3), and area of staining positivity as <10 percent (0) of all cells stained in the cytoplasm as viewed by microscope, 10 to 40 percent (1), 40 to 70 percent (2), or ≥ 70 percent (3). A total for grade and area of 3 or more was defined as positive expression and less than 3 as negative. Positive signal for VEGF was located in the cytoplasm or/and cell membrane^[2]. Immunoreactivity was graded as follows: +, ≥ 10 percent stained tumor cells; -, <10 percent stained tumor cells^[2]. The microvessel counting procedures have been described in the published studies^[2]. Briefly, the stained sections were screened at a magnification of $\times 100$ ($\times 10$ objective and $\times 10$ ocular lens) under a light microscope to identify 3 regions of the section with the highest microvessel density. Microvessels were counted in these areas at a magnification of $\times 200$, and the average numbers of microvessels were recorded. The average number is known as MVD of the tumor.

Statistical analysis

The difference between each group was analyzed by Chi-square test. $P < 0.05$ was considered significant.

RESULTS

COX-2 expression in colorectal cancer and clinicopathologic findings

COX-2 was expressed in the cytoplasm of cancer cells (Figure 1). COX-2 expression in primary tumor was noted in 67.9 % (87/128). The correlation between COX-2 expression and the clinicopathologic findings is shown in Table 1. The expression of COX-2 was significantly correlated with depth of invasion, stage of disease, metastasis (lymph node and liver). Patients in T3-T4, stage III-IV, with metastasis had much higher COX-2 expression than patients in T1-T2, stage I-II, without metastasis ($P < 0.05$). The expression of COX-2 was not correlated with age, gender and differentiation degree of the tumor ($P > 0.05$).

Negative	79	47(59.5)	32(40.5) ^a
MVD ($\bar{x}\pm s$)		56 \pm 16	43 \pm 12 ^a

^a $P < 0.05$, vs positive.

Relationship between COX-2 and VEGF expression and MVD

VEGF was localized mainly in the cytoplasm and cell membrane of the tumor cells (Figure 2). VEGF expression was detected in 49 tumors (38.3 %), and COX-2 expression was correlated closely with VEGF expression (Table 1). The positive expression rate of VEGF (81.6 %) in the COX-2 positive group was higher than that in the COX-2 negative group (18.4 %) ($P < 0.05$).

Figure 2 VEGF expression mainly in cytoplasm and membrane of tumor cell, S-P, $\times 400$.

The number of microvessel counts in all cases was 23-142 ($\bar{x}\pm s$, 50 \pm 19). Moreover, the microvessel counts were 56 \pm 16 in COX-2 positive tumors and 43 \pm 12 in COX-2 negative tumors ($P < 0.05$, Table 1). COX-2 expression, VEGF expression and MVD were significantly correlated with one another ($r=0.5635$, 0.2812, 0.5253, respectively, $P < 0.05$). The microvessel counts in tumors with both positive COX-2 and VEGF were the highest (60 \pm 18, 41-142; $P < 0.05$). The

microvessel counts in tumors with both negative COX-2 and VEGF were the lowest (39 ± 16 , $23-68$; $P < 0.05$). The microvessel counts in tumors with positive COX-2 and negative VEGF were 50 ± 16 ($29-130$), and that in tumors with negative COX-2 and positive VEGF were 51 ± 18 ($30-132$), lower than that in tumors with both positive COX-2 and VEGF ($P < 0.05$). The microvessel counts in tumors with positive COX-2 and negative VEGF were not different from that in tumors with negative COX-2 and positive VEGF ($P > 0.05$).

DISCUSSION

Angiogenesis is essential for tumor growth and metastasis. The process of angiogenesis is the outcome of an imbalance between positive and negative angiogenic factors produced by both tumor cells and normal cells. Numerous angiogenic factors have been described. Of these, VEGF plays a key role in the angiogenesis in colorectal cancer^[1-15]. VEGF is a multi-functional cytokine, and has direct relationship with angiogenesis. The factors that regulate VEGF expression in tumor and non-tumor cells have now been elucidated^[10-28]. COX-2 is an inducible enzyme catalyzing the conversion of arachidonic acid to biologically active prostanoids. COX-2 modulates the growth and function of many cells, including those with malignant transformation. The over-expression of COX-2 has been reported in tissue from patients with different carcinoma, and is believed to play a role in tumor transformation and progression, as well as in tumor regression^[23-33]. Recent experimental studies showed that COX-2 could inhibit cell apoptosis, regulate angiogenesis, and was associated with matrix metalloproteinases (MMP)^[16-48]. Uefuji *et al.*^[45] studied the correlation of COX-2 and angiogenesis of gastric cancer, and found COX-2 might regulate angiogenesis.

COX-2 was overexpressed in approximately 80 percent of colorectal cancer cases^[16], but the role of COX-2 in angiogenesis of colorectal cancer tissue has not been identified yet. This study found that the expression of VEGF and MVD in positive COX-2 group was significantly higher than that in COX-2 negative group. The expression of COX-2 was significantly correlated with the expression of VEGF. It demonstrated that COX-2 might be correlated indirectly with angiogenesis through an up-regulation of the expression of VEGF. The expression of COX-2 was also significantly correlated with MVD in colorectal cancer. It indicates that COX-2 may modulate angiogenesis directly or indirectly through up-regulating the expression of other angiogenic factors. The microvessel counts in tumors that were both positive COX-2 and VEGF were the highest of all. It suggests that COX-2 and VEGF may co-modulate angiogenesis.

COX-2 expression was detected in 87 tumors (67.9 %). The expression of COX-2 was correlated significantly with the depth of invasion, stage of disease and metastasis (lymph node and liver). Patients in T3-T4, stage C-D and with metastasis had much higher expression of COX-2 than patients in T1-T2, stage A-B and without metastasis ($P < 0.05$). It suggests that COX-2 is closely related to the invasion and metastasis of colorectal cancer, and COX-2 may be used as a possible biomarker.

Abstract

AIM: TRAIL (tumor necrosis factor-related apoptosis-inducing ligand) has been reported to specifically induce apoptosis of cancer cells although only a small percentage of cell lines were sensitive to it. Cell lines not responding to TRAIL *in vitro* were said to be more prone to apoptosis when TRAIL was combined with another anticancer agent. Generally, factors affecting drug-sensitivity involve many apoptosis-related proteins, including p53. The expression of wild-type p53 gene was proposed as an important premise for tumor cells responding to chemotherapy. The present study was to investigate the cell killing action of TRAIL on colon cancer cell line SW480, its synergistic effect with doxorubicin, and the possible mechanisms.

METHODS: SW480 cells were cultured in the regular condition and incubated with different levels of agents. Morphologic changes in these cells after treatment were observed under phase-contrast microscope and cytotoxicity by TRAIL alone and in combination with doxorubicin was quantified by a 1-day microculture tetrazolium dye (MTT) assay. In addition, flow cytometry assay (FCM) and transmission electron microscopy were used to detect apoptosis among these cells. Variation of p53 protein level among different groups according to concentrations of agents was measured by Western blot assay.

RESULTS: (1) SW480 cells were not sensitive to TRAIL, with $IC_{50} > 1 \text{ mg} \cdot \text{L}^{-1}$ and dose-independent cytotoxicity. (2) SW480 cells were sensitive to doxorubicin at a certain degree, with dose-dependent cytotoxicity and $IC_{50} = 65.25 \pm 3.48 \text{ } \mu\text{mol} \cdot \text{L}^{-1}$. (3) TRAIL could synergize with doxorubicin to kill SW480 cells effectively, which was represented by the boosted killing effect of doxorubicin on these cells. IC_{50} of doxorubicin against SW480 cells sharply reduced when it was combined with TRAIL. (4) Subtoxic TRAIL ($100 \text{ } \mu\text{g} \cdot \text{L}^{-1}$), combined with subtoxic doxorubicin ($0.86 \text{ } \mu\text{mol} \cdot \text{L}^{-1}$), could kill SW480 cells sufficiently. Cytotoxicity by MTT assay arrived at $80.12 \pm 2.67 \%$, which was significantly higher than that by TRAIL or doxorubicin alone, with $P = 0.006$ and 0.003 respectively. This killing effect was partly due to apoptosis. It was proved by large amounts of apoptotic cells under phase-contrast microscopy, cell apoptosis rate of $76.82 \pm 1.93 \%$ by FCM assay and typical apoptotic

morphology observed through transmission electron microscopy. Increase of apoptosis after combined treatment had no relation with protein level of p53 ($P > 0.05$).

CONCLUSION: SW480 cells are not sensitive to TRAIL, but TRAIL can synergize with lower concentration of doxorubicin to induce apoptosis effectively. The status of p53 protein is not involved in the mechanism of synergistic apoptosis. It suggests the potential therapeutic applicability of the combination of TRAIL with doxorubicin against colon cancers.

INTRODUCTION

The rapid induction of apoptosis by TRAIL (tumor necrosis factor-related apoptosis-inducing ligand) preferentially in tumor cells but not in normal cells has implied its potential use in therapy of malignancies^[1,2]. Recent studies indicated that many cancer cells *in vitro* were resistant to apoptosis-inducing effect of TRAIL^[3,4]. Enhancement of the antitumor activity of TRAIL by metabolic inhibitors has led to later studies encompassing the augmentation of antitumor effects of several kinds of chemotherapy or radiation therapy by TRAIL^[5-13].

Doxorubicin has been the regular chemotherapeutic agents for its strong cell killing ability. But severe systemic toxicity limited its use in the clinical treatment of cancer. Reduction of its dose and maintenance of its high efficacy will be necessary in the future treatment of tumors. More efforts have been made to explore the combination of chemodrugs with some other agents^[14].

MATERIALS AND METHODS

Materials

SW480 cell line was purchased from ATCC and maintained in Roswell Park Memorial Institute (RPMI)-1640 medium (Gibco) supplemented with $2 \text{ mmol} \cdot \text{L}^{-1}$ L-glutamine (Gibco), $100 \text{ kU} \cdot \text{L}^{-1}$ penicillin (Gibco), $100 \text{ g} \cdot \text{L}^{-1}$ streptomycin (Gibco) and $100 \text{ ml} \cdot \text{L}^{-1}$ heat-inactivated fetal bovine serum (Gibco), hereafter referred to as complete medium. Recombinant human soluble TRAIL (rhsTRAIL) was purchased from Pepro Tech, USA. Doxorubicin, p53 Mab and MTT were respectively from Sigma Co, Santa Cruz Company and Amresco Co.

Methods

Cytotoxicity assay Cytotoxicity was determined by MTT assay. In brief, the cells were cultured in 96-well microtiter plates under $50 \text{ ml} \cdot \text{L}^{-1} \text{ CO}_2$ in a humidified atmosphere at 37°C . Each well was then incubated for 4 h with MTT solution (final concentration $0.45 \text{ g} \cdot \text{L}^{-1}$, Sigma Chemical, St.Louis, MO) under the same condition. Culture medium in each well was discarded and replaced with $100 \text{ } \mu\text{L}$ of dissolving solution (DMSO). The absorbance of each well was determined by a spectrophotometer

with a 490 nm wavelength. The percentage of cell viability was calculated by multiplying the ratio absorbance of the sample versus the control by 100. Doxorubicin IC_{50} was determined as a doxorubicin concentration showing 50 % cell growth inhibition as compared with control cell growth.

Antitumor activity of doxorubicin and/or TRAIL The cells were placed at 4×10^4 cells/well in 96-well microtiter plates. After 24 h culture for cell adherence to the plate, doxorubicin and/or TRAIL were added to each well at a given concentration. Detection of cell viability by MTT assay was performed following further incubation of the cells with doxorubicin and/or TRAIL for another 24 h. One well treated by the complete medium with neither doxorubicin nor TRAIL served as a control. The experiments were repeated in triplicate, and the percentage of cell viability was expressed as mean \pm standard deviation.

Flow cytometry This analysis was conducted with a Facscan flow cytometer (Becton Dickinson, Mountain View, CA). It was to quantify cell apoptosis by the propidium iodide method. In brief, the cells were harvested by trypsinization at 24 hours after treatment and washed twice with PBS (pH 7.2). The medium and PBS were placed in tubes and centrifuged. A total of 1 ml of hypotonic buffer (propidium iodide, 50 mg \cdot L $^{-1}$, in 1 ml \cdot L $^{-1}$ sodium citrate, Rnase plus 1 ml \cdot L $^{-1}$ Triton X-100; sigma) was added directly to the tubes and gently pipetted off. The tubes were placed at 4 $^{\circ}$ C in the dark for half an hour before flow cytometry analysis. The propidium iodide fluorescence of individual nuclei was measured in the red fluorescence and the data were registered in a logarithmic scale. At least 10^4 cells of each sample were analyzed each time. Apoptotic nuclei appeared as a broad hypodiploid DNA peak before the G_1 phase of cell cycle, which was easily distinguished from the narrow hyperdiploid DNA peak at the G_1 phase or later G_2 and S phase.

Transmission electron microscopy Transmission electron microscopy was used to observe apoptosis directly through morphological changes at the subcellular level. In brief, the cells were cultured in the regular condition for 24 h. Then, TRAIL (100 μ g \cdot L $^{-1}$), doxorubicin (0.86 μ mol \cdot L $^{-1}$), their combination or the complete culture medium was added to them and maintained for another 24 h. After these, the cells were subsequently trypsinized, harvested, fixed in glutaral, immersed with Epon 821, imbedded in capsules and converged. Ultrathin sections of 60 nm were finally prepared and stained with uranyl acetate and lead citrate. Cell morphology was measured by transmission electron microscope.

Western blot analysis for p53 protein expression p53 levels following treatment with doxorubicin and/or TRAIL were investigated by Western blot analysis. The cells were incubated with the medium alone, doxorubicin alone, TRAIL alone, or the combination of doxorubicin and TRAIL at 37 $^{\circ}$ C for 24 h. The cells were lysed in a lysis buffer consisting of 1 mmol \cdot L $^{-1}$ dithiothreitol, 1 mmol \cdot L $^{-1}$ phenylmethyl sulphonyl fluoride, 5 mg \cdot L $^{-1}$ leupiptin, 1 mmol \cdot L $^{-1}$ NaF, 10 mmol \cdot L $^{-1}$ β -glycerophosphate, 2 mmol \cdot L $^{-1}$ Natrium orthovanadate, 50 mmol \cdot L $^{-1}$ HEPES, 250 mmol \cdot L $^{-1}$ NaCl, 1 mmol \cdot L $^{-1}$ EDTA, and 1 % Nonidet P-40. After centrifuged for 7 min at 14 000 g, the supernatant was collected and the total protein amount was determined by SPECTRAMax 250. Twelve μ g/lane of proteins were boiled in a sample buffer for 1 min at 100 $^{\circ}$ C, electrophoresed in a multigel 10/20, and then transferred to Immobilon-P membranes (Millipore). Nonspecific antibody bindings were blocked by preincubation of the membranes for 1 h with a 5 % skim milk suspension. Then the membranes were incubated for 1 h with the polyclonal rabbit anti-human p53 antibody (1:200) (Santa Cruz, Delaware, CA), followed by further incubation overnight with horseradish peroxidase conjugated anti-rabbit IgG (1:2 000) (Santa Cruz). After each

antibody incubation, the membranes were washed three times by Tris-buffer saline. To visualize the protein bands, ECL Western blot detection reagents (Amersham, Buckinghamshire, UK) were used and the membranes were exposed to X-ray film.

Statistical analysis

All determinations were made in triplicate, and the results were expressed as the mean \pm standard deviation (S.D.). Statistical significance was determined by Student's *t*-test. A *P* value of 0.05 or less was considered significant.

RESULTS

Effect of TRAIL or doxorubicin on SW480 cells

MTT assay demonstrated that SW480 cells were not sensitive to TRAIL. No dose-dependent cytotoxicity of TRAIL on these cells was found at the concentrations from 0 μ g \cdot L $^{-1}$, 10 μ g \cdot L $^{-1}$, 100 μ g \cdot L $^{-1}$, 500 μ g \cdot L $^{-1}$, to 1 mg \cdot L $^{-1}$, (as shown in Figure 1). IC_{50} was above 1 mg \cdot L $^{-1}$ which was significantly higher than 0.4 μ g \cdot L $^{-1}$ of TRAIL-sensitive leukaemic cell line Jurkat. 100 μ g \cdot L $^{-1}$ TRAIL could only affect 5.8 % of these cells, a subtoxic concentration. By contrast, SW480 cells responded to doxorubicin sensitively, with obvious dose-dependent cytotoxicity and IC_{50} of 65.25 ± 3.48 μ mol \cdot L $^{-1}$. 0.86 μ mol \cdot L $^{-1}$ doxorubicin could not damage any cell, also a subtoxic concentration (as shown in Figure 2). All values by MTT assay were proved by flow cytometry assay and apoptosis applauded parallel with cytotoxicity.

Figure 1 Effect of TRAIL on SW480 cells. SW480 cells were treated with TRAIL at the concentrations of 0, 10, 100, 500 and 1 000 μ g \cdot L $^{-1}$ for 24 h. Cell growth inhibition was assessed by MTT assay and confirmed by flow cytometry assay. Compared with TRAIL-sensitive leukaemic cell line Jurkat (IC_{50} 0.42 μ g \cdot L $^{-1}$), SW480 cells (IC_{50} >1 000 μ g \cdot L $^{-1}$) were not responsive to TRAIL at concentration more than 100 times those active on Jurkat.

1, 2, 3, 4 was respectively doxorubicin with TRAIL 0, 10, 100, 1000 μ g \cdot L $^{-1}$.

Figure 2 Effect of TRAIL and doxorubicin on SW480 cells. SW480 cells were treated with doxorubicin alone or a combination of doxorubicin with TRAIL at different concentrations. The combination resulted in the reduction of doxorubicin IC_{50} in cells ($P < 0.05$). Doxo-

rubicin IC_{50} was 65.25 ± 3.48 when cells were treated by doxorubicin alone, while it was further reduced with the increased concentrations of TRAIL. Doxorubicin IC_{50} was $43.17 \pm 2.54 \mu\text{mol} \cdot \text{L}^{-1}$ when it was combined with $10 \mu\text{g} \cdot \text{L}^{-1}$ of TRAIL, $0.51 \pm 0.02 \mu\text{mol} \cdot \text{L}^{-1} IC_{50}$ when combined with $100 \mu\text{g} \cdot \text{L}^{-1}$ TRAIL, and $0.44 \pm 0.02 \mu\text{mol} \cdot \text{L}^{-1} IC_{50}$ when combined with $1000 \mu\text{g} \cdot \text{L}^{-1}$ TRAIL.

Effect of TRAIL and doxorubicin on SW480 cells

SW480 cells were treated by doxorubicin alone, TRAIL alone, and a combination of doxorubicin and TRAIL, and cell viability after each treatment was determined by MTT assay. The cell growth inhibitory effects of the combined treatment were synergistic and more significant in proportion to the increasing concentrations of TRAIL as compared with doxorubicin alone. Furthermore, TRAIL could cause a decrease in doxorubicin IC_{50} (as shown in Figure 2).

Effect of subtoxic TRAIL with subtoxic doxorubicin on SW480 cells

Subtoxic concentration TRAIL of $100 \mu\text{g} \cdot \text{L}^{-1}$, with subtoxic concentration doxorubicin of $0.86 \mu\text{mol} \cdot \text{L}^{-1}$ was capable of killing $80.12 \pm 2.67\%$ cells by MTT assay. Much more apoptotic cells were observed under phase-contrast microscope in the group treated by this combination compared with those treated by TRAIL or doxorubicin alone. Flow cytometry assay also measured apoptosis rate of $76.82 \pm 1.93\%$ and obvious pre- G_1 apoptotic DNA peak among the cells (as shown in Figure 3). And electron microscopy observed a large number of apoptosis cells in them (as shown in Figure 4).

Figure 3 Apoptosis assay by flow cytometry. SW480 cells were treated with doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$) alone, TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$) alone or a combination of them for 24 h. The apoptosis-inducing effect was quantified by PI stain flow cytometry assay. A: There was no hypodiploid DNA peak before G_1 phase which was similar to normal cells when treated with TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$) or doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$) alone. B: There was an obvious hyperdiploid DNA peak before G_1 phase in combination treatment, with apoptotic rate of $76.82 \pm 1.93\%$. It was in accordance with cytotoxicity by MTT assay.

Protein level of mutant p53 before and after treatment of TRAIL and/or doxorubicin

SW480 cells were treated with $100 \mu\text{g} \cdot \text{L}^{-1}$ TRAIL alone, $0.86 \mu\text{mol} \cdot \text{L}^{-1}$ doxorubicin alone, and their combination or complete

control medium for 24 h. The protein level of mutant p53 was not different among them, with $P > 0.05$ (as shown in Figure 5). Variation of agent concentration turned out similar result.

Figure 4 Subcellular morphology of SW480 cells under treatment of TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$), doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$), or the combination of them. The electron microscopic morphology was observed after 24 hours treatment at the given concentration. A: TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$) or doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$) alone didn't affect the morphology of cells, with complete construction and evenly distributed chromatin ($\times 5000$). B: The combination of TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$) and doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$) induced apoptosis in many cells, presented as condensed chromatin, distributing along nuclear perimeter ($\times 15000$).

Figure 5 p53 protein level by Western blot assay. They were detected after 24 hours of treatment. A, B, C, D were respectively normal control, TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$), doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$) and TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$) + doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$) groups. There was no difference in p53 protein expression among these four groups ($P > 0.05$).

DISCUSSION

TRAIL, also named Apo-2L, is a new member of the TNF cytokine family. It resembles Fas/Apo-2L in its amino acid sequence, as well as in its ability to induce apoptosis. It conducts or regulates the activities via a set of receptors on the surface of various cells^[15-24]. TRAIL has attracted much interest for a profound feature since its discovery in 1995. That is the selectivity of killing cells, namely, TRAIL only induces apoptosis in transformed or tumor cells, but does not damage the normal ones^[1,2]. There was a proposal for its clinical use after a series of *in vitro* experimentations. But a variety of cancer cells of breast, lung, prostate, colon and bladder were reported resistant to the effect of TRAIL^[5-7].

Results in this study demonstrated that colon cancer cell line SW480 was relatively resistant to TRAIL, compared with TRAIL-sensitive leukaemic cell line Jurkat. The mechanisms of the underlying resistance was not clear update^[7-9]. The conditions of decoy receptors, caspase-inhibition protein (FLIP), caspases and some apoptosis-related genes might attribute to the different responses^[25-34]. It's necessary to find a way to reverse the resistance if it is used in clinic in the future. Previous articles indicated some chemotherapeutic drugs could sensitize the cancer cells to TRAIL-mediated apoptosis^[10-15]. Doxorubicin is a member of antibiotics, specifically for cancer cells. It belongs to the classical chemotherapeutic agents, with high anti-cancer efficacy. However, severe cardiac toxicity limits its broad use in clinic. Reducing concentration and maintaining efficacy of doxorubicin should be necessary for continuing its work. This study also demonstrated the sensitivity of SW480 cells to doxorubicin and its synergistic effect with TRAIL when percentage of cell viabilities were significantly decreased by the combined treatment at any dose as compared with those treated by doxorubicin or TRAIL alone. The degrees of growth inhibition were greater accompanied by the increased concentrations of TRAIL. Furthermore, augmentation of the cytotoxic effect of doxorubicin with TRAIL was significant even at low Doxorubicin ($0.86 \mu\text{mol} \cdot \text{L}^{-1}$) and low TRAIL ($100 \mu\text{g} \cdot \text{L}^{-1}$) concentrations in SW480 cells. It presented the evidence that TRAIL could reduce the dose of doxorubicin against tumor cells, which ultimately resulted in minimizing risks for systemic side effects while increasing the efficacy of doxorubicin, suggesting the clinical applicability of this combination for colon cancers.

Concentrations of TRAIL that were completely inactive on their own, boosted the activity of doxorubicin in the SW480 cells. This correlated well with the increased ability of this drug when combined with TRAIL to induce apoptosis and it did not correlate with the status of p53. Mutant-type p53 was said to contribute to drug-resistance of most cancer cells^[27, 28]. The precise mechanisms enabling TRAIL to augment the cytotoxicity of chemotherapeutic agents in the p53 mutant-type cells have not been extensively investigated; however, recent evidence has suggested several possibilities: First, the augmentation of TRAIL-induced apoptosis by adriamycin or 5FU in p53 wild- and mutant-type breast cancer cell lines was mediated through a selective activation of caspases by these agents^[28]. Subsequent investigations demonstrated that caspase activation, which was not observed with TRAIL or doxorubicin alone, became more evident after the combined treatment in p53 mutant-type cell lines. These findings implied that the up-regulation of intracellular apoptotic signaling events contributed to overcome resistance to TRAIL alone even in p53 mutant-type cells. Second, the increase of KILLER/DR5 expression by certain genotoxic stresses, which resulted in the enhancement of TRAIL, is regulated in a p53-dependent and -independent manner^[29, 30]. Finally, another TRAIL receptor, DR4, which transmitted a death signal through its binding with

TRAIL, is regulated in a p53-independent manner^[31-34].

The finding that TRAIL could boost the activity of doxorubicin against colorectal carcinoma cells should have important therapeutic implications. Since TRAIL itself is thought to have no apparent toxicity to normal cells and to be safe in systemic administration, the combination of doxorubicin and TRAIL will result in minimization of the toxicity and maximization of the antitumor activity.

Abstract

AIM: To investigate the expression of inducible nitric oxide synthase (iNOS) in aberrant crypt foci (ACF) -adenoma-carcinoma sequence and its relation with tumor cell apoptosis, proliferation and angiogenesis.

METHODS: The expression of iNOS, proliferating cell nuclear antigen (PCNA) and microvessel density (MVD) in different stages of colorectal cancer were studied by immunohistochemical method from 30 normal tissues, 30 nonhyperplastic ACF, 30 hyperplastic ACF, 30 dysplastic ACF, 30 adenomas and 60 carcinomas. The apoptotic cells were detected by terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling (TUNEL) method using an Apop Tag *in situ* detection kit.

RESULTS: The immunoreactivity of iNOS significantly increased in the transition from hyperplastic ACF to dysplastic ACF. This transition was associated with a significant decrease in the apoptotic index (AI) (0.73 ± 0.37 vs 0.61 ± 0.35 , $P < 0.05$) and significant increases in the PCNA labeling index (LI) (27.3 ± 2.80 vs 40.3 ± 3.11 , $P < 0.01$) and microvessel density (MVD) (55 ± 11.5 vs 70 ± 13.2 , $P < 0.01$). The expression of iNOS was in low levels and positively correlated with PCNA-LI ($r = 0.812$, $P < 0.01$) and MVD ($r = 0.863$, $P < 0.01$) during transition from normal mucosa to nonhyperplastic ACF and hyperplastic ACF. The expression of iNOS was in high levels and positively correlated with AI ($r = 0.901$, $P < 0.01$) after transition from hyperplastic ACF to dysplastic ACF, adenoma and carcinoma.

CONCLUSION: The results suggest that the transition from hyperplastic ACF to dysplastic ACF may be a crucial step in the ACF-adenoma-carcinoma sequence, in which iNOS plays an important role by regulating tumor cell apoptosis, proliferation and angiogenesis.

INTRODUCTION

Aberrant crypt foci (ACF) are recently described colorectal lesions that might be related to the earliest steps in multistage colorectal carcinogenesis^[1]. Nitric oxide (NO) is an important

bioactive agent and signaling molecule that mediates a variety of physical actions and may contribute to the pathogenesis of a variety of disorders including cancer^[2-6]. Several studies implicate iNOS in colorectal tumorigenesis^[7-9], but none has evaluated the expression of iNOS in ACF-adenoma-carcinoma sequence. In this study, TUNEL technique and immunohistochemical staining were used to detect biologic parameters of tumor and compare the state of apoptosis, proliferation, MVD and iNOS expression in ACF-adenoma-carcinoma sequence. The purpose was to find out the relationship between aberrant expression of iNOS and colorectal carcinogenesis and the possible mechanism.

MATERIALS AND METHODS

Tissue specimens

Human colorectal tissues were obtained from Zhongnan Hospital and the People's Hospital of Wuhan University and Hubei Cancer Hospital. We collected 90 ACF and their adjacent normal mucosa from 32 colorectal carcinomas (CRC) (19 males and 13 females; mean age, 54 ± 7.5 years). 30 adenomas (18 males and 12 females; mean age, 51 ± 7.3 years) and 60 carcinomas were included in this study. The cancer patients included 32 males and 28 females that had 7 Dukes' stage A, 24 stage B, 12 stage C, and 17 stage D. There were 22 well-differentiated CRCs, 26 moderately differentiated and 12 poorly differentiated CRCs. All specimens were routinely fixed in 10 % buffered formalin, embedded in paraffin, and cut into 5 μ m sections. Each of the 5 sections was stained with hematoxylin and eosin for classification.

Sampling of ACF

Immediately after bowel resection, freshly resected colorectal segments were opened longitudinally, and the mucosa from macroscopically normal segments were dissected from the underlying layers, spread over on a piece of filter paper, and fixed in 10 % buffered formalin solution. 24 hours later, the fixed mucosal strips were immersed in 0.2 % methylene blue solution for 5 to 10 minutes and screened under 40 \times magnification for ACF. Methylene blue-stained ACF were easily distinguished from normal crypts by their deeper blue color, larger diameter, and the shape of their crypt orifices (oval, serrated, or slit-like)^[10]. Randomly selected ACF were microdissected with a rim of normal surrounding mucosa, paraffin embedded, and serially cut perpendicular to the surface.

Histochemical detection of apoptosis and determination of apoptotic index

Apoptotic cell tissue sections were detected by terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling (TUNEL) method using an Apop Tag *in situ* detection kit according to the manufacturer's instructions. Morphologic characteristics of apoptosis were chromatin condensation, nuclear disintegration, and formation of crescent caps of condensed chromatin at the nuclear periphery. The apoptotic index (AI) was expressed as the ratio of positively stained cells

to total cells evaluated for each tissue section after counting 1 000 cells at 5 areas randomly selected for counting less than 400-fold magnification.

Immunohistochemical staining and evaluation of the sections
SP kit was used. The primary antibodies were iNOS polyclonal antibody (ready to use, Boster, Wuhan), PCNA monoclonal antibody (ready to use, Maxin, Fujian) and CD34 monoclonal antibody (ready to use, Maxin, Fujian), respectively. Before staining, the sections were heated in microwave heated in 0.01 mol/L citric acid solution for antigen retrieval. PBS was substituted for primary antibodies as negative control. The stained sections were reviewed and scored independently by two investigators using an Olympus microscope. The extent and intensity of immunoreactivity for iNOS of all specimens were recorded. The following scale was used to express the extent of positivity: 0, $\leq 5\%$; 1, $>5-25\%$; 2, $>25-50\%$; 3, $>50-75\%$; 4, $>75\%$. The intensity of iNOS expression was scored as follows: 0, negative; 1, weak; 2, moderate; 3, strong. The final score, obtained by multiplying the intensity and extent of positivity scores, ranged from 0-12. Scores of 0-4 were defined as “markedly reduced” or “no expression”; Scores 5-8 were defined as “intermediate expression”; and scores of 9-12 were defined as “strong expression”^[11]. The PCNA labeling index (LI) was expressed as the ratio of cells positively stained for PCNA to all epithelial cells in at least 5 areas randomly selected for counting less than 200-fold magnification. For microvessel density (MVD) determination, 5 areas were randomly selected and counted less than 200-fold magnification. The average count was recorded and expressed as the absolute number of vessels per 0.74 mm² (per $\times 200$ field) for each case.

Statistical analysis

T test was used for comparison of the means. The positivity of iNOS protein was analyzed by Fisher exact probability method. For the tendency of AI, LI and MVD in the ACF-adenoma-carcinoma sequence analysis of variance was performed based on the trend test. *P* value less than 0.05 was regarded as statistically significant.

RESULTS

Expression of iNOS in ACF-adenoma-carcinoma sequence

Although most cases of normal mucosa, nonhyperplastic ACF and hyperplastic ACF showed intermediate, weak or absent iNOS expression, the expression of iNOS increased markedly during transition from hyperplastic ACF to dysplastic ACF ($P<0.01$) (Table 1, Figure 1). Greater than 70 % of cases of dysplastic ACF, adenoma or carcinoma showed strong expression of iNOS. We found no relationship between expression of iNOS and the Ducks' classification and the differentiation of cancer.

Table 1 iNOS expression in normal mucosa-ACF-adenoma-carcinoma sequence

	iNOS expression			Total
	Strong	Intermediate	Weak or absent	
Normal mucosa	3	6	21	30
Nonhyperplastic ACF	6	8	16	30
Hyperplastic ACF	8	10	12	30
Dysplastic ACF	26	2	2	30
Adenoma	24	4	2	30
Carcinoma	41	10	9	60

Figure 1 Immunohistochemical analysis for iNOS protein in ACF. (A) weak staining was observed in the cytoplasm of nonhyperplastic ACF. (SP method, $\times 200$). (B) weak staining was observed in the cytoplasm of hyperplastic ACF. (SP method, $\times 200$). (C) strong staining was observed in the cytoplasm of dysplastic ACF. (SP method, $\times 200$).

Table 2 Changes in AI, PCNA-LI, and MVD in ACF-adenoma-carcinoma sequence ($\bar{x} \pm s$)

	<i>n</i>	AI (%)	PCNA-LI (%)	MVD (MVD /0.74mm ²)
Normal mucosa	30	0.21 \pm 0.13	12.1 \pm 2.48	50 \pm 10.3

Changes in AI, PCNA-LI, and MVD in ACF-adenoma-carcinoma sequence

Apoptotic index was highest in hyperplastic ACF, whereas it significantly decreased after transition to dysplastic ACF

(Figure 2), adenoma and carcinoma ($P<0.05$). Conversely, the proliferative activity as determined by PCNA-LI gradually increased during ACF (Figure 3)-adenoma-carcinoma

sequence ($P<0.01$). Microvessel density significantly increased after the transition to dysplastic ACF (Figure 4), and further elevated in adenoma and carcinoma ($P<0.01$) (Table 2).

Figure 2 Histochemical detection of apoptosis by TUNEL in ACF. Few apoptotic cells were detected in nonhyperplastic ACF (Panel A, original magnification $\times 200$), and more apoptotic cells were detected in hyperplastic ACF (Panel B, original magnification $\times 100$) whereas they decreased significantly after transition to dysplastic ACF (Panel C, original magnification $\times 200$).

Figure 3 Immunohistochemistry of PCNA protein in ACF. PCNA expression was gradually increased from nonhyperplastic ACF (Panel A, original magnification $\times 200$), hyperplastic ACF (Panel B, original magnification $\times 100$) to dysplastic ACF (Panel C, original magnification $\times 100$).

Figure 4 Immunohistochemistry of CD34 protein in ACF. MVD determined by anti-CD34 antibody was low in nonhyperplastic ACF (Panel A, original magnification $\times 200$) and hyperplastic ACF (Panel B, original magnification $\times 200$) whereas significantly increased in dysplastic ACF (Panel C, original magnification $\times 200$).

Correlations between iNOS expression and biologic parameters

The expression of iNOS was in low level and positively correlated with PCNA-LI ($r=0.812$, $P<0.01$) and MVD ($r=0.863$, $P<0.01$) during transition from normal mucosa to nonhyperplastic ACF and hyperplastic ACF. The expression of iNOS was in high level and positively correlated with AI ($r=0.901$, $P<0.01$) after transition to dysplastic ACF, adenoma and carcinoma.

DISCUSSION

The development of colorectal carcinoma usually occurs via the adenoma-carcinoma sequence^[12,13]. The search for the earliest morphological precursors led to the description of ACF. Currently, there is a tendency to consider ACF as putative preneoplastic lesions that could represent one of the earliest stages of the multistep colorectal carcinogenesis^[11,14]. Alteration of enzymes, specifically hexosaminidase, and carcinoembryonic antigen expression have been identified in ACF. Genetic mutations that include APC suppressor gene and k-ras gene as well as beta-catenin gene have been found in ACF^[15,16]. Genomic instability, manifested as altered lengths of microsatellites and oligo A sequences similar to alterations that occur in neoplasm, has been identified in some ACF^[17]. Morphological alterations from nonhyperplasia to hyperplasia to varying degrees of dysplasia have been found in ACF^[18]. One study suggested that some hyperplastic ACF can develop into the adenomatous type^[19]. In a carcinogen-induced colonic tumorigenesis model, these lesions may show dysplastic morphology and precede formation of adenomas and adenocarcinomas. Phenotypic and genetic abnormalities in ACF have been postulated as evidence that ACF are preneoplastic and the smallest lesions preceding adenoma and carcinoma. Recently, there was a direct evidence of the existence of an ACF-adenoma-carcinoma sequence^[20].

A disturbance in the balance between cell proliferation and cell loss, or apoptosis may underlie neoplastic development^[21-27]. In this study, we noticed that in normal mucosa the apoptotic cells were identified in colorectal surface epithelium and formed "an apoptotic zone". Proliferative cells were seen in the basal region of the mucosa glands and formed "a proliferating zone". However in colorectal carcinoma, apoptotic cells and proliferative cells clustered all over the tumor tissue. This phenomenon elucidated that the regulation of apoptosis and proliferation had already been beyond control. Angiogenesis also played a crucial role in tumorigenesis^[28-32]. In this study, we demonstrated that MVD increased gradually in ACF-adenoma-carcinoma sequence. This change indicated that the regulation of growth of vessel was also disordered.

We investigated iNOS expression in human colorectal cancer with respect to tumor staging. Only low levels were found in the surrounding normal tissue, nonhyperplastic ACF and hyperplastic ACF. However, we found markedly increased iNOS in dysplastic ACF, adenoma and carcinoma. After transition to dysplastic ACF, adenoma and carcinoma, iNOS activity decreased with increasing staging. The markedly increased iNOS expression during hyperplastic ACF-dysplastic ACF transition suggested that the increase of iNOS expression might be an early event in the development of colorectal tumor. The different expression of iNOS in the epithelial cells in ACF-adenoma-carcinoma sequence may provide important clues that host factor regulates iNOS differently in different tumor stages.

During transition from normal mucosa to nonhyperplastic ACF and hyperplastic ACF, the expression of iNOS was at low levels. This transition was associated with a gradual increase in the AI, PCNA-LI and MVD. Several reports suggest that low concentrations of NO and iNOS induce angiogenesis

and enhance the growth rate of tumor^[33]. Increased proliferation might result in a state of lacking of nutrients, competition for growth factors or oxygen starvation and then in turn induce apoptosis^[34]. Our results demonstrated that the initial neoplastic transformation was associated with a remarkable increase in rates of both proliferation and apoptosis, which suggested the increased instability of colorectal mucosa in this process. The immunoreactivity of iNOS significantly increased during the transition from hyperplastic ACF to dysplastic ACF. The perturbation of tissue homeostasis derived from the increased proliferation and decreased apoptosis detected at this transition. Microvessel density (MVD) was found markedly increased at this transition. These results suggested that the transition from hyperplastic ACF to dysplastic ACF might be a crucial step in the ACF-adenoma-carcinoma sequence, in which iNOS might play an important role. The expression of iNOS was in high level and associated with a significant increase in the PCNA-LI, MVD and marked decrease in the AI after transition to dysplastic ACF, adenoma and carcinoma. With the decreased expression of iNOS, AI decreased gradually and was lowest in carcinoma in this process. Several reports suggest that high concentrations of NO and iNOS are cytotoxic and can induce apoptosis^[33]. Because the increased instability of colorectal mucosa in former stages led to the formation of "supper clone" and the micro-environmental changes such as expression of EGF and TGF- α in the tumor tissues^[35,36], epithelial cells maintained at hyperproliferation and increased angiogenesis was present after transition to dysplastic ACF, adenoma and carcinoma. These results elucidate that iNOS might be an important factor of colorectal carcinogenesis by regulating tumor cell apoptosis, proliferation and angiogenesis. What may cause the overexpression of iNOS after transition to dysplastic ACF, adenoma and carcinoma remains unclarified and awaits further study.

Abstract

AIM: To describe distribution of the phosphorothioated antisense oligodeoxynucleotides (PS-asODNs) conjugated to galactosylated poly-L-lysine (Gal-PLL) in mice, and to observe their effects on expression of HBV gene in the 2.2.15 cells and transgenic mice.

METHODS: According to the result of direct sequencing of PCR amplified products, a 16 mer phosphorothioate analogue of the antisense oligodeoxynucleotides (PS-asODNs) directed against the HBV U₅-like region was conjugated to the hepatotropic Gal-PLL molecules. Its distribution was demonstrated using asODNs labeled with ³²P at the 5' terminus with a T4-polynucleotide Kinase. Its inhibition effect on HBV expression was observed in the transfected 2.2.15 cells and transgenic mice.

RESULTS: The Gal-PLL and asODNs could form stable complex at a molar ratio of 2:1. As shown in the HBV-transfected 2.2.15 cells, the inhibition effects of asODNs alone and asODNs conjugated to Gal-PLL, at 10 μmol/L for both, on HBsAg and HBeAg production were different, the former being 70 % and 58 %, respectively, and the latter being 96 % and 82 %, respectively. A more pronounced reduction was also observed in viral DNA load in the culture supernatant for the test with Gal-PLL-asODNs. Among many mouse organs, livers retained more asODNs molecules after administration. The preferential concentration in liver was found to be 52.14 % for Gal-PLL-asODNs, as high as 2.38-fold of that for asODNs (21.9 %). Both elements decreased gradually in liver, with 2.9 % of the former, 5.99 % of the latter retained 24 hours after the administration. The injection interval, therefore, was recommended to be 24 hours. In the transgenic mice, serum HBsAg decreased significantly ($P < 0.01$) at the 12th day after administrating Gal-PLL-asODNs, the serum HBV DNA turned negative in 4 of the 6 mice.

CONCLUSION: Antisense oligodeoxynucleotides conjugated to Gal-PLL can be concentrated in liver and intaked by hepatocytic cells. This may result in specific inhibition of expression and replication of HBV *in vitro* and *in vivo*.

INTRODUCTION

The antisense oligodeoxynucleotides (asODNs) have been demonstrated previously to be effective for inhibition of HBV gene expression and viral replication *in vitro* and *in vivo*, being potential new agents for anti-HBV therapy^[1-4]. However, there are still some hindlers for their potential application. First, their molecules must be water soluble and can penetrate the lipophilic cell membrane. Second, they must be resistant enough to enzymatic degradation to allow their concentration in liver. Third, They must be bound specifically to the target HBV sequence. In the present study, a 16-mer phosphorothioate analogue of the antisense oligonucleotides (PS-asODNs) directed against the HBV U₅-like region was synthesized and then conjugated to hepa tropic galactosylated poly-L-lysine (Gal-PLL). The anti-HBV effects of asODNs and Gal-PLL-asODNs were demonstrated in the 2.2.15 cells and transgenic mice. In addition, distribution of asODNs was studied in mice.

MATERIALS AND METHODS

PCR product sequencing

PCR was conducted using the primer pair P₁/ P₂ in a 50 μl system with the initial denaturation temperature at 94 °C for 4 min, followed by 30 cycles at 94 °C for 30 s, at 55 °C for 30 s and at 72 °C for 40 s. The reaction was for the pre-C and C genes of HBV (ayw1 subtype). The sequence of the PCR primers pair was as follows: P₁: 5' -AAGGTCTTTGTACTAGGAGGC-3' (1 761-1 781); P₂: 5' -TTCCCGATACAGAGCTGAGGC-3' (2 000-2 020). The PCR products were as long as 260 bp and were sequenced using the method given by the Pharmacia T₇ kit.

Cells and cell culture

2.2.15 cell line, human hepatoblastoma Hep G2 cell line stably transfected by HBV genome^[5-7], were cultured in PRMI1640 medium at 37 °C under 5 % CO₂, pH: 7.2-7.4, which contained 15 % fetal calf serum, 2 mmol/L glutamine, 0.1 mu/L penicillin and streptomycin, and 380 mg/L G418 (Sigma).

Preparation of targeting antisense ODNs

A targeting water soluble DNA carrier was prepared by coupling galactose and poly-L-lysine using the method of Schwartz and Gray^[8], with their molar ratio being 10:1. A 16-mer phosphorothioated antisense oligodeoxynucleotide (5' -CATGCCCCAAAGCCAC-3'), corresponding to the nucleotides 1 980-1 905, and complementary to preC/C regions of HBV genome (ayw1 subtype), was synthesized. As a reference molecule, another 16-mer phosphorothioated oligodeoxynucleotide (5' -AGTCACTCAGTCAGTC-3'),

unrelated to the HBV sequence, was prepared. By agarose gel (2.5 %) electrophoresis, conjunctive ratio of Gal-PLL to PS-asODNs was identified^[9].

Anti-viral effect of PS-asODNs in vitro

The 2.2.15 cells were incubated for 60 h, and then were transferred to the medium containing asODNs, HBV-specific Gal-PLL-asODNs, HBV-unrelated Gal-PLL-ODNs, or the medium without any oligodeoxynucleotides. The concentration of ODNs in the media was 10 μ mol/L. 72 h later, the 2.2.15 cells were transferred to the ordinary medium for 72 h, then 200 μ l of supernatant was used for the ELISA reaction for HBsAg and HBeAg, HBV DNA was detected by dot hybridization.

Animals

Kunming mice, (weighing 20 g in average) were used to describe the distribution of asODNs. HBV transgenic mice, were provided by 458 Hospital of PLA in Guangzhou, China, whose expression of HBsAg (126-930 ng/ml) was well documented in the previous studies^[10,11].

Radiolabeling of asODNs

The ³²P-labelling of asODNs was at 5' terminus with T4-polynucleotide kinase (Amersham) in the reaction mixture containing asODNs 6.6 μ g/20 μ l, [γ -³²P] ATP 90 μ l (10 mCi/ml), 10 \times buffer 18 μ l, T4-polynucleotide kinase 9 μ l and deionized water 43 μ l for 1.5 h. The reaction was stopped by adding 9 μ l 0.5M EDTA (pH 8.0). The product was extracted by chloroform and separated using Sephadex-G50. Using the same method, the reaction was carried out twice.

Distribution of as ODNs in Kunming mice

A total number of 24 Kunming mice were equally divided randomly into two groups, one for asODNs and the other for Gal-PLL-asODNs. The labeled asODNs were equally divided into 25 pieces, each piece for 200 μ l, with the radioactivity of 9.42×10^6 cpm. Twelve pieces of asODNs were mixed with Gal-PLL at a molar ratio of 1:2, and were incubated at room temperature for 60 min. Twenty-four pieces of asODNs were administered intravenously via tail vein to 24 mice, respectively. At 2 min, 30 min, 1 h, 4 h, 13 h, 24 h following intravenous administration, 2 animals were sacrificed for each group at each time point, their blood and organs were collected for determination of total radioactivity using liquid scintillation counter.

Anti-HBV effects of Gal-PLL-asODNs in the transgenic mice

Twelve mice, strongly positive for HBsAg and carrying HBV DNA in serum were equally divided into Gal-PLL-asODNs and control groups. Gal-PLL was then mixed with asODNs in a molar ratio of 2:1 at room temperature. The mixture was then administered intravenously via the tail vein in a dose of 15 μ g/g. weight/d of asODNs for successive 12 days. The same volume of saline was used for the control mice by the same means. Blood samples were collected at the venous plexus behind orbital cavity before, or 12 days after the treatment. Sera were separated by incubating at 37 $^{\circ}$ C for 30 min and centrifuged, and stored at -20 $^{\circ}$ C for use. Being diluted at 1:100 with normal saline, the sera were subjected to the ELISA for HBsAg and nested PCR (TakaRa Biotechnology Co.) for viral DNA, with its product being 230 bp in size.

RESULTS

PCR and sequencing of PCR products

Figure 1 shows that the band of PCR product was between the

size of 221-298bp. The sequence of the 132bp product was: 5'-CCAGCACCATGCAACTTTTTCACCTCTGCC-TAATCATCTCTTGTTCATGTCCTACTGTTCAAGCCTCCAA-GCTGTGCCTTGGGTGGCTTTGGGGCATGGACATC-GACCCTTATAAAGAATTTGGAGCTACTG-3'. This was in accordance with the corresponding sequence of HBV genome (ayw1 subtype) which contained the preC region (1 816-1 902), U₅-like sequence (1 857-1 918) and partial poly-A addition signal sequence (1 919-1 962)^[12,13].

Figure 1 Amplification of HBV DNA in the 2.2.15 cells with PCR. The PCR products were resolved on 1.5 % agarose gel. M: Molecule weight marker; A: HBV DNA in 2.2.15 cells.

The complexon of Gal-PLL and asODNs

Gal-PLL at different concentrations was incubated with asODNs, and the proper molar ratio for their binding was assessed by agarose gel electrophoresis. The binding was detectable at the molar ratio of 1:1, and complete at the molar ratio of 2:1 or more (Figure 2).

Figure 2 Analysis of Gal-PLL/asODNs complex formation at different molar ratios. A: Gal-PLL/asODNs=3:1; B: Gal-PLL/asODNs=2:1; C: Gal-PLL/asODNs=1.75:1; D: Gal-PLL/asODNs=1.5:1; E: Gal-PLL/asODNs=1:1; F: Gal-PLL/asODNs=0.5:1; G: Gal-PLL/asODNs=0:1.

Effects of antisense ODNs on HBV gene expression in vitro

As shown in Table 1, after incubation of 2.2.15 cells with asODNs for 8.5 days, the inhibition rates of HBsAg, HbeAg were 70 % and 50 %, respectively, while those with Gal-PLL-asODNs were 96 % and 82 %, respectively. Only slightly negative effects were observed for the reference agent Gal-PLL-ODNs on expression of HBsAg (19 %) and HBeAg (10 %). The Gal-PLL-asODNs treatment was shown to markedly reduce the amount of HBVDNA in the 2.2.15 cells and the culture medium, compared with free asODNs and conjugated HBV-unrelated Gal-PLL-ODNs.

Table 1 Inhibition of asODNs on HBsAg and HBeAg secretion in 2.2.15 cells (P/N values $\bar{x} \pm s$)

Groups	HBsAg	Inhibitory rate (%)	HBeAg	Inhibitory rate (%)
Cell control	9.4 \pm 0.16		15.10 \pm 0.15	
PS-asODNs	4.30 \pm 0.25	70	7.60 \pm 1.10	58
Gal-PLL:PS-asODNs	2.40 \pm 0.26	96	4.50 \pm 0.42	82
Gal-PLL:PS-ODNs	8.10 \pm 0.13	19	13.80 \pm 0.76	10

Distribution of asODNs in mice

Plasma level of asODNs declined rapidly after intravenous administration, with its half-life being approximately 1-2 min, and 7.6 % of asODNs was left in circulation one hour later. Among organs examined, liver retained more asODNs (21.9 %) 30 min after the administration, and the retained molecules decreased gradually, with 2.93 % of them detected 24 hours later. At the time point of 30 min, the retained radioactivity listed in the order of intensity was as following: liver> kidney > lung> heart > spleen> brain (Figure 3).

Figure 3 Distribution of asODNs in Kunming mice ($n=2$).

Figure 4 Distribution of Gal-PLL-asODNs in Kunming mice ($n=2$).

Figure 5 Comparison of the amount retained in liver between asODNs and Gal-PLL-asODNs ($n=2$).

Distribution of Gal-PLL-asODNs in mice

The elimination process of Gal-PLL-asODNs from bloodstream was similar to that of asODNs, with its half-life being 1-2 minutes. Less Gal-PLL-asODNs was shown to be retained in the circulation at the time points of 30 min (8.26 %), 60 min (6.24 %) than asODNs (10.17 % for 30 min, 7.65 % for 60 min) at the corresponding time points. Up to 52.14 % of

Gal-PLL-asODNs was shown to be in liver at the time point of 30 min, and only 5.99 % of the activity was retained in liver 24 hours after its administration. Kidney was the second radioactivity concentrating organ, retaining 5.89 % of injected Gal-PLL-asODNs at the time point of 2 min. The amount in the brain was the smallest (Figure 4). In comparison to that for asODNs, more radioactivity for Gal-PLL-asODNs was retained in liver at each time points (Figure 5). Evidently, Gal-PLL had prompted hepatic intake of asODNs. It might enhance the preferential concentration of agent in liver, with a factor of 8.98-fold to kidney, 42.66-fold to lung, 54.24-fold to spleen. However, there were only few asODNs in liver for both groups 24 hours later (5.99 % and 2.93 %, respectively).

Inhibition of viral protein expression by antisense oligonucleotides in vivo

After treatment for 12 days, serum HBsAg decreased significantly in the Gal-PLL-PSODNs treated group ($P<0.01$); in contrast, no apparent change was detected after treatment with HBV-unrelated Gal-PLL-ODNs (Table 2). In serum HBsAg level, as shown in Figure 6, serum HBV DNA turned negative in 4 of the 6 (66.7 %) Gal-PLL-asODNs treated transgenic mice, but it remained unchanged in the control mice.

Table 2 Change of serum HBsAg (the value of OD) between pretreatment and posttreatment in HBV transgenic mice

Groups	Pieces (n)	Days of therapy	
		Pretreatment	The 12th day
Normal saline	6	1.335 \pm 0.769	1.262 \pm 0.765 ^a
Gal- PLL-asODNs	6	1.608 \pm 0.658	0.733 \pm 0.547 ^b

Note: Matched t test analysis showed that, compared with pretreatment, ^a $P>0.05$; ^b $P<0.01$.

DISCUSSION

The 2.2.15 cells were shown to carry HBV DNA, being a useful model for screening of HBV-specific asODNs. Exonucleases and endonucleases were identified in serum, cells, and other body fluid, both being able to degrade ODNs. Nucleoside modifications may enhance the resistance of ODNs to nuclease digestion. Among them, phosphorothioate oligodeoxynucleotides were found to be more stable in cell culture medium, cells, the cell extraction, serum, tissue and urine. PSODNs, therefore, were used as a drug in this study.

Foreign DNA can be introduced into cells by transfection using several protocols, including electroporation, liposome and calcium phosphate-mediated procedure. In addition, some DNA delivery systems have been designed for binding foreign gene to target cells^[14,15]. The DNA-carrier system consisting

of an asialoglycoprotein (asialoorosomucoid, ASOR) covalently linked to poly-L-lysine has been used as a hepatotropic ligand to bring a foreign gene preferentially to hepatocytes via asialoglycoprotein receptors^[16-23].

For this purpose, Gal-PLL was prepared in this laboratory previously. Its selective affinity to hepatocytes was demonstrated *in vitro*, proposed to be mediated by asialoglycoprotein receptors on hepatocytes membrane^[24-30]. In this study, the optimized molar ratio 2:1 between Gal-PLL and ODNs was estimated to be 2:1, being in agreement with the reported data (17). Gal-PLL was also suggested to be useful as a liver-targeting plasmid DNA carrier *in vivo*^[27, 28, 30, 31]. This was approved in this study.

The distribution of different ODNs *in vivo* may vary with their length and sequence^[32], and this should be clarified before gene therapy. More than a half of asODNs conjugated to Gal-PLL was shown to be retained in liver, being 2.38-fold of that to free asODNs. In order to avoid the possible interference by plasma HBV DNA in HBV infected animal, normal Kunming mice were used to explore the distribution of asODNs *in vivo*.

According to the data presented, Gal-PLL appears to be a more favorable hepatotropic ligand for gene delivery *in vivo* regarding its convenient preparation and stability, as compared to other compounds such as the well characterized tetra-antennary cluster galactoside L₃G₄^[33].

Considering the dynamic of asODNs, free or conjugated to Gal-PLL, asODNs in liver were 2.97 % and 5.99 %, respectively, 24 hrs after administration, the recommended drug injection interval was 24 hours.

In the same condition of experiment, the inhibition rates of HBsAg and HBeAg by asODNs were 70 % and 58 %, respectively, while those of HBsAg and HBeAg by Gal-PLL-asODNs were 96 % and 82 %, These data indicate that asODNs conjugated to Gal-PLL can block HBV gene expression more efficiently *in vitro*.

HBV transgenic mice were proved to be the suitable animal model for screening anti-HBV drugs^[10,11,34,35,36]. In the present study, a pronounced inhibition was observed by Gal-PLL-asODNs treatment. In addition, serum HBVDNA turned negative in 4 of the 6 transgenic mice. These data show the potential application significance of Gal-PLL-asODNs as an anti-HBV agent.

Abstract

AIM: To analyze the amino acid sequences of hypervariable region 1 (HVR1) of HCV isolates in China and to construct a combinatorial chimeric HVR1 protein having a very broad high cross-reactivity.

METHODS: All of the published HVR1 sequences from China were collected and processed with a computer program. Several representative HVR1's sequences were formulated based on a consensus profile and homology within certain subdivision. A few reported HVR1 mimotope sequences were also included for a broader representation. All of them were cloned and expressed in *E.coli*. The cross-reactivity of the purified recombinant HVR1 antigens was tested by ELISA with a panel of sera from HCV infected patients in China. Some of them were further ligated together to form a combinatorial HVR1 chimera.

RESULTS: Altogether 12 HVR1s were selected and expressed in *E.coli* and purified to homogeneity. All of these purified antigens showed some cross-reactivity with sera in a 27 HCV positive panel. Recombinant HVR1s of No. 1, 2, 4, and 8# showing broad cross-reactivities and complementarity with each other, were selected for the ligation elements. The chimera containing these 4 HVR1s was highly expressed in *E.coli*. The purified chimeric antigen could react not only with all the HCV antibody positive sera in the panel but also with 90/91 sera of HCV-infected patients.

CONCLUSION: The chimeric antigen was shown to have a broad cross-reactivity. It may be helpful for solving the problem caused by high variability of HCV, and in the efforts for a novel vaccine against the virus.

INTRODUCTION

Hepatitis C virus (HCV) is a major etiological agent of non-A,

non-B hepatitis worldwide^[1-3], and HVR1, the N-terminal 27 amino acid residues of the putative HCV envelope protein E2, is known as the principal neutralization epitopes up to date^[4-7]. Antibodies to HVR1 in human sera have been shown to block viral attachment to human cell lines *in vitro* and to protect chimpanzees from HCV infection *in vivo*^[8-10]. The HVR1 sequence is highly variable, and is the greatest obstacle for the vaccine development and immune therapy^[11,12]. However, the highly variable HVR1s have been shown to have some cross-reactivities with each other, indicating that a broadly cross-reactive HVR1 peptide or their cocktails are helpful to solving the problem^[13]. Data were accumulated in this study all over the world^[14-17].

In China, HVR1 sequences of different HCV isolates have been reported by many authors, but few studies were on HVR1 cross-reactivity. Integrating the HVR1 sequences reported in China together with some published mimotopes, 12 representative HVR1 sequences were selected using bioinformatics technology. All of the representative HVR1 sequences were cloned and expressed, and their cross-reactivity was studied with a panel of 27 HCV positive sera. Finally we obtained an HVR1 fusion antigen broadly cross-reactive with the HCV-infected sera.

MATERIALS AND METHODS

Human sera

Samples of HCV-infected sera were obtained from blood donor applicants in Beijing Red Cross Blood Center and from chronic HCV-infected patients from 302 Hospital of PLA. All were positive for HCV antibodies using the 2nd-generation ELISA kit. (Ortho Diagnostics, Raritan N.J).

Selection of representative HVR1 sequences

All of the HVR1 sequences published in China were loaded into database and their consensus sequence was obtained by BASIC program according to the frequency of amino acid residues. All of these HVR1 sequences were divided into several groups according to their alignment, and one sequence was chosen as the representative from each group. All of the work above was operated on Goldkey (a molecular biology software developed by our institute). Some HVR1 sequences or mimotopes published were chosen as representative ones for their high cross-reactivity with sera of HCV infected patients from other countries.

Construction of expression plasmid HVR1-1 # to 12

The representative HVR1 sequences were modified considering the *Escherichia coli*'s favorable codon usage. The coding genes were synthesized chemically and to facilitate further ligation, two linkers with a specially designed restriction endonuclease site were incorporated into their N- and C-terminals respectively. The N terminal arm is F1 (5'-gc ctc gag ggt ggt gga tct -3'), The C terminal arm is R1 (5'-gc tct aga acc tcc acc act -3'). The fragments were digested with XhoI and XbaI enzymes and inserted into the expressing plasmid pBVIL1 digested by the same restrictive enzymes. In

the same way, 12 different pBVIL1-HVR1 constructs were prepared and the HVR1 genes were expressed as fusion protein with IL1 β in *E. coli*.

Construction of the chimeric plasmid

According to the cross-reactivity with the HCV antibodies positive sera panel, several HVR1s were chosen to ligate together one by one as illustrated in Figure 1. The plasmid pBVIL1-HVR1-1# (pHVR1#) was chosen as a vector digested by *Xba* I and *Bam*HI, while the plasmid pBVIL1-HVR1-2#, was chosen as the donor of pattern, amplified using constant primer F2 (5' gc act agt ggt ggt gga tct 3') and R2 (5'cg gga tcc tta gga aga cac aaa 3') which annealed to C-terminal of IL1 β . The PCR product was digested with *Spe* I and *Bam*HI, and inserted into the digested vector, pBVIL1-HVR1-1#. Owe to the same cohesive end of the endonuclease *Xba* I and *Spe* I, the digested PCR fragment could accurately linked to the digested plasmid and the new ligated site could be digested by neither of them.

The pBVIL1-HVR1-1+2# had the same enzyme sites with pHVR1# and so it could be used as a new vector and connected with other HVR1 gene fragments. In this way, the pBVIL1-chimeric-HVR1 was constructed to contain four HVR1 genes, HVR1-1#, HVR1-4#, HVR1-6# and HVR1-8#.

Figure 1 Four different HVR1 gene fragments were cloned on pBVIL-1. HVR1-2 gene fragment was ligated with pBVIL-1-HVR1-1 (pHVR1#). The new pHVR1+2 had the same site with pHVR1#, and the HVR1-4# gene fragments could be ligated by the same way. After 3 cycles, the chimera HVR1 plasmid was constructed.

Purification of representative HVR1-1-12# and the chimeric antigen

The plasmids carrying HVR1 fragments were transformed into HB101 as routine, and were examined for their orientation and nucleic acid sequences. The transformed HB101 was grown overnight, diluted 1:20 with fresh LB-medium and further incubated at 37 °C to an OD₆₀₀ of 0.6. After induction for 4 h at 42 °C the bacteria were harvested by centrifugation, and lysed by sonication. All of the recombinant proteins existed in inclusion bodies, and could be dissolved in a solution containing 8 M urea. The recombinant proteins were isolated and purified consecutively by Q-Sepharose-FF and Sephadex G50 chromatography.

ELISA

Microplates were coated with 0.3 µg recombinant HVR1

peptide in 100 mM phosphate buffer (pH7.4) by incubation overnight at 4 °C. The plates were then blocked with the phosphate buffer containing 0.2 % BSA at 4 °C for 3 h, and then incubated with 100 µl of the serum sample 1:10 diluted with a sample buffer (100 mM sodium phosphate buffer, pH7.5 containing 10 % goat serum and 0.05 % Tween) at 37 °C for 1 h. After being washed for five times with 100 mM phosphate buffer (pH7.5) containing 0.05 % Tween, the plates were then incubated for 30 min at 37 °C with 1:25 000 diluted HRP-conjugated monoclonal antibody against human IgG. After washing, the reaction was visualized in the substrate buffer (50 mM sodium phosphate-citric acid buffer, pH5.0 containing 0.4 mg/ml TMB and 0.4 µl/ml of 30 % hydrogen peroxide). The reaction was stopped by adding 50 µl of 2 M sulfuric acid, and the absorbance was measured in a microplates ELISA reader at 450 nm.

RESULTS

Determination of 12 representative peptides

A total number of 123 sequences on HVR1 were reported in China, and the derived consensus profile of them is shown in Figure 2A. Some amino acid residues of HVR1 were shown to be hypervariable, while those at position 385, 389, 406, 409 were conserved. The sequence on first line was defined as CCS (Chinese consensus sequence), whose amino acid residues emerged most frequently. CCS was chosen as the first representative sequence, named HVR1-1#, being different at some positions from Puntoriero's consensus sequence^[13] (Figure 2B). The homology of the 123 sequences was analyzed using the Goldkey software, and divided into 6 groups, HVR1-2 to 7# according to their alignment to CCS. In this way 6 sequences named were obtained. HVR1-8# 9# were from GenBank (L19383, S24080), both being broadly cross-reactive with mice sera induced by mimotopes. HVR1-10# and 11# were sequences for the mimotope R9 and M122 respectively (Puntoriero *et al.*, 1998), and HVR1-12# reported by Watanabe^[14].

Figure 2 Derivation of the Chinese consensus sequence. (A) Consensus pattern of the 123 natural variants of the HCV HVR1 sequence used in this work. Shaded residues accounted alone for 80 % of the observed frequency. Residues were listed in decreasing order of observed frequency from top to bottom. The first line was Chinese consensus sequence (CCS). (B) The Chinese consensus sequence (upper) was different with Puntoriero's (lower). Dashes indicate residues identical to the upper line.

Reactivity of representative peptide with sera of panel I

Twelve representative HVR1 gene as shown in Figure 3, were expressed in *E. coli* fused with human IL-1 β . The HVR1/IL-1 β fusion protein migrated at the expected position of about 21 kD (Figure 4). Twenty-seven HCV patients' sera were used as panel I to show the cross-reactivities of 12 representative HVR1 by ELISA. As shown in Figure 5, all of the HVR1 peptide reacted with more than one serum. No reactivity was detected to IL-1 β in sera of panel I, and none of the anti-HCV negative sera reacted with the 12 recombinant peptides. The most broadly cross-reactive HVR1 was HVR1-11#, and the Chinese consensus sequence (CCS) which showed a higher cross-reactivity too.

We took HVR1-1,2,4,8# as components for the best cocktail, because these 4 HVR1 peptides showed complementary reactivities to the sera in panel I, as showed in Figure 5. There overall cross-reactivity was found to be 25/27.

Figure 3 The amino acid sequence of 12 representative HVR1 sequences. Amino acid residues were indicated by standard single-letter codes.

Figure 4 The Coomassie stain after SDS-PAGE of 12 purified representative and chimera HVR1 antigen. M. marker; 1-12. 12 purified representative HVR1 antigen; 13. chimera HVR1 antigen.

Reactivity of chimera HVR1 antigen with panel I and panel II
HVR1-1#, 2#, 4# and 8# were ligated one by one in tandem within plasmid pBVIL1. The chimeric protein was expressed in HB101 and further purified (Figure 4).

As expected, a broader reactive spectrum was observed for the chimeric HVR1 antigen. It was shown to be reactive with all of the sera of panel I, including sera 73# and 39# which were not reactive with any single HVR1 (Figure 5). For more data 91 sera from HCV-infected patients were also used for the assay as panel II, with 90 reactive with chimera antigen (Table 1). The data indicated that application of the chimera protein helped to acquire a higher cross-reactivity.

Table 1 Reactivity of F4HVR1 with another panel (91 sera of HCV infected patient)

OD difference between sera and co	No. of reactive sera	The adding up percent of total sera
>2.0	56	61.5
1.5~2.0	14	76.9
1.0~1.5	13	91.2
0.5~1.0	6	97.8
0.371	1	98
0.065	1	

The cutoff of the ELISA was as defined in Figure 5.

DISCUSSION

HVR1, which contains a principal neutralization epitope in HCV, is important for the development of HCV vaccine^[4-7]. Due to the high mutation rate of HVR1, there are now hundreds of HVR1 isolates reported, presenting a great obstacle for HCV vaccine development^[18-21]. It was suggested that to select a highly cross-reactive HVR1 antigen could solve the variability problem^[22-27], thus highlighted the importance to study the cross-reactivity of HVR1.

Most of the work about the cross-reactivity of HVR1 focused on single HVR1 antigen. However we think the cross-reactivity of single HVR1 is limited. Recently, multi-epitope chimeric antigen was used to improve the sensitivity of HCV immunoassay reagents^[28,29]. Here we provided evidence for enhancing the cross-reactivity by constructing a chimeric antigen that incorporates several representative HVR1 peptides.

Considering geographical variation of HVR1^[30-33], we gave

Figure 5 Reaction of the 12 representative HVR1s and chimera HVR1 antigen (C) with 27 sera from HCV-infected patients. HVR1 names are indicated at the left of each column. For each serum (indicated on the bottom of each column) average values (A450) have been determined from two independent experiments. The mean of 10 sera from non-infected individuals plus 4SD defined the cutoff (co). Results were expressed as the difference between the average value of the HCV antibody positive sera and co. Strong positive values (>0.5) are indicated in black. And weak positive values are indicated in grey (0.15-0.5).

priority to Chinese sequence when we selected representative HVR1 sequences. The differences between CCS and Puntoriero's suggest the HVR1 variant found in China differs to a certain extent from what occurred elsewhere^[14]. The chimeric antigen contains 3 representative HVR1 sequences coming from China, and showed broad cross-reactivity with sera of the HCV-infected patients.

The reported HVR1 antigen or mimotope could cross-react with no more than 80 % of sera containing HCV antibodies^[22-27]. Chimeric HVR1 antigen could cross-react with 90/91 (98 %) of tested sera. The results also suggested that most of HCV infected patients could generate some antibodies against HVR1. The possible association between HVR1 antibody and the self-limiting course of HCV infection and a more favorable response to interferon^[34-40], remains to be evaluated in the following study.

Evidently, the reaction spectrum of the chimera HVR1 antigen include the total cross-reactivity of the representative HVR1 antigen contained. Interestingly, the chimera HVR1 antigen could react with sera 73# and 39#, which are not definitely reactive with any of the four representative HVR1. In our consideration, those samples might react with some of the representative HVR1 used for ligation, but reactions are too weak to be detected. The OD value would be elevated when 4 HVR1 is added up together.

In this study, we used a prepared chimeric antigen instead of synthetic peptides^[41-43]. The antigen may also be used in the study for the HCV vaccine. In addition, the chimeric antigen is fused with IL-1 β . The latter part contains a nano-peptide sequence. It may act as an immune adjuvant^[44-46], promoting a strong immune response when injected.

In summary, the chimeric HVR1 antigen, containing several representative HVR1 fragments, can show very high cross-reactivity, which may be helpful to overcome the variability of HCV. The chimeric HVR1 antigen is of potential application for HCV vaccination and immune therapy.

Abstract

AIM: To investigate the responses of TT virus (TTV) and hepatitis B virus (HBV) to a long-term lamivudine therapy.

METHODS: Sixteen patients infected with both TTV and HBV were treated with lamivudine 100 mg daily for 30 months. Blood samples were drawn at the beginning of the therapy and subsequently at month 3, 6, 9, 12 and 30. Serum TTV was quantified by real time PCR and serum HBV was detected by hybridization assay and nested polymerase chain reaction.

RESULTS: TTV infection was detected in 100 % of HBV-infected patients. Loss of serum TTV DNA after one year of treatment occurred in 1/16 (6 %) patients. At the end of therapy, TTV DNA was positive in 94 % of them. The decline of HBV viremia was evident at 3 months after therapy and the response rate was 31 %, 44 %, 63 %, 50 % and 50 % at month 3, 6, 9, 12 and 30, respectively.

CONCLUSION: TTV replication is not sensitive to lamivudine and is highly prevalent in HBV-infected patients.

INTRODUCTION

TT virus (TTV) was recently discovered in a patient with post-transfusional hepatitis of unknown etiology^[1]. Its genome is a circular, single-stranded DNA of negative polarity, which shares similarities with the members of the Circoviridae family^[2]. In contrast to DNA viruses, TTV isolates exhibit a high level of genetic heterogeneity^[3]. TTV presents an extreme diffusion of active infection throughout the world^[4]. Its presence in blood products could indicate that TTV can be transmitted through transfusion^[5]. Although it has been proposed that TT virus might be responsible for the small

proportion of acute and chronic forms of hepatitis that still remain unsolved, no other illness has yet been attributed to the virus.

Hepatitis B virus (HBV) causes transient and chronic infections of the liver, which may progress to cirrhosis and eventually to hepatocellular carcinoma (HCC)^[6]. Interferon (IFN)-alpha is the only approved drug for the treatment of chronic HBV infection, but the recent registration of lamivudine, a dideoxycytidine analogue that inhibits both the HIV and HBV reverse transcriptases, has provided new perspectives for the treatment of chronic HBV infection^[7, 8]. Coinfection of TTV and HBV is commonly seen because both viruses share the same transmission routes such as blood transfusion^[9]. In previous studies, IFN therapy has been reported effective against TTV^[10], but the possible susceptibility of the virus to lamivudine treatment has not yet been investigated. Thus, the aims of this study were: (1) to know the impact of TTV in patients with chronic hepatitis B; (2) to investigate the response of TTV to lamivudine therapy; and (3) to evaluate whether the outcome of long term lamivudine therapy in chronic hepatitis B is influenced by a TTV coinfection.

MATERIALS AND METHODS

Patients

The study group consisted of 16 patients (12 males and 4 females; mean age: 52.62 years; range: 33 and 66 years) with chronic dual HBV and TTV infection. The diagnosis of chronic hepatitis was made on the basis of clinical and histological results. Patients included 15 cases of liver cirrhosis and 1 hepatocarcinoma. In 9 patients the transmission route was unknown, 2 had a history of blood transfusion, 2 developed HBV infection after liver transplantation, 1 had primary biliary cirrhosis and 2 were addicts to alcohol. At the beginning of the therapy, all patients were positive to HBV DNA by solution hybridization assay and had elevated alanine aminotransferase (ALT) levels that were 3 times of the upper normal limit (normal range: 5-45 IU/L). Nine patients were hepatitis B e antigen (HBeAg) positive, 5 had antibodies against HBeAg (anti-HBe) and 2 patients were negative to both HBeAg and anti-HBe.

Ten patients underwent liver transplantation; 8 of them for HBV-related liver cirrhosis. The remaining 2 patients without evidence of HBV infection before allograft developed a *de novo* post-transplant HBV infection.

Lamivudine (Glaxo Wellcome, UK) was given orally to all patients at a dose of 100 mg daily for 30 months. Blood samples were taken at the baseline time and subsequently were obtained at month 3, 6, 9, 12 and 30. To evaluate the effects of lamivudine, levels of ALT, TTV DNA and HBV DNA and viral serological markers were evaluated at each time. HBV complete responders to lamivudine therapy were defined as patients showing clearance of serum HBV DNA by nested polymerase chain reaction (PCR) and normal ALT levels at 30 months of treatment. All patients gave written informed consent before the enrollment in the study, which was approved by the ethics committees of the hospital.

Detection and quantification of TTV DNA

TTV DNA quantification was carried out with a real time PCR by the SYBR Green approach using primers targeting the untranslated region (UTR) of the viral genome: forward primer T801: 5' -GCTACGTCACCTAACCACG-3', position 6 to 25; reverse primer T935: 5' -CTGCGGTGTGTAACTCACC-3', position 185 to 204^[11]. Total DNA was purified from 200 µl of serum using the High Pure Viral Nucleic Acid Kit (Roche Diagnostic, Mannheim, Germany) and eluted in a final volume of 50 µl. Real time PCR was done using 2 µl of the eluted DNA with 0.2 µM of each primer in 23 µl 2×SYBR Green PCR mix (Qiagen). The cycling conditions were: 95 °C for 10 min to activate the DNA polymerase followed by 45 cycles of amplification: 95 °C for 15 sec, 62 °C for 30 sec and 72 °C for 30 sec.

HBV markers

Hepatitis B surface antigen (HBsAg), hepatitis B e antigen (HBeAg) and antibodies to HBsAg, HBeAg and hepatitis B c antigen (HBcAg) were determined by immunoassay (EIA; Abbott Laboratories, N Chicago, IL). Serum HBV DNA levels at the beginning of lamivudine therapy were quantified using Abbott hybridization assay. Viral DNA during the following time points was detected by nested PCR^[12].

Statistical analysis

Statistical analysis was performed using Student's *t* test. Data were analyzed with the computer program SPSS (SPSS Inc., Chicago, IL, USA). A probability (*P*) value of less than 0.05 was considered statistically significant.

RESULTS

Detection and response of TTV to lamivudine therapy

Sixteen patients doubly infected with TTV and HBV were monitored for levels of both viruses in serum, at selected time points, during the lamivudine treatment by real time and nested PCR methodology, respectively. Of the 16 patients, serum TTV DNA could be detected in all of them by real time PCR at the beginning of lamivudine therapy, with TTV values that ranged between 8.7×10^3 to 1.9×10^8 genomes per ml of serum (mean: 5.7×10^8 genomes/ml). After 30 months of lamivudine treatment, 15/16 patients (94 %) still had TTV DNA in serum and TTV values ranged between 3×10^4 to 4.2×10^8 genomes per ml of serum (mean: 4.3×10^7 genomes/ml). The patient who became negative to TTV DNA lost this marker after 12 months of treatment and he still remained TTV DNA negative until the end of therapy. The TTV DNA value of this patient at baseline time point was 8×10^4 viral genomes per ml of serum. However, this patient did not respond to the lamivudine therapy and he was serum HBV DNA positive at each time point. With respect to the 15 positive TTV DNA patients, at the end of the treatment and relative to baseline levels, 1 patient (7 %) showed unchanged serum TTV DNA levels, 6 patients (40 %) had 6 times of reduction of serum TTV load and 8 cases (53 %) presented 8 times of increase of the levels of TTV DNA in serum.

Changes in serum TTV DNA concentration with respect to HBV non-responsive and responsive patients to lamivudine treatment were also analyzed. It was found that there was no statistically significant difference when basal and final serum samples were compared between both groups (Table 1) or when basal and final serum samples were compared in the same group (Table 2).

Finally, serum TTV DNA values in patients with or without liver transplants were evaluated as well. Once again, there were not significant differences when baseline and final serum

samples were compared between non-transplanted and transplanted patients (Table 3) or when baseline and final serum samples were compared between non-transplanted or transplanted patients (Table 4).

Table 1 Comparison of serum TTV DNA concentration changes before treatment and at the end of treatment

	Non-responders (n=7)	Responders (n=8)	P ^a
Before treatment	4.6×10^7	8.0×10^7	0.66
End of treatment	1.1×10^8	3.4×10^7	0.29

TTV DNA concentration was expressed as viral genomes/ml of serum. ^aStudent's *t*-test, HBV non-responsive patients vs. responsive patients to lamivudine therapy.

Table 4 Changes in TTV DNA concentration in non-transplanted and transplanted patients

	Before treatment	End of treatment	P ^a
Non-transplanted (n=5)	1.2×10^7	8.8×10^6	0.59
Transplanted (n=10)	8.9×10^7	1.0×10^8	0.87

TTV DNA concentration was expressed as viral genomes/ml of serum. ^aStudent's *t*-test, before vs at the end of treatment.

HBV response to lamivudine treatment

At the baseline time point, HBV DNA values ranged between 4.2×10^9 and 8.4×10^{11} DNA genomes per ml of serum (mean: 1.2×10^{11} genomes/ml). The decline of HBV viremia was clearly evident at month 3 after therapy and the response rate was 31 %, 44 %, 63 %, 50 % and 50 % at month 3, 6, 9, 12 and 30, respectively. When compared between responsive and non-responsive patients, the responders had almost 4 times the value of the non-responder ones but the difference was not significant (2.6×10^{11} vs 7×10^{10} genomes per ml of serum, respectively). Also, there was no significant difference in baseline of ALT levels between responsive and non-responsive patients (117 IU/L vs. 123 IU/L, respectively). However, differences were statistically significant in post-treatment ALT levels between responsive and non-responsive patients (37 IU/L vs 128 IU/L, respectively; *P*=0.03). Of the 5 HBeAg positive patients, 2 seroconverted to anti-HBe by month 12. The other 3 patients still remained HBeAg positive after 30 months of lamivudine therapy. In the 2 HBeAg and anti-HBe negative patients, they

developed anti-HBe by month 3.

With respect to the 10 liver transplant recipients, 4 patients (40 %) started to receive lamivudine treatment after recurrent allograft re-infection. In these cases, serum HBV DNA was still detectable after 30 months of therapy. However, in those 6 patients who started lamivudine administration before liver transplantation as a prophylaxis regimen, 5 (50 %) lost viral DNA at month 3 of treatment, and then they underwent liver allograft and remained HBV DNA negative throughout the therapy. By contrast, the remaining patient developed a recurrent HBV infection at month 6 of post-transplant.

DISCUSSION

Since TTV was discovered a few years ago, many studies have been done trying to assess whether it causes liver disease; however, there is still a poor understanding of its molecular properties and pathogenic potential.

This study shows, in agreement with other groups, that TTV infection is chronic and characterized by the continued presence of high virus loads in serum with wide variations ranging between 10^3 and 10^8 genomes per ml^[13, 14]. Over a period of 30 months, 96 % of the patients presented high TTV DNA levels; however, in some individuals, viremia levels fluctuated extensively while they remained essentially constant in others.

Different epidemiological studies have clearly indicated that TTV can behave as a transmissible blood-borne virus sharing common transmission routes with the hepatitis viruses. Then, coinfection of TTV is frequently observed in patients with chronic hepatitis B^[9]. One important finding in our study is that 100 % of patients infected with HBV were TTV DNA-positive by real-time PCR. These results suggest that the prevalence of TTV infection is very high in the HBV-infected population. However, our results are in disagreement with other studies that reported TTV DNA rates between 15 % and 36 %^[15-17]. One explanation for this result might be due to the different primers used for the detection of TTV DNA; we used a set of primers that already showed 92 % positivity to TTV in healthy adults in Japan^[11]. Another possible explanation why these patients were TTV positive is their histological status: 94 % of them presented cirrhosis. A TTV well-recognized feature is that TTV infection is chronic and tends to last many years, so it could be that TTV infection is more prevalent in patients with advanced HBV-associated liver disease than in those with stable disease.

However, the most novel and interesting information that emerged from this study is that lamivudine treatment in a regimen of 100 mg daily and for a period of 30 months did not inhibit TTV replication in patients coinfecting with HBV and TTV. Only one individual (6 %) of the 16 patients enrolled in the study became serum TTV DNA negative after 12 months of therapy. This observation could suggest that this patient lost TTV in a spontaneous way and not by effect of lamivudine on TTV replication.

With respect to the effect of lamivudine treatment of chronic hepatitis B, this study confirms earlier reports where HBV infection responded positively to lamivudine treatment^[18-20]. The response of HBV to lamivudine treatment was not affected with the concurrent TTV infection. This observation can be explained by two reasons. Firstly, the changes observed in ALT values during the lamivudine treatment period were correlated with the change of HBV DNA in chronic hepatitis B; it seemed that ALT dynamic was unrelated to TTV viremia. Secondly, TTV viremia was not related to different HBV DNA levels, so TTV did not seem to interfere with HBV replication. Thus, in agreement with many other published studies, TTV may lack clinical association with liver disease in these patients^[21, 22].

Finally, it has been suggested a relationship between an

increased TTV viral load and host immunological disorders^[23]. In immunosuppressed patients, such as recipients of liver transplants, TTV viremia could be higher than that in individuals without liver allografts. However, we did not find any significant difference in TTV viral load when both groups were compared, even if transplanted patients had always higher TTV titers. Based on our results it seems that immune system is not involved in elevated TTV viremia in HBV patients, although more extensive studies need to be performed to prove this hypothesis.

In conclusion, during the lamivudine therapy for chronic hepatitis B, disappearance of TTV does not occur in the majority of the HBV-infected patients which supports the interpretation that lamivudine does not inhibit TTV replication. Moreover, this study shows the highly prevalence of TTV infection in patients with chronic hepatitis B, but without any effect on the course of HBV infection.

Abstract

AIM: To determine the prevalence of antralization at the edge of proximal gastric ulcers, and the effect of *H. pylori* eradication on the mucosal appearances.

METHODS: Biopsies were taken from the antrum, body and the ulcer edge of patients with benign proximal gastric ulcers before and one year after treatment. Gastric mucosa was classified as antral, transitional or body type. *H. pylori* positive patients received either triple therapy, or omeprazole.

RESULTS: Patients with index ulcers in the incisura, body or fundus ($n=116$) were analyzed. Antral-type mucosa was more prevalent at the ulcer edge in *H. pylori*-positive patients than *H. pylori*-negative patients (93 % vs 60 %, OR=8.95, 95 %CI: 2.47-32.4, $P=0.001$). At one year, there was a significant reduction in the prevalence of antralization (from 93 % to 61 %, $P=0.004$) at the ulcer edge in patients with *H. pylori* being eradicated. However, there was no difference in the prevalence of antralization at the ulcer edge in those with persistent infection.

CONCLUSION: *H. pylori* infection is associated with antralization at the edge of proximal gastric ulcers, which may be reversible in some patients after eradication of the infection.

INTRODUCTION

Peptic ulcer disease is common, and is associated with considerable mortality due to complications such as bleeding

and perforation^[1]. *H. pylori* infection is now recognized to be a major cause for peptic ulcer, accounting for up to 90 % of duodenal ulcer cases and 80 % of gastric ulcer cases, with the use of non-steroidal anti-inflammatory drugs being another major cause^[2-4]. While gastric metaplasia in duodenum has been identified to be an important morphopathological change in the development of *H. pylori*-associated duodenal and prepyloric ulcer^[5-7], the mucosal morpho-pathogenesis of gastric ulcer, which occurs predominantly along the body-antrum transitional zone (particularly at the gastric incisura), remains unclear. Previous studies have observed a stem-cell-derived "ulcer-associated cell lineage" (UACL) at the sites of chronic gastrointestinal ulceration, commonly found in the borders of Crohn's ulcers in small bowel, and in gastroduodenal ulceration^[8-11]. In the literature, UACL was usually described as pseudopyloric (or pyloric) metaplasia, because it has morphological similarities to pyloric glands^[8, 9], and similar changes can occur in other tissues, such as gall bladder, bile ducts, and pancreatic ducts, often associated with malignant transformation of these tissues^[12-16]. In the stomach, pseudopyloric metaplasia is specifically defined as a replacement of specialized glands by mucous-secreting glands in the gastric body or at the body-antrum junction^[17], a concept identical to "antralization" as described in our previous studies^[18, 19].

In a previous study, we have demonstrated that in the absence of *H. pylori* infection, the gastric incisura mucosa belongs to either body-type or transitional type in most (82 %) individuals, suggesting that normal incisura mucosa is histologically distinct from the antral mucosa, but more homologous to the body and fundus mucosa^[18]. However, *H. pylori* infection is associated with the presence of antral (pyloric)-type mucosa in the proximal stomach (i.e. gastric incisura, body and fundus), indicating that *H. pylori* infection may be a causal factor for antralization of the proximal stomach^[18]. Thus, it is conceivable that *H. pylori*-induced antralization may play an important pathogenic role in proximal gastric ulceration, and eradication of *H. pylori* infection may reverse antralization to normal transitional or body type mucosa, and thus reduce the risk for ulcer relapse. Therefore, the present study was carried out to determine the prevalence of antralization at the edge of proximal gastric ulcer in relation to *H. pylori* infection, and the effect of *H. pylori* eradication on the mucosal appearances.

MATERIALS AND METHODS

Patients

One hundred and sixteen patients with newly diagnosed uncomplicated benign-looking proximal gastric ulcers (>5 mm in diameter and >1 mm in depth) at the Endoscopy Unit of Department of Medicine, Queen Mary Hospital were included in the study. The location of gastric ulcers and demographic and clinical characteristics of these patients were summarized in Table 1. Exclusion criteria at entry included patients who had been taking aspirin or non-steroidal anti-inflammatory drugs (NSAIDs) over the past year, or taking antibiotics, H_2 receptor blockers, bismuth or proton pump inhibitors in the

preceding 4 weeks, patients with previous gastric surgery, and those with a histological diagnosis of gastric carcinoma or lymphoma.

Informed written consent was obtained from all patients who participated in the trial. This project was approved by the Ethics Committee of the University of Hong Kong.

Table 1 The demographic clinical characteristics of the patients initially recruited, according to the location of gastric ulcers ($n=116$)

	Ulcer location		
	Incisura ($n=91$)	Body ($n=23$)	Fundus ($n=2$)
Age (mean \pm SD)	59.5 \pm 13.3	69.3 \pm 10.2	51.0 \pm 11.2
Gender (male/female)	60/31	17/6	2/0
Smoking (yes/no)	44/46	11/12	1/1
<i>H. pylori</i> status (positive/negative)	81/10	19/4	1/1

Diagnosis of *H. pylori* infection

During the first endoscopy, three biopsies were taken at the gastric antrum within 3 cm of the pylorus at the lesser curvature, two at the midway between the pylorus and cardioesophageal junction at the greater curvature, and four from the edge of gastric ulcer. When the ulcer was present in the body, the body biopsies were taken at least 3 cm apart from the ulcer. One antral biopsy was used for a rapid urease test (RUT) and the rest were sent for the detection of *H. pylori* infection and histological examination after haematoxylin & eosin (H&E) staining. All patients then received a ^{13}C -urea breath test following a standard protocol measured by an isotope ratio mass spectrometer^[20]. The definition of *H. pylori* infection in this study required that at least two of the three tests (the RUT, histology and ^{13}C -urea breath test) were positive. The absence of *H. pylori* infection required all three tests to be negative. This definition was used as the "gold standard" in this study.

Histological examination

Slides were read by experienced pathologists who were blinded to all clinical and endoscopic information, including the RUT results. The mucosa of gastric biopsies taken from different sites was classified as antral (mucous-secreting or pyloric) type, body (acid-secreting or oxyntic) type or transitional (junctional) type according to the definitions set out in the updated Sydney system^[21]. The characteristic feature of antral-type mucosa was the presence of coiled and branching antral glands, which were lined by mucus cells that were interspersed with endocrine cells (chiefly G and D types), and a few parietal cells. The glands in body-type mucosa were straight tubes that constituted acid-producing parietal cells along with scattered mucus cells in their upper portion and mainly chief cells in their lower portion, with scattered argyrophilic endocrine cells. Transitional type mucosa was a mixture of the architectural features and cell types found in the antral and body type mucosae^[21].

Treatment and endoscopy at one year

One hundred and one patients received triple therapy consisting of clarithromycin 250 mg, metronidazole 300 mg each given 4 times daily for 2 weeks and sucralfate 1 gm 4 times daily for 4 weeks ($n=54$), or acid suppression therapy consisting of omeprazole 20 mg daily for one year ($n=47$). Successful eradication was indicated if the rapid urease test, histological examination by H&E and Giemsa staining and ^{13}C -urea breath test were all negative at week 6 after treatment. 65 patients (male/female 44/21, age (mean \pm SD) 61.9 \pm 11.0 years) received either triple therapy ($n=28$), or omeprazole ($n=37$), with ulcers

completely healed at 12 weeks. Upper endoscopy and ^{13}C -urea breath test were repeated at month 12. Gastric biopsies were obtained from the antrum, body and ulcer site (visible scar area in 47 of 53 (90.6 %) cases with a healed ulcer) or the edge of ulcer in 12 patients with relapsed ulcers, and assessed as described above. Successful eradication was indicated if the rapid urease test, histological examination by H&E and Giemsa staining and ^{13}C -urea breath test were all negative at week 6 or month 12 after treatment. The histological characteristics of these biopsies were compared with those biopsies taken at the first endoscopy. Histological improvement of gastric mucosa over the period of one year was defined as changes from antral to transitional or body, or from transitional to body-type, whereas worsening of gastric mucosa was defined as changes from body to transitional or antral, or from transitional to antral-type. An upper endoscopy and a ^{13}C -urea breath test were repeated at month 12 for 65 patients (male/female 44/21, age (mean \pm SD) 61.9 \pm 11.0 years) who had their ulcers completely healed 12 weeks after treatment. Gastric biopsies were obtained from the antrum, body and ulcer site (visible scar area) in 47 of 53 (90.6 %) cases with a healed ulcer or the edge of ulcer in 12 patients with relapsed ulcers, and assessed as described above. The histological characteristics of these biopsies were compared with those biopsies taken at the first endoscopy. Histological improvement of gastric mucosa over the period of one year was defined as changes from antral to transitional or body, or from transitional to body-type, whereas worsening of gastric mucosa was defined as changes from body to transitional or antral, or from transitional to antral-type.

Statistical analysis

The Chi-squared test (with Yates' correction if required), the Fisher's exact test or McNemar test was used for categorical variables, and odds ratios (OR) and 95 % confidence interval (CI) were estimated where appropriate. All tests were carried out using the SPSS system (version 10.0, SPSS Inc. Chicago, Illinois, USA). All *P* values calculated were two-tailed. The alpha level of significance was set at $P<0.05$.

RESULTS

The presence of antral-type mucosa in the gastric body and at the edge of proximal gastric ulcers

Of the 116 patients, 91 had the index ulcers at the incisura, 23 in the body and 2 in the fundus. Of these, 101 were *H. pylori*-positive and 15 were *H. pylori*-negative. All biopsies taken from the antrum showed antral-type mucosa. Overall, antral-type mucosa was present in the gastric body in 6 (5.2 %) patients and at the edge of proximal gastric ulcers in 103 (88.8 %) patients. Of *H. pylori*-positive patients 6 (5.9 %) had antral-type mucosa and 4 (4 %) had transitional type mucosa whereas all (100 %) of *H. pylori*-negative patients had body-type mucosa at the gastric body. Antral-type mucosa was present at the edge of proximal gastric ulcers in 93.1 % (94/101) of *H. pylori*-positive patients and 60 % (9/15) of *H. pylori*-negative patients (OR=8.95, 95 % CI: 2.47-32.4, $\chi^2=14.35$, $P=0.001$) (Figure 1). In *H. pylori*-positive patients, 81 had ulcers at the incisura, 19 at the body and one at the fundus. In the presence of *H. pylori* infection, there was no difference in the prevalence of antral-type mucosa at the ulcer edge at different gastric sites: 92.6 % (75/81) at the incisura, 94.7 % (18/19) at the body and 100 % (1/1) at the fundus. In *H. pylori*-negative patients, antral-type mucosa was present at the edges of ulcers in 70 % (7/10), 50 % (2/4) and 0 % (0/1) of patients when the ulcer occurred at the incisura, body and fundus, respectively.

Changes of gastric mucosa in the gastric body and at the edge of proximal gastric ulcers at one year

Of the 65 patients who were followed up for one year, 28 had *H. pylori* infection eradicated and 27 had persistent infection. Of the 12 patients with ulcers relapse, one (3.6 %) was from patients in whom *H. pylori* infection was eradicated and 11 (29.7 %) were from those with persistent infection (OR=11.4, 95 % CI: 1.38-94.9, $\chi^2=5.61$, $P=0.018$).

There was a significant reduction in the prevalence of antral-type mucosa at both the gastric body (from 7.1 % to 0 %) and the gastric ulcer sites (from 92.9 % to 60.7 %, $P=0.004$, McNemar test) in patients in whom *H. pylori* infection was eradicated. However, there was no difference in the prevalence of antral-type mucosa when *H. pylori* infection was persistent (Figure 2).

Figure 1 Prevalence of antral-type mucosa at the edge of proximal gastric ulcers and non-ulcerated gastric body in *H. pylori*-positive patients (*H. pylori*+, $n=101$) and those without *H. pylori* infection (*H. pylori*-, $n=15$).

Figure 2 Presence of antral-type mucosa at the edge of proximal gastric ulcers and non-ulcerated gastric body in patients with *H. pylori* eradicated ($n=28$) and in those with persistent infection ($n=37$) before (month 0) and 12 months after treatment.

Table 2 Changes of gastric mucosa at the edge of proximal gastric ulcers and gastric body one year after treatment, in relation to post-treatment *H. pylori* status, treatment regimens, ulcer relapse and ulcer location ($n=65$)

	Mucosal type change (%)					
	Ulcer edge			Gastric body		
	Improvement ^a ($n=11$)	No change ^b ($n=49$)	Worsening ^c ($n=5$)	Improvement ($n=5$)	No change ($n=58$)	Worsening ($n=2$)
<i>H. pylori</i> infection						
Eradicated ($n=28$)	35.7 ^d	64.3	0	14.3	85.7	0
Persistent ($n=37$)	2.7	83.8	13.5	2.7	91.9	5.4

Incisura ($n=52$)	15.4	76.9	7.7	5.8	90.4	3.8
Body ($n=13$)	23.1	69.2	7.7	15.4	84.6	0

^a, Improvement, antral-type (A)→transitional type (T), A→body-type (B), or T→B; ^b, No change, A→A, T→T or B→B; ^c, Worsening, T→A, B→A or B→T. ^d, $P<0.001$, compared with persistent infection.

Figure 3 Gastric mucosa at the ulcer edge before and after eradication of *H. pylori* infection in the same patient. A, biopsy of the ulcer edge before *H. pylori* eradication showing antral-type gastric mucosa with severe active chronic inflammation; B, biopsy of the healed ulcer site after *H. pylori* eradication showing body-type gastric mucosa with presence of parietal and chief cells in the gastric glands and mild residual chronic inflammation. Haematoxylin & eosin (H&E) staining $\times 250$.

Histological improvement of gastric mucosa was observed in 14 (21.5 %) patients; 3 at the gastric body, 9 at the ulcer site and 2 at both sites (Figure 3). Histological improvement of gastric mucosa at the ulcer sites was more common in patients in whom *H. pylori* was eradicated than those with persistent infection (35.7 % vs 2.7 %, OR=20.0, 95 % CI: 2.37-168.6, $\chi^2=12.35$, $P<0.001$) (Table 2). When patients with relapsed ulcers were excluded, the association remained unchanged (37.0 % vs 3.8 %, OR=14.71, 95 % CI: 1.72-125.7, $\chi^2=8.87$, $P=0.003$). Similarly, triple therapy was associated with a higher rate of histological improvement at the ulcer site, compared to omeprazole treatment (31.0 % vs 5.6 %, OR=7.65, 95 % CI: 1.50-39.0, $\chi^2=5.72$, $P=0.017$). Gastric mucosa at the ulcer site was improved in more patients with cured ulcers than those

with relapsed ulcers, although the difference did not reach statistical significance (20.8 % vs 0 %, $P=0.109$). There was no difference in histological improvement between patients with ulcers at the body/fundus and those with ulcers at the incisura (23.1 % vs 15.4 %, $OR=1.65$, 95 % $CI: 0.37-7.35$, $P=0.804$) (Table 2). Age and gender were not associated with histological improvement (data not shown).

Overall, 7 (10.8 %) patients had worsened histology after treatment; 5 at the ulcer edge and the other 2 at the gastric body (Table 2). All of these patients had persistent *H. pylori* infection; 6 were treated with omeprazole and one with triple therapy. 3 (75 %) of these patients had ulcer relapsed.

DISCUSSION

In the present study, approximately 90 % of patients with proximal gastric ulcers had antral-type mucosa at the ulcer edge, and *H. pylori* infection was associated with a higher prevalence of antralization in the proximal gastric ulceration. Moreover, eradication of *H. pylori* infection resulted in histological improvement at the ulcer edge of 36 % of patients in 12 months, whereas the persistence of the infection was accompanied by worsening of histology (14 %). These findings suggest that *H. pylori* infection contributes to antralization, which may, in turn, play an important role in gastric ulceration.

H. pylori-associated antralization is believed to be a consequence of direct insults of chronic *H. pylori* infection, as a host defense and reparative response to the mucosal damage caused by organisms. As demonstrated in our previous study and in the present study, *H. pylori* infection is associated with antralization (or pseudopyloric metaplasia) at the gastric incisura and less frequently at the body and fundus^[18]. It has been established that *H. pylori* infection induces apoptosis of gastric epithelial cells, and subsequently stimulates cell proliferation in the gastric mucosa^[22]. Hanby *et al* reported that mucous neck cells formed an important cell lineage which secretes a series of peptides including the spasmolytic polypeptide, or trefoil family factor 2 (TFF-2) with luminal protective functions^[23]. It has been suggested that pseudopyloric metaplasia occurs in the body glands as a result of hyperplasia of mucous neck cells, and represents a mucosal response to damage associated with *H. pylori* infection^[18, 23]. Indeed, Schmidt *et al* reported that the spasmolytic polypeptide-expressing metaplastic (SPEM) lineage was closely associated with fundic *H. pylori* infection^[24]. Thus, we propose that the hyperplastic mucous neck cells move both upwards and particularly downwards in the oxyntic tubule, replace the specialized parietal and chief cells, and create a mucous cell lineage. This process can occur focally, occupying a single oxyntic tubule, groups of tubules, or on a fairly massive scale with many tubules involved^[25]. Eventually a mucous gland, which resembles pyloric glands, is formed, and thus antralization of proximal gastric mucosa follows. It is most likely that the weakened antralized mucosa in the proximal stomach is prone to be further damaged by *H. pylori*, resulting in ulceration even in the presence of subnormal acid production^[26]. Therefore, in the presence of persistent chronic infection with *H. pylori*, this defense and reparative mechanism probably facilitates rather than prevents the development of ulceration.

In the present study, eradication of *H. pylori* infection led to histological improvement, and persistent infection was associated with the development of antralization in the proximal stomach. These observations may have implications for the prevention of the development of gastric cancer, as we have previously reported that antralization of gastric incisura is strongly associated with precancerous lesions such as gastric atrophy and intestinal metaplasia^[18]. It has been shown that

the time-dependent progression of gastritis in grade (development of atrophy and intestinal metaplasia) and in extent (spreading of gastritis by pyloro-cardial extension) is correlated with the development of gastric cancer in the distal and angular stomach^[27], and that atrophic gastritis and intestinal metaplasia progress and exhibit a cephaloid shift (i.e. pyloro-cardial extension) in chronic *H. pylori* infection^[28]. Therefore, it is hypothesized that the initial events in gastric carcinogenesis occur at the junction of the oxyntic and antral mucosae, and it is the antral type mucosa that is prone to gastric atrophy and intestinal metaplasia, and expansion of antral mucosa towards the proximal stomach (either by pyloro-cardial extension or by differentiation) may be associated with an increased risk of developing intestinal metaplasia^[29]. However, gastric atrophy and intestinal metaplasia are unlikely to regress after eradication of *H. pylori* infection although this is controversial^[30-33]. On the other hand, the reversibility of antralization at the proximal gastric mucosa may provide a new hallmark in the chemoprevention of gastric cancer, although further studies on the role of antralization in gastric carcinogenesis are required. If the proposals of Schmidt *et al*^[24] are confirmed, the prevention or reversal of SPEM might be critical.

Sampling error might account for the difference in improvement of gastric mucosa between patients with *H. pylori* eradication and those with persistent infection. For example, biopsies may be more correctly taken at the edge of active ulcers than healed ulcers. In most cases, ulcer scars are visible, which helps to improve the accuracy of the biopsy site.

Notably, the rate of antralization reached 60 % (9/15) for patients with proximal ulcers but without *H. pylori* infection, suggesting that certain other factors that result in gastric mucosal damage also lead to antralization and gastric ulceration. In the present study, there were no documented records on the causes of *H. pylori*-negative gastric ulcers, and thus we were unable to identify the potential factors that may lead to antralization. Some NSAID users who were unaware of NSAID use at entry might have been included. Previously, Lanis *et al* demonstrated that between 13 % and 22 % of patients with gastrointestinal bleeding and perforation who claimed not to have used aspirin had objective evidence of current aspirin intake^[34, 35]. If this were the case in the present study, then NSAID use would account for proximal gastric ulcer in up to 3 of the 15 patients. Nevertheless, the significance of NSAID use and other factors in antralization of proximal stomach remains to be clarified.

In conclusion, *H. pylori* infection is associated with antralization at the edge of proximal gastric ulcers, which may be reversible in a proportion of patients after eradication of *H. pylori* infection. Antralization in the proximal stomach may play an important role in the pathogenesis of gastric ulceration.

Abstract

AIM: To explore and discuss the clinicopathologic characteristics of mucosa-associated lymphoid tissue (MALT) lymphoma in gastroscopic biopsy specimen.

METHODS: A retrospective study of 26 cases of lymphoma diagnosed by gastroscopic biopsy during 1999 to 2001 from gastroscopy files of Xijing Hospital was made. The diagnostic criteria were adopted according to the new classification of non-Hodgkin's lymphoma.

RESULTS: Twenty-six cases of primary gastric lymphoma consisting of 15 men and 11 women, aged between 23 to 76 years were recruited from 6 225 cases who received gastroscopy. All of them were diagnosed by both endoscopic findings and histological examinations. Histologically, 23 cases were MALToma (low grade) and 3 cases lymphoblastic lymphoma (high grade). Immunohistochemically, all cases were CD20 positive, while CK and EMA were negative.

CONCLUSION: The majority of the cases of primary low-grade gastric lymphoma have morphologic and clinical features that justify their inclusion in the category of low-grade lymphoma of mucosa associated lymphoid tissue.

INTRODUCTION

Primary gastric lymphoma is the most common extra nodal lymphoma, and the vast majority of them are of B cell origin. Most of the low-grade gastric lymphomas are of the mucosa-associated lymphoid tissue (MALT) type^[1-4]. The concept of MALT lymphoma was first proposed in 1983 by Isaacson and Wright^[1]. Histologically it is characterized by centrocyte-like cells, often with plasmacytic differentiation, and accompanied by lymphoepithelial lesions. The histopathological criteria for the diagnosis of gastric MALToma have largely been based on analysis of partial gastrectomy specimens. From routine biopsy diagnosis by gastroscopy, it is very difficult to

distinguish MALToma from reactive lymphoid hyperplasia on small pieces of tissue. In this article, twenty-six cases were retrospectively analyzed with regard to criteria of diagnosis and clinicopathologic characteristics.

MATERIALS AND METHODS

Materials

During the period of 1999-2001, 6 225 cases received gastroscopy in Xijing Hospital and 26 cases of gastric lymphoma were diagnosed according to the new classification of lymphoid neoplasms. The patients (11 women and 15 men) ranged in age from 23 to 76 years. According to the new classification of lymphoid neoplasms^[2], all the histology of MALToma was established if the following criteria were met: (1) invasion of epithelial structures resulting in "lymphoepithelial lesions"; (2) small lymphocytes, marginal zone cells and/or monocytoid B cells; (3) infiltration of diffuse, perifollicular, interfollicular, or even follicular type due to colonization of reactive follicles. Tissue specimens were embedded in paraffin, sectioned and stained with haematoxylin-eosin and immunohistochemical method.

Immunohistochemical analysis

Immunohistochemical staining of CD20, CD45, CD45RO, Keratin and EMA were performed on paraffin-embedded sections by using the monoclonal antibody (Dako, Copenhagen, Denmark). For antigen retrieval, the deparaffinized slides were microwaved in 0.01 mol/L sodium citrate buffer (pH 6.0) for 10 minutes. Endogenous peroxidase activity was inhibited by hydrogen peroxidase. The sections were incubated with the monoclonal antibody (1:100) overnight at room temperature, and then the detection was performed by the avidin-biotin peroxidase complex method. The sections were counterstained with hematoxylin. PBS buffer solution was substituted for the first antibodies as the negative control, whereas the lymphoma cases were used as positive control.

RESULTS

Clinical data

There were 26 cases of MALToma, of them 15 were males and 11 females, with age ranging from 23 to 76 years. Clinical manifestations were epigastric discomfort, abdominal pain, dyspepsia, fever, melena and mucous stool. Endoscopic evaluation showed the location of 5 cases in gastric body, 4 in gastric antrum, 15 in gastric body and antrum, 1 in gastric angulus and 1 in gastric fundus. By endoscopic diagnosis, 9 cases were gastric cancer and 17 cases were gastric ulcer.

Pathological data

Based on the appearance of biopsy specimens, all 26 cases were gastric lymphomas, of them 23 were MALToma (low grade) and 3 lymphoblastic lymphoma (high grade).

Macroscopically, MALToma could be categorized into erosion and ulcerative types; the size of tumor varied from millet to rice. The lymphomatous cells infiltrated into the

mucosa, sub-mucosa and muscular layer diffusely or locally. Typical features of a low-grade mucosa-associated lymphoma with an organized architectural arrangement including lymphoid follicles, centrocyte-like cells and classical lymphoepithelial lesions were seen. Lymphoid follicles were seen and the germinal centers were partly or entirely replaced by lymphoma cells. Dendritic cells and macrophages with chromophilic bodies disappeared. This phenomenon is called follicular colonization. Lymphoepithelial lesion was shown in which there were clusters of pleomorphic, mitotically active lymphomatous cells infiltration locally and gastric glands destroyed (Figure 1). The neoplastic cells presented a serial cell lineage of small lymphocyte, centrocyte-like cell, monocyte-like B cell, lymphoplasma cell, and also centroblast like cells. In all these cells, several kinds were in a mixed distribution, but usually one kind was predominant. Immunohistochemically, all cases of MALTomas were CD20 positive (Figure 2) and CD45 positive. CK and EMA were negative in all cases.

DISCUSSION

The gastrointestinal tract is the most frequently involved extranodal site of origin for non-Hodgkin's lymphoma, accounting for 12-15 % of all non-Hodgkin's lymphomas and 30-40 % of all extranodal lymphomas^[1,5]. The lymphomas in the stomach arise from MALT. Usually they are not present in the stomach but acquired following *H. pylori* infection of the gastric mucosa. *H. pylori*, a microaerophilic Gram-negative rod, has been proposed as the causative agent for low-grade primary gastric lymphoma of MALT^[6-10]. Presenting features

of primary gastric lymphomas are nonspecific, with dyspepsia, vague epigastric pain, nausea and vomiting^[11-15]. Fever with night sweats and elevated lactate dehydrogenase levels are very uncommon. By endoscopy, diffuse gastritis, thickened gastric folds, erosions and occasionally ulcers are more common findings. Although any region of the stomach may be involved, most MALTomas arise in the antrum or the distal body, the sites commonly colonized by *H. pylori*. Histologically, the prominent lymphoepithelial lesion on endoscopic biopsy specimens is one of the most important features for the diagnosis of MALToma of the stomach^[2, 16-18]. They are seen in 100 % of the biopsy specimens. It is a key point for the diagnosis of MALToma that the infiltrating lymphocytes showed homogeneity in marginal zone cells, small lymphocytes, or monocytoid B cells^[2, 16-18]. All of the three types of cells comprise low-grade lymphomas with a dense infiltrate of a superficial and peripheral plasma cell component. Cytologically, neoplastic lymphocytes are characterized by cellular heterogeneity, including centrocyte like cells (small, atypical cells, but with more abundant cytoplasm), monocytoid B cells, small lymphocytes, and plasma cells. Occasionally large cells (centroblast or immunoblast like) are present in most cases. If reactive follicles are present, neoplastic cells will occupy the marginal zone and/or the interfollicular region. When neoplastic lymphocytes take on a follicular pattern, it is called follicular colonization.

Therefore, the diagnosis of gastric MALToma is based on (1) prominent lymphoepithelial lesions; (2) dense lymphoid infiltrate with marginal zone cells, small lymphocytes, or monocytoid B cells. Lymphoepithelial lesions are considered as the characteristic features of MALToma. Nest formation could also be found in the inflammatory and reactive status, it might be difficult to distinguish them from the real lymphoepithelial lesions. In such cases, immunohistochemistry may be helpful. The former is several leukocytes of polyclone and the latter is the lymphocytes of mono-clone. Follicular colonization is easy to be misjudged as reactive follicles. The following morphological characteristics and immunophenotype may be helpful for the differentiation^[14-18]: (1) Follicular colonization has no dendritic cells or macrophages with chromophilic bodies. (2) Centrocyte like cell is the immunophenotype of B cells in the marginal area, rather than at the germinal center. Both lymphoepithelial lesion and follicular colonization are characteristic features for diagnosis, but they could only be seen in some of the cases. If one case is highly suspected for MALToma of the stomach, repeated biopsy should be performed if clinically indicated and then, immunohistochemistry and molecular biology technique should be done.

Understanding primary gastric lymphomas is undergoing rapid and significant transformation from both clinicopathological and therapeutic standpoints. The most important new developments in therapy are the use of *H. pylori* eradication as the initial treatment for localized low-grade primary gastric lymphomas, and the use of chemoradiation over a surgical approach for localized high-grade primary gastric lymphoma^[19-30]. Patients with low-grade primary gastric lymphoma should be treated with *H. pylori* eradication therapy as most patients respond with prompt amelioration of dyspeptic symptoms, although histological regression may take several months. Patients need to be followed-up with serial endoscopies. If no histologically proven lymphoma regression occurs, then biopsy should be done to rule out the presence of co-existing high-grade primary gastric lymphoma. The finding of high-grade primary gastric lymphoma usually indicates the need for more aggressive treatment with chemotherapy and radiotherapy. Surgery is an option in cases of significant

hemorrhage or perforation. With appropriate treatment, the long-term survival is 70-80 % for limited-stage disease and 50-60 % for advanced stage disease.

Abstract

AIM: To elucidate whether CCK receptors exist in lung tissues and their precise cellular localization in the lung.

METHODS: CCK-AR and CCK-BR mRNA expression and cellular distribution in the rat lung were detected by highly sensitive method of *in situ* reverse transcription-polymerase chain reaction (RT-PCR) and conventional *in situ* hybridization.

RESULTS: CCK-AR and CCK-BR gene positive signals were observed in bronchial epithelial cells, alveolar epithelial cells, pulmonary macrophages and vascular endothelial cells of the rats' lung by *in situ* RT-PCR. The hybridization signals of CCK-AR were relatively faint. By *in situ* hybridization, however, only the signals of CCK-BR but not CCK-AR were detected in the lung, and the positive staining was only found in vascular endothelial cells and macrophages.

CONCLUSION: CCK-AR and CCK-BR gene were present in pulmonary vascular endothelial cells, macrophages, bronchial epithelial cells and alveolar epithelial cells, which play an important role in mediating the regulatory actions of CCK-8 on these cells.

INTRODUCTION

Cholecystokinin (CCK) is a gut-brain peptide that exerts a variety of physiological actions in the gastrointestinal tract and central nervous system (CNS) through cell surface CCK receptors^[1]. CCK receptors have been pharmacologically classified into two subtypes CCK-A receptor (CCK-AR) and CCK-B receptor (CCK-BR) according to their affinity for the peptide agonists CCK and gastrin, which share the same COOH-terminal pentapeptide amide sequence but differ in sulfation at the sixth (gastrin) and seventh (CCK) tyrosyl residues^[2]. CCK-AR is highly selective to sulfated analogues

of CCK and the antagonist L-364 718, whereas CCK-BR has similarly high affinity to both sulfated and nonsulfated peptide analogues of CCK/gastrin peptides and the antagonist L-365 260^[2]. CCK-AR is found principally in the gastrointestinal tract and selective areas of the CNS, while CCK-BR is found principally in the CNS and selective areas of the gastrointestinal tract, on pancreatic acinar cells and parietal cells^[3,4]. CCK binds to CCK-AR present on a variety of gastrointestinal target tissues including pancreatic acini, islets, gastric mucosa and gallbladder to induce pancreatic enzyme secretion, insulin secretion, release of pepsinogen and gallbladder contraction^[5]. CCK-BR in the CNS regulates feeding, anxiety and memory, etc^[3]. CCK-AR and CCK-BR are also expressed in the neoplastic cells such as pancreatic cancer cells^[6,7], gastric cancer cells^[8,9], colonic cancer cells^[10] and small cell lung cancer cells^[11-13] where they may stimulate cell growth. In addition, CCK-BR is also present on T lymphocytes^[14,15] to regulate lymphocytes proliferation^[16,17]. These data suggested that CCK receptors were widely distributed around various kinds of tissues and their presence provided the structural basis for CCK to exert a broad array of physiological action.

Our previous data demonstrated that CCK-8, as an intestinal neuropeptide, not only protected gastric mucosa against alcohol-induced injury^[18-20], but also was a potent protective agent against acute lung injury by LPS^[21,22]. It obviously reduced the pulmonary artery hypertension (PAH) and lessened the inflammatory lesion in lung tissues of endotoxin shock (ES) rats^[21,22]. Moreover, CCK-8 could inhibit the reduction of endothelial-dependent relaxation of isolated pulmonary artery to acetylcholine (ACh) induced by LPS^[23]. Stretton and Barnes reported that CCK-8 produced a concentration-dependent contractile response in guinea-pig trachea and this effect was antagonized by the CCK receptor antagonists dibutyl cyclic guanosine monophosphate and L-364 718^[24]. These data indicated that there might be CCK receptors in the lung tissues to mediate the action of CCK-8. However, whether CCK receptors are present in lung tissues and their precise cellular localization remains unclear. In the present study, we detected the cellular localization of CCK receptors in the rats' lung using highly sensitive method of *in situ* RT-PCR.

MATERIALS AND METHODS

Animal model and tissue preparation

Healthy Sprague-Dawley rats (weighing 180-220 g BW) were anaesthetized with urethane (1 g/kg). Lung tissues were dissected from the rats. The inferior lobe of right lung was fixed in 4 % paraformaldehyde for 1 h and embedded in paraffin for *in situ* hybridization and *in situ* RT-PCR.

Primers and probe

The primers and probe of CCK receptor were designed according to Mostein's report^[25]. The sequences of CCK-AR primers were 5' -CTC GCT CGC CCA GAA CTC TAC CAA GGA ATC AAA TTT GAT GC-3' (sense) and 5' -CTG GTT CGG CCC ATG GAG CAG AGG TGC TCA TGT GGC TGT AG-3' (antisense). The sequences of CCK-BR primers were

5'-CTC GCT CGC CCA GAA CTC TAC CTA GGA CTC CAC TTT GA-3' (sense) and 5'-CTG GTT CGG CCC ACG CAC CAC CCG CTT CTT AGC CAG CA-3' (antisense). The sequences of CCK-AR and CCK-BR probes were respectively 5'-CGG GGG CCG GGG ACT TCT GCA AGT AAC AGC CAT CAC TAT CCT CAT A-3' and 5'-AGC TAC GCT GGT TAC AGG CCG GCA GCC CCC GTT-3'. The oligonucleotide probes were labeled with alkaline phosphatase (Boehringer Mannheim). All the primers and probes were synthesized by Sangon Corporation (Shanghai).

In situ RT-PCR

The sections (5 μ m) were baked and deparaffinized to water, and then treated with 0.2 mol/L HCl and EDTA. The slides were pretreated with 0.1 % proteinase K at 37 °C for 12 min to prevent background staining and inactivate endogenous enzyme. Then the tissues were treated overnight in a Rnase-free DNAase solution (Boehringer Mannheim) at 37 °C. The *in situ* reverse transcription step was performed in 30 μ l solution containing 2 μ mol/L CCK-AR or CCK-BR primers and 1 U/ μ l AMV-RT at 42 °C for 1.5 h. Then the slides were overlain with 50 μ l *in situ* PCR reaction mixture containing 1 \times PCR buffer, 4.5 mmol/L MgCl₂, 0.2 μ mol/L dNTPs, 1 μ mol/L each of primers, and 10 U Taq polymerase (Perkin Elmer). The PCR was performed at conditions of initial denaturation at 94 °C for 2 min, followed by 30 cycles of denaturation at 94 °C for 1.5 min, annealing at 55 °C for 1 min, and extension at 72 °C for 1 min. PCR-amplified products were detected with alkaline phosphatase (AP)-labeled CCK-AR and CCK-BR oligonucleotide probes (2 pmol/ml) at 37 °C for 24 h. The slides were then developed in NBT/BCIP solutions at room temperature for 48 h. To stop the color reaction, the slides were washed in distilled water and mounted with glycerol.

Controls

The brain sections were used as positive control. A series of negative controls were performed to guarantee the specificity of the method of *in situ* RT-PCR. Samples pretreated with RNase were used as negative control. Other five negative controls were samples treated without AMV-RT, or Taq polymerase, or primers, or probes specified or unspecified.

In situ hybridization

The procedure was carried out the same way as *in situ* RT-PCR, but without the RT-PCR steps.

RESULTS

The positive and negative controls of in situ RT-PCR

The rat brain sections expressed both CCK-AR and CCK-BR. The hybridization signal was present in the neuron. There was no positive signal in RNase-pretreated samples. Omission of AMV-RT, or Taq polymerase, or primers, or probes prevented specific staining (Figure 1, Table 1).

In situ expression of CCK-BR gene in rat lungs

By *in situ* RT-PCR, CCK-BR mRNA stainings (dark blue color) were found in bronchial mucosal epithelial cells, endothelial cells, alveolar epithelial cells and macrophages (Figure 2). By *in situ* hybridization, however, CCK-BR mRNA staining was only seen in endothelial cells and macrophages (Figure 3).

In situ expression of CCK-AR gene in rat lungs

By *in situ* RT-PCR, the hybridization signals of CCK-AR mRNA were also found in bronchial mucosal epithelial cells, endothelial cells, alveolar epithelial cells and macrophages, and the hybridization signals of CCK-AR were weaker than those of CCK-BR (Figure 4). By *in situ* hybridization, however, no expression of CCK-AR mRNA was detected (Figure 5).

DISCUSSION

In situ RT-PCR is a novel molecular biological technique that combines the high sensitivity of RT-PCR for generating a cDNA from small amounts of mRNA with cellular localization of *in situ* hybridization. The sensitivity of *in situ* hybridization is 10-20 copies per cell when detecting the single-copy and low-copy (less than 10 copies) target DNA or RNA in tissues, while using *in situ* RT-PCR could significantly enhance the sensitivity for detecting the target DNA or RNA^[26]. In the present study, we detected the *in situ* expression of CCK receptors by two methods of *in situ* hybridization and *in situ* RT-PCR. By *in situ* hybridization, only little amount of CCK-BR gene staining was found in vascular endothelial cells and macrophages, whereas by *in situ* RT-PCR, both CCK-AR and CCK-BR mRNA expressions were detected in bronchial mucosal cells and alveolar epithelial cells other than endothelial cells and macrophages. Our results also demonstrated that the sensitivity of *in situ* RT-PCR was obviously higher than that of *in situ* hybridization. Large amounts of cDNA were amplified by specially designed target-specific primers and followed by hybridization with highly specific probes^[27]. So the specific binding of nucleotide on the basis of base complementation was performed twice, which increased the specificity of *in situ* RT-PCR. High sensitivity and specificity made *in situ* RT-PCR a favorable technique to study the *in situ* expression and cellular distribution of target gene in tissues. To further ensure the specific results, we designed six negative controls: First, omission of AMV-RT prevented the positive staining, indicating that genome DNA was completely digested. Second, omission of Taq polymerase produced negative results, suggesting endogenous polymerase was inactive. Third, omission of primers produced weak positive reaction which was the results of little amounts of cDNA binding with specific probes, and it confirmed the specificity of the primers. Fourth, addition of RNase produced negative results, confirming that mRNA was detected during RT-PCR. Fifth, omission of specific probes and addition of nonspecific probes produced negative reaction, confirming the specificity of the probes. Sixth, addition of unlabeled specific probes prevented the positive staining, indicating that endogenous alkaline phosphatase was inactive.

Using *in situ* RT-PCR, we found that CCK-AR and CCK-BR were present in the rats' lungs. It is the first report about the distribution of CCK receptors in lung tissues. The results of *in situ* RT-PCR also demonstrated the cellular localization of CCK receptors in lung tissues: vascular endothelial cells, macrophages, bronchial epithelial cells and alveolar epithelial cells. Our previous study showed that exposure of rabbit pulmonary artery to LPS or TNF- α led to significant reduction of endothelial-dependent relaxation to ACh and enhancement of contractile response to phenylephrine, which could be reversed by CCK-8^[23,28]. This may be the mechanisms of CCK-8 to abolish PAH during endotoxin shock. The present study showed that pulmonary vascular endothelial cells expressed both CCK-AR and CCK-BR gene. So CCK-8 may bind to CCK receptors on pulmonary vascular endothelial cells to mediate its effects on isolated pulmonary artery. Gu *et al*^[29] reported that CCK-8 protected cultured bovine pulmonary artery endothelial cells (BPAEC) against the detrimental effect of LPS such as lipoperoxide damages and cell apoptosis as well as LPS-induced peroxynitrite formation, which might be in part reversed by proglumide, a nonspecific CCK receptor antagonist. These data suggested that there might be CCK receptors on BPAEC. Therefore, CCK receptors on pulmonary endothelial cells may mediate effects of CCK-8 on pulmonary vascular such as regulating the reactivity of pulmonary vascular to vasoactive agents and protecting the endothelial cells against damages.

Our present study also demonstrated existence of CCK-AR and CCK-BR gene expression in pulmonary macrophages. It is well known that activation of macrophages plays a critical role in inducing the inflammatory response^[30]. Macrophages stimulated by LPS or other inflammatory factors produce and release large quantities of various proinflammatory cytokines including TNF- α , IL-1 β , IL-6 etc. Overproduction of these cytokines can result in systemic inflammatory response syndrome (SIRS) and multiple organ dysfunction syndrome (MODS), which might lead to death^[31]. So controlling the overactivation of macrophages may be an effective measure in preventing the generation and development of SIRS and MODS. In another study, we found that CCK-8 could inhibit LPS-induced TNF- α release and gene expression in rat pulmonary interstitial macrophages (PIMs) *in vitro*^[32,33]. The study about its upstream signalling mechanisms demonstrated that CCK-8 inhibited LPS-induced NF- κ B activity and I κ B degradation in PIMs, which was abrogated by proglumide^[33]. Furthermore, LPS-induced expression of LPS receptor CD14 on PIMs could be downregulated by CCK-8 *in vitro*^[32]. These data suggested that CCK-8 might bind to CCK receptors on pulmonary macrophages to interfere with the activation of macrophages during inflammation. But the cellular signal transduction mechanisms through which CCK receptors mediated in macrophages were not fully clarified. Other than pulmonary macrophages, several functions of murine peritoneal macrophages were negatively modulated by CCK-8 including the production of superoxide anion, phagocytosis and mobility^[34,35]. Therefore, CCK receptors on macrophages provide the structural basis for CCK-8 to regulate the functions and activation of macrophages, which may be beneficial to the control of inflammatory responses.

In addition, CCK-AR and CCK-BR mRNA expressions were observed on bronchial epithelial cells and alveolar epithelial cells in this study. Stretton and Barnes reported that CCK-8 produced a concentration-dependent contractile response in guinea-pig trachea and this effect was antagonized by the CCK receptor antagonists dibutylryl cyclic guanosine monophosphate and L-364 718^[24]. So the CCK receptors present on bronchial epithelial cells may mediate the regulatory effect of CCK-8 on the tonus of bronchus. The functions of CCK receptors on alveolar epithelial cells remain unclear.

In summary, we successfully detected CCK-AR and CCK-BR mRNA expression in rats' lung tissues and clarified their cellular localization using *in situ* RT-PCR. To our knowledge, this is the first report about the CCK receptors gene expression in lung tissues. CCK receptors present on pulmonary endothelial cells, macrophages, bronchial epithelial cells and alveolar epithelial cells play an important role in mediating effects of CCK-8 such as protecting endothelial cells against damages, inhibiting the overactivation of macrophage and regulating the pulmonary vascular tonus and bronchial tonus.

Abstract

AIM: To investigate the role of nuclear factor- κ B (NF- κ B) inhibitor caffeic acid phenethyl ester (CAPE) in the proliferation, collagen synthesis and apoptosis of hepatic stellate cells (HSCs) of rats.

METHODS: The HSCs from rats were isolated and cultured in Dulbecco's Modified Eagle's Medium (DMEM) and treated with CAPE. The proliferation and collagen synthesis of HSCs were determined by 3 H-TdR and 3 H-proline incorporation respectively, and the expression of type I, III procollagen genes was further explored by *in situ* hybridization. Apoptosis cell indices (AIs) were examined using terminal deoxynucleotidyl transferase-mediated DIG-dUTP nick end labeling (TUNEL).

RESULTS: In activated HSC in culture, CAPE significantly inhibited 3 H-TdR and 3 H-proline incorporation by HSCs at concentrations of 5 μ mol/L and 10 μ mol/L respectively. CAPE also reduced the type I procollagen gene expression ($P < 0.05$) at higher concentration. Apoptosis of HSC was induced by CAPE and the AIs were time- and dose-dependently increased from 2.82 ± 0.73 % to 7.66 ± 1.25 % at 12 h ($P < 0.01$) and from 3.15 ± 0.88 % to 10.61 ± 2.88 % at 24 h ($P < 0.01$).

CONCLUSION: CAPE inhibits proliferation and collagen synthesis of HSC at lower concentration and induces HSC apoptosis at higher concentration.

INTRODUCTION

Liver fibrosis is a progressive pathological process involving multi-cellular and molecular events that ultimately lead to deposition of excess matrix proteins in the extracellular space. It is generally accepted that HSC is the most pathogenetically relevant cell type for the development of liver fibrosis^[1-5]. During liver injury and inflammation, quiescent HSCs transdifferentiate into activated-type HSCs, also termed

myofibroblasts (MFBs), which result in accumulation of a cell type that provides main collagenous and non-collagenous components of the extracellular fibrotic matrix, contribute to diminished degradation of extracellular matrix by the expression of tissue inhibitors of metalloproteinases (TIMPs) and also produce an array of proinflammatory cytokines and chemokines involving the development of liver fibrosis^[3-11].

It has recently been shown that the recovery from established experimental fibrosis can occur through the apoptosis of HSC, which is associated with reduction of collagen and expression of TIMPs in liver. Apoptosis, therefore, plays an important role in the resolution of fibrosis by eliminating the sources of both the neomatrix and TIMPs, and thereby facilitates net matrix degradation^[12-15]. Activation and apoptosis of HSCs could play a central role in turnover of liver fibrosis.

Recent research showed that cultured HSC underwent a rapid and persistent induction of a high-mobility NF- κ B DNA binding complex, and the activation of NF- κ B in cultured HSC was required for activated phenotype of HSCs and might be anti-apoptotic for HSCs^[16-19]. In this study, we investigated the effect of NF- κ B inhibitor CAPE on the proliferation, collagen synthesis and apoptosis of HSCs.

MATERIALS AND METHODS

Materials

Wistar rats, male, 450-500 g of body mass, were provided by the Center for Laboratory Animal of Kunming General Hospital. DMEM and FBS were obtained from GIBCO. CAPE and collagenase were purchased from SIGMA, 3 H-TdR and 3 H-proline were provided by Beijing Institute of Atomic Energy, RNA Mimi Kit and DIG DNA Labeling and Detecting Kit were respectively obtained from Gene and Boehringer Mannheim.

Methods

Isolation and culture of HSCs HSCs were isolated from normal liver by sequential *in situ* perfusion with collagenase, as previously described^[20,21]. Briefly, the livers were perfused first with Ca^{2+} - and Mg^{2+} - free solution for 10 min at 37 °C, and next with 0.05 % (w/v) collagenase solution for 30 min at 37 °C, the digested liver were excised, dispersed in D-Hanks, and filtered through gauze. The residual hepatocytes were removed by two low-speed centrifugation (50 g, 4 °C, 2 min). The stellate-cell enriched fraction was obtained by centrifugation with a triple-layered (9, 11, and 17 %) Nycodenz cushion (1 400 \times g, 4 °C 20 min). The cells in the upper-layer were washed and seeded onto uncoated plastic tissue culture plate in DMEM supplemented with 10 % FBS and grown for 14 days. Purity and viability of freshly isolated HSC were determined by Desmin immunohistochemistry and trypan-blue stain respectively.

3 H-TdR and 3 H-proline uptake by HSC Passaged HSCs were cultured in 24-well plates for 48 h and then treated with CAPE at concentrations of 0.0, 1.0, 2.5, 5.0, 10.0, 20.0, and 40.0 μ mol/L for 24 h. CAPE was dissolved in DMSO. The cells were then labeled with 1 μ ci/ml 3 H-TdR or 1 μ ci/ml 3 H-proline

respectively. After washed with D-Hanks, the HSCs were digested with trypsin and absorbed on glass fiber filter paper. The cells were then washed once with 10 % trichloroacetic acid and three times with saline and dried overnight at 80 °C, the radioactivity (CPM) of each sample was counted using liquid-scintillation analyzer.

Expression of procollagen gene in HSC Type I and III procollagen gene sequences were enquired from GeneBank of National Center of Biotechnology Information, and primers that amplified the procollagen genes were designed with OLIGO microsoft according to the gene sequences and synthesized by Sangon Company. The primers were 5' -CGA TGG ATT CCC GTT CGA GTA C-3' and 5' -GTC CAC AAC CCT GTA GGT G-3' for type I procollagen gene, 5' -GGA AAC AGC AAA TTC ACT TAC A-3' and 5' -TCA CTT GCA CTG GTT GAT AAG A-3' for type III procollagen gene. The RNA was extracted from the skin of newborn ICR mice by RNA mini kit, the genes were amplified by RT-PCR and procollagen gene probes were labeled with PCR and DIG-dUTP. HSCs cultured in 24-well plates were treated with 20 µmol/L CAPE for 24 h and the procollagen gene expression was detected according to the previously described procedure^[22].

Apoptosis assay Passaged HSCs were cultured for 48 h and then cultured in 5 % FBS DMEM and treated with CAPE at predetermined concentrations of 0.0, 20.0, and 40.0 µmol/L for 12 h and 24 h, the cells were fixed in formaldehyde solution and stained with TUNEL reaction solution containing DIG-dUTP and terminal deoxynucleotidyl transferase for 60 min at 37 °C. DIG was detected by anti-DIG-AP conjugate and colorimetric substrate NBT/BCIT. Positive cells were counted under microscope.

RESULTS

Characteristics of HSCs

Freshly isolated HSCs were round-shaped with many yellow-coloured droplets in cytoplasm, after 2-3 days in culture on uncoated plastic surface, the cells had spread and showed a typical 'star'-like configuration. More than 80 % of freshly isolated cells were desmin-positive, and the cell viability was about 90 % according to trypan-blue staining.

Figure 1 The hepatic stellate cells stained with toluidine after cultured for 10 days after isolation (×66).

Effect of CAPE on ³H-TdR and ³H-proline incorporation by HSC

We observed the effect of CAPE on ³H-TdR and ³H-proline incorporation by cultured HSCs. As shown in Figure 2, CAPE significantly and dose-dependently suppressed the incorporation of ³H-TdR and ³H-proline by HSCs. The median inhibitory concentrations were 5 and 10 µmol/L respectively for ³H-TdR and ³H-proline. These concentrations were lower, especially for the inhibition of HSCs proliferation, indicating

that CAPE was a potent inhibitor for proliferation, and collagen synthesis.

Figure 2 Effects of CAPE on ³H-TdR and ³H-proline uptake by HSCs. ^a*P*<0.05; ^b*P*<0.01 vs groups without CAPE treatment.

Figure 3 Effect of CAPE on type I and III procollagen gene expression. ^a*P*<0.05 vs the group without CAPE treatment.

Figure 4 Apoptotic HSCs detected by TUNEL without (A) or with 40 µmol/L CAPE treatment (B).

Effects of CAPE on procollagen gene expression

Type I and III collagens are the main components of extracellular matrix in liver fibrosis. *In situ* hybridization

analysis of type I and III procollagen genes showed that positive HSCs were reduced by CAPE at the concentration of 20 $\mu\text{mol/L}$. And the reduction of type I procollagen gene expression was statistically significant, indicating that CAPE suppressed the procollagen gene expression.

Apoptosis of HSC induced by CAPE

Apoptosis of HSC was demonstrated by TUNEL, the nucleus of apoptotic HSCs were stained with violet blue (Figure 4). After treatment with CAPE, AIs were time- and dose-dependently increased from $2.82 \pm 0.73\%$ to $7.66 \pm 1.25\%$ at 12h and from $3.15 \pm 0.88\%$ to $10.61 \pm 2.88\%$ at 24 h. The data indicated that CAPE induced HSC apoptosis at higher concentrations (Figure 5).

Figure 5 Effects of CAPE on HSC apoptosis. ^a $P < 0.05$; ^b $P < 0.01$ vs the groups without CAPE treatment; ^c $P < 0.01$ vs the group with 40 $\mu\text{mol/L}$ CAPE treated for 12 h.

DISCUSSION

HSCs, previously termed as fat or vitamin A-storing cells or Ito cells, localized in close proximity to sinusoidal endothelial cell and hepatocyte in the space of Disse, are the most pathogenetically relevant cell type for development of liver fibrosis^[2-5]. Activated HSCs in liver tissue provide virtually most main components of ECM, contribute to diminished degradation of ECM by expressing TIMPs, and produce an array of proinflammatory cytokines and chemokines involving the development of liver fibrosis^[3-11]. It is generally accepted that HSCs are important target cells for the treatment of liver fibrosis^[5,23].

In our study, we observed that the NF- κB inhibitor CAPE inhibited the proliferation and collagen synthesis of HSCs. CAPE dose-dependently suppressed the incorporation of ^3H -TdR and ^3H -proline by HSCs. This indicated CAPE inhibited the proliferation of HSCs. Because the reduction of either total cell number or collagen synthesis may contribute to the reduction of ^3H -proline incorporation by HSCs, the expressions of type I and type III procollagen genes were further explored in HSCs. Our data showed that the procollagen gene expressions were reduced by CAPE, and the reduction of ^3H -proline uptake partially indicated that CAPE inhibited collagen synthesis, in addition to the reduction of HSC number.

CAPE, a structural relative of flavonoids that is an active component of propolis from honeybee hives, has been shown to inhibit the growth of different types of cells including endothelial cells, keratinocyte and tumor cells, which involves in nuclear factor, protein kinase C and cytokine signal transduction^[24-29]. CAPE inhibited the proliferation and collagen synthesis of HSCs, properly by reducing the reactive oxygen intermediates, this is consistent with the antioxidant property of CAPE^[30,31]. Previous studies showed that reactive oxidant species induced HSCs activation and collagen gene expression *in vivo* and *in vitro*^[32-35]. The antioxidant phenolic

compounds reduced the proliferation and collagen synthesis by suppressing inositol phosphate metabolism, tyrosine and protein kinase activation^[33,36]. Since CAPE is a structural relative of flavonoids, CAPE probably inhibits the proliferation and collagen synthesis of HSCs similarly. Other mechanisms might include inhibition of the expression of COX2 and activation of NF- κB by CAPE, which are associated with the phenotype of activated HSCs^[37,38].

Activated HSCs undergo auto-apoptosis in serum-deprived DMEM and in experimental fibrosis induced by CCl_4 . P^{75} and Fas have already been identified as molecules associated with the apoptosis of HSCs, which were expressed in HSCs. Apoptosis of HSCs can be induced by nerve growth factor and soluble Fas-ligand^[39,40]. The recovery from established experimental fibrosis is relevant to the apoptosis of HSCs, which contributes to the reduction of neomatrix synthesis and expression of TIMPs. Recent reports showed the persistent activation of NF- κB was induced in activated but not in quiescent HSCs, which is required for activated phenotype of HSCs and may be antiapoptotic for HSCs^[16-18]. CAPE is a potent and specific inhibitor of NF- κB , CAPE inhibits the activation of NF- κB induced by TNF and other inflammatory agents including phorbol ester, ceramide, hydrogen peroxide, *etc*^[41]. Our data showed the AIs of HSCs were increased by CAPE, the inhibition of NF- κB activation by CAPE probably played a key role in HSC apoptosis. CAPE inhibited the activation of NF- κB and the expression of proinflammatory cytokines TNF- α and IL-1 β ; CAPE also induced apoptosis in macrophages^[42], similar results were observed in leucocytes as well^[43]. However, CAPE induced apoptosis of tumor cells by regulating the expression of caspas-3, bcl-2, bax and P^{53} ^[44-46]. For HSCs, the mechanism of apoptosis induced by CAPE needs further investigation.

CAPE has been shown to be a pharmacologically safe compound with known antiinflammatory, antimitogenic, anticarcinogenic, antioxidant, and immunomodulatory effects^[37,47]. Therefore, CAPE might have a therapeutic role in liver fibrosis by inhibiting the proliferation or inducing the apoptosis of HSCs.

Abstract

AIM: To isolate and analyze a novel gene over-expressed during liver regeneration.

METHODS: Total RNA of regenerating liver was extracted from liver tissue after 0-4-36-36-36 hr short interval successive partial hepatectomy (SISPH). Reverse transcription-polymerase chain reaction was used to synthesize double strand cDNA, after the tissue was digested by proteinase K and Sfi A/B. The double-strand cDNA was ligated to λ TriplEx2. λ phage packaging reaction was performed and *E. coli* XL1-Blue was infected for titering and amplifying. One expressed sequence tag was probed by Dig and phage *in situ* hybridization was carried out to isolate positive clones. Positive recombinant λ TriplEx2 was converted to the corresponding pTriplEx2, and bioinformatics was used to analyze full-length cDNA.

RESULTS: We isolated a novel full-length cDNA during liver regeneration following SISPH.

CONCLUSION: We have succeeded in cloning a novel gene, based on bioinformatics. We postulate that this gene may function in complicated network in liver regeneration. On the one hand, it may exert initiation of liver regeneration via regulating nitric oxide synthesis. On the other hand, it may protect damaged residue lobus following SISPH.

INTRODUCTION

Liver regeneration is a system suitable for investigating normally regulated growth^[1-4]. After surgical removal of 70 % of the mass of a healthy liver (two-thirds hepatectomy), residual tissue enlarges to make up for the mass of removed substance in entirety, in small animals, this process usually lasts 5 to 7 days^[5-7].

The growth response after partial hepatectomy is governed by priming and progression through the cell cycle^[2,6,8]. The

priming phase coincides with loss of growth inhibition and represents the G₀ to G₁ transition, whereas the progression phase acts on promoting cell replication and represents the G₁ to S transition. Priming involves the activation of a group of non-specific factors, which are necessary, but not sufficient for the S phase completion; they comprise the nuclear factor for kappa chains (NF- κ) in B cells, signal transducer and activator of transcription-3 (STAT3), activator protein-1 (AP-1), CCAAT enhancer binding protein, and several immediate early genes like epithelial growth factor (EGF), tumor necrosis factor-alpha (TNF- α , IL-6), insulin, and matrix changes^[9-15]. The priming step is reversible until the cells have crossed the so-called G₁ checkpoint, the cells thereupon being irreversibly committed for replication. Moreover, the initiation of the growth response depends on complex interactions among hepatocytes and nonparenchymal cells, the extracellular matrix (ECM), endocrine, autocrine, paracrine, and neuroregulatory factors, oxygen free radicals, metabolites, and nutrients^[2,6,9,16]. Progression signals include hepatocyte growth factor (HGF), transforming growth factor-alpha (TGF- α), EGF and insulin. The regulation of hepatic regenerative process depends on a number of myriad factors that ultimately modulate immediate-early, delayed-early, and liver-specific gene expression^[2,6,9,17-20].

The termination of hepatic regeneration still remains an enigma. A variety of factors have been touted as growth inhibitors/terminators during the regenerative response once recovery of the liver mass has been achieved. TGF- β and activins are regarded as potent inhibitors involved in the termination response^[21,22]. TGF- β is a fibrogenic cytokine secreted by hepatic stellate cells, TGF- β mRNA, almost undetectable in normal liver, increases within 3-4 h after partial hepatectomy, and attains a plateau after 48-72 h. TGF- β 1 overexpression in transgenic mice inhibits the abundance of the cyclin-dependent kinase activating tyrosine phosphatase cdc25A protein, and is associated with increased binding of histone deacetylase 1 to p130 in the liver^[23]. Activin A (the homodimer of the inhibin β A chain) inhibits but follistatin (anactivin-binding protein) promotes hepatocyte proliferation. Whereas activin A is a negative regulator of hepatocyte proliferation, mice deficient in both activin β C and activin β E, are not different from wild-type mice with respect to liver development and the regenerative response after partial hepatectomy. The activin system also plays a significant role in the dynamics of the ECM, in particular fibronectin; ECM components are reconstructed during desinualization and hepatocyte cluster formation. After rat liver injury and partial hepatectomy, hepatocyte activin A receptors are down-regulated at 24 hr and normalized at 72 hr. This phenomenon may be involved in rendering hepatocytes responsive to mitogenic stimuli, whereas increased activin A levels stimulate stellate cell production of fibronectin, important for the growth and proper placement of regenerating hepatocytes^[24].

Despite the research efforts, our knowledge on the regulatory mechanisms of cell growth, differentiation and tissue organization is limited. There may be some unknown factors that may play important roles in the process of liver regeneration. To acquire a better understanding on the

mechanisms involved, some researchers have established a series of successive partial hepatectomy (SPH) models. These mainly include the long interval successive partial hepatectomy (LISPH) in which an interval of more than three weeks is applied as described by Wu *et al.*, the SPH model where a one-third hepatectomy 2 weeks after a two-thirds hepatectomy is performed as described by Takeshi *et al.*^[25], and the short interval successive partial hepatectomy (SISPH) model (0-4-40-76-112 hr) which has an interval of 4 and/or 36 h because the cells would re-enter into dedifferentiation stage after 4 hr and reach the peak of cell division after 36 hr following partial hepatectomy as described by Xu *et al.*^[26]. Studies have demonstrated that SISPH could provide more useful materials for analyzing the mechanism of liver regeneration^[27]. We have begun identifying and characterizing some genes that are strongly expressed in liver regeneration. We took 0 h and 112 hr as driver and tester respectively in 0-4-36-36-36hr SISPH model and a suppression subtracted hybridization (SSH) method was performed^[28-30]. Then we constructed a forward-subtractive cDNA library from which we have cloned 53 up-regulated expressed sequence tags (ESTs). Among these, nine ESTs were 100 % homologous to GenBank and 44 ESTs were homologous to GenBank. one of these ESTs was found to be a novel gene in GenBank. In the present study, we have used one subtracted probe from suppression subtracted library in liver regeneration and isolated its full-length cDNA from cDNA library by the phage *in situ* hybridization method. Based on bioinformatics, we suggest that it might play important roles in the regulation of initiation of liver regeneration.

MATERIALS AND METHODS

Establishment of the SISPH model

Adult Spargue-Dawley rats (weighing 200-250 g) were provided by the Experimental Animal House of Henan Normal University, and the 0-4-36-36-36 hr SISPH model was made according to the method described by Xu *et al.*^[26]. Lobus external sinister and lobus centralis sinister, lobus centralis, lobus dexter and lobus candatus were removed one by one at four different time points, i.e. at 4, 36, 36 and 36 hr (total time: 4 hr, 40 hr, 76 hr, 112 hr), respectively. The fourth resected liver lobus was washed with precooled phosphate- buffered saline (PBS) thoroughly, then the sample was frozen in liquid nitrogen and transferred to the -80 °C freezer for storage.

Primers

A1: 5'-ATTCTAGAGGCCGAGGCGGCCGACATG-d (T)₃₀N-3'
 A2: 5'-AAGCAGTFFTATCAACGCAGAGT-3'
 A3: 5'-TCGAGCGGCCCGCCGGGCGAGGT-3'
 A4: 5'-AGCGTGGTTCGCGGCCGAGGT-3'
 A5: 5'-TCCGAGATCTGGACGAGC-3'
 A6: 5'-TAATACGACTCACTATAGGG-3'

Among these primers, A1 was used for synthesis of first cDNA strand, A1/A2 were used to amplify dscDNA, A3/A4 were used to probe expressed sequence tag with Dig, A5/A6 were used to detect full length cDNA.

RNA Isolation

Total RNA was isolated from 112 h liver tissue samples following SISPH by the method described by Chomczynski and Sacchi^[31]. Tissues were homogenized and extracted twice with acidic guanidinium isothiocyanate-phenol-chloroform. The poly(A)+ RNA fraction was isolated by oligo-dT cellulose chromatography (Pharmacia Diagnostics AB, Uppsala, Sweden). The purity and integrity of total RNA were monitored by absorbance of ultraviolet spectrometer at 260/280 nm, and electrophoresis was carried out on a denaturing formaldehyde agarose gel and the gel was stained with ethidium bromide.

RT-PCR

300 ng mRNA was reversely transcribed to single-stranded cDNA by Powerscriptase at 42 °C for 1 hr. First-strand cDNA was synthesized with a Sfi IB-oligo(dT) adapter-primer (A1). The resulting single strand cDNA was amplified by PCR using CDSIII/3' primer (A1) and 5' primer (A2) following parameters: 94 °C for 45 s, 68 °C for 6 min.

cDNA library construction

The double strand cDNA synthesis and library construction were carried out mainly according to the manual of SMART cDNA Library Construction Kit (Clontech, Heidelberg, Germany). After second-strand synthesis and ligation of Sfi IA adapters, cDNA was digested by Sfi IA/Sfi IB, generating cDNA flanked by Sfi IA sites at 5' ends and /Sfi IB sites at the 3' ends. Digested cDNAs were size-fractionated with Sephacryl S-500 spin columns and ligated into the λTriplEx2 express vector predigested by Sfi IA/Sfi IB. The resulting concatomers were packaged by using Gigapack Gold packaging extracts. After titration, aliquots of primary packaging mixture were stored in 7 % DMSO at -80 °C as primary library stocks. At the same time, the ratio of white (recombinant) to total (white + blue (nonrecombinant)) assay was determined^[32]. The remainder was amplified to establish stable library stocks.

Probe labeling and Phage in situ hybridization

A novel EST related to liver regeneration was probed with A3/A4 primers according to the user manual of Dig Probe Synthesis kit (Roche Diagnostics, Mannheim, Germany). Thermal cycle parameters were 94 °C for 2 min, 25 cycles including a denaturation step at 94 °C for 15 sec, an annealing step at 68 °C for 30 sec, extension at 72 °C for 1 min and 30 sec, and a final extension step at 72 °C for 7 min. The amplified phage cDNA library was diluted in 1×λ dilution buffer to obtain a concentration of 104 pfu/ml and then to infect *E. coli* XL1-Blue. Host bacterial cells were absorbed by phage at 37 °C for 15 min and the indicated volume of melted LB top agarose/MgSO₄ was added. The mixture was inverted once and poured onto a prewarmed, dry LB/MgSO₄ plate. The plate was inverted and incubated at 37 °C until plaques became distinctly visible. A nylon filter was numbered and placed onto the LB soft top agarose, then the filter was marked in three asymmetric locations. After 2 min, the filter was peeled off carefully. The filter was placed in petri dishes orderly containing DNA denaturing solution for 5 min, neutralizing solution for 5 min, or 2×SSC for 5 min. Hybridization and wash procedures were performed according to Sambrook^[33]. When positive signal appeared the process was performed as above for the secondary and tertiary screening until single clone was obtained. Then recombinant λTriplEx2 was converted to the corresponding pTriplEx2. Plasmid was extracted and sent to TaKaRa (Dalian, China) for sequencing analysis.

RESULTS

RT-PCR

The mRNA was isolated from the 112 h liver tissue following SISPH. A modified oligo (dT) primer (A1 primer) primed the first-strand synthesis reaction. The resulting single strand cDNA was amplified by PCR using CDSIII/3' primer (A1) and 5' primer (A2) derived from SMART oligonucleotide (Figure 1).

Determination of cDNA library

The unamplified library and amplified library were titrated when *E. coli* XL1-Blue was infected by λphage. The plaques were counted and cDNA library was calculated respectively as

follows: pfu/ml=number of plaques \times dilution $\times 10^3$ μ l/ml/ μ l of diluted phage plated. Results showed that unamplified cDNA library and amplified library were 6×10^6 pfu/ml and 6×10^{10} pfu/ml respectively. X-gal/IPTG was used to assess recombination efficiency. Among 500-1 000 plaques, the ratio of white (recombinant) to total (recombinant and blue (nonrecombinant)) was 99.52 %. These data suggest that the cDNA library was successfully established.

Screening result and bioinformatics

Figure 2 shows the tertiary positive clone screened by phage *in situ* hybridization. After conversion of a recombinant λ TriplEx2 to the corresponding pTriplEx2, the tertiary positive clones were analyzed by PCR with the sequencing primers A5/A6. The length detected by electrophoresis was consistent with the sequencing result and its full length cDNA was 1 354 bp (Figure 3). We identified that its ORF region encodes 344 amino acids, its start codon AUG was in 47-49 nucleotide and its termination codon TAG was in 1 079-1 081 nucleotides, and the sequence followed by TAG was polyA (Figure 4). It was compared with other sequences in the GenBank through Internet by BLAST and found to be 98.8 % homologous to mouse arginase. The sequence has been deposited in the GenBank database (accession No. AF508019).

Figure 4 The full length of cDNA and its amino acid sequence.

DISCUSSION

To understand and elucidate the mechanism of liver regeneration, we established short interval successive partial hepatectomy, and attached great importance to seeking some novel differential display genes responsible for cell differentiation and dedifferentiation by suppression subtracted hybridization (SSH) to obtain a bulk of up-regulated and down-

regulated expressed sequence tags (ESTs) in liver regeneration. In the 0-4-36-36-36h SISPH model, we took 0h and 112 hr as driver and tester respectively, and performed the SSH method. Then we constructed a forward-subtractive cDNA library from which we cloned 53 up-regulated ESTs. The 53 up-regulated ESTs may be classified as following: (1) Related to positive/negative major acute phase protein (MAPP) mRNA genes, such as serum amyloid A, transferrin, haptoglobin, alpha acid glycoprotein and fibrinogen like factor; (2) Related to mitochondrial oxidative phosphorylation genes such as ankyrin protein and mitochondrial cytochrome oxidase subunits I, II, III genes; (3) Related to protein synthesis genes such as mitochondrial ribosomal protein 63 (Mrp63); (4) Related to cell division genes, such as microtubulin associated protein (MAP); and (5) Related to signal transduction genes; for example, arginase gene may be related to NO signal pathway and regulate hepatic regeneration together with NO synthase I.

5'end cDNA is not completely reversely transcribed in constructing traditional cDNA library, which leads to some defaults in cloning full-length cDNA. In our study, we adopted a switching mechanism at 5'end of RNA transcript and successfully resolved this shortcoming. Moreover, the cDNA library we constructed may simultaneously express three open reading frames, and thus enables us to study from nucleic acid and protein aspects^[34].

Arginase is an important enzyme in ornithine cycle^[35]. In liver regeneration this enzyme is expressed highly, which may regulate the process of generating NO. Recent work has suggested that NO synthase (NOS) is necessary for liver regeneration^[36-38]. Arginase and NOS require the same substrate amino acid L-arginine, thereby they compete for the same substrate in liver regeneration^[38,39]. In our study, arginase was up-regulated, suggesting the involvement of arginase in regulating NO signal pathway.

Lepoivre *et al* proved that inducible NO could inhibit mouse DNA synthesis in hepatocellular carcinoma (HCC) *in vitro*. TA3 cell may stimulate L-arginine to produce nitrite in condition of adding IFN- γ or not adding LPS. NO affects nucleotide reductase activity by binding unferrohemoglobin, therefore, to inhibit DNA synthesis^[40]. NO may trigger phagocyte into G1 but negatively correlate with DNA synthesis of hepatocytes.

The increase of NO concentration in residue lobus following partial hepatectomy depends on gradual recovery of hepatocyte function. NO may expand vascular smooth muscle in liver to inhibit leukocyte adhesion and platelet aggregation, to improve microcirculation and reduce fat accumulation and deposition in liver accordingly. In normal state, arginine granted may enhance arginine transportation and NO synthesis by hepatocytes^[41,42]. Thereby up-regulated arginine will protect damaged liver, to some extent, following SISPH.

In conclusion, we succeeded in cloning a novel gene, based on bioinformatics. We postulate that this gene may function in complicated network in liver regeneration. On the one hand, it may exert initiation of liver regeneration via regulating NO synthesis. On the other hand, it may protect damaged residue lobus following SISPH. More detailed studies are required to clarify the biological functions of this gene in liver regeneration.

Abstract

AIM: To study the expression of IGF-1 and IGF-1R and its intervention by interleukin-10 in the course of experimental hepatic fibrosis.

METHODS: Hepatic fibrosis was induced in rats by carbon tetrachloride intoxication and liver specimens were taken from the rats administered CCl₄ with or without IL-10 treatment and the animals of the control group. Immunoreactivities for insulin-like growth factor-1 (IGF-1) and IGF-1 receptor (IGF-1R) were demonstrated by immunohistochemistry, and their intensities were evaluated in different animal groups.

RESULTS: The positive levels for IGF-1 and IGF-1R were increased with the development of hepatic fibrosis, with the positive signals localized in cytoplasm and/or at the plasmic membrane of hepatocytes. The positive signals of IGF-1 and IGF-1R were observed more frequently ($P < 0.01$) in the CCl₄-treated group (92.0 % and 90.0 %) compared to those in the control group. The positive signals decreased significantly ($P < 0.05$) in IL-10-treated group. The responses in IGF-1 and IGF-1R expression correlated with the time of IL-10 treatment.

CONCLUSION: The expression of IGF-1 and IGF-1R immunoreactivities in liver tissue seems to be up-regulated during development of hepatic fibrosis induced by CCl₄, and exogenous IL-10 inhibits the responses.

INTRODUCTION

Hepatic fibrosis is a common pathological change resulted from various chronic hepatic injuries, which is characterized by an increase of extracellular matrix (ECM) deposition in the Disse's

space and the imbalance between synthesis and degeneration of ECM. It is a change before cirrhosis^[1-6]. Many studies suggested that cytokines play important roles during hepatic fibrosis with different mechanisms^[1,7-16]. There is a contrary effect of insulin-like growth factor-1 (IGF-1) on rat hepatic stellate cells (HSC) *in vivo* and *in vitro*. IGF-1 and its receptor (IGF-1R) may play a significant role in hepatic fibrosis. The rat hepatic fibrosis model was established and the immunoreactivities for IGF-1 and IGF-1R in rat liver tissues were assessed to show the possible involvement of IGF-1 and IGF-1R in the process of hepatic fibrosis and the effect of interleukin-10 on this change.

MATERIALS AND METHODS

Materials

One hundred clean male Sprague-Dawley rats weighing 140-180 g (Provided by Shanghai Experimental Animal Center) were divided randomly into 3 groups. The control group (group C) included 24 rats; the model group (group M) included 40 rats and the IL-10 treated group (group T) included 36 rats. All the rats were bred under routine conditions.

Methods

Preparation of rats The rats of group C were injected intraperitoneally with saline 2 ml·kg⁻¹ twice a week. The rats of group M and group T were injected intraperitoneally with 50 % CCl₄ (dissolved in castor oil) 2 ml·kg⁻¹ twice a week. From the third week, the rats of group T were injected intraperitoneally with IL-10 4 ug·kg⁻¹ (dissolved in saline) 20 minutes before they were injected with CCl₄. All injections were given on Monday and Thursday. To the fifth week, 3 rats in group M and 2 rats in group T died; to the seventh week, 8 rats in group M and 4 rats in group T died; to the ninth week, 10 rats in group M, 6 rats in group T and 3 rats in group C died. In the 5,7,9 week, 10 rats of groups M and T and 7 rats of control group were sacrificed and their livers were taken. The specimens were fixed in 10 % formalin and embedded with paraffin. Sections were stained by hematoxylin and eosin and evaluated by pathologists.

Immunohistochemistry and data evaluation The rat liver tissues were sectioned at a thickness of 4 μm. The sections were deparaffinized with xylene, dehydrated with graded ethanol, incubated in PBS containing 3 % H₂O₂ to block endogenous peroxidase activity and then incubated in PBS containing 0.1M citrate to saturate nonspecific binding sites. After incubation with rabbit anti-rat IGF-1 or IGF-1R monoclonal antibody (American Neomarkers Company), the reactions were with the instance S-P immunohistochemistry reagents (American Zymed Company). And then, the sections were incubated in a buffer containing 3, 3'-diaminobenzidine tetrahydrochloride (DAB) and H₂O₂ to produce a brown reaction product, then were dehydrated and coverslipped. The reactions were graded according to their intensities and percentage of the positive cell as follows: negative=0, stained yellowish=1, stained with deep yellows or brown=2; the percentage of stained cell: <5 %=0, 6 % to

25 % = 1, 26 % to 50 % = 2, >50 % = 3. Then the eventual result was by these two scores according to the following predefined definitions: 0 to 1 = negative (-), 2 to 3 = positive (+), 4 and above 4 = strongly positive (++). Ridit analysis described the difference between groups.

RESULTS

Expression of IGF-1 and IGF-1R in the liver tissues of the three groups

The positive rates of IGF-1 in the control group, the CCl₄-treated group and the CCl₄-and IL-10-treated group were 38.1 %, 92.0 % and 71.4 %, respectively. Those of IGF-1R were 33.3 %, 80.0 % and 64.3 %, respectively. The granular positive products were localized in the cytoplasm and/or at the membrane, but not in the nuclei. In group C, IGF-1 and IGF-1R signals were weak, mainly located in the perivenular area (Figure 1,2). In group M, the expression increased obviously with the development of hepatic fibrosis, and the positive cells distributed

throughout the hepatic lobule (Figure 3,4). In group T, the changes were less pronounced than in group M (Figure 5,6).

Intensities of IGF-1 and IGF-1R immunoreactivities

The comparison of IGF-1 and IGF-1R system expression levels in groups C, M and T is listed in Table 1. Ridit analysis showed a significant difference among the three groups ($P < 0.01$). Expression levels of the IGF-1 and IGF-1R in group M were found to be higher than that in group C ($P < 0.01$). In group T, after the treatment with IL-10, the immunoreactivities for IGF-1 and IGF-1R decreased ($P < 0.01$ and $P < 0.05$, respectively). The data for IGF-1 and IGF-1R reactivities in different stages of hepatic fibrosis are listed in Table 2. With the development of hepatic fibrosis, intensities of IGF-1 and IGF-1R immunoreactivities increased significantly ($P < 0.05$). The data for IGF-1 and IGF-1R immunoreactivities in different stages of hepatic fibrosis in group T are listed in Table 3. A significant decrease was observed in IGF-1 and IGF-1R expression with the IL-10 treatment ($P < 0.05$).

DISCUSSION

Hepatic fibrosis is the early stage of hepatic cirrhosis, characterized by accumulation of excessive extracellular matrix, necrosis, nodular regeneration of hepatocytes and formation of fibrous septum^[1-6]. Cytokines play important roles in the formation and regression of hepatic fibrosis^[1,7-16].

In the present study, up-regulated expression of IGF-1 and IGF-1R was observed in liver tissues injured by CCl₄-intoxication, and was positively correlated with the development of hepatic fibrosis. However, the response was less pronounced in IL-10- treated group.

Insulin-like growth factors (IGFs) include two related homologous polypeptides: IGF-1 and IGF-2, which have similar structure and activity *in vitro*, but different biological effect *in vivo*. Activation of mitosis and induction or acceleration of differentiation are their major functions, which are mediated through IGF-1R by means of autocrine, paracrine and endocrine mechanisms. IGF-1R is a transmembrane tyrosine kinase receptor. After binding with its ligand, intracellular transcription and synthesis of proteins are activated and regulated through a series of signal transduction. This gives rise to insulin-like metabolic effects and promotes proliferation and differentiation of cells. It is also involved in the maintenance of transformed cell phenotypes. Its expression is essential for the transforming function of cell cycle-related protooncogenes and viral oncogenes^[17,18]. In addition, IGF-1 and IGF-1R have an anti-apoptosis effect on different cells^[13]. Liver is the main organ of IGF-1, but the function of IGF-1 and IGF-1R in hepatic fibrosis still remains controversial. Many authors

have observed a decreased serum concentration of IGF-1 and insulin-like growth factor-binding protein 3 (IGFBP3) in patients with hepatic cirrhosis, this change is correlative with cirrhosis progression. With the treatment of recombinant somatotropin, the serum concentration increased along with the improvement of protein synthesis and liver metabolism. For these patients, the IGF-1 concentration below 10 nmol/L was considered an unfavored response to the treatment and poor prognosis^[19-31]. Castilla *et al* and Myguez *et al* reported that the histological parameters in hepatic fibrosis animals were improved after being treated with exogenous IGF-1. So IGF-1 might act as an antifibrogenic factor^[32,33]. On the contrary, other researches speculated IGF-1 had a great influence on hepatic stellate cell (HSC), which was the main producer of ECM, such as activating proliferation, inhibiting apoptosis, accelerating the secretion of collagen type I, etc^[13,34]. The function of IGF-1 also seems to be regulated by IGF-BP, IGF-1R and other cytokines^[22-30].

The present study observed and evaluated IGF-1 expression with the fibrosis progression, which might be a compensatory reaction to the continuous loss of hepatocytes in the CCl₄-treated animals. We consider that IGF-1 may stimulate the replication of hepatocytes and interfere with fibrosis. The discordance was observed between the IGF-1 level in liver tissue and that in serum, with the former higher and the latter lower, this is likely due to the decrease of IGF-1 released from hepatocytes to blood circulation. In other words, the hepatocytic secretion of IGF-1 maybe regulated by means of autocrine under such a situation. The positive correlation between the expression of IGF-1 and IGF-1R and the fibrosis progression may be helpful for fibrosis staging.

IL-10 is an antifibrogenic cytokine produced by Th2 cells, macrophages, stellate cells and hepatocytes^[35-47]. It has been reported the deficiency of IL-10 prompted fibrosis probably by its failure in inhibiting the overproduction of TGF- β_1 and TNF- α . The latter two cytokines are secreted by macrophages and can enhance synthesis of collagen type I^[48]. The knock-out experiments (IL-10-/-mice) indicated that endogenous IL-10 actually relieved CCl₄-induced fibrosis^[49-51]. In our previous study, exogenous IL-10 was found to be able to inhibit the progress of fibrosis and might be used for treatment. Similar results were also reported by Nelson, but its mechanism remains obscure^[52,53]. The present study showed that IGF-1 and IGF-1R expression decreased with the improvement of fibrosis after treatment with IL-10. It seems that antifibrogenic effect of IL-10 is associated with down-regulation of IGF-1/IGF-1R. More works are demanded to clarify whether this action is regulated by IGF-1 and IGF-1R or the decrease of IGF-1R expression is only a phenomenon of hepatic cirrhosis remission.

Abstract

AIM: To observe the effects of Ganyanping on CCl₄-induced hepatic fibrosis in rats.

METHODS: The rats were separated randomly into five groups. Groups A to group D, each consisting of 15 rats, were for different tests, while 8 rats were used as normal controls (N). For group D, CCl₄ was injected subcutaneously, at a dosage of 3 ml/kg for 9 weeks. For group A, Ganyanping was administered via gastric tube at a dosage of 10 ml/kg. For group B, the treatment with Ganyanping was started 4 weeks after CCl₄ administration. In group C, Ganyanping was administered 8 weeks after the intoxication, and treatment lasted for 4 weeks. Liver tissues were fixed in 10 % formalin and embedded in paraffin. Pathologic changes, particularly fibrosis, were evaluated on the HE and V-G-stained sections. Ten middle-power fields were randomly selected for assessment of collagen deposition.

RESULTS: Loss of normal hepatic architecture, some with pseudo-lobule formation, was observed in group D, while hepatocytes steatosis and fibrosis were less pronounced in the animals treated with Ganyanping. Pseudo-lobule formation was not evident in the latter groups. The total collagen area and ratio were 840.23±81.65 and 7.0±0.9, respectively in group D, the ratio being reduced greatly in the Ganyanping-treated groups (148.73±45.89 and 1.16±0.33, respectively). The activities of MAO and ACP were elevated and that of SDH in group D decreased in the hepatic tissue as compared to the control group. The treatment with Ganyanping abrogated these enzymatic changes.

CONCLUSION: Our data approved that Ganyanping could improve the microcirculation in the liver, reduce oxygen-derived free radicals, and enhance the cellular metabolism and immune function, all resulting in an anti-fibrotic effect. Hence, Ganyanping can protect the liver from fibrosis. It

may be a safe and effective preparation for patient with fibrosis.

INTRODUCTION

Ganyanping, a preparation of Chinese herbs proposed by Li Shaobai *et al*^[1] has been used in clinical and experimental fields for many years. It has been shown to be protective for the animal liver against injury by D-GalN and cirrhosis caused by CCl₄ intoxication^[2-6]. In this study, the effects of Ganyanping on liver fibrosis used a CCl₄-intoxication model. The V-G and enzyme histochemistry techniques were employed to observe the effects of Ganyanping.

MATERIALS AND METHODS

Reagents

CCl₄ (Beijing Chemical Factory, Lot No. 20000225) was diluted to 40 % in vegetable oil (Southseas Oils & Fats Industrial (CHI Wan) Limited, Grade One, Lot No. KO'SOF Ts88). Ganyanping tablet preparation (Lot No.20001110) was provided by the Institute of Liver Disease, Tongji Hospital, Tongji Medical College, consisting of Radix Astragali seu Hedysari, Radix Salviae Miltiorrhizae, Rhizoma polygoni Cuspidati and other herbs. The tablets were prepared in the Chinese Medicine Pharmacy of Tongji Hospital. The powder of Ganyanping was dissolved into water (1.2 g/ml) before use.

Animals

68 Wistar rats (♂ & ♀, 38 for ♂ and 30 for ♀), weighing between 170 and 250 g, were provided by the Laboratory Animal Center of Tongji Medical College. The rats were separated randomly into five groups. Group N, normal control, consisted of 8 rats. For group A to group D, rats (15 for each) were treated with CCl₄ by subcutaneous injection at a dosage of 3 ml/kg for 9 weeks. For group A, Ganyanping (10 ml/kg) was also administered via gastric tube along with the CCl₄ intoxication. For group B, Ganyanping treatment was started 4 weeks later and lasted for the remaining 5 weeks. For group C, Ganyanping was given after 8 weeks of CCl₄ administration, and the treatment lasted for 4 weeks. Ganyanping was administered in the form of an aqueous suspension (2 g/ml). After 9 weeks, the overnight fasting animals were anesthetized with sodium pentobarbital (30 mg/kg, per injection). Blood was taken from inferior vena cava for the estimation of biochemical parameters including values of ALT, AST, and concentrations of protein and albumin.

Pathological observations

Hepatic tissues were fixed with formalin and embedded with paraffin. The sections were stained with hematoxylin and eosin.

Samples for electron microscopy were fixed in 25 g/L glutaraldehyde buffer for two hours, then with osmium acid, dehydrated in acetone, and embedded with epoxy resin. The sections were observed under an electron microscope (OPTON EM10C, Carl Zeiss Company, Made in Germany, No.5166, voltage is 60KV).

V-G staining and enzymatic reactions

Van Gieson's method was used to demonstrate collagen fibers^[7]. HPIAS-1000 auto medical image analyzing system was used for quantitative assessment of collagen fibers in liver. Ten middle power fields were selected randomly for the total area occupied by collagen fibers and its ratio against the total area observed. Activity of monoamine oxidase (MAO) was demonstrated using 15 μ m-thick frozen sections with the chayen method, that of succinic dehydrogenase (SDH) was visualized using lojda method, that of ALP with culling method, and that of ACP with Bancroft method^[8]. NOS was shown using NADPH method^[9].

Statistics

Statistical analysis with ANOVA: Data were presented as $\bar{x} \pm s$. Significant differences were determined by using ANOVA in statistical software SPSS11.0. Results were considered significant when $P < 0.05$.

RESULTS

Histologic and ultrastructural findings

Liver sample from group D showed loss of normal lobular architecture. The parenchyma showed steatosis, cellular swelling, necrosis, and was divided into rounded nodules, separated by bands of fibrous tissues, while in groups A, B and C, the steatosis was not severe and the fibrosis was not so pronounced, without any pseudo-lobule observed (Figures 1, 2). Hepatocellular degeneration was frequently seen in the intoxicated animals under electron microscope, characterized by marked swelling of mitochondria, loss of rough endoplasmic reticulum structures and distention of them. Glycogen particles were greatly reduced and more lipid droplets were found in the cytoplasmic compartment. In some hepatocytes, nuclear irregularity was noted, lipid droplets and some components resembling rough endoplasmic reticulum (nuclear or pseudo-nuclear inclusions) were also found within the nuclei. A few lipid droplets were found in the cytoplasm in the Ganyanping-treated groups (Figures 3, 4).

VG staining

Fibrosis was shown in group D by VG staining, with hepatic parenchyma separated by the rough, red-stained fibrotic septa. The change was less pronounced in the Ganyanping-treated groups. The total collagen-deposited area and ratio in group D, but not in the Ganyanping-treated groups ($P < 0.05$), were increased compared to those in the control group ($P < 0.001$) (Table 1, Figures 5, 6).

Table 1 Area occupied by fibrotic septa and its ratio to the total area examined

Groups	n	Area covered by fibrotic septa (μm^2)	Ratio (%)
N	8	35.30 \pm 13.86 ^b	0.32 \pm 0.18 ^b
A	15	200.74 \pm 33.84 ^a	1.63 \pm 0.45 ^a

Enzymatical reactions

Activities of MAO, SDH, ALP and NOS were demonstrated in

frozen sections with the procedures described above. Those for MAO and ACP were found to be elevated and that of SDH was reduced in group D compared to those in the control group. The changes were not so marked in any of the Ganyanping-treated groups (Tables 2, 3; Figures 7, 8).

DISCUSSION

It remains a problem to prevent cirrhosis or to control its progression in patients with a chronic liver disease^[10,11]. Great efforts have been made to find safe and effective drugs. Recent clinical and experimental observations have demonstrated that Chinese medicines might be of some preventive and therapeutic values against fibrosis^[12-20]. Ganyanping, prepared according to the regime of Li Shaobai *et al*^[21], has been used for many years for this purpose. However, its effect and associated mechanism need further experimental evidence. For this reason, we used CCl₄ to induce liver fibrosis and investigated herein the effects of Ganyanping on fibrosis.

Liver fibrosis is a pathologic process associated with over production and deposition of collagen fibers^[22, 23] and other extracellular matrix (ECM) components^[24-27] resulted from various hepatic diseases. It is considered a necessary intermediate step between liver parenchyma injury and cirrhosis^[28]. Activation of hepatic stellate cells (HSCs) has been shown to be one of the critical steps during hepatic fibrosis^[29-34]. It is associated to a number of pathological factors, resulting in ECM deposition and hepatic fibrosis. This was also observed in the fibrosis caused by CCl₄ intoxication, and this process could be effectively controlled by treatment with Ganyanping. The preparation was found to be inhibitory in the collagen production.

MAO is used as a marker for evaluating hepatic function in cirrhosis, its elevation indicating liver damage^[35]. An increase in MAO activity was observed in the intoxication group. Ganyanping was found to be able to abrogate this change. Thus, Ganyanping is considered to have some anti-cirrhotic effect. SDH is a rate-limiting enzyme in the tricarboxylic acid cycle^[36,37]. The elevation of its activities reflects more active metabolism. Our data indicate the treatment with Ganyanping might be helpful for liver parenchyma cells to

maintain this SDH activity through the intoxication. The treatment was also shown to be helpful for stabilizing the lysosome membrane in chronic hepatic injury, reflected by its interference to ACP values of the animals received intoxication. In the present study, activity of NOS was shown to be reduced in the CCl₄-intoxicated group, but the effect was partially abrogated by the treatment with Ganyanping, indicating that the treatment might help the liver to recover its function through the stress caused by CCl₄ administration.

In summary, Ganyanping was found to play some anti-fibrotic role. According to the theory of traditional Chinese medicine, Ganyanping may possess multiple pharmaceutical effects, such as invigorating “qi” and activating “blood”, dispersing stagnated hepatic “qi” and facilitating the discharge of “bile”, delivering “heat” and “toxins”, and eliminating “dampness” in view of its composition. Our experimental data have proved that Ganyanping could reduce oxygen-derived free radicals, and enhance the cellular metabolism and immune function, all resulting in an anti-fibrotic effect. Ganyanping may be used as a safe and effective preparation for patients with fibrosis.

Abstract

AIM: To investigate the role of NF- κ B activation and zinc finger protein A20 expression in the regulation of maturation of dendritic cells (DCs) derived from liver allografts undergoing acute rejection.

METHODS: Sixty donor male SD rats and sixty recipient male LEW rats weighing 220-300 g were randomly divided into whole liver transplantation group and partial liver transplantation group. Allogeneic (SD rat to LEW rat) whole and 50 % partial liver transplantation were performed. DCs from liver grafts 0 hour and 4 days after transplantation were isolated and propagated in the presence of GM-CSF *in vitro*. Morphological characteristics and phenotypical features of DCs propagated for 10 days were analyzed by electron microscopy and flow cytometry, respectively. NF- κ B binding activity, IL-12p70 protein and zinc finger protein A20 expression in these DCs were measured by EMSA and Western blotting, respectively. Histological grading of rejection was determined.

RESULTS: Allogeneic whole liver grafts showed no signs of rejection on day 4 after the transplantation. In contrast, allogeneic partial liver grafts demonstrated moderate to severe rejection on day 4 after the transplantation. After propagation for 10 days in the presence of GM-CSF *in vitro*, DCs from allogeneic whole liver grafts exhibited features of immature DC with absence of CD40 surface expression, these DCs were found to exhibit detectable but very low level of NF- κ B activity, IL-12 p70 protein and zinc finger protein A20 expression. Whereas, DCs from allogeneic partial liver graft 4 days after transplantation displayed features of mature DC, with high level of CD40 surface expression, and as a consequence, higher expression of IL-12p70 protein, higher activities of NF- κ B and higher expression of zinc finger protein A20 compared with those of DCs from whole liver grafts ($P < 0.001$).

CONCLUSION: These results suggest that A20 expression is up-regulated in response to NF- κ B activation in mature DCs derived from allogeneic liver grafts undergoing acute rejection. Given the NF- κ B inhibition function of this gene, it is suggested that their expression survives to limit NF- κ B activation and maturation of DCs,

and consequently inhibits the acute rejection and induces acceptance of liver graft.

INTRODUCTION

Dendritic cells (DCs) are specialized antigen-presenting cells (APCs) that play an essential role in the activation of lymphocytes^[1-10]. Among APCs, which also include macrophages and B cells, only DCs are believed to be capable of activating naive T cells. DC function is regulated by their state of maturation. Immature DCs resident in nonlymphoid tissues such as normal liver are deficient at antigen capture and progressing processing^[11, 12]. "Maturation" of DC can be induced by microbial stimuli, proinflammatory cytokines, as well as through interaction with CD40L-CD40 cross-linking^[13-20]. The control of DC maturation and activation plays an important role in regulating their T cell priming functions^[21]. Significantly, engagement of CD40 expressed on DCs with CD40L expressed on T cells not only stimulates maturation and cytokine production but also enhances DC survival and activation^[19, 22, 23]. Mature DCs are highly immunogenic due to high levels of expression of MHC I and II, costimulatory and adhesion molecules, including B7-1, B7-2, CD40, and ICAM-1^[11-19]. In the case of experimental skin, heart, or kidney allografts, mature dendritic cells resident in donor tissue have been implicated as the principal instigators of rejection. Whereas, DCs derived from normal liver display an immature phenotype with absence of costimulatory molecules (CD40, CD80 and CD86) surface expression, low levels of MHC class I and II, and as a consequence, low stimulatory capacity for naive allogeneic T cells. Unlike mature DC, these liver-derived immature DCs do not induce detectable levels of intracytoplasmic IFN- γ in allogeneic CD4⁺ cells in 72-h MLR, and elicit very low levels of CTLs *in vitro*^[11, 12]. It has been observed that liver-derived^[11, 24] or bone marrow-derived immature DCs^[25], propagated *in vitro* and lacking surface costimulatory molecules, can prolong heart or pancreatic islet allograft survival. Whereas, marked augmentation of DCs numbers and maturation of DCs in liver allografts by donor treatment with the hematopoietic growth factor fms-like tyrosine kinase 3 (Flt3) ligand (FL) results in acute liver graft rejection^[26, 27].

Although the significance of DCs as regulators of transplantation immunity is beyond doubt, little is known about intracellular mechanisms specifically responsible for regulation of DC activation and maturation. Previous studies have suggested that NF- κ B may play a key role in DC maturation^[20, 28-30], and NF- κ B inhibition could impair the maturation and function of DC^[28, 29].

A20 is a zinc finger protein originally identified as a TNF-

inducible gene product in endothelial cells (EC), and has been shown to be dependent upon NF- κ B for its expression. A20 is expressed in a variety of cell types including fibroblasts, B, T, and β -cells in response to different stimuli including LPS, IL-1 and CD40 cross-linking^[31-36]. A20 is itself a NF- κ B-dependent gene and is part of a negative regulatory loop critical for modulation of cell activation^[37, 38]. A20 serves a broad cytoprotective function in EC by protecting EC from apoptosis and down-regulating inflammatory responses via NF- κ B inhibition^[39]. A20^{-/-} knock-out mice are born cachectic and die within 3 weeks from severe and uncontrolled inflammation that further confirms the potent anti-inflammatory function of A20^[40]. A20 is also part of the physiologic NF- κ B-dependent survival response of hepatocytes to injury, limited expression of A20 in hepatocytes drastically improves the fate of mice in the D-gal/LPS model of toxic FHF where A20 protects hepatocytes from apoptosis and promotes the liver regeneration^[37]. In addition, investigation has shown that A20 expression is up-regulated in human renal allografts in response to immune injury inferred by acute rejection, and the result suggests that A20 could limit graft injury^[41].

Although A20 is a very effective inhibitor of NF- κ B activation induced by LPS, IL-1 and CD40 cross-linking, little is known about the role of A20 in the regulation of maturation of DCs derived from allogeneic liver grafts accompanied by acute rejection.

The purpose of the present study was to investigate the binding activity of NF- κ B DNA and A20 expression in mature DCs derived from allogeneic partial liver grafts undergoing acute rejection in rats. Attempts were made also to correlate A20 expression in DCs derived from liver grafts with the acceptance of allogeneic liver grafts.

MATERIALS AND METHODS

Animals

Sixty donor male SD rats and sixty recipient male LEW rats weighing 220-300 g were randomly divided into whole liver transplantation group and partial liver transplantation group. Allogeneic whole and 50 % partial liver transplantation were performed using a SD to LEW combination. The animals were purchased from Chinese Academy of Sciences and Sichuan University. They were maintained with a 12-hour light/dark cycle in a conventional animal facility with water and commercial chow provided *ad libitum*, with no fasting before the transplantation.

Liver transplantation

All operations were performed under ether anesthesia in clean but not sterile conditions. All surgical procedures were performed from 8 a.m to 5 p.m. Donors and recipients of similar weight (± 10 g) were chosen. Liver reduction was achieved by removing the left lateral lobe and the two caudate lobes, which resulted in a 50 % reduction of the liver mass. Whole liver transplantation (WLT) and partial liver transplantation (PLT) were performed according to the method described in our previous study^[42].

Histology

Part of liver tissues was sectioned and preserved in 10 % formalin, embedded in paraffin, cut with microtome, and stained with hematoxylin and eosin. The histological grading of rejection was determined according to the criteria described by Williams.

Propagation and purification of liver graft-derived DC populations

DCs from liver graft 0 hour and 4 days after the transplantation

were propagated in GM-CSF from nonparenchymal cells (NPC) isolated from collagenase-digested liver graft tissue, as described by Lu *et al.*^[24]. Nonadherent cells, released spontaneously from proliferating cell clusters, were collected after culture for 10 days, and purified by centrifugation 500 \times g, for 10 minutes at room temperature on a 16 % w/v metrizamide gradient (DC purity 80-85 %).

Morphological and phenotypical features of DCs

Morphological characteristics of DCs derived from liver graft were observed by electron microscopy. Expression of cell surface molecules was quantitated by flow cytometry as described in our previous study^[42]. Aliquots of 2×10^5 DCs propagated for 10 days *in vitro* were incubated with the following primary mouse anti-rat mAbs against OX62, CD40 (Serotec, USA), or rat IgG as an isotype control for 60 minutes on ice (1 μ g/ml diluted in PBS/1.0 % FCS). The cells were washed with PBS/1.0 % FCS and labeled with FITC-conjugated goat anti-mouse IgG, diluted 1/50 in PBS/1.0 % FCS for 30 minutes on ice. At the end of this incubation, cells were washed, propidium iodide/PBS were added, and the cells were subsequently analyzed in an FACS-4200 flow cytometer (Becton-Dickinson, USA).

Isolation of nuclear proteins

Nuclear proteins were isolated from DCs extract by placing the sample in 0.9 ml of ice-cold hypotonic buffer [10 mM \cdot L⁻¹ HEPES (pH7.9), 10 mM \cdot L⁻¹ KCl, 0.1 mM \cdot L⁻¹ EDTA, 0.1 mM \cdot L⁻¹ ethylene glycol tetraacetic acid, 1 mM \cdot L⁻¹ DTT; Protease inhibitors (aprotinin, pepstatin, and leupeptin, 10 mg \cdot L⁻¹ each)]. The homogenates were incubated on ice for 20 minutes, vortexed for 20 seconds after adding 50 μ l of 10 % Nonide-P40, and then centrifuged for 1 minutes at 4 $^{\circ}$ C in an Eppendorf centrifuge. Supernatants were decanted, the nuclear pellets after a single wash with hypotonic buffer without Nonide-P40 were suspended in an ice-cold hypertonic buffer [20 mM \cdot L⁻¹ HEPES (pH7.9), 0.4 M \cdot L⁻¹ NaCl, 1 mM \cdot L⁻¹ EDTA, 1 mM \cdot L⁻¹ DTT; Protease inhibitors], incubated on ice for 30 minutes at 4 $^{\circ}$ C, mixed frequently, and centrifuged for 15 minutes at 4 $^{\circ}$ C. The supernatants were collected as nuclear extracts and stored at -70 $^{\circ}$ C. Concentrations of total proteins in the samples were determined according to the method of Bradford.

Electrophoretic mobility shift assay (EMSA) for NF- κ B activation of DCs

NF- κ B binding activity was performed in a 10- μ l binding reaction mixture containing 1 \times binding buffer [50 mg \cdot L⁻¹ of double-stranded poly (dI-dC), 10 mM \cdot L⁻¹ Tris-HCl (pH7.5), 50 mM \cdot L⁻¹ NaCl, 0.5 mM \cdot L⁻¹ EDTA, 0.5 mM \cdot L⁻¹ DTT, 1 mM \cdot L⁻¹ MgCl₂, and 100 ml \cdot L⁻¹ glycerol], 5 μ g of nuclear protein, and 35 fmol of double-stranded NF- κ B consensus oligonucleotide (5' -AGT TGA GGG GAC TTT CCC AGG-3') that was endly labeled with γ -³²P (111TBq mM⁻¹ at 370 GBq⁻¹) using T4 polynucleotide kinase. The binding reaction mixture was incubated at room temperature for 20 minutes and analyzed by electrophoresis on 7 % nondenaturing polyacrylamide gels. After electrophoresis, the gels were dried by Gel-Drier (Biol-Rad Laboratories, Hercules, CA) and exposed to Kodak X-ray films at -70 $^{\circ}$ C.

Western blotting for IL-12 p70 and zinc finger protein A20 expression in DCs

DCs cultured for 10 days *in vitro* were starved in serum-free medium for 4 hours at 37 $^{\circ}$ C. These cells were washed twice in cold PBS, resuspended in 100 μ l lysis buffer (1 % Nonidet-P40, 20 mM Tris-HCl, pH8.0, 137 mM NaCl, 10 % glycerol,

2 mM EDTA, 10 $\mu\text{g} \cdot \text{mL}^{-1}$ leupeptin, 10 $\mu\text{g} \cdot \text{mL}^{-1}$ aprotinin, 1 mM PMSF, and 1 mM sodium orthovanadate), and total cell lysates were obtained. The homogenates were centrifuged at 10 000 $\times g$ for 10 minutes at 4 °C. Cell lysates (20 μg) were electrophoresed on SDS-PAGE gels, and transferred to PVDC membranes for Western blot analysis. Briefly, PVDC membranes were incubated in a blocking buffer for 1 hour at room temperature, then incubated for 2 hours with Abs raised against IL-12 p70 and A20 (Santa Cruz, CA). The membranes were washed and incubated for 1 hour with HRP-labeled IgG. Immunoreactive bands were visualized by ECL detection reagent. The binding bands were quantified by scanning densitometer of a Bio-Image Analysis System. The results were expressed as relative optical density.

Statistics analysis

Statistic analysis of data was performed using the Student's *t*-test; $P < 0.05$ was considered statistically significant.

RESULTS

Histological rejection

Histological rejection features of allografted livers were compared between the whole and partial groups on day 4 after the transplantation, allogeneic whole liver grafts demonstrated no rejection. In contrast, partial liver grafts demonstrated moderate to severe rejection, including inflammatory cellular infiltration in the portal tract, endometriitis, bile duct damage and hepatocytes necrosis.

Phenotypic characteristics of liver graft-derived DCs propagated in vitro

As shown in our previous study^[42], after cultured for 10 days in the presence of GM-CSF, DCs both from whole and partial liver grafts displayed typical morphological features of DC, including anomalous shape, bigger body, and numerous longer dendrites. Flow cytometry showed 80-85 % of these DCs strongly expressed rat DC - specific OX62 antigen molecule, which suggested that high purity DCs were obtained. Flow cytometric analysis showed that DCs from whole liver grafts and from partial liver grafts 0 hour after the transplantation were negative for the costimulatory molecule CD40 expression, which was an immature phenotype (CD40⁻), whereas DCs from partial liver graft 4 days after the transplantation showed high level of CD40 expression, which was a mature phenotype (CD40⁺). These results suggested maturation of DCs resident in allogeneic partial liver graft undergoing acute rejection.

IL-12 p70 protein expression in DCs derived from allogeneic partial liver grafts

Our previous study showed that IL-12 p35 and IL-12 p40 subunit expressions were significantly up-regulated in mature DCs derived from allogeneic partial liver grafts undergoing acute rejection^[42]. In the present study, we evaluated IL-12 p70 expression in DCs from allogeneic liver grafts. As shown in Figure 1, DCs derived from both whole and partial liver grafts 0 hour after the transplantation expressed detectable but very low level of IL-12 p70, and expression level of IL-12 p70 in DCs from whole liver graft 4 days after transplantation was not elevated compared with those of DCs from whole liver graft 0 hour after the transplantation ($P > 0.05$). However, expression of IL-12 p70 in DCs from partial liver graft 4 days after transplantation was markedly increased, and their expression levels were significantly higher than those of DCs both from partial liver graft 0 hour and whole liver graft 4 days after transplantation ($P < 0.001$).

Figure 1 Expression of IL-12 p70 in liver graft - derived DCs by Western blotting. Lanes 1, 2: Expression of IL-12 p70 in DCs from partial liver graft and whole liver graft 0 hour after transplantation. Lanes 3, 4: Expression of IL-12 p70 in DCs from partial liver graft and whole liver graft 4 days after transplantation. ^a $P < 0.001$ vs 4d WLT group; ^b $P < 0.001$ vs 0 hour PLT group.

Electrophoretic mobility shift assay (EMSA) for NF- κ B activation of DCs

As shown in Figure 2, EMSA analysis showed detectable but very low level of NF- κ B activity of DCs derived from both whole and partial liver grafts 0 hour after transplantation, and NF- κ B activity of DCs from whole liver graft 4 days after transplantation was not increased compared with those of DCs from liver graft 0 hour after transplantation ($P > 0.05$). However, NF- κ B activity of DCs from partial liver graft 4 days after transplantation was significantly elevated compared with those of DCs from partial liver graft 0 hour and whole liver graft 4 days after transplantation ($P < 0.001$).

Figure 2 NF- κ B activation of DCs derived from allogeneic liver grafts. Lanes 1, 2: NF- κ B activation of DCs from partial liver graft and whole liver graft 0 hour after transplantation. Lanes 3, 4: NF- κ B activation of DCs from partial liver graft and whole liver graft 4 days after transplantation. ^a $P < 0.001$ vs 4 d WLT group; ^b $P < 0.001$ vs 0 hour PLT group.

A20 protein expression in DCs derived from partial liver allografts
In order to investigate the intracellular mechanisms specifically

responsible for regulation of DC activation and maturation, we evaluated NF- κ B inhibitor zinc finger protein A20 expression in DCs derived from allogeneic liver grafts. As shown in Figure 3, DCs from both whole and partial liver grafts 0 hour after the transplantation expressed detectable but very low level of A20, and expression level of A20 in DCs derived from whole liver graft 4 days after transplantation was not increased compared with those of DCs from whole liver graft 0 hour after transplantation ($P>0.05$). However, expression of A20 in DCs from partial liver graft 4 days after transplantation was markedly up-regulated, and its expression level was significantly higher than those of DCs both from partial liver graft 0 hour and whole liver graft 4 days after transplantation ($P<0.001$).

Figure 3 Expression of A20 protein in DCs derived from allogeneic liver grafts. Lanes 1, 2: Expression of A20 protein in DCs from partial liver graft and whole liver graft 0 hour after transplantation. Lanes 3, 4: Expression of A20 protein in DCs from partial liver graft and whole liver graft 4 days after transplantation. ^a $P<0.001$ vs 4 d WLT group; ^b $P<0.001$ vs 0 hour PLT group.

DISCUSSION

Despite the emergence of DCs as key cellular players in the immune system, the signal transduction events that regulate DC maturation and function have been poorly understood. This study was conducted to explore whether NF- κ B activation and its inducible expression gene of A20 could be detected in mature DCs derived from liver allograft undergoing acute rejection. Our aim was to determine whether A20 gene is involved in NF- κ B inhibition of these mature DCs. In the present study, it has been shown that engagement of CD40 on DCs derived from allogeneic partial liver grafts undergoing acute rejection leads to a powerful NF- κ B activation of these mature DCs, and as a consequence, leads to high level expression of the protective gene A20 in these DCs. Expression of this gene in mature DCs derived from liver graft undergoing acute rejection is consistent with their known potential to be induced in response to NF- κ B activation.

It has been shown that DCs derived from allogeneic partial liver grafts undergoing acute rejection displayed mature phenotypic high level CD40 expression and NF- κ B activation. Although resting DCs residing in normal liver tissues display only low levels of CD40, B7, and MHC class II molecule expression^[11, 12, 24]. The ischemia/reperfusion injury which is consecutive to the transplantation procedure will rapidly activate them. In addition, partial hepatectomy has been reported to induce the expression of MHC II on Kupffer cell.

Interstitial dendritic cells and sinusoidal endothelium in rats, together with the up-regulated TNF- α production after partial hepatectomy would induce the expression of B7 and CD40 molecules on DCs^[16]. These factors could stimulate maturation of DCs derived from partial liver grafts. These mature DCs may contribute to the allogeneic liver graft rejection induction. Previously other studies showed that mature DC could provide signals able to trigger T cell proliferation after TCR engagement^[43, 44]. These accessory, or "costimulatory" signals, are consecutive to interactions between costimulatory molecules present on activated DC such as B7, CD40, and OX40-ligand and their respective counter-receptors, CD28, CD40-ligand, and OX40, on T cell membranes. Several intracellular signals follow the engagement of costimulatory molecules. Interactions of CD40L, CD28, and OX40 with their ligands on DCs activate the transcription factor NF- κ B in both T cells and DCs^[29, 30]. In turn, NF- κ B initiates the transcription of numerous genes involved in immune activation, such as chemokines and cytokines^[20, 30], and also of costimulatory molecules themselves. For instance, CD40 ligation on the APC will up-regulate its expression of B7 molecules. This initiates positive feedback loops ultimately contributing to T cell expansion^[45]. Among the costimulatory molecules, CD40 and B7 seem to play a crucial role in alloreactive responses. Indeed, blockade of both CD40 and B7 molecules at the time of transplantation prevents allograft rejection and induces alloreactive T cell anergy^[46, 47]. In the present study, DCs derived from allogeneic partial liver grafts undergoing acute rejection demonstrated high level expression of CD40, which could interact with the CD40-ligand on T cells, leading to a powerful NF- κ B activation and high level of IL-12p70 expression in these mature DCs. Given an essential role for NF- κ B transcription in LPS- and CD40L - induced expression of IL-12 (IL-12 p35, p40 and p70) in DCs^[20], IL-12 is a key inducer of liver graft rejection^[26], together with high level of IL-12 p35 and IL-12 p40 protein expression in the mature DCs derived from allogeneic liver grafts undergoing acute rejection^[42]. Our results suggest that NF- κ B may play a key role in the maturation of DCs derived from allogeneic liver grafts undergoing acute rejection.

To provide further insights into potential intracellular mechanisms responsible for maturation regulation of DCs derived from allogeneic liver grafts undergoing acute rejection, we measured the protective A20 gene expression in these DCs. Zinc finger protein A20 is a potent inhibitor of NF- κ B^[31], and although other studies have shown A20 is mainly expressed in endothelial and infiltrating mononuclear cells of human renal allografts undergoing acute rejection^[41], little is known about whether it is also involved in the regulation of DC maturation and activation. Our results first demonstrate that high level A20 expression is detected in the mature DCs (which present significant NF- κ B activation) derived from acute rejecting liver allografts, but few A20 is detected in the immature DCs (which present few NF- κ B activation) derived from nonrejecting liver allografts. Given A20 is itself a NF- κ B - dependent gene and is part of a negative regulatory loop critical for modulation of cell activation^[37, 38], together with NF- κ B which may play a key role in the maturation of DCs derived from liver allografts undergoing acute rejection, it is suggested that A20 expression in these mature DCs derived from liver allografts undergoing acute rejection survives to inhibit NF- κ B activation and to limit maturation of these DCs, and as a consequence to limit the graft rejection.

In summary, we demonstrate for the first time an association between NF- κ B activation and expression of the protective gene A20 and maturation of DCs derived from liver allografts undergoing acute rejection. NF- κ B binding activity and A20 expression in these mature DCs are strongly up-regulated in

response to acute rejection. NF- κ B may play a key role in the maturation of DCs derived from allogeneic liver grafts undergoing acute rejection, and A20 expression in these mature DCs derived from liver allografts undergoing acute rejection survives to inhibit NF- κ B activation and to limit maturation of these DCs.

Abstract

AIM: To evaluate the roles and mechanisms of celecoxib in inducing proliferation inhibition and apoptosis of human cholangiocarcinoma cell lines.

METHODS: Cyclooxygenase-2-overexpressing human cholangiocarcinoma cell line QBC939 and cyclooxygenase-2-deficient human cholangiocarcinoma cell line SK-CHA-1 were used in the present study. The anti-proliferative effect was measured by methabenzthiazuron (MTT) assay; apoptosis was determined by transferase-mediated dUTP nick end labeling (TUNEL) detection and transmission electron microscopy (TEM). Cell cycle was analyzed by flow cytometry (FCM). The PGE₂ levels in the supernatant of cultured cholangiocarcinoma cells were quantitated by enzyme-linked immunosorbent assay (ELISA).

RESULTS: Celecoxib suppressed the production of PGE₂ and inhibited the growth of QBC939 cells. Celecoxib at 10, 20, and 40 $\mu\text{mol/L}$ inhibited PGE₂ production by 26 %, 58 %, and 74 % in QBC939 cells. The PGE₂ level was much lower constitutively in SK-CHA-1 cells (18.6 ± 3.2) compared with that in QBC939 (121.9 ± 5.6) cells ($P < 0.01$) and celecoxib had no significant influence on PGE₂ level in the SK-CHA-1 cells. The PGE₂ concentration in SK-CHA-1 cells also reduced but not significantly after treatment with celecoxib. The PGE₂ concentration in SK-CHA-1 cells was (16.5 ± 2.9) ng/well, (14.8 ± 3.4) ng/well, (13.2 ± 2.0) ng/well and (12.6 ± 3.1) ng/well respectively, when pre-treated with 1 $\mu\text{mol/L}$, 10 $\mu\text{mol/L}$, 20 $\mu\text{mol/L}$ and 40 $\mu\text{mol/L}$ of celecoxib for 48 h ($P > 0.05$, vs control). The anti-proliferation effect of celecoxib (20 $\mu\text{mol/L}$) on QBC939 cells was time-dependent, it was noticeable on day 2 ($\text{OD}_{490} = 0.23 \pm 0.04$) and became obvious on day 3 ($\text{OD}_{490} = 0.31 \pm 0.07$) to day 4 ($\text{OD}_{490} = 0.25 \pm 0.06$), and the OD_{490} in the control group (day 1) was 0.12 ± 0.03 ($P < 0.01$, vs control). The anti-proliferation effect of celecoxib could be abolished by the addition of 200 pg/mL PGE₂. The proliferation of SK-CHA-1 cells was inhibited slightly by celecoxib, the cell density OD_{490} in the presence of celecoxib and in control group was 0.31 ± 0.04 and 0.42 ± 0.03 respectively on day 2 ($P > 0.05$), 0.58 ± 0.07 and 0.67 ± 0.09 respectively on day 3 ($P > 0.05$), and 0.71 ± 0.08 and 0.78 ± 0.06 respectively on day 4 ($P > 0.05$). Celecoxib induced proliferation inhibition and apoptosis by G₁-S cell cycle arrest: the percentage of QBC939 cells in G₀-G₁ phase after treatment with 40 $\mu\text{mol/L}$ (74.66 ± 6.21) and 20 $\mu\text{mol/L}$ (68.63 ± 4.36) celecoxib increased significantly compared

with control cells (54.41 ± 5.12 , $P < 0.01$). The percentage of SK-CHA-1 cells in G₀-G₁ phase after treatment with various concentrations of celecoxib didn't change significantly compared with control cells. The TUNEL index was much higher in QBC939 cells treated with 20 $\mu\text{mol/L}$ celecoxib for 2 d (0.063 ± 0.018) and for 4 d (0.102 ± 0.037) compared with control cells (0.017 ± 0.004 , $P < 0.01$).

CONCLUSION: The current *in vitro* study indicates that inhibition of proliferation and induction of apoptosis in human cholangiocarcinoma cells by cyclooxygenase-2 specific inhibitor celecoxib may involve in COX-dependent mechanisms and PGE₂ pathway. Celecoxib as a chemopreventive and chemotherapeutic agent might be effective primarily on COX-2-expressing cholangiocarcinoma.

INTRODUCTION

Prostaglandins (PGs) are important in the proliferation of various types of cancer cells^[1-13]. PGs are synthesized by two isoforms of cyclooxygenase (COX) enzymes, COX-1 and COX-2, each of which displays distinct physiological profile. Inducible isozyme COX-2 has been shown to be important in carcinogenesis^[14-26]. PGE₂ is the major metabolite of arachidonic acid in many human cells^[27,28]. The selective COX-2 inhibitors are currently being evaluated for their effectiveness as chemopreventive and chemotherapeutic agents^[29-32]. However, the effects of specific inhibitor of COX-2 on the proliferation of human carcinoma cells remain to be investigated. There are many controversies on whether or not these effects are mediated predominantly through the inhibition of COX-2 activity and prostaglandin synthesis^[33]. Our previous studies have demonstrated that overexpression of COX-2 may play a crucial role in the carcinogenesis and development of extra-hepatic cholangiocarcinoma. In this study we aimed to explore the effects and mechanism of celecoxib and the role of PGE₂ in inducing proliferation inhibition and apoptosis of COX-2 overexpressing human cholangiocarcinoma cell line QBC939 and COX-2-deficient human cholangiocarcinoma cell line SK-CHA-1.

MATERIALS AND METHODS

Materials

Human extra-hepatic cholangiocarcinoma cells SK-CHA-1 were a gift from Professor A. Knuth (Frankfurt, Germany)^[35], and human cholangiocarcinoma cell line QBC939 was established by Professor Wang SG in the Third Military Medical University, China, and was offered to us as a gift^[34]. Both cells were maintained as mono-layers in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10 %

fetal bovine serum (FBS, Gibco, USA.), 100 units/ml penicillin and 100 mg/ml streptomycin in a humidified atmosphere of 95 % air and 5 % CO₂ at 37 °C. They were subcultivated every 3–5 d and given fresh medium every other day. Cholangiocarcinoma cells at 70–80 % subconfluent were employed in all experiments. PGE₂ ELISA detection kit was purchased from Jingmei Biotech Co., Wuhan, China. TUNEL kit was purchased from Boster Co., Wuhan, China. PGE₂ was purchased from Sigma, USA. Celecoxib was synthesized by Dr. Mei ZN (Wuhan University, China) and given to us as a gift^[36]. Stock solution was prepared in dimethylsulfoxide (DMSO) and stored at -20 °C. In all experiments DMSO final concentration in the medium was ≤0.1 %.

Methods

MTT assay The human cholangiocarcinoma cells QBC939 and SK-CHA-1 proliferation status were determined by MTT assay. Cholangiocarcinoma cells were seeded at a density of 1×10^4 cells per well in flat-bottomed 96-well microplates. 12 h after incubation, cells were treated with celecoxib (40, 20, 10, or 0 μmol/L respectively). In some experiments 200 pg/mL PGE₂ was added to cells prior to addition of celecoxib. After 1, 2, 3, or 4 days' incubation, 20 μl MTT (5 g/L) was added to each well and incubated for 4 h. Supernatant was then removed and 150 μl DMSO was added. It was shaken for 5 min until the crystal was dissolved. OD_{490nm} value was measured by an enzyme-linked immunoabsorbent assay reader. The negative control well had no cells and was used as zero point of absorbance. Each well was read three times in triplicate.

TUNEL Preparation of specimens: cholangiocarcinoma cells QBC939 were subcultured on coverslips in 6-well culture plates. After 12 h, cells were treated with 20 μmol/L celecoxib. Every day medium and celecoxib were changed. After 2 and 4 d the coverslips were taken out and fixed with 4 % fresh polyformaldehyde in PBS (pH 7.4–7.6) for 30 min at room temperature. Cell apoptosis was measured by TUNEL method according to the instruction of the kit. Cells were washed with PBS for 2 min, 3 times, followed by washing with distilled water for 2 min, 3 times. Cells were soaked in fresh 3 % H₂O₂ for 10 min, and then rinsed with distilled water for 2 min, 3 times. Cells were digested with proteinase K (diluted 1:100 by TBS) for 5 min at 37 °C, and were rinsed with distilled water for 2 min, 3 times. Labelling buffer (20 μl/sample) was added to keep the slides wet. TDT and DIG-d-UTP (1 μl each) were mixed in 18 μl labelling buffer. The redundant liquid was removed and labelling reagent (20 μl/sample) was added. The slides were put in a humidified box and incubated for 2 h at 37 °C. The slides were washed with TBS for 2 min, 3 times. Blocking solution (50 μl/sample) was added to the slides for 30 min at room temperature. The blocking solution was removed from the slides. The biotin-DIG antibody was diluted with a blocking solution at a ratio of 1:100, and 50 μl/sample of it was added to the slides. The slides were kept in a humidified box, incubated at 37 °C for 30 min, and followed by washing with TBS for 5 min, 3 times. SABC was diluted to 1:100 with TBS and added to the slides. They were incubated at 37 °C for 30 min and washed with TBS for 5 min, 3 times. BCIP/NBT was diluted to 1:20 with TBS, and added to the slides. They were incubated at 37 °C for 10–30 min. The reaction was monitored under microscope: when purplish red was developed, the slides were washed with distilled water. After being stained with nuclear fast red, the slides were sealed with glycerite. Substitution of PBS for TUNEL staining solution was used as negative control. Three hundred cells were counted, and the TUNEL index was expressed as the number of positive cells/the total number of cells.

ELISA The PGE₂ levels in the supernatant of cultured human

cholangiocarcinoma cells QBC939 and SK-CHA-1 were quantitated by ELISA. Cells were seeded into 4.0×10^5 /well microplates and allowed to adhere overnight. The cells were then incubated in the presence or absence of celecoxib for 24 h. The supernatants were aspirated and centrifuged to prepare for the detection of PGE₂. Supernatant (0.5 ml) was added into 1 N HCl (0.1 ml) and centrifuged for 10 min at room temperature, then 1.2 N NaOH (0.1 ml) was used to neutralize the acidified samples. Standard solution (200 μl per well) or activated samples were added into the microplates. Then the steps for ELISA were performed as instructed. The value of OD of each well was measured at 450nm. The supernatants were harvested in triplicates and the experiment was performed twice.

FCM Human cholangiocarcinoma cells QBC939 and SK-CHA-1 were trypsinized and plated in 6-well culture dishes in the presence of celecoxib (40, 20, 10, 0 μmol/L respectively). After 48 h, cells were harvested, centrifuged at low speed and fixed in 70 % ethanol. After overnight incubation at 4 °C, cells were stained with 50 μg/ml propidium iodide in the presence of RNase A (10 μg/ml) and 0.1 % Triton X-100 and measured with a flow cytometer. The experiments were repeated three times.

TEM After treatment with celecoxib for 3 d cholangiocarcinoma cells QBC939 were digested by 0.25 % trypsin and collected. Cells were rinsed with PBS and fixed with 3 % glutaraldehyde for 30 min. After routine embedding and sectioning, cells were examined under electron microscope.

Statistical analysis

Data were expressed as mean ± standard deviation. Student's *t*-test was used for statistical analysis. $P < 0.05$ indicates significant difference.

RESULTS

PGE₂ production

The concentration of PGE₂ in culture medium of each cell line treated with or without celecoxib is shown in Figure 1. Celecoxib at 10 μmol/L inhibited PGE₂ production in QBC939 cells by 26 %. With 20 μmol/L and 40 μmol/L of celecoxib, PGE₂ production was further inhibited by 58 % and 74 %, which were statistically significant ($P < 0.01$, *vs* control). The PGE₂ level was much lower constitutively in SK-CHA-1 cells (18.6 ± 3.2) compared with that in QBC939 (121.9 ± 5.6) cells (*t* test, $P < 0.01$). The PGE₂ concentration in SK-CHA-1 cells was also reduced, but not significantly after treatment with celecoxib. The PGE₂ concentration in SK-CHA-1 cells was (16.5 ± 2.9) ng/well, (14.8 ± 3.4) ng/well, (13.2 ± 2.0) ng/well and (12.6 ± 3.1) ng/well respectively, when pre-treated with 1 μmol/L, 10 μmol/L, 20 μmol/L and 40 μmol/L of celecoxib for 48 h ($P > 0.05$, *vs* control).

Celecoxib inhibition on cholangiocarcinoma cells growth

QBC939 and SK-CHA-1 cells were incubated in the presence or absence of celecoxib (20 μmol/L) and the cell density OD₄₉₀ was measured. As shown in Figure 2, proliferation inhibition of QBC939 by celecoxib was time-dependent: it was noticeable on day 2 (OD₄₉₀ = 0.23 ± 0.04) and became obvious on day 3 (OD₄₉₀ = 0.31 ± 0.07) to day 4 (OD₄₉₀ = 0.25 ± 0.06), and the OD₄₉₀ in the control group (day 1) was 0.12 ± 0.03 ($P < 0.01$, *vs* control). The proliferation of SK-CHA-1 cells was inhibited slightly by celecoxib, but the effect was not statistically significant (Figure 3). The cell density OD₄₉₀ in the presence of celecoxib and in control group was 0.31 ± 0.04 and 0.42 ± 0.03 respectively on day 2 ($P > 0.05$), 0.58 ± 0.07 and 0.67 ± 0.09 respectively on day 3 ($P > 0.05$), and 0.71 ± 0.08 and 0.78 ± 0.06 respectively on day 4 ($P > 0.05$).

Figure 1 ELISA for PGE₂ detection using supernatants from QBC939 and SK-CHA-1 cells pre-treated with celecoxib at various concentrations for 48 h. Celecoxib at 10 μmol/L inhibited PGE₂ production in QBC939 cells by 26 %. With 20 μmol/L and 40 μmol/L of celecoxib, PGE₂ production was further inhibited by 58 % and 74 %, which were statistically significant (^a $P < 0.01$, vs control). The PGE₂ level was much lower constitutively in SK-CHA-1 cells (18.6 ± 3.2) compared with that in QBC939 (121.9 ± 5.6) cells (t test, ^b $P < 0.01$). The PGE₂ concentration in SK-CHA-1 cells was also reduced, but not significantly after treatment with celecoxib. The PGE₂ concentration in SK-CHA-1 cells was (16.5 ± 2.9) ng/well, (14.8 ± 3.4) ng/well, (13.2 ± 2.0) ng/well and (12.6 ± 3.1) ng/well respectively, when pre-treated with 1 μmol/L, 10 μmol/L, 20 μmol/L and 40 μmol/L of celecoxib for 48 h ($P > 0.05$, vs control).

Figure 2 Growth curves of QBC939 cells in the presence of celecoxib, celecoxib + PGE₂ and control group. Proliferation inhibition of QBC939 by celecoxib (20 μmol/L) was time-dependent: it was noticeable on day 2 and became significant on day 3 to 4 (^b $P < 0.01$, vs control). The anti-proliferation effect of celecoxib on QBC939 cells was abolished by pre-added PGE₂ (200 pg/mL).

Figure 3 Growth curves of SK-CHA-1 cells in the presence of celecoxib, celecoxib + PGE₂ and control group. The proliferation of SK-CHA-1 cells was inhibited slightly by celecoxib, the cell density OD490 in the presence of celecoxib and in control group was 0.31 ± 0.04 and 0.42 ± 0.03 respectively on day 2 ($P > 0.05$), 0.58 ± 0.07 and 0.67 ± 0.09 respectively on day 3 ($P > 0.05$), and 0.71 ± 0.08 and 0.78 ± 0.06 respectively on day 4 ($P > 0.05$).

PGE₂ abolished the anti-proliferation effect of celecoxib on QBC939 cells

To investigate whether the anti-proliferation effect of celecoxib on QBC939 cells was due to suppression of PGE₂ production by QBC939 cells, 200 pg/mL PGE₂ was added to QBC939 cells prior to the addition of celecoxib, and MTT assay was performed (Figure 2). The anti-proliferation effect of celecoxib on QBC939 cells was abolished by PGE₂. However, addition of 200 pg/mL PGE₂ had no significant influence on the proliferation of SK-CHA-1 cells when pre-treated with 20 μmol/L celecoxib (Figure 3).

Apoptosis induction and detection

The TUNEL index of QBC939 cells treated with 20 μmol/L celecoxib for 2 d (0.063 ± 0.018) and 4 d (0.102 ± 0.037) was much higher compared with control cells (0.017 ± 0.004 , $P < 0.01$).

Celecoxib induces G₁-S cell cycle arrest

Cell cycle analysis by flow cytometry showed that the percentage of QBC939 cells in G₀-G₁ phase after treatment with 40 μmol/L (74.66 ± 6.21) and 20 μmol/L (68.63 ± 4.36) increased significantly compared with control cells (54.41 ± 5.12 , $P < 0.01$, Figure 4). The percentage of SK-CHA-1 cells in G₀-G₁ phase after treatment with various concentrations of celecoxib did not change significantly compared with control cells.

Figure 4 Cell cycle analysis. Representative flow cytometry data from QBC939 cells after 48 h in the presence of various concentration of celecoxib: 0 μmol/L (A), 10 μmol/L (B), 20 μmol/L (C) and 40 μmol/L (D). The percentage of QBC939 cells in G₀-G₁ phase after treatment with 40 μmol/L (74.66 ± 6.21) and 20 μmol/L (68.63 ± 4.36) of celecoxib increased significantly compared with control cells (t test, $P < 0.01$).

Electron micrography of apoptosis of cholangiocarcinoma cells

QBC939 cells were treated for 3 d with 20 μmol/L of celecoxib. The chromatin became condensed and attached to the inner surface of nuclear membrane.

DISCUSSION

A substantial body of evidence indicates that COX and PGs are important in carcinogenesis. COX catalyzes the synthesis of PGs from arachidonic acid. Several PGs, most notably PGE₂, can promote tumorigenesis by stimulating angiogenesis, inhibiting immune surveillance^[37-40], modulating several signal

transduction pathways^[41-44]. Several studies have demonstrated that COX-2 selective inhibitor celecoxib has significant efficacy in animal cancer models: celecoxib inhibited intestinal tumor multiplicity by up to 71 % compared with controls in the Min mouse model and inhibited colorectal tumor burden in the rat azoxymethane (AOM) model^[45-48]. Recently celecoxib has been approved by FDA to reduce the number of adenomatous colorectal polyps in patients with familial adenomatous polyposis (FAP). However, the exact mechanisms that account for the anti-proliferative effects of celecoxib are still not fully understood. It is still controversial that whether or not these effects are mediated predominantly through the inhibition of COX-2 activity and prostaglandin synthesis. Several studies have shown both COX-dependent and COX-independent mechanisms are involved in non-steroidal anti-inflammatory drug (NSAIDs) induced growth in human colorectal tumor cells^[49].

Our previous studies have demonstrated that overexpression of COX-2 may play a crucial role in the carcinogenesis and development of extra-hepatic cholangiocarcinoma. In the present study we found the PGE₂ level was much lower constitutively in COX-2-deficient human cholangiocarcinoma cell line SK-CHA-1 cells than that in COX-2 overexpressing human cholangiocarcinoma cell line QBC939. In this study we have shown that the proliferation of QBC939 cells was inhibited by celecoxib in a time- and dose-dependent manner. Our study also showed celecoxib had no significant influence on the SK-CHA-1 cells. These findings indicate that COX-2 inhibitor might be an effective anti-proliferative agent, especially against cancer cells that express COX-2 and produce high-level PGE₂. Our data demonstrated that celecoxib suppressed the production of PGE₂ in QBC939 cells, and the anti-proliferative effect of celecoxib could be abolished by addition of PGE₂. These results suggest that COX-2 might play a central role in production of PGE₂ and the specific inhibition of COX-2 inhibits proliferation and induces apoptosis of QBC939 cells via suppression of PGE₂ production. Our data also indicate that celecoxib inhibits proliferation and induces apoptosis of human cholangiocarcinoma QBC939 cells by an accumulation of cells in the G₀/G₁ phase and the inhibition of G₀/G₁ phase transition to S phase.

In summary, our results in the present study demonstrate that inhibition of proliferation and induction of apoptosis by celecoxib in human cholangiocarcinoma cells may involve in COX-dependent mechanisms and PGE₂ pathway and these findings also suggest that celecoxib, as a chemopreventive and chemotherapeutic agent may be effective primarily on COX-2-expressing cholangiocarcinoma.

Abstract

AIM: To investigate the effects of melatonin (MT) on the expression of inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) in rat models of colitis.

METHODS: Healthy adult Sprague-Dawley (SD) rats of both sexes, weighing 280 ± 30 g, were employed in the present study. The rat models of colitis were induced by either acetic acid or 2,4,6-trinitrobenzene sulfonic acid (TNBS) enemas. The experimental animals were randomly divided into melatonin treatment and model control group that were intracolically treated daily with melatonin at doses of 2.5, 5.0, 10.0 mg·kg⁻¹ and equal amount of saline respectively from 24 h following induction of colitis in rats inflicted with acetic acid enema and the seventh day in rats with TNBS to the end of study. A normal control group of rats treated with neither acetic acid nor TNBS but saline enema was also included in the study. On the 28th day of the experiment, the rat colon mucosal damage index (CDMI) was calculated, and the colonic prostaglandin E₂ (PGE₂), nitric oxide (NO), as well as the iNOS and COX-2 expression were also determined biochemically or immunohistochemically.

RESULTS: CDMI increased to 2.87 ± 0.64 and 3.12 ± 1.12 respectively in rats treated with acetic acid and TNBS enema, which was in accordance with the significantly elevated colonic NO and PGE₂ contents, as well as the up-regulated colonic iNOS and COX-2 expression in both of the two rat models of colitis. With treatment by melatonin at the doses of 5.0 and 10.0 mg·kg⁻¹, CDMI in both models of rat colitis was significantly decreased ($P < 0.05-0.01$), which accorded synchronously and unanimously with the reduced colonic NO and PGE₂ content, as well as the down-regulated expression of colonic iNOS and COX-2.

CONCLUSION: Melatonin has a protective effect on colonic injury induced by both acetic acid and TNBS enemas, which is probably via a mechanism of local inhibition of iNOS and COX-2 expression in colonic mucosa.

INTRODUCTION

Inflammatory bowel disease (IBD) consists of a group of illnesses with chronic inflammation of the gastrointestinal tract, which causes life-impairing symptoms, necessitates long-term dependence on powerful drugs, and often results in debilitating surgery and even death. Although the etiology remains unclear, IBD appears to result from a dysregulated immune response. In recent years, plenty of studies have shown that nitric oxide (NO) and prostaglandin (PG) as the main inflammatory mediators take part in the pathogenesis of inflammatory bowel disease, with enhanced expression of inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) in the morbid colonic mucosa^[1,2]. Meanwhile, it has been noted melatonin (MT) normally produced mainly in the gastrointestinal tract besides the pineal gland bears a number of beneficial properties including anti-oxidation, anti-inflammation and immunoregulation^[3-15], and could alleviate colonic injury caused by both dextran sulfate sodium^[16] and dinitrobenzene sulfonic acid^[17] in rats. It is reasonable to extrapolate that the protective roles of melatonin might be related to its effect on the expression of iNOS and COX-2 in local tissue. We therefore performed the present study in an attempt to confirm this hypothesis.

MATERIALS AND METHODS

Animals

Healthy adult Sprague-Dawley (SD) rats of both sexes, weighing 280 ± 30 g, were employed in the study. They were purchased from the Experimental Animal Center, Anhui Medical University, housed in a temperature conditioned room (22-24 °C) with a 12 h light-dark cycle, allowed access to standard rat chow and water ad libitum, and acclimatized to the surroundings for one week prior to the experiments. The study protocol was in accordance with the guideline for animal research and was approved by the Ethical and Research Committee of the hospital.

Reagents

Melatonin, TNBS, and N-1-naphthylethylenediamine hydrochloride came from Sigma Corp. Acetic acid was purchased from Bangbu Chemical Corp. PGE₂ assay kit was from Radio-immunity Institute of PLA General Hospital. Immunohistochemical assay kits for iNOS and COX-2 were provided by Beijing Zhongshan Reagent Corp. Other reagents used in the present study were all with a quality of analytical grade.

Experimental protocol

Rat model of colitis induced with either acetic acid or TNBS enema was described in the literature^[18, 19]. According to different treatment regimens, the experimental animals were randomly divided into melatonin treatment and model control group that were intracolically treated under anesthesia with melatonin at doses of 2.5, 5.0, 10.0 mg·kg⁻¹ and equal amount of saline respectively and daily (8:00 am) from 24

h following induction of colitis in rats inflicted with acetic acid enema and the seventh day in rats after TNBS treatment to the end of the experiment. A normal control group of rats treated with neither acetic acid nor TNBS but saline enema was also included in the study. On the 28th day of the experiment, the animals were killed and the colon mucosal damage index (CDMI) was evaluated with the methods reported elsewhere^[19, 20]. At the same time, colon tissue prostaglandin E₂ (PGE₂) and nitric oxide (NO), as well as the expression of iNOS and COX-2 were determined biochemically or immunohistochemically.

Determination of NO and PGE₂

Colonic specimen was prepared to a concentration of 20 g·L⁻¹ by adding dehydrated alcohol-saline (1:4), and then centrifuged at 4 000 g for 30 min, 4 °C. Two milliliters of the supernatant were added into 0.1 ml of HCL (0.1 mol·L⁻¹) and further adjusted pH to 3.5 by 0.05 mol·L⁻¹ of NaOH. After mixed with ethyl acetate 5 ml for 2 min, they were centrifuged at 1 500 g for 15 min. Repeat the procedures above and the sample solution was evaporated to dryness by N₂ and stored at -20 °C until analysis. The samples were dissolved to 1 ml of phosphate buffered saline, from which 0.1 ml of specimen was taken to perform the PGE₂ measurement following the manufacturer's instruction of the assay kit^[21]. The colonic tissue NO was detected as described in the literature^[22].

Immunohistochemistry detection

The expression of iNOS and COX-2 in colon tissue was exhibited immunohistochemically as reported before^[23], in which the employed first polyclonal antibody was 1:80 rabbit-anti-rat-iNOS and 1:50 goat-anti-rat-COX-2, and the second antibody was biotinylation goat-anti-rabbit IgG and biotinylation rabbit-anti-goat IgG respectively. The iNOS or COX-2 negatively expressed cells were manifested as blue-stained nuclei and the positive cell was with brown-yellow cytoplasm or nuclear membrane. The expression of target protein was further semiquantitated according to the percentage of positively-stained cells, in which positive cells appeared less than 5 %, from 6 % to 30 %, from 31 % to 70 % and more than 71 % were scored as 0, 1, 2 and 3 respectively.

Statistical analysis

Experimental results were analyzed by ANOVA and *t*-tests for multiple comparisons between groups. Data were finally expressed as mean ± standard error of the mean. *P* value less than 0.05 was considered statistically significant.

RESULTS

Protective effects of melatonin on rat colonic lesion

Pronounced pathological changes of colonic mucosa similar to that in human IBD were observed in rats with colitis induced by both acetic acid and TNBS enema, which were in accordance with the colon mucosal damage index that was significantly increased in these experimental animals compared with normal controls (*P*<0.01). Local treatment with different doses of melatonin by enema could effectively reduce the severity of gut injury and the CDMI was significantly decreased in a dose dependent manner in rats treated by melatonin compared with that in model control animals (*P*<0.05-0.01, Table 1).

Effects of MT on NO content and iNOS expression

In normal controls, colonic iNOS expression was mainly observed on histocytes, neutrophils and smooth muscle

cells with a sparse distribution in epithelial cells. The NO content and the expression of iNOS in colonic tissue were synchronously and significantly increased in rats inflicted with both acetic acid and TNBS enema compared with that of the normal controls (*P*<0.01), which were significantly inhibited by different doses of melatonin employed in the present study (*P*<0.05-0.01 vs. Model control, Table 2, 3, Figure 1).

Effects of melatonin on PGE₂ content and COX-2 expression

Compared with normal group, the content of PGE₂ and the expression of COX-2 in rat colitis, the number of positive granules and the degree of staining were enhanced significantly. The content of PGE₂ was decreased after different doses of melatonin were given by enema. The expression of COX-2 was inhibited by melatonin, which proved that melatonin decreased the synthesis of PGE₂ and it might be related with inhibition of the expression of COX-2 (Figure 2, Table 2, 3).

Figure 1 Abnormal expression of iNOS in colonic tissue of rats with colitis induced by both acetic acid and TNBS enemas and its

improvement by melatonin. A. Immunohistochemical localization of iNOS in normal control, which was manifested as fine brown granules distributed mainly in the cytoplasm of histocytes, neutrophils and smooth muscle cells. B. Positively stained granules for iNOS were significantly increased in both number and intensity in colonic tissue of model control rats. (a) Acetic acid treated rats; (b) TNBS treated rats. C. The colonic iNOS expression was significantly reduced in both acetic acid (a) and TNBS (b) treated rats after intervened with 10.0 mg·kg⁻¹ of melatonin.

Figure 2 Abnormal expression of COX-2 in colonic tissue of rats with colitis induced by acetic acid or TNBS enema and its improvement by melatonin, which was in accordance with the observation in clonic iNOS expression. A. Positively stained COX-2 granules in colonic tissue of normal control rats. B. iNOS expression was significantly increased as manifested by the augmented and intensified positively stained granules in colonic tissue of model control rats. (a) Acetic acid treated rats; (b) TNBS treated rats. C. The colonic COX-2 expression was significantly reduced in both acetic acid (a) and TNBS (b) treated rats after intervened with 10.0 mg·kg⁻¹ of melatonin.

DISCUSSION

Although the etiology of IBD remains unclear, dysregulated immune response has been widely accepted as a possible mechanism in the pathogenesis of inflammatory bowel disease. Numerous reports have revealed that certain local bioactive agents including NO and PGE₂ are involved in colonic injury by various inducers^[1,2]. Meddleton and other authors^[24,25] found NO concentration was rather higher in ulcerative colitis patients with obviously strengthened iNOS activity. As an important inflammatory mediator, NO could react with superoxide anion to form more poisonous nitrite anion, which then disturbs the function of inflammatory cells and further impairs the colonic mucosa^[26,27]. PGE₂, another major local inflammatory mediator that might come from activated eosinophils and monocytes^[28], is also considered as a marker of colitis. In the two rat models of colitis respectively induced by acetic acid and TNBS in the present study, the mucosal NO and PGE₂ contents in the morbid colon were significantly increased with enhanced expression of iNOS and COX-2, which was in accordance with the previous reports.

Melatonin, a major hormone produced in pineal gland, was also found in recent years to be secreted for a certain amount from gastrointestinal tract and played an important role in the adjustment of gastrointestinal function^[7-14]. As a potent anti-oxidant agent that could clear oxygen-derived free radicals, inhibit the activation of NF-κB and reduce inflammatory response, melatonin has been widely used to treat inflammatory bowel diseases^[29,30]. Pentney and his coworker^[16] have shown melatonin could reduce the severity of dextran-induced colitis in mice. Protective effects of melatonin on dinitrobenzene sulfonic acid induced colitis have been proved by Cuzzocrea and his colleagues^[17]. In the present investigation, melatonin was demonstrated to reduce colonic lesions induced by acetic acid and TNBS enemas, which combined with the reports above, suggested that the protective effect of melatonin on the induced colitis might be universal. The present study also revealed the improvement of colonic lesions by melatonin accorded synchronously and unanimously with the decrease of colonic NO and PGE₂ content, as well as the down-regulated expression of colonic iNOS and COX-2, which indicates the improvement is probably via a mechanism of local inhibition of iNOS and COX-2 expression in the colonic mucosa. Further studies are needed to explore other mechanisms involved in the protection of colonic mucosa by melatonin.

Abstract

AIM: Previous studies showed that exogenous basic fibroblast growth factor (bFGF or FGF-2) could improve physiological dysfunction after intestinal ischemia/reperfusion (I/R) injury. However, the mechanisms of this protective effect of bFGF are still unclear. The present study was to detect the effect of bFGF on the activities of mitogen-activated protein kinase (MAPK) signaling pathway in rat intestine after I/R injury, and to investigate the protective mechanisms of bFGF on intestinal ischemia injury.

METHODS: Rat intestinal I/R injury was produced by clamping the superior mesenteric artery (SMA) for 45 minutes and followed by reperfusion for 48 hours. Seventy-eight Wistar rats were used and divided randomly into sham-operated group (A), normal saline control group (B), bFGF antibody pre-treated group (C), and bFGF treated group (D). In group A, SMA was separated without occlusion. In groups B, C and D, SMA was separated and occluded for 45 minutes, then, released for reperfusion for 48 hours. After the animals were sacrificed, blood and tissue samples were taken from the intestine 45 minutes after ischemia in group A and 2, 6, 24, and 48 hours after reperfusion in the other groups. Phosphorylated forms of p42/p44 MAPK, p38 MAPK and stress activated protein kinase/C-Jun N-terminal kinase (SAPK/JNK) were measured by immunohistochemistry. Plasma levels of D-lactate were examined and histological changes were observed under the light microscope.

RESULTS: Intestinal I/R injury induced the expression of p42/p44 MAPK, p38 MAPK, and SAPK/JNK pathways and exogenous bFGF stimulated the early activation of p42/p44 MAPK and p38 MAPK pathways. The expression of phosphorylated forms of p42/p44 MAPK was primarily localized in the nuclei of crypt cells and in the cytoplasm and nuclei of villus cells. The positive expression of p38 MAPK was localized mainly in the nuclei of crypt cells, very few in villus cells. The activities of p42/p44 MAPK and p38

MAPK peaked 6 hours after reperfusion in groups B and C, while SAPK/JNK peaked 24 hours after reperfusion. The activities of p42/p44 MAPK and p38 MAPK peaked 2 hours after reperfusion in group D and those of SAPK/JNK were not changed in group B. D-lactate levels and HE staining showed that the intestinal barrier was damaged severely 6 hours after reperfusion; however, histological structures were much improved 48 hours after reperfusion in group D than in the other groups.

CONCLUSION: The results indicate that intestinal I/R injury stimulates the activities of MAPK pathways, and that p42/p44 MAPK and p38MAPK activities are necessary for the protective effect of exogenous bFGF on intestinal I/R injury. The protective effect of bFGF on intestinal dysfunction may be mediated by the early activation of p42/p44 MAPK and p38 MAPK signaling pathways.

INTRODUCTION

Previous studies have shown that intestinal ischemia/reperfusion (I/R) injury reduce the expression of endogenous basic fibroblast growth factor (bFGF) in rats, and the intravenous administration of exogenous bFGF could induce the expression of endogenous bFGF and improve the physiological functions of the intestine, lung, kidney, and other internal organs after I/R injury^[1-6]. However, the protective mechanisms of bFGF on intestinal I/R injury remain unknown.

Mitogen-activated protein kinase (MAPK) cascade, a cytoplasmic protein kinase that requires dual phosphorylation on specific threonine and tyrosine residues for their activation, can transmit mitogen or differentiation signals from the cell surface into the nucleus, thus regulating the gene expression^[7-10]. P42/p44 MAPK, p38MAPK and stress activated protein kinase/C-Jun N-terminal kinase (SAPK/JNK) are three important members of the MAPK family. The purpose of the present study was to detect the activities of mitogen-activated protein kinase (MAPK) signaling pathway in rat intestine after administration of bFGF, and to investigate the protective mechanisms of bFGF on intestinal (I/R) injury.

Rat intestinal I/R injury was produced by clamping the superior mesenteric artery (SMA) for 45 minutes and by different durations of reperfusion^[11]. The activities of p42/p44 MAPK, p38 MAPK, and SAPK/JNK were measured after administration of bFGF or bFGF monoclonal antibody. The results indicate that the early activation of p42/p44 MAPK and p38 MAPK is necessary for the protective effect of bFGF on intestinal I/R injury.

MATERIALS AND METHODS

Animal model

Seventy-eight healthy Wistar rats weighing 220 ± 20 g (Animal Center, Academy of Military Medical Sciences, Beijing) were used. All animals were housed in the laboratory and given free access to food and water for 1 week before being used. The animal was under anesthesia by 3 % sodium pentobarbital (40 mg/kg), a middle incision was made. The superior mesenteric artery (SMA) was identified and freed by blunt dissection. A microvascular clamp was placed at the root of SMA to cause complete cessation of blood flow for 45 minutes, and thereafter the clamp was loosened to form reperfusion injury^[1,11]. After 2, 6, 24 and 48 hours reperfusion, the animals were sacrificed and blood samples and intestinal tissue biopsies were taken. Blood samples were centrifuged and serum was frozen to measure plasma D-lactate. Tissue biopsies were fixed with 4 % paraformaldehyde.

In this study, all operations were performed under aseptic conditions. The animal experiments were approved by the local animal management committee.

Experimental design

The animals were randomly divided into four groups: sham-operated (A), normal saline control (B), bFGF monoclonal antibody (Sigma, St. Louis, MO, USA) pre-treated (C) and bFGF (Sigma, St. Louis, MO, USA) treated groups (D). In group A, SMA was freed but without occlusion and blood samples and tissue biopsies were taken 45 minutes after exposure of the SMA. In groups B and D, 0.15 ml saline or 0.15 ml saline plus bFGF (2 μ g/rat) was injected immediately 45 minutes after SMA occlusion from the tail vein. In group C, 0.15 ml saline plus bFGF monoclonal antibody (25 μ g/rat) was injected right before SMA occlusion from tail vein for pre-treatment.

Measurement of phosphorylated forms of p42/p44 MAPK, p38 MAPK and SAPK/JNK

Formalin-fixed, paraffin-embedded small intestinal tissues were used to measure the expression of phosphorylated forms of p42/p44 MAPK, p38 MAPK, and SAPK/JNK by immunohistochemistry. Immunohistochemical staining was performed according to the instructions of the PowerVision™ kit (Santa Cruze, USA). Briefly, sections (5 μ m) were dewaxed and rehydrated in graded alcohols. Endogenous peroxidase activity was quenched, and antigen retrieval was performed by heating for 20 minutes at 100 °C in 0.01 mol/L sodium citrate. The primary monoclonal antibodies for p42/p44 MAPK, p38 MAPK and SAPK/JNK (Cell Signaling Technology, Inc., USA) were diluted to 1:100 in buffer and incubated for 40 minutes at 37 °C. The sections were then incubated with HRP-conjugated secondary antibodies (Santa Cruz, USA) for 20 minutes at 37 °C. Positive expression was detected with diaminobenzidine (DAB) (Sigma, St. Louis, MO, USA). The sections were lightly counterstained with hematoxylin, dehydrated in graded alcohol, and mounted. For negative control, the sections were processed similarly but PBS was used as primary antibodies instead of the MAPKs monoclonal antibodies.

The result of positive staining was semi-quantitatively defined as -, +, ++ and +++. This was observed under microscope with 10 times eyepiece and 40 times objective. "-" represents no visible positive staining, "+" less than 10 stained cells and "++" 10-30 stained cells, while "+++" represents more than 30 positively stained cells within one high power field.

Measurement of plasma D-lactate

The levels of plasma D-lactate were measured with modified Brandt's method^[12]. Briefly, heparinized blood was centrifuged at 3 200 rpm for 10 min and 2 ml of the plasma was deproteinized with 0.2 ml perchloric acid (PCA) (1/10 vol),

mixed and kept in an ice bath for 10 min. The denatured protein solution was centrifuged at 3 200 rpm for 10 min and the supernatant solution was removed. To 1.4 ml of supernatant solution, 0.12 ml KON was added and they were mixed for 20 s. Precipitant KClO₄ was removed by centrifugation at 3 200 rpm for 10 min. The supernatant solution and neutralized-protein-free plasma were used to measure the absorbency at 340 nm. Plasma D-lactate concentration was expressed as mmol/L.

Histological observation

Paraformaldehyde fixed, paraffin embedded small intestine samples were also cut 5 μ m in thickness, deparaffinized in xylene, rehydrated in graded ethanol, and then stained with haematoxylin-eosin (HE) for histological observation under light microscope (Olympus, Japan).

Statistical analysis

Data were expressed as mean \pm standard error. Comparisons between groups of data were analyzed by Student's *t*-test. *P* values <0.05 were considered statistically significant.

RESULTS

Activities of p42/p44 MAPK and p38 MAPK

Quantitative immunohistochemical results for phosphorylated forms of p42/p44 MAPK and p38 MAPK were evaluated (Tables 1 and 2). The expression of activated p42/p44 MAPK was localized in the cytoplasm and nuclei of villus cells and in the nuclei of crypt cells, mainly in the epithelium and villus cells (Figure 1). Activated p38 MAPK was localized primarily in the nuclei of crypt cells, very few in villus cells (Figure 2). There was a consistent correlation between positive expression levels and the intensity of p42/p44 MAPK and p38 MAPK. The positive expression of p42/p44 MAPK and p38 MAPK was weak in the sham-operated intestinal tissues and ischemic tissues. However, the number of positive staining cells increased with high staining intensity after reperfusion injury. In the normal saline and bFGF antibody pre-treated groups, the number of positive staining cells of p42/p44 MAPK (Figures 1B and C) and p38 MAPK (Figures 2B and C) increased 2 hours after reperfusion, peaked at 6th hours, and decreased from 24 to 48 hours. In the bFGF treated group, however, the number of positive staining cells and the intensity of p42/p44 MAPK and p38 MAPK peaked 2 hours after reperfusion (Figures 1D and 2D) and decreased afterwards, but they were still higher than those in the sham-operated control at 48 hours. Compared with the normal saline and bFGF treated groups, the intensity of p42/p44 MAPK and p38 MAPK positive staining in the bFGF antibody pretreated group was weaker from 2 hours to 48 hours after reperfusion.

Activities of SAPK/JNK

Weak staining of SAPK/JNK was observed in small intestine after I/R injury. Positive staining was localized in the nuclei and cytoplasm of villus and crypt cells. The staining, however, was weak without much difference among the groups (Table 3). The positive staining of SAPK/JNK in bFGF treated group was slightly higher only at 24 hours after reperfusion. Among all the groups, the positive staining of SAPK/JNK was weaker than that of p42/p44 MAPK and p38 MAPK.

Changes of plasma D-lactate levels

Plasma D-lactate levels were measured 2, 6, 24, and 48 hours after reperfusion in all groups. They were elevated 2 hours after reperfusion in all groups, peaked at 6th hour, and decreased to nearly normal 48 hours later (Table 4). The levels at 45 min after ischemia in the sham-operated group were served as controls.

Figure 1 Immunohistochemical staining of phosphorylated p42/p44 MAPK in intestinal biopsies in rats after ischemia/reperfusion injury (SP×200). A: Negative control of p42/p44 MAPK staining. There was no positive expression signal in this group. B: The expression of phosphorylated p42/p44 in intestinal biopsies in the saline control group 2 hours after reperfusion. The activated p42/p44 MAPK expression was localized in the cytoplasm and nuclei of villus cells and in the nuclei of crypt cells, mainly in the epithelium and villus cells. C: Phosphorylated p42/p44 staining in the bFGF antibody pre-treated group. The number of positive cells and intensity in this group were weaker compared with those in the saline control and bFGF treated groups. D: The expression of phosphorylated p42/p44 in the bFGF treated group 2 hours

after reperfusion. The activated p42/p44 MAPK expression was localized in the cytoplasm and nuclei of villus cells and in the nuclei of crypt cells, mainly in the epithelium and villus cells. The number of positive cells in this group was more than that in the bFGF antibody pre-treated group. ISH×400.

Figure 2 Immunohistochemical staining of phosphorylated p38 MAPK in intestinal biopsies in rats after ischemia/reperfusion injury (SP×200). A: Negative control of p38 MAPK staining. There was no positive expression signal in this group. B: Phosphorylated p38 MAPK staining in the saline control group 2 hours after reperfusion. Few p38 MAPK positive expression were localized in the cytoplasm and nuclei of villus cells and in the nuclei of crypt cells, mainly in the

epithelium and villus cells. C: P38 MAPK staining in the bFGF antibody pre-treated group. The number of positive cells and localization of p38 MAPK positive cells were similar with those in the saline group. D: Phosphorylated p38 staining in the bFGF treated group 2 hours after reperfusion. Activated p38 MAPK was localized primarily in the nuclei of crypt cells, few in villus cells. The number of positive cells was more than that in the saline control and bFGF antibody pre-treated groups. In the bFGF treated group, the number of positive expression cells of p38 MAPK as well as its intensity peaked 2 hours after reperfusion.

Histological evaluation

Intestinal I/R injury resulted in the damage of intestinal barrier and the increase of mucosal permeability. HE staining showed partial loss of the mucosa 2 hours after reperfusion. 6 hours after reperfusion, however, the damage of intestinal epithelial cells, hemorrhage and necrosis were observed and accompanied by inflammatory cell infiltration into the intestinal wall. Histological structure of the intestinal mucosa was markedly improved after administration of bFGF.

DISCUSSION

Intestinal I/R injury causes release of bacteria and toxin from the gut into the host blood circulation and changes of inflammatory factors, cytokines and growth factors, resulting in damage to the intestinal barrier and other internal organs^[1-3,13-17]. We found that administration of exogenous basic fibroblast growth factor (bFGF) could reduce the intestinal injury caused by I/R insult. However, the mechanisms of this protective effect of bFGF are not elucidated. bFGF is expressed in many normal adult tissues and has mitogenic activity in a wide variety of cells of mesenchymal, neuronal, and epithelial origins, and regulates events in normal embryonic development, angiogenesis, wound repair, and neoplasia^[18-20]. Also, it can regulate migration and replication of intestinal epithelial cells in culture^[21]. Recent studies have shown that L-glutamine, tumor necrosis factor- α and epidermal growth factor (EGF) stimulate proliferation of intestinal crypt cells by activating the MAPK pathway, and that p42/p44 MAPK activities are necessary for both cell cycle progression and differentiation of the intestinal cells^[22-25]. In many other cell types, growth factor controls proliferation and differentiation

via the MAPK pathway. MAPK is a common signal pathway to transmit the mitogen or the differentiating signals from the cell surface to the nucleus, and thus ultimately regulates different gene expression^[26-28]. Hence, we hypothesized that MAPK activation might be involved in the regulation of bFGF signals in the process of intestinal barrier repair.

To investigate this hypothesis, we evaluated changes of the activated MAPK signal pathway after administration of bFGF and bFGF antibodies. We found that intestinal I/R injury stimulated the activities of phosphorylated forms of the p42/p44 MAPK and p38MAPK pathways, and increased the SAPK/JNK activity slightly. p42/p44 MAPK and p38MAPK activities were increased 2 hours after reperfusion, and peaked at 6 hours. At the same time, the levels of SAPK/JNK increased slightly 24 hours after reperfusion compared with those of the normal control. Phosphorylated forms of p42/p44 MAPK were mainly localized in the nuclei of crypt cells and in the cytoplasm and nuclei of villus cells, whereas those of p38MAPK were primarily localized in the nuclei of crypt cells, few in villus cells. After administration of bFGF, the expression of both p42/p44 MAPK and p38MAPK was quickly stimulated, and the activation of both p42/p44 MAPK and p38MAPK peaked 2 hours after reperfusion, declined gradually to normal at 48 hours. A coherence was noted between the changes of p42/p44 MAPK and p38MAPK and histological findings. These results indicate that intestinal I/R injury induces the activities of the MAPK pathways, and p42/p44 MAPK and p38MAPK activities are necessary for the protective effects of exogenous bFGF on intestinal I/R injury. The early stimulation of the p42/p44 MAPK and p38MAPK signal pathways may mediate the protective effects of bFGF on intestinal dysfunction.

MAPK family is composed of "extracellular signal regulated" p42/p44 MAPK, "stress-regulated" MAPK (SR-MAPKs), stress-activated protein kinases (SAPKs)/c-Jun N-terminal kinases (JNKs) and p38-MAPKs. On stimulation, MAPKs are translated into the nucleus where they may phosphorylate nuclear transcription factors and thus regulate gene expression. The four principal differentiated cell lineages of intestinal epithelium are derived from common multipotent stem cells located near the base of each crypt. These crypt stem cells divide to produce daughter stem cells as well as more rapidly replicating transit cells, which in turn undergo 4-6 rapid cell divisions in the proliferative zone located in the lower half of each crypt^[29,30]. Factors determining whether cells continue to proliferate, cease dividing, and begin to differentiate, appear to operate during the first gap phase (G1) of the cell cycle. P42/p44 is activated during G0 to G1 transition, and the activity remains elevated up to S phase entry, implicating this family of protein kinases in the control of G1 progression^[31,32]. Activation of p42/p44 MAPK is also necessary for growth factor-dependent proliferation of some cell lines.

We propose the possible mechanisms of the protective effects of bFGF on intestinal I/R injury be involved in the activation of MAPK pathway. First, to protect the survival of intestinal stem cells within crypt and mediate the proliferation and differentiation of these cells. Intestinal epithelium is maintained by continuous and rapid replacement of differentiated epithelial cells by replication of undifferentiated epithelial cells. Exogenous bFGF markedly enhances the survival of crypt stem cells before and after irradiation injury^[33]. Microvascular endothelial apoptosis is the primary lesion leading to stem cell dysfunction, while endothelial apoptosis could be inhibited by intravenous bFGF^[34]. Second, to regulate the inflammation reactions after I/R injury. The TNF translation by IL-10 is inhibited mainly by inhibiting the activation of the p38 MAPK pathway^[35]. This is necessary for maintenance of immune homeostasis in the gut.

In the perfused heart, ischemia/reperfusion activates stress-

regulated MAPKs, direct pharmacological activation of p38 triggers delayed preconditioning of the heart, and there is minimal activation of the p42/p44 MAPK subfamily by heart I/R injury^[35-37]. Yet phosphorylation of p42/p44 MAPK occurs consistently in the grey matter penumbra of brain tissue after ischemic stroke, and may be associated with neuronal survival and/or angiogenic activity in the recovering brain tissue^[38]. The results indicate that the MAPK pathways respond differently to ischemic injury in different sites.

The changes of serum D (-)-lactate were used as a predictor of intestinal I/R injury in this study. D (-)-lactate is the stereoisomer of mammalian L (+)-lactate. Mammalian tissue does not produce D (-)-lactate and only slowly metabolizes it. It is a strict product of bacterial fermentation. Since mammals do not possess the enzyme systems to rapidly metabolize D (-)-lactate^[11, 39,40], the released D (-)-lactate will pass through the gut barrier and liver in an unchanged form and appear in the peripheral blood. As intestinal ischemia injury causes mucosal injury and subsequent bacterial proliferation, D (-)-lactate is released from gut into the circulation. In this study, the serum D (-)-lactate level was increased after injury, but in the bFGF treated group, it was not significantly increased as in the control group, indicating that bFGF exerts a positive protective effect on the mucosal barrier and decreases the intestinal permeability.

In summary, intestinal I/R injury induces the activities of the MAPK pathways, and p42/p44 MAPK and p38MAPK activities are necessary for the protective effect of exogenous bFGF on intestinal I/R injury. The protective effect of bFGF on intestinal dysfunction may be mediated by the early stimulation of the p42/p44 MAPK and p38 MAPK signaling pathways.

Abstract

AIM: To evaluate effects of nitric oxide (NO) and peroxynitrite anion (ONOO⁻) on lung injury following intestinal ischemia-reperfusion (IR) in rats.

METHODS: A rat model of intestinal ischemia was made by clamping superior mesenteric artery and lung injury was resulted from reperfusion. The animals were randomly divided into 3 groups: sham operation (Sham), 2 h ischemia followed by 2 h reperfusion (IR) and IR pretreated with aminoguanidine (AG) - an inhibitor of inducible NO synthase (iNOS) 15 minutes before reperfusion (IR+AG). The lung malondialdehyde (MDA) and nitrate/nitrite (NO₂⁻/NO₃⁻) contents and morphological changes were examined. Western blot was used to detect the iNOS protein expression. Immunohistochemical staining was used to determine the change of nitrotyrosine (NT) - a specific "footprint" of ONOO⁻.

RESULTS: The morphology revealed evidence for lung edema, hemorrhage and polymorphonuclear sequestration after intestinal IR. Compared with sham group, lung contents of MDA and NO₂⁻/NO₃⁻ in IR group were significantly increased (12.00±2.18 vs 23.44±1.25 and 76.39±6.08 vs 140.40±4.34, *P*<0.01) and the positive signals of iNOS and NT were also increased in the lung. Compared with IR group, the contents of MDA and NO₂⁻/NO₃⁻ in IR+AG group were significantly decreased (23.44±1.25 vs 14.66±1.66 and 140.40±4.34 vs 80.00±8.56, *P*<0.01) and NT staining was also decreased.

CONCLUSION: Intestinal IR increases NO and ONOO⁻ production in the lung, which may be involved in intestinal IR-mediated lung injury.

INTRODUCTION

A devastating consequence of tissue reperfusion is the damage

in organs uninvolved in the initial ischemic insult^[1]. Multiple organ dysfunction syndrome (MODS), as it is known, is the leading cause of death in critically ill patients and is a documented consequence of gut reperfusion^[2-5]. Although systemic inflammatory characteristic of MODS can result in damage to any organ, onset of the syndrome is usually heralded by the development of respiratory insufficiency^[2-9]. The pathophysiology of lung injury associated with intestinal ischemia-reperfusion (IIR) probably involves a variety of inflammatory and vasoactive mediators. Recently, the production of large amounts of nitric oxide (NO), a free radical produced by the inducible isoform of NO synthase (iNOS) has been implicated as a cytotoxic factor in a variety of pathophysiological processes, including various forms of inflammation and circulatory shock^[10-14]. The cytotoxic effects of NO are in part, mediated by peroxynitrite anion (ONOO⁻), a reactive oxidant species formed from NO and superoxide at an almost diffusion-controlled rate^[15-18]. The production of ONOO⁻ has been demonstrated in various lung injury^[19-21]. However, no evidence exists about its change and role in the lung injury following IIR. The major aim of the present study, therefore, was to determine the change and role of iNOS and peroxynitrite in lung injury induced by IIR.

MATERIALS AND METHODS

Animal model^[22]

Male healthy Sprague-Dawley rats (250-300 g) were anesthetized with intraperitoneal administration of sodium pentobarbital (40 mg·kg⁻¹) and secured in a supine position on a heated restraining board at 37 °C after being shaved. Following midline laparotomy, a microvascular clip was placed across the superior mesenteric artery (SMA) for 120 minutes. Removal of the clip allowed reperfusion for 120 minutes. This degree of IIR is consistently associated with intestinal, hepatic and pulmonary injury with a 12-hour mortality rate of 100 %.

Experimental protocols

To determine the effect of iNOS induction on the peroxynitrite formation and the lung injury, aminoguanidine (AG), an inhibitor of iNOS^[23], was used. The rats were randomly divided into 3 groups (*n*=8 in each): Sham, IR and IR+AG. The surgical sham group underwent full surgical preparation including isolation of the SMA without occlusion. After that they were followed for the same aggregate period of time. The IR group received 2 h of ischemia and 2 h of reperfusion. The IR + AG group was given AG (10 mg·kg⁻¹ intravenously, Sigma, USA) 15 min before reperfusion. The animals in IR group and sham group were treated with equal volume of the vehicle (normal saline solution, NS; 1 ml·kg⁻¹). All animals were killed by exsanguination at designated time. Both lungs were harvested immediately for the following detection.

Lung histology

The right middle lung lobe was harvested and fixed in 10 % formalin. After embedded in paraffin, sections of 8 μm were stained with hematoxylin and eosin for light microscopy.

Assessments of lung malondialdehyde (MDA) content

The right base of lung was harvested and immediately homogenized on ice in 9 volumes saline. The homogenates were centrifuged at $4\,000\text{ r}\cdot\text{min}^{-1}$ at $4\text{ }^{\circ}\text{C}$ for 10 min. The MDA content in the supernatants was measured using MDA assay kit (Nanjing Jiancheng Corp. China).

Lung nitrite/nitrate ($\text{NO}_2^-/\text{NO}_3^-$) detection

$\text{NO}_2^-/\text{NO}_3^-$ production, an indicator of NO synthesis, was measured in the lung homogenate with a NO assay kit (Nanjing Jiancheng Corp. China) following the manufacturer's instruction.

Western blotting analysis for iNOS

The left lung was homogenized with PBS (pH 7.2) and centrifuged at $4\text{ }^{\circ}\text{C}$, $18\,000\text{ r}\cdot\text{min}^{-1}$ for 10 min. After precipitated unsolubilized fraction was discarded, the protein concentration in the supernatant was determined by Coomassie blue dye-binding assay (Nanjing Jiancheng Corp. China). Aliquots ($30\text{ }\mu\text{g}$) of protein from each sample were electrophoresed on a $120\text{ g}\cdot\text{L}^{-1}$ SDS-polyacrylamide gel for 4 hour at 100V. The protein samples were transferred onto a nitrocellulose membrane (Amersham, USA). The membrane was then probed with polyclonal rabbit anti-rat iNOS antibody (1:50 dilution, Santa Cruz Co., USA) for 2 hours at $37\text{ }^{\circ}\text{C}$. After 3 washes with TPBS, blots were visualized with the use of an amplified HRP kit (Wuhan Boshide, China). The presence of iNOS was indicated by the development of brown color.

Immunohistochemical analysis of NT

Tyrosine nitration, a specific "footprint" of peroxynitrite formation^[16], was detected in the left lung by immunohistochemical technique. The left lung was harvested and fixed in 10 % formalin. Sections of $8\text{ }\mu\text{m}$ thickness of lung tissue were treated with 0.3 % H_2O_2 in methanol to block endogenous peroxide activity. Immunohistochemical staining was performed using rabbit polyclonal antibody against NT (1:50 dilution, Cayman Chemical, USA) by indirect streptavidin/peroxidase technique (SP kit, Zymed Co., USA). Experiments were performed following the manufacturer's instruction. Paraffin-embedded sections were incubated with polyclonal anti-rat NT antibody for 12 hours at $4\text{ }^{\circ}\text{C}$ after antigen retrieval. Biotinylated IgG was added as second antibody. Horseradish peroxidase labeled streptomycin-avidin complex was used to detect second antibody. Slides were stained with diaminobenzidine, and examined under light microscope. The brown or dark brown stained cytoplasm was considered as positive.

Statistical analysis

Values were expressed as mean \pm SD ($\bar{x}\pm s$). Statistical analyses were performed using paired Student's *t* test. $P<0.05$ was considered significant.

RESULTS

Pathological alternations of lung tissue

The histological structure of alveolar and mesenchymal cells was normal in the lungs of sham group, while the lung tissues from the IR group were significantly damaged, with pulmonary edema, hemorrhage and inflammatory cell infiltration. Administering AG before reperfusion could attenuate significantly the lung injury as showed by light microscope (Figure 1).

Change of MDA content

The lung MDA content was increased significantly in IR group

when compared with the sham control ($P<0.05$). Compared with the IR group, the MDA content was decreased markedly in IR +AG group ($P<0.05$) (Table 1).

Table 1 Changes of MDA and $\text{NO}_2^-/\text{NO}_3^-$ contents in lung tissue after IIR with pretreatment of AG in rats ($\bar{x}\pm s$, $n=8$)

Groups	MDA (nmol.ml ⁻¹)	$\text{NO}_2^-/\text{NO}_3^-$ (umol.L ⁻¹)
Sham	12.00 \pm 2.18	76.39 \pm 6.08
IR	23.44 \pm 1.25 ^a	140.40 \pm 4.34 ^a
IR+AG	14.66 \pm 1.66 ^c	80.00 \pm 8.56 ^c

^a $P<0.05$ vs Sham group. ^c $P<0.05$ vs IR group.

Figure 1 Light microscopic observation on the lung after IIR with pretreatment of AG in rats (HE \times 400). A. The normal lung tissue structure was found in sham group. B. Lung edema, hemorrhage and inflammatory cells sequestration were found in the IR group. C. Decreased morphological changes induced by the intestinal IR were found in the IR+AG group.

Change of nitrite/nitrate

Compared with the sham group, the lung content of nitrite/nitrate in IR group was increased significantly ($P<0.05$). Compared with the IR group, the content of nitrite/nitrate in IR+AG group was decreased significantly ($P<0.05$) (Table 1).

Change of iNOS expression

Western blotting showed that weak positive signal was found in the lung in sham group. In contrast, marked increase of iNOS protein expression was found in the IR group. There was still notable positive signal in the IR+AG group (Figure 2).

Figure 2 Western blotting analysis of iNOS in rat lung after IIR with pretreatment of AG in rats. 1. Sham; 2. IR; 3. IR+AG.

Change of NT formation

The formation of peroxynitrite in the lung sections was demonstrated by immunohistochemical staining with monoclonal anti-NT antibodies. In the sham group, no brown deposits were present in lung sections. In contrast, very strong staining was observed in lung tissue sections from the IR group. Compared with the IR group, the immunostaining for NT in the IR+AG group decreased significantly, indicating that inhibition of iNOS activity and decrease of NO production could reduce the peroxynitrite formation (Figure 3).

Figure 3 Immunohistochemical analysis of NT in the lung after IIR with pretreatment of AG in rats. SP stain $\times 400$. A. No

positive signal was found in the lung in sham group. B. Intense positive NT staining was found in the IR group. C. Positive NT staining decreased in the IR+AG group.

DISCUSSION

The lung is one of the very important target organs in multiple organ dysfunction syndrome (MODS) or multiple system organ failure (MOSF) caused by severe injury^[1-9]. It has been found that in addition to the direct trauma, the lung could also be damaged by indirect injury such as gut, liver and skeletal muscle reperfusion, as well as aortic occlusion-reperfusion and circulatory shock^[1-9]. The present results showed that 2 h of intestinal ischemia followed by 2 h of reperfusion induced lung injury, manifested as the histological evidence of lung edema, hemorrhage and PMN infiltration. Moreover, the IIR mediated lung injury was oxygen-dependent, as indicated by the increase in the levels of MDA, an established marker of oxidative stress.

The mechanism of respiratory failure after intestinal I/R is complex and poorly understood. Under the condition of an inadequate mucosal blood flow, the gut barrier function can be progressively impaired and invaded by bacteria or endogenous endotoxin^[24-26]. This process is associated with activation of systemic inflammatory mediators including bacteriotoxin, inflammatory mediators, such as tumor necrosis factor (TNF) and interleukin (IL) and immunocytokines^[26-31]. In addition, several recent observations implicate that NO may be an important participant in the pulmonary response to IIR^[32]. It has been suggested that nitric oxide (NO), produced from endothelial constitutive nitric oxide synthase (eNOS), may be an important protective molecule at the onset of the IR of the small bowel. In this regard, inhibitors of endogenous NO production greatly exacerbate the increase in epithelial permeability and cardiovascular dysfunction in the reperfused post-ischemia intestine^[32-34], while administration of NO donors prevents the early rise in epithelial permeability and tissue dysfunction^[35,36]. Excess NO production has been attributed to a second NOS (induced NOS, iNOS) that is not present under normal condition but can be induced in response to systemic inflammatory states, including IR. The induction of iNOS has been implicated in the pathogenesis of IIR and it was reported that inhibition of iNOS activity and nitric oxide production could attenuate the intestinal ischemia/reperfusion injury^[37-40]. In the present experiment, we studied the contribution of iNOS to the IIR-induced lung injury. The results demonstrated that 2 h of intestinal ischemia followed by 2 h of reperfusion up-regulated significantly the lung iNOS expression, accompanied by the elevation of pulmonary nitrate/nitrite (stable metabolites of NO) level. This is consistent with the findings of Virlos IT, *et al*^[34] who demonstrated that pulmonary iNOS activity in rats subjected to IIR was significantly increased. The effect of increased iNOS expression on IIR-induced lung injury was indirectly assessed by administration of AG, a selective inhibitor of iNOS. The results that *in vivo* treatment with AG reduced markedly the nitrate/nitrite levels and the lung injury demonstrated that the induction of iNOS and the excessive NO production in the lung following intestinal IR involved in the IIR-induced lung injury.

Though the cytotoxic actions of the excessive NO production may be involved in several potential mechanisms, recent studies suggested that peroxynitrite, may be a key mediator for cytotoxicity of excess NO generation and is involved in many pathological processes^[15-18]. The cytotoxic processes triggered by peroxynitrite include initiation of lipid peroxidation, inhibition of mitochondrial respiration, inhibition of membrane pumps, depletion of glutathione, and damage to DNA with subsequent activation of poly (ADP-ribose) synthetase and

concomitant cellular energy depletion^[19-21, 41, 42]. Peroxynitrite is now generally considered an oxidant more toxic than either NO or superoxide anion alone. Furthermore, it has been shown that a major product of the reaction of peroxynitrite with protein is the addition of a nitro group in the ortho position of tyrosine to form NT which could be detected by antibodies specific to protein NT^[16]. The present results of immunohistochemical staining with monoclonal anti-NT antibodies demonstrated that peroxynitrite formation occurred in the reperfusion phase of ischemic intestine. The results also suggested that the formation of peroxynitrite was correlated with iNOS expression and involved in the IIR-induced lung injury, because inhibiting iNOS activity with AG reduced significantly the NT immunoreactivity and attenuated the IIR-induced lung injury. The cytotoxic actions of iNOS-NO and peroxynitrite may be associated with their damages to the endothelial barrier, their oxidant to the membrane lipid and the triggering of the PMN sequestration in the lung, manifested as the detection of lung MDA content and the observation of the lung pathological changes.

In summary, the present results demonstrate that the systemic inflammatory response and lung injury occur following IIR with an increase of NO, iNOS expression and the formation of peroxynitrite in the lung. Inhibition of iNOS prevented the lung injury and the formation of NT, suggesting that excessive NO production and peroxynitrite formation are cytotoxic to the cell and tissue and are involved in the secondary lung injury induced by the IIR. These results may partially explain the mechanism of MOF and suggest that inhibiting peroxynitrite may be a novel pharmacological approach to prevent cell injury and MOF.

Abstract

AIM: To evaluate the effects of n-3 fatty acids (n-3FA), fructose-1,6-diphosphate (FDP) and glutamine (GLN) on mucosal cell proliferation and apoptosis of small bowel graft.

METHODS: One hundred and ninety-six inbred strain Wistar rats were grouped as donors and recipients, and underwent heterotopic small bowel transplantation (SBT). n-3FA, FDP and GLN were administered via gastric tube as well as venous infusion for 10 days before and after surgery, respectively. The proliferation and apoptosis of mucosal cells were analyzed with flow cytometry and *in situ* cell death detection kits.

RESULTS: Apparent apoptosis and minor proliferation of mucosal cells of small bowel graft after transplantation were observed. A higher mucosal cell proliferative index and lower apoptotic index were found in all small bowel grafts after supplying with n-3FA, FDP and GLN.

CONCLUSION: Nutritional support with n-3FA, FDP and GLN promotes mucosal cell proliferation significantly, and prevents mucosal cell from undergoing apoptosis with different degrees. These regulatory effects on the apoptosis alter the structure and absorption function of transplanted small bowel favorably.

INTRODUCTION

The atrophy and malabsorption of transplanted small intestine are the main obstacles to small bowel transplantation (SBT). The effects of n-3 fatty acids (n-3FA), fructose-1, 6-diphosphate (FDP) and glutamine (GLN) on mucosal cell

proliferation and apoptosis of small bowel graft were evaluated. The mechanisms of mucosal atrophy and malabsorption of small bowel graft were studied at cellular and molecular levels.

MATERIALS AND METHODS

Animals

One hundred and ninety-six inbred male Wistar rats (180-310 g) purchased from Shanghai Animal Center of Chinese Academy of Medical Sciences were housed in laminar-flow cabinets under specific pathogen-free (SPF) condition. All studies on rats were conducted in accordance with the "Guideline for the Care and Use of Laboratory Animals" by National Institute of Health. The protocol approved by Shanghai Medical Experimental Animal Care Committee was followed during study. The rats were divided into 5 groups with 10 rats in each group. Group (1) was treated with non-essential amino acids. Group (2) was treated with FDP, group (3) with n-3FA, group (4) with GLN and group (5) with n-3FA+FDP+GLN. A modified heterotopic SBT was utilized^[1]. End to side anastomosis between graft abdominal aorta and recipient abdominal aorta was performed. The left kidney of recipient was resected. The portal vein of graft was anastomosed to the left renal vein of the recipient. Fistulizations of the distal and proximal ends of graft were performed through left abdominal wall.

Administration of special nutrition

In group (3) and (5), n-3FA (Sigma Company, USA), 1 mL·d⁻¹, was given via gastric tube to both donor and recipient 10 days before and after operation, respectively. All animals received TPN. The dosage of FDP was 1 g·kg⁻¹·d⁻¹ (Foscama Company, Italy). The nutritional solution in group (4) contained 2 % GLN (Ajinomoto company, Japan). L-alanine, glycine, L-proline and L-serine were applied to the nutritional solution of group (1), (2) and (3). The nitrogen and calorie in the nutritional solution were equal in each group.

Specimen collection

Prior to transplantation, 5 cm of jejunum distal to the treitz ligament of graft was resected as baseline samples. Ten days postoperative TPN support, 5 cm of proximal jejunum of the graft in the recipient was resected for examination.

Preparation of specimen

Flow cytometry The mucosae of the specimen were scissored into tiny pieces in saline and filtered to get cell suspension. The nucleus was stained by hypotonic propidium iodide at 4 °C over night.

TdT-mediated X-dUTP nick end labeling (TUNEL method) The specimen was sectioned in 3 μm-thick and dehydrated through 70-90 % ethanol in series. After digestion with proteinase K (20 μg·mL⁻¹), the work solution of TUNEL was added. The reaction was terminated with ddH₂O. The positive nucleus was stained with brownish yellow. Ten fields were selected randomly from each section under light microscope.

Two thousand mucosal cells were examined from each section. The apoptotic index (AI) was calculated with the formula: AI = (number of positive cells/total number of cells examined)×100 %.

Flow cytometry analysis

Epics XL flow cytometer (Coulter Company, USA) was used in the analysis. The proportions of cells in stage G₁, S and G₂ were calculated in 10 000 cells examined. The proliferative index (PI) indicating the proliferation of mucosal cells was calculated using the formula: PI = [(S+G₂)/(G₁+S+G₂)]×100 %.

Statistical analysis

Newman-Keuls' *s q* test and Student' *t* test were used. The statistical analysis software package stata 5.0 was used for the tests, and *P*<0.05 was considered statistically significant.

RESULTS

Flow cytometry

All the data from flow cytometry study are showed in Table 1.

Table 1 Changes of proliferation of graft mucosal cells in each group ten days before and after SBT and TPN ($\bar{x}\pm s$)

Group	Stage of cell cycle	Before SBT and TPN (%)	After SBT and TPN (%)	<i>P</i>
(1)	G ₁	94.73±2.33	94.08±2.15	0.7440
	G ₂	0.38±0.31	1.38±1.44	0.3296
	S	4.88±2.42	4.55±0.92	0.8480
	PI	5.25±2.29	5.85±2.26	0.7682

^a*P*<0.05, ^b*P*<0.01 vs before SBT.

G₁ stage No change of the proportion of graft mucosal cells in G₁ stage in group (1) was observed after transplantation. Most cells remained at G₁ stage. However, the proportions of graft mucosal cells in G₁ stage in the rest groups after transplantation decreased significantly.

G₂ stage Changes of proportion of graft mucosal cells in G₂ stage of group (1) and (5) after transplantation were not obvious. The proportions of graft mucosal cells in G₂ stage in the rest groups increased with great statistical significance.

S stage Following transplantation the change of proportion of graft mucosal cells in S stage was increased significantly in all groups except group (1).

PI Compared with the baseline before transplantation, the PI of graft mucosal cells changed significantly in all groups except group (1).

Apoptosis in situ

Group (1) After SBT, the number of graft mucosal cells with apoptosis was increased. The AI was increased significantly after transplantation (Table 2). The AI in group (1) was significantly higher than those in other groups.

Group (2) The AI of graft mucosal cells increased after SBT and TPN with significant difference (Table 2). The AI in group (2) was higher than those in other groups with significance.

Group (3) The AI of graft mucosal cells after transplantation increased slightly without significance compared with baseline (Table 2). The AI was similar among groups (3), (4) and (5) without any significant difference.

Group (4) The AI of graft mucosal cells in group (4) was similar to that in group (5), decreased slightly after SBT without significant difference (Table 2).

Group (5) No change of the AI of graft mucosal cells was observed after SBT (Table 2).

Table 2 Change of AI of graft mucosal cells in each group ten days before and after SBT and TPN ($\bar{x}\pm s$)

DISCUSSION

Rejection of graft will not occur in organ transplantation between two individuals from same strain of inbred animals. Thus, the effect of special nutrition on the transplanted small intestine could be observed in our research without the influence of transplant immunological factors.

Our results indicated that the proliferation of graft mucosal cells after SBT in group (1) was obviously less active than that before SBT. Most cells were rested in stage G₁. The ratios of cells in stage S over stage G₂ decreased, which suggested that DNA synthesis in graft mucosal cells after SBT reduced, and that mucosal cells were at rest stage instead of active proliferation. These changes in cytodynamics might be the underling cause of cytopathy of graft with the characteristics of atrophy and malabsorption.

Compared with the results of group (1), after SBT the proliferation of graft mucosal cells in rest groups was more active. The ratios of cells in stage S over stage G₂ increased, which suggested that n-3FA, FDP and GLN contributed to the proliferation and repair of graft mucosal cells, and were helpful in preventing atrophy and maintaining the normal structure and function of intestinal mucus.

The number of apoptotic cells and AI of graft mucosal cells in groups (1) and (2) after SBT and TPN increased significantly compared with those before SBT and TPN. On the contrary, those of groups (3), (4) and (5) did not change obviously. The AI in groups (2), (3), (4) and (5) after SBT and TPN decreased significantly in comparison with that in group (1). The result suggested that n-3FA, FDP and GLN could inhibit the apoptosis of graft mucus after SBT to a certain degree.

GLN might influence the graft in several ways, in which it promotes the proliferation of graft mucosal cells and inhibits the cell apoptosis. (1) GLN offers the energy and metabolic substrate which are necessary to the proliferation of intestine mucosal cells^[2-15], including carbon chains for energy releasing

(30 mol ATP/mol) and nitrogen for synthesis of amino acid, protein and nuclear acid. (2) GLN also participates in the synthesis of glutathione (GSH). Administration of exogenous GLN will result in high level of GSH. It is indicated in some experiments that GSH could antagonize the oxidation injury to the biomembrane caused by oxygen-derived free radicals, and improve the survival of cells^[16-19]. (3) GLN may indirectly stimulate the secretion of hormones which are beneficial to the nutrition of intestine, and improve the hormone environment of intestinal mucosal cells. This may help establish normal physiological metabolism and the balanced proliferation and apoptosis of intestinal mucosal cells^[20]. (4) The apoptosis of host cells could be induced by bacterial and viral infections^[21]. GLN may improve the structure and function of the transplanted intestine and reduce bacterial translocation, which could prevent infection and reduce apoptosis^[22-32].

It is not clear why FDP could promote proliferation of mucosal cells of intestinal graft and inhibit apoptosis. The possible reasons might include: (1) As a kind of potent energy substrate, FDP can offer plenty of ATP quickly whether it is on normal or stress occasion, such as ischemia or anoxia^[33,34]. So, FDP can meet the energy need of proliferation of intestinal mucosal cells with quick metabolism. (2) As a promoter of energy synthesis, FDP may activate pyruvate kinase and phosphofructokinase on stress occasion, such as ischemia or anoxia. These enzymes may promote the metabolism of carbohydrate to offer adequate energy^[33], which is helpful to cell proliferation. The products of zymolysis could be decomposed in the energy-producing process^[35]. Thus tissue damage caused by these products could be avoided and the inducing factors of apoptosis were reduced. (3) FDP could reduce the retention of intracellular calcium at stress, and inhibit endogenous calcium dependent endonuclease which is important to nuclear changes in apoptosis^[36]. (4) The cell injuries during ischemia/reperfusion and cold storage of graft are associated with apoptosis^[37-39]. FDP could inhibit the production of toxic oxygen group by activated polymorphonuclear leukocyte and scavenge the hypoxanthine accumulated in the tissues during ischemia and reperfusion^[40]. Thus, the apoptosis caused by these factors could be reduced^[41].

The mechanism of n-3FA in improving the proliferation of mucosal cell of intestinal graft and inhibiting apoptosis is not clear. It may involve the following factors: (1) As a kind of energy substrate, n-3FA could offer energy for the proliferation of mucosal cells. (2) n-3FA could be esterified into phospholipid and neutral lipid which are essential to neogenetic mucosal cells as important component of structure membrane^[42-45]. (3) n-3FA could inhibit the production of IL-1 α , IL-1 β and TNF secreted by monocytes. It is indicated that IL-1 β and TNF can promote apoptosis^[46]. (4) Apoptosis might be one of the ways of cell death in rejection after allogeneic transplantation^[47,48]. As a kind of immunosuppressant^[49-51], n-3FA could inhibit the apoptosis of graft cells through immunosuppression.

In conclusion, special nutrition with n-3FA, FDP and GLN after SBT can promote the proliferation of graft mucosal cells and inhibit apoptosis. Our results may provide new ways to treat intestinal atrophy and malabsorption after SBT.

Abstract

AIM: To evaluate the protective effect and mechanism of glutamine on the intestinal barrier function in total parenteral nutrition (TPN) rats with trauma or endotoxemia.

METHODS: To perform prospective, randomized and controlled animal experimentation of rats with surgical trauma, TPN and endotoxemia, thirty-four male, adult Sprague Dawley rats were divided into four groups: control group ($n=8$), TPN group ($n=9$), trauma and endotoxemia group (LPS, $n=8$) and trauma plus endotoxemia supplemented with glutamine in TPN solution group (Gln group, $n=9$). All groups except the control group were given TPN solutions in 7-day experimental period. For Gln group, 1 000 mg/kg/d of glutamine was added to TPN solution during day 1-6. On the 7th day all the animals were gavaged with lactulose (66 mg) and mannitol (50 mg) in 2 ml of normal saline. Then 24 h urine with preservative was collected and kept at -20 °C. On day 8, under intra-peritoneal anesthesia using 100 mg/kg ketamin, the intestine, liver, mesenteric lymph nodes and blood were taken for examination.

RESULTS: The body weight of LPS group decreased most among the four groups. The structure of small intestinal mucosa in TPN group, LPS group and Gln group showed impairments of different degrees, and the damage of small intestinal mucosa in Gln group was remarkably alleviated. The concentrations of interleukins in small intestine mucosa were lower (for IL-4 and IL-6) or the lowest (IL-10) in Gln group. The IgA level in the blood plasma and the mucosa of Gln group was the highest among all of the groups. The urine lactulose/mannitol test showed that the intestinal permeability in LPS group was lower than that in TPN group ($P<0.001$), but there was no difference between LPS group and Gln group. The rate of bacterial translocation in Gln group was lower than that in LPS group ($P<0.02$).

CONCLUSION: Prophylactic treatment with glutamine could minimize the increments of intestinal permeability and bacterial translocation caused by trauma and endotoxemia in rats treated with TPN.

INTRODUCTION

Trauma, burn, infection, surgical operations and the use of intravenous alimentation over a long period can damage the barrier function of the intestine, leading to atrophy of the intestinal mucosa, increase of mucosal permeability, decrease of immunity, and occurrence of bacterial/endotoxin translocation^[1-5]. If the causes could not be removed or the stress is too severe when the intestinal barrier is protected, the damage of the intestinal mucosa would become more severe and multiple organ dysfunction syndrome (MODS) would ensue. These adverse outcomes are commonly seen clinically and methods of their prevention need to be investigated. Therefore we studied the mechanism of protective effect of glutamine on the intestinal barrier function in TPN rats with trauma and endotoxemia.

MATERIALS AND METHODS

Experimental animals and grouping

Adult, healthy male Sprague-Dawley rats, with body weight of 150-180 g (supplied by Shanghai Experimental Animal Center, the Chinese Academy of Sciences) were used. The rats were fed for over a week in our lab for their adaptation and then were put into metabolic cages for 5-7 days. The temperature in the animal rooms was 17-21 °C with 60 % humidity and illumination of 12 h/day (6:00-18:00). During the adaptation period all rats were fed with regular rat chow and tap water ad libitum. When the rat's weight reached 200-300 g, thirty-four rats were chosen randomly and divided into four groups: 1. control group ($n=8$), fed rat chow and tap water freely; 2. TPN group ($n=9$), infused with a whole nutrients solution through a central venous catheter, and with drinking water ad libitum; 3. LPS group (trauma + TPN + endotoxemia, $n=8$), in which an exploratory laparotomy and central venous catheterization served as the trauma. After this, TPN was their sole nutrition source plus drinking water ad libitum. On the 7th day 5 mg/kg of lipopolysaccharide (LPS) was injected intraperitoneally; 4. Gln group, (trauma + TPN + endotoxemia + glutamine, $n=9$) in which all the treatments were the same as LPS group but on days 2-6, 1 000 mg/kg/d glutamine (Dipeptiven) was added to TPN solution. All groups except the control one received isonitrogenous, isocaloric and isovolumic TPN solution during the 7-day period. All the protocols and procedures were approved by our University Committee of Animal Experiment Administration.

Intravenous nutrients and other relevant chemicals

TPN ingredients 11.4 % compound amino acids injection (Novamin), 20 % mid-long chain fat emulsion (Lipovenoes MCT), Dipeptiven (alanyl-glutamine dipeptide solution), multivitamin mixture (Soluvit, Vitalipid) and a trace element mixture (Addamel), all from Sino-Sweden and Fresenius Pharmaceutical Corp. LTD.

Chemicals and reagents Lipopolysaccharide (LPS, from *E Coli*, 055: B5) was purchased from Sigma Co.; IL-4 from Diaclone Co. of France; IL-6 and IL-10, from Biosource Co., USA; and IgA, from Bethyl Co. USA.

Experimental model

Operation procedures Under anaesthesia of 100 mg/kg of ketamin injected into the animals intraperitoneally, the TPN model was constructed and a rotary transfusion apparatus was used for TPN infusion^[6,7]. For surgical trauma, the animal's abdomen after shaving and incision (4 cm in length) was exposed and examined from the epigastrium to the pelvic cavity. The incision was sutured in double layers with silk suture No. 1 and operation was performed aseptically.

TPN solution The rats were put in the metabolic cages after surgical recovery. Each rat received 230 cal/kg body wt of calories and 1.42 g nitrogen/kg each day in 50 ml of TPN solution. The ratio of glucose to lipid in this solution was 2:1, and nonprotein calorie to nitrogen (kcal/g), 137:1. Multivitamins, electrolytes, trace elements and 500 units of heparin were also included in the TPN solution. All the nutrient solutions were prepared under aseptic conditions daily and the infusion was done with an injecting micropump continuously and uniformly during 24 h each day. The TPN infusion was started immediately after recovery from the laparotomy. On the first and last days of the experiment, each rat was given half of the total calories without any changes of other TPN ingredients.

Inducing endotoxemia On the 7th day of the experiment, 5 mg/kg of LPS in 5 ml of sterile distilled water was injected into the animals' peritoneal cavity to cause a septic state.

Lactulose and mannitol solution gavage On the 7th day of the experiment, 66 mg of lactulose and 50 mg of mannitol dissolved in 2 ml of normal saline were gavaged. Twenty-four hour urine was collected, with the volume recorded and 0.2 ml of mercury salicylosulfide added. Then 5 ml of the urine specimen was stored at -20 °C until measured.

Samples preparation and measurements

Twenty-four hours after gavaging with lactulose and mannitol and injecting endotoxin, 100 mg/kg of ketamine was injected intraperitoneally as an anesthetic. After the laparotomy was done, tissue and blood samples were collected and examinations were performed.

Bacteriological test 0.5 ml of blood from the portal vein was drawn for culture. One gram of anterior lobe liver tissue and about 0.5 g mesenteric lymph nodes were excised. Each sample was put in a tissue homogenizer and an equivalent amount of normal saline was added before they were homogenized. The specimens were sent to microbiological laboratory for aerobic culture and bacterial identification by morphological and biochemical examinations.

Bacterial culture (1) 10 µl homogenates of the lymph nodes and liver homogenates were separately taken and put on blood agar plates. Another 10 µl lymph nodes and liver homogenates were mixed with 10 ml saline for a dilution and the diluted samples were inoculated also on blood agar plates. (2) 0.5 ml of portal vein blood was inoculated into 4.5 ml of common broth for bacterial enrichment of 16 hours, then 20 µl of the enrichment solution was inoculated on blood agar plates. (3) The cultured media were put in a CO₂ incubator at 35 °C for 24-48 hours. If there was no bacterial growth, they would be regarded as negative, but if there was growth, it would be further identified.

Identification of bacteria First, Gram stained smears were made to determine whether they were coccus or bacillus and G+ or G-. Second, biochemical and serological identifications were made using standard and routine methods.

Preparation and examination of small intestine specimens The whole small intestine below the Treitz ligament was excised and immediately placed in icy 0.9 % saline. The intestine was opened longitudinally and the contents of the intestine were washed out with icy saline. Two cm of proximal jejunum and distal ileum was cut and put into 10 % neutral formalin solution

promptly and sent to be examined histologically.

Histological examination of intestinal mucosa Specimens were embedded in paraffin, 4 µm sections made and stained with H.E., analyzed with an HPIAS-1000 Multimedia Color Analysis System. Three low power (10×10) fields in each slide were read. The length of 5 villi, the depth of 5 crypts and the thickness of the mucosa at 5 sites were read and analyzed. The average value was calculated and documented. All the manipulations were done blindly by two experienced pathologists.

Bloodletting and animal execution Three ml of blood from the right ventricle was drawn and 1 250 u of heparin was added. The blood was centrifuged and the serum was stored at -70 °C. Then the animals were sacrificed by exsanguination.

Lactulose/mannitol test The lactulose and mannitol concentrations in the preserved urine sample were measured by a high-performance liquid chromatograph (Waters Co., USA). The ion-exchange column used was bought from Transgenomic Co., USA. The ratio between the two sugars was then calculated.

Identification of the interleukins About 5 cm intestine segments from the upper, middle and lower paste were resected and then the surfaces of the mucosa were dried with cotton swabs. The mucous membrane of the icy specimens was scraped, weighed and divided into two equal parts. They were immediately put into liquid nitrogen and then stored at -70 °C. For the tests, the specimens were melted to room temperature, and 1 ml normal saline was added before homogenates were made. The homogenates were then centrifuged for 15 minutes at 4 °C and then IL-4, IL-6 and IL-10 in the supernatants were measured with ELISA method described by Kudsk^[8]. The results were described as pg/g of mucosal tissue of the small intestine.

Determination of IgA The frozen samples of blood plasma and the mucosa of the small intestine were melted to room temperature and the concentration of IgA in them was measured by ELISA method. The results were shown as IgA µg/ml of blood plasma and IgA µg/g of small intestinal mucosa.

Statistical analysis

All the values were expressed as the mean ±SD. One-way ANOVA was used to check the differences between them. ChiSquare test was used to check the differences of bacterial translocation rates between the groups. When *P* was less than 0.05, the difference was considered statistically significant. The degree of correlation was described using Pearson Correlation coefficient. Software SPSS10.0 was used in all statistical analyses.

RESULTS

Body weight

The body weight changes of the animals in each group are illustrated in Figure 1. At the beginning of the experiment there was no difference in the body weight of the animals among the groups. At the end of the experiment, the body weight decrease was greatest in the animals of LPS group.

Morphology and morphometry of small intestinal mucous membrane

The degree of damage of villi and crypts and the thinning of mucous membrane in jejunum and ileum were most significant in LPS group among all groups (Figure 2 and 3).

Interleukins of small intestinal mucosal tissue

The concentrations of IL-4 and IL-6 in Gln group were the lowest among these groups except control group. IL-10 level in Gln

group was also the lowest among the four groups, and it was significantly lower than that in TPN group ($P<0.01$, Figure 4).

Figure 1 Graphs of body weight changes. (a) Graphs of body weights of animals at the start and end of the experiment; Day 1 means the date when experiments started; Day 8 means the date when experiments ended; ^b $P<0.001$, vs control group, TPN group, and Gln group; (b) The illustration of body weight increase or decrease at the endpoint of the experiment; ^a $P<0.001$, vs TPN group, LPS group and Gln group; ^b $P<0.02$, vs LPS group; ^c $P<0.03$, vs Gln group.

Figure 3 Graphs of morphometry of small intestinal mucosa. (a) Morphometry of jejunal mucous membrane; ^a $P<0.01$, vs TPN group, LPS group and Gln group; ^b $P<0.01$, vs TPN group and LPS group; ^c $P<0.02$, vs LPS group; ^d $P<0.04$, vs Gln group; (b) Morphometry of ileal mucous membrane; ^a $P<0.004$, vs TPN group, LPS group and Gln group; ^b $P<0.005$, vs LPS group; ^c $P<0.02$, vs Gln group; ^d $P<0.02$, vs Gln group; ^e $P<0.001$, vs TPN group and Gln group.

Figure 2 Alterations of structure in mucous membrane of small intestine under microscope. A. The normal structure of jejunum mucosa in normal group rats; B. The normal structure of ileal mucosa in normal group rats; C. Slice of the structure of ileal

mucosa in TPN group. The section shows an evident damage in mucosal architecture. The villi become shorter, blunted and swollen. Infiltration of leukocytes occurs within the lamina propria. The lymphatic ducts in lamina propria reveal dilatation and edematous; D. Slice of the jejunal mucosa of LPS group. The villi are more sparse and shorter than control group. It also shows infiltration of leukocytes within lamina propria, and dilatation of lymphatic ducts in lamina propria; E. The section of ileum mucosa of Gln group. The morphology of ileal mucosa is similar to that of control group (B).

Figure 4 Graph of interleukins in mucous membrane of small intestine. ^a $P < 0.02$, vs TPN group; ^b $P < 0.001$, vs Control group, LPS group, Gln group; ^c $P < 0.01$, vs Gln group.

IgA levels in plasma and small intestinal mucous membrane

IgA levels in blood plasma in Gln group were the highest among the four groups, and so was that in small intestinal mucosa. There was a positive correlation for IgAs level between those in plasma and small intestinal mucosa ($r = 0.961$, $P < 0.04$, Table 1).

Table 1 IgA Levels in blood plasma and small intestinal mucous membrane

	Blood plasma IgA (ug/ml)	Mucosal tissue IgA (ug/g)
Control Group	146.73±50.98 ^a	507.48±167.39 ^c
Group TPN	133.94±64.41 ^b	544.62±100.78 ^d
Group LPS	194.52±111.18	611.89±171.60
Group Gln	255.13±160.59	827.89±279.96

Note: Values were expressed as mean ± SD; ^a $P < 0.02$, vs Gln group; ^b $P < 0.04$, vs Gln group; ^c $P < 0.01$, vs Gln group; ^d $P < 0.02$, vs Gln group; There 's a positive correlation for IgA levels in blood plasma and mucosal tissues ($r = 0.961$, $P < 0.04$).

Correlation of IgA with interleukines

There was no significant correlation between IgA level in plasma and mucosa with the level of interleukins in mucosal tissue of small intestine (Table 2).

Table 2 Correlation of IgAs with interleukins

	IgA of blood plasma			IgA of mucous membrane		
	IL-4	IL-6	IL-10	IL-4	IL-6	IL-10
r value	-0.562	-0.584	-0.744	-0.614	-0.373	-0.396
P value	0.438	0.416	0.256	0.386	0.627	0.604
Correlation ^a	no	no	no	no	no	no

Note: Values were expressed as mean ± SD; ^aThere was no correlations between each IgA level in plasma and mucosal tissue with that of three interleukins respectively in intestinal mucosa.

Lactulose and mannitol (L/M) test

The recovery rates of lactulose and mannitol in the urine of TPN group, LPS group and Gln group were increased. The ratio of L/M was the biggest in LPS group, and the value of the ratio in LPS group was not different statistically from that in Gln group (Figure 5).

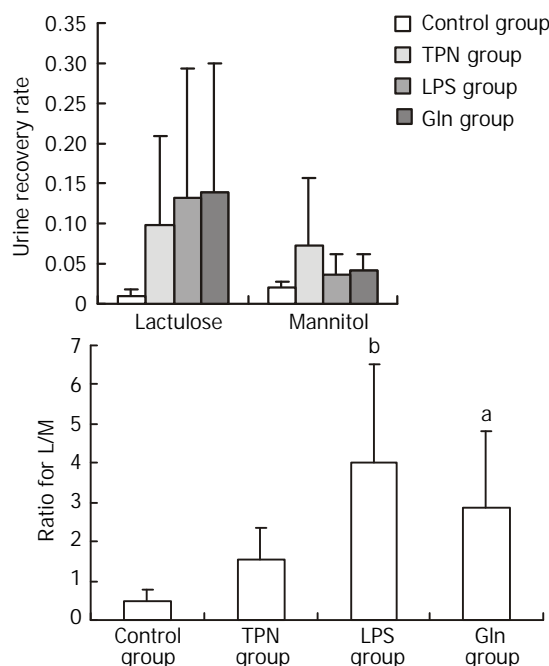

Figure 5 Illustration of dual sugar test. (a) Recovery rate of urine for lactulose and mannitol; (b) Graphic of intestinal permeability expressed by L/M ratio. ^a $P < 0.003$, vs control group; ^b $P < 0.001$, vs control groups and TPN groups.

Bacterial identification and translocation

The results of bacterial culture were labeled as positive when the CFU found per gram of tissue (or ml of blood) was more than or equivalent to $10^{3[9]}$. In LPS group the rate of bacterial translocation was the highest. The second highest rate was seen in TPN group. The logarithm of the number of translocated bacteria correlated positively with the bacterial translocation rate (Table 3). The bacteria translocated, in order of frequency, were proteus, *E. coli*, enterococcus and other Gram negative bacteria. One or two, even three bacteria were usually recovered from the same organ when translocation was present^[6,9].

Table 3 Bacteriologic tests

	MLN	Liver	PVB	Rate of BT	Logarithm of TB
Control group	3/8	0/8	0/8	12.5 % (3/24) ^a	0.5414±1.4799 ^d
TPN group	4/9	4/9	4/9	44.4% (12/27)	2.3279±2.3609
LPS group	5/8	6/8	7/8	75.0% (18/24) ^b	3.0782±2.2824 ^c
Gln group	2/8	5/8	3/8	41.7% (10/24) ^c	1.5845±2.3209

Note: Values were expressed as mean ± SD; MLN, mesenteric lymph node; PVB, portal vein blood; BT, bacterial translocation; TB, translocated bacteria; BTR, rate of BT; ^a $P < 0.01$, vs TPN group and LPS group; ^b $P < 0.02$, vs Gln group; ^c $P < 0.03$, vs group control; ^d $P < 0.01$, vs TPN group and LPS group; ^e $P < 0.01$, vs Gln group; The rate of bacterial translocation is positively correlated to the logarithm of the number of translocated bacteria ($r = 0.978$, $P < 0.022$, $P < 0.03$).

DISCUSSION

Damage of intestinal barrier function and the resulting bacterial

translocation and endotoxemia caused by stress was well documented in the literature^[11-4, 10-14]. How to protect this barrier function and prevent bacterial translocation and toxemia during stress are important research topics^[15-17].

Animal experiments showed some good results in protecting intestinal barrier function and decreasing bacterial translocation, toxemia and enterogenous infection by various measures^[6, 8, 9, 15, 17-22, 30]. Glutamine has many biological functions^[23, 24]. It comprises more than 50 percent of the body's free amino acid pool and is a precursor for synthesis of nucleic acids and glutathione. It is the main fuel for rapid proliferating and dividing cells such as enterocytes, lymphocytes, and other immunocytes etc. It can promote hyperplasia of the epithelial cells of ileum and colon^[25]. The structure and function of small intestinal mucosa are maintained and the increment of intestinal permeability is reduced when glutamine is supplemented to animals fed parenterally^[26-28]. Besides, glutamine could enhance body's immunity through immune modulation^[8, 24, 29]. Results from a series of experiments and clinical investigations indicate that supplementation with glutamine parenterally and/or enterally has improved the gut barrier function and body's immunity when used in human and animals^[13, 17, 23, 29-35]. It has been generally accepted that glutamine could maintain intestinal barrier function through the improvement of architecture of small intestinal mucosa. Formerly, researches along this line usually paid attention to only one aspect of the functions of the intestinal barrier. For this reason, no interrelationship among the permeability and immunity of intestinal mucosa and bacterial translocation was discussed or fully explained^[6, 11, 30].

It is known that the cause of the damage of intestinal permeability in animals fed with TPN is mainly the atrophy of intestinal mucous membrane^[11, 34]. The mechanism of the increase of intestinal permeability caused by endotoxin is very complicated. It may relate to many inflammation mediators such as cytokines, vasoactive amines and oxygen free radicals^[16, 36]. The problem needs further investigation. Our experiment showed that injection of LPS intraperitoneally to rats indeed led to impairment of gut barrier function and an increase in bacterial translocation. Although there were no differences in body weight change when comparing that in glutamine-supplemented group with those in TPN group and LPS group, the damage of architecture of small intestinal mucosa in the former, especially in mucous membrane of ileum, was greatly alleviated than those in the latter two groups.

Glutamine has a visible effect on the secretion of interleukins in mucous membrane of small intestine. The three interleukins in small intestinal mucosa in glutamine group were lower (for IL-4 and IL-6) or lowest (IL-10) than those in other groups of our experiment. There are different opinions about the effects of interleukins on intestinal barrier function. Some authors mentioned that intestinal IL-4 and IL-10 were important in maintaining IgA concentration in the respiratory and alimentary tracts and in the blood^[8]. In the present experiment, we have not found a correlation between IgA level and IL-4 and IL-10 levels in intestinal mucosa. It has been considered that type II cytokines such as IL-4 and IL-10 have an anti-inflammatory function and then it could alleviate tissue and cell damage caused inflammatory mediators and type I cytokines such as IL-6^[37-39]. But there was a report that held a completely different opinion^[40]. We could see from our experiment that glutamine could reduce secretion of interleukins, and it seems that the lower interleukin concentrations are beneficial in reducing the damage of intestinal permeability^[40].

It is known that the digestive tract is the largest immune organ in human body and intestinal mucosal IgA is the first defense line of intestine immunity barrier. This has an important function in preventing bacterial adherence and translocation

within intestinal lumen. In our experiment, the IgA levels in blood and intestinal mucosa in glutamine group were the highest among all groups. There was statistically significant difference between the mucosal IgA levels in glutamine group and those in the control and TPN groups. This result meant that the alleviation of bacterial translocation rate in animals supplemented with glutamine correlated with the increase of IgA secretion in mucous membrane of the small intestine. There was a positive correlation between IgA levels in mucous membrane and blood plasma. It confirmed that the intestine is a vital organ for IgA secretion^[32].

Many changes of the immunological indicators in our experiment did not reach a statistically significant level. The reason for this might be that our experiment and observation period ended at the time when the peak of stress reaction had just passed and the animals had no sufficient recovery time^[12]. In this experiment we have made a model in which the animal is injured by laparotomy and parenteral nutrition, and endotoxemia is caused by an injection with a higher dosage of LPS intraperitoneally 6 days after the injury. The protective mechanism of glutamine on gut barrier was investigated. We found that the model simulated well the conditions of the clinical infectious complications.

In summary, using 1 000 mg/kg/d glutamine parenterally can alleviate the atrophy and impairment of the mucous membrane of small intestine in rats. It can also increase the concentration of IgA and decrease concentrations of IL-4, IL-6 and IL-10 that are secreted by the mucous membrane of small intestine. Thus, the immune function of the small intestinal mucosa was modulated and the damage of gut barrier caused by trauma and endotoxemia was alleviated. The rate of bacterial translocation was also decreased. Changes of intestinal permeability measured with the dual sugar test did not completely correlated with alterations of gut barrier function^[41].

ACKNOWLEDGEMENTS

We would like to thank Prof. Shao Haifeng and Prof. Xu Genbao for their technical guidance and help; we are grateful to the staff of Animal Lab. and Institute of General Surgery for their selfless work and support in this investigation.

Abstract

AIM: Human hepatitis B virus enhancer II B1 binding factor (hB1F) was cloned and characterized as a novel member of the Ftz-F1 (NR5A) nuclear receptor subfamily. Although progresses have recently been made, its biological function remains largely unidentified. The aim of this study was to establish an hB1F transgenic mouse model to promote the functional study of hB1F.

METHODS: Transgene fragments were microinjected into fertilized eggs of mice. The manipulated embryos were transferred into the oviducts of pseudopregnant female mice. The offsprings were identified by PCR and Southern blot analysis. Transgene expression was analyzed with RT-PCR and Western blot analysis. Transgenic founder mice were used to establish transgenic mouse lineages. The F1 and F2 mice were identified by PCR analysis.

RESULTS: Seven mice were identified as carrying copies of transgene. RT-PCR and Western blotting results showed that the transgene was expressed in heart, liver, lung, kidney and stomach in one of the transgenic mouse lineages. Genetic analysis of the transgenic mice demonstrated that the transgene was integrated into the chromosome at a single site, and was transmitted stably.

CONCLUSION: In this study we established an hB1F transgenic mouse model, which will facilitate the investigation of the biological function of hB1F *in vivo*.

INTRODUCTION

Nuclear receptor (NR) is a superfamily of eukaryotic transcription factors that are crucial for gene regulation and

development. Members of this superfamily include receptors for steroid and non-steroid hormones as well as a large number of orphan receptors whose regulatory ligands have not been identified^[1,2]. *Fushi tarazu* factor 1 (Ftz-F1) is one of the six subfamilies of the NR superfamily^[3], which has been nominated as NR5^[4]. Members of the Ftz-F1 subfamily all possess a particular Ftz-F1 box located at the C-terminal of the DNA-binding domain (DBD) and bind to their response elements as monomer.

Human hepatitis B virus (HBV) enhancer II B1 binding factor (hB1F) has been cloned and characterized as a novel member of the Ftz-F1 subfamily^[5]. hB1F (also known as NR5A2, CPF, and hFTF) binds specifically to the B1 element in the enhancer II of HBV and activates its function, thus regulating the viral gene expression and replication. RT-PCR and 3' -RACE have previously revealed that utilization of two polyadenylation signals results in the 3.8 and 5.2 kb transcripts^[6,7]. hB1F is the human homologue of the mouse transcription factor mLRH-1. It has been reported that NR5A2 may play an important role in regulating the liver-specific expression of several genes^[8]. Recent findings demonstrate that NR5A2 is a critical transcription factor in the bile acid biosynthesis pathway^[9,10] and may also regulate the expression of bile acid and cholesterol transporters in the liver and intestine^[11,12].

To facilitate the functional studies of hB1F, we reported here the establishment of transgenic mice carrying hB1F gene. 7 transgenic mice were identified by PCR and Southern blotting and used as founders to establish transgenic mouse lineages. The results of the F1 identification with PCR showed that the transgenes could be transmitted stably. RT-PCR and Western blotting analysis demonstrated that the transgenes expressed in multiple tissues of transgenic mice.

MATERIALS AND METHODS

Plasmid

pcDNA3-hB1F contains the full length hB1F cDNA under the control of CMV promoter. A Flag tag was placed upstream to the hB1F coding sequence to facilitate the characterization of the expressed protein.

Animals

C57 and CBA mice were maintained by Shanghai Nanfang Research Center for Model Organisms. Transgenic mice were raised, and bred in the Laboratory Animal Centre of Second Military Medical University.

Generation of transgenic mice

The 6.9 kb linearized pcDNA3-hB1F was purified from agarose gel with QIAGEN gel extraction kit (Qiagen, CA, USA), adjusted to a final concentration of 1 µg/ml in TE buffer and used as the DNA solution in microinjection. The F1 female hybrids of C57 and CBA mice were hormonally superovulated and mated with F1 male hybrids. Next morning the fertilized one-cell eggs were collected from the oviduct. The eggs were microinjected with the DNA solution under a microscope. The injected fertilized eggs were transplanted into the oviduct of pseudo-pregnant F1 hybrids of C57 and CBA mice.

Identification of transgenic mice

Founder (G0) mice were identified by PCR and Southern blotting analysis. For PCR, DNA was extracted from tails with Genomic DNA MINIPREPES kit (Sangon Inc. China). PCR amplification was performed with hB1F primers (P1: 5'-CCGACAAGTGGTACATGGAA-3' P2: 5'-CTGCTGCGGGTAGTTACACA-3') and pcDNA3 primers (P3: 5'-ATGCGGTGGGCT CTATG-3' P4: 5'-CGGCTTCCATCCGAGTA-3') which would produce 300 bp and 1 353 bp fragments from mice carrying the transgene, respectively. For Southern blotting, genomic DNA was digested overnight with HindIII and subjected to electrophoresis on a 1.0 % agarose gel. DNA was transferred onto nylon membrane (MILLIPORE Co., Ltd, London, UK). Hybridization was performed under a stringent condition with a randomly-primed (α - 32 P)-labeled hB1F probe.

Expression of the transgene

One of the transgenic mouse lineages was used to study the expression of transgene. Total RNA was isolated from tissues with the TRIzol reagent (Invitrogen, CA, USA), according to manufacturer's instructions. First strand cDNA was synthesized by reverse transcription (Promega, USA). Semiquantitative RT-PCR reactions were performed using primer pairs 5'-CCGACAAGTGGT ACATGGAA-3' and 5'-CTGCTGCGGGTAGTTACACA-3' for hB1F cDNA, and 5'-AACTTTGGCATTGTGGAAGG-3' and 5'-TGTGAGGGAGATGCTCAGT G-3' for mouse glyceraldehyde-3-phosphate dehydrogenase (GAPDH) cDNA, which resulted in the generation of 300 bp and 600 bp products, respectively. PCR was performed for 30 cycles at 94 °C for 1 min, at 57 °C for 1 min, and at 72 °C for 1 min. PCR products were electrophoresed on 1.5 % agarose gels. Signals were quantified by density analysis of the digital images using BioStar image software, version 2.

For Western blotting, protein samples from tissues were prepared according to the protocols by the manufacturer (Santa Cruz Biotechnology, Inc. WA, USA). 50 μ g protein of each sample was electrophoresed on 10 % SDS-polyacrylamide gel and transferred to PVDF membrane. Membranes were blocked with 5 % (w/v) non-fat milk in Tween-TBS (TBST) overnight at 4 °C and incubated with anti-Flag antibody (Sigma, USA) at a dilution of 1:500 in TBST for 2 h at room temperature. Membranes were washed three times with TBST and incubated with a secondary antibody (horseradish peroxidase-conjugated anti-mouse IgG) at a dilution of 1:2 000 at room temperature for 1 h. Immunodetection was carried out with an enhanced chemiluminescence kit (Amersham Pharmacia Biotech, USA).

Transmission of transgene

To study the transmission of transgene in mice, transgenic founder mice were mated to normal C57 mice to produce the first generation (F1) transgenic mice which were identified by PCR analysis using hB1F primers P1 and P2, and primers P5 (5'-GTTGGAGGTCGCTGAGTA-3') and P6 (5'-AGTAGGAAAGTCCCATAGGTC-3'), yielding 300 bp and 500 bp products, respectively, from mice carrying the transgene. The F1 mice of the same founder carrying the transgene were mated between brother and sister mice to produce the second generation (F2). The F2 transgenic mice were identified by the same methods for the F1 transgenic mice.

RESULTS

Establishment of hB1F transgenic mice

The transgene fragment containing the full length hB1F cDNA was microinjected into the male pronucleus of 653 fertilized

oocytes of F1 hybrids between C57 and CBA mice. The injected eggs were implanted into the oviducts of 24 pseudo-pregnant foster mothers, of which 13 mice became pregnant and gave birth to 97 offsprings. Eleven offspring mice were identified to carry the hB1F cDNA as demonstrated by PCR analysis (Figure 1), seven out of which were further confirmed by Southern blotting analysis (Figure 2). The ratio of transgene integration was 11.3 % and 7.2 %, respectively, by PCR and Southern blotting analysis.

Figure 1 PCR results of transgenic mice. 1: DNA molecular weight marker, up 100bp ladder, down 1kb ladder; 2: Positive control (pcDNA3-hB1F); 3: Negative control (normal mouse); 4: Water as template; 5-15: Transgenic founder mice; Up: P1-P2 primers amplified; Down: P3-P4 primers amplified.

Figure 2 Genomic DNA Southern blotting results of transgenic mice. 1: Positive control (pcDNA3-hB1F); 2: Negative control (normal mouse); 3-13: Transgenic founder mice.

hB1F transgene expressed in multiple tissues of transgenic mice

As the transgene was driven by the CMV promoter, to study if it can express in multiple tissues of transgenic mice, we analysed the tissue expression profile of the hB1F transgene by RT-PCR and Western blot. The results (Figure 3, Figure 4) showed that the hB1F transgene was expressed in the heart, liver, lung, stomach and kidney, but not in intestine and encephalon.

Figure 3 RT-PCR results of transgene expression. 1: DNA molecular weight marker DL 2000; 2: Positive control (pcDNA3-hB1F); 3: Negative control (non-reversely transcribed RNA); 4: C57 mouse liver; 5-11: Transgenic mice tissues. $^aP<0.05$.

Figure 4 Western blotting analysis of transgene expression.

Genetics of transgenic mice

To establish the transgenic mouse lineages, founder mice were mated to C57 mice to produce F1 mice. Among 128 mice of the first generation, 60 were identified as carrying hB1F cDNA transgene by PCR analysis (Figure 5). The ratio of transgene transmission was 46.9 %. The F1 mice from the same founder were mated each other to produce the F2 mice. 45 out of 64 F2 mice were hB1F transgenic mice, with a ratio of transgene transmission of 70.3 %. These results showed that the inheritance of hB1F transgene was in accordance with Mendel's laws, and the transgene was integrated into the chromosome in a single site and could be transmitted stably.

DISCUSSION

hB1F (NR5A2) is a novel member of the FTZ-F1 nuclear receptor subfamily. It was originally cloned based on its interaction with hepatitis B virus (HBV) enhancer II B1 element^[5]. It has been shown to be a critical regulator of HBV gene expression and replication. Recent studies have revealed that hB1F is mainly involved in the regulation of cholesterol related gene expression in the hepatic-intestinal system. hB1F and its mouse homolog mLRH-1 are essential for the transcription of the gene encoding cholesterol 7 α hydroxylase (CYP7A1), the first and rate limiting enzyme in bile acid biosynthesis^[6,9,10]. Together with two other nuclear receptors, FXR and SHP, and hB1F/mLRH-1 can mediate the feedback effect of bile acids on the transcription of CYP7A1. Moreover, hB1F/mLRH-1 can also regulate the expression of sterol 12 α -hydroxylase (CYP8B1)^[13], multidrug resistance protein-3 (MRP-3)^[11], cholesterol ester transport protein (CETP)^[12] and aromatases^[14]. There is evidence that mLRH-1 may also regulate the expression of several critical transcriptional factors, such as HNF1, HNF3 β and HNF4^[15]. It is possible that hB1F/mLRH-1 may exert broad influences on many genes by regulating these important factors. Since the regulation of cholesterol and bile acid homeostats is complicated, prone to be influenced by various genetic and environmental factors, it is vital to establish a transgenic or knock-out animal model for the studies of the biological role

that hB1F plays in a living organism. The strategy to knock out mLRH-1 in mice has not been successful, due to early embryo lethality (personal communication), which suggests that hB1F/mLRH-1 has yet unidentified crucial functions during embryogenesis. The attempt to generate hB1F transgenic mice has not been reported either. To our knowledge, we have generated the first transgenic mice carrying and expressing the hB1F transgene.

In vivo hB1F/mLRH-1 is mainly expressed in the liver and pancreas. However, weak expression of hB1F has also been detected in other tissues such as heart, lung, skeletal muscle and intestine^[5,6]. Recent studies have also demonstrated that hB1F is expressed abundantly in human ovary, testis^[16] and preadipocytes^[14], as well as in human adrenal and placenta in small amount^[16], thus hB1F has a broader expression tissue profile than previously thought. In this study, the hB1F transgene was expressed in multiple tissues, most of which are capable of expressing endogenous hB1F *in vivo*. Therefore, the hB1F transgenic mice we generated in this study is an invaluable animal model, for investigating hB1F function not only in hepatic tissues, but also in other tissues, which may ultimately reveal the yet unidentified biological functions of hB1F.

In conclusion, we reported here the successful generation of a transgenic mouse model expressing the orphan nuclear receptor hB1F (NR5A2). Future studies will focus on the physiological and pathological changes in this mouse model using powerful analytic methods e.g. microarray comparisons of gene expression profiles between normal and transgenic mice.

Abstract

AIM: The structural and functional characteristics of cells are dependent on the specific gene expression profile. The ability to study and compare gene expression at the cellular level will therefore provide valuable insights into cell physiology and pathophysiology.

METHODS: Individual cells were isolated from frozen colon tissue sections using laser microdissection. DNA as well as RNA were extracted, and total RNA was reversely transcribed to complementary DNA (cDNA). Both DNA and cDNA were analyzed by nested polymerase chain reaction (PCR). The quality of isolated DNA and RNA was satisfactory.

RESULTS: Single cells were successfully microdissected using an ultraviolet laser micromanipulator. Nested PCR amplification products of DNA and cDNA of single cells could clearly be visualized by agarose gel electrophoresis.

CONCLUSION: The combined use of laser microdissection and nested-PCR provides an opportunity to analyze gene expression in single cells. This method allows the analysis and identification of specific genes which are involved in physiological and pathophysiological processes in a complex of variable cell phenotypes.

INTRODUCTION

Techniques for isolating a specific cell population from a tissue complex for subsequent analysis of its molecular and biochemical contents have long been critical in cellular and molecular biology. To this end, various microdissection techniques have been developed to reduce contamination of surrounding cells^[1-3]. Microdissection originally involved manual or micromanipulator guidance of a needle to scrape

off an area of interest of a thin tissue section^[4]. Selective ultraviolet radiation fractionation, which relies on negative selection and ablation of the unwanted areas of the tissue on the slide, provides a technical advancement in this field^[1]. Micromanipulators and microdissection have improved the accuracy and reliability of microdissection; however, it remains an intrinsically slow, technique-dependent process of procuring pure cell populations from tissues. Modern techniques, such as flow cytometry with cell sorting and affinity-labeled magnetic beads, allow separation of cell subpopulations from heterogeneous pools of single cells in suspension. To apply these techniques to tissues, there is a requirement for the dissolution of intercellular adhesion and the formation of a suspension of individual cells, which is not generally practical in solid tissues and may change the characteristics of the isolated cells. Perhaps the biggest breakthrough in this approach and one that is rapidly gaining popularity is laser microdissection (LM)^[5,6]. LM can be used to collect individual cells or specific cell populations from complex tissues without any contamination, and an individual operator can collect many samples in a single session.

The use of LM to obtain pure cell populations has so far been applied to DNA analysis^[5], protein analysis^[7] and mRNA analysis^[8]. A variety of approaches are routinely used to assess the expression of specific genes in cells and tissues, such as Northern blot and RNase protection assay. The quantity of mRNA that can be harvested from a single cell is on the order of 1 pg at best. Thus, the techniques used to analyze gene expression are limited when applied to single cells. Nested PCR has proved to be a sensitive and specific procedure^[9], and the use of nested PCR increases both the sensitivity and specificity of the standard PCR assay^[10,11].

We now present an approach that allows analysis of DNA and mRNA down to the cellular level within intact tissue sections using a combination of LM and nested PCR.

MATERIALS AND METHODS

Preparation of tissue sections

Normal colon tissues were obtained from operation specimens in which a partial colon resection was performed for colon cancer. The Human Subject Committee of the University of Bern approved the studies. Immediately following surgical removal, tissues were snap-frozen in liquid nitrogen and maintained at -80 °C until use. Tissues were embedded in Tissue Tek OCT medium (VWR Scientific Products Corporation, San Diego, CA, USA) and sectioned at 8 µm in a cryostat, mounted on uncoated glass slides, and immediately stored at -80 °C once air dried. Slides containing frozen sections were fixed in 70 % ethanol for 2 min, stained with hematoxylin and eosin, then dehydrated in 70 %, 94 % and 100 % alcohol (each for 2 minutes) and finally dehydrated for 2 minutes in xylene.

Laser microdissection

The ultraviolet-laser Robot-Microbeam (P.A.L.M., Wolfratshausen, Germany) used for microdissection consists

of a nitrogen laser of high-beam precision (wavelength 337nm) coupled to an inverted microscope (Axiovert 135; Zeiss, Jena, Germany) via the epifluorescence illumination path. The microscope stage and micromanipulator are digitally controlled and moved by a computer mouse. The high photon density within the laser focus catapults the material to the cap without any heating effect-a so-called cold ablation-so that DNA and RNA would not degrade during microdissection. With the combination of laser-manipulated microdissection (LMM) and the laser pressure catapulting (LPC) technique, single cells could be processed in seconds^[12].

DNA extraction from microdissected samples

DNA was extracted using DNA extraction solution with 100 mM Tris-HCl, pH 8.0, 400 µg/ml proteinase K (Sigma, Deisenhofen, Germany). After incubation at 37 °C for 3 h, the samples were boiled to inactivate proteinase K. After centrifugation, the supernatants of the DNA extraction buffer, now containing DNA from the microdissected cells, were used for nested PCR.

RNA isolation from microdissected samples and reverse transcription

Total RNA was independently isolated by means of a modification of the RNA microisolation protocol, as described previously^[13]. Briefly, caps were placed in Eppendorf tubes containing guanidinium isothiocyanate buffer, inverted several times, extracted with phenol/chloroform/isoamyl alcohol, and precipitated with sodium acetate and glycogen carrier (10 µg/µl) in isopropanol. After initial recovery and resuspension of the RNA pellet, a DNase treatment was performed for 2 h at 37 °C using 10 units of DNase (Roche Diagnostics, Mannheim, Germany) in the presence of 10 units of RNase inhibitor (Roche Diagnostics, Mannheim, Germany), followed by re-extraction and precipitation. The pellet was resuspended in 24 µl of RNase-free water. 12 µl of total RNA was reversely transcribed into complementary DNA (cDNA) using random hexamers according to the manufacturer's instructions (Roche Diagnostics, Rotkreuz, Switzerland)^[14]. For each cDNA reaction tube, an identical tube containing the same amount of RNA was prepared as a negative control (mock RT). In these tubes, the same amount of water was substituted for reverse transcriptase. After incubation, the reaction was terminated by heating to 95 °C for 10 min. The cDNA preparations were used immediately or stored at -20 °C until use.

Gene analysis by nested PCR

The human beta-actin gene, a ubiquitously and constitutively expressed gene, was used as the target gene^[15] for nested PCR. This approach involves the use of two pairs of PCR primers. The primers were synthesized by Amplimmun (Amplimmun AG, Madulain, Switzerland); the sequence is shown in Table 1. PCR amplification was carried out using beta-actin-outer primers in a final volume of 25 µl with a Perkin-Elmer GeneAmp System 9700 using 0.625U of Taq DNA polymerase (Roche Diagnostics GmbH, Mannheim, Germany). Cycling conditions were as follows: 35 cycles of denaturation at 94 °C for 1 min, annealing at 62 °C for 1 min, and elongation at 72 °C for 2.5 min. The first PCR cycle was preceded by denaturation at 94 °C for 3 min, and the last PCR cycle was followed by incubation at 72 °C for 8 min. Nested PCR was performed using 0.5 µl of the first PCR product as a template. The PCR cycling conditions for the beta-actin-inner primers were the same as above except for an annealing temperature of 60 °C. The amplification products were analyzed by electrophoresis on 1 % agarose gels and stained with ethidium bromide.

Table 1 β-actin primers used for nested PCR analysis

Primer	Sequence	Primer size (bp)	Size of PCR products (bp)

Reverse primer	CCA TCT CTT GCT CGA AGT CC	20	
β-actin-inner			
Forward primer	AAA TCT GGC ACC ACA CCT TC	20	240
Reverse primer	AGG GCA TAC CCC TCG TAG AT	20	

RESULTS

Laser microdissection of cells from cryostat sections

Eight-micrometer cryostat sections were prepared from normal colon tissues. Single colon mucosa cells were selected and cut with LM and catapulted by LPC under visual control (Figure 1). For LPC, the setting of laser energy was sufficiently high to catapult the microdissected cells into the microcentrifuge cap. Cell clusters of interest were also selected and laser-microdissected under visual control (Figure 2). The laser precisely circumscribed a selected area or a single cell, which yielded a clear-cut gap between selected and non-selected areas.

DNA analysis in microdissected cells by nested PCR

100 cells, 10 cells and 1 cell were microdissected from normal colon sections. Samples were digested by proteinase K and boiled for 10 min to denature proteinase K. After centrifugation, the supernatants were used for PCR with the beta-actin-outer primers. The amplification products were analyzed by electrophoresis on 1 % agarose gels; the results are shown in Figure 3A. The bands from a complete section, 100 cells, and 10 cells could be clearly visualized. Nested PCR was performed using 0.5 µl of the first PCR product as a template; the amplification results are shown in Figure 3B. Amplification products from single cells could be clearly visualized by agarose gel electrophoresis after nested PCR. Control amplifications without DNA templates did not yield any signal.

Figure 2 Amplification results from nested PCR of colon cells after laser microdissection. Nested PCR amplification products of DNA of single cells could clearly be visualized by agarose gel electrophoresis. A: Amplification results of β-actin-outer primers. B: Amplification results of β-actin-inner primers. M: DNA markers (upper to lower: 2000, 1000, 900, 800, 700, 600, 500, 400, 300, 200, and 100 bp). 1: PCR positive control; 2: one complete section; 4, 6 and 8 are 100, 10 and 1 cell(s), respectively; 3, 5, 7 and 9 are negative controls of 2, 4, 6 and 8; 10: PCR negative control.

Figure 1 Examples of laser microdissection in colon tissues (hematoxylin and eosin, magnification $\times 200$). Single cells were picked by combination laser-manipulated microdissection (LMM) and laser pressure catapulting (LPC). A, C, E, G: Before Laser microdissection. B, D, F, H: Using LMM, the laser precisely circumcised selected cells, yielding a cut gap between selected and non-selected areas. Then the selected cells were catapulted using the LPC technique. A-F: Typical images before and after LMM and LPC. G, H: Laser microdissection could also be used to cut out the nucleus of a selected cell.

mRNA expression in microdissected cells by nested PCR

Normal colon RNA was obtained from complete sections, 200 cells, 100 cells, 10 cells and single cells. cDNA was transcribed from total RNA. The amplification products were analyzed by electrophoresis on 1 % agarose gels; the results are shown in Figure 3C. Signals from complete sections could

be clearly visualized. However, the signals from 200 cells and 100 cells could only be seen on the original gels, and the signals from 10 cells and single cells were below the level of detection. Nested PCR was performed using 0.5 μ l of the first PCR product as a template; the amplification results are shown in Figure 3D. Amplification products of even single

cells could be clearly visualized by agarose gel electrophoresis. Control amplifications without cDNA templates did not yield any signal.

Figure 3 Amplification results from nested RT-PCR for cDNA of single cells after laser microdissection. A: Amplification results of β -actin-outer primers. B: Amplification results of β -actin-inner primers. M: DNA markers (upper to lower: 2000, 1000, 900, 800, 700, 600, 500, 400, 300, 200, and 100 bp). 1: PCR positive control; 2: one complete section; 4, 6, 8 and 10 are 200, 100, 10 and 1 cell(s), respectively; 3, 5, 7, 9 and 11 are negative controls of 2, 4, 6, 8 and 10; 12: PCR negative control.

DISCUSSION

In this study, single colon mucosa cells could be selectively microdissected and collected from frozen tissue sections under direct microscopic visualization using LM. Microdissected mucosa cells were used for further gene analysis using nested PCR.

Most tissues are composed of a number of different cell types, and cellular heterogeneity in most tissues is very complex. In normal or developing organs, specific cells express different genes and undergo complex molecular changes both in response to internal control signals, signals from adjacent cells, and humoral stimuli. In disease pathologies, the diseased cells of interest, such as precancerous cells or invading groups of cancer cells, are surrounded by these heterogeneous tissue elements. The percentage of non-neoplastic cells present in such specimens can be as high as 95 %^[16]. This tissue heterogeneity has proved one of the major obstacles to molecular research using current methods, since varying numbers of normal cells could mask the presence of single abnormal cells when analysis of its gene expression and total DNA or RNA from heterogeneous tissue is used^[17-24].

LM is a new method for performing microdissection of selected regions down to a single cell^[5,6,25]. There have been other reports describing methods to collect specific regions of tissue, such as graded sieving of glomeruli or pancreatic islet cells^[26,27] and isolation of suspension of proximal tubular cells^[28]. These methods make it possible to obtain relatively pure and large amounts of samples; however, it is difficult to avoid possible contamination of other tissue compartments, which can cause problems with sensitive RT-PCR methods. Using LM, our study has shown that it is feasible to examine mRNA expression of single cells without the risk of contamination by neighboring cells. If more than one cell is needed, single unwanted cells can selectively be destroyed from the tissue section using LM, resulting in an area composed of a

homogenous cell population. Utilizing a computer-controlled microscope stage, the cells of interest are visually selected and marked and their positions are stored electronically. The stage then automatically goes to and moves around the selected cells, while the laser fires with a preselected pulse energy and repetition rate. With a further slightly defocused laser shot, the target cells can selectively be catapulted into a microcentrifuge cap using LPC for further study. As reported in this article, this method allows gene analysis in the particular tissue region isolated from the frozen cryostat specimen, avoiding the contamination of other cells.

The quantity of mRNA that can be harvested from a single cell is approximately 1 pg at best. Therefore, to obtain meaningful gene-expression data, well-optimized or specialized amplification protocols must be applied. Using conventional PCR, the theoretical limit of detection is one copy of a single-stranded DNA molecule, and so with efficient harvesting of cytoplasm and a well-optimized PCR protocol, single-cell PCR is feasible^[29]. However, this is not a trivial undertaking, and identifying the expression of rare or particularly labile transcripts would prove to be technically demanding^[30].

In this study, amplification signals from DNA of single cells were only faintly present in the agarose gels, and amplification signals from cDNA could not be visualized by gel electrophoresis. Therefore, certain modifications to this approach have to be applied to provide more comprehensive single-cell expression analysis. In this study, a straightforward method of expanding the results obtained from single-cell PCR involves the use of nested PCR. Essentially, a primary conventional PCR increases the target concentration so that a second PCR reaction can be carried out to assay for the presence or absence of gene expression. The present study has shown that nested PCR is feasible for the analysis of gene expression after LM, even at the cellular level, and that this approach has the advantage of being relatively simple to apply. Further studies on the gene expression profiles of single microdissected cells will provide novel insight into different physiological and pathophysiological processes.

Abstract

AIM: Cytochrome P450 2C9 (CYP2C9) is a polymorphic enzyme responsible for the metabolism of a large number of clinically important drugs. Individuals with mutant enzymes may risk serious side effects under routine therapy with certain drugs metabolized by CYP2C9. In order to facilitate the detection of the known SNPs of CYP2C9, an allele-specific oligonucleotide (ASO) based microarray was made.

METHODS: An oligonucleotide microarray was made to facilitate the SNP (single nucleotide polymorphism) screening and was applied for the detection of CYP2C9 polymorphism in 62 high blood pressure (HBP) patients who received Irbesartan for treatment. Part of the genotyping results was confirmed by direct sequencing. And the relation between CYP2C9 polymorphism and therapeutic outcome of Irbesartan was statistically analyzed.

RESULTS: Heterozygous alleles of CYP2C9*1/*3 were found in 7 out of 62 subjects. No mutant alleles of CYP2C9*2, *4 and *5 and no homozygous mutant alleles were detected. The 7 heterozygous CYP2C9*1/*3 and 13 random wild type DNA samples were subjected to direct sequencing with purified PCR products and same genotyping results were obtained with the 20 DNA samples. There was no significant difference in the odds of effectiveness of Irbesartan between the wild type (normal) group and CYP2C9*1/*3 (mutant) group ($P>0.05$).

CONCLUSION: The oligonucleotide microarray made in this study is a reliable assay for detecting the CYP2C9 known alleles and the heterozygous CYP2C9*1/*3 has no significant effects on the therapeutic outcome of Irbesartan.

INTRODUCTION

Pharmacogenetics was established on the fact that certain genetic polymorphisms may cause significantly different responses among individuals on exposure to a particular drug^[1-3]. Recent advances in the understanding of the molecular genetics of drug-metabolizing enzymes (DME), particularly

cytochrome P450, have enabled the molecular basis of many polymorphisms to be elucidated and the genotyping assays to be developed^[4-6].

Cytochrome P450 is one of the key enzymatic mechanisms for the metabolism of drugs, pesticides, environmental pollutants, and carcinogens^[7-9]. In this superfamily, CYP2C9^[10-12] is a polymorphic enzyme responsible for the metabolism of a large number of clinically important drugs such as S-warfarin, phenytoin, tolbutamide, losartan and nonsteroidal anti-inflammatory drugs. To date, 5 alleles of CYP2C9 including the wild type CYP2C9*1 and the mutants CYP2C9*2 (430C-T), CYP2C9*3 (1075A-C), CYP2C9*4 (1076T-C) and CYP2C9*5 (1080C-G) have been found (www.imm.ki.se/cypalleles). In the four mutant alleles, single nucleotide variations in the exon 3 and exon 7 cause amino acid substitutions Arg144Cys, Ile359Leu, Ile359Thr and D360E, respectively, and therefore lead to a slow metabolizing capacity of the enzymes. The altered pharmacogenetics may result in prolonged or shortened effect time. The individuals with mutant enzymes risk serious side effects under routine therapy with certain drugs metabolized by CYP2C9. So frequent variants of CYP2C9 should be analyzed in participants of clinical trials where the enzymes may play a key role.

In order to facilitate the detection of the known SNPs of CYP2C9, an ASO (allele-specific oligonucleotide) hybridization based microarray was made, which could simultaneously screen the 4 mutant alleles of CYP2C9 of 10 individuals, and was applied for the detection of CYP2C9 polymorphism in 62 hypertension patients who received Irbesartan for treatment. Irbesartan is a selective antagonist of the AT1 receptor of angiotensin II receptor (AT1R) used in the treatment of hypertension and congestive heart failure^[13,14]. Previous studies indicate that Irbesartan is mainly metabolized by CYP2C9 to the inactive form^[15].

MATERIALS AND METHODS

DNA samples

A total of 62 peripheral blood samples were collected from unrelated HBP patients who received Irbesartan for treatment and the therapeutic outcome was classified as outstanding (11 persons), effective (38 persons) and failed (13 persons). Genomic DNA was extracted with the Genomic DNA purification kit (Promega) and quantified by UV spectrophotometer (DU®640, Beckman coulter).

Oligonucleotides synthesis

Oligonucleotides (primers or probes) were synthesized using automatic DNA synthesizer (ABi 391A). For signal detection, the reverse primers were fluorescein (Cy3) labeled at 5' end. A probe was synthesized with the 3' end amino-modified to have a primary NH₂ group for immobilization onto aldehyde-coated slides, and the NH₂ group was linked by a polyethyleneglycol spacer to a specific allele-discriminating sequence, which was 16-17 nucleotides in length with a nucleotide complementary to either the normal or mutant allele in the middle of the sequence. A list of oligonucleotides used in this study is presented in Table 1.

Table 1 Oligonucleotides used in this study

##	Sequence (5' --3')	Application

PCR amplification

The 2 target segments containing the SNP sites to be typed were amplified by PCR in one tube. Asymmetric PCR method was used to generate single-stranded target segments. The ratio of forward primer to reverse primer (fluorescein labeled) was optimized at 1:40 in a PCR reaction (data not shown). Reaction mixtures of 20 μ L contained 100 μ M dNTP, 0.5 μ M forward primer, 20 μ M reverse primer, 100 ng of a genomic DNA or 40 ng of a plasmid DNA, 1* PCR buffer and 1 U Taq enzyme. Amplification was conducted in a thermal cycler (PTC-100™ programmable thermal controller, MJ. Research Inc) under the following conditions: initial denaturation (5 min at 94 °C) followed by 40 cycles of denaturation (30 sec at 94 °C), annealing (30 sec at 62 °C) and extension (30 sec at 72 °C). A final extension step was carried out for 5 min at 72 °C. The PCR products were analyzed by 2 % agarose gel electrophoresis.

Construction of standard templates

DNA segments of wild type or mutant CYP2C9 were subcloned to PGEM®T4-vector (Promega) according to the protocol. The plasmids were used as standard wild type or mutant templates for the optimization of hybridization conditions and establishment of signal intensity ratio of match to mismatch after verification by sequencing. The artificial heterozygous templates were constructed by mixing equal amounts of wild type and mutant plasmid DNA. To introduce a mutant nucleotide at specific position in a DNA segment, site-directed mutagenesis method^[16] with mutant primers was used.

Preparation of DNA microarrays

The 3' end amino-modified probes were diluted to a final concentration of 20 μ mol/L in spotting solutions (3*SSC and 0.01 % SDS). The spotting solutions were transferred into 96-well plates in volumes of 10 μ L and spotted to aldehyde-coated glass slides with a microarray printer (Cartisan), which deposited 0.5 nL at each spotting site, resulting in spots of 200 μ m in diameter. Each probe was spotted in duplicate. The humidity during spotting was 70 % and the temperature was kept at 23 °C. After spotting, slides were incubated for another 1 h under the same conditions and stored at room temperature for at least 1 day before use. The pattern of slide and array format are shown in Figure 3.

Hybridization and signal detection

Two μ L of the single-stranded Cy3-labeled target PCR products was mixed with 10 μ L hybridization solution (5*SSC, 0.1 % SDS, 1 % salmon DNA), and the 12 μ L final volume was transferred to the hybridization area on the glass slide. The slide was incubated in 40 °C water bath for 30 min in a hybridization chamber. After incubation, the slide was washed sequentially in washing solution A (1*SSC, 0.2 % SDS), washing solution B (0.2*SSC) and washing solution C (0.1 *SSC) for 1 min each.

The glass slides were scanned using the confocal Scanarray 3 000 (GSI Lumonics), with excitation at 540 nm and emission at 570 nm (Cy3). Sixteen-bit TIFF images of 10 μ m resolution were analyzed. After subtraction of local background, the average signal intensity of the duplicate spots of each probe was used to calculate the signal ratios defining the genotypes.

Direct sequencing with PCR products

Part of the DNA samples was subjected to direct sequencing using DNA sequencer (CEQ™ 2000XL DNA analysis system, Beckman) to confirm the results. PCR reaction was carried out in 50 μ L solution and the PCR products were purified to be the sequencing templates with PCR products purification kit (Promega).

Statistical analysis

Statistics was made by χ^2 test.

RESULTS**Determination of the signal intensity ratio of match to mismatch**

According to the hybridization result of standard wild type or mutant plasmid templates, under the optimized hybridization and stringent washing conditions, there was a great difference in signal intensities between the perfect match and the single base mismatch probes. The ratio of match to mismatch of signal pairs was above 4 at least. Detection of heterozygous alleles was a hard point for microarray. In the present study, the hybridization results of the heterozygous templates showed that the signal intensity ratio of the probe pair corresponding to heterozygous alleles was below 2.5 (the ratio was always

the stronger to the weaker). Typical results are shown in Figure 1. Repeated experiments with genomic DNA gave a statistically similar result (data not shown). So the ratio value above 4 or below 2.5 was considered sensible for genotype judgement while sample with the ratio value within 2.5-4 should be re-genotyped.

Figure 1 The TIF image of hybridization results of (A) wildtype template, (B) mutant template, (C) heterozygous template of CYP2C9*1/CYP2C9*3, and (D) heterozygous template of CYP2C9*1/CYP2C9*4. The discriminating power of a pair of probes was represented by the ratio of match to mismatch listed below.

Genotype results of 62 DNA samples by DNA microarray

In the genotype result of the 62 samples determined by the microarray, heterozygous alleles of CYP2C9*1/*3 were found in 7 out of 62 subjects. No heterozygous or homozygous mutant alleles of CYP2C9*2, *4 and *5 were detected. Repeated experiments gave the same result. A brief procedure is illustrated in Figure 2 and Figure 3.

Figure 2 2 % agarose gel electrophoresis of the PCR products of 10 samples. 1-10: PCR products of 10 DNA samples, M: DGL2000 marker.

Figure 3 Array format and microarray hybridization result of 10 samples.

DNA samples genotyped by direct sequencing

To confirm the genotype result determined by microarray, the 7 heterozygous CYP2C9*1/*3 and 13 random wild type DNA samples were subjected to direct sequencing with purified PCR products. The same genotype results were obtained with the

20 DNA samples typed with two methods. The typical sequencing results of the heterozygous CYP2C9*1/*3 and wild type are compared in Figure 4.

Figure 4 Part of the sequencing results. The letters in square indicate wildtype and heterozygous of CYP2C9*1/CYP2C9*3 (1075A-C) in two samples.

Allele frequency and effects of CYP2C9 polymorphism on therapeutic outcome of Irbesartan

The microarray described here is a reliable assay for detecting the CYP2C9 known alleles. The analysis of 62 HBP patients DNA samples yielded frequencies for CYP known alleles (Table 2) that were in agreement with previous study^[7,17,18]. There was no significant difference in the odd of effectiveness of Irbesartan between the wild type (normal) group and the CYP2C9*1/*3 (mutant) group (Table 3, $P>0.05$).

Table 2 CYP2C9 allele frequency in the study population

Allele	Number of alleles	Frequency %
*2	0/124	0
*3	7/124	5.6
*4	0/124	0
*5	0/124	0

Table 3 Therapeutic outcome of Irbesartan in wild type group and CYP2C9*1/*3 group

	Effective	Failed
Wild type	43	12
CYP2C9*1/*3	6	1

$P>1$ (χ^2 test), no significant difference in the odd of effectiveness of Irbesartan between wild type group and CYP2C9*1/*3 group.

DISCUSSION

Single nucleotide polymorphism (SNP) is the most common variation form in human genome^[19-21]. The early methods to type SNPs include SSCP, RFLP, AS-PCR, etc^[22-24], making genotyping judgement coupled with gel electrophoresis analysis. The methods above are unfit for a large scale screening due to the limitation of detection methods. With the advance of organic fluorescence labeling and detection technology, significant change has taken place in genotyping technology. Molecular beacon^[25], TaqMan^[26] probe methods, which detect fluorescence signal in homologous reaction, and DNA microarray^[27-29], which is based on hybridization coupled with solid phase reaction, make genotyping easier and more accurate. In the newly developed technologies, DNA microarray is more preferable in the genetic linkage and association study between large number of genetic markers and phenotypic traits in pharmacogenomics, disease genomics etc, due to its parallel detection of a large quantity of genetic markers.

Fluorescence-labeled sample preparation is a critical step in microarray genotyping. The quality and amount of genomic DNA used as template in PCR reaction are essential to the hybridization results. In the present study, the two target segments containing the SNP sites to be typed were PCR amplified in one tube. Asymmetric PCR method was used to generate single-stranded target segments complimentary to the probes.

The fluorescence signal intensity and discriminating power (ratio of match to mismatch) of the probe pairs are the key results from microarray for genotyping judgement, which can be affected by many factors. When other conditions (the quality and amount of single stranded PCR products, the quality of aldehyde-coated slides, hybridization/washing conditions, etc) are strictly controlled, the specific sequence context of the probes is the determining factor. Because there was no simultaneous mutation reported in the CYP2C9 known alleles, the probes were designed without consideration of crosslink of SNP sites of 1075A-C, 1076T-C, 1080C-G, any two of which were assumed normal when the other one was set as SNP site to be typed. The assumption reduced the number of probe to be designed and was confirmed by the genotyping result in the present study. Four pairs of probes were designed to discriminate the normal and the four mutant alleles. However, as an improvement to probe redundancy, all possible probe patterns should be fabricated. In probe design, the probes were chosen to have a common algorithmically calculated T_m value of 50 ± 2 °C with length of 16-17 nt. Under the optimized hybridization/washing conditions, the P1/P2 and P7/P8 probe pairs had a less intense signal and discriminating power than the P3/P4 and P5/P6 pairs. The signal intensity ratio value above 4 or below 2.5 is considered a critical limit for genotype judgement. When the value fell into 2.5-4, the sample should be re-genotyped.

The allele frequency of CYP2C9 determined in this study was in accordance with the published data. Yoon YR *et al.*^[17] showed that there were no CYP2C9*2 (430C-T) allele in Asian population. Dickmann *et al.*^[18] found CYP2C9*5 (1080C-G) only in Black people. In the present study, heterozygous CYP2C9*1/*3 (1075A-C) were detected in 7 out of 62 unrelated Chinese. There were marked ethnic/geographic differences in the distribution of allelic variants of many DMEs^[30]. It is of obvious importance that such ethnic/geographic differences be taken into account in routine pharmacogenetic diagnosis or screening. Considering that it is challenging to optimize oligonucleotide probes to achieve global maximum discrimination of many genetic variants simultaneously, it is of importance to reduce the probe number to ensure the reproducibility and reliability of ASO hybridization based-microarray genotyping performance. For example, microarray for genotyping frequent SNP sites (>1 %) in DME-coding gene specific to Chinese should be made and applied in Chinese population.

There were no homozygous mutants detected in the studied population, and there may be other factors that affect the effectiveness of Irbesartan, such as the polymorphism in drug targets (ATIR), other potential mutation sites in CYP2C9, etc. The results of genotyping in this study suggest that there is no significant difference in the odd of effectiveness of Irbesartan between the wild type group and CYP2C9*1/*3 group. Provided that the heterozygous individuals have prolonged effective time, a better therapeutic outcome may be obtained as long as no additional side-effects occur.

Abstract

AIM: Bacillary dysentery caused by *Shigella flexneri* is still a threat to human health. Of four invasion plasmid antigen proteins (IpaA, B, C and D), IpaC plays an important role in the pathogenicity of this pathogen. The purpose of this study was to investigate the proteins interacting with IpaC in the host cell during the pathogenic process of this disease.

METHODS: By applying two-hybrid system, the bait plasmid containing *ipaC* gene was constructed and designated pGBKT-ipaC. The bait plasmid was transformed AH109, and proved to express IpaC and then HeLa cDNA library plasmids were introduced into the above transformed AH109. The transformation mixture was plated on medium lacking Trp, Leu, and His in the initial screen, then restreaked on medium lacking Trp, Leu, His and Ade. Colonies growing on the selection medium were further assayed for β -galactosidase activity. BLAST was carried out in the database after sequencing the inserted cDNA of the positive library plasmid.

RESULTS: Among the 2×10^6 transformants, 64 positive clones were obtained as determined by activation of His, Ade and LacZ reporter genes. Sequence analysis revealed that cDNA inserts of two colonies were highly homologous to a known human protein, RanBPM.

CONCLUSION: These results provide evidence that IpaC may be involved in the invasion process of *S. flexneri* by interacting with RanBPM, and RanBPM is most likely to be the downstream target of IpaC in the cascade events of *S. flexneri* infection.

INTRODUCTION

Shigella is a Gram-negative bacterium responsible for intestinal diseases ranging from mild watery diarrhea to bacillary

dysentery in humans. The severe forms of shigellosis are due to colonization and destruction of the colonic mucosa by this invasive pathogen. The infectious potential of *Shigella* is very high, since as few as 100 microorganisms administered orally are sufficient to cause dysentery in volunteers. Each year, at least a billion cases of diarrheal diseases account for about three million deaths. In the developing world, children under 5 years of age are the most susceptible victims, with over half a million deaths occurred annually worldwide^[1].

The phenotype which is essential to the pathogenicity of *S. flexneri* is encoded by a 31kb sequence^[2,3] located on the 200kb large virulence plasmid^[4,5]. One locus in this fragment, composed of the *ipa* operon (invasion plasmid antigen), is necessary to encode and secrete the effectors, the Ipa proteins or invasins. The *ipa* operon encodes four secreted proteins: IpaB(62kDa), IpaC(42kDa), IpaD(37kDa) and IpaA(70kDa), which elicit the formation of the entry focus via localized actin polymerization^[6]. The Ipa proteins are rapidly secreted from *S. flexneri* when the bacterium comes into contact with epithelial cells^[7-10]. Following their secretion, IpaB and IpaC are found as part of a protein complex and this complex is absolutely required for entry into epithelial cells^[7,11,12]. Latex beads coated with anti-IpaC antibodies have been used to recover the extracellular Ipa complex containing IpaB and IpaC, and were shown to be internalized in HeLa cells through the formation of membrane ruffles similar to those induced upon bacterial entry^[13]. These results have led to the proposal that IpaB and IpaC play major roles in the entry of *shigella* into epithelial cells.

Although IpaB is undoubtedly important for *S. flexneri* invasion^[14-17], a great deal of foci were shifted to IpaC as a potential effector of *S. flexneri* invasion when purified IpaB was shown not to possess *in vitro* membranolytic activity^[11], and purified IpaC was demonstrated to have such activities consistent with its contribution to invasion^[18]. Effector-related functions that have been demonstrated for purified IpaC include: enhanced invasion of cultured cells by *S. flexneri* at nanomolar IpaC concentrations^[16,19]; induced uptake of virulence plasmid-cured at micromolar IpaC concentrations^[24]; association with model phospholipid membranes^[16,21]; and triggering of cytoskeletal changes in cultured cells^[22,27]. Additional activities associated with IpaC also include *in vitro* reconstitution into complexes with IpaB, which may promote the uptake of non-invasive strains of *Escherichia coli*^[12, 19].

Shigellosis provides a model to study how a pathogenic microorganism can subvert an integrated defense barrier and interact with the host cells, which in turn facilitates invasion at the early stage of the process. A major challenge is to understand the role of Ipa proteins in entry into epithelial cells. In order to investigate the mechanism of IpaC in the entry process, two-hybrid system was exploited to identify the proteins in host cells that interacted with IpaC invasin.

MATERIALS AND METHODS

Materials

The strains and plasmids used in this study are listed in Table 1.

Table 1 Strains and plasmids

	Relevant characteristics	Source
Strains		
<i>S. flexneri</i> 2a, 2 457T	Wild type, Nal ^r	Maurelli AT
<i>E. coli</i> DH5 α	SupE44, Δ lacU169 (ϕ 80 lacZ Δ M15), hsdR17, recA1, endA1, gyrA96, thi-1, relA1, Nal ^r	Our lab
<i>S. cerevisiae</i> AH109	MATa, trp1-901, leu2-3, ura3-52, his3-200, gal4 Δ , gal80 Δ , LYS2::GAL1 _{UAS} -GAL1 _{TATA} -HIS3, GAL2 _{UAS} -GAL2 _{TATA} -ADE2, URA3::MEL1 _{UAS} -MEL1 _{TATA} -LacZ	Clontech
Plasmids		
pGBKT7	GAL4 DNA-BD, TRP1, c-Myc epitope tag, Km ^r	Clontech
pGBKT-ipaC	GAL4 DNA-BD fusion of IpaC, TRP1, c-Myc epitope tag, Km ^r	This study
pACT2	GAL4 DNA-AD, HA epitope, LEU2, Ap ^r	Clontech
pLAM5'-1	GAL4 DNA-BD fusion of the human lamin C, TRP1, a false-positive detection plasmid, Ap ^r	Clontech
p1	A positive library plasmid	This study

Human HeLa MATCHMAKER cDNA library (HL4048AH), c-Myc monoclonal antibody, YPD medium, minimal SD base and DO supplement medium were purchased from Clontech. Peroxidase-conjugated goat anti-mouse IgG was from Santa Cruz. Mini- and Megapreps plasmid kits were obtained from Promega. Restriction endonucleases and T4 DNA ligase were purchased from New England Biolabs. Taq DNA polymerase, deoxyribonucleotides, and PCR fragment recovery kit were from TaKaRa. Primers for the 5' and 3' ends of *ipaC* gene, P1 and P2, were synthesized in our lab.

Methods

Growth and maintenance of strains *Shigella flexneri* 2a was grown at 37 °C with constant stirring in trypticase soy broth (TSB). Prior to use, the bacteria were streaked onto trypticase soy agar (TSA) containing 0.025 % Congo red so that colonies binding the dye could be selected. Bacteria that had lost the invasion plasmid were not able to bind this dye and thus appeared white in the presence of Congo red. Yeast strain AH109 was grown at 30 °C with vigorous shaking in YPAD. Antibiotics were used at the following concentrations: ampicillin (Ap), 100 mg·L⁻¹; kanamycin (Km), 50 mg·L⁻¹; nalidixic acid (Nal), 40 mg·L⁻¹.

Construction of bait plasmid Isolation of plasmid and all other molecular biology procedures were carried out according to the standard published procedures^[22]. *ipaC* gene was amplified by PCR in a standard 100- μ l reaction containing 2.5 mM MgCl₂, 0.25 mM of each dNTP, 100 pmol of P1 and P2 primers, 10 μ l boiled *S. flexneri*, and 5U Taq DNA polymerase. Reactions were allowed to proceed in a Perkin-Elmer 2400 thermal cycler programmed for 30 cycles (94 °C, 30 s; 56 °C, 30 s; and 72 °C, 90 s) with one additional cycle for 7 min at 72 °C. PCR product was purified by agarose gel electrophoresis, digested by NcoI and SalI, then ligated into the pGBKT7 plasmid digested by NcoI and SalI. The ligation products were then transformed into *E. coli* DH5 α . The insert of *ipaC* gene was then confirmed by PCR using the conditions described above. To confirm if the *ipaC* gene was fused in frame to the coding sequence of the GAL4 DNA-binding domain, the plasmids were subjected to double-stranded DNA sequencing with T7 sequencing primer according to the manufacturer's specifications.

Yeast transformation The lithium acetate (LiAc)-mediated method was performed to transform DNA into yeast as described in the reference^[23]. In brief, the yeast competent cells were prepared and suspended in a LiAc solution with the plasmids DNA to be transformed, along with excess carrier DNA. Polyethylene glycol (PEG) with an appropriate amount of LiAc was then added and the mixture of DNA and yeast was incubated at 30 °C. After incubation, DMSO was added and the cells were heat shocked at 42 °C. The cells were then

plated on the appropriate medium to select transformants. The amount of plasmids used for transformation was 0.1 μ g except that 50 μ g library plasmid was used.

SDS-PAGE and western blot analysis Extraction of yeast protein sample was carried out by using urea/SDS method as described in reference^[24]. SDS-PAGE was performed using the standard procedure of Laemmli^[22]. The samples were resolved on a 12 % polyacrylamide gel. The samples could be stained with Coomassie brilliant blue R250, or the proteins electroblotted to NC membranes for western blot analysis using a Bio-Rad Transbolt Semi-dry Blotter according to the manufacturer's instructions. Western blot analysis was performed as previously described^[22,25]. Briefly, the membranes were blocked following protein transfer by incubation in TBS (50 mM Tris-HCl pH7.4, 5 % BSA, 500 mM NaCl) and then incubated with c-Myc monoclonal antibody diluted in TBS containing 0.1 % Tween 20 (v/v). After several rinses in the same buffer, the membrane was incubated with HRP-conjugated secondary antibody in the same buffer. The membrane was then rinsed in TBS containing 10 mM EDTA, 0.5 M NaCl, and 0.1 % Tween 20 (w/v). Blots were developed using TBS (50 mM Tris-HCl pH7.4, 5 % BSA, 500 mM NaCl) containing 0.7 mg/ml 3,3'-diaminobenzidine (DAB) and 0.003 % H₂O₂, finally terminated with 2M H₂SO₄.

Two-hybrid strategy Before the screening process, intrinsic activation function of the bait was tested as demonstrated by a bait-testing assay. To perform the two-hybrid screening, the bait plasmid pGBKT-ipaC was transformed into the yeast strain AH109. The HeLa cDNA libraries were extracted from *E. coli* and introduced into the AH109 transformed with the bait. Cells were first spread on plates lacking Leu, Trp and His, and containing 1mM 3-aminotriazole to select colonies by prototrophy for histidine. The His⁺ colonies were streaked on selective plates lacking Leu, Trp, His and Ade. The His⁺, Ade⁺ colonies were assayed for expression of β -galactosidase by an X-Gal overlay assay, and blue colonies were streaked twice on selective plates. After that, individual His⁺, Ade⁺, LacZ⁺ colonies were cultured in liquid SD synthetic medium. Yeast DNA was recovered and transformed into *E. coli* DH5 α by electroporation. The insert carried by the prey plasmid in each of the selected clones was amplified by PCR and grouped. Representative plasmids from each group were retransformed back into yeast to test their interaction with IpaC. The cDNA inserts were subjected to sequencing.

RESULTS

Construction of bait plasmid

PCR primers for the 5' and 3' ends of *ipaC* gene were designed as follows based on its published sequences^[26]: P1, 5' -

CGGCCATGGTAATAGAACTGATGTTGC-3' containing an *NcoI* restriction site and 18 bases of the 5' end of *ipaC* gene; and P2, 5' -GCGTCCGACTTAAGCTCGAATGTTAC-3' containing a *SalI* restriction site and 18 bases of the 3' end of *ipaC* gene. After amplification of *ipaC* gene by PCR, there was a band of about 1.1kb by agarose gel electrophoresis (data not shown). The fragment was purified, digested by *NcoI* and *SalI*, and cloned into the *NcoI* and *SalI* sites of pGBKT7. The resulting plasmid was designated as pGBKT-*ipaC* (Figure 1). Sequencing revealed that the *ipaC* gene was fused in the correct reading frame with the coding sequence of GAL4 DNA-binding domain (data not shown).

Figure 1 Construction of recombinant plasmid expressing IpaC.

Expression of *IpaC* in yeast

SDS-PAGE and western blotting were carried out with the protein extracted from yeast AH109, AH109 transformed with pGBKT7 and pGBKT-*ipaC* (Figure 2). An approximate 20kDa GAL4 DNA binding domain containing c-Myc epitope tag was expressed in AH109 transformed with pGBKT7, while a 62kDa peptide was expressed in AH109 transformed with pGBKT-*ipaC*. This showed that IpaC could be expressed in frame with the GAL4 DNA binding domain and the bait plasmid could be used in two-hybrid screening.

Figure 2 Western blot analysis of the fused expression of IpaC with c-Myc monoclonal antibody as a primary antibody. Lane 1, AH109; lane 2, AH109 transformed with pGBKT-*ipaC*; lane 3, AH109 transformed with pGBKT7.

Two-hybrid screening

In order to identify whether the fused bait protein could activate the expression of reporter genes, yeast containing the bait plasmid (pGBKT-*ipaC*) and yeast containing the empty vector of library (pACT2) were tested as demonstrated by a bait-testing assay (Table 2). The results indicated that IpaC was devoid of transcriptional activity and could be used as bait in a yeast two-hybrid assay.

The bait plasmid and cDNA library were sequentially transformed into yeast strain AH109. Initial screening of 2×10^6 colonies of a human HeLa MATCHMAKER cDNA library identified 92 clones that showed specific activation of His reporter gene. Further testing of the specificity of interaction

screening on selective media lack of Trp, Leu, His, Ade and by β -galactosidase assay showed that only 64 colonies interacted specifically with the bait BD-IpaC protein, but not with fusion proteins between BD and human lamin C (Table 3).

Table 2 Detection of transcriptional activity of bait fusion protein in AH109

Transformed plasmids	Growth on SD His ⁻	X-Gal
pGBKT- <i>ipaC</i>	-	white
pGBKT- <i>ipaC</i> + pACT2	-	white

Table 3 Verification of the interaction in positive clones

Transformed plasmids	β -Gal activity
1 p1	white
2 p1 + pGBKT7	white
3 p1 + pLAM5'-1	white
4 p1 + pGBKT- <i>ipaC</i>	blue

Sequence analysis of the clones revealed that two independent colonies (p1 and p25) contained the same gene. A database search using the BLAST program showed that this gene encoded the protein which had as much as 99 % homology with RanBPM (GenBank accession number AB055311). The two library colonies isolated from the yeast-two hybrid assay contained amino acid sequences that were upstream of the BPM55 start codon, but were within the coding region of BPM90. The resulting product of p1 contained 584 C-terminal amino acids of RanBPM, which fused in the frame with the GAL4 activation domain.

DISCUSSION

An important step in *S. flexneri* infection is bacterial invasion of colonic epithelial cells, as characterized by host cytoskeletal rearrangements at the site of bacterial contact^[27]. These localized changes in the host cytoskeleton lead to the formation of filopodia that combine and trap the pathogen within a membrane-bound vacuole that is rapidly lysed, thereby providing the bacterium with access to the host cell cytoplasm^[6]. Evidence indicates that IpaC is necessary and sufficient to promote the formation of filopodial extensions localized at the edge of fibroblastic cells^[21]. These extensions appear within seconds after exposure of permeabilized cells to IpaC. The data presented above and those from other laboratories indicate that IpaC proteins play an important role in this process.

Current understanding of the role of *S. flexneri* Ipa proteins in epithelial cell invasion is primarily based on deletion mutagenesis, genetic complementation, and immunological analyses^[12-14,28,29]. To better understand the roles of the Ipa proteins in the pathogenesis of shigellosis, it is necessary to isolate proteins that interact with Ipa proteins in host cells. The two-hybrid system is an effective genetic method to identify protein-protein interaction and has been increasingly used^[30,31]. Therefore, we exploited a two-hybrid screen to identify the IpaC-interacting protein in host cells. The foci of infection of this pathogen are human colonic epithelial cells, so a library prepared from them should be used in our screening. Unfortunately, it is not commercially available. The mechanism of entry of *Shigella* into cells has been studied extensively in cultured cell lines. Of these cell lines, HeLa was derived from human epithelial cells and has been frequently used in the invasion of *S. flexneri*^[32-35]. Therefore a HeLa cDNA library was used instead in our screening. Two library colonies that were isolated in the yeast-two hybrid assay contained amino

acid sequences with high homology to RanBPM.

RanBPM was originally identified by its interaction with Ran, a small Ras-like GTPase. Ran shuttles between the nucleus and the cytoplasm to complete its GTPase cycle, carrying out nucleocytoplasmic transport of macromolecules and inducing microtubule self-assembly by interacting with distinct Ran binding protein^[36,37]. RanBPM was initially identified as a 55kD protein (BPM55) which contains 500 amino acids^[37]. A subsequent report has shown that BPM55 is a truncated protein and the full-sized RanBPM is a 90kD protein (BPM90) which contains 729 amino acids^[38]. Here we demonstrated that the function domain within BPM90 was able to interact with IpaC *in vivo*. RanBPM was predominantly localized both in the nucleus and in the cytoplasmic region surrounding the centrosome^[38]. When truncated RanBPM was overexpressed in green monkey kidney COS7 cells, the multiple spots which were colocalized with γ -tubulin were formed and acted as ectopic microtubule nucleation sites, resulting in a reorganization of microtubule network^[37]. The function of BPM90 is still unclear, but it has recently been linked to the Ras/Erk signaling pathway^[39].

Actin filaments and microtubule (MT) arrays have been regarded as constituting separate cytoskeletal systems with distinct functions. However, it has become clear that the cell's system of cytoskeletal filaments and its network of signaling pathways are intimately linked and function cooperatively to generate a cell phenotype tailored to the immediate conditions of the cell^[40]. When a signal occurs, the structural responses driven by the cytoskeleton are usually complex, such as establishing new axes of polarity, making and breaking contacts, moving or dividing, especially generating protrusions as observed in the entry process of *S. flexneri*.

Taken the data presented above together, we therefore become greatly interested in possible involvement of IpaC in the signaling cascade resulting in massive cytoskeletal rearrangements (Figure 3).

Figure 3 A schematic diagram of possible IpaC signaling cascade in *S. flexneri* entry.

The early step of infection is the invasion of epithelial cells of the colon. As bacteria contact the cell surface, Ipa invasins are secreted through the specialized secretory apparatus, two of which (IpaB and IpaC) form a complex. IpaC has hydrophobic regions that form transmembrane helices and insert into cell membrane^[41]. This complex constitutes the primary effector of *Shigella* entry and is able to activate entry via its interaction with the host cell membrane. Then IpaC stimulates localized accumulation of filamentous actin at the site of bacterial contact. Meanwhile IpaC also leads to

microtubule nucleation and/or nucleocytoplasmic transport of macromolecules possibly by interacting with RanBPM. So it is likely that IpaC elicits major rearrangements of host cell cytoskeleton, and these cytoskeletal filaments function cooperatively and form bundles supporting the membrane projections which achieve bacterial entry. Both the pathogen and the host cell actively contribute to this process.

This is the first report that IpaC interacts with RanBPM identified by two-hybrid screening. This information provides an important step in studying the protein-protein interaction that occurs in the host cells during initiation of *Shigella* pathogenesis. Although our understanding of the mechanisms that govern *Shigella* entry and actin-based intracellular motility has improved at a considerable pace, many questions remain open. In particular, it will be interesting to establish various connections between signaling pathways involved in *Shigella* entry and responses linked to the ipa proteins. Understanding how these responses integrate together and act in a concerted manner to induce bacterial entry will represent another exciting field of investigations.

ACKNOWLEDGMENTS

We would like to thank Prof. Qi-Nong Ye for his technical assistance and helpful discussions. We also thank Prof. Jian-Guang Zhou, Dr. Hao Zhang for their support in this project. We acknowledge the technical assistance of De-Hui He, Kun Hu and Zhi-Yong Gao.

Abstract

AIM: To construct and express a humanized M₂ autoantigen trimer designated as BPO and to apply it in the diagnosis of primary biliary cirrhosis (PBC).

METHODS: cDNA fragments encoding M₂-reactive epitopes of pyruvate dehydrogenase complex E₂ (PDC-E₂), branched chain 2-oxo-acid dehydrogenase complex E₂ (BCOADC-E₂) and 2-oxo-glutarate dehydrogenase complex E₂ (OGDC-E₂) were amplified with PCR using total RNA extracted from human peripheral mononuclear blood cells. The fragments were cloned into the plasmid vector pQE-30 and then transferred into *E. coli* M15 (pREP4) for expression, which was induced by isopropylthio-β-D-galactoside. The expressed recombinant BPO protein was demonstrated by SDS-PAGE, Western-blotting and Immunoabsorption test, its antigenic reactivity and specificity were identified with seven M₂-positive sera confirmed at Euroimmun Research Center (Germany). Using the purified BPO, M₂ antibodies in sera from patients with PBC and other liver related diseases were detected with ELISA.

RESULTS: The expressed BPO was observed with both antigenic reactivity and specificity of M₂ autoantigens. The determination of M₂ antibodies by BPO with ELISA was more sensitive than using the Euroimmun's kit with the coefficients of variation less than 10 % in both interassay and intraassay. With the newly established method, M₂ antibodies were found in 100 % (20/20) of patients with PBC. Six cases of liver disease with unknown etiology and 1 patient with drug induced liver injury had detectable levels of serum M₂ antibodies. There were also 2 patients with autoimmune cholangitis and 1 with autoimmune hepatitis showing M₂-antibody positive.

CONCLUSION: Compared with the routine immunofluorescence assay and commercially available assay kit using porcine heart mitochondrial protein as the antigen, the detection system established in the present study shows higher sensitivity and specificity and may be used as a powerful tool for the diagnosis of PBC.

INTRODUCTION

Primary biliary cirrhosis (PBC) is a chronically progressive cholestatic liver disease with autoimmune basis. According to some reports, the incidence of this disease has been consistently increased in recent years^[1-4]. One of the remarkable features of PBC is the appearance of high titre antimitochondrial antibodies (AMA) in the patient's sera. Generally, these antibodies are categorized into nine subgroups termed M₁-M₉ according to the antigens they recognize, in which only M₂ antibodies are considered specific for PBC patients that are detectable years or decades before the clinical and histological diagnosis^[5-11].

The major autoantigens recognized by M₂ antibodies are the members of 2-oxo-acid dehydrogenase complex including pyruvate dehydrogenase complex E₂ (PDC-E₂), branched chain 2-oxo-acid dehydrogenase complex E₂ (BCOADC-E₂) and 2-oxo-glutarate dehydrogenase complex E₂ (OGDC-E₂), whose immunodominant epitopes have been mapped within lipoyl domains. Antibodies to these corresponding autoantigens have been reported in PBC patients with a positive rate of 95 %, 53-55 % and 39-88 % respectively^[6,12]. However, when all of these antibodies are determined simultaneously, the patients with PBC can be diagnosed as high as 92-100 %^[13-16]. These facts suggest such a possibility that if there is a constructed antigen containing the specific immunodominant epitopes and the antibodies above can be detected synchronously, the diagnosis of PBC patients would be more specific, sensitive and convenient.

Therefore, we designed and constructed a M₂ autoantigen trimer (BPO) expression vector, which could coexpress the immunodominant lipoyl domains of PDC-E₂, BCOADC-E₂ and OGDC-E₂ from human origin, in an attempt to establish a more accurate and sensitive method with BPO to detect M₂ antibodies in patients with PBC. Besides, because it has never been reported that M₂ antibodies were found in other liver related diseases other than PBC^[17-20], a survey to detect M₂ antibodies under these circumstances with our constructed M₂ autoantigen trimer was also included in the present study.

MATERIALS AND METHODS

Patients

Eight groups of adult patients with both sexes who were treated in Shanghai Changzheng Hospital were enrolled in the present study. Group 1 consisted of 20 patients with PBC diagnosed on the criteria: the presence of AMA and at least one of the followings: (1) Elevation of serum alkaline phosphatase (ALP) and/or gamma glutamyl transpeptidase (γ-GT). (2) Liver biopsy with PBC characteristics^[21]. Group 2 consisted of 5 patients with autoimmune hepatitis (AIH)^[22]. Two patients diagnosed

as autoimmune cholangitis (AIC) were included in group 3, and group 4 was composed of 18 patients diagnosed as liver disease with unknown etiology (LDUE) that was defined as lack of obvious causes including drug use, alcohol abuse, exposure to hepatotoxic medication or chemicals and virus infection. Group 5 consisted of 8 patients with drug induced liver injury (DILI). Group 6 enrolled 201 patients with other liver diseases (Post-viral hepatitis and liver cirrhosis, $n=153$; Obstructive jaundice, $n=25$; Acute hepatitis A, $n=15$; Hepatic abscess, $n=3$; Wilson's disease, $n=1$; Cardiac cirrhosis, $n=4$). Thirty-three patients with various autoimmune diseases (AID) (Rheumatoid arthritis, $n=12$; Systemic lupus erythematosus, $n=12$; Polymyositis, $n=4$; Vasculitis, $n=3$; Hashimoto's thyroiditis, $n=2$) were included in group 7 and 1 225 healthy volunteers taking a health checkup aged less than 28 served as the control. In the experiment, fasting serum from each patient was prepared with routine procedures and stored at -20°C until further analysis.

Materials

Reverse transcriptase and PCR amplification system were purchased from Roche Company (U.S.A). Restriction endonucleases and T₄ DNA ligase were from New England Biolabs (U.S.A). Plasmid vector pQE-30 and *E.coli* M15 (prep 4) were from Qiagen Company (Germany). Indirect immunofluorescence (IIF) test kit for AMA and Western-blotting kit for M₂ antibodies were all from Euroimmun Company (Germany).

Figure 1 Construction protocol of recombinant plasmids.

Expression and identification of M₂ autoantigen trimer

Recombinant plasmids were constructed as illustrated in Figure 1. Briefly, total RNA was extracted from human peripheral mononuclear blood cells. The objective cDNAs were synthesized by reverse transcriptase and used as the template to amplify the immunodominant epitopes of BCOADC-E₂, PDC-E₂ and OGDC-E₂ with polymerase chain reaction. The PCR products were digested with relevant restriction endonuclease and purified cDNA fragments were inserted into the expression vector pQE-30 to form recombinant plasmids

pQE-30/BCOADC-E₂, pQE-30/PDC-E₂, pQE-30/OGDC-E₂ and pQE-30/BPO respectively. The pQE-30/BPO was then transferred into *E. Coli* M15 (pREP4) and induced by isopropylthio- β -D-galactoside to express BPO protein, which was finally confirmed with SDS-PAGE, Western-blotting and Immunoabsorption test.

The antigenic reactivity and specificity of the recombinant BPO trimer were identified with seven M₂-positive sera confirmed at Euroimmun Research Center (Germany) by immunoblotting using beef heart mitochondrial preparations.

Detection of M₂ antibodies with BPO

The obtained recombinant BPO protein fused with the 6 \times His affinity tag in the N-terminus was purified by Ni-NTA affinity chromatography under denaturing conditions. After renatured by removing denaturants slowly with dialysis, the BPO protein was used as the specific antigen to detect M₂ antibodies with the routine procedures of ELISA. The coefficients of variation for this assay method, the mean OD \pm SD for the control sera, as well as the critical OD value for the positive determination were respectively calculated or defined based on the experimental results. The measurements of M₂ antibodies and AMA with Euroimmun's kits as a comparison of the present assay method were also simultaneously performed in the study.

RESULTS

Identification of expressed M₂ autoantigen trimer

The segment analysis by restriction endonuclease digestion confirmed that inserted cDNA sequences in the constructed plasmids were completely consistent with that of the published data (Figure 2). The molecular mass of BPO protein was examined by SDS-PAGE in 15 % polyacrylamide gel, in which a specific 42 KD protein band was clearly visualized (Figure 3).

Figure 2 Segment analysis of recombinant plasmids by restriction endonuclease digestion. 1, 7. Markers; 2. pQE-30 (Bamh1); 3. pQE-30/BCOADC-E₂ (Bamh1+Sph1); 4. pQE-30/PDC-E₂ (Sph1+Sac1); 5. p30/OGDC-E₂ (Sac1+Sall); 6. pQE-30/BPO (Bamh1+Sall).

Figure 3 Expression products of recombinant plasmids detected by SDS-PAGE stained with Coomassie Brilliant Blue R-

250. Lane 1: pQE-30 (control); Lane 2: pQE-30/BCOADC-E₂; Lane 3: pQE-30/PDC-E₂; Lane 4: pQE-30/OGDC-E₂; Lane 5: pQE-30/BPO; Lane 6: protein marker.

The expressed BPO protein could react with all of the seven M₂-positive sera confirmed at Euroimmun Research Center (Germany) by immunoblotting using beef heart mitochondrial preparations, which identified the antigenic reactivity of the recombinant BPO trimer (Figure 4). When mixed beforehand with the lysates of *E. coli* expressing BPO overnight, the sera became M₂-negative by Western-blotting, which confirmed the BPO specificity determined by the immunodominant epitopes of PDC-E₂, BCOADC-E₂ and OGDC-E₂.

Figure 4 Immunoreactivity of sera against recombinant proteins. Three M₂ antibody positive sera (A, B, C) and a M₂ antibody negative serum (D) were probed with SDS-PAGE-separated recombinant proteins of BCOADC-E₂ (lane a), PDC-E₂ (lane b), OGDC-E₂ (lane c), BPO (lane d).

Effectiveness of BPO in the detection of M₂ antibodies

The coefficients of variation for the detection of M₂ antibodies by BPO with ELISA were less than 10 % in both interassay and intraassay. The mean OD \pm SD for the control sera was 0.073 \pm 0.046. The critical OD value for positive was defined as ≥ 0.303 based on the mean control value + 5 SD.

M₂ antibodies in patients with PBC

In the patients with PBC who were AMA positive determined by IIF test kit, the positive rate of M₂ antibodies detected by BPO with ELISA and Euroimmun's kit was 100 % (20/20) and 80 % (16/20) respectively (Table 1).

Table 1 AMA and M₂ antibodies in patients with different diseases

Group	n	AMA positive	M ₂ - positive		AASLD's guideline (+)
			Euroimmun's kit	ELISA	
PBC	20	20	16	20	20
AIH	5	0	0	1	0
AIC	2	0	1	2	0
LDUE	18	7	6	6	6
DILI	8	1	1	1	1
Other liver diseases	201	ND	ND	0	ND
AID	33	3	0	0	0
Control	1225	ND	ND	0	ND

PBC: primary biliary cirrhosis; AIH: autoimmune hepatitis; AIC: autoimmune cholangitis; LDUE: liver disease with unknown etiology; DILI: drug induced liver injury; AID: autoimmune disease; AMA: antimitochondrial antibodies; ND: not done.

M₂ antibodies in patients with other diseases

Seven patients with liver disease of unknown etiology were all AMA positive; However, only one was M₂ antibody negative and didn't agree with the guideline by the American Association for the Study of Liver Diseases (AASLD), and his plasma ALP and γ -GT were in normal range but alanine aminotransferase was elevated (120 U/L). The other 6 patients with M₂ antibody positive had no specific symptoms except the unexplained elevation of serum ALP (187-1 525 U/L) and γ -GT (88-2 685 U/L).

One patient with drug induced liver injury was demonstrated as M₂ antibody positive by both ELISA and Euroimmun's kit, whose additional laboratory data were as follows: AMA positive, antinuclear antibodies positive, ALP 153 U/L, γ -GT 321 U/L; alanine aminotransferase 281 U/L, aspartate transaminase 225 U/L, total bilirubin 25 μ mol/L (normal < 18 μ mol/L). This patient suffered from lymphatic tuberculosis and had taken rifampisin for one year before the onset of liver disease. He was in agreement with the AASLD's guideline.

It was noteworthy that the sera from 1 AIH and 2 AIC patients with AMA negative had detectable M₂ antibody by BPO with ELISA, while they were M₂ antibody negative with the Euroimmun's kit. The prominent elevation of plasma ALP and γ -GT was observed in all of the three patients.

No M₂ antibody positive sera were found in control, other liver disease and the AID group by BPO with ELISA.

DISCUSSION

In the guideline by AASLD in 2000 and the standards by other researchers, AMA has long been used as an important marker for the primary biliary cirrhosis^[21, 23]; however, only M₂ antibodies are considered as specific for the PBC diagnosis. Other AMA sub-types have been found in drug-induced disorders, cardiomyopathies, systemic lupus erythematosus, rheumatoid arthritis, tuberculosis, syphilis and hepatitis C, indicating the nonspecific nature of AMA in the diagnosis of PBC^[24]. Besides, there were about 5-17 % of the patients with biochemical and histological features compatible with PBC not having detectable AMA with the IIF method^[25-34]. To get better diagnostic results, approaches to detect M₂ antibodies by ELISA or Western-blotting using recombinant antigen of PDC-E₂, BCOADC-E₂ and OGDC-E₂ have been reported in several literatures^[15-17].

In 2001, Miyakawa and his coworkers^[35] developed a new ELISA for the detection of M₂ antibody using porcine heart mitochondrial protein as the antigen. The sensitivity of this method was only 78 %, despite the specificity was 100 %. In the present study, we employed BPO as the antigen to determine M₂ antibodies with ELISA, which was more sensitive than the Euroimmun's kit. The reason for this was partially because the antigen used in our approach was derived from human sources instead of that from porcine used in Euroimmun's kit. The antigen heterogeneity might affect the assay results^[36]. Furthermore, the three major autoantigens, BCOADC-E₂, PDC-E₂ and OGDC-E₂, with no cross-reactivity between, were constructed together as a trimer by molecular biological techniques, which could provide more positive chance for the detection of M₂ antibodies. Therefore, the use of this recombinant molecule offered a rapid, simple and sensitive ELISA for the immunodiagnosis of PBC.

According to the investigation by James and his associates^[3], the incidence of PBC has been increased in recent years. In northern England, the prevalence of PBC from 201.9 per 10⁶ adults and 541.4 per 10⁶ women over 40 in 1987 rose to 334.6 and 939.8 respectively in 1994. Owing to the lack of sensitive diagnostic methods, there have no reliable data related to the epidemiology of PBC in China so far and more seriously,

clinical doctors have not yet paid appropriate attention to this disease. We checked 10 patients with liver cirrhosis hospitalized in January, February and April in 2000 whose serum immunological variables showed no signs of viral infection, and the reason for liver cirrhosis seemed unclear. However, 7 of the 10 patients were found M₂ antibody positive by the detailed studies at the Euroimmun Research Center (Germany). In the past six months since we detected M₂ antibody by BPO with ELISA for the PBC diagnosis, over 120 patients' sera have been examined, in which 69 demonstrated M₂ antibody positive and 30 cases with comparatively complete clinical data listed in this paper. Our recent research and the related domestic reports in 2001 indicate that PBC is probably not so rare in China as it has been thought^[4, 37].

Abstract

AIM: Irritable bowel syndrome (IBS) is characterized by abdominal pain and changes in stool habits. Visceral hypersensitivity is a key factor in the pathophysiology of IBS. The aim of this study was to examine the effect of rectal balloon-distention stimulus by blood oxygenation level-dependent functional magnetic resonance imaging (BOLD-fMRI) in visceral pain center and to compare the distribution, extent, and intensity of activated areas between IBS patients and normal controls.

METHODS: Twenty-six patients with IBS and eleven normal controls were tested for rectal sensation, and the subjective pain intensity at 90 ml and 120 ml rectal balloon-distention was reported by using Visual Analogue Scale. Then, BOLD-fMRI was performed at 30 ml, 60 ml, 90 ml, and 120 ml rectal balloon-distention in all subjects.

RESULTS: Rectal distention stimulation increased the activity of anterior cingulate cortex (35/37), insular cortex (37/37), prefrontal cortex (37/37), and thalamus (35/37) in most cases. At 120 ml of rectal balloon-distention, the activation area and percentage change in MR signal intensity of the regions of interest (ROI) at IC, PFC, and THAL were significantly greater in patients with IBS than that in controls. Score of pain sensation at 90 ml and 120 ml rectal balloon-distention was significantly higher in patients with IBS than that in controls.

CONCLUSION: Using fMRI, some patients with IBS can be detected having visceral hypersensitivity in response to painful rectal balloon-distention. fMRI is an objective brain imaging technique to measure the change in regional cerebral activation more precisely. In this study, IC and PFC of the IBS patients were the major loci of the CNS processing of visceral perception.

INTRODUCTION

Irritable bowel syndrome (IBS) is the most common disorder

seen in gastroenterological practice^[1,2]. The disorder affects approximately 15 % to 20 % of the world's population and is predominately found in women^[2]. It comprises a group of functional bowel disorders in which abdominal discomfort or pain is associated with defecation or a change in bowel habit, and with features of disordered defecation^[3,4]. The pathophysiology of the symptom remains unclear, and visceral hypersensitivity or decreased pain thresholds to distension of the gut is considered to be a biologic marker for IBS and is present in most patients with this gastrointestinal disorder^[5]. Possibly, there are dysfunctions in the processing of sensory stimuli in the "brain-gut" axis that may cause visceral hypersensitivity and secondary motility changes^[6]. The central nervous system is believed to play a strong modulatory or etiological role in the pathophysiology of the disease^[7].

In animals, the perception of somatovisceral pain is derived from the expression of the immediate early gene c-fos^[8-11]. Numerous positron emission tomography (PET)^[12-15] or functional magnetic resonance imaging (fMRI)^[16-18] studies have dealt with the central processing of somatic pain in humans. In contrast, the neural networks involved in the perception of visceral pain in humans, especially rectal pain, have been the subjects of a limited number of functional brain imaging studies^[19-23].

Previous studies of somatic pain using PET scanning to measure the regional cerebral blood flow have suggested that the anterior cingulate cortex (ACC), prefrontal cortex (PFC), insular cortex (IC), and thalamus (THAL) are important loci in pain perception^[12,24]. Studies of visceral pain have generally suggested that these brain centers are important in sensation. fMRI is an alternative technique to measure changes in regional cerebral activity during stimulation. Using fMRI, the cerebral loci activated by rectal distention were also characterized in healthy volunteers^[22].

In this study, we examined the effect of rectal balloon-distention stimulus by blood oxygenation level-dependent functional magnetic resonance imaging (BOLD-fMRI) in the visceral pain center and to compare the distribution, extent, and intensity of activated areas between irritable bowel Syndrome (IBS) patients and normal controls.

MATERIALS AND METHODS

Subjects

Eleven normal right-handed control subjects (6 men and 5 women; age, 24-49 years; average age, 39 years) and twenty-six right-handed patients with IBS (12 men and 14 women; age, 18-61 years; average age, 47 years) participated in the study. All volunteers were free of any gastrointestinal complaint. The IBS patients were all diagnosed in Ruijin Hospital, and met the Rome II criteria for IBS^[4], which include at least 12 weeks, not necessarily to be consecutive in the preceding 12 months of abdominal discomfort or pain that has two of the following three features: (1) Relieved with defecation; (2) Onset associated with a change in frequency of stool; (3) Onset associated with a change in form (appearance) of stool. Each patient underwent a basic evaluation to exclude organic disease including a history, physical examination, and colonoscopy.

Distention protocol

Subjects reclined on the magnetic resonance imaging (MRI) table with head resting on a beanbag saddle that reduced head motion. A plastic balloon (Medtronic Synectics, USA) was placed in rectum at 10-15 cm from the anal margin. First, the subjects were tested for the rectal sensation, including the thresholds for sensation of gas, defecation and pain. Second, subjects reported the subjective pain intensity at 90 ml and 120 ml rectal balloon-distention by using visual analogue scale (0=no pain, 10=unbearable pain). Then, fMRI scanning was begun. Subjects were instructed to expect 4 series of rectal stimuli. Each set of distention included 3 stimuli of the same volume lasting 30 seconds each, with a 30-second rest period in between. The balloon inflation and deflation for each stimulus required an average of 6 seconds. The baseline volume during the rest periods was 0 ml. The first series of stimulus volume was 30 ml, the second 60 ml, the third 90 ml, and the last 120 ml.

MRI scanning

BOLD imaging was performed on a 1.5-T GE Signa MRI system. Each scanning consisted of a T1-weighted (the parameters included TR/TE=400 ms/14 ms, matrix=256×256, NEX=1). Next, four 10-mm-thickslices aligned at an approximately 20° angle above the anterior commissure-posterior commissure line to include the ACC, IC, PFC, and THAL. A functional scan was performed using echo planar imaging, and a matrix of 64×64, NEX=1. The pulse sequence parameters included a 90° flip-angle with a TR (image repetition rate)/TE (effective echo time) of 3 000 ms/60 ms. Each run consisted of 3 repetitions of 30 seconds of rest, followed by 30 seconds of stimulus. In each 30-second period, 10 parameters were collected, 60 data during each series.

Data processing and analysis

Data analysis was performed using correlation-coefficient tool in Functional software (AW3.2, SUN workstation). The confidence level was 0.05. Brain areas thought to mediate painful sensation included the ACC, the IC, the PFC, and THAL. These regions of interest (ROI) were identified and circled on the high-resolution anatomic images by a radiologist, who was blind to the identity of the patient and to the active pixels. The regional cerebral activation was evaluated by the percentage area of ROI and the percentage change in MR signal intensity of ROI. The percentage area of ROI was calculated by the formula: the percentage area of ROI = the pixels of ROI/the total pixels of selected pain center ×100 %. The percentage change in MR signal intensity of ROI = (the MR signal intensity during stimulation - the Mean baseline signal)/the mean baseline signal ×100 %. The average percentage change in MR signal intensity was calculated for each subject at each stimulus volume in each ROI. To exclude the influence of balloon inflation and deflation, the first and the tenth MR signal intensity of the rest and stimulus phase were eliminated.

Statistical analysis

The data were expressed as means ±SEM. For comparison of means, an unpaired Student's *t* test was used. The primary comparisons were the thresholds for sensation and VAS score between IBS patients and controls. Secondary analysis included the percentage of ROI and the average percentage change in MR signal intensity of ROI comparing IBS patients with controls. Statistically significant differences by 2-tailed *t* tests were defined by *P*<0.05.

RESULTS

Rectal sensation test

In the control group, the average thresholds for sensation of

gas, defecation and pain were 28 ml, 127 ml, and 208 ml. They were 24 ml, 90 ml, and 150 ml respectively in IBS group. The thresholds for sensation of defecation and pain were significantly lower in IBS group than in control group (*P*<0.05, Figure 1).

Figure 1 Rectal sensation test (the thresholds for sensation).

VAS score

At 30 ml rectal distention, subjects generally sensed a very-low-intensity stimulation, using the terms “gas”, “mildly felt”. At 60 ml rectal distention, some IBS patients expressed sensation of defecation. At 90 ml rectal distention, a large number of IBS patients and some normal controls expressed sensation of stool, associated with mild-moderate pain, and VAS score was 4.42 ± 2.00 vs 2.71 ± 1.78 . At 120 ml rectal distention, most IBS patients reported moderate-severe painful sensation, and VAS score was 5.90 ± 1.84 vs 3.95 ± 2.04 . In this study, three IBS patients could not tolerate 120 ml rectal distention. The VAS score of 90 ml and 120 ml rectal distention (painful rectal distention) was significantly higher in IBS patients than in control (*P*<0.05, Figure 2).

Functional brain imaging

The time course of rectal stimulation sensation center response indicated immediate increase and rapid decline in BOLD signal

Figure 4 Functional brain map. The red area is the ROI.

in parallel with the mechanical distending stimulus (Figure 3). For both IBS patients and control subjects, rectal distention stimulation increased the activity of anterior cingulate cortex (35/37), insular cortex (37/37), prefrontal cortex (37/37), and thalamus (35/37) in most cases.

In patients with IBS, the average percentage area of ROI increased in parallel with rectal distention volumes in the IC, PFC, and THAL, only that in PFC had statistical significance ($P < 0.05$). In controls, this increasing tendency only occurred in the ACC (Figure 4). At 120 ml rectal distention, the average percentage area of ROI and the average percentage change in MR signal intensity of ROI in the IC, PFC, and THAL were significantly greater in patients with IBS than in control subjects ($P < 0.05$, Figure 5 and 6).

DISCUSSION

fMRI is a useful technology to measure changes in regional CNS blood oxygenation, which is in parallel with regional metabolic activity^[25-27]. The BOLD technology detects changes in the ratio of deoxyhemoglobin to oxyhemoglobin. When brain-center neurons are metabolically active, there is an increase in local blood flow and a relative increase in the amount of oxyhemoglobin, and an increase in magnetic resonance signal^[25-29]. Accordingly, the magnetic resonance signal in a given pixel will increase above baseline if the region is activated in response to stimulation. fMRI offers advantages over PET such as direct anatomic correlation, avoidance of radioisotopes, and acceptable signal-to-noise ratio that do not require large numbers of stimuli. fMRI images give similar results as PET^[30,31].

It showed that fMRI has adequate sensitivity to measure regional cerebral blood flow changes in response to visceral - in this case rectal - stimulation. Activity in the 4 selected CNS pain centers, ACC, IC, PFC, and THAL, promptly increase with rectal distention stimulation. The 4 selected pain centers are components of the brain's pain-processing system^[12,24,32,33]. Current studies pointed to the THAL as a relay center, connecting afferent signals from the spinothalamic tract and spinoreticular tracts to higher centers such as the cingulate, prefrontal, and insular cortices^[34,35]. The IC is believed to mediate primarily visceral sensations (taste, smell, gastric, colonic, and other visceral inputs) including rectal stimuli, whereas the ACC is thought to mediate the affective or "emotional" content of sensory information. The insular cortex neurons distributed between the taste area and the visceral area receive convergent inputs from baroreceptor, chemoreceptor, gustatory and nociceptive organs and may have roles in taste aversion or in regulation of visceral responses^[36]. Using positron emission tomography (PET), Craig's^[37] group found contralateral activity correlated with graded cooling stimuli only in the dorsal margin of the middle/posterior insula in humans. Furthermore, Krushel^[38] referred to the region of convergence in the agranular insular cortex as the visceral cortex, and suggested its involvement in the efficient integration of specific visceral sensory stimuli with correlated limbic or motivational consequences. The visceral cortex may help regulate the organism's visceral response to stress.

The PFC is thought to exert higher executive functions in pain perception^[39]. There are several different functional

divisions of the PFC, including the dorsolateral, ventromedial, and orbital sectors. Each of these regions plays some role in affective processing that shares the feature of representing affect in the absence of immediate rewards and punishments as well as in different aspects of emotional regulation^[40].

In this study, the thresholds for sensation of defecation and pain were significantly lower in IBS group than in control group, and VAS score was significantly higher in IBS patients than in controls. The results were similar to the previous studies^[41]. Normal volunteers and IBS patients had significant cerebral activation in the 4 selected brain centers (ACC, IC, PFC, and THAL) during distention stimulation at 30 ml, 60 ml, 90 ml, and 120 ml. Significant differences in cerebral activation (both the percentage area and the percentage change in MR signal intensity of ROI) were found between IBS patients and controls. In IBS patients, there was significantly greater area of ROI of the PFC with 120 ml distention than with other volume distention. Conversely, in control subjects there was no significant increase in activation of these areas with 120 ml distention compared with others. Furthermore, at 120 ml rectal distention, there was significantly greater activation of the IC, PFC, and THAL in patients with IBS than in control subjects. In summary, by a variety of measures, it is possible that IC and PFC responses to visceral pain in IBS are greater than that in controls.

There were several studies about the CNS activity in response to visceral stimulation by using PET and fMRI, but the results differed. Silverman^[20] found a lack of activation within the ACC or PFC with nonpainful stimuli, and reported activation of PFC in response to rectal pain only in IBS and the ACC only in normal subjects. In contrast, more recently Mertz^[23], using fMRI, observed that pain led to a greater activation of the ACC than nonpainful stimuli. In Bernstein's^[42] study, they also found that normal controls and subjects with IBD and IBS shared similar loci of activations to visceral sensations of stool and pain. A significantly higher percentage of pixels activated in the anterior cingulate gyrus over both pain and stool conditions for the control group than for the IBS group and for the IBS group than for the IBD group ($P < 0.035$). In another study, Bonaz *et al* revealed significant deactivations within the right insula, the right amygdala, and the right striatum^[7]. There were gender differences in cortical representation of rectal distension in healthy humans. Male subjects showed localized clusters of fMRI activity primarily in the sensory and parietooccipital regions, whereas female subjects also showed activity in the anterior cingulate and insular regions^[43]. Thus, somatic and visceral sensation including pain perception can be studied noninvasively in humans with functional brain imaging techniques. Positron emission tomography and functional magnetic resonance imaging have identified a series of cerebral regions involved in the processing of somatic pain, including the anterior cingulate, insular, prefrontal, inferior parietal, primary and secondary somatosensory, and primary motor and premotor cortices, the thalamus, hypothalamus, brain stem, and cerebellum^[44]. Experimental evidence supports possible specific roles for individual structures in processing the various dimensions of pain^[44].

In conclusion, our data conform that fMRI is an objective brain imaging technique to measure the change in regional cerebral activation exactly. Using fMRI, some patients with IBS could be detected having visceral hypersensitivity in response to painful rectal balloon-distention. In this study, IC and PFC of IBS patients are the major loci in CNS processing of visceral perception.

Abstract

AIM: To determine the clinical, radiographic and laboratory characteristics, diagnostic methods, and therapeutic variables in immunocompetent patients with tuberculosis (TB) of the pancreas and peripancreatic lymph nodes.

METHODS: The records of 16 patients (6 male, 10 female; mean age 37 years, range 18-56 years) with tuberculosis of the pancreas and peripancreatic lymph nodes from 1983 to 2001 in the Southwest Hospital were analyzed retrospectively. In addition, 58 similar cases published in Chinese literature were reviewed and summarized. We reviewed the clinical, radiographic and laboratory findings, diagnostic methods, therapeutic approaches, and outcome in the patients. Criteria for the diagnosis of pancreatic tuberculosis were the presence of granuloma in histological sections or the presence of *Mycobacterium tuberculosis* DNA by polymerase chain reaction (PCR).

RESULTS: Predominant symptoms consisted of abdominal nodule and pain (75 %), anorexia/weight loss (69 %), malaise/weakness (64 %), fever and night sweats (50 %), back pain (38 %) and jaundice (31 %). Swelling of the head of the pancreas with heterogeneous attenuation echo was detected with ultrasound in 75 % (12/16). CT scan showed pancreatic mass with heterogeneous hypodensity focus in all patients, with calcification in 56 % (9/16) patients, and peripancreatic nodules in 38 % (6/16) patients. Anemia and lymphocytopenia were seen in 50 % (8/16) patients, and pancytopenia occurred in 13 % (2/16) patients. Hypertransaminasemia, elevated alkaline phosphatase (AP) and GGT were seen in 56 % (9/16) patients. The erythrocyte sedimentation rate (ESR) was elevated in 69 % (11/16) cases. Granulomas were found in 75 % (12/16) cases, and in 38 % (6/16) cases caseous necrosis tissue was found. Laparotomy was performed in 75 % (12/16) cases, and ultrasound-guided fine needle aspiration (FNA) was done in 63 % (10 of 16). The most commonly used combinations of medications were isoniazid/rifampin/streptomycin (63 %, $n=10$) and isoniazid/rifampin pyrazinamide/streptomycin or ethambutol (38 %, $n=6$). The duration of treatment lasted for half or one year and treatment was successful in all cases. The characteristics of 58 cases from Chinese literature were also summarized.

CONCLUSION: Tuberculosis of the pancreas and peripancreatic lymph nodes should be considered as a diagnostic possibility in patients presenting with a pancreatic mass, and diagnosis without laparotomy is possible if only doctors are aware of its clinical features and investigate it with appropriate modalities. Pancreatic tuberculosis can be effectively cured by antituberculous drugs.

INTRODUCTION

Tuberculosis (TB) is a potentially systemic disease that can infect any organ and system. It was a prevalent disease in the developing countries about 50 years ago, but its incidence has been controlled with the availability of effective anti-tuberculous drugs. However, the last decade has witnessed a rise in the incidence of tuberculosis even in developed countries. In the United States, the Centers for Disease Control reported that the incidence of TB was significantly greater in 1994 than in 1985^[1]. Nowadays, TB is often an acquired immune deficiency syndrome (AIDS)-defining illness in individuals found to be human immunodeficiency virus (HIV) antibody-positive; however, it can still cause a devastating disease in immunocompetent hosts^[1,2]. In China, there is a revival trend in the incidence of TB although AIDS remains uncommon nationally.

Abdominal infection with tuberculosis commonly affects the spleen, liver, and ileocecal region^[2,3]. Pancreatic tuberculosis is an extremely rare disease, especially when it is isolated in the pancreas. There were a few case reports published before in literature, but its clinical characteristics remain unclear^[4-6]. In this retrospective study, we reported 16 patients with TB of the pancreas and peripancreatic lymph nodes, and summarized the clinical features of 58 similar cases in the Chinese language literature where the HIV antibody status of the patients was either negative or not stated. The clinical, radiographical and laboratory findings, diagnostic methods, therapeutic approaches, and outcome in patients in an endemic area were reviewed in this study.

MATERIALS AND METHODS

The records of 16 patients who were admitted to Hepatobiliary Surgery Center, Southwest Hospital, Third Military Medical University, Chongqing, China with TB of the pancreas and peripancreatic lymph nodes between 1983 and 2001 were reviewed. The clinical, radiographic and laboratory findings, diagnostic methods, therapeutic approaches, and outcome in these patients were summarized. Ten patients were screened for anti-HIV antibodies. Criteria for the diagnosis of pancreatic TB were (1) paraffin-embedded tissues with granuloma or (2) the presence of *Mycobacterium tuberculosis* DNA by

polymerase chain reaction (PCR). IS 6110-specific primers, which could amplify all *M. tuberculosis* complex strains, were used for amplification. In addition, all available bacteriological and histological studies were performed to confirm the diagnosis. The clinical and laboratory features of patients were collected from the casebooks. Details of follow-up were obtained from medical records. In addition, 58 similar cases published in the Chinese literature were also reviewed and summarized.

RESULTS

A total of 16 patients with TB of the pancreas and peripancreatic lymph nodes had been documented. Six patients were male and 10 were female, with a mean age of 37 years (range 18-56 years). Eight patients had predisposing factors. Six patients had a history of pulmonary TB or TB of lymph nodes, one had diabetes mellitus, and one had connective tissue disease.

Presenting symptoms and physical findings

Predominant symptoms consisted of fever, abdominal pain, abdominal nodule, back pain, jaundice, malaise/weakness, anorexia/weight loss and night sweats. In twelve patients with abdominal nodule and pain, eleven had anorexia/weight loss, ten had malaise/weakness, eight had fever and night sweats, six had back pain, and five had jaundice.

Fever, usually the intermittent type, was present in eight patients. The mean duration of fever prior to the diagnosis was 23 days (range 11-35 days).

Radiographic findings

Chest X-rays revealed relic of TB focus in 8 patients, 6 with pneumonitis. All of the patients had been examined with ultrasound and computed tomography (CT) scan. Twelve patients showed swollen head of the pancreas with ultrasound image of heterogeneous attenuation echo. Four patients were demonstrated to have inner heterogeneous attenuation echo in head or body of the pancreas. CT scan showed pancreatic mass with heterogeneous hypodensity focus in all of the patients, with calcification in 9 of 16 patients, and peripancreatic nodules in 6 of 16 patients (Figures 1, 2 and 3). Endoscopic retrograde cholangiopancreatography had been performed for 12 cases, and 2 cases had pancreatic duct dilatation. Magnetic resonance imaging and digital subtraction angiogram had been done for 6 patients, and the results showed pancreatic nodules and/or peripancreatic mass.

Tuberculin skin test

Tuberculin skin test was performed on 9 patients before initiation of therapy. Four in 9 were positive (≥ 10 mm of induration) to 5TU of intradermally purified protein derivative (PPD).

Haematology and biochemistry

In 8 patients, anemia and lymphocytopenia were seen. Pancytopenia occurred in 2 patients. Hypertransaminasemia, elevated alkaline phosphatase (AP) and GGT were seen in 9 patients, respectively. The erythrocyte sedimentation rate (ESR) was elevated in 11 cases.

Results of smears and mycobacterial cultures

Secretions and body fluids were examined microscopically and cultured in 9 patients. Acid-fast bacilli were demonstrated in 1 case, and cultures for *M. tuberculosis* were positive in 4 out of 9 specimens tested. Anti-TB drug susceptibility was studied in 4 patients, and two *M. tuberculosis* strains were sensitive to the major anti-TB drugs including isoniazid (INH), rifampin

(RMP), pyrazinamide (PZA), streptomycin (SM), and ethambutol (EMB). The other 2 cases were not sensitive to rifampin, isoniazid and streptomycin, respectively.

Figure 1 Mass with heterogeneous hypodensity located in the head of pancreas. The body and tail of the pancreas appeared atrophy, and with enlarged main pancreatic duct.

Figure 2 Pancreas appeared swollen diffusely with heterogeneous enhancement and vague margin. A circle lymph nodes showed enhancement under pancreas.

Figure 3 Calcification of pancreatic TB occurred under the body of the pancreas and retroperitoneal lymph nodes.

Biopsy data

Granuloma was found in 12 cases among specimens harvested from the pancreas and peripancreatic nodule by laparotomy (12 of 16) and ultrasound-guided fine needle aspiration (FNA) (10 of 16). Caseous necrosis tissue was found in 6 of 16 cases, and results of smears showed that there were Langhans' giant cells, epithelioid cells and lymphocytes. Seven of the 16 patients had combined TB in the liver, bile duct or spleen.

Initial diagnosis

Eleven of 16 patients were initially given a diagnosis of pancreatic tumor. The diagnosis of pancreatic TB had been firstly confirmed for only three of 16 cases. Another three cases were diagnosed with retroperitoneal tumor.

Treatment regimen and outcome

Biopsy and/or FNA were done for all of the patients. Twelve in 16 cases received laparotomy. In one case, cholangiojejunostomy was performed for CBD obstruction, and in another two cases splenectomy was performed for splenic tuberculosis. All 16 patients received treatment with antituberculous drugs for TB. The most commonly used combinations were INH/RMP/SM ($n=10$) and INH/RMP/PZA/SM or EMB ($n=6$). The therapeutic duration lasted for a half or one year.

Twelve patients received follow-up from a half to 14 years. No recurrence of TB was found in the pancreas or other organs. In 11 patients, follow-up CT scans in abdomen were available. Resolution was complete in all patients. The mean time to resolution was 132 days (range 78-186 days).

Literature review

A total of 58 cases of pancreatic TB have been described in the Chinese language literature^[7-17]. Fifteen of the 58 patients were stated to be HIV antibody-negative, and the HIV status of the other patients was not confirmed. All of the 58 patients were diagnosed by histological appearance being consistent with characteristics of tuberculosis, or positive organisms by acid-fast staining, culture of *Mycobacterium tuberculosis* or PCR analysis. Twenty patients were male and 36 were female, with a mean age 43.5 years (from 14 to 73). The main symptoms were epigastric pain and discomfort (37 cases), fever (31 cases), weight loss (23 cases) and anorexia (21 cases). The other unusual symptoms included malaise/weakness (11 cases), back pain (9 cases), nausea/vomiting (8 cases), jaundice (6 cases), night sweats (6 cases), upper gastrointestinal bleeding (3 cases), cough (3 cases) and diarrhea (1 case). The duration of symptoms prior to presentation ranged from 5 days to 5 months (mean 2.6 months). Thirteen cases gave a past history of TB pneumonia (10 cases) and TB lymph nodes (3 cases). The appearance of the chest X-ray was reported in 49 cases. There was relic of TB focus in 14 patients, 9 with pneumonitis. 34 patients received tuberculin skin testing, of which 21 were positive. Single or multiple modalities of investigation were performed for the patients. Ultrasound revealed pancreatic mass in 38 cases and failed to do so in another 9 cases. Abdominal CT scan was used in 41 cases and reported pancreatic mass and/or peripancreatic nodules in all cases. MRI was performed in 19 cases and also showed a mass in all instances. ERCP found abnormalities with CBD and pancreatic duct in 7 cases. Abdominal X-ray showed focal calcification in 6 cases and DSA located a mass in 4 cases. Ultrasound-guided fine needle aspiration was performed in 21 cases and was successful in diagnosis in 14 cases. Laparoscopic biopsy was performed in 7 cases and confirmed diagnosis in all cases. Fifteen patients had combined TB in other organs.

The initial diagnoses included pancreatic tumor (35), chronic pancreatitis (7), retroperitoneal tumor (5), acute pancreatitis (4) and pancreatic TB (3). Thirty-nine patients underwent laparotomy, 24 for biopsy, 12 for FNA, 5 for pus cavity draining, 4 for choledochojejunostomy, 2 for pancreatoduodenectomy, and 1 for celiac ganglia resection. Pathological report showed granuloma in 27 patients. Acid-fast bacilli were demonstrated in 14 of 27 cases, and cultures for *M. tuberculosis* were positive in 8 out of 19 specimens tested.

The treatment details were given in 41 of 58 cases. The common agents were isoniazid, rifampicin, streptomycin, pyrazinamide and ethambutol. Combinations of 3 or 4 drugs were used for 36 patients. The duration of treatment was recorded in 28 cases, ranging from 3 to 12 months. 24 patients were reported to have resolution after treatment for 3 to 12 months. One death was reported among the 58 cases.

DISCUSSION

We have presented a description of a series of 16 cases with tuberculosis of the pancreas and peripancreatic lymph nodes in immunocompetent patients. Having reviewed Chinese literature we found 58 similar cases and summarized their clinical findings. Pancreatic TB is extremely rare. Diagnosis remains difficult for most of the patients, and it is especially difficult to differentiate pancreatic TB from pancreatic tumor. Our series and review of Chinese literature revealed several clinical characteristics as follows: (1) pancreatic TB is mostly suffered by young people, with a predominance of female over male. In contrast, pancreatic tumor is common in old people; (2) some patients have a history of TB in past, and most of them come from areas with high prevalence of active tuberculosis; (3) the patients often present with epigastric pain, fever and weight loss; (4) ultrasound and CT scan show pancreatic mass and peripancreatic nodules, sometimes with focal calcification; (5) FNA and laparoscopic biopsy are the diagnostic procedures of choice for patients with a high suspicion of pancreatic TB. It can lead to confirmed diagnosis and hence avoids laparotomy. Treatment using combination of 3 or 4 antituberculous drugs is effective for most patients. However, attention should be paid to the possibility of drug resistance to some agents that have being used for a long time.

Recently, the incidence of tuberculosis is increasing^[1-6]. Cases of pancreatic TB are being reported with increasing frequency, too^[18-22]. The reasons may be related to evolutionary changes in the biology of the mycobacterium, drug resistance, and new populations with immunological deficits. Cases related to acquired immunodeficiencies, AIDS or immunosuppression for transplantation have been reported more frequently. Jenney *et al.* had reviewed English language literature before 1998. A total of 37 cases of pancreatic TB in patients not stated to be HIV antibody-positive was found^[23]. The authors concluded that it was important to consider the diagnosis of TB when a patient presented with epigastric pain, fever and weight loss and a mass lesion in the pancreas by diagnostic imaging. Three forms of mycobacterial infection of the pancreas have been described as follows: (1) generalized (military) tuberculosis, in which *Mycobacterium tuberculosis* is the agent; (2) spread to the pancreas from celiac and other retroperitoneal lymph nodes, in which *Mycobacterium bovis* is the main agent to be considered; (3) primary localized pancreatic tuberculosis due to *Mycobacterium tuberculosis*, which may reflect a point of origin from the intestinal tract^[24-32].

In conclusion, tuberculosis of the pancreas and peripancreatic lymph nodes in immunocompetent patients is rare and could present a diagnostic challenge. However, if doctors are aware of its clinical features and conduct appropriate investigations with multiple modalities including CT scan and ultrasound-guided FNA or laparoscopic biopsy, diagnosis of pancreatic tuberculosis without laparotomy is possible and the disease can be effectively treated with antituberculous drugs.

Abstract

AIM: To estimate the age-specific prevalence of anti-ulcer drug use and to calculate the usage of different anti-ulcer drugs over 5 years within the universal health insurance program in Taiwan area.

METHODS: The National Health Insurance Research Database in Taipei supplied the cohort data sets of 200 000 people. The ambulatory and inpatient claims of the cohort from 1997 to 2001 were analyzed. The anti-ulcer drugs included all drug items of the group A02B (drugs for treatment of peptic ulcer) in the Anatomical Therapeutic Chemical classification system (version 2000). The amount of drug usage was measured in unit of defined daily dose.

RESULTS: Among the totally 13 034 393 visits with 56 672 631 ambulatory prescription items, there were 398 150 (0.7 %) prescribed items of anti-ulcer drugs in 378 855 (2.9 %) visits. Among the 107 649 admissions with 5 762 312 inpatient prescription items, there were 24 598 (0.4 %) prescribed items of anti-ulcer drugs in 11 548 (10.7 %) admissions. The annual prevalence of anti-ulcer drug use was 9.6 % in 1997, 11.6 % in 1998, 15.4 % in 1999, 14.5 % in 2000, and 15.9 % in 2001 respectively. The 5-year prevalence was 36.1 %. The age-specific prevalence among the people younger than 20 years was 9.2 % in 2001 and 23.7 % during the 5-year period. Cimetidine not only was the most popular ingredient among anti-ulcer drugs (57 634 cimetidine users in 70 729 all anti-ulcer drug users during the 5-year period) but also had the largest prescribed amount (42.3 % of DDDs for all anti-ulcer drug users during the 5-year period). The annually prescribed amount of anti-ulcer drugs had grown from 4.9 DDDs/1000 inhabitants/day in 1997 to 7.5 in 2001. This increase was largely attributed to H₂-receptor antagonists and the expanding number of users.

CONCLUSION: Prescribing of anti-ulcer drugs is indeed popular among the Chinese population in Taiwan area. The disproportionate use of anti-ulcer drugs by children demands further investigation.

Chen TJ, Chou LF, Hwang SJ. Prevalence of anti-ulcer drug use in a Chinese cohort. *World J Gastroenterol* 2003; 9(6):1365-1369 <http://www.wjgnet.com/1007-9327/9/1365.asp>

INTRODUCTION

In the past three decades, the invention of several revolutionary

anti-ulcer drugs, *e.g.* H₂-receptor antagonists, synthetic prostaglandins, proton pump inhibitors, and cytoprotective agents, has changed the physicians' treatment patterns in gastroenterology and greatly improved the ulcer-healing rate of patients with peptic ulcer disease^[1-6]. In spite of effectiveness and popularity, the cost of these drugs has also aroused concern in the health care systems of developed countries^[7-11]. The concern has been aggravating in recent years because of expanding use of proton pump inhibitors in treating gastroesophageal reflux disease. Although prescribing of these potent acid-suppressing drugs is popular, their patterns of utilization have been infrequently documented in national surveys^[12-21].

In Taiwan area, a single and universal health insurance program started in 1995 and covered nearly all inhabitants (21 653 555 beneficiaries at the end of 2001)^[22]. The prescription drug benefits are included in the insurance. Because all claims data for the reimbursement purpose are in electronic form and available to researchers, we can perform a survey of anti-ulcer drug use among the Chinese population in Taiwan area.

The aims of this study were twofold: to estimate the age-specific prevalence of anti-ulcer drug use and to calculate the usage of different anti-ulcer drugs over 5 years within the universal health insurance program in Taiwan area. The strengths of our study were to use the longitudinal data sets of a representative cohort of 200 000 people and to adopt the unit of international standards in measuring the anti-ulcer drug usage.

MATERIALS AND METHODS

Data sources

We obtained 4 cohort data sets (R01-4) from the National Health Insurance Research Database (NHIRD; <http://www.nhri.org.tw/nhird/>) in Taipei in November 2002. The total 200 000 people in these 4 cohort data sets had been randomly sampled from 23 753 407 people who were ever insured under the universal health insurance program in Taiwan area from March 1, 1995 to December 31, 2000. Not every person of the cohort was insured through the study period because of new birth, death, immigration, and emigration. The cohort data sets contained all insurance claims of 200 000 people from 1996 to 2001. The structure of the insurance claim files had been described in details in our previous study^[23].

In the current study, we analyzed the ambulatory and inpatient files of the cohort data sets from 1997 to 2001. Totally, there were 13 034 393 visits, 56 672 631 ambulatory prescription items, 107 649 admissions, and 5 762 312 inpatient prescription items.

Besides, we obtained a complete file of 21 146 approved drug items of Western medicine in Taiwan area from the web site of the Bureau of National Health Insurance (BNHI; <http://www.nhi.gov.tw/>; accessed January 12, 2002). Each drug of different brand, strength and form was officially assigned a unique code for use in the claims file. The BNHI also offered a list of ATC codes (the Anatomical Therapeutic Chemical classification system, version 2000)^[24] for each drug item.

Study design

The anti-ulcer drugs in our study included all drug items of the group A02B (drugs for treatment of peptic ulcer, renamed to 'drugs for peptic ulcer and gastroesophageal reflux disease')

in 2002) in the ATC classification system. This group of drugs has 5 subgroups of the fourth level: A02BA (H_2 -receptor antagonists, H_2RA), A02BB (prostaglandins), A02BC (proton pump inhibitors, PPI), A02BD (combinations for eradication of *Helicobacter pylori*), and A02BX (other drugs for treatment of peptic ulcer, renamed to 'other drugs for peptic ulcer and gastroesophageal reflux disease' in 2002). A total of 428 anti-ulcer drug items, including the original brands and generics, have been registered in Taiwan area since 1995. Some drugs might be no more available on the market or not reimbursable by the insurance during the study period.

In estimating the age-specific prevalence of anti-ulcer drug use, we first identified the people receiving anti-ulcer drug items in each year. Because the number of people in the cohort fluctuated during the study period, we calculated the number of the denominator in each year by excluding those people who were not insured at any time of that year. A person's age in a year was defined as the difference between her/his birthday and the end of that year. In estimating the 5-year age-specific prevalence from 1997 to 2001, we took December 31, 2001 as the index date to calculate a person's age.

In describing the distribution of anti-ulcer drug prescriptions among the cohort, we calculated the number of recipients and the total prescribed amount for each ingredient (ATC 5th level) in each year. Supposed that the cohort did not take anti-ulcer drugs before the base year of 1997, the number of new anti-ulcer drug users was additionally computed for each year after 1997. The prescribed amounts of anti-ulcer drugs were measured in unit of defined daily dose (DDD) by ATC classification system^[24]. The original dose of each prescription was converted to a number of DDDs according to the DDD of the ingredient. Some anti-ulcer drugs (e.g. cetraxate, urogastone, and gefarnate) lacked either ATC codes or DDDs; we used the most commonly prescribed daily doses as their DDDs. For international comparison, the numbers of DDDs per 1,000 inhabitants per day were also computed.

Statistical analysis

The database software of Microsoft SQL Server 2000 was used

for data linkage and processing. The regular statistics were displayed.

RESULTS

General information of the cohort

Among the 200 000-people cohort, only 195 971 people were eligible during the 5-year study period. The other 4 029 people who had dropped out of the insurance before 1997 would not be included in the following analyses. The number of eligible people varied from year to year (Table 1). There were more men than women (100 257 vs. 95 654), and the status of sex was unknown in 60 persons.

General information of anti-ulcer drug prescriptions

During the 5-year study period, 356 distinct anti-ulcer drugs had existed in the cohort data sets. The drugs belonged to 18 ingredients of ATC 5th level. At the ambulatory sector, there were 398 150 (0.7 %) prescribed items of anti-ulcer drugs in 378 855 (2.9 %) visits; at the inpatient sector, there were 24 598 (0.4 %) prescribed items in 11 548 (10.7 %) admissions.

Age specific prevalence of anti-ulcer drug use

In 1997, as high as 9.6 % (17 414/180 781) of eligible cohort received anti-ulcer drugs. The percentage increased by two-thirds to 15.9 % (29 181/183 976) in 2001. More than a third (36.1 %) of the cohort had ever received anti-ulcer drugs during the 5-year study period. Generally, the prevalence of anti-ulcer drug use increased with age. Another noteworthy finding was that anti-ulcer drugs had been prescribed to an appreciable percentage of children and adolescents (Table 1).

Recipients of anti-ulcer drugs by ingredient

Cimetidine was the most popular ingredient of anti-ulcer drugs among the cohort, followed by sucralfate, ranitidine, famotidine, omeprazole, pirenzepine, and lansoprazole (Table 2). The majority of new anti-ulcer drug users in each year were also attributed to cimetidine.

DDDs / 1000 inhabitants / day		4.9	5.7	7.3	6.5	7.5

^aATC=Anatomical therapeutic chemical classification system.

Total prescribed amounts of anti-ulcer drugs

Measured in unit of DDDs, cimetidine again had the largest prescribed amount (42.3 %) of all anti-ulcer drugs among the cohort during the 5-year study period (Table 3). It was then followed by ranitidine (16.2 %), famotidine (10.8 %), omeprazole (9.7 %), and lansoprazole (4.5 %). The majority of anti-ulcer drugs were used at the ambulatory sector (93.7 % of total DDDs).

The total prescribed amount of anti-ulcer drugs grew from 4.9 DDDs/1 000 inhabitants/day in 1997 to 7.5 in 2001 (Table 3). This increase was attributed to the expanded number of users because the average prescribed amount of anti-ulcer drugs per user in a year remained relatively stable (18.7 ± 54.8 DDDs in 1997, 17.9 ± 41.0 in 1998, 17.3 ± 51.0 in 1999, 16.5 ± 40.5 in 2000, and 17.3 ± 40.8 in 2001).

On the other hand, H₂-receptor antagonists and proton pump inhibitors had contributed to the growth of the total prescribed amount of anti-ulcer drugs during the study period (Figure 1). While H₂-receptor antagonists had the largest share of growth, proton pump inhibitors had the highest growth rate. In the meantime, the usage of prostaglandins had remained stable, but other drugs for treatment of peptic ulcer had fewer users and smaller prescribed amount totally.

Figure 1 Trend of total prescribed amount of anti-ulcer drugs by pharmacological subgroups from 1997 to 2001.

DISCUSSION

To the best of our knowledge, our study might be one of the few reports that surveyed the anti-ulcer drug use in the Chinese population. Only with the computerization of insurance reimbursement, pharmacoepidemiological studies of such a large scale could be feasible. Besides, the person-based sampling in our study could estimate both the total amount and prevalence of drug use among the population.

Our study revealed that prescribing of anti-ulcer drugs was indeed popular in Taiwan. Nearly a sixth of the population received anti-ulcer drugs covered by the health insurance in 2001 and more than a third of the population had been exposed to such drugs during the 5 years. But the total usage of anti-ulcer drugs in Taiwan was not high in international comparison. According to the statistics of the OECD (Organization for Economic Co-operation and Development), 8 countries supplied their national consumption of anti-ulcer drugs in 1998: Australia (38.8 DDDs/1 000 inhabitants/day), Sweden (29.0), Iceland (28.1), Denmark (16.5), Norway (16.0), Czech Republic (13.1), Finland (12.4), and Slovakia (8.7)^[25]. In contrast, Taiwan had only 5.7 DDDs/1 000 inhabitants/day of anti-ulcer drugs in the same year. However, the statistics has not been adjusted by age.

In the 1990s, the developed countries experienced a drastic increase of anti-ulcer drug consumption since the introduction of proton pump inhibitors. For example, the national consumption of anti-ulcer drugs in Sweden increased from 9.2 DDDs/1 000 inhabitants/day in 1990 to 34.4 in 2000^[25]. During

the 5 years of our study, a growing trend of anti-ulcer drugs was also observed in Taiwan. But the increase was largely attributed to H₂-receptor antagonists and expanding user group. The explanation might be that the reimbursement policy of the health insurance in Taiwan limited the use of expensive proton pump inhibitors on the one hand and loosened the regulation over the much cheaper generics of H₂-receptor antagonists on the other hand.

While overuse of proton pump inhibitors has become a research topic^[26,27], our study found that at least the children in Taiwan might be disproportionately exposed to anti-ulcer drugs. Because children were generally not able to receive upper gastrointestinal endoscopy, their use of anti-ulcer drugs could be seldom justified. It demanded further studies to explore such a situation in Taiwan.

Our study with insurance claims in Taiwan had some limitations. At first, the drug use outside the insurance was not included in the analysis. However, the majority of anti-ulcer drugs, including the low-dose cimetidine, were prescription-only drugs in Taiwan. Besides, the compulsory health insurance covered nearly all inhabitants in Taiwan and reimbursed most prescription-only drugs. The use of anti-ulcer drugs at the private market should be of a less significant scale.

Secondly, the actual duration of drug treatment was not computed in our study because of missing dosage frequency in the inpatient files of the NHIRD data sets. Instead, we calculated the cumulated numbers of DDDs for each person as a proxy of treatment duration. But the DDD is arbitrarily set for trend and international comparisons. It does not consider the dosing at the specific conditions of children, elderly, and other risk groups. However, our data showed that the yearly amount of anti-ulcer drugs per user was low on average. It might be inferred that most people took anti-ulcer drugs only for a short term.

Thirdly, the purpose of cohort data sets in the NHIRD was to trace a cohort retrospectively and prospectively. The people of the cohort were chosen in 2000 and it was planned to follow them up continuously in the next years. Thus, the data sets of 2001 did not include anyone born after December 31, 2000. The denominator in 2001 should be smaller than the actual number of people and the prevalence correspondingly became a little overestimated.

Finally, we did not analyze the distribution of diagnoses in our study because a claims diagnosis served for the purpose of reimbursement and was seldom verified. The NHIRD data sets did provide the information whether the patients had received the endoscopic or radiological examinations of upper gastrointestinal tract. But no laboratory findings were routinely transmitted to the insurer in electronic form. Conventional epidemiological surveys are still needed to understand the prevalence of peptic ulcer and gastroesophageal reflux disease in Taiwan.

ACKNOWLEDGMENTS

This study was based in part on data from the National Health Insurance Research Database provided by the Bureau of National Health Insurance, Department of Health and managed by National Health Research Institutes in Taiwan. The interpretation and conclusions contained herein do not represent those of Bureau of National Health Insurance, Department of Health or National Health Research Institutes.

Abstract

AIM: To explore the role and significance of costimulatory molecules B7H1, B7H2 and ICOS within tissues of human gastric carcinoma and the possible mechanisms in tumor escape.

METHODS: mRNA expressions of costimulatory molecules including B7H1, B7H2, ICOS and B7-1 in tissues of human gastric carcinoma were investigated by *in situ* hybridization using digoxigenin-labeled oligonucleotide-probes. The tissue of chronic gastric ulcer was used as a control. All data were analyzed by SPSS statistic software.

RESULTS: At the site of gastric carcinoma, mRNA expression levels of B7H1, B7H2 and ICOS were much higher than that of B7-1. Their mRNA positive expression indexes were 0.512 ± 0.333 , 0.812 ± 0.454 , 0.702 ± 0.359 and 0.293 ± 0.253 , respectively. The positively stained cells were mainly tumor infiltrating lymphocytes (TILs), and some tumor cells. The difference between them was greatly significant $P < 0.005$. The mRNA expression levels of four molecules were not correlated to the pathological grade and metastasis of gastric carcinoma.

CONCLUSION: ICOS-B7H costimulatory pathway may be predominant at the site of gastric carcinoma. B7-1 mRNA might be the basis of ICOS-B7H interaction. ICOS-B7H interaction induces the production of IL-10 which inhibits the antitumor immune responses. Therefore, it is supposed that ICOS-B7H costimulatory pathway may be involved in the negative regulation of cell-mediated immune responses.

INTRODUCTION

Tumor immunity is primarily cell-mediated. The tumor antigen leads to anti-tumor immune response of the host. A body of evidences have shown that the specific activation of

lymphocytes requires two signals; one is provided by T-cell receptor complex coupled to CD3/MHC peptide antigen, and the other is costimulatory signal delivered by interaction of costimulatory molecules with their ligands expressed on antigen presenting cells (APCs). In the absence of costimulatory signals, antigen-MHC complex interaction may lead to T-cell clonal anergy or deletion, and thus, the effective cellular immune response can not be induced. Furthermore, there are evidences that activation of lymphocyte subpopulation with different function needs unique costimulation factors. Therefore, investigation of costimulators on infiltrating lymphocytes and tumor cells at the tumor site and of their significance will be of great help in developing new methods of anti-tumor immunotherapy. Cell-mediated immunity is the main mechanism of anti-tumor immunity of the host. With presentation of antigen recognition and deepening of the understanding of activated T-cells, it is believed that in the presence of costimulatory signals, effective anti-tumor immune response presents tumor antigen multi-peptide to T cells and stimulates T-cell immune response. B7 is an important costimulatory molecule. Most tumors lack or have a low expression of B7-1, so they do not induce effective anti-tumor immune response. The tumor cells escape from immune system of the host and continue to grow^[1-15]. Although many *in vitro* experiments support this idea, *in situ* studies on human tumors have shown that most tumor tissues express the B7-1 or B7-2 molecules. So the idea meets challenges. An *in vitro* study on new members of B7 family - B7H1, B7H2 and ICOS suggested that the role of ICOS-B7H costimulatory pathway stimulated IL-10 production and induced secretion of Th2 type cytokines. The present study was to explore the role and biological significance of ICOS-B7H costimulatory signals and the possible mechanisms in tumor escape, and to provide the theoretical foundation for designing effective schemes of immunotherapy of carcinoma.

MATERIALS AND METHODS

Patients

17 patients with gastric carcinoma (10 metastatic, and 7 non-metastatic) and 6 patients with gastric ulcer were identified by pathological diagnosis at the Department of Pathology, Second Hospital of Xi'an Jiaotong University. The fresh tissue samples were instantly fixed in 10 % formalin, and embedded in paraffin according to routine procedures. Tonsil tissue served as a positive control.

Main reagents

Digoxigenin (DIG)-labeling and detection kits were purchased from Boehringer Mannheim Company in Germany. Solution for *in situ* hybridization was mixed with diethyl pyrocarbonate (DEPC) water. All apparatuses were baked at 180 °C for four hours and DEPC water was digested with RNase.

Specimens

Sections (4-5 μm) cut from the tissue block were de-paraffined in 65 °C oven for 24 hours and then stored at -70 °C until being used.

Labeling of oligonucleotide probes and detection of their sensitivities

Labeling On the ice, 4 μ l reaction buffer (vial 1), 4 μ l CoCl₂ solution (vial 2), 1 μ l probe (100 pmol), 1 μ l DIG-dUTP solution (vial 2), 1 μ l dATP solution (vial 4), 1 μ l terminal transferase (vial 5) and 8 μ l DEPC water, were consecutively added into an eppendorf tube, and carefully mixed and incubated at 37 °C for 15 minutes. 2 μ l stopping solution (prepared by mixing 1 μ l glycogen solution (vial 9) with 200 μ l 0.2 mol/L EDTA solution) was added into the tube to stop the labeling reaction. Then, 2.5 μ l 4mol/L CrCl₂ and 75 μ l pro-cold pure alcohol were added to deposit the labeled. After the supernatants were drained out, the probe was washed with 50 μ l 70 % pre-cold alcohol and dried with a frozen dry machine, and stored at -20 °C until being used.

Detection of sensitivity Sensitivity of each probe was measured by the detection kit following the manufacturer's instructions. The lowest concentration for positive staining was 1.25 pmol/ml. The oligonucleotide probe sequences were as follow. B7-1 5' -CAT GAA GCT GTG GTT GGT TG-3'; B7H1 5' -TGC TTG TCC AGG TGA CTT CG-3'; B7H2 5' -CCA TCG CTC TGA CTT CCT TC-3'; and ICOS 5' -TTC AGC TGG CAA CAA AGT TG-3'.

Hybridization

Sections stored at -70 °C were recovered at room temperature, deparaffined in dimethylbenzene, and hydrated in gradient alcohol. They were digested in 0.5 μ g/ml fresh proteinase K solution at room temperature for 20 minutes, and fixed in 4 % poly-formaldehyde for 20 minutes after digestion was stopped in 0.2 % glycine, and then repeatedly rinsed with 1 \times PBS for 10 minutes. The sections were treated in 0.2N HCl solution at room temperature for 10 minutes, rinsed with DEPC water for 3 minutes; and dehydrated in gradient alcohol. At 42 °C in a bio-hybridization oven, all sections were pre-hybridized for 2 hours, and then hybridized for 20 hours. After hybridization, they were rinsed with 2 \times SSC for two times, 15 minutes each, rinsed with 1 \times SSC for 30 minutes and finally with buffer I solution (pH 7.5) for 6 minutes.

Detection

50 μ l blocking reagent (containing 8 % normal goat serum, 0.3 % Triton X-100 buffer I) was instilled onto each section. The sections were incubated at 37 °C for one hour and a half, and then 30 μ l anti-DIG-AP conjugate (1:500) was added onto each section, and all sections were incubated at 37 °C for two hours and rinsed with buffer I two times, 15 minutes each, then rinsed with buffer III (100 mmol/L Tris-HCl, 100 mmol/L NaCl and 50 mmol/L MgCl₂, pH 9.5) for 5 minutes, and stained with NBT-BCIP at 20 °C for 12 hours. Finally, the reaction was stopped with buffer IV solution (10 mmol/L Tris-HCl, and 1 mmol/L EDTA, pH 8.0), and the sections were washed in running water, counterstained with methyl green, dehydrated, cleaned in xylene and coverslipped.

Evaluation of results

Under a light microscope, positively hybridized signals were mainly located in the infiltrating lymphocytes and colored purple blue. Reactivity was scored using a semi-quantitative method. First, each section was randomly scored one thousand cells. The positive cell ratio in each section was calculated. Then, according to the staining intensity of positive cells, results were graded as following: intense 3+, moderate 2+, weak 1+ and negative, a score of 3, 2, 1, 0 was assigned respectively. Finally, the positive cell ratio multiplied with staining intensity score of the positive cells was regarded as positive index of mRNA expression of costimulatory molecules.

Control experiment

Expression of ICOS mRNA of the chronic tonsillitis lymphocytes was regarded as a positive control. The results were negative control when no probe was used.

Statistical analysis

All data were expressed as $\bar{x} \pm s$ and analyzed by SPSS statistic software. Differences in values were considered significant if $P < 0.05$.

RESULTS

mRNA expression of costimulatory molecules within tissues of human gastric carcinoma

At the site of gastric carcinoma, positive cells for B7H1, B7H2, ICOS were mainly tumor infiltrating lymphocytes (Figure 1). Some positive cells were tumor cells. Their mRNA positive expression indexes were 0.512 ± 0.333 , 0.812 ± 0.454 and 0.702 ± 0.359 , respectively. B7-1 mRNA was expressed on tumor cells and TILs (Figure 2), with a positive expression index being 0.293 ± 0.253 . The mRNA expression levels of B7H1, B7H2 and ICOS were significantly higher than that of B7-1 (all $P < 0.05$).

Figure 1 B7H1 mRNA expression of tumor infiltrating lymphocytes (TILs) within tissues of human gastric carcinoma (*In situ* hybridization, NBT-BCIP Staining, counterstained with methyl green, $\times 1000$).

Figure 2 B7-1 mRNA expression of tumor infiltrating lymphocytes (TILs) within tissues of human gastric carcinoma (*In situ* hybridization, NBT-BCIP Staining, counterstained with methyl green, $\times 1000$).

Expression of costimulatory molecules in relation to metastasis of gastric carcinoma

The expression levels of B7-1, B7H1, B7H2 and ICOS had no statistical significance between metastasis and non-metastasis

of gastric carcinoma ($P>0.05$), which suggested that expressions of costimulatory molecules at tumor site were not correlated to the metastasis of tumor.

Expression of costimulatory molecules in relation to differentiation of gastric carcinoma

mRNA expression levels of B7-1, B7H1 and ICOS on infiltrating lymphocytes at the tumor site was not significantly different between well-differentiated and poorly-differentiated. However, the expression level of B7H2 mRNA was significantly higher in well-differentiated than in poorly-differentiated (1.040 ± 0.400 vs 0.651 ± 0.436 , $P=0.047$). mRNA expression of B7-1 was greatly lower than that of B7H1, B7H2 and ICOS in both well-differentiated and poorly-differentiated gastric carcinoma which might indicate that function of B7-1 was different from other costimulatory molecules in gastric carcinoma.

Expression of costimulatory molecules in comparison between gastric carcinoma and gastric ulcer

In the tissue of gastric ulcer, the expression levels of B7-1, B7H1, B7H2 and ICOS on infiltrating lymphocytes were higher than those in gastric carcinoma. But there was no difference in the expression of B7H1, B7H2 and ICOS between the tissues of gastric carcinoma and gastric ulcer except B7-1. The effect of costimulators in the gastric ulcer was not clear.

DISCUSSION

Cell-mediated immunity is the main mechanism of antitumor immunity of the host. With presentation of antigen identification and deepening of the understanding of T-cells activated, it is believed that in the presence of costimulatory signals, effective antitumor immune response presents tumor antigen multi-peptide to T cells and stimulates T-cell immune response^[16-18]. B7 is an important costimulatory molecule. Most tumors lack or have a low expression of B7-1, so they do not induce effective antitumor immune response. The tumor cells escape from immune system of the host and continue to grow. Though many *in vitro* experiments support this idea, *in situ* studies on human tumors have shown that most tumor tissues express the B7-1 or B7-2 molecules^[19]. So the idea meets challenges.

The effective anti-tumor immune response requires three factors, including immunogenicity, costimulatory signals and Th1 type cytokines. In the past, it was emphasized that cytokines or/antigen essence determined the classification of immune responses. Generally, weak immunogenicity of tumor cells primarily induced Th2 response^[20]. In recent years, studies on costimulatory signals *in vitro* have shown that different costimulatory signals play a determinant role in immune response type. There might be Th2 predominant costimulatory signals in human tumor site. The present study has detected mRNA expression of B7H1, B7H2 and ICOS within the tissue of human gastric carcinoma, using *in situ* hybridization with DIG-labeled oligonucleotide probes. The results suggest that tumor infiltrating lymphocytes in tissue of gastric carcinoma express high levels of recently discovered members of B7 costimulatory family, B7H1, B7H2 and ICOS^[21-26]. Compared with mRNA expression level of B7-1, difference was dramatically significant. But mRNA expression levels of B7H1, B7H2 and ICOS were not correlated to the pathological grade and metastasis of gastric carcinoma. The experiments^[27-35] *in vitro* have verified that the interaction between B7h and ICOS stimulates the proliferation of T-cells and production of Th2 cytokines, preferentially secretion of IL-10. This is probably the main reason that Th2 cytokines may predominate at the tumor immune- microenvironment of gastric carcinoma, and thus the type of immune response shifts from Th1 to Th2. There was an

increase of Th2 cytokine-IL-10 in tumor immune-microenvironment of gastric carcinoma^[36].

In this study, we have also observed the expression of B7-1 in the tissue of gastric carcinoma, and found that tumor infiltrating lymphocytes (TIL) and tumor cells expressed low gastric carcinoma levels of B7-1 mRNA. Now that there were costimulatory molecules in the tissues of gastric carcinoma, why did not the host produce the effective antitumor immune response? With the further study of immunology and tumor immunology, a new concept related to interaction between TIL and tumor cells was introduced. That is the tumor microenvironment. This theory supposes that immune system of the host cannot eliminate tumors because there are many inhibitors of tumor immunity at the site of tumor microenvironment. For example, tumor cells produce TGF- β , PGE₂ and so on, which are accumulated at tumor site and interfere with the activity of recruited immunocytes. Activated immunosuppressive cells further augment the immunodepression mechanism in tumor microenvironment. In addition, a recent study^[27] has shown that B7-1 costimulation also enhances the up-regulation effects of ICOS costimulation which results in the increase of Th2 cytokines, preferentially inducing the secretion of IL-10.

The present experimental results suggest that the tumor infiltrating lymphocytes in the tissues of gastric carcinoma express high levels of B7H1, B7H2 and ICOS mRNA. Some tumor cells also express them but the expression levels are low. This indicates that there are costimulatory signal pathways in the site of gastric carcinoma. Since the interaction between B7H1, B7H2 and ICOS stimulates proliferation of T cells by various ways and induces secretion of IL-10. IL-10 is known to be an immune inhibitor, which down-regulates function of Th1 type cells, and inhibits antitumor immune response of the body, and thus the body is in the state of immune inhibition. Therefore, it is supposed that although interaction between B7H1, B7H2 and ICOS delivers costimulatory signals to T-cells, promotes their activation, the effective antitumor immunity can not be induced. Tumor cells can escape from the immunosurveillance of the host and continue to grow. This is due to the fact that many inhibitors at tumor site have blocked the role of specifically activated T cells. As far as most tumors are concerned, the host's immunoreaction can not eliminate the tumor because Th2 type response is stimulated, or it can be recognized by immune system of the body. Maybe there are other regulation mechanisms. The present study indicates that costimulatory pathways might exist at the tumor site with different functions. ICOS-B7h pathway is predominant and plays an important role in negative regulation of cell-mediated immune response. This finding might provide a new approach for designing effective immune-therapy of carcinoma.

Abstract

AIM: This retrospective study was designed to analyze the results and the failure patterns of late course accelerated hyperfractionated radiotherapy for clinical T₁₋₂N₀M₀ esophageal carcinoma.

METHODS: From Aug. 1994 to Feb. 2001, 56 patients with clinical T₁₋₂ esophageal carcinoma received late course accelerated hyperfractionated radiotherapy in Cancer Hospital, Fudan University. All patients had been histologically proven to have squamous cell carcinoma (SCC) and were diagnosed to be T₁₋₂N₀M₀ by CT scan. All patients were treated with conventional fractionation (CF) irradiation during the first two-thirds course of the treatment to a dose of about 41.4Gy/23fx/4 to 5 weeks, Which was then followed by accelerated hyperfractionation irradiation using reduced fields, twice daily at 1.5Gy per fraction, to a dose about 27Gy/18 fx. Thus the total dose was 67-70Gy/40-43fx/40-49 d.

RESULTS: The 1-, 3- and 5-year overall survival was 90.9 %, 54.6 %, 47.8 % respectively. The 1-, 3- and 5-year local control rate was 90.9 %, 84.5 % and 84.5 %, respectively. Twenty-five percent (14/56) patients had distant metastasis and/or lymph nodes metastasis alone. Eight point nine percent (5/56) patients had local disease alone. Another 3.6 % (2/56) patients had regional relapse and distant metastasis.

CONCLUSION: Late course accelerated hyperfractionated radiotherapy is effective on clinical T₁₋₂ esophageal carcinoma. The main failure pattern is distant metastasis.

INTRODUCTION

Surgery has been the main treatment method for clinical T₁₋₂ esophageal carcinoma. But the treatment of upper thoracic esophageal carcinoma is challenging. The intimate relationship of the esophagus to the airway, arch of the aorta, and recurrent laryngeal nerve poses special technical problems. Radiotherapy is as effective as surgery, and preserves esophagus.

In 1988, Shi designed the schedule of late course accelerated hyperfractionated radiotherapy (LCAF) on SCC of the esophagus. The results were very encouraging. The 5-year survival and local control rate were markedly improved in the

LCAF group. Compared with CF radiotherapy, the 5-year overall survival of 34 % versus 15 % was statistically significant, the local control rate was 55 % versus 21 %^[1]. However, the outcome of clinical T₁₋₂ esophageal carcinoma treated with LCAF has not been investigated extensively. Therefore, we conducted a retrospective evaluation of clinical T₁₋₂ patients treated with LCAF.

MATERIALS AND METHODS

Materials

From August 1994 to February 2001, 56 patients with clinical T₁₋₂N₀M₀ SCC of esophagus were treated by LCAF radiotherapy in the Department of Radiation Oncology, Cancer Hospital, Fudan University. All patients had detailed medical records. Pretreatment evaluation generally included history and physical examination, complete blood cell count, chest radiograph, chest computed tomographic (CT) scan, esophageal barium examination, ultrasonic examination for abdomen, including liver, kidney, spleen, and retroperitoneal lymph nodes. All patients were restaged according to the TNM classification of the International Union Against Cancer (devised in 1997). The patients' eligibility for this study was as follows: (1) Primary lesion was single, and a flat plane separating the esophageal mass from the periesophageal structures was visible on all CT sections. (2) Mediastinal and upper abdominal lymph nodes were smaller than 5 mm on short-axis diameter. And (3) No supraclavicular lymph nodes and distant metastasis. The patients' clinical characteristics are listed in Table 1.

Table 1 Pretreatment characteristics

>1.5	14	25
Median		1.2
Range		0.5-2.7

Methods

Radiation source was 6MV or 18 MV linear accelerator. The design of the radiation fields was based on the diagnosis by CT and barium examinations. For patients with lesions in cervical region, two anterior oblique fields with wedge filters were used. For patients with lesions in the thoracic a three-field approach was used: one anterior and two posterior oblique portals. The width of the fields was adjusted to cover gross tumor with 2 cm to 3 cm margins to include the subclinical lesions and the length of the field should cover clinical tumors with 3 cm to 5 cm extended margin at both ends of the lesion. All patients received 1.8Gy per fraction, five fractions a week during the first two thirds of the course of radiotherapy to a dose of about 41.4Gy/23fx/4 to 5 weeks. This was then followed by accelerated hyperfractionation using reducing fields, twice daily at 1.5Gy per fraction with a minimum interval of 6 hours between fractions. The dose contributed by the accelerated technique was about 27Gy. The total dose given to the clinical tumor was 67-70Gy/40-43fx/40-49d. No prophylactic irradiation was given to the supraclavicular region. Details of the schedule had been reported previously^[1].

End-points in this analysis were overall survival and local control. Death from any cause was calculated from the date of radiotherapy until death or last follow-up evaluation. Patterns of failure were first failure (local, regional, or distant), time to any local failure, and time to any distant metastasis. If recurrences occurred within 60 days of each other, they were counted simultaneously. The time to these end points was calculated from the date of treatment until disease relapse or last follow-up.

Four patients were lost to follow-up. Median follow-up for the survival patients was 38.0 months (range 5-67 months), follow-up rate was 92.9 %.

The statistics was done by SPSS (Version 10.0). Survival rate and local control rate were estimated by the Kaplan-Meier method.

RESULTS

Acute toxicities (RTOG)

The incidence of grade 1, 2, 3 and 4 of acute radiation-induced bronchitis was 19.6 % (11/56), 17.9 % (10/56), 3.6 % (2/56), and 1.8 % (1/56), respectively. The incidence of grade 1, 2, 3 and 4 of acute radiation-induced esophagitis was 25.0 % (14/56), 46.4 % (26/56), 10.7 % (6/56), and 0 % (0 cases), respectively.

Late complications (SOMA)

Three patients (53.6 %) developed grade 2 radiation-induced late esophageal stenosis, and one patient (1.8 %) developed grade 3 esophageal stenosis (the patient had required dilatation). One patient (1.8 %) developed grade 2 late pulmonary fibrosis. Two patients (3.6 %) died of late complications (1 case died of pulmonary fibrosis, 1 case died of myelitis).

Survival rates and local control rates

The overall survival curve and the local control rates for all patients are shown in Figure 1, 2. The overall survival rate at 1-, 3- and 5-year was 90.9 %, 54.6 % and 47.8 %, respectively. The local control rate at 1-, 3- and 5-years was 90.9 %, 84.5 % and 84.5 %, respectively.

Failure patterns

The patterns of first failure are listed in Table 2. The main first failures were local regional failure and distant metastasis (including lymph metastasis). Twenty-five percent (14/56) patients had distant metastasis and/or lymph nodes metastasis alone. Eight point nine percent (5/56) had local disease alone.

Another 3.6 % (2/56) had local regional relapse and distant metastasis. The median local regional failure time was 9 months (rang: 0-18 months). The median distant metastasis time was 17.5 months (rang: 7-65 months).

Hemorrhage	1	1.8
Complications	2	3.6
Unknown	1	1.8
Total	56	100

DISCUSSION

Surgery is the main treatment for clinical T₁₋₂ esophageal carcinoma. In a nationwide surgical series from 1983 to 1987 in Japan^[2], the survival rate of 127 patients with mucosal tumors was 92.26 % at 1 year, 81.09 % at 3 years, and 89.85 % at 5 years. A total of 533 patients with submucosal tumor had survival rate of 83.51 % at 1 year, 66.76 % at 3 years, and 59.66 % at 5 years. T₁ classification by UICC (1987) combines mucosal and submucosal tumors. Seven hundred forty patients with invasion to the muscularis propria, equal to T₂ by UICC classification, had survival rate of 69.86 % at 1 year, 41.88 % at 3 years, and 34.47 % at 5 years. Because a nearly total esophagectomy is often required, higher mortality and morbidity occur often. Orringer^[3] reported 800 patients with cancer of the intrathoracic esophagus and cardia treated with transhiatal esophagectomy. Major complications included

anastomotic leaks (13 %), recurrent laryngeal nerve injury (7 %), wound infection (3 %), pulmonary complications (2 %), bleeding (1 %), and chylothorax (1 %). More than 90 % of patients were discharged within 21 days of hospitalization. Complications were more severe in the patients with carcinoma of upper thoracic esophagus. The operation of upper thoracic esophageal cancer is challenging. The intimate relationship of the esophagus to the airway, arch of the aorta, and recurrent laryngeal nerve poses special technical problems. The survival rate is often lower, and the mortality and morbidity are often higher. Vigneswaran^[4] reported 49 patients treated with extended esophagectomy. There was one postoperative death (2.0 %). Fifteen patients (30.6 %) had a cervical anastomotic leak, and all occurred in patients with a gastric conduit. Leaks occurred in 5 of 10 (50 %) subternally placed stomachs and in 10 of 36 (27.7 %) transposed through the esophageal bed. Wound infection occurred in five patients. Postoperative vocal cord paralysis developed in 11 patients (22.4 %) and was unilateral in 10 and bilateral in one. Six patients developed pulmonary complications. Ten patients (20.8 %) developed mild to severe late dysphagia, which was a result of benign stenosis in eight patients and recurrent carcinoma in two. Four patients required dilatations.

Chemoradiotherapy has been widely used in Western countries. Reports on definitive chemoradiotherapy for clinical T₁₋₂ esophageal carcinoma are few. Zenone *et al.* concluded that the combined multimodality therapy, might be an alternative to radical surgery, based on 5-year survival of 56.3 % for T₁ patients and 29.8 % for T₂ patients^[5]. Roca *et al.* also suggested the feasibility of organ preservation in a report using intensive chemoradiotherapy^[7]. Murakami *et al* reported in a randomized study comparing chemoradiation with surgery that overall 1- and 3-year survival rates were 100 % and 83 % in the T₁/protocol group versus 82 % and 72 % in the T₁/surgery group ($P=0.36$), and 100 % and 51 % in the T₂/protocol group, versus 95 % and 68 % in the T₂/surgery group ($P=0.61$), respectively. There was no treatment-related mortality in either group. The rate of esophageal conservation was 92 % in the T₁/protocol group and 58 % in the T₂/protocol group^[2]. These results indicate that chemoradiation for clinical T₁₋₂ patients is a feasible radical treatment. However, there has been no report that compares surgery and chemoradiotherapy. Although there was a significant improvement in local control and overall survival with combined multimodality therapy compared with radiation therapy alone, the combined treatment had more severe and life-threatening hematologic side effects. Grade 3-5 acute toxicity was seen in 64 % of patients treated by concurrent chemoradiotherapy, much higher than 28 % in patients treated by radiotherapy alone. Approximately 80 % of patients completed chemotherapy according to the protocol guidelines.

In China, Shi^[1] modified the concomitant boost schedule designed by Anderson Cancer Center to LCAF radiotherapy on SCC of the esophagus. The results were very encouraging. The 5-year survival and local control rate were markedly improved in the LCAF group. Compared with CF radiotherapy, the 5-year overall survival was 34 % versus 15 % which was statistically significant, the local control rate was 55 % versus 21 %. Henceforth, more randomized and retrospective trials confirmed the results^[7-9]. LCAF radiotherapy is the most

frequently used radiotherapeutic management for localized SCC of esophageal carcinoma in some cancer hospitals in China including our department.

The survival rate and local control rate are comparable with operation and chemoradiotherapy in the patients treated with LCAF radiotherapy alone. Esophagus can be preserved, and the severe complications can be decreased. In the retrospective study, most patients were clinical stage T₂N₀M₀, at upper thoracic and middle thoracic. The 5-year survival rate was 47.8 %, and the 5-year local control rate was 84.5 %. Grade 3-5 acute radiation-induced toxicities were 16.1 %. The incidence of grade 3-5 late complications was 7.0 %.

In analyzing failure patterns, there was significant difference between the patients in early-stage and advanced-stage. Local/regional recurrence was the main reason of failure in the advanced patients treated with conventional radiotherapy. Forty-two percent patients died of local recurrence, and nineteen percent patients died of metastasis in the advanced patients treated with LCAF radiotherapy^[1]. Forty-five percent patients had local regional disease as the first failure, distant metastasis as the first failure occurred in 13 % of concurrent chemoradiotherapy^[2]. In our retrospective study, distant metastasis rate (28.6 %) increased significantly, and local regional recurrent rate (12.5 %) decreased markedly.

Abstract

We reported a female patient with unrecognized celiac disease and multiple extra intestinal manifestations, mainly related to a deranged immune function, including macroamilasemia, macrolipasemia, IgA nephropathy, thyroiditis, and anti-b2-glicoprotein-1 antibodies, that disappeared or improved after the implementation of a gluten-free diet.

INTRODUCTION

Celiac disease (CD), the most common life-long food sensitive enteropathy in humans, is characterized by malabsorption, chronic inflammation of small intestine mucosa, villous atrophy and crypt hyperplasia, which occur as a consequence of the ingestion of wheat gluten or related rye and barley proteins^[1,2]. CD is strongly associated with HLA-DQ2, coded by the DQA1*0501 and DQB1*02 alleles, and/or the DQ8 (DQA1*03, DQB1*0302 alleles), but a role of non-HLA genes has also been postulated^[2,3]. The current prevalence of celiac disease has increased from 1:1 000 to 1:300 inhabitants, or even more^[4]. Typical symptoms include chronic diarrhea, abdominal distension, and failure to thrive^[2,5]. However, only few patients with CD show clinical malabsorption, while most patients have subtle symptoms, if any^[6]. Therefore, the disease is clearly under diagnosed^[2,7]. The recent introduction of tests for IgA anti-endomysial antibodies and the anti-tissue transglutaminase test has proved promising with a sensitivity and specificity of over 95 %^[2, 8, 9].

Celiac disease may be associated with a wide range of diseases^[2, 8], including thyroid, dermatological and lymphoproliferative disorders, mainly intestinal lymphomas^[2]. Furthermore, there is a greater than expected prevalence of immune disorders in CD patients^[2, 10-12] as well as of CD in patients with autoimmune diseases^[13-15].

The current report dealt with a female patient with unrecognized CD and recurrent miscarriage, macroamilasemia, macrolipasemia, IgA nephropathy, and thyroiditis that

disappeared or improved when a correct diagnosis was made and the patient was given a gluten-free diet.

CASE REPORT

A 34 years old, non drinker, non smoking woman, was admitted to the third Medical Clinic, Careggi University Hospital, Florence because of hyper-amilasemia and hyper-lipasemia of unknown origin. The patient had acute meningitis at the age of three. At age of 23, she was admitted to hospital because of syncope, referred to acute gastroenteritis complicated by metabolic acidosis; laboratory evaluation performed on that occasion showed iron deficient anemia, polyclonal hypergammaglobulinemia, elevated erythrocyte sedimentation rate (ESR), reduced C3 levels and circulating antinuclear antibodies (1:80), that led to suspicion of a not otherwise specified collagen disease. Iron deficiency was unresponsive to supplement of oral iron, while it improved following intravenous therapy. The patient had two spontaneous abortions when aged 30 and 31 years, respectively, both at the 16th week of gestation. During admission because of the second abortion, a thorough investigation was performed that was negative for potential causes of fetal demise, including fasting glucose, basal FSH, LH and estradiol levels on day 3 of a natural cycle, TSH and prolactin levels, antinuclear antibodies, antibodies against infectious agents, hysterosalpingography and genetic karyotyping of the couple. On that occasion, she was found to have hyperamilasemia and hyperlipasemia, together with the previously reported laboratory alterations; so further investigations were performed including CT, which turned out to be negative for any pancreatic disease.

At the time of admission to our hospital unit, physical examination was completely negative. Routine blood analysis showed anemia (Ht: 32.8 %, Hb: 11.2 g/dL), thrombocytosis (452 000 platelets/mL), high ESR (124 mm/h), low plasma albumin (3.05 g/dL), and high levels of IgA (1 100 mg/dL) and IgM (369 mg/dL) with no monoclonal component. The patient also had low ferritin (<9 mg/mL) and tetrahydrofolate levels (1.9 ng/mL; normal range 3-17 ng/mL). A coagulation study showed the presence of lupus anticoagulant (Table 1). Enzyme studies confirmed a remarkable increase of serum amylase (1 196 IU/L), pancreatic isoamylase fraction (798 IU/L), and serum lipase (1 650 IU/L). On the other hand, urinary amylase excretion was normal (120, normal value <1 500 IU/day), and ultrasound examination of the pancreas was normal. A chromatographic assay was therefore performed at another Institution (Ospedali Riuniti, Padova, Italy), which demonstrated the presence of macroamilasemia and macrolipasemia.

Our patient had iron-deficient anemia, which was refractory to oral iron supplementation, a well known presenting sign of CD^[2, 6, 16], together with low albumin and tetrahydrofolate levels. In addition, she had macroamilasemia and macrolipasemia which could be associated with CD^[17]. Therefore, a search was performed for circulating anti-gliadin, anti-endomysial and anti-transglutaminase (TTG) antibodies. Detection of these antibodies (Table 1) led us to perform upper gastrointestinal tract endoscopy and duodenal biopsy, which confirmed the diagnosis of CD. A gluten free diet was therefore introduced.

Due to the patient's clinical history of repeated abortions and the results of coagulation studies, other autoantibodies such as anti-thyroglobulin (1:40) and anti- β 2-glycoprotein-1 antibodies (24 UI/mL) were detected. Further characterization of the latter antibodies showed that IgG was 6.3 (normal range < 9) and IgM 48.7 (normal range < 5) IU/mL. All parameters of thyroid function were within the normal range.

Urinalysis showed glomerular proteinuria (0.7 g/day), microscopic hematuria, hyaline and granular casts; creatinine clearance (74 mL/min) was reduced with respect to the patient's age. These results raised the suspicion of IgA nephropathy, but the patient did not consent to undergo kidney biopsy. HLA analysis revealed the presence of HLA DQB1*-02. The main laboratory data during the first admission at our unit and the follow up are shown in Table 1.

Table 1 Main results of laboratory studies in baseline conditions and after implementation of gluten free diet

Parameter (normal values)	Baseline determinations	Gluten free diet	
		6 th month	24 th month
Serum amylase (IU/L) (< 220)	1196	146	132
Serum lipase (UI/L) (< 200)	1650	39	ND
Ig A (mg/dL) (60-318)	1100	119	155
Immunocomplexes (meq/mL) (< 5)	6.5	ND	ND
Antigliadin antibodies IgA (%) (< 7)	96.9	5.8	ND
Antigliadin antibodies IgG (%) (< 12)	61	18.5	ND
Antientomysial antibodies	Positive	Positive	ND
Anti-transglutaminase antibodies (UI/L) (<8)	20.5	ND	ND
Anti-thyroglobulin antibodies (ND)	1:40	ND	ND
Total b2 GP 1 antibodies (IU/mL) (< 4 IU/mL)	24	ND	ND
Lupus anticoagulant	Positive	ND	ND
Creatinine clearance (mL/min) (70-120 mL/min)	74.07	88.05	107
Protein excretion rate (mg/24h)	322	2268	320

IU=international units; ND=not detectable.

After six months of controlled gluten free diet, the patient's body weight increased 12 kg; laboratory investigations demonstrated normalization of serum amylase, serum lipase and immunoglobulin levels; antigliadin, anti- β 2-glycoprotein-1 and anti-thyroglobulin antibodies were no longer detectable, but antiendomysial antibodies were still present. Endoscopy showed a normal appearance of duodenal mucosa, and duodenal biopsy revealed a partial recovery of duodenal morphology. Due to the persistence of proteinuria (2.3 g/day), microscopic hematuria and hyaline and granular casts, a kidney biopsy showed that it was IgA nephropathy.

After 18 months of gluten-free diet, antiendomysial antibodies disappeared; creatinine clearance increased (Table 1), but proteinuria further worsened (2.9 g/day, Table 1), and albumin levels were still low.

After 24 months of gluten-free diet, a new duodenal biopsy showed complete recovery of villous architecture. Renal function further improved and proteinuria markedly decreased (Table

1). Amylase, lipase, and immunoglobulin levels were within the normal range. Anti- β 2-glycoprotein-1, anti-thyroglobulin, antigliadin, antiendomysial and anti-TTG antibodies were undetectable. A coagulation study was normal (Table 1).

DISCUSSION

The increased prevalence of immune disorders in patients with CD is well recognized^[2, 10-12]. The association between CD and other immune disorders may be due to the sharing of a common genetic background, such as HLA antigens. However, in a very large study, involving 909 patients with celiac disease, Ventura and his associates^[12] found that the development of immune disorders in CD was clearly related to the duration of exposure to gluten. It is also interesting to note that multiple immune diseases in CD patients are uncommon. In the study of Ventura *et al.*^[12], only 15/909 patients had two kinds of immune manifestations and only one patient had three kinds of immune manifestations.

In this report, we described a female patient with unrecognized CD, who developed several clinical and/or sub clinical immune diseases.

Macroamylasemia with or without macrolipasemia occurs in approximately 0.4 % of general population and about 2.5-5.9 % of patients have hyperamylasemia^[18, 19]. It may be either an isolated, benign condition without pathological significance or may be associated with underlying diseases such as lymphoma, AIDS, carcinoma, liver disease and autoimmune disorders. The macroamylase complex is formed by amylase bound with serum proteins, commonly IgG and/or IgA. This molecule is too large to be filtered by the kidney and excreted in the urine, so it accumulates in plasma, whereas urinary amylase is normal or even low, a finding that should point to the correct diagnosis. Similarly, the macrolipase complex is a macroenzyme formed by association of polyclonal IgA with lipase. The incidental finding of macroamylasemia, if unrecognized, directs the diagnostic work-up to the pancreas and patients undergo unnecessary examinations and even surgery. Some case reports dealt with the occurrence of macroamylasemia with or without macrolipasemia in adult and pediatric patients with CD^[20-23]; in the large study by Rabsztyń *et al.*^[17], 21 out of 124 newly diagnosed CD patients (16.9 %) had macroamylasemia. Interestingly, serum macroamylase usually remained elevated despite strict gluten free diet^[17], and only in few cases, macroamylasemia and macrolipasemia disappeared after gluten free diet^[22, 23], as it occurred in our patient.

IgA nephropathy is the most common glomerulonephritis and is considered a relatively benign disease. However, longitudinal follow-up studies demonstrated that about 20 % of patients would progress to end stage of renal disease within 20 years from its onset. Patients with IgA nephropathy often have circulating IgA-antigliadin antibodies. However, lack of IgA-antireticulin, IgA-antiendomysium antibodies or jejunal mucosal atrophy suggests that most of these patients do not have latent CD^[24-26]. On the other hand, oral immunization with gliadin can induce IgA nephropathy in mice^[27]. Data on the association between CD and IgA nephropathy in humans are controversial, and only few cases of IgA nephropathy had definite CD and showed remission or improvement of renal disease after gluten withdrawal^[28, 29]. In our patient, the effect of gluten free diet on proteinuria was delayed, since this parameter showed increments at the 6th and the 18th month, despite the disappearance of antigliadin antibodies and normalization of IgA levels.

Patients with insulin-dependent diabetes mellitus, autoimmune thyroid disease, Addison's disease, and alopecia areata are at increased risk of CD. A recent study addressed whether patients

with more than one autoimmune endocrine disorder were even more susceptible to CD or had celiac-type mucosal inflammation. Seven out of the 62 patients studied (11 %) were found to have CD; in addition, 2 had minor villous deterioration and 5 had an increased density of mucosal intraepithelial gamma-delta+ T-cells. HLA-DQ2 or DQ8 alleles were found in all subjects with mucosal changes^[30]. The association of CD with autoimmune thyroiditis has been proved. A study in 172 patients with autoimmune thyroiditis found a 10-fold higher prevalence of CD in this population than expected^[31]. The Authors concluded that the association of CD with autoimmune thyroid disease was not surprising as they shared common immunopathogenesis and suggested that it was advisable to screen patients with autoimmune thyroid disease for CD as there might be an increased risk for gluten intolerance^[31]. In our patient, anti-thyroglobulin antibodies disappeared after six month of gluten free diet. This finding confirmed that autoimmune thyroid disease and CD may share a common pathogenetic mechanism and that the disappearance of the immunological activation due to intestinal inflammation may lead to normalization of concomitant immune disorders.

Antiphospholipid antibodies, the most commonly detected of which are lupus anticoagulant, anticardiolipin and anti- β 2-glycoprotein-1 antibodies, are associated with the so-called antiphospholipid syndrome, a syndrome of arterial and venous thrombotic disease, thrombocytopenia, and fetal wastage^[32, 33]. Antiphospholipid antibodies are found in young, apparently healthy subjects with a prevalence of 1-5 %. Their prevalence increases with age, especially among elderly patients with coexistent chronic diseases, and is even higher in patients with autoimmune diseases. Untreated patients with CD also have an increased prevalence (about 14 %) of anticardiolipin antibodies^[34, 35], a phenomenon that Di Sabatino *et al.*^[35] found that an increased susceptibility of peripheral blood lymphocytes would undergo Fas-mediated apoptosis which resulted in immunogenic exposure of phospholipids with subsequent production of autoantibodies. As we know, lupus anticoagulant was observed in one patient^[36], while the female patient reported here had both lupus anticoagulant and anti- β 2-glycoprotein I antibodies which disappeared within 6 months after the introduction of gluten free diet.

Untreated CD in women resulted in a 8.9-fold increase in the relative risk of pregnancy miscarriage and in an about 30 % reduction of the baby's birth weight. Both miscarriage frequency and babies' low birth weight would normalize in response to gluten free diet^[37, 38]. Antiphospholipid antibodies were also associated with an unusually high proportion of pregnancy losses after the 10th week of gestation^[32, 33]. Our patient therefore had two different risk factors for abortion, both related to untreated CD. Unfortunately, it was not possible to establish whether the gluten-free diet corrected her miscarriage tendency, since until now the patient did not wish to plan a new pregnancy.

In conclusion, we found a high prevalence of immune diseases and a large number of organ-specific autoantibodies in a patient with CD. Although both CD and the other manifestations of a deranged immunity might be explained on the basis of a common genetic predisposition to this kind of disorders, some findings suggest that CD itself is responsible for the initiation of the immunological response. Indeed, persistent stimulation by some proinflammatory cytokines, such as interferon γ and tumor necrosis factor α , could induce further processing of autoantigens and their presentation to T lymphocytes by macrophage-type immunocompetent cells. As a matter of fact, the prevalence of immune diseases among patients with CD seems proportional to the time of exposure to gluten^[12], and many immune alterations disappear following

the recognition of CD and appropriate treatment, just as it occurred in our patient.

ACKNOWLEDGEMENT

The authors gratefully acknowledged Rosanna Abbate, MD (Dipartimento dell' area critica medico-chirurgica) and Antonio Calabrò, MD (Dipartimento di Fisiopatologia clinica, University of Florence), for their kind help in revising the manuscript.

Abstract

We reported a case of non-Hodgkin's lymphoma where liver involvement was the predominant clinical manifestation. A 27-year old man presented with markedly elevated serum aspartate aminotransferase, alanine aminotransferase and lactate dehydrogenase, reduced prothrombin activity, thrombocytopenic purpura and hepato-splenomegaly without adenopathy. Viral, toxic, autoimmune and metabolic liver diseases were excluded. Bone marrow biopsy showed an intracapillary infiltration of T-lymphocytes with no evidence of lipid storage disease. Because of a progressive spleen enlargement, splenectomy was performed. Histological examination showed lymphomatous intrasinusoid invasion of the spleen. Immunohistochemical investigation revealed the T phenotype of the neoplastic cells: CD45+, CD45RO+, CD3+, CD4-, CD8-, TIA1-. About 50 % of the lymphoid cells expressed CD56 antigen. The diagnosis of hepatosplenic T cell lymphoma was done. The patient was treated with chemotherapy, which induced a complete remission. Eighteen months later, he had a first relapse with increased aspartate aminotransferase, alanine aminotransferase, lactate dehydrogenase, thrombocytopenic purpura and blast in the peripheral blood. In spite of autologous bone marrow transplantation, he died twenty months after the diagnosis. Even in the absence of a mass lesion or lymphadenopathy, hepatosplenic T-cell lymphoma should be considered in the differential diagnosis of a patient whose clinical course is atypical for acute hepatic dysfunction.

INTRODUCTION

Liver and splenic involvement is commonly seen during a malignant lymphoma, but rarely occurs as a prominent clinical feature at diagnosis. Hepatosplenic lymphoma is a rare and poorly recognized entity^[1] characterized by neoplastic

proliferation of T-cell bearing a gd or, more rarely, ab clonal rearrangement of the receptor (TCR). This lymphoma shows a specific morphological pattern characterized by a preferential hepatic sinusoids and splenic red pulp involvement without lymphadenopathy and discrete or absent bone marrow involvement. Moreover the diagnosis is complicated in several cases by the presence of misleading symptoms. We reported the case of a young man without palpable lymphadenopathy and clinical and laboratory presentations resembling an acute liver disease.

CASE REPORT

A 27-year old caucasian man was admitted in an Internal Medicine unit in February 1999 because of fever (38 °C), malaise, anorexia, and erythematous macules and papules on the face, trunk and arms. The patient referred similar but transient cutaneous lesions in the previous two-months. Laboratory investigations yielded the following results: aspartate aminotransferase (AST) 240 IU/L (normal range: 0-37 IU/L), alanine aminotransferase (ALT) 520 IU/L (normal range: 0-40 IU/L), γ -glutamyl-transpeptidase (γ -GT) 46 IU/L (normal range: 11-43 IU/L), alkaline phosphatase (ALP) 298 IU/L (normal range: 60-270 IU/L) and platelets 120×10^9 /L (normal range: $130-400 \times 10^9$ /L). Serological tests for Epstein Barr virus (EBV) showed a positivity for nuclear antigen (IgG 248 ACU/ml) (normal value: <56 ACU/ml) whereas serology for hepatitis A (HAV), hepatitis B (HBV) and hepatitis C (HCV) viruses was negative. Physical examination showed a mild hepato-splenomegaly. There was no palpable lymphadenopathy.

Two weeks later he was transferred to our Internal Medicine unit with the clinical diagnosis of "acute hepatitis with hepato-splenomegaly and recidivant purpuric exanthema". Physical examinations showed an enlarged tender liver (2 cm below the rib border) and splenomegaly (2 cm below the rib border) without peripheral lymphadenopathy. The cutaneous lesions of the trunk and the face were already present as purpuric palpable papules. Fever was absent. Abdominal ultrasonography revealed a mild hepatomegaly and splenomegaly (major axis of 18 cm), without ascite and abdominal lymphadenomegaly. Doppler sonography revealed an increased blood flow in the spleen and the portal vein without obstruction of the main hepatic veins. An upper gastrointestinal endoscopy did not reveal esophageal varices. Chest x-rays at the time of admission yielded normal findings. Liver function test showed AST 498 IU/L, ALT 958 IU/L, γ -GT 49 IU/L, ALP 426 IU/L, total bilirubin 1.15 mg/dl (normal range: 0.2-1.0 mg/dl) and lactate dehydrogenase (LDH) 1 234 U/L (normal range 190-450 IU/L). Peripheral blood counts showed hemoglobin 16.1 g/dl, hematocrit 45 %, leukocytes 4.9×10^9 /L with normal differential count and platelets 80×10^9 /L. Coagulation indices showed prothrombin activity 53 % (normal range: 90-100 %), international normal ratio 1.4, activated partial thromboplastin time 53 sec (normal range: 25-40 sec) and fibrinogen 267 mg/dl (normal range: 200-400 mg/dl). Albumin levels were 4.25 g/dl (normal range: 3.3-5.1 g/dl) and γ -globulin were 1.44 g/dl (normal range:

0.84-1.44 g/dl). Serological tests were negative for HAV, HBV, HCV, cytomegalovirus and human herpes simplex N° 1, 2, and 6. EBV serologic findings were heterophile test (heterophile antibody) negative, viral capsid antigen (VCA) immunoglobulin IgM negative and IgG positive. Serological tests exploring infective agents able to induce an acute hepatitis such as Chlamydia pneumoniae, Bartonella spp, Borrelia burgdorferi, Toxoplasma gondii, Coxsackie virus groups A and B (N° 1-6) and Echovirus, were negative as well as the serological test for Rickettsia and Parvovirus B19. Results of serology for human immunodeficient virus (HIV) 1 and 2 including cDNA Polymerase Chain Reaction and the screening of the antigen p24 of HIV1 were negative. Serum α -fetoprotein and carcinoembryonic antigens were within the normal range. To exclude autoimmune disease, serological tests for anti-nuclear, anti-mitochondrial, anti-liver/kidney microsomal (LKM), and anti-smooth muscle (ASM) were performed but the results were negative; cryoglobulins and circulating immune complexes were absent. Serum ceruloplasmin levels, circulating serum copper levels, 24-h urine excretion of copper and α 1-antitrypsin levels were in the normal range and Kayser Fleischer rings were absent on slit-lamp examination. To exclude a thrombocytopenia induced by EDTA (pseudothrombocytopenia) blood was drawn on test tube with sodium citrate as anticoagulant but the result confirmed the presence of a true thrombocytopenia. Anti-platelet antibodies were negative in two consecutive different samples and reticulate platelets were in the normal range. Toxic (including also ingestion of hepatotoxic mushrooms such as Amanita Phalloides) and drugs inducing hepatitis were excluded by a careful and detailed personal and family history. During the following weeks, patient complained increasing fatigue and tenderness in the upper left quadrant and physical examination revealed an enlarged spleen that extended his lower pole 4-cm below the rib border. Liver function tests continued to rise with AST 658 IU/L, ALT 1 074 IU/L, γ -GT 72 IU/L, ALP 473 IU/L, and LDH 1 365 U/L. Serum β -2 microglobulin levels were 2.4 mg/dl; (normal range: 1.2-2.5 mg/dl). Coagulation indices showed prothrombin activity 51 %, international normal ratio 1.4, fibrinogen 146 mg/dl and activated partial thromboplastin time 42.4 sec without serological evidence of circulating anticoagulants such as lupus anticoagulant or anticardiolipin antibodies. A decreased activity of coagulation factor II (57 %; normal range: 70-120 %), VII (58 %; normal range: 70-120 %) and X (41 %; normal range: 70-120 %) were also demonstrated, despite i.v. Vitamin K treatment; factor VIII activity was also reduced (63.9 %; normal range: 70-150). The bleeding time was slightly prolonged (8 minutes and 20 seconds; normal range: 3-7 min.) Because of coagulopathy and thrombocytopenia percutaneous liver biopsy was not performed. Biopsy of the skin showed neither vasculitis findings nor lymphoproliferative disease. An abdominal CT scan revealed a massive enlargement of the spleen (20 cm of sagittal diameter and 14 cm of antero-posterior diameter) and mild hepatomegaly without either focal lesions or abdominal lymphadenomegaly. Thorax and neck CT scan yielded normal findings. Although in type 1 Gaucher disease the liver function tests were not so seriously altered, the presence of hepatomegaly with a progressive and massive splenomegaly together with thrombocytopenia prompted us to undergo the patient to bone marrow examination and to a measurement of acid β -glucosidase activity in circulating leukocyte cells. Although β -glucosidase activity was slightly decreased (5.5 nmol/mg/h; normal range: 8-15.1 nmol/mg/h), the bone marrow examination did not reveal the presence of the characteristics of Gaucher cells with the typical "wrinkled paper" cytoplasm. However, an intracapillary T-lymphocytes

infiltration was observed. The circulating leukocytes were $14.6 \times 10^9/L$ (normal range: 4.8-8.5) with absolute lymphocytosis ($8.8 \times 10^9/L$, normal range: 1.6-2.4). Immunophenotype of circulating lymphocytes showed that CD3 positive lymphocytes were about $5.4 \times 10^9/L$ (normal range: 1.1-1.7), CD4 positive lymphocytes were $2.5 \times 10^9/L$ (normal range: 0.65-1.4), CD8 positive lymphocytes were $3.01 \times 10^9/L$ (normal range: 0.32-0.90) with CD4 to CD8 ratio of 0.8 % (normal range: 1-1.5 %) and CD19 positive lymphocytes were $1.23 \times 10^9/L$ (normal range: 0.2-0.4). Circulating T lymphocytes (65 % of overall; $5.65 \times 10^9/L$) bearing the ab type of TCR were 92.5 % (normal range: 90-95 %) while circulating T lymphocytes bearing gd TCR were about 7.5 % (normal range: 5-10 %). Over half (60 %) of circulating leukocytes were small to medium sized lymphoid cell with moderate amount of pale, agranular cytoplasm without villous projections. Some lymphocytes showed round or folding nucleus, with moderate clumped chromatin surrounding a small nucleolus. In spite of the opportunity to perform a transjugular liver biopsy, the presence of massive splenomegaly with pain in the left upper abdominal quadrant and early satiety, urged us to do splenectomy which was performed in April 1999. The histologic examination of the spleen revealed a hepatosplenic lymphoma. After the splenectomy, skin lesions disappeared, liver enzyme values progressively decreased and coagulation indices showed normalization in one week. As expected, platelets count increased until $738 \times 10^9/L$ one week after the splenectomy and decreased to $417 \times 10^9/L$ one month later. In the post surgical period, patient was treated with 4 cycles of chemotherapy (Fi2/89; epirubicine, vincristine, bleomycine and cyclophosphamide). This resulted in a complete clinical remission with negative bone marrow biopsy. In view of autologous bone marrow transplantation (ABMT) he was treated with 2 cycles of chemotherapy (BAVEC-MiMA; BiCNU, adriablastine, vepeside, vincristine, mitoxantrone, methotrexate and cytosine arabinoside). In January 2000, he was submitted to three consecutive leukapheresis but, unfortunately, the number of peripheral circulating levels of CD34 positive cells was not sufficient for the ABMT and the patient refused new leukapheresis. Two other cycles of BAVEC-MiMA chemotherapy were performed as intensive consolidation therapy after the remission. One month later (May 2000), the patient was admitted to a hematological unit because of fatigue, malaise and erythematous papules of the face and trunk similar to those that characterized the beginning of the disease. Significant laboratory values included AST 225 IU/L, ALT 255 IU/L, LDH 1773 U/L, platelets $46 \times 10^9/L$ and leukocytes $27.9 \times 10^9/L$, the latter characterized by medium and large size lymphocytes with cleaved and folding nucleus. The immunophenotype of circulating lymphocytes was NK (CD16+, CD56+, CD2+, CD7+; CD8 were expressed on about 63 % of NK population while CD3 was negative). He was treated with four weekly infusions of chemotherapy (MACOP-B; vincristine, adriamycin, bleomycine, cyclophosphamide, methotrexate and prednisone) with normalization of liver enzyme values, peripheral blood counts and skin lesions. The second relapse occurred 10 weeks later. Patient was readmitted in the same hematological unit for salvage ABMT. One-month later, he developed an acute leukemia. The patient died in December 2000, twenty months after the diagnosis. Post-mortem examination was not performed.

MATERIALS AND METHODS

Informed consent for all procedures was obtained from the patient. Bone marrow specimen was fixed in 10 % buffered formalin and processed according to standard technique. Paraffin sections were stained with hematoxylin-eosin, Giemsa,

PAS and Gomori method. Biopsy of the skin and specimens of the spleen were fixed in 10 % buffered formalin, and in B5; paraffin sections were stained with hematoxylin-eosin, Giemsa and PAS. An immunohistochemical investigation was performed on bone marrow and spleen sections according to streptavidin-biotin method. Monoclonal antibodies were used for detection of CD45, CD20, CD79a, CD10, CD45RO, CD30, CD15, CD56, CD8, CD4, TIA-1, AE1/AE3, EMA, HMB45, MIB1 antigens, and polyclonal antibodies for CD3 and S-100 protein detection. The positive reaction was revealed using diaminobenzidine as chromogen.

Histologic findings

Biopsy of the skin showed a moderate aspecific lymphoid infiltration of perivascular space associated with erythrocytes. Bone marrow biopsy showed intense eritroid and megakaryocytic hyperplasia and a mild hypoplasia of myeloid compartment. Moreover an important intracapillary infiltration of medium-sized T-lymphocytes (CD45+, CD3+, scattered CD56+, CD 20-) was observed (Figure 1). The spleen weight was 3 000 g. Microscopic examination showed the presence of a diffuse intrasinuses infiltrate in the red pulp of medium-sized T-lymphoid cells with round to irregular nuclei and moderately abundant pale cytoplasm (Figure 2). All neoplastic cells expressed CD45, CD45RO and CD3 membrane antigens (Figure 3), whereas they were CD4-, CD8- and TIA-1-. CD56 antigen was positive on about 50 % of the T-lymphoid cells (Figure 4). The diagnosis of hepatosplenic T cell lymphoma was done. Because of the unavailability of frozen sections, the analysis of gd TCR expression was not done.

Figure 1 Immunohistochemical analysis of the bone marrow: the neoplastic cells within sinuses were CD3 positive and scattered CD56 positive (insert).

Figure 2 Clusters of medium-sized cells seeped through the red pulp of spleen.

Figure 3 The neoplastic cells were CD3 positive in the spleen.

Figure 4 The neoplastic cells were scattered CD56 positive (arrows) in the spleen.

DISCUSSION

Lymphomatous involvement of the liver has been described in three clinical situations: disseminated disease, primary liver lymphoma and hepatosplenic T-cell lymphoma. Secondary hepatic involvement by lymphoma is relatively common and indicates advanced disease. Non-Hodgkin's primary lymphoma of the liver is an uncommon entity, often clinically indistinguishable from more commonly occurring primary carcinoma and metastatic neoplasms; the correct diagnosis is based on liver biopsy or even on post-mortem examination because of lacking of suggestive clinical or imaging features. The hepatosplenic T-cell lymphoma has been recognized by Farcet *et al.* in 1990^[1] as a distinct entity characterized by a $\gamma\delta$ T lymphocytes sinusal infiltration of the red pulp of the spleen and by sinusoidal infiltration of the liver without lymph node involvement^[2]. Because of its striking uniformity with respect to clinical, morphological and immunophenotypical features, this lymphoma was listed as a provisional entity in the Revised European-American Lymphoma (REAL) classification^[3]. Later on, it has been incorporated as a distinct entity in the WHO classification of lymphoid neoplasms^[4] and termed hepatosplenic $\gamma\delta$ T-cell lymphoma. Since then, to our knowledge, 45 cases have been described^[5]. According to Weidmann revision, clinical symptoms at presentation are hepato-splenomegaly, constitutional symptoms and less frequently jaundice due to hepatic involvement. The predominant laboratory findings are reduced peripheral blood cells ranging from hemolytic anemia (Coombs negative) to thrombocytopenia or pancytopenia, high levels of LDH and mild increase of liver enzymes. Moreover, recently, 14 cases of hepatosplenic lymphoma expressing $\alpha\beta$ TCRs have been described^[6].

These $\alpha\beta$ lymphomas fulfill all the clinical, morphological and immunophenotypical criteria required for the diagnosis

of hepatosplenic lymphoma, with the exception of the female preponderance (11/14 patients) and age of distribution (more wide than the $\gamma\delta$ counterpart). Early diagnosis of this lymphoma, even if mandatory, is complicated in several cases because of the absence of lymphadenomegaly, not specific bone marrow involvement and normal peripheral blood cell counts. The diagnosis of hepatosplenic T-cell lymphoma in the case we reported had considerable difficulties because its clinical and laboratory features were similar to acute hepatitis. As a matter of fact, the liver chemistry evaluation was typical of hepatic inflammatory disease with hepatocellular necrosis (about tenfold increase of AST and ALD and threefold increase of LDH) and impaired synthesis of liver coagulation factors whereas, the mild increase of ALP level together with normal levels of serum β -2 microglobulin and γ -GT were unusual for a lymphoproliferative disease of the liver. Probably these unusual laboratory findings were related to the quite exclusive sinusoidal infiltration by lymphoid cells without or with minimal portal involvement. However, this clinical presentation prompted us to exclude all causes of acute liver diseases such as viral hepatitis drugs, toxins, chemical ingestion and/or exposition, vascular abnormalities, autoimmune hepatitis and metabolic diseases. As the present case illustrated, an early diagnosis of hepatosplenic lymphoma was unlikely to be possible on bone marrow specimen alone. According to Galaud^[7] even when the hepatosplenic involvement is clear, the presence of few T-cells within bone marrow sinus is neither specific nor conclusive without a molecular analysis on frozen tissue. Liver biopsy, which is another way to confirm the diagnosis of hepatosplenic T-cell lymphoma, was not performed in this case because of the presence of coagulopathy and thrombocytopenia. Nevertheless, the presence of an intracapillary infiltrate by T lymphocytes on the bone marrow specimen as well as the progressive and symptomatic enlargement of the spleen prompted us to suspect the presence of a lymphoproliferative disease and consequently to perform splenectomy. As reported in literature, splenectomy was the cornerstone for the diagnosis of hepatosplenic T-cell lymphoma. Immunophenotype studies on the spleen specimens showed the typical pattern of hepatosplenic T-cell lymphoma characterized by expression of CD45 and CD3 antigens and by double negativity for CD4 and CD8 antigens. The NK cell associated antigen CD56 expression has been reported in approximately 70-100 % of hepatosplenic T-cell lymphoma^[8, 9]. The presence in the bone marrow of T-lymphocytes bearing the CD56 antigen could explain the late involvement of peripheral blood by lymphoid cell with NK immunophenotype. Furthermore, in contrast with other previous investigations, in all specimens of the spleen examined, neoplastic cells were negative for TIA-1 (restricted intracellular antigen, also called granular membrane protein of 17 Kd, GMP 17), a very sensitive marker of cytosol granules independent of their activation status. Concerning the recurrence of cutaneous skin lesions, a skin biopsy, performed early in the course of disease, showed only a moderate and aspecific lymphoid infiltration of perivascular spaces, without the morphological and immunophenotypical findings that characterized the peripheral lymphoma involving the skin. Although thrombocytopenia was not severe, a complete remission of skin lesions was achieved

after its correction. It seems likely to ascribe these purpuric lesions to the reduced number of circulating platelets, but a cytotoxic activity of cutaneous T lymphocytes could have a role in the pathogenesis of these skin lesions. As the present case illustrated that the prognosis for this type of lymphoma is poor. Complete remission was reported only in few patients after chemotherapy (second and third generation regime for high-grade lymphomas), followed by autologous and allogenic bone marrow or peripheral stem cell transplantation. The median survival time was 8 months (range 0-42 month)^[5].

In conclusion, the current report described the unusual clinical presentations of hepatosplenic lymphoma. This patient, in fact, shared several distinctive features including: 1) the initial clinical presentations mimicking an acute hepatitis, 2) the presence of cutaneous lesions, contemporary with the hepatosplenic involvement and 3) a negativity of TIA-1 expression of lymphoid T cells. Even in the absence of a mass lesion or lymphadenopathy, hepatosplenic T-cell lymphoma should be included in the differential diagnosis of an acute hepatic dysfunction in young patient who shows no evidence of viral, toxic, autoimmune or metabolic liver disease.
