Abstract

AIM: To investigate the roles of PLCγ2 and PKCα in TPA-induced apoptosis of gastric cancer cells.

METHODS: Human gastric cancer cell line MGC80-3 was used. Protein expression levels of PLCγ2 and PKCα were detected by Western blot. Protein localization of PLCγ2 and PKCα was shown by immunofluoscence analysis under laser-scanning confocal microscope. Apoptotic morphology was observed by DAPI fluorescence staining, and apoptotic index was counted among 1 000 cells randomly.

RESULTS: Treatment of gastric cancer cells MGC80-3 with TPA not only up-regulated expression of PLC-γ2 protein, but also induced PLC-γ2 translocation from the cytoplasm to the nucleus. However, this process was not directly associated with apoptosis induction. Further investigation showed that PKCa translocation from the cytoplasm to the nucleus was correlated with initiation of apoptosis. To explore the inevitable linkage between PLC-γ2 and PKCα during apoptosis induction, PLC inhibitor U73122 was used to block PLC-γ2 translocation, in which neither stimulating PKCα translocation nor inducing apoptosis occurred in MGC80-3 cells. However, when U73122-treated cells were exposed to TPA, not only PLC-γ2, but also PKCα was redistributed. On the other hand, when cells were treated with PKC inhibitor alone, PLC-γ2 protein was still located in the cytoplasm. However, redistribution of PLC-γ2 protein occurred in the presence of TPA, no matter whether PKC inhibitor existed or not.

CONCLUSION: PLC-γ2 translocation is critical in transmitting TPA signal to its downstream molecule PKCα. As an effector, PKCα directly promotes apoptosis of MGC80-3 cells. Therefore, protein translocation of PLCγ2 and PKCα is critical event in the process of apoptosis induction.

INTRODUCTION

Once binding to the cell surface receptors, many extracellular signaling molecules could elicit intracellular responses by activating inositol phospholipid-specific phopholipase C (PLC)[1,2]. Activated PLC could catalyze the hydrolysis of phosphatidylinositol 4,5-biphosphate (PIP_2) to diacylglycerol (DAG) and inositol 1, 4, 5-triphosphate (IP_3). DAG and IP3 are second messengers, the former could function to activate protein kinase C (PKC), and the latter could stimulate release of Ca^{2+} from internal stores[1,3-5]. This bifurcating pathway constitutes the cornerstone of a transmembrane signal transduction mechanism that was known to regulate a large array of cellular processes[5-9].

Ten types of PLC isoform have been divided into three types, β, γ and δ[4-6,10,11]. One PLC isoform, PLC-γ, is a substrate of epidermal growth factor (EGF) receptor, and its catalytic activity could be stimulated by tyrosine phosphorylation[12]. PLC-γ has been implicated in mitogenic signaling by platelet-derived growth factor (PDGF) receptor. Through the pleiotropic actions of IP_3 and DAG, PLC-γ could participate in regulation of cell proliferation and differentiation[13]. PLC-γ overexpression could favor cell survival in response to acute oxidative stress[14,15]. In rat pheochromocytoma PC12 cells, overexpression of PLC-γ could inhibit apoptosis induced by short wave length ultraviolet radiation[16].

Protein kinase C (PKC) could play a variety of regulatory roles in proliferation, differentiation, apoptosis, gene expression, membrane transportation, and signal transduction[17-19]. There have been at least 11 distinct PKC isoforms[20]. In many tissues, both PKC activation and Ca2+ mobilization could act synergistically to evoke some cellular responses[21-24]. For example, activation of PKC and increase in Ca^{2+} were the "on" signals for T-cell activation[27,28]. By contrast, this PKC activator could also act as a negative regulator of T-cell activation[27,28]. Thus, PKC activation in T-cells has bidirectional effects on the cellular activation process.

Several evidences suggest that activation of PKC could attenuate receptor-coupled PLC activity in certain types of cell, providing a negative feedback signal to limit the magnitude and duration of receptor signaling[3,5]. Although such a regulatory mechanism has not been fully understood, it is possible that the targets might include receptors, G protein, PTK, protein tyrosine phosphatase and PLC itself[5]. Phosphorylation of Thr-654 of the EGF receptor by PKC reduced the ability of the receptor tyrosine kinase to phosphorylate PLC-γ, thereby preventing PLC-γ activation[29]. A decrease in the extent of tyrosine phosphorylation of PLC-γ has also been proved to be the mechanism by which the PKC activator, TPA and cAMP could attenuate the PIP2 hydrolysis induced by TCR[30]. Thus, interaction between PLC-γ and PKC is related to PLC-γ phosphorylation.

To date, little is known about the molecular event of PLC-γ translocation, and the functional consequences of PLC-γ in response to extracellular signal stimulation. It is generally accepted that PLC-γ localizes and functions in cytosol. EGF or PDGF treatment of cells could induce translocation of PLC-γ1 from a predominantly cytosolic localization to membrane

fraction[31], showing a preliminary clue that the function of PLC-γ may be in relation with its intracellular changes. In this study, we found that 12-O-tetradecanoylphorbol-1, 3-acetate (TPA) not only up-regulated the expression level of PLC-γ2, but also induced PLC-γ2 translocation from the cytoplasm to the nucleus in gastric cancer cells MGC80-3. In addition, according to our previous studies concerning the critical role of PKC-associated signaling pathway in promoting apoptosis of gastric cancer cell[32], we hypothesized that PLC-γ2 may play an important role in transmitting TPA signal to PKCα, which finally lead to apoptosis induction in gastric cancer cells. This notion may provide a novel strategy for exploring the cross-talk between PLC-γ2 and PKCα in apoptosis.

MATERIALS AND METHODS

Cell line and culture condition

Human gastric cancer cell line, MGC80-3 was established by Cancer Research Center, Xiamen University[33]. The cells were maintained in RPMI-1640 medium, supplemented with 10 % FCS, 1 mmol/L glutamine, and 100 U/ml penicillin.

Western blot analysis[34]

The cells were harvested, and suspended in RIPA buffer (10 mmol/L Tris (pH7.4), 150 mmol/L NaCl, 1 % Triton X-100, 1 % deoxycholic acid, 0.1 % SDS, 5 mmol/L EDTA (pH8.0), 1 mmol/L PMSF). Protein concentration was determined using the Bio-Rad protein assay system according to the manufacturer' s instructions (Bio-Rad Hereules, CA). 50 μg protein was subjected to SDS-PAGE and transferred to nitrocellulose membrane for Western blot analysis. The membrane was subsequently blocked with 5 % dry milk in TBS-T and then immunnoblotted with the responding antibody. Binding was detected by using the ECL kit (Pierce) according to the manufacturer' s instructions.

Apoptosis analysis[32]

The cells were trypsinized, and washed in PBS. The harvested cells were fixed in 3.7 % paraformaldehyde on ice, washed in PBS and stained with 50 μg/ml of 4, 6-diamidino-2-phenylindole (DAPI, Sigma) containing 100 μg/ml of DNase-free RNase A per ml. The cells were observed under fluorescence microscope. Apoptotic cells were counted among 1 000 cells randomly. The apoptotic index was the mean of three independent experiments.

Immunofluorescence analysis[35]

The cells were cultured on a cover glass overnight. After washed in PBS, the cells were fixed in 4 % paraformaldehyde. To display PLC-γ2 or PKCα protein, the cells were incubated first with anti-PLC-γ2 or anti-PKCα antibody (Santa Cruz), and then reacted with their corresponding FITC-conjugated anti-IgG (Pharmingen) as secondary antibodies. To visualize the nuclei, the cells were stained with propidium iodine (PI, 50 μg/ml) containing 100 μg of DNase-free RNase A per ml. Fluorescent image was observed under laser-scanning confocal microscope (Bio-Rad MRC-1024ES).

RESULTS

Expression and translocation of PLC-g2 in response to TPA

To determine the effect of TPA on PLC-γ2 protein expression, Western blot analysis was carried out. As shown in Figure 1A, PLC-γ2 protein was normally expressed in MGC80-3 cells. When exposed to TPA for different time, expression level of PLC-γ2 protein was increased in a time-dependent manner (Figure 1A), implying that PLC-γ2 might play a role in response to TPA. To examine whether redistribution of PLC-γ2 protein also occurred in response to TPA, immunofluorescent localization of PLC-γ2 protein was conducted and observed by laser-scanning confocal microscope. The result illustrated that in intact MGC80-3 cells, PLC-γ2 protein was more abundant in cytoplasm, and formed a much brighter circle a round the nuclear membrane (Figure 1B). After treatment of TPA for different time, PLC-γ2 protein was translocated from the cytoplasm to the nucleus by degrees (Figure 1B). To further confirm this translocation, cytoplasmic and nuclear protein fractions were prepared, and expression level of PLC-γ2 protein was analyzed by Western blot. Figure 1C shows that PLC-γ2 protein in intact cells mainly appears in the cytoplasmic fraction, and only a trace amount in the nuclear fraction. However, TPA-treatment changed the proportion of PLC-γ2 protein between the two fractions and such a change was time-dependent. After 48 hr TPA treatment, PLC-γ2 protein could only be detected in the nuclear fraction (Figure 1C). Clearly, this result was in accordance with that of Figure 1B, indicating that transloation of PLC-γ2 protein by TPA occurred in MGC80-3 cells.

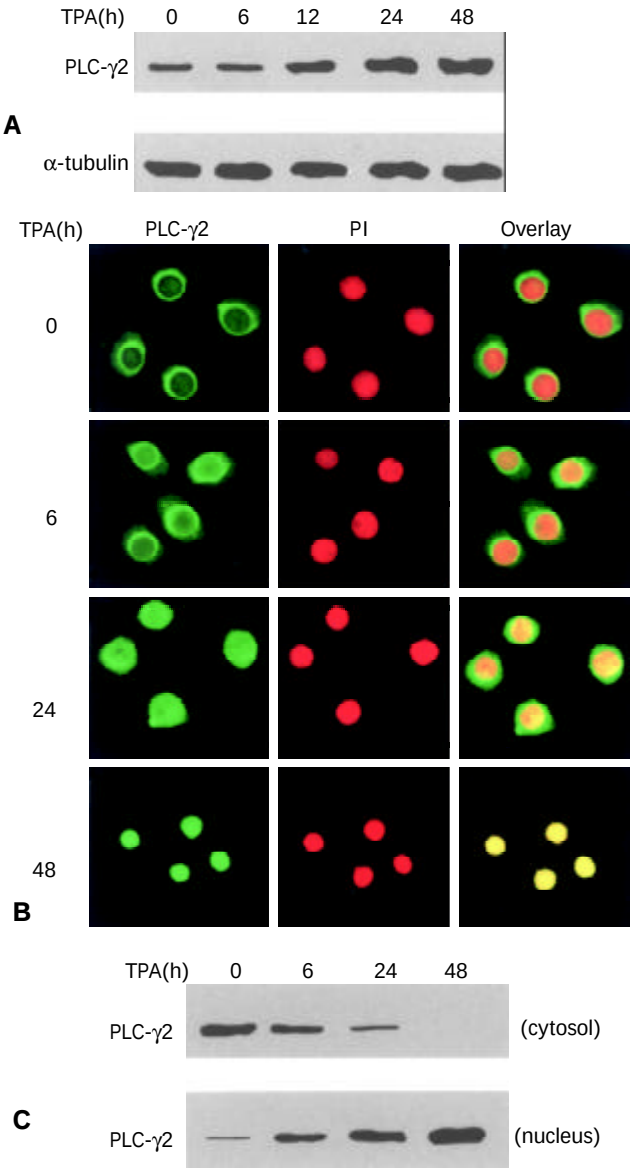

Figure 1 Expression and redistribution of PLC-γ2 in response to TPA. A: Effect of TPA on PLC-γ2 protein expression. Cells were treated with TPA (100 ng/ml) for indicated time, and expression level of PLC-γ2 protein was analyzed by Western blot. α-tubulin was used as a control to quantify the amount of

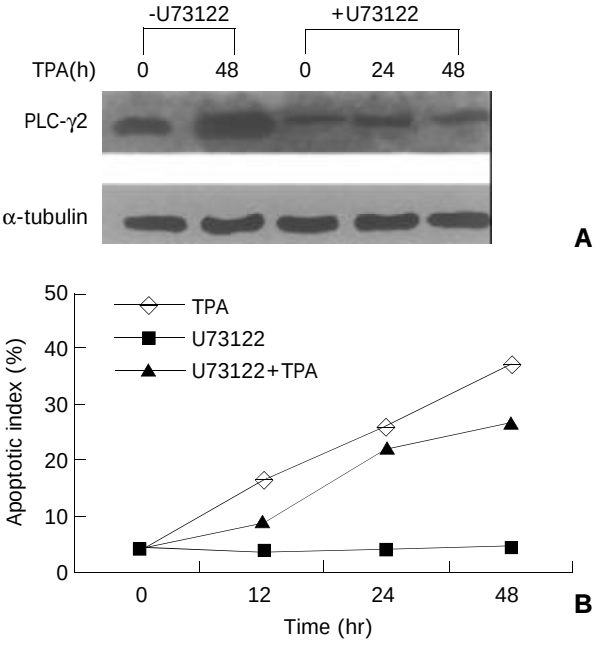
protein used in each lane. B: Translocation of PLC-γ2 in response to TPA. Cells were treated with TPA for indicated time, then immunostained with corresponding antibodies or dye as described in Materials and Methods. The fluorescent images were observed under laser-scanning confocal microscope. C: Redistribution of PLC-γ2 protein in response to TPA. The nuclear and cytosolic fractions were prepared as described in Materials and Methods.

PLC-γ2 expression was not required for apoptosis induction by TPA

Since TPA could induce apoptosis in many types of cancer cell lines[32,35-37], it would be interesting to know whether activation of PLC-γ2 was a necessary link for apoptosis induction by TPA. A PLC-specific inhibitor U73122[38] was thus used upon gastric cancer cells. Prior to be stimulated with TPA, U73122 partially repressed the expression level of PLC-γ2 protein (Figure 2A). In the presence of U73122, TPA-induced increase of PLC-γ2 expression was also blocked. Even after TPA treatment was prolonged for 48 hr, the expression level of PLC-γ2 was always lower than the control or TPA treatment alone (Figure 2A). In parallel, apoptosis of MGC80-3 cells was examined by DAPI staining. When the cells were treated with TPA alone, apoptotic cells became smaller, the nuclei became condensed and fragmented with bright chromatins. Importantly, an increased apoptotic index was clearly shown with the extension of TPA treatment (Figure2B: TPA). However, no such a change was observed in cells treated with U73122 alone (Figure 2B: U73122). By contrast, when cells pretreated with U73122, followed by TPA stimulation, many apoptotic cells were still seen, which not only showed morphological changes similar to those treated with TPA alone, but also had an increased apoptotic index with the extension of TPA treatment (Figure 2B: U73122+TPA). Therefore, these results showed that additional expression of PLC-γ2 protein was not required for TPA-induced apoptosis in MGC80-3 cells.



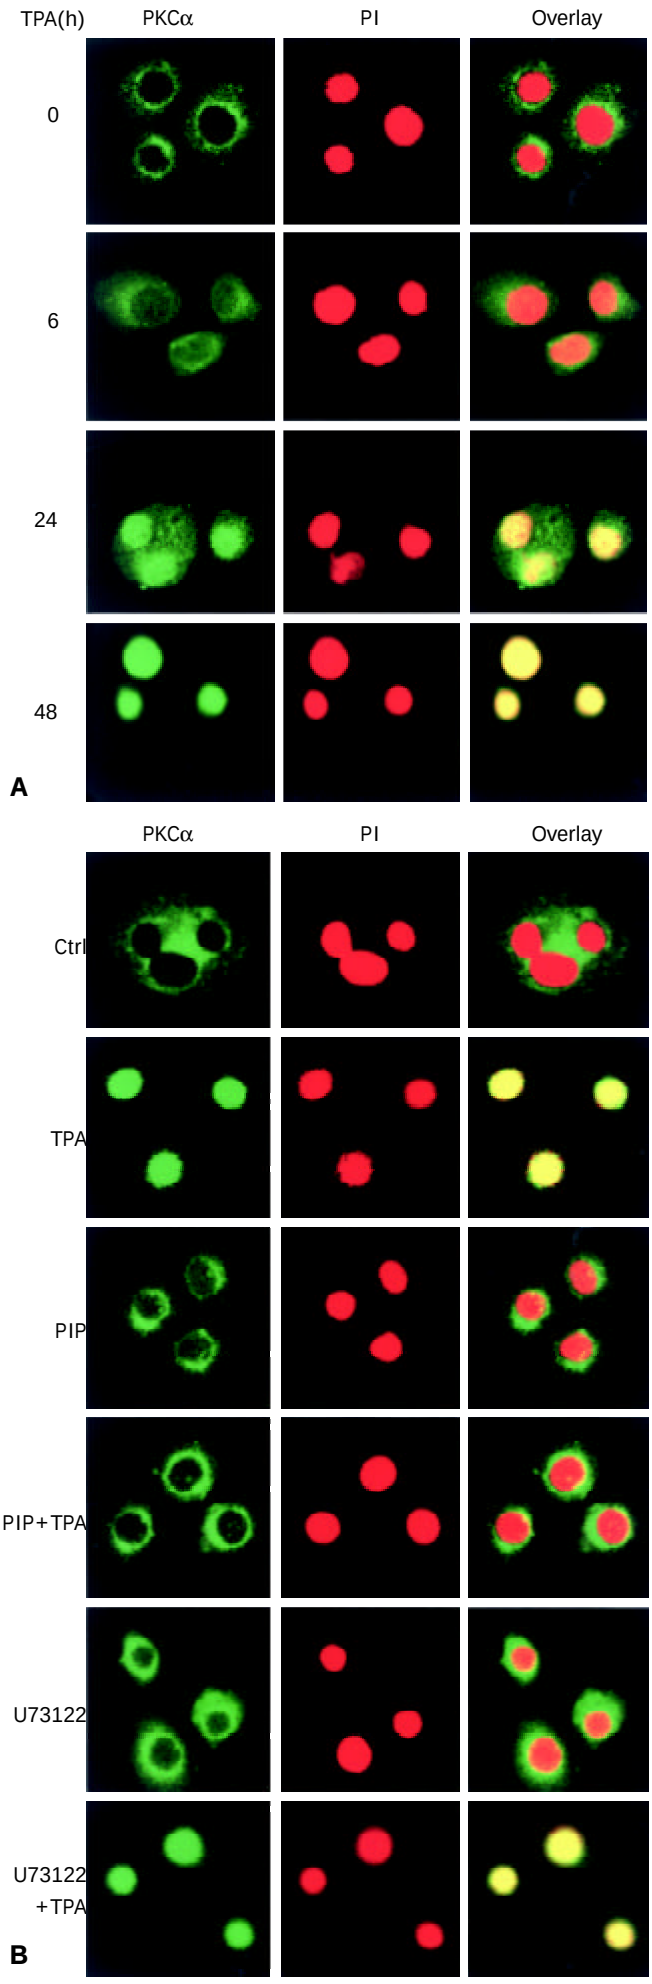


Figure 2 Effect of PLC-γ2 protein expression on apoptosis inducted by TPA. A: Effect of PLC-specific inhibitor U73122 on PLC-γ2 protein expression detected by Western blot. Cells were pretreated with or without U73122 (10^{-3} mmol/L) for 3 hr, and followed by TPA for indicated time. B: Analysis of apoptotic index. Cells were pretreated with or without U73122 for 3 hr, and then exposed to TPA for indicated time. Apoptotic cells were counted among 1 000 cells randomly.

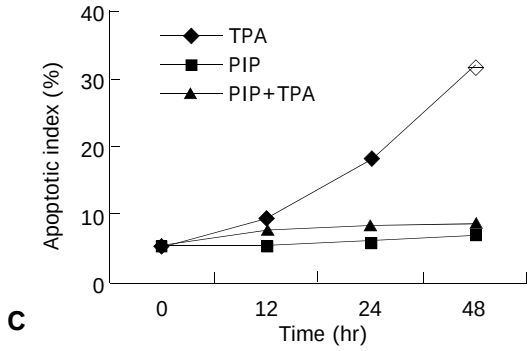

Figure 3 Translocation of PKCα protein in the process of apoptosis induced by TPA. A: Redistribution of PKCα protein. Cells were treated with TPA for indicated time, then immunostained with corresponding antibodies or dye as described in Materials and Methods. The images were observed under laser-scanning confocal microscope. B: Effects of various inhibitors, including PKC-specific inhibitor (PIP., 12 μmol/L) and PLC-specific inhibitor (U73122), on redistribution of PKCα. The detecting method was the same as described in Figure 3A. C: Analysis of apoptotic index. The method was similar as in Figure 2B.

PKCα translocation was directly associated with induction of apoptosis by TPA

The consequent question was that since TPA could induce rapid expression of PLC-γ2 protein which seemed to be not critical in TPA-induced apoptosis in MGC80-3 cells, then, what was the role of rapidly expressed PLC-γ2 protein in TPA-induced event? As PKC was a downstream molecule of PLC[3,4], it was inferred that PLC-γ2 might indirectly play its final effect through the downstream PKC signaling pathway in relation to TPA-induced apoptosis. To test this possibility, the effects of TPA on PKCα were investigated. Firstly, the expression of PKCα protein was determined by Western blot analysis. The result showed that PKCα was intrinsically expressed in MGC80-3 cells, but its expression was not changeable by TPA (data not shown). Secondly, the possible TPA-induced translocation of PKC in MGC80-3 cells was observed. PKCα protein was shown to localize in cytoplasm (Figure 3A). However, TPA treatment stimulated the translocation of PKCα protein from cytoplasm to nucleus in a time-dependent manner. After 48 hr of TPA treatment, cellular PKCα protein was completely translocated into the nucleus, showing a unique yellow color (Figure 3A). Finally, to investigate the behavior of PKCα translocation, PKC-specific inhibitor, a PKC inhibitor peptide(PIP)[39], was used. As expected, PKC inhibitor peptide could not induce PKCα protein translocated to the nucleus (Figure 3B, PIP.), even plus TPA for 48 hr it no longer initiated PKCα protein translocation (Figure 3B, PIP+TPA).

Since TPA could regulate redistribution, but not expression of PKCα protein, it would be attractive to ask whether redistribution of PKCα was in action in TPA-induced apoptosis. The results showed that TPA could no longer induce apoptosis when translocation of PKCα was blocked by PKC inhibitor peptide. Even though these cells were subsequently treated by TPA for 48 hr, the apoptotic index was obviously reduced reduced as compared with the TPA treatment alone (Figure 3C), suggesting that translocation of PKCα protein into the nucleus might be intrinsic in the mechanism of TPA-induced apoptosis.

PKCα was a downstream factor of PLC-γ2

It was then necessary to probe into the intrinsic mechanism of whether there was some inevitable linkage between PLC-γ2 and PKCα in the process of TPA-induced apoptosis. Since enhanced expression of PLCγ2 protein was not required for apoptosis induction (Figure 2), we therefore focused on the translocation behavior of PLC-γ2 with regard to the TPA-induced apoptosis effect. Out of our expectation, when cells were pre-treated with PLC-specific inhibitor U73122 for 3 hr alone, both PLC-γ2 and PKCα proteins did not redistribute (Figures 3B and 4A, U73122). However, when cells were exposing to TPA for 48 hr, not only PLC-γ2 protein but also PKCα protein were translocated into the nucleus (Figures 3B and 4A, U73122+TPA), although expression level of PKCα protein was not changed (Figure 4B). Together with the results in Figure 2, it was suggested that PLC-γ2 might function in passing TPA message to its downstream molecule PKCα in gastric cancer cells.

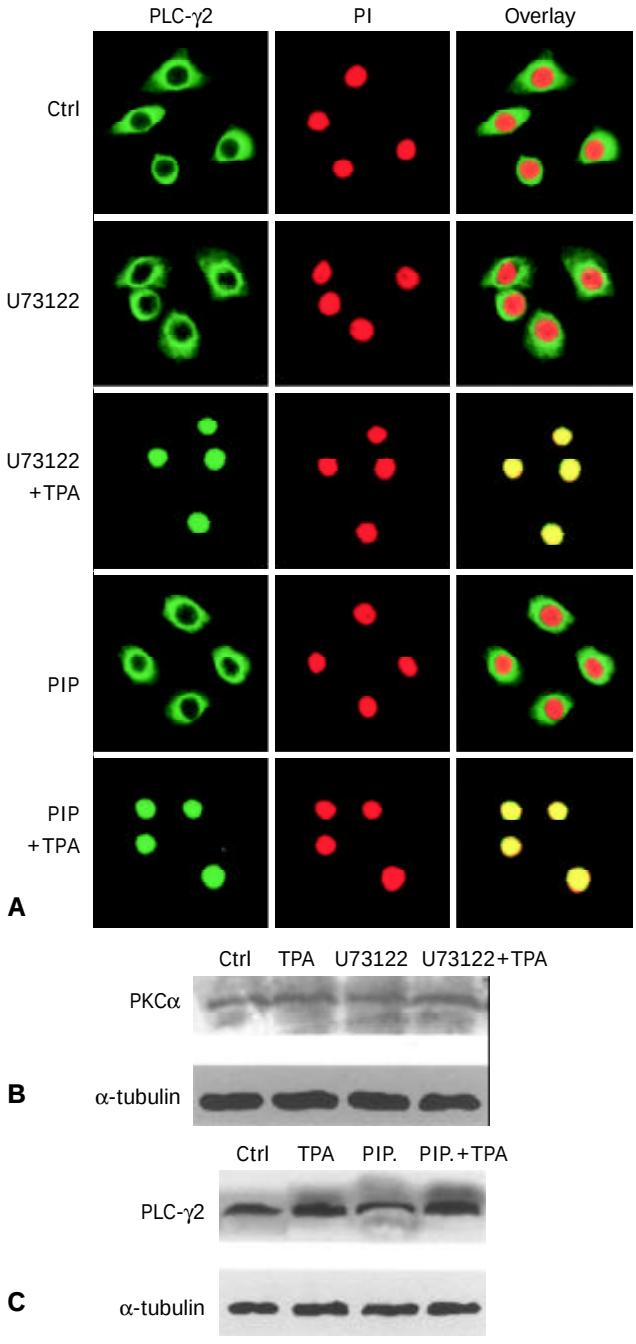

Figure 4 Correlation between PLC-γ2 and PKCα in their redistribution. A: Effects of PKC- and PLC-specific inhibitors on PLC-γs redistribution. The Method was as described in Figure 3B. B: Effects of PKC- and PLC-specific inhibitors on PKCα expression detected by Western blot. C: Effects of PKC- and PLC-specific inhibitors on PLC-γ2 expression.

On the other hand, PKC-specific inhibitor was also used to test its role in the expression of PLC-γ2 protein. When cells were treated with PKC inhibitor peptide (PIP) for 2 hr, PLC-γ2 protein was still located in the cytoplasm (Figure 4A, PIP). However, followed by TPA treatment for 48 hr, translocation of PLC-γ2 protein into the nucleus was not blocked by this inhibitor (Figure 4A: PIP+TPA). Similar result was observed in Western blot analysis, in which the expression level of PLC-γ2 protein was enhanced by TPA, no matter whether PKC inhibitor existed or not (Figure 4C). Taken together, all these findings above convincingly indicated that PKC inhibitor-induced inhibition of PKCα protein (mainly its translocation) and TPA-induced PLC-γ2 protein expression and translocation were two separate events. It also suggested that induction of PLC-γ2 protein translocation was a critical event in signal transmission between TPA and PKCα.

DISCUSSION

PLC-γ has been reported to be activated and up-regulated in response to external signals[13,15,40-44]. Most of these previous studies focused on PLC-γ2 phosphorylation and the relevant growth factor receptor(s), but its physiologic function and signaling pathway were rarely concerned. In the present study, we found that the enhanced expression of PLC-γ2 by TPA was not directly correlated to apoptosis induction. PLC-γ exerted its influence on intracellular process largely through the initiation of second messengers IP3 and DAG, and the subsequent Ca^{2+} mobilization and PKC activation. More importantly, these PLC-γ-induced chain reactions could be stimulated by some external stimuli[40,41]. Taking this fact into account, we therefore turned to investigate the possible regulatory mechanism of PLC-γ2 not correlated with its expression level.

PLC-specific inhibitor U73122 alone could partially suppress the expression of PLC-γ2 protein, but not induce apoptosis in MGC80-3 cells. However, TPA could still induce apoptosis in U73122-pretreated MGC80-3 cells, even though the expression of PLC-γ2 was in its supressed state, indicating that up-regulation of PLCγ2 expression was not required for apoptosis induced by TPA. However, TPA-induced apoptosis in MGC80-3 cells depended on PKCα protein translocation from cytoplasm into nucleus. When translocation of PKCα protein was blocked by its specific inhibitor PKC inhibitor peptide, the apoptosis decreased dramatically even in the presence of TPA. Therefore, these evidences strongly suggest that PLC-γ2 and PKCα can exert distinct effects in response to TPA, and regulation of PKCα protein translocation is closely associated with apoptosis induction.

We have indicated that TPA could promote PLC-γ2 translocation from cytoplasm to nucleus in a time-dependent manner, so it is interesting to figure out why PLC-γ2 is regulated (particularly its translocation) in response to TPA, and what the underlying functional implication is. Recently, some important evidences revealed that PLC-γ2 was critical for transmission of the B-cell antigen receptor complex (BCR)-dependent signals that led to the nuclear translocation of NF-κB[45], and PLC-γ1 was important for transducing survival signals against the cytotoxic effect of oxidant exposure[15]. These studies strongly imply that PLC-γ is capable of transducting signal, leading to translocation of its downstream molecule. To clarify whether TPA-induced apoptosis via PKC pathway was correlated with PLC-γ2, we investigated the effect of PLC-γ2 protein translocation on promoting PKCa translocation and initiating apoptosis. PLC-inhibitor U73122 alone could block the expression of PLC-γ2, but did not initiate the translocation of PLC-γ2 protein and induce PKCα expression, in which neither PKCα translocation nor apoptotic process could be detected. It is thus conceivable that PKCα translocation and cell apoptosis induced by TPA are PLC-γ2 translocation dependent in gastric cancer cells. Furthermore, our present study strongly supports the view that protein redistribution is an important event, which is critical for the function of protein.

Some literatures pointed out that down regulation of surface receptor expression represented an obvious mechanism by which PKC might block PLC activation[29,30]. For example, in Jurkat T cells, activation of PKC by PKC-stimulating agonists resulted in a decrease in its tyrosine phosphorylation, which was responsible for the apparently decreased PLC activity[5]. By contrast, in the present study, the relation between PLC-γ2 and PKCα seemed to be inter-dependent and synergistic. Our results showed a definite linkage between PLC-γ2 and PKCα translocation, and the synergistic effect of PLC-γ2 and PKCα in the initiation of apoptosis in MGC80-3 cells induced by TPA. In addition, the fact that pretreatment of cells with PKC inhibitor did not affect PLC-γ2 activation and translocation by TPA was consistent with the observation in which pretreatment of 293 cells for 30 min with PKC inhibitor Gö6976 did not stimulate PLC activation by EGF[46], demonstrating that PKC is a downstream molecule of PLCγ pathway. Taken together, PLC-γ2 functions in signal transmission to initiate TPA-induced apoptosis via PKCα pathway.

In summary, PLC-γ2 and its downstream molecule PKCα are essential for initiating TPA-induced apoptosis in gastric cancer cells. Translocation of PLC-γ2 and PKCα proteins is critical events in the process of apoptosis. In the cross-talk between TPA, PLC-γ2 and PKCα, PLCγ2 receives TPA message, then transmits it to PKCα. PKCα functions as an effector, directly promoting apoptosis of MGC80-3 cells. This is a novel concept for PLC-γ2 and PKCα functions, which will help us to get further insights into the relationship between PLC-γ2/PKCα and the subsequent cellular events.

Abstract

AIM: To construct subtracted cDNA libraries of human vascular endothelial cells (VECs) related to gastrocarcinoma using suppression substractive hybridization (SSH) and to analyze cDNA libraries of gastrocarcinoma and VECs in Cancer Gene Anatomy Project (CGAP) database.

METHODS: Human VECs related to gastric adenocarcinoma and corresponding normal tissue were separated by magnetic beads coupled with antibody CD31 (Dynabeads CD31). A few amount of total RNA were synthesized and amplified by SMART™ PCR cDNA Synthesis Kit. Then, using SSH and T/A cloning techniques, cDNA fragments of differentially expressed genes in human VECs of gastric adenocarcinoma were inserted into JM109 bacteria. One hundred positive bacteria clones were randomly picked and identified by colony PCR method. To analyze cDNA libraries of gastrocarcinoma and VECs in CGAP database, the tools of Library Finder, cDNA xProfiler, Digital GENE Expression Displayer (DGED), and Digital Differential Display (DDD) were used.

RESULTS: Forward and reverse subtraction cDNA libraries of human VECs related to gastrocarcinoma were constructed successfully with SSH and T/A cloning techniques. Analysis of CGAP database indicated that no appropriate library of VECs related to carcinoma was constructed.

CONCLUSION: Construction of subtraction cDNA libraries of human VECs related to gastrocarcinoma was successful and necessary, which laid a foundation for screening and cloning new and specific genes of VECs related to gastrocarcinoma.

INTRODUCTION

The microvascular system is indispensable throughout the full life span of an organism. Malformation and / or malfunction of VECs contribute to numerous human pathologies including various congenital abnormalities, arteriosclerosis, benign tumors, and cancer. Angiogenesis, the development of new blood vessels by sprouting from the preexisting vasculature, plays an important role in a number of physiological and pathological processes. Stimulated growth or strengthening of so-called collateral vascular branches might circumvent areas with obstructed blood flow in the case of stroke or coronary heart disease. On the other hand, there is substantial evidence suggesting that inhibition of tumor vascular rise might slow down, stop or eventually even reverse tumor growth and could thus become an important part of cancer therapy. The growth of micro vessel accompanying tumor development has, in particular, aroused greater interest and helped improve our understanding of the central role of Vices. Suppression subtractive hybridization (SSH), a PCR-based coda subtracted method, is an important method to reach this aim[1-4]. Because it still needs a lot of initiating RNA, bulk tissues (normal and cancerous) instead of individual cells are routinely used in the analysis. In recent two years, many articles have been publicized employing this method using various tissues[5,6] or cell lines[7,8]. However, bulk tissue contains many different cell types, which will burden the latter work for identifying special genes, and cell lines are different from cells *in vivo* especially for disease cells. With the introduction of Laser Capture Microdissection (LCM), the quantity and purity of RNA from either malignant or benign individual cells invariably yield more reliable and comprehensive experimental results[9-12]. But cell selection and extraction by LCM is currently a manual process, and at most only a few thousand cells can be extracted in an amount of time necessary to limit RNA degradation, and the machine is too expensive for average laboratory. Gastrocarcinoma, one of the most common human malignant tumors, ranks worldwide as the first leading cause of cancer-related mortality. A great deal of articles have been publicized about differentially expressed genes in normal and tumor gastric tissues[13-15]. Some researchers used cells separated from tissues digested with collagenase or cultured cells as material[16-18]. However, with cell culture even primary cell culture, the expressed gene map may change a lot. Likewise, in cells treated with collagenase at 37 ℃ for 30 minutes for separating the target cells from tissue, the specially expressed genes may lose before disposal or new genes may appear after disposal. The Cancer Gene Anatomy Project (CGAP) database of the National Cancer Institute has thousands of expressed sequences, derived from diverse normal and tumor cDNA libraries, but has no appropriate VECs cDNA library related to tumor. The aim of the present study was to select all genes specially expressed in VECs related to gastrocarcinoma rather than in normal gastric tissue. Using VECs mechanically separated by Dynabeads CD31 as materials without collagenase and culture, we built a cDNA library through SSH method, thus paved the way for further research on changes of VECs in gastrocarcinoma.

MATERIALS AND METHODS

Materials

The resected specimens about 2 cm^3 from gastric adenocarcinoma

confirmed pathologically and from normal gastric tissues 7 cm away from the edge of the adenocarcinoma in same patients who were admitted to Henan Provincial Hospital were put into RNA protecting solution (RNAlater™, Ambion Company) after being rinsed with PBS immediately after resection.

Methods

Separation of ECs with Dynabeads CD31 About 1 cm^3 of tissue cut from tissues stabilized by RNA*later* was put into a mortar with a little RNA*later* RNA Stabilization Reagent, and then was scissored and ground with scissors and pestle. To make cell suspension, 1 ml RNA*later* RNA Stabilization Reagent was added to it, then filtered through a sterile 80-μm-nylon filter. 25 μl washed Dynabeads®CD31 beads were added to the suspension for 30 minutes at 2-8 ℃. For identification, slide was made with one drop of this mixture and stained with hematoxylin and eosin (H&E). Then bead-bound cells were separated in a magnetic device (Dynal MPC®).

Isolation of total RNA

Rnaeasy Mini Kit and Rnase-Free Dnase set (QIAGEN Company) were used to extract the total RNA from bead-bound cells. RNA purified by Rnaeasy Column was analyzed for integrity and size by formaldehyde agarose gel electrophoresis and quantification and purity of RNA by OD value.

Synthesis, amplification and purification of cDNA

About 100 ng total RNA was used to synthesize the first strand of cDNA with SMART™ PCR cDNA Synthesis Kit (Clontech Company), then amplified by LD-PCR with 15, 18, 21, 24, 27 cycles separately and analyzed through 1.2 % agarose gel electrophoresis in order to get the perfect cycle number with which we harvested a suitable amount rather than a superfluous one to build the library. Placental total RNA was performed as control. CHROMA SPIN-100 Column was used to purify the cDNA.

Digestion with RsaI and purification of digested products

SampleI, cDNA from VECs of gastrocarcinoma, and sample II, cDNA from VECs of normal stomach tissue, and sample III, cDNA from VECs of placental tissue were treated with enzyme RsaI respectively. From each sample, 10-μl solutions was taken before digestion and 1 h, 3 h and 3.5 h after digestion, and 1.2 % agarose gel electrophoresis was performed for identification of digestion efficiency. Digested products were purified by QIAquick PCR purification Kit (QIAGEN Company), and subsequently concentrated to 6.7 μl by ethanol precipitation method.

Isolation of specially expressed cDNA fragments

Based on the instructions of Clontech PCR-Select™ cDNA Subtraction Kit, sample I and sample II were used as test 1 and driver 1, correspondingly sample II and sample I were used as test 2 and driver 2. Mixture of sample III and ω×174/Hae III DNA was treated as test 3, correspondingly sample III alone was performed as driver 3. Each sample test was divided into two parts, and each part was ligated separately with Adaptor 1 and Adaptor 2, and then hybridized with the corresponding sample driver. The mixture of two parts was hybridized with corresponding sample driver again. The fragments with both Adaptor 1 and Adaptor 2, namely specially expressed cDNA fragments in sample test rather than in sample driver, were amplified by nested PCR. Adeptors possessed outside primer and inside primer. So forward and reverse subtraction fragments were obtained. Subtraction efficiency was checked by G3PDH, a housekeeping gene, according to PCR cycles needed in subtracted sample and unsubtracted sample, with which the gene could be observed on agarose/EtBr gel.

Purification of subtraction fragments

QIAquick PCR Purification Kit was utilized to purify the subtraction fragments.

Clone and screening of subtraction fragments

1 μl, 2 μl, 3 μl PCR fragments of subtraction and non-subtraction and 2 μl control DNA were respectively taken to ligate with 1 μl pGEM-T easy Vector. 10-μl ligation reaction solutions were transformed into 150 μl competent cells JM109. Background control was set up by pGEM-T easy Vector without any insert, and transformation control was also set up by an uncut plasmid pGEM@-5Zf (+) Vector. The transformation culture was plated on petri dishes containing LB/ampicillin/IPTG/X-Gal, and then screened white colony for inset fragment.

Identification of positive recombination of vector

Select 100 white colonies separately from forward and reverse library and replant 5 ml LB/Amp solution. Then it was shaken at 37 ℃ overnight. Take 1 μg culture solution as model and Nested Primer 1 and Nested Primer 2R to amplify the insert and test it by electrophoresis.

Storage of library

Select white colonies separately from forward and reverse library and inoculate 5 ml LB/Amp solution. Then it was shaken at 37 ℃ overnight. Add 700 μl culture solution into 1.5 ml EP tube containing 50 % glycerin and keep it at -80 ℃.

Analysis of related library

cDNA library of stomach cancer tissue, normal stomach tissue and vascular endothelial cell were analyzed using GLS, cDNA xProfiler, DDD, DGED and Library Finder in Cancer Genome Anatomy Project (CGAP). dbEST was categorized using the GLS tool of CGAP. We considered precancer libraries as cancer libraries. All of the cDNA libraries were categorized according to tissue type (tissue origin), tissue histology (cancerous, normal, or fetal), and the library preparation method (microdissected, bulk, cell line, or flow cytometric sorted).

RESULTS

Through Dynabeads®CD31, about 8×10^6 endothelial cells were obtained with almost 100 % purity. Slides were made and stained with H&E (Figure 1).

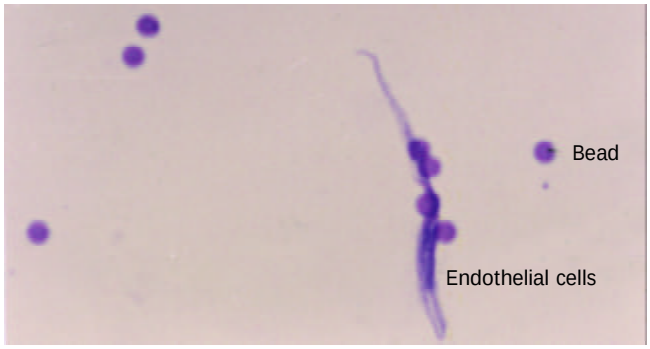

Figure 1 Endothelial cell attached with several beads.

The amount of RNA extracted from stomach cancer and normal stomach tissue was respectively 1.0 μg and 0.85 μg with OD_{260}/OD_{280} ratio 2.10 and 1.96. By formaldehyde agarose gel electrophoresis, the integrity and size were analyzed and clear bands of 18s and 28s were seen (Figure 2).

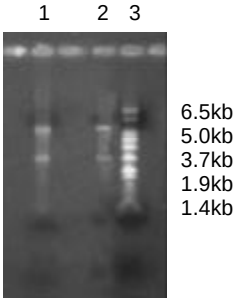

Figure 2 Lane 1, total RNA of stomach cancer. Lane 2, total RNA of normal stomach tissue. Lane 3, marker.

Figure 3 Lanes 1, 2, 3 demonstrate 21, 24, 27 PCR cycles of cDNA products of stomach cancer tissue. Lanes 4, 5, 6 demonstrate 21, 24, 27 PCR cycles of cDNA products of normal stomach tissue. Lanes 7, 8, 9 demonstrate 15, 18, 21 PCR cycles of cDNA products of placental tissue. Lane 10, marker.

Synthesis and amplification of cDNA

The first strands of cDNA have been amplified by LD-PCR with different cycles: 15, 18, 21, 24, and 27. The products could be viewed on 2 % agarose gel electrophoresis (Figure 3). For both normal tissue and cancer tissue, a total of 27 cycles were performed, respectively, and for placental tissue, totally 18 cycles were performed.

Analysis of RsaI digestion efficiency

cDNA, before digestion with *RsaI*, appeared as a smear of 0.5-10 kb on 1 % agarose gel electrophoresis, and after digestion the average cDNA size was smaller (0.1-2 kb) (Figure 4).

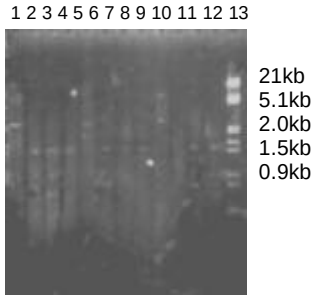

Figure 4 Lanes 1, 2, 3, 4: sampleI. Lanes 5, 6, 7, 8: sampleII. Lanes 9, 10, 11, 12: sample III. Lane 13, marker. Lanes 1, 5, 9: cDNA undigested. Lanes 2, 6, 10: cDNA digested for 1 h. Lanes 3, 7, 11: cDNA digested for 3 h. Lanes 4, 8, 12: cDNA digested for 3.5 h.

Analysis of ligation efficiency

That the intensity ratio of PCR products determined by G3PD primer 3' and Adaptor primer 1 to PCR products determined by G3PD primer 3' and 5' was over 1:4 on 2.0 % agarose/EB gel showed that ligation efficiency was above 25 % (Figure 5).

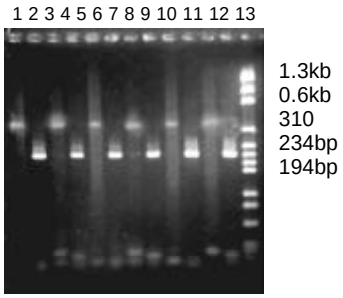

Figure 5 Lanes 1, 2, 3, 4 : sampleI. Lanes 5, 6, 7, 8: sample II. Lanes 9, 10, 11, 12: sample III. Lane 13, marker. Lanes 1, 5, 9: PCR products using cDNA ligated Adaptor 1 as model, and G3PDH 3' primer and PCR Primer 1. Lanes 2, 6, 10: PCR products using cDNA ligated Adaptor 1 as model, and G3PDH 3'primer and G3PDH 5'primer; Lanes 3, 7, 11: PCR products using cDNA ligated Adaptor 2 as model, and G3PDH 3' primer and primer 1. Lanes 4, 8, 12: PCR products using cDNA ligatefd Adaptor 2 as model, and G3PDH 3' primer and G3PDH 5' primer.

Analysis of differentially expressed cDNA with nest PCR

The second hybridization products were amplified by outside primers. The products presented unclear smear on 2 % agarose/EB gel. After second PCR with inside primers, several bands could be seen clearly among the smears. Based on the manual, the experiment was successful (Figure 6).

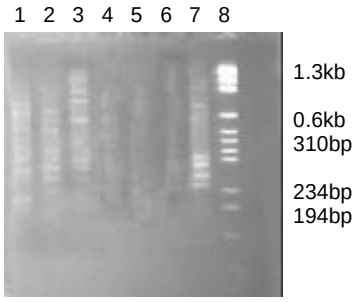

Figure 6 Lanes 1, 2, 3 indicated subtracted samples I, II, III. Lanes 4, 5, 6 indicated unsubtracted sample I, II, III. Lane 7 showed the subtracted control provided by the kit. Lane 8: Marker.

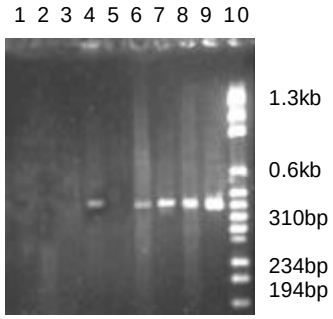

Figure 7 Lanes 1, 2, 3, 4 indicated the subtracted sample I was amplified by PCR wth different cycles: 18, 23, 28, 33. Lanes 6, 7, 8, 9 indicated the unsubtracted sample I was amplified by PCR wth different cycles: 18, 23, 28, 33. Lane 10: Marker.

PCR analysis of subtraction efficiency

After PCR amplification, the housekeeping gene G3PDHs appeared at 18 cycles in unsubtraction samples and at 33 cycles in subtraction samples. This result indicated that G3PDHs expressed in both parts have been greatly decreased

through the subtraction method. If five cycles corresponded roughly to 20-fold cDNA enrichment, G3PDHs would have been decreased almost 300 times. It implied that other genes expressed in both tissues have been reduced the same fold and the specially expressed genes in the test sample were selected (Figure 7).

Screening transformants for inserts

720 white colonies were observed on two petri dishes of positive control with 7 % presence ratio of blue colony. Two white colonies were observed on one petri dish of background control with 15 blue colonies. On one petri dish of transformation control, 160 white colonies without blue colony were observed. 992 white colonies appeared on 5 petri dishes of forward subtraction, and 890 white colonies appeared on 5 petri dishes of reverse subtraction. 60 white colonies were selected from forward and reverse subtractions, and amplified with nested Primer 1 and nested Primer 2R. 54 and 50 fragments ranged from 100 bp to 1 000 bp were selected from the corresponding forward and reverse subtraction libraries.

Analysis of CGAP database

dbEST was categorized using the GLS tool of the CGAP. All of the cDNA libraries were categorized according to tissue type (tissue origin), tissue histology (cancerous, normal, or fetal), and the library preparation method (microdissected, bulk, cell line, or flow cytometric sorted). Among 319 stomach cDNA libraries, all 73 libraries of normal stomach were from bulk tissues instead of cells and none was established by SSH method except those without label. Among the 245-cDNA libraries of stomach cancer, 28 originated from cell lines with 9 libraries built by SSH, and none of the other 217 libraries originating from tissue was built by SSH. All 15 vascular cDNA libraries came from normal tissue or cell line or cultured cells, and SSH method was not used. And appropriate VECs related to tumor have not been built into cDNA library. Among the libraries derived from cell lines, two derived from umbilical vein endothelium, one derived from aortic endothelium, another one came from endothelial cells of foreskin through primary culture of dermal microvascular endothelial cells. Among the 11 non-cell line libraries, 6 were from aorta, 2 umbilical veins, 1 unlabeled vein; another two were from choroidal plexus and basilar artery.

DISCUSSION

Bio-behavior such as growth and metastasis of cancer is closely related with proliferation of microvessel. Newborn capillaries of cancer differ from normal ones in growth process or distribution. For instance, VECs of breast cancer can grow 50 times faster than VEC in normal tissue[19] and vascular endothelial growth factors (VEGFs) play an important role in tumor angiogenesis[20,21], and their over- expression is closely related to clinical staging, lymph node metastasis and recurrence of gastric carcinoma[22]. So increasing attention has been paid to VECs[23].

Differentially expressed genes between the corresponding normal and cancer tissue can help us understand the molecular basis of malignancy and potentially serve as biomarkers or prognostic markers of malignancy. The identification and characterization of human genes expressed exclusively or preferentially in microvascular system of tumor will hopefully shed light on the mechanisms of tumor development and provide useful genetic markers for screening, diagnosis, prognosis, therapeutic monitoring and development of therapeutic vaccines. There are many techniques that aim at producing an inventory of differential transcripts between two populations of mRNAs. High-throughput gene expression techniques (microarrays, genechips) to identify cancer-specific genes are becoming available[24-26], however, the technology is not cost effective for average laboratories. SSH method allows identifying overexpressed genes (designated forward +SSH) but also underexpressed genes (designated reverse -SSH) by exchanging the driver and tester populations during the procedure (Clontech, Palo Alto, USA). Since this technique was established by Diatchenko, many new genes have been separated from almost all tissues, such as renal cell cancer, lung cancer, liver cancer[27-30], etc.

The CGAP database of the National Cancer Institute has thousands of expressed sequences, both known and novel, in the form of expressed sequence tags (ESTs). These ESTs derive from diverse normal and tumor cDNA libraries. In CGAP database, there are 8 221 libraries from various tissues. Among these libraries, 54 libraries are based on SSH method, and 69 material samples are prepared through microdissection. Among those 54 libraries with SSH method, none of the material sample has been prepared through microdissection.

CGAP also offers different data-mining tools: tools of the GLS, the cDNA xProfiler, the DDD, and the DGED. With these tools and database in CGAP, differently expressed genes can be predicted too[31-33]. Using DGED tool to compare normal stomach libraries and cancer libraries, 117 differently expressed genes can be found. But endothelial cells related to cancer have no appropriate library that can be matched and compared. So cDNA library of endothelial cells related to cancer needs to be built, and the more the better, just like prostate libraries.

TO separate VECs from microvessel, tissues were usually treated with collagenase at 37 ℃ for 30 minutes according to present common techniques, and magnetic beads coupled with monoclonal antibody CD31(Dynabeads CD31) have also been used[34,35]. VECs separated by monoclonal antibody have been identified without change[36]. Instead of using collagenase and cell culture, we separated VECs with Dynalbeads CD31 after mechanically grinding tissue and filtering through a sterile 80-μm-nylon filter. In this way, we obtained about 10^6 VECs, from which 1 μg total RNA was harvested. Although the amount of the cells was limited and even some cells were connected by fibers, they were relatively pure. The process of separating VECs from tissue with Danalbeads CD31 lasted almost 1 h, as a result RNAlater, solution-inhibiting degradation of RNA, has been used to substitute PBS required by the Danalbeads CD31 Kit. Because the amount was far from 1-2 mg total RNA required by SSH method, Smart cDNA Synthesis Kit was introduced to synthesize and amplify cDNA from the relatively few RNA, which requires only 50 ng total RNA. In the process of amplification, after the first 15 cycles, for each three more cycles, a little sample was taken and tested in order to get suitable copies of cDNA, as more copies would add burden to later screening work.

In performing SSH, each step was operated exactly according to the manual of the kit and the results were verified correct before each following step. G3PDH was used to identify the forward and reverse subtractions. On agarose/EB gel, appearance of G3PDH band was 15 PCR cycles later in subtraction sample than in unsubtraction sample. It implied the amount of G3PDH decreased 300 times by subtraction technique. Finally, with T/A technique, subtracted PCR products were ligated to T vector and transformed into bacteria JM109. So, both the forward subtraction cDNA library containing cDNA fragments only expressed in VECs of stomach cancer but not normal stomach tissue, and the reverse subtraction cDNA library containing cDNA fragments not expressed in VECs of stomach cancer tissue but normal stomach tissue were built up successfully, which was a good beginning for researching into new genes of VECs related to gastrocarcinoma and gene therapy of gastrocarcinoma.

Abstract

AIM: To study the therapeutic mechanism of Ginkgo biloba exocarp polysaccharides (GBEP) on gastric cancer.

METHODS: Thirty patients with gastric cancer were treated with oral GBEP capsules. The area of tumors was measured by electron gastroscope before and after treatment, then the inhibitory and effective rates were calculated. The ultrastructures of tumor cells were examined by transmissional electron microscope. Cell culture, MTT, flow cytometry were performed to observe proliferation, apoptosis and changes of relevant gene expression of human gastric cancer SGC-7901 cells.

RESULTS: Compared with the statement before treatment, GBEP capsules could reduce the area of tumors, and the effective rate was 73.4 %. Ultrastructural changes of the cells indicated that GBEP could induce apoptosis and differentiation in tumor cells of patients with gastric cancer. GBEP could inhibit the growth of human gastric cancer SGC-7901 cells following 24-72 h treatment *in vitro* at 10-320 mg/L, which was dose- and time-dependent. GBEP was able to elevate the apoptosis rate and expression of c-fos gene, but reduce the expression of c-myc and bcl-2 genes also in a dose-dependent manner.

CONCLUSION: The therapeutic mechanism of GBEP on human gastric cancer may relate to its effects on the expression of c-myc, bcl-2 and c-fos genes, which can inhibit proliferation and induce apoptosis and differentiation of tumor cells.

INTRODUCTION

Ginkgo biloba exocarp polysaccharide (GBEP) is polysaccharides isolated from ginkgo biloba exocarp. Many studies showed that GBEP was able to inhibit tumors and enhance immune function of tumor bearing mice. Clinical studies showed that GBEP had certain therapeutic effects but few toxic side-effects on patients with tumors, and had good prospects in clinical application[1-4]. This study was to investigate the therapeutic effect and mechanism of GBEP on human gastric cancer.

MATERIALS AND METHODS

Patients

A total of 30 patients with gastric adenocarcinoma (20 males aged from 28 to 81 years old, 10 females aged from 52 to 75 years old) were all ascertained by the pathological examination in Jiangsu Provincial Subei People Hospital or the First People Hospital of Yangzhou, China. Their Karnofsky scores were all above 60. All the patients did not receive any other anti-tumor treatments recently.

Cell line

Human gastric cancer cells (SGC-7901) purchased from Department of Cellular and Molecular Biology, Shanghai Institute of Biochemistry and Cell Biology Academia Sinica, were sub-cultured every 2 or 3 days.

Reagents

GBEP was extracted from exocarp of ripe ginkgo biloba. The content of polysaccharides was higher than 80 %. RPMI 1640 was from GibcoBRL(Maryland, USA). MTT and trypsin (1:250) were from Sigma (ST. Louis, USA). Monoclonal mouse anti-human c-myc and bcl-2 were purchased from Antibody Diagnostica Inc., USA. Monoclonal rabbit anti-human c-fos was from Santa Cruz (Santa Cruz, USA).

Methods

Influence of GBEP on gastric carcinoma patients GBEP capsules are composed of GBEP dry powder and a certain proportion of excipient, and 0.25 g per capsule. Each patient with gastric carcinoma was treated with oral GBEP capsule, 2 pills each time, twice a day, for over 30 d. Changes of tumor size were measured by electron gastroscope. The inhibitory rates (IR) were calculated according to the formula: IR=(tumor area before treatment - tumor area after treatment) ÷ tumor area before treatment×100 %, which is used in the assessment of therapeutic effects. The assessment followed the clinical assessment standards for solid tumors made by WHO, which are classified as complete response (CR), partial response (PR), stable disease (SD) or no change (NC), and progressive disease (PD). The effective rate equals CR plus PR. At the meantime tumor biopsies were obtained for ultrastructural examination by transmissional electron microscope (HV-300). Images captured by transmissional electron microscope were analysed, and the nucleocytoplasmic ratio as well as the surface density of heterochromatin in the tumor cells were calculated before and after treatment.

MTT experiment SGC-7901 cells growing exponentially were digested by 0.25 % trypsin for 1-2 minutes, then washed in Hanks' balanced salt solution (HBSS) for 2 times, and RPMI

1640 containing 10 % new born bovine serum medium was added to adjust the cell density to 1×10^8 cells/L. After addition of the final cell suspensions of 100 μl/well, 96-well plates were put into an incubator containing 5 % CO_2, and incubated at 37 ℃ for 24 hours. Then, 100 μl RPMI 1640 containing different concentrations of GBEP was added to each well. Each concentration had 3 wells, and the control was added with 100 μl RPMI 1640. They were cultured for 24 hours, 48 hours and/or 72 hours. Fresh medium was changed per 24 hours, and GBEP was added. Four hours before the end of culture, 10 μl MTT (the final concentration was 5 g/L) was added, and cultured for 4 hours. Optical density (OD) values for each well were measured at 570 nm with the enzyme linked immunosorbent assay meter[5,6]. The inhibitory rates were calculated according to the formula: IR=[1-(the mean of treated group)/(the mean of control group)]×100 %.

Measurement of cell apoptosis SGC-7901 cells growing exponentially were digested with 0.25 % trypsin for 1-2 minutes. After that, the cells were washed 2 times with PBS buffer (pH 7.2), counted and mixed with RPMI 1640 containing 10 % new born bovine serum to create a final cell density of 2×10^8 cells/L. Four ml final cell suspension was added into each culture bottle, and cultured for 24 h in the condition of 5 % CO_2, at 37 ℃. Then the culture bottles were randomly mixed with different concentrations of GBEP or a positive control drug adriamycin. The negative control group was mixed with an equal volume of RPMI 1640. Then, all the culture bottles were cultured for another 48 h. After that, they were digested and washed. At last they were fixed with alcohol and kept at 4 ℃. The tumor cells were fixed with alcohol and kept in citrate buffer for at least 1 hour after washed in PBS to create a final cell density of 1×10^9 cells/L, they were then centrifuged and mixed with 1 800 μl solution A (trypsinization solution). After 10 minutes, they were mixed with 1 500 μl solution B (RNASE) for 20 minutes, then mixed with 1 500 μl solution C (PI) and filtered by a nylon net after 15 minutes. Finally, the apoptotic rate of the cells was examined.

Analysis of protein content Cell culture was carried out as previously described. The SGC-7901 cells were centrifuged (2 000 ω/minute for 5 minutes) after washed in PBS, mixed with monoclonal mouse anti-human c-myc, or bcl-2, or rabbit anti-human c-fos, and kept at 4 ℃ for 45 minutes. The cells were washed in PBS and mixed with sheep anti-mouse or sheep anti-rabbit IgG and kept at 4 ℃ for another 45 minutes. After washed in PBS and centrifugation, the cells were mixed with 300 μl PBS in sediment and the rate of positive protein for c-myc, bcl-2 and c-fos gene was measured by flow cytometry.

RESULTS

Effect of GBEP capsules on gastric cancer cells

Compared with that before treatment, the tumor area was apparently reduced, which was further proved by electron gastroscopy, and the inhibitory rate of GBEP on tumors was 53.5 %. According to the standards proposed by WHO for the short-term therapeutic effectiveness of solid tumors, there were 2 cases of CR (6.7 %), 20 PR (66.7 %), 5 SD (16.7 %), 3 PD (10 %) in the 30 cases, and the total effective rate was 73.4 %. Images captured by transmissional electron microscope showed that most of the cancer cells had sufficient euchromatins but deficient heterochromatins in the nuclei, the cancer cells had sufficient free ribosomes and deficient glycogens in the cytoplasm before treatment. After treatment with GBEP, most of the cancer cells had sufficient heterochromatins in the nuclei. Some cancer cells became pyknosis. Heterochromatin margination was seen in some of the cancer cells (in the course of apoptosis). Some euchromatins were dissolved, mitochondria were swollen, and rough endoplasmic reticulum was dilated. The results of image analysis showed that nucleocytoplasmic ratio in most of the cancer cells was reduced, surface density of heterochromatin was increased. Influence of GBEP capsules on the tumor area of gastric cancer, on the tumor cells' nucleocytoplasmic ratio and the surface density are shown in Figure 1.

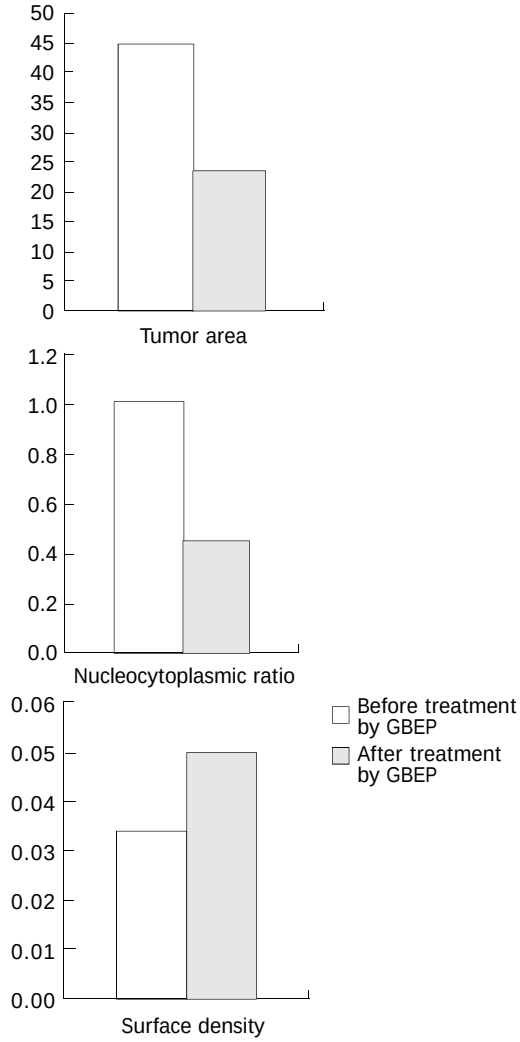

Figure 1 Influence of GBEP capsules on tumor area of gastric cancer, and on tumor cells' nucleocytoplasmic ratio and surface density.

Inhibition of GBEP on human gastric cancer SGC-7901 cells

GBEP could inhibit SGC-7901 cell proliferation following 24-72 hours treatment *in vitro* at 10-320 mg/L. Compared with the control group, the inhibition of SGC-7901 cell proliferation by GBEP was dose- and time-dependent ($P<0.01$) (Figure 2).

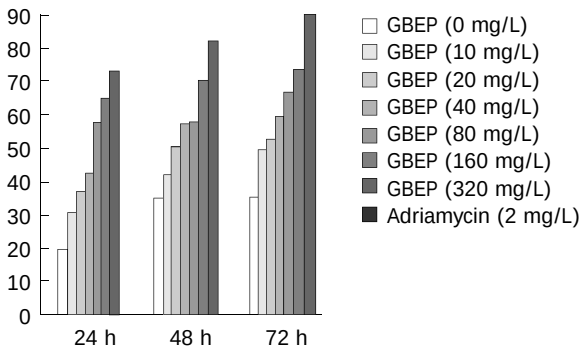

Figure 2 Inhibition of GBEP on human gastric cancer SGC-7901 cell proliferation *in vitro*.

Effects of GBEP on human gastric cancer SGC-7901 cell apoptosis

DNA contents of human gastric cancer SGC-7901 cells were analysed by flow cytometry. The results showed that GBEP could induce apoptosis in SGC-7901 cells at a certain degree (Figure 3).

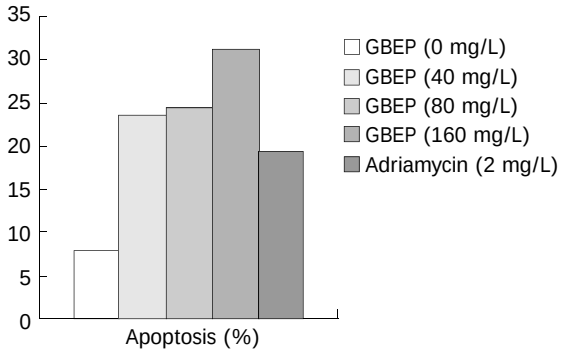

Figure 3 Effects of GBEP on human gastric cancer SGC-7901 cell apoptosis.

Effect of GBEP on expression of c-myc, bcl-2 and c-fos genes in SGC-7901 cells

Protein contents of human gastric cancer SGC-7901 cells were analysed by flow cytometry. The results showed that GBEP could inhibit the expression of c-myc and bcl-2 genes, but enhance the expression of c-fos in SGC-7901 cells (Table 1).

Table 1 Effect of GBEP on expression of c-myc, bcl-2 and c-fos genes in SGC-7901 cells

Group	Dose (mg/L)	Rate of positive protein sign (%)		
		c-myc	bcl-2	c-fos
RPMI 1640	-	22.05	19.35	12.68
GBEP	40	20.33	15.29	17.35
GBEP	80	12.50	11.74	24.96
GBEP	160	7.34	7.17	45.26
Adriamycin	2	9.67	9.31	68.01

DISCUSSION

Gastric cancer is one of the most common malignant tumors in China. Surgical treatment is the main therapy of it. Anti-tumor drugs still play an important role in comprehensive therapy. Now cytotoxic compounds remain the main part of the chemotherapy drugs. The main defects of the cytotoxic compounds are the poor therapeutic effects on solid tumors, higher toxic side-effects and easy occurrence of drug resistance. Many Chinese drugs can enhance the immune function of the body. When used in the treatment, they showed less toxic side-effects but lower inhibitory rate on tumors.

Polysaccharides are big molecules linked by monosaccharides. The sugar-chain of polysaccharides can regulate cell proliferation, differentiation, growth and aging. They showed definite therapeutic effectiveness in anti-tumor therapy, and the ability to enhance body' s immune function, as well as a lower toxic side-effect[7-10]. For example, mushroom polysaccharides have already been used as a drug to regulate the organism reaction in clinical therapy and to prevent tumors in Japan. Umbellate pore fungus polysaccharides which were developed and used in clinical therapy in China, could reduce side-effects of chemotherapy and enhance the effects of chemotherapy against tumors.

We performed this clinical experiment by treating 30 gastric cancer patients with oral GBEP capsules. The images captured by electron gastroscope showed the average inhibitory rate of its capsules on gastric tumor was 53.5 %. The effective rate was 73.4 %. It indicated that GBEP had good clinical therapeutic effectiveness on gastric cancer.

Apoptosis is an active cellular process whereby individual cells are triggered to undergo self-destruction. Recent studies showed apoptosis played a main role in the prevention and treatment of tumors[11-13]. Anti-tumor effect of many chemotherapy drugs could induce apoptosis in tumor cells[14,15]. Cell apoptosis was regulated by genes[16,17]. We have known that apoptosis regulators can be divided into two kinds, namely apoptosis-inducing genes and apoptosis-inhibitory genes. Up-regulation of apoptosis-inducing gene expression could elevate the sensitivity of cells to factors or signals inducing apoptosis, and trigger apoptosis in this way. Up-regulation of apoptosis-inhibitory gene expression could reduce the sensitivity of cells to factors or signals inducing apoptosis, and apoptosis could be inhibited or delayed in this way. Bcl-2 was an important apoptosis-inhibitory gene[18-20], it included a nucleus molecule that can block cell apoptosis, prolong cell lives, accelerate DNA repairing, and thus promoting tumor genesis and development. So it could down-regulate cell apoptosis[21-25]. This clinical study and examination of cellular ultrastructures showed clues of apoptosis induced by GBEP in human gastric cancer cells. Using techniques of cell culture *in vitro* and flow cytometry, the contents of DNA and protein of human gastric cancer SGC-7901 cells were analysed. The results showed GBEP could increase SGC-7901 cell apoptosis rate, down-regulate bcl-2 at concentrations of 40-160 mg/L. It indicated that one of the therapeutic mechanisms of GBEP on gastric cancers might be that it induced tumor cell apoptosis. It also indicated that bcl-2 was involved in this process.

Malignant cells are similar to undifferentiated embryonic cells in morphology, function and metabolism. When tissue changes into malignancy, many phenotypes of the cells go back to the embryonic cell phenotypes, which is called de-differentiation or retro-differentiation. Malignant cells can be induced to differentiate towards normal cells in the presence of differentiation-inducer. Many malignant cells can approach to normal cells, even transform into normal cells completely, which is called re-differentiation or reversion. Change of cells from normal to malignancy is a break of the balance between proliferation and differentiation. Uncontrollable proliferation and de-differentiation are the characteristics of most malignant tumors. Differentiation-inducers can decelerate proliferation, enhance differentiation, thus creating a new normal balance. Like apoptosis, proliferation and differentiation are regulated by genes. C-myc is an important gene involved in the control of cell proliferation, and could up-regulate cell cycle progression, and induce cell proliferation[26-29]. C-fos gene is considered as an early response gene, and its expression level was in proportion to the differentiation degree of gastric cancer[30-32]. This clinical study and results of the cell ultrastructural examination showed clues of apoptosis induced by GBEP in human gastric cancer cells. The results of MTT experiment *in vitro* showed GBEP could inhibit the proliferation of human gastric cancer SGC-7901 cells. The results measured by flow cytometry showed GBEP could down-regulate the expression of c-myc gene and up-regulate the expression of c-fos in SGC-7901 cells at the concentrations of 40-160 mg/L. It indicates that inhibition on cell proliferation and inducement on cell differentiation might be involved in the therapeutic mechanism of GBEP on gastric cancer. C-myc and c-fos genes might contribute to the regulation of proliferation and differentiation.

Abstract

AIM: To explore the mode of inheritance of hepatocellular carcinoma (HCC) in a moderately high-incidence area of East China.

METHODS: A pedigree survey was conducted in 210 families (3315 individuals) ascertained through 210 HCC probands in Haimen, Jiangsu Province. Simple segregation analysis was conducted using SEGRANB software. The probability of ascertainment (p), segregation ratio (p), and the proportion of sporadic cases (x) were estimated. Complex segregation analysis was performed using the REGTL program of S.A.G.E. Models were fitted on the data of 3212 individuals that allowed for personal HBsAg status and variable age of onset in REGTL program.

RESULTS: The estimate of segregation ratio was 0.191 by SEGRANB. The probability of ascertainment was 0.0266, and the proportion of sporadic cases was 0.465. The results of complex segregation analysis showed that Mendelian autosomal recessive inheritance of a major gene that influenced the age of onset distribution of HCC, provided the best fit to the data. In the best-fitting recessive model, the frequency of the disease allele was 0.11138. HBsAg seropositive status would significantly increase the risk of developing HCC.

CONCLUSION: These results suggest that at least one major gene is involved in the genetic predisposition to develop HCC at an earlier age of onset. The seropositive HBsAg status can significantly increase the risk of developing HCC, which provides strong support for the interaction between genetic and environmental risk factors.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common types of malignant tumor in the world, the estimated number of new cases worldwide annually is over 500 000[1], ranking third in cause of cancer deaths in China. An estimated 26 000 deaths are from HCC annually worldwide, among which about 40 % are in China[2]. Classical epidemiological studies have shown that certain risk factors are associated with HCC, though the odds ratios (ORs) vary considerably from study to study[3-5]. On a worldwide basis, chronic infection with hepatitis B virus (HBV) appears to be the most important risk factor for HCC. About 80 % of the patients of HCC in China are seropositive for hepatitis B surface antigen (HBsAg)[6]. An IARC working group in 1993 found that the evidence for a causal association of HBV with HCC was pretty strong. HCC is common in cirrhotic patients when cirrhosis is secondary to chronic viral hepatitis[1]. In addition to viral factors, environmental exposures and genetic susceptibility are clearly involved. Dietary aflatoxin exposure is an important codeterminant of HCC risk in Africa and parts of Asia[7]. Aflatoxins together with chronic hepatitis B virus (HBV) infection contribute to the high incidence of hepatocellular carcinoma in developing countries[8-10]. Contaminated drinking water and chemical carcinogens are also associated with the development of HCC[3].

Many familial clusterings of HCC have been reported[11,12]. The prevalence of HCC among the first-degree relatives is significantly higher than that among the second-degree and third-degree relatives, which suggests that genetic mechanisms may be responsible for familial HCC. Haimen city is a HCC high-incidence area of East China, however, only a few studies have been performed to explore the genetic mode of HCC in this area. Consequently, in this study, data of 210 pedigrees ascertained through HCC probands were collected and segregation analysis of HCC was performed.

MATERIALS AND METHODS

Materials and data collection

Probands were 210 HCC patients from an eight-year follow-up of a 90 000-person Haimen City cohort. All the patients were pathologically diagnosed in hospitals of counties and cities. Information on four-generation pedigrees was obtained for 210 families. Data on 3 315 individuals in the 210 families were collected primarily by face-to-face interviews or by checking the medical records and according to the recall of their relatives if the proband patients were dead. Data on 3 212 individuals (97 %) were used to fit models in the REGTL program of S.A.G.E. The remaining individuals were excluded because of little information available.

Family history interview and data management

A family history of HCC was collected as part of an interview to gather information on the medical history of probands and their relatives. The questionnaire included questions on age, occupation, tobacco use, drinking water source by decades (60 s, 70 s, 80 s, 90 s), staple food consumption by decades, result of HBsAg test, history of chronic hepatitis B, history of other chronic diseases, family history of HCC and relationship of family member with HCC to proband cases.

All the questionnaires were reviewed and checked for quality control. Pedigree information database was developed using Epi-Info v5.0.

Statistical methods

Simple segregation analysis by SEGRANB program In SEGRANB, models were fitted to the data and maximum likelihood scores of parameters were estimated. Hypothesis tests were performed to determine which set of parameter was most consistent with the observed data. The involved parameters were probability of ascertainment (p) (the probability for a patient to be identified as a proband), segregation ratio (p), and the proportion of sporadic cases (x). S is the sibship size, r is the total number of the affected siblings and a is the total number of the probands. The function for the probability of ascertainment is:

$$P(a \mid a>0;\ r, \pi) = \frac{\binom{r}{a} p^{a}(1-p)^{r-a}}{\left[1-(1-p)^{r}\right]}$$

The function for the estimate of the segregation ratio in the pedigrees with more than one patient is:

$$P(r>1) = \frac{\binom{s}{r} p^{r} q^{s-r}\left[1-(1-p)^{r}\right]}{1-(1-pp)^{s}-psq^{s-1}}$$

The functions for estimate of p and x are:

$$P(r=1) = \frac{spp\left[x+(1+x)\ q^{s-1}\right]}{xspp+(1+x)\left[1-(1-pp)^{s}\right]}$$

$$P(r>1) = \frac{(1-x)\binom{s}{r} p^{r}(1-p)^{s-r}\left[1-(1-p)^{r}\right]}{sppx+(1-x)\left[1-(1-pp)^{s}\right]}$$

U_{π},U_{p}, and U_{x} are the maximum likelihood scores for p, p and x, respectively. If the value of U was negative, the initial estimated value of the parameter should be reduced to fit the observed data, and vice versa.

Complex segregation analysis using REGTL program of S.A.G.E. (Statistical analysis for genetic epidemiology, v3.1. Case Western Reserve University, Cleveland, OH) The REGTL program of S.A.G.E. (1997) (release 3.1) under a Window' s 9x operating system was used to perform complex segregation analysis. This program uses maximum-likelihood methods to estimate parameters of mathematical models of disease occurrence in families. It assumes that under a class A regressive model, a censored trait, such as age of onset to a disease or of the disease susceptibilities, follows a logistic distribution. Sibs are dependent on one another only because of common parentage. Mendelian inheritance, if present, is presumed to be through a single autosomal locus with two alleles, A and B, A being associated with the affected state. The "type" was used to describe the discrete factors that affect a person' s phenotype. The same concept was denoted as "ousiotype". Genotypes are the special case of types, or ousiotypes, that transmit to offspring in Mendelian fashion. Thus we should use the term "type" to allow for any kind of discrete transmission, whether Mendelian or not. Two general models can be assumed. In model 1, the segregation of a possible major locus is allowed for by letting the baseline and age coefficient parameters of the age of onset distribution, but not the susceptibility, depends on an unobserved qualitative factor u=AA, AB, BB. Susceptibility depends solely on randomly distributed environmental characteristics of the population studied. In model 2, type is presumed to influence susceptibility to the affected state, but not the parameters of the age-at-onset distribution, and groups of individuals of different types have the same mean age at onset. Analysis was performed under the model 1 in this study. HCC was represented by a dichotomous variable y, in which y=1 for affected and 0 for unaffected. The following parameters were estimated: type frequencies Ψ_{u} (u=AA, AB, BB. If the type frequencies are in Hardy-Weinberg equilibrium proportions, then they are defined in terms of q_{A}=frequency of allele A), transmission probabilities τ_{u} (the probability that a parent of type u transmits allele A to an offspring, under Mendelian transmission, τ_{AA}=1, τ_{AB}=0.5, τ_{BB}=0), baseline parameter β which can be sex-dependent and/or type-dependent, covariate coefficient ζ_{HbsAg} which is coded 1 if the individual is HBsAg positive and is coded 0 if negative or 9 if unknown. Thus, the coefficient ζ_{HBsAg} is the change in the logit (the risk of HCC) according to the HBsAg status, age adjustment coefficient α, and susceptibility parameter γ which can be sex-dependent. Susceptibility is the probability that an individual is susceptible.

To correct for ascertainment bias, the likelihood of each pedigree is conditioned on the proband' s HCC status by age at exam or death and his or her actual age of onset. This assumes single ascertainment, which is a reasonable approximation since only 1 (0.5 %) of 210 families has more than one patient eligible to be a proband. Under single ascertainment, the probability that any one family will be ascertained is small and proportional to the number of affected children in the family.

As the process of parameter estimate is complex and time consuming when complex models are fitted, a program written in Perl program was used to facilitate the estimate of the initial value of parameters. This program was used to generate random values for the initial estimate of parameters and to call modules in the REGTL program of the S.A.G.E. package to perform segregation analysis. For each model, thirty converged results were saved, among which the best-fitted result of each model was chosen.

Under the model 1, six hypotheses were tested against the likelihood of a general (unrestricted) model, in which all parameters were unrestricted and allowed to fit the empirical data. Thus this general model would give the best fit to the data. The six hypotheses of transmission are as follows: major gene type, Mendelian dominant, Mendelian recessive, Mendelian additive, purely environmental effect and no transmission. Twice the differences between the natural log likelihood (InL) for the data under the hypothesis of interest and that under the unrestricted model is in accordance with χ^{2} distribution, thus it is used to assess the degree of departure from expectation statistically. The degree of freedom (df) for the χ^{2} statistic is given by the differences in the number of estimated parameters between the hypothesis and the unrestricted model. If one or more parameters are fixed at a bound at the end of the estimation process, a range of the df and P values are given when appropriate. A non-significant χ^{2} indicates that the hypothetical model cannot be rejected. When covariates and major gene effects are considered simultaneously, the number of potential hypothesis tests is large and the natural hierarchy of the models may not be clear. In this case, models can also be compared with use of Akaike' s (1974) information criterion (AIC), which is defined as AIC= -2lnL+2×(Number of parameters estimated). A lower value of AIC represents a better fitting model.

RESULTS

Distribution of HCC and HBsAg status among relatives

Of 3 315 individuals in the 210 extended pedigrees, 330 (10.0 %)

including probands were affected with HCC. The distribution of HCC and HBsAg status among the relatives is summarized in Table 1. Among the first-degree relatives, the prevalence of HCC was 6.6 % (100/1511). Among the second-degree relatives, it was 2.1 % (20/945). The prevalence of HCC was 23.1 % (30/130) among the HBsAg positive first-degree relatives, it was 19.2 (5/26) among the HBsAg positive second-degree relative. As shown in Table 2, among the fathers of the probands, the

prevalence of HCC was 5.5 % (11/200). Among siblings, it was 11.1 % (74/664) (16.1 % for brothers, 5.0 % for sisters). Among offsprings, it was 0.2 % (1/448), and among spouses of the probands, it was 1.0 % (2/202).

Parameter estimate in simple segregation analysis by SEGRANB software

The distribution of probands and their affected siblings among the 210 families is shown in Table 3. There was one family with two patients eligible to be a proband. The best fitted probability of ascertainment p was 0.026556, U_p was 6.500244×10^{-3}, χ^2 was 2.848217×10^{-8}. The estimated sets of parameters are shown in Table 4. The best fitted probability of ascertainment p was 0.0266, the segregation ratio p was 0.191, and the proportion of sporadic cases x was 0.465.

Results of complex segregation analysis by REGTL program of S.A.G.E.

Of the 210 families, 48 (22.9 %) had two or more HCC patients. The mean age at onset was 50 (range 21-83). Complex segregation analyses were performed by REGTL under model 1 that did not include regressive familial effects in the models and in which age at onset and susceptibility were not sex-dependent. One environmental covariate, HBsAg status, as a dichotomous variable was included in the models.

In Table 5, the best fitted parameter estimates for general and hypothetical models were reported. As a result, the Mendelian recessive and additive (codominant) hypotheses were not rejected (P>0.1) and the major gene model was marginally not rejected (0.01<P<0.03). All other models were rejected at a 0.001 significance level. According to AIC, Mendelian recessive inheritance was the best-fitted hypothesis, but the AICs for recessive (811.68716) and major gene (812.20661) models were very close. The recessive model suggested that approximately 11.1 % of the population could be expected to carry the candidate gene (or gene pattern). The coefficient of the covariate HBsAg was positive. If its standard deviation is to do the Wald' s test, we got $|\beta_{HBsAg}|/|S_{HBsAg}|$=1.36380/0.40661=3.354>1.96, P<0.05, which suggested that HBsAg seropositive status would increase the risk of developing HCC.

DISCUSSION

In this study, we explored the inheritance mode of HCC in the 210 extended pedigrees in Haimen City by simple and complex segregation analyses. This study used SEGRANB software and REGTL program of S.A.G.E. analyzing a population-based family data set to investigate the presence of a major gene effect for HCC. In simple segregation analysis procedure, as the estimate of segregation ratio p could be substantially affected by the estimated value of the probability of ascertainment p [13,14], especially on complex traits, therefore p was calculated using maximum likelihood method by SEGRANB program in this study. The estimated value of p was 0.0266, which suggested a single ascertainment for this study. Then the segregation ratio and the proportion of sporadic cases were also estimated by maximum likelihood method using SEGRANB. The best-fitted parameter set is shown in Table 4. The segregation ratio was 0.191 and the proportion of sporadic cases was 0.465 for this data, which suggested that HCC did not follow a mono-gene inheritance pattern in this population and environmental factors appeared to influence the development of HCC since 46.5 % of the cases were sporadic.

Due to the modest sample size and relatively high proportion of missed information for the elder generations of the probands in the studied pedigrees, gender and familial residual effects were not estimated simultaneously with other parameters of the corresponding models in complex segregation analysis. The results showed that although both the recessive and additive (codominant) hypotheses could not be rejected, Mendelian autosomal recessive inheritance of a major gene that influenced baseline and age of onset of HCC provided the best fit to the data. The estimated gene frequency under the recessive hypothesis was 0.11138. The result in this study was consistent with the result of an earlier complex segregation analysis by Shen *et al*. (1991) using the POINTER program in which an autosomal recessive major gene yielding lifetime risk of PHC (primary hepatocellular carcinoma) was suggested. In this study, the information of serum HBsAg status for relatives was obtained through the questionnaire and sometimes the report of laboratory test was unavailable. Although this situation could cause miss of information for many individuals in analysis, which might ruin the statistical power, the significance of seropositive HBsAg effect could still be observed. It strongly suggested that chronic HBV infection was a risk factor in developing HCC in this population.

The ultimate test of the utility of segregation analysis is whether the resulting models can be used in linkage analysis to identify disease-susceptibility loci. Although the recessive hypothesis provided the best fit to the data, segregation analysis had its limitation that it could not distinguish the effect of a single locus that underlied a trait from the effects of two or more independently acting loci with similar transmission patterns[15]. Thus, more than one gene, with different penetrances and modes of inheritance, may be involved. Even under oligogenic inheritance, the parameters derived from a single locus segregation analysis can provide power for detecting the susceptibility loci. Many studies have been performed to search for susceptibility genes for HCC[16-29], and several novel genes have been suggested to play a role in HCC development[30-32]. The HCC mortality differs in different areas in China and there are some environmental factors (e.g. local economic status, geographical factors, habit of food consumption and viral infection) that might differ in different areas. With the same environmental exposures, HCC occurrence differs a great deal from family to family, which is typified by the existence of highly aggregated "cancer families". It is hard to say which factor (environmental or genetic) is more important. All can play important roles in the etiology of HCC. The mutation of HCC gene (s) may act as a trigger for HCC onset, or people with the gene (s) may tend to be more susceptible to HCC under the influence of certain environmental risk factors.

In conclusion, our study showed that a Mendelian autosomal recessive major gene might play an important role in the etiology of HCC in a moderately high-incidence area of East China. This study provides some modeling parameters of HCC (in this area) for further linkage studies. The identification of the putative gene detected by the study is warranted.

ACKNOWLEDGEMENTS

This work was supported in part by the National Natural Science Foundation of China (No: 39930160). Some of the results in this paper were obtained by using the program package S.A.G.E., which was supported by a U.S. Public Health Service Resource Grant (1 P41 RR03655) from the National Center for Research Resources. Prof. Fu-Min Shen donated the version of the program package S.A.G.E. used in this study. We thank Dr. Yin Hu of the NCI Center for Bio-informatics for his help on compiling Perl script and on tackling some technical problems.

Abstract

AIM: To investigate the expression of TNF-related apoptosis -inducing Ligand (TRAIL) receptors and antitumor effects of TRAIL in hepatocellular carcinoma (HCC).

METHODS: Expression of TRAIL receptors was determined in 60 HCC tissues, 20 normal liver samples and two HCC cell lines (HepG2 and SMMC-7721). The effects of TRAIL on promoting apoptosis in HCC cell lines were analyzed after the cells were exposed to the recombinant TRAIL protein, as well as transfected with TRAIL-expression construct. *In vivo* effects of TRAIL on tumor growth were investigated by using nude mice HCC model of hepG2.

RESULTS: Both death receptors were expressed in all HCC tissues and normal hepatic samples. In contrast, 54 HCC tissues did not express DcR1 and 25 did not express DcR2. But both DcR were detectable in all of the normal liver tissues. The expression patterns of DR and DcR in HCC samples (higher DR expression level and lower DcR expression level) were quite different from those in normal tissue. DR5, DR4, and DcR2 expressed in both cell lines, while no DcR1 expression was detected. Recombinant TRAIL alone was found to have a slight activity as it killed a maximum of 15 % of HCC cells within 24 h. Transfection of the TRAIL cDNA failed to induce extensive apoptosis in HCC lines. *In vivo* administration of TRAIL gene could not inhibit tumor growth in nude mice HCC model. However, chemotherapeutic agents or anticancer cytokines dramatically augmented TRAIL-induced apoptosis in HCC cell lines.

CONCLUSION: Loss of DcR (especially DcR1) in HCC may contribute to antitumor effects of TRAIL to HCC.HCC is insensitive towards TRAIL-mediated apoptosis, suggesting that the presence of mediators can inhibit the TRAIL cell-death-inducing pathway in HCC. TRAIL and chemotherapeutic agents or anticancer cytokines combination may be a novel strategy for the treatment of HCC.

INTRODUCTION

Apoptosis, the process of programmed cell death, is a fundamental mechanism in developmental and homeostatic maintenance of complex biological systems. Maladjustment or disturbance in apoptotic process will result in transformation and provide a growth advantage to transformed cells. Members of the tumor necrosis factor (TNF) superfamily contribute to a variety of cell biological functions, including cellular activation, proliferation and death, by interaction with their corresponding receptors[1-3]. TNF and fasL have been focused on because of they can induce tumor cells apoptosis, whereas TNF and fas ligand were unlikely to provide useful target neoplastic elimination of tumors cells for two reasons. One is that many tumor cells are resistant to FasL or TNF-mediated cell death, as shown in the present studies, the other is that systemical administeration of TNF and FasL is limited by their acute cytotoxic effects on normal tissues *in vivo*, thereby limiting their widespread use in the treatment of cancer[4-7].

TNF-related apoptosis-inducing ligand (TRAIL), another TNF superfamily member, is a promising cancer therapeutic agent[8]. TRAIL appears to specifically kill transformed cells, and spare most normal cells[9]. TRAIL induces apoptotic death on binding to either of two proapoptosic TRAIL receptors, DR5 or DR4.Normal cells are believed to be resistant to TRAIL because of expressing higher levels of TRAIL decoy receptors DcR1 or DcR2 on their cell surface.

A recent study reported that chemotherapeutic agents could augment TRAIL-induced apoptosis in human hepatocellular carcinoma cell lines, indicating that TRAIL may have therapeutic potential in the treatment of human HCC[28]. In the present study, we investigated the expression of TRAIL receptors and antitumor effects of TRAIL in human HCC, in order to find an effective treatment of HCC.

MATERIALS AND METHODS

HCC and control liver Tissues

Sixty surgically resected specimens employed in this study were obtained from patients with HCC who had undergone potentially curative tumor resection at the Hepatic Surgery Center, Tongji Hospital during January, 2000-December, 2000. All HCC tissues were pathologically confirmed. Tweenty normal liver samples obtained from patients with benign tumor were used as control at the same time. We obtained informed consent from all patients. Resected tissues were frozen immediately at -70 ℃. All cases were selected on the basis of availability of frozen materials for study and in the absence of extensive tumor necrosis. Materials were composed of 5 cases of grade I, 23 cases of grade II, 27 cases of grade III and 5 cases of grade IV according to TNM system (1987). The tumor

lesions analyzed here including 35 poor differentiations, 15 moderate differentiations and 10 well differentiations. There were 53 males and 7 females, and the age was from 18 to 75 years with an average of 45.8 years (s, 13.5 years), HBsAg positive 55 and negative 5. Routinely processed 4 % paraformaldehyde-fixed, paraffin-embedded blocks containing principal tumor were selected. Serial sections of 5 μm thickness were prepared from the cut surface of blocks at the maximum cross-section of tumor.

Cell lines and cell culture

Human HCC cell lines (HepG2, SMMC-7721), Jurkat T-cell line and human colangiocarcinma cell line QBC939 were purchased from ATCC. Cells were cultured in DMEM supplemented with 1 % penicillin/streptomycin and 10 % heat-inactivated fetal calf serum in a 5 % CO_2 incubator at 37 ℃.

Detection of TRAIL-R

The expression of TRAILR1, TRAILR2, TRAILR3 and TRAILR4 in HCC cell lines and human HCC tissues was detected by *in situ* hybridization. Digoxigenin-labeled antisense and sense TRAILR probes were purchased from Boster Biotechnology Inc. *In situ* mRNA expressions were performed according to the manufacturer' s protocol. Deparaffinized, rehydrated tissue sections (5 μM) on silane-coated slides were permeabilized by incubation in proteinase 75 (20 μg/ml) for 30 min at 37 ℃ and acetylated in PBS containing 0.25 % acetic anhydride and 0.1 M triethanolamine for 10 min at room temperature. Prehybridization was carried out in 50 % formamide, 4×SSC, 1×Denhardt' s solution, 125 μg/ml tRNA, and 100 μg/ml freshly denatured salmon sperm DNA for 2-4 h at 42 ℃. Hybridization was performed using prehybridization solution containing denatured TRAILR antisense or sense probes (50 ng/slide) for 36 h at 42 ℃ and followed by washes at 52 ℃ with different solutions (2×SSC and 50 % formamide, 30 min; 1×SSC and 50 % formamide, 30 min; 0.5×SSC and 50 % formamide, 30 min). After that, the sections were incubated in turn in buffer 1 [150 mM NaCl and 100 mM Tris-HCl (pH 7.5)] containing 5 % BSA and 0.3 % Triton X-100 for 30 min and in horseradish peroxidase-conjugated antidigoxigenin antibody diluted 1:500 with buffer 1 containing 5 % BSA and 0.3 % Triton X-100 for 2 h at room temperature. After washed in buffer 1, the sections were immersed briefly in buffer 2 [100 mM NaCl, 50 mM $MgCl_2$, and 100 mM Tris-HCl (pH 9.5)] and incubated in buffer 2 containing 0.025 % diaminobenzidine and 0.02 % H_2O_2 for 15 min at 4 ℃. Finally, the sections were immersed in 10 mM Tris-HCl, 1 mM EDTA buffer (pH 8.0), rinsed in water, and mounted with glycerol mountant.

In vitro effects of TRAIL on cellular apoptosis of HCC

HCC cells were seeded into 96-well microtiter plates with 5×10^3 cells per well and cultured in DMEM supplemented with 10 % fetal calf serum at 37 ℃ under a humidified atmosphere of 5 % CO_2 for 24 h when the cells were in the exponential phase of growth. After treated with TRAIL at the indicated concentration (1, 10, 100, 1 000 ng/ml), the cell viability was assessed with MTT method and the absorbance was measured at 490 nm with a microtiter plate reader. Cell death was estimated with the following formula.

% specific death=A(untreated cells)-A(treated cells)/A (untreated cells)×100.

Results were derived form 3 individual experiments. Each experimental condition was repeated at least in sextuplicate wells for each experiment. We used the same method to detect the effects of TRAIL on Jurkat T-cell line and human colangiocarcinma cell line QBC939.

Construction of TRAIL expression plasmids

The sequence corresponding to the C-terminus extracellular region of 114-281 amino acid (aa) of TRAIL was amplified by PCR, and subcloned into the EcoRV/EcoRI site of expression vector pIRES-EGFP. Following DNA plasmid transfection with superfect reagent for 72 hours, cells were evaluated for apoptosis. The expression of cellular TRAIL protein was verified with Western blot. Briefly, cells were collected by centrifugation at 2 000 g for 10 minutes, cells lysed with lyse cell solution (50 mmol/L Tris-cl, 150 mmol/L NaCl, 0.02 % sodium azide, 0.1 % SDS, 100 ug/ml PMSF, 1 μg/ml aprotinin, 1 % NP-40, 0.5 % deoxysodium cholate), protein in the supernants was separated by 12 % SDS-PAGE and transferred by electroblotting to nitrocellulose membranes. The membranes were blocked by TBST (TBS-Tween) with 5 % non-fat milk, and then incubated with primary antibody (anti-hTRAILmAb) in TBST with 5 % non-fat milk overnight. Proteins were detected with horseradish peroxidase-conjucated secondary antibody and performed chemiluminscence according to the manufacturer' s instructions. MTT assay was used to measure cell viability. The tumor cells were infected with pIRES-EGFP-null as a control.

Flow cytometry

Collected cells were washed with PBS, fixed in 70 % ethanol, digested with RNase A (10 mg/L) in PBS for 30 min and then stained with propidium iodide (PI), and analyzed on a FACScan.

Gene therapy of experimental nude mice subcutaneous hepatocellular carcinoma by direct intratumoral injection of TRAIL gene

5×10^6 HepG2 cells were inoculated subcutaneously into the back of nude mice. One cm tumors were formed in nude mice about ten days after inoculation. Plasmid carrying TRAIL gene was delivered into the tumor by intra-tumor injection (n=10). pIRES-EGFP-null injection as a control (n=10). RT-PCR was adopted to examine the expression of TRAIL gene in tumor. The expression of TRAIL protein was detected by Western blotting. The anti-tumor effect of gene therapy was evaluated according to the sizes of tumors for 4 weeks. Therapeutic effects of TRAIL gene on experimental cholangiocarcinoma induced in nude mice were detected using the same method.

Treatment of HCC cell lines in combination with TRAIL and IFN-γ, IL-2 or chemotherapy drug

HCC cells exposed to IL-2 (different concentrations) combined with recombinant TRAIL protein (50 ng/ml) for 72 h were compared with treatment of TRAIL alone. In the same time, the effect of TRAIL in combination with IFN-γ or chemotherapy drugs (such as mitomycin, 5-fluorouracil) was investigated. Cell viability was examined by MTT assay.

Statistical analysis of data

Quantitative comparisons were performed by Student t test or the chi-square and Fisher exact tests. All statistical analyses were performed using SAS software. Statistical significance was set at 0.05.

RESULTS

Expression of TRAIL-R in HCC cell lines and tissues

DR5 and DR4 were present in all HCC tissue as well as normal hepatic tissues. In contrast, 54 tumors did not express DcR1 and 25 tumors did not express DcR2, but DcR1 and DcR2 were detected in all of the normal liver tissues. The expression patterns of DR and DcR in HCC samples (higher DR expression

level and lower DcR expression level) were quite different from those in normal tissue. DR5, DR4, and DcR2 were expressed, but DcR1 did not express in both cell lines. Expression of TRAIL-R was located mainly in the cytoplasm (Figure 1).

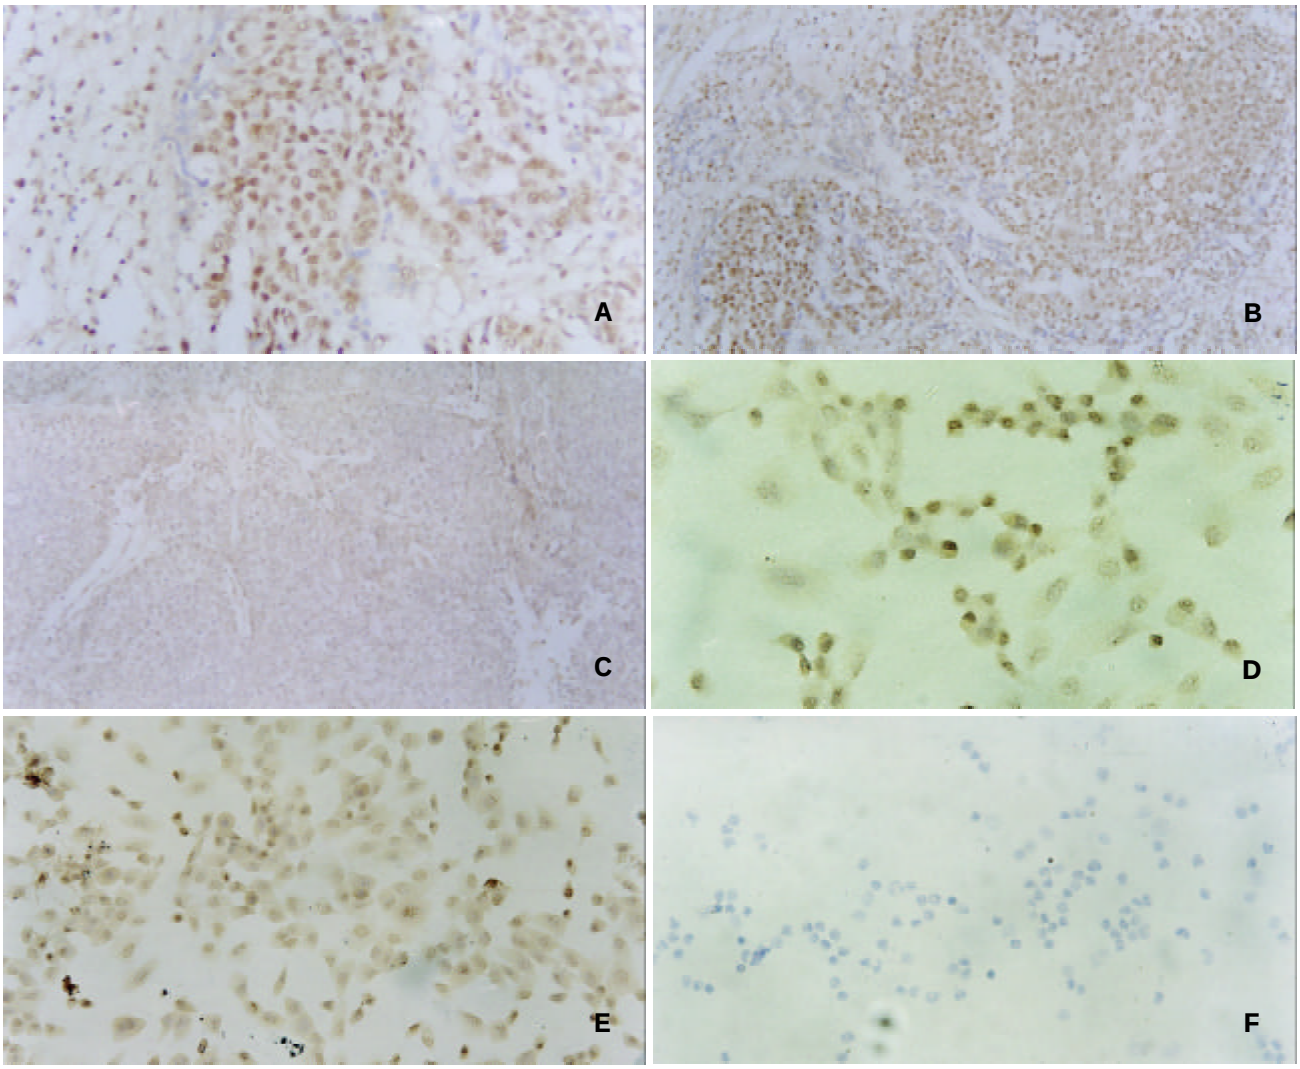

Figure 1 Expression of TRAILR in human HCC tissues and HCC cell lines by *in situ* hybridization. Stronger expression of DR5 (A and D) and DR4 (B and E) as well as negative expression of DcR1 C and F) in both human HCC tissues and HCC cell lines. Note that TRAIL-R staining was found mainly in the cytoplasm and membrane.

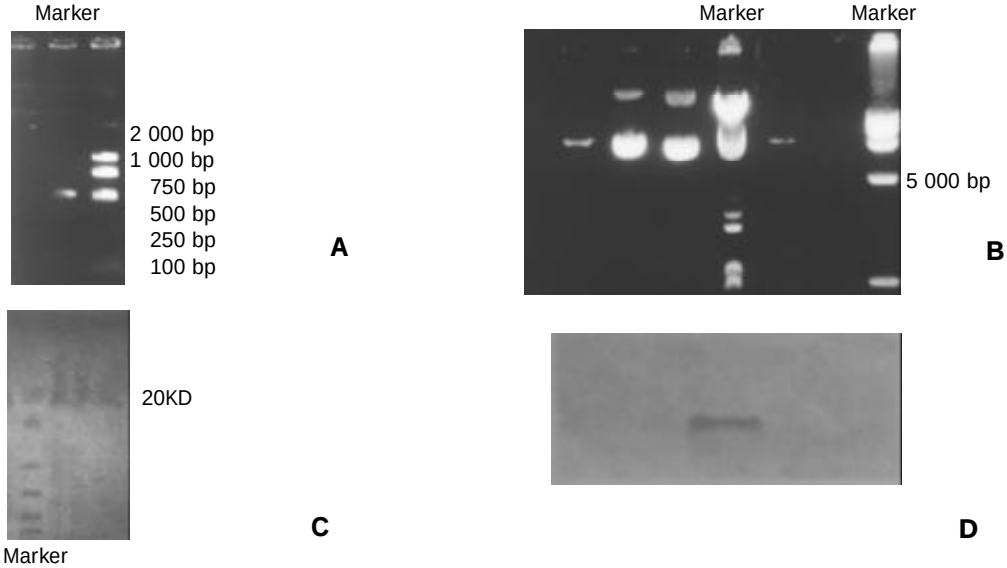

Figure 2 Construction of pIRES-EGFP-TRAIL. A: the C-terminus extracellular region of 114-281 amino acid (aa) was amplified by PCR, including EcoRV / EcoRI at two end, 523 bp. B: TRAIL expression plasmids pIRES-EGFP-TRAIL. C: The cellular proteins were separated by SDS-PAGE. D: Western blot identified expression of TRAIL, negative expression of TRAIL in control.

Production of TRAIL protein

TRAIL expression was assayed by Western blotting as shown, a 19.6 KD band sTRAIL monomers. In contrast, no corresponding bands were present in the negative control. These results demonstrated that the transfection of pIRES-EGFP-TRAIL resulted in transgene expression in human liver cancer cell lines (Figure 2).

Resistance of human HCC cells to both TRAIL and pIRES-EGFP-TRAIL transfection

TRAIL protein alone failed to induce significant apoptosis in both HCC cell lines, even at a dose up to 100 ng/ml, it killed only about 10 % of HCC cells within 24 h, compared with 70 % of Jurkat cells and about 50 % of cholangiocarcinoma cell line QBC939. Production of TRAIL following pIRES-EGFP-TRAIL transfection also failed to lead to tumor cell death. HCC cell lines were adequately transfected with pIRES-EGFP-TRAIL. Minimal cell death of HepG2 cells was observed upon infection with pIRES-EGFP-TRAIL. Analysis of TRAIL protein production by Western blot revealed detectable levels in HepG2 cell lysed by 6h post infection, with levels increasing over the entire time course. These results demonstrated that tumor cells infected with pIRES-EGFP-TRAIL could produce TRAIL protein, however failed to lead to their extensive death (Figure 3).

Effects of gene therapy on experimental hepatocellular caricinoma

Direct intra-tumor injection of pIRES-EGFP carrying TRAIL gene was performed on experimental hepatocellular caricinoma induced in nude mice. RT-PCR was adopted to examine the expression of TRAIL gene in nude mice tumor,the anti-tumoral

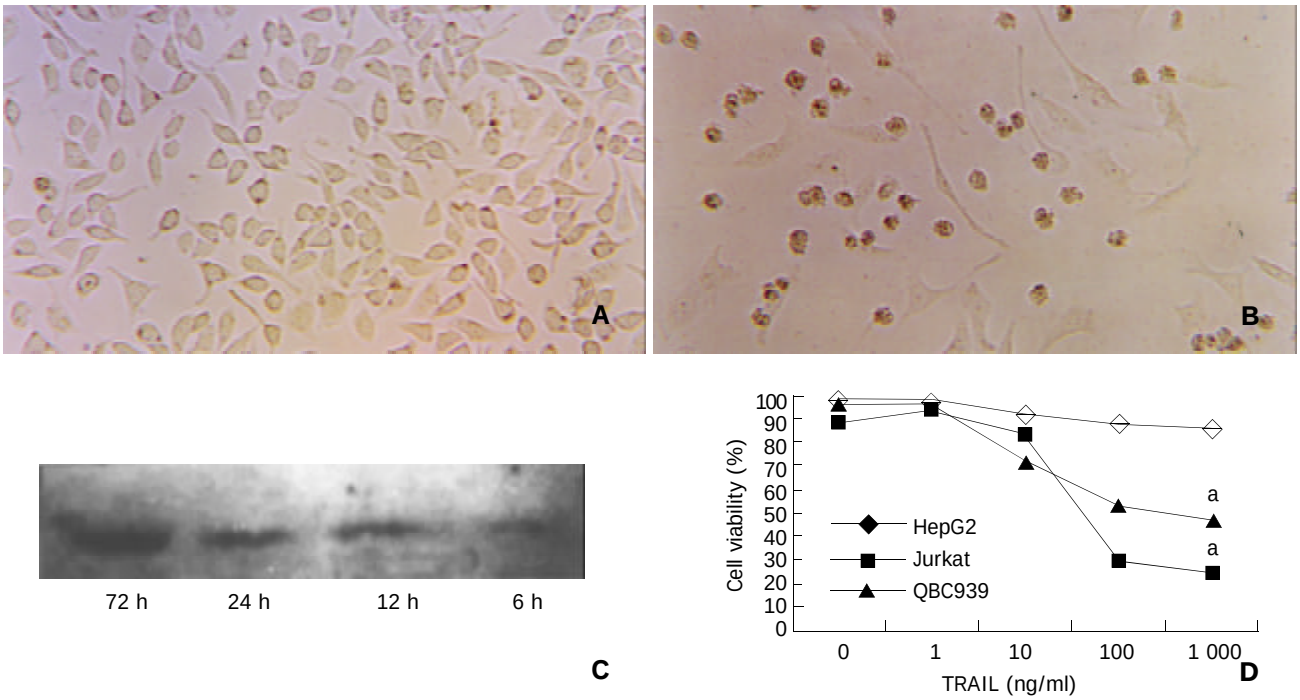

Figure 3 Determination of the percentage of cell viability by *in vitro* administration of recombinant TRAIL.A: Normal HepG2 shapes. B: HepG2 shaped treatment with TRAIL (100 ng / ml, 24 h). C: Western blot analyzed expression of TRAIL protein transfected with pIRES-EGFP-TRAIL (6 h, 12 h, 24 h 72 h). D:Survival of tumor cells treatment with TRAIL, detected by MTT. Each value represents the mean of the three wells. For clarity, SD bars are omitted from the graph, but are less than 5 % for all data points. Experiments were performed at least three separate times with similar results. [a]: Compared with hepG2, statistical significant (P<0.05). The results similar to HepG2 were obtained in SMMC-7721.

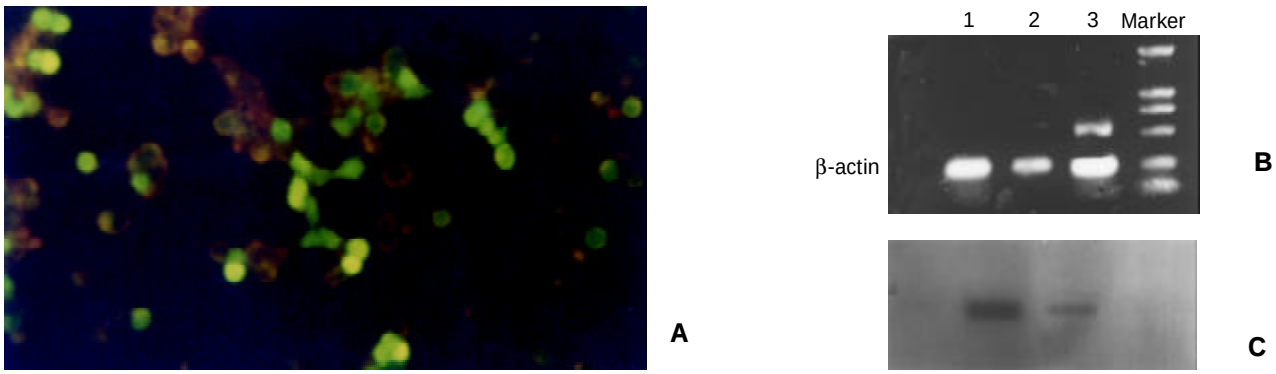

Figure 4 Transfection of pIRES-EGFP-TRAIL *in vitro* and *in vivo*. A: Transfected efficiency observed with fluorescence microscope (*in vitro*). B: The expression of TRAIL gene in nude mice tumor was all relatively strong (*in vivo*). (1), the expression of TRAIL gene in tissue near the tumor was weak (2) and that in normal liver tissue was negative after transfection of TRAIL gene (3). C: TRAIL protein production was determined by Western blot analysis. (a) Nude mice HCC tissue, (b) Adjacent tissue and (c) Normal tissue.

effect of gene therapy was evaluated according to the sizes of the tumors (as shown by Figure 4). Ten days after transfection of TRAIL gene, the expression of TRAIL gene in nude mice tumor was relatively strong, the expression of TRAIL transgene in tissue near the tumor was weaker and that in normal liver tissue was negative.

However, the tumor sizes were slightly less than those in control group (as shown in Table 1). TRAIL gene intra-tumor injection could lead to effective gene delivery and gene expression but had limited effect on experimental HCC in nude mice.

Table 1 Antitumor effects of pIRES-EGFP-TRAIL transfection on tumor growth in nude mice (tumor size $\bar{x}\pm s$, cm)

Target cell	pIRES-EGFP-TRAIL (n=10)	pIRES-EGFP-null (n=10)	P
HepG2	1.05±0.39	1.30±0.27	0.174
QBC939	0.85±0.23	0.32±0.15	0.023

Synergistic induction of apoptosis by combination of TRAIL and chemotherapeutic drugs

We incubated HCC cells with mitomycin (0.001 mg/ml) or 5-fluorouracil (5-Fu) (0.025 mg/ml) in combination with TRAIL (50 ng/ml). Cell viability was examined after 24-72 h. Cytoxicity of the combination of TRAIL and chemotherapeutic agents was compared with either agent alone (Figure 5). Sensitization of HCC cells to TRAIL-inducing apoptosis was independent of p53 status because both HepG2 and SMMC-7721 were similarly sensitized to TRAIL in combination with chemotherapeutic agents, and transfection of p53 could not enhance the sensitivity of SMMC-7721 to TRAIL-inducing apoptosis. The results demonstrated TRAIL could decrease the threshold of some chemotherapeutic drugs 50-100 folds.

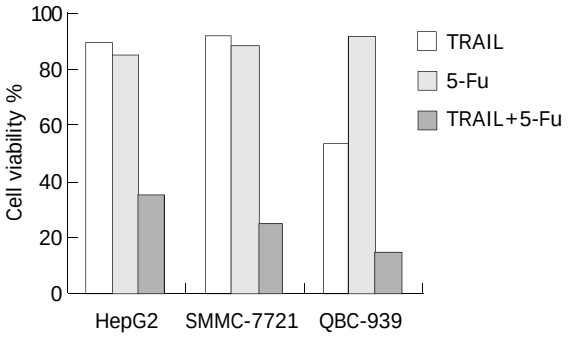

Figure 5 Cell viability of tumor cells incubated with TRAIL in combination with 5-Fu. Cell viability is shown as the percentage of viable cells relative to control cell after 24 h of incubation with TRAIL (50 ng/ml), 5-Fu (0.025 mg/ml) or both. SD bars are less than 5 % for all data points and omitted.

Low dose of interleukin-2 enhanced TRAIL-inducing apoptosis in HCC cells

HCC cells were cultured in the presence of TRAIL or TRAIL plus IL-2 or IFN-γ. Cultures were examined by phase contrast light microscopy at 6, 12, 24, 48, and 72 h. A rounded cytopathic effect was detectable in HCC cell cultures in the presence of TRAIL plus low dose IL-2 after 12 h, but was more prominent after 24 h. Extensive cell death was apparent in HCC cell cultures treated with TRAIL plus IL-2 at 48-72 h. To quantitate the extent of cell death, we measured cell viability treated with IL-2, TRAIL, or IL-2 and TRAIL using MTT. In contrast, HCC cultures treated with IL-2 alone appeared healthy throughout the experiment. Importantly, the death-inducing synergistic effects of TRAIL in combination with IL-2 were not specific to HCC cells, but also induced other tumor cells death (such as cholangiocarcinoma cell line QBC939, data not shown). These data indicated that TRAIL in combination with low dose IL-2 could induce cell death in HCC cells cultures *in vitro*. To our surprise, Low dose of IL-2 significantly enhanced TRAIL-inducing apoptosis in HCC cells after 48-72 h, but high dose of IL-2 only had a weaker role.

To delineate that TRAIL and IL-2 specifically killed HCC cells and spared normal liver cells, we cultured primary normal liver cells and normal fetal liver cell line L02 in the presence of TRAIL and IL-2 for 48 or 72 h. We subsequently determined whether they were undergoing apoptosis. By contrast to HCC cells, normal cells cultured in the presence of TRAIL and IL-2 exhibited no signs of apoptosis. These data indicated that TRAIL in combination with IL-2 could selectively induce apoptosis of HCC cells but not normal liver cells. Furthermore, we obtained similar synergistic results with combination of TRAIL and IFN-γ.

Apoptosis detection by FACScan

Cell death might occue through apoptosis or necrosis. Here, we found that TRAIL could kill HCC cells through apoptosis by FACScan (Figure 6).

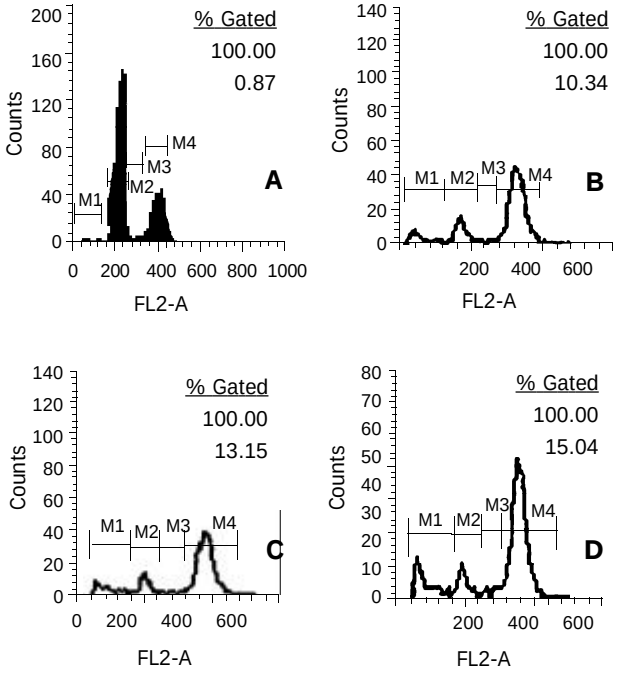

Figure 6 Apoptosis of HepG2 after treatment with TRAIL.A: HepG2 without treatment. B, C, D: HepG2 treatment with TRAIL for 24 h (B, 10 ng/ml. C, 100 ng/ml. D, 1 000 ng/ml). Compared to A P<0.05.

DISCUSSION

To selectively kill target tumor cells and spare normal tissues are one of the ultimate goals of cancer research. TRAIL, a type II transmembrane protein, was initially identified based on the homology of its extracellular domain with FasL, TNF and lymphotoxin-α[8]. TRAIL transcripts have been detected in the adult spleen, thymus, lung, prostate, ovary, small intestine, peripheral blood lymphocytes, colon, heart, placenta, skeletal muscle, and kidney, but not in the adult liver, brain, and testis. Receptors that bind to TRAIL include death receptor (DR) 4/TRAILR1[10], DR5/KILLER/TRAILR2/TRICK2[11-16], decoy receptor (DcR) 1/TRAILR3/TRID (TRAIL without an extracellular domain)/LIT (Lymphocyte Inhibitor of TRAIL)[12-15,19], DcR2/TRAILR4/TRUDD (TRAIL receptor

with a truncated death domain)[19-21] and a soluble receptor called osteoprotegerin (OPG)[22]. DR4, DR5, DcR1, and DcR2 have been shown to bind TRAIL with similar affinities. However, only two of the TRAIL receptors, DR4 and DR5, contain functional death domains and are capable of inducing apoptosis. DcR1, DcR2 are highly expressed in normal tissues, but have substantially lower expression in malignant cells, indicating a low cytotoxic effect in normal tissues. In contrast, DR4 and DR5 are expressed in malignant cells as well as in normal tissues. Despite having multiple receptors, TRAIL can selectively target tumor cells to undergo apoptosis while leaving normal cells unaffected. The selectivity of TRAIL-induced apoptosis has been demonstrated by systemic administration of TRAIL, which reduces tumor growth *in vivo*, without the severe toxic effects often seen in TNF or FasL treated mice. A relatively large number of tumor cell lines, such as leukemia, lymphoma, myeloma, melanoma, breast cancer, colon carcinoma, cholangiocarcinoma or thyroid carcinoma, are sensitive to cytotoxic effects of TRAIL, indicating that TRAIL may be a powerful selective cancer therapeutic [8,21-31].

However, the potential utility and safety of systemic administration of TRAIL have been recently questioned because results showed sensitivity of human but not monkey or mouse hepatocytes to a polyhisidine-tagged recombinant soluble form of TRAIL (amino acids 114-281,114-281TRAIL. his)[32]. Fortunately, another study showed that the toxicity of histidine-tagged TRAIL to human hepatocytes *in vitro* had aberrant biochemical properties, i.e., loss of zinc with the formation of intersubunit disulfide bonds. When this reagent was replaced by a nontagged soluble TRAIL zinc-replete TRAIL (114-281.TRAIL.rs), normal liver cell cytotoxicity was not observed[33-35].

Another potential drawback of TRAIL therapy was that not all cancer cells were sensitive to TRAIL. The regulation of TRAIL signaling is extremely complex, the mechanisms of TRAIL-resistance remain unclear. It has been suggested that the reason why some cells are susceptible to TRAIL while others appear to be resistant lies in the endogenous presence of the non-death-signaling TRAILR[35]. However, examination of various tumor cell types has shown that basal expression of TRAILR did not correlate with susceptibility to TRAIL[36,37]. Alternatively, the presence or absence of intracellular inhibitors of apoptosis such as the cellular inhibitor of caspase 8/FLICE-inhibitory protein (cFLIP) might be important[38-44], and in some circumstances, cFLIP expression did correlate with the susceptibility of tumor cells to TRAIL[37]. It has been found that NF-κB activation also protected cells against TRAIL-induced apoptosis[19]. Taken together, previous studies indicated that TRAIL resistance to apoptosis might be cell-type specific requiring up-regulation or down-regulation of one of the TRAIL receptors, assembly of different receptors, involvement of decoy receptors, and functions of intracellular inhibitors or intracellular anti-apoptotic/survival pathways working in concert. There is long way to clarify TRAIL-resistance mechanisms. How to reverse TRAIL-resistance is also an important topic before TRAIL is developed into an effective anticancer drug. Therefore, as the first step we detected the assembly of different receptors in HCC.

In the present study, both DR were present in all HCC tissue as well as in normal hepatic tissues derived from surgically resected margins of benign tumor. In contrast, 54 HCC tumors did not express DcR1 and 25 HCC tumors did not express DcR2. Both DcR were detectable in all of the normal liver tissues. High expression of DR and low or no expression of DcR in HCC tissue differed from low expression of DR and high expression of DcR in normal hepatic tissues. DR5, DR4, and DcR2 were expressed in both cell lines examined, but DcR1 did not express in both cell lines. Although expressed detectable TRAIL-R1 and -R2, both HCC cell lines showed strong resistance to TRAIL-induced apoptosis. Recombinant TRAIL (100 ng/ml) alone was found to have a slight activity as it killed about 10 % of HCC cells within 24 h compared with over 70 % of Jurkat cells and about 50 % of human cholangiocarcinoma cell line QBC939. Transfection of TRAIL cDNA also failed to induce extensive apoptosis in HCC lines. *In vivo* administration of TRAIL gene could not inhibit tumor growth in nude mice HCC model. These results suggest that some possibly endogenous suppressors of TRAIL-mediated apoptosis might exist in HCC cells. Certainly, components for TRAIL-induced apoptosis existed in these cell lines, and resistance to apoptosis in HCC was more likely mediated by intracellular signaling events than by alternations in receptor expression or the presence of decoy receptors. The mechanisms of TRAIL resistance in HCC should be identified in order to reverse TRAIL resistance.

The pharmacokinetic profile of soluble TRAIL indicated that after iv injection the majority of protein was cleared within 5 hours. Increasing in *vivo* t1/2 of soluble TRAIL or developing an alternative means of delivery may increase the relative tumoricidal activity of TRAIL. Identification of alternate methods to deliver TRAIL to the tumor site is also critical for further developing and testing anti-tumor activity of TRAIL *in vivo*. The results in our work described the production of an expression vector engineered to carry the gene for TRAIL. Shortly after cell tranfection, TRAIL protein was detected, rapidly leading to the induction of apoptosis in TRAIL-sensitive tumor cells (such as cholangiocarcinoma cell line QBC939, data not shown) *in vitro*, indicating the potential of using TRAIL gene and local expression of TRAIL to destroy TRAIL-sensitive tumor cells *in vivo*. As for TRAIL resistant tumor cells, effective treatment would be attached by new therapy strategies such as combining gene therapy.

How to reverse TRAIL-resistance is an important topic before TRAIL is developed into an effective anticancer drug. Consistent with several previous reports, our results showed that chemotherapeutic agents significantly sensitized HCC cell lines to TRAIL-induced apoptosis. TRAIL could decrease the threshold of some chemotherapeutic drugs 50-100 flods. The mechanism of overcoming tumor resistance to TRAIL-induced apoptosis by chemotherapeutic agents must be reserved for further investigation. Therefore, our results also showed that cytokines that compose part of the arsenal of the immune system against tumors might alter HCC sensitivities to TRAIL, For example, a subtoxic level of interlukin-2 could overcome the resistance of HCC cells. No significant apoptosis was induced in cells pretreated with IL-2 alone even at 10 000 unit/ml, and TRAIL (50 ng/ml) induced 10 % cell death after 24 h treatment. However, HCC cells treated with IL-2 (50 unit/ml) in combination with TRAIL (50 ng/ml) were killed about 50 % at 48 h, indicating that IL-2 could sensitize HCC cells to TRAIL-induced apoptosis. The effect of IL-2 which enhanced TRAIL-mediated apoptosis was not dose-depent, low dose IL-2 had a stronger sensitizing effect while high dose IL-2 had a weaker role. HCC cells could become sensitive to TRAIL-mediated cell death after treatment IFN-γ, too. The possible explanations for these effects are that IFN-γ could induce TRAIL expression, up-regulate DR and Caspase 8, significantly decrease NF-κB-activation, and prevent IAP2[45-48]. These findings have therapeutic implications because resistance to apoptosis in HCC cells may be dramatically overcome by agents used in combination.

In summary, TRAILR expression is prevalent in HCC and there is a different expression of receptor types in HCC cells compared with normal hepatic tissue. HCC cells are insensitive

to TRAIL-mediated apoptosis, suggesting the presence of mediators can inhibit the TRAIL-inducing apoptosis pathway in HCC and has a limited therapeutic role for TRAIL as a single agent in HCC. However, TRAIL-based tumor therapy in combination with chemotherapeutic agents or anticancer cytokines might be a powerful treatment for HCC.

Abstract

AIM: To investigate the inhibitory effect of serum preparation from rabbits orally administered cobra venom (SRCV) on implanted hepatocellular carcinoma (HCC) cells in mice.

METHODS: An HCC cell line, HepA, was injected into mice to prepare implanted tumors. The animals (n=30) were divided randomly into SRCV, 5-fluorouracil (5-FU), and distilled water (control) groups. From the second day after transplantation, 20 mg/kg 5-FU was administered intraperitoneally once a day for 9 days. SRCV (1 000 mg/kg) or distilled water (0.2 mL) was given by gastrogavage. Tumor growth inhibition was described by the inhibitory rate (IR). Apoptosis was detected by transmission electron microscopy (TEM), flow cytometry (FCM), and terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling (TUNEL). Student's t-test was performed for statistical analysis.

RESULTS: The tumor growth was inhibited markedly by SRCV treatment compared to that in the control group (P<0.01). The treatment resulted in a significant increase in the apoptotic rate of cancer cells by the factors of 10.5±2.4 % and 20.65±3.2 % as demonstrated through TUNEL and FCM assays, respectively (P<0.01). The apoptotic cells were also identified by characteristic ultrastructural features.

CONCLUSION: SRCV can inhibit the growth of implanted HepA cells in mice, and the apoptosis rate appears to elevate during the process.

INTRODUCTION

Snake venoms are complex mixtures of pharmacologically active polypeptides, some are of potential therapeutic value for embolism, cancer and other severe human disorders. Several snake venoms and their components have been demonstrated to be able to inhibit tumor growth and to induce apoptosis of neoplastic cells *in vitro* and *in vivo*[1-7]. We prepared a serum preparation from rabbits administered cobra venom (SRCV)[8]. Our *in vitro* studies have shown its growth-inhibitory and apoptosis-inducing effects of SRCV on cancer cells[9]. In the present study, we observed its effects *in vivo* using implanted hepatocellular carcinoma (HCC) cell line HepA in mice.

MATERIALS AND METHODS

Drugs and reagents

5-FU was purchased from Nantong Pharmaceutical Co (Cat. No. 001121; Nantong, Jiangsu, China). SRCV was prepared as described previously[8]. Briefly, the rabbits were given oral Chinese cobra (*Naja naja atra*) venom 45 mg/kg (Guangzhou Research Institute of Snake Venom, Guangzhou, Guangdong, China) once a day for 3 days. Serum was collected from the rabbits at 4 h after the last administration, then heated in a water bath for 30 min at 56 ℃, frozen at -20 ℃, lyophilized using a vacuum drier and stored at 4 ℃.

Animals

Female Kunming mice (18-22 g, No. 26-2002A002) were supplied from the Medical Animal Center of Guangdong Province. All animals were fed on basic diet and water. The cell line HepA was provided by the Cancer Institute of Sun Yet-Sen University.

Experimental schedule

As described previously[10,11], HepA cells, 2×10^7/mL, were injected subcutaneously into mice, 200 μL for each. Thirty Kunming mice with implanted HepA tumor were divided randomly into SRCV-, 5-FU-treated groups and control group. From the second day after the implantation, 20 mg/kg 5-FU was administered intraperitoneally once a day for 9 days. SRCV (1 000 mg/kg) or distilled water (0.2 mL, control group) was given by gastrogavage. The mice were sacrificed at 24 h after the last administration. The tumors were isolated and weighed immediately in order to calculate the inhibitory rate (IR) according to the formula: IR of tumor (%)=(1-tumor weight in test groups/mean tumor weight in control group)×100 %. Then, the tumors were fixed and used for transmission electron microscopy (TEM), flow cytometry (FCM) and terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling (TUNEL). All of the tests were repeated twice.

Morphological analysis of apoptosis

Dissected tumor samples were fixed with 2.5 % glutaraldehyde for 1 h. After washed three times in a buffer, the samples were post-fixed in 1 % OsO_4 in a cacodylate buffer for 1 h, then dehydrated in graded ethanol and embedded in epoxy resin (Agar 100). Thin sections (70 nm) were stained with uranyl acetate and reynolds lead citrate and examined at 75 kV in an electron microscope (JEM-100CX 11/T). Morphological changes in the nuclear chromatin of cells undergoing apoptosis were detected by TEM.

Flow cytometry analysis

Cell apoptotic rate was quantitatively determined by flow cytometry. The percentage of cells with a sub-G1 DNA content was taken as the fraction of apoptotic cell population[12,13]. According to the procedure described previously[14-16], tumor tissues were sliced at a thickness of 400-500 μm, then the slices were gently pulverized using a mortar and pestle in phosphate-buffered saline (PBS) (pH7.2). The cell suspension was infiltrated through 200 and 350 μm meshes to remove residues. The cells were collected by centrifugation at 2 000 rpm for 10 min. The cell suspension was fixed in 70 % ice-cold ethanol in PBS, and stored at -20 ℃. Prior to analysis, the cells were washed and resuspended in PBS, then incubated with 10 mg/mL RNase A for 3-5 min and 50 μg/mL propidium iodide (PI) at 4 ℃ for 30 min in a dark chamber. The apoptotic cells having DNA strand breaks that had been labeled were detected by a flow cytometer (FACSCan, Becton Dickinson, San Jose, California, USA).

TUNEL reaction

An ApopTag plus peroxidase *in situ* apoptosis detection kit (Intergen Co Ltd., Burlington, Massachusetts, USA) was used to visualize the cells with DNA fragmentation. The procedure was performed following instructions of the manufacturer and in reference of the previous observations[17-19]. Briefly, 4-μm thick sections were dewaxed and hydrated, treated with 20 μg/mL proteinase K for 15 min at 37 ℃, equilibrated in a buffer for 5 min at room temperature, and incubated in a buffer containing terminal deoxynucleotidyl transferase (TdT) enzyme for 1 h in a humidified chamber at 37 ℃. The reaction was demonstrated by incubation with anti-digoxigenin-peroxidase for 30 min in a humidified chamber at room temperature and visualized in a buffer containing diaminobenzidine (DAB).

The positive cells were identified, counted and analyzed based on morphological characteristics of apoptotic cells as previously described[17]. Under the light microscope, apoptotic cells manifested as brownish staining in the nuclei. Non-necrotic zone was selected in the tissue section and images were randomly selected. At least 1000 tumor cells were counted, and the percentage of TUNEL-positive cells was determined.

Statistical analysis

The data shown were mean values of 8-10 samples and expressed as mean ± standard deviations. Student' s *t*-test was performed for statistical analysis. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Anti-tumor effect of SRCV on implanted HepA tumor

In two separate experiments, the IRs were 30.4 % and 35.8 % after treatment with SRCV. The data, listed in Table 1, demonstrated the inhibitory effect of SRCV treatment on implanted HepA tumor growth, though it was not as strong as that of 5-FU.

Apoptosis - inducing effect of SRCV in mice with implanted HepA tumor

The apoptosis-inducing effect of SRCV was confirmed by electron microscopy. Compared with control group (Figure 1A), morphological changes indicative of apoptosis included cell shrinkage, nuclear chromatin condensation and peripheral shift of condensed chromatin to nuclear membrane or formation of crescent. In addition, the nuclear membrane was intact and there was little or no swelling of mitochondria or other organelles (Figure 1B).

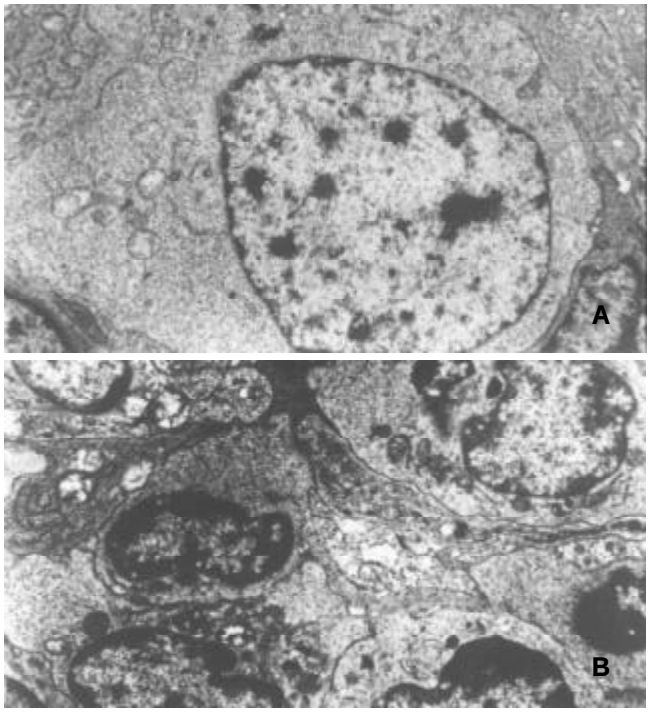

Figure 1 Morphological changes characteristic of apoptotic cells under transmission electron microscope in implanted tumors after treatment with SRCV. A: The normal tumor cells in distilled water control group (×5000). B: The apoptotic cells in SRCV group (×5000).

Table 2 Apoptotic rates (AR) of implanted tumor in SRCV treated mice determined by TUNEL and FCM methods (n=8, $\bar{x}\pm s$)

Groups	Mean apoptotic rate ± SEM (%)	
	TUNEL	FCM
SRCV	10.50±2.42[b]	20.65±3.2[b]
Control group	1.67±1.3	2.28±1.54

[b]P<0.01 *vs* control group.

The apoptosis-inducing effect of SRCV was further confirmed by FCM and TUNEL. After treatment with SRCV, the apoptotic rate was significantly increased in the SRCV group compared with the control group (Table 2). In TUNEL

Table 1 Anti-tumor effect of CVSR on implanted HepA tumors in mice (n=10, $\bar{x}\pm s$)

Group	Dose	Tumor weight/(g)		Inhibition rate (%)	
		First	Twice	First	Twice
SRCV	1 000 mg/kg	1.14±0.28[a]	1.14±0.13[a]	30.35±17.07	35.83±7.11
5-FU	20 mg/kg	0.78±0.14[a]	0.99±0.22[a]	52.57±8.56	44.39±10.5
Control	0.2 ml	1.63±0.26	1.78±0.47		

[a]P<0.01 *vs* control group.

assay, induction of apoptosis was represented by an increase in DNA fragments detected by a peroxidase reaction (Figure 2A), and the apoptotic cells in control tumors were scarcely scattered (Figure 2B).

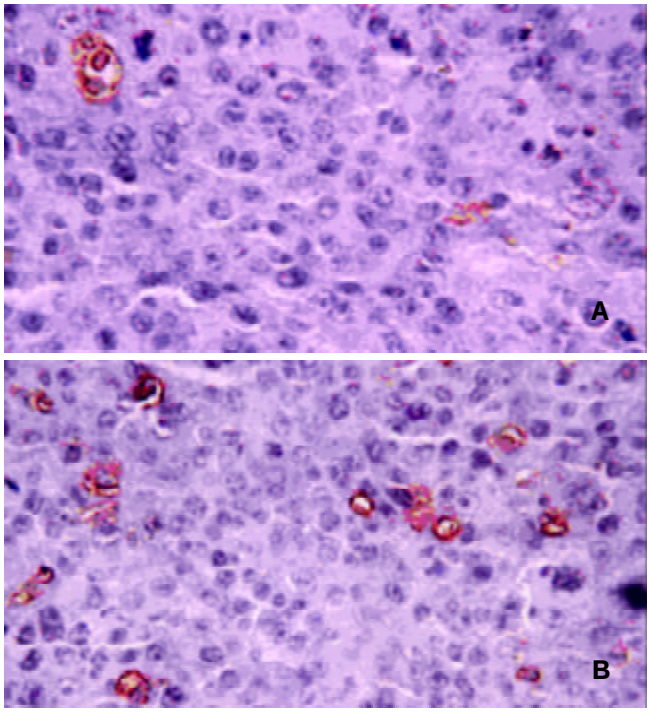

Figure 2 Apoptotic cells of implanted HepA tumors in SRCV treated mice detected by TUNEL assay. A: control group (× 400), B: SRCV 1 000 mg / kg group (×400).

DISCUSSION

Snake venoms have inhibitory effects on the growth of a variety of tumors *in vitro* and *in vivo*[20,21]. Markland *et al*. found that contortrostatin (CN), a homodimeric disintegrin from southern copperhead venom, inhibited dissemination ovarian cancer in a nude mouse model[22]. According to Da Silva *et al*., *Bothrops jararaca* venom (BjV) had anti-tumor effects on Ehrlich ascites tumor (EAT) cells in *vivo* and *in vitro*[23].

Snake venom was also shown to induce apoptosis in tumors. Apoptosis, in contrast to necrosis, was an active process of gene-directed cellular suicide[24]. It has been clear that apoptosis is often upregulated in tumor by many anticancer drugs[25-32].

Since Araki *et al*. first described that hemorrhagic snake venoms induced apoptosis in vascular endothelial cells (VEC)[33], data have been accumulated rapidly about apoptosis-inducing action of various snake venoms and their active components. In 1994, Strizhkov *et al*. reported that both neurotoxin II (NT II) from venom of *Naja naja oxiana* and 20-30 kDa proteins partially purified from pig brain (NTlm) cross-reacting with antibodies to NT II were cytotoxic to L929 and K562 tumor cells at concentrations of 10^{-6}-10^{-8} M, and induced apoptosis in L929 and K562 cells *in vitro*[34]. After that, L-amino acid oxidase (LAO) was found to induce apoptosis in human embryonic kidney cell line 293T[35] and human monocyte line MM6[36]. Recently, Araki *et al*.[37] and Masuda *et al*[38] associated integrins with vascular apoptosis-inducing protein 1 (VAP1)-induced apoptosis. Data from Zhao *et al*. indicated that snake venom secreted phospholipase A_2 ($sPLA_2$) induced apoptosis in Mv1Lu cells in a dose- and time-dependent manner, and was associated with a rapid increase in intracellular ceramide level[39].

The clinical trial using snake venom and their active components have succeeded in cancer therapies, but its application was confined to the auxiliary treatment of patients in the late stage[40,41]. Its toxic and side effects were unavoidable. Great efforts have been made[42-45], but the problem remains unresolved. So a long-standing goal in snake venom therapy of cancer is to find a stable, low toxic, highly effective chemotherapeutic agent that selectively targets tumor cells. Based on this idea, we prepared the SRCV agent[8].

In our previous studies, the anti-tumor activity and apoptosis-inducing effect of SRCV were shown *in vitro* using HepG-2, HL-60 and human lung adenocarcinoma cell line, and no cytotoxicity was observed on human fetal lung fibroblast cells[46-48]. The results presented herein demonstrate that SRCV has inhibitory and apoptosis-inducing effects on implanted HepA tumors. Further studies are needed to identify the active components of SRCV and to elucidate their underlying mechanism.

Abstract

AIM: After transarterial chemoembolization (TACE), the residual cancer cells are under extensive hypoxic or even anoxic environment. Hypoxia can lead to adaptive responses. For example, angiogenesis will help these cells survive. In this study, we examined the effect of TACE on angiogenesis and expression of vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (b-FGF) and to assess their relevance to Walker-256 transplanted hepatoma.

METHODS: Male Wistar rats were inoculated with Walker-256 tumor in the left lobe of liver. Angiography and transarterial chemoembolization were performed at d14 after transplantation. Sixty rats bearing walker-256 transplanted hepatoma were randomly divided into control group, arterial infusion group and TACE group. Each group consisted of twenty rats. Normal saline, 5-Fu, 5-Fu and lipiodol were infused through hepatic artery respectively. Two weeks after the infusion, staining of factor VIII, VEGF and b-FGF was performed by immunohistochemistry method in routine paraffin-embeded sections. Microvessel density (MVD) was counted in endothelial cells with positive factor VIII. Their expression levels were analyzed in conjunction with the pathologic features.

RESULTS: While a smaller tumor volume was found in TACE group (F=37.818, P<0.001), no statistical differences between MVD and expression of VEGF and b-FGF were found among the 3 groups. MVD of the control group, chemotherapy group and chemoemoblization group was 80.84±24.24, 83.05±20.29 and 85.20±23.91 (F=0.193, P=0.873), respectively. The positive expression of VEGF and b-FGF was 75 %, 75 %, 85 % (χ^2=0.449, P=0.799) and 30 %, 25 %, 30 % (χ^2=0.141, P=0.922), respectively. Statistical analysis revealed a positive correlation between the expression of VEGF and MVD (r=0.552, P<0.001).

CONCLUSION: There has been little influence of lipiodol chemoembolization on the formation of tumor angiogenesis, but the development of neovascularization and expression of VEGF play important roles in establishment of collateral circulation and reconstruction of blood supply of residual cancer tissue.

INTRODUCTION

Transarterial chemoembolization (TACE) has been widely practiced in the treatment of unresectable hepatocellular carcinoma (HCC)[1-5], but long-term TACE therapy was as yet unsatisfactory[6-8]. Histopathologic examination showed although TACE could induce significant necrosis, yet complete tumor necrosis was rare, the residual tumor cells remained viable in the peripheral region, which may play an important role in local recurrence or as a source of metastasis affecting the long-term efficacy of TACE[9-11].

Tissue in hypoxic environment is common in both experimental and human solid tumor[12]. Hypoxia cells have reduced metabolic rate, reduced transcription and translation, even cell cycle arrest. Hypoxia can inhibit cell division or even lead to cell death[13]. But body compensatory reaction can also lead to a wide range of responses including angiogenesis, anti-apoptosis gene expression and changes in metabolic rate at both systemic and cellular levels[14,15]. After TACE, the tumor cells are under extremely hypoxic or even anoxic environment. It is possible that some adaptive responses to hypoxia will help these cells survive, but to our knowledge, studies regarding these are very few.

Recent studies revealed that TACE might enhance the expression of VEGF in meningiomas[16,17]. In the study of hepatoma, TACE could enhance the expression of VEGF[18-21], but not the MVD level[22] or expression of b-FGF[19,22]. All these studies were retrospective.

Walker-256 transplanted hepatoma is a useful model for the study of cancer therapy[20,23,24]. In hepatic arteriography, the tumor is usually hypervascular and receives its blood supply almost exclusively from hepatic artery just as that seen in human HCC[23]. Our study was designed to observe the influence of TACE on the *expression of angiogenesis, VEGF and b-FGF and to assess their relevance to Walker-256 transplanted hepatoma.

MATERIALS AND METHODS

Walker-256 tumor inoculation into the rat livers

Walker-256 carcinoma cells (Cell Preserve Center, Wuhan University, Wuhan, P.R.China) were inoculated subcutaneously

in intact rats. Male Wistar rats (200-250 g) were anesthetized with pentobarbital sodium (30 mg/kg ip), then the tumor was inoculated as described in our previous study[23]. Walker-256 carcinoma cells were inoculated into the subcapsular parenchyma of the left lobe of liver.

Experimental methods

Fourteen days after transplantion, a second laparotomy was performed. A 0.6 mm polyethylene catheter was inserted into the gastroduodenal artery and fixed by a suture. The common hepatic artery and right hepatic artery were temporarily ligated during injection of the drugs. In this study, sixty rats were randomly divided into three groups, twenty rats each group (Table 1).

Table 1 Drug administration in the three groups

Group	Drug administration
Control	0.3 ml normal saline
Arterial infusion (AI group)	5-fluorouracil (5-FU) 20mg/kg
Transarterial chemoembolization (TACE group)	lipiodol ultra-fluis (Andre Guerbet Laboratories, Aulnay-Sous-Bios, France) 0.5ml/kg and 5-Fu 20mg/kg

Tumor volume and degree of tumor necrosis

MR images were performed on 1.5-Tesla system (Siemens Vision, Siemens, Germany) supplemented with a cervical coil. T1-weighted (TR/TE, 450/12 msec) and T2-weighted (TR/TE, 2 800/96 msec) transverse SE images (slice thickness 2 mm) were obtained by acquisition times of 7:25 min and 6:16 min, respectively.

The tumor volume was determined by MR measurements of the largest and smallest diameters and calculated according to the following formula: Tumor volume (mm^3)=largest diameter (mm)×[smallest diameter (mm)]^2/2.

Fourteen days after TACE, hepatoma specimens were obtained and fixed in 10 % formalin for 12 hours, then embedded in paraffin according to routine procedures. The histological sections were stained with hematoxylin-eosin (HE) for observation under light microscopy and measurement of the extent of tumor necrosis.

Immunohistochemistry

Immunohistochemistry was performed in sections from a selected block of each specimen. 5-μm thick sections mounted on 3-aminopropyltrietoxysilane-coated slides were dewaxed in xylene and rehydrated at graded concentrations of alcohol. Endogenous peroxide was blocked with 0.6 %H_2O_2 for 20 min. Then the sections were pretreated in a microwave oven in citrate buffer for 15 min at 95 ℃. Thereafter, the slides were processed according to the standard methods with ABC kit. The primary antibody used was polyclonal antibody of von-Willebrand factor at dilution of 1:100, polyclonal antibodies to VEGF and b-FGF at dilution of 1:50. All these antibodies were from Santa Cruz Biotechnology; Santa Cruz, Calif USA. Diaminobenzine was used for the coloration development. Negative controls were generated by substituting the primary antibody with distilled water.

Determination of MVD

The tumors were frequently inhomogeneous in their microvessel density. For determination of MVD, the five most vascular areas within a section were chosen and counted under a light microscope with a 200-fold magnification as described by Weidner[25]. A brownstain structure clearly separated from the adjacent microvessels was regarded as a single countable microvessel. The average count was recorded as MVD for each case.

Determination of VEGF and b-FGF expression

The counting of VEGF and b-FGF immunoreactive cells was made by scanning and scoring of five high-power fields using ×400 magnification. Positive VEGF and b-FGF were recognized as intensely stained in tumor cell cytoplasm.

The expression of VEGF was semi-quantitatively evaluated as follows. Those having positive staining less than 5 % were regarded as -, between 5 % and 15 % as +, between 15 % and 50 % as 2+, and greater than 50 % as 3+. The b-FGF immunostaining was evaluated by a qualitative method as follows. Positive staining less than 10 % was regarded as negative, greater than 10 % as positive.

Statistical analysis

Statistical analysis was carried out by SPSS packed program. Variance tests, chi-square tests, Mann-Whitney test and linear regression test were used. P value <0.05 based on a two-tailed test was considered statistically significant.

RESULTS

Histopathology findings in tumor

Hematoxylin-eosin (H&E) stained sections of the liver specimens showed poorly-differentiated carcinomas, which were apparently spherical or ovoid in shape. The tumor cells were arranged irregularly with hyperchromatosis, polymorphism and numerous mitoses. The mass was sharply demarcated from the surrounding normal parenchyma, its capsule was thin and composed of collagen fibers caused by tumor compression. The tumor showed inhomogeneous hypervascularization consisting mainly of small arteries and capillaries. Satellite nodules or portal vein tumor thrombus could be seen in some rats.

In TACE group, examination of the sections showed extensive central necrosis of the tumor in all cases. The central necrosis enlarged to moderate (16/20) or severe degree (4/20). Intra-tumoral hemorrhage or bile stases were seen in some, but the tumor cells tended to remain viable at the periphery of the nodules 2 weeks after embolization therapy. We also found thick fibrous capsules with chronic inflammatory and cells infiltration. Various degrees of degeneration and necrosis were seen in normal hepatic parenchyma adjacent to the tumor. In the control and AI groups, the interior of the tumor had many viable tumor cells with spotty and scattered necrosis, the capsules were thin and composed of collagen fibers. Tumor volume and tumor growth rate before and after therapy are listed in Table 2.

Table 2 Tumor volumes and tumor growth rate before and after therapy ($\bar{x}\pm s$)

Group	Tumor volume (mm^3)		Tumor growth rate(%)
	Before therapy	2 weeks after therapy	
Control	195.6±65.9	963.6±214.8	459.2±52.7
AI	218.9±48.7	868.9±179.8	412.2±18.9
TACE	210.2±59.2	356.5±78.4	173.4±20.4
F value	0.272	37.818	197.932
P value	0.764	<0.001	<0.001

Microvessel counts

The von Willebrand Factor (Factor-VIII) antibody gave an intense staining of the vascular endothelial cells (Figure 1). A substantial inhomogeneity in microvessel counts was found

Table 3 MVD counts, expression of VEGF and b-FGF in each group

Group	*n*	MVD ($\bar{x}$±*s*)	VEGF					b-FGF	
			0	+	++	+++	Mean	0	
Control	20	80.80±20.94	5	8	5	2	1.2	14	6
AI	20	83.55±18.26	5	7	6	2	1.25	15	5
TACE	20	85.20±23.91	3	9	5	3	1.4	14	6
Statistic value		*F*=0.193			χ^2=0.449			χ^2=0.141	
P value		*P*=0.873			*P*=0.799			*P*=0.922	

in different areas in the same section. In TACE group, the positive factor VIII cells were found focusing in the newly formed tumor. The MVD of each group is shown in Table 3.

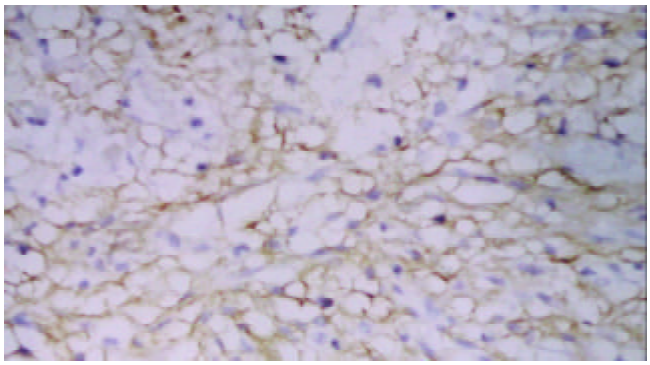

Figure 1 Positive factor-VIII endothelial cells in tumor nest (SABC ×100).

VEGF protein expression and its correlation with MVD

Immunohistochemical staining of VEGF showed strong immunoreactivity in tumor cells and vascular endothelial cells within the tumor tissues (Figure 2). In contrast, non-neoplastic hepatocytes showed weak staining. The staining of VEGF was inhomogeneous. In the sections after TACE, at the tumor nests, boundary of necrotic and non-necrotic area and pericapsular area, VEGF positive tumor cells were relatively easy seen. The expression of VEGF in each group is shown in Table 3.

Linear regression analysis showed a clear correlation between tumor MVD and VEGF protein expression (r=0.452, P<0.01). The MVD counts in negative and positive VEGF groups were 67.86±11.66 and 87.36±22.97 (per high power field), respectively (Table 4).

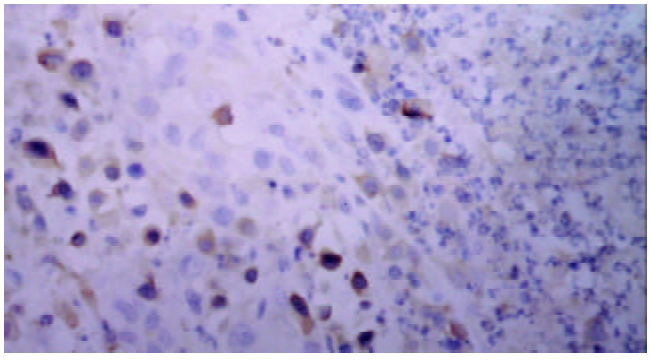

Figure 2 Positive VEGF cells in newly formed tumor nest after TACE (SABC ×200).

b-FGF protein expression and its correlation with MVD

b-FGF protein was identified sporadically in tumor tissues. No statistical differences were found between these groups (P=0.922) (Table 3). There was no correlation between b-FGF and MVD counts (r=0.036, P=0.786).

Table 4 MVD count in negative and positive VEGF groups after TACE

Expression of VEGF	*n*	MVD (per high power field) ($\bar{x}$±*s*)
Negative group	13	67.86±11.66
Positive group	47	87.36±22.97
T value		2.543
P value		0.014

DISCUSSION

Angiogenesis is an inherent property of tumor. It is important in its development and progression. Among many solid tumors, the degree of tumor angiogenesis was closely related to its biological behaviors, which reflect its ability for infiltration, recurrence and metastasis[26-30]. Intratumoral microvessel density (MVD) is commonly used to assess angiogenic activity. Defining and measuring MVD in the residual tumor cells after TACE might help judge the blood supply of residual tumor tissue and prognosticate the activity of these cells to a certain extent indirectly[31].

TACE could hardly abolish tumor blood supply. The possible causes included: incomplete embolization or partial recanalization of the artery, presence of intrahepatic porto-arterial shunt, formation of collateral circulation, and opening of potential communicating vessels[9,32,33]. The present study suggested that neovascularization and expression of VEGF might be another important factor. At the newly formed tumor nests, abundant factor VIII and positive VEGF cells could be found, and slight necrosis was seen in regions that had abundant neovasculature. These suggest that neovascularization plays an important role in the formation of collateral circulation, and relatively abundant blood supply will help tumor cells escape from the damage by TACE and increase the opportunity of survival.

Some authors considered that TACE might increase the chance of tumor recurrence or metastasis[20,34,35], which might be related to hypoxia caused by TACE and increased level of angiogenesis due to hypoxia[36-38]. The present study showed that MVD of TACE group was slightly higher than that of the control group and AI group, but no statistical difference was found, suggesting that TACE would not increase the level of tumor angiogenesis. Although the exact mechanism is currently unclear, we consider the possible explanation would be that the tumor cells were in an extreme hypoxia or even anoxia environment for a longer duration after TACE, which resulted in extensive necrosis and apoptosis of timorous and endothelial cells and decrease of secretion of angiogenic factor and weakening of the paracrine effect.

The intratumoral distribution of tumor neovasculature was inhomogeneous after embolization therapy. The newly formed blood vessels were less in the center of tumor but much more in the periphery and subcapsular area. This phenomenon might be related to the characteristics of tumor blood supply. Although blood supply of the tumor mainly came from hepatic artery, the peripheral area also received portal blood. There

were potential collateral circulations both between the artery-portal veins and between the lobular arteries. After TACE, the portal blood supply increased with opening of collateral circulation, the blood supply of the peripheral region of the tumor restored more easily.

A balance between angiogenic and angiostatic factors regulates the angiogenesis. These factors may be produced either by tumor cells or host cells. The most commonly studied angiogenic factors were VEGF and b-FGF. VEGF could stimulate endothelia cells to proliferate, migrate, and alter their patterns of gene expression, increase microvascular hyperpermeability, extravasate plasma proteins into extravascular space and induce plasma-derived matrix[39,40]. VEGF played a key role in tumoral angiogenesis, it could induce neovascularization and was considered to be crucial in tumor biology[41,42]. b-FGF had synergistic effects with VEGF[43].

In the present study, the expression of VEGF was slightly higher in TACE group than in the control and AI groups, but no statistical difference was found. There was a significant correlation between MVD and VEGF expression. MVD counts in positive VEGF group were much higher than in negative VEGF group. At the newly formed tumor nests, the boundary of necrotic and non-necrotic area and the subcapsular area, positive VEGF tumor cells were more abundant and this was consistent with the distribution of neovasculature. Taken together, the results in the current study strongly suggested that VEGF played a key role in the formation of tumor neovasculature after TACE.

In conclusion, the influence of lipiodol chemoembolization on formation of tumor angiogenesis is relatively limited, but the development of neovascularization and expression of VEGF play important roles in establishing collateral circulation and reconstructing blood supply of residual cancer tissue.

Abstract

AIM: To investigate the expression of p*27*, cyclin E and cyclin A in hepatocellular carcinoma (HCC) and its potential clinical significance.

METHODS: Expression of p27, cyclin E and cyclin A in 45 HCC specimens and 30 adjacent noncancerous lesions obtained from 45 patients during surgery was examined by immunohistochemical SABC assay. The diameter of tumor ranged from 1 cm to 19 cm (d≤5 cm, 9 samples; 5 cm<d≤ 10 cm, 19 samples; d>10 cm, 17 samples). The tumors were graded according to the criteria described by Edmondson-Steiner: well-differentiated HCC group (Grade I+II), 26 samples; poorly-differentiated HCC group (Grade III+IV), 19 samples. According to the clinical-pathologic features, 19 samples were poorly encapsulated, 15 samples had portal invasion of cancer, 11 samples had extrahepatic metastasis, and 12 samples had intrahepatic metastasis. All of the samples were classified as the invasive and metastatic group, while the remaining was classified as the non-invasive and non- metastatic group.

RESULTS: The average labeling index (LI) of p27 in HCC lesions was significantly higher than that in adjacent noncancerous lesions (45.87±14.21 *vs* 33.77±12.92, t=3.745, P<0.001). The LI of p27 was associated with differentiation, invasiveness and metastasis of the tumors (34.46±12.29 *vs* 52.80±11.36, t=5.17; 41.42±12.86 *vs* 51.44±14.10, t=2.48; P<0.05). Cyclin E was overexpressed in 16 cases (35.6 %) while cyclin A was overexpressed in 21 cases (46.7 %) in HCC lesions. No overexpression of cyclin E or cyclin A could be observed in adjacent non-carcinoma lesions and normal liver tissues. The overexpressions of cyclin E and cyclin A were correlated with differentiation, tumor thrombus, invasiveness and metastasis (P<0.05). Expression of cyclin E was significantly correlated with expression of cyclin A (r=0.329, P<0.05). The LI of p27 was significantly decreased in cyclin E, cyclin A positive groups (40.33±11.91 *vs* 49.50±13.76, t=3.05; 38.86±11.19 *vs* 52.57±12.62, t=3.89; P<0.05).

CONCLUSION: p27, cyclin E, cyclin A play cooperative roles in HCC tumorigenesis, differentiation, invasiveness and metastasis. Detection of their expression may be helpful in prediction of tumor progression.

INTRODUCTION

Hepatocellular carcinoma is one of the most common malignant tumors in China and has poor prognosis due to its high incidence of recurrence and metastasis. Recent studies on HCC have been focused on tumorigenesis, progression, invasiveness as well as novel strategy of therapeutics.

It has been implicated that the activity of cell proliferation is directly associated with tumorigenesis, progression and invasiveness. Therefore estimation of cell proliferative activity is important in prediction of the biological aggressiveness of tumor cells. The regulatory molecules of cell cycle are parameters for the prediction of cell proliferative activity[1]. Cell cycle progression is controlled by protein complexes such as cyclins, cyclin dependent kinases (CDKs) and cyclin dependent kinase inhibitors (CDKIs). The sequential activation and subsequent inactivation of cyclin-CDK complexes govern the progression of eukaryatic cells throughout cell cycle[2]. In cell cycle, the period from the late G1 to S phase is the most important restriction point for cell proliferation. Whether cells pass the G1/S restriction point determines the continuity of cell proliferation[3]. The most direct protein at G1/S point is retinoblastoma protein (pRb)[4]. Phosphorylated pRb can bind to transcription factor (E2F) that regulates cell cycle by activation of DNA synthesis. Both cyclin E and cyclin A play important roles in G1/S restriction point[5,6]. Cyclin E dramatically increases from the late G1 phase to the early S phase[5] which binds to CDK2 and phosphorylates pRb. When cell enters S phase, cyclin E and cyclin A-CDK2 complex cooperate continuously for the phosphorylation of pRb until the end of M phase[6]. As one of CDKIs, p27 can prevent pRb from phosphorylation and arrest the cell cycle at G1 phase[7]. Cyclin E and cyclin A are direct substrates of p27. Recent researches have shown that the activity of p27 protein can be up-regulated by multiple tumorigenesis related factors such as transforming growth factor β[8], interferon[9] and cAMP[10]. The expression of p27 has been implicated in the tumorigenesis of many kinds of tumors[11-15]. However, little is known about the association between cyclins and hepatocellular carcinoma. In the present study, we detected the expression of p27, cyclin E and cyclin A in 45 HCC samples and 30 adjacent noncancerous lesions by immunohistochemical assay to elucidate their correlation with tumorigenesis, progression and metastasis of HCC.

MATERIALS AND METHODS

Data of patients

From 1998 to 1999, 45 HCC specimens and 30 adjacent noncancerous lesions were obtained from 45 patients with HCC during surgery in our hospital. A senior pathologist made the final diagnosis on the basis of histological examination. No patient had received radioactive therapy, chemotherapy,

transcatheter arterial chemoembolization or immunotherapy before operation. There were 36 (80 %) males and 9 (20 %) females, aged from 30 to 65 with an average age of 45±11. A total of 30 (66.67 %) patients had AFP levels over 400 ng/ml, 32 (71.1 %) patients were HbsAg positive. The diameter of tumor in this group ranged from 1 cm to 19 cm (less than 5 cm in 9 samples, 5 cm to 10 cm in 19 samples, more than 10 cm in 17 samples). These tumors were graded based on the criteria of Edmondson-Steiner (Grade I+II in 26 samples, grade III+IV in 19 samples). According to the clinical-pathologic features, 19 specimens had no or little capsule, 12 samples had portal vein invasion of the tumors, 11 samples had extrahepatic metastasis and 12 samples had intrahepatic metastasis. The criteria for invasiveness or metastasis of tumor were the tumor tissue with no or poor capsule, or portal vein invasion, or intrahepatic or extrahepatic metastasis[16]. Twenty-five cases (55.56 %) were defined as invasive/metastatic group.

Tissue sampling

Fresh surgical tissue samples were fixed immediately in formaldehyde solution for 12-24 h and paraffin-embedded for immunohistochemical assay.

Immunohistochemical assay

Immunohistochemical study was performed using avidin-biotin-complex method. Briefly, 4 μm slices of tissue section were deparaffinized and rehydrated. Endogenous peroxidase activity was blocked with 0.3 % hydrogen peroxide for 10 min. Sections were then incubated with 0.03 mol/L citrate buffer (pH=6.0) and heated in microwave oven for 10 min. After three times of rinsing with phosphate-buffered saline (PBS) (pH=7.4), the slides were incubated with 10 % normal goat serum at room temperature for 20 min to block the nonspecific reaction, and incubated overnight with primary antibody (p27 monoclonal antibody 1:50, cyclin E polyclonal antibody 1:50 and cyclin A polyclonal antibody 1:100) at 4 ℃. After rinsed in PBS, they were incubated with second antibody (1:100) for 30 min at room temperature, and reacted with the avidin-biotin peroxidase complex at a concentration of 1:100 for 30 min after washed in PBS. The peroxidase reaction was visualized by incubating the section with 0.01 % 3,3'-diaminobenzidine tetrahydrochloride and hydrogen peroxide mixture. The slides were counterstained with hematoxylin. In negative control, primary antibody was replaced by normal mouse serum.

Immunohistochemical evaluation

The protein reaction (p27, cyclin E or cyclin A) was considered as positive when nuclei showed staining signals. At least 500 *p*27 positive cells from at least 5 randomly selected fields (×400) were counted[17]. When the positive rate for each protein of carcinoma cells was over 5 %, overexpression of cyclin E and cyclin A was defined according to the report[18,19].

Statistical analyses

The correlation of *p*27, cyclin E or cyclin A with carcinogenesis, differentiation, invasion and metastasis of HCC was analyzed with SPSS8.0 software. The χ^2 test and Student *t* test were employed for analyses, *P* value less than 0.05 was regarded as statistically significant.

RESULTS

*p*27 was expressed both in HCC and in adjacent noncancerous lesions (Figures 1,2). The average LI of p27 in HCC lesions was significantly higher than that in adjacent noncancerous lesions (45.87±14.21 *vs* 33.77±12.92, *P*<0.001). The LI of p27 was associated with differentiation, tumor size, invasiveness and metastasis of HCC (*P*<0.05). No correlation was found between the LI of p27 and the number of cancer foci (Table 1).

The overexpression of cyclin E and cyclin A could be exclusively seen in HCC (Figures 3,4), the overexpression rate was 35.6 %(16/45) for cyclin E and 46.7 %(21/45) for cyclin A. The overexpression of cyclin E and cyclin A was associated with differentiation, invasiveness and metastasis of HCC (P<0.05). No correlation could be found between the LI of p27 and the tumor size (P>0.05)(Table 2).

The LI of p27 decreased significantly both in cyclin E and in cyclin A overexpressed tissues (40.33±11.91 *vs* 49.50±13.76, 38.86±11.19 *vs* 52.57±12.62, P<0.05). The overexpression of cyclin E was significantly correlated with that of cyclin A (P<0.05, r=0.329), (Table 3).

Table 3 Relationship between expressions of cyclin E and cyclin A

		Cyclin A		*P*
		+	-

DISCUSSION

Uncontrollable proliferation is the property of tumor cells. Cell proliferation activity involves in tumorigenesis and progression, and is one of the prominent parameters in evaluating the biological aggressiveness of carcinoma.

As one of the major CDK inhibitors, p27 can arrest cell cycle by blocking phosphorylation of pRB. Its substrate is G1 cyclins such as cyclin E and cyclin A. Low p27 protein levels were found in aggressive stomach[11], lung[12], prostate[13], breast[14] and pituitary[15] cancers, suggesting that p27 might suppress the progression of tumor[20].

Our data showed that the LI of p27 was higher in HCC than in adjacent noncancerous tissues, and the expression of p27 was mainly localized in nuclei. This might suggest that p27 works as a positive regulator in tumorigenesis of HCC. Two possible mechanisms could be involved. First, p27 might be regulated by self-stabilization. It has been demonstrated[21] that expression of p27 was regulated primarily at the posttranscriptional level and its mRNA level was stable throughout the cell cycle. When cells are stimulated by

mitogen, p27 protein undergoes rapid degradation via the ubiquitin-proteasome pathway. However, this proteolysis was dramatically reduced in resting cells[22]. Thus, increased expression of p27 in some tumors may be resulted from self-stable regulating mechanism by which increased expression of cyclins attenuates the activity of the proteasome pathway for p27, and then causes an increased expression of free p27 protein that can counteract the increased cyclins in tumorigenesis. Second, gene mutation may also be responsible for this situation. Recent studies have revealed a gene deletion and polymorphism in primary breast cancer and leukemia[23,24]. Whether increased expression of p27 in HCC is caused by mutant protein remains to be elucidated.

In the present study, the expression of p27 was decreased in cases with biologically aggressive phenotypes such as poor differentiation, metastasis and invasiveness. It has been reported that cultured tumor cells expressed more p27 as they grew from single layer to tri-dimension and cell contact inhibition could be suppressed by p27 antisense oligonucleotide[25]. All these suggested that decreased expression of p27 was related with tumor progression and could be used as a potential prediction factor for HCC.

Although many researchers focused on the role of cyclin E and cyclin A in cell cycle in tumor cells[26,27], few studies have ever addressed on the aspect of HCC. Our data showed that cyclin E and cyclin A proteins were exclusively expressed in HCC but not in adjacent noncarcinous lesions. The expression of cyclin E and cyclin A was mainly localized in nuclei, suggesting that overexpression of cyclin E and cyclin A could promote cell cycle and cell proliferation, and therefore was associated with tumorigenesis. Cyclin E expressed in cytoplasm of tumor cell may be caused by increased synthesis, decreased degradation and failure to transportation. Our data also showed that overexpression rate of cyclin E and cyclin A was associated with low histological grade of tumors with high expression rate in poorly differentiated tumors, suggesting the overexpression of cyclin E and cyclin A was associated with poor differentiation. Overexpression of cyclin E was correlated with formation of tumor thrombi, while overexpression of cyclin A was associated with tumor thrombi, metastasis and satellite lesions. Thus overexpression of cyclin E and cyclin A is linked to tumor invasiveness and metastasis potency, suggesting a poor prognosis for patients with overexpression of cyclin E and cyclin A. Patients with cyclin E overexpression had a four-year survival rate[28] and overexpression of cyclin A had a positive relationship with the amount of cells at S-phase and a reverse correlation with the four-year survival rate[18]. Our data were partially similar to these findings. Unfortunately, we were unable to evaluate the correlation of overexpression of cyclin E and cyclin A with the prognosis due to incomplete follow-up data of the patients.

p27 suppresses cyclin/CDK complexes mainly by binding itself to cyclins. It has been reported that p27 could bind to CDK2 and played an inhibitory role in regenerating liver[29]. Zerfass-Thome[30] reported that p27 arrested cell cycle by blocking transactivation of cyclin-A gene which is dependent on cyclin-E gene expression, suggesting a mechanism of interaction among p27, cyclin E and cyclin A. The lower p27 LI in positive cyclin E and cyclin A group in our study might be resulted from the interaction of cyclin-CDK complexes that can suppress its expression. And expression of cyclin E had a positive relationship with expression of cyclin A. These suggest that p27, cyclin E and cyclin A play cooperatively important roles in tumorigenesis, differentiation, aggressiveness and metastasis of HCC.

Although a lot of studies on cyclins/CDKI have been done, many questions remain to be answered. It has been reported that proliferative tumor cells *in vitro* could be arrested in G1 phase by using antibody IgM against cyclin E and cyclin A in culture[31]. Other studies *in vivo* showed that invasiveness of tumor could be dramatically suppressed by down-regulation of G1 and S phase proteins[32]. It seems that cyclins may become potential targets for tumor therapy in the near future. Further studies are needed to elucidate the mechanism of interaction among cyclins and the pathway of regulation before they can finally be used as a novel strategy for prediction of prognosis and therapeutics of HCC.

Abstract

AIM: To investigate multidetector CT (MDCT) findings of hepatocelluar carcinoma (HCC)- associated hepatic arteriovenous shunt (HAVS) and to evaluate their clinical significance.

METHODS: Thin-slice and dynamic enhancement MDCT of HAVS was performed on 56 patients with HCC. MDCT findings, including those of portal veins, hepatic veins, superior mesenteric veins, splenic veins, HCC foci, liver parenchyma without HCC foci, spleens, and thromboses in portal veins and hepatic veins, were all confirmed by digital subtract angiography and analyzed.

RESULTS: MDCT demonstrated earlier enhancement of main portal trunks and/or the first order branches than that of superior mesenteric veins or splenic veins (n=31). One patient had strong early enhancement of left hepatic vein with thromboses in left hepatic vein and upper part of inferior vena cava and 1 patient had transient patchy enhancement peripheral to HCC foci in late hepatic arterial phase among them. It demonstrated stronger opacification of main portal trunks and/or the first order branches than that of superior mesenteric veins or splenic veins (n=18), and earlier enhancement of the second order and smaller branches of portal veins than that of main portal trunks (n=4), stronger opacification of the second order and smaller branches of portal veins than that of main portal trunks (n=3), with transient patchy enhancement (n=3) or wedge-shaped enhancement (n=4) peripheral to HCC foci in late hepatic arterial phase. Enhancement degree of HCC foci was all decreased. As for 49 patients with severe or moderate shunts, enhancement degree of liver parenchyma without HCC foci was increased with heterogeneous density, but enhancement degree of spleens was decreased. There were thromboses in main portal trunks and/or the first order branches in 32 patients.

CONCLUSION: The main MDCT findings of HCC-associated HAVS are earlier enhancement and stronger opacification of portal veins and/or hepatic veins. Understanding of these findings will contribute to the diagnosis and prognosis of the disease and improve therapy for the patients.

INTRODUCTION

Hepatic arteriovenous shunt (HAVS) is the communication between hepatic artery or its branches and portal vein or hepatic vein, forming hepatic artery portal venous shunt (HAPVS) or hepatic artery hepatic venous shunt (HAHVS) respectively. Hepatocelluar carcinoma (HCC) is the most common condition associated with HAVS because of its easy invasion of portal vein and hepatic vein. HAVS could result in direct blood flow between hepatic artery and portal vein or hepatic vein, which may cause severe portal hypertension and consequently, splenomegaly, ascites, and esophagogastric varices and bleeding, accelerating intrahepatic dissemination and extrahepatic metastasis of carcinoma cells[1,2]. Understanding of CT findings of HCC-associated HAVS is of significant clinical implications. Multidetector CT (MDCT) could contribute to the diagnosis of HAVS associated with HCC due to its fast scanning and improved image resolution and quality[3]. The purpose of this study was to examine MDCT findings of HCC-associated HAVS and to evaluate their clinical significance.

MATERIALS AND METHODS

Clinical data

Fifty-six patients (49 men and 7 women, range 29-73 years, mean age 49.8 years) with HCC-associated HAVS were included in the present study. The diagnosis of HCC was based on the results of percutaneous needle biopsy (n=5) or laboratory testings, including elevated serum alpha-fetoprotein level, in combination with imaging appearance and follow-up images (n=51) according to the diagnostic criteria for HCC formulated by Chinese National Association of Anticancer Committee.

MDCT

MDCT scanning was performed with a LightSpeed QX/i MDCT scanner (General Electronic Medical System, Milwaukee, USA). Multidetector row helical technique was applied to the scanning in cranial to caudal direction. Plain scanning of the liver was carried out first. This was followed by enhancement scanning of 2.5 mm axial section performed at 15 seconds, 25 seconds and 65 seconds after injection of contrast media for early hepatic arterial phase, late hepatic arterial phase and portal venous phase image acquisition respectively. A total of 100 ml contrast medium (Ultravist 300, Schering Pharmacy, Guangzhou, China; or Iopamiro 300, Bracco S.P.A., Milano, Italy) was administered to each patient, with a power injector at a rate of 3.5 ml.sec^{-1} through a catheter placed in the peripheral vein of the antecubital fossa.

Digital subtract angiography (DSA)

DSA was performed using a TOSHIBA Digital 1000 MAX (Toshiba Corporation, Tokyo, Japan) within 2 weeks of MDCT examination. A catheter was introduced via the right femoral artery by the Seldinger technique. The celiac (6 patients) or selective hepatic (50 patients) DSA was carried out with a catheter placed in the celiac trunk or in the proper hepatic artery and 40 ml Ultravist 300 (Schering Pharmacy, Guangzhou, China)

or Iopamiro 300 (Bracco S.P.A., Milano, Italy) was injected with a power injector at a rate of 5.0 ml.sec^{-1}. Serial anterior-posterior images were obtained at 1 every 2 seconds for the first 8 seconds and a slower rate thereafter.

Diagnostic criterion for HAVS

Diagnostic criteria for HAPVS[4] were the earlier enhancement of main portal trunk and/or its first order branches than that of superior mesenteric vein or splenic vein, or stronger opacification of main portal trunk and/or its first order branches than that of superior mesenteric vein or splenic vein; or earlier enhancement of the second order and smaller branches of portal veins than that of main portal trunk, or stronger opacification of the second order and smaller branches of portal veins than that of main portal trunk. Diagnostic criteria for HAHVS were the earlier enhancement and stronger opacification of hepatic vein, approaching the density of enhanced aorta. The diagnosis of HAVS based on MDCT was confirmed by DSA.

Determination of shunting types and degrees of HAVS

According to the location of shunting, HAVS was divided into three types. The central HAVS was the shunting located in porta hepatis with earlier enhancement of main portal trunk and/or the first order branches, or hepatic veins at early hepatic arterial phase. The peripheral HAVS was the shunting located in peripheral liver parenchyma with earlier enhancement of the second order and smaller branches of portal vein, and transient patchy or wedge-shaped enhancement peripheral to HCC foci at late hepatic arterial phase. The mixed HAVS showed both central and peripheral HAVS.

According to the time of appearance of HAVS on images, HAVS was divided into three degrees. The severe HAVS showed opacification of main portal trunk and/or the first order branches, or hepatic veins, with enhancement of hepatic arterial and its branches at early hepatic arterial phase, without enhancement or with early enhancement of HCC foci. The moderate HAVS showed opacification of main portal trunk and/or the first order branches, or hepatic veins, with middle or late enhancement of HCC foci at late hepatic arterial phase. The mild HAVS showed opacification of the second order and smaller branches of portal veins at late hepatic arterial phase, with transient patchy or wedge-shaped enhancement peripheral to HCC foci.

Image analysis

Image analysis included examination of the shunting types and degrees of HAVS with or without thromboses in portal veins and/or hepatic veins; locations, gross pathologic patterns and enhancement of HCC; enhancement of liver parenchyma without HCC foci, spleens, superior mesenteric veins and splenic veins.

RESULTS

Earlier enhancement and stronger opacification of portal veins and hepatic veins

Earlier enhancement and stronger opacification of portal veins and hepatic veins were the major MDCT findings of HAVS. Their relations with shunting types and degrees of HAVS are shown in Table 1.

There was transient patchy (n=3, Figure 1) or wedge-shaped (n=4, Figure 2) enhancement peripheral to HCC foci at late hepatic arterial phase in patients with mild and peripheral HAVS, in addition to earlier enhancement of the second order and smaller branches of portal veins than that of main portal trunks, or stronger opacification of the second order and smaller branches of portal veins than that of main portal trunks.

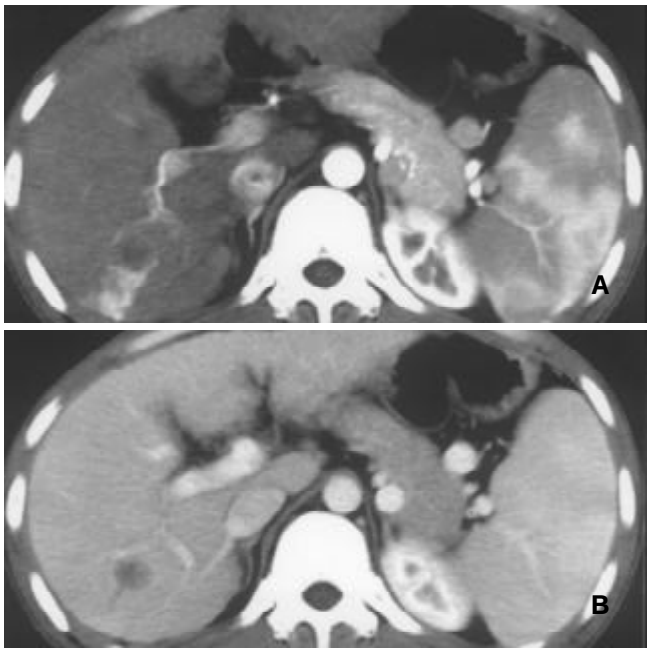

Figure 1 Nodular pattern of HCC with mild and peripheral HAVS. Transient patchy enhancement lateral to HCC foci at late hepatic arterial phase (A), becoming isoattenuation at portal vein phase (B).

Table 1 MDCT findings of earlier enhancement and stronger opacification of portal veins and hepatic veins and their relations with shunting types and degrees of HAVS

MDCT findings	Shunting patterns			Shunting degrees		
	Central	Peripheral	Mixed	Severe	Moderate	Mild
Earlier enhancement of MPT and / or the first order branches than that of SMV or SV	30	0	1[a]	31	0	0
Stronger opacification of MPT and / or the first order branches than that of SMV or SV	18	0	0	11	7	0
Earlier enhancement of the second order and smaller branches of PV than that of MPT	0	4	0	0	0	4
Stronger opacification of the second order and smaller branches of PV than that of MPT	0	3	0	0	0	3
Earlier enhancement and stronger opacification of HV, approaching density of enhanced aorta	1[b]	0	0	1[b]	0	0

a: mixed HAPVS, with transient patchy enhancement peripheral to HCC foci at late hepatic arterial phase at the same time. b: HAHVS+HAPVS, combined with earlier enhancement of main portal trunk and the first order branches than that of superior mesenteric vein. MPT=main portal trunk, SMV=superior mesenteric vein, SV=splenic vein, HV=hepatic vein.

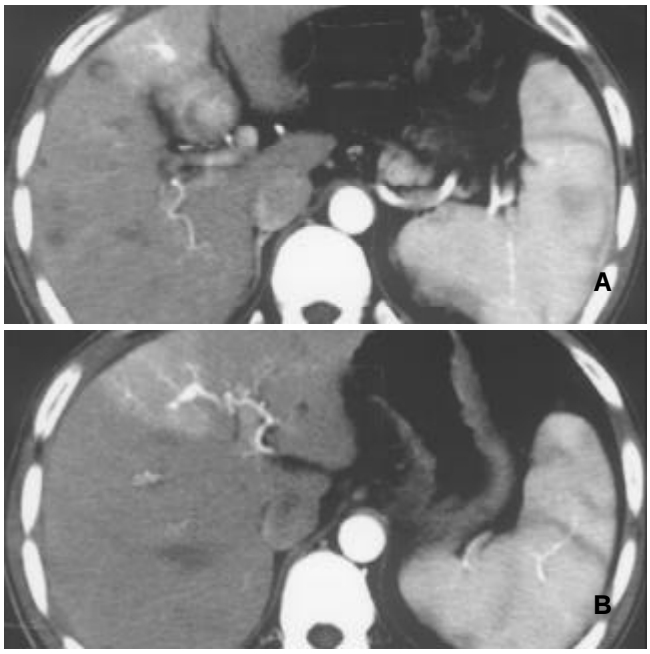

Figure 2 Nodular pattern of HCC accompanied by mild and peripheral HAVS. Stronger opacification of the third order portal vein branches than that of main portal trunk at late hepatic arterial phase with transient wedge-shaped enhancement lateral to HCC foci (A, B).

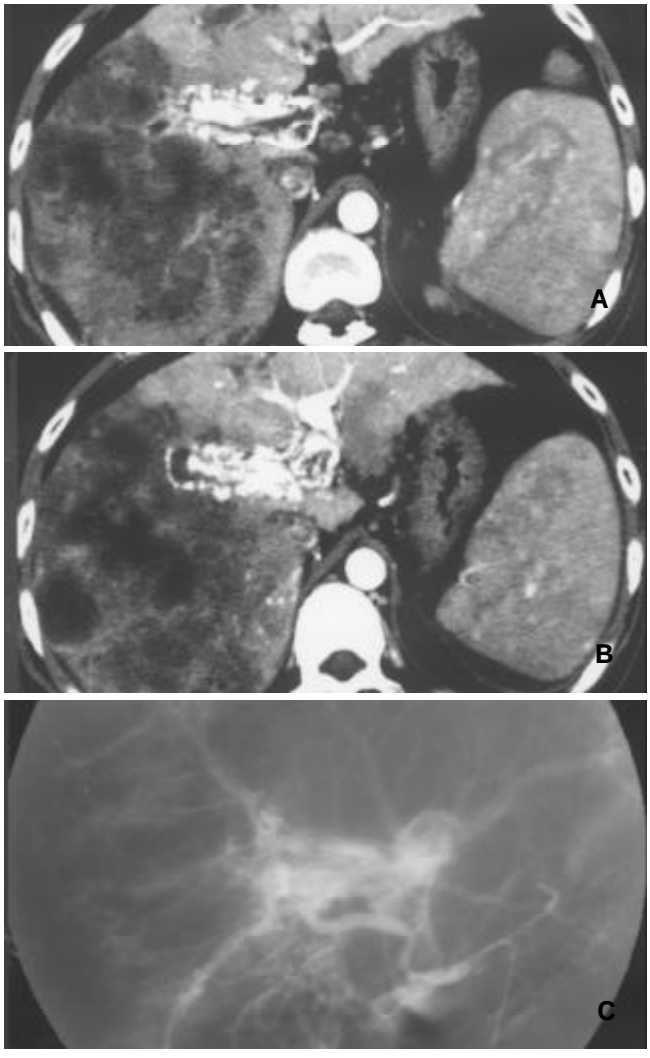

Figure 3 Massive and nodular pattern of HCC associated with severe and central HAVS. Earlier enhancement and stronger opacification of main portal trunk and the left and right first order branches with thromboses in them were shown. Enhancement degree of HCC foci was decreased, and enhancement degree of liver parenchyma without HCC foci was increased with heterogeneous density (A and B). DSA finding of the same patient (C).

Thromboses in portal veins and hepatic veins

Thromboses in portal veins and hepatic veins were seen in all cases of central HAVS. Thirty-two patients had thromboses in portal veins, including 18 patients with thromboses in main portal trunks and the first order branches (Figure 3), 11 patients with thromboses in the right first order branches and 3 patients with thromboses in the left first order branches. One patient with mixed HAVS had thromboses in the left hepatic vein and upper part of inferior vena cava.

Location, gross pathologic pattern and enhancement of HCC

HCC was located in different parts of liver parenchyma. Of the 49 patients with severe or moderate HAVS, 40 had foci adjacent to porta hepatis and 1 patient had foci nearby the secondary porta hepatis. Gross pathologic patterns included massive pattern (n=17), nodular pattern (n=11), massive and nodular pattern (n=23) and diffuse pattern (n=5). The enhancement of HCC foci was all decreased.

Enhancement of liver parenchyma without HCC foci and spleens

Liver parenchyma without HCC foci showed transient patchy (n=3) or wedge-shaped (n=4) enhancement peripheral to HCC foci at late hepatic arterial phase in 7 patients with mild and peripheral HAVS. In the 49 patients with severe or moderate and central HAVS, the enhancement degree of liver parenchyma without HCC foci was increased and heterogeneous, and enhancement degree of the spleen was all decreased (Figure 4).

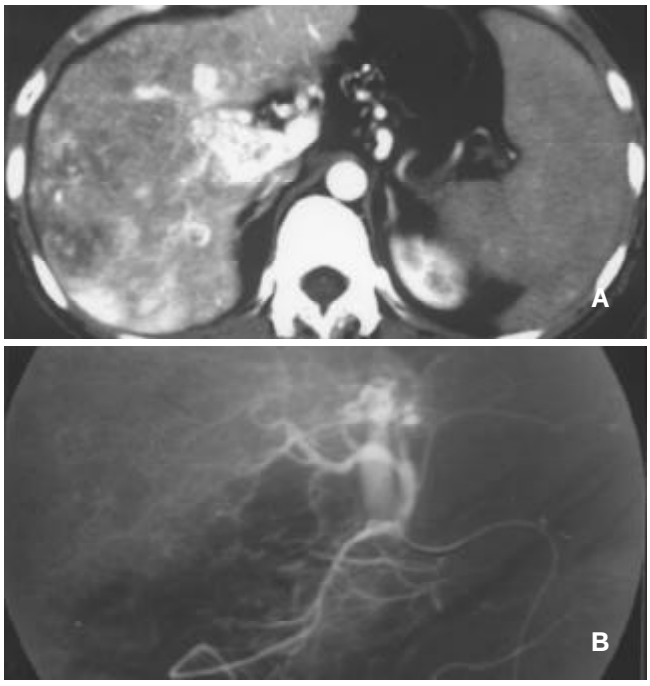

Figure 4 Massive pattern of HCC complicated with severe, central and slight, peripheral HAVS. Earlier enhancement and stronger opacification of main portal trunk with small thromboses in it were seen, with patchy enhancement internal and lateral to HCC foci. Enhancement degrees of HCC foci and spleen were decreased, enhancement degree of liver parenchyma without HCC foci was increased with heterogeneous density (A). DSA finding of the same patient (B).

DISCUSSION

Mechanism of formation of HAVS associated with HCC and MDCT findings

The formation of HAVS might be attributed to complex anatomy and various pathological conditions. Anatomically, hepatic artery and portal vein respectively branch and converge into hepatic sinuses, followed by entering into central vein and hepatic veins before into system circulation. Hence, there were abundant anastomoses between hepatic artery and portal vein[5, 6]. The pathological conditions may include followings. With continued progression of HCC adjacent to porta hepatis, it might directly invade and destroy portal veins and/or hepatic veins, forming tumor thromboses in them or growing along the venous wall. The tumor thromboses are vascularized by arterial network nourished by hepatic artery branches around the vein and are growing up. The enlarged and dilated hepatic artery branches might become the main supplying arteries of the tumor thromboses and their blood flow might enter directly into portal veins and/or hepatic veins which act as the efferent vessels, resulting in transvasal HAVS. In our serial, HCC foci of 40 patients were adjacent to porta hepatis and 1 patient adjacent to the secondary porta hepatis with apparent invasion of main portal trunks and/or the first order branches or hepatic veins. Irregular, tortuous and dilated arterial networks were seen around the porta hepatis or the secondary porta hepatis, which were confirmed by DSA as the supplying arteries of HAVS. The direct invasion and destruction of main portal trunks and/or the first order branches, or hepatic veins, were the main causes of transvasal HAVS. It was specially the case for HCC in internal left hepatic lobe where HAVS might occur even if HCC focus was small. The transvasal HAVS had severe shunts shown as an earlier enhancement of main portal trunks and/or the first order branches, or hepatic veins than that of superior mesenteric veins or splenic veins at early hepatic arterial phase (n=31), or as stronger opacification of main portal trunks and/or the first order branches than that of superior mesenteric veins or splenic veins (n=11), but livers and spleens were ischemia due to "stolen blood" by HAVS. HCC might thus show no or little enhancement, and enhancement of the spleen decreased.

Blood flow of portal veins might be obstructed due to compression of the first order branches of portal vein by HCC or carcinoma thromboses in the first order branches of portal vein. The compensative hyperplasia of vessel plexus around larger biliary ducts in the central part of liver might result in opening of hepatopetal collateral vessels and formation of transplexal HAPVS. In our study, 7 patients with moderate shunts manifested as stronger opacification of main portal trunks and/or the first order branches than that of superior mesenteric veins or splenic veins at late hepatic arterial phase with MDCT.

Compression and invasion of branches of hepatic veins by HCC might obstruct hepatic veins and cause hypertension of hepatic sinuses. The portal veins might thus become their efferent vessels and receive blood supply of hepatic arteries directly when pressure of hepatic sinuses was higher than that of portal veins, resulting in transsinusoidal HAPVS. Subsequently, functional blood flow of portal veins in this area decreased and blood flow of hepatic arteries increased as a compensation, aggravating transsinusoidal HAPVS[6]. In addition, because tumor vessel had no muscular layer and its capability of regulating blood flow by systolic function of vessel wall was poor, the normal branches of hepatic arteries around HCC would preferably take in compensatively increased hepatic arterial blood due to obstruct of hepatic veins, resulting in further intensifying of transsinusoidal HAPVS. On MDCT, it had mild shunts shown as an earlier enhancement of the second order and smaller branches of portal veins than that of main portal trunks (n=4), or stronger opacification of the second order and smaller branches of portal veins than that of main portal trunks (n=3) at late hepatic arterial phase, with transient patchy or wedge-shaped enhancement peripheral to HCC foci. In our series, 7 cases of peripheral HAPVS and 1 case of mixed HAPVS showed these findings.

Diagnosis and differential diagnosis of HCC- associated HAVS

It could be seen from above analyses that there seemed no much difficulty in diagnosis of severe or moderate and central HAVS associated with HCC. However, mild HAVS and peripheral HAVS should be differentiated from hepatic perfusion abnormalities of physiological conditions and other pathological causes[7-14].

Hepatic perfusion abnormalities caused by physiological conditions such as origin variety of segment or subsegment hepatic artery, aberrant biliary bladder vein or gastric vein were only shown as local transient hepatic parenchyma hyperattenuation at hepatic arterial phase with no abnormality at portal vein phase and no HCC foci[15]. HAPVS in hepatic hemangioma manifested as a wedge-shaped or irregular homogenous hyperattenuation in the liver parenchyma adjacent to the tumor at hepatic arterial phase, becoming isoattenuation or slight hyperattenuation, and hemangioma itself tending to show rapid enhancement at portal vein phase, specially for hemangioma of 2-3 cm in diameter or less[16-18]. Hepatic adenoma and focal nodular hyperplasia appeared as homogenous enhancement at hepatic arterial phase, being hypoattenuation at delayed time phase. Abnormal perfusion in cirrhotic liver had the typical wedge-shaped and homogeneous appearance with or without internal linear branching structures at hepatic arterial phase, returning to isoattenuation or slight hyperattenuation at portal vein phase[5]. The site of abnormal perfusion associated with thrombosis in portal vein was conformed to respective portal vein distribution. Hepatic metastasis with abundant blood supply, liver infection, Budd-Chiari syndrome, changes after transjugular intrahepatic portosystemic shunt (TIPS), HAVS following liver biopsy, abnormal perfusion resulted from acute biliary bladder inflammation and acute pancreas inflammation all had their own MDCT features. With the help of clinical materials, they could be differentiated from mild and peripheral HAVS[5,19-26].

Clinical significance of diagnosis of HCC- associated HAVS by MDCT

Diagnosis of HAVS was mainly based on transcatheter hepatic angiography (including DSA) in the past. However, a proportion of patients could not undergo transcatheter hepatic angiography due to restriction of equipment conditions and technology, cost and invasive examination etc., resulting in missed diagnosis of HAVS and loss of treatment opportunity[24, 27].

MDCT is a breakthrough in medical imaging examination technology. Equipped with a multidetector array, MDCT can perform multislice data acquisition simultaneously, which greatly reduces the time of volume scanning. In addition, image quality is improved due to increased image resolution and clarity. MDCT could therefore offer thin-slice and dynamic enhancement scanning of liver at early hepatic arterial phase, late hepatic arterial phase and portal venous phase and provide a convenient, fast and noninvasive new technology for examination of HAVS associated with HCC[3, 28].

Clinically, correct interpretation of MDCT findings of HCC-associated HAVS could assist in making right diagnosis and prognosis and working out effective therapeutic strategy. Forty-nine patients with severe or moderate and central HAVS in our series underwent transcatheter supplying artery embolism of HAVS under the guidance of MDCT information and their esophagogastric varix bleeding, ascites and stubborn diarrhea were all brought under control timely. Moreover, MDCT

provides a new technology for the study of mechanism of HAVS formation. With MDCT, shunting locations, types and degrees of HAVS can be determined, and mechanism of HAVS formation can be estimated. These may form the basis for comprehensive therapy of HCC and embolism of HAVS. Our study suggested that transvasal, transplexal and transsinusoidal HAVS might be the causes of severe, moderate and mild HAVS respectively, and enlarged and dilated nourishing artery manifested as irregular arterial network, originating from proximal proper hepatic artery, might be the main supplying artery of severe and central HAVS. Therefore, in embolism of HAVS, superselective embolism of nourishing artery rather than hepatic artery trunk was performed. If HAVS was supplied by many arteries, they should be embolized respectively. In addition, embolism agent should arrive at the end of nourishing artery to achieve permanent embolism and reduce the possibility of recanalization and recurrence of HAVS[29-33]. Our above-mentioned forty-nine patients with severe or moderate and central HAVS were all completely embolized by absolute ethanol combined with spring steel coil via 4.0F catheter or 3.0F microcatheter superselective embolism without recanalization and recurrence of HAVS by follow-up MDCT examinations.

In conclusion, our study investigated the complex MDCT findings of HAVS associated with HCC. The classification of shunting degrees into severe, moderate and mild shunts according to appearing time of HAVS at early or late hepatic arterial phase can contribute to the diagnosis and treatment of patients. It is also noted that transvasal, transplexal, transsinusoidal HAVS may be behind the formation of severe, moderate and mild HAVS respectively.

Abstract

AIM: To elucidate the association of Epstein-Barr virus (EBV) with colorectal tumors and to demonstrate whether infection of EBV existed in different stages of colorectal tumors involves in the carcinogenesis.

METHODS: One hundred and thirty paraffin-embedded tissues of colorectal tumors were classified into 5 groups: 26 adenomas, 23 adenomas complicated with dysplasia, 22 adenomas complicated with carcinomatous, 36 colon carcinoma and 23 HNPCC, were examined by PCR, IHC and ISH, respectively.

RESULTS: EBV DNA was detected by PCR in 26 cases out of the 130 specimens, including 5 cases of adenomas, 5 adenomas complicated with dysplasia, 5 adenomas complicated with carcinomatous, 7 colorectal carcinoma and 4 HNPCC. IHC detection showed the expression of LMP1 in 7 cases, including 1 adenoma, 1 adenoma with dysplasia, 1 HNPPC, 2 adenomas complicated with carcinomatous, and 2 colorectal carcinomas. The expression of EBER1 detected by ISH was positive in 6 cases, including 1 adenoma with dysplasia, 2 adenomas complicated with carcinomatous and 3 colorectal carcinomas. There were no significant differences among the results of PCR, IHC and ISH in the 5 groups. In all cases of HNPCC, none of the tumor cells showed positive signals of EBER1, but some EBV-positive tumor infiltrating lymphocytes were found in 2 of 23 cases.

CONCLUSION: Our results showed that infection of EBV exists in human colorectal tumors, which indicates that EBV may be involved in the carcinogenesis of colorectal tumors but does not play an important role. The mechanisms need to be clarified further.

INTRODUCTION

Epstein-Barr virus (EBV) is a ubiquitous herpes virus that infects and establishes a persistent infection in the host. Clinically, its primary infection ranges from a mild self-limited illness in children to infectious mononucleosis in adolescents and adults[1,2]. EBV is associated with a number of human malignancies,including Burkitt lymphoma and nasopharyngeal carcinoma,etc. Recently, involvement of EBV has been demonstrated in gastric carcinoma. Detection rates of EBV in gastric carcinomas varied in different studies from 4 % to 18 %[5-15]. Although there are many similar features in histology and pathogenesis between gastric and colorectal carcinoma, there have been few papers about the relationship of EBV with colorectal cancers. However, a great deal of evidences support an etiologic role of EBV in carconogenesis in patients with EBV-positive gastric carcinomas[16,17,20]. In this study, we investigated the presence of EBV in 130 cases of colorectal tumors, including colorectal adenomas, adenomas complicated with dysplasia, adenomas complicated with carcinomatous, colorectal cancer and hereditary non-polyposis colorectal cancer (HNPCC) using immunohistochemical demonstration (IHC), polymerase chain reaction (PCR) and *in situ* hybridization (ISH).

MATERIALS AND METHODS

Tissue specimens

Surgical specimens for EBV detection were collected from 129 patients with colorectal tumors from February, 1998 to February, 2002. All cases were diagnosed by the Department of Pathology, NanFang Hospital, First Military Medical University. All specimens were formalin-fixed and paraffin-embedded. The age and sex of the patients among the five groups were similar (ANOVA analysis, $P>0.05$). As positive controls, Hodgkin' s disease and nasopharyngeal carcinoma specimens confirmed as EBV positive were used in every staining batch.

Immunohistochemitry

The monoclonal antibody LMP1 (DAKO) was used. Immunohistochemitry was performed on paraffin sections. Four-micrometer-thick specimens sectioned from a paraffin-embedded block were dewaxed in xylene and rehydrated in serially graded ethanol (100 %, 95 %), then treated with 0.28 % iodic acid for 60 sec,horse serum and first antibody for 10 minutes at 37 ℃, S-P-second antibody for 10 minutes at 37 ℃, S-P-third antibody for 10 minutes at 37 ℃, then detection was performed using the avidin-biotin-peroxidase complex technique and DAB (diaminobenzidine). A section of Hodgkin' s disease lymph node was used as an external positive control, while negative controls were obtained by replacing the primary antibody with nomal mouse serum.

Polymerase chain reaction

DNA was extracted from formalin-fixed and paraffin-embedded tissues. Two 5 μm thick rections were cut from each block, the samples were suspended in 50-150 μl of extraction buffer containing 100-300 μg/ml of proteinase K(Sigma, Missouri,USA), 50 mM tris-hydrochloric acid (ph8.5), 1 mM EDTA (PH8.0), and 0.5 % Tween20. After incubation for 36 h at 55 ℃, the samples were heated at 100 ℃ for 10 min. The primers corresponding to the 409 base pair region of the EBV BamHI W fragment, were synthesized based on the DNA sequences of GenBank (from www.icnet.uk/bmm) (primer: 1,5' -TCGCGTTGCTAGGCCACCTT-3' ; 2, 5' -CTTGGATGGCGGAGTCAGCG-3'), the PCR reaction mixture contained 1 μl model-DNA, 2.5 μl of 10×PCR buffer (mg^{2+}free), 1.5 μl of 25 mM$MgCl_2$, 2 μl of 2.5M dNTP mixture, 1 μl of 10 pmol/μl primer, and 1 μl of 1 Unit/ μl Taq polymerase

(HuaMei Biotech,China) in a final volume of 25 μl. After an initial incubation for 5 min at 94 ℃, the samples were subjected to 34 amplification cycles (at 94 ℃ for 45 s, at 55 ℃ for 45s and at 72 ℃ for 45 s). After the last cycle, the samples were held at 72 ℃ for 5 min.

In situ hybridization

Oligonucleotide probes used to detect EBER-1 were designed by our reseach group using Primer5.0 software, then synthesized and labeled with Dig by Bioasia Biotech, ShangHai. Each probe was labeled with 2 Dig. The method of *in situ* hybridization was described in the manual of BOSD Biotech. Four-micrometer-thick specimens sectioned from a paraffin-embedded block were dewaxed in xylene and rehydrated in serially graded ethanol (100 %, 95 %), then digested with pepsin (3 %) for 5-10 min at 30 ℃ and hybridized for 14 hours at 40 ℃. The slides were washed with 2×SSC for 5 min×2, 0.5×SSC for 15 min,0.2×SSC for 15 min at 37 ℃, then blocked with BSA at 37 ℃ for 30 min after trickled with biotin-rabbit antibodies to Dig at 37 ℃ for 60 min, slides were washed with 0.5M PBS for 5 min×4, then added SABC at 37 ℃ for 20 min and biotin- peroxidase at 37 ℃ for 20 min. At last, the slides were wished with 0.5M PBS for 5 min×4, stained with DAB for 10 min and counter-stained with hematein for 8 min. Two cases of nasopharyngeal carcinoma known to contain EBV were routinely used as positive controls, two slides treated without probe were used as negative controls.

Statistical analysis

Difference in proportions among the groups was calculated by Pearson χ^2 test using the spss 8.0 statistical software program (SPSS inc, Chicago, il). *P* values <0.5 were considered statistically significant.

RESULTS

The results of LMP1 immunohistochemistry (IHC) are shown in Table1. The positive-signals were localized over the cytoplasm of tumor cells. The cases which exhibited LMP1 staining in more than 10 % of the tumor cell cytoplasm were considered to be LMP1-positive (Figures1-4). A section of Hodgkin' s disease lymph node was used as an external positive control, while negative controls were obtained by replacing the primary antibody with normal mouse serum.IHC revealed that 7 of the 130 cases of colorectal tumors showed LMP1 signals, whereas non-carcinomatous colorectal mucosa was negative for LMP1.

Table 1 Results of immunohistochemistry

Group	*n*	EBV-positive	Positive rate (%)
Adenoma	26	1	3.8
Adenoma with dysplasia	23	1	4.3
Carcinomatous adenoma	22	2	9.1
Colorectal carcinoma	36	3	8.3
HNPCC	23	0	0
Total	130	7	5.4

χ^2 test, $\chi^2=0.0403<\chi^2_{0.05,4}=9.49$, $P>0.05$.

EBV DNA was amplified by PCR using the primers flanking the site of BamHI W fragment in 26 of 130 colorectal tumor tissues,including 5 cases of adenoma-group, 5 cases of adenomas complicated with dysplasia group, 5 cases of carcinomatous adenoma group, 7 cases of colorectal cancer and 4 cases of hereditary non-polyposis colorectal cancer (HNPCC) (Table 2 and Figue 5).

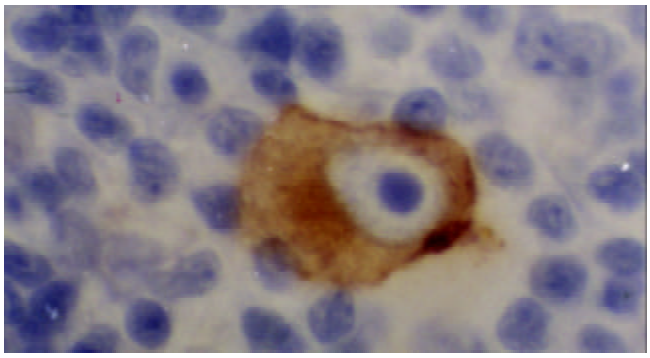

Figure 1 Positive-control of LMP1 from lymphoma of Hodgkin' disease. The cytoplasm of R-S cell showed clear positive signal.

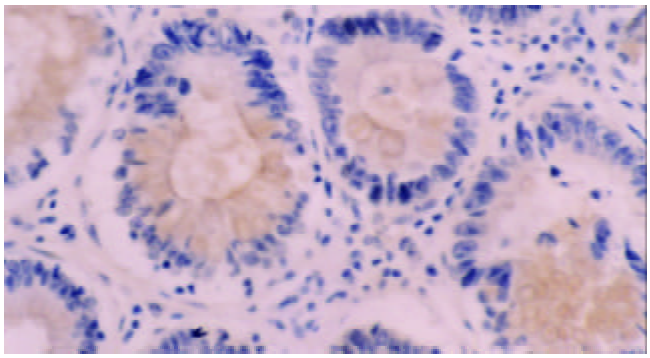

Figure 2 Immunohistochemical staining with anti-LMP1 antibody of adenoma specimen with dysplasia. The positive signals were localized at cytoplasm and membranes.

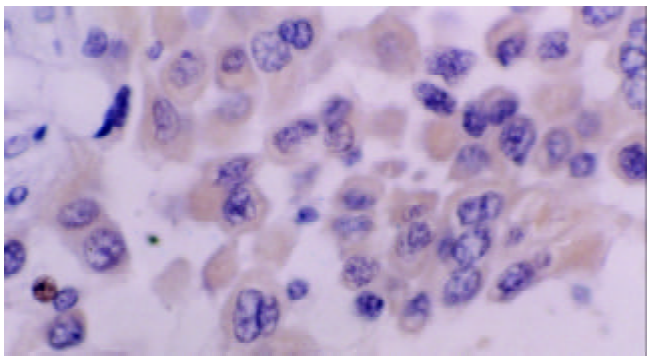

Figure 3 Immunohistochemical staining with anti-LMP1 antibody of colorectal carcinoma cells. The positive signals were localized at cytoplasm. But no clear positive signals localized at membranes.

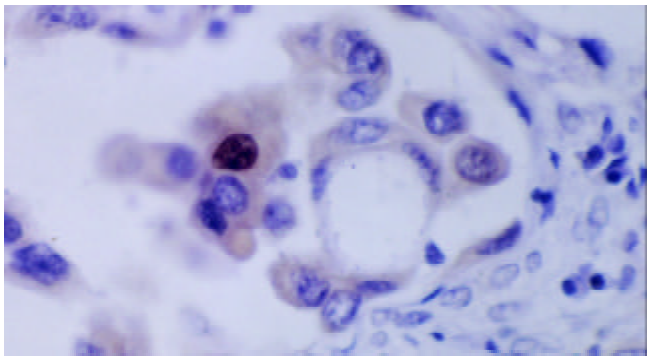

Figure 4 Metastatic colorectal carcinoma cells in lymphatic. The cytoplasm of neoplasm cells showed LMP1 positive, the nucleic showed positive signals too.

Table 2 Results of PCR

Group	*n*	EBV-positive	Positive rate (%)
Adenoma	26	5	19.2
Adenomas with dysplasia	23	5	21.7
Carcinomatous adenoma	22	5	22.7
Colorectal carcinoma	36	7	19.4
HNPCC	23	4	17.4
Total	130	26	20.0

χ^2 test, $\chi^2=2.725<\chi^2_{0.05,4}=9.49$, $P>0.05$.

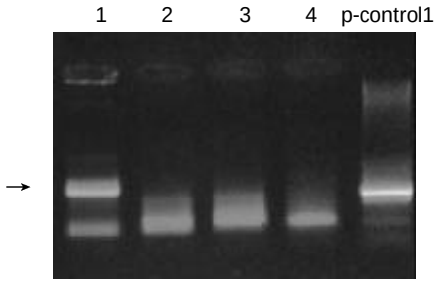

Figure 5 The electrophoresis photo of PCR. Arrow points to the positive lane.

The result of EBER *in situ* hybridization was similar to that of IHC, the signals of EBER were localized over the nuclei of most tumor cells (Figures 6-9), only the signal of EBER within the tumor nuclei was considered as a positive case. 6 of 130 cases showed EBER signals, and 5 cases that showed LMP1 signals were EBER positive (Table3). All cases with LMP1-positive and all cases with EBER-positive were PCR positive.

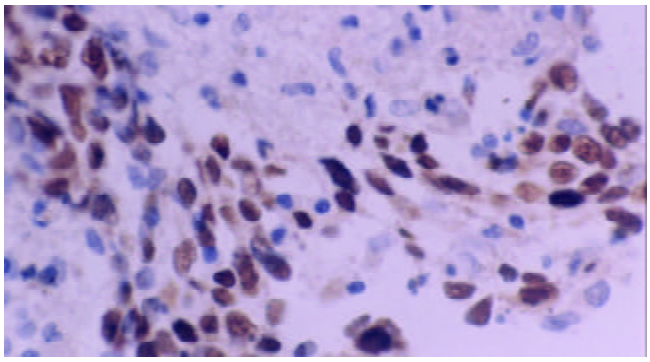

Figure 6 Positive control of EBER1 from a NPC specimen. Clear and strong hybridization signals (yellow nuclear grains) were shown in nuclei of the tumor cells. DAB and hematoxylin counterstaining,×200.

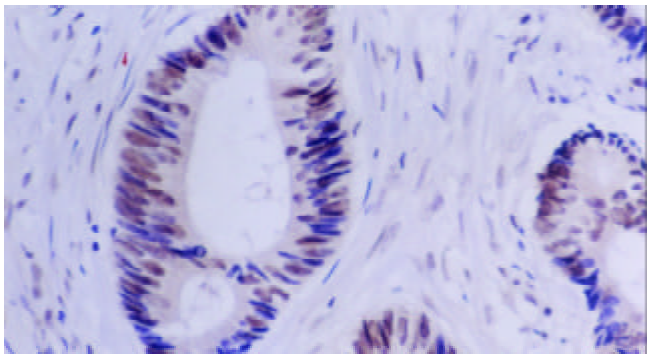

Figure 7 *In situ* hybridization with EBER1 (from an carcinomatous adenoma). Positive signals were shown in nuclei of the tumor cells. DAB and hematoxylin counterstaining, ×200.

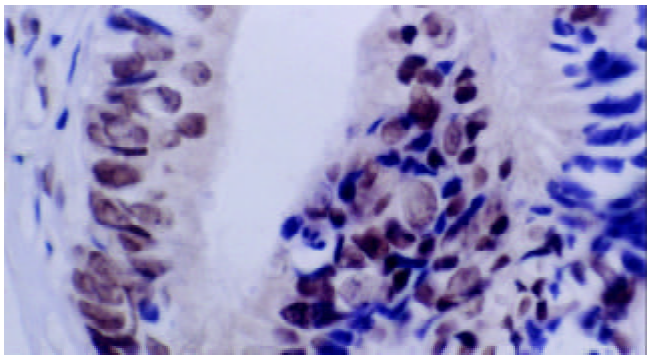

Figure 8 *In situ* hybridization with EBER1 (from a colorectal carcinoma). Clear and strong hybridization signals were shown in nuclei of the tumor cells. DAB and hematoxylin counterstaining, ×400

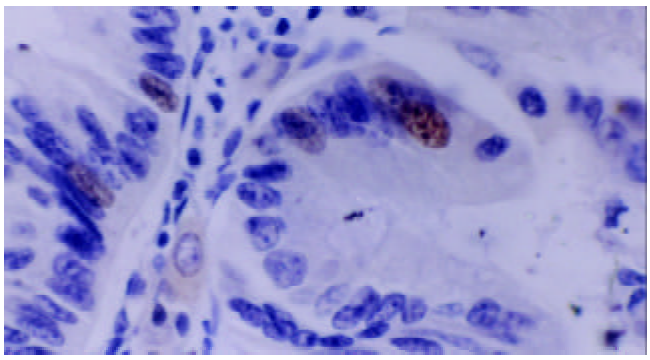

Figure 9 *In situ* hybridization with EBER1 (from a colorectal carcinoma, too). Interspersed positive signals were shown in neoplasm cells. DAB and hematoxylin counterstaining, ×400.

Table 3 Results of EBER-ISH

Group	*n*	EBV-positive	Positive rate (%)
Adenoma	26	0	0
Adenomas with dysplasia	23	1	4.3
Carcinomatous adenoma	22	2	9.1
Colorectal carcinoma	36	3	8.3
HNPCC	23	0	0
Total	130	6	4.6

χ^2 test, $\chi^2=5.39$, $P>0.05$.

DISCUSSION

The relationship between EBV and gastric carcinoma has been testified by Shibata, Tokunaga, Oda and Cho[13-15,19,24]. Throughout the world, EBV is detected in the tissues of about 10 % of gastric carcinoma cases[4]. Though colorectal epithelium is similar to that of gastric, and colorectal carcinoma is similar to gastric carcinoma, too, the association of EBV and colorectal tumors remains controversial. Yuen *et al*[22] investigated for the presence of EBV in 74 cases of gastric adenocarcinoma and 36 cases of colorectal adenocarcinoma from Chinese patients by *in situ* hybridization (ISH) using an antisense EBER probe, but none of the colorectal carcinomas showed a positive signal. Kijima *et al*[21] demonstrated the association of Epstein-Barr virus (EBV) with primary epithelial neoplasm in the south part of Kyushu, Japan, they found that there were no positive signals in 102 cases of colorectal cancer using EBER *in situ* hybridization. Cho *et al*[24] reported the same result that EBV was not associated with colorectal tumors. However, Yanai *et al*[23] found that EBV was detected in 63.6 % of Crohn's disease cases and 60 % of ulcerative colitis

cases using *in situ* hybridization for EBV-encoded small RNA1 (EBER-1), indicating that EBV infection may be related to IBD colonic diseases. Ioachim *et al*[26] studied 15 cases of primary anorectal lymphoma in AIDS patients and compared them with 4 cases of anorectal lymphoma unrelated to AIDS. In the AIDS-associated anorectal lymphomas, the presence of Epstein-Barr virus (EBV) in a latent form was demonstrated by an abundance of Epstein-Barr-encoded RNA (EBER) in 14 of 15 cases and latent membrane protein (LMP) in 4 cases, suggesting EBV may be associated to this kind of anorectal lymphomas. Samaha *et al*[25]and Kon *et al*[29] reported that lymphoepithelioma-like carcinoma of rectum was probably related to EBV, Ruschoff *et al*[27] used polymerase chain reaction test to examine the EBV DNA in 3 cases out of 20 differentiated colorectal adenocarcinomas. Though the positive signals restricted to the peritumor lymphoid infiltrate as shown by *in situ* hybridization, all of these findings suggest that EBV may associate to colorectal tumors. Moreover, Kim *et al*[30] investigated for the presence of EBV in 20 cases of colorectal adenocarcinomas and found 2 cases were EBER-positive. As a similarity, Grinstein *et al*[28] results suggested that EBV was not restricted to lymphoepithelioma-like carcinomas but might play an oncogenic role in frequent epithelial cancers, including colorectal cancers, and possibly also in hyperplasias and certain dysplasias preceding carcinomas.

In the current study, we analyzed 130 cases of colorectal tumors for the presence of EBV using immunohistochemistry, polymerase chain reaction and *in situ* hybridization. EBV was detected by each method, but the positive rates were different with different methods. Among the three methods, *in situ* hybridization was considered as the golden standard[3], nevertheless, we found 6 cases of colorectal tumors were EBER-positive. In our study, 1 case of adenoma complicated with dysplasia showed positive signals for EBER. This finding was different from the observation of Kijima *et al*, Yuen *et al* and Cho *et al*[21,22,24]. Moreover, detection of EBV in 1 case of dysplastic adenoma suggested that EBV infection occurred in the dysplastic phase before the occurrence of colorectal carcinoma, further indicating that EBV may play a role in tumor progression.

In all the EBV-assciated carcinomas,the virus was detected in the neoplasm cells but not in the nomal colorectal epithelium using ISH and IHC. However, we found much more positive-cases using PCR technique. In our study, 19 cases of PCR-positive colorectal tumors showed IHC negative and 20 cases showed EBER-negative. This could be interpreted as colorectal tumors with lymphoid stroma because the possibility of false positives using the PCR technique should be included[17]. Furthermore, reactive lymphocytes might possibly be contaminated during the micro dissection of a tumor portion and might become PCR-positive for EBV[16]. This supports the hypothesis that EBER *in situ* hybridization without further PCR method is enough to facilitate the detection of EBV within cancer cells. But Glaser *et al*[32] found that EBV EBER-1 transcript was not commonly expressed in breast cancer, based on a broadly representative case series. Therefore, in order to clarify the infection of EBV, more than one kind of methods should be used. Gulley *et al*[3] thought that new molecular tests combined with traditional serological or histochemical assays were helpful for diagnosis and monitoring of EBV-related diseases, PCR and IHC test were indispensable to the diagnosis of EBV associated diseases.

Our findings showed that in all EBV-positive colorectal tumors, male was preponderance. Other researchers, such as Chang *et al*[9], Oda *et al*[14] and Tokunaga *et al*[16] found the same results in the study of relationship between EBV and gastric carcinoma, the mechanism needs to be clarified further. Human cancer tissues are infiltrated by tumor-infiltrating lymphocytes (TILs), which have been considered a manifestation of a host immune response to cancer cells[22], the role of EBV-positive TILs in carcinoma remains unclear. Our data suggest that regardless of the site, the chances for epithelial cells to be exposed to EBV are similar in the gastrointestinal tract, because it is believed that EBV-carrying lymphocytes are a reservoir of EBV and may transfer EBV to the epithelial cells. Therefore, whether EBV plays an etiologic role in the carcinigenesis of this tissues is probably dependent on the infectability of epithelial cell interaction after infection.

Our data showed no significant differences in the frequency of EBV using PCR, IHC or ISH among adenoma, adenomas complicated with dysplasia, carcinomatous adenomas, colorectal cancer and hereditary non-polyposis colorectal cancer (HNPCC). The low frequency of EBV in HNPCC might be explained by different histological types of carcinoma, and the susceptibility to EBV of HNPCC might be lower than the other four groups. Our findings suggest that EBV does exist in colorectal tumor tissues in South China population, and the frequency of EBV positive colorectal tumors in Guangzhou, South China, where NPC is the most common in the world, may be higher than that in other parts of China. These findings agree with Hao *et al*[11] and Qiu *et al*[12]. Corvalan *et al*[18] thought that Epstein-Barr virus associated gastric carcinoma(EBVaGC) was linked to regional, ethnic, location of carcinoma in the organism and the histology type of tumors.

In conclusion, the present study has shown that EBV may play an etiologic role in the carcinogenesis of these tissues. But our data showed a very low frequency of EBV in these colorectal tumors, indicating that EBV does not play a major role in the etiology of colorectal carcinoma, and the carcinogenesis mechanism needs to be further elucidated.

Abstract

AIM: A myriad of healthful effects has been attributed to the probiotic lactic acid bacteria, perhaps the most controversial issue remains that of anticancer activity. This study was aimed at investigating the putative anti-cancer effects of lactic acid bacteria strains on the progression of colon tumor in 1,2-dimethylhydrazine (DMH)-treated animals.

METHODS: The strain of lactic acid bacteria used in this study was lactic acid bacteria NZ9000 that conformed to the characteristics of plasmid free. Sixty male Wistar rats were given subcutaneous injections of DMH at a dose of 40 mg/kg body wt or saline once a week for 10 weeks. The rats were divided into 6 experimental groups. After the last DMH injection, animals in groups 1 and 4 were gavaged with 1 ml of lactic acid bacteria at a dose of 5×10^9 per day or vehicle until sacrifice at the end of week 22 or week 52. Animals in groups 1-3 were killed at the end of week 22 for histopathological examination. The whole period of experimental observation was 52 weeks.

RESULTS: By the end of 22nd week, final average body weights of the rats treated with DMH alone and all animals receiving lactic acid bacteria were significantly decreased compared with the vehicle control ($P<0.05$). No differences in tumor incidence, multiplicity, dimensions and stage in the colonic mucosa were observed among the groups. At week 52, the survival rate of the rats administered lactic acid bacteria was lower than that of the rats treated with DMH that were fed on control fluids of non-*lactococcus lactis*. The mean survival time of lactic acid bacteria-treated animals was 39 weeks.

CONCLUSION: These results indicate that lactic acid bacteria lacks inhibitory effects on the progression of colon tumor in DMH-treated animals, and does not support the hypothesis that alteration of colonic flora may exert an influence on the progression of colon tumor.

INTRODUCTION

Epidemiological studies have provided evidences that the morbidity of colon cancer is influenced by diet. Several studies of humans and experimental animals suggested that the influence of diet was mediated by altering the metabolic activity of intestinal bacterial flora[1,2]. Some of these enteric bacteria are beneficial to the host and have been shown to exert antimutagenic and anticarcinogenic properties[3-5]. By definition, probiotic bacteria can beneficially affect the host by improving its intestinal microbial balance. Bacterial flora that ferment the dairy products (e.g. lactic acid bacteria) might be used for cancer chemoprevention[4].

Lactobacilli are one of the dominant species in the small intestine, and these micro-organisms presumably affect metabolic reactions occurring in this part of the gastrointestinal tract. Some metabolites of lactic bacteria, such as lactic acid and enzymes, have been reported to have some chemotherapeutic value[6]. Furthermore, several studies have also shown that consumption of *bifidobacteria* reduces colon cancer risk in carcinogen-treated animals, suggesting that consumption of certain bacteria has a beneficial effect on the balance of colon *bacteria*[7,8]. Although a myriad of healthful effects have been attributed to the probiotic lactic acid *bacteria*, perhaps the most controversial issue is its anticancer activity. How dietary components, including lactic acid *bacteria*, interact with genes contributes to tumor development?

An autochthonous colon cancer model is useful to evaluate the clinical therapeutic efficacy of drugs for colorectal cancer[9,10]. The experimental carcinogen DMH has been used in the study of the effect of diet in experimental animals[1,11]. As the DMH model is known to closely parallel the human disease in term of disease presentation, gross and microscopic pathology[12], it is anticipated that DMH-induced colon tumor in rats would respond to chemotherapeutic drugs used in man[13]. Although clinical use of 5-fluorouracil (5-FU) derivatives was tested in the DMH model, few studies on the effect of lactic acid bacteria on chemically induced colon tumor progression have been reported.

Supplementation of diet with components possessing antimutagenic and anticarcinogenic properties might result in a significant decrease of tumor frequency. A number of studies indicate that administration of *bifidobacteria* or lactobacilli alone or in combination with fermentable carbohydrate(defined as a prebiotic) can alter colonic microflora populations and decrease the development of early preneoplastic lesions and tumors. This study was aimed at investigating the putative anti-cancer effects of lactic acid bacteria strains on the progression of colon tumor in DMH-treated animals.

MATERIALS AND METHODS

Materials

Animals and chemicals Male Wistar rats at 5 weeks of age were obtained (Department of Animals, Chinese Academy of Medical Sciences, Beijing, China) and housed in plastic cages with wood chips for bedding in an animal room with a 12 h light/dark cycle at 22±2 ℃ and 44 %±5 % relative humidity. The rats were fed on the basal diet. Water was available *ad libitum*, and body weight and food consumption were measured weekly

during the experiments. DMH was purchased from Tokyo Kasei Co. (Tokyo, Japan).

Methods

Treatment protocol The experimental design is shown in Figure 1. One week after acclimatization, sixty rats of 6-week-old were randomly divided into six groups (10 rats/group). Animals in Groups 1 and 4 were given subcutaneous injections of DMH dissolved in normal saline solution (40 mg/kg body wt) once a week for 10 weeks. Rats in groups 2 and 5 were injected 0.9 % normal saline (vehicle) at the same time. After the last DMH treatment, the animals in groups 1 and 4 were additionally gavaged with 1 ml of lactic acid bacteria at a dose of 5×10^9 per day for 12 weeks or until they were dead. Groups 2 and 5 were gavaged with 1 ml of protective reagents per day (the vehicle control). Groups 3 and 6 served as a carcinogen control. The course of treatments differed slightly from each experiment. All surviving animals were sacrificed under ether anesthesia at week 22 (Groups 1-3) and at the end of experiment (Groups 4-6), respectively. The whole period of experimental observation was 52 weeks.

Tissue processing All animals were autopsied. The colons were removed, flushed with saline, opened along the longitudinal median axis. Macroscopically, the number of tumors in each colon was counted. Tumor width (*W*) and length (*L*) were measured with calipers. Tumor volume (*TV*) was determined according to the following formula: $TV=(L\times W^2)/2$[14]. After the gross pathologic changes (number, dimensions and distribution of the tumors) were recorded, the colons were fixed flat between pieces of filter paper in 10 % phosphate-buffered formalin. The liver and kidneys were removed and weighed. Other major organs (stomach, small intestine, spleen, lungs and lymph nodes) were also excised and fixed in 10 % phosphate-buffered formalin solution. Afterward, all tissues were embedded in paraffin and used for sectioning. After the sections were stained with routine hematoxylin and eosin, the colons were divided into proximal, intermediate, and distal segments and examined for histopathological analysis.

Tumor staging Animals with DMH-induced colon cancer characteristically developed multiple tumors and each tumor was at a different histological stage[15]. Consequently, for the purpose of this experiment, animals were staged (Duke's stage) with reference to a single index tumor, defined as the largest macroscopically and histologically identifiable colon tumor.

Preparation of lactococcus lactis The strain of *L. lactis* used in this study was lactic acid bacteria NZ9000 that conformed to the characteristics of plasmid free. The strain was obtained from French Academy of Agricultural Sciences. All cloning steps were done with *E.coli* Top10. *E. coli* was grown on Luria-Bertani (LB) medium and incubated at 37 ℃ under aeration. *L.lactis* was grown without shaking on M17 medium in which 1 %(wt/vol.) glucose was added (M17-Glu) and incubated at 30 ℃. When appropriate, antibiotics was added to the culture medium. For lactic acid bacteria strains, chloramphenicol was used at a final concentration of 10 ug/ml. Ampicillin was supplied at a concentration of 100 ug/ml in the case of *E.coli*. In the experiments, the lactic acid bacteria was induced with nisin as follows. An overnight culture of lactic acid bacteria was transferred into a fresh medium at a dilution of 1:50. After 3-4 h of incubation, 1 ng/ml of nisin (Sigma) was added to the culture, which was incubated for 3-4 h. For *L.lactis*, nisin induction was performed as described previously[16].

After incubation, lactic acid bacteria was concentrated to 5×10^9 cells/ml in PBS buffer (pH 7.0). This concentration would be used as an oral dosage for a rat. PBS buffer (pH 7.0) was used as a liquid protecting solution for lactic acid bacteria. The preparations were preserved at 4 ℃ for a week.

Statistical analysis

Statistical analyses were completed with SPSS 9.0 (Statistical Package for the Social Science). The significance of differences between the average values of the groups was analyzed using Cochran's two-tailed Student's *t*-test. The significance of differences in lesion incidences between the groups was assessed by chi-square test. Rat mortality was analysed by the Log Rank method of Peto *et al*[17].

RESULTS

All rats in groups1-3 and 5 survived to the final termination and maintained a relatively healthy appearance throughout the experiment. No signs of severe toxicity or diarrhea were observed in all animals given lactic acid bacteria. No tumors were found in vehicle-treated animals fed on the protective reagents. By the end of 22nd week, final average body weights of the rats treated with DMH alone and all animals receiving lactic acid bacteria were significantly decreased compared with the vehicle control ($P<0.05$). Relative liver and kidney weights

DMH	10 (100)	40	27 (67.5)	3 (7.5)	10 (25)	4.00±2.96	4.31±4.56	0	0	3

a: Values are means ±SD. b: No. of tumors/tumor-bearing rat. c: No. of rats with carcinoma were allocated to one of three tumor stages.

and food consumption were not significantly differ among the groups (shown in Table 1). Macroscopically, the distribution of colon tumors was predominantly observed in the proximal and middle colon at the end of 22nd week, there were no significant differences among the groups (data not shown). Histo-pathological examinations of adenocarcinomas in the proximal and middle colon showed that all were invasive through the *muscularis mucosa* and moderately differentiated.

Histo-pathological findings are summarized in Table 2. Colon epithelial lesions were divided into adenoma, carcinoma *in situ* and carcinoma. At the end of 22nd week, the incidence of colon tumor was not significantly affected by lactic acid bacteria. The mean tumor incidence per tumor-bearing rat was 3.11 in group 1 and 4.00 in group 3. Tumor volume was decreased in rats receiving lactic acid bacteria, however, the differences were also not significant compared with DMH- treated group. On the other hand, there was no significant difference in the incidence of metastasis (Duke's stage) between the animals treated with DMH alone and those received lactic acid bacteria.

At the termination, the survival rate of rats in groups 4-6 is shown in Figure 2. None of the rats received *L. lactis* survived the full duration of the experiment, while the DMH-treated rats had a 20 % survival rate. However, the survival rats were sacrificed and macroscopically visible metastases were found in their lungs and livers. There was no significant differene in the survival rate between the lactic acid bacteria treated rats and DMH treated rats. All rats in Group 5 (the vehicle control) survived. The mean survival in lactic acid bacteria-treated animals was 39 weeks.

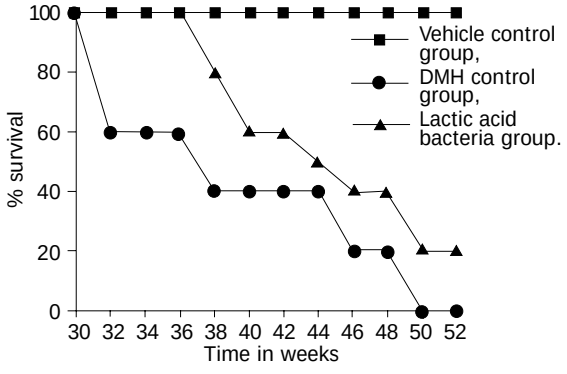

Figure 2 Survival rate of rats injected DMH followed or not by lactic acid bacteria and normal saline.

DISCUSSION

Oral administration of lactic acid bacteria has been shown to effectively reduce DNA damage in animals induced by chemical carcinogens, especially the damage of gastric and colonic mucosa in rats[7]. Certain strains of lactic acid bacteria have also been found to be able to prevent putative preneoplastic lesions induced by carcinogens and have antitumor activity[18,19]. However, findings of in current study do not support the suggestion that addition of lactic acid bacteria may protect against the progression of DMH-induced colon tumor in rats.

The exact change in tumor size or survival of the animals may be crucial for sensitivity determination of anticancer drugs. In this regard, our experimental results seem to be not ideal. The present data did not show any inhibitory effect of lactic acid bacteria on the dimension, multiplicity and invasion of colon tumors. By the end of 22nd week, although there was a reduction in colon tumor volume in animals received lactic acid bacteria, this difference was not statistically significant. The Duke's staging system for human colorectal cancer provides accurate prognostic information. In other words, animals with less advanced diseases (stage A) can survive significantly longer than those with more advanced diseases (stage B and C), irrespective of treatment. In the present study, there was no significant difference in the incidence of metastases at necropsy in lactic acid bacteria-treated and untreated animals. Moreover, the survival rate of rats received lactic acid bacteria was lower than that of rats treated with DMH that were fed on non-lactic acid bacteria. The lower survival rate of rats administered *L. lactis* suggested that lactic acid bacteria had no protective role in decreasing DMH-induced mortality. Whether lactic acid bacteria has some promoting role in the progression of colon tumor is not clear.

In fact, the data from experimental studies indicated that ingestion of certain lactic cultures or their fermented dairy products could reduce the risk of certain types of cancer and inhibit tumor growth[20-22]. The animal experiments did indicate that feeding certain lactic cultures or fermented milk not only suppressed the incidence of DMH-induced colon carcinogenesis but also increased the survival rate of rats with chemically induced colon cancer[23]. These lactic cultures have been shown to possess antimutagenic properties[24], and the probiotic was given during the initiation and promotion phases. However, the antimutagenic activity of lactic acid-producing bacteria was suspected to reside in cell wall[25], as lactic acid itself had no antimutagenic effects[26]. In a previous study, the findings failed

to demonstrate that *bifidobacteria* or *lactobacilli* administration alter colonic microflora had effects on the host[27], and no significant effect was observed when probiotic was given after the promotion phase. In the present study, the lower survival rate of the lactic acid bacteria group (Figure 2) suggested that lactic acid bacteria had no protective role in decreasing DMH-induced mortality. The observed results in survival rats might be due to the fact that lactic acid bacteria can not decrease faecal enzymes involved in formation of carcinogenesis. In addition, our studies failed to show a significant reduction in total number of colon tumors in rats. We believe that this indicates lactic acid bacteria lacks effects on colon cancer in rats. At present, the results from epidemiological studies do not appear to support the results from experimental studies of lactobacilli or lactic acid bacteria on colon cancer prevention or treatment. The reason for this is unclear but might be explained by differences in bacterial strains. The precise mechanisms by which lactic acid *bacteria* may inhibit colon cancer are presently unknown. However, many antitumor activities attributed to lactic cultures have been suggested to involve an enhanced immune response. Therefore, more work needs to be done to identify the specific strains and their antitumor effects and the mechanisms underlying these effects.

Human cancer-nude mice subcutaneous xenograft system as a sensitivity test for chemotherapeutic drugs was studied[28], but it has not been established that the system is a predictive model for screening anticancer drugs. Recently, investigators have been giving greater attention to more rigorous experimental endpoints, such as tumor regression[29-31]. In this respect, autochthonous colon cancer in rats may be suitable to disease oriented *in vivo* screening. DMH-induced rat colon tumor model might be a valuable for new therapeutic agents[9,10]. The fact that clinically used drugs such as 5FU could inhibit the growth of DMH-induced colon tumors and prolong the survival of their rodent hosts suggested a parallel in tumor sensitivity[13]. Therefore, colon tumors induced by DMH at present were the most popular models used in experimental oncology to study various aspects of the morphology, pathogenesis, prevention and treatment of colorectal cancer[9-13]. The animal model described in this study was a truly adjuvant model since the rats developed primary colon tumors *in situ*, which resembled the histopathologic features of human colon tumors. Moreover, DMH decreased animal body weight at the end of week 22, but had no effect on food intake, probably due to its aggressive effect on the mucosa and carcinogenicity.

In the present study, two possible reasons for the failure to alter rat colon tumor were put forward. One was that *L. lactis* lacked inhibitory effects because the initiation of DMH was too strong in our study. The other was that the dose of *L. lactis* might be inadequate to significantly alter colonic flora. It is clear that an optimal condition must be met for each inhibitor to be used for animal and possibly for human cancer prevention and treatment. Otherwise, the same substance, it might enhance the processes of growth of tumor instead of inhibiting. Therefore, it will be extremely difficult, to devise an optimal diet because of the wide variety of cancer inhibitors and enhancers present in human diet.

In conclusion, this study did not find any inhibitory effect in experimental colon tumor progression by addition of lactic acid bacteria after the promotion stage of carcinogenesis and thus does not support the hypothesis that alteration of colonic flora may exert an influence on the progression of DMH-induced colon tumor.

Abstract

AIM: To establish an efficient, sensitive, cell-based assay system for NS3 serine protease in an effort to study further the property of hepatitis C virus (HCV) and develop new antiviral agents.

METHODS: We constructed pCI-neo-NS3/4A-SEAP chimeric plasmid, in which the secreted alkaline phosphatase (SEAP) was fused in-frame to the downstream of NS4A/4B cleavage site. The protease activity of NS3 was reflected by the activity of SEAP in the culture media of transient or stable expression cells. Stably expressing cell lines were obtained by G418 selection. Pefabloc SC, a potent irreversible serine protease inhibitor, was used to treat the stably expressing cell lines to assess the system for screening NS3 inhibitors. To compare the activity of serine proteases from 1b and 1a, two chimeric clones were constructed and introduced into both transient and stable expression systems.

RESULTS: The SEAP activity in the culture media could be detected in both transient and stable expression systems, and was apparently decreased after Pefabloc SC treatment. In both transient and stable systems, NS3/4A-SEAP chimeric gene from HCV genotype 1b produced higher SEAP activity in the culture media than that from 1a.

CONCLUSION: The cell-based system is efficient and sensitive enough for detection and comparison of NS3 protease activity, and screening of anti-NS3 inhibitors. The functional difference between NS3/4A from 1a and 1b subtypes revealed by this system provides a clue for further investigations.

INTRODUCTION

The infection of hepatitis C virus (HCV) is associated with a high frequency of chronic hepatitis (up to 80 %), which often progresses to liver cirrhosis and hepatocellular carcinoma (up to 20 %)[1]. Until now, there has been no vaccine against HCV and the most efficacious pharmacological treatment, a combined therapy of interferon alpha and ribavirin, which could lead to sustained remission only in a minority of cases[2,3]. Considerable efforts have been therefore undertaken to develop specific antiviral agents.

HCV is a positive-sense, single-stranded RNA virus and belongs to the flaviviridae family. Its genome is about 9.6 kb in length and encodes the structural proteins C, E1, E2, and the non-structural proteins NS2, NS3, NS4A, NS4B, NS5A and NS5B, which are released by action of both host cell and virally encoded proteases[4,5]. The N-terminal domain of the NS3 protein contains a serine protease, belonging to the chymotrypsin family[6], which is responsible for the proteolytic cleavage at the NS3/4A, NS4A/NS4B, NS4B/NS5A and NS5A/5B junctions of the viral polyprotein[4]. The NS3 thus plays a pivotal role in the viral maturation and replication. It is also known to affect normal cellular functions, such as cell proliferation and cell death, suggesting its involvement either direct or indirect in HCV hepatocarcinogenesis[7-9]. Therefore, the NS3 protease has become one of the most attractive targets for the development of HCV specific antiviral agent.

To establish an efficient, sensitive, cell-based assay system for NS3 serine protease in an effort to study further the property of HCV and develop new antiviral agents, we first constructed the pCI-neo-NS3/4A-SEAP chimeric plasmid, in which the secreted alkaline phosphatase (SEAP) gene was fused in-frame to the downstream of NS4A/4B cleavage site. The protease activity of NS3 was reflected by the activity of SEAP in the culture media of transient or stably expressing cells. Stably expressing cell lines were obtained by G418 selection. To explore the possibility of applying this system to the screening of NS3 inhibitors, Pefabloc SC, a potent irreversible serine protease inhibitor, was then used to treat the stably expressing cell lines. After that, we investigated the difference of serine protease activity between HCV genotype 1b and 1a by constructing two pCI-neo-NS3/4A-SEAP chimeric clones and studying them in both transient and stable expression systems.

MATERIALS AND METHODS

Cloning of HCV NS3/4A and SEAP genes

To amplify NS3/4A region (HCV 1b) using PCR from a near-full length HCV cDNA (from a patient with 1b genotype), two pairs of primers were used: NS3/4A5' , 5' -CCG GAA TTC ATG GCC CCC ATC ACA GCC TAT-3' (nucleotides [nt] 3 420-3 437), and NS3/4A3' , 5' -CAGT CTC GAG GAG GTG TGA GGC GCA-3' (nucleotides [nt] 5 472-5 486); NS3/4A (TGA)3' , 5' - CCG CTC GAG *TCA* GCA CTC CTC CAT CTC ATC-3' (nucleotides [nt] 5 457-5 474, with stop codon, as negative control). RNS3/4A (HCV 1a) was amplified with primer RNS3/4A5' , 5' -AT GAA TTC ATG GCG CCC ATC ACG GCG TAC-3' (nucleotides [nt] 3 420-3 437) and primer RNS3/4A3' , 5' -GCC AAG CTT TAA GTG CTG AGA GCA-3' (nucleotides [nt] 5 472-5 486) from p90/HCV FL-long pU (AF009606) (a generous gift from Professor Charle M Rice from the Center for the Study of Hepatitis C, Rockefellor

University). SEAP fragment was obtained by PCR with two pairs of primers: SEAP(XhoI)5' , 5' -AT CTC GAG ATG CTG CTG CTG CTG CTG CTG-3' (nucleotides [nt] 54-74), SEAP (HindIII)5' , 5' -AT AAG CTT ATG CTG CTG CTG CTG CTG CTG CTG-3' (nucleotides [nt] 54-77), and SEAP3' , 5' -AT GCGGCCGC TCA GGG AGC AGT GGC CGT C-3' (nucleotides [nt] 1 628-1 647) from pCMV-SEAP (generously provided by Professor Byan R.Cullen of the Medical Center, Duke University).

Construction of pCI-neo-NS3/4A-SEAP

The NS3/4A fragment from HCV 1b genotype and digested with *Eco*RI and *Xho*I, was ligated into *Eco*RI/*Not*I site of pCI-neo vector (Stratagene) with the SEAP fragment digested with *Xho*I and *Not*I to generate pCI-neo-NS3/4A-SEAP. The HCV 1a RNS3/4A fragment digested with *Eco*RI and *Hind* III and the SEAP fragment digested with *Hind* III and *Not* I were ligated into *Eco*RI/*Not* I site of pCI-neo vector to generate pCI-neo-RNS3/4A-SEAP. The schematic diagram is shown in Figure 1. The *Eco*RI/*Xho* I fragment from the pET28a-NS3/4A(TGA) was ligated into *Eco*RI/*Sal* I site of pCI-neo vector and the clone was named as pCI-neo-NS3/4A(TGA).

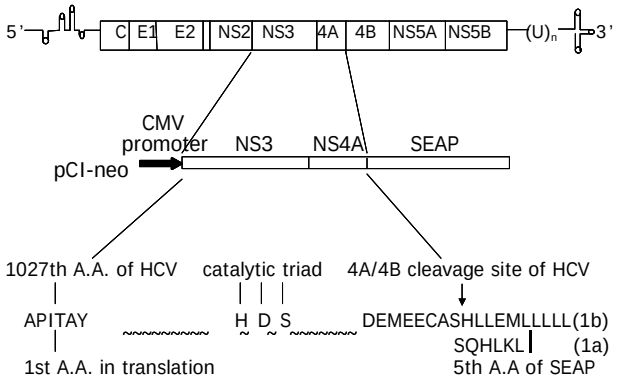

Figure 1 Schematic diagram of the pCI-neo-NS3/4A-SEAP and pCI-neo-RNS3/4A-SEAP expression vectors. The SEAP gene, which has N-terminal signal sequence, was fused in-frame to the HCV sequence encoding the full-length NS3 proteins followed by the NS4A cofactor. Amino acid sequences of (R)NS3/4A and SEAP in the fusion regions are shown by capitalized, bold characters. The cleavage site between NS4A and NS4B is indicated by arrow. HDS is the catalytic triad of NS3 protease.

Cell culture and transfection

HepG2 cells or Cos7 cells were cultured in Dulbecco's modified Eagle's medium (DMEM) with penicillin (100 U/ml) and streptomycin (100 μg/ml), supplemented with 10 % fetal calf serum. Recombinant plasmid DNA used for transfection was extracted and purified with the Qiagen Midiprep kits. DNA (5 μg) was used to transfect HepG2 or Cos7 cells in 6-well NUNC multidish by the calcium phosphate precipitation method as reported previously[10]. Duplicate dishes were used for all samples, and 3 μg of reporter plasmid pcDNA3.1-CAT expressing chloramphenicol acetyltransferase (CAT) was cotransfected as an internal control to normalize the transfection efficiency among dishes. Forty-eight hours after transfection, culture media and cells were collected separately to monitor the secretion of SEAP in the supernatant and NS3 protease expression in transfected cells. pCI-neo-NS3/4A (TGA) was used as a mock transfection control. Transfection experiments were repeated twice on separate days.

Colorimetric assay for SEAP

The SEAP activity of the culture media was measured at 48 h after transfection by performing a colorimetric assay according to the author's recommendation[11]. Briefly, 20 μl heat-treated (at 65 ℃ for 5 min) medium was adjusted to 1×SEAP assay buffer (1.0 M diethanolamine pH9.8, 0.5 mM $MgCl_2$, 10 mM L-homoarginine) in a final volume of 200 μl and prewarmed to 37 ℃ for 10 min in a 96-well flat-bottom culture dish. Twenty μl of prewarmed 120 mM *p*-nitrophenylphosphate dissolved in SEAP assay buffer was then added with mixing. The A_{405} of the reaction mixture was read in a BIO-RAD (Benchmark) microplate reader at 5-min intervals. The change in absorbance was plotted and the maximum linear reaction rate determined. The SEAP activity was expressed in milliunits (mU) per ml. One mu equals an increase of 0.04 A_{405} units per min. Each SEAP assay was performed in triplicate.

Establishment of NS3/4A-SEAP stable expression system

Two different cell lines of Cos7 and HepG2 cells were transfected with the plasmid pCI-neo-NS3/4A-SEAP, pCI-neo-RNS3/4A-SEAP or pCI-neo-NS3/4A (TGA), respectively by calcium phosphate precipitation method mentioned above. At 48 h after transfection, the cells were subcultured and selected with the 600 mg/l of G418. After 3 weeks of selection, the colonies were picked up and amplified in the presence of 200 mg/l G418.

Inhibition of HCV protease activity by Pefabloc SC

Cos7 cell lines (1b and 1a type) were seeded into a 6-well NUNC multidish at a density of 10^5 cells/ml in 3 ml medium and cultured overnight at 37 ℃ in a 50 ml· L^{-1} CO_2 incubator. The overnight culture media were changed with fresh one containing Pefabloc SC at the concentration of 0.1 mM, 0.2 mM, 0.4 mM, 0.5 mM, or 0.6 mM. The cells without Pefabloc SC treatment were set as control. After 24 hours, the media were collected for the colorimetric assay for SEAP activity. Effect of Pefabloc SC on the viability of Cos7 stable cells was evaluated by the alamarBlue™ assay (Biosource International Corp.)[12]. Alamar Blue was added in an amount equal to 10 % of the culture volume and after 2 hours of incubation at 37 ℃, the panels were read spectrofluorometrically (excitation, 544 nm; emission, 590 nm) by Ascent FL. The experiment was performed twice and each sample was detected in duplicate.

Northern blot analysis of NS3/4A expression in transfected cells

Total RNA was extracted using GIBCO-BRL TRIZOL Reagent (Cat No. 15596 Gibco Life Tech) according to the instructions of manufacturers. It was digested with RNase free DNase (Promega) to wipe off the transfected plasmid DNA. After electrophoresis in a 1 % agarose gel, 10 μg total RNA was blotted onto a positively charged Nylon membrane (Roche). HCV NS3/4A (100 ng of PCR products, 1a and 1b respectively) and random primers were used to prepare the [^{32}P] dCTP labled probes for hybridization. The signals were detected by autoradiography and scanned with densitometry for semiquantification of the intensity of signals. The corresponding intensity of β-actin signals was used as controls.

Western blot analysis of NS3/4A expression in transfected cells

To assess the expression levels of the HCV NS3/4A of two HCV genotypes in the transfected HepG2 or Cos7, Western blot analysis was conducted as described[13] with some modifications. Briefly, cells were lysed in 200 μl TSA buffer (50 mM Tris-HCl, 140 mM NaCl, 5 ml· L^{-1} NP40, 1 mM PMSF, 1 mM DTT). Ten μl aliquot was subjected to 7.5 % SDS-PAGE eletrophoresis. The separated proteins were transferred to nitrocellulose membrane in transfer buffer (20 mM Tris-HCl, 190 mM Glycine, 200 ml· L^{-1} methanol, pH 8.3) using Mini Trans-blot transfer system (Bio-Rad) at 100V for 1 h. The membrane was blocked with 50 mg· L^{-1} nonfat dried milk in

PBST (Tris-buffered saline containing 0.5 ml· L^{-1} Tween-20) and then incubated with mouse anti-NS3 multiclonal antibody. After three washes in PBST, the membrane was incubated with peroxidase-conjugated goat anti-mouse second antibody (A90-131P, BETHYL Co.). The blot was incubated with TMB substrate to reveal the antigen bands. Cellular protein La (a phosphoprotein, 47 KD, present at proximately 2×10^7 molecules per cell) was used as a quantificational control. The expression levels of the NS3 of two HCV isolates were compared by the semi-quantification of scanned intensity of antigen bands.

RESULTS

Transient expression of NS3/4A-SEAP

The plasmids pCI-neo-NS3/4A-SEAP, pCI-neo-NS3/4A (TGA) and pCMV-SEAP were transfected into HepG2 or Cos7 cells by calcium phosphate method and the SEAP activity of the culture media was measured at 48 h after transfection. As expected, in HepG2 cells, the pCMV-SEAP produced SEAP activity about 30.16±3.46 mu/ml, while pCI-neo-NS3/4A (TGA) produced 0.34±0.48 mu/ml, which is almost the background level (Figure 2). The culture media from cells transfected with pCI-neo-NS3/4A-SEAP showed a SEAP activity of about 12.05±1.25 mu/ml. Similar results were obtained in Cos7 cells (data not shown). The processing of fusion proteins expressed in transfected cells was examined by immunoblotting with anti-HCV human sera and mouse derived multiple-clonal sera. Processed NS3 protein of 70KD was detected (Figure 6). The results indicate that, depending on the cleavage activity of the NS3 protease, the SEAP could be cleaved and secreted into the extracellular media.

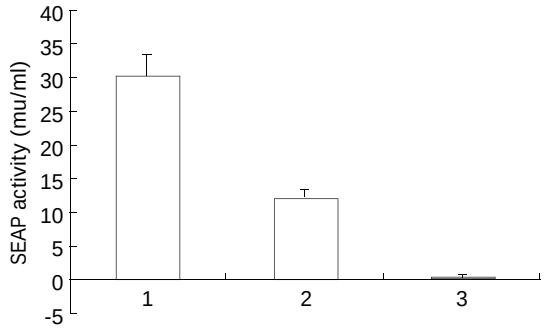

Figure 2 SEAP activity in the media of the transfected HepG2 cells. Lane 1: pCMV-SEAP, Lane 2: pCI-neo-NS3/4A-SEAP, Lane 3: pCI-neo-NS3/4A(TGA)(as negative control).

Stable expression of NS3/4A-SEAP

To establish the NS3/4A-SEAP assay system in stable expression cells, HepG2 and Cos7 cells transfected with the pCI-neo-NS3/4A-SEAP were selected for stable expression ones. During 600 mg/l G418 selection, most transfected HepG2 or Cos7 cells died out after 4 changes of media and the selected colonies were picked up and amplified in the presence of 200 mg/l G418. Results of SEAP assay showed that all selected stably expressing cell lines produced SEAP in their supernatant. However, the media from Cos7-derived stably expressing cell lines showed higher SEAP activity than those from HepG2-derived cell lines. Initially, the two kinds of stably expressing cell lines did not show any significant differences. Then, the HepG2-derived cell lines appeared to lose supernatant SEAP activity, depending on the passages and showed finally, very low SEAP activity (data not shown) while selected cell lines derived from Cos7 appeared to express high levels of SEAP during continuous passages over 4 months.

Comparison of protease activity of NS3/4A from HCV 1a and 1b two subtypes in both transient and stable expression systems

To compare the activity of serine proteases from HCV subtype 1b and 1a, two chimeric clones were constructed and studied in both transient and stable expression systems. Results of SEAP assay showed that, in transient expression system, the Cos7 cells transfected with the pCI-neo-NS3/4A(1b)-SEAP produced higher supernatant SEAP activity (37.49±3.06 mu/ml) than those transfected with pCI-neo-RNS3/4A(1a)-SEAP (3.48±0.15 mu/ml). The overall assay results were similar in HepG2 cells with pCI-neo-NS3/4A(1b)-SEAP at 11.82±0.92 mu/ml and pCI-neo-RNS3/4A(1a)-SEAP at 2.49±0.67 mu/ml. The above results indicated that cells transfected with pCI-neo-NS3/4A-SEAP from HCV 1b isolate produced 5-10 folds higher supernatant SEAP activity than those transfected with pCI-neo-RNS3/4A-SEAP from HCV 1a isolate (Figure 3). Consistently, the 1b derived stable cell lines also produced higher SEAP activity in media (39.11±2.97 mu/ml, 25.36±1.41 mu/ml) than those derived from 1a (6.92±0.56 mu/ml, 7.85±0.57 mu/ml, Figure 4).

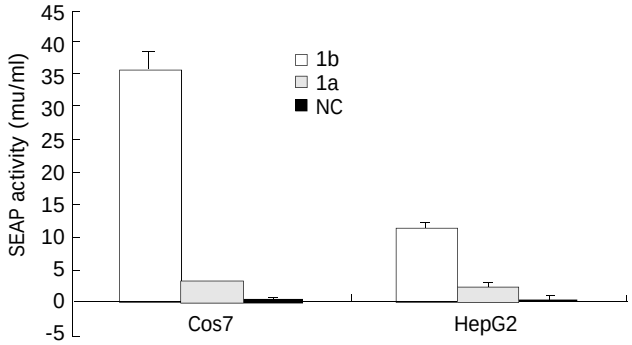

Figure 3 SEAP activity in the media of the transfected HepG2 and Cos7 cells. 1b: pCI-neo-NS3/4A-SEAP; 1a: pCI-neo-RNS3/4A-SEAP; NC: pCI-neo-NS3/4A(TGA)(as negative control).

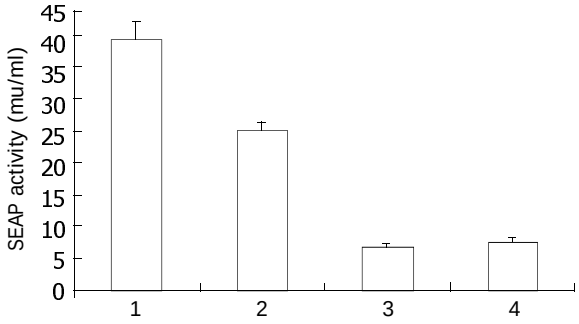

Figure 4 SEAP activity in the media of Cos7-derived stably expressing cell lines. Lane 1, 2: 1b type stable expression cell lines; Lane 3, 4: 1a type stable expression cell lines.

Northern blot analysis of NS3/4A mRNA level in transfected cells

To compare the amounts of NS3/4A mRNAs in transfected HepG2 and Cos7 cells, Northern blotting was carried out using the isotope-labeled DNA probes corresponding to NS3/4A regions of 1b and 1a. The NS3/4A specific signals could be detected in both HepG2 and Cos7 cells transfected with pCI-neo-NS3/4A-SEAP(1b), pCI-neo-NS3/4A(TGA), or pCI-neo-RNS3/4A-SEAP(1a) respectively. The hybridization signals of NS3/4A mRNA were similar between conspecific cells transfected with 1b or 1a constructs as the ratio of signal densities of NS3/4A to β-actin in pCI-neo-NS3/4A-SEAP(1b),

pCI-neo-NS3/4A(TGA) and pCI-neo-RNS3/4A-SEAP(1a) transfected cells were similar (2 066/2 360/2 400 in transfected Cos7 cells and 0.8/0.6/0.7 in transfected HepG2 cells) (Figure 5).

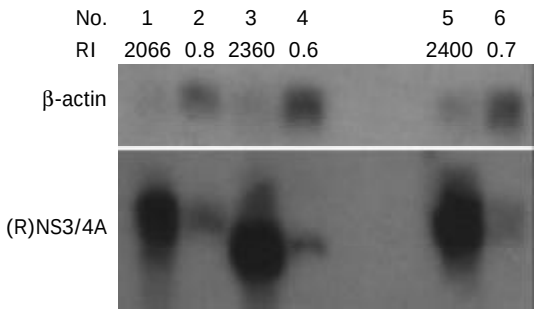

Figure 5 Northern blot analysis of NS3/4A mRNA level in transfected Cos7 cells (Lane 1, 3, 5) and HepG2 cells (Lane 2, 4, 6). Lane 1, 2 pCI-neo-NS3/4A-SEAP (1b type); Lane 3, 4 pCI-neo-NS3/4A (TGA) (control); Lane 5, 6 pCI-neo-RNS3/4A-SEAP (1a type); Intensity of hybridization signal was measured by densitometry, and the relative intensities of NS3/4A signal to β-actin are indicated below the lane No.

Western blot analysis of NS3 protein level in transfected cells

To compare the levels of NS3 proteins in transfected cells, Western blotting was carried out to detect the HCV protease expression with mouse anti-NS3 antibody. The expression levels of the NS3 were compared by the semiquantification of bands detected by immunoblotting. The relative intensities (RI) of NS3 to cellular protein La are indicated in Figure 6. The results showed that NS3 level expressed by pCI-neo-NS3/4A-SEAP (1b) was similar to the one expressed by pCI-neo-RNS3/4A-SEAP (1a) (3/3 in transfected Cos7 cells and 1/1 in transfected HepG2 cells) in transfected cells (Figure 6).

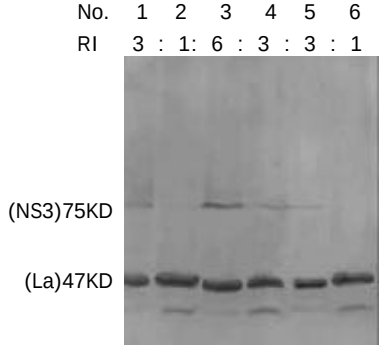

Figure 6 Western blot analysis of NS3 protein level in transfected Cos7 cells (Lane1, 3, 5) and HepG2 cells (Lane 2, 4, 6). Lane 1, 2 pCI-neo-NS3/4A-SEAP (1b type), Lane 3, 4 pCI-neo-NS3/4A(TGA) (control), Lane 5, 6 pCI-neo-RNS3/4A-SEAP (1a type). Intensity of hybridization signal was measured by densitometry, and the relative intensities (RI) of NS3 to cellular protein La in samples are indicated.

Inhibition of protease activity of NS3/4A by Pefabloc SC

Pefabloc SC, a serine protease inhibitor was added into the media of Cos7-derived stable expression cells at the concentration of 0.1 mM, 0.2 mM, 0.4 mM, 0.5 mM, or 0.6 mM. After 24 hours, the media were collected for the colorimetric assay of SEAP activity. The effect of Pefabloc SC on the viability of stable expression cells was evaluated by the alamarBlue™ assay. Results showed that, although the Pefabloc SC was relatively toxic to cells, it had some specific inhibitory effect on the protease activity of NS3/4A as the secretion of SEAP, which was dependent on the active HCV protease, was decreased more than the metabolic activity of the cells after treatment, and it was 60-70 % when the treated cells still kept almost 100 % metabolic activity (Figure 7).

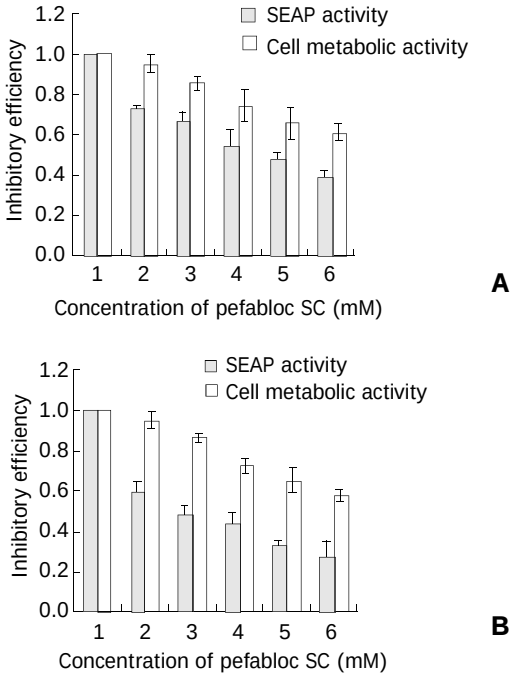

Figure 7 SEAP activity and viability of Cos7 stable cells treated with Pefabloc SC. The SEAP activity and viability of cells were measured with colorimetric and alamar Blue™ assay according to manufactures' recommendations. Each assay was performed in triplicate. A: 1b type stable expression cell lines, B: 1a type stable expression cell lines. 1: no treatment, 2: 0.1 mM, 3: 0.2 mM, 4: 0.4 mM, 5: 0.5 mM, 6: 0.6 mM.

DISCUSSION

It has been reported that the cleavage activity of NS3 could be detected by *in vitro* transcription/translation and transient expression experiments[14-16], or using purified active NS3 protease[17,18]. But they are known to be difficult to apply for screening specific NS3 inhibitors at large scale. Another problem has to be considered referring to the rather featureless substrate binding pocket of NS3[19], which may make the development of specific inhibitors rather difficult. Alternative *in vivo* assay systems for NS3 protease, which can differentiate the inhibitors' effects on NS3 protease and cellular metabolic activity (including cellular serine-type protease), will accelerate the screening of specific inhibitors. Several chimeric viral replication systems had been developed to screen HCV inhibitors in tissue culture[20,21]. These systems have some disadvantages regarding instability of chimeric viruses and difficulty in evaluating the inhibition quantitatively. Comparably, our cell-based NS3/4A-SEAP expression system is safe, easy to handle and the report gene of SEAP can be sensitively and quantitatively measured continuously without killing cells[11].

In the scheme of pCI-neo-NS3/4A-SEAP constructs, the NS4A/SEAP junction has the sequence DEMEEC ↓ ASHL (HCV 1b subtype)[22] or DEMEEC ↓ SQHL (HCV 1a subtype) which contains NS4A/4B cleavage site. The rationale for this system was based on the assumption that the secretion of SEAP protein into the culture media depends on the cleavage between NS4A protein and SEAP protein by HCV NS3 protease. The unusual substrate specificity, which is quite distinct from cellular serine-type proteases, makes it possible for the system to generate inhibitors with a high degree of selectivity[23,24]. To make the system more suitable for the screening of NS3

inhibitors, we also established the stably expressing cell lines. During the screening, the inhibitor could be introduced into the stable cells by transfection or simply adding in culture media[25] according to their own characteristics.

In the process of establishing both transient and stable expression systems, we found that Cos7-derived cells always showed higher SEAP activity in media than HepG2-derived ones. It is consistent with the previous report that Cos7 cells and other cell lines expressing the SV40 large T-antigen, have been of great benefit to the transfection studies using transient expression vectors containing the SV40 origin of replication, as these cells yield plasmid replication to a high copy number[26]. In addition, we also observed that the two kinds of cell lines initially did not show any significant differences in cell growth and morphology, but depending on the passages, the HepG2-derived cell lines appeared to lose SEAP activity and finally showed very low SEAP activity (data not shown). However, the Cos7-derived cell lines appeared to express high levels of SEAP activity during continuous passages even after 4 months. It is likely that the expression of active protease is relatively toxic in some cells, leading to selection of cells with low protease activity in the process of G418 selection and passage[22].

When this assay system was used to compare the activity of HCV serine proteases from different genotypes (1b and 1a), the cells transfected with 1b type plasmid DNA showed 5-10 folds higher SEAP activity in culture media than those with 1a type one in transient system. And there were no significant differences in protein and mRNA levels of NS3/4A between them in either transiently transfected Cos7 or HepG2 cells. The results indicated that the cleavage efficiency of 1b type NS3 protease was 5-10 folds higher than that of 1a type. Consistently, we observed similar results in the stable expression system. Since the NS3 serine protease activity is required for cleavages at the downstream 3/4A, 4A/4B, 4B/5A, 5A/5B sites, its cleavage efficiency will affect the assembly of functional HCV RNA replication complex, viral particle maturation and host-virus interaction. It has been reported that the success in establishing efficient HCV replication depended on the particular genotype 1b consensus cDNA clone studied[27]. Whether the higher protease activity of 1b subtype NS3 contributes to the above phenomenon is worthy of further investigations. The availability of replication system[27-29] will promote such studies.

In this study, the cell-based system was also successfully used to evaluate the inhibition effect of Pefabloc SC on the NS3 protease *in vivo*. Pefabloc SC[30] is one of the most potent inhibitors of the class of sulfonyl fluorides like phenylmethylsulfonylfluoride (PMSF). It has been widely used to inhibit all kinds of serine proteases (including HCV NS3)[31,32]. It was reported that 8mM of Pefabloc SC showed strong effects on NS3-4A junction in a trans-cleavage assay system[33]. Due to its toxicity to cells, the concentrations of Pefabloc SC used in our system were only from 0.1 mM to 0.6 mM. However, results here still showed that it had some specific inhibitory effect on the protease activity of the HCVNS3/4A as the secretion of SEAP, which depended on the active HCV protease, was decreased more than the metabolic activity of the cells after treatment (Figure 6). As shown in Figure 6, when the cells treated with 0.1 mM Pefabloc SC still kept near 100 % metabolic activity, the SEAP activity in culture media had decreased to 60-70 %. These data reflected the sensitivity of our system and its practicability for the detection and comparison of NS3 protease activity and the screening anti-NS3 inhibitors.

In summary, we reported the establishment of the cell-based NS3/4A-SEAP expression system in both transiently transfected and stable cell lines. It was further applied to the evaluation of Pefabolc SC, a known protease inhibitor and the comparison of activities of NS3 protease from 1a, 1b genotypes. It could be concluded that this cell-based system is efficient and sensitive enough for the detection and comparison of NS3 protease activity and the screening of anti-NS3 inhibitors. The functional difference between NS3/4A from 1a and 1b subtypes revealed by this system provides a clue for further investigations.

Abstract

AIM: To evaluate the efficacy and safety of capsule oxymatrine in the treatment of chronic hepatitis B.

METHODS: A randomised double-blind and placebo-controlled multicenter trial was conducted. Injection of oxymatrine was used as positive-control drug. A total of 216 patients with chronic hepatitis B entered the study for 24 weeks, of them 108 received capsule oxymatrine, 36 received injection of oxymatrine, and 72 received placebo. After and before the treatment, clinical symptoms, liver function, serum hepatitis B virus markers, and adverse drug reaction were observed.

RESULTS: Among the 216 patients, six were dropped off, and 11 inconsistent with the standard were excluded. Therefore, the efficacy and safety of oxymatrine in patients were analysed. In the capsule treated patients, 76.47 % became normal in ALT level, 38.61 % and 31.91 % became negative both in HBV DNA and in HBeAg. In the injection treated patients, 83.33 % became normal in ALT level, 43.33 % and 39.29 % became negative both in HBV DNA and in HBeAg. In the placebo treated patients, 40.00 % became normal in ALT level, 7.46 % and 6.45 % became negative both in HBV DNA and in HBeAg. The rates of complete response and partial response were 24.51 % and 57.84 % in the capsule treated patients, and 33.33 % and 50.00 % in the injection treated patients, and 2.99 % and 41.79 % in the placebo treated patients, respectively. There was no significance between the two groups of patients, but both were significantly higher than the placebo. The adverse drug reaction rates of the capsule, injection and placebo were 7.77 %, 6.67 % and 8.82 %, respectively. There was no statistically significant difference among them.

CONCLUSION: Oxymatrine is an effective and safe agent for the treatment of chronic hepatitis B.

INTRODUCTION

Oxymatrine is a kind of alkaloid extracted from a Chinese herb *Sophora alopecuraides L.*[1]. Basic and clinical researches suggested that oxymatrine had the following pharmacological effects such as anti-virus, protecting hepatocytes, anti-hepatic fibrosis, immune regulation, etc[2-7]. In particular, wide attention was paid to its inhibitory effect on hepatitis B virus (HBV) in recent years. Oxymatrine has been proved to have distinct anti-virus effect in the treatment of chronic hepatitis B (CHB)[8-11]. But no information is available about the therapeutic efficacy and safety of oxymatrine capsule treated CHB. In this paper, we evaluated the therapeutic efficacy and safety of oxymatrine (kurorinone) capsule in the treatment of CHB based on a randomized multi-centre, double-blind and placebo-controlled clinical trial.

MATERIALS AND METHODS

Research design

This study was a clinical trial characterized by multi-centre, randomization, double blinding and placebo-control, which was fulfilled by Renji Hospital of Shanghai Second Medical University, Zhongshan Hospital of Fudan University, Changhai Hospital of Second Military Medical University.

Selection of subjects

Enrolled criteria: Age: 18-65 years old, regardless of sex, positiveness of serum HBsAg and HBV DNA for at least 6 months before enrolling, positiveness of serum HBeAg for at least 6 months before enrolling, abnormal serum value of alanine transaminase (ALT) twice or more with a value 1.2 times greater than normal upper limit and a duration more than 8 weeks between two tests within 6 months before enrolling, the serum

level of ALT was more than normal upper limit when screening, total serum bilirubin (TB) level less than or equal to 85.5 μmol/L, non-history of administrating antiviral and immunoregulating drugs, signing in the informed consent form, promising not to receive other drugs in clinical trial and systemic anti-viral agents, cytotoxic agents, hormone, immunoregulators, drugs capable of reducing serum enzyme activity and bilirubin level and Chinese traditional medicines, etc.

Exclusion criteria Patients with positive laboratory test of HIV, positiveness of serum anti-HCV and/or HCV RNA, uncompensable liver diseases, suggestive of autoimmune diseases with antinuclear antibody (ANA) titer greater than a 1:160 dilution, abnormality of serum creatinine with a value of 1.5 times greater than normal, concurrence of other associated severe diseases which might affect the present treatment, hypersensitive to oxymatrine capsule, women with pregnancy and during breast-feeding period.

Treatment procedures and drugs

A total of 216 selected patients were randomly divided into 3 groups: 108 in capsule oxymatrine group, 36 in injection oxymatrine group and 72 in placebo group. Both capsule oxymatrine and injection oxymatrine were provided by Ningxia Pharmaceutic Institute, Ningxia, China (Batch numbers 990426 and 990325, respectively). The magnitude, colour, shape and taste of the vacant placebo capsule were consistent with capsule oxymatrine. Capsule oxymatrine group: 300 mg oxymatrine capsules orally 3 times a day. Injection oxymatrine group: 400 mg intramuscularly once a day. Placebo group: 3 tablets, three times a day. Treatment course of the 3 groups was 24 weeks. After completion of selection and assessment, qualified subjects were allocated randomly into capsule oxymatrine group, injection oxymatrine group and placebo group for a treatment course of 24 weeks according to the treatment code based on stratified randomization.

Observing indexes and assessment

Clinical manifestations Weakness, pain in hepatic region, jaundice, hepatomegaly, splenomegaly, etc.

Liver function indexes Serum levels of total protein, albumin, ratio of albumin and globulin, ALT, aspartate aminotransferase (AST), γ-glutamyl transpeptidase (GGT), total bilirubin (TB), direct bilirubin (DB) and alkaline phosphatase (ALP).

Detection of serum markers of HBV HBV DNA was measured by dot blotting assay. HBsAg, anti-HBsAg, anti-HBc, HBeAg and anti-HBe were measured by Abbott kit before the treatment, 12 and 24 weeks after the treatment.

Analysis of blood and urine All parameters including electrolytes and renal function were measured before the treatment, 12 and 24 weeks after the treatment.

Assessment criteria of therapeutic effect and safety

Mainly evaluated indexes were negatively converting rate of serum HBV DNA and HbeAg, and the normalization rate of serum ALT. The assessment criteria of therapeutic effect were as follow. Complete response: negative conversion of HBeAg and HBV DNA, and normalization of serum ALT. Partial response: negative conversion of HBeAg and HBV DNA or normalization of serum ALT. Nonresponse: the effect didn' t reach the above criteria. Any abnormal clinical manifestations and laboratory tests occurred during the treatment were recorded and filled in a report form of side effects in time whether they were associated with drugs for trial or not.

Statistical analysis

Statistical analysis of the data was performed with SAS 6.12 software kit.

RESULTS

Number of subjects

A total of 216 patients were enrolled in the study, of them 108 in capsule oxymatrine group, 36 in injection oxymatrine group, and 72 in placebo control group. Twelve cases withdrew, and the withdrawal rate was 2.78 %. Eleven cases were excluded for not conforming selection criteria, and the excluding rate was 5.09 %. One hundred and ninety-nine cases entered statistical analysis of therapeutic effect included 102 cases in capsule oxymatrine group, 30 cases in injection oxymatrine group, and 67 cases in placebo control group.

General state of patients in three groups before treatment

Before treatment, the following data were similar among three groups (P>0.05, respectively), including sex, age, duration of hepatitis, abnormality of serum ALT and AST 2-fold higher than normal elevation, etc. There were no significant differences among three groups in symptoms and signs before treatment (P>0.05).

Negative conversion of serum virus markers

Negative conversion rate of serum HBsAg in capsule oxymatrine group, injection oxymatrine group and placebo group was 1.98 %, 3.33 %, and 0.00 %, respectively (Table 1). There were no obvious differences among 3 groups (P=0.269). The negative conversion rate of HBV DNA was 38.61 %, 43.33 % and 7.46 % respectively in the above groups. There were obvious differences between capsule oxymatrine group and placebo group or between injection oxymatrine group and placebo group (P=0.001), but there were no significant difference between capsule oxymatrine group and injection oxymatrine group (P=0.643). The negative conversion rate of serum HBeAg was 31.91 %, 39.29 % and 6.45 % respectively in the above groups. There was an obvious difference between capsule oxymatrine group and placebo group or between injection oxymatrine group and placebo group (P=0.001), but no significant difference between capsule oxymatrine group and injection oxymatrine group (P=0.469).

Normalization rate of serum ALT

The normalization rate of serum ALT in capsule oxymatrine group, injection oxymatrine group and placebo group was 76.47 %, 83.33 % and 40.00 %, respectively. There was an obvious difference between capsule oxymatrine group and placebo group or between injection oxymatrine group and placebo group (P=0.001, Table 2), but no significant difference between capsule oxymatrine group and injection oxymatrine group (P=0.425).

Comparison of therapeutic effect among 3 groups of chronic hepatitis B

The complete and partial response rates were 24.51 % and 57.84 % in capsule oxymatrine group, 33.33 % and 50.00 % in injection oxymatrine group, 2.99 % and 41.79 % in placebo group. There was an with obvious difference between capsule oxymatrine group and placebo group or between injection oxymatrine group and placebo group (P=0.001, Table 3), but no significant difference between capsule oxymatrine group and injection oxymatrine group (P=0.4589).

Adverse effects

In this study, 8 patients had adverse effects in capsule oxymatrine group with an incidence of 7.77 %, 2 patients in injection oxymatrine group with an incidence of 6.67 %, and 6 patients in placebo group with an incidence of 8.82 %. The difference among 3 groups had no statistical significance

Table 1 Negative conversion rates of serum HBsAg and comparison among capsule oxymatrine group, injection oxymatrine group and placebo group

Index	Group	Positive number	Number of negative conversion	Negative conversion rate (%)	Comparison among 3 groups	
					χ^2	*P* value
HBsAg	Capsule	101	2	1.98		
	Injection	30	1	3.33		0.269
	Placebo	67	0	0.00		
HBV DNA	Capsule	101	39	38.61		
	Injection	30	13	43.33	22.716	0.001
	Placebo	67	5	7.46		
HBeAg	Capsule	94	30	31.91		
	Injection	28	11	39.29	17.042	0.001
	Placebo	62	4	6.45		

The comparison of negative conversion rates of serum HBsAg, HBV DNA and HBeAg was performed with chi-square test, statistic was χ^2.

Table 2 Normalization rate of serum ALT and comparison among capsule oxymatrine group, injection oxymatrine group and placebo group

Group	Number of ALT abnormality before treatment	Number of ALT normalization after treatment	Normalization rate (%)	Comparison among 3 groups	
				χ^2	*P* value
Capsule	102	78	76.47		
Injection	30	25	83.33	28.352	0.001
Placebo	65	26	40.00		

The comparison of ALT normalization rate was performed with chi-square test, statistic was χ^2.

Table 3 Comparison of therapeutic effect among 3 groups with chronic hepatitis B

Group	Complete response	Partial response	Non-response	Comparison among 3 groups	
				χ^2	*P* value
Capusle (*n*=102)	25 (24.51 %)	59 (57.84 %)	18 (17.65 %)		
Injection (*n*=30)	10 (33.33 %)	15 (50.00 %)	5 (16.67 %)	35.957	0.0001
Placebo (*n*=67)	2 (2.99 %)	28 (41.79 %)	37(55.22 %)		

The comparison of therapeutic effect among 3 groups was performed with K-W test, statistic was χ^2.

(*P*=0.931). The adverse effects were mild or moderate and mainly manifested as symptoms of upper alimentary tract, rash, bad taste. No severe adverse effect occurred. The statistical analysis of adverse effects included 2 cases withdrawn because of side effects.

DISCUSSION

Hepatitis B virus is a DNA virus that produces both acute and chronic infections of the liver in humans. It has been estimated that over 300 million people worldwide are chronically infected with HBV and that over 250 000 people would die each year due to HBV-associated complications of cirrhosis and primary hepatocellular carcinoma[12-18]. For many years, alpha interferon has been the only approved therapy for chronic HBV infection in most countries. Interferon was effective in 30-40 % of patients, and it must be given by injection and was frequently associated with fever and influenza-like symptoms[19-23]. Recently, lamivudine was approved for the treatment of chronic HBV infection in many regions of the world. Although convenient and well-tolerated, lamivudine' s efficacy rate was similar to interferon and prolonged administration of lamivudine was associated with development of resistance[24-30]. New agents, such as adefovir dipivoxil, offered a promise either alone or in combination with lamivudine in the treatment of individuals who were ' treatment naï ve' have developed lamivudine resistance[31-33]. Up to date, no specific therapy is available for chronic hepatitis B. The following factors may be associated with its pathogenesis such as virulence of HBV strains, number of infected hepatocytes and host immune response, antiviral agents, immunomodulators and drugs might be capable of improving liver function[12-15,34-41].

Traditional Chinese medicine has been widely used for the treatment of liver disease in China[11]. Oxymatrine extracted from *Sophora alopecuraides L.* has been shown to have a remarkable HBV suppressing effect with 40 % serum conversion rate for HBeAg and HBV DNA, similar to that of alpha interferon[8,9,11]. Experiment *in vitro* indicated that oxymatrine had an inhibitory role in the secretion of HBsAg and HBeAg by 2.2.15 cell line transfected with HBV DNA and the inhibitory rates increased gradually following increased oxymatrine concentration and the extension of effect time within a definite range[42]. *In vivo* study of HBV transgenic mouse showed that when mice were injected intraperitoneally oxymatrine at 100 mg/kg, 200 mg/kg and 300 mg/kg once a day for 30 days, the quantity of HBsAg and HBeAg in the liver decreased obviously compared with control group, and there was no significant difference among 3 doses[10]. Clinical research suggested that the normalization rates of serum ALT and TB, and the negative conversion rates of serum HBsAg and HBV DNA were similar to alpha interferon when oxymatrine was applied to treatment of chronic hepatitis B. The results in

present study were similar to the therapeutic effect of interferon in the treatment of chronic hepatitis B at home and abroad[9,11,17,43], indicating that capsule oxymatrine is an effective and safe agent for treatment of chronic hepatitis B.

Abstract

AIM: To select valuable ultrasonographic predictors for the evaluation of hepatic inflammation and fibrosis degree in chronic hepatitis, and to study the value of ultrasonography in the evaluation of liver fibrosis and compensated liver cirrhosis in comparison with serology and histology.

METHODS: Forty-four ultrasonographic variables were analyzed and screened using color Doppler ultrasound system in 225 patients with chronic viral hepatitis and compensated liver cirrhosis. The valuable ultrasonographic predictors were selected on the basis of a comparison with histopathological findings. The value of ultrasonography and serology in the evaluation of liver fibrosis degree and the diagnosis of compensated liver cirrhosis was also studied and compared. Meanwhile, the influencing factors on ultrasonographic diagnosis of compensated liver cirrhosis were also analyzed.

RESULTS: By statistical analysis, the maximum velocity of portal vein and the degree of gall-bladder wall smoothness were selected as the valuable predictors for the inflammation grade (G), while liver surface, hepatic parenchymal echo pattern, and the wall thickness of gall-bladder were selected as the valuable predictors for the fibrosis stage (S). Three S-related independent ultrasonographyic predictors and three routine serum fibrosis markers (HA, HPCIII and CIV) were used to discriminate variables for the comparison of ultrasonography with serology. The diagnostic accuracy of ultrasonography in moderate fibrosis was higher than that of serology ($P<0.01$), while there were no significant differences in the general diagnostic accuracy of fibrosis as well as between mild and severe fibrosis ($P<0.05$). There were no significant differences between ultrasonography and serology in the diagnosis of compensated liver cirrhosis. However, the diagnostic accuracy of ultrasonography was higher in inactive liver cirrhosis and lower in active cirrhosis than that of serology (both $P<0.05$). False positive and false negative results where found when the diagnosis of compensated liver cirrhosis was made by ultrasonography.

CONCLUSION: There are different ultrasonographic predictors for the evaluation of hepatic inflammation grade and fibrosis stage of chronic hepatitis. Both ultrasonography and serology have their own advantages and disadvantages in the evaluation of liver fibrosis and compensated liver cirrhosis. Combined application of the two methods is hopeful to improve the diagnostic accuracy.

INTRODUCTION

Viral hepatitis is one of the most common and prevalent infectious diseases in China. It was found that 25-40 % of the patients with chronic viral hepatitis would become liver cirrhosis or even hepatocellular carcinoma[1,2]. Prompt and effective treatment could postpone or interrupt the development of chronic hepatitis into liver cirrhosis. Accurate estimation of the disease severity is helpful for the evaluation of the therapeutic effect and the prognosis of the disease. At present, there are three ways for this purpose, namely histology, serology and imaging. Liver histological diagnosis based on needle biopsy is the gold standard to evaluate the degree of hepatic inflammation and fibrosis. However, liver biopsy can not be performed routinely at clinical settings becouse of its invasiveness. In addition, it is well known that liver parenchymal damage in chronic hepatitis and cirrhosis is not uniform. Sample errors were commonly encountered[3-5]. Serological examination is a non-invasive routine method. However, serological markers of fibrosis with high specificity have not been available yet in addition to the lack of organ specificity of these markers[6-8]. Imging technologies such as ultrasonography, computed tomography, magnetic resonance imaging could provide useful information on the morphological changes of the liver, and are important in the evaluation of chronic liver diseases[9-15]. Among them, ultrasonography has become the most common and valuable method because of its low cost, easy performance and high acceptability by the patient. It could provide not only valuable information on the morphological changes of the liver but also liver hemodynamics by color Doppler flow imaging[16-19].

It was reported that evaluating liver morphology and hemodynamics in patients with cirrhosis and portal hypertension had an important value for the estimation of the disease severity and prognosis[17-21]. As the disease progresses from chronic hepatitis to cirrhosis, a variety of intra- and extrahepatic abnormalities would occur. Using multiple ultrasonographic variables to evaluate morphological and hemodynamic changes of the liver, gallbladder and the spleen could be expected to reveal these abnormalites and improve the diagnostic ability of ultrasound[15,22,23].

In this study, 44 ultrasonographyic variables were analyzed and screened using color Doppler ultrasoud system in 225 patients with chronic viral hepatitis and compensated liver cirrhosis. The results were compared with histological findings based on the assessment criteria of the imflammation grade and fibrosis stage for chronic hepatitis, which were proposed

by the academic meeting of Chinese Medical Association on epidemic and parasitosis in 1995 (95-Protocol)[24]. The valuable predictors were selected by statistical analysis. The value of ultrasonography in the evaluation of fibrosis and compensated liver cirrhosis was investigated and compared with serology.

MATERIALS AND METHODS

Patients selected

Two hundred and twenty-five patients with chronic viral hepatitis and compensated liver cirrhosis were treated in our hospital from 1996 to 1999. Among them, 199 were males and 26 were females, their average age was 30.5 years (range from 10 to 57 years). The pathogenic diagnoses were: hepatitis B in 208 patients, hepatitis C in 10 patients, coinfection of hepatitis B and C in 3 patients, coinfection of hepatitis B and E in 2 patients, hepatitis B plus A and hepatitis B plus D in 1 patient, respectively. Clinical diagnoses were mild chronic hepatitis in 78 patients, moderate chronic hepatitis in 114 patients, severe chronic hepatitis in 12 patients, and cirrhosis in 21 patients. No clinical manifestations of decompensated liver cirrhosis were found in all the patients.

Fifty-one healthy volunteers were examined as a control group. There were 26 males and 25 females, their average age was 27.8 years (range from 18 to 76 years). Serological and biochemical tests were normal.

Ultrasonographic examination

Using Esaote AU4 color Doppler system with 3.5-5.0 MHz curved probe, ultrasonographic examination was performed for the patients fasted for about 8 hours 12-24 hours after liver biopsy. First, sonographic findings of the liver, spleen and gallbladder, such as size, form, surface, internal echo, and diameter of vessels were observed and measured. Second, blood flow parameters of the hepatic and splenic vessels were measured by color Doppler flow imaging with the patient holding his/her breath at the end of a quiet breathing. Sample volume was adjusted slightly smaller than the diameter of vessels, and the sample angle was less than 60 degrees. Doppler spectrum with 3-5 stable heart cycles was selected for the measurement, which was performed at least two times and the average value was used.

Forty-four ultrasonographyic variables were analyzed, including the largest oblige diameter (RL_{OD}) and anterior-posterior diameter (RL_{AP}) of the right liver lobe, longitudinal diameter and anterior-posterior diameter of the left liver lobe (LL_L, LL_{AP}), the caudate liver lobe (CL_L, CL_{AP}), the ratio of CL_L/LL_L, transverse diameter (SP_T) and longitudinal diameter (SP_L) of the spleen, liver surface (L_{sur}) and hepatic parenchymal echo pattern (L_E), size (GB_{siz}) and wall thickness (GB_T) of the gall-bladder, degree of gall-bladder wall smoothness (GB_{sm}), complication of gall-bladder stone (GB_{st}) and gall-bladder pulypus (GB_P), umbilical vein patent (U); diameter of the main portal vein trunk (PV_D), right portal vein (RPV_D) and left portal vein (LPV_D); maximum and mean blood flow velocity of the main portal vein trunk (PV_{max},PV_{mea}), right portal vein (RPV_D, RPV_{max}) and left portal vein (LPV_{max}, LPV_{mea}), blood flow volume of the main portal vein trunk (PV_F), right portal vein (RPV_F) and left portal vein (LPV_F); congestive index of the portal vein (CI); diameter (HV_D) and Doppler waveform (HV_W) of the hepatic vein; diameter (HA_D), peak systolic blood flow velocity (HA_S), blood flow volume (HA_F) and resistant index (HARI) of the hepatic artery; diameter (SPA_D), peak systolic blood flow velocity (SPA_S), blood flow volume (SPA_F), and resistant index (SPARI) of the splenic artery; diameter (SPV_D) and maximum blood flow velocity (SPV_{max}) of the splenic vein, and the ratio of SPV_F/PV_F.

The measurements and evaluation of the parameters referred to the methods described in the literature[1,4-6]. Liver surface and the degree of gall-bladder wall smoothness were classified into 3 grades, namely smooth, less smooth and rough. Hepatic parenchymal echo patterns were classified into 5 grades according to the distribution and echogenicity of the parenchymal echo texture as the renal parenchymal echo was used as the contrast.

Examination of serum fibrosis markers

One hundred and ninety-seven cases underwent ultrasonographic and serologic examinations successively. Among them, 48 had compensated cirrhosis, and the rest had chronic hepatitis. The serum fibrosis markers including hyalurionic acid (HA), human procollagen III(HPCIII) and collagen type IV(CIV) were tested using radioimmunological method. The normal ranges were HA(57±27 ng/L), HPCIII($\leqslant$120 μg/L)and CIV (38.22±11.88 μg/L)

Histological study

All the patients underwent liver biopsy. The tissue sections were stained with HE and reticular fibers respectively. Histological study was performed according to the 95-Protocol[24], in which inflammation grade (G) and fibrosis stage (S) were classified from G1 to G4, and S0 to S4, respectively, based on the various degrees of inflammation or fibrosis. Furthermore, G1-2, G3 and G4 were defined as mild, moderate and severe inflammation, respectively, while S0-2, S3 and S4 were defined as mild, moderate and severe fibrosis, respectively. S4 also meant early or definite cirrhosis.

Quantitative assessment of liver fibrosis

Quantitative assessment of liver fibrosis was performed in 107 liver specimens with reticular fiber stain using an imagine analysis system (KONTRON IBAS2.5, German). The images were amplified by 400 times. Fibrosis degree was expressed as the ratio of fibrous area to the section area. Three to five fields of vision were selected randomly at the peripheral and center of the section for the average value of the ratio.

Statistical analysis

SPSS 9.0 software was used for this study. Numerical variables were described as mean ±standard deviation. For the comparison of means in different groups, univariate analysis and Student-Newman-Keuls test were used. While for the categorical variables, non-parameter analysis and χ^2 test were used for the comparison. A P value less than 0.05 was considered statistically significant. Spearman' s rank correlation coefficient was used for the correlation analysis. As for the selection of useful variables from categorical and numerical data, stepwise discriminant analysis and multiple linear regression analysis were used, respectively.

RESULTS

Screening for valuable ultrasonographic predictors

Histological diagnosis of the case group is shown in Table 1.

Table 1 Histological results in case group

Inflammation grade (G)	No. subjects	Fibrosis stage (S)	No. subjects
0	0	0	7
1	31	1	54
2	85	2	66
3	85	3	52
4	24	4	46
Total	225		225

According to univariate analysis, there were 21 variables with significant difference (P<0.05) among groups classified by the inflammation grade. While there were 19 variables with significant difference (P<0.05) among groups classified by the fibrosis stage (Tables 2 and 3). When stepwise correlation analysis was used, 20 variables were correlated with G (P<0.01), and 18 variables were correlated with S (P<0.01).

Table 2 Univariate analysis of quantitative variables

Variables	Grouped by G		Grouped by S	
	F value	*P* value	F value	*P* value
PV_{max}	29.17	<0 .001	19.38	<0.001
GB_T	24.03	<0.001	14.60	<0.001
PV_D	20.43	<0.001	18.07	<0.001
PV_{mea}	18.69	<0.001	11.28	<0.001
HV_D	16.88	<0.001	20.21	<0.001
RPV_{max}	14.24	<0.001	7.18	<0.001
SP_L	11.57	<0.001	14.87	<0.001
SPV_D	9.47	<0.001	12.76	<0.001
SP_T	9.28	<0.001	11.18	<0.001
CI	5.22	<0.01	3.96	<0.01
RPV_D	5.30	<0.01	3.43	<0.01
LL_L	2.99	<0.05	3.41	<0.05
SPV_F	2.72	<0.05	4.97	<0.01
SPA_D	4.20	<0.01	2.29	>0.05

Table 3 Non-parametric analysis of categorical variables

Variables	Grouped by G		Grouped by S	
	χ^2 value	*P* value	χ^2 value	*P* value
L_E	50.17	<0.001	91.34	<0.001
GB_{siz}	22.18	<0.001	21.00	<0.001
HV_W	22.14	<0.001	33.34	<0.001
GB_{sm}	20.07	<0.001	78.99	<0.001
L_{sur}	18.31	<0.001	66.92	<0.001
U	13.66	<0.01	32.07	<0.001
GB_{st}	8.45	<0.05	6.06	>0.05

The correlation coefficient between the quantitative analysis results of liver fibrosis and S was 0.76 (P<0.001). The correlation coefficient between G and S was 0.75 (P<0.001).

Twenty-two ultrasonographic variables associated with G and 19 variables associated with S were selected on the basis of univariate and correlation analysis results (Table 4), and used as the preliminary valuable variables for further analysis. When compared between case group and control group, there were significant differences in these selected variables (P<0.05).

Table 4 Ultrasonographic variables with significant correlation with G and S

	Ultrasonographic variables
Associated with G (22 items)	GB_{sm}, PV_{max}, GB_T, L_E, PV_D, HV_D, PV_{mea}, RPV_{max}, SP_L, SP_T, SPV_D, HV_W, GB_{siz}, L_{sur}, CI, RPV_D, RPV_{mea}, U, LL_L, GB_{st}, SPV_F and SPA_D
Associated with S (19 items)	GB_T, $L_{E,,}$, GB_{sm}, PV_D, PV_{max}, L_{sur}, HV_D, PV_{mea}, RPV_{max}, SP_L, SP_T, SPV_D, HV_W, GB_{siz}, CI, U, LL_L, SPV_F and RPV_D

Stepwise discriminant analysis was used for further selection of valuable predictors. GB_{sm}, PV_{max} were finally selected as independent predictors which were significantly correlated to G, while the independent predictors of L_E, GB_T and L_{sur} were significantly correlated to S.

Comparison of ultrasonography and serology in evaluation of fibrosis degree and diagnosis of compensated cirrhosis

Evaluation of fibrosis degree Liver fibrosis was divided into mild, moderate and severe fibrosis on the basis of fibrosis stage according to the 95-Protocol. The case distribution was mild fibrosis in 127 patients, moderate fibrosis in 52 patients, and severe fibrosis in 46 patients.

Three independent ultrasonographyic predictors associated with S (L_E, GB_T, L_{sur}) and three serum fibrosis markers (HA, HPCIII and CIV) were taken as discriminating variables for the comparison.

The correlation coefficients of L_E, GB_T and L_{sur} were 0.63, 0.58 and 0.5, respectively (P<0.001). While the correlation coefficients of HA, HPCIII and CIV were 0.60, 0.46 and 0.50, respectively (P<0.001).

The comparison between ultrasonographic variables and serologic fibrosis markers for the evaluation of fibrosis degree is shown in Table 5.

Table 5 Diagnostic accuracy of ultrasonography and serology for the evaluation of fibrosis degrees (%)

	Mild fibrosis	Moderate fibrosis	Severe fibrosis
Serology	79.5	19.1[b]	66.7
Ultrasonography	74.5	46.8[b]	62.5

[b]P<0.01 serology *vs* ultrasonography.

The diagnostic accuracy of ultrasonography and serology was higher in mild liver fibrosis than in severe and moderate liver fibrosis. There were no significant differences between ultrasonography and serology in the general diagnostic accuracy of fibrosis and diagnostic accuracy of mild and severe fibrosis (P>0.05). However, the diagnostic accuracy of ultrasonography in moderate fibrosis was higher than that of serology (P<0.01).

Diagnosis of compensated cirrhosis

Among the 48 patients with compensated cirrhosis, 46 patients had hepatitis-related cirrhosis, and 2 patients had cholestatic cirrhosis. The fibrosis stage of all these patients was S4. All of them had no symptoms of decompensated cirrhosis.

The diagnostic accuracy of ultrasonography for compensated cirrhosis was 80.7 %, while that of serology was 79.7 %. There was no significant difference between them. However, ultrasonography had a lower sensitivity (62.5 % *vs* 72.9 %) and a higher specificity (86.6 % *vs* 81.9 %) compared with serology (P<0.05).

According to the 95-Protocol, it would be regarded as active cirrhosis when G>2 and S=4, while it was regarded as inactive cirrhosis when G⩽2 and S=4. In our patient group, there were 41 patients with active cirrhosis and 7 patients with inactive cirrhosis. Among the 7 patients with inactive cirrhosis, the clinical diagnoses were mild chronic hepatitis in 3 patients, moderate chronic hepatitis in 2 patients, and liver cirrhosis in 2 patients.

For the evaluation of inactive liver cirrhosis, the diagnostic accuracy of ultrasonography was higher than that of serology (100 % *vs* 42.9 %, P<0.05). However, the diagnostic accuracy of ultrasonography was lower than that of serology in active cirrhosis (56.1 % *vs* 78.0 %, P<0.05).

Ultrasonographic, histological and clinical figures of compensated cirrhosis with false positive and false negative results on ultrasonography

False negative results of cirrhosis on ultrasonography Eighteen patients who were predicted as mild or moderate

fibrosis by ultrasonography were finally diagnosed as cirrhosis by histology. Among them, 9 patients were diagnosed as moderate chronic hepatitis, 5 patients as severe chronic hepatitis and 4 patients as liver cirrhosis according to their clinical manifestations.

The ultrasonographic features were coarse and homogenous hepatic parenchymal echo patterns (Figure 1). All of these patients had active liver cirrhosis with fine and sparse fibrotic septa (Figure 2) or small and uniform pseudolobular nodules on histology. Serologic tests showed that liver dysfunction was evident. The serum level of fibrosis markers in these patients increased obviously (HA: 408.06±219.26, HPC3: 217.78±84.96, and IVC: 210.28±181.88).

Figure 1 Active cirrhosis. Ultrasonography showed that the hepatic parenchymal echo became coarse and dot-shaped, and the distribution was still homogenous.

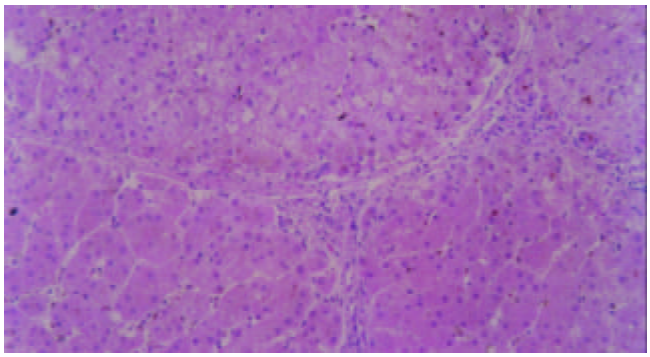

Figure 2 Active cirrhosis. Small and sparse fibroitc septa were shown on histology. (HE stain ×100).

Figure 3 Chronic viral hepatitis. On ultrasonography, the hepatic parenchymal echo became coarse and heterogeneous with speckled hyper- and hypoechoic areas.

False positive results of cirrhosis on ultrasonography

Twenty patients who were predicted as liver cirrhosis by ultrsonography were finally diagnosed as mild (n=6) and moderate (n=14) fibrosis by histology. Among them, 3 patients were diagnosed as mild chronic hepatitis, 12 patients as moderate chronic hepatitis, 1 patient as severe chronic hepatitis and 4 patients as liver cirrhosis according to their clinical manifestations.

The ultrasonographic and histological features were as follows. Hepatic parenchymal echo patterns became coarse and heterogeneous with speckled hyper- and hypoechoic areas (Figure 3), the correspondent histological findings were fatty degeneration foci heterogeneously distributed within the sections in addition to the inflammation and fibrosis changes (Figure 4), and changes of liver cirrhosis were not found. Hepatic parenchymal echoes were strip-shaped and coarse (Figure 5), the correspondent histology showed wide and compact fibrotic septa (Figure 6), lobular generation was not evident.

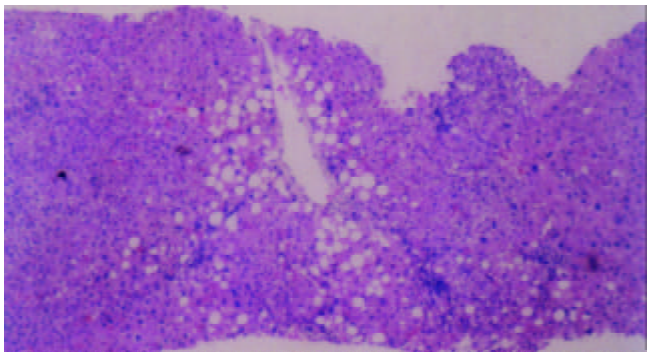

Figure 4 Chronic viral hepatitis. On histology, focal fatty degeneration foci were shown. (HE stain, ×40).

Figure 5 Chronic viral hepatitis. Ultrasonography showed the hepatic parenchymal echo to be strip-shaped and coarse.

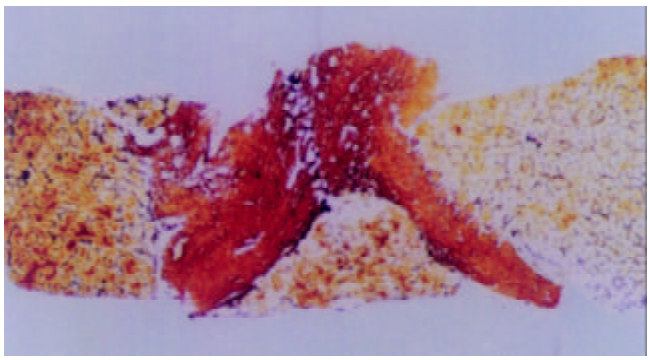

Figure 6 Chronic viral hepatitis. Wide and compact fibrotic septum was shown histologically. (Reticular fiber stain, ×40).

DISCUSSION

Among the multiple ultrasonographic parameters, PV_{max} and

GB_{sm} were selected as the independent predictors for the evaluation of fibrosis stage, while L_E, L_{sur} and GB_T were the independent predictors for the evaluation of inflammation grade. The results of this study showed that the portal venous velocity decreased and the wall of gallbladder became rough with the progress of fibrosis stage. While as the aggravation of inflammation grade, the liver parenchymal echo became coarse and heterogeneous, liver surface was rough and irregular, and the gallbladder wall became thick.

The decrease of portal venous velocity might relate to the increase of portal venous resistance. It was reported that patients with acute hepatitis and fulminant hepatitis developed portal hypertension with the aggravation of hepatic inflammation degrees[25,26].

There have been only a few reports about the relationship between the hemodynamic changes of portal vein and the histological changes in chronic hepatitis[22,27]. Aube *et al*[22] considered that the decrease of portal venous velocity was closely correlated with the histological degree of fibrosis. Our investigation showed that the decrease of portal venous velocity was significantly correlated not only with fibrosis stage but also with inflammation grade. The difference in the histological evaluating protocol used, and the difference in the sample size might partially account for the discrepancy.

The development of liver fibrosis into cirrhosis is a gradient course. There are non-specific findings on imaging. However, as the progresses of liver fibrosis reached to a certain degree, the liver pathological changes would become obvious. The acoustic interfaces would increase and the acoustic impedance between fibrotic tissue and other hepatic tissues would become large. On ultrasonography, the echo pattern of liver parenchymal would become coarse and echogenic, and the liver surface would become irregular. In this sense, the ultrasonographic features of liver parenchymal echo and liver surface would directly reflect the fibrotic changes in chronic hepatitis and liver cirrhosis, and thus playing an important role in the evaluation of fibrosis degree.

There is a close relationship between biliary system and the liver in histogenesis, anatomy and function. Viral hepatitis is often associated with biliary disorders. It was reported that abnormal ultrasonographic findings of the gallbladder such as wall thickening and double-edge sign, and abnormal size of the gallbladder and gallbladder stones were frequent in patients with hepatitis and liver cirrhosis[28-31]. The mechanism underlying the gallbladder disorders in viral hepatitis is still unclear. Some factors have been considered to be related with it[31,32] such as direct invasiveness of hepatitis virus, secondary infections, immunity injury, and edema of the gallbladder wall due to portal hypertension, circumfluence obstruction of the gallbladder vein, ete.

Ultrasonography and serology are both non-invasive methods in the evaluation of liver fibrosis and cirrhosis. However, their viewing aspects are different. The former is given priority to the reflection of morphological changes, while the latter reflects the function and metabolic changes. The knowledge about what are the similarities and differences between them in evaluating the liver fibrosis degree and diagnosis of cirrhosis is rarely known at present.

In our investigation, three independent ultrasonographic predictors correlated with fibrosis stage were chosen and compared with three serologic variables. Results showed that the correlation coefficients of ultrasonographic variables were similar to those of serological variables. There was the same tendency that the diagnostic accuracy of mild liver fibrosis was higher than that of moderate and severe fibrosis in both ultrasonography and serology, and the diagnostic accuracy of moderate liver cirrhosis was higher in ultrasonography. There were no significant differences between ultrasonography and serology in evaluating mild and severe liver fibrosis.

Referring to the diagnosis of compensated liver cirrhosis, there was no significant difference between ultrasonography and serology. However, the diagnostic sensitivity of ultrasonography was lower than that of serology, but its diagnostic specificity was higher than that of serology. It suggested that serological results should be mainly consulted for the early detection of pathological changes, while for the sake of exceptional diagnosis of cirrhosis, doctors had better to consult the results of ultrasonography in clinical practice.

Although the general diagnostic accuracy of compensated liver cirrhosis by ultrasonography and serology was similar, they were different in evaluating active and inactive stage cirrhosis. Results in our study showed that the diagnostic accuracy of ultrasonography for evaluating active stage cirrhosis was lower than that of serology with a high possibility of false-positive results, while the diagnostic accuracy for evaluating inactive stage cirrhosis was higher by ultrasonography than by serology. This difference might reflect the different features of the two modalities.

The serum fibrosis markers might reflect the activity of liver fibrosis and cirrhosis. When there was extensive inflammation in the liver, the level of serum fibrosis markers would raise with the active aggradation and degradation of the extracellular stroma. However, even if there was extensive fibrosis in the inactive stage cirrhosis, the level of serum fibrosis markers would be normal without active aggradation of the extracellular stroma[7]. Our results also illuminated that the level of serum fibrosis variables was distinctly higher in active stage cirrhosis than in inactive stage cirrhosis. Ultrasonography reflected the morphological changes of liver fibrosis and cirrhosis. When the accumulation of tissue morphological changes reached a certain degree, ultrasonography could depict these changes to a certain extent even if it was in the inactive fibrosis stage. Nevertheless, for the active fibrosis course at the level of cell and molecule, ultrasonography might fail to detect these fine morphological changes, and thus could not accurately evaluate the state of the disease.

It was inferred from our investigation that it was important to combine the two modalities for the evaluation of liver fibrosis and cirrhosis in clinical practice. When the level of serum fibrosis markers was normal, and the liver function damage was mild, liver cirrhosis should not be easily excluded with the distinct findings of cirrhosis showed by ultrasonography. The inactive stage cirrhosis might be possible at this situation. While the level of serum fibrosis markers rose obviously, and the liver function damage was severe, diagnosis of active stage cirrhosis should be considered with a long history of hepatitis viral infection even if there were no typical findings of cirrhosis on ultrasonography.

These results indicated that ultrasonography and serology both had their own advantages and disadvantages in the evaluation of liver fibrosis and liver cirrhosis.

The limitation of our investigation was that the case number of inactive stage cirrhosis was small. It was only a preliminary study and should be conducted more profoundly with a large sample size.

Ultrasonography is valuable in the evaluation of liver cirrhosis because of its low cost, easy performance, and high acceptability by the patients. However it is not a specific method and the diagnostic accuracy is still to be improved. Several factors could affect the diagnostic accuracy such as extra- and intraobserver variability, technical level of the operator, interference of obesity, ascites and intestinal gas, and modulation of the apparatus.

False positive and negative results might appear when diagnosis of compensated liver cirrhosis was made by ultrasonography. In patients with active stage liver cirrhosis,

ultrasonography could not depict the abnormalities caused by histological changes such as fine and sparse fibrotic septa or small and uniform pseudolobular nodules, thus false negative diagnosis might be made. However, high level of serum fibrotic markers might be valuable for the accurate diagnosis.

In some patients with a relative long history of chronic hepatitis, liver active inflammation and inactive phase occurred by turns, which made the pathological changes of the liver more complicated. The changes such as focal fatty degeneration or wide and compact fibrotic septa might cause coarse and heterogeneous parenchyma echo patterns in the liver, leading to a false positive diagnosis of liver cirrhosis on ultrasonography. The possible mechanisms might be assumed as follows. The acoustic interfaces between different liver tissues changed and the scatters increased because of focal fatty degeneration of the liver cells, thus causing focal echo attenuation and heterogeneous parenchyma echo patterns in the liver. When the fibrotic septa became wide and compact, the acoustic interfaces also became large and the acoustic impedance increased, causing coarse parenchyma echo patterns in the liver.

Hepatic pathological changes are often heterogeneous in patients with chronic hepatitis and liver cirrhosis. Sampling errors are liable. Gaiani *et al*[23] reported that thirty-two patients considered as liver cirrhosis by ultrasonography were identified as chronic hepatitis by histology. However, eight of these patients showed clinical manifestations of decompensated cirrhosis in the follow-up for half a year later. It indicated that ultrasonography could make up the deficiency of histology in the diagnosis of liver cirrhosis in certain situations.

In summary, there are different ultrasonographic predictors for the evaluation of hepatic inflammation grade and fibrosis stage of chronic hepatitis. Both ultrasonography and serology have their own advantages and disadvantages in the evaluation of liver fibrosis and compensated liver cirrhosis. False positive and negative results may occur in the diagnosis of compensated liver cirrhosis by ultrasonography. Combined application of ultrasonography and serology can contribute to the improvement in their diagnostic accuracy.

Abstract

AIM: Noninvasive diagnosis of hepatic fibrosis has become the focus because of the limited biopsy, especially in the surveillance of treatment and in screening hepatic fibrosis. Recently, regulatory elements involved in liver fibrosis, such as platelet derived growth factor-BB (PDGF-BB), transforming growth factor-β_1 (TGF-β_1), matrix metalloproteinase-1 (MMP-1), and tissue inhibitor of matrix metalloproteinase-1 (TIMP-1), have been studied extensively. To determine whether these factors or enzymes could be used as the indices for the diagnosis of hepatic fibrosis, we investigated them by means of receiver operating characteristic (ROC) curve.

METHODS: Serum samples from sixty patients with chronic viral hepatitis B and twenty healthy blood donors were assayed to determine the level of PDGF-BB, TGF-β_1, MMP-1, and TIMP-1 with ELISA, and HA, PCIII, C-IV, and LN level with RIA. The message RNA (mRNA) expression of TIMP-1 and MMP-1 in peripheral blood mononuclear cells (PBMCs) was detected by RT-PCR and Northern blot hybridization. Liver biopsy was performed in all patients. The biopsy samples were histopathologically examined. The trial was double-blind controlled.

RESULTS: The serum level of PDGF-BB, TIMP-1, the ratio of TIMP-1 and MMP-1 (TIMP-1/MMP-1), mRNA expression of TIMP-1 (TIMP-1mRNA), and the ratio of TIMP-1mRNA and MMP-1mRNA (TIMP-1mRNA/MMP-1mRNA) in patients was significantly higher than those in the healthy blood donors (t=2.514-11.435, P=0.000-0.016). The serum level of PDGF-BB, TIMP-1, TIMP-1/MMP-1, and TIMP-1mRNA was positively correlated with fibrosis stage and inflammation grade (r=0.239-0.565, P=0.000-0.033), while the serum level of MMP-1 was negatively correlated with fibrosis stage and inflammation grade, and TIMP-1mRNA/MMP-1mRNA was positively correlated with inflammation grade. Through the analysis by ROC curve, serum PDGF-BB was the most valuable marker, and its sensitivity was the highest among the nine indices. The markers with the highest specificity were TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs. The area under the curve (AUC) of PDGF-BB, TIMP-1mRNA, TIMP-1mRNA/MMP-1mRNA, TIMP-1/MMP-1, HA, PCIII, TIMP-1, C-IV, and LN was 0.985, 0.876, 0.792, 0.748, 0.728, 0.727, 0.726, 0.583, and 0.463, respectively. The sensitivity and the specificity in the parallel test was 99.0 % and 95.0 % when serum PDGF-BB, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA was detected simultaneously.

CONCLUSION: Serum level of PDGF-BB, TIMP-1mRNA, TIMP-1mRNA/MMP-1mRNA in PBMCs, and serum level of TIMP-1 and TIMP-1/MMP-1 can be used as the indices for the diagnosis of hepatic fibrosis, but the former three are more useful. The combination of serum PDGF-BB, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs is even more efficient in screening liver fibrosis.

INTRODUCTION

Fibrosis is the leading cause of morbidity and mortality in hepatic diseases. More attention has been paid to its mechanism, diagnosis and treatment. The proper and rapid treatment depends on the accurate and simple diagnosis. Noninvasive diagnosis of hepatic fibrosis has become the focus because of the limited biopsy, especially in the surveillance of treatment and in screening hepatic fibrosis. Recently, regulatory factors involved in the mechanism of liver fibrosis such as PDGF-BB, TGF-β_1, interstitial enzyme, MMP-1 and its inhibitor, TIMP-1, have been studied extensively[1-14]. To find out whether these factors or enzymes could be used as the indices for diagnosis of liver fibrosis, protein level and mRNA expression were studied in sixty patients with chronic viral hepatitis B and twenty healthy blood donors. At the same time, these markers were compared with liver biopsy results and the routine serum markers (HA, PCIII, C-IV and LN) to identify their values in clinical practice via ROC curve and the combination test.

MATERIALS AND METHODS

Subjects

During the Sixth National Conference on Infectious and Parasitic Diseases in 2000, the Protocol of Prevention and Treatment for Viral Hepatitis (abbreviated as "2000 Criteria")[15] was modified. According to the "2000 Criteria", 60 patients with typical presentations of chronic hepatitis were included. Among them, 54 were men with an average age of 34.9±8.1 years, 6 were women with an average age of 36.6±1.0 years. Twenty-eight and thirty-two patients showed moderate and severe

degree of the disease, respectively. The patients' histories were mainly collected from the First Affiliated Hospital, School of Medicine, Zhejiang University and several other hospitals in Zhejiang Province between July 1998 and September 1999. All were positive in HBV markers without other viral infections or disorders except liver disease. The diagnosis was made by liver biopsy according to the "2000 Criteria". The normal control group included 20 healthy blood donors selected according to the random number table.

Histology

Biopsy samples of the liver >1 cm in length were fixed in 10 % neutralized formaldehyde, embedded in paraffin and stained with hematoxylin and eosin. The reticulin and Masson trichrome techniques were used specially for staining fibrous tissue components. Histological assessment of the liver for the division of fibrosis stage and inflammation grade, expressed as S1 to S4 and G1 to G4, was performed according to the "2000 Criteria".

Determination of serum level of PDGF-BB, TGFb_1, TIMP-1, MMP-1, HA, PCIII, C-IV, and LN

Serum specimens were stored at -20 ℃. The serum level of PDGF-BB, TGF-β_1, TIMP-1 and MMP-1 was assayed by ELISA. The kits of PDGF-BB and TGF-β_1 were provided by the American Genzyme Corporation, the American AND Corporation, respectively. The kits of TIMP-1 and MMP-1 were provided by the American ChemCon Corporation. The serum level of HA, PCIII, C-IV and LN was determined by RIA. The kits of HA, C-IV and LN were provided by Shanghai Navy Medical Institute. The PCIII kit was provided by Chongqing Tumor Institute. Assays were done following the manufacturers' manual.

Determiantion of TIMP-1mRNA and MMP-1mRNA in PBMCs

Total RNA extraction PBMCs were separated by Ficoll (GiBco. Life Technologies Inc) and the total RNA was extracted by Trizol reagent (GiBco. Life Technologies Inc).

Northern blot hybridization Total RNA 20 μg was denatured and undergone electrophoresis with 1 % agarose containing 2.2 mol/L formaldehyde and was transferred onto nitrocellulose membrane, which was dried at 80 ℃ for two hours. The filters were prehybridized at 68 ℃ for 1 hour in the solution containing 6×standard saline citrate (SSC), 5×Denhardt' s solution, 0.5×sodium dodecyl sulfate (SDS), and 100 mg/L salmon sperm DNA. The denatured probes were added into the solution for hybridization at 68 ℃ overnight. The filters were washed for three times, and then autoradiographed at -70 ℃.

RT-PCR Total RNA 1 μg and primer Oligo (dT) were used for reverse transcription (Promega). 5 μl reverse transcription template was used for amplification through PCR. The primers are MMP-1: 5' CTTCAGTGGTGATGTTCAGC3', 5' CATCGATATGCTTCAACGTTC3', 412 bp, TIMP-1: 5' GGAGTCCAGCAGACCACCTTA3', 5' -TGGGACACAG GTGCATGCCCTGCT-3', 110 bp. The amplified sequence length of β-actin is 224 bp. The PCR products were through 1.5 % (w/v) agarose gel electrophoresis and analyzed by gel imaging system.

Statistical analysis

Results were expressed as mean ± standard deviation ($\bar{x}\pm s$). *t* test and Spearman rank-correlation test were used. The results were considered statistically significant at $P<0.05$. Evaluation of the diagnostic test was made via ROC curve.

RESULTS

Comparison of serum level of PDGF-BB, TGF-b_1, TIMP-1, MMP-1 and TIMP-1/MMP-1 between patients and healthy blood donors

The serum level of PDGF-BB, TIMP-1 and TIMP-1/MMP-1 in 60 patients was significantly higher than that in the normal control group with an increase of 2.52, 0.5 and 1.67 fold, respectively. However, there was no difference in the serum level of MMP-1 and TGF-β_1 between patients and normal controls (Table 1). The serum level of MMP-1 was further studied. A declining tendency along the increase of fibrosis stage, inflammation grade and severity of the hepatic disease was observed while a significant difference appeared only between the patients in S4, G4 or with severe diseases and blood donors (Table 2). Moreover, it was also different between patients in S4 and those in S2 (Table 2). As to the serum level of TGF-β_1, there was no difference between patients and normal controls, even no significant difference among patients with the increase of fibrosis stage, inflammation grade and severity of the disease (Table 2).

Table 2 Comparison of the serum level of MMP-1 and TGF-β_1 between patients at different fibrosis stages, inflammation grades, and with different severities of the disease and the healthy controls ($\bar{x}\pm s$)

Group (*n*)	MMP-1(μg/L)	TGF-β_1(μg/L)
Controls (20)	7.98±3.13	26.28±16.69
S2(16)	6.34±2.96	31.66±18.01
S3(31)	6.80±5.34	34.19±26.23
S4(13)	3.93±2.93[ac]	25.16±20.90
G2(2)	7.66±0.36	18.25±6.01
G3(28)	6.41±4.91	31.89±21.61
G4(30)	5.61±4.15[a]	32.14±25.25
Mild disease (28)	6.56±3.66	34.39±24.43
Severe disease (32)	5.61±5.05	29.08±21.97

There was a statistically significant difference as compared with the control group [a]$P<0.05$, and a statistically significant difference as compared with S2 group [c]$P<0.05$.

Comparison of TIMP-1mRNA, MMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs between patients and healthy controls

As shown in Table 3, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA were significantly elevated in patients than those in healthy controls with an increase of 1.6 and 1.79 fold, respectively. However, no difference was found in MMP-1mRNA expression between patients and healthy controls.

Table 1 Comparison of the serum level of PDGF-BB, TGF-β1, TIMP-1, MMP-1 and TIMP-1/MMP-1 between patients and healthy blood donors ($\bar{x}\pm s$)

Relationship between serum level of PDGF-BB, TGF-b_1,TIMP-1, MMP-1 and TIMP-1/MMP-1, TIMP-1mRNA, MMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs and fibrosis stage and inflammation grade

The serum level of PDGF-BB, TIMP-1, TIMP-1/MMP-1 and TIMP-1mRNA in PBMCs was positively correlated with fibrosis stage and inflammation grade, while the serum level of PDGF-BB had a stronger correlation than the other three indices. The serum level of MMP-1 was negatively correlated with fibrosis stage and inflammation grade. TIMP-1mRNA/MMP-1mRNA was positively correlated with inflammation grade. However, the serum level of TGF-β_1 and MMP-1mRNA was correlated with neither fibrosis stage nor inflammation grade.

Diagnostic value of serum level of PDGF-BB, TIMP-1, TIMP-1/MMP-1, MMP-1, HA, PCIII, CIV, LN and TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs

Table 5 shows that serum level of PDGF-BB, TIMP-1, TIMP-1/MMP-1, HA and PCIII, and TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs could be used to diagnose hepatic fibrosis. Among them, the serum level of PDGF-BB was most useful for its AUC and YI were close to 1, followed by TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs. Furthermore, the serum level of PDGF-BB was most sensitive, and the next was TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs. TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs were most specific, followed by the serum level of PDGF-BB and TIMP-1. When both the sensitivity and the specificity were taken into consideration, serum PDGF-BB, serum HA, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA were the relatively efficient indices.

Diagnostic value of the single index combination

When both the sensitivity and the specificity needed to be taken into account, we could combine the following four indices, namely serum PDGF-BB, serum HA, TIMP-1mRNA/MMP-1mRNA and TIMP-1mRNA in PBMCs. Table 6 indicates that the combination of serum level of PDGF-BB, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs was more useful in the parallel test. However, no efficient combination in the serial test was observed (Table 7).

DISCUSSION

Hepatic fibrosis is characterized by imbalanced deposition and degradation of extracellular matrix (ECM). Many factors are involved in the process. Thus, it is difficult to evaluate the fibroproliferative activity. Liver biopsy is still regarded as the gold standard for the diagnosis of fibrosis, but even elaborated scores of histological activity are limited to evaluate the prognosis in the individual case. Moreover, it is not convenient, to some degree, to use it as a routine method for the diagnosis, evaluation and supervision of the disease in clinical practice. Unfortunately, there have been no established noninvasive markers or tests for the diagnosis of hepatic fibrosis. Therefore, it is essential to explore the noninvasive and reliable indices for assessing the progress of liver fibrosis. Previously, we revealed the diagnostic value of ultrasonography on assessing liver fibrosis resulted from Schistosomiasis japonica[16], but sometimes we could not distinguish benign fatty infiltration from fibrosis, because both of their echogenicities appeared increased or diffuse. Detection of the biochemical indices in serum has been the focus in the filed of hepatic fibrosis. At present, the serum indices revealing the progress of hepatic fibrosis mainly include two kinds, reflecting deposition and degradation. Previously, more attention was paid to the factors reflecting the deposition or metabolism of ECM, and the serum level of HA, PCIII, PIIIP, CIVand LNwas studied. Zheng *et al*[17,18] confirmed the clinical value of the serum fibrosis indices (HA, PCIII, CIVand LN) through comparing them with the histological reports performed on liver fibrosis patients resulted from chronic hepatitis B. Furthermore, the serum level of HA was considered to be the most sensitive among the four indices, this result was also reported by others[19,20]. However, the four indices did not fully reflect the histological changes and were often influenced by other factors, moreover, in some chronic hepatitis B cases, they did not correspond to the biopsy results[21]. Thus, it is important and necessary to explore new and more reliable indices. With the mechanism of hepatic fibrosis elucidated further, the focus has been the elements involved in the degradation of ECM such as MMP-1[14,22,23] and TIMP-1[24-27] and the regulatory factors such as PDGF-BB and TGF-β_1 whose vital roles in hepatic fibrosis have been confirmed.

To establish the noninvasive index, the first step was to observe whether it demonstrated a difference between patients and normal controls. In our study, we compared the serum level of PDGF-BB, TIMP-1, MMP-1, TIMP-1/MMP-1 and TGF-β_1 between 60 fibrosis patients and 20 healthy blood donors. The serum level of PDGF-BB, TIMP-1 and TIMP-1/MMP-1 in patients was significantly elevated than that in healthy controls. However, the serum level of MMP-1 demonstrated a declining tendency with the severity of liver fibrosis, inflammation and the disease condition although the difference between two groups existed only when the patients were in S4, G4 or with severe hepatitis. This result indicted that the abnormal serum MMP-1 did not appear until the patients were in the advanced fibrosis. With regard to TGF-β_1 serum level, it was not different from that of the control group with the progress of liver fibrosis, inflammation and the severity of the disease, showing that serum TGF-β_1 may not be sensitive as a diagnostic index. Similar results were also reported. Daniluk *et al*[28] found that serum level of TGF-β_1 in alcohol-related liver cirrhosis was similar to that in controls. Oberti *et al*[29] detected several indices of chronic hepatitis patients, including HA, PT, GGT, alph2 macroglobulin, PIIIP, LN and TGF-β_1. They found that HA and PT were significant in cirrhosis. In fact, TGF-β_1 is secreted from cells in the manner of the complex formed by TGF-β_1 and its binding protein. However, pre TGF-β_1 can be activated to its active form only after its binding protein is released. This does not mean that TGF-β_1 may play a role freely once it is released into blood, for its corresponding receptors still block it. There are a lot of studies about the correlation of plasma TGF-β_1 with chronic hepatitis, liver fibrosis or cirrhosis[30,31]. But, in general, analysis of plasma level is fraught with difficulties related to contamination of the sample by TGF-β from platelets. Moreover, the plasmin in the plasma may increase the amount of TGF-β_1 through opening the LAP-TGF-β_1 complex. Clearance of TGF-β is also complicated. It binds locally at sites of injury to ECM and generally to vascular endothelium, it may be sequestered by soluble proteins, and can also undergo renal excretion or be taken up by hepatocytes. These modes of sequestration or clearance may vary at different circumstances. Thus, increase in plasma TGF-β may not reflect pericellular concentrations at the injury site, and due to this reason, plasma TGF-β is unlikely to be diagnostically useful[32,35]. But Kobayashi *et al*[36] found that serum TGF-β_1 could be used as an accurate indicator of progressive fibrogenesis in postoperative biliary atresia patients. The reason for the disagreement may be the different criteria for the division of liver fibrosis.

Correlation analysis was carried out to elucidate the cause leading to the difference in some indices between patients and normal controls. We found that the serum level of PDGF-BB,

TIMP-1 and TIMP-1/MMP-1 was positively correlated with fibrosis stage and inflammation grade while the serum level of MMP-1 was inversely correlated with fibrosis stage and inflammation grade. The data indicated that histological changes could directly result in the higher level of serum PDGF-BB, serum TIMP-1 and TIMP-1/MMP-1 in patients and could explain the declining tendency appearing in the comparison between each group of patients and the controls as well. Serum level of TGF-β_1 was not correlated with fibrosis stage or inflammation grade. This may confirm that detection of serum TGF-β_1 was not reliable in clinical practice.

It has been reported that mRNA levels of TIMP and MMP and corresponding proteins were related to liver fibrosis or cirrhosis. Chen *et al*[37] studied the collagen metabolism of liver fibrosis at transcription level in rabbits infected by Schistosomiasis japonica, and found that mRNA levels of MMP-1 and MMP-9 declined almost to the normal level at the later stage of fibrosis. Yata *et al*[38] found that mRNA expression of hepatic TIMP-1 increased in hepatic fibrosis. Lichtinghagen *et al*[27] investigated the mRNA levels of hepatic TIMP-1, 2, 3 and MMP-2, 7, 9 in 29 chronic active hepatitis C patients (CAH) and 7 cirrhosis patients resulted from hepatitis C virus, and found that none of mRNA levels was significantly different between CAH patients with and without fibrosis, while MMP-2, MMP-7, and TIMP-1 provided the best discrimination between cirrhosis and pre-cirrhotic stages. Lichtinghagen *et al*[39] found that mRNA expression of MMP-2, MMP-9 and TIMP in peripheral blood cells had no correlation with the circulating concentrations of these proteins, which indicated that detection of MMP mRNA and TIMP mRNA in peripheral blood cells may also give us important information about liver fibrosis. Boker *et al*[40] reported that TIMP-1 could be detected in lymphocytes and granulocytes. To determine whether TIMP-1mRNA and MMP-1mRNA in PBMCs could be used as the diagnostic markers, we detected them and TIMP-1mRNA/MMP-1mRNA, and compared these indices between patients and the healthy blood donators. The results demonstrated that TIMP-1mRNA, TIMP-1mRNA/MMP-1mRNA significantly increased while no change in mRNA expression of MMP-1 was observed. Correlation analysis revealed that TIMP-1mRNA was positively correlated with fibrosis stage and inflammation grade, while TIMP-1mRNA/MMP-1mRNA was only positively correlated with inflammation grade. No relationship was found between MMP-1mRNA and fibrosis stage or inflammation grade. With regard to MMP-1mRNA in PBMCs, no statistical difference may attribute to the higher standard deviation among individual values. Other factors influencing mRNA expression may also involve. Therefore, it could be more useful to detect TIMP-1mRNA in PBMCs for evaluating liver fibrosis.

As there was a difference in the serum level of PDGF-BB, TIMP-1, TIMP-1/MMP-1, MMP-1, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs between patients and the normal controls, we wanted to know whether these indices could be used for diagnosis, and if they could, the following problem was whether they were more valuable than those four routine serum markers (HA, PCIII, CIV, LN). AUC and YI of the serum level of PDGF-BB were the closest to 1 through ROC curve. This revealed that the diagnostic value of serum level of PDGF-BB was the highest among nine indices (Table 5). Although TGF-β_1 as the main fibrogenic mediator mediates HSC activation and transformation, additional growth factors like PDGF become important in the later stage of HSC transformation. That means PDGF is vital in the progress of liver fibrosis. PDGF has been proved to be the main stimulator of HSC proliferation, migration and the strong mitogen for HSCs. Among the three subunits-AA, AB and BB, PDGF-BB is the vital cytokine for the signaling pathway in HSC and other cells[41-44]. In recent years, studies have not been adequately performed on the serum level of PDGF-BB for assessing liver fibrosis. Our results indicated that detection of the serum level of PDGF-BB had profound significance. TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs was inferior to serum PDGF-BB. The diagnostic value of serum level of HA, PCIII, TIMP-1 and TIMP-1/MMP-1 is similar, for their AUC are closer, but detection of serum level of HA and TIMP-1/MMP-1 was more applicable if we evaluated them according to YI. Researchers have studied TIMPs from hepatic tissues, serum level to mRNA expression, revealing the important relationship of TIMPs with fibrosis stage or inflammation grade. But it is still unclear whether the serum level of TIMP-1 and TIMP-1mRNA in PBMCs can be used as the markers for the diagnosis of liver fibrosis. If they can, are they superior or inferior to other established markers[45-47]? Our results demonstrated that TIMP-1mRNA was more sensitive than TIMP-1. Some studies[26,39] have revealed the role of the ratio of MMPs and TIMPs such as MMP-1/TIMP-1, MMP-2/TIMP-1, but did not report whether the ratio could be used for the diagnosis of liver fibrosis. We observed that both TIMP-1mRNA/MMP-1mRNA in PBMCs and TIMP-1/MMP-1 in serum could be used for the diagnosis of hepatic fibrosis. However, the former was superior to the latter. The data suggested that we should take both the protein level and mRNA expression into account to explore the noninvasive markers. The value of the serum level of CIV and LN was relatively low. In fact, their AUC values were 0.5 for their *P* values were above 0.05. The roles of serum MMPs in liver fibrosis had been studied[22,47]. Murawaki *et al*[22] found that the serum MMP-1 test was superior to the serum PIIINP test in assessing liver necroinflammation, and thought that the serum MMP-1 test might be useful clinically to differentiate active from inactive types of hepatitis in patients with chronic viral hepatitis, but they did not elucidate whether serum MMP-1 could be more efficient than other indices for assessing liver fibrosis. We evaluated the diagnostic value of MMP-1 for pre-cirrhosis and severe inflammation as there was a difference between patients in S4 or G4 and the normal controls. But the results revealed that the serum level of MMP-1 was of no use for assessing liver fibrosis and evaluating the severity of inflammation. However, our results revealed the declining tendency of the serum MMP-1 with the progress of hepatic fibrosis. The problem is worth further investigating.

The diagnostic value, the sensitivity and the specificity should be taken together, when an index is evaluated for the diagnosis of liver fibrosis. ROC curve analysis revealed that the sensitivity and the specificity of one index were not desirable. Thus, to overcome the limitation of the single index, combination test should be used. There are two kinds of combination test in clinical practice. One is the parallel test and the other is the serial test. The former is often used to screening diseases because it focuses on improving the sensitivity and decreasing the missing incidence. The latter is used to confirm the diagnosis. Table 6 showed that indices in the parallel test were more sensitive than one index. Furthermore, its specificity was also improved. These results revealed that the parallel test was beneficial to screening hepatic fibrosis because hepatic fibrosis continue to progress even though the pathogen have been eliminated. Table 7 showed that the specificity was improved, while the sensitivity was evidently decreased. The data demonstrated that the combination of serum PDGF-BB, HA, TIMP-1mRNA, and TIMP-1mRNA/MMP-1mRNA in PBMCs was clinically limited. However, the specificity of each kind of the combination in the serial test reached close to 100 %, indicating that the diagnostic value of any kind of combination was important and could provide the key information for doctors once some abnormal

results appeared.

In conclusion, we think that serum PDGF-BB, TIMP-1, TIMP-1/MMP-1, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs may be used to diagnose hepatic fibrosis. Among them, serum PDGF-BB, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA are more sensitive and could be used in clinical practice. The combination of serum PDGF-BB, TIMP-1mRNA and TIMP-1mRNA/MMP-1mRNA in PBMCs is more efficient in screening liver fibrosis. However, the ideal combination for confirming the diagnosis need to be further explored.

Abstract

AIM: To analyze the factors which influence the serum levels of hyaluronic acid (HA), type III pro-collagen (PCIII), laminin (LN) and type IV collagen (C-IV) in liver fibrosis.

METHODS: The serum specimens from 141 chronic hepatitis patients were assayed for fibrosis indexes including HA, PCIII, LN and C-IV with radioimmunoassay (RIA) and liver function indexes by an automatic biochemistry analyzer. The patients were then divided into consistent group and inconsistent group. The patients' clinical manifestations were recorded, routine blood pictures were done by a blood counter and analyzer (AC-900). Liver biopsy specimens were examined path-morphologically. The inner diameters of portal vein, splenic vein and thickness of spleen were all measured by ultrasonography.

RESULTS: Sixteen patients (14.16 %) had serum fibrosis indexes inconsistent with histological stage of their hepatic fibrosis. Their serum fibrosis indexes did not correlate with the stage of hepatic fibrosis ($P>0.05$), but were positively correlated with the grade of inflammation ($\chi^2=12.07$, $P<0.05$). At the same time, serum albumin (ALB) and the ratio of albumin and globulin (A/G) were significantly increased ($t=3.06$, $P<0.01$), ($t=3.70$, $P<0.01$). Serum levels of glutamic-pyruvic transaminase (ALT), glutamic-oxaloacetic transaminase (AST), γ-glutamyl transferase (GGT) and globulin (GLB) were all significantly decreased ($t=2.45$, $P<0.05$), ($t=2.33$, $P<0.05$), ($t=2.08$, $P<0.05$), ($t=3.03$, $P<0.01$). Weary degree also decreased more obviously ($\chi^2=7.52$, $P<0.05$), but other clinical manifestations, routine blood indexes, serum levels of alkaline phosphatase (AKP), total bilirubin (TBIL), total protein (TP), width of main portal vein, width of splenic vein and thickness of spleen had no significant change ($P>0.05$).

CONCLUSION: Serum fibrosis indexes can be influenced by the grade of inflammation, some liver function indexes and clinical manifestations. Comprehensive analysis is necessary for its proper interpretation.

INTRODUCTION

Many chronic injuries can lead to fibrosis of liver[1-11]. Hepatic fibrosis is resulted from the loss of normal liver cell function due to disorganized over-accumulation of extra-cellular matrix (ECM) components in the liver[12-17]. It is clear that the increased production and degradation of ECM components are responsible for the altered ECM metabolism. Liver biopsy has traditionally been the standard method for assessing hepatic fibrosis, but the procedure is invasive in nature and has complications though with a low incidence. So its popularity is somewhat hindered. Reports showed that serum fibrosis indexes, including HA, PCIII, LN, C-IV and others, could reflect the activity of hepatic fibrosis to some extent[18-27]. Mean ± SD has always been used to express the standard for hepatic fibrosis. We have explored the clinical significance of the four serum fibrosis indexes by detecting them in 2 600 patients with chronic hepatitis including 280 patients undertaken biopsy[28,29]. At same time, patients whose four serum fibrosis indexes were not consistent with the degree of hepatic fibrosis were found, so we selected these patients to analyze what factors might influence the four serum fibrosis indexes (HA, PCIII, LN and C-IV) in diagnosing liver fibrosis.

MATERIALS AND METHODS

Subjects

During the Sixth National Conference for Infectious and Parasitic Diseases, the protocol of prevention and treatment for virus hepatitis was modified in 2000 (abbreviated as "2000 criteria")[30]. One hundred and forty-one patients had typical presentations of chronic hepatitis, 121 were males and 20 females. There were mild, moderate and severe degrees of the disease in the group. Case histories were mainly collected from the First Affiliated Hospital, School of Medicine, Zhejiang University. Some were from other hospitals in Zhejiang Province between July, 1998 and May, 2000. The age ranged from 18 to 62 years, the average age was 38.75±14.53. Weary Degree: 0: did not feel weary; 1: could join routine activities, but felt weary; 2: could join light work, but felt weary; 3: could not work, felt weary while moving. The disease course was from one to 30 years.

Clinical manifestations

Total volume of food taken by the patient every day, length of liver and spleen under costal margin were recorded. The criteria of clinical manifestations were as following: (1). Weary degree: as stated above. (2). Degree of abdominal distension: 0: did not feel abdominal distension; 1: felt abdominal distension while taking food or abdominal distension usually; 2: felt abdominal distension while taking a little food, but can endure; 3: felt abdominal distension, did not want to take food, felt abdominal distension while taking food, can not endure. (3). Secret anguish degree: 0: did not feel secret anguish; 1: felt secret anguish, but could take food; 2: felt secret anguish, could endure; 3: felt secret anguish, could not endure, needed medication.

Histology

The needles (18G) were purchased from Angiomed Corporation in German. The length of liver biopsy specimen exceeded 1 cm. Biopsy fragments of the livers were fixed in 10 % neutralized formaldehyde, embedded in paraffin, and then stained with hematoxylin and eosin. Reticulum fibrosis

stain and Sirius red method were used specially for staining fibrous tissue components. Histological assessment of the liver was done according to Wang' s report[31], and staging of fibrosis was divided into four, expressed as S1 to S4 according to the "2000 criteria"[30]. S0 showed no fibrosis. S1 showed expansion in portal tract areas with fibrosis. S2 showed fibrosis around portal tract areas with formation of fibrosis segregation while maintain lobular structure. S3 showed formation of fibrosis segregation and disorder of lobular structure without hepatic cirrhosis, and S4 showed early stage or confirmed cirrhosis.

Determination of serum fibrosis tests and liver function indexes

The serum specimens from 141 chronic hepatitis patients were stored at -20 ℃. Assay of the levels of serum HA, PCIII, C-IV and LN was done by RIA. The kits of HA, C-IV and LN were provided by the Shanghai Navy Medical Institute. The kit of PCIII was supplied by the Chongqing Tumor Institute. The procedures were performed according to the user' s manual. The assay of liver function indexes was measured by an automatic biochemistry analyzer, these indexes included total bilirubin (TBIL), gliutamic-pyruvic transaminase (ALT), glutamic-oxaloacetic transaminase (AST), γ glutamyl-transferase (GGT), alkaline phosphatase (AKP), total protein (TP), albumin (ALB), globulin (GLB) and the ratio of albumin and globulin (A/G).

Determination of routine blood indexes

Blood samples were drawn from the veins and treated with EDTA-K_2 (the concentration was 1.5 mg/ml). WBC, RBC and platelet were determined by a blood cell counter and analyzer (AC-900).

Ultrasonic examination

All patients were forbidden to take water and food for eight hours before examination. Inner diameters of the portal vein, splenic vein and thickness of the spleen were measured, all the procedures were performed by the same physician.

Definition of patients whose serum fibrosis indexes were inconsistent with histologic staging of their hepatic fibrosis

All patients were divided into two groups. If in S≥2 group, all four serum fibrosis indexes were less than or equal to the mean value of that in S1 group, these patients would then be classified as inconsistent group. On the contrary, they would be classified as the consistent group. There was also inconsistency in a single index, that meant staging belonged to S≥2, but the index was less than or equal to the mean of that in S1 group.

Statistical analysis

Results were expressed as mean ± standard deviation ($\bar{x}\pm s$) and *t* test was done when necessary, nonparametric one-way ANOVA was used for nonparametric data, all tests were done by SPSS 10.0 statistical program and considered statistically significant at $P<0.05$.

RESULTS

Inconsistency between each serum fibrosis index and stage of hepatic fibrosis

When hepatic fibrosis was in stage 1, the mean of HA was 187.23 ng/ml, LN was 144.68 ng/ml, PCIII was 151.42 μg/L, and C-IV was 74.26 μg/L. One hundred and thirteen patients were found in hepatic fibrosis stage II or more than that, 33 cases were inconsistent with staging of hepatic fibrosis for HA. More cases were inconsistent for C-IV, 43 cases were inconsistent with staging of hepatic fibrosis for LN (Table 1).

Table 1 Inconsistency between each serum fibrosis index and stage of hepatic fibrosis

Stage (S)	*n*	HA	C-IV	PCIII	LN
S2	30	13	14	16	17
S3	31	9	10	10	11
S4	52	11	12	13	15
Total	113	33 (29.20%)	36(31.86%)	39(34.51%)	43 (38.05%)

Distribution of patients whose four serum fibrosis indexes were inconsistent with stage of hepatic fibrosis

Among 113 patients, 16 (14.16 %) were in inconsistent group and 97(85.84 %) in consistent group, no significant difference was found in staging of hepatic fibrosis between two groups ($P>0.05$), (Table 2).

Table 2 Staging comparison between two groups

Groups	Stage of hepatic fibrosis		
	S2	S3	S4
Consistent group	24	27	46
Inconsistent group	6	4	6

$\chi^2=1.18$, $P>0.05$.

Inflammation grading of patients in inconsistent group

Table 3 shows that inflammation grade was mainly G2 in inconsistent group, while mainly G3 and G4 in consistent group. The difference was significant between two groups ($P<0.05$).

Table 3 Comparison of inflammation grade between two groups

Groups	Inflammation grade			
	G1	G2	G3	G4
Consistent group	5	17	49	26
Inconsistent group	1	9	4	2

$\chi^2=12.07$, $P<0.05$.

Clinical manifestations in inconsistent group

Table 4 and table 5 show no patient whose degree of weary, abdominal distension and secret anguish exceeded 2 in consistent group. There was no patient whose degree of weary, abdominal distension and secret anguish exceeded 1 in inconsistent group. The daily food volume of the patients increased slightly, the palpable length of liver and spleen decreased slightly. The difference was not significant between two groups ($P>0.05$) except weary degree ($P<0.05$).

Table 4 Comparison of clinical manifestations between two groups

Groups	Weary degree			Abdominal distension degree			Secret anguish degree		
	0	1	2	0	1	2	0	1	2
Consistent group	39	41	17	72	24	1	86	8	3
Inconsistent group	12[a]	4	0	14	2	0	16	0	0

$\chi^2=7.52$, $P<0.05$.

Table 5 Comparison of clinical manifestations between two groups ($\bar{x}\pm s$)

Groups	*n*	Volume of food(g)	Length of liver (cm)	Length of spleen(cm)
Consistent group	97	427.11±194.15	0.31±0.63	0.53±0.85
Inconsistent group	16	456.25±160.08	0.28±0.55	0.34±0.60

Change of routine blood indexes in inconsistent group

No significant difference was found in WBC, RBC and PLT between two groups (P>0.05), (Table 6).

Table 6 Comparison of routine blood tests between two groups ($\bar{x}\pm s$)

Groups	*n*	WBC	RBC	PLT
Consistent group	97	5.07±1.12	4.61±0.52	116.52±34.14
Inconsistent group	16	4.90±1.24	4.64±0.57	117.00±26.38

Change of liver function tests in inconsistent group

Serum ALT, AST, GGT and GLB decreased obviously in inconsistent group (P<0.05) or (P<0.01), ALB and A/G increased evidently (P<0.01), but AKP, TBIL and TP did not change significantly (P>0.05), (Table 7).

Table 7 Comparison of liver function tests between two groups ($\bar{x}\pm s$)

Groups	*n*	TBIL (μmol/L)	TP (g/L)	ALB (g/L)	GLB (g/L)	A/G
Consistent group	97	18.19±8.51	74.60±6.75	42.34±4.81	32.13±5.18	1.35±0.28

[a]P<0.05 *vs* consistent group.

Results of ultrasonic examination in inconsistent group

Table 8 shows no significant difference in width of main portal vein, splenic vein and thickness of spleen between two groups (P>0.05).

Table 8 Comparison of ultrasonic examination between two groups (cm, $\bar{x}\pm s$)

Groups	*n*	Width of main portal vein	Width of splenic vein	Thickness of spleen
Consistent group	97	1.20±0.13	0.74±0.12	4.02±0.64
Inconsistent group	16	1.23±0.12	0.77±0.13	4.09±0.62

DISCUSSION

The basic pathological changes of chronic liver disease are inflammation and fibrosis, so they were analysed respectively in pathological diagnosis in recent year. Many semi quantitative score systems, such as Chevallier's criterion, Scheuer's criterion were developed[31-33], so chronic liver disease has been recognized more accurately and profoundly. Staging of liver fibrosis can help us to recognize the development of chronic liver disease. Serum indexes such as HA, PCIII, LN and C-IV which reflect the stage of liver fibrosis have been paid much attention to by many scholars[34-36] HA, PCIII, LN and C-IV were mainly produced by hepatic stellate cells[35,36]. HA and PCIII were absorbed and degraded by endothelial cells of hepatic sinusoids[37,38]. When liver fibrosis takes place, the phenotypes of the membrane of endothelial cells of hepatic sinusoids change, their absorption is blocked, the contents of serum HA, PCIII increase to some degree. LN and C-IV reflected basement membrane transformation and had some relation to portal hypertension[39,40]. Many scholars agreed the four serum fibrosis indexes had values in the serodiagnosis of hepatic fibrosis, including the diagnostic value of each serum fibrosis index and combination of several indexes[20,29]. When these indexes were applied to clinical diagnosis, we found some of them were inconsistent with pathological diagnosis. Even with a high stage of hepatic fibrosis, the four serum fibrosis indexes could still be around normal range. So we think it is necessary to find the influencing factors of this phenomenon.

Our results showed the rate of inconsistency between the four serum fibrosis indexes and stage of hepatic fibrosis was 14.16 % in the patients with chronic hepatitis. Table 1 shows the rate of inconsistency of serum HA was 29.21 %, C-IV 31.86 %, PCIII 34.51 % and LN 38.05 %. The rate of consistency between serum HA and stage of hepatic fibrosis was highest, followed by C-IV. This suggests that among the four serum fibrosis indexes, HA is the most ideal index for diagnosing hepatic fibrosis. This was consistent with the results of our previous study on the relationship between serum fibrosis indexes and liver histological changes[41], and was also consistent with other reports in the literature[42]. Stage distribution of hepatic fibrosis in inconsistent patients had no significant difference from that of consistent group. This indicates that inconsistency between the four serum fibrosis indexes and stage of hepatic fibrosis has no relationship with the staging. By further study we found inflammation grade of inconsistent patients was lower than that of consistent group. This suggests that the four serum fibrosis indexes are influenced by inflammation grade. In the patients with chronic hepatitis when their stage of hepatic fibrosis is at high level, such as S3 or S4, and inflammation grade is at low level, it is possible that the four serum fibrosis indexes can be inconsistent with stage of hepatic fibrosis. This could be found in patients with advanced stage of schistosomiasis japonica having severe liver fibrosis, but almost no inflammation or decompensation of hepatic function. In addition, it was also suggested that these four serum fibrosis indexes could be lowered by anti-inflammation treatment in patients with chronic hepatitis. As to clinical manifestations, weary degree of inconsistent patients decreased more obviously than that in consistent group. Other profiles had no obvious change. In liver function tests, we found serum ALT, AST, GGT and GLB of inconsistent patients were decreased more obviously, while serum ALB and A/G increased more evidently, serum AKP, TP and TBIL had no significant change. All these suggest that changes of weary degree, serum ALT, AST, GGT, GLB, ALB and A/G were affected by inflammation grade. So they should be taken into account when we assess the diagnostic value of the four serum fibrosis indexes for stage of hepatic fibrosis. At the same time, change of liver function indexes is more sensitive than clinical manifestations. So even without any clinical symptoms, patients should be checked regularly by liver function tests. In clinical practice, width of main portal vein, splenic vein and thickness of the spleen are usually used to determine whether the pressure of main portal vein is increased or not. Table 7 shows they had no significant change, indicating that these patients' condition did not reach the stage of liver cirrhosis.

We conclude that serum fibrosis indexes can only reflect abnormal metabolism of ECM. They are non-specific biochemical markers, when they are used in the diagnosis of hepatic fibrosis, other diseases should be ruled out. They should not be called hepatic fibrosis markers, serum fibrosis indexes should be the appropriate term. Our study indicates the influencing factors include hepatic inflammatory activity, weary degree and some liver function tests. The activity of inflammation is determined by pathological diagnosis of liver biopsy. So in clinical practice, we should put liver function, case history and clinical manifestations all into consideration in assessment of the diagnostic value of these four fibrosis indexes in the staging of hepatic fibrosis. While assessing therapeutic efficacy of anti-fibrosis drugs, we can also not

depend only on these four fibrosis indexes, a comprehensive analysis is necessary. Further studies on new indexes are needed to better understand the pathological changes of liver.

Abstract

AIM: To investigate the seroprevalence of *Helicobacter pylori* infection in patients with different digestive malignant tumors.

METHODS: Enzyme linked immunosorbent assay (ELISA) was used to detect serum anti-*Helicobacter pylori* IgG antibody in 374 patients with different digestive malignant tumors and 310 healthy subjects (normal control group).

RESULTS: The seroprevalence of *Helicobacter pylori* infection was 61.50 %(230/374) and 46.77 % (145/310), respectively, in patients with digestive tumors and normal controls ($P<0.05$). The seroprevalence was 52.38 % (33/63), 86.60 % (84/97), 83.14 % (84/101), 45.24 (19/42), 51.13 % (18/35) and 44.44 % (16/36), respectively in patients with carcinomas of esophagus, stomach, duodenum, rectum, colon and liver ($P<0.01$). In patients with intestinal and diffuse type gastric cancers, the seroprevalence was 93.75 % (60/64) and 72.73 % (24/33), respectively ($P<0.05$). In patients with gastric antral and cardiac cancers, the seroprevalence was 96.43 % (54/56) and 73.17 % (30/41), respectively ($P<0.05$). In patients with ulcerous and proliferous type duodenal cancers, the seroprevalence of *H pylori* infection was 91.04 % (61/67) and 52.27 % (23/44), respectively ($P<0.05$). In patients with duodenal bulb and descending cancers, the seroprevalence was 94.20 % (65/69) and 45.20 % (19/42), respectively ($P<0.05$).

CONCLUSION: *H pylori* infection is associated with occurrence and development of gastric and duodenal carcinomas. Furthermore, it is also associated with histological type and locations of gastric and duodenal carcinomas.

INTRODUCTION

Helicobacter pylori is a gram-negative, spiral-shaped, microaerophilic bacterium that colonizes gastric epithelium of humans[1-4]. Clinical and epidemiological studies have shown a close association between *H pylori* and gastric cancer[5-10]. However, the relationship between *H pylori* and other digestive tumors has not been clarified. In order to investigate the relationship between *H pylori* infection and different digestive cancers, we detected serum anti-*H pylori* IgG in 374 patients with different digestive cancers and 310 healthy subjects, using an enzyme linked immunosorbent assay -(ELISA).

MATERIALS AND METHODS

Materials

Populations A total of 374 patients with different digestive cancers were involved in this study, including 63 esophagus carcinomas, 97 gastric cancers (64 of intestinal type and 33 of diffuse type, and 56 in gastric antrum and 41 in the cardia as displayed under gastroscopy), 101 duodenal carcinomas (67 of ulcerous type and 44 of proliferous type, and 65 in the bulb and 42 in the descending part of duodenum as manifested under gastroscopy), 42 rectal cancers, 35 carcinomas of colon, 36 liver cancers. There were 240 males and 134 females, aged from 23 to 71 years old. At the same time, 310 healthy subjects were recruited as a control group. There was no difference in age and gender between the two groups.

Reagents and instruments The test kit for *H pylori*-IgG was provided by Bioseed Company (USA, batch Hillbough CA 94010). The enzyme-labeling meter was SLT-Spectra-I type (Bio-rad, USA).

Methods

Blood samples were collected from all patients and the control group for the detection of anti-*H pylori* IgG.

Detection of anti-*H pylori* IgG In order to eliminate possibly disrupted other proteins, each sample was diluted at 1:100 and detected in duplicate according to the manufacturer's instructions. A series of standard samples with concentrations of 0, 5, 10, 20, 35 and 70 units/ml were added in corresponding reactive wells. When the reaction was stopped, the optical density (OD) values were tested within 10 min at light wavelength 450nm. To measure the concentrations of anti-*H pylori*-IgG in the serum samples, a standardized curve of each board was mapped with the concentrations of standard samples as the abscissa, and OD values of the two correspondent parallel wells as the ordinate. The average OD value of each sample in the two parallel wells above 12 units/ml was regarded to be positive, otherwise to be negative.

Statistical analysis Data analysis was conducted with χ^2 test.

RESULTS

Detection of serum anti-H pylori IgG in patients with different digestive cancers

The positive rates of anti-*H pylori* IgG in patients with digestive cancers and healthy subjects were 61.50 % (230/374) and 46.77 % (145/310), respectively, which were significantly different ($P<0.01$). The positive rates were 52.38 % (33/63), 86.60 % (84/97), 83.14 % (84/101), 45.24 % (19/42), 51.13 % (18/35) and 44.44 % (16/36), respectively, in patients with esophageal carcinoma, gastric cancer, duodenal carcinoma,

rectal cancer, colon carcinoma and liver cancer. There was a significant difference (P<0.01). The detailed results are shown in Table 1.

Table 1 Positive rates of *H pylori*-IgG in patients with different peptic cancers

	n	Anti-*H pylori* IgG	
		-	+ (%)
Normal group	310	165	145 (46.77)[a]
Cancer group	374	144	230 (61.50)[a]
Esophagus carcinoma	63	30	33 (52.38)[b]
Gastric cancer	97	13	84 (86.60)[b]
duodenal Carcinoma	101	17	84 (83.17)[b]
Rectal cancer	42	23	19 (45.24)[b]
Carcinoma of colon	35	17	18 (51.43)[b]
Liver cancer	36	20	16 (44.44)[b]

Serum anti-H pylori IgG in patients with gastric cancer

The positive rates of anti-*H pylori* IgG in intestinal and diffuse type gastric cancer were 93.75 % (60/64) and 72.73 % (24/33), respectively (P<0.05).In addition, the positive rates in gastric antrum and cardia were 96.43% (54/56) and 73.17% (30/41) (P<0.05). The detailed results are shown in Table 2.

Table 2 Positive rates of anti-*H pylori* IgG in patients with gastric cancer of different types and at different locations

Group	*n*	*H pylori*-IgG	
		Positive	Positive rates (%)
Gastric cancer	97	84	86.60
Intestinal type	64	60	93.75[c]
Diffuse type	33	24	72.73[c]
Gastric antrum	56	54	96.43[d]
Gastric cardiac	41	30	73.17[d]

[c]P<0.05, χ^2=8.29; [d]P<0.05, χ^2=11.03.

Serum anti-H pylori IgG in patients with duodenal carcinoma

The positive rates of anti-*H pylori* IgG in patients with ulcerous and proliferous type duodenal carcinoma were 91.04 % (61/67) and 52.27 % (23/44) (P<0.05). In addition, the positive rates of *H pylori*-IgG in the bulb and descending part of duodenum were 94.20 % (65/69) and 45.20 % (19/42), (P<0.05). The detailed results are shown in Table 3.

Table 3 Positive rates of *H pylori*-IgG in patients with duodenal carcinoma of different types and at different locations

Group	*n*	*H pylori*-IgG	
		Positive	Positive rates (%)
Duodenal carcinoma	101	84	83.17
Ulcerous type	67	61	91.04[e]
Proliferous type	44	23	52.27[e]
Bulb of duodenum	69	65	94.20[f]
Descending part	42	19	45.20[f]

[e]P<0.05, χ^2=19.74; [f]P<0.05, χ^2=28.97.

DISCUSSION

H pylori is one of the common bacteria causing chronic infection, infects more than 50 % of the human population, causes chronic gastritis and plays an important role in the pathogenesis of gastroduodenal ulceration. *H pylori* has also been suggested to be involved in the genesis of adenocarcinoma and MALT lymphoma of the stomach[11-13]. It is believed that *H pylori* infection might result in the release of various bacterial and host dependent cytotoxic substances including ammonia, platelet activating factor, cytotoxins and lipopolysaccharide as well as cytokines such as interleukins (IL)-1-12, tumor necrosis factor alpha (TNF-alpha) and reactive oxygen species[14-20], tissue damage and gastro-duodenal disease[21-25]. In 1994, the World Health Organization and International Agency for Research on Cancer (IARC) classified it as a class I carcinogen[26-28]. In this study sera from 374 patients with digestive cancers and 310 healthy controls were tested for *H pylori* using a specific IgG ELISA. The results showed that the positive rate of anti-*H pylori* IgG was 61.50 % in the patients, which was significantly greater than that (46.77 %) in the control group (P<0.01). This finding indicated that patients with digestive cancers were more susceptible to infection by *H pylori* than healthy subjects, which might be related to a lower immunity in these patients. Furthermore, there was a significant difference in the positive rate among patients with cancers of esophageal, stomach, duodenum, rectum, colon and liver. This observation indicated that the prevalence of *H pylori* infection in patients with different digestive cancers was different, which was significantly higher in gastric and duodenal carcinomas than in other digestive cancers. All of these results were concordant with those previously reported[29-34].

In this study, the infection rate was 86.60 % (84/97) in patients with gastric cancer, with a rate of 96.43 % in antral cancer and 93.75 % in intestinal type cancer. We postulate that *H pylori* infection plays an important role in carcinomatous changes in gastric antrum, and is an important pathogenic factor causing intestinal type gastric cancer. This notion is consistent with previous literatures[35-39]. The histological process of intestinal type gastric cancer has been described as normal gastric mucosa→superficial chronic gastritis→atrophic gastritis→intestinal metaplasia→atypical hyperplasia→gastric cancer[40]. After long-term infection of *H pylori* in gastric mucosa, secretion of gastric acid could be reduced, flora in intestinal tract might survive and breed in stomach, and some bacteria recovering nitrate salts might form N-nitroso compounds that are important carcinogens. Moreover, *H pylori* leads to a decrease of vitamin C, which is a strong antioxidant and protective factor in gastric juice, preventing against the occurrence of gastric cancer. As a result, the levels of reactive oxygen and free radicals would increase, and direct DNA damage would incur. Thus, the chances of gene mutation would increase, and further accelerate the development of gastric cancer[41,42].

At present, the definite etiological factors of duodenal carcinoma are not clear, although many studies have suggested that some cholic acids like deoxycholic acid and its degradation products be related to the occurrence and development of duodenal carcinoma. Additionally, ulcerous and genetic factors have been considered to be associated with duodenal carcinoma. Stromberg *et al* found that the levels of several cytokines, such as interleukin-8 (IL-8), transforming growth factor beta (TGF-beta) and gamma interferon (IFN-gamma), were significantly lower in duodenal ulcer (DU) patients than in asymptomatic carriers (AS) and uninfected individuals. Then it was suggested that a number of cytokines might be important for the mucosal host defense against *H pylori* and a down-regulated immune response would play a role in the development of duodenal ulcers[43]. Colonizing in gastric antrum, *H pylori* can destroy the inhibitory feedback adjustment of gastrin release, which results in increased acid load in

duodenum, raises the risk of impairment of duodenal mucous membrane and thus convering of duodenal mucosa to gastric metaplasia. The metaplastic epithelium could provide a site where *H pylori* colonize, and cause duodenitis that was pre-ulcer status of DU and formed ulcer in the end[44]. In addition, some studies have suggested that the development of DU is related to *H pylori* density in patients. There was a tendency of higher *H pylori* density when the degree of deformity of the duodenal bulb increased[45]. The results of our study showed that 83.17 % of the patients with duodenal carcinoma were infected by *H pylori*, with the rate being 91.04 % in ulcerous type and 94.20 % in the bulb carcinoma. Therefore, we conclude that *H pylori* infection is associated with the development of duodenal carcinoma, especially with ulcerous type and in duodenal bulb.

Abstract

AIM: To investigate the effect of tetramethylpyrazine (ligustrazine, TMP) on the secretion of exocrine pancreas (and biliary).

METHODS: In *in vivo* study, we investigated the effect of TMP on the secretion of pancreatic-bile juice (PBJ) in rats. Using human pancreatic duct cell line, CAPAN-1, combined with the short-circuit current (I_{SC}) technique we further studied the effect of TMP on the pancreatic anion secretion.

RESULTS: Administration of TMP (80 mg/kg, ip) significantly increased the secretion of PBJ ($P<0.05$), but the pH of PBJ and the secretion of pancreatic protein were not significantly affected. Basolateral addition of TMP produced a dose-dependent increase in I_{SC} (EC_{50}=1.56 mmol/L), which contained a fast transient I_{SC} response followed by a slow decay. Apical application of Cl^- channel blockers, DPC (1 mmol/L), decreased the response by about 67.1 % ($P<0.001$), whereas amiloride (100 μmol/L), a epithelial sodium channel blockers, had no effect. Removal of extracellular HCO_3^- abolished TMP-induced increase in I_{SC} by about 74.4 % ($P<0.001$), but the removal of external Cl^- did not. Pretreatment with phosphodiesterase inhibitor, IBMX(0.5 mmol/L), decreased the TMP-induced I_{SC} by 91 % ($P<0.001$).

CONCLUSION: TMP could stimulate the secretion of PBJ, especially pancreatic ductal HCO_3^- secretion via cAMP or cGMP-dependent pathway. It need further study to investigate the roles of cAMP or cGMP in the effect of TMP on the secretion of exocrine pancreas.

INTRODUCTION

Tetramethylpyrazine (TMP, $C_8H_{12}N_2$, molecular mass 136.20 u, also known as ligustrazine) is an active alkaloid contained in the rhizome of *Chuanxiong*[1]. TMP has been widely used for the treatment of patients with cardiovascular and cerebrovascular diseases[1-5]. Its proposed pharmacological actions include antagonizing calcium mobilization[6], inhibiting platelet aggregation[7] and increasing intracellular cAMP level by inhibiting phosphodiesterase activity[8]. Recently it has been reported that TMP has antioxidant effect, reducing free radical generation[9,10] and decreasing nitric oxide production[11,12]. However, the effect of TMP on the pancreatic exocrine secretion are unknown. Since TMP is known to activate cAMP, it may act similarly to secretin, a physiological regulator of pancreatic secretion by elevating intracellular cAMP to act on pancreatic epithelial CFTR, which is a cAMP/cGMP-regulated Cl^- channel[13,14] and involved in pancreatic HCO_3^- secretion. In the present study, we investigated the effect of TMP on the secretion of pancreatic-bile juice (PBJ), which includes both pancreatic protein and HCO_3^-. We also undertook the present study using the short-circuit current (I_{SC}) technique to investigate TMP effect on HCO_3^- secretion by human pancreatic duct cell line, CAPAN-1, which retains most of the properties of pancreatic duct cells[15,16].

MATERIALS AND METHODS

Materials

Hydrochloride tetramethylpyrazine was purchased from the First Chengdu pharmaceutical Factory (Chengdu, China). RPMI 1640 medium and fetal bovine serum, trypsin-EDTA were supplied by Gibco Laboratories (New York). Hanks' balanced salt solution (HBSS), diphenylamine-2, 2'-dicarboxylic acid (DPC), glucose, calcium gluconate, N-2-hydroxethypiperazine-N'-2-ethanessulfonic acid (HEPES), sodium bicarbonate, DMEG, penicillin-streptomycin (P/S) and Bradford reagent were supplied by Sigma Chemical (St.Louis, MO). Calcium chloride, magnesium sulfate, potassium chloride, sodium chloride, were obtained from Merck (Darmstadt, Germany). Potassium gluconate and sodium gluconate were from BDH Chemicals (Poole, England). Tris was from Amersham Biosciences (Stockholm, Sweden).

Methods

Animal preparation Animal experimentation was conducted according to institutional guidelines. Adult male Sprague-Dawley rats, weighing 220-280 g, were housed under controlled temperature (23 ℃) and fasted for 12 h with free access to water before surgery. Midline abdominal incisions were made under xylazine and ketamine anesthesia (13 and 87 mg /kg body weight, respectively, im), followed by insertion of a polyethylene tube into the proximal duodenum for diversion of PBJ to the duodenum. A pancreatic duct cannula was made by inserting a polyethylene tube at the junction between the pancreatic duct and the duodenal wall for collection of PBJ[17-19].

Collection and measurement of exocrine pancreatic-bile secretions The animals were divided into two groups randomly: TMP group (TMP 80 mg/kg, ip. pH 2.3) and control

group (9 g/L NaCl solution, ip. pH 2.3). After a 30-minute stabilization period, pancreatic-bile secretions were collected every 15 minutes for 90 minutes. The volume was measured by a 1mL syringe and the pH value of PBJ was determined by a pH analyzer. 10 μL of PBJ was taken and diluted for pancreatic protein determination using spectra MAX 250 and Brandford reagent. The remaining undiluted PBJ was pumped into the duodenum via the duodenal cannula during the next collection period. Administrations were given after 2-time collections (30 minutes) and the second 15-minute-secretion was the basal PBJ secretion.

Cell culture Experiments were performed on the human pancreatic duct cell line, CAPAN-1 at a passage of 50-58. Cells were grown in RPMI 1640 medium with 200 mL/L fetal bovine serum and 10 g/L penicillin-streptomycin (P/S) as described previously[20,21]. Briefly, a volume of 0.2 mL of the cell suspension (1.5×10^9/L) was plated onto each permeable support, which was made of a millipore filter and a silicon ring with a confined area of 0.45 cm^2, floating on culture medium and incubated at 37 ℃ with 50 mL/L CO_2 and 950 mL/L O_2 for 7-8 days. The cells were used for I_{SC} once the monolayers reached confluence.

Short-circuit current measurement The basic principles of the short-circuit current experiments performed in the present study were the same as previously described[20,21]. Monolayers grown on permeable supports were clamped vertically between two halves of the Ussing chamber and bathed in Krebs-Henseleit (K-H) solutions with following compositions (mmol/L): NaCl, 117; KCl, 4.7; $MgSO_4$, 1.2; KH_2PO_4, 1.2; $NaHCO_3$, 24.8; $CaCl_2$, 2.56; Glucose, 11.1; with an osmalarity of 285 gassed with 950 mL/L O_2 and 50 mL/L CO_2. In some experiments, gluconate was used to replace Cl^-. For HCO_3^--free solution, HEPES and Tris were used and the solution was gassed in air. All the electrodes were connected to the voltage-current clamp amplifier. The signal output from the amplifier was the I_{SC} measured and recorded online by chart recorders. A 0.1 mV voltage pulse was applied intermittently across the epithelium and the transepithelial resistance was calculated from the corresponding current changes.

Statistical analysis

The data were collected and analyzed by SPSS statistical package 10.0. The results were expressed as $\bar{x}\pm S_{\bar{x}}$. Comparisons between groups of data were carried out using Student' s paired or unpaired *t*-test. Comparisons in one group of data were carried out using One-way ANOVA. A *P*-value less than 0.05 was considered to be statistically significant. EC_{50} values were determined by non-linear regression by GraphPad Prism software.

RESULTS

Effect of TMP on secretion of PBJ

Table 1 shows the volume of pancreatic-bile juice (PBJ) collected at different time points before and after intraperitoneal administration of TMP or 9 mL/L NaCl (control). Compared with the basal secretion, the PBJ secretion in TMP treated rats was increased by 7.0 % ($P<0.05$), 22.3 % ($P<0.001$), 14.3 % ($P<0.01$), 18.2 % ($P<0.01$) and 14.2 % ($P<0.01$) at 15, 30, 45, 60 and 75minutes, respectively ($n=13$) (Figure 1). However, the same treatment with of 9 mL/L NaCl solution did not produce significant effect ($n=12$) (Figure1). Protein content in PBJ and pH of PBJ were shown to have no differences between TMP-treated and control groups (data not shown).

Effect of TMP on CAPAN-1 cell line

The CAPAN-1 monolayer clamped in Ussing chambers bathing with normal K-HS (Cl^-/HCO_3^--containing) exhibited a potential difference of 0.52±0.04 mV, basal I_{SC} of 5.70±0.53 μA/cm^2 and transmembrane resistance of 93.6±4.5 Ωcm^2 ($n=77$). In Cl^--free ($n=9$) and HCO_3^--free ($n=9$) K-H solution, the transepithelial potential difference was 0.62±0.15 mV and 0.86±0.28 mV and the basal I_{SC} was 1.90±0.50 μA/cm^2 and 3.98±1.32 μA/cm^2, respectively, and the resistance of the monolayers were 208.6±33.6 Ωcm^2 and 161.8±25.6 Ωcm^2.

Table 1 Volume of secretion of pancreatic bile juice ($\bar{x}\pm S_{\bar{x}}$, μL)

	Groups	TMP $n=13$	Control $n=12$
	Basal	372.3±22.2	342.5±15.8
	15 min	398.5±23.3	326.7±1.74
After	30 min	455.4±18. 8	344.2±14.5
administration	45 min	425.4±19.8	331.7±17.5
	60 min	440.0±25.8	357.5±18.8
	75 min	425.0±25.2	342.5±18.2

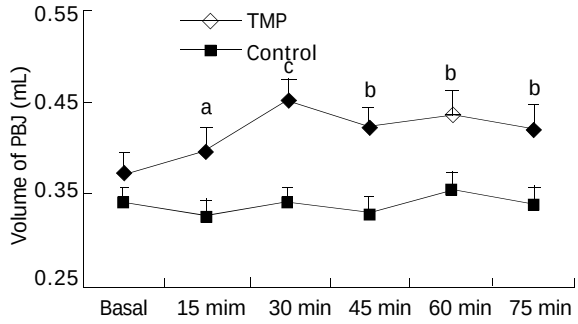

Figure 1 Effect of TMP on Volume of pancreatic-bile juice secretion. The volume of pancreatic-bile juice secretion collected before (basal) and 15, 30, 45, 60 and 75 minutes after intraperitoneal administration of TMP (80 mg/kg) and 9 mL/L NaCl in rats. The results were expressed as $\bar{x}\pm S_{\bar{x}}$. $^aP<0.05$, $^bP<0.01$, $^cP<0.001$, as compared to basal values.

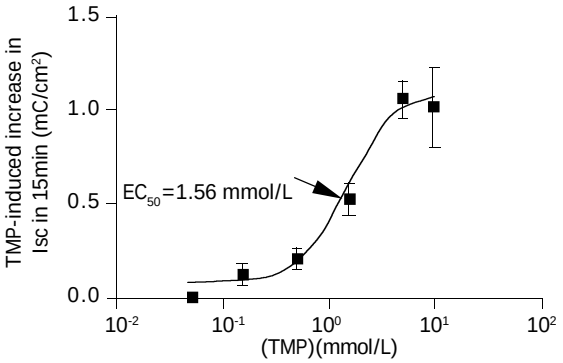

Figure 2 Concentration-response curve for TMP-induced I_{SC} in CAPAN-1 cells. Different concentrations of TMP were added to basalateral side. Each data point was obtained from at least 4 individual experiments. Arrow shows EC_{50}.

Basolateral addition of TMP (0.05, 0.15, 0.5, 1.5, 5 and 10 mmol/L) produced a dose-dependent increase in I_{SC}. EC_{50} was about 1.56 mmol/L (Figure 2). TMP (5 mmol/L)-induced I_{SC} increase was biphasic: a fast transient peak followed by a slow decay. The total transported charges for 15 minutes (the area under the curve of the TMP-induced I_{SC} response) were about 1.06±0.99 mC/cm^2 ($n=27$, Figure 3.A and C). TMP-induced current increase was inhibited by 67.1 % after apical pretreatment of 1 mmol/L DPC, a non-specific Cl^- channel blockers ($n=8$, $P<0.001$) (Figure 3.B and C). However apical application of epithelial sodium channel blockers, amiloride

(100 μmol/L) did not affect the TMP-produced response (n=3, Figure 3.C). After the removal of external HCO_3^-, TMP-induced I_{SC} was blocked by 74.4 % (n=9, P<0.001) (Figure 3. D), but the removal of external Cl^- did not reduce but increase the TMP-induced I_{SC} (n=8, P<0.05) (Figure 3.D). Pretreatment of phosphodiesterase inhibitor, IBMX (0.5 mmol/L) for 15 minutes decreased the TMP-induced I_{SC} by 91 % (n=4, P<0.001) (Figure 4.A and B).

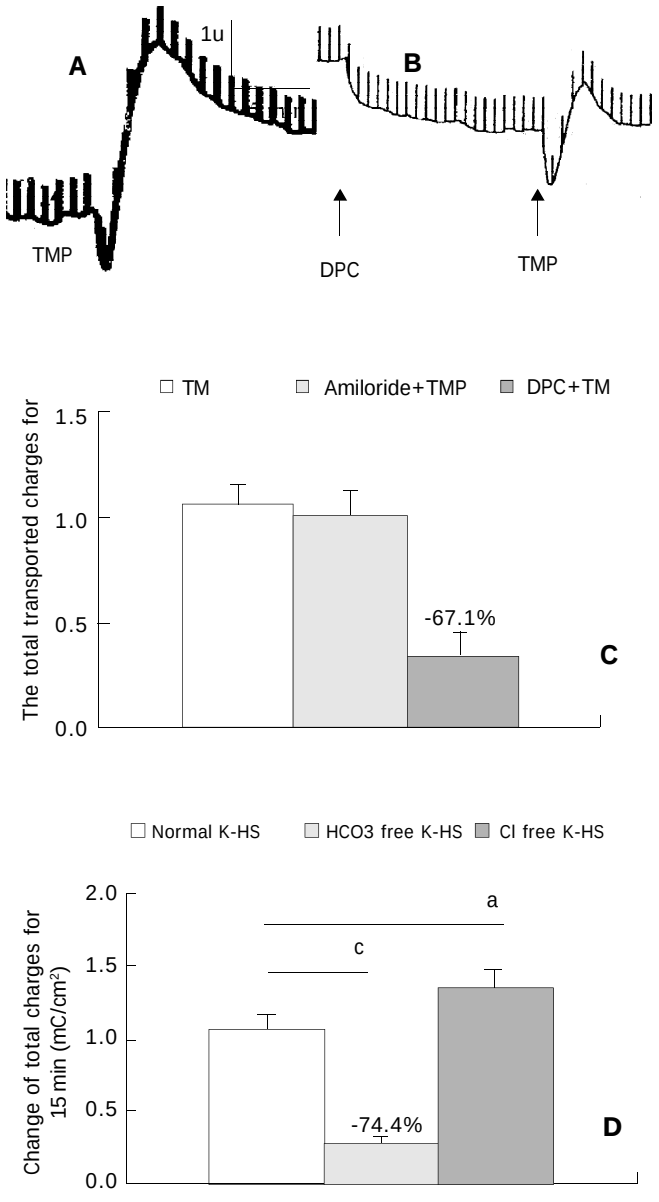

Figure 3 TMP-induced HCO_3^- secretion in CAPAN-1 cells. Comparison of TMP (5 mmoL/L)-induced I_{SC} (mC/cm²) obtained in control (A, C), pretreatment with DPC (1 mmoL/L) (B, C), Amiloride 100 umoL/L (C), HCO_3^--free solution (D), Cl^--free solution (D), Values are $\bar{x}\pm S_{\bar{x}}$, ^aP<0.05, ^cP<0.001.

DISCUSSION

While TMP has been widely used clinically for treating cardiovascular disorders and cerebrovascular diseases[1-5], little is known about its effect on pancreatic secretion. In the present study, intraperitoneal application of TMP increased secretion of pancreatic-bile juice (PBJ), but the protein content and pH value were not affected. It is known that PBJ consists of both bile and pancreatic juice, the volume of the basal secretion (or agonist induced) of pancreatic juice is normally very low, only about 9-18 μL in 15 minutes in rat[17,18], as compared to that of

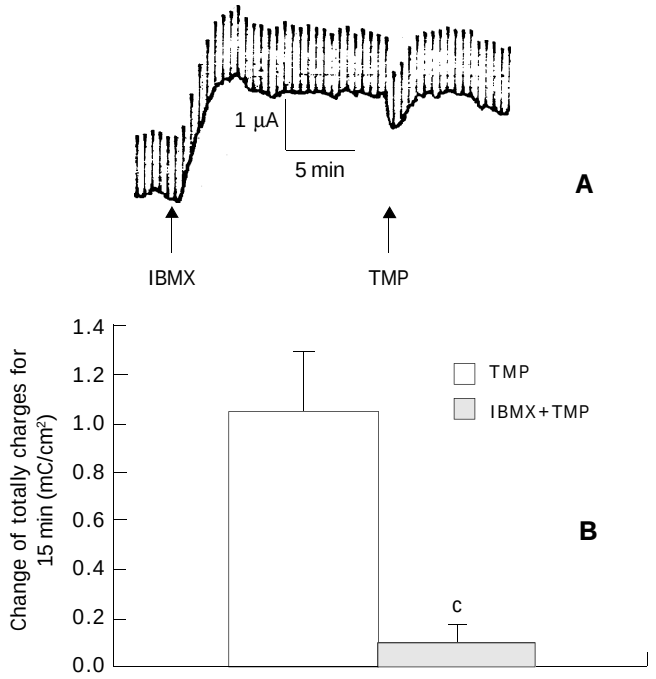

Figure 4 Pretreatment with IBMX decreased TMP–induced I_{SC} by 91 %. Values are $\bar{x}\pm s$, ^cP<0.001.

the liver. Although TMP increased the secretion of PBJ by 26-83 μL in 15 minutes, it was difficult to assess the contribution to exocrine pancreatic secretion from our experiments *in vivo*. Therefore, CAPAN-1 cell line was used to further demonstrate the effect of TMP on the pancreatic secretion. Our data suggested that TMP could directly stimulate HCO_3^- secretion in human pancreatic duct cells.

According to the HCO_3^- secretory model[22], the intracellular HCO_3^- was accumulated from the tissue fluid via the basolateral membrane[23-25] and mainly secreted by a Cl^-/HCO_3^- exchanger[26,27] and/or directly via cAMP/cGMP-dependent Cl^- channel (CFTR)[13,26,28]. Recently, it was reported that CFTR could also secrete HCO_3^- as Cl^-/HCO_3^- exchanger[29,30]. The TMP- increased I_{SC} in CAPAN-1 could be blocked by Cl^- channel blockers, as well as phosphodiesterase inhibitors, which were known to increase cAMP and cGMP, and abolished by removal of extracellular HCO_3^-, suggesting that TMP can stimulate pancreatic HCO_3^- secretion via CFTR since it has been shown to be activated by both cAMP and cGMP. The TMP-induced increase in the volume of PBJ observed in the rats could be due to an increase in pancreatic HCO_3^- secretion, as well as bile secretion, leading to enhanced water secretion. However, the inability of TMP to increase the pH of PBJ appeared to contradict to its observed effect on the increase in HCO_3^- secretion. This could be explained by two possible reasons. One is that the mechanism of HCO_3^- secretion in human pancreatic duct cells was different from that in rats since the HCO_3^- concentration of pancreatic juice in rats was only 70 mmol/L while in human was 145 mmol/L[22]. The other is that the HCO_3^- secreted by the pancreas might be diluted by bile juice and thus having less prominent effect on pH. It is interesting to note that TMP could stimulate HCO_3^- secretion that could be inhibited by extracellular Cl^- as evidenced by the increase in the TMP-induced I_{SC} observed in the absence of extracellular Cl^-. However, the mechanism for the observed inhibition of HCO_3^- secretion by extracellular Cl^- remains to be elucidated.

In conclusion, the present *in vivo* and *in vitro* results suggest that TMP can promote the secretion of PBJ in rats and HCO_3^- secretion in human pancreatic duct cells, which may be beneficial to improving digestive function.

Abstract

AIM: To investigate whether IL-10-transduced dendritic cells (DCs) could induce tolerogenicity and prolong allograft survival in rat intestinal transplantation.

METHODS: Spleen-derived DCs were prepared and genetically modified by hIL-10 gene. The level of IL-10 expression was quantitated by ELISA. DC function was assessed by MTT in mixed leukocyte reaction. Allogeneic T-cell apoptosis was examined by flow cytometric analysis. Seven days before heterotopic intestinal transplantation, 2×10^6 donor-derived IL-10-DC were injected intravenously, then transplantation was performed between SD donor and Wistar recipient.

RESULTS: Compared with untransduced DC, IL-10-DC could suppress allogeneic mixed leukocyte reaction (MLR). The inhibitory effect was the most striking with the stimulator/effector (S/E) ratio of 1:10. The inhibition rate was 33.25 %, 41.19 % ($P<0.01$) and 22.92 % with the S/E ratio of 1:1, 1:10 and 1:50 respectively. At 48 hours and 72 hours by flow cytometry counting, apoptotic T cells responded to IL-10-DC in MLR were 13.8 % and 30.1 %, while untransduced group did not undergo significant apoptosis ($P<0.05$). IL-10-DC pretreated recipients had a moderate survival prolongation with a mean allograft survival of 19.8 days ($P<0.01$), compared with 7.3±2.4 days in control group and 8.3±2.9 days in untransduced DC group. Rejection occurred in the control group within three days. The difference between untreated DC group and control group was not significant.

CONCLUSION: IL-10-DC can induce allogenic T-cell hyporesponsiveness *in vitro* and apoptosis may be involved in it. IL-10-DC pretreatment can prolong intestinal allograft survival in the recipient.

INTRODUCTION

Dendritic cells (DCs) play critical roles in the initiation and modulation of immune responses and may determine the balance between tolerance and immunity[1-3]. Evidence has demonstrated that immunosuppressive cytokines modified DCs favour the induction of alloantigen-specific T cells anergy and prolong allograft survival. To date, there have been only a few reports of genetic manipulation of DCs for therapeutic application in organ transplantation. Retroviral and adenoviral gene transfer methods, for example, have been used to express immunosuppressive molecules such as vIL-10, TGF-β by DC[4,5]. In the present study, we demonstrated the feasibility of liposome transduction of DC to express hIL-10. In addition, we tested the *in vivo* ability of IL-10-DC to prevent small bowel graft rejection in rat intestinal transplantation model.

MATERIALS AND METHODS

Animals

Healthy adult Sprague-Dawley (SD) and Wistar-Furth rats, weighing 200-250 g, were used as donors and recipients, respectively. They were obtained from the Experimental Animal Center of Tongji Medical College, Huazhong University of Science and Technology.

DC propagation and transfection

Splenocyte suspensions from SD rats were prepared in RPMI1640 complete medium (Gibco/BRL), supplemented with 10 % v/v heat-inactivated fetal calf serum (Hyclone) in the presence of granulocyte-macrophage colony-stimulating factor (GM-CSF, 10 ng/ml, R&D) and IL-4 (10 ng/ml, R&D). Cultures were fed every 3 days by complete medium exchange including cytokines. After 6-8 days of culturing, when the adherent cells presented with primitive dendrites observed under electronic microscope, DC was propagated successfully. pcDNA3/hIL-10 vector encoding human IL-10 cDNA sequence was transfected to DC by the liposome method using the Lipofectamin 2000 kit (Gibco/BRL) according to the manufacturer' s instructions and the vector without insert was also transduced as a control. After 10-14 days in selective medium, DCs were then selected for geneticin-resistant colonies.

ELISA

The supernatant from transfected DCs was assayed for IL-10 expression by ELISA kit(Genzyme). The clone that gave the maximum ELISA reading was chosen for use in *in vivo* and *in vitro* experiments.

Mixed leukocyte reaction (MLR)

The ability of transduced DC to stimulate naive allogeneic T cells, assayed by using MTT (Sigma) method, was determined by MLR. Various numbers (2×10^3-2×10^5/well) of DC and IL-10-DC, pretreated with mitomycin C (25 μg/ml, Amresco), were cocultured with allogenic T-cells from Wistar rats as responders (2×10^5/well) at a ratio of 1:1, 1:10 and 1:50 for 72 hours in 0.2 ml RPMI-1640 complete medium in a 96-well U-bottomed microtiter plate. The results monitored by a microtiter plate reader (Bio-Rad, Tokyo, Japan) at 570 nm, were expressed as inhibition rate and calculated according to

the following equation: inhibition rate=1-(mean OD_{570nm} value of experiment group/mean OD_{570nm} value of control group)×100.

Flow cytometric analysis

At the indicated time point, supernatant cells were washed twice in cold PBS and then resuspended in 1×binding buffer at a concentration of 1×10^6 cells/ml. One hundred μl of the solution (1×10^5cells) was transferred to a 5 ml culture tube, then 5 μl of FITC-Annexin V and 10 μl of propidium iodide (Gibco/BRL) were added. The cells were gently vortexed and incubated for 15 min at room temperature in the dark and subjected to FACS. Those cells with negative propidium iodide staining and positive annexin V staining were considered as the proportion of cells actively undergoing apoptosis.

Experimental group and intestinal transplantation

All rats were randomized into three groups and each group had six pairs of rats. These groups were treated with a single intravenous injection of IL-10-DCs (2×10^6), untransduced DCs (2×10^6) or empty plasmid through tail vein seven days before intestinal transplantation. Operation procedures were performed under ether anesthesia. The small intestine was transplanted according to the modified procedure described by Monchik *et al*[6]. In brief, after an overnight fast, a 10-cm segment of proximal jejunum or distal ileum, including the superior mysenteric artery and vein, was removed from the donor after ligation of small mysenteric vessel branches and intravascular irrigation with cold heparinized saline solution. The graft was kept in 4 ℃ cold Ringer's solution until transplantation. The recipient abdomen was opened and the graft was reperfused by end-to-side anastomosis of the superior mesenteric artery and vein to the recipient's abdominal aorta and inferior vena cava under operative microscope, respectively. Both ends of the graft were then exteriorized through the right abdominal wall as stomas, isolating the segment from the recipient's native gastrointestinal tract. Death due to technical failure that occurred within 72 hours of operation was excluded from the study.

Histological examination

The rats were sacrificed and used for histological examination when recipients showed clinical signs of rejection[7,8]. After fixed in 10 % buffered formalin, embedded in paraffin, samples were stained with hematoxylin and eosin and examined by light microscope. Three samples were obtained at the time of donor operation and used as normal group for histological study.

Statistical analysis

All data were expressed as mean ± standard deviation. Statistical analyses were performed using Student's *t* test. Probability values of less than 0.05 were considered significant.

RESULTS

IL-10-DCs induced allospecific T cell hyporesponsiveness

We examined the responses of naï ve allospecific T cells to IL-10-DCs. As shown in Figure 1, IL-10-DCs could suppress allogeneic MLR compared with that of untransduced DCs. The latter were potent stimulators of allogeneic T-cell proliferation. The inhibitory effect was most striking with the stimulator / effector (S/E) ratio of 1:10. The inhibition rates were 33.25 %, 41.19 % and 22.92 % with the S/E ratio of 1:1, 1:10 and 1:50 respectively (Figure 1).

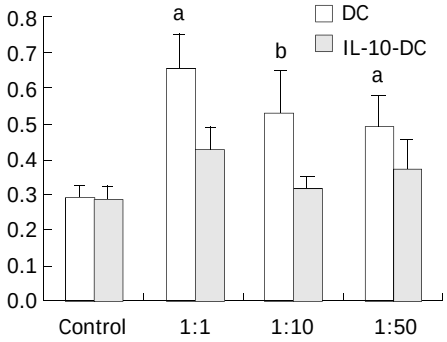

Figure 1 Inhibitory effect of IL-10-DC on allogenic T cell proliferation. [a]$P<0.05$, [b]$P<0.01$, *vs* DC group.

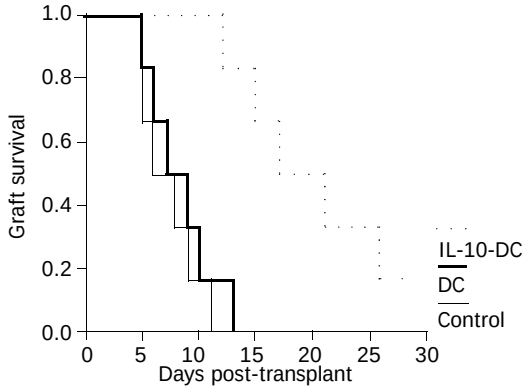

Figure 3 Survival (%) of recipient small intestines from control group (n=6), untransduced DC group (n=6) and IL-10-DC group (n=6).

Apoptosis assay by flow cytometric analysis

Supernatant T cells cocultured with IL-10-DCs in MLR underwent apoptosis. At 48 hours and 72 hours by flow cytometry counting apoptotic T cells were 13.8 % and 30.1 % with the S/E ratio of 1:10, but control group did not undergo significant apoptosis ($P<0.05$) (Figure 2).

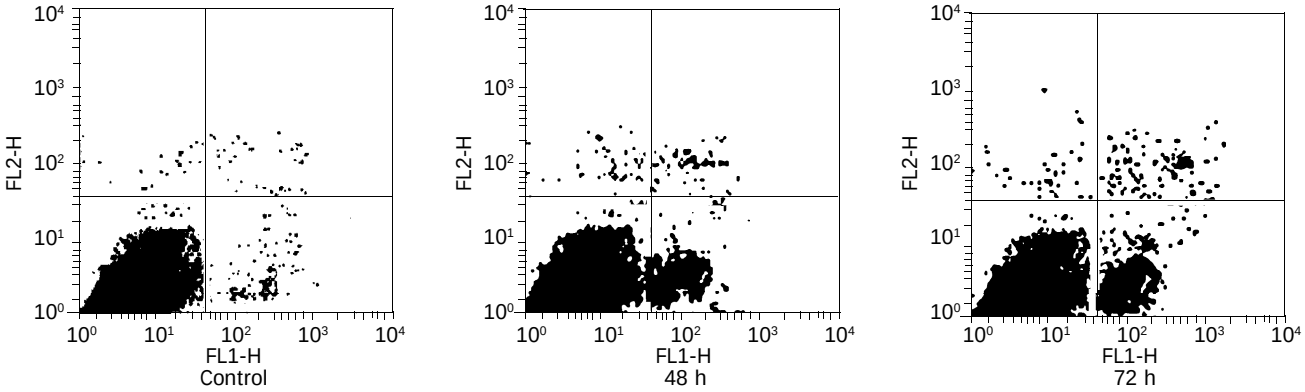

Figure 2 Flow cytometric analysis for apoptotic T cells induced by IL-10-DC.

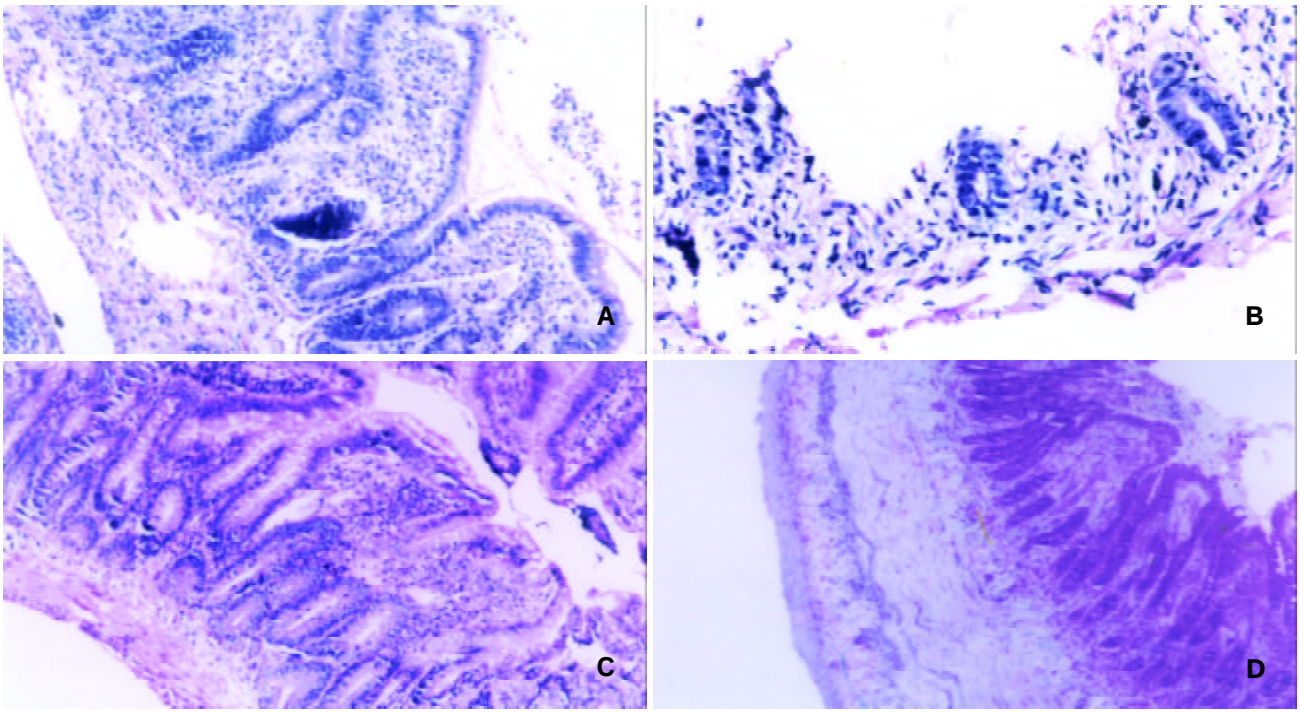

Figure 4 Histological comparison of allografts between control group rats and IL-10-DC pretreated rats. Control group showed acute rejection sign on POD 3 (A) and mucosal sloughing and necrosis and destruction of normal glandular architecture on POD 7(B). IL-10-DC group demonstrated mild lymphocyte infiltration and blunting of villi with edema on POD 7 (C) and fibroblastic proliferation extending from the submucosa to the lamina muscularis (D). (hematoxylin-erosin staining, ×200).

Allograft survival and histological evaluation

Untransduced DCs pretreatment did not affect allograft survival and the recipients pretreated with IL-10-DCs had a moderate allograft prolongation. Mean allograft survival in IL-10-DCs group was 19.8±6.3 days (P<0.01), compared with 7.3±2.4 days in control group and 8.3±2.9 days in untransduced DCs group (Figure 3). Although untreated recipient on postoperative day (POD) 3 showed acute rejection with blunted villi, the number of goblet cells was decreased and a large amount of inflammatory cell infiltration occurred in lamina propria mucosa, the grafts treated with IL-10-DCs demonstrated normal intestinal mucosa negative for rejection on POD 5 and mild lymphocyte infiltration and blunting of villi with edema on POD 7(Figure 4).

DISCUSSION

Despite improvements in the posttransplantation immunosuppressive therapeutic regimens, the management of allograft rejection has been still dependent on the use of nonspecific immunosuppressive agents[9], which could prevent the host from complications, such as infections and lymphoproliferative disorders[10,11]. In this regard, the successful induction of donor-specific immune tolerance remains a major challenge in organ transplantation. However, the lymphoid-rich small intestinal allograft might differ from such lymphoid-poor organs as the heart and kidney, making tolerance induction a particularly troublesome approach specific to this organ[12-14]. An approach to modify donor-derived DC in order to induce an immunological hyporesponsive state in the recipient has been attractive as a potential strategy in transplantation as it would theoretically let the possibility of donor-specific tolerance come true[15,16].

IL-10 has been regarded as an immunosuppressive cytokine because of its ability to down-regulate the synthesis of a broad spectrum of proinflammatory cytokines by DCs, monocytes or macrophages, and to inhibit allogeneic proliferative responses *in vitro*[17-19]. It is for these reasons that IL-10 has been considered as a potential means in the induction of tolerance. In the immature state, DC could express low levels of CD80, CD86 and co-stimulatory molecules that are essential for the amplification of immune response to foreign peptides[16,20-22]. IL-10 has been shown to block DC maturation *in vitro*[23,24]. Our approach was therefore to investigate strategies that might delay maturation of DC to prolong their immature phenotype. In our studies we found that these IL-10-DCs were less stimulatory in the MLR compared with untransduced DCs. One of the major mechanisms by which IL-10 inhibited DC antigen presenting function was to down-regulate MHC class II and costimulatory molecule expression on DC[25].

Our data confirmed that IL-10-DC could inhibit the proliferation of allogeneic T cells and induce these cell apoptosis, which may be related to the prolonged survival of graft. It has been accepted that the initiation of T-cell responses to grafted tissues requires two distinct signals[26-28]. The essential signal is the engagement of T cell receptors (TCR) to antigen peptide in the content of major histocompatibility complex molecules on antigen presenting cells. Other costimulatory receptor-ligand interactions between T cell and APC are needed. Signals through the TCR alone could lead to allospecific T-cell anergy or apoptosis[29]. Schartz[30] has demonstrated that lack of second signal would result in increased amounts of a negative regulatory factor, Nil-2a, in anergic human T cells. This factor has been shown to suppress IL-2 nuclear transcription factors of AP-1 and NF-κB. NF-κB could inhibit apoptosis by induction or up-regulation expression of anti-apoptotic gene such as Bcl-2. Therefore, the suppression of NF-κB activation could give rise to decreased IL-2 expression and T cell apoptosis[31,32].

Our studies were consistent with previous studies, perhaps not surprisingly, showing that IL-10-DC could exert tolerogenic effects on organ transplantation[25, 33]. In IL-10-DC group, median intestine allograft survival time was 19.8±6.3 days. Compared with control group (7.3±2.4 days) and untransduced DC group (8.3±2.9 days), the survival time was 2.5-fold longer. There are two possible explanations for the lack of long- term

survival in our study. One is that IL-10-DC might not survive long enough to induce a permanent state of tolerance. Long-term survival of IL-10-DC *in vivo* would be particularly important if apoptosis induction of allogeneic T cells was a major mechanism of allograft survival. The other, as far as long-term tolerance is concerned, is that the level of expression of IL-10 by IL-10-DC was still not high enough to affect the recipient immune modulation for all alloreactive T cells, though the level of IL-10 expression was higher than that in normal condition. For intestine, considering its high immunogenicity, it would be necessary to enhance gene transfer efficiency and transgene expression level[34].

In conclusion, these studies demonstrate the feasibility of immunosuppressive gene delivery system. We believe that this highly targeted method of inducing tolerogenicity of donor derived DC may reduce the need for recipient nonspecific immunosuppression and play an important role in clinical strategies of tolerance induction.

Abstract

AIM: Proinflammatory cytokines TNF-α and IL-6 play a main role in acute pancreatitis (AP). Cytokine biosynthesis runs through two major signaling pathways at the level of proteins: nuclear transcription factor-κB (NF-κB) and p38 mitogen-activated protein kinase (p38 MAPK). The aim of the study was to investigate the effect of NF-κB and p38 MAPK in activated monocytes/macrophages on cytokines of rats with acute pancreastitis.

METHODS: Taurocholate (3 % and 5 %) at doses of 1 mL/kg was administered into the biliopancreatic duct of male Sprague-Dawley (SD) rats to reduce acute edematous pancreariris (AEP) and acute necrotizing pancreatitis (ANP). Pancreatic tissues were prepared immediately after death. At this point, blood was obtained for determination of serum amylase and pro-inflammatory TNF-α and IL-6. Activated monocytes/macrophages were captured from blood and so were ascites. NF-κB and p38 MAPK in activated monocytes/macrophages were measured by immunohistochemistry method. Pancreatic tissue samples were prepared for routine light microscopy, using hematoxylin and eosin (HE) staining.

RESULTS: The serum levels of amylase were 3 056.00±1 232.35 IU/L and 4 865.12±890.34 IU/L at 3 and 6 hours in ANP group, which were significantly higher than those (3 056.00±1 232.35 IU/L and 3 187.17±821.16 IU/L) ($P<0.05$, respectively) in AEP group. In ascites the levels were 3.32±1.01 g and 3.76±1.12 g at 3 and 6 hours in ANP group, which were significantly higher than those (1.43±1.02 g and 2.56±1.21 g) ($P<0.05$, respectively) in AEP group. The serum levels of TNF-α were 54.27±23.48 pg/ml and 67.83±22.02 pg/ml in AEP group and 64.28±20.79 pg/ml and 106.59±43.71 pg/ml in ANP group, and the serum levels of IL-6 were 428.12±140.30 pg/ml and 420.13±139.40 pg/ml in AEP group and 1 600.32±309.78 pg/ml and 2 203.76±640.85 pg/ml in ANP group, which were far significantly higher than those in sham group ($P<0.001$, respectively). The serum level of TNF-α 6 hours after establishment of the studied model and that of IL-6 at 3 and 6 hours in ANP group were significantly higher than those in AEP ($P<0.05$, $P<0.001$, $P<0.05$). In ANP group, the levels of serum TNF-α and IL-6 6 hours after establishment of the studied model were significantly higher than those 3 hours after establishment of studied model ($P<0.05$, $P<0.05$, respectively). Three and 6 hours after establishment of the model, typical pathological changes of AEP and ANP were found, such as large numbers of inflammatory cells, edema, hemorrhage, necrosis, large amount of ascites. In AEP, NF-κB and p38 MAPK in activated monocytes/macrophages were moderately found at 3 and 6 hours after introduction of the model. However, in ANP, the expression of NF-κB and p38 MAPK in activated monocytes/macrophages was upregulated evidently at 3 and 6 hours after introduction of the model, reaching their highest levels at 6 hours after introduction of the model, which were consistent with the levels of TNF-α and IL-6.

CONCLUSION: Cytokine TNF-α and IL-6 play a main role in acute pancreatitis, expression of NF-κB and p38 MAPK in activated monocytes/macrophages might play a major role in cytokine transcription and biosynthesis.

INTRODUCTION

The etiology of acute pancreatitis (AP) is mostly alcoholic or gallstone. Whatever the etiologic factors are, once the disease is initiated by an early molecular mechanism (which is still controversial) in or around acinar cells, a host inflammatory response is evoked in the pancreas. This locally limited inflammation is then manifested and amplified by the actions of diverse inflammatory mediators, such as cytokines (tumor necrosis factor-α (TNF-α), interleukin-1(IL-1) and interleukin-6(IL-6)), reactive oxygen species, proteolytic enzymes, lipids, as well as gaseous mediators, resulting in the induction of systemic inflammatory response syndrome (SIRS)[1-3]. Although SIRS is principally considered to be the normal host response to the insults, sustained or exaggerated SIRS, followed by the development of multiple organ dysfunction syndrome (MODS), is ultimately responsible for most pancreatitis- associated mortality and morbidity. Thus, the most distinctive feature of AP could be defined as its propensity to propagate locally limited inflammation into SIRS, and subsequently into MODS[4,5].

In AP, the very early phenomena that appear to occur are monocytes and neutrophils in the circulation migrating into the pancreatic interstitial space, mainly mediated by adhesion molecules on leukocytes[6,7]. These infiltrating cells accelerate further production and secretion of cytokines, as well as other inflammatory mediators. As a result, leukocytes in the circulation, as well as endothelial cells, in the pancreas and specific distant organs such as the lung, liver and spleen, are activated, eliciting further microcirculatory derangements, such as increased vascular permeability and accelerated leukocyte transmigration. The contribution of cytokines during this cascade of events has been increasingly apparent in the past decade, as indicated by several clinical and experimental studies exhibiting increased levels of cytokines in plasma, lymph, and ascites,as well as enhanced activitity of circulating leukocytes. Of the

various kinds of inflammatory mediators, TNF-α and IL-1 are regarded as most prominent "first-line" cytokines[8-10]. IL-6 is well known to be the primary inducer of acute-phase response. Therefore, IL-6 was recently reported to be the best prognostic parameter of pulmonary failure[11]. IL-6, IL-8 and TNF-α can be synthesized by monocytes/macrophages, neutrophils, endothelial cells, and even pancreatic duct cells.

Recent experimental studies appeared to have shed some light on the intracellular signaling pathway in the inflammatory cascade in AP. For example, recent evidence strongly suggested the crucial role of NF-κB in the initiation of AP, not only in pancreatic acinar cells and monocytes/macrophages but also in specific distant organs, such as the lung. NF-κB is able to mediate a variety of inflammatory mediators involved in AP, including cytokines and adhesion molecules, as well as specific inducible isoform of nitric oxide synthase enzymes[12-21]. Additionally, recent evidence has also shown the contribution of p38 MAP kinase to the mechanism underlying cytokine expression in pancreatic acinar cells and monocytes/ macrophages. An *in-vitro* experiment showed that cytokine expression of acinar cells was mediated by two separate signal pathways, i.e, NF-κB and p38 MAP kinase. of which p38 MAP kinase is now suggested to play a major role[22-27]. The definitive role of these intracellular signaling cascades may lead to new designs for cytokine modulation therapy.

This study was to investigate the effect of NF-κB and p38 MAPK in activated monocytes/macrophages on pro-inflammatory cytokines of mice with acute pancreatitis and to explore the biosynthesis mechanism of pro-inflammatory cytokines TNF-α and IL-6.

MATERIALS AND METHODS

Materials

Sixty pathogen-free male Sprague-Dawley (SD) rats (Animal Center, Xi' an Jiaotong University), weighing 250-300 g, were used in this experiment. The animals were kept at a constant room temperature of 25 ℃ with a 12-hour light-dark cycle, and were allowed free access to water. The animals were housed in the animal facility for at least seven days prior to use in order to stabilize their intestinal flora. All procedures including the rats receiving a very small amount of methoxyflurane for induction and pentobarbital intra-peritoneal injection (50 mg/kg) for anesthesia were performed under sterile conditions. SD rats were divided into subgroups of pancreatitis and controls. Taurocholate (3 % and 5 %, Sigma) at doses of 1 mL/kg was administered into the biliopancreatic duct of the rats to establish acute edematous pancreatitis (AEP) and acute necrotizing pancreatitis (ANP). In the sham group, the mice were only operated but not infused anything. All values reported were from animals killed at defined time points. During experiments the rats were closely observed, and pancreas tissues were prepared immediately after death. At this point, blood was obtained for determination of serum amylase and TNF-α and IL-6. The activated monocytes/ macrophages were captured from blood and ascites respectively.

Macroscopic assessment of the pancreas

Necrosis, hemorrhage and edema of the pancreas were each graded from 0 to 3 as follows: (a) necrosis: no necrosis =0, isolated necrotic lesion (<5 % of the pancreas)=1, necrotic areas 5-25 %=2, necrotic areas >25 % and partial destruction of the organ=3; (b) hemorrhage: not evident=0, single focal hemorrhage=1, multiple disseminated hemorrhagic dots=2, massive confluent hemorrhage=3; (c) edema: normal size=0, enlargement of the pancreas=1, recognizable accumulated fluid in the tissue=2, massive swelling and fluid accumulation=3. The scores of these parameters were summed, and the highest possible total score for an individual rat was 9[28].

Microscopic assessment of the pancreas

Pancreas tissue samples were prepared for routine light microscopy, using hematoxylin and eosin (HE) staining and examined by a pathologist who was unaware of the source of specimens. HE-stained pancreas sections were observed with a standard light microscope to evaluate morphologic alterations following AP.

Pancreatic water contents

The wet weight-dry weight ratio of the pancreas was obtained after about 200 mg of freshly prepared pancreatic tissue was dried for 20 h at 105 ℃.

Amylase assay

Amylase activity in plasma was determined using the a-amylase EPS assay purchased from Roche (Sigma) at 37 ℃.

Serum of TNF-α and IL-6

Blood was collected and centrifuged (3 000 rpm/min, for 5 min). The serum was captured and stored at -30 ℃. The pro-inflammatory TNF-α and IL-6 were measured by enzyme-linked immunosorbent assay (ELISA).

NF-κB and p38 MAPK in activated monocytes/macrophages

The activated monocytes/macrophages were captured from blood and ascites, respectively. They were separated and pasted for 12 hours in 10 % calf serum of 1640. NF-κB and p38 MAPK in activated monocyte/macrophage were measured by immunohistochemistry method (S-ABC). In brief, endogenous peroxidases were blocked for 15 min with methanol-H_2O_2, and after several washes unspecific-binding sites were blocked for 2 h with 3 % normal horse serum. Samples were then incubated overnight in a humidified chamber at 4 ℃ with the primary antibody against NF-κB and p38 MAPK(Sigma) diluted 1:200. This was followed by biotinylated goat anti-mouse antibody diluted 1:200 for 1 h, and the avidin-biotin complex (ABC kit, Vector Laboratories) (1:100) for 1 h. The reaction was developed with 0.05 % diaminobenzidine and 0.03 % H_2O_2. Negative controls were carried out by omission of the primary antibody in the overnight incubation. Several sections were counterstained with hematoxylin.

Statistical analysis

The values were expressed as the mean ±standard error (SEM). The data were analyzed for statistical significance using Student' s *t* test. There were six animals in each group at each time point. As the values in some data sets were not normally distributed or exhibited unequal standard deviations, the nonparametric Wilcoxon rank sum test was used to test for statistical differences between groups. In all instances $P<0.05$ was considered to be significant.

RESULTS

Amylase assay and ascites

The serum levels of AMS and ascites in AEP and ANP groups were significantly higher than those in sham group ($P<0.01$). The serum levels of AMS and ascites at 3 and 6 hours after the establishment of the studied model in ANP group were significantly higher than that in AEP ($P<0.05$). In ANP group, the levels of serum AMS and ascites 6 hours after the establishment of the studied model were not significantly higher than those 3 hours after the establishment of the studied model ($P>0.05$) (Table 1).

Table 1 Levels of AMS and ascites of AEP and ANP($\bar{x}\pm s$)

Group	AMS (IU/L)		Ascites (g)	
	3 h	6 h	3 h	6 h
Sham	792.80±265.08	793.8 0±265.08	0	0
AEP	3 056.00±1232.35[b]	3 187.17±821.16[b]	1.43±1.02[b]	2.56±1.21[b]
ANP	4 345.30±1005.77[ab]	4 865.12±890.34[ab]	3.32±1.01[ab]	3.76±1.12[ab]

[b]P<0.01 *vs* sham, [a]P<0.05 *vs* AEP.

Pancreatic water contents

The extent of pancreatic edema was determined as the wet weight/dry weight ratio of the tissue, and the macroscopic appearance of the pancreas was evaluated by a score (Table 2). In pancreatitis both parameters were significantly increased compared to the control (P<0.05).

Table 2 Macrocopic appearance and edema of pancreas in AEP and ANP (at 6 hours after of model)

	n	Sham	AEP	ANP
Score	0.2	1.1	6.9[a]	6.3[ac]
ww/dw	4.3	5.3	7.1[a]	8.2[ac]

The macroscopic appearance of the pancreas was scored. For an individual rat the highest possible score was 9. Pancreatic water content was estimated as the wet weight/dry weight ratio (ww/dw) of the tissue. N: untreated animals, anesthesia omitted; S: sham operations. [a]P<0.05 compared to the untreated group; [c]P<0.05 compared to the control group at 6 hours after induction of model.

Serum levels of TNF-α and IL-6

The serum levels of TNF-α and IL-6 in AEP and ANP groups were far significantly higher than those in sham group (P<0.001). The serum levels of TNF-α and IL-6 6 hours after establishment of the model in ANP group were significantly higher than those in AEP (P<0.05, P<0.001, P<0.05). In ANP group, the levels of serum TNF-α and IL-6 6 hours after establishment of the studied model were significantly higher than those 3 hours after establishment of the studied model (P<0.05) (Table 3).

Table 3 Serum levels of TNF-α and IL-6 in AEP and ANP ($\bar{x}\pm s$)

Group	TNF-α (pg/ml)		IL-6 (pg/ml)	
	3 h	6 h	3 h	6 h
Sham	4.13±2.5	55.87±3.79	100.79±53.89	151.04±91.79
AEP	54.27±23.48[b]	67.83±22.02[b]	428.12±140.30[b]	420.13±139.40[b]
ANP	64.28±20.79[b]	106.59±43.71[abc]	1 600.32±309.78[ab]	2 203.76±640.85[abc]

[b]P<0.001 *vs* sham group; [a]P<0.05 or 0.001 *vs* AEP group; [c]P<0.05 *vs* 3 h group.

Morphological examination

After induction of the AEP and ANP models, the pancreas showed mild edema and congestion. Three and 6 hours after introduction of the model, typical pathological changes of AEP and ANP were found, such as large numbers of inflammatory cells, edema, hemorrhage, necrosis, large amount of ascites (Table 1).

NF-κB and p38 MAPK in activated monocytes/macrophages

The expression of NF-κB and p38 MAPK in activated monocytes/macrophages at 3 and 6 hours was assessed by immunohistochemistry. In AEP, mild expression of NF-κB and p38 MAPK in activated monocytes/macrophages was found 3 and 6 hours after introduction of the model. However, in ANP, the expression of NF-κB and p38 MAPK in activated monocytes/macrophages was upregulated evidently 3 and 6 hours after introduction of the model, reaching their highest levels at 6 hours after introduction of the model (Figures 1,2,3 and 4).

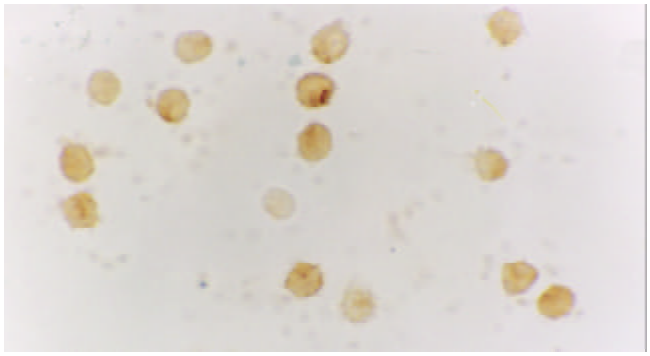

Figure 1 Moderate expression of NF-κB in the cytoplasm/nucleolus of monocytes in AEP (6 hours) 10×100.

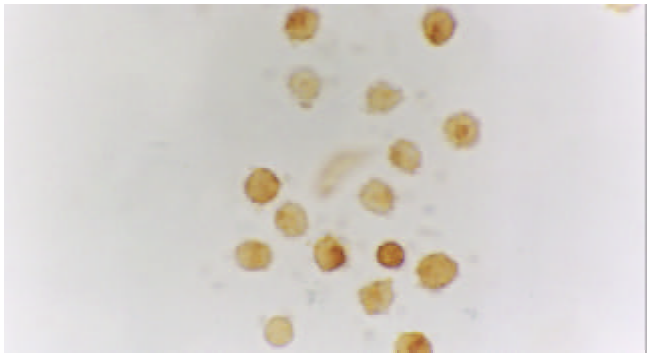

Figure 2 Strong expression of NF-κB in the cytoplasm/nucleolus of monocytes in ANP (6 hours) 10×100.

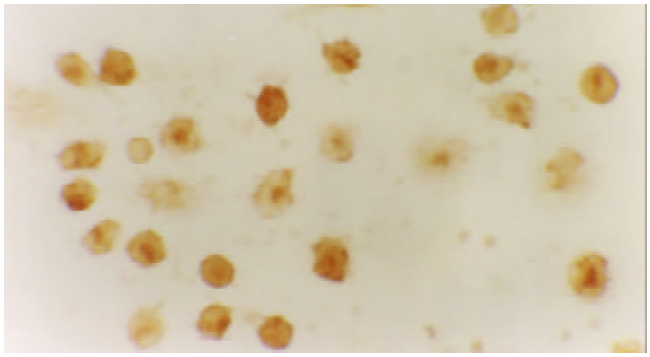

Figure 3 Moderate expression of p38MAPK in the cytoplasm/nucleolus of monocytes in AEP (6 hours) 10×100.

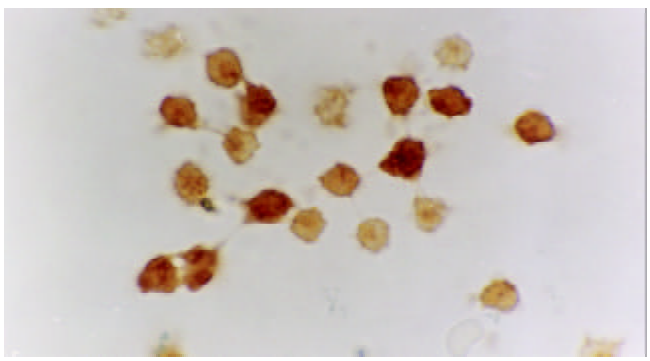

Figure 4 Strong expression of p38MAPK in the cytoplasm/nucleolus of monocytes in ANP (6 hours) 10×100.

DISCUSSION

The clinical manifestations of AP vary significantly from mild to lethal, severity of the disease is largely determined by the actions of various kinds of inflammatory mediators, including cytokines, reactive oxygen species, proteolytic enzymes, and lipids, as well as gaseous mediators. Despite increasing knowledge implicating the involvement of cytokines in the progression of AP, no clinical trials pertaining to cytokine modulation have been performed so far. Progress in intensive care technologies has contributed to the improvement of mortality and morbidity rates in severe AP in the past decade. However, it appears to be reasonable for clinicians to "line up their sights" on the modulation of cytokines as a direct treatment.

Pro-inflammatory cytokines played a main role in acute pancreatitis and complications due to acute pancreatitis[29,30]. Failure of different organ systems is a frequent problem in severe acute pancreatitis. The majority of fatalities in patients with severe acute pancreatitis are associated with the failure of at least one or more organ systems. Organ failure in severe acute pancreatitis has to be regarded as part of the inflammatory response following the liberation of activated enzymes from the pancreas. The mediators involved in this process include IL-1, TNF-α, IL-6, platelet activating factor, and IL-8. Of the various kinds of inflammatory mediators, TNF-α and IL-1 are regarded as the most prominent "first-line" cytokines. The primary involvement of TNF-α was demonstrated by elevation of TNF-α levels in rat severe AP models. This was confirmed by subsequent TNF-α antagonism experiments, using anti-TNF-α antibodies or a recombinant dimeric form of p55 TNF receptor. Similarly, the concurrent blockade of cytokines showed no additional benefit in the amelioration of pancreatic injury, however, it attenuated the systemic response, as indicated by reduced IL-6 levels and decreased mortality rates. With few exceptions, most studies carried out with the purpose of blocking proximal cytokines, such as TNF-α, IL-1 or IL-6, during the progression of AP showed favorable results in experimental settings. However, neither TNF-α nor IL-1 has a causative role in the initiation of AP. For example, exposure of isolated acinar cells to TNF-α and IL-1 *in vitro* did not induce either intracellular zymogen activation or release of enzymes. In addition, these cytokines were not able to induce either biological or histological evidence of pancreatitis by *in-situ* perfusion of isolated human pancreas[31].

As to the primary site of cytokine production, infiltrating macrophages in the pancreas and ascites are suggested to be the initial cellular origins of TNF-α. In a mouse cerulein AP model, the expression of TNF-α messenger RNA within the inflamed pancreas was observed as early as 30 min after the induction of AP, and was followed by elevation of intrapancreatic and serum TNF-α levels. In addition, neutrophils that have migrated into the inflamed pancreas appear to be equally involved in the production of TNF-α, IL-6 and IL-1. The production of these cytokines was subsequently observed in specific distant organs, such as the lungs, liver, and spleen. In particular, production of TNF-α and IL-1 in the lung was known to be closely associated with the development of adult respiratory distress syndrome (ARDS), which was the major cause of early death in patients with SAP[32].

IL-6 is well known to be the primary inducer of acute-phase response, while its level in circulation during AP reaches the maximum value 24-48 h before the maximal C-reactive protein level is reached. Therefore, IL-6 has been recently reported to be the best prognostic parameter of pulmonary failure. IL-6 is synthesized by monocytes/macrophages, neutrophils, endothelial cells, and even pancreatic duct cells. It is able to stimulate neutrophil chemotaxis and release of enzymes, thereby leading to tissue destruction when overproduced. In clinical settings, some authors have reported elevated IL-6 levels in AP patients, particularly in those with complications. This observation has been supported by *in-vitro* studies, using isolated blood monocytes from patients with AP, in which systemic complications were found to be closely associated with enhanced secretion of IL-6 and IL-8 from the cells. Based on an increasing body of evidence, both IL-6 and IL-8 are now considered to be early and excellent predictors of patient outcome, and are widely used as secondary end points in clinical trails[33].

Recent experimental studies have shed some light on the intracellular signaling pathway in the inflammatory cascade in AP. For example, recent evidence strongly suggested the crucial role of NF-κB in the initiation of AP, not only in pancreatic acinar cells, monocytes/macrophages and neutrophils, but also in specific distant organs such as the lung. NF-κB is able to mediate a variety of inflammatory mediators involved in AP, including cytokines and adhesion molecules, as well as specific enzymes. NF-κB plays a key role in the transcriptional regulation of adhesion molecules, enzymes and cytokines involved in acute inflammatory diseases. NF-κB is a key transcription factor for the expression of various proinflammatory molecules such as chemokines, cytokines, and adhesion molecules. This notion has recently been verified by adenoviral-mediated gene transfer of an active subunit, RelA/p65, into acinar cells delivered through an injection into the rat pancreatic duct. The overexpressed RelA/p65 protein trans-activated NF-κB and induced pancreatic inflammation, a pathological state very similar to acute pancreatitis. In addition to the importance of NF-κB in the pathogenesis of acute pancreatitis, it was also reported that NF-κB activation in macrophages was a key event both in the development of generalized complications during severe acute pancreatitis and as a cause of the high mortality in this condition. Studies also showed that glucocorticoids were one of the most potent inhibitors of NF-κB, which might be attributable to the inhibition of this key transcription factor both in acinar cells and in inflammatory cells such as monocytes/macrophages. It is known that the mechanism of the inhibition of NF-κB by corticosteroids is multifactorial. One is via the induction of IκBa, the inhibitor molecule of NF-κB, which can form a complex with NF-κB in the cytoplasm, inhibiting the translocation of NF-κB into the nucleus, where it enhances the transcriptional activation of various proinflammatory genes. The other is a cross-coupling mechanism of inhibition between activated glucocorticoid receptors and activated NF-κB. Because the activation of NF-κB is an early event in the pathogenetic mechanism of acute pancreatitis, it is reasonable that in most studies corticosteroids showed beneficial effects on acute pancreatitis[34].

Moreover, inflammatory mediators released during acute diseases activate multiple intracellular signalling cascades including the MAPK signal transduction pathway, which plays a significant role in the recruitment of leukocytes to sites of inflammation. Stimulation of leukocytes by pro-inflammatory cytokines is known to result in activation of MAPK isoform p38. However, the functional consequences of p38 MAPK activation during leukocyte recruitment, including adhesion, migration and effector functions such as oxidative burst and degranulation, are only just beginning to be elucidated. Recently, p38 MAPK has been implicated in the activation of NF-κB. Several groups have demonstrated that p38 MAPK-specific inhibitor SB203580 potently attenuated NF-κB-dependent transcription. However, phosphorylation of NF-κB subunits, nuclear translocation and DNA binding to NF-κB were not affected by this p38 inhibitor. This suggests that NF-κB and p38 MAPK are activated by separate effector pathways, which might converge further downstream in the cell nucleus.

So recent experimental studies have shed some light on the intracellular signaling pathway in the inflammatory cascade. Cytokine transcription and biosynthesis bifurcate into two major signaling pathways at the level of proteins. One runs through the NF-κB inducing kinase route, which regulates phosphorylation of inhibitory-kb (IκB) protein, the cytosolic inhibitor of NF-κB which allows NF-κB complex to translocate to the nucleus and promotes gene expression. The other is mediated through p38MAPK pathway and makes p38MAPK phosphorylated and activated[35].

So in recent years, much effort has been focused on delineating intracellular signaling cascades in inflammatory pathways. The intracellular signaling pathways used by leukocytes in response to pro-inflammatory stimuli have only begun to be unravelled. Much attention has been given to MAPK superfamily owing to their activation by pro-inflammatory cytokines IL-6 and TNF-α, which play a central role during inflammatory responses and in inflammatory diseases.

In this study, it showed that retrograde infusion of sodium taurocholate into the pancreatic duct resulted in an increase of amylase activity and ascites 3 and 6 hours after pancreatitis. The levels of serum AMS and ascites in AEP and ANP groups were far significantly higher than those in sham group (P<0.01). The serum levels of TNF-α and IL-6 in AEP and ANP groups were far significantly higher than those in sham group (P<0.001). The serum level of TNF-α of the studied model and the serum level of IL-6 3 and 6 hours in ANP group were significantly higher than that in AEP (P<0.05, P<0.001, P<0.05). In ANP group, the levels of serum TNF-α and IL-6 6 hours after establishment of the studied model were significantly higher than those 3 hours after establishment of the studied model (P<0.05, P<0.05).

After induction of AEP and ANP models, pancreas showed mild edema and congestion. Three and 6 hours after introduction of the model, typical pathological changes of AEP and ANP were found, such as large numbers of inflammatory cell, edema, hemorrhage, necrosis, large amount of ascites.

The expression of NF-κB and p38 MAPK in activated monocytes/macrophages at 3 and 6 hours after pancreatitis was assessed by immunohistochemistry. In AEP, moderate expression of NF-κB in activated monocytes/macrophages was found 3 and 6 hours after introduction of the model. However, in ANP, the expression of NF-κB and p38 MAPK in activated monocytes/macrophages were upregulated evidently 3 and 6 hours after introduction of the model, reaching their highest levels 6 hours after introduction of the model. So the expression of NF-κB and p38 MAPK in activated monocytes/macrophages at 3 and 6 hours assessed by immunohistochemistry was consistent with the increase of pro-inflammatory cytokines TNF-α and IL-6.

Thus, increased understanding of the signal transduction pathways involved in the regulation of cytokine production and cytokine signaling in inflammatory cells has opened the door for the discovery of novel therapeutics for treating a variety of inflammatory diseases in which cytokine production or signaling is implicated. The availability of potent and selective inhibitors of such signaling pathways also provides a means to further dissect the pathways to increase our understanding about the complex events underlying a particular immune mediated event at the cellular and molecular level. NF-κB and p38 MAPK are the most studied signaling molecules in this regard and their relevance to such disease states has been established primarily through the use of inhibitors. Indeed, selective inhibition of NF-κB and p38 MAP kinase inhibitors has demonstrated efficacy in a variety of animal models[36-40]. Specific p38 inhibitors and selective inhibition of NF-κB aimed at reducing the production of inflammatory mediators are now being developed, and might in the future provide more effective treatment for inflammatory diseases. At present, it may be too early to take an optimistic view of therapeutic cytokine modulation in AP. There are many obstacles to overcome. However, direct therapy by cytokine modulation sounds very attractive to clinicians.

Abstract

AIM: To understand the influence of Kupffer cell (KC) on signal transduction pathways in the liver.

METHODS: To decrease selectively the number and function of KC, Kunming mice were ip injected with a single dose of gadolinium chloride ($GdCl_3$, 20 mg·kg^{-1}), the time-effect relationship assessment was performed after 1 d, 3 d and 6 d. sALT, sGST, liver glycogen content, phagocytic index, and expression of CD68 were assessed as the indexes of hepatotoxicity and functions of KC respectively, and morphology of KC was observed with transmission electron microscopy. Furthermore, cAMP, PGE_2 level, nitric oxide(NO) content, and mRNA expression of NFkappaBp65, Erk1, STAT1 were examined.

RESULTS: $GdCl_3$ could selectively cause apoptosis of KC and obvious reduction of KC's activity, but no hepatotoxicity was observed. One day after KC blockade, NO, PGE_2, cAMP contents in the liver were reduced 21.0 %, 6.94-fold, 8.3 %, respectively, and mRNA expression of NFkappaBp65 was decreased 3.0-fold. The change tendency of NO, PGE_2, and cAMP contents and mRNA expression of NFkappaBp65 were concomitant with recovery of the functions of KC. The contents of NO, PEG2, cAMP were increased when the functions of KC was recovered. However, all of the changes could not return to the normal level except NO content after 6 d $Gdcl_3$ treatment. No obvious changes were found in STAT1 and Erk1 mRNA expression in the present study.

CONCLUSION: Hepatic NO, PGE2, cAMP level and mRNA expression of NFkappaBp65 are closely related with the status of KC. It suggests that KC may play an important role in the cell to cell signal transduction in the liver.

INTRODUCTION

Kupffer cells (KCs) account for a major portion of the tissue macrophages and play an important role in the defense mechanisms of the body[1]. KCs are involved in the pathogenesis of chemically mediated liver injury through release of biologically active mediators that promote the pathogenic process[2]. KCs can synthesize and release a variety of immunomodulating and inflammatory mediators such as oxygen-derived free radicals, nitric oxide, lipid mediators, and cytokines, etc. There are certain points to be elucidated that KCs involve in the pathophysiologic response of liver injury[3]. And now, many new functions have been found. KCs can reverse liver fibrosis and are critical for the progression of alcoholic injury[3,4]. Abolishment of KCs sensitization could prevent alcoholic liver injury[5]. KCs are major contributors to cytokine production in hepatic ischemia/reperfusion[6] and play a stimulatory role in liver regeneration[7]. Up to now, few studies about the influence of KCs on signal transduction in the liver have been reported. NO, PGE_2, cAMP are important second messengers transmitting and magnifying messages to modulate gene expression. NFkappaB, STAT, Erk are important nuclear transcription factors, which are involved in the regulation of cell proliferation and differentiation[8,9]. To understand the effect of KCs on the second messengers and nuclear transcription factors is of great importance in studying the mechanism of liver diseases. $Gdcl_3$, as an inhibitor of KCs, is often used as a tool for studying the role of KC[10]. Kupffer cell toxicant $GdCl_3$ prevents stellate cell activation and the development of fibrosis[11]. The present study was designed to clarify the effect of KC on signal transduction pathway in the liver following $GdCl_3$-induced KC blockade.

MATERIALS AND METHODS

Reagents

Gadolinium chloride ($GdCl_3$), collagenase IV, Indian ink were purchased from Sigma, USA. NO, PGE_2 detection kits were obtained from Bangding Biotechnology Co., Ltd. cAMP detection kit was obtained from Shanghai College of Chinese Traditional Medicine. CD68 immunohistochemical kit and NFkappaBp65, STAT1, Erk1 *in situ* hybridization kit were purchased from Wuhan Boster Biological Technology Co., Ltd. Other reagents were all of A.R.

Animal treatment

Kunming ♂ mice (aged 4-6 wk), weighing 22±3 g were obtained from the Experimental Animal Center of School of Medicine, Wuhan University. The animals were fed on a standard diet in pellets, and allowed free access to water. The mice were randomly distributed to control group, $GdCl_3$-1d

Table 1 Influence of $GdCl_3$ on hepatic function and activity of KCs in mice (n=8, $\bar{x}\pm s$)

Group	sALT ($mmol\cdot min^{-1}\cdot L^{-1}$)	sGST ($\mu mol\cdot min^{-1}\cdot L^{-1}$)	Liver glycogen ($\mu mol\cdot mg^{-1}\cdot pro^{-1}$)	Phagocytic activity(α)	Expression of CD68 (relative O.D.)
Control	2.4±0.3	15.2±2.2	4.9±0.9	9.7±0.7	0.131±0.018
$GdCl_3$-1d	2.6±0.9	14.9±1.9	5.4±1.4	5.2±0.4[b]	0.065±0.010[b]
$GdCl_3$-3d	2.6±1.0	16.5±3.1	5.8±1.1	6.0±1.1[a]	0.084±0.015[b]
$GdCl_3$-6d	2.6±1.4	15.7±2.3	5.0±0.2	6.8±1.3[a]	0.108±0.014[b]

[a]P<0.05, [b]P<0.01 *vs* control.

group, $GdCl_3$-3d group, $GdCl_3$-6d group, in which the mice received ip injection of a single dose of 20 $mg\cdot kg^{-1}$ of $GdCl_3$, and were sacrificed after administration of $GdCl_3$ for 1 d, 3 d, 6 d, respectively.

Test for phagocytic function

14 % Indian ink (10 $ml\cdot kg^{-1}$) was injected into the mice tail vein. After 1 min and 5 min, 20 μl blood was obtained from the orbital vein of the mice and added into 2 ml of 0.1 % Na_2CO_3 solution. Absorbance (OD) at 600 nm was read, and the phagocytic activity (α) of KCs was calculated as described[12].

Biochemical assay

Twenty-five percent liver homogenate was prepared, the glycogen content was quantified by an enzymatic reaction as previously described[13]. NO content was measured by Griess reaction[14]. PGE_2 and cAMP concentration were determined by radioimmunoassay, and the radioactivity of the samples was measured with a P△CK△RD CA-2000 liquid scintillation spectrometer[15]. The protein content of liver homogenate was determined by Lowry[16].

In situ hybridization and immunohistochemistry methods

The livers were briefly washed in cold 0.1 M phosphate buffer containing 0.1 % DEPC and then fixed in cold 4 % formaldehyde (in 0.1 M phosphate buffer, pH7.4), paraffin-embedded sections in 5-6 μm thickness were cut and placed onto aminopropyltriethoxysilane-coated glass slides. The expression of CD68 was determined by i*n situ* hybridization with DIG detection system kit. The anti-sense sequence of the probe was 5' -AAGCT TGGCC CAAGC CACCT TGGTT TTAGA-3' for Erk1 (extracellular signal-regulated kinase), 5' -CAGGT TGTCT GTGGT CTGAA GTCTA GAAGG-3' for STAT1 (signal transducers and activators of transcription), 5' -AGTTG ATGTC CGCAA TGGAG GTCTT-3' for NF-kBp65 (nuclear factor kappa B p65).

Image analysis of immunohistochemistry and in situ hybridization

Microscopic images through an interference filter (Nikon, Tokyo, Japan) were transferred to the processor (HPIAS image analysis system, Wuhan Tongji Medical University). Average absorbances in defined areas of the sections were measured, relative optical density(OD) was used to evaluate expression level.

Liver cells isolation and transmission electron-microscopic study

Liver cells were isolated as described[17]. In brief, after washed in D-Hanks, liver tissue was digested with 0.075 % collagenase for 30 min. The resulting suspension was passed through 70 μm gaze and then 1 g of sediment was generated after 10 min. Hepatocytes were fixed in 2.5 % glutaraldehyde in 0.1 $mol\cdot L^{-1}$ phosphate buffer, transmission electron- microscope was used to observe the morphology of KCs.

Statistical analysis

The data were presented as $\bar{x}\pm s$, and statistical analysis was performed with Student's t-test.

RESULTS

Effect of $GdCl_3$ on sALT, sGST, liver glycogen and activity of KCs

After administration of $GdCl_3$, no changes in sALT, sGST level and liver glycogen content were observed. Liver expression of CD68 (specific surface antigen of macrophage) and phagocytic activity (α) obviously reduced 102 %, 86 % respectively after 1 d of $GdCl_3$ treatment, then the function of KCs was gradually recovered. However they could not return to the normal level after 6 d of $GdCl_3$ treatment.

Electron microscopic study

The characteristics of apoptosis (the membrane of KCs was integrate, chromatin in the nucleus presented uneven distribution and was close to nuclear measure) were observed after treatment of $GdCl_3$ (Figure 1).

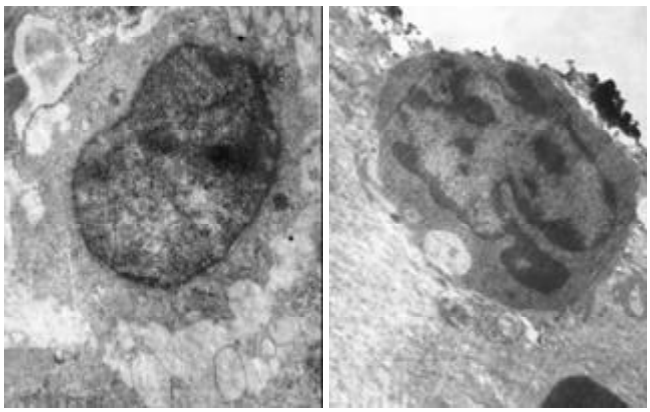

Figure 1 Influence of $GdCl_3$ on morphology of KCs under EM.

Effect on NO, PGE_2, cAMP content

After 1 d of $GdCl_3$ treatment, NO, PGE_2, cAMP contents were reduced 21.0 %, 6.94-fold, 8.3 %, respectively, and then they were gradually recovered. However, PGE_2 and cAMP contents could not return to the normal level after 6 d of treatment.

Table 2 Influence of $GdCl_3$ on NO, PGE_2, cAMP contents in liver (n=8 mice, $\bar{x}\pm s$)

Group	NO content ($pmol\cdot mg^{-1}\cdot pro^{-1}$.)	PGE_2 content ($pg\cdot mg^{-1}\cdot pro^{-1}$.)	cAMP content ($pmol\cdot mg^{-1}\cdot pro^{-1}$.)

[a]P<0.05, [b]P<0.01 *vs* control.

Effect on NFkappaB, STAT1 and Erk1 mRNA expression

The time course of alteration of NFkappaB, STAT1 and Erk1 mRNA expressions after administration of 20 mg· kg^{-1} $GdCl_3$ showed that NFkappaB mRNA expression was decreased (3-fold) after administration of $GdCl_3$ for 1 d, then it was gradually recovered, but did not return to the normal level after 6 d of treament. No obvious influence on STAT1, Erk1 mRNA expressions was observed (Figure 2).

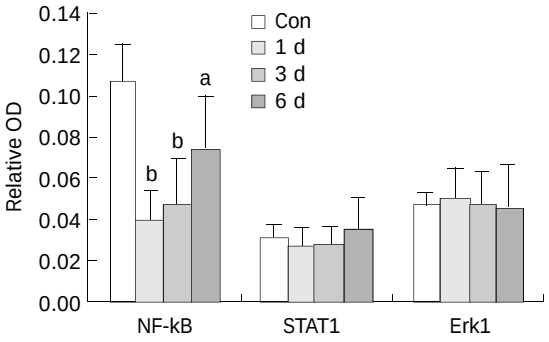

Figure 2 Time course of alteration of NFkappaB, STAT1 and Erk1 mRNA expressions after administration of 20 mg· kg^{-1} $GdCl_3$ (n=6, $\bar{x}\pm s$). $^aP<0.05$, $^bP<0.01$ *vs* control.

DISCUSSION

In the present study, ip injection of a single dose of $GdCl_3$ could selectively cause apoptosis of KCs, but did not induce hepatotoxicity. Therefore, it can be used as a tool for studying the role of KCs.

KCs are the phagocytic macrophages in the liver. NO, PGE_2, and cAMP could transmit and magnify extracellular messages to cells through a cascade system to regulate gene expression and cell proliferation and differentiation[18]. NO, PGE_2, and cAMP had different functions in hepatoprotection and hepatic injury. NO from KCs could induce membrane barrier dysfunction in liver sinusoid[19]. But according to Abou-Elella *et al*, the exacerbation of hepatocyte death by KCs was not related to NO[20]. Hsu *et al*, sproposed that KCs be the major source of induction of inducible NO synthase(iNOS) activity and NO production have a beneficial role in hepatic IR injury and the constitutive isoforms of NOS play a hepatoprotective role in hepatic injury[21-23]. The protective function of NO against hepatic injury might lie in that it could reduce tissue oxygenation[24]. PGE_2 derived from KCs increased cAMP, which caused triglyceride accumulation in the liver and fatty liver[3]. Increase of cAMP levels in KCs occurred during the late stage of polymicrobial sepsis, and might contribute to the depression of macrophage phagocytic function[25]. The current study showed that NO, PGE_2, and cAMP contents in the liver were reduced following KC blockade, and recovered following the functional recovery of KCs. It suggests that Kupffer cells may mediate signaling of second messengers in the liver. Moreover, in the present experiment, the hepatic function did not change following the alterations of NO, PGE_2, and cAMP content, the reasons remain to be researched.

It has widely been accepted that NFkappaB activation plays an important role in the pathophysiology of inflammatory disorders[26]. NFkappaB is an essential component of TNF proliferative pathway and TNF-induced changes in IL-6 mRNA, STAT3, and c-myc mRNA are dependent on NFkappaB activation[27]. NFkappaB activation may be important in "switching off" the cytokine cascade during acute pancreatitis[28]. The current study showed that mRNA expression of NFkappaB in the liver was down-regulated after KC blockade, suggesting that KCs may play an important role in mediating liver diseases and inflammatory disorders via changes of the signal transduction pathway in the liver.

In this experiment, STAT1 and Erk1 mRNA expressions were not affected by $GdCl_3$. STAT1 played a harmful role in Con A-mediated hepatitis, whereas STAT3 protected against liver injury[29]. Inhibition of STAT1 activation without reduction of STAT1 protein level might be one of the factors that are involved in the cAMP-dependent stellate cell growth arrest[30]. In this study, we only examined the expression of STAT1 mRNA, the relationship between STAT1 and hepatic injury needs to be further studied.

Abstract

AIM: To observe the gene and protein expression changes of p28^{GANK} in regenerating liver tissues, and to reveal the biological function of p28^{GANK} on the regulation of liver regeneration.

METHODS: One hundred and thirty two adult male Sprague-Dawley rats were selected, weighing 200-250 g, and divided randomly into sham operation (SO) group and partial hepatectomy (PH) group. Each group had eleven time points: 0, 2, 6, 12, 24, 30, 48, 72, 120, 168 and 240 h, six rats were in each time point. The rats were undergone 70 % PH under methoxyflurane anesthesia by resection of the anterior and left lateral lobes of the liver. SO was conducted by laparotomy plus slight mobilization of the liver without resection. Liver specimens were collected at the indicated time points after PH or SO. The expression level of p28^{GANK} mRNA was determined by Northern blot as well as at protein level via immunohistochemical staining. The expressions of p28^{GANK} mRNA in these tissues were analyzed by imaging analysis system of FLA-2000 FUJIFILM and one way analysis of variance. The protein expressions of p28^{GANK} in these tissues were analyzed with Fromowitz' method and Rank sum test.

RESULTS: The expression of p28^{GANK} mRNA in the regenerating liver tissues possessed two transcripts, which were 1.5 kb and 1.0 kb. There was a significantly different expression patterns of p28^{GANK} mRNA between SO and PH groups (P<0.01). The expression of p28^{GANK} mRNA increased 2 h after PH, the peak time was 72 h (SO group: 163.83±1.4720; PH group: 510.5±17.0499, P<0.01). There was a significant difference in the 1.5 kb transcript, which decreased gradually after 72 hours. The protein expression of p28^{GANK} was mainly in the cytoplasm of regenerating hepatocytes, and increased near the central region 24 h after PH, and became strongly positive at 48 h (+++, *vs* the other time points P<0.05), but decreased 72 h after PH.

CONCLUSION: The expression of p28^{GANK} mRNA increases in the early stage of rat liver regeneration, the protein expression of p28^{GANK} is mainly in the cytoplasm of regenerating liver cells. It suggests that the gene of p28^{GANK} may be an important regulatory and controlled factor involved in hepatocyte proliferation during liver regeneration.

INTRODUCTION

Liver regeneration after 70 % partial hepatectomy in an adult rat involves initiation of proliferation of the remaining parenchymal cells and is a useful model for studying signaling molecules and other factors involved in cell proliferation. Cell proliferation begins very early during liver regeneration, peaking at 24 hours, followed by proliferating biliary epithelium at 48 hours, and kupffer cells and stellate cells at 72 hours. The proliferation of sinusoidal endothelial cells was peaked at 96 hours. Through its regenerative ability, the liver provides a model system for *in vivo* study of cell proliferation events following reentry into the cells cycle from the quiescent G_0 phase. The damage caused by surgical resection or treatment with toxins results in a cascade of growth factors and cytokines to restore the liver mass to its original size[1-6]. The residual hepatic parenchymal cells and nonparenchymal cells can proliferate and differentiate through the action of some cytokines, hormones and growth factors. When liver regeneration is induced by partial hepatectomy or inflammation, the cell cycle can transit from G_0 phase to G_1 phase, enter into the preparing stage of division and proliferation, and then into S phase, G_2 phase and M phase in turn. The late G_1 phase contains a restriction point (R point), which has a selective division function and decides cell entry into S phase or reverse to G_0 phase. The hepatic parenchymal and nonparenchymal cells can reconstitute the hepatic volume when they proliferate to some extent, and the liver regenerating response can be terminated by some factors[1,7,8], but the mechanisms of initiation and termination of liver regeneration have not been eventually clarified and need further study. Recently, a novel gene named *gankyrin* was cloned and identified from human hepatocellular carcinoma[9]. The *gankyrin* gene sequence is identical to one subunit of 26S proteasome named *p28* which was firstly cloned from human cDNA library by comparing a subunit amino acid of purified bovine erythrocyte PA700 complex (also defined as 19S complex) with protein structure of human protein cDNA library databases. The product of *gankyrin* or *p28* gene (p28^{GANK} protein) was an oncoprotein consisting of six conservative ankyrin repeats. The mRNA and protein level of p28^{GANK} increased substantially in hepatocellular carcinomatous tissues, compared with levels in the respective non-cancerous portion of the resected livers, but the increase was not related to the grade or stage of the cancer. The finding that the increase occurred regardless of the staging or grading of cancer indicates that p28^{GANK} may be involved in an early and essential step of liver carcinogenesis. However, the liver regeneration is involved in hepatocyte division, proliferation and termination. It is unclear whether p28^{GANK} can participate in hepatocyte proliferation. This study was intended to disclose the biological function of p28^{GANK} by establishing a liver regeneration rat

model and determining the expression of p28^{GANK} mRNA and protein levels.

MATERIALS AND METHODS

Experimental animal

One hundred and thirty two adult male Sprague-Dawley rats were obtained from the Experimental Animal Center of the Second Military Medical University, weighing from 200-250 g, and were randomly divided into sham operation (SO) group and partial hepatectomy (PH) group. Each group had eleven time points: 0, 2, 6, 12, 24, 30, 48, 72, 120, 168 and 240 h, six rats in each time point. The rats were housed in a room at 21 ℃ under a 12 -hour light/dark cycle and given tap water and commercial rat chow. The animals were acclimatized to the laboratory conditions for 1 week prior to the experiments.

Establishment of liver regenerating model

The rats were undergone 70 % PH under methoxyflurane anesthesia by resection of the anterior and left lateral lobes of the liver[10]. SO was undertaken only by laparotomy plus slight mobilization of the liver without resection. The rats were injected intraabdominally with 0.5-1 ml normal saline for fluid resuscitation after operation. Liver specimens were collected at 0, 2, 6, 12, 24, 30, 48, 72, 120, 168 and 240 h after PH or SO. The liver specimens obtained were snap frozen in liquid nitrogen. Total RNA was extracted using the guanidine isothiocyanate and phenol-chloroform method and aliquots of RNA samples were stored at -85 ℃ until use. The remaining liver was fixed in 4 % formaldehyde polymerisatum, embedded in paraffin and then sectioned for histological examination and analysis of protein expression.

Cloning of rat p28^{GANK} cDNA

The rat p28^{GANK} cDNA was cloned from rat placenta based on the GenBank (Rattus novegicus mRNA for p28^{GANK} homologue: AB022014), sense (11 bp-30 bp, G1): 5' -GTGTGTCTAACCTAATGGTC-3' , anti-sense (643bp-662 bp, G2): 5' -TTGAGTATTAACCCCAGGCC-3' . The segment length was 651 bp. The primers were synthesized by Sangon Company, Shanghai, P.R.China. Briefly, 5 μg of total RNA extracted from rat placenta served as template to synthesize the first strand cDNA. Polymerase chain reaction system was consisted of 1×buffer, 1.5 mM $MgCl_2$, 200 μM dNTPs, 0.5 μM of the oligonucleotide primers specific for rat p28^{GANK} gene, 1 μl of the first strand cDNA synthesized as described above, and 1.25 units of Taq DNA polymerase. Amplification was undertaken by initial denaturation at 94 ℃ for 4 min, followed by 30 reaction cycles (for 50 s at 94 ℃, for 50 s at 53 ℃, and for 60 s at 72 ℃) and a final cycle at 72 ℃ for 10 min. The PCR product with an expected size of 651 bp fractionated on a 2 % agarose gel was purified with QIAQUICK gel extract kit (QIAGEN, Germany) and subcloned into PMD18 vector[11], and then sequenced and compared. The synthetic segment was verified the same sequence as the GenBank.

Northern blot analysis

Rat p28^{GANK} cDNA released from PMD18 vector was labeled with α-^{32}P-dCTP using Promega-gene labeling system (Promega, USA) according to the protocol of the manufacturer[12]. 90 μg of total RNAs was separated on a 1 % formaldehyde/agarose gel by electropherosis, transferred to nitrocellulose and hybridized with α-^{32}P-labeled p28^{GANK} cDNA[13]. The hybridized nitrocellulose filters were exposed to X-ray film at -80 ℃ for 2 weeks. The developed signals were assayed for p28^{GANK} mRNA expression level after normalizion with 18S rRNA as internal standard using FujiFilm image gauge V3.3 analysis software (FujiFilm, Japan).

Immunohistochemistry

Immunohistochemical assay was performed as described by the manufacturer using SP kit (Dako Reagent, Denmark). Briefly, the rat liver sections of four-micrometer were deparaffnized, followed by blockage of endogenous peroxidase activity and restoration of the interested antigens. The sections were then subjected to incubation with purified primary polyclonal antibody (1:50 dilution, obtained from signal transduction laboratory, Shanghai, China) against p28^{GANK} protein at 4 ℃ overnight and with horseradish peroxidase-biotinylated anti-rabbit IgG at 37 ℃ for 30 min. The sections were finally incubated with benzidine and counterstained with hematoxylin for examination. The experiment was performed on control sections with omission of the primary antibody in the same way. The expression of p28^{GANK} was analyzed comprehensively by the staining extent and range referring to Fromowitz standard[14]. 5 visual fields were observed randomly, 100 cells were counted in each visual field. The average number of stained cells in 5 visual fields was regarded as the percent ratio of positively stained cells in each section. Positive range score: 0, 0-5 %; 1, 6-25 %; 2, 26-50 %; 3, 51-75 %; 4, >75 %. Positive extent score: 0, no staining; 1, light yellow; 2, brown; 3, dark brown. Judged by positive range score plus positive extent score: <2, negative (-); 2-3, slight positive (+); 4-5, moderately positive (++); 6-7, strongly positive (+++).

Statistical analysis

The expression level of p28^{GANK} mRNA detected by Northern Blot was presented as mean ± SD. ANOVA software (SPSS 8.0) was used to analyze the difference in mRNA level between the groups and Rank sum test for p28^{GANK} protein assay in immunohistochemical study. *P* values less than 0.05 were considered as having significant difference.

RESULTS

The expression of p28^{GANK} mRNA in regenerating liver tissues possessed two transcripts, which were 1.5 kb and 1.0 kb respectively. There was a significant difference between SO and PH groups ($P<0.01$). The expression of p28^{GANK} mRNA increased 2 h after PH, the peak time was at 72 h (SO group: 163.83±1.4720; PH group: 510.5±17.0499, $P<0.01$). There was a significant difference in the 1.5 kb transcript, which decreased gradually after 72 hours (Figures 1-2).

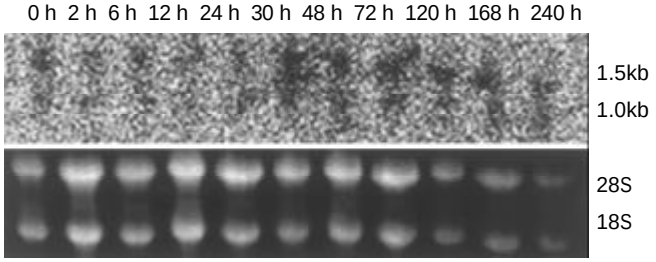

Figure 1 Northern blot of p28^{GANK} mRNA in rat regenerating liver tissues showed two transcripts of 1.5 kb and 1.0 kb. Expression level of p28^{GANK} mRNA increased 2h after PH, and reached the peak level at 72 h. More significant variation was found for 1.5 kb transcript.

The protein expression of p28^{GANK} was mainly in the cytoplasm of regenerating hepatocytes, and became increased near the central region 24 h after PH. The strongly positive expression was observed at 48 h (+++, *vs* the other time points, $P<0.05$), which decreased 72 h after PH (Figure 3).

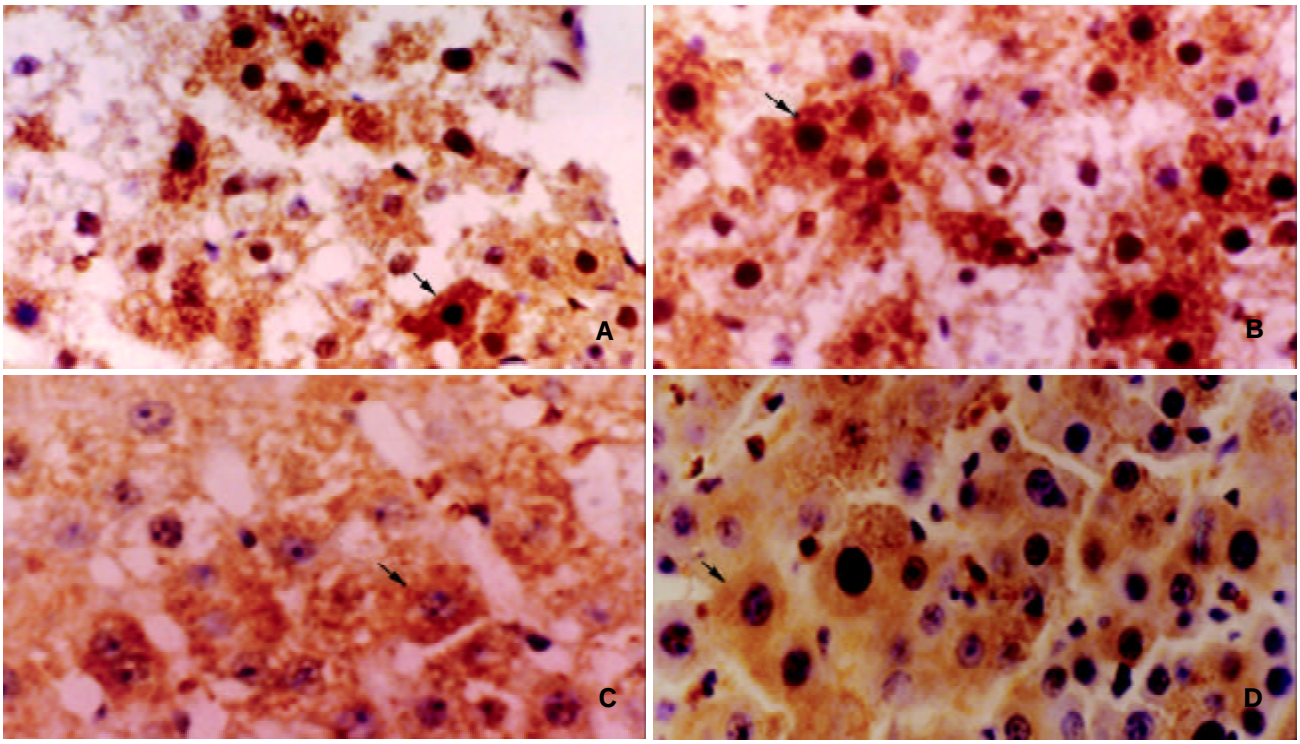

Figure 3 The expression of p28^{GANK} protein in regenerating liver tissues was examined by immunohistochemistry. A: Local brown expression of p28^{GANK} in the cytoplasm and nucleus of regenerating hepatocyte near central region 24 h after PH. IHC×400. B: Diffuse brown expression of p28^{GANK} in the cytoplasm and nucleus of regenerating hepatocyte 48 h after PH. IHC×400. C: Regional light yellow expression of p28^{GANK} in cytoplasm of regenerating hepatocyte 72 h after PH. IHC×400. D: Dispersed light yellow expression of p28^{GANK} in cytoplasm of regenerating hepatocyte 120 h after PH. IHC×400.

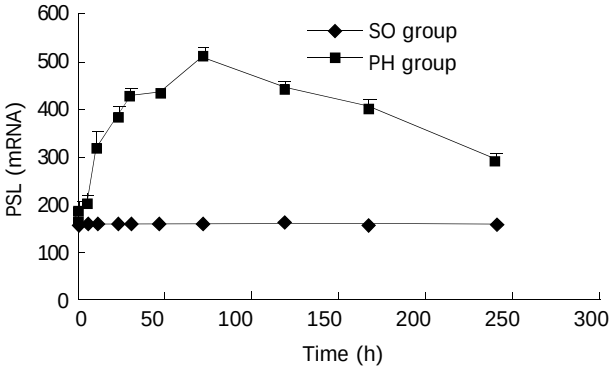

Figure 2 No significant difference of the expression of p28^{GANK} mRNA was seen in the SO group. In the PH group, the expression increased in 1.5 kb transcript 2 h after PH. The peak time was at 72 h, but gradually decreased after 72 hours.

DISCUSSION

Hepatocytes proliferate firstly according to the cascade response induced by growth factors and cytokines after hepatectomy or toxin damage. The first peak of DNA synthesis in hepatocytes occurs at about 24 hours, with a smaller peak between 36 and 48 hours. The restoration of the original number of hepatocytes theoretically requires 1.66 proliferative cycles among the residual hepatocytes. Most of the hepatocytes (95 % in the young and 75 % in very old rats) in the residual lobes participate in one or two proliferative events. The hepatocytes begin to proliferate early, the peak time is at 24 hours. Then biliary epithelial cells proliferate, the peak time is at 48 hours. Then the Kupffer cells and stellate cells proliferate and the proliferative peak is at 72 hours. The proliferative peak of sinusoidal endothelial cells is at 96 hours. Thus these cell proliferations result in restoration of the original volume[3,15]. Hepatocyte proliferation starts in the periportal zone, and then proceeds to the pericentral zone at 36 to 48 hours. The other cells of the liver enter into DNA synthesis about 24 hours after the hepatocytes proliferation, with a peak of DNA synthesis at 48 hours or later. The changes in the extracellular matrix after PH are undetectable until approximately 24 h post-PH. The hepatocytes begin to replicate in the periportal zones without corresponding increases in matrix within 3 days. The periportal areas consist of hepatocyte clusters of 10-14 cells without intervening sinusoids or matrix, as the wave of hepatocyte replication proceeds from periportal to pericentral regions of the lobule. The formation of cell clusters follows, the hepatocyte mitotic activity significantly decreases 4 days post-PH[16-20]. Liver regeneration is a complicated regulatory process, the volume and function of the liver restore after several periods. Many studies focus on the early factors associated with liver regeneration recently and on the important roles of these factors permitting the hepatocytes entering into cell division cycles. Activations of transcription factors (NF-kB and STAT3), immediately early protooncogenes (C-fos, C-myc, C-jun) and proinflammatory factors (TNF-α and IL-6) constitute the early responses to PH congenerically. The early changes play an important role in promoting the hepatocytes into cell cycles induced by hepatocytic reduction. Recruitment of early factors may be a part of ubiquitous response to stress protection and antiapoptosis of the liver, but it is unclear why the late downstream signal dissociates similar to the early response and certain time difference of cell proliferation process and atrophy or maintenance of liver size[21-24].

p28^{GANK} is a novel gene cloned and identified from human hepatocellular carcinoma and is identical to one of the PA700 non-ATPase subunits, a 700 kD multi-subunit regulatory complex of human 26S proteasome. p28^{GANK} contains six conservative ankyrin repeats, which suggests it may contribute to 26S proteasome interaction with other proteins, and its effect in hepatocellular carcinoma may be related to ubiquitin-

proteasome pathway which is often the target of cancer-related deregulation, and is involved in the processes such as oncogenic transformation, tumor progression, escape from immune surveillance and drug resistance[25-29]. The mRNA and protein levels of $p28^{GANK}$ was increased in cancerous tissues of hepatocellular carcinoma, and the increase was more substantial than that of non-cancerous tissues and was not related to the grading or staging of the tumors, indicating that $p28^{GANK}$ plays an early and crucial role in liver carcinogenesis. Moreover, the population doubling times in $p28^{GANK}$-transfected mouse NIH/3T3 cells were 18-20 hours, the control cells were 22-25 hours. All cells transfected with $p28^{GANK}$ formed colonies in soft agar, whereas the control cell did not. In homozygous nude mice, inoculation of all positive clones overexpressing $p28^{GANK}$ produced tumors within 30 days, in contrast, none of nude mice inoculated with control clone developed tumors. These results demonstrated that $p28^{GANK}$ remarkably promoted cell proliferation and was an oncogene. $p28^{GANK}$ had the retinoblastoma (RB_1)-binding motif LxCxE, resulted in an increased amount of the hyperphosphorylated form of RB_1, and accelerated the degradation of RB_1, activated the E2F transcription factors of nuclear partners of RB_1 by increasing the phosphorylation of RB_1, and induced the growth and oncogenity of anchoring independent cells. RB_1 exerts its growth-inhibitory effects in part by binding to and inhibiting essential regulatory proteins, including members of the E_2F family of transcription factors. E_2F is selectively associated with hypophosphorylated RB_1. Inactivation of RB_1 by phosphorylation, mutation or binding to viral oncoprotein seems to release E2F from an inhibitory complex, enabling it to promote the transcription of genes necessary for progression into late G_1 and S phases. $p28^{GANK}$ could bind to S6ATPase of the 26S proteasome and RB_1, increase E_2F activity and destabilize RB_1. It was demonstrated that $p28^{GANK}$ was a cellular protooncogene whose functions were more similar to those of the viral oncoprotein E_7 and related to protein degradation by 26S proteasome. Furthermore, ubiquitin-proteasome pathway played an important role in regulating cell growth and oncogenic transformation[9,30-34].

$p28^{GANK}$, as a positive cell proliferation regulatory factor, could promote cell proliferating process. We found that the expression of $p28^{GANK}$ mRNA was not significantly different at indicated times in control liver tissues during liver regeneration, but the expression of $p28^{GANK}$ mRNA possessed two transcripts in regenerating liver tissues after 70 % PH, about 1.5 kb and 1.0 kb. The mRNA level of $p28^{GANK}$ increased at 2 h, with a peak time at 72 h, but decreased gradually after 72 h, especially in the 1.5 kb transcript. The protein expression of $p28^{GANK}$ was mainly in the cytoplasm of the regenerating hepatocytes, strongly positive local expression of $p28^{GANK}$ in the cytoplasm and nucleus of regenerating hepatocyte near the central region at 24 h after 70 % PH, strongly positive diffuse expression of $p28^{GANK}$ in the cytoplasm and nucleus of regenerating hepatocyte at 48 h, and the expression of $p28^{GANK}$ decreased gradually at 72 h. These demonstrated the mRNA and protein levels of $p28^{GANK}$ occurred a curved changes, because three mitotic replicative waves occurred from 18 to 72 h, the two peak times occurred at 24 h and 36-38 h. Moreover, the two peak times of DNA synthesis occurred at 24 h and 36-48 h. All these suggest that $p28^{GANK}$ might be involved in the whole process of hepatocyte proliferation and the expression of $p28^{GANK}$ restores to its basic level with the termination of liver regeneration. It is necessary to be studied further whether it is the effect of $p28^{GANK}$ on hepatocyte proliferation through S6ATPase-$p28^{GANK}$-Rb-E2F1 pathway or through other pathways during liver regeneration and interaction with positive or negative cytokines, protooncogenes and anti-oncogenes associated with liver regeneration.

Abstract

AIM: To determine the changes of CD8+ T subsets especially CD8+CD28- T regulatory cells in rat model of experimental colitis induced by 2,4-dinitrofluorobenzene (DNFB).

METHODS: The rat model of experimental colitis was induced by enema with DNFB. Ten days later, colonic intraepithelial and splenic lymphocytes were isolated from colitis animals (n=16) and controls (n=8). The proportion of CD8+ T cells, CD8+CD28+ T cells and CD8+CD28- T regulatory cells were determined by flow cytometry.

RESULTS: The model of experimental colitis was successfully established by DNFB that was demonstrated by bloody diarrhea, weight loss and colonic histopathology. The proportion of CD8+ T cells in either splenic or colonic intraepithelial lymphocytes was not significantly different between colitis animals and controls (spleen: 34.6±7.24 % *vs* 33.5±9.41 %, colon: 14.0±8.93 % *vs* 18.0±4.06 %, P>0.05). But CD8+CD28- T regulatory cells from colitis animals were significantly more than those from controls (spleen: 11.3±2.26 % *vs* 5.64±1.01 %, colon: 6.50±5.37 % *vs* 1.07±0.65 %, P<0.05). In contrast, CD8+CD28+ T cells from colitis animals were less than those from controls (spleen: 23.3±6.14 % *vs* 27.8±9.70 %, P=0.06; colon: 7.52±4.18 % *vs* 16.9±4.07 %, P<0.05). The proportion of CD8+CD28- T regulatory cells in splenic and colon intraepithelial CD8+ T cells from colitis animals was higher than that from controls (spleen: 33.3±5.49 % *vs* 18.4±7.26 %, colon: 46.0±14.3 % *vs* 6.10±3.72 %, P<0.005).

CONCLUSION: Experimental colitis of rats can be induced by DNFB with simplicity and good reproducibility. The proportion of CD8+CD28- T regulatory cells in rats with experimental colitis is increased, which may be associated with the pathogenesis of colitis.

INTRODUCTION

It is well known that immune system was involved in the pathogenesis of inflammatory bowel disease(IBD)[1-4]. Several extraintestinal autoimmune phenomena are accompanying IBD and immunosuppressive agents could alleviate the disease. Abnormalities in T-cell mediated immunity have also been noted in these patients[5]. But the exact mechanism remains to be clarified. The changes in T-cell subsets were controversial in the literature and should be deeply explored[6]. Although CD8+ T cells represent a major T-cell subset, there is little information available regarding the role of CD8+ T cells in the pathogenesis of colitis. CD8+ T cells specific for an epithelial cell-derived antigen have been shown to induce intestinal inflammation. It is possible that, like CD4+ T cells, functionally distinct CD8+ T-cell subsets may coexist. Thus we discussed the changes of CD8+ T-cell subsets in experimental colitis.

Another important part of ongoing studies of IBD was to use animal model to replicate some of the clinical features of this disease entity and to explore the mechanisms of IBD[7]. One of the important lessons learned from experimental models has been that recognition of the role of T regulatory cells plays in chronic intestinal inflammation. The ability of T cells to regulate colitis was first shown by studies of Powrie *et al*, who demonstrated that OX-22^{low} T cells could suppress the colitis induced by transfer of CD4+OX22^{high} T cells[8]. In the subsequent studies, several types of regulatory T cells have been identified. The Tr1 cells were initially reported to produce IL-10 and regulate the development of colitis in CD45RB model[9]. The effectiveness of immunosuppressive drugs in IBD may be partly related to the fact that Tr1 cells can be also generated in the presence of dexamethasone and vitamin D3. CD4+CD25+ T regulatory cells also have been demonstrated to prevent colitis in the CD45RB model[10]. A recent human study also showed that CD8+ CD28- T cells activated by the interaction with intestinal epithelial cells through gp-180 possessed a regulatory activity[11], which perhaps played important roles in the pathogenesis of colitis. However, until now there is no study reported about the roles of CD8+CD28- T regulatory cells in colitis.

In previous studies, several models of experimental colitis have been described such as TNBS, DDS, DNCB and CD45RB T-cell infusion. 2,4-dinitrofluorobenzene (DNFB) - inducing experimental colitis in mice was demonstrated to be a suitable cell-immune model[12-14]. Thus we have established the same model in rats to explore the changes in CD8+ T cell subsets especially CD8+CD28- T regulatory cells and their possible roles in the pathogenesis of DNFB-induced experimental colitis.

MATERIALS AND METHODS

Animals

Specific pathogen-free Sprague-Dawley male rats weighing 250-300 g were kept in standard laboratory conditions (room temperature of 22 ℃ with a controlled 12-hour light-dark cycle and free access to animal chow and water). Animal care was in compliance with guidelines from the Peking University Health Science Center Policy on Animal Care and Use. The rats were allowed to adapt to our laboratory environment for

one week before the onset of the experiment.

Reagents

DNFB was purchased from Acros Organics (NJ, USA), olive oil and acetone from Sigma Chemical Co. (St. Louis, Missouri, USA). Mouse anti-rat PE-conjugated-CD8b mAb (clone 341, Mouse IgG1) and FITC-conjugated-CD28 mAb (clone JJ319, Mouse IgG1) were from Serotec (Oxford, UK). Isotype control PE-conjugated mouse IgG1 and FITC-conjugated mouse IgG1 were from BD Pharmingen (San Diego, CA). RPMI 1640 and FCS were obtained from Gibco BRL (Gaithersburg, MD).

Induction of colitis

The animals in the experimental group (n=16) were pretreated with two sensitizing doses of 1 ml of 0.5 % w/v DNFB solution by rubbing the substance on previously shaved abdominal skin, 96 and 72 h before challenge[5]. The DNFB solution was prepared by diluting the original DNFB preparation with 4:1 acetone and olive oil. Freshly prepared solutions were used for each application. All the animals in the experimental group received a rectal enema with 0.4 ml of 0.2 % w/v DNFB solution in acetone and olive oil into the lumen of the colon by means of an 8-cm plastic catheter with an outer diameter of 0.9 mm, attached to a 1-ml syringe. Rectal enemas were administered under light ether anesthesia. The animals in the control group (n=8) received a rectal enema with 0.9 % w/v saline only.

Histology

Animals were killed on day 10 after the challenge enema. The entire colon was dissected, opened longitudinally, washed in ice-cold PBS. The ratio of colon / body weight was calculated, which has been shown to be a marker of colonic inflammation[15].

Macroscopic damage was assessed, according to a previously established score as follows[16]: 0: no ulcer and no inflammation, 1: no ulcer and local hyperemia, 2: ulceration without hyperemia, 3: ulceration and inflammation at one site only, 4: two or more sites of ulceration and inflammation, 5: ulceration extending more than 2 cm, 6-10: increment of 1 for each centimeter of ulceration greater than 2.

Randomized tissue samples from the site of DNFB application were subsequently excised for histology. Paraffin sections were stained with haematoxylin and eosin. Microscopic damage was quantified by image analysis of stained sections in a blinded fashion as follows[17]: 0: No evidence of inflammation. 1: Low level of lymphocyte infiltration seen in $\leqslant$10 % high power field and no structural changes observed. 2: Moderate lymphocyte infiltration seen in 10-25 % high power field and crypt elongation, bowel wall thickening that did not extend beyond the mucosal layer and no evidence of ulceration. 3: High level of lymphocyte infiltration seen in 25-50 % high power field, high vascular density, and thickening of the bowel wall that extended beyond the mucosal layer. 4: Marked degree of lymphocyte infiltration seen in $\geqslant$50 % high power field, high vascular density, crypt elongation with distortion and transmural bowel wall thickening with ulceration.

Isolation of lymphocytes

Splenocytes were isolated by conventional methods. Red blood cells were removed from spleen cell suspensions by using a standard lymphocyte gradient (Chemical Co, Shanghai, China). Intestinal intraepithelial lymphocytes were isolated according to a previously published method[18]. An average of 2-4×10^6 intraepithelial lymphocytes was yielded per colon.

Flow cytometry

A total of 1×10^6 spleen or intraepithelial lymphocytes were prepared in 100 μl and anti-CD8b and anti-CD28 mAb were added to the cell suspension. The cells were incubated at 4 ℃ for 30 min, and then the cells were washed two times with PBS/10 % v/v FCS. The cells were finally resuspended in 250 μl PBS containing 2 % w/v paraformaldehyde and then analyzed using a FACSCalibur with CellQuest software (BD Biosciences, San Jose, CA). 10 000 gated events were acquired for analysis. Isotype control was done according to the manufacturer.

Statistical analysis

Results were expressed as means ± standard deviation (SD). Comparison of results between groups was performed by unpaired t test. A probability (P) value <0.05 was considered as significant.

RESULTS

General findings

One day post-enema, diarrhea, hematochezia and reduced activity were observed in all experimental animals, but not in controls. Ten days later, the body weights of experimental animals were significantly lower than those of controls (P<0.05, as shown in Figure 1). The body weight of experimental animals decreased to the lowest on day 2 (92.8±5.0 % compared with pretreatment *vs* 106.4±1.4 % in controls, P<0.05). One rat died of colonic necrosis on the second day after DNFB enema.

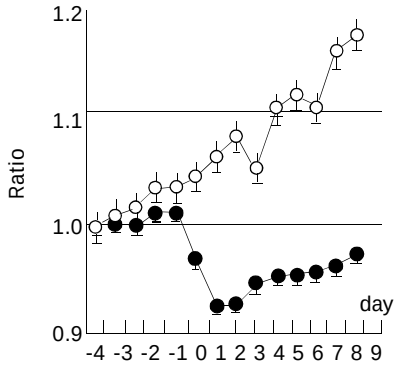

Figure 1 Body weight of experimental animals was significantly lower than that of controls (P<0.01), ○ controls, ● colitis.

Colon inflammation

The ratio of colon/body weight in experimental animals was two times more than that in controls (0.015±0.004 *vs* 0.007±0.002, P<0.05). Oedema, hemorrhage, superficial ulcerations, and necrosis were observed in the colon of experimental animals. Moreover, macroscopical characteritics of chronic phase such as adhesions, thickening of the colonic segments with narrowing of the lumen and prestenotic dilatation, atrophy and even with megacolon formation, were obviously in experimental animals but not in controls. Microscopically, active inflammatory process was characterized by mononuclear infiltration, fibrosis, smooth-muscle hypertrophy and lymphoid hyperplasia (as shown in Figure 2 left). Both the macroscopical and microscopical damage scores in experimental animals were higher than those in controls (macroscopical: 5.2±1.4 *vs* 1.4±0.6, P<0.0001; microscopical: 3.3±0.5 *vs* 1.2±0.5, P<0.0001, Figure 2 right).

Splenic CD8+ T-cell subsets

There was no difference in the proportion of CD8+ T cells between experimental animals and controls. However, CD8+CD28- T regulatory cells of experimental animals were significantly more than controls (as shown in Figure 3). Even

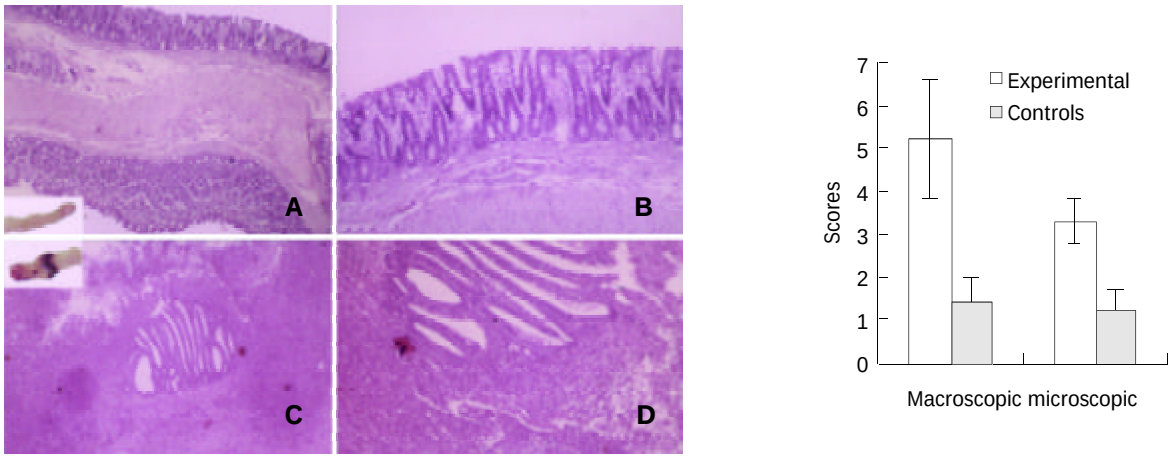

Figure 2 Left: Colon histological manifestation of experimental animals (C: 4×10, upper left is colon; D: 10×10) compared with controls (A: 4×10, lower left is colon; B: 10×10) (haematoxylin and eosin). Right: Macroscopical and microscopical damage scores in experimental animals are higher than those in controls.

Figure 3 Flow cytometry shows the proportion of CD8+CD28- T regulatory cells was 12.4 % in experimental animals (right) and 4.9 % in controls (left).

though it was not significantly, CD8+CD28+ T cells of experimental animals were less than controls. In CD8+ T cells pool, the proportion of CD8+CD28- T regulatory cells of experimental animals was also significantly higher than that of controls (as shown in Table 1).

Table 1 Splenic CD8+ T-cell subsets of experimental animals and controls on day 10 after enema

	Experimental colitis (%, *n*=16)	Control (%, *n*=8)	*P* value
CD8+CD28-T	11.3±2.26	5.64±1.01	0.0001
CD8+CD28+T	23.3±6.14	27.8±9.70	0.41
CD8+T	34.6±7.24	33.5±9.41	0.83
CD8+CD28-T/CD8+T	33.3±5.49	18.4±7.26	0.003

Table 2 Intraepithelial CD8+ T-cell subsets of experimental animals and controls on day 10 after enema

	Experimental colitis (%, *n*=16)	Control (%, *n*=8)	*P* value
CD8+CD28-T	6.50±5.37	1.07±0.65	0.049
CD8+CD28+T	7.52±3.16	16.9±4.07	0.004
CD8+T	14.0±6.83	18.0±4.06	0.38
CD8+CD28-T/CD8+T	46.0±14.3	6.10±3.72	0.0001

Intraepithelial CD8+ T-cell subsets

There was no difference in the proportion of CD8+ T cells between experimental animals and controls. However, CD8+CD28- T regulatory cells of experimental animals were significantly more than those of controls, and CD8+CD28+ T cells of experimental animals were significantly less than those of controls. In CD8+ T cells pool, the proportion of CD8+CD28- T regulatory cells of experimental animals was also significantly higher than that of controls (as shown in Table 2).

DISCUSSION

DNFB, a highly reactive compound with hapten characteristics, could bind to and covalently modify cell surface proteins, changing their antigenic conformation and their immunogenecity. T lymphocytes could recognize and lyse hapten-modified autologous cells quite efficiently in presensitized animals[19]. Thus DNFB was capable of inducing a delay-type hypersensitivity reaction when applied to the skin or to the intestinal mucosa[20]. In addition, DNFB was more reactive in protein modification than DNCB[21,22]. This is a possible explanation for DNFB causing the lesions, more pronounced in both acute phase and chronic phase than in previously described models induced by DNCB. In 1992, Banic *et al.* demonstrated that experimental colitis of mice was induced by DNFB, mimicking inflammatory bowel disease by the intestinal histopathological and extraintestinal manifestations[12-14]. It also responded well to glucorticosteroid and cyclosporine A, resembling TNBS-induced colitis[23,24]. Because of its simplicity and reproducibility this model represents a suitable preparation for investigating pathogenetic mechanisms of IBD especially that involves cellular immunity. We further explored this model in rats as the first time and the results were consistent with Banic *et al*. All morphologic changes in experimental group were similar to the changes characteristically observed in IBD in humans. Thus

experimental colitis model of rats induced by DNFB could be used to study the pathogenesis of IBD.

There is increasing evidence that IBD is a kind of autoimmune diseases. IBD could be envisioned as an imbalance between proinflammatory and anti-inflammatory cytokines[1-4]. It is suspected that changes in certain cytokines could be a result of changes in proportion or function of certain T-cell subsets. In a series study of Jewell *et al*, however, no difference was found in CD4+ and CD8+ T cells of peripheral blood and colonic mucosa between IBD and healthy controls[25-27]. Regretfully, subsets of CD4+ and CD8+ T cells were not further studied. Several studies demonstrated that T cells from IBD patients or experimental colitis model had diminished response to mitogen stimuli[28-30], and it could be recovered partially by exogenous IL-2[5]. The exact mechanism still remains unknown, but the roles of T regulatory cells should be considered[31,32]. Roman *et al*. found that CD4+CD45RO+ T cells were significantly expanded in Crohn' s disease but not in healthy controls[5], and CD4+ T regulatory cells were contained in CD4+CD45RO+ T cells[33]. The role of CD4+ T regulatory cells in pathogenesis of colitis has been studied in detail by Powrie *et al*[8]. To our knowledge, however, few studies have explored the roles of CD8+ T cells especially CD8+CD28- T regulatory cells in pathogenesis of colitis. Our study showed that the proportion of CD8+ T cells of spleen and colonic mucosa in experimental animals was not different from that in controls, which is consistent with previous findings. But we further found that there was increasing population of CD8+CD28- T regulatory cells in experimental animals compared to controls, and decreasing population of CD8+CD28+ T cells at the same time. These results have not been reported before.

CD8+ T cells comprise cells that are in different states of differentiation and under the control of complex homeostatic processes. In a number of situations such as chronic inflammatory conditions, infectious diseases, ageing, immunodeficiency, iron overload, heavy alcohol intake and transplantation, major phenotypic changes, usually associated with an increase in CD8+CD28- T cells, took place[34]. CD8+CD28- T cells are characterized by functional features of suppression. CD8+CD28- T cells could suppress alloreactive immune responses in an antigen-specific, major histocompatibility complex (MHC)-restricted manner[35].

The emergence of expanded CD8+CD28- T-cell clones has been ascribed to extensively continuous or repeated antigenic stimulation leading to immune exhaustion, as suggested by the accumulation of such cells in patients with human immunodeficiency virus (HIV) infection and autoimmune disease. Although the nature of the signals that give origin to this T-cell subset is uncertain, growing evidence argues for the existence of an interplay between epithelial cells, molecules with the MHC-class I fold and CD8+ T cells. By stimulation of antigen especially intestinal epithelial cells, CD8+CD28+ T cells can further differentiate into CD8+CD28- T regulatory cells, which was a kind of ending-stage cell and could suppress the proliferation of lymphocytes[11]. Stimulated by DNFB hapten-antigen, it is possible that CD8+CD28+ T cells differentiate into CD8+CD28- T regulatory cells. Thus the changes of CD8+ T cell pools mentioned above can be explained. We suspect that the increase of CD8+CD28- T regulatory cells is a feedback to autoimmune disease and it could explain diminished response to mitogen stimuli of T cells in IBD. Further study is urgently needed to explore the function of CD8+CD28- T regulatory cells and its exact role in the pathogenesis of IBD.

Abstract

AIM: To investigate the ameliorative effects of sodium ferulate (SF) on acetic acid-induced colitis and their mechanisms in rats.

METHODS: The colitis model of Sprague-Dawley rats was induced by intracolon enema with 8 % (V/V) of acetic acid. The experimental animals were randomly divided into model control, 5-aminosalicylic acid therapy group and three dose of SF therapy groups. The 5 groups were treated intracolonically with normal saline, 5-aminosalicylic acid (100 mg·kg^{-1}), and SF at the doses of 200, 400 and 800 mg·kg^{-1} respectively and daily (8: 00 am) for 7 days 24 h following the induction of colitis. A normal control group of rats clystered with normal saline instead of acetic acid was also included in the study. Pathological changes of the colonic mucosa were evaluated by the colon mucosa damage index (CMDI) and the histopathological score (HS). The insulted colonic mucosa was sampled for a variety of determinations at the end of experiment when the animals were sacrificed by decapitation. Colonic activities of myeloperoxidase (MPO) and superoxide dismutase (SOD), and levels of malondialdehyde (MDA) and nitric oxide (NO) were assayed with ultraviolet spectrophotometry. Colonic contents of prostaglandin E_2 (PGE_2) and thromboxane B_2 (TXB_2) were determined by radioimmunoassay. The expressions of inducible nitric oxide synthase (iNOS), cyclo-oxygenase-2 (COX-2) and nuclear factor kappa B (NF-κB) p65 proteins in the colonic tissue were detected with immunohistochemistry.

RESULTS: Enhanced colonic mucosal injury, inflammatory response and oxidative stress were observed in the animals clystered with acetic acid, which manifested as the significant increase of CMDI, HS, MPO activities, MDA and NO levels, PGE_2 and TXB_2 contents, as well as the expressions of iNOS, COX-2 and NF-κB p65 proteins in the colonic mucosa, although the colonic SOD activity was significantly decreased compared with the normal control (CMDI: 2.9±0.6 *vs* 0.0±0.0; HS: 4.3±0.9 *vs* 0.7±1.1; MPO: 98.1±26.9 *vs* 24.8±11.5; MDA: 57.53±12.36 *vs* 9.21±3.85; NO: 0.331±0.092 *vs* 0.176±0.045; PGE_2: 186.2±96.2 *vs* 42.8±32.8; TXB_2: 34.26±13.51 *vs* 8.83±3.75; iNOS: 0.365±0.026 *vs* 0.053±0.015; COX-2: 0.296±0.028 *vs* 0.034±0.013; NF-κB p65: 0.314±0.026 *vs* 0.039±0.012; SOD: 28.33±1.17 *vs* 36.14±1.91; P<0.01). However, these parameters were found to be significantly ameliorated in rats treated locally with SF at the given dose protocols, especially at 400 mg·kg^{-1}and 800 mg·kg^{-1} doses (CMDI: 1.8±0.8, 1.6±0.9; HS: 3.3±0.9, 3.1±1.0; MPO: 63.8±30.5, 36.2±14.2; MDA: 41.84±10.62, 37.34±8.58; NO: 0.247±0.042; 0.216±0.033; PGE_2: 77.2±26.9, 58.4±23.9;TXB_2: 18.07±14.83; 15.52±8.62; iNOS:0.175±0.018, 0.106±0.019; COX-2: 0.064±0.018, 0.056±0.014; NF-κBp65: 0.215±0.019, 0.189±0.016; SOD: 32.15±4.26, 33.24±3.69; P<0.05-0.01). Moreover, a therapeutic dose protocol of 800 mg·kg^{-1} SF was observed as effective as 100 mg·kg^{-1} of 5-ASA in the amelioration of colonic mucosal injury as evaluated by CMDI and HS.

CONCLUSION: Administration of SF intracolonically may have significant therapeutic effects on the rat model of colitis induced by acetic acid enema, which was probably due to the mechanism of antioxidation, inhibition of arachidonic acid metabolism and NF-κB expression.

INTRODUCTION

Inflammatory bowel disease (IBD) is a collection of chronic idiopathic inflammatory disorders of the intestine and/or colon. Although the pathophysiology of these disorders is not known with certainty, a growing body of experimental and clinical data suggested that this kind of chronic gut inflammation might be resulted from a maladjusted immune response to certain bacterial antigens[1-3]. This uncontrolled immune system activation results in a sustained overproduction of cytokines, eicosanoids, oxygen and nitrogen reactive species, which has been thought to be the major causative factors leading to intestinal and/or colonic injury and dysfunction in inflammatory bowel disease.

Based on this hypothesis, current therapeutic strategy for IBD has therefore focused on the use of anti-inflammatory agents, aminosalicylates and corticosteroids[1,4-9]. However, some notable limitations are found existing in the management of IBD patients and meanwhile some patients are refractory to these therapies. Long term use of glucocorticoids, for example, although effective in suppressing active inflammation, was associated with high rates of relapse and unacceptable toxicity[10-12]. On the other hand, 6-mercaptopurine and its prodrug azathioprine are effective in inducing and maintaining remission, however, a significant number of patients were resistant or intolerant to thiopurines[10]. All these suggest that seeking for more preferable drugs harboring better therapeutic results and less side-effects for the treatment of patients with IBD is urgently necessary.

Sodium ferulate (SF) is one of the effective components of Radix Angelica sinensis. Many researches have revealed that

SF possesses plenty of beneficial pharmacological effects such as inhibiting the production of inflammatory mediators, improving endothelial function, relieving oxidative stress and safe in use[13-18]. We presumed that SF might be a possible candidate to be used for the treatment of IBD, which to our knowledge has not been investigated in previous studies. The present study was therefore conducted to confirm our hypothesis with an effort to demonstrate the therapeutic effects of sodium ferulate on experimental colonitis.

MATERIALS AND METHODS

Animals

Healthy Sprague-Dawley rats of both sexes, weighing 250±30 g, from the Animal Center, Academy of Hubei preventive medical sciences were employed in the present study. The animals were fed on standard rat chow, allowed access to tap water *ad libitum* and acclimatized to the surroundings for one week prior to the experiments. The study protocol was in accordance with the guideline for animal research and was approved by the Ethical and Research Committee of the hospital.

Reagents

Acetic acid was obtained from Wuhan Chemical Corp. SF injection was provided by Pharmaceutical Factory of Zhongnan Hospital, Wuhan University (Lot. 20011219). 5-aminosalicylic acid (5-ASA) was purchased from Guoyi Pharmaceutical Ltd (Lot. 20029477). Polyclonal rabbit anti-rat-iNOS, COX-2 and NF-κB P65 were from Santa Cruz Company. S-P kits were obtained from Beijing Zhongshan Biological Technology CO Ltd. PGE_2 and TXB_2 radioimmunoassay kits were provided by Radioimmunity Institute of PLA General Hospital. MPO, SOD, MDA, NO detection kits were purchased from Nanjing Jiancheng Bioengineering Institute. Other reagents used in the present study were all of analytical grade.

Experimental protocol

The preparation of rat model of colitis was described in the literature[19,20]. Briefly, after rats were anesthetized with ether, a flexible plastic catheter with an outer diameter of 2 mm were inserted rectally into the colon with the aim to place the catheter tip at 8 cm proximal to the anus. Twenty seconds following enema with 2 ml of 8 % (V/V) acetic acid through the catheter, colon lumen was rinsed twice with 5 ml of normal saline. The experimental animals were randomly divided into normal control, model control, 5-aminosalicylic acid therapy and three dose SF therapy groups, and treated intracolonically with normal saline, normal saline, 5-aminosalicylic acid (100 mg· kg^{-1}), and SF 200, 400 and 800 mg· kg^{-1} respectively and daily (8: 00 am) for 7 days 24 h following the induction of colitis. Then the colon mucosa damage index (CMDI) and the histopathological score (HS) were evaluated and the colon mucosa was sampled for a variety of determinations and observations after the animals were sacrificed by decapitation.

Assessment of CMDI and HS

The colon segment taken from 10 cm proximal to anus of the sacrificed rats was excised longitudinally, rinsed by saline buffer and fixed on a wax block. CMDI and HS were assessed respectively by two independent researchers. The scoring formula for assessment of CMDI was reported in previous literature[20]. That is, 0: normal mucosa, no damage on the mucosal surface; 1: mild hyperemia and edema, no erosion or ulcer on the mucosal surface; 2: moderate hyperemia and edema, erosion appearing on the mucosal surface; 3: severe hyperemia and edema, necrosis and ulcer appearing on the mucosal surface with the major ulcerative area extending less than 1 cm; 4: severe hyperemia and edema, necrosis and ulcer appearing on the mucosal surface with the major ulcerative area extending more than 1 cm. For histopathological examination, the colonic samples were fixed in 4 % neutral buffered paraformaldehyde overnight and 4-μm thick sections were routinely prepared and stained with haematoxylin and eosin. The colonic pathological changes were observed and evaluated by two independent researchers with a modified histopathological score formula[19] as: (1) Infiltration of acute inflammatory cells: 0, without; 1, mild; 2, severe. (2) Infiltration of chronic inflammatory cells: 0, without; 1, mild; 2, severe. (3) Fibrin deposition: 0, negative; 1, positive. (4) Submucosal edema: 0, without; 1, focal; 2, diffuse. (5) Necrosis of epithelial cells: 0, without; 1, focal; 2, diffuse. (6) Mucosal ulcer: 0, negative; 1, positive.

Determination of colonic MPO, SOD activities and MDA, NO contents

For determination of colonic MPO activity, the sampled tissues were homogenized (50 g· L^{-1}) in 50 mmol· L^{-1} ice-cold potassium phosphate buffer (pH 6.0) containing 0.5 % of hexadecyltrimethylammoninm bromide. The homogenate was frozen and thawed thrice, then centrifuged at 4 000 rpm for 20 min at 4 ℃. The MPO activity in the supernatant was measured by the assay kit according to its provider' s instructions. The colonic samples for the determination of SOD activity, MDA and NO contents were homogenized in ice-cold PBS (pH 7.4) and centrifuged at 3 000 rpm for 10 min at 4 ℃. The resulting supernatant was stored at 20 ℃ until analysis with corresponding assay kits according to the manufacturer' s guide.

Measurement of colonic PGE_2 and TXB_2 level

Colonic specimens used for the assay of arachidonic acid metabolites were prepared according to the protocol by Raab *et al*[21] and Taniguchi *et al*[22], and their levels of PGE_2 and TXB_2 were measured by using the corresponding radioimmunoassay kits following the manufacturer' s instructions.

Detection of colonic iNOS, COX-2 and NF-κB p65 expression

The immunohistochemical methods for formalin-fixed and paraffin-embedded sections were described previously[23]. The determinations of colonic iNOS, COX-2 and NF-κB p65 expression were all performed with S-P technique following the recommendations of assay kit providers. Briefly, polyclonal rabbit anti-rat-iNOS, COX-2 and NF-κB p65 were diluted with PBS to 1:150, 1:120, 1:200 respectively and used as the primary antibody in the corresponding detections. For each of these determinations, dewaxed sections were incubated first with the primary antibody overnight at 4 ℃ after antigen retrieval. The binding of antibodies to their antigenic sites in the tissue sections was further amplified with biotinylated goat anti-rabbit antibody and followed by reaction with 3, 3' -diaminobenzidine. Sections prepared by substituting PBS for the primary antibody served as the negative control. iNOS, COX-2 or NF-κB p65 negatively expressed cells manifested as blue-stained nuclei while the positive cells as brown or dark brown cytoplasm and/or cell membrane. Expressions of these target proteins were semiquantitated respectively with automatic image analyzer (Nikon, Japan) and HPIAS-2000 image analyzing program, in which the average value of positive cell' s absorbance (A) in ten randomly selected high power fields (400×) for each section was used for the comparison of the target protein expressions.

Statistical analysis

Experimental results were expressed as $\bar{x}$±s. Statistical comparisons between groups were made by ANOVA followed

by Student's *t* test. *P* value less than 0.05 was considered statistically significant.

RESULTS

Inflammatory changes of the colonic mucosa

CMDI, HS and MPO activities were the main parameters for evaluating the degree of colonic inflammation in inflammatory bowel disease. Compared with the normal control, these parameters were all significantly increased in the colonic mucosa of the model control induced by acetic acid ($P<0.01$). After the model rats were treated with SF (400, 800 mg· kg^{-1}) or 5-ASA (100 mg· kg^{-1}) as described in the experimental protocol, these elevated parameters were significantly ameliorated ($P<0.05$ or 0.01) as shown in Table 1, in which a therapeutic dose protocol of 800 mg· kg^{-1} SF was observed as effective as 100 mg· kg^{-1} 5-ASA in the treatment of this rat model of colitis.

Colonic oxidative alterations

Prominent oxidative stress in colonic mucosa was induced by enema of acetic acid in the model controls as shown by the significant elevation of colonic MDA and NO contents and decrease of colonic SOD activities (Table 2). These oxidative abnormalities in colonic mucosa were obviously ameliorated by the treatment with SF at the dose protocols of 200, 400, 800 mg· kg^{-1}, which manifested as the significant reduction of colonic MDA content and the increase of SOD activity compared with the model control rats ($P<0.05$-0.01). Furthermore, a significant improvement for the elevated colonic NO content was also noted in animals treated with SF at the dose protocol of 400 or 800 mg· kg^{-1} ($P<0.05$-0.01) as shown in Table 2.

Effects of SF on the colonic PGE_2, TXB_2 levels

After the rats were insulted by enema of acetic acid, their colonic contents of PGE_2 and TXB_2 were significantly increased compared with the normal control ($P<0.01$). A significant amelioration of PGE_2 contents was observed in animals treated with SF at all dose protocols ($P<0.05$-0.01). However, significant reduction of colonic TXB_2 contents compared with the model control was only seen in rats treated with SF at the dose protocol of 400 and 800 mg· kg^{-1} ($P<0.05$-0.01) as shown in Table 3.

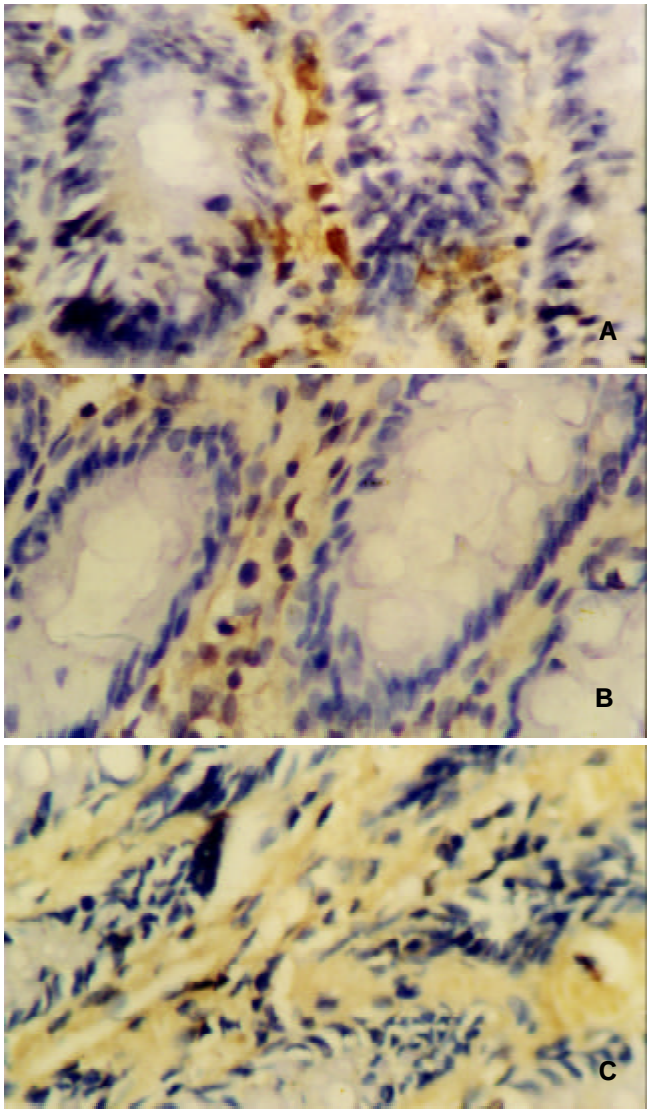

Figure 3 Expressions of iNOS (A), COX-2 (B) and NF-κB p65 (C) were significantly decreaed in the colonic tissue from rats with colitis induced by acetic acid enema after treasted with 800 $mg\cdot kg^{-1}$ ASP, respectively. The weakly positive staining could be found. SP stain ×400.

SF reduces the expression of colonic NOS, COX-2 and NF-κB p65

As shown in Figure 1, 2 and 3, the expressions of colonic NOS, COX-2 and NF-κB p65 proteins were observed to be significantly increased in animals clystered with acetic acid compared with the normal controls (P<0.01), which were ameliorated significantly in a dose-dependent manner as the animals treated with SF at the given doses (P<0.05-0.01).

DISCUSSION

Induction of colitis by acetic acid (AA) in rats is the classical method to produce an experimental model of inflammatory bowel disease (IBD). Several major causative factors in the initiation of human IBD such as exorbitant oxidative stress, enhanced vasopermeability, prolonged neutrophils infiltration and increased production of inflammatory mediators were all involved in the induction of this animal model[19,20,24]. It is therefore acknowledged nowadays that this experimental model is suitable for the investigation of IBD pathogenesis and evaluation the therapeutic agents of this disease.

In the present study, we employed this rat model to make sure whether or not the ameliorative effects of SF on the experimental colitis existed as assessed by CMDI, HS and MPO activities that were usually regarded as the main parameters to evaluate the severity of colonic inflammation in inflammatory bowel disease[19,20]. Compared with the normal control, these parameters were all significantly increased in the colonic mucosa of the model control animals induced by acetic acid (P<0.01). However, these elevated parameters were significantly ameliorated (P<0.05 or 0.01) as shown in Table 1 after the model rats were treated with SF (400, 800 $mg\cdot kg^{-1}$) or 5-ASA (100 $mg\cdot kg^{-1}$) as described in the experimental protocol, in which a therapeutic dose protocol of 800 $mg\cdot kg^{-1}$ SF was observed as effective as 100 $mg\cdot kg^{-1}$ 5-ASA in the treatment of this rat model of colitis. The results confirmed our previous speculation and strongly suggested that SF might serve as an alternative modality for the treatment of inflammatory bowel disease.

Although the pathogenesis is not known with certainty, some hypotheses have been proposed as the major causative factors contributing to inflammatory bowel disease. A large number of studies have revealed that the increase of oxidative stress and iNOS activity was a notable feature of IBD, which resulted in a pathological cascade of free radical reactions and further yielding more oxidative free radicals such as peroxynitrite ($ONOO^-$) to impair the structure and function of cells[2,25-27]. Meanwhile, excessive NO could dilate vasculature and enhance vasopermeability, as well as inactivate the activity of antioxidases such as SOD, CAT, and GSH-Px by means of reacting with hydrosulfide group (-SH) in the enzymes. Some oxidants have been known to modulate the expression of a variety of genes that are involved in the immune and inflammatory responses, which lead to the apoptosis of intestinal epithelial cells, cascades of inflammatory response and the disruption of integrity and function of the intestinal mucosa[28-30].

Abnormal metabolism of arachidonic acid is another vital factor in the IBD pathogenesis. As the crucial synthetase in the arachidonic acid metabolic pathway, COX-2 could be activated to produce excessive PGE_2 and TXB_2, two important inflammatory mediators, in the inflammatory bowel disease, which contribute to the bowel hyperemia, edema and even dysfunction. In addition, TXB_2 could also induce platelet aggregation, vasoconstriction and microthrombosis, aggravating the inflammatory reaction[31-35]. Administration of either COX-2 or thromboxane synthase inhibitors has been shown to be useful for the treatment of IBD[32-34].

Recently, plenty of literatures reported that NF-κB played a critical role in the early transcriptional changes of various immunoregulatory genes[28, 36], whose activation and increased expression have been demonstrated to be involved in the pathogenesis of inflammatory bowel disease[37]. Activated NF-κB could promote the production of various inflammatory factors, chemotaxins, cytokines, and adhesive factors, and the expression of iNOS and COX-2, which interact further with each other and lead to an uncontrollable cascade of inflammatory response[38-41]. NF-κB could also activate anti-apoptotic genes

including TNF receptor related genes (TRAF1, TRAF2), Bcl-2 homologens (A1/Bfl-1, IEX-1L), and repress the apoptosis of some inflammatory cells such as neutrophils and activated macrophages, thereby elongating and worsening tissue inflammatory injury[42-45]. In the NF-κB family, p65 is the major functional subunit, and an antisense oligonucleotide to NF-kappa B p65 has been shown to ameliorate inflammation even after induction of colitis[1].

To elucidate the mechanisms underlying the therapeutic effects of SF on this rat model of colitis, we observed simultaneously the changes of these oxidative and inflammatory variables mentioned above in the colonic tissue after SF therapy. The results revealed that the SOD activity, MDA and NO levels, PGE_2 and TXB_2 contents, as well as the expressions of iNOS, COX-2 and NF-κB p65 proteins in the colonic mucosa were significantly ameliorated in the rats treated locally with SF at the given dose protocols, especially at the 400 mg· kg^{-1} and 800 mg· kg^{-1} doses, compared with that in model control animals (P<0.05-0.01). Taken together, these observations suggest the anti-oxidative stress and anti-inflammatory response are the fundamentals of SF action in the therapy of IBD, although the ameliorating effects of SF might be involved in other multiple mechanisms.

In summary, the results of this study show that intracolonic treatment with SF at 400 mg· kg^{-1} and 800 mg· kg^{-1} dose protocols can ameliorate the pathological changes of experimental colitis in rats, which suggests that SF may serve as an effective therapeutic agent for the treatment of IBD.

Abstract

AIM: The present study was undertaken to purify and partially characterize the 33.5-kilodalton (33.5 kDa) vesicular protein in human bile and to explore the possible molecular mechanisms of the initial crystal nucleation process.

METHODS: The 33.5 kDa vesicular protein was isolated by ultracentrifugation and further purified by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) under nonreducing conditions. The purified 33.5 kDa vesicular protein was subjected to N-terminal amino acid sequencing and amino acid analysis. Cholesterol crystallization activity was detected by cholesterol crystal growth assay. The sugar chain of the 33.5 kDa vesicular protein was analyzed by dot-immunobinding assay of lectin coupled to a peroxidase (HRP-DSA, HRP-ConA, HRP-WGA) and was deglycosylated using two different enzymatic approaches (*N*-deglycosylation and *O*-deglycosylation) to determine the molecular weight of the protein component, the type of linkage between polypeptide and carbohydrate components.

RESULTS: The 33.5 kDa vesicular protein with complicated glycan was an extensively glycosylated (37.3 %) monomer and these sugar chains strongly bound to DSA, but did not bind to ConA. Amino acid sequencing indicated that the protein was unique. The 33.5 kDa vesicular protein exhibited potent cholesterol crystallization promoting activity *in vitro* with derived crystal growth curve indices It, Ig, Ic presented as 0.57, 1.52, and 1.63 respectively. Both enzymatic proteolysis and *N*-deglycosylation of the protein removed all activity.

CONCLUSION: These data suggest the 33.5 kDa vesicular protein may be responsible for the pathogenesis of cholesterol gallstone disease, and the sugar chains play an important role in pro-nucleating process.

INTRODUCTION

Cholesterol nucleation process represents a critical step in the cholesterol gallstone formation. Cholesterol pro-nucleating and anti-nucleating proteins can accelerate or retard the rate of cholesterol crystallization in supersaturated bile, and thus may play important roles in cholesterol crystallization[1-3]. From 1988, both inhibitors and promoters of cholesterol crystallization have been isolated from human bile and characterized[4-7]. The major cholesterol crystallization promoting activity was localized at the concanavalin A-binding fraction of biliary glycoproteins (CABG). These proteins include mucin[8], immunoglobulins[9-11], α_1-acid protein[12], aminopeptidase N[4], low-density protein-lipid complex[5,13], and some unidentified proteins such as 70 kDa[14] and 200 kDa[15] pro-nucleating glycoproteins. Abei *et al*[16] provided comparative data regarding the relative potency of these different glycoprotein promoters and found that α_1-acid protein accounted for the greatest portion (33 %) of the net biliary Con A-bound promoting activity derived from currently defined and well-identified glycoproteins. But still more than 60 % of total Con A-bound promoting activity remains unaccounted for. It was speculated that there was still some other more important proteins involved in cholesterol nucleation process.

Lecithin vesicles are the primary cholesterol carriers in bile supersaturated with cholesterol and have been shown to play an important role in the nucleation of cholesterol. This nucleation takes place after aggregation and fusion of cholesterol-rich biliary vesicles, a process modulated by biliary proteins. Miquel *et al*[17] found a potent cholesterol pro-nucleating activity in purified biliary vesicles. Further study demonstrated that this activity was related with specific vesicular proteins including immunoglobulins IgA, IgG and IgM[18].

In this study, a novel 33.5 kDa vesicular protein obtained from human gallbladder bile of cholesterol gallstone patients was isolated, purified and partially characterized. We attempted to determine whether pro-nucleating activity occurred in the 33.5 kDa vesicular protein and to detect whether the protein was lectin-specific. Our results showed that the 33.5 kDa vesicular protein exhibited potent pro-nucleating activity *in vitro*, which depends on intact structure of peptide and sugar chain, and especially bound DSA lectin.

MATERIALS AND METHODS

Materials

Sodium salts of taurocholic(STC) and taurodeoxycholic (STDC) greater than 99 % purity, cholesterol(CH), egg lecithin and Tween 20 were obtained from Fluka Company. Metrizamide, nitrocellulose sheets, and all the chemicals for SDS-PAGE were obtained from Sigma Chemical Co. Datura stramonium agglutinin (DSA), wheat germ agglutinin (WGA), concanavalin A(Con A), peroxidase(HRP), and Sephadex G150 were also from Sigma Chemical Co. Periodic acid($NaIO_4$) was purchased from Wako Pure Chemical. *N*-glycosidase F, endo-α-N-acetyl-galactosaminidase, neuraminidase, and *Pronase K* were purchased from Boehringer Mannheim Corp., Germany, and 0.22 μm micropore filters were obtained from Millipore Corp., Bedford, MA. USA.

Methods

Patients and bile collection All patients gave written informed consent to participate in the study, which was approved by the ethical committee. Gallbladder bile was obtained from three patients by directly puncturing the gallbladder with a sterile 19G needle at cholecystectomy for cholelithiasis. The bile (20 ml) was immediately transported to the laboratory and stored at -80 ℃ until processed.

Protein purification procedure Pooled bile specimens were separated on a molecular sieving chromatography column (BioGel A-5m, 5×100 cm), eluted with 10 mmol/L Tris-HCl buffer to remove soluble mucin glycoprotein. The main fraction was centrifuged at 10 000 rev/min for 10 minutes at room temperature. The upper fraction was filtered through 0.22 μm micropore filters, and metrizamide (13 % w/v) was directly dissolved in the elution and centrifuged at 45 000 rev/min for 3.5 h at 10 ℃ in a Vti-50 vertical rotor (Beckman Instruments Inc., USA). The top opalescent vesicular fraction was collected by tube puncturing and loaded on SDS-PAGE under nonreducing conditions. The 33.5 kDa vesicular protein lane was resected according to the protein marker position and dialyzed in Tris-HCl buffer and concentrated as Ma *et al*[19] described.

SDS-PAGE SDS-PAGE(5-12 %) was developed in a buffer system described by Laemmli[20]. Aliquots (100 μl) of protein and bile samples were resolubilized with a sample buffer (60 mmol/L Tris-HCl, 2 % SDS, 10 % glycerol, pH 6.8). On completion of the electrophoretic run, gels were fixed in a 50 % methanol, 10 % acidic acid solution for 6 h and stained with Coomassie blue.

Preparation of lectin-HRP conjugate The lectin-HRP conjugate of DSA-HRP, WGA-HRP and Con A-HRP was made according to Guo *et al*[21]. Briefly, 5 mg HRP was dissolved in 0.5 ml distilled water, then added with 0.5 ml 60 mmol/L $NaIO_4$ and kept at 4 ℃ for 30 minutes. Five mg lectin such as DSA, WGA and Con A was mixed with HRP and 0.1 mol/L α-methyl mannose for Con A, and N-acetylglucosamine for DSA and WGA was added to protect the glycan binding site of the lectin. The reaction mixture was dialyzed in 50 mmol/L carbonate buffer (pH 9.5) and centrifuged at 4 000 rev/min for 10 minutes. The supernatant was removed and the pellet was dissolved and dialyzed in sodium phosphate buffer (20 mmol/L, pH 7.4).

Lectin affinity staining Five, 10, 15 μg/ml of purified 33.5 kDa vesicular proteins were blotted to nitrocellulose membrane respectively. The membrane was blocked with 1 % BSA overnight at 37 ℃. Subsequent incubation of the membrane with 1:500 peroxidase-labeled Datura stramonium agglutinin (DSA), wheat germ agglutinin (WGA), concanavalin A(Con A) in the same solution was followed by washing three times in the TTBS buffer (0.05 % Tween 20, 0.1 mol/L Tris-HCl, pH7.5) and chemiluminescent detection.

Amino acid analysis The purified 33.5 kDa vesicular protein was hydrolyzed for 16 hours at 115 ℃ in 6 N HCl/0.2 % phenol containing norleucine as an internal standard. After incubation, samples were dried and redissolved in 100 μl of NaS sample dilution buffer (Beckman Instruments Inc., USA) and run on a Beckman model 7300 Amino Acid Analyzer.

Amino acid sequencing The amino-terminal sequences of the 33.5 kDa vesicular protein were subjected to N-terminal amino acid sequencing with an automated sequencer (model 477A: Protein Sequencer, Applied Biosystems). Determined sequences were compared with those well-identified glycoproteins in the Pub-Med NCBI human gene bank database.

Enzymatic deglycosylation The 33.5 kDa vesicular protein was treated with *N*-glycanase enzyme according to supplier's specifications based on the work of Elder and Plummer *et al*[22,23]. Five hundred μg 33.5 kDa vesicular protein boiled for 5 minutes was diluted with 0.1 mmol/L sodium phosphate buffer, pH 8.6, 10 mmol/L 1, 10-phenanthroline, and then mixed with 10 U *N*-glycanase, and the reaction mixture was incubated for 24 h at 37 ℃. The molecular weight of deglycosylated polypeptide backbone was then detected using SDS-PADE.

In the *O*-deglycosylation study, the vesicular protein was diluted with 10 mmol/L calcium acetate, 20 mmol/L sodium cacodylate buffer (pH 7.0) and was incubated with 10 U/ml of neuraminidase for 12 h at 37 ℃. This was followed by further incubation with 2 U/ml of endo-α-N-acetyl-galactosaminidase for 12 h at 37 ℃. Finally, the mixture was examined using SDS-PAGE.

Proteolysis studies One hundred μg of 33.5 kDa vesicular protein was dissolved in 50 μl ammonium bicarbonate (25 mmol/L, pH 11), and then incubated with 1.5 U *Pronase K* for 24 h at 37 ℃. After incubation, the sample was concentrated and loaded on SDS-PAGE.

Cholesterol crystal growth assay Supersaturated model bile was prepared with a cholesterol saturation index of 1.4, a total lipid concentration of 125 g/L, and a bile acid/phospholipid ratio of 4.4. This model bile was made as Busch *et al*[24,25] described. In brief, this lipid mixture was evaporated to dryness, lyophilized, and then resolubilized with 20 mmol/L Tris-HCl/150 mmol/L NaCl (TBS), pH 7.4 at 55 ℃. After filtration (0.22 μm), 25 μl of this model bile mixed with 50 μg protein or its enzymatic samples was diluted with 475 μl TBS/10 mmol/L STDC solution. After 20 minutes, absorbance at a single wavelength within the visible range (700 nm) was sequentially measured. The cholesterol crystal growth curves of the supersaturated model bile without (control) and with (experimental) protein samples were thus generated for each sample. The three growth curve parameters were derived: growth index Ig=maximal slope of experimental curve/maximal slope of control, crystal index Ic=final crystal concentration of experimental/final crystal concentration of control, time index It=onset time of experimental/onset time of control.

Statistical analysis

The cholesterol crystal growth curves were compared by using analysis of variance (ANOVA) at each time to determine whether difference existed between the study groups. When the ANOVA was statistically significant ($P<0.05$), the Dunnett's multiple comparison procedure was made to compare each of the study groups to the control group.

RESULTS

Purification and identification of novel 33.5 kDa glycoprotein

The bile was divided into three fractions after ultracentrifugation (Figure 1). The top opalescent vesicular fraction was collected by tube puncture and the targeted vesicular protein was further separated by SDS-PAGE. The protein profile from three different gallstone patients with Coomassie blue staining is shown in Figure 2. The protein marker is shown at lane 1 and a single band of 33.5 kDa protein at lanes 2-4 on SDS-PAGE was stained under nonreducing condition. Amino acid analysis of the purified glycoprotein showed that the protein was composed of 153 amino acid residues of which almost one third were the following amino acids: glutamine/glutamic acid and asparagines/aspartic acid (Table 1). N-amino-terminal sequencing of the protein showed H_2N-Asp-Asn-Ser-Gln-His-Arg-Tyr-Val-Phe-Ile, which was different from α_1-acid protein, Ig, aminopeptidase N and phospholipase C. Lectin staining showed higher affinity for *Datura stramonium agglutinin* (DSA) than for wheat germ agglutinin (WGA) and concanavalin A(Con A)(Figure 3). *N*- deglycosylation studies showed disappearance of the original 33.5 kDa protein and the presence of a new 21kDa band on SDS-PAGE (Figure 4), indicating

the protein was heavily glycosylated (37.3 %) and the connection mode between polypeptide and carbohydrate components was *N*-linkage. Proteolysis studies showed the protein was sensitive to *Pronase K* digestion.

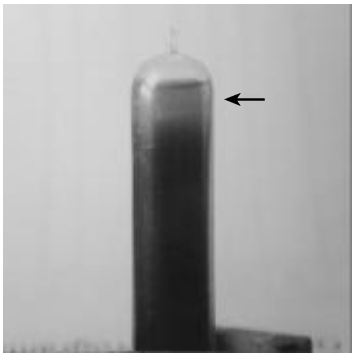

Figure 1 Pretreated bile centrifuged at 45 000 rev/min and divided into three fractions. Horizontal arrows indicate the vesicular phase bile.

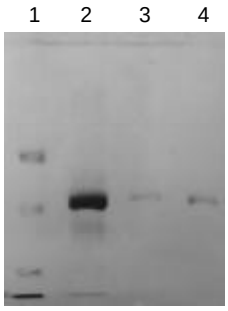

Figure 2 Purified 33.5 kDa vesicular proteins from three different bile samples run on SDS-PAGE. Lane 1: protein marker, Lanes 2-4: the 33.5 kDa vesicular protein.

Table 1 Amino acid composition of 33.5 kDa vesicular protein

Amino acid	nmol/total protein	No. of residues/mol protein
Asp/Asn	6.761	19
Thr	4.488	13
Ser	1.589	5
Glu/Gln	10.434	30

Total	64.76	153

Cholesterol crystal growth assay

Figure 5 depicts the promoting effect of 33.5 kDa vesicular protein on cholesterol crystal growth curve at the concentration of 100 μg/ml. The protein strongly promoted cholesterol crystallization, accelerated the onset and increased the total quantity of crystal plates with derived crystal growth curve indices It, Ig, Ic presented as 0.57, 1.52, 1.63 respectively. But no promoting activity was detected in the same supersaturated model bile after incubation with *N*-glycanase enzyme or complete protein degradation (Table 2).

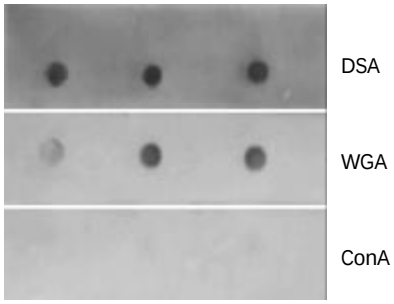

Figure 3 Lectin affinity staining with DSA, WGA, Con A labeled with peroxidase. The 33.5 kDa vesicular protein was strongly connected with DSA, and weakly bound to WGA, but did not react with Con A.

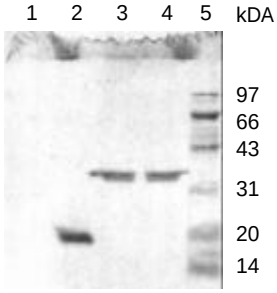

Figure 4 SDS-PAGE (reduced condition) of the 33.5 kDa vesicular protein after *N*-deglycosylation, *O*-deglycosylation and proteolysis. Complete disappearance was observed after incubation with *Pronase K* at lane 1. A single 21 kDa band was stained after treated with *N*-glycanase at lane 2, but no change of the protein after enzymatic *O*-deglycosylation at lane 3. The band of lane 4 and lane 5 represented the 33.5 kDa vesicular protein and protein marker respectively.

Table 2 Effect of 33.5 kDa vesicular protein on activity indices of cholesterol crystallization (100 μg/ml)

	It	Ig	Ic	*P* value
Purified 33.5 kDa protein	0.57	1.52	1.63	<0.05[a]
+ *N*-deglycosylation	1.08	1.01	0.98	<0.05[b]
+ *O*-deglycosylation	0.58	1.61	1.54	<0.05[a]
+ Proteolysis	1.12	0.87	0.99	<0.05[b]

a: compared with control, b: compared with 33.5 kDa vesicular protein group.

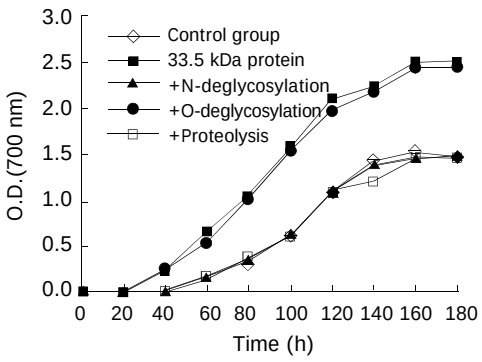

Figure 5 Promoting effect of 33.5 kDa vesicular protein and its enzymatic products on cholesterol crystal growth curves in model bile (TL=125 g/L, BA/PL=4.4, CSI=1.4). All curves are given as the mean ±SD, n=4. P<0.05 *vs* control at each time.

DISCUSSION

Since the first report of the presence of pro-nucleating activity in cholesterol patient' s bile by Burnstein *et al*[26], many groups have tried to purify and identify the active protein-related components[16,17,25,27,28]. Of particular interest are the presence and role of concanavalin A-binding fraction of biliary glycoproteins (CABG), which have a potent cholesterol crystallization-promoting activity. Proteins thought to explain this activity included α_1-acid protein[12], immunoglobulins[9-11], aminopeptidase N[4,6], and a pronase resistant carcinoembryonic antigen-related cell adhesion molecule 1 most recently described by Jirsa *et al*[29], and some unidentified proteins such as 200 kDa pro-nucleating glycoprotein[15]. But still most of the activity has not been identified[30]. In this study we purified and characterized a novel promoting-nucleation glycoprotein with molecular weight of 33.5 kDa in vesicular bile of cholesterol gallstone patients. In 1992, Miquel *et al*[17] isolated and purified human vesicles with potent cholesterol-nucleation-promoting activity, and found that this protein-related activity belonged to immunoglobulins. Although they were from the same vesicular bile, the difference between the immunoglobulin family of glycoprotein and the 33.5 kDa vesicular protein was obvious. We took considerable care to rule out the possibility that the present glycoprotein shared similar features with the immunoglobulins. First, the potent cholesterol-nucleation-promoting vesicular protein had a strong activity of accelerating the onset and increasing the total quantity of crystals appearance and was unique to have a high affinity for *Datura stramonium agglutinin* (DSA), and did not bind to *concanavalin A* (Con A). This was different from the previously described promoting-nucleation glycoprotein. Amino acid sequencing study further demonstrated that the 33.5 kDa vesicular protein with N-amino-terminal sequencing of H_2N-Asp-Asn-Ser-Gln-His-Arg-Tyr-Val-Phe-Ile, was a novel glycoprotein from vesicular bile.

In additional experiments, the 33.5 kDa vesicular protein could not only accelerate onset of nucleation, but also induce rapid cholesterol crystallization growth. We speculate the factor identified in this study may play an important role in the initial stage of the gallstone formation. To study the underlying mechanism and pathophysiological significance of the peptide and carbohydrate moiety, the 33.5 kDa vesicular protein was treated with glycanase enzyme and p*ronase* respectively. Incubation with *N*-glycanase resulted in disappearance of the original 33.5-kilodalton band and presence of a strong 21-kilodalton band on SDS-PAGE, and no cholesterol crystallization promoting activity of 33.5 kDa vesicular protein was detected in supersaturated model bile. It suggested that the sugar chain might be responsible for the promoting-nucleation activity. This striking characteristic of the vesicular protein was very similar to α_1-acid protein. Abei *et al*[12] reported that α_1-acid protein was 37 % glycosylated with mannose, sialic acid content, and some other multiple antennae and the carbohydrate moiety were essential to the promoting activity of glycoprotein. In addition, vesicular glycoprotein was completely degradated and no promoting activity existed after proteolytic digestion.

In conclusion, our results indicate that, the 33.5 kDa vesicular protein with complicated glycan and high affinity for DSA, is a novel and unique pro-nucleating glycoprotein, which exhibits potent cholesterol crystallization promoting activity *in vitro*. However, further studies are needed to evaluate the predictive value, concentration, relative potency and origin of the 33.5 kDa vesicular protein before we can ascertain its specific role in the pathogenesis of cholesterol gallstone disease.

Abstract

AIM: To examine the participation of HSP90 in portal hypertensive rat mesentery *in vitro*.

METHODS: Immunohistochemistry and Western-blot were used to examine the expression of HSP90 in mesenteric vasculature. HSP90 mRNA was detected by RT-PCR, and the role of HSP90 in hyperdynamic circulation was examined by *in vitro* mesenteric perfusion studies.

RESULTS: HSP90 was overexpressed in endothelium of mesentery vasculature in animals with experimental portal hypertension induced by partial portal vein ligation (PVL) compared with normal animals. Geldanamycin (GA), a special inhibitor of HSP90 signaling, attenuated ACh-dependent vasodilation but did not affect vasodilation in response to sodium nitroprusside in normal rats. In PVL animals, the perfused mesentery was hyporesponsive to vasoconstrictor methoxamine. GA significantly potentiated methoxamine-induced vasoconstrictor after PVL.

CONCLUSION: HSP90 plays a key role in NO-dependent hyperdynamic circulation in portal hypertension and provides a novel method for future treatment of portal hypertension.

INTRODUCTION

Cirrhosis of the liver, which usually develops as a long-term consequence of viral hepatitis or alcohol abuse, is a major cause of morbidity and mortality worldwide. The principal pathophysiologic feature of cirrhosis is an increase in portal pressure initiated by an increase in outflow resistance to the portal circulation. However, advanced cirrhosis was also associated with mesenteric arteriolar vasodilation[1], which contributes to portal hypertension and variceal hemorrhage by increasing portal inflow. It has been well established that portal hypertension was not a purely mechanical phenomenon[2]. There have been a large body of experimental evidences that demonstrated increased synthesis of nitric oxide (NO) in animal models of cirrhosis. Aortic cAMP, a surrogate marker of NO synthesis, was significantly elevated in CCl_4-induced cirrhosis rats compared to controls and the highest levels were observed in those with ascites[3]. Similar evidences also existed for elevated NOS activity in animal models of portal hypertension induced by partial vein ligation[4]. NO and endothelin-1-dependent increases in intrahepatic resistance in conjunction with vasodilation of splanchnic arterioles raised portal pressure and flow, thereby contributing to the vascular component of portal hypertension[5]. Indeed, the importance of splanchnic vasodilation in this process was highlighted by clinical utility of nonselective beta-blockers and octreotide, both of which could reduce splanchnic vasodilation and portal venous inflow[6]. However, cirrhotic vasculature was highly resistant to conventional vasopressors[7], and attempts to correct the hyperdynamic circulation in cirrhosis by antagonism of putative endogenous vasodilator mediators have been unsuccessful so far[8,9]. Pressure and resistance changes in perfused mesenteric vasculature occurred, in part through NO-dependent mechanisms, and in experimental portal hypertension this vascular bed demonstrated a hyporeactivity to vasoconstrictors such as methoxamine (MTX), mainly due to excessive endothelium-derived NO production[10,11].

NO is derived from L-arginine by the enzymatic action of NOS. Two isoforms of NOS have been shown to exist in the vasculature, one is a constitutively expressed and calcium-calmodulin-dependent isoform (eNOS)[12], the other is an inducible and calcium-independent isoform (iNOS)[13]. Indirect evidences for eNOS as the main source of elevated NO from studies showed that endothelial denudation could normalize vascular levels of NO[14] and reverses the hyporeactivity to vasoconstrictors[15,16] in cirrhotic rats. Several studies now suggested that eNOS was the major enzymatic source of NO overproduction[17-20] in vascular endothelium in cirrhosis. However, the molecular mechanism is still unknown. 90 kD heat shock protein (HSP90) has been found to be a molecular chaperon, and a constitutive homodimer, its main intersubunit contacted within COOH-terminal 190 residues[21]. The highly conserved 25 kD NH_2 - terminal domain of HSP90 is the binding site for geldanamycin (GA), a representative of ansamycin drugs, which specially targets HSP90[22]. HSP90 mediates the conformational regulation of a wide range of client proteins involved in signal transduction, cell proliferation and apoptosis. The recently demonstrated importance of HSP90 as an intermediate in the signaling cascades leading to activation of eNOS[23] suggested the possibility of a contributory role of this pathway in NO-dependent mesenteric vascular responses and excessive NO production in experimental portal hypertension.

The goals of this study were to examine HSP90 expression and localization in rat mesenteric microvasculature, to determine whether GA inhibited mesenteric vasodilation, and to test whether GA reversed the hyporeactivity to vasoconstrictors detected in mesenteric vasculature of portal hypertensive animals.

MATERIALS AND METHODS

Animals and reagents

Male Sprague-Dawley rats (Tongji Hospital Laboratories) weighing 250-300 g were used for experiments. Animal experiments and tissue harvesting were performed in accordance with the animal care guidelines of the institution. GA was dissolved in DMSO, and the final concentration of DMSO used in experiments was <0.006 %. MTX, ACh, and sodium nitroprusside (SNP) obtained from Sigma Chemical, were dissolved in distilled water and prepared daily.

Induction of portal hypertension

Prehepatic portal hypertension was provoked by partial portal vein ligation (PVL) as previously described[24]. In brief, rats were anesthetized, and after laparotomy, the portal vein was isolated and a stenosis created by placing a single ligature of 3-0 silk around both the portal vein and a 20-gauge blunt-tipped needle. The needle was then removed from the ligature, creating a calibrated constriction of the portal vein. In sham-operated (SO) rats, the portal vein was isolated but not ligated. Studies were performed in 24 hours fasted rats 21 days after PVL.

Immunohistochemistry

Mesenteric tissue was perfusion fixed *in situ* with 4 % paraformaldehyde, postfixed in sucrose, and embedded in OCT[25]. Frozen tissue sections were incubated overnight with HSP90 MAb, and a secondary incubation was performed with horse anti-mouse IgG for 30 min. Sections were developed with amino ethylcarbazole. Negative controls were incubated with appropriate serum substituted for the primary antibody.

RNA isolation and reverse transcriptase and polymerase chain reaction (RT-PCR)

Mesenteric tissue was harvested by dissecting and removing the highly vascular tissue situated between the mesenteric lymph nodes and small intestine. Mesenteric specimens from SO and PVL rats were immediately frozen in liquid nitrogen, then homogenated with Tripure isolation reagent to isolate total RNA. The RNA concentration in each sample was determined spectrophotometrically, and the quality of each RNA preparation was documented by visualization of 18S and 28S ribosomal bands after electrophoresis through a 1 % agarose gel. Total RNA samples were subjected to reverse transcription with Oligo-dt used as a template-primer. First strand synthesis was carried out for 1 hour at 37 ℃ in 25 μl of a reaction mixture containing 200 U M-MLV, 1 X reaction buffer, 0.5 mmol/L dNTP, 10 mmol/L DTT, 20 U RNAsin ribonuclease inhibitor and 0.25 -μg oligo-dT. The PCR primer sequences were as follow: HSP90 sense 5' GTCTGGGTATCGGAAAGCAAG3', antisense 5' CTGAGGGTTGGGGATGATGTC 3'. PCR assays contained 0.5 U Taq DNA polymerase, 0.5 μmmol/L of each oligonucleotide primer, 0.2 mmol/L dNTP, 1 X reaction buffer, 1.5 mmol/L MgCl in a final volume of 50 μl. 25 cycles were performed at 95 ℃ for 1 min, at 55 ℃ for 1 min, and at 72 ℃ for 2 min. PCR products were analyzed by electrophoresis in TAE buffer with ethidium bromide stained with (0.5 mmol/L) 2 % agarose gel. Each band was selected and used to measure the number of photons emitted.

Western blotting

Mesenteric sections were weighed and homogenized in 10 volumes of ice-cold 1 % NP-40 in 50 mM Tris (pH 8.8) buffer. The homogenates were centrifuged, and the supernatants were transferred into sterile tubes. Fifteen-microgram of protein aliquots of each sample, as determined by the Coomassie blue method, was resolved on 15 % SDS-polyacrylamide gels and transferred onto nitrocellulose membranes. The membranes were blocked with BSA before being incubated with primary antibody overnight at 4 ℃, and rinsed and then incubated for 1 h with peroxidase-conjugated secondary antibody. Immunoreactive proteins were visualized using the enhanced chemiluminescence system.

In vitro mesenteric perfusion

In vitro mesenteric perfusion was performed 14 days after PVL or after sham surgery, using the method described by McGregor and Sieber with some modifications[26]. In brief, the superior mesenteric artery (SMA) was cannulated with a PE-60 catheter and blood was removed by perfusion with 15 ml of warm Krebs solution. The gut was dissected at the mesenteric border, and the SMA with its adjoining mesenteric tissue was placed in a 37 ℃ water-jacketed container. The preparation was continuously perfused in a nonrecirculating system at a fixed rate of 4 ml/min throughout the course of the experiment with Krebs solution. Perfusion pressure was continuously monitored using a strain gauge transducer on a sidearm proximal to the perfusing cannula. The initial preparation was allowed to stabilize for 30 min, after which vehicle was infused for 15 min. Immediately after infusion of vehicle, concentration-response curves were examined in response to MTX infusion (30 and 100 μM). When a stable baseline was maintained in response to 100 μM MTX, responses to ACh boluses (0.1 ml) were examined (1 and 10 μg). All compounds were allowed to wash out over the next 50 min, after which GA was infused (3 μg/ml) for 15 min. Responses to MTX and ACh were repeated as described above. Additional experiments were performed after endothelial denudation. The denudation was achieved by combined treatment with cholic acid and distilled water as previously described[27]. In brief, after cannulation of the SMA and gentle flushing with 10 ml of warmed Krebs solution to eliminate blood, the mesentery was perfused with 1.5 ml of 0.5 % cholic acid for 10 s followed by 15 ml of warmed Krebs solution. The preparation was then transferred to a 37 ℃ water-jacketed container and perfused with warmed, oxygenated Krebs solution for 10 min. After the mesenteric vasculature was relaxed, warmed distilled water was perfused for 10 min. After a 45-min stabilization period, vehicle or alternatively GA was perfused for 15 min. Immediately after pretreatment with vehicle or GA, an infusion of 100 μM MTX was begun. When a stable baseline was maintained in response to 100 μM MTX, concentration-response curves to 0.1-ml SNP boluses (0.001-10 μg) were examined. Additional experiments were also performed in sham and PVL mesenteric vessels in response to GA preinfusion using MTX doses that allowed equivalent levels of constriction in response to preinfusion of vehicle. Equivalent constriction was achieved with 10 and 30 μM MTX in sham and PVL mesentery, respectively.

Statistics

All data were expressed as means ± SE. Statistical analysis was performed using paired and unpaired Student's *t*-tests as well as ANOVA where appropriate.

RESULTS

Expression and localization of HSP90 in mesenteric vasculature

The expression of HSP90 was significantly enhanced in PVL animals compared with SO and normal animals by Western blot and by RT-PCR (Figures 1A and B). The immunohistochemistry showed that HSP90 staining was not only found in vascular endothelium but also in mesenteric smooth cells (Figure 1C).

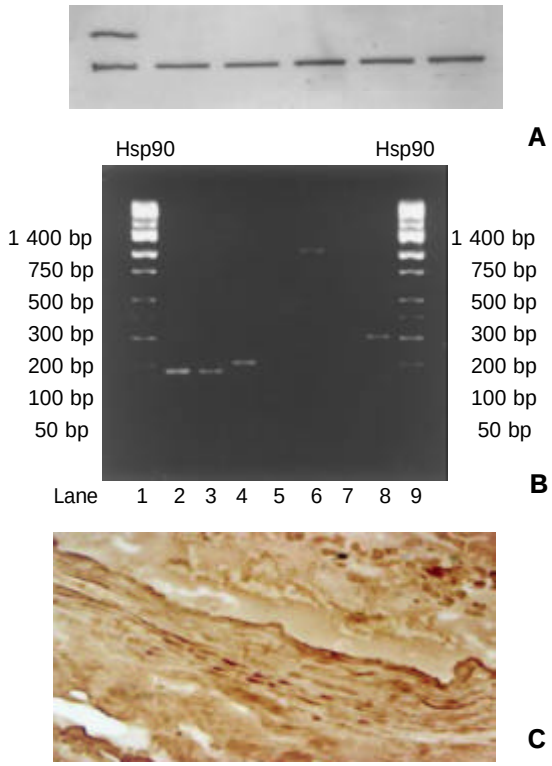

Figure 1 A: Expression of HSP90 by Western blot in PVL anima, B: Expression of HSP90 mRNA in PVL animals, C: Immunohistochemistry showed that HSP90 staining was not only found in vascular endothelium but also in mesenteric smooth cells.

GA potentiated mesenteric vascular responses to MTX in portal hypertensive animals

In response to 100 μM MTX, GA significantly potentiated the increase in perfusion pressure in portal hypertensive animals (Figure 2) (P<0.05, GA vs. vehicle) but not in sham animals. This result suggested that HSP90 was responsible for the hyporesponsness in portal hypertensive rats, thus playing a key role in hemodynamic dysfunction of portal hypertensive animals.

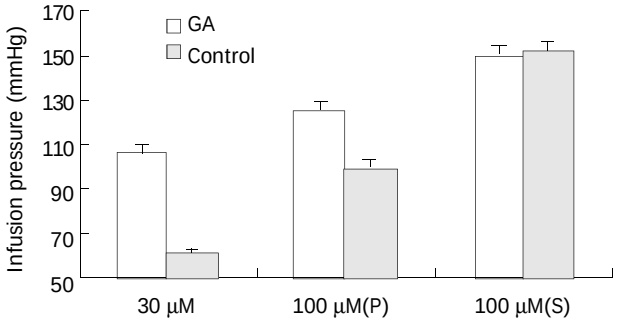

Figure 2 GA potentiates increase of perfusion pressure in portal hypertensive animals.

GA attenuated ACh-dependent vasorelaxation of the normally isolated and perfused rat mesentery but did not affect vasodilation in response to sodium nitroprusside

In this preparation, ACh induced vasorelaxation in a dose-dependent manner after preconstriction of the circulation with MTX. Mesenteric vasorelaxation in response to ACh (1 and 10 μg) was significantly attenuated after preinfusion of GA (3 μg/ml) compared with preinfusion of vehicle (Figure 3) (P<0.05, vehicle vs. GA; n=5). After endothelial denudation, pretreatment with GA did not affect vasodilation in response to SNP (n=6), indicating that the effects of GA were dependent on the endothelium and that GA did not directly affect soluble guanylate cyclase or other smooth muscle cell machinery required for NO-dependent vasodilation. These results showed that HSP90 was an important modulator in vasodilation of mesenteric vasculature.

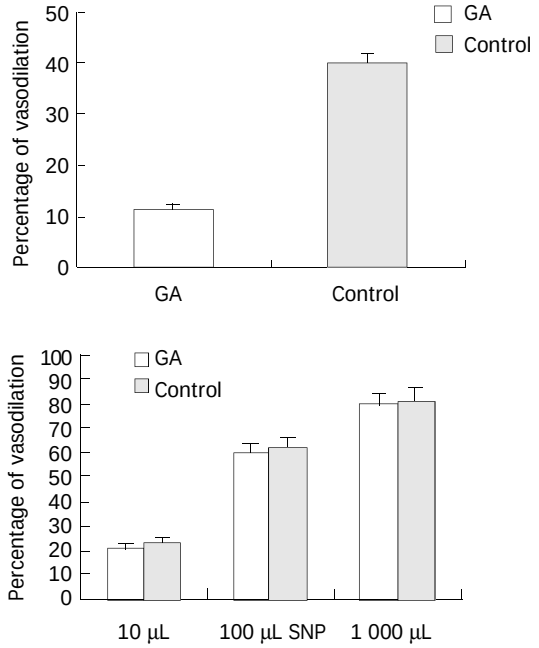

Figure 3 A: GA attenuates Ach dependent vasodilation. B: GA does not affect vasodilation in response to SNP.

DISCUSSION

This study suggested that HSP90 was overexpressed in the endothelium of mesenteric vasculature in PVL induced animals compared with SO and normal animals. Moreover, in PVL animals, the perfused mesentery was hyporesponsive to the vasoconstrictor methoxamine. GA, a special inhibitor of HSP90 signaling, significantly potentiated methoxamine-induced vasoconstrictor after PVL. It thus indicated a mechanism linking protein-protein interactions with vascular manifestations observed in portal hypertension.

HSP90, an ATP-dependent chaperon[28], facilitated the folding and stabilization of cellular proteins, and played a key role in cellular signal transduction networks. The highly conserved 25 kD NH_2-terminal domain of HSP90 was the binding site for ATP and GA[22], and crystallography has shown that GA occupied the nucleotide-binding cleft within the NH_2-terminal domain[28], which thereby has been used as a specific reagent to probe the importance of HSP90 in cellular pathways. An *in vivo* requirement for HSP90 has been established for some steroid hormone receptors[29], several serine/threonine kinases such as pp60/v-src and RAF[30,31] and disparate proteins such as NOS and calcineurin[23,32]. The present study demonstrated that GA also blocked vascular responses mediated by eNOS, without influencing the direct vasodilatory effects of SNP. These data, in conjunction with the above evidences for the specificity of GA, suggested that HSP90 participated in vasodilation of mesentery vasculature as a regulator of endothelial cell signal transduction, leading to eNOS activation and vasorelaxation.

Vessel homeostasis is maintained by a balance of vasoactive substances and hemodynamic forces, including shear stress which mediates vascular responses in part through modulation of eNOS. Two isoforms of NOS have been shown to exist in the vasculature, one is a constitutively expressed and calcium-calmodulin-dependent isoform (eNOS)[12], the other is an

inducible and calcium-independent isoform (iNOS)[13]. Several studies suggested that eNOS was the major enzymatic source of NO overproduction[17-20] in the vascular endothelium in cirrhosis. Our study found that the effects of GA were dependent on the endothelium and that GA did not directly affect soluble guanylate cyclase or other smooth muscle cell machinery required for NO-dependent vasodilation. These studies, in conjunction with the recent demonstration that activation of eNOS was facilitated through HSP90 signaling[23], suggested that eNOS activation in the portal hypertensive vasculature might be linked to a signaling pathway depending on HSP90. Thus we put forward the hypothesis that HSP90 signaling pathway potentiates the activity of eNOS, which results in NO overproduction and thereby induces hyperdynamic circulation in portal hypertension. However, the inability of GA to completely reverse the hyporesponsiveness to MTX in portal hypertensive mesentery suggested that other regulatory pathways for NOS activation in portal hypertension were also involved. In addition, it is possible that a small part of NO derived from iNOS might also contribute to hyperdynamic circulation in portal hypertensive vessels.

In summary, this study suggested that HSP90 played a key role in the NO-dependent hyporeactivity observed in portal hypertension. This interaction likely served to mediate NO-dependent responses in the perfused mesenteric vasculature. Taken together, the present study indicates that HSP90 is responsible for hyperdynamic circulation in portal hypertension, and pharmacological inhibition of the signal system may provide a novel target for future treatment of portal hypertensive complications such as ascites and fatal variceal bleeding.

Abstract

AIM: To investigate the expression and mutation of c-kit gene and its correlation with the clinical pathology and prognosis of gastrointestinal stromal tumors (GISTs).

METHODS: A total of 94 cases of GISTs, 10 leiomyomas and 2 schwannomas were studied for the expression of KIT by immunohistochemistry. The c-kit gene mutations in exon 11 of these specimens were detected by PCR-SSCP technique.

RESULTS: Of the 94 cases of GISTs, 91 (96.8 %) expressed the KIT protein. Leiomyomas and schwannomas were negative for KIT. The c-kit gene mutations of exon 11 were found in 38 out of the 94 cases of GISTs (40.4 %). The mutations involved point mutations (Val560-Asp, Ile563-Met), del 557-559 and 579ins12. No mutations were detectable in benign GISTs, leiomyomas or schwannomas. The patients with mutation-positive GISTs showed more frequent recurrences, invasion and metastasis in adjacent tissues than those with mutation-negative ones.

CONCLUSION: KIT is a useful marker for diagnosis of GISTs. Mutation of the c-kit gene may play a significant role in the pathogenesis of GISTs and may be associated with poor prognosis in patients with GISTs.

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the human gastrointestinal tract that may occur in the entire gastrointestinal tract[1-4]. In recent years, much attention has focused on GISTs. Studies have shown that GISTs strongly express the KIT protein[1,5,6], a type III tyrosine-kinase receptor encoded by the c-kit proto-oncogene[7,8]. The c-kit gene located in the long arm of chromosome 4, is the cellular homologue of oncogene v-kit of the HZ4 feline sarcoma virus[9]. KIT, which is structurally related to the receptors for platelet-derived growth factor and colony-stimulating factor, consists of an extracellular domain, a transmembrane domain, a juxtamembrane domain and a kinase domain with an insert that splits the kinase domain[10]. KIT and its ligand, stem cell factor (SCF), are known to play crucial roles in the development of germ cells, melanocytes, mast cells and interstitial cells of Cajal[11].

Recently, activated c-kit mutations have been identified in GISTs. Most mutations were detected in the juxtamembrane domain (Lys-550 to Val-560)[1,12-14]. These mutations were related to a poorer prognosis. The purpose of this study was to examine the KIT expression and characterize the range of c-kit mutations in GISTs, and to evaluate the significance between c-kit mutations and prognostic factors.

MATERIALS AND METHODS

Patients

Ninety-four cases of GISTs (62 male, 32 female) diagnosed at Changhai Hospital with a median age of 53 years (ranging from 5-77) were included in the study between January 1991 and December 2002. Forty-six tumors were located in the stomach, thirty-two in the small bowel, ten in the large intestine, three in the esophagus and three in the omentum and mesentery. We used Lewin's determination to separate benign from malignant lesions[15]. Sixty-seven cases of GISTs were malignant and 27 were benign. Of the patients in the malignant group, ten received reoperation due to recurrences, distant metastasis was found in 6 patients at the time of surgery, four to the liver and two to both the liver and peritoneum. The remaining patients were free of distant metastasis. One patient with liver metastasis died after operation. Twelve control tumors were also analyzed, including 10 leiomyomas and 2 schwannomas.

Immunohistochemistry

A rabbit polyclonal antibody against human KIT and an EnVision kit were purchased from DAKO. Immunohistochemistry was performed using the two-step technique. All specimens were fixed in 10 % buffered formalin and embedded in paraffin. Four-μm thick sections were cut from the tissue blocks. The sections were deparaffinized and rehydrated, then treated using a microwave epitope retrieval technique with citrate buffer, pH 6.0 at 85 ℃ for 3 min. After cooled at room temperature, the sections were washed in PBS (0.01M, pH7.2) and incubated with the antibody against c-kit (1:100) at room temperature for 1 hour. After washed in PBS, the sections were incubated with the EnVision compound at room temperature for 30 min. Staining was developed by immersing slides in 0.05 % DAB with 0.33 % hydrogen peroxide. All slides were counterstained with haematoxylin, dehydrated and mounted. PBS substituted for the primary antibody was used as the negative control.

DNA Extraction

DNA was extracted from formalin-fixed, paraffin-embedded tissues using standard methods with proteinase K digested and phenol/chloroform purified.

PCR-SSCP

Exon 11 of the c-kit gene was amplified by PCR using the following oligonucleotide primer pairs: sense primer 5'-

AACTCAGCCTGTTTCTGG-3' and antisense primer 5'-GATCTATTTTTCCCTTTCTC-3'. PCR was carried out with the following conditions: 50 μl total reaction volume, with 5 μl template, 5 μl of each oligonucleotide primer, 10 μl dNTP, 10 μl ddH_2O, 2 μl Taq polymerase, 8 μl Mg^{2+} and 5 μl 10×PCR buffer. Cycling conditions were as follows: an initial penetration at 95 ℃ for 4 min, 38 cycles each at 94 ℃ for 1 min, at 56 ℃ for 1 min, at 72 ℃ for 1 min, followed by one cycle at 72 ℃ for 10 min. PCR products were visualized by gel electrophoresis in 1.7 g/L agarose. Then the PCR products were subjected to 8 % non-denaturation polyacrylamide gel electrophoresis (aer: bis=49:1) with 5 % glycerin and silver nitrate staining.

DNA sequencing

PCR products that showed abnormal gel shift by PCR-SSCP were selected for sequencing after cloned into PMD18-T vector. The sequencing procedures were performed by Sangon Co., Shanghai.

Statistical methods

The data were analyzed with χ^2 test.

RESULTS

Immunohistochemistry

Immunohistochemical analyses revealed strong and diffuse KIT expression in 91 out of the 94 cases of GISTs. The positive signals were localized in cytoplasm and membrane (Figures 1 and 2). Ninety-seven percent of malignant GISTs and ninety-six percent of benign GISTs were KIT positive. Compared with the benign group, some malignant GISTs showed weaker and focal positivity. There was no significant difference in the expression of KIT between benign and malignant GISTs (P>0.05). Leiomyomas and schwannomas were negative for KIT.

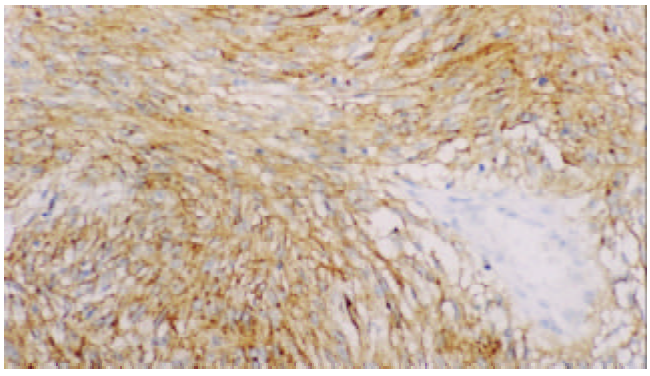

Figure 1 KIT staining in cytoplasm and membrane of GISTs (spindle type)×200.

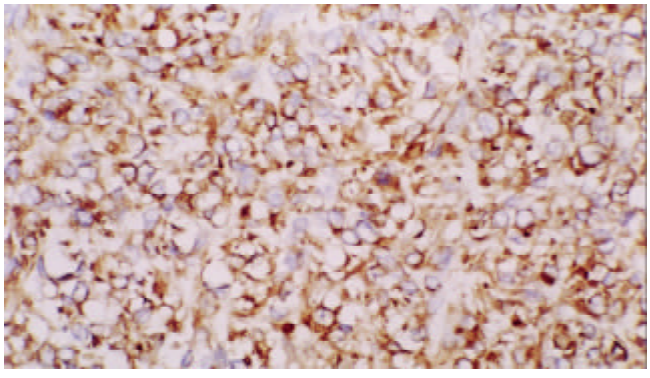

Figure 2 KIT staining in cytoplasm and membrane of GISTs (epithelioid type)×200.

Evaluation of mutations in exon 11 of c-kit gene

Analysis of PCR-SSCP showed abnormal gel shifts in 38 out of the 67 (56.7 %) malignant GISTs. No mutant bands were observed in benign GISTs, as well as in leiomyomas and schwannomas. Sequencing of 6 mutant bands revealed three types of mutations. One case showed point mutations (Val560-Asp and Ile563-Met), one case a 6-bp deletion involving codons 557 to 559, one case a 12-bp insertion at the codon 579 (Figure 3).

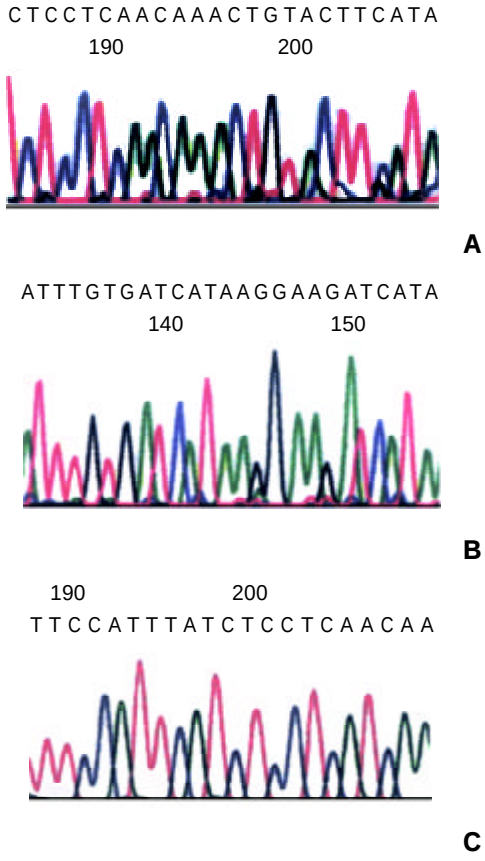

Figure 3 Sequence of the exon 11 of c-kit from the mutant bands obtained from the GISTs. A: 6-bp deletion involving codons 557 and 559 (GGAAGG), B: 12-bp insertion at codon 579 (CTTCCTTATGAT), C: two point mutations (Val 560-Asp, Ile 563-Met).

Correlation of c-kit mutations with clinicopathological parameters

Of the 38 cases of GISTs with c-kit mutations, six developed distant metastasis, eight had local recurrences and one died of liver metastasis. Only two recurrences were found in the remaining 56 cases of GISTs without c-kit mutations.

DISCUSSION

It has been reported that GISTs are strongly and nearly consistent KIT positive and mutations of the c-kit gene were observed in GISTs. In this study, we examined the sequences and expression of c-kit in the spectrum of GISTs, including benign and malignant variants from different sites. The expression and mutations of the c-kit gene were also evaluated in leiomyomas and schwannomas.

As this study has shown, 96.8 % (91/94) GISTs strongly and diffusely expressed KIT irrespective of tumor location, histologic subtype and grade. Neither age nor sex was significantly correlated with the expression levels of KIT. The findings were in agreement with the previous studies[16-18]. No

expression of KIT was found in leiomyomas and schwannomas. These results verified that KIT was a sensitive diagnostic marker for GISTs, but it could not be used as a prognostic index[19,20].

Recently, mutations of the c-kit gene were observed in GISTs. Most mutations were located at the juxtamembrane domain encoded by exon 11, especially between codons 550-560. Mutations of exon 11 were observed in 40.4 % (38/94) of GISTs in our study, and other group observed mutations of exon 11 in 57 %, 42 % and 21 % of GISTs[6,13,21]. The difference in mutation rates appeared to be due to the proportion of malignant GISTs, as suggested by our data and the previous reports. Some studies have shown that the mutant types including insertions or duplications, in addition to deletions and point mutations. These were consistent with our results. DNA sequencing showed that point mutations, deletions and insertions were found in our six GISTs and the range of the c-kit mutations was not only between codons 550-560 but also at codon 579. Although 96.8 % of GISTs expressed KIT, only 40.4 % of GISTs showed mutations in the juxtamembrane region of the c-kit gene. This indicated that some KIT-positive GISTs could occur without mutation of the c-kit gene or with mutations other than exon 11 of the c-kit gene. There was another possibility that some mutations of the NF-1 gene might result in the occurrence of KIT-positive GISTs[1,16,22]. Moreover, the mutations of exons 9, 13, 17, 14 and 15 in GISTs have been identified in recent years[23-25]. But mutations in these exons were found to be few compared with in exon 11[26,27]. These observations demonstrate that multiple mutations of c-kit, irrespective of domain-extracellular, juxtamembrane or kinase, are crucial tumorigenic events in GISTs.

Since c-kit mutations are commonly found in GISTs, how these mutations lead to kinase activation is a field of active investigation. KIT participates in complex networks of signal cascade proteins, and some of these proteins regulate KIT activation in positive or negative manners. Under normal conditions, KIT activation occurs when the receptor is bound to its ligand, a stem cell factor. Ligand-mediated KIT activation triggered various cell-signaling cascades that regulate cell behavior[28,29]. The c-kit mutations of these domains resulted in activation of kinase by allowing ligand-independent receptor dimerization[30-32]. In other words, the mutations in GISTs lead to structural changes of KIT oncoproteins that favor receptor oligomerization and cross-phosphorylation, even in the absence of ligand binding. Because activation of KIT is a ubiquitous oncogenic pathway in most GISTs and important to the growth of GISTs, it has become possible that patients with GISTs can be treated with STI571, a KIT tyrosine kinase inhibitor. STI571 is a 2-phenylaminopyrimidine that selectively inhibits protooncogenic and oncogenic forms of the ABL, PDGFR and c-kit tyrosine kinases[33,34]. STI571 has a potent activity against GIST cells grown *in vitro* and the majority of patients with malignant GIST have shown a benefit to treatment with STI571 in recent clinical trials[35-37].

Finally, we compared clinical outcome between the mutation-positive and negative GISTs, and found more frequent recurrences and poorer prognosis were related with mutation-positive GISTs. In our study, 6 out of the 38 patients with mutation-positive GISTs developed distant metastasis, 8 had local recurrences and 1 died of GIST, whereas only 2 out of the 56 patients with mutation-negative GISTs had recurrences. These findings are consistent with some other previous results[1,6,13,38,39], and indicate that the c-kit mutations seem to be related to poorer prognosis. But there is an opposite opinion recently. The results showed that these mutations occurred very early in the course of GISTs development and were of little prognostic importance in GISTs[40]. And now cytogenetic abnormalities have been detected in GISTs[41-43]. These findings suggest that molecular alterations and c-kit mutations are likely to be involved in determining the biologic behaviors of both benign and malignant GISTs.

Considering these findings, we conclude that most GISTs strongly and diffusely express KIT protein, and KIT is a useful and sensitive marker for diagnosis of GISTs. C-kit mutation is undoubtedly a pivotal event in GISTs and may be associated with poor prognosis. Evaluation of KIT mutation may have both prognostic and therapeutic significances as the new tyrosine kinase inhibitor (STI571) treatments are available. The correlation between c-kit mutations and clinical behaviors is far more complex than initially appreciated, and further studies are needed.

Abstract

AIM: To explore the correlation of magnifying endoscopic patterns and histopathology, *Helicobacter pylori (H pylori)* infection of the gastric mucosa.

METHODS: Gastric mucosal patterns in 140 patients with chronic gastritis were studied using Olympus GIF-Q240Z magnifying endoscope. Histopathological examination, rapid urease test and Warrthin-Starry staining were taken with biopsy samples from the magnified sites of stomach. The magnifying endoscopic patterns were compared with histopathological results and *H pylori* detection.

RESULTS: The pit patterns of gastric mucosa were classified as types A (round spot), B (short rod), C (branched), D (reticular) and E (villus). The detection rate of chronic atrophic gastritis (CAG) by magnifying endoscopy was 94.3 % (33/35), which was significantly higher than that by routine endoscopy (22.9 %, 8/35) ($P<0.01$). The pit patterns of 31 cases of intestinal metaplasia (IM) appeared as type E in 18 cases (58.1 %), type D in 8 cases (25.8 %) and type C in 5 cases (16.1 %). Fourteen out of 18 patients (77.8 %) with complete type (type I) of IM appeared as type E of pit patterns, whereas only 4 of 13 (30.8 %) patients with incomplete type (types II and III) of IM appeared as type E ($P<0.05$). Collecting venules in the anterior of lower part of gastric corpus were subgrouped into types R (regular), I (irregular) and D (disappeared). *H pylori* infection was found in 12.2 %(9/74), 60 %(9/15) and 84.3 %(43/51) cases in these types respectively. *H pylori* infection rate in type R was significantly lower than that in other two types ($P<0.01$).

CONCLUSION: Magnifying endoscopy may have an obvious value in diagnosing chronic atrophic gastritis, intestinal metaplasia and *H pylori* infection.

INTRODUCTION

Recently, magnifying endoscope has been used clinically for its developments in amplifying power, definition and operational capability. Lots of international studies on clinical application of magnifying endoscope especially from Japan have been reported, but most of them were focused on colon and esophagus, only a few of them on gastric mucosa have been published[1-28]. These studies implicate that classification of superficial mucosal appearances defined by magnifying endoscopy can reflect not only histological features but also mucin phenotypes. Magnifying endoscopy is helpful for more correctly distinguishing hyperplastic lesions from adenomatous and cancerous lesions, and for improving detection of early flat and depressed cancer. More interestingly, according to Japanese data, magnifying endoscopy could also be used to predict invasive depth and lymph node metastasis of cancer[6,16]. Up to now only a few studies on the field have been reported in China[29-33]. In this article, we reported our study on correlation of magnifying endoscopic patterns and histopathology, *Helicobacter pylori (H pylori)* infection of gastric mucosa in 140 patients with chronic gastritis to understand the value of magnifying endoscopy in diagnosing the minute lesions of gastric mucosa.

MATERIALS AND METHODS

Subjects

Subjects were 140 out-patients and in-patients (male: 68, female: 72, age range: 18-77 years old, average age: 50.6) with chronic superficial gastritis (CSG, $n=105$) and chronic atrophic gastritis (CAG, $n=35$) during June-August, 2002. All the patients had gastrointestinal symptoms such as abdominal distention, abdominalgia, belch and hyperhydrochloria.

Magnifying endoscope

New model of electronic magnifying endoscope GIF Q-240Z (Olympus Optical Co., Ltd., Tokyo, Japan) was used. It could be used to perform routine endoscopy (observation at standard magnification) as well as to magnify the image 80 times (in 14-inch monitor) as large as the original size through manual adjustment of the focal length.

Endoscopy

Magnifying endoscopy was performed by senior endoscopists and the real time static and successive images were recorded by computer image and text reporting system and video tape recorder. In order to inhibit gastrointestinal peristalsis, 10 mg of anisodaminum (654-2) and 5-10 mg of diazepamum were injected intramuscularly at 10 minutes pre-endoscopy. Routine endoscopy was performed first, and if necessary, dilution of dimethyl silicone oil was used to flush off the foam and mucus, then the appearance of gastric pits in the antrum, angel, corpus and fundus, and collecting venules in the anterior of lower part of gastric corpus were observed so that the patterns of gastric pits and collecting venules could be decided.

Histological examination

One piece of tissue in the greater curvature of gastric antrum was extracted for rapid urease test using RUT kit (Kedi Technology Co., LTD, Zhuhai, China). Two biopsies from the magnified sites in gastric antrum and corpus were performed for hematoxylin-eosin (HE) and Warrthin-Starry staining. Rapid urease test and Warrthin-Starry staining were used for

H pylori detection[34,35]. According to the national standard of China, *H pylori* infection was established after positive results were confirmed by both rapid urease test and Warrthin-Starry staining[35]. HE staining was performed for routine histopathological examination. Inflammatory levels were graded as mild, moderate and severe types according to the infiltration depth of <1/3, 1/3-2/3 and >2/3 of inflammatory cells in the mucous layer and CAG was graded as mild, moderate and severe types according to the decreased levels of <1/3, 1/3-2/3 and >2/3 of the intrinsic glands[35]. At the same time, mucus histochemical stainings of AB/PAS for distinguishing acid mucus from neutral mucus and AF/AB for distinguishing sulphomucins from sialomucins were performed on the samples with IM confirmed by histopathological examination. According to the histological structures and properties of mucus excreted by cells, IM was classified into type I (complete type), type II (incomplete small intestinal type) and type III (incomplete colonic type)[36].

Statistical analysis

Chi-square test was applied and *P* values less than 0.05 were considered significant.

RESULTS

Pit patterns and pathohistological findings

Classification of gastric pits Based on the analysis of recorded static and successive images and refered to Guelrud' s study on mucosal patterns of Barrett' s esophagus with enhanced magnification endoscopy[18], we classified gastric pits into the following five fundamental types: type A, round-spot-like, distributing only in the gastric corpus and fundus with basically normal histology; type B, short-rod-like, with deeper pits, branches and curvatures fewer than those in type C, mainly distributing in the gastric antrum without obvious lesions such as inflammation; type C, with elongated and tortuous pits with obviously increased branches and curvatures, connected to present branch-like form, seen in mucosa with pathological changes as inflammation, edema and IM; type D, with reticular pits, seen in areas with more severe inflammation, edema and IM, also found in mucosa around erosion and ulcers; and type E, with villus-like pits, or with finger-like tubers, similar to enteral villus-like changes, seen only in the areas with IM (Figure 1). Overlappings and crossings of gastric pits might be present except the above five fundamental patterns. For example, a combination of type A and type B of gastric pits was frequently presented in the gastric angle.

In types B, C, D and E, moderate and severe inflammations were seen in 18.6 %(26/140), 85.1 %(40/47), 100 %(13/13) and 88.9 %(16/18) cases respectively. The inflammatory levels in types C, D and E were significantly higher than those in type B ($P<0.01$).

Features of atrophic gastritis under magnifying endoscope Under routine endoscope, changes of rough mucosa, unflat granules, increased white areas, exposure of submucous vessels could be seen in CAG[35]. Generally, theses changes could be

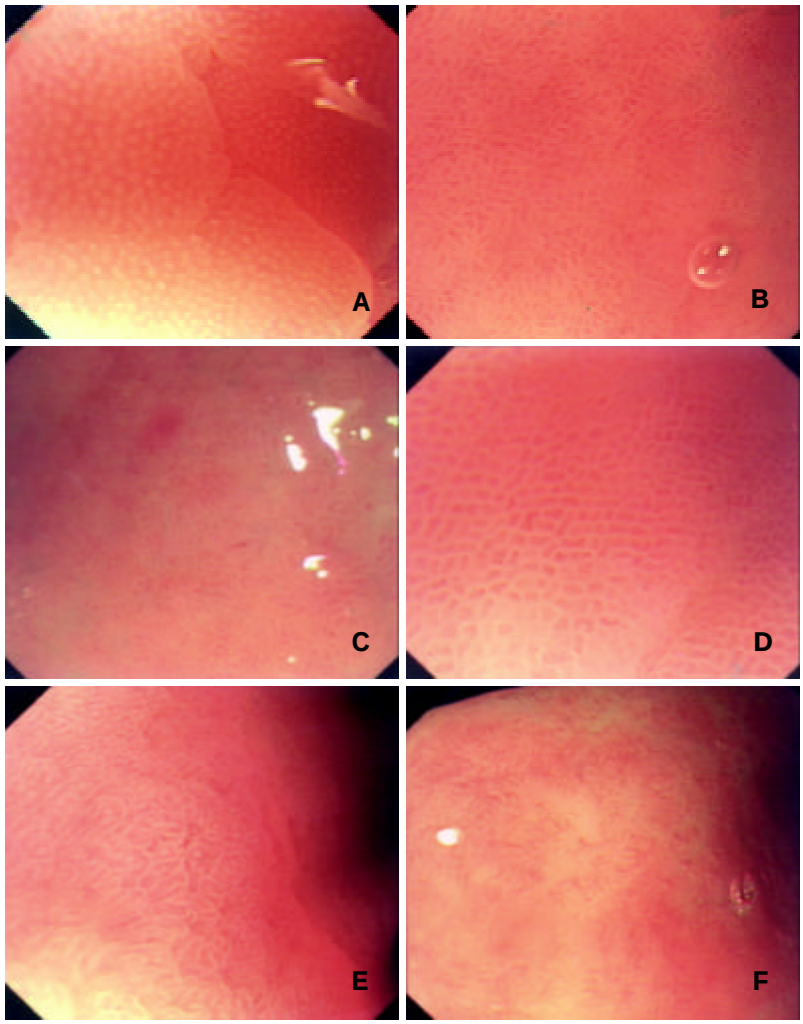

Figure 1 Pit patterns of gastric mucosa under magnifying endoscope. A: Type A: Gastric pits appeared as round spot, B: Type B: Gastric pits appeared as short rod, C: Type C: Gastric pits appeared as branched, D: Type D: Gastric pits appeared as reticular, E: Type E: Gastric pits appeared as villus, F: CAG: Decrease and disappearance of gastric pits.

more easily found in severe CAG, but it was hard to identify them in mild CAG. However, under magnifying endoscope, remarkably characteristic changes of CAG could be seen. With a comparatively low magnifying power, obvious red-white mucosa and increased white areas could be identified. When with enhanced magnifying power, disordered structures, decrease in quantity and even disappearance of pits as scar-like change could be observed in white areas (Figure 1-F).

Thirty-five patients with different grades of gastric mucous atrophy were confirmed by pathological examination in 140 patients, in which 27 in gastric antrum, 5 in gastric angle, 3 in gastric corpus, 16 with mild atrophy, 7 with moderate atrophy and 12 with severe atrophy. By routine endoscopy, only 8 patients (2 with moderate atrophy, 6 with severe atrophy), but by magnifying endoscopy, CAG-related changes were found in 33 patients (14 with mild atrophy, 7 with moderate atrophy, 12 with severe atrophy). The detection rates of atrophic gastritis by routine endoscopy and magnifying endoscopy were 22.9 %(8/35) and 94.3 %(33/35) respectively and significant difference was found by comparison of the two kinds of endoscopy (P<0.01).

Features of intestinal metaplasia under magnifying endoscope It was reported that characteristic changes such as light yellow or ivory-white nodosity-like, fishscale-like and diffusing granule-like appearances of IM in gastric mucosa could be found under routine endoscopy[37]. In this study, by analysis of magnifying endoscopy images of 31 patients with IM, we found that there were mainly three patterns of gastric pits in IM mucosal areas: type C (5 cases), type D (8cases) and type E (18cases). Particularly, very high specificity was found in type E. IM was confirmed pathologically in all the samples of 18 patients with type E. After classification of all the samples with IM by mucous histochemical staining, a certain relation was found between the patterns of gastric pits and classification of IM mucin phenotypes, as was shown in Table 1. Fourteen out of 18 patients (77.8 %) with complete type (type I) of IM appeared as type E of pit patterns, whereas only 4 of 13 (30.8 %) patients with incomplete type (types II and III) of IM appeared as the same type of pit patterns (P<0.05).

Table 1 Relation between IM pit patterns and IM mucin phenotypes

Pit patterns	Cases	Type I IM	Type II IM	Type III IM
Type C	5	2	3	0
Type D	8	2	5	1
Type E	18	14	3	1
Total	31	18	11	2

Architecture of collecting venules and H pylori infection

With reference to Yagi's literature[26], we classified the architecture of collecting venules into the following three types: type R (regular type) with diameter of minor venules being 0.4-0.5 mm and regular spider-like and jellyfish-like arrangement, type I (irregular type) in which decrease in quantity of collecting venules could be unclearly found with irregular arrangement, and type D (disappeared) in which collecting venules could not be found under magnifying endoscope (Figure 2).

When the patients in which positive *H pylori* was confirmed by both rapid urease test and Warrthin-Starry staining were regarded as being infected by *H pylori*, the *H pylori* infection rates in the patients with regular (R), irregular (I) and disappeared (D) types of collecting venules were 12.2 %, 60 % and 84.3 %, respectively. Statistical analysis revealed that *H pylori* infection rates in the patients with types D and I were markedly higher than those in patients with type R (P<0.01), but there was no significance between type I and type D (P>0.05). A comparison of different types of collecting venules by the corresponding rapid urease test and by Warrthin-Starry staining is shown in Table 2.

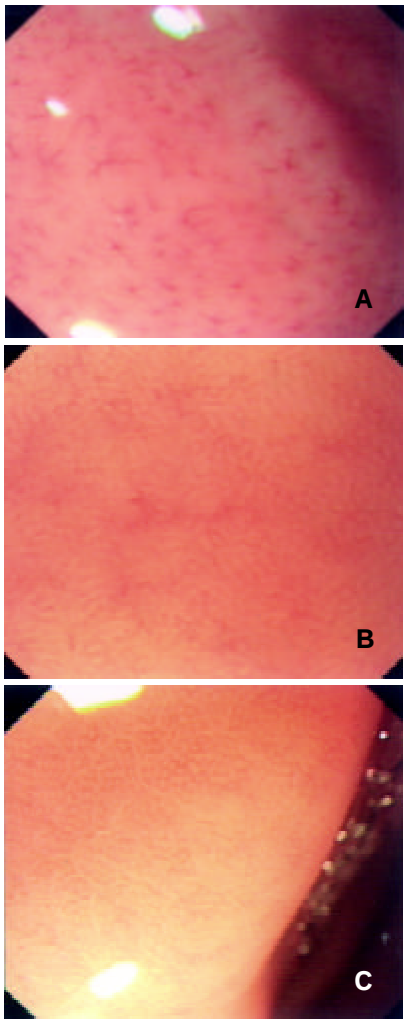

Figure 2 Architecture of collecting venules under magnifying endoscope. A: Type R: Regular spider-like arrangement of collecting venules, B: Type I: Unclear irregular arrangement of collecting venules, C: Type D: Disappearance of collecting venules.

Table 2 Relation of different architectures of collecting venules and *H pylori* infection

Collecting venules	Cases	Rapid urease test (+)	W-S staining (+)	Both methods(+)
Type R	74	9(12.2 %)	13(17.6 %)	9(12.2 %)
Type I	15	11(73.3 %)	9(60 %)	9 (60 %)
Type D	51	43(84.3 %)	45(86.3 %)	43(84.3 %)

DISCUSSION

The pit patterns observed on the mucosal surface are considered to reflect the arrangement and structure of surface epithelia, morphology, number, distribution, and function of glands, mucosal edema and inflammation, and vascular morphology, arrangement, number and distribution. The basic units of the microstructures on the surface of gastric mucosa are countless gastric pits that form gastric areas separated by minor gastric grooves (also called interval grooves). As the openings of glands, gastric pits are the first to have changes of the structures due to gastric mucosal lesions. Magnifying endoscope can be

used to observe the minute architecture of gastric pits because it has the similar magnifying power to that of stereomicroscope.

In this research, we studied the correlation of magnifying endoscopic patterns and histopathology, *Helicobacter pylori* infection of the gastric mucosa in 140 patients with chronic gastritis. There has been no widely accepted standard to the classification of gastric pits under magnifying endoscope, so the classification method, we used, was based on the analysis of our recorded static and successive images by magnifying endoscopy in the 140 patients and referred to Guelrud' s study on mucosal patterns of Barrett' s esophagus with enhanced magnification endoscopy[18]. Type A and type B represented the manifestation of normal gastric pits in gastric corpus and antrum, which concerned the distribution of gastric glands. Single tabular glands with short and fine neck were found in the gastric corpus and fundus, so gastric pits were presented with round spots as the openings of the gastric glands. Glands in frontal area of pyloric ostium and in gastric antrum were of multi-branches and curvatures and 3-5 glands often shared the same opening in one pit, thus the pits in frontal area of pyloric ostium and gastric antrum were short rod-like and deeper and longer than those of type A. Types C and D were formed by the enlargement, elongation, tortuosity of pits and connection of pits due to the pathological changes as inflammation and edema but type E might be the characteristic changes of intestinal metaplasia. Studies by Endo *et al.* of the mucosa with intestinal metaplasia in Barret esophagus in gastric cardia also revealed that villus-like pits were the characteristic change due to intestinal metaplasia[15].

Gastric mucosal atrophy could be identified by routine endoscopy usually when it was at more severe grade. Under magnifying endoscopy, disordered structures, deficiency and even disappearance of gastric pits were of high detection rate and accuracy for atrophic gastritis. As to mild and moderated grades of atrophy, the diagnostic sensitivity by magnifying endoscopy was higher than that by routine endoscopy. The decrease and disappearance of gastric pits due to atrophy were different from mucosal defect due to erosion in which there usually smooth-edged pits belonging to types C and D.

It was reported that characteristic changes such as light yellow or ivory-white nodosity-like, fishscale-like and diffusing granule-like appearances of intestinal metaplsia in gastric mucosa could be found under routine endoscopy[37]. The intestinal metaplasia could be classified into complete and incomplete types according to the histological structures and the properties of mucus excreted by cells[36]. In our study, the pit patterns of 31 patients with intestinal metaplasia appeared as type E in 18 (58.1 %), type D in 8 (25.8 %) and type C in 5 (16.1 %). Fourteen out of 18 patients (77.8 %) with complete type (type I) of intestinal metaplasia appeared as villus-like and finger-like changes (type E) of pit patterns, whereas only 4 out of 13 (30.8 %) patients with incomplete type (types II and III) of intestinal metaplasia appeared as the same type of pit patterns ($P<0.05$), suggesting type E of gastric pits was the result of characteristic change of complete intestinal metaplasia. In addition, our study also reveals that pits of incomplete intestinal metaplasia mainly belonged to types C and D (9/13, 69.2 %). Nevertheless, the above studies were still at preliminary stage with a small number of samples and further studies should be conducted to draw the final conclusion.

Collecting venules are tiny venules in gastric mucosa directly connected with capillary vessels. A few reports have been made on the architecture of collecting venules in gastric mucosa by magnifying endoscopy in which it was regarded as having certain specificity and feasibility to detect *Helicobacter pylori* infection[25,26]. It has also been verified by our study that *Helicobacter pylori* infection rate of patients with type R collecting venules was significantly lower than that with types I and D, suggesting that magnifying endoscopy was of high value in the diagnosis of *Helicobacter pylori* infection in gastric mucosa. As to the causes leading to the changes of collecting venules when *Helicobacter pylori* infection occurs, it has been reported that they were found in types I and D, in which remarkable increase of infiltration of neutrophils and monocytes was found and the architecture of collecting venules might be affected by edema of mucosa due to *Helicobacter pylori* infection[25,26]. However, further studies of the precise mechanism should be conducted because there are some other causes resulting in edema of mucosa.

In conclusion, it is a novel topic in the field of digestive endoscopy to diagnose minute lesions in gastric mucosa by magnifying endoscopy. Our preliminary study has shown that magnifying endoscopy is of high value in the diagnosis of gastric mucosal atrophy, intestinal metaplasia and *Helicobacter pylori* infection. However, the pit patterns of gastric mucosa, particularly those under magnifying chromoendoscopy are very complicated and there has been no widely accepted standard on the classification. Therefore, further studies are suggested on the clinicopathological significance of different patterns of gastric pits, particularly the characteristic changes of gastric pits and microvessels of intramucosal gastric carcinomas.

Abstract

AIM: To examine the regional variations in mortality rates of pancreatic cancer in China.

METHODS: Aggregated mortality data of pancreatic cancer were extracted from the 1990-1992 national death of all causes and its mortality survey in China. Age specific and standardized mortality rates were calculated at both national and provincial levels with selected characteristics including sex and residence status.

RESULTS: Mortality of pancreatic cancer ranked the ninth and accounted for 1.38 percent of the total malignancy deaths. The crude and age standardized mortality rates of pancreatic cancer in China in the period of 1990-1992 were 1.48/100 000 and 1.30/100 000, respectively. Substantial regional variations in mortality rates across China were observed with adjusted mortality rates ranging from 0.43/100 000 to 3.70/100 000 with an extremal value of 8.7. Urban residents had significant higher pancreatic mortality than rural residents.

CONCLUSION: The findings of this study show different mortality rates of this disease and highlight the importance of further investigation on factors, which might contribute to the observed epidemiological patterns.

INTRODUCTION

Pancreatic cancer is a relatively common malignant disease in the world, both its incidence and mortality rate are ranked in the first ten cancers[1,2]. Especially in recent years, a gradually increased tendency of the disease has been found[3-6]. About 200 000 new cases of pancreatic cancer are reported worldwide annually. Despite the overall improvement in cancer diagnosis and treatment in the past half century, there has been little change in the survival of pancreatic cancer patients. The reported worldwide annual incidence accounts for 2 % of all malignant tumors and is associated with about 196 000 deaths from the disease[7-11]. Though pancreatic cancer is relatively uncommon in China, but it still accounts for substantial cancer related deaths because of its dismal survival rate. Thus, the mortality rate of this disease serves as a mirror for its incidence. Notwithstanding previous studies in China have shown that there were significant geographic variations for several cancer sites, such as liver and esophagus, little is known for pancreatic cancer[12-14]. As the causes of pancreatic cancer are largely unknown, epidemiological studies on regional mortality rate variations may shed light on seeking possible modifiable factors associated with this disease.

MATERIALS AND METHODS

Data source

1990-1992 national mortality survey As China does not have a centralized vital statistics system and cancer registration, national level information on disease specific mortality is often based on periodic national mortality surveys (NMS), the first of which was initiated in the early 1970s. Its purpose was to generate nationally representative estimates of mortality due to various health conditions, such as cancer, heart disease and stroke. The more recent one was conducted between 1990 and 1992 with the primary focus on malignant tumors, which was the data source for this study.

Briefly, the 1990-1992 NMS was a two-stage stratified probability survey. At the first stage, each of the 22 provinces, 5 autonomous regions, and 3 municipatities directly administrated cities under the Central Government (Beijing, Shanghai, and Tianjin) represented one of 30 strata. For the ease of the presentation, we referred to the 30 strata as "areas". The second stratum was formed at county or district level according to the cancer mortality levels (2-3 levels from low to high) from the previous survey. Thus, the primary sampling unit for this survey was county or district (for Beijing, Shanghai and Tianjin). Overall, the sample size for this survey was designed to cover 10 % of all deaths or 242 million baseline person years during the study period. Detailed information can be found from the National Mortality Survey Manual. With respect to pancreatic cancer, samples from 8 of the first level strata did not have sufficient number of cases to generate meaningful estimates, thus the mortality estimates were only applicable to 22 of the first level strata. Specifically, the 22 areas were Beijing, Tianjin, Hebei, Shanxi, Neimeng, Liaoning, Jilin, Heilongjiang, Shanghai, Jiangsu, Anhui, Jiangxi, Fujian, Henan, Hunan, Hainan, Guangxi, Sichuan, Yunnan, Guizhou, Gansu, and Ningxia.

Case assessment and baseline population All death certificates were retrieved from the local death registration offices for the sampled counties or districts. Local neighborhood representatives were also interviewed to further verify each deceased person for possible misreporting and discover deaths not reflected at death registration offices. Causes of deaths obtained from death certificates were checked with clinical records. When clinical records were missing or

not available, possible diagnoses were solicited from the medical professionals who had once treated the case. Each reported cause of death was further converted into 3-digit ICD-9 codes and pancreatic cancer was determined for ICD-9 157. Age-sex specific population data for each surveyed county or district were derived from interpolation using the data from the two most recent censuses conducted in 1982 and 1990.

Statistical analysis

Both crude and age-sex adjusted mortality rates were calculated both at provincial and national levels. In order to make the estimates comparable to reported mortality data from other populations, two standard populations were used: the 1980 Chinese population and the world standard population. The extremal quotient (EQ) was used to quantify regional variation[15]. The EQ is the ratio of the mortality from area with the highest level relative to the area with the lowest level. Age standardised mortality rates from each individual area (defined by resident status) were derived and compared with the corresponding national mean and median using the 1990-1992 NMS. In addition to assessing differences in mortality rate among areas and national levels, we also juxtaposed pancreatic cancer with other leading cancers, such as lung and breast cancers in terms of their relative ranking.

RESULTS

In total, pancreatic cancer deaths were identified from the 181 primary sampling units (counties or districts), among which 54 and 127 were considered as urban and rural respectively.

Table 1 displays the crude and standardized mortality rates of pancreatic cancer. As shown in this table, the crude and Chinese population adjusted mortality rates were 1.29 and 1.08 per 100 000 person-year during the study period.

Table 1 Selected indices derived from pancreatic cancer mortality (1/100 000) in China, 1990-1992

	Crude rate	ASMR1	ASMR2	Mortality proportion to all cancer death (%)
Total	1.48	1.30	1.74	1.38
Male	1.65	1.52	2.03	1.25
Female	1.29	1.08	1.46	1.62

ASMR: Age adjusted mortality rate, 1=the Chinese population in 1980, 2=world population.

Table 2 compares the mortality of pancreatic cancer with other leading cancers in terms of standardized rates, mortality proportion, and relative ranking. Overall, the mortality of pancreatic cancer ranked the 9th and accounted for 1.38 % of total cancer deaths after colon cancer.

While pancreatic cancer could occur at any age, its mortality varied greatly among different age groups. The mortality remained low and did not increase until age 45, there was a steep increase in both males and females from age 45 to age 75 before it reached a plateau around 75. There seemed to be a mortality drop in males after age 75. Pancreatic cancer mortality rates were apparently higher in males than in females, with the ratio 1.4:1.

Regional comparisons (Table 3) suggested that a substantial variation in pancreatic cancer mortality across the 22 regions and standardized mortality rates varied from the lowest 0.47/100 000 person-year in Hunan Province to the highest 3.73/100 000 person year in Shanghai with an extremal quotient of 8.76. Using the national average level as a standard, eight provinces had a rate higher than average and they were Shanghai, Tianjin, Liaoning, Heilongjiang, Jiangsu, Jilin, Beijing, and Ningxia. However, there was little variation in terms of mortality, sex ratios varying between 1.07 and 2.3, most of the values were around 1.5.

Female	Urban	2.47	21.89
	Rural	0.92	0.80
	U/R ratio	2.68	2.36

DISCUSSION

In this study, we described some epidemiological characteristics of pancreatic cancer using the most recent Chinese mortality survey data. Compared with other previous studies in China, the age standardized mortality rates from this study appeared to be higher than those reported previously. This may suggest that the mortality rate of pancreatic cancer is increasing.

Ecological studies[16-24] found as shown in Figures 2-3 that the mortality of pancreatic cancer seemed to be correlated with the level of economic development. Developed countries, such as Japan and the United States[25-29] had a higher pancreatic cancer mortality than that of less developed countries, such as some African countries[30-33]. China is a big country with unbalanced economic development and diverse lifestyles. The economic developmental gaps between urban and rural areas seen in China are greater than those in the developed countries. Findings from this study suggest substantial regional variations in the mortality rates of pancreatic cancer and in general, economically more developed regions have higher mortality rates than that of less developed regions. For example, Beijing, Shanghai, and Tianjin shared the 3 highest mortality rates. Thus, results from this study are in accord with previous observations.

The use of a population based national representative sample in the present study was unique in its reliability. Also, in this study most death certificates were crossly validated and consequently the reported causes of death were more believable. Furthermore, as all studied areas used uniform standards, the mortality rate estimates across areas had a good comparability. However, there were also limitations associated with this study. First, all information used in this study was derived from the survey, thus the case assessment method could not be compared with clinical diagnosis. Second, since this survey did not collect life style information (such as smoking and diet) for the deceased subjects, we were restricted from further exploring the impact of potential risk factors on this condition. Lastly, only aggregated data were available to the authors, we were unable to calculate the variances for the estimated mortality rates. As a result, we could only provide point estimates without 95 % confidence intervals.

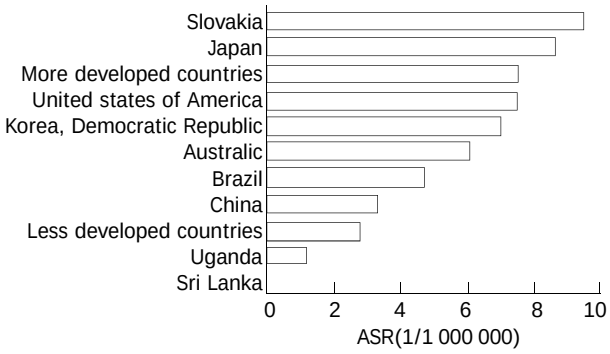

Figure 2 World pancreatic cancer mortality in different countries (male).

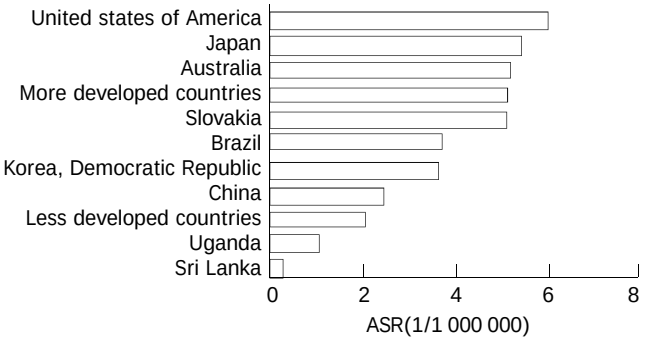

Figure 3 World pancreatic cancer mortality in different countries (female).

In conclusion, we have demonstrated a substantial variation in pancreatic cancer mortality rates across the Mainland China. The results reported in this study beg for answers to the observed differences. As pancreatic cancer is a fast growing disease associated with high fatality, more in-depth epidemiological studies on identifying modifiable risk factors are warranted.

ACKNOWLEGEMENTS

We are grateful to all medical workers from 22 provinces (cities, districts) in China for our data collection and preparation. We want to thank Tianjin Cancer Institute and Hospital for its financial support.

Abstract

AIM: To explore whether intensity modulated radiation therapy (IMRT) in combination with chemotherapy could increase radiation dose to gross tumor volume without severe acute radiation related toxicity by decreasing the dose to the surrounding normal tissue in patients with locally advanced pancreatic cancer.

METHODS: Twenty-one patients with locally advanced pancreatic cancer were evaluated in this clinical trial. Patients would receive the dose of IMRT from 21Gy to 30Gy in 7 to 10 fractions within two weeks after conventional radiotherapy of 30Gy in 15 fractions over 3 weeks. The total escalation tumor dose would be 51, 54, 57, 60Gy, respectively. 5-fluororacil (5-FU) or gemcitabine was given concurrently with radiotherapy during the treatment course.

RESULTS: Sixteen patients who had completed the radiotherapy plan with doses of 51Gy (3 cases), 54Gy (3 cases), 57Gy (3 cases) and 60Gy (7 cases) were included for evaluation. The median levels of CA19-9 prior to and after radiotherapy were 716 U/ml and 255 U/ml respectively ($P<0.001$) in 13 patients who demonstrated high levels of CA19-9 before radiotherapy. Fourteen patients who suffered from pain could reduce at least 1/3-1/2 amount of analgesic intake and 5 among these patients got complete relief of pain. Ten patients improved in Karnofsky performance status (KPS). The median follow-up period was 8 months and one-year survival rate was 35 %. No patient suffered more than grade III acute toxicities induced by radiotherapy.

CONCLUSION: Sixty Gy in 25 fractions over 5 weeks with late course IMRT technique combined with concurrent 5-FU chemotherapy can provide a definitely palliative benefit with tolerable acute radiation related toxicity for patients with advanced pancreatic cancer.

INTRODUCTION

The incidence of pancreatic carcinoma has been continuously increasing worldwide in recent years. The incidence in Shanghai of China has increased to 9.6 per 100 000 for males and 9.2 per 100 000 for females. Most patients have locally advanced unresectable disease at the time of initial diagnosis because of lacking clinical symptoms and signs. Without treatment intervention, the mean time of survival was approximately 4 to 6 months[1]. Although surgery was considered to be the only curative treatment method, there were only 10-20 % patients who had resectable tumors suitable for radical resection and 30-85 % patients would have local recurrences[2].

At present, there are no satisfactory treatment modalities for patients with advanced pancreatic carcinoma. Adenocarcinoma of pancreas is a disease characterized by resistance to cytotoxic therapy including chemotherapy and radiotherapy. Treatment response of systemic chemotherapy is relatively poor with only 20 % response rate, which would last only a short time and most of the treatment effects are partial response. Meanwhile, the conventional radiation dose to gross tumor volume is not large enough to cure patients with pancreatic carcinoma because of the limited tolerant dose to the surrounding normal tissues such as gastrointestinal tract and kidneys. Many studies have shown that the local control and survival would be maximized if patients with pancreatic carcinoma were treated by surgery combined with chemoradiation therapy[3-6]. There were full laboratory and clinical evidences of potent radiosensitizing properties and significant systemic activity of 5-fluorouracil (5-FU) and/or gemcitabine (GEM) used in combination with radiothetapy in pancreatic carcinoma[7-12].

In addition, since 1990' s, radiation treatment equipments and related techniques have been developed dramatically. Especially, more attention has been paid to intensity modulated radiation therapy (IMRT), which is an approach with the aid of modern computer treatment planning system to conformal radiation therapy that conforms a high dose to the target (tumor) volume while restricting dose to the surrounding sensitive structures, and encouraging results have been achieved in clinical trials in head and neck carcinoma and thoracic carcinoma.

However, conventional radiotherapy can not give a higher dose needed to eradicate pancreatic carcinoma cells which are moderately sensitive to radiation due to the dose limited tissues adjacent to pancreas. In general, the dose adopted in conventional radiotherapy was approximately or less than 50Gy in 25 fractions over 5 weeks[5,11,12]. But the optimal dose of IMRT to treat patients with pancreatic carcinoma has not been established, especially in combination with chemotherapies such as 5-FU or GEM.

In this study, we reported our experience in the combination of IMRT and chemotherapy with 5-FU or GEM in a group of patients with locally advanced nonresectable pancreatic carcinoma. Our goal was to determine the feasibility of this treatment modality by evaluating the acute radiation toxicity and the treatment efficacy in this dose escalating trial. A second

purpose was to determine the palliation of symptoms, response rate and survival in this group of patients.

MATERIALS AND METHODS

Eligibility

From November 2001 to December 2002, patients with histologically proved pancreatic adenocarcinoma were enrolled into this study. Eligible patients included those with locally unresectable disease due to vascular invasion or extensive regional adenopathy, partial resection or local recurrence after operation. Patients with known metastasis to distant organs, ascites, Karnofsky performance status less than 70 were excluded. Required laboratory parameters included white blood cell count $\geqslant 4\times10^9$/L, platelet count $\geqslant 100\times10^9$/L, creatinine $\leqslant 264$ μmol/L. Patients with biliary or gastroduodenal obstruction must have had prior drainage before radiotherapy and chemotherapy were started. A complete history and physical examination were performed in all patients prior to scheduled treatment. Height, weight, performance status, tumor stage and serum level of tumor markers including carbohydrate antigen (CA) 19-9 were recorded. Required examinations for staging studies included a chest radiograph and abdominal computed tomographic (CT) scan or magnetic resonance image (MRI) scan, abdominal type B ultrosound and sometimes bone isotopic examination. All patients were required to sign a written informed consent according to national and institutional guidelines.

Radiotherapy

Patients were CT simulated and treated in the supine position with their arms overhead. In order to make it easier to define tumor target volume from the stomach and duodenum, 300 ml of oral CT contrast with 2 % gastrografin solution was administered respectively one hour and half an hour before starting CT simulation scan with ACQsim spiral CT. For immobilization, a customed thermoplastic cast extending from the mid-thoracic spine to the mid-pelvis was made. Each patient was scanned from the upper dome of the right diaphragm (approximately at the level of T9-T10) to the bottom of the L4 vertebral body. The patient was imaged with overlapping CT slices that were 5 mm thick at 3 mm intervals. Center of CT scanning was marked on the thermoplastic cast. The gross tumor volume (GTV) and the surrounding critical structures of concern including the liver, kidneys, stomach, small intestine and spinal cord were defined after the data of CT scan were sent to the workstation of ACQsim (version 4.3) CT simulation software system. GTV represents tumor in the pancreas, the surrounding tissue infiltrated and adjacent lymph node metastasis. The clinical target volume (CTV) includes GTV plus any microscopic extension of disease that is suspected around GTV. The planning target volume (PTV) represents CTV plus any additional margins that are required to compensate for daily setup variations. Isocenter coordinate of radiotherapy was marked on the thermoplastic cast with the help of a laser mark system. Cadplan treatment plan system using Helios reverse treatment planning software was adopted to optimize the dose distribution after the images of CT scan and digitally reconstructed radiographs were transmitted. Then, the treatment data were sent to Varian 2100C/D accelerator by Varis network. Port films were taken at the first time and once every week of treatment to verify the radiation position.

Radiotherapy was divided into two phases. Conventional radiotherapy was delivered to a total of 30Gy in 15 fractions of 2Gy per fraction to the initial fields including the primary tumor plus the regional peripancreatic, celiac, and porta hepatis lymph nodes at the first phase. IMRT was given at the second phase and GTV was covered by the 95 % prescribed isodose curve. The dose of IMRT ranged from 21Gy to 30Gy in 7-10 fractions of 3Gy per fraction. The total dose escalation levels were 51Gy, 54Gy, 57Gy and 60Gy respectively. Three patients were needed for each dose level. Dose-limiting toxicity (DLT) from radiotherapy was defined as grade IV hematologic toxicity or grade III nonhematologic toxicity according to common toxicity criteria (CTC, 2.0 version). Dose escalation continued to the next dose level if no patients suffered from DLT. Two or more instances of DLT among 3 patients occurred in the preceding dose level would declare it as the maximum tolerant dose (MTD). Another 3 patients would be needed for observation if one of them had DLT at a certain dose escalation level. If no one had DLT in these additional 3 patients, dose escalation would continue. However, if one patient developed DLT among the added 3 patients, the preceded dose level would be the MTD. In this study, the maximum escalation dose level was 60Gy.

Chemotherapy

Gemcitabine (GM), 150 mg/d, was administered daily prior to radiotherapy on weeks 1, 3, 5, or 5-fluorouracil (5-FU), 250 mg/d, was given every week from Monday to Friday during the days of whole radiotherapy course.

Toxicity and response evaluation

Toxicity was evaluated according to common toxicity criteria: version 2.0 (CTC 2.0)[13]. Hematologic parameters were assessed weekly, and all other adverse reactions were evaluated during the course of radiotherapy. Analgesic intake and weight were recorded at initial consultation and weekly during radiation therapy. Karnofsky performance status (KPS) was estimated prior to radiotherapy and recorded as it was improved, stable, or deteriorated after treatment. Weight change was classified as weight gain/loss if there was a weight increase/decrease $\geqslant$5 % over baseline value, otherwise it was classified as stable. Pain control was recorded when it was improved/deteriorated if there was a $\geqslant$50 % increase/decrease respectively in the daily intake of equivalent analgesic dose at least lasting for 4 weeks. The clinical response index was defined as a sustained improvement in at least one parameter (among three factors as KPS, weight and pain control) without the other two factors worsening for more than 4 weeks. Tumor volume response was assessed based on the tumor size pre- and postradiation CT scans. A complete response (CR) was defined as the disappearance of all clinical evidences of tumor without appearance of new lesions for more than 4 weeks. A partial response (PR) required a 50 % decrement in the maximal perpendicular tumor measurements, with no new lesion appearance for at least 4 weeks. No change (NC) was defined as less than 50 % reduction and less than 25 % increase of measurable tumor lesions. Progressive disease (PD) was defined as more than 25 % increase of measurable tumor lesions or new lesion developed. Response rate included the patients with CR and PR. Survival rate was calculated by the method of Kaplan Meier with the statistic software SPSS (version 9.0).

RESULTS

Dose escalation

Twenty-one patients were enrolled in this clinical study, 15 were unresectable as a result of major vascular invasion, 2 patients had partial tumor resected and other 4 patients had local recurrence at the primary site. Twelve were males and 9 females, and the median age of all patients was 64 years (range: 46-72 years).

Among these twenty-one patients, the primary lesions were

located at the head of 13 patients, at the body or tail of pancreas in 8 patients. Sixteen out of 21 patients completed the whole course of radiotherapy. The number of patients treated with different dose levels of 51Gy, 54Gy, 57Gy, 60Gy were 3, 3, 3 and 7 cases respectively. Dose volume histogram demonstrated that the median percentage of volume of small intestine received 80 % and 90 % of the prescribed dose was 10 % and 6 % respectively. Five out of 21 patients gave up the plan of radiotherapy because 4 patients had hepatic metastasis or ascites and another one had high fever, grade IV hematologic toxicity at the time of administration of GEM with a dose of 200 mg for the second time.

Clinical benefit

Sixteen patients were analyzed. CA19-9 levels prior to radiotherapy were elevated in 13 patients with a median value of 716 U/ml. At the end of radiotherapy, the levels of CA19-9 decreased significantly with a median value of 255 U/ml (P<0.001). Compared with that before radiotherapy, the value of CA19-9 decreased more than half after radiation treatment in 10/13 patients. Fourteen out of 16 patients suffered from pain at the start of chemoradiation had a decrease of oral analgesic consumption at the end of radiotherapy by more than 1/3 of the total amount before treatment. Ten out of 14 patients had a reduction of analgesic consumption more than 50 % and 5 patients were virtually painless. KPS was improved in 10/16 patients while 4 patients deteriorated during treatment, the other 2 patients remained unchanged. Only one patient (1/16) gained weight $\geqslant$5 % during treatment and maintained it for more than four weeks. Nine patients suffered from weight loss in excess of 5 % of their pretreatmeant weight. The other 6 patients remained stable in weight during the treatment. In total, seven patients were improved in at least one parameter of KPS, analgesic consumption or weight without simultaneous deterioration of any other parameters. So the clinical benefit ratio was 33 % (7/21). If the 5 patients who did not complete the radiation schedule were excluded, the benefit ratio increased to 44 % (7/16).

Radiological examination and survival rate

CT scanning after completion of radiotherapy demonstrated that no patient acquired CR, 5 out of 16 patients attained PR. Therefore, the response rate was 31 %. The median follow-up time was 8 months (range 3-17 months). One-year survival rate was 35 %.

Toxicity

No patient had radiation-induced acute reactions such as nausea, vomiting, diarrhea of greater than grade II. Among the six patients (6/21) who received chemotherapy with GEM as radiosensitizer, 3 patients had grade II neutropenia, 1 patients had grade IV neutropenia, and one patient had grade IV hematologic toxicities of neutropenia, thrombocytopenia and anemia. The latter was excluded from the dose escalation study. For patients receiving 5-FU as a radiosensitizer, only 3 patients had grade II neutropenia and two other patients had grade II abnormal liver function. All of them were able to complete the radiotherapy schedule with the support of some medication.

DISCUSSION

Locally advanced, surgically unresectable pancreatic carcinoma is a highly lethal disease. Its one-year survival rate is less than 10 %. Since diagnosis is usually made too late in the course of development of the disease to the chance of radical surgical resection, most patients experience progressive symptoms of pain, jaundice, weight loss, nausea, vomiting, or anorexia. An effective locoregional treatment would be the only chance for such patients. GEM and 5-FU have been studied in clinical trials by Radiation Therapy Oncology Group (RTOG) as radiation sensitizers in pancreatic cancer[14,15]. Studies of 5-FU and radiation have demonstrated that 5-FU was an effective radiation sensitizer by inhibiting tumor cell DNA synthesis. Gemcitabine (GEM) is also a radiosensitizer. It requires intracellular phosphorylation resulting in accumulation of difluorodeoxycytidine triphosphate (dFdCTP). dFdCTP competed with deoxycytidine triphosphate (dCTP) for incorporation into DNA and subsequently inhibited DNA synthesis and decreased intracellular deoxynucleoside triphosphate pools by curbing ribonucleotide reductase[14,15]. Both 5-FU and GEM have significant radiosensitization effect on tumor cells in which DNA band breakage induced by radiation is more difficult to be repaired. The severe toxicity reported by Crane *et al*[16] was significantly higher in patients treated with gemcitabine-based chemoradiation than in those treated with 5-FU-based chemoradiation, in which 12 out of 53 patients (23 %) treated with gemcitabine and one out of 61 patients (2 %) treated with 5-FU suffered from severe acute toxicity (P<0.001). But in a phase II trial of protracted 5-fluorouracil (200 mg/m^2/day) with concurrent radiotherapy, grade III or worse toxicity was observed in 20 % (4/20) patients[17]. In this study, among the 6 patients who were given GEM as a radiosensitizer with a dose of 200 mg/d on weeks 1, 3, 5, grade IV hematologic toxicities were found in two (33 %) patients. However, no one had acute toxicity greater than grade III in patients receiving 5-FU as a radiosensitizer. Therefore, in our study, 5-FU was the only drug used as a radiosensitizer at the later period of all cases. Boz *et al*[8] reported that it was relatively safe to use 5-FU through a central venous catheter at a dose of 300 mg/m^2/d, 7 d/wk, from the first day of external beam radiotherapy throughout the entire course of radiation treatment. In our study, only 5 patients who received 5-FU had grade II acute reaction and it was considered safe to combine the treatment with radiotherapy. No patient had radiotherapy induced severe acute reactions that interrupted the completion of radiotherapy.

Most cases in our study were patients with locally advanced unresectable pancreatic carcinoma. The aim of this study was to find the optimal maximum dose of external beam radiation using IMRT technique, which would not result in severe acute reaction induced by radiotherapy while improving the life quality and prolonging the survival as long as possible. Among the patients who received a total dose of 60Gy, no one suffered from dose-limiting toxicities resulted from radiotherapy. However, the dose greater than 60Gy was not given because of the possible occurrence of severe late toxicities due to radiation to normal tissue. Therefore, this study did not acquire the MTD of radiotherapy. Normalized with conventional dose 2Gy per fraction, the biological equivalent dose of 60Gy with IMRT technique for the early response tissues and the late response tissues were 62.2Gy and 66Gy respectively (for early response tissue: α/β=10Gy, for late response tissue: α/β=3Gy). Consequently, this study suggested that the IMRT adopted in this trial surely could improve the biological dose to tumor volume. The analysis of dose volume histogram (DVH) showed that the median volume of small intestine receiving 80 % and 90 % prescribed dose was 10 % and 6 % respectively. Moreover, late complications of gastrointestinal tract such as intestinal perforation, hemorrhage and obstruction were not found during follow-up. But we were not sure that patients given total dosage of 60Gy would not have severe complications in the future even the expected survival was relatively short. Therefore, our maximum escalation dose was limited to 60Gy. The tolerance of the patients were quite good in terms of normal tissue acute toxicities induced by radiation

when 30Gy was given in 10 fractions with IMRT technique (PTV margin was 5 mm from GTV) in addition to the conventional dose of 30Gy over 15 fractions.

A recent study by Crane *et al*[16] demonstrated that weekly administration of GEM combined with radiation led to 1-year survival rate of 42 % and median survival duration of 11 months. The response rate and 1-year survival rate of this series were 31 % and 35 % respectively. The difference between our results compared with that in literature may be due to discrepancy of patient' s selection. Up to now, no randomized prospective study in patients with pancreatic carcinoma compared the toxicities in gemcitabine-based *versus* 5-FU-based chemoradiation. Although the case number in our present study was relatively small, the primary results of our study indicated that the tolerance to 5-FU based chemoradiotherapy was much better than GEM based chemoradiotherapy.

In conclusion, for locally unresectable or recurrent pancreatic disease, this dose escalation clinical trial demonstrates that the dose level of 60Gy in 25 fractions over 5 weeks with IMRT technique combined with concurrent 5-FU is effective in improving survival, decreasing pain and the level of CA19-9 and promoting clinical benefit index without radiation-induced severe acute toxicities. Long term treatment effects and late toxicities remain to be evaluated.

Abstract

AIM: To observe the therapeutic efficacy of high-dose Vitamin C (Vit. C) on acute pancreatitis (AP), and to explore its potential mechanisms.

METHODS: Eghty-four AP patients were divided into treatment group and control group, 40 healthy subjects were taken as a normal group. In the treatment group, Vit. C (10 g/day) was given intravenously for 5 days, whereas in the control group, Vit. C (1 g/day) was given intravenously for 5 days. Symptoms, physical signs, duration of hospitalization, complications and mortality rate were monitored. Meanwhile, serum amylase, urine amylase and leukocyte counts were also determined. The concentration of plasma vitamin C (P-VC), plasma lipid peroxide (P-LPO), plasma vitamin E (P-VE), plasma β-carotene (P-β-CAR), whole blood glutathione (WB-GSH) and the activity of erythrocyte surperoxide dimutase (E-SOD) and erythrocyte catalase (E-CAT) as well as T lymphocyte phenotype were measured by spectrophotometry in the normal group and before and after treatment with Vit. C in the treatment and the control group.

RESULTS: Compared with the normal group, the average values of P-VC, P-VE, P-β-CAR, WB-GSH and the activity of E-SOD and E-CAT in AP patients were significantly decreased and the average value of P-LPO was significantly increased, especially in severe acute pancreatitis (SAP) patients (P <0.05. P-VC, P =0.045; P-VE, P =0.038; P =0.041; P-β-CAR, P =0.046; WB-GSH, P =0.039; E-SOD, P =0.019; E-CAT, P =0.020; P-LPO, P =0.038). Compared with the normal group, CD_3 and CD_4 positive cells in AP patients were significantly decreased. The ratio of CD_4/CD_8 and CD_4 positive cells were decreased, especially in SAP patients (P<0.05. CD_4/CD_8, P =0.041; CD_4, P =0.019). Fever and vomiting disappeared, and leukocyte counts and amylase in urine and blood become normal quicker in the treatment group than in the control group. Moreover, patients in treatment group also had a higher cure rate, a lower complication rate and a shorter in-ward days compared with those in he control group. After treatment, the average value of P-VC was significantly higher and the values of SIL-2R, TNF-α, IL-6 and IL-8 were significantly lower in the treatment group than in the control group (P<0.05 P-VC, P =0.045; SIL-2R, P =0.012; TNF-α, P =0.030; IL-6, P =0.015; and IL-8, P =0.043). In addition, the ratio of CD_4/CD_8 and CD4 positive cells in the patients of treatment group were significantly higher than that of the control group after treatment (P<0.05. CD_4/CD_8, P =0.039; CD_4, P =0.024).

CONCLUSION: High-dose vitamin C has therapeutic efficacy on acute pancreatitis. The potential mechanisms include promotion of anti-oxidizing ability of AP patients, blocking of lipid peroxidation in the plasma and improvement of cellular immune function.

INTRODUCTION

In the occurrence and progress of acute pancreatitis (AP), system inflammatory response syndrome (SIRS) often appears as a complication, and may result in pyemia and multiple organ dysfunction (MODS), and death may be the last consequence[1,2]. Many investigations have made it clear that over-activation of leucocytes and their cytokines, the imbalance between release and clearance of free radicals and other pathophysiological changes play important roles in this progress[3-5]. The prognosis of AP patients has a close correlation with infection and pyemia, whereas the occurrence and progress of infection and pyemia also have a correlation with the changes of host immune function[6]. It has been confirmed that vitamin C is an important antioxidant which protects the body from damage of inflammation[7,8], and high-dose vitamin C can improve the immune function[9]. In the present, randomized control study, we observed the clinical efficacy on a high-dose of vitamin C (10 g/day, intravenously) on AP and also monitored its influence on plasma vitamin C (P-VC), plasma lipid peroxide (P-LPO) and other biochemical and immunological markers in order to explore its underlying mechanisms.

MATERIALS AND METHODS

Patients

Based on the AP diagnostic criteria worked out by the Pancreatic Surgery Subgroup of Chinese Medical Association, we selected 84 cases of AP patients. They included 53 males and 31 females, and were aged from 25 to 71 (mean ± SD, 42±13) years. Patients with serious diseases in main visceral organs such as the heart, brain, liver and kidney, peptic ulcer disease, diabetes mellitus, auto-immune diseases ,and tumors were excluded. According to the classification criteria (2nd edition 1996), 70 patients were mild AP (MAP) cases, 14 patients were severe (SAP) cases. Forty healthy volunteers (male 26, female 14, age 28-66 (47±14) years old) were included in the study as a normal group. There was no

significant difference in age and gender between AP patients and healthy volunteers (P>0.05).

Methods

Treatment regimen the routine therapy was used in both treatment and control groups, which consisted of pancreatic excretion inhibition, anti-spasm, analgesia, maintenance of the water-electrolyte balance, prevention and cure of infection and other complications, and if necessary, fasting and gastrointestinal decompression. The patients were randomly divided into two groups. In the treatment group (n=40), vitamin C (10 g/day) was given intravenously for 5 days, while in the control group (n=44), vitamin C (1 g/day) was given intravenously for 5 days. There was no significant difference in age (40±12 *vs*. 43±14 years old), gender (M/F, 25/15 *vs*. 28/16) and disease severity (MAP/SAP, 33/7 *vs*. 37/7) between the treatment and control groups (all P>0.05).

Detection of clinical, biochemical and immunological markers Symptoms such as abdominal pain, fever, vomiting, and hospitalization duration were monitored. Serum amylase, urine amylase, leukocyte counts, concentrations of plasma vitamin c (P-VC), plasma lipid peroxide (P-LPO), plasma vitamin E (P-VE), plasma β-carotene (P-β-CAR), whole blood glutathione (WB-GSH) and the activity of erythrocyte surperoxide dimutase (E-SOD), erythrocyte catalase (E-CAT), serum interleukin-2 receptor (SIL-2R), tumor necrosis factor-alpha (TNF-α), IL-6, IL-8 and complement reaction protein (CRP), as well as T lymphocyte phenotypes CD_3, CD_4, and CD_8 were measured. P-VC and P-VE (μmol/L) were measured by spectrometry using ferrocyanide. P-LPO (μmol/L) was measured by spectrometry using sulfbarbitone. P-β-CAR (μmol/L) was measured with alcohol-petroleum ether spectrometer. WB-GSH (mmol/L) was measured by spectrometry using disulfhydry-dinitrobenzoic acid. E-SOD (U/g*Hb) was measured by spectrometry using pyrocatechol. E-CAT (K/g*Hb) was measured by spectrometryusing oxydol-acetic diachromic acid potassium. SIL-2R, TNF-α, IL-6 and IL-8 (pmol/L) were measured by enzyme-linked immunosorbent assays (ELISA). All reagents were supplied by the Roche Company (Swiss). CRP (mg/L) was measured by the quick immune extinction spectrometry. T-lymphocytephenotypes (%) were determined by spectrometry using anti-AKP monoclonal antibody AKP.

Clinically, cure of the disease was defined if symptoms such as abdominal pain, vomiting and fever disappeared, serum amylase, urine amylase and leukocyte counts returned to normal, and imaging examinations showed no abnormality. Improvement of the disease was defined if symptoms relieved or disappeared, and laboratory examinations showed almost normal results. The disease was defined to be unchanged if symptoms, physical signs and laboratory examinations had remained unchanged since hospitalization, and to be deteriorated if patient' s condition was getting worse, with occurrence of severe complications and death.

Statistics analysis

All the data were expressed as mean ± SD, when appropriate. SPSS 10.0 statistical package was used for statistical analysis. T-test and χ^2-test were used for the analysis, and P<0.05 was regarded as statistically significant.

RESULTS

Comparison of the results between patients and healthy volunteers

As shown in tables 1, 2 and 3, the serum levels of SIL-2R, TNF-α, IL-6, IL-8 and CRP in AP patients were much higher than those in healthy volunteers (P<0.05 or P<0.01). The average contents of P-VC, P-VE, P-β-CAR, WB-GSH, E-SOD and E-CAT were significantly lower, while the level of P-LPO was significantly higher in patients than in healthy volunteers. More importantly, all the above variables were higher in SAP patients than in MAP patients (P<0.05). The percentage of CD_3 and CD_4 positive cells in AP cases was significantly lower in AP patients compared to the healthy group (both P<0.05), CD_4 and the ratio of CD_4/CD_8 were much lower in SAP patients than in healthy group (both P<0.05).

Before therapy: each index in the two group, $P>0.05$. After therapy: [a]$P<0.05$, [b]$P<0.01$ *vs* treatment and control groups.

Comparison of results between treatment and control groups

As shown in in tables 4 and 5, except for abdominal pain, all symptoms disappeared and serum and urine amylase normalized at a much faster speed in the treatment group than in control group (all $P<0.05$). The treatment group had a higher cure rate and lower deterioration rate than the control group 5 days after therapy (both $P<0.05$).

Comparison of cytokines between treatment and control groups before and after therapy

There was no significant difference in the levels of SIL-2R, TNF-α, IL-6, IL-8 and CRP between the two groups before treatment (all $P>0.05$) (Table 6). However, the levels of cytokines decreased significantly 5 days after therapy in both groups ($P<0.05$), although they were still higher compared with the healthy group. The contents of SIL-2R, TNF-α, IL-6 and IL-8 were significantly lower in the treatment group than in the control group (all $P<0.05$) 5 days after therapy. The CRP level was lower compared with the control group, but the difference was not statistically significant ($P>0.05$, Table 6).

Comparison of oxidation and anti-oxidation levels between treatment and control groups before and after therapy

No notable difference in levels of P-VC, P-VE, P-LPO, P-β-CAR, WB-GSH, E-SOD and E-CAT was observed between the two groups ($P>0.05$) before treatment (Table 7). The average concentration of P-VC, WB-GSH, E-SOD and E-CAT was elevated significantly and P-LPO level was decreased in treatment group 5 days after therapy compared with the control group (all $P<0.05$, Table 7). The contents of P-VE and P-β-CAR had no remarkable difference between the two groups ($P>0.05$).

Comparison of cellular immunity between MAP cases in treatment and control groups before and after therapy

There was no significant difference in CD_3, CD_4 CD_8 and the ratio of CD_4/CD_8 between the MAP patients in the two groups before treatment (Table 8). The mean count of CD_3 and CD_4 and the ratio of CD_4/CD_8 were higher 5 days after treatment than those before treatment in both groups (all $P<0.05$). As far as the comparison of the CD_3 and CD_4 positive cells and the ratio of CD_4/ CD_8 between these two group was concerned, the levels in the former group were slightly higher than that in the latter group ($P>0.05$, Table 8).

Table 8 Immunity change before and after therapy in MAP cases of two groups ($\bar{x}\pm s$)

	Treatment group (*n*=33)		Control group (*n*=37)	
	Before therapy	After therapy	Before therapy	After therapy

Before therapy: $P>0.05$ *vs* the two groups. After therapy: $P>0.05$ *vs* the two groups.

Comparison of cellular immunity between SAP cases treatment and control groups before and after therapy

There was no significant difference in CD_3, CD_4 CD_8 and the ratio of CD_4/CD_8 between the MAP patients in the two groups before treatment (Table 9). The mean count of CD_3 and CD_4 and the ratio of CD_4/CD_8 were higher 5 days after treatment than those before treatment in both groups (all $P<0.05$).

Moreover, the CD_3 and CD_4 positive cells and the ratio of CD_4/CD_8 were remarkably higher in the treatment group than in the control group (all $P<0.05$).

DISCUSSION

Many free radicals are produced in body metabolic procedure. It is estimated that oxygen-derived free radicals account for 95 %. They are cleaned by antioxidants and antioxidases rapidly, and thus the production and clearance keep a homeostasis in normal conditions. Free radicals could exert physiological functions to some degree, such as taking part in biosynthesis, detoxification and microorganism clearance[10,11]. However, overdose free radicals could lead to tissue and cell injuries in pathologic conditions through different approaches[12]: (1) Free radicals attacked bio-membrane, which led to unsaturated fatty acid lipid peroxidation (LPO) and affected the function of membrane of cells and cell organelle. (2) Free radicals might destroy the major enzymes and other molecules, making them lose their functions. (3) Free radicals might disturb the synthesis and replication of DNA. (4) LPO could produce more toxic substances and free radicals. Usually the free radicals produced in metabolism can be cleared by the defence system of anti-oxidation. This system is mainly composed of anti-oxidases and antioxidants. These materials catch and clear the excessive free radicals, prevent the chain reaction of a serial of free radicals from pathologic acceleration and keep the homeostasis of antioxidation from imbalance. Vit. C, Vit. E and β-CAR were the most important anti-oxidases and antioxidants, and played an important role in anti-infection[7-9].

The occurrence and development of acute pancreatitis were related to the disturbance in release and clearance of free radicals, which resulted in the imbalance between oxidation and anti-oxidation[13]. Many studies have indicated that excessive free radicals could lead to tissue and cellular injury in pathological conditions[11]. Free radicals took part in the edema of AP, and probably in the necrosis process[13]. When AP happened, vitamin C was depleted at first by reacting with superoxide, anion hydroperoxide anion and hydroxylperoxide anion, and then by forming vitamin C free radicals to prevent DNA and membrane lipid from damage[14]. The concentration of vitamin C in AP cases decreased to various extents[15], reached the lowest level in the first 1-5 days of the disease course, and the vitamin C level correlated with the severity of the disease[16]. The output of free radicals was increased, and peroxidation reaction was reinforced, therefore a large amount of vitamin C, vitamin E, β-CAR, WB-GSH, E-SOD and E-CAT were depleted so that they could hardly prevent pancreas and other organs from damage caused by lipid peroxidation. Furthermore, the elevation of cytokines is a frequent phenomenon and the extention was closely associated with the severity of AP[17]. The reason why MAP developed into SAP was a chain and amplification reaction (so-called waterfall effect) of inflammatory agents that led to SIRS and MODS[18]. Therefore, the serum levels of cytokines SIL-2R, TNF-α, IL-6, IL-8 and CRP could be regarded as the biomarkers of therapeutic efficacy[19].

Recent studies have shown that the prognosis of AP is closely associated with infection and pyemia. At the same time, the occurrence, development and conversion of infection and pyemia were intimately associated with the changes of immune function[20,21]. Because histamine, bradykinin and many other cytokines produced in AP progression could inhibit the immune function in AP cases, especially in those with SAP, the injuries of immune function took place. Theses injuries included decreased proliferation of T cells, especially Th cells, decreased IL-2 level, reduced monocytes in peripheral blood and increased prostaglandin E2 from monocytes[22-24]. Our study indicated that cellular immune function damage took place in AP patients. The percentage of CD_3 and CD_4 positive lymphocytes was higher in treatment group than in control group after treatment, while that of CD_4 positive lymphocytes and the ratio of CD_4/CD_8 were lower in SAP than in MAP[25]. CD_4 positive T-lymphocytes could excrete IL-2, which stimulated the silent T-lymphocytes to express IL-2 receptor, and thus IL-2 conjugated its receptor, leading to a series of immune reactions and increased DNA synthesis[26]. Therefore, the decrease of CD_4 positive T-lymphocytes certainly influenced the body immune function and resistibility, and the susceptibility to infection increase[27].

We found that the average concentration of P-VC, P-VE, β-CAR, WB-GSH, E-SOD and E-CAT was significantly lower while P-LPO level was significantly higher in AP patients than in healthy volunteers. All these indicate that free radical reaction and lipid peroxidation, and disturbance can speed up free radical elimination and anti-oxidation. We also found that high-dose of vitamin C at early stage could contribute to the improvement of the levels of P-VC, P-VE, WB-GSH, E-SOD and E-CAT, which took part in eliminating injurious free radicals and protecting cells from damage by the free radicals. Simultaneously, the P-LPO level was lower in treatment group than in control group, further confirming the preventive effect of high-dose vitamin C against lipid peroxidation. It was also revealed that there was no significant difference in CD4/CD8 ratio between the MAP patients and the control group. The possible reason is that the immune system of MAP cases has not been seriously impaired, so that the immune adjusting mechanism is able to adjust the CD_8 cells to keep the CD_4/CD_8 ratio at a normal level. However, in SAP patients this mechanism was seriously impaired and could no longer keep the CD_4/CD_8 ratio. Vitamin C could improve the immune function by increasing CD_3, CD_4 and the CD_4/CD_8 ratio, and decreasing CD_8[28], elevating transformation efficiency of lymphocytes, stimulating the production of IL-1, IL-2, IL-6 and other cytokines, and reinforcing cell-mediated immune reaction parameters[29]. In the present study, the percentage of CD4 positive lymphocytes and CD_4/CD_8 ratio in SAP cases were much lower compared with the healthy volunteers, but these indices were significantly higher than those of control group after high-dose vitamin C application. These findings indicate that severe cellular immune defection exists in SAP cases. However, high-dose vitamin C can not only eliminate free radicals and reduce the damage of lipid peroxidation, but also improve the cellular immune function in SAP patients, and thus is useful in reducing the incidence and mortality of pyemia and MODS. SIL-2R, TNF-α, IL-6, IL-8 and CRP concentrations in AP patients were significantly higher than those in healthy volunteers. However, SIL-2R, TNF-α, IL-6 and IL-8 levels decreased significantly after high-dose of vitamin C application, and were significantly lower than those in the control group. It took a shorter time to cure or improve

the clinical symptoms (fever, abdominal pain and vomiting) and to normalize serum amylase, urine amylase and leukocyte counts in patients taking high dose of vitamin C, compared with those taking low dose of vitamin C. Thus, the therapeutic efficacy of high dose of vitamin C was much better than that of low dose of vitamin C. Therefore, we conclude that high-dose vitamin C has therapeutic efficacy on acute pancreatitis. The potential mechanisms include promotion of anti-oxidizing ability of AP patients, blocking of lipid peroxidation in the plasma, and improvement of cellular immune function.

Abstract

AIM: To investigate the relationship between severe acute pancreatitis (SAP) and organ failure.

METHODS: Clinical data of 74 cases of SAP from Jan. 1993 to Dec. 2002 were retrospectively reviewed, and the relationship between organ failure and age, gender, etiology, extent of necrosis, infection of necrosis and mortality was analyzed.

RESULTS: A total of 47 patients (63.5 %) showed organ failure, 20 patients (27.0 %) multiple organ failure, whereas 27 patients (36.5 %) with dysfunction of a single organ system. Pulmonary failure was the most common organ dysfunction (23.0 %) among single organ failures. There were no significant differences in age, gender and gallstone pancreatitis among patients with or without organ failure ($P>0.05$). The incidence of organ failure in infected necrosis was not higher compared with sterile necrosis, and patients with increased amount of necrosis did not have an increased prevalence of organ failure ($P>0.05$). Patients with organ failure had a higher mortality rate compared with those without organ failure ($P<0.05$). The death of SAP was associated with multiple organ failure ($P<0.005$), pulmonary failure ($P<0.005$), cardiovascular dysfunction ($P<0.05$) and gastrointestinal dysfunction ($P<0.05$).

CONCLUSION: Organ failure is common in patients with SAP, and patients with multiple organ failure and pulmonary failure have a higher mortality rate. Prevention and active treatment of organ failure can improve the outcome of patients with SAP.

INTRODUCTION

Severe acute pancreatitis (SAP), as a common acute abdomen, is characterized by complicated causes, lots of morbidities, difficulties in the treatment, and high mortality[1-8]. The natural course of SAP progresses in two phases. The first 14 days are characterized by systemic inflammatory response syndrome resulted from the release of inflammatory mediators. In patients with SAP, organ failure is common and often occurs in the absence of infection. The second phase, beginning approximately 2 weeks after the onset of the disease, is dominated by sepsis-related complications resulted from infection of pancreatic necrosis. This is associated with multiple systemic complications, such as pulmonary, renal, and cardiovascular failure[9-18]. Despite considerable improvements in understanding of the pathophysiologic mechanisms and management of these patients, mortality of SAP remains between 15-50 %[19-22]. Organ failure is a severe complication of SAP and death occurs usually only in patients with SAP and is commonly associated with failure of at least one organ system[23-25]. From Jan. 1993 to Dec. 2002, a total of 74 patients with a diagnosis of SAP were admitted to Department of Hepatobiliary Surgery, the First Hospital of Xi' an Jiaotong University, 12 patients died in hospital. The aim of this study was to analyze the relationship between extent of necrosis, pancreatic infection, hospital death due to organ failure.

MATERIALS AND METHODS

Patients

From Jan. 1993 to Dec. 2002, a total of 74 patients with a diagnosis of SAP were admitted to Department of Hepatobiliary Surgery, the First Hospital of Xi' an Jiaotong University. Pancreatic necrosis was defined by findings on CT scan or in operation. There were 40 men and 34 women with a ratio of 1.18:1, the average age of the patients was 49.3 years (range 14-94). The presence of infected necrosis was determined by bacterial culture of CT or ultrasonography-guided percutaneous aspiration and pancreatic tissues debrided at surgery. Organ failure was defined according to the Criteria of Clinical Diagnosis and Classification System for Acute Pancreatitis (the second project, 1996, Pancreatic Surgery Association of CMA)[26]. Causes of SAP were identified as gallstone and non-gallstone. Initial management of these patients included bowel rest, gastric secretions, intravenous fluid resuscitation, suppression of pancreatic external secretion, and use of prophylactic antibiotics. The indication for surgical treatment was difined in the following instances, such as infection of necrosis, pancreatic abscesses, cholangitis, obstructive jaundice and pseudocyst formation for a long time.

Methods

The patients were divided into two groups according to patients with or without organ failure within 2 weeks after admission. The differences of age, gender, gallstone pancreatitis, APACHE II scores, and mortality were analyzed. According to the results of CT scan and findings in operation, the extent of pancreatic necrosis was estimated to be (1) <33 %, (2) 33-50 %, (3) >50 %. The relationship of organ failure to the extent of pancreatic necrosis and infection of necrosis was analyzed. Finally, the relationship between multiple organ failure and specific single organ failure with infected necrosis and mortality was evaluated.

Statistics

Continuous data were evaluated by *t* test, and categorized data were analyzed by Chi-square test. Significance was defined by $P<0.05$.

RESULTS

There were no significant differences in age, sex, gallstone

pancreatitis. Mortality and APACHE II scores were significantly higher in patients with organ failure than in those without organ failure (P<0.05 and P<0.001, respectively) (Table 1).

Table 1 Characteristics of 74 patients with or without organ failure

	Organ failure (n=47)	No organ failure (n=27)	Sig.
Age (Y)	48±15	49±15	NS
Gender (M/F)	26/21	14/13	NS
Etiology			
Gallstones	21	11	NS
Non-gallstones	26	16	
APACHE II scores	29±7	23±3	<0.001
Mortality (%)	12/47(25.5)	0	<0.05

Among the 74 patients, 20 patients (27.0 %) showed multiple organ failure (maximum 5 organ systems) and 9 of them died, 27 patients showed single organ failure. In patients suffering from single organ failure, 17 patients (23.0 %) had pulmonary failure and 3 patients (17.6 %) died, 7 patients showed hepatic failure and 3 patients showed gastrointestinal failure, but none of these patients died. No patient in this group was accompanied by cardiovascular failure, renal failure, or neurologic failure (Table 2).

Table 2 Number of patients with organ failure in 74 patients

Organ failure	Morbidity(%)	Mortality(%)
Multiple organ failure	20(27.0 %)	9(45 %)
Specific single organ failure		
Pulmonary failure	17(23.0 %)	3(17.6 %)
Renal failure	0	0
Cardiovascular failure	0	0
Hepatic failure	7(9.4 %)	0
Neurologic failure	0	0
Gastrointestinal failure	3(4.1 %)	0

As for the frequency of different specific single organ failure, pulmonary failure occurred in 45.9 % (34/74), renal failure in 16.2 % (12/74), cardiovascular failure in 17.6 % (13/74), hepatic failure in 18.9 % (14/74), neurologic failure in 5.4 % (4/74) and gastrointestinal failure in 10.8 % (8/74) (Table 3).

Table 3 Frequency of organ failure in 74 patients

Organ failure	No. organ failure	Frequency (%)
Multiple organ failure	20	27.0
Pulmonary failure	34	45.9
Renal failure	12	16.2
Cardiovascular failure	13	17.6
Hepatic failure	14	18.9
Neurologic failure	4	5.4
Gastrointestinal failure	8	10.8

No relationship was found between organ failure to the extent of necrosis and infected necrosis (Tables 4, 5). No difference was found between patients with infected necrosis and those with sterile necrosis in the development of multiple organ failure and specific organ failure (Table 6). Nevertheless patients died in hospital had a significantly higher incidence rate of multiple organ failure, pulmonary failure, cardiovascular failure and gastrointestinal failure compared with survivors (Table 7).

Table 4 Relationship between infected versus sterile necrosis and organ failure in 74 patients

	Organ failure (%)	No. organ failure (%)
Sterile necrosis	31(66.0)	16(34.0)
Infected necrosis	16(59.3)	11(40.7)

Note: χ^2=0.3320, P>0.05.

Table 5 Relationship between amount of necrosis and organ failure in 74 patients

Amount of necrosis (%)	Organ failure (n=47)	No. organ failure (n=27)
<33 %	21(55.3 %)	17(44.7 %)
33-50 %	11(64.7 %)	6(35.3 %)
>50 %	15(78.9 %)	4(21.1 %)

Note: χ^2=3.0784, P>0.05.

Table 6 Relationship between infected versus sterile necrosis and single organ failure in 74 patients

Organ failure (%)	Sterile necrosis (n=47)	Infected necrosis (n=27)	χ^2	Sig.
Multiple organ failure	13(27.7 %)	7(25.9 %)	0.0261	NS
Pulmonary failure	24(51.1 %)	10(37.0 %)	1.3585	NS
Renal failure	6(12.8 %)	6(22.2 %)	1.1287	NS
Cardiovascular failure	10(21.3 %)	3(11.1 %)	1.2237	NS
Hepatic failure	7(14.9 %)	7(25.9 %)	1.3607	NS
Neurologic failure	4(8.5 %)	0		NS[a]
Gastrointestinal failure	4(8.5 %)	4(14.8 %)	0.7068	NS

a: Fisher's exact probabilities test.

Table 7 Relationship between hospital death and organ failure in 74 patients

Organ failure	Survivor (n=62)	Nonsurvivor (n=12)	χ^2	P value
Multiple organ failure	11(17.7 %)	9(75 %)	16.7130	<0.005
Pulmonary failure	22(35.5 %)	12(100 %)	16.8501	<0.005
Renal failure	8(12.9 %)	4(33.3 %)	1.7680	NS
Cardiovascular failure	8(12.9 %)	5(41.7 %)	3.9295	<0.05
Hepatic failure	11(17.7 %)	3(25 %)	0.0342	NS
Neurologic failure	0	4(33.3 %)		NS[a]
Gastrointestinal failure	4(6.5 %)	4(33.3 %)	5.0050	<0.05

a: Fisher's exact probabilities test.

DISCUSSION

Most of SAP mortality is associated with organ failure. In the early courses, organ failure is resulted from inflammatory mediator released by systemic inflammatory response syndrome even if in the absence of infection. In the septic phase, organ failure occurs because of sepsis, so organ failure is common in SAP. Previous study showed that in SAP, organ failure occurred in 72-90.3 %, single organ failure in 24.7-37 %, multiple organ failure in 35-65.6 %. Among the single organ failures, pulmonary failure was the most commonly organ failure (39.1-63 %), followed by cardiovascular failure (23-37.7 %), hepatic failure (20.7 %), renal failure (8.5-13 %)[27,28]. The present data showed that organ failure occurred in 63.5 % (47/74), multiple organ failure in 27.0 % (20/74), single organ failure in 36.5 % (27/74) (Table 2). No relationship existed between organ failure and age, sex, gallstone pancreatitis,

but the severity (APACHE II scores) and mortality were significantly higher in patients with organ failure than in those without organ failure (Table 1). Pulmonary failure was the most common single organ failure (23.0 %, 17/74) in SAP. The mortality rate in patients with single pulmonary failure was 17.6 % (3/17), followed by hepatic and gastrointestinal failure. No patient in this group was accompanied by single renal failure, or cardiovascular organ failure, or encephalic failure (Table 2). Among all the organ failures, pulmonary failure was the most frequent organ failure (45.9 %), the second was multiple organ failure (Table 3).

Conflicting results about the relation between extent of necrosis, infected necrosis and organ failure have been reported[28-31]. The present study demonstrated that although the incidence of organ failure in sterile necrosis was slightly higher than that in infected necrosis (66.0 % *vs* 59.3 %), there was no difference in the prevalence of organ failure in sterile necrosis compared with infected necrosis (Table 4). The incidence of organ failure increased with increased extent of necrosis, but patients with increased amounts of necrosis did not have increased prevalence of organ failure (Table 5).

As to the relation between specific single organ failure and sterile and infected necrosis, previous study showed that the incidence of pulmonary failure was increased in infected necrosis compared with sterile necrosis, and there was no difference in the prevalence of renal failure, cardiovascular failure in infected necrosis compared with sterile necrosis[31]. Our study showed that there was no difference in the prevalence of specific single organ failure in infected necrosis compared with sterile necrosis (Table 6).

The mortality rate was 30 % in patients with multiple organ failure, and was 8 % in those with single organ failure[31]. Our data showed the mortality rate was 45 % (9/20) in patients with multiple organ failure, and was 11 % (3/27) in those with single organ failure (Table 2). Halonen *et al*[32] compared multiple organ dysfunction (MOD) score, sequential organ failure assessment (SOFA) score, and logistic organ dysfunction (LOD) score in predicting hospital mortality rates of 178 SAP patients. The results demonstrated that three different multiple organ dysfunction scores showed good accuracy and were comparable with APACHE II in predicting hospital mortality. In multiple logistic regression analysis, only hepatic, renal, and cardiovascular failures were independent risk factors for hospital mortality. Our study revealed that non survivors had a significantly higher morbidity of multiple organ failure, pulmonary failure, cardiovascular failure and gastrointestinal failure compared with survivors, there was no difference in the morbidity of renal failure, hepatic failure and neurologic failure in nonsurvivors and survivors (Table 7). The results demonstrated that the hospital mortality of SAP was associated with multiple organ failure, pulmonary failure, cardiovascular failure and gastrointestinal failure. Therefore, prophylactic and active treatment of these organ failures are very important in the treatment of SAP. Recently, hemoconcentration (hematocrit $\geqslant$44 % and/or failure of admission hematocrit to decrease at approximately 24 hours)[33,34], plasma concentrations of sTNF-Rs[35], activated polymorphonuclear leucocytes-elastase (PMN-E) and IL-6[36] have been reported as early markers for organ failure and necrotic pancreatitis. Patients coincident with this standard should be treated with strong fluid resuscitation and closely monitored in intensive care units, and new approaches have to be found to counteract these severe complications.

Abstract

AIM: To explore the grade and stage of pathology and the relationship between grading and staging of hepatic fibrosis and noninvasive diagnostic parameters.

METHODS: Inflammatory activity and fibrosis of consecutive liver biopsies from 200 patients with chronic liver disease were determined according to the Diagnostic Criteria of Chronic Hepatitis in China, 1995. A comparative analysis was made in these patients comparing serum markers, Doppler ultrasonography, CT and/or MR imaging with the findings of liver biopsy.

RESULTS: With increase of inflammatory activity, the degree of fibrosis also rose. There was a close correlation between liver fibrosis and inflammatory activity. AST, GGT, albumin, albumin/globulin, ALP, AFP, hyaluronic acid, N-terminal procollagen III(P III NP), collagen type IV(Col IV), tissue inhibitors of metalloproteinases-1(TIMP-1), alpha-2-macroglobulin, natural killer cells(NK), some parameters of Doppler ultrasonography, CT and/or MR imaging were all related to the degree of inflammatory activity. GGT, albumin, albumin/globulin, ALP, AFP, hyaluronic acid, Col IV, TIMP-1, alpha-2- macroglobulin, transforming growth factor-beta 1(TGFβ1), NK, some parameters of Doppler ultrasonography, CT and/or MR imaging were all related to the staging of fibrosis. By regression analysis, the parameters used in combination to differentiate the presence or absence of fibrosis were age, GGT, the parameter of blood flow of portal vein per minute, the maximum oblique diameter of right liver by B ultrasound, the wavy hepatic surface contour by CT and/or MR. The sensitivity, specificity and accuracy of the above parameters were 80.36 %, 86.67 %, and 81.10 %, respectively.

CONCLUSION: There is close correlation between liver fibrosis and inflammatory activity. The grading and staging of liver fibrosis are related to serum markers, Doppler ultrasonography, CT and/or MR imaging. The combination of the above mentioned noninvasive parameters are quite sensitive and specific in the diagnosis of hepatic fibrosis.

INTRODUCTION

Hepatic fibrosis has been a common response to chronic liver injury and might result in potentially lethal sequelae[1-3]. In chronic liver diseases, determination of stage and activity of the fibrotic process and evaluation of anti-fibrotic treatment required accurate variables, the commonly so-called ' fibrotic markers' [4-11]. Since the value of laboratory test to diagnose liver fibrosis was limited, biopsy has been still the golden criterion of the diagnosis of liver fibrosis and cirrhosis at present[12,13]. But it is an invasive diagnostic method, so its application and further propagation are somewhat limited. Searching for a noninvasive diagnostic approach is an interesting subject both at home and abroad. Although some parameters have been found to have important values in iconography and laboratory tests, they are still far from satisfactory. So it is of great realistic value to explore a credible, specific, and noninvasive diagnostic parameter of liver fibrosis for the prevention and treatment of chronic liver disease[14-28]. Therefore, on the basis of histology of chronic liver diseases, this study was designed to explore the relationship between the grade and stage of pathology, and noninvasive diagnostic parameters. We hoped that we could provide the basis for the noninvasive diagnosis of liver fibrosis, so as to improve the prevention and treatment of liver fibrosis.

MATERIALS AND METHODS

Selection of patients

The study was organized and carried out by Shanghai Cooperative Group of Hepatic Fibrosis Project. The Cooperaitive Group was led by Renji Hospital and Changhai Hospital in Shanghai. Cases collected by the Cooperative Group were 37 from Changhai Hospital, 36 from Renji Hospital, 30 from Putuo District Central Hospital, 22 from Shanghai Liver Disease Center of Nanjing Military Command, 20 from Changzheng Hospital, 14 from Zhongshan Hospital,

11 from Huashan Hospital, 9 from Shibei Hospital, 8 from Shanghai No.6 Hospital, 6 from Shanghai Infectious Disease Hospital, 3 from Ruijin Hospital, 3 from Shanghai No.9 hospital, and 1 from Shanghai No.1 hospital. A total of 200 patients were collected between July and October in 1999 according to both clinical and pathological criteria. There were 156 males and 44 females with an average age of 34 years (range 15-60).

Histological examination

One week after admission, all patients underwent liver puncture biopsy under the guide of B type ultrasound with the 14G Quick-cut needle (8-Light Company, Japan) or Menghini needle. The length of liver specimen was more than 1 cm. The samples were fixed with 10 % formaldehyde, paraffin slides were made and stained with hematoxylin-eosin, reticular fiber and collagen fiber according to the grading and staging of Diagnostic Criteria of Chronic Hepatitis in China in 1995[29]. Eleven patients were graded and staged for inflammatory activity and liver fibrosis. Three pathologists read the slide independently. The results were checked with Kappa test by statistical experts. It was shown that the coherence of grading and staging of hepatitis fibrosis was excellent. The pathological diagnosis of liver biopsy was finally made by the Department of Pathology , Medical Collage of Fudan University.

Laboratory tests

Blood and urine routine tests: α-fetoprotein(AFP) and prothrombin time were examined by the Cooperative Units.

Serum biochemical tests: Total bilirubin, indirect bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), AST/ALT, γ-glutamyl transpeptidase(GGT), alkaline phosphatase(ALP), albumin, albumin/globulin, blood urea nitrogen(BUN), creatinine(Cr), triglyceride, cholersterol, high density lipoprotein and low density lipoprotein were all measured by Shanghai Institute of Digestive Disease.

Markers of hepatitis virus and immunological parameter: HBsAg, Anti-HBs, HBeAg, Anti-HBe, Anti-HBc, HBV- DNA, Anti-HCV, HCV- RNA, $CD3^+$, $CD4^+$, $CD8^+$, natural killer cell (NKC), interleukin-2 (IL-2), and interferon-γ (IFN-γ) were detected by Shanghai Institute of Digestive Disease.

Related liver fibrosis markers: α-2-macroglobulin(α-MA), transferrin, apolipoproteinA1, hyaluronic acid (HA), laminin, N-terminal procollagen III(PIIINP), 7S collagen IV (7S-IV), and transforming growth factor-β1(TGF-β1) were detected by the Clinical Immunology Center of Changzheng Hospital in Shanghai.

Tissue inhibitor of metalloproteinase-1(TIMP-1) were assayed by Shanghai Hongqiao Medical Reagent Institute.

B ultrasound examination

All B ultrasound examinations of the patients were carried out in Shanghai Institute of Digestive Disease. The patients had empty stomach for 14 hours before examination. Two skillful doctors performed the examination with color Doppler ultrasonic instrument(HDI 5000). The results were saved in compact disk, three experts judged the examination results and made the final reports.

CT and/or MR imaging

All CT and/or MR examinations were performed by Ruijin Hospital, Changzheng Hospital, Changhai Hospital, Zhongshan Hospital, and Shanghai No.6 Hospital in the Cooperative Group. CT scanners with PQ-2000 and/or PQ-5000 (Picker Company), Plus-s (Siemens Company), Hispeed Adv (GE Company), and MR scanners with Cyroscan T10-NT (Philips Company),Vision Plus and Magnetron Impact (Siemens Company) were used.

Statistical analysis

All the data were analyzed with SAS software by Statistical Department in Shanghai Second Medical University.

RESULTS

Histological examinations

It was revealed that there was a significantly positive correlation between the inflammatory activity and the staging of liver fibrosis. With increase of inflammatory activity, liver fibrosis became more serious (Table 1).

Table 1 Pathological diagnostic results of 200 liver biopsy samples

Staging of fibrosis	Grading of inflammation					value	
	1	2	3	4	Total	χ^2-value	*P*-value

received only MR examination.

The results demonstrated that the longitudinal diameter of the left lobe, volume index, the wavy hepatic surface contour, liver crack widening, size of the gallbladder, thickening of the gallbladder wall, changes like little bursa of peri-gallbladder tube, to and fro diameter of the spleen, and thickness of the spleen were all correlated with the grading of inflammation. The wavy hepatic surface contour, changes like little bursa of peri-gallbladder tube, and the to and fro diameter of the spleen were correlated with the staging of liver fibrosis.

DISCUSSION

At present, the diagnosis of liver fibrosis still depends on pathological examination of liver puncture tissue. Since the procedure is invasive, its application and extensive use in clinical practice are still limited. So great attention has been paid to search for and clinical study of a non-invasive diagnostic parameter for liver fibrosis[15,27,28]. It would not only speed up the study of basic medical theory about liver disease, but also be of value[1,3].

In 1995, a new pathological classification method was carried out in our country[29]. The criteria were established respective to distinguish inflammation from liver fibrosis by grading and staging. Both of them have quantified parameters, which are convenient for statistical analysis. Following these criteria, we compared pathological classification with some non-invasive parameters (serologic and imaging parameters), so as to evaluate the value and significance of different parameters in reflecting pathological changes. In the liver puncture tissue of 200 patients with chronic hepatitis, there was a significant positive correlation between inflammatory activity and staging of liver fibrosis. With the increase of inflammatory activity, liver fibrosis became more serious.

In serology, RBC, PLT, AST, GGT, albumin, albumin/globulin, ALP, AFP, HA, PIIINP, 7S-IV, TIMP-1, α2-MA, NK, *etc*. had a relationship with inflammatory activity, but GGT, albumin, albumin/globulin, ALP, AFP, HA, 7S-IV, and α2-MA had a relationship with liver fibrosis. So these latter parameters might be used as the parameters of liver fibrosis[5,10,30-34]. With the development of inflammation and fibrosis, the level of HA and 7S-IV rose gradually in different inflammatory grading and liver fibrosis staging. In pathological diagnosis, Stage 1 and Stage 2 indicated mild fibrosis, Stage 3 and Stage 4 indicated severe fibrosis. The accuracy, specificity and sensitivity of HA were 82.9 %, 93 %, and 56 %, respectively. The accuracy, specificity and sensitivity of 7S-IV were 72.4 %, 94.3 %, and 18 %, respectively. To some extent, PIIINP might reflect mild and severe changes of inflammation, but it might not reflect the fibrotic changes. This study revealed that laminin had no diagnostic value either in inflammation or in fibrotic changes. It was found that the level of TGFβ1 and TIMP-1 increased more significantly in inflammation and early stage of fibrosis, indicating that they could reflect the changes of liver inflammation and fibrosis[35-38]. In this study, PIIINP, laminin, transferrin, and apoproteinA1 which were known to have significant diagnostic value, were not confirmed. So, we should do more work to probe into their diagnostic significance. In the following study, we would increase the number of cases to further study the diagnostic value of the related parameters in liver fibrosis and evaluate the efficacy of anti-fibrotic drugs, so as to provide a sound basis for the reasonable combined use of the different parameters, and to improve the specificity, accuracy and sensitivity of noninvasive diagnostic tests for liver fibrosis[3,15,19,28].

With the development of modern medical imaging techniques, ultrasound, CT and MR would be widely used. These methods could significantly improve the diagnosis and differential diagnosis of liver disease[17,18,20-26]. In this study, ultrasound examination indicated that the thickness of liver capsule, maximum oblique diameter of right liver, tube diameter of portal vein trunk, diameter of left portal vein, diameter of right portal vein, thickness of gallbladder wall, thickness of spleen, diameter of splenic vein, parameter of blood stream quantity per minute in portal vein, light dot shape, and shape of gallbladder were correlated with the staging of liver fibrosis. CT and/or MR imaging only revealed that the volume of spleen was correlated with liver fibrosis. The results demonstrated that B ultrasound had more value than CT and/or MR imaging in the diagnosis of liver fibrosis. This of course needs further study. It should be noted that factors such as individual variation, nature of the instrument used, patient' s condition at the time of examination and difference of the performer' s skill might affect the evaluation of the result[21-24]. At the same time, we should carry out quantitative and/or semi-quantitative research on ultrasonic two-dimensional imaging and Doppler blood stream, so as to increase the sensitivity, specificity and accuracy of the diagnostic parameters.

Abstract

AIM: To compare the difference of expression of Bcl-2 and Bax in extrahepatic biliary tract carcinoma and dysplasia, and to analyze the role of Bcl-2 and Bax proteins in the progression from dysplasia to carcinoma and to evaluate the correlation of Bcl-2/Bax protein expression with the biological behaviors.

METHODS: Expressions of Bcl-2 and Bax were examined immunohistochemically in 27 cases of extrahepatic biliary tract carcinomas (bile duct carcinoma: n=21, carcinoma of ampulla of Vater: n=6), and 10 cases of atypical dysplasia. Five cases of normal biliary epithelial tissues were used as controls. A semiquantitative scoring system was used to assess the Bcl-2 and Bax reactivity.

RESULTS: The expression of Bcl-2 was observed in 10 out of 27 (37.0 %) invasive carcinomas, 1 out of 10 dysplasias, none out of 5 normal epithelial tissues. Bax expression rate was 74.1 % (20/27) in invasive carcinoma, 30 % (3/10) in dysplasia, and 40 % (2/5) in normal biliary epithelium. Bcl-2 and Bax activities were more intense in carcinoma than in dysplasia, with no significant difference in Bcl-2 expression (P=0.110), and significant difference in Bax expression (P=0.038). Level of Bax expression was higher in invasive carcinoma than in dysplasia and normal tissue (P=0.012). Bcl-2 expression was correlated to Bax expression (P=0.0059). However, Bcl-2/Bax expression had no correlation with histological subtype, grade of differentiation, or level of invasion.

CONCLUSION: Increased Bcl-2/Bax expression from dysplasia to invasive tumors supports the view that this is the usual route for the development of extrahepatic biliary tract carcinoma. Bcl-2/Bax may be involved, at least in part, in the apoptotic activity in extrahepatic biliary carcinoma.

INTRODUCTION

Extrahepatic biliary tract carcinoma is a relatively rare disease[1], and its mortality is 5 % of all deaths from malignant neoplasms in Japan[2] and its prognosis is poor[3,4]. Its pathogenic mechanisms remain unknown. Genetic and some risk factors contribute to its pathogenesis[1]. It has been suggested that invasive carcinoma of extrahepatic biliary tract is preceded by dysplasia[1,5], which provides a good model for the study of genetic abnormalities and neoplastic progression.

Genetic control of cell death (apoptosis or programmed cell death) and cell survival play a crucial role in tumor growth[6]. Among the molecules related to the apoptotic process, Bcl-2 family proteins are important and critical regulators in a variety of physiological and pathological contexts[6-10]. Bcl-2 and Bax are members of the Bcl-2 family. Bcl-2 prevents cells from death through a variety of mechanisms, whereas overexpression of Bax protein increases the susceptibility of cells to apoptosis[11]. Although Bax and Bcl-2 have different functions, they share similar structures. Bax is a homologue protein of Bcl-2 and possesses two conserved regions, BH1 and BH2 that appear to be important for Bax/Bcl-2 binding[10]. Bax and Bcl-2 may form homodimers (Bax/Bax, or Bcl-2/Bcl-2) or heterodimers (Bax/Bcl-2). The balance of Bcl-2 and Bax determines survival or death of cells exposed to apoptotic stimuli[12] and relates with chemotherapeutic response and prognosis in some diseases[11].

Expressions of Bcl-2 and Bax in intrahepatic bile duct have been studied extensively by immunohistochemical methods[12-18], but little is known about extrahepatic biliary tract carcinoma and dysplasia. In this study, we attempted to clarify the difference of Bcl-2/Bax protein expression between extrahepatic biliary tract carcinoma and dysplasia, to analyze the role of Bcl-2/Bax proteins in the progression from dysplasia to carcinoma, and to evaluate the correlation of Bcl-2/Bax protein expression and biological behaviors.

MATERIALS AND METHODS

Specimens

Pathological slides of surgically removed extrahepatic biliary tract carcinoma were retrieved from a database file at Department of Pathology, Suwa Red Cross Hospital, Nagano, Japan, from 1993 to 2000. The slides stained with hemaloxylin and eosin (H&E) were reviewed, and slides in 27 cases were selected for this study. These 27 cases composed of 21 biliary duct carcinomas and 6 carcinomas of ampulla of Vater. Histological criteria for diagnosis of dysplasia have been described[1], that is, dysplasia is characterized by cuboidal or columnar cells showing mild to moderate nuclear dysplasia, with or without pseudostratification, loss of polarity, and occasional mitotic figures. Slides in 3 cases had both dysplasia and carcinoma, and other 7 dysplasia lesions were obtained from the margins of malignant tissue. In all, dysplasia (Figure A) was observed in 10 (37.1 %) of invasive carcinomas. As non-neoplastic controls, 5 cases of normal epithelial tissue adjacent to the lesions were used. The histopathological diagnosis was made according to literature[1] using the specimens stained with H&E. There were 17 cases of well-differentiated adenocarcinoma (17/27, 63.0 %), 7 moderately differentiated (7/27, 25.9 %), and 3 poorly differentiated (3/

27, 11.1 %). Clinical stages were determined according to Union International Centre le Cancer (UICC) classification[19]. The numbers of cases in stages I, II, III and IV were 4, 9, 10 and 4, respectively.

Immunohistochemistry

All specimens were fixed in 10 % buffered formalin and embedded in paraffin. The deparaffinized sections were treated in 0.3 % hydrogen peroxide in methanol for 30 minutes to eliminate endogenous peroxidase activity. Retrieval of antigenecity was performed by microwave. Slides were placed in 10 mmol/l citrate buffer (pH 6.0), boiled for 15 min in a microwave oven, cooled for 15 min, and rinsed in distilled water. Anti-Bcl-2 antibody (Clone 124, DAKO Corporation, Glostrup, Denmark, 1:40 dilution) or anti-Bax antibody (Clone 4F11, Immunotech, Marseille, France, pre-diluted) was applied and incubated for 1 hour at room temperature. Each antigen was detected by LSAB-2 kit (DAKO) with 3, 3-diaminobenzidine and hydrogen peroxide and the sections were finally counterstained with hematoxylin. For positive controls, mature lymphocytes in the sections were stained positively for Bcl-2 and neutrophils for Bax.

The results of Bcl-2 and Bax immunostains were scored as described previously[20]. The percentage of positive tumor cells was graded as follows: 0: 0 %, 1: 1-25 %, 2: 26-50 %, 3: more than 50 %. Immunostaining intensity was rated as follows, 0: none, 1: weak, 2: moderate, 3: intense. When a score of intensity multiplying percentage of positive cells is equal to or more than 1, the specimen was considered as immunopositive. Only cytoplasmic staining was evaluated and nuclear reaction was interpreted to be nonspecific staining.

Statistical analyses

Fisher' s exact test was used for statistical analysis. Spearman relation analysis was used for comparison of Bcl-2 and Bax expression. All statistical analyses were performed using STATA software (STATA Inc, Texas, USA). $P<0.05$ was considered as significant.

RESULTS

Bcl-2 and Bax protein expression

The results of immunostaining are shown in Table 1.

Significant Bcl-2 protein expression was observed in 9 out of 21 (42.9 %) bile duct carcinomas and 1 out of 6 (16.7 %) carcinomas of ampulla of Vater. The immunoreactive cases showed diffuse cytoplasmic staining (Figure 1 B). There was no significant difference according to the primary site of carcinoma (P=0.363). On the other hand, only one case out of 10 dysplasia was stained (Figure 1 C). Although there was an increasing tendency of Bcl-2 positive cases from normal to dysplasia and carcinoma, no statistical significance was observed among these three groups (P=0.110).

For Bax expression, the positive cases showed a granular cytoplasmic staining pattern. The positive rate of Bax expression was 17 out of 21 (81.0 %) cases of bile duct carcinoma (Figure 1D) and 3 out of 6 (50.0 %) carcinomas of ampulla of Vater, without statistical significance (P=0.290). Bax was positively stained in 3 out of 10 cases of dysplasia, and 2 out of 5 normal epithelia. There was a significant difference among these three groups (P=0.038), the Bax expression in invasive carcinoma was more obvious than that in dysplasia and normal group when further compared (P=0.012).

Table 1 Expression of Bcl-2 and Bax in biliary tract carcinoma and dysplasia lesions

Lesions	Bcl-2 expression			Bax expression		
	No. positive/tested	%	*P*	No. positive/tested	%	*P*
Invasive carcinoma	10/27	37.0		20/27	74.1	
Bile duct	9/21	42.9		7/21	81.0	
Ampulla of Vater	1/6	16.7	0.363	3/6	50.0	0.290
Dysplasia	1/10	10.0		3/10	30.0	
Normal	0/5	0	0.110	2/5	40.0	0.038[a]

a: Further compared, it was shown that the difference of Bax expression between dysplasia and normal epithelium was not significant (P=1.00), but Bax expression of carcinoma differed from that in dysplasia and normal tissues significantly (P=0.012).

Table 2 Comparison of Bcl-2/Bax protein expression with histological features or clinical stages in biliary tract carcinoma

Histological features	Bcl-2 expression			Bax expression

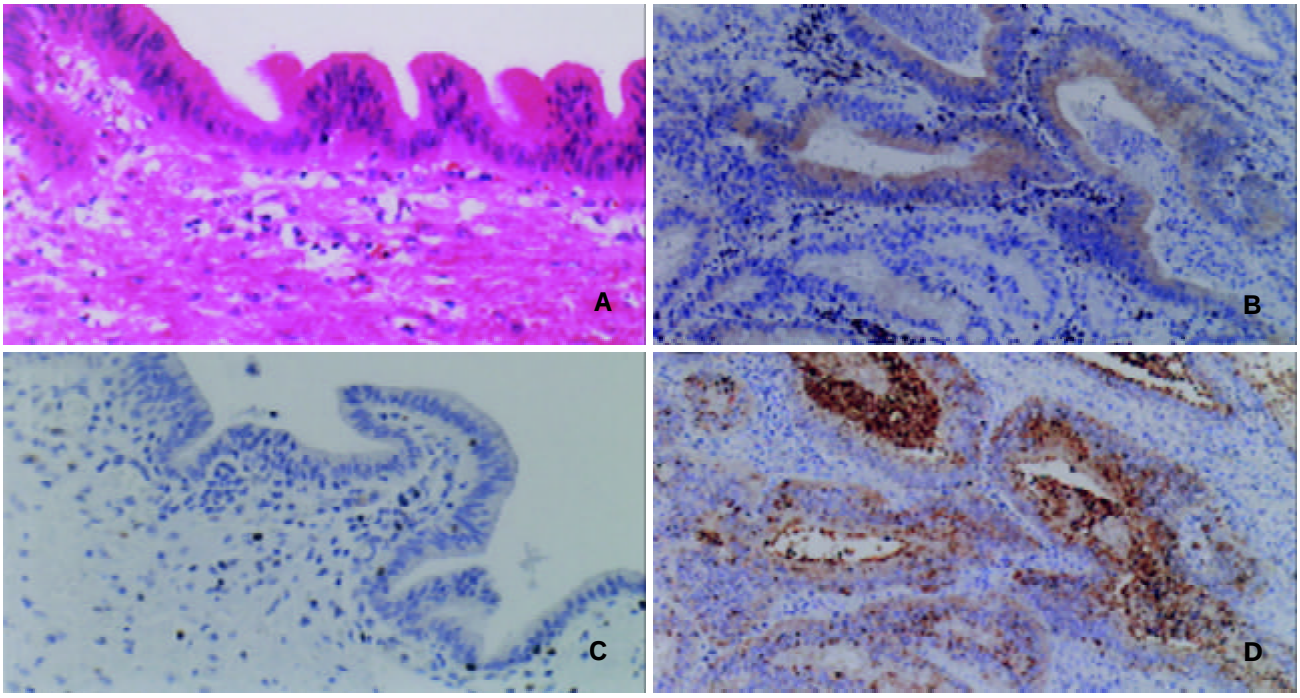

Figure 1 A: Cytological features of dysplasia (Hematoxylin-eosin stain, original ×100 magnification). B: Cytoplasmic expression of Bcl-2 in 1 % to 25 % cells in carcinoma (original magnification ×100). C: Bcl-2 expression in dysplasia with weak staining (original magnification ×100). D: Cytoplasmic expression of Bax in more than 50 % cells in carcinoma stained as intense granular patterns (original magnification ×100. B, D: serial sections).

Comparison between positive expression of Bcl-2/Bax protein and histological characteristics in carcinoma tissue

The results are shown in Table 2.

Out of 27 specimens with invasive carcinoma, the positive rate of Bcl-2/Bax expression was higher in well differentiated type than in poorly differentiated one, and higher in cases without invasion of vessels and lymph nodes than in those with tumor invasion with statistical significance, and higher in cases at stages I and II than in those at stages III and IV without statistical significance.

Correlation of Bcl-2 and Bax protein expression

Expression of Bcl-2 had a significant correlation with that of Bax in malignant tissues, dysplasia and normal epithelium (P=0.0059). Six invasive carcinomas expressed both Bcl-2 and Bax, 5 cases expressed only Bcl-2 protein, 10 cases expressed only Bax protein, 6 cases expressed neither Bcl-2 nor Bax.

DISCUSSION

Dysplasia-carcinoma sequence was regarded as a usual pathway in the development of invasive carcinoma of extrahepatic biliary tract[1]. The foci of dysplasia are multicentric in most cases, which probably explain the high incidence of local recurrence. Laitio [21] and Davis *et al*[22]. noted dysplasia in 45 % and 30 % of extrahepatic bile duct carcinomas, respectively. Suzuki *et al*[23]. found high grade dysplasia in 75 % of invasive carcinoma. In our study, dysplasia accounted for 37 % (10/27) of invasive carcinomas in extrahepatic bile duct and ampulla of Vater, which could be interpreted as an evidence for the theory that dysplasia is a precursor lesion of invasive carcinoma of biliary tract.

Apoptosis has caused great interest in many fields in recent years. Apoptosis-related genes such as p53, bcl-2, bax, c-myc, and bcl-x influence the susceptibility of normal and neoplastic cells to apoptosis[11]. High expression of Bcl-2 protein inhibited apoptosis of cells subjected to chemotherapy, irradiation, and nutritional withdrawal, whereas overexpression of Bax protein facilitated cell death[11]. In this study, we investigated the expression of Bcl-2 and Bax protein in 27 cases of biliary tract carcinoma and found that Bcl-2 protein was expressed in 37 % cases. Previous study showed that varying amounts of Bcl-2 protein were expressed in intrahepatic bile duct[24], while Okaro [14] and Arora[25] reported none of cholangiocarcinoma samples examined expressed Bcl-2 protein. For extrahepatic bile duct carcinoma, Ito *et al*[26]. reported Bcl-2 expression in 17 out of 38 (44.7 %) cases, which was similar to our result (10/27, 37.0 %). On the other hand, Bax was diffusely expressed along the intrahepatic biliary tree[15]. In biliary epithelial cells of rats the expression of Bax protein was visualized by immunohistochemistry and quantified stereologically[12], but in human extrahepatic biliary epithelium, Bax protein expression has not been reported. We observed Bax expression in 74 % cases of extrahepatic biliary carcinoma. Moreover, intensity of Bax staining was generally stronger than that of Bcl-2. Although further studies should be performed, our results suggest that both Bcl-2 and Bax play a role in regulating apoptosis in extrahepatic biliary tract carcinoma. Whether there is a difference of expression of Bcl-2 and Bax between carcinomas of intrahepatic and extrahepatic biliary tract should be clarified in the future.

Our study also showed that Bcl-2 protein expressed in 10 % biliary dysplasia, and no expression of Bcl-2 in 5 normal biliary epithelial cells. These findings were consistent with the results described by Okaro *et al*[14]. Bax protein expression rate was 30 % in dysplasia and 40 % in normal biliary epithelium. Incidence of Bcl-2 and Bax expression in invasive carcinoma was higher than that in dysplasia and normal tissue. Expression of Bax but not Bcl-2 showed a statistically significant difference among the malignant tissue, peri-cancerous tissue and normal one. Previously we demonstrated that Bcl-2 expression in premalignant lesions was an early event in the carcinogenesis of colorectal, gastric and cervix glandular tumors[27]. However, this was not true for biliary tract tumors. Bcl-2 and Bax might play some roles in the development from dysplasia to carcinoma. As the number of cases in each group was too small for statistical analysis, further studies are needed.

The ratio of anti-apoptotic to pro-apoptotic Bcl-2 family proteins appeared to control the relative sensitivity or resistance of many types of cells to apoptotic stimuli[15]. In our study, Bcl-2 expression was related to Bax protein expression in malignant, dysplasia and normal lesions. This finding was consistent with the conclusion of Harada *et al*[28], and supported that Bcl-2 and Bax were involved in the apoptotic activity in the development of extrahepatic biliary tract carcinomas as a couple of contrary functions.

There was a tendency that the low expression of Bcl-2/Bax was found in less differentiated and more advanced cases with metastasis of lymph node and perineural and vascular invasion, although statistical analysis revealed no significance. The impact of Bcl-2 expression on clinical outcome was demonstrated by Ito *et al*[29], who showed that Bcl-2 expression was inversely related to the incidence of apoptosis, and that Bcl-2 expression was more frequently absent in cases of advanced stages, lymph node metastasis, and perineural invasion (inverse relationship). On the other hand, previous study showed that Bax expression might be involved in tumor differentiation/histological types and metastatic progression in colorectal cancer[30], no reports on Bax expression/Bcl-2 in extrahepatic biliary tract tumor has been published yet. The study could not show any distinct correlation between Bcl-2/Bax expression and clinical stage or aggression, and a larger number of cases may be required to clarify this issue.

In conclusion, the increased incidence of Bcl-2/Bax expression observed from dysplasia to invasive tumor supports that this is the usual route for the development of extrahepatic biliary carcinoma. Bcl-2/Bax may be involved in the pathogenesis of extrahepatic biliary carcinoma and there is a correlation between Bcl-2 and Bax protein expression, suggesting that Bcl-2 and Bax regulate the apoptotic activity in extrahepatic biliary carcinoma as a couple of opposite functions.

ACKNOWLEDGMENT

The authors thank Mr. M.Yajima, Mr. M. Shimomura, Ms. H. Yabusaki, and Ms. R. Komatsu for their excellent technical assistance, and Ms. LM. Tang for her help with statistical analysis.

Abstract

AIM: To study the effect of rabeprazole (RAB) on nocturnal acid breakthrough (NAB) and nocturnal alkaline amplitude (NAKA) and to compare it with omeprazole (OME) and pantoprazole (PAN).

METHODS: By an open comparative study, forty patients with active peptic ulcer were randomly assigned to receive one of the three PPIs (proton pump inhibitor) with a single oral dose. They were divided into RAB group (10 mg), OME group(20 mg) and PAN group (40 mg). Twenty healthy volunteers were enrolled to the control group (without taking any drug). Intragastric pH monitoring was then performed 1 hour before and 24 hours after the dose was given.

RESULTS: No clinically undesirable signs and symptoms possibly attributed to the administration of RAB or OME and PAN were recognizable throughout the study period. All subjects completed the study according to the protocol. All data were processed by a computer using the Student *t* test or *t* ' test followed by an analysis of covariance. $P<0.05$ was considered to have statistical significance. The intragastric pH of NAB was significantly higher in RAB group (1.84±0.55) than in either OME group (1.15±0.31) or PAN group (1.10±0.30) (both $P<0.01$). RAB produced a longer sustaining time (4.65±1.22 h) on NAKA than OME (3.22±1.89 h) ($P<0.05$), PAN (3.15±1.92 h) ($P<0.05$), and the sustaining time of NAKA in RAB group was longer than that in the healthy control group ($P<0.01$) too. In addition, RAB produced a much higher pH on NAKA (6.41±0.45) in comparison with PAN (6.01±0.92) ($P<0.05$).

CONCLUSION: A single oral dose of 10 mg RAB may increase the pH of NAB and shorten the sustaining time of NAB, and it may increase the pH of NAKA as well as prolong the sustaining time of NAKA.

INTRODUCTION

The first-generation proton pump inhibitors (PPIs) (such as omeprazole, lansoprazole and pantoprazole) have been considered to be the most primary and potent treatments of acid-related diseases since they were put into clinical application, and their efficacy and safety have been well-documented and widely recognized. However, researches during the last 10 years have shown that, despite the multiple treatment modalities such as modifying administer methods, increasing the dosages or adding H_2 receptor antagonist, the first-generation PPIs can not suppress the nocturnal acid secretion successfully especially NAB[1,2]. The objective in designing this trial was to observe the effect of the newer-generation of PPI rabeprazole on NAB (nocturnal acid breakthrough) and NAKA (nocturnal alkaline amplitude).

MATERIALS AND METHODS

Subjects and grouping

Forty patients with endoscopically proven active gastric or duodenal ulcer at our hospital from June, 2001 to May, 2002 entered into the study. They were randomly assigned to three groups: RAB group (n=15), OME group (n=15) and PAN group (n=10). The male/female ratio of patients was 9:6, 8:7, 6:4 in the three groups respectively. Their age (mean) was 20-61 (34.5±7.8)years, 22-60(30.6±6.7)years and 25-59(29.3±6.5) years respectively. Twenty healthy volunteers (10 men and 10 women) were enrolled as the control group, aged from 18 to 60 years (mean 25.7±9.5).

Methods

Administering method This study was an open comparative trial. With a single oral dose, every one was administered 10 mg RAB, 20 mg OME or 40 mg PAN respectively, ambulatory intragastric pH measurements were then performed. All subjects ceased the drugs that might affect acid secretion and gastrointestinal motility 2 weeks before the study.

Instruments and processes[3] Portable pH recorder (DIGITRAPPER MKIII, CTD Co., Sweden). After fasted for 12 hours, an electrode was placed via a nostril into the stomach at 8 am, to record the baseline pH for an hour, a dose of drug was given to one patient at 9 am, pH was recorded continuously for hours. All participants kept their normal daily activities and consumed their customary diet, except to abstain from drinking acid and alkali beverages during the test period. The pH electrode was withdrawn at the following morning 9 am, pH data were downloaded onto a computer for analysis.

Measuring indicator The impact of the three agents on NAB (identifying criterion[4]: Intragastric pH dropped to <4 and remained below that level for at least 1 hour during the 12 hours of night sleeping period after the dose of PPI). The impact of the three agents on NAKA (identifying criterion[5]: The time that intragastric pH remained >4 lasted for>1 hour from 0:00 to 8 am).

Statistical analysis

All data were processed by a computer. Data were presented as the mean ±SD. Comparisons between two groups and among three groups were made using the Student *t* test or *t*' test followed an analysis of covariance. $P<0.05$ was considered to have statistical significance.

Table 1 Effect of single dose of PPI on NAB

PPI group	*n*	Occurring cases(%)	Time range	pH($\bar{x}$±s)	Persisting time ($\bar{x}$±s)(h)
RAB10 mg	15	9(60 %)	0:00-4:0	1.84±0.55[ac]	4.10±2.38
OME20 mg	15	9(60 %)	20:00-2:0	1.15±0.31	5.40±2.73
PAN40 mg	10	8(80 %)	20:00-6:0	1.10±0.30	5.71±2.60

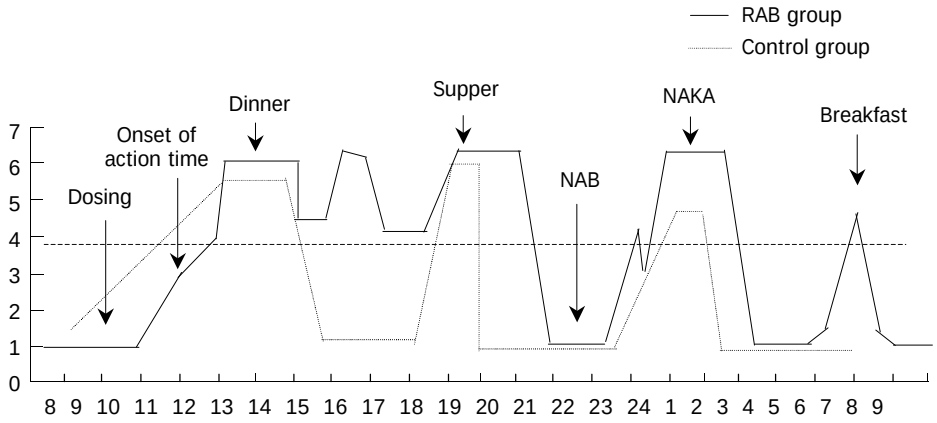

Figure 1 Simulating figure of NAB and NAKA. NAB and NAKA all occurred after midnight, and NAKA always appeared after NAB. Compared with the control group (didn't receive either PPI or placebo), RAB increased the pH of NAKA as well as prolonged the persisting time of NAKA.

RESULTS

Impacts of RAB, OME and PAN on NAB (Table 1)

NAB often occurs after 8 pm. Of the 40 patients, 26 (65 %) exhibited NAB, which occurred mostly from 8 pm to 4-6 am next morning. The results showed that RAB increased pH of NAB significantly (1.84±0.55) than OME and PAN (*P*<0.05), it also shortened persisting time of NAB. NAB occurred frequently in PAN group.

Impacts of RAB, OME and PAN on NAKA (Table 2)

Compared with the healthy group, all three PPIs could increase pH of NAKA and prolong the sustaining time of NAKA. The persisting time that pH>4 of NAKA in RAB group was longer than that in the other three groups (*P*<0.05, <0.05, <0.01), intragastric pHs in RAB group and OME group were all higher than that in the healthy control group (*P*<0.01) (Table 2).

DISCUSSION

NAB and NAKA are two common clinical phenomena, but the developing mechanisms are remain unclear. Our attention was to investigated the effects of PPIs on NAB and NAKA.

NAB was defined as the occurrence of intragastric pH dropped to below 4 and remained below that level for at least 1 hour during the 12 hours of night sleeping period (typically the second 6-hours) after the dose of PPI[1,4]. This study showed that the pH(1.84±0.55) of NAB was significantly higher in RAB group than in OME group and PAN group (*P*<0.05), the persisting time of NAB was shortened. Additionally, the occurrence of NAB was lower in RAB group than in PAN group. The above results suggested that RAB had an advantage over OME and PAN on suppressing NAB, which was consistent with other reports[6,7]. It might contribute to the pharmacological features of RAB such as longer half-life, rapid onset of action, acid-stability, no influences on foods, dosing time or patterns[8-10]. NAB had a high occurrence after midnight and typically in the second 6-hours during night sleeping[1,4,11]. NAB after taking PPIs was first reported by Peghini and Katz[4]. Peghini *et al.* considered that NAB could be explained by food-related factors (for example, the absence of the buffering effect of meals after midnight) which resulted in weakened acid-inhibiting efficacy of PPIs and increased night acid production. This might help to explain why the acid-suppressing effect of PPIs during daytime was greater than that during nighttime[12]. According to the fact that adding a dose of H_2RA at bed time could produce a much better controllable action than that of PPIs on NAB. Peghini *et al*. suggested that histamine played a major role in nocturnal acid secretion[4,13,14]. A study revealed that 70 % of patients with gastro-oesophageal reflux disease (GERD) receiving PPIs had NAB which was often accompanied by esophageal acid exposure. The prevalence of ineffective esophageal motility and low LES pressure was significantly higher in refluxers than in non-refluxers[15], so GERD was considered to correlate with NAB closely. This might be the result of gastric acid secretion following a circadian profile

which was characterized by an increase in the evening , with a peak at about midnight[16]. This might explain why only some refluxers developed esophagitis. There was another opinion that eradication of *H pylori* appeared to be closely related to the occurrence of nocturnal NAB when a dose of PPI was given[17]. There were important clinical implications of NAB, because there existed a close relationship between night acid-control and GERD as well as peptic ulcer. Esophageal protective mechanism was decreased during this time and it was unbeneficial for ulceric mucosa to restore[18,19]. It was thought that NAB might be particularly injurious to the esophageal mucosa and might arise lasting nocturnal heartburn or acid regurgitation and even respiratory complaints. Hence, there was a clinical rationale and greater importance for reducing or abolishing nocturnal acid secretion and increasing intragastric pH or intra-esopgageal pH in treatment of acid-related disorders to promote the healing of peptic ulcer, severe GER and Barrett' s esophagus in order to improve the quality of life[20]. But NAB was also reckoned to prove reversely the safety of PPI (i.e it was extremely difficult to render achlorhydric)[11]. Many studies supported that the addition of a low dose of H_2RA did enhance the control effect on NAB of PPIs because H_2RAs reduced basal gastric acid secretion, H_2RA nizatidine has been known to stimulate gastric emptying and elevate LES pressure and therefore decrease NAB as well as nightly reflux[21], low dose of H_2RA following a provocative dinner or a large fatty meal might effectively reduce esophageal acid exposure. Being prone to produce a tolerance to H_2RA due to its long-term intaking, an intermittent dosing fashion might be an optimal approach[22].

NAKA was also termed as "spontaneous nocturnal gastric alkalinization" (SNGAK), "spontaneous nocturnal alkalinization" (SNA), "nocturnal anhydrochloric wave" and "inversion of gastric pH"[23-25], which was defined as a phenomenon that an abrupt physiological or pathological raise of intragastric pH to above 4 to 6 after sleeping (mostly in the early morning). The prevalence of NAKA ranged between 40-80 % in normal populations, mostly beginning in the latter part of the night. Bianco *et al*[25] found that SNA lasted for 87.82±12.47min/time in normal volunteers and for 3.27±1.62 min/time in patients with duodenal ulcer. Ke *et al*[26]. reported that NAKA presented in 67 % of normal group, lasting for 169.7±40.2 min (total), and raised in 70 % of patients with duodenal ulcer, lasting for 57.6±12.0 min (total). In this study, NAKA presented in 45 %(9/20) of normal subjects, which sustained for 135.0±73.8 min (total), and in 55 %(22/40) of patients with duodenal ulcer. The results were lower than the above, the mean sustaining time of NAKA was 220.4±100.6 min (total) in patients with duodenal ulcer after a single administration of PPI. These findings indicated that RAB might increase the pH of NAKA and prolong persisting time of NAKA. We have previously conducted a simultaneous monitoring of intragastric pH and bile in normal subjects and patients with duodenal gastric reflux (DGR), and found that the pH and cholerythrin exhibited 2 models and 4 types[27]. The 2 models were simultaneous and non-simultaneous raise of pH and cholerythrin, and the 4 types were simultaneouse raise and drop of pH and cholerythrin. pH raised alone and cholerythrin raised alone. The test of neutralizing bile with gastric juice *in vitro* showed that until the absorbency had already raised to 0.900 when bile concentration was 20 %, while pH remained at 1 or so. Furthermore, only when bile concentration raised to >60 %, did gastric pH begin to raise to >4, suggesting that it was not until bile reached to a considerable level when it had an influence on intragastric pH. As bile is nocuous to esophageal mucosa, so only a solitary pH raise produces a protective action. NAKA was proposed by Bianco *et al*. at first in 1970s, there were several opinions about its pathophysiological mechanism. NAKA appeared to be a kind of self-protective mechanism for gastric mucosa against the damages of acid and mucosa-injuring agents, and helping expulse H^+ to gastric cavity continuously so as to relieve clinical symptoms[28]. In this trial, all 3 PPIs increased peak value and persisting time of NAKA(there was a significant difference in comparison with the control). The increase was more prominent for RAB than for OME and PAN, one likely explanation was that H^+-K^+ATPase was inhibited much more. Further investigation is needed. Based on earlier studies[23,27,29], we hypothesed that NAKA was related to DGR, this hypothesis was supported by conclusions of other countries[30,31]. Alkali reflux mostly occurred during MMC phase II and phase III, suggesting that NAKA together with duodenal uncoordinated motor activity could lead to the reflux of duodenal juice (not always bile) into gastric cavity and hence antrum "alkalinization" state at the end of phase III. NAKA was thought to be strongly related to sleeping and interrupted by waking up[31]. Some investigators deduced that NAKA correlated with reduced vagal tension and chlecystectomy as well as modulation of gastric secretions[24,32]. There were evidences that ulcer patients did not show SNA phenomenon before treatment, but the therapy led it to recurrence, and the lack of SNA in duodenal ulcer patients was so frequent that its absence might be a diagnostic sign of peptic ulcer (positively predictive value 82 %)[25,33]. In addition, we had an interesting observation that NAKA always appeared following NAB (Figure 1). There have been no findings concerning this phenomenon yet, and its etiology needs to be identified.

NAB is the most notable limitation of PPIs used at present. By comparison we can understand that available PPIs are unable to resolve the problem of NAB, including rabeprazole. In summary, we have shown that a single dose of 10 mg rabeprazole can achieve a much superior acid-suppressing efficacy as compared to omeprazole and pantoprazole. It can elevate pH of NAB, shorten persisting time of NAB, increase pH as well as sustaining time of NAKA. These findings show that rabeprazole may provide a profound control on nocturnal gastric acid secretion. However, there remain problems demanding further evaluations. For example, whether it is beneficial by increasing the dose or administering time of rabeprazole (i.e twice daily) or an on-demand treatment[19] should be given to enhance the acid-inhibiting efficacy of rabeprazole, whether the onset of NAKA correlates with more effective inhibiting on H^+-K^+ATPase of rabeprazole, etiology and clinical implications of NAB and NAKA, and why NAKA is always present after NAB.

Abstract

AIM: To report the long-term effect of stent placement in 115 patients with Budd-Chiari syndrome (BCS).

METHODS: One hundred and fifteen patients with BCS were treated by percutaneous stent placement. One hundred and two patients had IVC stent placement, 30 patients had HV stent placement, 17 of them underwent both IVC stent and HV stent. All the procedures were performed with guidance of ultrasound.

RESULTS: The successful rates in placing IVC stent and HV stent were 94 % (96/102) and 87 % (26/30), respectively. Ninety-seven patients with 112 stents (90 IVC stents, 22 HV stents) were followed up. 96.7 %(87/90) IVC stents and 90.9 %(20/22) HV stents remained patent during follow up periods (mean 49 months, 45 months, respectively). Five of 112 stents in the 97 patients developed occlusion. Absence of anticoagulants after the procedure and types of obstruction (segmental and occlusive) before the procedure were related to a higher incidence of stent occlusion.

CONCLUSION: Patients with BCS caused by short length obstruction can be treated by IVC stent placement, HV stent placement or both IVC and HV stent placement depending on the sites of obstruction. The long-term effect is satisfactory. Anticoagulants are strongly recommended after the procedure especially for BCS patients caused by segmental occlusion.

INTRODUCTION

Budd-Chiari syndrome (BCS) is characterized by obstruction of outflow in hepatic vein (HV) and inferior vena cava (IVC) leading to hepatomegaly, portal hypertension, impaired liver function, formation of communicating channel, and edema in lower extremities. Various patterns of vascular obstruction can be seen in BCS. The most common type in the orient is short length obstruction (membranous and segmental) in IVC and/or in the ostium of main hepatic vein (HV), and most of them are chronic and idiopathic[1-3]; whereas thrombotic obstruction is the the most common cause in Western country[4,5].

The optimal management of BCS is difficulty, surgical shunting has been recommended as the most appropriate choice to relieve symptoms in most instances[6,7]. But the long-term patency of these shunts varied with high morbidity and mortality[7-9]. Orthotopic liver transplantation has been used to treat BCS cases, but it was mainly for patients with fulminant hepatic failure caused by acute BCS and those with end stage of cirrhosis[10,11]. Recently, the transjugular intrahepatic portosystemic shunt (TIPS) has been reported as an effective therapeutic method for BCS[12,13]. But primary TIPS shunt dysfunction occurred in 60 % of patients with TIPS stent modifications, and angioplasties were required to keep a long-term patency[13,14].

With the development of percutaneous transluminal angioplasty (PTA) and stent placement in the 1990's, a pseudosurgical technique has been employed as an alternative to the major portosystemic shunts[15]. This procedure, applied by Furuil for the first time in a case of BCS in 1990[16], has shown beneficial results. Up to now, almost all of the reports were based on small numbers of patients without long-term follow-up. PTA and stent placement were limited to case report especially for patients with hepatic vein occlusion[17,18]. The role of these therapies in the overall management of BCS has not been clearly established.

From 1994, we have performed percutaneous IVC stent placement in 102 patients and HV stent placement in 30 patients with BCS, 17 out of 102 were treated with combined IVC and HV stent placement. Different from the other reports, all procedures were performed under ultrasound guidance instead of x-ray guidance. Our previous reports demonstrated the safety and advantages of IVC and/or HV stent placement under ultrasound guidance[19,20]. In this study, the long-term effects of stent placement in BCS were reported. The large series of patients enabled us to evaluate the outcome of stent placement and to establish protocol for management of BCS.

MATERIALS AND METHODS

Patients

From April 1994 to June 2001, 115 patients with BCS underwent stent placement in our hospital (All were performed by Dr. Chunqing). There were 65 males and 50 females. The average age was 37.3±12.7 years (SD, range 17-67). The duration of the illness ranged from 3 months to 17 years. Underlying etiological factors for BCS were identified in 5 patients. Two patients had a history of tuberculosis infection, 2 patients took oral contraceptives, 1 patient was pregnant. No patients were examined for the levels of antithrombin-III, protein C and protein S. The main clinical features are listed in Table 1 according to the site of obstruction (see below). Patients manifested mainly as abdominal fullness, weakness, hepato-splenomegaly and ascites.

All patients underwent gray-scal sonography and colour Doppler sonography prior to the stent placement. Ultrasound scanning could identify the site, degree and extent of obstruction of hepatic IVC and hepatic veins, while colour

Doppler could demonstrate the altered hemodynamic within the IVC and HV. In our early study only 11 patients underwent venography.

Based on the findings by ultrasound, colour Doppler and the subsequent probing of the lesions with a guide wire or a 5F-cathetor during the interventional procedure, the patients were divided into obstruction of inferior vena cava with at least one patent hepatic vein (IVC group, *n*=85 patients), obstruction of three main hepatic veins (HV group, *n*=13 patients), obstruction of both inferior vena cava and three main hepatic veins (Combined group, *n*=17 patients). IVC stent were placed in both IVC group and combined group (102 patients). HV stent placement were performed in both HV group and combined group (30 patients). Of the102 patients who underwent IVC stent placement, 49 patients had membranous obstruction, and 53 patients had IVC segmental obstruction (range 1.0-7.6 cm, Table 2). While in 30 patients who underwent HV stent placement, 17 patients had membranous obstruction in HV and 13 patients had segmental obstruction in HV(range 1-4 cm, Table 2).

During the same period, sonography did not reveal hepatic IVC and the main hepatic vein in 30 patients, patients with thrombosis below the obstruction were excluded from this study.

Methods

All the procedures were performed under ultrasound guidance[19,20]. Before the procedure, all the patients were given cisapride 10 mg and pipemidic acid 0.5 three times daily for 3 days. They were fasted and asked to have bed rest for 12 hours to reduce intestinal tympanites and to keep a clear image of ultrasound. In patients with massive ascites, before the procedure a therapeutic paracentesis was performed followed by intravenous administration of albumin. The methods were approved by the ethic committee of our hospital.

IVC stent placements: Briefly, the transducer of ultrasound unit was positioned in the infrasternal angle to show the longitudinal axis of hepatic IVC, the lesion and interventional devices. Though the right femoral vein, a 14F sheath was advanced over a guide wire into the IVC. Echo contrast in 5-10 ml normal saline was injected through the sheath. The soft end of a guide wire or a 5F-catheter was then introduced to probe the lesion under US guidance. If the obstruction was incompletely, the guide wire could easily cross the narrowed part of IVC into the right atrium. For complete obstruction, an 8-F Teflon catheter and its appropriate metal cannula were inserted through the sheath and were pushed carefully into the occluded IVC. If necessary, a Brockenbrough needle was inserted to cut through the lesion. Once the catheter or the needle was placed into right atrium, its strong rebound echo could be shown on US and blood return could be obtained. Then, a balloon catheter with a 1.8-2.4 cm diameter was inserted to dilate the IVC. At the end, under US guidance, the stent (Gianturco stent, Jayu Medical Equipment, Shenyang, China) was pushed into the obstructive part of IVC where it could completely support the obstructive portion after deployment.

HV stent placement: The procedures were performed by percutaneous and transhepatic route. Under ultrasound guidance, a 16-gauge needle was inserted into the hepatic vein via either an intracostal (for right HV) or infrasternal (for middle and left HV) approach. Then over a guide wire, a 10F sheath was put into HV, and all other operations were done thought the sheath to prevent damage of hepatic parenchyma. In patients with partially obstructed HV, the guide wire could cross the entrance of hepatic vein into IVC and finally into the right atrium. Otherwise, a Brockenbrough needle was used to make a tract from the hepatic vein into IVC. Then, the obstructive hepatic vein was dilated by a 1.0-1.2 cm diameter balloon catheter, and a metallic stent (Giantureco Z stent or Wallstent, Jayu Medical Equipment, Shenyang, China) was placed through the 10F catheter to support the hepatic vein. At the end, the 10-F sheath was withdrawn under guidance of ultrasound, and pieces of gelatin sponge were placed over the sheath to plug the tract.

After the procedure, antibiotics were given to all patients. Intravenous heparin was given for for 1 week and followed by aspirin (75-100 mg per day) at least for 6 months to prevent stent thrombosis.

Follow-up

During the follow-up period, manifestations of BCS were evaluated and the liver function was valued, and Doppler duplex ultrasonography was obtained to assess patency of the stent and the hemodynamics in HV and IVC. All patients underwent these examinations before discharge, and then they were seen at 3-6 month intervals, or when they had recurrence of symptoms of BCS.

Statistical analysis

Results were expressed as mean ± SD, range or absolute numbers. Chi-square test, Wilcoxon' s, or Student' s *t* test was used. $P<0.05$ was considered statistically significant.

RESULTS

IVC stent placement

IVC stent was placed successfully in 94 %(95 /102) of patients (IVC group and HV group). The procedure failed in 6 patients (all in IVC group) with segmental occluded IVC (3-4 cm). Pericardial effusion occurred in 3 patients and inferior infarction in 1 patient during dilatation of the occluded IVC with balloon, the Brockenbrough needle failed to cut through

the hard occlusive segment of IVC in 2 patients. Stent migrated into right atrium in one patient who had mesoatrial shunt with the stent fixed to the wall of right atrium and no procedural death occurred.

Hemodynamic features in patients with successful stent placement improved significantly, the inferior vena cava pressure below the obstruction decreased from 29±12.7 cm H_2O to 11.5±7.3 cm H_2O (P<0.05), and satisfactory antegrade flow in IVC was observed with a normal flow spectrum in colour Doppler ultrasound. All patients in IVC group improved clinically. Ascites, hepatomegaly, lower extremity edema, and distended abdominal veins disappeared or diminished at discharge.

Seventy-nine patients in IVC group were followed for 12-84 months (mean 58 months). Four patients were lost in follow-up. Of the remaining 75 patients, 48 had no symptoms, 24 improved clinically, but they still had mild weakness or abdominal swelling on physical examination. On the latest follow up, 68 patients were employed or engaged in full house keeping (Table 3). Of the 17 patients in combined group, 2 were lost to follow-up, the other 15 patients had no symptoms of IVC obstruction.

Thirty-four of the 90 patients (75 in IVC group and 15 in combined group) were followed up for 5 years, 31 patients for 3 years, 25 patients for 1 year. Doppler ultrasonography showed that IVC stent was patent and worked effectively in 87 patients. The overall IVC stent patency rate was 96.6 % (87/90). Stent occlusion occurred in 3 patients at 12-24 months (mean 19 months) following stent placement, these 3 patients had recurrence of abdominal fullness and edema of lower extremity, and 1 patient had ascites. Two patients underwent caval-portal shunt and the others were treated with diuretics and anticoagulants.

HV stent placement

Hepatic vein stent was placed in 30 patients, including 13 patients in HV group and 17 in combined group. In HV group, the patients had hepatic vein stent placement alone, although some patients had narrowed IVC pressed by enlarged caudate lobe. In combined group, successful IVC stent placement resulted in disappearance of all symptoms of IVC obstruction. However, ascites, and hepatosplenomegaly were not alleviated. Therefore, hepatic vein stent was placed 1 week after IVC stent placement.

HV stent were successfully placed in 86.6 % (26/30) patients. Four patients in HV group failed due to a long occluded hepatic vein (3.0-3.5 cm), which was difficult to cut through. All but one of the 26 successful patients had hemodynamic improvement immediately after the procedure. HV pressure dropped from 36.5±16.4 cm H_2O to 12.7±9.5 cm H_2O and satisfactory antegrade flow was noted with a normal phasic flow spectrum in the stented HV. At the time of discharge, 10 patients were free of ascites, the massive ascites decreased without diuretics, and hepato-splenomegaly disappeared or diminished obviously in 25 patients.

Early stent occlusion occurred in one patient of HV group on the third day after the procedure, because the stent immigrated into the hepatic vein and the ostium of hepatic vein was not support by the stent. The patient was treated with repeated paracentesis, intravenous albumin, and a portocaval shunt. Severe haemorrhage from the unplugged transhepatic access occurred in one patient in our early study. Emergent surgical haemostasis was performed, and the patient survived well with a patent hepatic vein stent. One patient with peritonitis and ascitis was treated with paracentesis and parenteral antibiotics. Two patients experienced pleural effusion resolved within 2 weeks. No other major complications occurred.

During a mean follow-up period of 53 months (range 15-78 months), three patients missed the follow-up (1 in HV group, 2 in combined group). Of the 22 follow-up patients (7 in HV group, 15 in combined group), 7 patients were followed up for 5 years, 11 for 3 years, 4 for 1 year. Clinical symptoms and signs of BCS patients improved (Table 3). In these patients, ascites disappeared or decreased, hepatomegaly and splenomegaly were greatly alleviated or dissapeared. Periodic liver function tests were consistent normal or improved. Colour Doppler ultrasonography examinations demonstrated patency of the stents in hepatic vein in 20 patients. The overall HV stent patency rate was 90.9 % (20/22). All were gainfully employed and leading productive lives of good quality. One woman married, pregnant and delivered a healthy baby.

Ascites recurred in 1 patient in combined group at 6 months after the procedure, varices bleeding occurred in 1 patient in HV group at 12 months after the stent placement. Doppler ultrasonography confirmed the stent occlusion and dysfunction in 2 patients. One patient underwent mesocaval shunt, the other was treated with diuretics.

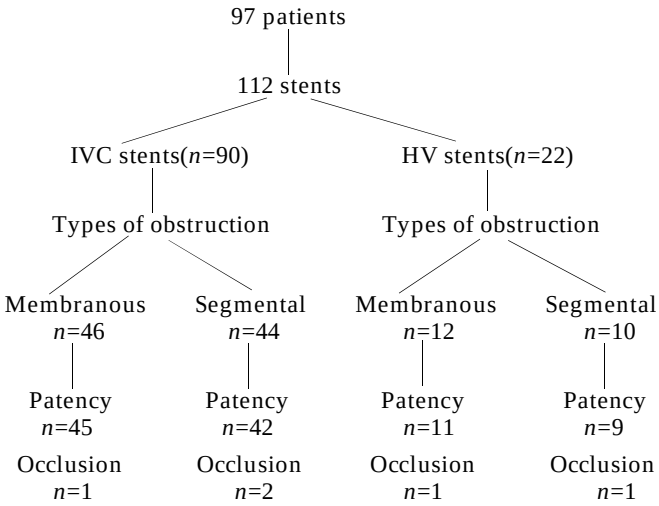

Table 4 The results of 112 stents in 97 follow patients.

Evaluation of risk of stent reocclusion

Of the 112 stents in 97 follow-up patients, occlusion was observed in 5 (4.5 %) stents (3 in IVC stents, 2 in HV stents) (Table 4). Risks of stent occlusion were evaluated (Table 5), and stent occlusion in HV stents (9.1 %) was more common than that in IVC stents (3.3 %) ($P<0.05$). Absence of long-term anticoagulants was related to stent occlusion, stent occlusion was observed in 3 out of 25 (12 %) stents in patients without anticoagulant therapy *versus* 2 of 87 (2.3 %) stents in patients with at least 6 months of anticoagulants for.

No significant difference was found between stent occlusion and severity of obstruction (Table 5). Stent occlusion occurred in 11 % (3/27) patients with segmental obstruction and occlusion *versus* 2.9 % (1/34) patients without them, the difference was significant ($P<0.05$).

DISCUSSION

Since the location, extent and rapidity of venous obstruction are highly variable, a range of clinical presentations necessitates an individualized therapeutic strategy. The management of BCS has traditionally been classified as medical, surgical and radical. Conventional medical therapy with diuretics and anticoagulation has been reported to be of limited value in relieving hepatic venous outflow obstruction[21]. The use of fibrinolytic therapy might be of benefit for patients at early stage of acute thrombosis[23]. Surgical treatment was the most frequently reported approach for BCS[6,7]. When venous obstruction is limited to the main HV without serious involvement of IVC, a portacaval shunt or a mesocaval shunt is proposed. In cases of BCS complicated with obstruction of IVC, the mesoatrial shunt may be used to allow the portal flow to drain directly into the right atrium. Liver transplantation as the second surgical option for BCS was indicated for BCS in acute or chronic liver failure in the Western world[23,24]. Radiological interventions including balloon angioplasty, stent insertion and transjugular intrahepatic portosystemic shunts have been shown to be effective for selected patients with BCS during the past 10 years[11,25], but these results were confined to small series of patients with short term follow up.

In this series, all BCS patients were caused by short length obstruction of the hepatic IVC and/or of the main HV. Most patients were chronic and idiopathic. Our series was the largest report to date for the use of stent placement in BCS. The results demonstrated the long-term efficacy of stent placement for BCS.

In this series, stent placement was performed based on the locations of vascular obstruction.

IVC obstruction with short length lesion was a common cause for BCS in the Eastern countries including China[2,3,26]. Although balloon angioplasty has been regarded as the first choice for patients with IVC obstruction, restenosis and redilitation was reported[2,27], even in patients with membranous obstruction[28]. In our study, the residual membrane in most cases was often pushed back into the lumen of IVC once the balloon catheter moved back. This might be a cause of reccurrence of BCS. Therefore, stents were placed in the restricted part in all patients whether the lesion was a membraneous or a segmental obstruction. During a period of 12-84 months follow-up, 87 out of 90 (96.7 %) IVC stents remained patent and functioned well, the manifestions of BCS disappeared or improved in all the patients. The results demonstrate that IVC stent placement is effective and reliable in management of BCS and has a satisfactory long-term patency.

HV obstructon was one of the main causes of BCS, both in Eastern and in Western countries[2,29]. However, treatment of HV obstruction has been challenging. Usually the hepatic vein angioplasty or stent were performed under x-ray guidance via the jugular vein or both transhepatic and jugular veins. Under this condition, the ostium of hepatic vein could not be revealed directly. Thus, it was very difficult to cut through the occluded orifice of the hepatic vein from the vena cava, cardiac perforation or IVC rupture was reported during the procedure[30,31]. Up to now, reports on treatment on HV obstruction were limited with a small number of patients, and its successful rate was low[2,25]. We performed percutanous hepatic vein recanalization, dilation and stent placement in 26 out of 30 patients with a success rate of 86.7 %. This was a report involving the treatment of BCS with short length hepatic vein obstruction. All the patients had three obstructed hepatic veins, we chose to place stent in one of them. By intrahepatic communicating channels of hepatic veins, the stent was sufficient to drain the entire liver. During a period of 15-78 months follow-up, 90.9 % (20/22) patients had patent stents, the clinical manifestations of BCS improved obviously or disappeared. The long term stent patency was rather good compared with PTA of hepatic vein that had a high incidence of restenosis[31]. In our study, percutanous trashepatic hepatic vein stent placement was the first choice in the treatment of BCS caused by short length hepatic vein obstruction.

For the treatment of HV obstruction, percutanous transhepatic route was safe if the tract was plugged with gelatin sponge before removal of the sheath. Patients with short length HV obstruction should be treated by stent placement instead of simple angioplasty, because hepatic vein webs were more likely to restenose compared with caval webs following angioplasty[31]. Performance under ultrasound guidance contributed to a high success rate and low morbidity, reducing intestinal tympanites and ascites before the procedure was necessary for a clean image of ultrasound.

Combined IVC and HV obstruction was a special kind of BCS consisting of 15 % of our patients. Management of these patients was usually difficult[2,6,7]. When the procedures were divided into 2 steps, the treatment became simple. In 17 patients, the IVC stent were placed first, and the HV stent was placed one week later. During a long-term follow-up, only one patient developed HV stent occlusion, and all IVC stents worked well. The results showed that the combined procedure was an advisable choice for BCS patients with both IVC and HV obstruction.

The total stent occlusion rate was 4.5 % during the follow-up. The long term results were satisfactory. The stent occlusion was more likely to occurred in BCS patients with segmental and occluded obstruction than in patients with membraneous and stenosis obstruction, the stent occlusion rate was higher in patients without anticoagulants after operation than that in

patients with anticoagulants at least for 6 months. Stent occlusion occurred more likely at HV (9.1 %) than at IVC (3.3 %). Therefore, we suggest that anticoagulants should be used routinely after the procedure, especially for patients with segmental and occluded obstruction, and for patients having HV stent placement.

In conclusion, IVC and HV stents or combined IVC and HV stent can be applied to BCS patients with short length obstruction depending on the sites of obstruction. The stents can be placed under ultrasound guidance with a high successful rate and a low morbidity. Excellent long-term results can be obtained in IVC and HV stents as well as in combined stents. Anticoagulants are strongly recommended for at least 6 months after the procedure.

Abstract

AIM: Type IV collagenase participates in invasion and metastasis of cancer cells. Malignant ascites is a manifestation of advanced malignant disease that is associated with invasion and metastasis of the peritoneal cavity. Thus, it is reasonable to hypothesize that type IV collagenase is linked to malignant ascites. The purpose of our study was to detect type IV collagenase activity in malignant ascites so as to provide the scientific basis for clinic diagnosis and treatment of malignant ascites.

METHODS: Cirrhotic ascites (n=36), tuberculous ascites (n=8) and malignant ascites (n=23) from patients with gastric cancer (n=6), colon cancer (n=5), ovarian cancer (n=8) and other cancers (n=4), including 2 hepatocellular cancers, 1 pancreatic cancer, 1 primary peritoneal carcinoma were collected by paracentesis. The ascites were made cell-free by centrifugation and stored frozen at -70 ℃ before determination. Type IV collagenase activity was determined by gelatin zymography.

RESULTS: The activity of matrix metalloproteinases-2 and -9 could not be detected in ascites of hepatic cirrhosis and tuberculous peritonitis but could be detected in 20 and 18 out of 23 malignant ascites respectively. The positive rate of type IV collagenase (MMP-2, 87.0 % and MMP-9, 78.3 %) was higher than that by routine ascites tests (P<0.01) in malignant ascites. Furthermore, the activity of MMP-2 was higher than that of MMP-9 (P=0.022<0.05).

CONCLUSION: Type IV collagenase is positive in malignant ascites. Detection of type IV collagenase activity is useful in qualitative diagnosis of ascites. Type IV collagenase may play an important role in malignant ascites formation.

INTRODUCTION

Although tumor invasion and metastasis are considered to be a dynamic, complex and multi-step process, proteolytic degradation of the extracellular matrix (ECM) made of interstitial matrix and basement membrane is the essential step[1-4]. The basement membrane, a specialized ECM containing large amounts of type IV collagen and laminin, serves a barrier function separating epithelial cells from the underlying stroma. For the occurrence of metastasis, a tumor cell must repeatedly cross this basement membrane barrier, a process for which proteolysis of ECM components is required[5,6]. It is reasonable to hypothesize that proteolysis of ECM also plays a key role in intraperitoneal metastasis of tumor cells, such as in disruption of the mesothelial cell layer, during extension of the implanted tumor through the submesothelial basement membrane into the visceral organ stroma, and importantly, in gaining access to the host vascular supply, a necessary step in progression of the implant.

In disruption of the ECM, the contribution of matrix metalloproteinases (MMPs) of proteolytic enzymes is direct and important in that it catalyzes the hydrolysis of numerous ECM molecules[7-11]. While in the matrix metalloproteinase, type IV collagenase, one of the most important members of MPPs family, including a 72 kD enzyme resembling matrix metalloproteinase-2 (MMP-2), also named gelatinase A and a 92 kD enzyme resembling matrix metalloproteinase-9 (MMP-9), also named gelatinase B, has been demonstrated to be closely associated with several tumor systems and linked to invasive potential of tumor cells[12-16]. Type IV collagenase can degrade not only interstitial matrix, but also basement membrane, and malignant ascites is the direct and prominent manifestation of advanced malignant disease that is associated with invasion and metastasis of peritoneal cavity by tumor cells. Thus it is possible and feasible to detect type IV collagenase in malignant ascites. In the present study, we detected type IV collagenase activity in various kinds of ascites by gelatin zymography so as to explore the relationship between type IV collagenase and malignant ascites, and to provide the scientific basis for clinic diagnosis and treatment of malignant ascites.

MATERIALS AND METHODS

Reagents and instruments

The common reagents and principal apparatus used in SDS-PAGE were provided by the Biochemical Laboratory, Medical College, Wuhan University. Gelatin was purchased from Sigma Co. Type IV collagenase was the product of Invitrogen. Matrix metalloproteinase inhibitor, 1,10-phenanthroline, was purchased from Sangon, Shanghai, China.

Clinical specimems

Sixty-seven inpatients with ascites were recruited respectively at Renmin Hospital of Wuhan University, Zhongnan Hospital of Wuhan University and Tumor Hospital of Hubei Province from July 2002 to March 2003. The ascites were obtained by therapeutic or diagnostic paracentesis. In all cases, informed consent of the patient and approval of the hospital were obtained prior to collection of ascites and medical records. All the diagnoses were confirmed by cytologic examination of the ascites, biopsy for pathological examination, B-ultrasound and CT scan. Details of the patient data are shown in Table 1. The ascites were made cell-free by centrifugation at 3 000 rpm for 15 min and stored frozen at -70 ℃ before determination. At the same time, the protein content of the ascites was measured.

Table 1 Patient data

Characteristics	*n*
Number of patients	67
Male	38
Female	29
Median age (y)	
Male	50.68
Female	48.60
Disease categories	
Cirrhotic ascites	36
Tuberculous ascites	8
Malignant ascites	23
Ovarian cancer	8
Gastric cancer	6
Colon cancer	5
Hepatocellular cancer	2
Pancreatic cancer	1
Primary peritoneal carcinoma	1

Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) zymography

Samples were analyzed by SDS-PAGE zymography according to the method of Kleiner and settler-Stevenson[17] to determine the molecular weights and relative abundance of the gelatinases present. Samples containing 70 μg of protein were incubated for 40 min at 37 ℃ and electrophoresed without reduction (no DTT) on 8 % SDS polyacrylamide gels copolymerized with 0.1 % gelatin. Electrophoresis was performed at 4 ℃ at a constant current of 20 mA. When the tracking dye at the front reached the bottom of the gel, the gel was removed and shaken gently for 45 min in 2.5 % Triton x-100 to remove SDS. Then, the gel slabs were transferred to a bath (without Triton x-100) and washed for 20 min to remove Triton x-100. The above operation was repeated twice both at 4 ℃. Next, the gels were incubated and shaken for 60 h in 0.1 mol/L glycine, 50 mmol/L Tris-HCl, 5 mmol/L $CaCl_2$, 1 μmol/L $ZnCl_2$, 0.5 mol/L NaCl, pH 8.3 , at 37 ℃. At last, following staining with 0.075 % Coomassie blue for 3 h, regions of proteolytic activity were visualized as clear zones against a blue background. Gelatinolytic bands were assessed for semiquantitative analysis using an arbitrarily graded scale. Scale categories were defined as follows: +/-, faint band detected, <1.0 mm in width: 1+, clear band detected, 1.0-1.5 mm in width: 2+, intense band detected, 1.5-3.0 mm in width.

Matrix metalloproteinase inhibition test[18]

In order to verify that the clear zones resembled matrix metalloproteinase, 2.5 mmol/L 1,10- phenanthroline was added into the samples before electrophoresis to inhibit matrix metalloproteinase activities.

Detection of LDH, cytologic examination of ascites and serum complex index

Detection of LDH, cytologic examination of ascites and serum complex index were performed by the Department of Clinical Laboratory and Pathology.

Statistical analysis

Chi-square test and Fisher' s exact probabilities test were used for statistical analysis. Differences were considered significant when *P* value was less than 0.05.

RESULTS

Metalloproteinase inhibition test

Except that when 2.5 mmol/L 1,10-phenanthroline was added to the sample prior to electrophoresis, the result of electrophoresis for the identical samples was negative, indicating what we had detected was matrix metalloproteinase (Figure 1).

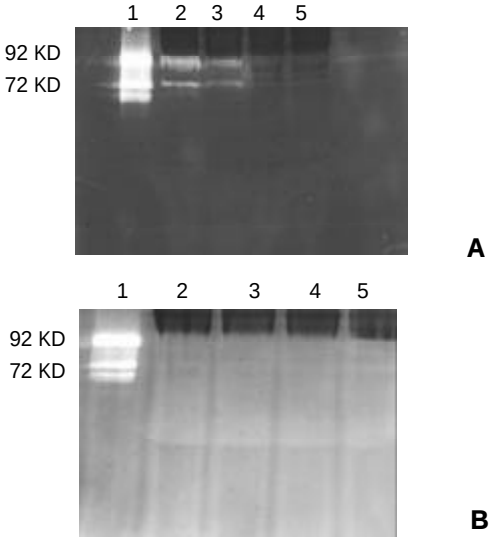

Figure 1 Results of SDS-PAGE zymography. A, Lane 1: type IV collagenase as marker, Lanes 2, 3: cancerous ascites, Lane 4: cirrhotic ascites (no bright bands), Lane 5: tuberculous ascites (no bright bands). B, Lane 1: Marker, Lanes 2-5: identical samples with A, except the addition of 2.5 mmol/L 1,10-phenanthroline. The result was negative.

Qualitative analysis of type IV collagenase activity in various kinds of ascites

Type IV collagenase activity could not be detected in ascites of hepatic cirrhosis and tuberculous peritonitis but could be detected in majority of malignant ascites (Table 2, Figure 1A).

Table 2 Qualitative analysis of type IV collagenase activity in various kinds of ascites

Ascites type	MMP-2 (Positive cases)	MMP-9 (Positive cases)
Cirrhotic ascites	0	0
Tuberculous ascites	0	0
Malignant ascites	20	18
Gastric cancer	5	5
Colon cancer	3	5
Hepatocellular cancer	2	1
Pancreatic cancer	1	0
Ovarian cancer	8	6
Primary peritoneal carcinoma	1	1

Table 3 Semi-quantitative analysis of MMP-2, MMP-9 activity in different kinds of malignant ascites

Type	Case (*n*)	MMP-2 activity (*n*)			MMP-9 activity (*n*)		
		+/-	1+	2+	+/-	1+	2+
Gastric cancer	6	1	4	0	3	2	0
Colon cancer	5	1	2	0	4	1	0
Hepatocellular cancer	2	1	1	0	0	1	0
Pancreatic cancer	1	0	1	0	0	0	0
Ovarian cancer	8	1	5	2	3	1	2
Primary peritoneal carcinoma	1	0	0	1	0	0	1

+/-, faint band detected, <1.0 mm in width; 1+, clear band detected, 1.0-1.5 mm in width; 2+, intense band detected, 1.5-3.0 mm in width.

Table 4 Comparison of detection of type IV collagenase and other indexes in malignant ascites

	Type IV collagenase		LDH in ascites / serum LDH (>1: positive)	Cytologic examination	Serum complex indexes (AFP, CEA, CA)
	MMP-2	MMP-9			
Positive numbers	20	18	10	11	13
Positive rates	87.0 %	78.3 %	43.4 %	47.8 %	56.5 %

Semi-quantitative analysis of type IV collagenase in different kind of cancerous ascites

Gelatinolytic bands were assessed for semiquantitative analysis using an arbitrary grade scale as described in Materials and Methods. The 72 kD MMP-2 was detected in 87.0 % of malignant ascites (n=23), with 80.0 % being scaled >1+; and the 92 kD MMP-9 was found in 78.3 %, with 44.4 % scaled >1+. The activity of MMP-2 was higher than that of MMP-9 ($0.01<P=0.022<0.05$). Additionally, three cases had the highest type IV collagenase activity (2+) for MMP-2 and MMP-9 respectively. Both included one primary peritoneal carcinoma, and two ovarian cancers (Table 3).

Comparison of detection of type IV collagenase and other indexes in malignant ascites

In 23 cases of carcinoma ascites, MMP-2 was found in 20 (87.0 %), significantly higher than that by routine ascites tests (including LDH, cytologic examination of ascites and complex indexes in serum) ($P<0.01$, respectively). MMP-9 was detected in 18 (78.3 %), higher than that by LDH and cytologic examination. However, compared with the two detection methods of type IV collagenase and serum complex indexes, there was no significant difference ($P>0.05$) (Table 4).

DISCUSSION

Type IV collagenase is closely linked with malignant ascites

Overexpression of type IV collagenase has been demonstrated in a variety of cancers, including colorectal cancer, gastric cancer, and breast cancer. Substantial evidences indicate that type IV collagenase activity or concentration was increased in plasma of patients with advanced carcinoma[19-24]. Recently, some researches found that type IV collagenase activity was increased in urine of patients with metastatic breast cancers[25,26] and in cerebrospinal fluid of patients with brain tumors[27]. However, few reports on type IV collagenase activity in ascites could be seen[18,21]. In the present study, we found that type IV collagenase activity could not be detected in ascites of hepatic cirrhosis and tuberculous peritonitis but could be detected in malignant ascites. At the same time, MMP-2 activity was higher than MMP-9 activity in malignant ascites, which might be attributed to the difference of expression of MMP-2 and MMP-9 in ascites of different kinds of tumor. Furthermore, the detection rate of type IV collagenase in ascites of malignant tumor was higher than that by routine ascites tests. Additionally, 2 out of 4 unidentified cases of ascites were identified by peritoneal biopsy. One was metastatic ovarian cancer, the other was primary peritoneal carcinoma. In these two cases, the activity of MMP-2 and MMP-9 was positive, and scale categories all exceeded 1+. Another 2 cases, gastric cancer and colon cancer, were identified by gastroscopy and colonoscopy respectively. The activity of MMP-2 and MMP-9 in these 2 cases was positive also. It was suggested that the peritoneal implants of tumors might secrete type IV collagenase (MMP-2 and/or MMP-9) into peritoneal cavity. Type IV collagenase activity in ascites reflects tumor biological behavior to some extent and is related with malignant ascites. So detection of type IV collagenase activity may probably provide a new approach with high sensitivity and specificity for differential diagnosis of benign and malignant ascites.

Type IV collagenase is correlated with malignant ascites formation

Some reports demonstrated that MMPs played a key role in intraperitoneal metastasis[21]. Others found metalloproteinase inhibitor could reduce ascites in patients with advanced malignant disease[28-30]. Our experiments indicated no expression of type IV collagenase in nonmalignant ascites. On the contrary, majority of malignant ascites showed higher activity of type IV collagenase. Thus, it is reasonable to infer that type IV collagenase is associated with malignant ascites formation to some extent. The probable mechanism of inducing malignant ascites formation by type IV collagenase may be explained as follows[31-37]: breakdown of apparent physical barriers to metastasis of peritoneal cavity, role of MMPs in angiogenesis, formation of new blood vessels which increases overall capillary membrane surface available for fluid filtration, inducing fluid accumulation. These new observations indicate that use of metalloproteinase inhibitors may offer a novel treatment of malignant ascites.

ACKNOWLEDGEMENTS

Abstract

AIM: To detect the vascular endothelial growth factor (VEGF) and soluble splice variant 6 of CD44 (sCD44v6) levels in ascites and to explore their role in differentiating benign from malignant ascites.

METHODS: Cirrhotic ascites (n=36), tuberculosis ascites (n=8) and malignant ascites (n=23) were collected and studied. Concentrations of soluble VEGF and sCD44v6 in various kinds of ascites (n=67) were measured using a sandwich enzyme-linked immunoadsorbent assay.

RESULTS: VEGF and sCD44v6 levels in malignant ascites were 640.74±264.81 pg/ml and 89.22±38.20 ng/ml, respectively, both of which were significantly higher than those in cirrhotic ascites and tuberculous ascites (q=18.98, 11.89 and q=8.92, 5.09; P<0.01). However, the levels of VEGF and sCD44v6 in cirrhotic and tuberculous ascites had no significant difference (q=0.48, 0.75; P>0.05). Furthermore, VEGF levels in malignant ascites in patients with ovarian cancer were higher than those with gastric and colon cancer (q=5.03, 6.79; P<0.01, respectively). But differences of VEGF levels between gastric and colon cancer were not significant (q=1.90, P>0.05). Whereas, sCD44v6 levels in malignant ascites from patients with ovarian, gastric and colon cancer had no significant difference (q=0.06, 0.91, 0.35; P>0.05, respectirely). In comparison with cirrhotic and tuberculous ascites, when the upper limit of its VEGF mean levels 119.44 pg/ml (70.90±48.54) and sCD44v6 mean levels 63.59 ng/ml (44.42±19.17) was taken as the minimum cutoff limit, the sensitivity and specificity of VEGF and sCD44v6 of this assay to the diagnos is of malignant ascites were 91.3 %, 90.9 % and 73.9 %, 88.7 % respectively.

CONCLUSION: Elevated levels of VEGF and sCD44v6 may be useful in differential diagnosis of benign and malignant ascites.

INTRODUCTION

Angiogenesis is an absolute requirement for neoplastic growth of solid tumors after tumors reach a critical size of 1-2 mm^3[1], and is also essential for tumor invasion and metastasis, facilitates the shedding of tumor cells into surrounding blood vessels. Tumor cells have been shown to secrete a variety of angiogenic factors and thereby induce local formation of new blood capillaries. Among these factors, vascular endothelial growth factor (VEGF), also called vascular permeability factor (VPF), is a bifunctional cytokine and has the role in enhancing vascular permeability and stimulating endothelial growth[2-5], and is recognized as one of the most important molecules in the growth, invasion, metastasis and recurrence of human tumors[6-9].

However, tumor invasion and metastasis are considered to be a complex and multi-step process. Since the initial observation that a splice variant of CD44 (CD44v) could endow non-metastasizing cells with metastasis potential[10]. Many studies have demonstrated that CD44v, especially splice variant 6 of CD44 (CD44v6), probably promoting cancer cells to adhere to vascular endothelium and base membranes and enhancing moving ability of cancer cells, is most likely responsible for the invasion and metastasis of several tumor systems[11-15].

Malignant ascites is the direct and prominent manifestation of advanced carcinoma metastasized to the peritoneum[16]. Thus it is reasonable to hypothesize that VEGF and CD44v6 can be detected in malignant ascites. In the present study, we measured the concentration of VEGF and soluble CD44v6 (sCD44v6) using an enzyme-linked immunoadsorbent assay (ELISA) in various kinds of ascites in order to assess the value of VEGF and CD44v6 in identifying benign and malignant ascites.

MATERIALS AND METHODS

Patients

A total of 67 inpatients with ascites were collected at Renmin Hospital of Wuhan University, Zhongnan Hospital of Wuhan University and Tumor Hospital in Hubei Province from July 2002 to March 2003(Table 1). Informed consent of the patient and approval of the hospital were provided prior to collection of samples and medical records. All the cases were confirmed by cytologic examination of ascites, pathological examination, B-ultrasound and CT scan, etc.

Table 1 Patient characteristics

Diagnosis	No. of Patients	Mean age (range)	Female / male
Ascite	67	47(19-86)	26 / 41
Cirrhotic ascites	36	48(30-86)	10 / 26
Tuberculous ascites	8	28(19-33)	4 / 4
Carcinoma ascites	23	66(35-76)	12 / 11
Ovarian cancer	8	60(35-70)	8 / 0
Gastric cancer	6	68(38-74)	1 / 5
Colon cancer	5	64(48-71)	2 / 3
Hepatocellular cancer	2	-	0 / 2
Pancreatic cancer	1	-	0 / 1
Primary peritoneal carcinoma	1	-	1 / 0

Sample processing

Ascites samples were collected during therapeutic or diagnostic paracentesis and centrifuged at 3 000 rpm for 15 minutes at 4 ℃. Cell free supernatants were collected and aliquots were stored at -70 ℃ before determination.

Experimental groups

Cirrhotic, tuberculous and malignant ascites were defined as groups 1, 2 and 3, respectively. Malignant ascites from patients with ovarian, gastric and colon cancer were grouped as groups A, B and C, respectively.

Immunoassay for human VEGF

Concentrations of VEGF in ascites were determined with an ELISA kit (R & D Systems) following the manufacturer' s guidelines. All samples were analyzed in the laboratory of the Department of Gastroenterology, Renmin Hospital, Wuhan University. For determination of VEGF, samples were analyzed in duplicate, human recombinant $VEGF_{165}$ was diluted in series and used as a standard. VEGF concentrations were measured according to the standard curve. Samples with VEGF values beyond the standard curve were diluted and reanalyzed.

ELISA for human sCD44v6

Levels of sCD44v6 in ascites were measured with a sCD44v6 ELISA kit (Bender MedSystems, Austria). Briefly, monoclonal antibody against CD44v6, VFF-7, was absorbed by microwells in 96-well microtiter plates. sCD44v6 in the sample or in the standard bound to antibodies was adsorbed by each microwell. Horseradish peroxidase-conjugated monoclonal antibody against CD44v6 was then added and bound to the sCD44v6 that had been captured by the first antibody. After incubation, unbound enzyme conjugated antibodies were removed by washing and a substrate solution was added to each well. A colorful reactive product was formed , the reaction was terminated by addition of acid, and absorbance was measured at 450 nanometers. A standard curve was prepared from six standard dilutions of sCD44v6, which allowed determination of the levels of sCD44v6 in our samples.

Statistical analysis

The data were presented as $\bar{x}\pm s$. One-way analysis of variance was used for statistical analysis. Differences were considered significant when P value was less than 0.05.

RESULTS

Concentrations of VEGF in ascites

Figure 1 shows VEGF levels in malignant ascites (640.74± 264.81 pg/ml), which were significantly higher than those in cirrhotic ascites (67.05±51.91 pg/ml), tuberculous ascites (88.25±24.12 pg/ml) (P<0.01). However, there was no significant difference of VEGF levels between cirrhotic and tuberculous ascites (P>0.05).

Levels of sCD44v6 in ascites

sCD44v6 levels in malignant ascites (89.22±38.20 ng/ml) were higher than those in cirrhotic ascites (44.79±18.02 ng/ml), tuberculous ascites (50.25±12.57 ng/ml) (P<0.01). But the difference of sCD44v6 levels in cirrhotic and tuberculous ascites was not statistically significant (P>0.05) (Figure 2). We found both VEGF and sCD44v6 levels were increased in malignant ascites.

Comparison of VEGF and sCD44v6 levels in different kinds of malignant ascites

Statistical comparison of VEGF and sCD44v6 levels in these kinds of malignant ascites was not performed due to the limited number of hepatocellular cancer (n=2), pancreatic cancer (n=1) and primary peritoneal carcinoma (n=1).

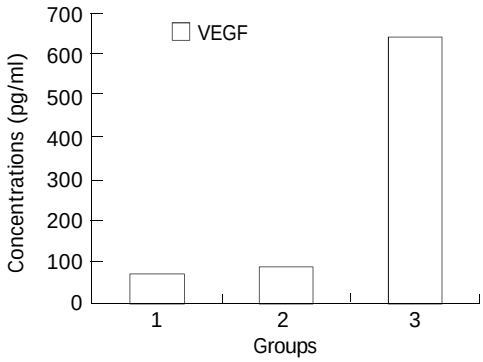

Figure 1 Comparison of VEGF concentrations in different kinds of ascites. Group 1: cirrhotic ascites, Group 2: tuberculous ascites, Group 3: malignant ascites.

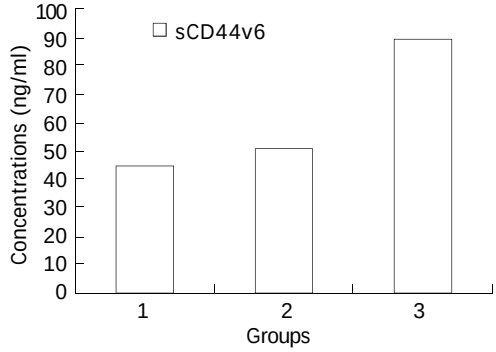

Figure 2 Comparison of sCD44v6 concentrations in different kinds of ascites. Group 1: cirrhotic ascites, Group 2: tuberculous ascites, Group 3: malignant ascites. Concentrations of sCD44v6 in group 3 were significantly higher than those in groups 1 and 2 (P<0.01).

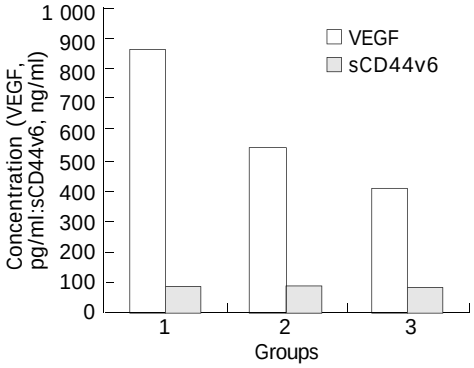

Figure 3 Concentrations of VEGF and sCD44v6 in different kinds of malignant ascites. Group A: ovarian cancer, Group B: gastric cancer, Group C: colon cancer. Concentrations of VEGF in group A were higher than those in groups B and C (P<0.01), while the difference of CD44v6 levels among groups A, B and C was not statistically significant (P>0.05).

Figure 3 shows VEGF levels in ascites from patients with ovarian cancer (866.25±208.46 pg/ml), which were higher than those with gastric cancer (541.30±123.17 pg/ml) and colon cancer (402.80±140.10 pg/ml), respectively (P<0.01). There was no significant difference of VEGF levels between gastric and colon cancer (P>0.05). Whereas, no statistical difference of sCD44v6 levels in ascites of patients with ovarian cancer

(89.42±25.70 ng/ml), gastric cancer (83.91±32.62 ng/ml) and colon cancer (80.10±9.97 ng/ml) was found (P>0.05).

Additionally, in our study, 2 out of 4 unidentified ascites cases were identified by peritoneum biopsy as metastatic ovarian cancer and primary peritoneal carcinoma. In these two cases, the levels of VEGF exceeded 1 200 pg/ml, and sCD44v6 levels exceeded 100 ng/ml. Another 2 cases of gastric and colon cancer, were identified by gastroscopy and colonoscopy, respectively. The concentration of VEGF and sCD44v6 in these 2 cases exceeded 650pg/ml and 80ng/ml respectively.

Sensitivity and specificity of VEGF and sCD44v6 levels to diagnosis of malignant ascites

Using benign ascites including cirrhotic and tuberculous ascites as control, and the upper limit of its VEGF mean levels, 119.44 pg/ml (70.90±48.54), as positive boundary value, 21 out of 23 malignant ascites cases and 4 out of 44 benign ascites cases exceeded the boundary line. So the sensitivity and specificity of this assay to the diagnosis of malignant ascites were 91.3 % (21/23) and 90.9 %(40/44), respectively, and calculated positive value, negative value and accurate rate were 84.0 %(21/25), 95.2 %(40/42) and 91.0 %(61/67), respectively. With same method, the sensitivity, specificity, positive value, negative value and accurate rate of sCD44v6 to the diagnosis of malignant ascites were 73.9 %(17/23), 88.7 % (39/44), 77.3 %(17/22), 86.4 %(39/45) and 83.4 % (56/67), respectively.

DISCUSSION

Human VEGF could be expressed in at least 5 isoforms, which have 206, 189, 165, 145 and 121 amine acids, respectively[17]. It is a multifunctional cytokine that has potent angiogenic activity and enhances microvascular permeability by direct action on vascular endothelium, promoting tumor growth and metastasis[18,19]. Strong VEGF expression has been demonstrated in various solid tumor types, including gastric[20-24], colorectal[25,26] and ovarian carcinomas[27,28]. Recently, substantial evidences indicated that serum concentration of VEGF was increased in cancerous patients[29-32]. Although some studies showed that VEGF levels were high in malignant ascites[30,33], its value to the diagnosis of malignant ascites has not been elucidated.

In the present study, we found that VEGF protein levels in malignant ascites were markedly higher than those in benign ascites, which were consistent with the previous results[30,33], and possessed a high sensitivity and specificity to the diagnosis of malignant ascites. Meanwhile, we also found that VEGF levels in malignant ascites in patients with ovarian cancer were higher than those in patients with gastric or colon cancer. No significant difference of VEGF levels was observed among those with gastric and colon cancer. Additionally, although the number of cases studied in our experiment was small, extremely increased VEGF levels in ascites of patients with ovarian cancer (n=8) and primary peritoneal carcinoma (n=1) could be measured. These data suggested that VEGF levels in ascites could reflect tumor biological behavior to a great extent, and cells of ovarian cancer and primary peritoneal carcinoma might secrete VEGF into peritoneal cavity directly[27]. Most importantly, detection of VEGF levels could provide a new approach for differential diagnosis of benign and malignant ascites, which remains a knotty problem all the time[34,35]. Moreover, detecting VEGF levels may contribute to the diagnosis of primary cancer that causes malignant ascites to a certain extent.

CD44 is an integral cell membrane glycoprotein, and is known to function in homing of lymphocytes, cell adhesion, activation of leukocytes and migration of cells. At least 20 variants (v) of CD44 have been reported due to the alternative splicing of 10 exons (v1-v10) that encode the membrane's proximal portion of the extracellular domain[36-38]. NH2-terminal function area of CD44 on the surface of cells could join the hyaluronate in the basement membrane to extracellular matrix, thus regulate the movement and function of cells. By this mechanism, neoplastic cells could adhere to the extracellular matrix and basement membrane of the host cell, resulting in invasion and metastasis of malignancy. On the other hand, the degraded products of hyaluronic acid could motivate the growth of local vessels, providing the basis for invasion and metastasis[39,40]. Many studies have reported that expression of CD44v, especially CD44v6, was correlated with invasion and metastasis of certain type of human cancer[11,40-47], including gastric cancer[48-50], colorectal cancer[51-53], ovarian cancer[54] and prostate cancer[55]. Furthermore, serum concentrations of sCD44v6 were found to be significantly increased in patients with advanced carcinoma[13,15,56]. To our knowledge, however, concentration of sCD44v6 has not been examined in malignant ascites, this might be the first study to document sCD44v6 in malignant ascites.

We found sCD44v6 levels were high in malignant ascites, and relatively low in nonmalignant ascites. It implies that elevated CD44v6 appears to be correlated to the invasion and metastasis of cancer cells into peritoneal cavity. But it is unclear why CD44v6 is closely associated with malignant ascites. The ability of CD44v6 to bind peritoneal mesothelial surfaces of abdominal cavity, and a subsequent cancer cell implantation may contribute to it. At the same time, our results showed a higher sensitivity and specificity of sCD44v6 to the diagnosis of malignant ascites. However, no evidence is available to show that detection of sCD44v6 could contribute to the determination of a potential primary cancer causing malignant ascites. It is reasonable to consider sCD44v6 may be a diagnostic index of malignant ascites.

In summary, VEGF and sCD44v6 are detectable in ascites and are significantly elevated in malignant ascites. Prospective monitoring of VEGF and sCD44v6 levels in ascites would be helpful in differential diagnosis of benign and malignant ascites.

Abstract

AIM: To evaluate the effects of bowel rehabilitation and combined trophic therapy on intestinal adaptation in short bowel patients.

METHODS: Thirty-eight patients with severe short-bowel syndrome (SBS) were employed in the present study, whose average length of jejunum-ileum was 35.8±21.2 cm. The TPN treatment was initiated early to attain positive nitrogen balance and prevent severe weight loss. The TPN composition was designated to be individualized and altered when necessary. Enteral feeding was given as soon as possible after resection and increased gradually. Meals were distributed throughout the day. Eight patients received treatment of growth hormone (0.14 mg/kg.day) and glutamine (0.3 g/kg.day) for 3 weeks. D-xylose test, ^{15}N-Gly trace test and ^{13}C-palmitic acid breath test were done to determine the patients' absorption capability.

RESULTS: Thirty-three patients maintained well body weight and serum albumin concentration. The average time of follow-up for 33 survival patients was 5.9±4.3 years. Twenty-two patients weaned from TPN with an average TPN time of 9.5±6.6 months. Two patients, whose whole small bowel, ascending and transverse colon were resected received home TPN. An other 9 patients received parenteral or enteral nutritional support partly as well as oral diet. Three week rhGH+GLN therapy increased nutrients absorption but the effects were transient.

CONCLUSION: By rehabilitation therapy, most short bowel patients could wean from parenteral nutrition. Dietary manipulation is an integral part of the treatment of SBS. Treatment with growth hormone and glutamine may increase nutrients absorption but the effects are not sustained beyond the treatment period.

INTRODUCTION

Short-bowel syndrome (SBS) is resulted from extensive small bowel resection due to infarction of the mesenteric vessels, intestinal volvulus, trauma, malignancy, or from complications of Crohn's disease, and is defined as the manifestations of signs, symptoms and complications associated with the inadequate absorptive surface area of functional bowel[1]. It is usually characterized by severe diarrhea, malabsorption, dehydration, electrolyte and metabolic disturbances, and progressive malnourishment.

The pathophysiological consequences following extensive intestinal resection depend on the length and site of resection and the extent of adaptation of the remaining intestine[2-4]. Patients often have to be supported with total parenteral nutrition (TPN) until maximal adaptation of the residual small bowel is complete. This process can take place for up to a year and sometimes longer. Certain patients may require lifelong TPN support depending on the length and health of the residual small bowel. TPN is associated with certain complications, which include catheter sepsis and liver failure[5-8]. It is therefore important for dietary management and pharmacological treatment in the short bowel patients hopefully to wean from TPN. Dietary management and some trophic factors are important in promoting intestinal adaptation after resection. The aim of the study was to define the role of bowel rehabilitation, trophic factors in intestinal adaptation in short bowel patients.

MATERIALS AND METHODS

Patients

Thirty-eight patients (28 men, 10 women; mean age 38.0±16.0 years, range 7-68 years) with severe short-bowel syndrome were eligible for this study. All patients had previously undergone extensive bowel resection for intestinal volvulus, mesenteric infarction or inflammatory bowel disease with or without colonic resection. The average length of jejunum-ileum, as determined from operative reports and confirmed by perioperative radiographs, was 35.8±21.2 cm (range, 0-110 cm) in all patients. Two patients had entire jejunum, ileum and right colon resected. The ileocecal valve and a portion of colon were resected in 13 patients, and 25 patients had intact colon (Table 1). The patients were clinically stable, and did not demonstrate evidence of infection, or extradigestive organ failure. In addition, they did not have a history of cancer. The protocol for the present study was approved by the Ethics Committee of Zhongshan Hospital.

Bowel rehabilitation

Clinical management Massive fluid and electrolyte losses were noted due to transient gastric hypersecretion and profound diarrhea during the initial postoperative periods. So, initial postoperative treatment was designed to maintain adequate fluid and electrolyte balance. TPN began early to attain positive nitrogen balance and to prevent severe weight loss. It should continue until the adaptive processes were complete or indefinitely, if clinically indicated. The composition of TPN was individualized and altered when necessary. Caloric requirements were delivered in accordance with the resting energy expenditure of patients, and it was reassessed often as the patient's clinical condition warranted. As the patient's oral

intake increased, the amount of TPN was reduced, the frequency of TPN was reduced to every other day in the first week, three times in the next week, and twice during the third week. If the patient lost 1 kg/week or more or if diarrhea exceeded 600 g/day or if laboratory abnormalities developed, then the patients were placed back on TPN. If the patient's eventual adaptation was insufficient to allow survival on oral/enteral feeding alone, the patients usually required lifelong TPN support.

Patients with SBS received at least some enteral feeding as soon as possible after resection. Usually this was administered for a postoperative period of 7-10 days. The ideal composition of enteral formulas for patients with SBS was also dependent upon the length of the small bowel and the presence of a colon. Originally, elemental and peptide based enteral formulas were favored for patients with SBS. Gradually, the diet with intact protein nutrient formulas and dietary fiber was given in accordance with the patients' need. Meals were distributed throughout the day.

Combined trophic therapy

Eight patients (4 males, 4 females, mean age 36±8 years) with severe SBS (mean jejunoileal length 44 cm, range 0 to 80 cm)

Table 1 Patient characteristics and status

Patient No.	Gender	Age(a)	Cause of resection	Jejunum-ileum(cm)	Colon	TPN(a)	Current status	Survival time(a)
1	F	28	Small bowel volvulus	0	ACR	17	HPN	17
2	M	7	Small bowel volvulus	0	ACR	7.6	HPN	7.6

^{15}N-Gly trace test (%)	62.4±14.2	73.2±15.3[a]	58.4±11.8[b]
^{13}C-palmitic acid breath test (%)	55.3±8.8	64.5±11.2[a]	62.6±10.4[b]

Values are mean ±SEM, [a]$P<0.05$ *vs* baseline, [b]$P>0.05$ *vs* baseline.

who previously adapted to the provision of TPN and enteral feedings were admitted for 0.8±0.5 years in the study after surgical resection. The first week served as a control period when nutritional (parenteral and enteral) and medical managements were delivered as the routine therapy. Thereafter, the patients who received treatment of subcutaneous recombinant human growth hormone (rhGH) (0.14 mg/kg.day; Saizen, Serono Co., Switzerland) were divided into two daily injections, intravenous alanyl-glutamine solution (0.3 g/kg.day, Dipeptiven, Fresenius Co., Germany) was delivered daily for 3 weeks. D-xylose test, ^{15}N-Gly trace test and ^{13}C-palmitic acid breath test were done respectively before, at the end of therapy and one week after treatment to determine the patients' absorption capability.

Statistical analysis

Data were analyzed using standard statistical software (SPSS 10.0). For normally distributed data, a paired Student' s *t* test was used for statistical analysis. A probability value less than or equal to 0.05 was considered statistically significant. Data are expressed as mean ±SEM.

RESULTS

Thirty-eight patients were admitted and received nutritional support and rehabilitation therapy, among them 2 died of severe malnutrition 2 years after treatment because they failed to receive nutritional therapy, 2 died of accidental event, 1 died of liver failure 5 years later. Thirty-three patients maintained well body weight and serum albumin concentration. The average time of follow-up for 33 survival patients was 5.9±4.3 years (range, 0.5-17 years). Twenty-two patients weaned from TPN, their average TPN time was 9.5±6.6 months. They maintained their nutritional status well on normal oral diet. Two patients, whose whole small bowel, ascending and transverse colon were resected received home TPN. An other 9 patients received parenteral or enteral nutritional support partly as well as oral diet (Table 1). Eight patients developed gall bladder stones. Cholecystectomy was performed for three patients.

For the eight patients, the 3 week rhGH+GLN therapy resulted in weight gain, and stool output dramatically decreased. Three patients weaned from TPN completely after the treatment period, 3 patients reduced TPN requirements, and 2 patients failed the therapy. The absorption capability of D-xylose, ^{15}N-Gly and ^{13}C-palmitic acid in these SBS patients was much lower than normal level. After 3 week rhGH+GLN therapy, the absorption capability of D-xylose, ^{15}N-Gly and ^{13}C-palmitic acid improved. However, it dropped to the level of baseline at one week after treatment (Table 2).

DISCUSSION

After extensive resection of the small intestine, the remaining bowel, to some degree, had a significant adaptation response to resection. Bowel adaptation, characterized by epithelial hyperplasia and increase in villus diameter, height, and crypt depth, occurred weeks to months after resection[9-11]. Various nutritional and medical therapies can be tried to improve bowel absorptive capacity. TPN is the most important factor responsible for prolonging the lives of patients with SBS. In the initial stages after massive resection of bowel, TPN should begin early to attain positive nitrogen balance and to prevent severe weight loss[12,13]. TPN has been shown to greatly increase the chances of long-term survival. It should be delivered until the adaptive processes were complete or indefinitely, if clinically indicated[14]. This process can take place for up to a year and sometimes longer. Long-term TPN resulted in small bowel mucosa atrophy and was associated with certain complications, such as catheter sepsis and liver failure[15]. So, oral diet is encouraged, if there is any absorptive capacity of the remaining bowel, bowel adaptation should be promoted. An enteral tube feeding might be used to supplement the diet in an effort to wean patients from TPN[16]. At first, diluted solutions of chemically defined diets containing simple amino acids and short-chain peptides were offered. Gradually, the diet with intact protein nutrient formulas and dietary fiber was given in accordance with the patients' need. The parenteral supply had to be adjusted according to the oral intake. As the patient' s oral intake increased, the amount of TPN was reduced, the frequency of TPN was reduced to every other day for 1 week, three times in the next week, and twice during the third week or weaned from TPN at last[17]. If the patient lost or more 1 kg/week of body weight or more, if diarrhea exceeded 600 g/day or if laboratory abnormalities developed, then the patients were placed back on TPN[18]. In our group, 22 patients weaned from TPN among the 33 survived patients after receiving rehabilitation therapy. They maintained their nutritional status well on normal oral diet. It indicated that rehabilitation therapy for SBS played important roles in the intestinal adaptation.

Combination of glutamine, human recombinant growth hormone has been shown to influence bowel adaptation[19-24]. The study by Byrne *et al*[25,26] indicated that at one year of follow-up 40 % of treated patients were able to reduce or discontinue parenteral nutrition. Patients in the study were also receiving other medical therapy, including medications known to slow down intestinal motility and oral rehydration solutions. It is not clear whether glutamine, growth hormone, diet, or other factors contributed to the favorable outcome. It did not necessarily mean that fluid and nutrients absorption was increased because absorptive studies were not performed. Szkudlarek *et al*[27] reported in a randomized control study of eight short-bowel patients the combination of growth hormone and glutamine for 28 days did not result in a significant increase in fluid or nutrient absorption. In our clinical trial, we used D-xylose test, ^{15}N-Gly trace test and ^{13}C-palmitic acid breath test to determine the patients' nutrient absorption capability. The results showed that the absorption of carbohydrates (from 5.4 % to 7.6 %), protein (from 62.4 % to 73.2 %) and fat (from 55.3 % to 64.5 %) increased. Weight gain was observed and stool output dramatically decreased. Three patients weaned from TPN completely after the treatment period and 3 patients reduced TPN requirements. However, the absorption capability dropped to the level of baseline at one week after treatment. We found that the treatment with growth hormone and glutamine might increase absorption of nutrients but the effect seemed to be transient with no long term improvement in gut function when treatment was discontinued. This has been supported by recent clinical studies[28-30].

In conclusion, by rehabilitation therapy, most short bowel patients could wean from parenteral nutrition. Dietary manipulation is an integral part of the treatment of SBS. Treatment with growth hormone and glutamine may increase nutrients absorption but the effects are not sustained beyond the treatment period. Therapeutic efficacy can be achieved only when the treatment plan is tailored to meet individual need.

Abstract

AIM: To elucidate the mechanism of restenosis following balloon dilation of benign esophageal stenosis.

METHODS: A total of 49 rats with esophageal stenosis were induced in 70 rats using 5 ml of 50 % sodium hydroxide solution and the double-balloon method, and an esophageal restenosis (RS) model was developed by esophageal stenosis using dilation of a percutaneous transluminal coronary angioplasty (PTCA) balloon catheter. These 49 rats were divided into two groups: rats with benign esophageal stricture caused by chemical burn only (control group, *n*=21) and rats with their esophageal stricture treated with balloon catheter dilation (experimental group, *n*=28). Imaging analysis and immunohistochemistry were used for both quantitative and qualitative analyses of esophageal stenosis and RS formation in the rats, respectively.

RESULTS: Cross-sectional areas and perimeters of the esophageal mucosa layer, muscle layer, and the entire esophageal layers increased significantly in the experimental group compared with the control group. Proliferating cell nuclear antigen (PCNA) was expressed on the 5th day after dilation, and was still present at 1 month. Fibronectin (FN) was expressed on the 1st day after dilation, and was still present at 1 month.

CONCLUSION: Expression of PCNA and FN plays an important role in RS after balloon dilation of benign esophageal stenosis.

INTRODUCTION

Balloon catheter dilation is a common nonsurgical treatment for benign esophageal stricture. Its short-term effect is good, but its long-term effect is not so good, because esophageal restenosis is a major complication. The underlying mechanism of esophageal restenosis has not been understood yet. To study this mechanism, we established a benign esophageal stricture model and restenosis model in Sprague-Dawley (SD) rats. We performed quantitative histopathological image analysis of sections of the rat esophagus, and qualitative immunohistochemical analysis of the related indicators of proliferation and restenosis of mucous and striated muscle layers of rat esophagus dilated by a balloon catheter at different time points. This provided us with an effective experimental model for investigation of the causes of restenosis.

MATERIALS AND METHODS

Materials

All protocols used for animal experiment and maintenance were approved by the Animal Ethics Committee in our university and conformed to the highest international standards of humane care.

70 male Sprague-Dawley (SD) rats weighing 305±50 g were obtained from the Shanghai Experimental Animal Center (Shanghai, China). The animals were weighed on day 0 and then 1 day before sacrifice. After anesthesia with 10 % ketamine (80 mg/kg) by abdominal injection, the animals were placed in a supine position and stabilized on an operating table. A 3F segmental epidural catheter was inserted into the mouth, and 10 ml of edible vinegar was injected into the stomach. The epidural catheter was then replaced by two 3F percutaneous transluminal coronary angioplasty (PTCA) balloon catheters at the mid-to-lower segment of the esophagus. The two balloons were at least 2 cm apart. These balloons were simultaneously inflated with air until they expanded to cling to the wall of the esophagus. Then 5 ml of a freshly prepared 50 % sodium hydroxide solution was injected through the orifice of the balloon catheter. After three minutes the air was released from the balloon. Distilled water was injected repeatedly through the same orifice for rinsing for 1 minute. The balloon catheters were removed and the animals returned to their cages for feeding. An esophageal barium-contrast examination was performed 2 and 4 weeks later to ascertain whether benign esophageal strictures had formed. We achieved 49 animal models from the 70 rats. These 49 rats were divided into two groups: rats with benign esophageal stricture caused by chemical burn only (control group, *n*=21) and rats with their esophageal stricture treated with balloon catheter dilation (experimental group, *n*=28).

Samples were collected at different times for immunohistochemical assay. We divided rats in both groups into seven subgroups according to the time after the dilation procedure when the samples were collected on day 1, 3, 5, 7, 14, 21 and 30. At the time of sacrifice, samples were fixed in 4 % buffered formaldehyde solution.

Table 1 Source of antigens and their effective concentrations

First antibody			Second antibody		
Goat antihuman PDGF	Promega	1:40	Biotinylated house antigoat IgG	Vector	1:200
Mouse antihuman FN	Life	1:20	Biotinylated house antimouse IgG	Vector	1:200
Mouse antihuman PCNA	Maxim	1:20	Biotinylated house antimouse IgG	Maxim	1:200

Statistical analysis: Data were expressed as the mean±SD. Statistical analysis was performed using the unpaired or paired *t*-test. A probability value less than 0.05 was considered significant.

Methods

Image analysis: Esophageal sections were stained with hematoxylin and eosin, and images were taken by a CCD camera (JVC, Osaka, Japan) and analyzed by a VIDAS imaging system (Carl Zeiss, Germany). The indicators used comprised the cross-sectional areas and perimeters of esophageal mucous layer, esophageal muscle layer, and the entire esophageal layers.

Immunohistochemical staining: ABC methods and SP methods were performed following the manufacturer's instructions using an ABC kit (Vector, USA) and an SP immunochemistry kit (Zymed Maxim, USA). The source of antibodies and their effective concentrations are listed in Table 1. The presence of platelet-derived growth factor (PDGF) and fibronectin (FN) was tested by the ABC method, and proliferating cell nuclear antigen (PCNA) was tested by the SP method.

RESULTS

Models of benign esophageal stricture and esophageal restenosis

Of the 49 model rats with benign esophageal stricture, 28 rats with esophageal restenosis were established.

Morphologic changes in benign esophageal stricture and esophageal restenosis

The control group showed chemical-burn lesions with an inflammatory reaction on the mucous layer of the esophagus, and comparatively slight thickening on the muscle layer of the esophagus. No broken regions were found in the muscle layer of the esophagus, and the esophageal wall was intact. Besides chemical-burn lesions, the experimental group showed mechanical damage in the mucosa of the esophagus. The muscle layer of the esophagus was thickened and broken, with accompanying inflammatory reactions (Figure 1). On the 5th day after the procedure, the broken section of the muscle layer of the esophagus became thickening, and 14 days later the degree of thickening was obvious. The changes in the cross-sectional areas and perimeters of mucosa, muscle layers, and the entire esophagus wall are listed in Table 2.

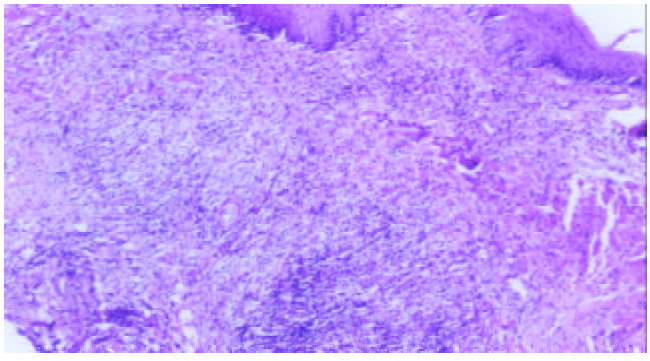

Figure 1 In the experimental group, on the 5th day after the procedure, muscle layers of the rat esophagus exhibited an inflammatory reaction. H&E stain, ×4.

Table 2 Morphologic changes in benign esophageal stricture and esophageal restenosis (area, mm^2; perimeter, mm)

	Control group	Experimental group
A1	0.49±0.14	0.75±0.18[b]
A2	1.70±0.42	1.97±0.33[a]
A3	2.20±0.45	2.72±0.46[a]
P1	4.83±1.52	6.65±1.22[b]
P2	6.89±1.96	8.80±1.67[b]
P3	9.86±2.25	14.19±2.89[b]

[b]$P<0.01$, [a]$P<0.05$ *vs* control group and experimental group. Abbreviations: A1: cross-sectional area of mucosa of esophagus, A2: cross-sectional area of muscle layer of esophagus, A3: cross-sectional area of entire esophagus wall, P1: perimeter of mucosa of esophagus, P2: perimeter of muscle layer of esophagus, P3: perimeter of entire esophagus wall.

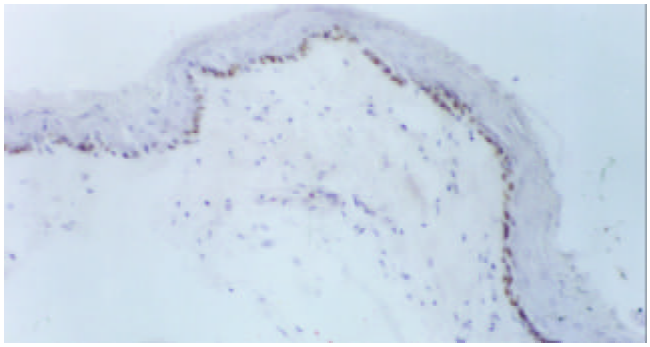

Figure 2 In the experimental group, on the 5th day after the procedure, the basal cells of the squamous epithelium in rat esophagus exhibited strong PCNA expression. Immunostaining, ×4.

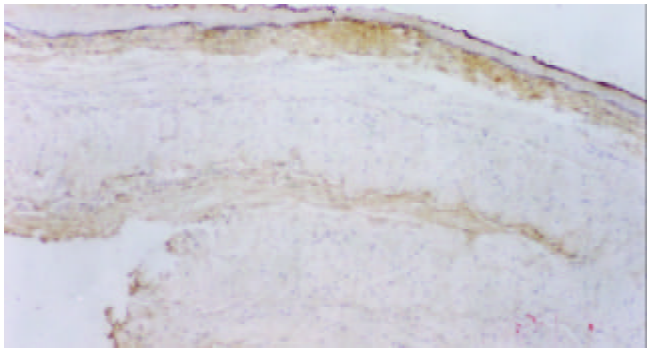

Figure 3 In the experimental group, on the 30th day after the procedure, the substratum of the rat esophageal mucosa and muscle layers exhibited strong FN expression. H&E stain, ×4.

Immunohistochemical staining of benign esophageal stricture and esophageal restenosis: In the control group, basal cells of the squamous epithelium and striated-muscle cells of the esophagus exhibited no PCNA expression. Five days after the dilation procedure, PCNA expression became obvious in

basal cells of the squamous epithelium, and this positive expression lasted for 30 days (Figure 2). In the control group, 3-7 days after the dilation procedure, the basal layer of the esophagus exhibited weak positive expression. Fourteen days later there was no FN expression in the basal layer. In the experimental group, on the 1st day after the procedure, the collagen fibers in submucosa and in the striated-muscle layer of esophagus were positive for FN, and this was still the case on the 14th day. After 1 month, FN positive expression was still reasonably strong (Figure 3). PDGF was not expressed at all in striated-muscle cells from the 1st to the 30th day in both control and experimental groups.

DISCUSSION

Models of benign esophageal stricture and esophageal restenosis

The causes of benign esophageal stricture are numerous and complicated, and hence the models thereof are difficult to reproduce consistently. However, benign esophageal stricture eventually manifests as thickened scars and reduced luminal sizes. We used chemical burns to develop the model of benign esophageal stricture because it allowed timing to be controlled and exhibited a high rate of success. Early in the 1970s, Przymanowski *et al*[1] used sodium hydroxide to establish a model of benign esophageal stricture. Their method was to perform an abdominal midsection on rats, thereby exposing the lower segment of the esophagus. They used surgical thread to tightly tie the region 2-cm either side of the lower segment of the esophagus. They then inserted a stomach tube via the mouth until it reached the tied point. Sodium hydroxide solution was injected, and then rinsed out three times for 3 minutes with distilled water later. Then they withdrew the tube, cut the threads, and closed the abdomen. Based on their procedure, we developed a nonsurgical method to establish a model of benign esophageal stricture. Since our method did not involve surgery, it was simpler and faster. Our experimental observations demonstrated that the model was satisfactorily established. Our use of two balloon catheters made manipulation somewhat difficult. We intended to make a single catheter with two balloons, but this was found to be too difficult since the rats had a narrow esophagus that demanded fine catheters and balloons. In contrast, a double-balloon catheter with a larger caliber was easy to be constructed. Therefore, the double-balloon method was used to establish the model of benign esophageal stricture.

The technique used to establish the model of esophageal restenosis is easier. After ascertaining the stricture position by esophageal visualization, we performed balloon catheter dilation under X-ray. In this way, the esophageal restenosis model was established. In a very few cases of severe stricture, the restenosis model could not be produced due to the catheters being unable to pass through.

Morphological changes in benign esophageal stricture and esophageal restenosis

After the benign esophageal stricture formed, its morphology was relatively stable. It manifested as thickened muscle layers, reduced luminal sizes, and inelastic lumens. Thus it caused dysphagia. The esophageal morphology was altered by balloon catheter dilation. The esophageal mucosa exhibited not only chemical-burn lesions, but also lesions caused by mechanical damage. The thickened muscle layer of the esophagus was torn or broken, causing the areas of mucosal and muscle layers of the esophagus to increase siginficantly in the experimental group. Significant differences were also observed in the perimeters of the mucosal and muscle layers of the esophagus and in the perimeter of the entire esophagus wall. Within the same group, after the dilation procedure the areas of each layer increased rather than decreased, whilst the perimeters also increased. This indicated that dysphagia improvement was due to an enlargement of the lumen of the esophagus after dilation. Up to a certain time, these new scar tissues would further contract and cicatrize. As a result, the duct lumen was further reduced and lacked elasticity. This was one of the key factors in esophageal restenosis. This also illustrated that if there was no treatment plan after balloon dilation in benign esophageal stricture, esophageal restenosis could not be resolved[2-28].

Immunohistochemical observation of benign estophageal stricture and estophageal restenosis

PCNA is a type of nuclear protein equivalent to the binding protein of DNA polymerase. It coordinates the synthesis of DNA up and down strands. The quantity of PCNA is minimal in normal cells at the G_0, whereas at the M stage the quantity of PCNA in transforming cells changes dramatically. The quantity of PCNA mostly declines at stage G_0/G_1. This quantative change coincides with DNA synthesis. Therefore, PCNA is used as an indicator to assess cell proliferation. There were a number of reports on the application of immunohistochemical methods to the study of tumor-cell proliferation[29]. In our study, we used the new method involving PCNA to investigate the basal-cell proliferation of the squamous epithelium in benign esophageal stricture by the procedure of balloon dilation. We found that there was no PCNA expression in the control group in basal cells of the squamous epithelium of the esophagus. However, in the experimental group, PCNA was expressed strongly from day 5 onwards 30 days later, PCNA expression was still positive. This consistently high proliferation of basal cells illustrated their importance in the development of esophageal restenosis.

FN was a glucoprotein with multiple functions[30]. As a noncollagenous substance in the extracellular matrix, it participates in various reactions between cells as well as between cells and the extracellular matrix, including adhesion, migration, injury, restoration, and tumor metasis. FN has two forms: a soluble dimerization in humor and a barely soluble polymerization in the extracellular matrix. After combining with its receptor through a tripeptide sequence Arg-Gug-(RGD), FN transmits cellular signals and facilitates cells' interfacing and kinetics. The study of FN expression in the lesion of benign estophageal stricture caused by balloon dilation is therefore helpful to elucidate the mechanism of proliferation and migration of cells. In the control group, we noticed that the expression of FN in the basal mucosa of the esophagus was weak, which indicates that FN expression after a chemical burn is related to the esophageal stricture. In the experimental group, soon after the procedure the squamous epithelium and striated-muscle cells expressed a large amount of FN. This reaction might be related to regulated cellular proliferation and chemotaxis. Previous studies have shown that FN has the similar function to growth factor in fibroblast cells. Even in small doses it can accelerate proliferation. An *in vitro* study has also shown that fibroblasts could adhere directly to the FN matrix or adhere to collagen through FN. FN can also facilitate unfolding of cells that adhere to the matrix. We also noticed that in the experimental group, FN was strongly expressed at both early and later stages after the procedure. This illustrates that FN is one of the key factors in the production of esophageal restenosis, especially at the late stage.

PDGF could stimulate the proliferation of fibroblasts *in vitro*[31-38]. Initially it was found in platelet granules, and afterwards its secretion was also found in normal cells and transformed cells. It exists in three biologically active isoforms: PDGF-AB, PDGF-AA, and PDGF-BB; comprising PDGF-A and PDGF-B polypeptide chains. It acts on target cells through receptors consisting of two subunits, α and β. PDGF-AB

combines αα and ββ functions. In our experiment, PDGF was not expressed in striated muscle cells of the esophagus, which indicates that PDGF is not a key factor in esophageal restenosis produced by balloon dilated esophageal stricture. However, the enhanced expression of PDGF was involved in the proliferation of smooth-muscle cells. In the study of restenosis, PDGF was regarded as a strong split promoter and chemotactic factor, playing an important role in the formation of blood vessel restenosis. The full length of the esophagus in SD rats (as used in our experiments) comprised striated muscle, and hence PDGF and its function could not be shown in esophageal restenosis in these rats. Besides, in clinical settings, relatively severe chemical burns of the esophagus are usually located at the middle and lower segments of the esophagus, while the upper segment is rarely involved. The middle and lower segments of the esophagus comprise smooth muscle, while the upper segment is striated muscle. This indirectly demonstrates that PDGF expressed in smooth-muscle cells plays a greater role than that in striated-muscle cells in the formation of benign esophageal stricture and restenosis.

Abstract

AIM: To determine the best mothod for benign stricture of the upper gastrointestinal tract (UGIT) with stent insertion by follow-up evaluation.

METHODS: A total of 110 stents insertions were performed in 110 cases of benign stricture of the UGIT. Permanent (group A) and temporary (group B) placement of an expandable metal stent in 30 cases and 80 cases respectively. All cases were completed under fluoroscopy.

RESULTS: In group A, 30 uncovered or antireflux covered or partially covered expandable metal stents were placed permanently. In group A, 5 cases (16.7 %) in 3-months, 5 cases (20.0 %) in 6-months, 6 cases (25 %) in the 1st year, 6 cases (50 %) in the 3rd year, and 4 cases (80 %) in the 5th year exhibited dysphagia relapse. In group B, a partially-covered expandable metal stent was temporarily placed in each patient and removed after 3-7 days via gastroscopy. Follow-up data in this group showed that 8 cases (7.5 %) in 3-months, 9 cases (12.0 %) in 6-months,10 cases (15.4 %) in the 1st year, 6 cases (20 %) in the 3rd year, and 3 cases (25 %) in the 5th year exhibited dysphagia relapse. The placement and withdrawal of all stents were all performed successfully. The follow-up of all cases lasted for 3-99 months (mean 41.6±19.7 months).

CONCLUSION: The best mothod for benign stricture of UGIT with stent insertion is temporary placement of a partially-covered expandable metal stent.

INTRODUCTION

Benign stricture of the upper gastrointestinal tract (UGIT) refers to stenosis caused by benign pathological changes in the pharynx, esophagus, stomach, and duodenum. Such stenosis includes marginal stricture after surgery, chemical-burn-related stricture, simple scar-related stricture after radiation therapy for tumor, digestive stricture, and functional stricture (achalasia). Since July 1994 , 110 cases with benign stricture of the UGIT have been treated with stent insertion and followed-up. We herein report our experiences.

MATERIALS AND METHODS

Materials

Our subjects were 110 patients with benign stricture of the UGIT (61 males, 49 females; age 18-84 years, mean 53.9 years). Sequential trials were adopted for these cases who were nonrandomly divided into the following two groups according to the method of stent insertion: 30 cases with permanent uncovered or antireflux covered or partially covered metal stent dilation (group A), and 80 cases with temporary partially covered metal stent dilation (group B). In group A there were 6 cases of simple cicatricial stricture after radiation therapy for esophageal carcinoma, 8 cases of achalasia, 13 cases of esophageal and esophagogastric marginal stricture, 2 cases of gastroduodenal marginal stricture, and 1 case of esophageal chemical-burn-related stricture. The mean diameter of the strictured UGIT was 3.2±2.3 mm before stent placement and 17.8±2.4 mm after stent placement. In group B there were 2 cases of simple scar-related stricture after radiation therapy for esphageal carcinoma, 67 cases of achalasia, 9 cases of esophageal and esophagogastric marginal stricture,and 2 cases of esophageal chemical burn. The mean diameter of the strictured UGIT was 3.3±2.1 mm before stent placement and 22.3±2.7 mm after stent placement. All cases had dysphagia grades 2-4 before stent insertion and dysphagia grades 0-2 after stent insertion. All casess were examined by barium-meal radiography of the UGIT and gastroscopy.

Methods

It involved an empty stomach for at least 4 h and examination of the normal bleeding and clotting time. Two types of metal stent were used: covered stainless steel wire Z-stent (COOK, USA), and partially covered or uncovered or antireflux covered nitinol stent (Zhiye Medical Equipment Research Institute, Changzhou, China; and Youyan Yijin Advanced Materials Co. Ltd, Beijing, China). The COOK stents were constructed from multiple fragments, each fragment was typically 2-cm long. The stent was completely coated on the outer layer and mounted with a metal barb. The diameter of the stent body was 18 mm and that of the horn was 25 mm. The body of the partially covered metal stents was coated with intracavity silica gel. The areas within 2 cm of both ends of the stents were not covered. Stents were 4-14 cm in length and 16-30 mm in diameter. They had single or double horns, the horn diameter was 20-35 mm.

The different types of metal stents were placed differently. For example, placement of the partially-covered nitinol internal stent used in groups B and C firstly involved spraying the

pharynx with 1% lidocaine (as a mist) for anesthesia. When a stent was a placed, the patients were placed in a sitting position or lying on the side, and where applicable with their false teeth removed and a teeth bracket mounted. A 260-cm-long guidewire was first led into the distal end of the benign stricture. The stent was mounted on the propeller whose front end was coated with sterilized liquid paraffin. Guided by the wire, the propeller on which the stent was mounted was moved through the strictured section. Under fluoroscopic control, the outer sheath was slowly withdrawn and the stent expanded under its own tension. After the stent was placed, radiography was performed to observe the patency of the UGIT. In group B, 500-1 000 ml of ice-cold water was injected 3-7 days after stent placement via a bioptic hole under gastroscopy, which caused the stent to reduce its diameter. Bioptic pliers were then used to withdraw the stent using a gastroscope. Gastroscopy was performed again in the UGIT to detect complications, such as bleeding, mucosal tearing, or perforation of the UGIT. The patients returned to the ward and consumed cold drinks and snacks for 2 days before resuming a normal diet. It was preferable for patients to eat solid food since the natural expansion caused by ingesting food reduced the retraction of the UGIT.

Criteria for therapeutic efficacy included diameter of the most-strictured section of the UGIT before and after dilation, and dysphagia score before and after dilation.

After stent placement barium-meal radiography was performed to observe patency of the UGIT. The patients ate semifluid food on the day after surgery, and were treated with antibiotics, antacids, and antireflux drugs. One week after stent removal, barium-meal radiography of the UGIT was performed to observe patency of the UGIT. The patients went to a clinic or were followed-up by telephone at the 3rd, 6th months, 1st, 3rd and 5th year.

RESULTS

In group A, 30 uncovered or antireflux covered or partially-covered stents were placed. Stent placement was successful in all the cases. In group B, 80 partially- covered stents were placed and removed under gastroscopy guidance 3-7 days after stent insertion. The successful rate of stent placement and extraction was 100 %. Relapse rate of dysphagia treated with stent insertion during follow-up is shown in Table 1.

DISCUSSION

Since Domschke *et al*[1] reported the first successful treatment of malignant esophageal strictures with an uncovered expandable metal stent in 1990, placement of covered or uncovered or antireflux covered expandable UGIT metal stents has been shown to be a safe, easy, and effective treatment for malignant UGIT strictures. Cwikiel *et al*[2] reported the first successful treatment of benign esophageal strictures in 1993. Cheng *et al*[3] reported the first successful treatment of benign esophageal strictures with temporary partially covered stent in 1999. Many patients with benign UGIT strictures have received treatment with uncovered or covered or temporary partially covered metal stents[4-26]. Permanent uncovered metal stent insertion for benign functional stricture in the UGIT had poor mid-term and long-term therapeutic efficiency, mainly due to frequent severe gastroesophageal reflux and restenosis (hyperplasia of granulation tissue). After a 12-month follow-up, three uncovered metal stents could not be removed in three cases of achalasia, and we had to resect and reconstruct the esophageal cardia. Therefore, permanent uncovered metal stent dilation is not suitable for cases of functional stricture of the UGIT. Permanent partially covered metal stent dilation had poor mid-term and long-term therapeutic efficiency, mainly due to reflux and stent migration[27-37].

Temporary partially-covered metal stent dilation was used for benign stricture of the UGIT with both excellent immediate and mid- and long-term therapeutic efficacy. Firstly, the design of the stent coincided with the specific anatomy of the UGIT and pathological manifestations of benign stricture. If a stent was not well designed, it did not exhibit therapeutic efficacy, and was also associated with a higher frequency of complications such as stent migration. With the aim of solving these problems, we designed a special stent for benign stricture of the UGIT. The stent was partially covered. A membrane covered the inner wall of the stent, with the area within 2 cm of the stent orifice not covered. The upper orifice of the stent was a large horn, which increased the stability of the stent but made it difficult to withdraw. Secondly, the diameter of the stents used in this group was 16-30 mm. By dilating the stent, the stricture could almost be returned to the maximum diameter of a normal strictured UGIT. What the diameter of a stent is most appropriate is that the stent should expand the strictured part without complications. We found that the bigger the diameter of stents was, the better the mid- and long-term therapeutic efficacy was ,but the ideal size still needs to be further investigated.

The further development of biologically degraded stents for the gastrointestinal tract would provide advantages of a very long retention time without the necessity to remove the stent[38]. This would provide potentially superior stent insertion for cases of benign stricture of the UGIT. In the treatment of UGIT benign stricture with stent insertion, temporary partially-covered metal stent dilation will gradually replace others and become the preferred method for the nonsurgical treatment of

Table 1 Relapse rate of dysphagia treated with stent insertion

Group	Follow-up >3 months (*n*)	Dysphagia relapse (*n*)	Dysphagia relapse rate (%)	Follow-up >6 months year (*n*)	Dysphagia relapse (*n*)	Dysphagia relapse rate (%)
A	30	5	16.7%	25	5	20.0%
B	80	8	7.5%	75	9	12.0%

Group	Follow-up>1st year (*n*)	Dysphagia relapse (*n*)	Dysphagia relapse rate (%)
A	24	6	25.0 %
B	65	10	15.4 %

Group	Follow-up >3rd year (*n*)	Dysphagia relapse (*n*)	Dysphagia relapse rate (%)	Follow-up >5th year (*n*)	Dysphagia relapse (*n*)	Dysphagia relapse rate (%)
A	12	6	50.0 %	5	4	80.0%
B	30	6	20.0 %	12	3	25.0%

benign stricture in gastrointestinal tract due to its superior mid-term and long-term therapeutic efficacy[39,40].

According to our experiences in the treatment of 110 casess of benign stricture of the UGIT with stent insertion, we consider that the method chosen for an individual case should be based on the nature of the stricture, course of disease, and complications. Moreover, long-term therapeutic efficacy and medical expense need to be comprehensively assessed. Finally, other combined therapies should be carried out concurrently both before and after the treatment in order to achieve a high therapeutic efficacy.

Abstract

AIM: To study the correlation between genetic polymorphism of cytochrome P450IIE1 (CYPIIE1) and fatty liver.

METHODS: Peripheral blood mononuclear cells were collected in 56 patients with fatty liver, 26 patients without fatty liver and 20 normal controls. Then PCR-RFLP was used to analyze genetic polymorphism of CYPIIE1 in monocytes on the region of Pst I and Rsa I.

RESULTS: The frequency of homozygotic C1 gene in patients with alcoholic fatty liver (28.6 %), obese fatty liver (38.5 %), or diabetic fatty liver (33.3 %) was significantly lower than that of the corresponding patients without fatty liver (100 %, 100 % and 80 % respectively), while the frequency of C2 genes, including C1/C2 and C2/C2, was significantly higher (71.4 %/0 %, 61.5 %/0 %, and 66.7 %/20 %) (P<0.01). The frequency distribution of the above genes of non-fatty liver patients (100 %/0, 100 %/0, and 80 %/20 %) was not significantly different from that of the normal controls (85 %/15 %) (P>0.05).

CONCLUSION: The genetic polymorphism of CYPIIE1 on the position of Pst I and Rsa I is related to the susceptibility of fatty liver. Besides, C2 gene may play a key role in the pathogenesis of fatty liver.

INTRODUCTION

Cytochrome P450 (CYP) is a group of isoenzymes encoded by genes with similar structure and function, whose molecular weight is 40-60KD. CYP is a kind of monooxygenase, located in the smooth endoplasmic reticulum of cells. According to the similarity of amino acid sequence, CYP is divided into CYPI, CYPII, CYPIII, and CYPIV gene families. The subfamily is named alphabetically, and every enzyme is named in number order. Cytochrome P450IIE1 (CYPIIE1) is a N-nitrosodimethylamine demethylase, which is mainly expressed in the liver with an evident racial and individual difference in activity. It not only takes part in the metabolism of drugs, but also activates a lot of precarcinogens and prepoison[1-4]. Human CYPIIE1 is located in 10q2403-qter. It is 1104Kb consisting of 9 extrons and 8 introns, encoding a 493-amino acid protein[5]. The polymorphism of CYPIIE1 gene is significantly different among races and individuals. It may be related to some genetic factors. CYPIIE1 has 6 restriction fragment length polymorphisms (RFLP), among which 5' -flanking region of Pst I and Rsa I affects CYPIIE1 expression at the transcription level. C2 allelic gene can enhance the transcription, which causes the different activities of CYPIIE1[6-11].

Fatty liver is common and is resulted frequently from alcohol excess, obesity, diabetes or drugs[12-17]. Its pathogenesis remains unclear. Studies on the relationship between genetic polymorphisms of CYPIIE1 and the development of alcoholic fatty liver has been reported, but the results are disputable[17-21]. In this study, we used PCR-RFLP to study the relationship between genetic polymorphisms of CYPIIE1 and alcoholic or non-alcoholic fatty liver.

MATERIALS AND METHODS

Reagents

Heparin and lymphocyte separation medium were purchased from Tianjin Hematologic Institution of Chinese Academy of Medical Sciences. The primers of CYPIIE1, PCR buffer, dNTP, and Taq enzyme were obtained from Roche (America). Restriction endonucleases (PstIand RsaI), their buffer, and pUC19-DNA marker were obtained from MBI Ferments.

Patients and controls

From October 1998 to January 2001, 82 patients from several hospitals in Jilin Province were studied, among them 28 cases had alcoholic fatty liver, 8 cases had alcoholism but no liver disease, 13 cases had obese fatty liver, 8 cases had obesity but no fatty liver, 15 cases had diabetic fatty liver, and 10 cases had diabetes but no fatty liver. Twenty health blood donors were used as normal controls. The standard of alcoholism for female was drinking alcohol >40 g/d, for male drinking alcohol >80 g/d, for at least 5 years. The age and sex distribution of the two groups were similar. Five ml venous blood was taken from every person and anticoagulated with heparin.

PCR-RFLP

Peripheral blood mononuclear cells (PBMC) were separated by density gradient centrifugation. Then DNA was extracted. The two primers of CYPIIE1 were 5' -ccagtcgagtctacattgtca-3' (1 370-1 349) and 5' -ttcattctgtcttctaactgg-3' (999-978) respectively. PCR was conducted for 40 cycles with denaturing at 94 ℃ for 1 min, annealing at 50 ℃ for 1 min, extending at 72 ℃ for 1 min, and then designed to extend at 72 ℃ for 10 min. The PCR products were digested with Pst I or Rsa I at 37 ℃ for 2 hours, then loaded onto a 20 g/L agarose gel for electrophoresis. At last, the DNA fragments were observed under ultraviolet lamp.

Statistical analysis

Analysis of data was performed using χ^2 test. P<0.05 was considered to be statistically significant.

RESULTS

Genetic polymorphism of CYPIIE1

The PCR products were fragments of 410 bp (Figure 1). After digestion with restriction enzyme Pst I or Rsa I, CYPIIE1 was divided wild type homozygote group (C1/C1, type A), heterozygote group (C1/C2, type B) and mutant homozygote group (C2/C2, type C) (Figure 2). C1 referred to wild type gene (PstI+, RsaI-), and C2 referred to mutant gene (PstI-,RsaI+).

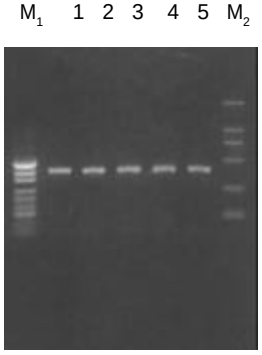

Figure 1 Electrophoregram of PCR products (Lanes 1-5). The signals of pUC19-DNA marker (M_1) present 489 bp, 404 bp, 331 bp, 242 bp, 190 bp, 147 bp and 110 bp from up to bottom. The signals of DL2000-DNA marker (M_2) present 2 000 bp, 1 000 bp, 750 bp, 500 bp, 250 bp and 100 bp from up to bottom.

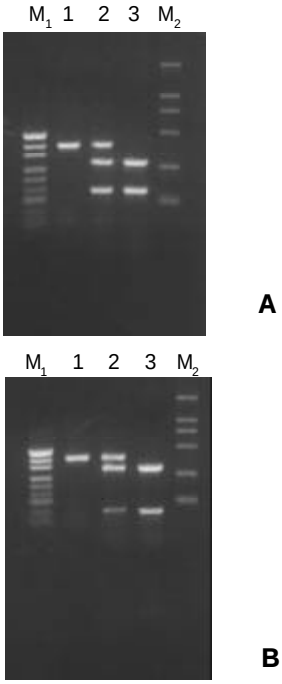

Figure 2 After digested with restriction enzyme PstI(A) or RsaI (B), CYPIIE1 was divided into three types, namely wild type homozygote (C1/C1) (Lane 1), heterozygote (C1/C2)(Lane 2) and mutant homozygote (C2/C2)(Lane 3). C1 means wild type gene (PstI+, RsaI-), and C2 mutant gene (PstI-, RsaI+). pUC19-DNA marker (M_1) and DL2000-DNA marker (M_2).

Genotype distribution

The genotype distribution of each group of patients and controls are presented in Table 1.

Comparison of gene frequency

The frequency of homozygotic C1 gene in patients with alcoholic, obese, or diabetic fatty liver was significantly lower than that of patients with corresponding diseases but without fatty liver, while the frequency of C2 genes, including C1/C2 and C2/C2, was significantly higher (P<0.01) (Table 2). Compared with healthy controls, the frequency of homozygotic C1 gene of the patients with alcoholic, obese, or diabetic fatty liver was apparently lower and the frequency of C2 gene was apparently higher (P<0.01). At the same time, there was no obvious difference in homozygotic C1 gene or C2 gene between healthy controls and patients with alcoholism, obesity or diabetes but without fatty liver (P>0.05).

Table 1 Genotype distribution of each group of patients and controls

Group	*n*	A (C1/C1)	B (C1/C2)	C (C2/C2)
Patients with alcoholic fatty liver	28	8	14	6
Patients with alcoholism but without liver diseases	8	8	0	0
Patients with obese fatty liver	13	5	6	2
Patients with obese but without fatty liver	8	8	0	0
Patients with diabetic fatty liver	15	5	8	2
Patients with diabetes but without fatty liver	10	8	2	0
Healthy controls	20	17	3	0

Table 2 Comparison of gene frequency of each group (%)

Group	A	B	C	C2 frequency
Patients with alcoholic fatty liver	28.6	50.0	21.4	71.4
Patients with alcoholism but without liver diseases	100	0	0	0
Patients with obese fatty liver	38.5	46.1	15.4	61.5
Patients with obese but without fatty liver	100	0	0	0
Patients with diabetic fatty liver	33.3	53.4	13.3	66.7
Patients with diabetes but without fatty liver	80	20	0	20
Healthy controls	85	15	0	15

DISCUSSION

There are three metabolic pathways of ethanol in the liver, alcohol dehydrogenase (ADH) in cytoplasm, microsomal ethanol oxidazing system (MEOS) in smooth endoplasmic reticulum, and catalase in peroxidase. The major component of MEOS is CYPIIE1[22,23]. When concentration of ethanol in blood and liver tissue is low, most of ethanol is oxidized by ADH. While for the alcoholism or the people in whose liver tissue the concentration of ethanol is higher than 10 mmol/L, the activation of MESO plays a key role in metabolism of ethanol. In the pathogenesis of alcoholic fatty liver, the function of CYPIIE1 was mainly to take part in lipid peroxidation (LOP) reaction and to increase the contents of microsomal oxygen and carbonyl free radical[16,24,25]. It has been proved in rat models that generation of microsomal oxygen and carbonyl free radical formed from oxidated ethanol was related to CYPIIE1[26,27]. It was presumed that these oxygen-derived free radicals might impair the liver by directly damaging liver cells, affecting the sensititity of the liver to LPO, and inducing antibody-dependent cytotoxic effect through combination with CYPIIE1 on the cell membrane[28-30]. Not every alcoholic abuser could inevitably induce liver injury. Iwahashi K and colleagues[31] reported that in the people who had C2 allele, CYPIIE1 activity was much

higher, and metabolic ability on ethanol was much stronger. Our results showed that homozygotic C1 gene frequency of the patients with alcoholic fatty liver was significantly lower than that of the controls or the patients with alcoholism but without fatty liver, while C2 gene frequency was much higher. It suggested that C2 gene might induce the expression of CYPIIE1 and facilitate genesis of alcoholic fatty liver.

LPO also took part in the pathogenesis of non-alcoholic fatty liver induced by obese or diabetes[32,33]. Now the precise stimulator of LPO reaction is unclear. The expression of CYPIIE1 in the animal models and patients with nonalcoholic fatty liver might be related to the induction of acetone and fatty acid[34,35]. It has been proved that the level of CYPIIE1 in the rats with obesity was four times as high as that of the rats without obesity[36]. The rising concentration of fatty acid and pyruvic acid in the liver might be a risk factor in pathogenesis of nonalcoholic fatty liver. When the increased fatty acid concentration in blood of patients with obesity could not be oxidated by mitochondria completely, CYPIIE1 would have the ability to oxidize fatty acid and in turn is activated by it so as to strengthen the oxidation ability. During oxidation of fatty acid, high reactivity carbonyl free radicals would be produced, which then stimulated the production of LPO, at last injured the liver[37]. In patients with diabetes, the ketone bodies produced by the liver could not be totally utilized by extrahepatic tissues, and the level of acetone would rise in the liver. The acetone could not only induce CYPIIE1 activation, but also be resolved by it. A great many of free radicals were produced, thus injuring the liver[38]. Not all patients with obesity or diabetes suffer from fatty liver. Our results showed that C2 gene frequency in patients with obese fatty liver or diabetic fatty liver was obviously higher than that of the patients without fatty liver. In conclusion, C2 gene frequency in patients with alcoholic or nonalcoholic fatty liver is much higher than that of controls. So C2 gene may be important for the pathogenesis of fatty liver.

Abstract

AIM: To evaluate the significance of hsp90α expression in human gastric cancer tissues.

METHODS: Immunohistochemical staining was used in clinical specimens from 33 cases of gastric cancer and 33 cases of gastritis with rabbit anti-human hsp90α multi-clonal antibody in order to explore the relationship between the expression of hsp90α in gastric carcinoma tissue and gastritis tissue as well as in mucous membrane adjacent to cancer and lymph node metastasis.

RESULTS: Hsp90α was detected in 88 % of gastric carcinoma cases and 55 % of gastritis cases. The hsp90α positive rate in gastric cancer group was significantly higher than that in gastritis group ($P<0.01$, $P=0.005$). The hsp90α positive rate in gastric cancer and in mucous membrane adjacent to cancer was 88 % and 55 % respectively ($P<0.01$,$P=0.005$). The hsp90α positive rate in lymph node metastasis group and non-lymph node metastasis group was 100 % and 60 % respectively, and a significant correlation between hsp90α expression and lymph node metastasis was shown ($P<0.01$, $P=0.005$).

CONCLUSION: The hsp90α expression rate in gastric cancer group was significantly higher than that in gastritis group as well as that in the group of mucous membrane adjacent to cancer. The hsp90α expression in lymphatic node metastasis group was higher than that in non-lymphatic node metastasis group. The results indicate that increased hsp90α expression has a close relationship with occurrence and lymph node metastasis of gastric cancer.

INTRODUCTION

Heat shock protein90α, commonly known as heat stress protein, is a highly conserved cytosolic protein during the evolution of living things. It extensively exists in the living organisms and has many important biological functions such as enhancing cellular tolerance to stress and maintaining cellular homeostasis, etc. There are two forms of hsp90 in the advanced organisms, i.e. α form and β form. Under stress, the synthesis of hsp90 increases. For example, high temperature and infection can induce increase of hsp90 synthesis. However, different inducers play different roles in inducing hsp90 synthesis. hsp90α is more sensitive to heat induction, hsp90β is more sensitive to mitosis induction[1]. Recent studies showed that hsp90 had a close relationship with carcinoma. It was highly expressed in cancer tissue[2]. hsp90 combines with many transformed proteins to form complexes that are transported into intracellular special sites and correlated with cancer cell proliferation and differentiation[3,4]. There is a close relationship between the occurrence of gastric cancer and the synthesis of heat shock protein. At present there have been few reports on the study of hsp90 expression during the genesis of gastric cancer. In our study, we used immunohistochemical staining SP method to detect the expression of hsp90α in gastric cancer, gastritis, mucous membrane adjacent to cancer and gastric cancer tissue with or without lymph node metastasis in order to explore the relationships among them and their clinical significances,as well as the roles of hsp90α expression in the genesis and development of gastric cancer. Our study showed that the hsp90α expression rate in gastric cancer group was significantly higher than that in gastritis group, and in group of mucous membrance adjacent to cancer, hsp90α expression in the lymphatic node metastasis group was higher than that in the non-lymphatic node metastasis group.

MATERIALS AND METHODS

Samples collection

A total of 66 samples were collected from our hospital which were cut off from the stomach after operation, including 33 cases of gastric cancer and 33 cases of gastritis. Twenty-three of the 33 cases of gastric cancer had lymph nodes metastases and 10 cases had no lymph node metastasis. The samples were fixed in 10 % formaldehyde, dehydrated and embedded in paraffin. Five μm-thick sections were sliced. All samples were confirmed by pathological diagnosis.

Immunohistochemistry reagents

Rabbit anti-human hsp90α multi-clonal antibody (650-871-1919 CA, U.S.A), immunohistochemical staining S-P kit and DAB were purchased from Maixin LTD.

Methods

Immunohistochemical SP staining method was used in our experiment. The conventional staining procedures were carried out. The main procedures were as follows. The tissue sections were routinely dewaxed and hydrated, then treated with 3 % peroxide for 10 minutes. Antigen restoration was carried out by heating in citrate buffer, blocked with normal goat serum, incubated overnight with anti-human hsp90α multi-clonal antibody at 4 ℃, washed three times with PBS, treated with antibody II for 30 minutes at 37 ℃ and then with antibody III

for 30 minutes at 37 ℃. Color was displayed with DAB. Negative control was designed with PBS instead of antibody I. The known positive tissue sections were used as positive control.

Statistic analysis

SPSS10.0 software was used for statistical analysis.

RESULTS

Evaluation standard

Under light-microscope the hsp90α immunoreactive products showed as granules with brown color. These granules were mainly located in cytoplasm, only a few in nuclei. According to the amount and color density of granules, the staining was divided into three grades: +: few granules, canary color; ++: lots of granules filled cytoplasm, brown color ; +++: cytoplasm was filled with brown-black granules. The granules were also found in nucleoli. Detailed expressions of hsp90α in tissues of gastric cancer, gastritis and lymph nodes are shown in Tables 1, 2 and 3.

Table 1 Hsp90α expression in tissues of gastric cancer and gastritis

Pathologic types	*n*	Grade of hsp90α expression				Positive rate (%)
		-	+	++	+++	
Gastric cancer	33	4	23	4	2	88
Gastritis	33	15	13	4	1	55

[b]$P<0.01$ *vs* group of Gastritis, $\chi^2=8.943$.

Table 2 Hsp90α expression in gastric cancer tissues and tissues adjacent to cancer

Pathologic types	*n*	Grade of hsp90α expression				Positive rate (%)
		-	+	++	+++	
Gastric cancer	33	4	23	4	2	88
Tissues adjacent to cancer	33	15	17	1	0	55

[b]$P<0.01$ *vs* group of tissue adjacent to cancer, $\chi^2=8.943$.

Table 3 Hsp90α expression in tissues of gastric cancer with and without lymph node metastasis

Pathologic types	*n*	Grade of hsp90α expression				Positive rate (%)
		-	+	++	+++	
With lymph node metastasis	23	0	17	4	2	100
Without lymph node metastasis	10	4	5	1	0	60

[b]$P<0.01$ *vs* group without ymph node metastasis, $\chi^2=10.469$.

The hsp90α immunoreactive signals in gastric cancer were mostly strong or very strong. The positive rate was 88 %. However, in gastritis samples, the positive rate of hsp90α immunoreactive signals was 55 %, most of which were weakly positive. There was a significant difference between gastric cancer and gastritis ($P<0.01$). The hsp90α immunoreactive positive rates in gastric cancer or in mucous membrane adjacent to cancer were 88 % and 55 % respectively. There was also a significant difference between them ($P<0.01$). A significant difference also existed between gastric cancer with lymph node metastasis (100 %) and that without lymph node metastasis (62.5 %) ($P<0.01$).

DISCUSSION

The expression of hsp90α in normal cells is controlled by cell cycle[5], but it can continuously express at high level in tumor cells without heat stimulation. The existence of mutant or abnormal proteins also stimulates HSPs synthesis[6-9]. Heat shock proteins can maintain oncogene products in inactive state[10]. On the other hand, it has the functions of transportation and transfer. In tumor cells, the expression of hsp90α is higher than that in normal cells. An increasing trend of hsp90α expression was seen in virus-transformed and chemical-induced tumor cells[11,12]. In pancreatic cancer, hsp90α showed a selective expression at high level. Jamell[13] found that hsp90α expressed in all human breast cancers and hsp90α expression was higher in malignant breast tissue[14]. An increased expression of hsp90α mRNA was also found in ovary cancer and the more serious the disease was, the higher the expression of hsp90α mRNA was[1]. It was also found that hsp90α showed a high expression in 29 % of endometrium cancer. Yano' s research[1] showed that the hsp90α mRNA level in breast cancer was higher than that in non-cancer tissues[14,15]. The expression of hsp90α mRNA has a close correlation with proliferating cell nuclear antigen labeling index (PCNA LI), indicating that high expression of hsp90α mRNA should have an important role in cell proliferation. It was identified in our study that the expression of hsp90α in gastric cancer was obviously higher than that in gastritis and mucous membrane adjacent to cancer.

HSPs take part in cell growth and proliferation by several means such as signal transduction and cell cycle regulation. HSPs express highly in germ cells and embryonic cells, but express lowly in aging cells. This suggests that the increase of protein synthesis in proliferating cells needs much more HSPs to take part in the formation of protein activities. Because tumor cells are a group of high proliferation heteromorphic cells, they may need much more HSPs to sustain their proliferation[16,17]. Our results also showed that the expression of hsp90α in gastric cancer with lymph node metastasis was higher than that without lymph node metastasis. All of these were consistent with the results from Jamell' s report that the higher the breast cancer malignancy is, the higher the hsp90α expresses. This indicats increase of hsp90α expression probably has some relationship with genesis, development, invasion and lymph node metastasis of gastric cancer.

Under various stimulations, gastric mucous membrane can transcript and translate high levels of HSPs that can change the metabolism and functions of cells in order to alleviate the damage caused by deleterious factors including exogenous stimulants such as heat, chemicals and ethanol, and endogenous stimulants such as acid, local ischemia, hypoxia. In this case, gastric mucous membrane should synthesize HSP rapidly to exert the protecting role for gastric mucous cells[1]. The genesis of gastric cancer is a gradual process under the long-term influence of various stimulants as well as other factors. During the process, HSPs synthesis increases gradually[16]. This viewpoint was confirmed by our results that hsp90α positive rate in gastric cancer was higher than that in gastritis and gastric tissues adjacent to cancer. The discovery of our study may provide some useful clues for early detection and clinical diagnosis of gastric cancer.

Abstract

AIM: To investigate the prevention and therapy of fungal infection in patients with severe acute pancreatitis (SAP).

METHODS: Seventy patients with SAP admitted from Jan. 1998 to Dec. 2002 were randomly divided into garlicin prevention group, fluconazole (low dosage) prevention group and control group. The incidence of fungal infection, the fungal clearance and mortality after treatment were compared.

RESULTS: The incidence of fungal infection in garlicin group and fluconazole group was lower than that in control group (16 % *vs* 30 %, $P<0.05$ and 9 % *vs* 30 %, $P<0.01$, respectively). Amphotericin B or therapy-dose fluconazole had effects on patients with fungal infection in garlicin group and control group, but had no effects on patients with fungal infection in fluconzole group.

CONCLUSION: Prophylactic dosage of antifungal agents (garlicin or low dosage fluconazole) can reduce the incidence of fungal infection in patients with SAP. But once fungal infection occurs, amphotericin B should be used as early as possible if fluconazole is not effective.

INTRODUCTION

Severe acute pancreatitis (SAP) accounts for about 20 % of acute pancreatitis. With understanding of the natural course of SAP and advances in critical care medicine, most SAP patients can survive systemic inflammatory response syndrome and accompanying dysfunction of important organs such as the heart, lung, kidney, etc[1]. The major complication in the middle and later phases of SAP is infection, its incidence is 40-50 % and its mortality is 10-20 %. About 80 % of mortality at the later phase of SAP is caused by infection[2]. For the time being, drug resistant bacteria infection, especially fungal infection is obviously increasing, and has become one of the major difficulties in the treatment of SAP[3]. In order to prevent and treat the deep fungal infection of SAP, this clinical research was conducted on fungal infection prevention and treatment by adopting garlicin, fluconazole and amphotericin B for SAP patients admitted from Jan. 1998 to Dec. 2002.

MATERIALS AND METHODS

Selection of cases

The selected cases accorded with the clinical diagnosis criteria proposed by the Pancreas Surgery Group of the Chinese Medical Association in 1997[4], and were complicated with one of the following predisposing factors of deep fungal infections[5-8], such as gerontism, history of diabetes, dysfunction of one or more organs, non-iatrogenic fasting hyperglycemia ($\geqslant$9 mmol/L), central venous catheter, TPN, retaining urethral catheterization, operation, gastrointestinal fistula, ICU, breathing machine supported$\geqslant$5d, user of glucocorticoid$\geqslant$5d, administration of broad spectrum antibiotics$\geqslant$5d or super broad spectrum antibiotics (such as Tienam, etc.)$\geqslant$3d.

Groups and methods

A total of 70 cases conforming to the above criteria were randomly divided into 3 groups. The garlicin group (25 patients) was given venous instillation of 120 mg garlicin one time per day plus routine treatment. The fluconazole group (22 patients) was given venous instillation of 100 mg fluconazole one time per day plus routine treatment. The control group (23 patients) received routine treatment only. The prophylactic medication for the garlicin and fluconazole groups was applied until relief of the predisposing factors (except gerontism and history of diabetes). The fungal infection treatment protocol was applied when the patients showed signs of deep fungal infection. The clinical data of these three groups are shown in Table 1.

Monitoring

Smears from peritoneal permeated liquid, pus of the infected wounds, throat specimen, sputum, urine and stool were prepared for fungus detection or/and fungal cultivation 2 times per week. If there was fungal infection, smears from the above sources were prepared for fungal identification 3 times per week. If the central venous catheter was suspected as the infection source, it was removed and cultured for fungi. Incidence and mortality of the patients with SAP complicated with deep fungal infection were observed.

Statistics analysis

All data were analyzed with SPSS11.0 software package, and a P value <0.05 was considered statistically significant. The average age, hospitalization duration, APACHE II grading etc, were displayed by $\bar{x}\pm s$, and differences were analysed using analysis of viariance and F test. Sex, etiological factor, death, fungal infection and number of cleared fungi and other data were analyzed using χ^2 or Fisher' s exact test.

Table 1 General clinical data of three groups

Group	Cases		Age	Etiological factor				APACHII
	Male:	Female		Biliary	Alcoholemia	Injury	Others	
Garlicin	12:	13	51.4±15.2	14	6	1	4	11.8±3.8
Fluconazole	12:	10	48.7±17.3	11	6	-	5	13.2±2.5
Control	13:	10	50.5±20.1	11	7	1	4	11.6±4.7

There were no statistically significant differences in three groups.

RESULTS

Incidence rate of fungal infection

Diagnostic criteria for SAP deep fungal infection[5,6] Doubtful clinical manifestations were fever after the broad spectrum antibiotics treatment with no drug resistant bacteria infection, cough, glue-like mucus or blood streak sputum, pseudo-membrane of the oral cavity or oral ulceration and symptoms of urinary tract stimulation, diarrhea with brown or/and jam-like feces, consciousness changes with unknown reasons, or bleedings irrelevant to pancreatitis such as fistula bleeding of the biliary and digestive tracts.Pathogenic evidences of fungi included positive fungal cultivation of blood, central venous catheter, smears of the fine-needle aspiration before operation, aspiration ascites or necrotic pancreas tissue during the operation, and drained bile, samples of sputum, peritoneal permeated fluid, pus of the infected wounds, throat specimen, sputum, urine and stool. Deep fungal infection could be diagnosed according to the suspicious clinical manifestations together with the same fungi existed in two or more systems.

Incidence rate of fungal infection The SAP patients infected with fungi in the garlicin and fluconazole groups were obviously less than those in the control group, and the number infected by fungi was the fewest in the fluconazole group (Table 2).

Table 2 Incidence rate of fungal infection in 3 groups

Group	Cases	Rate of fungal infection	Times of fungal infection after SAP(d)
Garlicin	25	4(16%)[a]	39-57
Fluconazole	22	2(9 %)[b]	35-62
Control	23	7(30 %)	24-183

[a]$P<0.05$, [b]$P<0.01$ *vs* control.

Treatment results of fungal infection

Protocol of treatment For highly suspicious pathogenic proofs of fungi or those with fungal infection, fluconazole was intravenous used to treat fungal infection, 200 mg (double dosage for the initial injection) once per day until the fungi were cleared. Amphotericin B was used for those with fungal infection in the fluconazole group. The dosage was started from 0.1 $mg.kg^{-1}$, and increased by 5 mg daily according to the patient's tolerance, and the treatment was continued till the dosage reached to 0.6 $mg.kg^{-1}$, the total accumulated amount reached 1.5-2 g. If the patients in garlicin and control groups were not sensitive to fluconazole, amphotericin B was then used.

Treatment results The fluconazole group had the lowest incidence of fungal infection, and the shortest hospital stay, but amphotericin B could not clear the fungi in fluconazole group, in which the patients were once complicated with fungal infection, they would inevitably died. When fungal infection occurred, the garlicin group had the highest clearance rate of fungi after treatment, and its mortality and average hospital stay were obviously lower or shorter than those in the control group. In the garlicin and control groups, each had one patient infected with fungi who was not cured by fluconazole therapy for 3 days, and their fungi were cleared when they changed to receive amphotericin B and they finally recuperated (Table 3).

Table 3 Treatment results of fungal infection in 3 groups

Group	Rate of fungal clearance	Mortality[#]	Times of Hospitalization
Garlicin	3(75 %)[a]	1(25 %)[a]	48.1±30.7[a]
Fluconazole	-	2(100 %)	43.3±26.9[b]
Contrast	4(57%)	3(43 %)	57.4±27.3

Note: # Mortality is the percentage (%) of patients who died of fungal septicemia. [a]$P<0.05$, [a]$P<0.01$ *vs* control.

DISCUSSION

Deep fungal infection often occurs in patients with impaired immunity, e.g. diabetes, AIDS, malignant tumor and organ transplantation, etc. In recent years, the incidence of SAP deep fungal infection has obviously increased. Before routine administration of prophylactic antibiotics for SAP, the proportion of fungi was 7 % in the bacteria spectrum of SAP infection[9]. After that, the incidence of fungal infection in SAP has increased to 12-41 %[2,3,5,6,8,10-14], which has become an important cause for death and mutilation by SAP[3,5,6,8,10-14]. Since lack of specific manifestations, unrecongizability of symptoms, a long time for fungal cultivation, and apparent relevance between the fungal infection and prognosis, active and effective measures to prevent SAP deep fungal infection will contribute to further decreasing the mortality of SAP.

It has been reported[7] that prophylactic application of fluconazole in patients after bone marrow transplantation or chemotherapy could reduce the incidence of fungal infection. But there was not any systematic or prospective study in preventing SAP fungal infection. This study initially showed that prophylactic application of anti-fungi garlicin or fluconazole could significantly reduce the incidence of deep fungal infection of SAP patients who had some predisposing factors. Garlicin is cheap but good in quality, which not only has anti-fungi effects, but also anti-bacteria and anti-viral effects. The normal prophylactic dosage of garlicin is 1-2 $mg.kg^{-1}.d^{-1}$. With respect to prevention alone, fluconazole is better than garlicin, but we have noticed that once those who used fluconazole to prevent infection were indeed infected by fungi, their treatment might become more difficult and the prognosis was much worse. Once fungal infection occurred, an in-time use of fluconazole could quickly clear fungi, and significantly improve prognosis. Low dosage (100-150 mg/d) of fluconazole is often used in prevention while high dosage (200-600 mg/d) is often used in treatment.

About 80 % of the fungal strains in SAP fungal infection are candida[3,5,6,10-14]. Once fungal infection has been ascertained, anti-fungal drugs should be applied in time. Besides direct application of amphotericin B for mucor infection, fluconazole has be the priority for other fungal infections. Like maphotericin B[15], fluconazole has a good permeability in pancreas. If

fluconazole is not effective, it should change for amphotericin B in time or combined medication. In this research, two patients with fungal infection died in fluconazole group possibly due to delayed treatment besides drug resistance.

Deep fungal infection is different from shallow one, sometimes its diagnosis depends on biopsy, because it is hard to differentiate "passenger" bacterial parasites from real infection under many circumstances. As shown by autopsy statistics, only less than 20 % of the patients with fungal infection received anti-fungal treatment[16]. It is believed that for SAP patients, even "passenger" bacterial parasites may probably develop into infection, the finding of fungi in extra-peritoneal positions has provided clues to fungal infection within abdominal cavity, especially when fungi have been cultured from the peritoneal draining liquid. Hoerauf *et al*[12] reported that anti-fungi chemotherapy could increase survival rate. Aloia *et al*[11] suggested small dosage and short course amphotericin B treatment. Grewe *et al*[10] and Gotzinger *et al*[13] reported that although amphotericin B could quickly clear fungi, it could not improve prognosis. This might be related to the fact that anti-fungi treatment was only started when the blood cultivation became positive. The authors agree with Keiser' s viewpoint[17] that the failure of treatment was unable to be realized in time because the fungi were the pathogenic bacteria, instead they were often regarded as pollution and "passenger" in the infection course of surgery, therefore treatment was delayed.

SAP complicated with fungal infection could be classified into primary infection (fungus found in samples of fine-needle aspiration before operation or the first operation) and secondary infection (no fungus found in samples of fine-needle aspiration before operation or the first operation, and fungal infection happens later)[10,13]. In time clearing and draining of the necrotic tissues should be done for primary fungal infection, conservative treatment is mainly for the secondary infection, operation should be done actively if there is a fungal abscess formation. There is no special clinical manifestation in fungal infection, and repeated fungal cultivation on sputum, urine, stool and peritoneal permeated liquid and blood sample can contribute to in-time diagnosis and treatment. Zhang[18] reported that it was helpful to rapid diagnosis of fungal infection in patients with severe acute pancreatitis by PCR using universal primers targeting the 18s rRNA gene of fungus.

Abstract

AIM: To investigate a formalized therapeutic guideline for hyperlipidemic severe acute pancreatitis (HL-SAP).

METHODS: Thirty-two consecutive patients with severe acute pancreatitis were included in the clinical trial. All of them met the following five criteria for admission to the study, namely the Atlanta classification and stratification system for the clinical diagnosis of SAP, APACHEII score more than 8, time interval for therapeutic intervention less than 72 hours after onset of the disease, serum triglyceride (TG) level 6.8 mmol/l or over, and exclusion of other etiologies. They were divided into severe acute pancreatitis group (SAP, 22 patients) and fulminant severe acute pancreatitis group (FSAP, 10 patients). Besides the conventional therapeutic measures, *Penta-association therapy* was also applied in the two groups, which consisted of blood purification (adsorption of triglyceride and hemofiltration), antihyperlipidemic agents (fluvastatin or lipanthyl), low molecular weight heparin (fragmin), insulin, topical application of Pixiao (a traditional Chinese medicine) over the whole abdomen. Serum triglyceride, pro-inflammatory cytokines and anti-inflammatory cytokines were determined before blood purification (PF), at the end of blood purification (AFE) and on the 7th day after onset of the disease (AF7) respectively. Simultaneously, severity of the diseases was assessed by the APACHE II system. Prognosis was evaluated by non-operation cure rate, absorption rate of pseudocyst, time interval pseudocyst absorption, hospital stay and survival rate.

RESULTS: Serum triglyceride level (mmol/L), TNFα (U/ml) concentration and APACHE II score were significantly decreased ($P<0.05$) at AFE and AF7, as compared with PF. However, serum IL-10 concentration (pg/ml) was increased significantly ($P<0.001$) at AFE, and decreased significantly ($P<0.05$) at AF7 when compared with PF. Operations: The First surgical intervention time was 55.8±42.6 days in SAP group (5 patients) and 12.2±6.6 days in FSAP group (7 patients), there was a significant difference between the two groups ($P=0.02$). The number of operations in the two groups was 1.33±0.5 *vs* 3.5±1.2 ($P=0.0037$), respectively. Prognosis: Non-operation cure rate, absorption rate of pseudocyst, hospital stay and survival rate in SAP group and FSAP group were 100 % (22/22) *vs* 11.1 % (1/9), 77.3 % (17/22) *vs* 11.1 % (1/9), 54.2±35.9 *vs* 99.1±49.5 days ($P=0.008$) and 100 % (22/22) *vs* 66.7 % (6/9) ($P=0.0044$). The time for absorption of pseudocyst was 135.1±137.5 days in SAP group.

CONCLUSION: *Penta-association therapy* is an effective guideline in the treatment of hyperlipidemic severe acute pancreatitis at its early stage (within 72 hours).

INTRODUCTION

Currently, cholilithiasis, alcohol abuse, hyperlipidemia and other specific factors, are the main causues of acute pancreatitis. The morbidity of severe acute pancreatitis secondary to hyperlipidemia (HL) has been apparently increased in recent years, acute pancreatitis occurred in 12-38 % of hyperlipidemic patients[1,2]. Hypertriglyceridemia (HTG) was the second cause of acute pancreatitis in our specialty center. However, this is in contrast with Yadav' s views point[3] that it was a rare cause of severe acute pancreatitis, obviously different from our situation.

Serum triglyceride (TG) level more than 10 to 20 mmol/l in patients with types I, IV, or V hyperlipidemia (Fredrickson' s classification) might lead to acute pancreatitis, so it has been considered as an identifiable risk factor[3]. It was reported that the mechanism leading to severe acute pancreatitis was that combining capacity of albumin surpassed by over production of free fatty acid would cause tissue toxicity. Thus, pancreatic acinar cells and microvessels were injured[4-8]. The main treatment for hyperlipidemic severe acute pancreatitis (HL-SAP) is to decrease serum triglyceride level and to prevent systemic inflammatory response. Although serum triglyceride could be decreased by plasmapheresis[9], there has been no formal therapeutic strategy to treat HL-SAP at present. We retrieved references about the treatment of HL-SAP from MEDLINE during 1966-2003 using severe acute pancreatitis and hyperlipidemia as the key words, and found that reports were all case reports of single treatment measure[10-12]. No formalized therapeutic strategy was found. Therefore, we prospectively treated patients with HL-SAP by *Pent-association therapy* which consisted of purification, antihyperlipidemic agents, insulin, heparin and topical application of Pixiao (a traditional Chinese medicine) over the whole abdomen to observe its therapeutic effects and influence on prognosis.

MATERIALS AND METHODS

Patients and groups

Patient Thirty-two consecutive patients with SAP admitted to Department of Surgical Intensive Care Unit, Ruijin Hospital, Shanghai, China, from April 2000 to March 2003 were included in the clinical trial. Therapeutic strategies to all patients were determined by a group of doctors from SICU and Department of Surgery.

Groups Five entry criteria for admission to the study were the Atalanta classification system to stratify patients with acute

pancreatitis (1992)[13], APACHEII score more than 8, within 72 hours after onset of the disease, serum triglyceride level more than 6.8 mmol/L, and exclusion of other etiologies.

The diagnosis of fulminant severe acute pancreatitis (FSAP) was made according to the following criteria.

FSAP was diagnosed by meeting one or more of the following indices within 72 hours after onset of the disease with adequate fluid resuscitation such as APACHEII score 20 or more, acute renal failure, ARDS, DIC, and Glasgow score less than 8.

According to the aforementioned criteria, 32 patients were divided into SAP group (22 patients) and FSAP group (10 patients). Of the FSAP group, one patient was excluded from the clinical trial due to giving up of the therapy. The patient did not undergo triglyceride adsorption and hemofiltration, and thus developed ARDS and acute renal failure within 48 hours. According to theoretical speculation and references, the *Penta-association therapy* might have some positive effects on patients. Therefore, we did not set control group in the present study. In addition, patients and/or their family were told about the trial in details. We were thus authorized to perform the study.

Etiology This included uncontrolled diabetes mellitus, long period alcohol abuse, heredity, pregnancy, obesity, *etc*. Among them, 23 men aged 45±9.4 years, 9 women aged 41.9±14.9 years.

Methods

Thearpy Conventional therapy: It included appropriate fluid resuscitation, fasting, gastrointestinal decompression, use of pancreatic enzyme inhibitors, prophylactic antibiotics, decoction of raw rhubarb poured into stomach via gastric tube, enteral nutrition and operation if necessary.

Specific therapy (Penta-association therapy) This included blood purification (adsorption of triglyceride and hemofiltration), triglyceride decreasing antihyperlipidemic agents (fluvastatin sodium capsules 40 mg, qn, P.O; lipanthyl, 200 mg qn, P.O), low molecular weight heparin (fragmin 5 000 IU, subcutaneous injection, qd, for 3 days), insulin by intravenous infusion (blood sugar controlled to less than 200 mg/dl), topical application of Pixiao over the whole abdomen.

Adsorption of triglyceride and hemofiltration Blood purification was performed using Diapact CRRT machine (B. Braun Co., Germeny). Polysulfone filters were used (Cut-off-point 30 000 Dalton, AV 600S, Fresenius Medical Care). Systemic anticoagulation was undergone with low molecular weight heparin (fragmin, 5 000 IU/ampule) at a dose of 100-140 IU/kg for bolus injection. Ultrafiltrate was replaced with substitutes made according to patient' s electrolyte and blood glucose. Pre-dilution mode was used. Extracoporeal blood flow ranged from 250 to 360 ml/min. Ultrafiltrating rate was controlled within 50-500 ml/h. In order to remove triglyceride rapidly, we changed the filter every 4 hours.

Indications for stopping blood purification Short veno-venous hemofiltration was stopped when the abdominal symptoms and signs disappeared, or the heart rate was less than 90 beats/min and the respiration rate was 20 times/min, respectively. Continuous veno-venous hemofiltration was stopped if the renal function was recovered and/or heart rate was less than 90 beats/min and the respiration rate was 20 times/min respectively.

Determination of Indices Serum levels of triglyceride, TNFα and IL-10 were determined before blood purification (PF), at the end of therapy (AFE) and on the 7th day (AF7) after onset of the disease. APACHE II scores were evaluated simultaneously. Activity of TNFα was assessed in the L929 cell line. IL-10 was tested using a commercially available ELISA kit (From Endogen Company, USA.).

Follow-up Enhanced CT scan of abdomen was performed every month for the patients with successful conservative treatment, and intra- and extra-pancreatic radiological changes were observed.

Prognosis Non-operation curative rate, survival rate, hospital stay, absorption rate of pseudocyst, time of first operation and total operation time were calculated and compared between the two groups.

Statistics

Data were reported as mean ± standard deviation, and analyzed using Student' s *t* and or chi square test.

RESULTS

Serum level of triglyceride, cytokine and APACHEII score

Serum concentrations of triglyceride and TNFα, and APACHE II scores were significantly decreased at AFE (t=5.687, P<0.001; t=6.342, P<0.001; t=12.12, P<0.001) and AF7 (t=7.576, P<0.001; t=10.19, P<0.001; t=15.09, P<0.001) compared with PF. Serum triglyceride level was decreased to safe range within 10 hours after the beginning of blood purification, and to normal range at AF7 when triglyceride was decreased as well as heparin and insulin were used continuously. But serum level of IL-10 at AFE was significantly increased compared with PF (t=19.21, P<0.001). However, it was significantly decreased (t=9. 87, P<0.001) at AF7 compared to PF.

Thus, serum triglyceride and pro-inflammatory cytokines were decreased, and anti-inflammatory cytokine was increased through blood purification (hemofiltration and adsorption of triglyceride), and severity of the disease was significantly decreased (Table 1).

Table 1 Levels of serum triglyceride, cytokines and APACHE II score

	PF	AFE	AF7
Serum triglyceride (mmol/L)	13.1±8.1	4.5±2.3	2.02±0.83
APACHE II score	18.4±4.4	7.38±2.5	5.8±1.5
TNFα (u/ml)	43.1±12.7	26.3±7.5	17.7±5.6
IL-10 (pg/ml)	72.1±20.0	179.6±23.9	31.2±11.5

Time duration for blood purification and number of filters used

Systemic inflammatory response syndrome (SIRS) was prevented through adsorption of triglyceride and short veno-venous hemofiltration in SAP group, but long time blood purification and/or drainage of large amounts of exudates from abdominal cavity and retroperitoneal space were needed in FSAP group. The number of filters used and time duration for blood purification in SAP group and FSAP group were 2.6±1.3 *vs* 2.9±1.5 h, 6.5 ±2.7 *vs* 48±62 h, respectively.

Surgical intervention

Time interval from onset of the disease to the first operation was significantly longer in SAP group (5 patients) than in FSAP group (7 patients) (t=2.715, P=0.02). Debridement of pancreatic necrosis and internal drainage of pseudocyst were performed in SAP group. Only debridement of pancreatic necrosis was performed in FSAP group, but operation number was more than that in SAP group (t=3.775, P=0.0037). This indicated that *Penta-association therapy* had better results in hyperlipidemic SAP than in FSAP group (Table 2).

Prognosis

We compared the results from this clinical trial with 283 patients treated with conventional therapy in our hospital, and found that non-operation cure rate was 100 %(22/22) in the present

SAP group, and was 43.5 % in our previous group (123/283) (χ^2=26.16, P=3.3×10^{-7}). The survival rate was 100 %(22/22) and was 84.1 % in our previous group (238/283) (χ^2=4.104, P=0.043). In SAP group, pancreatic pseudocysts were resolved spontaneously in 17 patients, with an absorption rate of 77.3 % (17/22), and surgical intervention was thus avoided. Absorption time was 135.1±137.5 days with a variation constant of 102 %.

In FSAP group, only one patient was cured through conservative treatment, its time interval for absorption of pseudocyst was 96 days. Another patient died without operation. Surgical drainage and debridement of pancreatic necrosis were done for the rest of 7 patients within 2 weeks after onset of the disease. The survival rate of 66.7 %(6/9) was slightly higher than 58 % (27/47) from Beger' s report[14] [χ^2=0.2653, P=0.61] without significant difference.

Absorption rate of pseudocyst, non-operation cure rate and survival rate in SAP group were higher than those in FSAP group. Hospital stay was also shortened compared to FSAP group (P=0.008, Table 3).

Table 2 Surgical intervention

	SAP	FSAP
Number of cases	5	7
Time of first operating (days)	55.8±42.6	12.2±6.6
Surgical procedures	Debridement and gastro-or jejuno-pancreatic anastomosis for pseudocyst	Debridement with drainage and nutritional jejunostomy
Number of operation	1.33±0.5	3.5±1.2

Table 3 Prognosis of SAP and FSAP

	SAP group	FSAP group
Number of cases	22	9
Rate of adsorption of pseudocyst	77.3 %(17 / 22)	11.1 %(1 / 9)
Time interval for absorption of pseudocyst	135.1±137.5	96
Non-operation cure rate	100 %(22 / 22)	11.1 %(1 / 9)
Hospital stay (days)	54.2±35.9	99.1±49.5
Survival rate	100 %(22 / 22)	66.7 %(6 / 9)

DISCUSSION

With an increased incidence of hyperlipidemia and its complication, acute pancreatitis also increased accordingly. SAP secondary to hypertriglyceridemia (HTG), presented typically as an episode of SAP, rarely as chronic pancreatitis. A level of serum triglyceride (TG) more than 6.8 mmol/L in patients with types I, IV, or V hyperlipidemia (Fredrickson' s classification) is an identifiable risk factor. The typical clinical profiles of hyperlipidemic pancreatitis were a patient with a preexisting lipid abnormality along with the presence of a secondary factor (e.g., poorly controlled diabetes, alcohol abuse or a medication) that could induce HTG[15]. Patients with isolated hyperlipidemia (type V or I) without a precipitating factor would rarely have pancreatitis. Interestingly, serum pancreatic enzymes might be normal or only minimally elevated even in the presence of SAP as diagnosed by imaging studies. The clinical course of HL-SAP was not different from severe acute pancreatitis caused by other causes. Although conventional management of SAP caused by hyperlipidemia is similar to that by other causes, but it still needs some specific management. So we did this clinical trial to investigate systematically how to manage HL-SAP within 72 hours after onset of the disease.

Formation of therapeutic regimen and its mechanism

At present, there have no formalized therapeutic strategies for the treatment of HL-SAP in the literature, besides single case report or the use of certain measures. In 2000, our Pancreatic Disease Therapy Center considered a therapeutic strategy aiming at HL-SAP that was based on the concepts that hyper-triglyceride, fatty acid and inflammatory mediators were the pathological mechanism of deterioration of HL-SAP[8,16-19]. A prospective investigation was thus carried out. Principles of the strategy included r*apid lowering serum triglyceride, blocking of induction pancreatic damage by pro-inflammatory mediators, preventing recurrence by the use of antihyperlipidemic agents, promoting self- absorption of pancreatic pseudocyst.* Concrete measures could be found in the details of *Penta-association therapy*, which included blood purification (adsorption of triglyceride and hemofiltration), fluvastatin (40 mg, qn, P.O) or lipanthyl (200 mg, qn, P.O), low molecular weight heparin (fragmin, 5 000 IU subcutaneous injection, qd, for three days.), insulin (intravenous infusion, blood sugar level controlled well below 200 mg/dl), and topical application of Pixiao (Chinese traditional medicine) over the whole abdomen. Hyperchylomicronemia caused by hyperlipidemia could lead to not only pulmonary edema[20] and systemic microcirculatory dysfunction, but also release of fatty acids, which would play an important role in causing pancreatic injury[8,17]. Thus, the first item of the therapeutic regimen was adsorption of serum triglyceride, and it was essential to lower blood triglyceride level within the safe range. Simultaneously, heparin could stimulate lipoprotein-lipase activity and accelerate chylomicron degradation[9]. It could also contribute to the decrease of serum triglyceride level. Besides this effect on blood triglyceride, it could also improve microcirculation and prevent activation of neutrophils activity[21]. Polymorphonuclear cells (PMN) could play an important role in the deterioration of severe acute pancreatitis, especially release of elastase (PMNE), which would lead to persistent pancreatic necrosis and acute lung injury[22]. Insulin could not only decrease blood sugar, but also accelerate degradation of chylomicrons[9]. Therefore insulin was given to control blood sugar well below 200 mg/dL. Simultaneously, fluvastatin sodium or lipanthyl was given to decrease blood lipid in order to avoid recurrence of acute pancreatitis.

Though the etiologies of patients with acute pancreatitis could be different, but their pathophysiological changes were just the same[23]. Activated enzymes and oxygen free radicals injured the acinar cells and caused release of cytokines and vasoactive mediators, attracted inflammatory cells and activated vascular endothelium as well as the expression of adhesion molecules. The disturbance of pancreatic microcirculation could induce progression from edematous to necrotizing pancreatitis independent of the early intracellular events, including protease activation. Specific therapy must be directed towards microperfusion failure as the secondary pathogenetic step, since the initial enzyme activation and cytokine release were irreversible by the time of clinical presentation. In experiments comparable to the clinical situation, following therapeutic principles have been proven to be beneficial: increase of blood fluidity, inhibition of leukocyte-endothelium interaction and blockade of systemic inflammatory response. As we know, Short time veno-venous hemofiltration could significantly decrease circulatory TNFα level and increase circulatory IL-10 level[24]. This could block systemic inflammatory response and pancreatic necrosis. Due to dynamic balance of pro-inflammatory and anti-inflammatory cytokines, long time hemofiltration was prohibited to avoid creation of new imbalance in SAP[25]. However, FSAP usually resulted in Ultra-SIRS (systemic inflammatory response syndrome), thus continuous veno-venous hemofiltration and

drainage of abdominal, retroperitoneal toxic exudates were essential to prevent recurrence of Ultra-SIRS. Based on this concept, hemofiltration could be used as a specific measure to treat HL-SAP.

After acute response phase, emphasis should be put on the prevention of infection, rapid subsidence of fluid accumulation in the third space as well as promotion absorption of pancreatic pseudocyst. Topical application of Pixiao (Chinese traditional medicine) over the whole abdomen could ameliorate tissue edema including that of abdominal wall, peritoneum and intestinal wall, and accelerate absorption of pancreatic pseudocyst. Therefore, Pixiao was used through out the whole course of the disease in order to relieve tissue edema and resolve pancreatic pseudocyst spontaneously. When patients were discharged with pancreatic pseudocyst, application of Pixiao was continued until it no longer absorbed fluid and became dry. Though the effect of this measure was slow, but it played an important role in decreasing operation rate.

Efficacy and prognosis

Although *Penta-association therapy* is far from perfect, especially for the prevention of recurrence of the disease, but good clinical efficacy has been obtained by these specific measures in the acute response phase of the episode.

In acute pancreatitis, medications, such as heparin and insulin *etc*. decreased trigylceride levels to less than 10 mmol/L within 2.8 days (1 to 6), the amylase and lipase levels returned to normal after 3 and 4 days respectively, and the abdominal pain was resolved[9,10]. Also, it was reported that plasmapheresis removed blood triglyceride[26-31] and got good results. Clinically, this method could not be propagated to wider use due to the problems of equipments and the need for large amounts of plasma. So we adopted the present measure to adsorb triglyceride. Within 72 hours after onset of the disease, serum triglyceride concentration was decreased to 6.8 mmol/l within 10 hours. At this time, abdominal pain was resolved in 31 patients. So adsorption of triglyceride can not only decrease triglyceride level rapidly, but also resolve abdominal pain and prevent deterioration of the disease. This has been regarded as a necessary measure in the treatment of HL-SAP at its early stage. As to the safe range of blood triglyceride level, it was reported that the level should be decreased to 5.65 mmol/L[32], but in our series when it was below 6.8 mmol/l, abdominal pain in 31 patients was resolved. This discrepancy might be due to different etiologies of hypertriglyceridemia or different preexisting factors. All the patients received insulin, heparin and antilipidemic agents to prevent deterioration of the disease by controlling serum triglyceride level at normal range 7 days after onset of the disease. Even though etiologies resulting in each SAP patients might be different, but pathophysiological lesions were just the same, such as overproduction of cytokines, microcirculation failure and over-activated neutrophils. Therefore, hemofiltration was continued after lipid adsorption to regulate the balance between proinflammatory and anti-inflammatory cytokines. This caused decrease of proinflammatory cytokines as well as temporary increase of anti-inflammatory cytokines with APACHEII score decreased. Our results were in accordance with the report in the literature[24]. Thus, hemofiltration used in the early treatment of HL-SAP was of important clinical significance.

Five patients with SAP underwent the first operation on the 56th day after onset of the disease. Surgical modalities used coincided with literature reports[31]. The major methods were debridement and drainage of pancreatic necrosis as well as internal drainage of pancreatic pseudocyst. But FSAP group underwent the first operation on the 12th day after onset of the disease. The first operation time was earlier than that of SAP group (P<0.01). Surgical methods in FSAP group were mainly debridement and drainage. Furthermore, the number of operations was also increased (P<0.01).

Non-operation cure rate and survival rate were both 100 % in SAP group, they were increased significantly compared with non-operation rate of 43.5 % and survival rate of 84.1 % in 283 patients with SAP in our hospital in the past. Meanwhile, the survival rate of 100 % was higher than that of 62 % (8/13) in literature report[31] [χ^2=9.872, P=0.002]. Incidence of pseudocyst in SAP group was 81.8 % (18/22) which was significantly higher than that of 37 % in literature report of[33]. Pseudocysts in 17 patients resolved spontaneously without operation. The reason why the morbidity and absorption rate of pseudocyst were very high was that the full-blown summit of SAP was at 72 hours, so pancreatic microcirculation was compromised, and ischemia occurred in the pancreas within 72 hours. Thirty-one patients were treated on time within 72 hours, thus pancreatic necrosis was prevented. After onset of the disease, the whole abdomen was covered with Pixiao (rough-wrought Glauber' s salt) until it could not be moistened. This treatment could accelerate absorption of pseudocyst. Ischemia occurred in the major component of Pixiao (rough-wrought Glauber' s salt) is Glauber' s salt, additionally, it contains magnesium sulfate, calcium chloride, magnesium chloride *etc*. and acts on inflammatory mass by the effect of shrinkage, anti-inflammation, dehydration and others. Based on the aforementioned results, we think that *Penta-association therapy* has quite good clinical efficacy, and should be regarded as a specific measure in the treatment of HL-SAP.

HL-FSAP is a sub-type of HL-SAP. Although we applied the same conservative therapeutic measures as those of SAP, but the efficacy was not the same. Only one patient recovered through conservative treatment. It took 96 days for the pseudocyst to resolve spontaneously. Another patient died. If conservative treatment could not control the disease, it was taken as the indication for operation in FSAP. Seven of them underwent debridement and drainage of abdominal and/or retroperitoneal exudates through laparotomy within 2 weeks after onset of the disease. Although its cure rate was 66.7 %, it was still higher than Beger' s 58 %[14] and Bosscha' s 61 %[34], the percentage of mortality was still 33 %. According to our data and literature data[34], survival rate has not been improved through early enthusiastic operation and surgical drainage. This demonstrated that conventional treatment and *Penta-association therapy*, optimal surgical indication, proper timing of operation and choice of drainage method, such as laparoscopy, drainage through single lumen catheter puncture guided by ultrasound, play an important role on survival rate in the treatment of HL-FSAP. Although the viewpoint that conservative treatment should be applied to treat FSAP during it' s early stage (within 2 weeks)[35] was controversial, it is advisable to apply cautiously drainage through laparotomy in the treatment of FSAP during its early stage, and this could achieve curing rate. Some authors suggested that management and clinical surveillance required specific expertise, and management of these patients was best undertaken in specialized centers.

It is thus evident that *Penta-association therapy* upon the basis of conventional therapy for HL-SAP can give good clinical results, but its efficacy in treating FSAP needs to be further improved.

Recommendation of formalized therapeutic regimen

Efforts has been made by the pancreatic disease specialists all over the world in the past hundred years, the therapy of acute pancreatitis has been basically formalized, and therapeutic principles were also basically established. Thus, the cure rate of SAP has reached 80 %. But there were still 20 % of patients who could not be cured. Among them, 15 % were still SAP,

5 % were another subtype - FSAP. Regardless of the etiologies of SAP, their pathophysiological changes were identical, and this determined the accordance of their management. But why there were still 15 % of these patients who could not be cured? Based upon our experimental results, we think some of them were not treated appropriately with regard to their etiologies during early stage (within 72 hours). Although pancreatic lesions could not be prevented from progression even after the etiologies were resolved, continuing existence of the etiological factors would aggravate the disease, such as choledocholithiasis and hyperlipidemia. At present, there are a lot of measures to treat biliary acute pancreatitis, such as EST, ENBD or surgical operation. Nevertheless, there is no formalized regimen to manage HL-SAP. On account of this, our Pancreatic Disease Therapy Center has suggested a formulated specific regimen to treat HL-SAP in order to save some of the 15 % patients. In the present study, from the standpoint of cure rate, almost all the patients were recovered from the disease. Based upon our results, we suggest that it is important to determine whether hyperlipidemia is existent or not by history and laboratory examinations or simply by the presence of chylous blood. Once the diagnosis of HL-SAP is established, besides the conventional therapy, *Penta-association therapy* should be given immediately to mange HL-SAP.

Additionally, 5 % of the patients belonged to FSAP. Although the therapeutic efficacy of HL-FSAP in the present group was somewhat improved, but it was not significant. This should be further investigated.

In summary, HL-SAP has not only the general characteristics of severe acute pancreatitis, but also some specific characteristics. So, besides conventional therapy of SAP, specific strategy should be taken into consideration. *Penta-association therapy* is not a perfect regimen, further refinement, especially to treatment for FSAP, is urgently required.

Abstract

AIM: To evaluate the relationship between uPA, PAI-1, CEA, PI3K and metastatic potential in three colorectal tumor cell lines.

METHODS: Metastatic model in nude rats was established by variants HT-29c and HT-29d cell lines and the metastatic potential of two tumor cell variants was compared. Urokinase-type plasminogen activator (uPA) and plasminogen activator inhibitor type 1 (PAI-1) were determined using ELISA in colorectal carcinoma WiDr, HT-29 and HT-29d cell lines with different metastatic potentials. Expression of carcinoembryonic antigen (CEA) and phosphoinositide 3-kinase (PI3-Kinase) was analyzed using immunohistochemistry (IHC) in these cell lines *in vitro* and *in vivo*. CEA expression was compared using fluorescence activated cell sorter (FACS) *in vitro*.

RESULTS: The number of HT-29d cells arrested in liver dramatically decreased within the initial 24 hours after injection. The taking rate of liver metastases in the variant HT-29d increased as compared with parental HT-29 cells (70 % versus 50 %) and a variant HT-29b cells (70 % versus 60 %), and extensive organs were synchronously involved in metastases. The uPA concentration of variant HT-29d cell line was significantly higher than that of the non-metastatic WiDr and the low metastatic HT-29 cell lines. The variant HT-29d cells produced stronger PI3-kinase expression as compared with the non-metastatic WiDr cells and the low metastatic HT-29 cells *in vivo*.

CONCLUSION: The selected variant HT-29d cell exhibited an enhanced metastatic potential. The level of uPA and PAI-1 is positively correlated with the metastatic capacity of tumor cells. The expression of PI3-kinase correlates with tumor development and metastasis.

INTRODUCTION

The malignancy of a solid tumor is due to its ability to invade and metastasize. Metastasis is a major cause of cancer death. Cancer metastasis consists of multiple sequential and selective steps. The aggressiveness of a tumor is primarily dependent on its ability to invade adjacent tissues and to metastasize to distant sites. In recent years special attention has been paid to tumor-associated protease systems, such as urokinase-type plasminogen activator (uPA)[1]. A role of uPA in regulating tumor cell invasiveness has been proposed on the basis of generally increased uPA activity in several metastatic tumors[2,3]. For many malignant tumors, there is a significant correlation between the production of uPA and tumor invasion[4,5]. The activation of uPA is controlled by well-characterized plasminogen activator inhibitors: type 1 (PAI-1). Numerous studies have shown that PAI-1 antigen levels in primary tumor with lymph node involvement were significantly higher than those in cancers without lymph node involvement[6,7], and in metastatic lymph nodes their levels were also increased compared to primary tumors[8].

Carcinoembryonic antigen (CEA) is one of the most common tumor-associated substances produced by colorectal carcinoma, and it has been used in numerous studies as a tumor marker. Although the functional role of CEA in liver metastasis from colorectal carcinomas has been assumed to be an adhesion factor or receptor binding to Kupffer cells[9,10], a conclusive evidence *in vivo* has not been clarified yet.

Phosphoinositide 3-kinase (PI3-kinase) is a key signaling enzyme implicated in a variety of receptor-stimulated cell responses[11]. This lipid product is believed to act as the second messenger in a variety of signaling processes including cell survival and migration[12,13]. Numerous studies have implicated PI3K in signal transduction pathways correlated with cell proliferation, cell cycle progression, cell apoptosis, tumorigenesis, tumor angiogenesis and tumor invasiveness[14,15].

In this study, uPA, PAI-I, CEA and PI3K were determined in three colorectal cancer cell lines with different metastatic capacities *in vitro* and *in vivo*, and the relationship between metastatic potential and these biological factors in colorectal tumor was investigated.

MATERIALS AND METHODS

Experimental animals

Three-week old male athymic Rowett nude rats (Hsd:RH-nu/nu) were obtained from Harlan/Winkelmann (Borchen, Germany). All rats were housed under special pathogen-free conditions in a laminar flow cabinet (EHRET, DIPL.-ING. W. EHRET GmbH, Germany) with constant temperature (24-26 ℃), humidity (40-50 %) and 12-hour light/12-hour dark cycle. The rats were fed with standard rat food and water. All cages, bedding and operative equipments were autoclaved at 121 ℃ for 30 minutes. The nude rats were stabilized for one week in the laboratory before the experiments were started.

Cell lines and cell culture

Human colonic adenocarcinoma cell lines WiDr and HT-29

as well as their variants HT-29c and HT-29d were used in the present study. WiDr cell line was established from a moderately differentiated human primary rectosigmoid adenocarcinoma with non-distasnt metastatic capability and obtained from American Type Culture Collection (ATCC, Rockville, MD, USA). HT-29 cell line was established from a moderately differentiated human colon adenocarcinoma and was a gift of Dr. Dippold (Mainz, Germany). HT-29c and HT-29d cell lines were two variant cell lines after three and four cycles of selection of liver metastases from parental HT-29 cells[16].

All the cell lines were grown in RPMI-1640 medium (Life Technologies, Eggenstein, Germany) plus 10 % fetal bovine serum (FCS, Life Technologies) supplemented with 2 mM L-glutamine and 1 mM sodium pyruvate (Life Technologies) and maintained in a 37 ℃ incubator (Heraeus, Germany) with 100 % relative humidity and 5 % CO_2. Cells were seeded and grown as monolayers in 75 cm^2 culture flasks (Falcon, England).

Establishment of metastatic model

Cells were harvested from exponential growth phase by brief trypsinization. The number of cell concentration was determined using a hemocytometer (Marienfeld, Germany). The cell suspensions were resuspended in HBSS at a final concentration of 4×10^7 cells/ml. A toal of 12 rats were anesthetized, an abdominal incision about 2 cm long was made in midline and the portal vein and mesenteric vein were isolated and exposed. Single-cell suspension of 0.5 ml containing 2×10^7 cells of HT-29c or HT-29d was injected into the mesenteric vein of 2 or 10 rats, respectively. The rats were explored for the first time about 4 weeks after injection and killed and autopsied at 6-10 weeks or when moribund after injection. The liver, lung and other organs were removed and frozen in liquid nitrogen, then stored at -80 ℃ for IHC.

To investigate the distribution and fate of tumor cells in the liver at the initial 48 hours after injection, 3-4 rats were killed at 1, 24, 48 hours after injection, respectively. The livers were removed, frozen in liquid nitrogen immediately, then the liver tissues were sliced at 5 μm cryosections and analysed for tumor cells by IHC with anti-CK mAb KL-1.

Quantitative detection of uPA and PAI-1

Six-well tissue culture plates were used. The single cell suspension of WiDr cells, HT-29 cells and HT-29d cells containing 3×10^5 tumor cells in supplemented RPMI-1640 was seeded into each well, respectively, and incubated at 37 ℃ in a humidified 5 % CO_2 incubator. After incubation for 24 hours, the medium of each well was sucked away and freshly supplemented RPMI-1640 medium (1.5 ml/per well) was added. The cells were incubated under the same conditions as above for 24 and 48 hours, respectively. Then the medium of each well was removed into Eppendorf tubes and centrifuged at 10 000 rpm for 15 minutes at 4 ℃. The supernatant was for detection of uPA and PAI-1. To measure the concentration of uPA and PAI-1 antigen in tumor cell culture supernatants, the uPA and PAI-1 ELISA kits (Imubind, American Diagnostica, Greenwich, CT, USA) were used. The sample value was multiplied by the dilution factor to determine the uPA and PAI-1 concentration of the cell culture supernatant. Meanwhile, the cells in six-well tissue culture plates were harvested by brief trypsinization and cell number was determined using a hemocytometer.

Determination of PI3-kinase expression

Tumor cells were seeded on 10-well mask slides at a density of 2×10^5 cells/ml supplemented medium and incubated at 37 ℃ in an incubator with 100 % relative humidity and 5 % CO_2 as described above. 48 hours later, the slides were washed twice with PBS and fixed in cold acetone for 5 minutes. Tumor tissue samples were cut into 5 μm cryosections and placed on microscope slides. The 10-well mask cell slides or tissue cryosections were fixed in cold acetone (4 ℃) for 5 minutes. The rabbit polyclonal antibody against PI3-kinase p85α and P110α (Santa Cruz Biotechnology) was used for immunohistochemical evaluation. The standard ABC immunostaining method was employed as immunohistochemical staining with ABC kit (Vector Laboratories, CA, USA). A semiquantitated score of 5 categories based on color intensity was assigned as -: no reaction, +: weak positive reaction, ++: moderate positive reaction, +++: strong positive reaction. The percentage of positive tumor cells was determined by calculating 1 000 tumor cells in 5 random areas of one section.

CEA determination

FACS analysis of cell lines WiDr, HT-29 and HT-29d cells were harvested from exponential growth phase with 0.002 % EDTA in PBS and inactivated with supplemented medium, then centrifuged at 1 410 rpm for 5 minutes. The pellet was washed in Na-azide-PBS (7.5 mM) at 4 ℃, and cells were counted with 5×10^5 cells removed to each FACS tube. The cells were washed in 1 ml Na-azide-PBS and centrifuged again. The supernatant was sucked away, primary mAb to human CD66e (clone 85A12, 100 μg/ml, Cymbus Biotechnology, Chandlers Ford, Hants, UK) was diluted (2:3) with 3 % BSA in azide-PBS and added to each tube. The tube was vortexed and incubated on ice at 4 ℃ for 1 hour. One ml azide-PBS was added for inactivation and the cells were centrifuged. The supernatant was sucked away, the second antibody of dichlorotriazinyl amino fluorescein (DTAF)-conjugated affinipure goat anti-mouse IgG+IgM (1.3 mg/ml, Dianova, Hamburg, Germary) diluted (1:100) with 3 % BSA in azide-PBS was added to each tube. The tube was vortexed and incubated on ice in the dark at 4 ℃ for 30 minutes. One ml azide-PBS was added for inactivation and the cells were centrifuged. The supernatant was sucked away, 300 μl of azide-PBS was added to each tube and vortexed, then 100 μl of 4 % paraformaldehyde was added. The samples were stored at 4 ℃ in the dark for FACS analysis. The primary antibody and secondary antibody were replaced by 3 % BSA in azide-PBS as negative controls, the primary antibody was replaced by 3 % BSA in azide-PBS as the second antibody control.

Immunohistochemistry analysis To investigate the CEA expression of different cell lines, s.c tumor and liver metastasis tumor, mouse monoclonal antibody to human CD66e were used for immunohistochemical evaluation. The standard ABC immunostaining method and a semiquantitated score were performed as described above.

Statistical analysis

The data were presented as mean ± standard deviation. Statistical analyses were performed using the F test and χ^2 test. Differences were considered significant if the P-values were <0.05.

RESULTS

Phenotype of HT-29 variants with enhanced tumorigenicity in vivo

The distribution and fate of tumor cells HT-29d in the liver at the initial phase after inoculation were observed in the rats of each group at different time intervals, respectively. The number of HT-29d cells arrested in the liver was dramatically decreased within the initial 48 hours after injection. By 1 hour after mesenteric vein injection, many tumor cells could be found in

Table 1 Macroscopical pattern of HT-29c/d cell metastases

Cell	Hepatic metastasis				Lung metastasis			Other organs
	No of metast[a]	I	II	III	No of metast[a]	I	II	
HT-29c	1/2	0/2	0/2	1/2	1/2	1/2	0/2	2/2
HT-29d	7/10	2/10	3/10	2/10	3/10	1/10	2/10	9/10

a: metastasis.

the livers, with a mean of 14.7 tumor cells/mm^2, and the single and clustered cells in the liver were located surrounding portal vein and in hepatic sinusoids. By 24 hours, however, the number of tumor cells surviving in the liver was significantly decreased. Only a few cells were found, with a mean of 2.3 tumor cells/mm^2 (range, 0-9 tumor cells/mm^2), and the cells were located mostly in parenchyma of the liver. At 48 hours after injection, a similar tumor cell distribution was found.

Metastatic potential of HT-29c and HT-29d cells was studied by injecting tumor cells into the mesenteric vein of nude rats. All rats survived the surgery and tumor-cell injection. Exploration was performed at the fourth week after injection. The rats were killed 8 to 10 weeks after injection or when moribund. The metastases were determined either by macroscopy or by microscopy. Liver tumor burden was evaluated based on the number of lesions as Class I: histological evidence of tumor growth, Class II: <10 tumor foci (macroscopically), Class III: >10 tumor foci (macroscopically). Lung metastasis was evaluated as Class I: histological evidence of tumor growth, Class II: macroscopically positive. The results are shown in Table 1. One of the two rats injected HT-29c cells developed extensive hepatic metastases, in which 60 % of the right liver was occupied by tumor tissue. The other developed micrometastases in the lung, diaphragm, left kidney with hemorrhagic ascites. The two rats developed mesenteric metastases. Seven of the ten rats (70 %) injected HT-29d cells had either liver macrometastases or micrometastases. Still three of the ten rats (30 %) had lung metastasis, of which two developed extensively dispersed metastatic nodules in their lungs. Three of the ten rats (30 %) developed metastatic tumors in their thoracic cavity. Five developed metastatic tumors in the diaphragm. Two produced hemorrhagic ascites. Nine developed extensive mesenteric metastases within 8 to 10 weeks after injection of HT-29d. One suffered from hindlegs paralysis at day 30 after injection.

Level of uPA and PAI-1

The concentrations of uPA and PAI-I in cell supernatants were statistically significantly different among WiDr, HT-29 and HT-29d cells. The uPA and PAI-I concentrations of variant HT-29d cell line were significantly higher than those of HT-29 and WiDr cell lines at 24 hours (F value was 17.4, P=0.03) and at 48 hours (F value was 98.3, P=0.001). The uPA and PAI-I concentration of variant HT-29 cell line was also higher than that of WiDr cell line (Table 2).

Expression of CEA in cell lines and tumor tissues

The results by FACS showed that mAb CD66e could react with CEA on the surface of cells *in vitro*, but no differences were observed between WiDr, HT-29 and HT-29d cell lines. Their fluorescence intensities were 212, 215 and 207, respectively, (F value was 0.07, P=0.93).

CEA expressions among WiDr, HT-29 and HT-29d cell lines *in vitro* by IHC were not significantly different (χ^2 value was 2.311, P=0.315). However, HT-29d showed a slightly higher ratio of positive cells and stronger staining compared with WiDr and HT-29 in s.c. tumor, without significant difference (χ^2 value was 4.397, P=0.111). The ratio of positive cells and staining intensity showed no significant difference in liver metastases between HT-29 and HT-29d (χ^2 value was 0.823, P=0.364) (Table 3).

Expression of PI3-kinase

For detection of expression of PI3-kinase, we stained PI3-kinase with Abs against p85α and p110α subunits of PI3-kinase in WiDr, HT-29 and HT-29d cell lines. Immunochemical reactivity with polycolonal antibodies p85α and p110α subunits of PI3-kinase was present among all tumor cell lines *in vitro*. No significant difference was observed in positive cell ratio and staining intensity among WiDr, HT-29 and HT-29d cell lines (χ^2 value was 2.041, P=0.360).

PI3-kinase expression of HT-29d showed stronger staining intensity compared to WiDr and HT-29 in s.c tumor, and the ratio of positive cells of HT-29 and HT-29d was significantly higher than that of WiDr (χ^2 value was 6.161, P=0.046). HT-29d cells exhibited stronger staining and a slightly higher ratio than that of the parental HT-29 in liver metastatic tumor using mAb p85α and p110α (Table 3).

Table 2 uPA and PAI-1 level of different cell lines at 24 h

Cell	Level(pg/10^5 ell)	
	uPA($\bar{x}\pm s$)	PAI-1($\bar{x}\pm s$)
WiDr	16.7±5.8	1 613±90

DISCUSSION

Tumor metastasis in the liver is a complex process of tumor-cell invasion into normal tissue on the one hand and the anti-invasive mechanisms of host defense system on the other hand. Lodgment of tumor cells in a blood vessel is an important step of tumor cell invasion. The survival of cancer cells after they enter the circulation depends upon their abilities to successfully reach the microcirculation, invade the capillary endothelium, establish a microenvironment for subsequent vascularization and growth. In the present study the capacity of arrested tumor

cells in the liver was observed in HT-29d cell line. One hour after tumor cell injection via the mesenteric vein, the number of tumor cells arrested in the liver was very high. Most tumor cells were located in the portal vein and its surrounding hepatic sinusoids. Furthermore, at 24 hours, the number of tumor cells surviving in the liver was significantly decreased, most tumor cells had been removed from the liver, the survived cells were located mostly in parenchyma of the liver. The remaining tumor cells were likely to be able to proliferate and to develop metastatic colonies. The results suggested that not all cells that entered the liver via hematogenous dissemination produced metastasis, the majority of circulating tumor cells died and only a minority of the cells escaped from host defense systems (e.g. NK cell activity in nude rats), arrested and survived in the liver could develop metastasis.

Neoplasms are heterogeneous with regard to invasion and metastasis, they contain a variety of subpopulations of cells with different metastatic potentials[17]. The outcome of metastasis is to a large extent dependent on a selection process that favors the survival and growth of a special subpopulation of cells. Isolation of clonal populations of cells that differed from the parent neoplasm in their metastatic capacity supported the hypothesis that not all the cells in a primary tumor could successfully disseminate[18]. The liver is the first and primary site affected by the hematogenous spread in colorectal carcinoma. In the present study, although only two rats were injected variant HT-29c cells with three selections *in vivo* into the mesenteric vein, still they showed a higher metastatic potential. One of the two rats developed extensive hepatic metastases, and the other developed synchronous multiple organ metastases. Both rats developed mesenteric metastases. The variant HT-29d with four-cycle selections had a higher metastatic efficiency in nude rats. The taking rate of liver metastases was increased as compared with parental HT-29 cells (70 % versus 50 %), and variant HT-29b cells with two-cycles selections (70 % versus 60 %)[16]. Three of the ten rats developed lung metastasis, and extensive organs were synchronously involved in metastases. The results showed that HT-29d cells had more extensive metastatic potential than parental HT-29, variant HT-29b and HT-29c. The present study supported the hypothesis of metastatic heterogeneity. Pre-existing tumor cell subpopulations with heterogeneous metastatic capacity could be isolated from their parental neoplasms by means of cycles of selection *in vivo*. The availability of selected human colorectal cell lines and the *in vivo* model of metastasis in rats allows to search for the molecular determinants of human colorectal cancer metastases and for the establishment of relevant models to test novel therapeutic agents against colorectal cancer metastasis.

uPA is a serine protease with multiple actions that could enable it to play a role in cellular migration, tissue remodeling, and cancer spread[19]. Some investigators reported that patients with a high uPA or high PAI-1 level had a poorer prognosis for relapse than those with a low uPA or low PAI-1 antigen level. It was concluded that uPA and PAI-1 antigen levels in tumor tissue were an independent and useful prognostic marker in a variety of malignancies[20,21], especially breast cancer[22,23]. However, there have been no studies concerning the relation between uPA as well as PAI-1 level of high-metastatic cells and low-metastatic cells or non-metastatic cells. We analyzed the difference of uPA and PAI-1 level produced by WiDr (non-metastatic), HT-29 (low metastatic) and variant HT-29d cells (highly metastatic) in their supernatants by ELISA. It showed that variant HT-29d cells produced higher a levels of uPA and PAI-1 as compared with non-metastatic WiDr cells and low metastatic HT-29 cells. HT-29 cells produced higher levels of uPA and PAI-1 as compared with WiDr cells. uPA might act as an offensive mechanism for tumor cell invasion and metastasis. Although the functional role of PAI-1 in tumor biology has been unknown, PAI-1 might play a role in enhancing tumor spread by mechanisms involving in angiogenesis or promote tumor cell division[24]. Since PAI-1 is present in endothelial cells and platelets of normal tissues, increased PAI-1 levels may reflect a high degree of angiogenesis, which offers the possibility of tumor spread and metastasis. Our results showed that levels of uPA and PAI-1 in variant HT-29d cells were higher than that in HT-29 cells, suggesting that the process of metastasis might depend on the selection of tumor cell clones with increased expression of plasminogen activator, which was positively correlated with the metastatic potential of colorectal carcinoma cells in this study.

CEA has been implicated in the development of hepatic metastases from colorectal cancers, and has been described as an adhesion molecule either by Ca^{2+}-independent homophilic binding or heterophilic binding. The present results showed that CEA levels on cell surfaces *in vitro* were not different among WiDr, HT-29 and HT-29d cells. In CEA immunostaining, no difference was observed among the cell lines, s.c. tumor and liver metastases of WiDr, HT-29 and HT-29d cells, repectively. These results showed that CEA surface expression might not be correlated with the metastastic potential in this model. However, the secretion of CEA was significantly altered in metastatic cells. Moreover, other members of the CEA family might also be differently expressed in metastatic cells.

PI3-kinase is a heterodimer consisting of an 85-kDa regulatory subunit (p85), and a 110-kDa catalytic subunit (p110). The role of PI3-kinase in growth factor signaling pathways has been studied intensively[25]. Several reports have shown PI3-kinase was involved in signal transduction pathways associated with cell growth regulation, cell cycle progression, and cell survival[26]. Some studies showed increased cellular content of PI3-kinase products and also physical association of the enzyme with transmembrane receptor tyrosine kinases following stimulation by various growth factors, including hepatocyte growth factor[27,28] and insulin-like growth factor[29]. A recent research indicated the importance of PI3-kinase in increased cell motility stimulated by growth factors such as PDGF and hepatocyte growth factor[30]. However, these data do not indicate whether expression of PI3-kinase is associated with the metastatic potential of colorectal carcinoma cells. In this study, we investigated the PI3-kinase expression in colorectal carcinoma cell lines WiDr, HT-29 and HT-29d *in vitro* and in s.c. tumors and liver metastases of rats immunohistochemically. *In vitro*, non-metastatic WiDr cells, metastatic HT-29 cells and highly-metastatic vairant HT-29d cells all expressed PI3-kinase. No significant differences were found in positive cell ratio and staining intensity. In s.c. tumors, highly metastatic vairant HT-29d cells showed a stronger PI3-kinase expression in staining intensity and a higher ratio of positive cells compared to WiDr and HT-29 cells. In liver metastases, vairant HT-29d cells showed a stronger staining intensity and a higher positive ratio than that of parental HT-29 cells. These results suggest metastatic potential may positively correlate with synthesis of PI3-kinase in this *in vivo* model. The highly-metastatic HT-29d variant highly expresses PI3-kinase. The expression of PI3-kinase correlates with tumor development and metastasis, and it may be a late event of tumor development of colorectal carcinoma and may correlate with an invasive stage of cancer.

Abstract

AIM: To elucidate the clinical and laboratory features of localized gastric amyloidosis via a rare report along with a review of related literatures.

METHODS: The clinical manifestations, laboratory results and surgical treatment of a female patient with localized gastric amyloidosis in our hospital were summarized. The relevant literatures were reviewed on the etiology, clinical features, diagnosis, treatment and prognosis of this disease.

RESULTS: The patient was lack of specific clinical manifestations and positive laboratory results. Prior to the treatment, she was suspected to be of malignization from gastric ulcer by both gastroscopy and endoscopic ultrasonography, which was denied by the gastric biopsy. The patient was treated with subtotal gastrectomy and clearance of perigastric lymph nodes. The postoperative pathological diagnosis determined the lesion to be the deposition of amyloid materials in the gastric mucosa, submucosa and blood vessel walls with intestinal metaplasia and atrophy of the gastric glands, in which no malignant tumor was found. Congo red staining with prior potassium permanganate incubation confirmed the AA type of amyloid in this case. Multiple biopsies from esophagus, remnant stomach, duodenum, colon and bone marrow in the follow-up survey showed no amyloidal deposition in these tissues and organs. Up to the present, no signs of recurrence have been found in this patient.

CONCLUSION: Localized gastric amyloidosis, being rare in incidence, should be considered in the differentiation of gastric tumors, in which biopsy is the only means to confirm the diagnosis. Currently, surgical resection of pathological tissue and circumambient lymph nodes may be a preferable therapeutic strategy for the localized amyloidosis to prevent possible complications. Although with a benign prognosis, gastric amyloidosis possesses a recurrent tendency as suggested by the literatures.

INTRODUCTION

Amyloidosis is an abnormal intercellular deposition of insoluble proteins that share a remarkably similar and stable core structure of β sheets[1]. It may be resulted from a heterogeneous group of disorders and result in impairment or even dysfunction of involved organs. Generally, amyloidosis is more commonly manifested as a systemic involvement of multiple tissues and organs including the heart, liver, spleen, kidneys, lymph nodes, adrenals, thyroid, as well as many others. In contrast, the clinical implication of a single organ or tissue is relatively rare in this pathological condition[2-6], in which the amyloidal deposit confined to the stomach is extremely scarce in the previous literatures[7-9]. Recently, we have experienced and cured a case of localized gastric amyloidosis and now report it as follows.

CASE REPORT

A 50-year-old female was admitted to our hospital on Aug 23, 2002, with chief complaints of recurrent epigastric discomfort for 10 years and a newly-appeared dull pain in the upper abdomen for 4 months. The Inpatient No of this patient was 370655. Ever since being diagnosed as gastric ulcer and erosive gastritis with intestinal metaplasia 10 years ago by gastroscopy, she has not received any normal treatment except for long-term administration of metronidazole and omeprazole tablets herself. Prior to hospitalization, she was suggested to be of cancerization from gastric ulcer by gastroscopy at another medical institution. On admission, the patient displayed a good general condition and no positive signs including enlargement of superficial lymph node were revealed by physical check-up. Laboratory data showed negative results in the detection of serum anti-streptolysin O, rheumatoid factor and urine Bence-Jones protein. No abnormal signs were found on the chest radiograph. An upper gastrointestinal endoscopy revealed a gastric ulcer of 3 cm×1 cm in size that was located at the posterior wall of small curvature at the inferior part of gastric corpus. The margin of the ulcer was heaped up and rugged, the ambient mucosa was erosive, friable and prone to bleeding. The base of the ulcer was shaggy and covered with fibrinous layers. The malignization of this ulcer was suggested by endoscopic ultrasonography with low echo findings that the sick part of gastric wall was markedly and unevenly thickened, and some parts of the submucosa were infiltrated. On the contrary, a diagnosis of gastric amyloidosis, along with chronic gastritis with intestinal metaplasia, proliferation of lymphatic tissue and negative finding of *Helicobacter pylori*, was made by the biopsy of gastric mucosa. Exploratory laparotomy was carried out on Sep 3, 2002, in which no abnormal signs including enlargement of lymph node were found except that part of tumor-like, stiff and diffusely-thickened gastric wall was recognized at the inferior part of gastric corpus. Subtotal gastrectomy and clearance of perigastric lymph nodes were performed. Final pathological diagnosis determined the lesion to be the deposition of amyloidal materials in the gastric mucosa, submucosa and blood vessel walls with intestinal metaplasia and atrophy of the gastric glands, and no malignancies or other tumors were found. When stained with hematoxylin-eosin (Figure 1) and Congo red (Figure 2) respectively, the amyloidal deposits displayed as amorphous, homogeneous, translucent and acidophilic material under light microscope. The amyloidal protein was further proved to be

the AA type by the fact that it exhibited green birefrigence with Congo red staining under polarized light, which was disappeared when the specimens were pretreated with potassium permanganate. The patient got recovered and no complications occurred after operation. Multiple biopsies from esophagus, remnant stomach, duodenum, colon and bone marrow in the follow-up survey of 5 months post operation showed no amyloidal deposition in these tissues and organs. Up to the present, no signs of recurrence have been found in this patient.

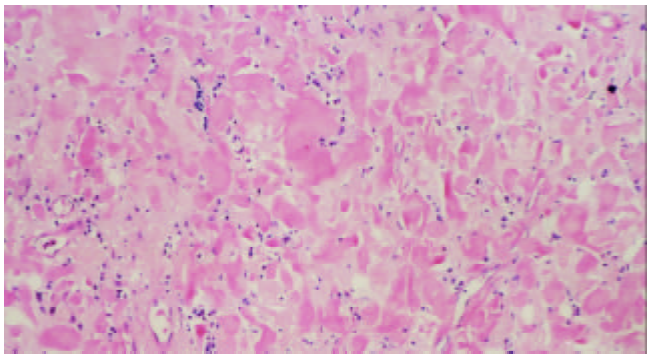

Figure 1 Stained with hematoxylin-eosin, amyloidal deposits in gastric mucosa and submucosa display amorphous, homogeneous, translucent and acidophilic materials under light microscope. (Magnification ×100).

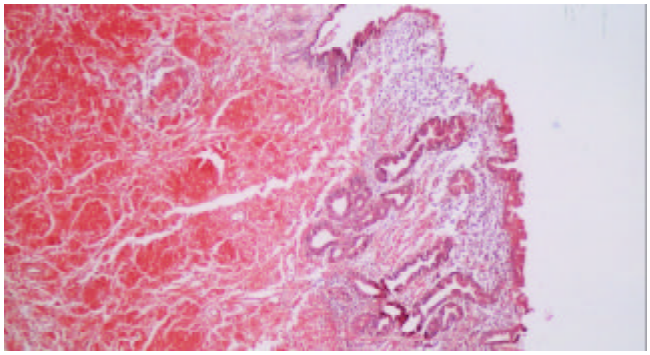

Figure 2 Stained with Congo red, deposition of amyloid could also be observed extending from gastric mucosa to submucosal layer. (Magnification ×50).

DISCUSSION

Amyloidosis, a disorder marked by the deposition of amyloid in various organs and tissues of the body, is usually associated with a variety of chronic diseases such as rheumatoid arthritis, tuberculosis, multiple myeloma and many others. Its classifications have been notoriously unsatisfactory for donkey' s years because the definition of this disorder was initially based on the morphological features, in which the amyloidosis was categorized according to the tissue distribution of amyloid (e.g. systemic versus localized amyloidosis) and the presence or absence of the identifiable predisposing factors (e. g. secondary versus primary amyloidosis). As the unique feature of amyloidal substance was, the component of the precursor protein that forms the fibrillar deposit has been now accepted as the basis for the classification of amyloidosis[10]. Up to the present, several types of the precursor proteins such as serum amyloid A (SAA), amyloid immunoglobulin light chains (AL), abnormal transthyretin (ATTR), β_2 microglobulin (β_2-M), amyloid precursor protein *etc* have been identified in amyloidosis.

Gastrointestinal tract is one of the regions to be commonly involved in the systemic amyloidosis. However, amyloidosis confined to the stomach is a rare occurrence. Although the detailed mechanism for the deposition of amyloidal materials in a specific tissue or organ remains unclear, the excessive accumulation of proteinaceous metabolites in local tissue might be a possible explanation[11]. The patient in our report suffered from gastric ulcer and gastritis for more than 10 years, which might cause a local disorder in protein metabolism and lead to localized deposition of amyloidal materials.

The clinical manifestations of amyloidosis were often uncharacteristic and varied with the involved organs. As for localized gastric amyloidosis, a variety of common gastrointestinal symptoms such as epigastric discomfort, poor appetite, hematemesis, hematochezia and gastric perforation might occur in the process of this disease because of involvement of local autonomic nervous system[7] and gastric wall structure damage[8]. Although localized gastric amyloidosis might associate with gastric malignancies in some cases[6,12,13], its non-tumorous form usually tended to be misdiagnosed as gastric tumors due to the likeness of gross appearance in endoscopic and imaging examinations. In this respect, biopsy has been suggested to be the only means to confirm the diagnosis[15]. The fact that pretreatment with potassium permanganate made biopsy specimens unstained by Congo red is helpful to determine the amyloidal component as AA type rather than AL protein. Scintigraphy with radiolabeled serum amyloid P (SAP) component could provide support for the diagnosis of amyloidosis in patients with negative histological studies[11] and distinguish localized lesion from systemic amyloidosis[14]. Besides, Immunohistochemical staining or immunofixation electrophoresis of biopsy specimens with the specific antibodies might guarantee the accurate classification of this disease[15-17].

The prognosis of amyloidosis depends on both the specific types of lesions and the involved organs. Systemic amyloidosis is usually with an unfavorable prognosis while the localized types of this disease such as the localized gastric amyloidosis have a relatively better outcome. Untreated AL amyloidosis often had the worst prognosis with a median survival time of one to two years[18], especially when cardiac involvement occurred. Patients with ATTR amyloidosis might survive up to 15 years from diagnosis but this time also varies with the specific mutation and the time of diagnosis - the younger the age of presentation the worse the outcome. However, the prognosis of patients with AA type was affected mainly by the underlying conditions[1,15]. Currently, there is no specific therapy for systemic amyloidosis. The treatment strategy has been directed both to support the affected organs and to deal with the underlying specific disease[19] in an attempt to reduce the deposition of amyloidal substances and improve prognosis, in which several supportive protocols and chemotherapeutic drugs including melphalan, iodinated anthracycline 4-iodo-4-deoxydoxorubicin, dimethylsulfoxide and colchicines have been widely used, although their effectiveness in ameliorating this disease has remained to be determined[15]. With the advances in molecular biology, some promising attempts have been made to reduce inflammatory response and amyloidal deposits by blocking the signal conduction of RAGE-NF-κB in monocytes/macrophages[20]. In patients with localized amyloidosis, thorough resection of the foci and their circumambient lymph nodes as performed in our case is probably the preferable therapeutic modality and the key measures to prevent postoperative recurrence. Up to the present, no signs of recurrence have been found in the follow-up survey of our patient.

Abstract

Regenerating gene (Reg or REG) family, within the superfamily of C-type lectin, is mainly involved in the liver, pancreatic, gastric and intestinal cell proliferation or differentiation. Considerable attention has focused on Reg family and its structurally related molecules. Over the last 15 years, 17 members of the Reg family have been cloned and sequenced. They have been considered as members of a conserved protein family sharing structural and some functional properties being involved in injury, inflammation, diabetes and carcinogenesis. We previously identified Reg IV as a strong candidate for a gene that was highly expressed in colorectal adenoma when compared to normal mucosa based on suppression subtractive hybridization (SSH), reverse Northern blot, semi-quantitative reverse transcriptase PCR (RT-PCR) and Northern blot. *In situ* hybridization results further support that overexpression of Reg IV may be an early event in colorectal carcinogenesis. We suggest that detection of Reg IV overexpression might be useful in the early diagnosis of carcinomatous transformation of adenoma. This review summarizes the roles of Reg family in diseases in the literature as well as our recent results of Reg IV in colorectal cancer. The biological properties of Reg family and its possible roles in human diseases are discussed. We particularly focus on the roles of Reg family as sensitive reactants of tissue injury, prognostic indicators of tumor survival and early biomarkers of carcinogenesis. In addition to our current understanding of Reg gene functions, we postulate that there might be relationships between Reg family and microsatellite instability, apoptosis and cancer with a poor prognosis. Investigation of the correlation between tumor Reg expression and survival rate, and analysis of the Reg gene status in human maliganancies, are required to elucidate the biologic consequences of Reg gene expression, the implications for Reg gene regulation of cell growth, tumorigenesis, and the progression of cancer. It needs to be further attested whether Reg gene family is applicable in early detection of cancer and whether Reg and Reg-related molecules can offer novel molecular targets for anticancer therapeutics. This has implications with regard to prognosis, such as in monitoring cancer initiation, progression and recurrence, as well as the design of chemotherapeutic drugs.

INTRODUCTION

Reg and Reg-related genes constitute a family belonging to calcium dependent lectin (C-type lectin) gene superfamily[1-4]. It represents a group of small secretory proteins, which can function as acute phase reactants, lectins, antiapoptotic factors or growth factors for pancreatic β-cells, neural cells and epithelial cells in the digestive system[5,6]. They play a wide range of roles in researching mammal physiology and human diseases. Ever since Reg (regenerating gene) I was discovered, special attentions have been paid to the regeneration of pancreatic β-cells and administration of Reg I protein and/or activation of the Reg I gene to be used as a potential therapeutic approach for diabetes[7]. Successively, the potential role of Reg family in tumors especially in digestive tract has drawn more attention[8-14]. We here focus on the members of Reg family, their functions and possible mechanisms.

REG FAMILY

Discovered members

In 1984, Yamanoto *et al*. found that administration of nicotinamide accelerated the regeneration of pancreatic islets in partially pancreatectomized rats. Subsequently, Terazono *et al.* screened a rat regenerating islet-derived cDNA library and isolated a novel gene encoding a 165 amino acid protein with a 21 amino acid signal peptide[15,16], which was called Reg gene. It was not termed Reg I until 1997. They also cloned human Reg I cDNA encoding a 166 amino acid protein with a 22 amino acid signal peptide. Reg I has other synonyms such as PTP (pancreatic thread protein), PSP (pancreatic stone protein) and lithostathine[17]. Human Reg I gene is a single copy gene spanning 3.0 kb, and is composed of six exons and five introns. The gene mRNA was detected predominantly in the pancreas, and at lower levels in gastric mucosa and kidneys[18]. Later they isolated two genes, one of which was a mouse homologue to rat and human Reg gene, the other a novel type of Reg gene. The two genes were designated as Reg I and Reg II, respectively.

In 1999, Okamoto grouped the members of the family, Reg and Reg-related genes from human, rat and mouse, into three subclasses, types I, II, and III[19]. Stephanova *et al.* determined that the three rat PAP genes and the related Reg gene (REGL, regenerating islet-derived-like/ pancreatic stone protein-like/ pancreatic thread protein-like) were all located at 4q33-q34[20]. The mouse Reg family genes were mapped to a contiguous 75 kb region in chromosome 6, including Reg I, Reg II, Reg III alpha, Reg III beta, Reg III gamma, and Reg III delta[21]. Reg III delta was expressed predominantly in exocrine pancreas, whereas both Reg I and Reg II were expressed in hyperplastic islets and Reg III alpha, Reg III beta and Reg III gamma were expressed strongly in the intestinal tract and weakly in pancreas.

Although Reg IV (1q12-q21), identified by Hartupee *et*

al, has not been found in the same chromosome as other members of human Reg gene and Reg-related gene (2p12), it shares some common features with other members such as: sequence homology, tissue expression profiles, and exon-intron junction genomic organization[1]. Thus by 2001, four types of Reg gene family had been identified. Data of RT-PCR results in our laboratory were consistent with the hybridization result of Hartupee and colleagues, and Reg IV mRNAs level was higher in colon than in rectum. We compared the results with Reg I expression pattern. Kawanami *et al*. discovered that expression of Reg I mRNA was higher in the stomach than in any other region of the gastrointestinal tract[22], which also suggested that Reg mRNA was higher in proximate gastrointestinal tract.

Table 1 Members of Reg family, length of amino acids and chromosome localization

Superfamily memeber	Species	Length of amino aAcid	Chromosome localization
Reg I	Mouse Reg I	165	6
	Rat Reg	165	4q33-q34
	Human Reg / PSP / PTP	166	2p12
Reg II	Mouse Reg II	173	6
Reg III	Rat PAP	175	4q33-q34
	Rat peptide 23	175	4q33-q34
	Human HIP	175	2p12
	Bovine PTP	175	
Reg IV	Human Reg IV	158	1q12-q21

So far, 17 members have been identified in mammals across human, pig, mouse, bovine and rat species. Table 1 lists some most important members of Reg family[23,24]. Among the mammalian members of this family, there is only mouse Reg II in type II and human Reg IV in type IV. Hartupee *et al*. also reported that a mouse homologue of Reg IV was likely existed[1], but up to now, there are no reports and also no investigations on mouse Reg IV.

Structure and function

Most members of Reg family have similar organization with respect to exon number and chromosome location. The most interesting characteristic is its common domain of lectin. Data have revealed a significant similarity of the sequences of Reg family with the C-type (Calcium-dependent) lectin superfamily. This domain of lectin could account for complex events such as human malignancy and other diseases[25,26].

Studies on Reg I protein receptor (Reg-R) revealed that regenerating protein might act not only as a regulator of gastric epithelial cell proliferation but also as a modifier of many other multiple physiologic functions[27,28]. Reg-R gene was isolated from a rat islet cDNA library[27] encoding a cell surface 919-amino acid protein. Its expression was detected mainly in chief cells and parietal cells of the deep layers and faintly in surface epithelial cells and mucous neck cells of the proliferating zone[29]. Reg I protein could induce β-cell proliferation via the Reg I receptor and ameliorate experimental diabetes[30].

Under physiological conditions, Reg I protein is not expressed in pancreatic β-cells, although Reg-R is expressed. In the regenerative process of pancreatic islets, Reg I gene expression is induced. Therefore, activation of Reg I gene is thought to be one of the important events in β-cell regeneration.

REG FAMILY AND HUMAN DISEASES

Injury response and inflammation

Regenerating gene family members are expressed in tissue injury. As tissue injury is concerned, pancreatitis is most frequently studied. Experimental induction of acute pancreatitis caused a coordinate increase both in PSP/reg (Reg I) and in PAP (Reg III). Since the regulation of this protein family was affected even under mild stress, they were defined as secretory stress proteins[31-33]. Reg levels are sensitive markers for pancreatic injury and early stage of the disease, which might be useful prognostic indicators for disease severity[34]. The expression level of PSP/Reg I protein varies with different degrees of injury. Mild to moderate injury to pancreatic tissue might stimulate the synthesis of PSP/reg-protein, whereas more severe injury tended to depress it[32,34].

There are other evidences supporting Reg' s roles in the healing of gastrointestinal mucosal lesions. Miyaura *et al*. measured Reg expression after implantation or resection of a solid insulinoma in rats and found that the diminution in pancreatic β-cell mass caused by subcutaneous implantation of insulinoma tissues was associated with reduced Reg I gene expression and increase of β-cell proliferation after resection of the tumor was preceded by return of Reg I gene expression toward normal[35]. In an injured state following indomethacin treatment, Reg I gene expression was sharply increased, accompanied by an overexpression of c-fos and healing of mucosal lesions[22]. In addition, Reg I mRNA was detected predominantly in the deepest mucosal layer. It was expressed almost exclusively in cells that were less than 11 μm in diameter, which suggested a role of Reg I in the healing.

This also may be one of reasons why Reg genes have been frequently screened as differentially expressed genes[8,10,36-38]. Shinozaki *et al*. isolated seven candidate genes that were presumed to be up-regulated in inflammatory colonic epithelia and Reg I was among them. Expression of Reg I alpha was confined to the crypt epithelia[36] and its selective expression in the crypt epithelia of inflammatory colonic mucosa might suggest its important regulatory functions.

Another interesting change was the length of Reg mRNA. The elongated mRNA of PAP II/Reg III was strongly induced in the early phase after acute pancreatitis. The elongated mRNA might affect the function of PAP II/Reg III protein because the elongated mRNA with long 3' untranslated regions (3' UTR) was involved in the translation efficiency and thus played an important role in the progression of pancreatitis[39].

Diabetes

Islet cells originate from the epithelial cells of primitive pancreatic ducts during embryogenesis, and can regenerate in response to the loss of islet cells even in adult pancreas. The ability of islet cells to regenerate could increase the possibility, which could restore the impaired and decreased islets of diabetic patients[40]. On the other hand, aging may be associated with selective dysfunction of β-cells, which may involve the expression of Reg I gene. Reg I gene could play an important role in β-cell growth/regeneration[41,42] and its expression could parallel to islet physiology, thus Reg I gene may become one of the targets of genetic engineering for diabetic β-cells.

In early 1980s, Takasawa *et al.* proposed a unifying model for β-cell damage (the okamoto model). In 1984, they demonstrated Reg I protein could induce β-cell proliferation and ameliorate experimental diabetes. Later, they showed that combined addition of IL-6 and dexamethasone could induce Reg I gene expression in β-cells and that inhibitors could enhance the expression[43]. In 2002, they reported that PARP and its inhibitors had key roles in inducing β-cell regeneration, maintenance of insulin secretion, and prevention of β-cell death[28].

The expression of Reg is a defense mechanism of the exocrine pancreas that is conserved in evolution. Sanchez *et al*. demonstrated that pancreatic Reg I and Reg II genes were overexpressed in non-obese diabetic (NOD) mice during active diabetogenesis[44,45]. They suggested that overexpression of the Reg gene(s) might represent a defense of acinar cells against pancreatic aggression. Although some results were opposite to their hypothesis[46,47], they further confirmed their previous findings by conducting the same protocol as Fu did.

Studies on differentially expressed genes have added proof to reveal Reg' s potential application in treatment. As we know, genes overexpressed in pancreatic islets of patients with diabetes are potential candidates for novel disease-related autoantigens. Subtractive hybridization was used on islets from a patient who died at the onset of type I diabetes, and a type I diabetes-related cDNA encoding hepatocarcinoma-intestine-pancreas/pancreatic-associated protein (HIP/PAP, Reg III) was identified[48]. In addition, treatment aimed at abrogation of autoimmunity combined with expansion of β-cell mass has become a potential therapeutic approach for the treatment of insulin-dependent diabetes[49]. Therefore, diabetes might be ameliorated with Reg protein treatment.

Tumors

Watanabe *et al*. firstly studied the relationship between cancer and Reg[16]. Reg I mRNA was detected at various levels in gastric cancer and colorectal cancer, but was not in esophageal cancers and nontumoral mucosae of the colon, rectum and esophagus. Reg gene family has been found to be up-regulated in human colorectal cancer cell lines during differentiation[50], this was reflected at the protein level by Western blotting in a small series of human colorectal cancers[14]. Macadam *et al*. later analyzed 142 cases of primary colorectal adenocarcinoma and demonstrated that 53 % tumors expressed Reg I mRNA, which was only detected in 16 out of 88 (18.1 %) paired normal mucosae[12]. PAP was also over-expressed in colorectal cancer[14]. Reg genes were expressed in a portion of cancers, whereas no expression was found in paired normal mucosae. The mechanisms altering the transcriptional control of Reg genes might be of interest from a therapeutic standpoint[12].

Even though there is a long history of observations related to up-regulated Reg expression in cancer. Only in the last five years, there have been experimental evidences directly supporting a role of these proteins in neoplastic transformation and tumor progression. Bernard-Perrone *et al*. localized Reg I protein in Paneth cells and immature columnar cells of human small intestinal crypts[50], which appeared to be associated with cell growth. Reg I protein may be down-regulated when growth is achieved and differentiation is induced.

Our study on Reg IV suggested that Reg IV might play an important role in initiating colorectal adenoma, and its detection might be useful in the early diagnosis of colorectal adenoma formation[8]. Reg IV has been screened 13 times in a subtracted cDNA library of human colon adenoma/normal mucosa by using suppression subtractive hybridization (SSH) method[8, 38]. The overexpression of Reg IV in colorectal adenomas was testified by reverse Northern blot. Our recent results showed that Reg IV was up-regulated in colorectal adenoma and carcinoma. Violette *et al*. also found its overexpression in colorectal cancer[10], and pointed out the potential role of Reg IV in colorectal tumors and its subsequent interest as a prognostic indicator.

Another interesting topic is involved in Reg I and gastric cancer. Reg I could be expressed in gastric enterochromaffin-like (ECL) cells[51,52]. Mutations of Reg I that inhibit secretion are associated with ECL cell carcinoids, suggesting that Reg I functions as an autocrine or paracrine tumor suppressor. Chiba suggested that Reg I might normally function as a negative regulator of ECL cell growth to restrain the stimulatory effect of gastrin in humans[53]. Abolition of Reg I protein secretion might result in an enhanced proliferation of ECL cells, and eventually lead to the development of ECL carcinoid tumors.

In addition to the study on relationships between diseases of gastrointestinal tract and Reg expression, there are many reports dealing with Reg and other digestive organs. Harada *et al*. examined the expression of Reg I in intrahepatic cholangiocarcinoma (ICC) and its precursor lesion (biliary dysplasia) and showed that the expression of Reg I protein was significantly dependent on the histologic differentiation[54]. HIP at a transcriptional level was elevated in liver tumors while it was not detected in nontumorous adjacent areas or in normal adult and fetal liver, suggesting that HIP could be involved in liver cell proliferation or differentiation. HIP mRNA expression is tissue specific, since it is expressed in the normal small intestine and pancreas, while it could not be evidenced in colon, brain, kidney, or lung[37]. HIP gene shows several potential regulatory elements, which might account for the enhanced expression of the gene during pancreatic inflammation and liver carcinogenesis[55]. Both Reg I mRNA and its product were localized in acinar cells of the pancreas, but neither was found in ductal or islet cells. Reg I protein has been considered as a useful marker for acinar cell differentiation[56] and immunohistochemical application of reg I protein may help to show histogenesis and differential diagnosis of pancreatic tumors.

Few reports are available on the association of Reg and tumors outside the digestive system. Bartoli *et al*. showed a weak expression of PAP/HIP gene in the pituitary gland, Reg I expression was not observed in tested adenomas or in pituitary gland[57], whereas REGL gene was observed in pituitary gland and in some subtypes of adenomas. Reg gene was expressed only in fetal pancreas and in some adult tissues. In contrast, REGL transcript was expressed not only in fetal pancreas but also in fetal colon and brain as well as in some adult tissues. In our results, we firstly reported Reg IV' s potential role in prostate cancer[8]. From the original results of bioinformatics analysis based on public databases (serial analysis of gene expression, SAGE), we could state that Reg IV was expressed in normal colon mucosa, colon adenocarcinoma, pancreatic cancer, gastric adenocarcinoma and prostate adenocarcinoma. Since Reg family was associated with different kinds of tumors in the digestive system, this was the report of Reg IV expression in prostate adenocarcinoma although its transcript level was rather low. On the other hand, if Reg is expressed in most cancers independent of their origins and is only expressed in limited normal tissues, it is of clinical significance that Reg expression is applied to early detection and treatment of cancer. But the most important point is to make sure whether its expression is tumor-specific.

ASPECTS TO BE FURTHER STUDIED

Reg family and microsatellite instability

Microsatellite instability (MSI) has been reported to be an important feature of solid malignancies[58]. Inactivation of the mismatch repair system (MMR) would lead to MSI that can profoundly affect cellular behaviors, since many genes playing important roles in inducing signal transduction, apoptosis, DNA repair and cell cycle control could be altered in tumors with MSI[59].

From the report of Akiyama *et al*.[30], we can hypothesize the possible relationship between Reg and DNA repair. Although it cannot supply strong evidences for the relationship between Reg and microsatellite instability, but other reports may further reveal its potential relationship. Cancers with MSI have a unique histological appearance and an altered response

to chemotherapy and radiotherapy. It has been more frequently seen in mucoid cancer with poor differentiation[60-64] and the subtype with MSI also has a characteristic of drug resistance. Interestingly, Violette *et al*. discovered that Reg IV mRNA-positive tumor cells displayed unique phenotypes such as: mucus-secreting, enterocyte-like or undifferentiated ones. What is more, it was overexpressed in HT-29 drug-resistant cells[10].

Possible early biomarkers of carcinogenesis

Zenilman *et al*. observed a phenomenon of Reg I protein expression changed in colorectal cancer[9] and postulated that colorectal production of Reg I might either be a marker for the presence of cancer or a risk of mucosa for development of neoplasia based on the fact that Reg I protein was ectopically expressed in colorectal mucosa at the transitional zone of colorectal cancer, and occasionally within the tumor itself[9].

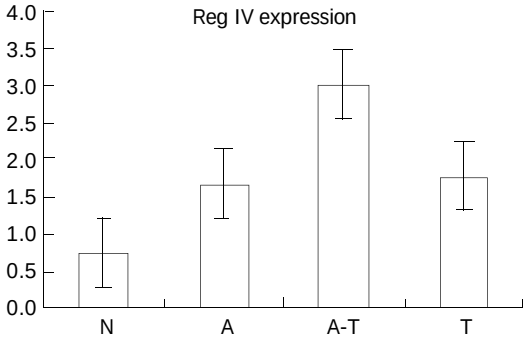

Figure 1 *In situ* hybridization results of 12 cases of colorectal adenoma with carcinomatous change. (N=normal mucosa, A=residual adenoma, A-T=adenoma with carcinomatous change, T=invasive cancer)[13].

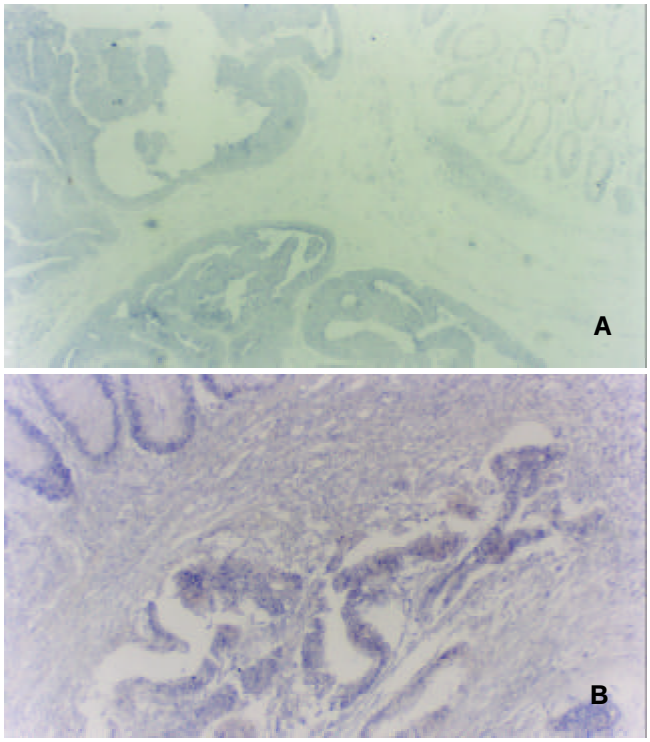

Figure 2 *In situ* hybridization of Reg IV. A: Reg IV is up-regulated in colorectal cancer, B: Reg IV is up-regulated in normal mucosa adjacent to adenoma and adenocarcinoma.

Other reports on Reg family can add some evidences to the confirmation of Reg family' s role as a predicator of early cancer. Harada *et al*. suggested that expression of Reg I was a good marker for biliary mucosa at risk for development of ICC, and that Reg I played a role in the early stages of biliary carcinogenesis, probably via a cell-proliferative effect[54]. Our results of *in situ* hybridization showed that Reg IV was up-regulated in colorectal adenoma and carcinoma and the greatest Reg IV positivity was typically observed at regions with carcinomatous change (Figures 1, 2). Another interesting phenomenon was that at some regions near adenoma or adenocarcinoma (Figure 2b), Reg IV was also up-regulated as it was in colorectal adenoma and carcinoma, and the expression became weaker with increasing distance away from the tumor border in the direction of normal epithelia. Thus Reg IV may be thought as the biomarker of early transformations such as *in situ* carcinoma. This further presented evidences that overexpression of Reg IV might be an early event in colorectal adenoma-carcinoma sequence and carcinogenesis. Our present data also show that Reg IV is more frequently overexpressed in poorly differentiated colorectal carcinomas and carcinomas with metastasis.

The tumor-promoting activity of Reg protein should be considered for its possible clinical applications[43]. Moreover, its sensitivity to carcinogenesis might be used for early diagnosis.

Antiapoptotic factors

Reg I might reduce epithelial apoptosis in inflammation[65,66]. In addition, tumor necrosis factor (TNF) pathway also reflects Reg' s potential role as an antiapoptotic factor. TNF-alpha contributes to the development of acute pancreatitis. Because TNF-alpha was involved in the control of apoptosis, Malka *et al*. studied its interaction with the pancreatic apoptotic pathway[65,66]. The antiapoptotic pancreatitis-associated protein (PAP) I is a candidate for mediating TNF-alpha activity. Its expression is induced by TNF-alpha, and cells overexpressing PAP I show significantly less apoptosis on exposure to TNF-alpha. Therefore, PAP I is one of the effectors of apoptosis inhibition.

Reg gene product may regulate a series of regeneration. This regenerative response may switch off apoptotic signals. Thus, those cells, which exhibit both a regenerative response and genetic mutations in some growth promoting or metastasis inducing genes, would have a survival advantage[12].

Up to now, we cannot confirm whether Reg I directly take part in apoptotic inhibition. But it is of interest to clarify the relationship between Reg I expression and inhibitors of apoptosis.

Predictions of poor prognosis

Expression of Reg might reflect the degree of tissue injury. Thus overexpression degree of Reg might be a useful marker to judge whether the tumor has a poor prognosis. The expression of Reg I alone and co-expression of Reg I with PAP have a significantly adverse effect on survival. Thus the expression of Reg I might provide a valuable selective indicator of adjuvant therapy in patients with early-stage colorectal cancer which would recur after curative surgery[12].

Reports also revealed that a role of Reg gene in the healing of gastrointestinal mucosal lesions. Up-regulation of Reg I expression in ulcerative colitis might reflect the activation of mucosal injury followed by down-regulation when the injury was healed. Interestingly, a similar feature was also appeared in Reg IV. Our results showed that higher levels of Reg IV mRNA were consistently scored in regions with more severe dysplasia in the same adenoma sample displaying a varying degree of dysplasia. We postulate that Reg IV overexpression may reflect the degree of body injuries. However, when two tumors coexisted in a single case, Reg IV transcript was usually

higher in adenomas compared with paired carcinomas. The mechanism is not clear.

In addition to these mechanisms, Reg family has been found to be implicated in other physiological processes. Reg II has a distinctive role in injury response[67] and its expression is a crucial step in ciliary neurotrophic factor (CNTF) survival pathway. Reg II has been found to be a neurotrophic factor and also an intermediate in the survival signalling pathway of CNTF-related cytokines[68].

In conclusion, we have characterized the structure and expression of Reg genes. Their possible functions and mechanisms were also discussed. These studies have led to a better understanding of the essential functions of these Reg family genes in mammalian physiological processes and human diseases. In addition to its potential application in diabetes, future studies on Reg family and human malignancy will shed lights on Reg' s unusual features on cancer. As we know, expression of Reg I inversely correlated with the level of cell differentiation, and it could be modulated via the glucocorticoid receptor, and has been found to be a potential marker of gastrointestinal epithelial differentiation[69]. Rechreche *et al*. suggested that inhibition of PAP/reg expression in normal colon cells by silencing their gene promoters could be relieved during colon carcinogenesis, allowing their up-regulation by mediators such as cytokines. Reg' s role in human malignancy especially in the digestive system should be further studied[11,14]. More recently, Kamarainen *et al*. identified and characterized a gene encoding a regenerating protein (REG)-like protein called RELP[70], and found there were several transcripts of RELP and the predicted protein product of the major transcript was annotated Reg IV.

All these encourage us to further study the potential roles of Reg family, especially Reg IV in human tumors. Are they sensitive reactants of tissue injury? Do they play oncogenic roles in colorectal cancers? Is there any potential if they are used as early biomarkers of carcinogenesis? Could they be used as prognostic indicators of tumor survival and disease severity? Before these conclusions can be drawn, further investigations are needed. Thus, detection of the expression level of Reg in cancers with different histological features and survival rates, and analysis of Reg gene status in human tumors at different stages or sites, are required to elucidate the pathophysiologic roles of Reg family.

Abstract

Since the first detection of aberrant crypt foci (ACF) in carcinogen-treated mice, there have been numerous studies focusing on these microscopically visible lesions both in rodents and in humans. ACF have been generally accepted as precancerous lesions in regard to histopathological characteristics, biochemical and immunohistochemical alterations, and genetic and epigenetic alterations. ACF show variable histological features, ranging from hyperplasia to dysplasia. ACF in human colon are more frequently located in the distal parts than in the proximal parts, which is in accordance with those in colorectal cancer (CRC). The immunohistochemical expressions of carcinoembryonic antigen (CEA), β-catenin, placental cadherin (P-cadherin), epithelial cadherin (E-cadherin), inducible nitric oxide synthase (iNOS), cyclooxygenase (COX-2), and $P16^{INK4a}$ are found to be altered. Genetic mutations of K-ras, APC and p53, and the epigenetic alterations of CpG island methylation of ACF have also been demonstrated. Genomic instabilities due to the defect of mismatch repair (MMR) system are detectable in ACF. Two hypotheses have been proposed. One is the "dysplasia ACF-adenoma-carcinoma sequence", the other is "heteroplastic ACF-adenoma-carcinoma sequence". The malignant potential of ACF, especially dysplastic ACF, makes it necessary to reveal the nature of these lesions, and to prevent CRC from the earliest possible stage. The technique of magnifying chromoscope makes it possible to detect "*in vivo*" ACF, which is beneficial to colon cancer research, identifying high-risk populations for CRC, and developing preventive procedures.

INTRODUCTION

Genetic changes in the malignant transformation process of colorectal mucosa include deletions, rearrangements, and mutations leading to either inactivation or activation of specific target genes[1-3]. A number of biomarkers associated with genetic changes have been identified for early detection of CRC. Two major classes of genes, oncogenes and suppressor genes, are involved in addition to mismatch repair (MMR) genes[4-6], which are associated with genomic instability. The major advances in understanding CRC include identification of the involvement of APC, p53, K-ras and MMR genes, as well as epigenetic alterations, such as CpG island methylation, in the formation and progression of the disease. Identification of ACF as an early preinvasive lesion and its relationship to the development of cancer have aroused an increasing interest in recent years.

Since the first detection of ACF in carcinogen-treated mice by Bird in 1987 and the hypothesis of ACF as the earliest precursors of CRC, there have been numerous studies focusing on these microscopically visible lesions both in rodents and in humans. The following table (Table 1) shows some highlights of studies on human ACF.

a: ileal microadenoma; b: in colorectal cell lines.

Identification of ACF both in carcinogen-treated rodents and in human colon makes the study of CRC at precancerous stages possible. The growth, morphological and molecular features of ACF support the contention that ACF are putative preneoplastic lesions. The traditional "adenoma-carcinoma" sequence of colorectal carcinogenesis has been extended to "ACF-adenoma-carcinoma" sequence. A better understanding of the underlying cellular and molecular events affected by cancer preventive or promoting agents will provide more insights into colorectal carcinogenesis and lead to the development of different cancer preventive strategies for high-risk individuals and the general population.

DEFINITION OF ACF

ACF was first reported by Bird in 1987[7] in the colons of carcinogen-treated C57BL/6J or CF1 female mice, and the assumption of ACF as potential preneoplastic lesions in murine colon was put forward one year later, coming up with the methodological approach to detect ACF[8]. Under microscope, aberrant crypts appeared larger and had a thicker epithelial lining compared to normal crypts, and usually gathered into a focus, consisting of aberrant crypts from one to hundreds[9,10]. These aberrant crypts sometimes were slightly elevated from the surrounding normal mucosa and often had oval or slit-like lumens[9,11-13]. It has been described as single or clusters of abnormally large crypts of the colon mucosal surface after stained with methylene blue. On colonoscopy, ACF were defined as being deeper with methylene blue staining than normal surrounding mucosa, and as a cluster of two or more crypts with dilated or slit-like openings rising above the surrounding mucosa[14,15].

ACF with a single crypt met the following criteria by McLellan[16]. The size of the crypt was at least twice that of the normal surrounding ones, the luminal opening was more elliptical than circular, and the epithelial lining was thicker than that of the normal surrounding crypts. ACF consisting of more than one crypt were defined as crypts to form a distinct focus. Individual crypts within the focus had a thicker epithelial lining and an elliptical luminal opening, and the total area occupied by the crypts of ACF was greater than that occupied by an equivalent number of surrounding morphologically normal crypts.

In humans, ACF were described and partially characterized for the first time in 1991[9,11], and in 1994, Pretlow first detected altered enzymatic activity, crypt dynamics and proliferation. ACF in human colon closely resembled aberrant crypts seen in rodents treated with carcinogens[7]. Some lines of evidences supported the view that ACF or at least some of them, might be precursors of CRC. In particular, ACF in human colon were more often located in the distal parts than in the proximal parts[17], which was verified in animal model[18]. Aberrant crypts had a hyperproliferative epithelium[19-21]. The size of ACF could increase with time, and it was evident that the nuclear atypia noted in some ACF was similar to those seen in the crypts of adenocarcinomas in rat colons[16]. In ACF, the immunohistochemical expressions of carcinoembryonic antigen[22] and β-catenin[23-25] were increased. K-ras, APC and P53 mutations, have been shown to be important genetic alterations in the development of CRC[26,27], have been demonstrated in ACF[28-33]. Identification of dysplasia and monoclonality in a putative precursor lesion would strongly link this lesion to neoplastic progression. ACF have been confirmed to arise from independent initiation events[28-30,34], and when examined histologically, ACF showed variable features, ranging from mild hyperplasia to dysplasia[12,22,35,36] as "nondysplasia", "dysplasia" and "mixed type"[10,12,16,17,35-40].

HISTOPATHOLOGICAL CHARACTERISTICS OF ACF

The final histological criteria for ACF are generally accepted

ACF without dysplasia

ACF with normal mucosa: lacking significant modifications of the epithelium lining the crypts, enlarged crypts (at least 1.5 times larger than normal) with only slightly enlarged and elongated nuclei, but no crowding or stratification, and no mucin depletion. Crypt cells with positive staining of PCNA and Ki-67 remain at the lower part of the crypts.

ACF with hyperplasia: analogous to the manifestations of hyperplastic polyps of colon. The crypts are larger or longer than normal crypts sometimes showing apical branching. The luminal opening is serrated and slightly elevated from the surrounding normal mucosa, but without dysplasia. Goblet cells are mixed with absorbing cells, with partial mucin depletion. Nuclei are enlarged or sometimes crowded without stratification. Cells with positive staining of PCNA and Ki-67 remain at the lower and middle parts of the crypts.

ACF with dysplasia (microadenoma)

Both crypts and cells have different degree abnormalities, with enlarged, elongated and sometimes stratified and depolarized nuclei. The number of goblet cells is decreased obviously and mucin is depleted. The major site of positive staining cells of PCNA and Ki-67 is extended to the upper part of the crypts. Serrated adenomatous ACF[41] could also be found to have similar histopathological manifestations of serrated adenomas[42].

Dysplastic ACF were common in FAP patients, and also occurred in sporadic patients at a low frequency[12,31,35]. Sporadic ACF had the characteristics similar to those of dysplastic ACF in FAP patients with less frequent APC mutations[10,43] and more frequent methylation[44].

Investigations showed the possibility of ACF transition from one pathological type to another. ACF have also been found to contain carcinoma *in situ*, or severe dysplasia in focal areas of human colon[36,40,41], and invasive carcinoma in the rat model[13], showing evidences of ACF as precancerous lesions[10,21,30,38,43,45].

ACF with mixed type of hyperplasia and dysplasia

ACF with mixed hyperplastic and adenomatous components histologically showed the combination of various proportions of pure adenomatous pattern with dysplasia and pure hyperplastic pattern without dysplasia[41].

The WHO classifications of ACF are simplified as hyperplastic ACF and dysplastic ACF.

ACF EVALUATION

The density of ACF is the number of ACF per square centimeter of mucosa surface, which was higher in diseases at a high risk of malignancy such as familial adenomatous polyposis (FAP) and in CRC, and was lower in patients with benign diseases of the colon such as diverticulosis[11,37]. ACF density is also significantly and progressively higher from proximal colon toward distal, being the highest in sigmoid and rectum, which was in accordance with the location of CRC[19,37]. It has been found that the density of FAP ACF was significantly higher than that of sporadic CRC and benign large bowel diseases[9]. In a comparative research of sporadic CRC, Gardner' s syndrome, and benign diseases such as diverticulosis, ACF density in Gardner' s syndrome was more common and ACF occupied a larger area of mucosa as compared to sporadic CRC[11]. All these findings showed that hereditary diseases prone to colon cancer had a higher density and crypt multiplicity of ACF than CRC, which shed lights on the differences between hereditary ACF and sporadic ACF, and helped to reveal the neoplastic nature of ACF.

The mechanism by which ACF increase in size seems to be a process of crypt division, which begins at the base of the crypt and proceeds upwards until two crypts are generated. Thus, the number of crypts per ACF, also termed "crypt multiplicity", would be an important parameter for evaluating ACF progression. It has been demonstrated that crypt multiplicity was significantly lower from proximal toward distal colon, which was opposite to that of ACF density, and was significantly larger when it was associated with carcinoma or adenoma than with nonneoplastic diseases[39]. Also no gradient in ACF density and crypt multiplicity was observed according to the distance from the tumor[11,37,39].

Increased mitotic activity, which has been proposed as a biomarker of colon cancer at early stages, was observed in a majority of ACF. Most of the crypts showed a mitotic pattern similar to that of normal adjacent crypts[19,46]. In some of the dysplastic foci, mitotic activity was seen to distribute throughout the crypts, as reported in adenomas. The above findings may be consistent with the assumption that ACF were preneoplastic lesions[47].

Protein kinase C (PKC) is a family of twelve distinct serine/ threonine kinases that participate in signaling pathways involved in cell proliferation, differentiation, and apoptosis. Alterations in PKC isozyme levels also played a role in colon carcinogenesis[48-50]. Elevated expression of PKC β_{II} was associated with neoplastic transformation both in rat and in human colonic epithelia[48,50]. It has been demonstrated that overexpression of protein kinase C β_{II} (PKC β_{II}) made transgenic mice more susceptible to carcinogen-induced colonic hyperproliferation and ACF formation[47], and the level of PKC β_{II} protein expression was strikingly increased in ACF compared with that in normal colonic epithelium[51].

The study of ACF and their relationships to growth factors, such as TGF-α, TGF-β, EGFR, TGFβRII, phosphorylated cellular tyrosine (P-tyr) revealed a strong correlation between altered expression of TGFs in all ACF that have been examined and the degree of dysplasia and crypt multiplicity[52]. TGF-α was undetectable in ACF[52,53], which had a high incidence of apoptosis (AI). The result was similar to that both in adenomas and in carcinomas[53]. Apoptosis provides a protective mechanism against neoplasia by moving genetically damaged stem cells from the epithelium before they can undergo clonal expansion. Manifestations are indicative of a high level of apoptosis in human ACF and carcinogen-treated animal ACF, in which apoptosis was said to eliminate cells damaged by carcinogen administration[54].

DIFFERENCES OF FAP AND SPORADIC ACF

Most FAP ACF are histopathologically, phenotypically and genetically different from sporadic ACF. Apart from the differences in ACF density between FAP ACF and sporadic ACF, there are significant differences in regard to dysplasia. Most FAP ACF were dysplastic, whereas sporadic ACF had the histopathological features of hyperplastic polyps with little or no dysplasia[38]. The degree of dysplasia in FAP ACF was severer than that of sporadic ACF[9]. Most ACF from FAP patients have phenotypic characteristics of adenomas, which are vital to carcinogenesis, and lack ras gene mutations, while sporadic ACF and a subset of FAP ACF closely resemble hyperplastic polyps, which are benign, but usually have ras gene mutations. There are also evidences identified in the colon of Min/+ mice after azoxymethane (AOM) treatment. Germline mutations in murine Apc homologous to human APC, caused multiple intestinal neoplasia in mice (Min/+ mice)[55]. ACF_{Min} resemble dysplastic ACF, which were described previously as potential precursors of adenomas in rodent and human colon carcinogenesis[35,36,39,52], and more severe in FAP ACF than in sporadic ACF. ACF_{Min} followed a continuous development from a single crypt to adenoma with fast crypt multiplication and altered expression of β-catenin, while classical ACF homologous to hyperplastic human ACF showed slow-growing crypts with normal β-catenin expression, and were probably not related to tumorigenesis[56]. In carcinogen-treated rodents and patients with sporadic CRC, only a very small fraction of ACF progressed to tumor[38]. This was consistent with the observation that a large fraction of ACF was hyperplastic whereas only a small fraction of ACF showed dysplasia, a hallmark of malignant potential[38,55]. In contrast, most ACF in FAP patients were dysplastic, resembling that of adenomas[38]. It has been proposed that only dysplastic ACF progressed to adenomas and carcinomas[35]. In non-FAP cases, K-ras mutations were detected in 82 % (89/106) of nondysplastic ACF and 63 % (17/27) of dysplastic ACF. FAP patients showed K-ras mutations in only 13 % (1/8) of dysplastic ACF, which was the predominant form of ACF found in FAP. In FAP patients, somatic APC mutations were found in 100 % of dysplastic ACF, as they were in adenomas[41]. A previous study showed an association between CpG island methylation in cancer and K-ras mutations[55]. It was found that CpG island methylation was present in more ACF from sporadic cancer than in FAP ACF, implying that FAP ACF usually lacked methylation or K-ras mutations and were frequently dysplastic, while sporadic ACF usually had methylation and/or K-ras mutations and lacked dysplasia[57].

BIOCHEMICAL AND IMMUNOHISTOCHEMICAL ALTERATIONS OF ACF

What we have discussed above is concerned about the determination of ACF under a microscope, and the histopathological characteristics of ACF. Yamada reported another kind of crypts with normal appearance harboring altered β-catenin expression, which was regarded as lesions different from ACF, and might occur earlier than ACF in rat models[58-60]. Previous studies explored phenotype alterations of ACF by means of biochemical and immunohistochemical methods. Pretlow reported enzyme-altered foci with normal morphology in colon and decreased expression of hexosaminidase in these lesions for the first time[61]. By using serial glycolmethacrylate-embedded sections of grossly normal colons from F344 rats treated with colon carcinogen, Pretlow' s group was able to detect multiple lesions with altered enzyme activities in the distal colon and rectum of those rats, and found that histochemically decreased demonstrable hexosaminidase activity could observed in more than 95 % of ACF in rats[22,29,61], and was also able to demonstrate two groups of lesions with decreased hexosaminidase activity: one with aberrant morphology resembling ACF, the other with normal appearance[29]. A decrease in hexosaminidase activity was also seen in colon tumors developed in those animals[13]. Hexosaminidase provided a marker of colon epithelial cells throughout the carcinogenesis progression[62]. Human ACF clearly resembled those seen in animals in morphology and histological appearance[11,12,22,36,63], but hexosaminidase activity was not a useful marker of human ACF because human colonic neoplasia was accompanied by a number of phenotypic changes that frequently included increased expressions of a variety of tumor-associated glycoproteins[64]. Carcinoembryonic antigen (CEA), a member of the immunoglobulin superfamily, was first isolated from human colon cancers, and seems to function as an intracellular adhesion molecule. The immunohistochemical expression of CEA was altered in as many as 93 % (39/42) of ACF in 15 patients, and was related to the size of the foci, but not to the presence or degree of dysplasia in Pretlow' s study[22]. The immunohistochemical localization of CEA in the

cytoplasms and on the basolateral membranes in ACF was similar to that of carcinomas. The finding that CEA appeared to be a marker of human ACF by means of immunohistochemistry should facilitate the identification and characterization of these lesions in human.

The other two members of the cadherin family of cell adhesion molecules were placental cadherin (P-cadherin) and epithelial cadherin (E-cadherin). It has been shown that striking membranous and/or cytoplasmic P-cadherin up-regulation and its co-expression with E-cadherin usually represented a pre-invasive dysplastic transformation[65,66]. P-cadherin was expressed from ACF to hyperplastic and adenomatous polyps, and was prior to and independent of disturbance in E-cadherin and β-catenin expression in ACF. P-cadherin was aberrantly expressed at the earliest stage of aberrant crypt formation, before the disturbance in E-cadherin and β-catenin[67].

β-catenin, which was originally discovered as a cadherin-binding protein, has been proved to function as a transcriptional activator[68]. Inactivation of β-catenin with the product of adenomatous polyposis coli (APC) gene highlighted a role of catenins in epithelial tumorigenesis. Target genes of the β-catenin-Tcf pathway were determined to be growth-promoting genes, such as c-myc and cyclin D1[69,70], suggesting β-catenin-Tcf pathway was oncogenic. Excessive β-catenin protein has been shown in colon cancers of rats and humans[71,72], and the aberrant expression of β-catenin in ACF was also seen. It was reported that in most ACF, namely ACF with hyperplasia, β-catenin was localized at the cell membrane like normal colon epithelium[25], and in ACF with dysplasia, reduced membranous expression of β-catenin was associated with increased nuclear and cytoplasmic expression. The membranous expression of β-catenin was reduced, and cytoplasmic and nuclear expression increased in ACF according to their degrees of dysplasia. Likewise, membranous expression of β-catenin was reduced, and the nuclear expression increased from ACF to adenoma and carcinoma[24], strongly suggesting that ACF and their aberrant expression of β-catenin played an important role in colorectal carcinogenesis, and the immunohistochemical staining of ACF for β-catenin could evaluate the malignant potential of ACF[25].

In carcinogen-treated animal carcinomas, it has been reported frequent mutation and altered cellular localization of β-catenin, and inducible nitric oxide synthase (iNOS) and cyclooxygenase (COX-2) were also found to be expressed in these carcinomas[72]. In carcinogen-treated animal colon, an altered cellular localization of β-catenin in all dysplastic ACF, adenomas and adenocarcinomas was shown, and iNOS expression was also observed in all but one of the lesions in which β-catenin alterations were observed. Neither iNOS expression nor β-catenin alterations were observed in any hyperplastic ACF. Nitric oxide (NO) was known to cause DNA damage and nitrosylation of proteins[73,74], and increased production in tumor cells would be expected to facilitate accumulation of sequential mutations. Since altered localization of β-catenin was apparent in all lesions expressing iNOS, it might be possible that β-catenin alteration was related to induction of iNOS expression. The positive expression of iNOS in dysplasia, but not hyperplastic ACF suggested that iNOS, like β-catenin, could be important at the early stages of tumor formation, and the cause of dysplastic changes[68]. There was also an overexpression of COX-2 detected in ACF, adenomas and carcinomas[68], which has been demonstrated to render tumor cells resistant to apoptosis[75] and to enhance neovascularization[76], thus conferring a survival advantage. The overexpression of COX-2 may contribute to ACF growth and sequential tumor growth.

P16^{INK4a} expression was seldom seen in epithelial cells at the base of normal colonic crypts. But at all the stages of tumor progression, including ACF, a higher fraction of epithelial cells was seen to express p16^{INK4a}. The staining of p16^{INK4a} correlated inversely with that of Ki67, cyclin A, and the retinoblastoma protein in ACF, adenomas and carcinomas, suggesting that cell cycle progression was inhibited. Thus, p16^{INK4a} appeared to constrain the proliferation of subsets of cells throughout intestinal tumorigenesis, however, the exact mechanisms remain unclear[77].

GENETIC AND EPIGENETIC ALTERATIONS OF ACF

Further development of ACF described by Gregorio had two pathways. One was headed for dysplastic ACF, which were to progress to adenomas, and the other was headed for hyperplastic polyps, which had little malignant potentials[40]. The investigation of ACF by using 25 different genetic markers, such as microsatellite instabilities and mutations of APC, H-ras, k-ras, p53, DCC, and DNA repair genes hMLH1, hMSH2, showed no difference between hyperplastic ACF and normal mucosa[78], which was in accordance with the latter hypothesis. Dysplastic ACF have been further identified to be precancerous lesions of CRC. However, an alternative pathway to the general adenoma-carcinoma sequence was also proposed as a hyperplastic polyp/serrated adenoma-carcinoma one[79-83]. Nucci' s study showed genetic differences between hyperplastic ACF and hyperplastic polyps in that the former had more frequent K-ras mutations. Therefore hyperplastic ACF should be named as "heteroplasia ACF" ("hetero' meaning "other", and "plasia" meaning "form") to avoid potential misleading as to their relationships[38]. Though the role of heteroplastic ACF in colorectal carcinogenesis remains controversial because of the lack of dysplasia in spite of the high frequency of K-ras mutations, there have been still lines of evidences supporting heteroplastic ACF as a precursor to a subset of CRC. They were clonal[84] and had genetic alterations of K-ras mutations[10,29,35,38,41], chromosome 1p loss[44], and CpG island methylation[44], hence the heteroplastic ACF-adenoma-carcinoma sequence, in which K-ras mutations preceded APC mutations in rodents and humans[41,85].

Stopera identified K-ras point mutation in carcinogen-induced colonic aberrant crypts in Sprague-Dawley rats in 1992 for the first time[86], and numerous studies have proved K-ras mutation as one of the major events in ACF formation since then. The mutation rate of K-ras in ACF was similar to that of small adenomas[28,29,35], and was found to be even significantly higher than that identified in CRC[86]. K-ras 12 codon mutation was most frequently observed, and in Losi' s study, different mutational types of GTT, TGT, GAT, *etc*, occurred in ACF of the same patient[31]. There were also different mutational types between carcinomas and ACF, the former had predominant GTT mutation, while the latter had GAT mutations almost as frequently as GTT in codon 12 of K-ras[30]. Therefore each ACF might originate independently from different clones[28-30,34]. Identification of monoclonality in a putative precursor lesion would strongly link this lesion to neoplastic progression. The monoclonality of various degrees of dysplastic ACF was determined by studying the differential methylation of a highly polymorphic site in the first exon of the androgen receptor gene to determine the pattern of X chromosome inactivation[34]. Controversial results were produced also by using the same method of clonality analysis based on X chromosome inactivation of the polymorphically X-linked human androgen receptor (HUMARA) gene, in addition to K-ras mutation detection. It was observed that a significant fraction of individual aberrant crypts that made up an ACF to be polyclonal, although by K-ras mutation genotyping, all ACF appeared to be monoclonal[84].

Other oncogenes as COX and c-myc were also found to

have an increased mRNA or protein expression in carcinogen-induced rats[18,88]. The immunoreactivity of oncoproteins of c-fos, ras, bcl-2 and p53 was evaluated in ACF, and abnormal expression and coexpression of oncoproteins could be identified in colorectal tumorigenesis at the earliest stages[89].

APC gene is considered to be "gatekeeper gene", maintaining the stability of colon epithelium. In carcinogen-treated rats, a decreased mRNA expression of APC was observed[18]. APC mutations could be detected in human ACF, but the mutation rates of APC in ACF were lower or undetectable compared to those in adenomas and carcinomas[28,41,90], which were the same as in animal models[85], suggesting that APC mutation was unlikely to initiate ACF. If a ras gene mutation occurred first, ACF would be nondysplasia, and if an APC mutation was the first to occur, it would result in a dysplastic ACF, whose progression was driven by subsequent K-ras and other gene mutations[35]. It has been proposed that in sporadic colorectal carcinogenesis, assuming the biological potential of ACF as a precursor of adenomas, there was a route where K-ras mutations mainly occurred during the formation of ACF. Some ACF then became adenomas in which APC mutations occurred. In FAP, however, somatic mutations of APC predominantly occurred during ACF formation, followed by K-ras mutations[35].

Apart from oncogene and tumor suppressor gene alterations in ACF, there is some other kind of genes concerning DNA repair. Inactivation of the mismatch repair (MMR) system can result in instability of the whole genome and an increased rate of spontaneous mutations of other vital genes to carcinogenesis. In addition to the cause of genomic instability, DNA mismatch repair proteins have several other functions that are highly relevant to cancer progression. Some MMR components have been found to be involved in cell-cycle regulation, and p53-dependent apoptotic response to a variety of DNA damages[91-97]. Germline mutations of any of them, especially hMSH2 and hMLH1, gave rise to hereditary nonpolyposis of colorectal cancer (HNPCC)[6,98]. There was also a link between hMSH6 mutations and a high incidence of endometrial cancer[99], and prevalence of colon cancer with TGFβRII gene and Tcf-4 gene[100,101]. hMSH2 deficiency resulted in the development of many ACF in mice colons, as well as reduced survival of the mice[102].

Epigenetic alterations such as CpG island methylation, and genetic phenotype alterations such as microsatellite instability (MSI) as a result of MMR defect, also play important roles as in ACF. Inactivation of genes might occur not by mutation or loss, but through silencing mediated by CpG island methylation of the gene' s promoter region. hMLH1 and MGMT are examples of DNA repair genes that were silenced by methylation. It has been demonstrated[103-105] that hMLH1 gene promoter had aberrant methylation in sporadic CRC. A novel pathway characterized by methylation of multiple CpG islands in colorectal carcinomas and adenomas, including genes known to be vital in tumorigenesis, such as p16 tumor suppressor gene and hMLH1 mismatch repair gene, was proposed as a CpG island methylator phenotype (CIMP)[57,106]. Ahuja questioned whether hMLH1 methylation preceded or was a consequence of the MSI phenotype[107]. The answer was presented by Chan that methylation of hMLH1 mismatch repair gene in ACF was not associated with the development of MSI, suggesting that hMLH1 methylation preceded MSI[44]. The frequency of CpG island methylation in ACF was related to the type of patients, as was concluded in Chan' s research, that methylation was detected in 53 % of ACF from sporadic colorectal carcinomas but only in 11 % of ACF from FAP patients[44], and methylation was more frequent in dysplastic sporadic ACF than in dysplastic FAP ACF. The epigenetic differences of CpG island methylation in ACF were similar to those in colorectal carcinomas.

Extensive genomic instabilities due to the defect of MMR system could be detected as MSI both in animal model and in human ACF[108,109]. MSI could occur either in dysplastic or hyperplastic (or "heteroplastic" as mentioned before) ACF from HNPCC patients, suggesting no association of MSI with histological features, being present even in small ACF. MSI in sporadic ACF also seemed to be independent of ACF size[110]. Heinen *et al*[45] detected MSI status in ACF, and found two ACFs from the same patient with different MSI status. One showed MSI-positive, while the other was MSI-negative, indicating independent initiation of individual ACF, as has been verified by sequential studies with different methods[28-30,34,84]. The role of ACF as precursors of some CRCs was verified by the presence of MSI in ACF from HNPCC patients, in whom carcinoma with high levels of MSI was the hallmark, and in ACF from sporadic CRC as well[44,108].

SUMMARY

The malignant potential of ACF, especially dysplastic ACF, makes it necessary to reveal the nature of these lesions. Many researches nowadays are focused on the mechanisms of ACF initiation, their genetic and environmental backgrounds, methods of early detection, dietary and chemoprevention. In spite of the increasing evidences of ACF as precancerous lesions of colorectal carcinomas, a lot remain to be clarified so as to reduce the incidence of CRC at the earliest stages.

First reported by Yokota in 1997[14], the application of endoscopy, either magnifying or dye/chromoscopic colonoscopy, made it possible to detect "*in vivo*" ACF. It is of great advantage over the detection of surgical specimens from with CRC. It may offer much benefit to colon cancer researches and identify high-risk populations for colorectal tumors. Recent studies have proved the validity of chromoendoscopy, or dye colonoscopy, which allows easy detection of mucosal lesions in the colon and facilitates visualization of the margins of flat lesions[111,112].

In summary, ACF, especially dysplastic ACF, are widely accepted as precursors of colon cancer morphologically, histologically, biologically, and genetically. They have an aberrant appearance of crypts, and display both hyperplasia and dysplasia. They are supposed to have alterations of enzymology and cell dynamics. They also harbor gene mutations that are vital to tumor formation and progression. By studying these lesions both grossly and genetically, it may be possible to learn more about the causes of colon carcinogenesis. By testing new compounds through ACF assay, it is possible to discover not only potentially new chemopreventive drugs, but also the mechanisms behind them. In addition, by developing available methods for "*in vivo*" ACF examination, it may be possible to evaluate high-risk individuals at the earliest possible stages, as well as the preventive procedures.

Abstract

AIM: To construct the recombinant pEgr-P16 plasmid for the investigation of its expression properties in esophageal squamous cell carcinoma induced by ionizing irradiation and the feasibility of gene-radiotherapy for esophageal carcinoma.

METHODS: The recombinant pEgr-P16 plasmid was constructed and transfected into EC9706 cells with lipofectamine. Western blot, quantitative RT-PCR and flow cytometry were performed to study the expression of pEgr-P16 in EC9706 cells and the biological characteristics of EC9706 cell line after transfection induced by ionizing irradiation.

RESULTS: The eukaryotic expression vector pEgr-P16 was successfully constructed and transfected into EC9706 cells. The expression of P16 was significantly increased in the transfected cells after irradiation while the transfected cells were not induced by ionizing irradiation. The induction of apoptosis in transfection plus irradiation group was higher than that in plasmid alone or irradiation alone.

CONCLUSION: The combination of pEgr-P16 and irradiation could significantly enhance the P16 expression property and markedly induce apoptosis in EC9706 cells. These results may lay an important experimental basis for gene radiotherapy for esophageal carcinoma.

INTRODUCTION

Early growth response gene-1 (Egr-1), also known as zif/268, NGFI-A, Krox-24 and TIS-8, encodes a nuclear phosphoprotein with a cysteine/hystidine zinc finger structure, which is partially homologous to the corresponding domain of the Wilm's tumor susceptibility gene[1-4] Zinc fingers are a protein structural motif that serves as DNA-binding domains in several transcriptional regulatory proteins. It was reported that Egr-1 was transcriptionally induced following exposure to irradiation. Promoter deletion analysis of Egr-1 promoter elements linked to the CAT reporter gene demonstrated that the first 5' CArG boxes (CC $(A/T)_6$GG elements) were of paramount importance for the induction of Egr-1 by irradiation or free radicals[5-7].

In this study, the pEgr-P16 plasmid was constructed and transfected into the human esophageal cancer cell line EC9706. The expression of P16 in the transfected cells exposed to different doses of γ-ray irradiation and its bioactivities were detected to explore the feasibility of gene- radiotherapy for esophageal carcinoma.

MATERIALS AND METHODS

Cell line and vectors

The EC9706 was maintained in Dulbecco's modified Eagle's medium (DMEM), high glucose media (Life Technologies) and generously supplemented with 100 ml· L^{-1} fetal bovine serum (Hyclone Laboratories), penicillin, streptomycin and nonessential amino acids (Life Technologies). The pcDNA3.1$^+$ vector was purchased from Invitrogen and pGL3-enhancer vector from Promega-Biotec.

Construction of pEgr-P16 plasmid

The expression vector for P16 was constructed as shown in Figure 1.

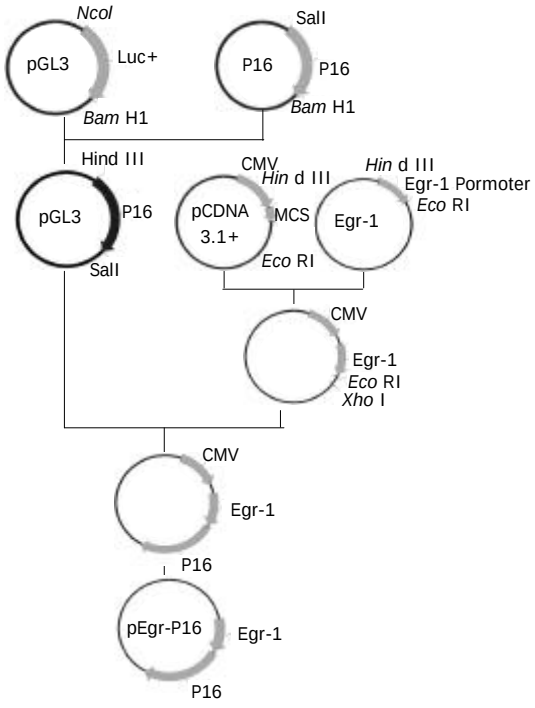

Figure 1 Diagram of the construction of the plasmid pEgr-P16.

Transfection

The transfection of EC9706 cells was carried out in a 6-well

plate. The transfection procedure began when the cells reached 70 % confluence on the surface of plate wells. Solution A was prepared by separate addition of 10 μg of pEgr-P16 and pcDNA3.1$^+$ to 100 μl serum-free medium (SFM), and solution B by addition of 10 μl Lipofectimine 2000 (Life Technologies) to 100 μl SFM. The two solutions were combined for 30 min at room temperature, 0.8 ml SFM was added to the tube containing the above solutions, and the mixture was added to the rinsed cells. The medium was replaced with fresh and complete one after 18 h in transfection. The cells were exposed to irradiation after 36 h in transfection.

Ionizing irradiation

The dose rate was 0.784 Gy/min for 0, 2, 4, 8, 10 and 20 Gy Co^{60} γ-ray irradiation, respectively.

Quantitative RT-PCR

Total RNAs of the transfection of EC9706 cells and control were obtained by extracting cells in Trizol (Invitrogen) and treated with heat-inactivated DNase I (Invitrogen). RNA quality and quantity were evaluated by UV spectrophotometry. Two μg total RNA was used for cDNA synthesis (25 μl) using M-MLV reverse transcriptase and random primers (Invitrogen).

A standard curve was constructed separately by the serial dilutions of PCR purified products of p16 and glyceraldehyde-3-phosphate-dehydrogenase (GAPDH). Template concentrations for reactions in the relative standard were 10^8, 10^7, 10^6 and 10^2 copies/μl. The cDNA (1:5 dilution) from the sample was analyzed as unknown. Real-time PCR was performed containing SYBRgreen I (1:20 000 QIAGEN), forward and reverse primers (50 nmol each), sample cDNA (1 μl) or standard sample (1 μl) under the following condition: denaturation at 95 ℃ (3 min); 40 cycles at 95 ℃ (45 s), at 59 ℃ (45 s), at 72 ℃ (40 s), at 80 ℃ (5 s). GAPDH was used as an internal reference in each PCR reaction. Primers were as follows: GAPDH, forward primer 5' -TGCACCACCAACTGCTTAGC-3' and reverse one 5' -GGCATGGACTGTGGTCATGAG-3' . P16, forward primer: 5' -GAATAGTTACGGTCGGAG-3' and reverse one 5' -CGGTGACTGATGATCTAA-3' . Amplification was followed by melting curve analysis using the program run at the step acquisition mode to verify the presence of a single amplification product in DNA contamination-free. For each set of primers, a non-cDNA template control was included to assess the overall specificity. Accumulation of PCR products was monitored and determined using the Icycler (Bio-Rad), and the crossing threshold (Ct) was determined using the Icycler software.

Flow cytometry analysis

Approximately 5×10^6 of centrifugally sedimented cells were immediately fixed in 700 ml· L^{-1} ethanol and stored at 4 ℃ in PBS in preparation for fluorescent-activated cell sorting. Flow cytometry analysis was performed on a FACStar flow cytometer (Becton Dicikinson). Histograms of cell number logarithmic fluorescence intensity were recorded for 10 000 cells per sample. The apoptotic cell rate was calculated.

Statistical analysis

Student' s *t* and correlation tests were used to determine the comparability of groups. Statistically significant *P* value was defined as <0.05.

RESULTS

Expression of P16 in EC9706 cells transfected with pEgr-P16 followed by different doses of γ-irradiation

EC9706 cells transfected with pEgr-P16 were irradiated by different doses of γ-rays. The cells of control group were transfected with pcDNA3.1$^+$. Eight hours after irradiation, the protein was extracted and the expression of P16 was detected by Western-blot. The results showed no P16 expression in the control and higher p16 expression in 2, 4, 8, 10 and 20 Gy groups than in 0Gy one.

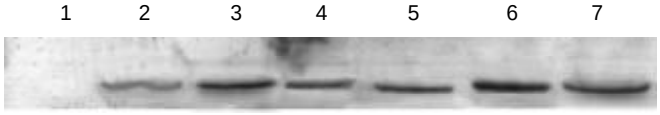

Figure 2 Expression of P16 in EC9706 cells after γ-irradiation. Lane 1: control; Lane 2: 0Gy; Lane 3: 2Gy; Lane 4: 4Gy; Lane 5: 8Gy; Lane 6: 10Gy; Lane 7: 20Gy.

P16 expression in EC9706 cells transfected with pEgr-P16 at different time points after 2Gy irradiation

EC9706 cells transfected with pEgr-P16 were irradiated by 2Gy irradiation. Total RNA was isolated at different time points after irradiation and the mRNA levels were detected by quantitative RT-PCR.

The results showed that P16 levels after 2Gy irradiation increased with time from 0 to 24 h. It reached the highest level at the 24th h and was about 4 times of that at the 2nd h (P<0.01).

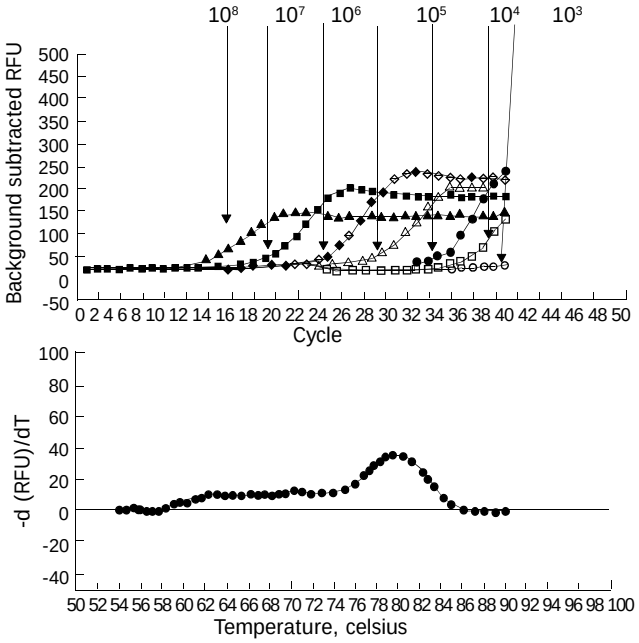

Figure 3 Amplification curves and post-amplification dissociation curves for P16 in EC9706 cells.

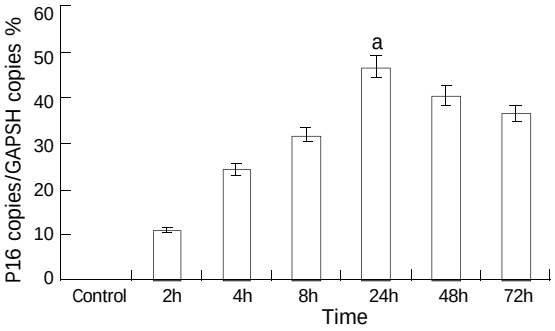

Figure 4 Expression of P16 in EC9706 cells at different time points after 2Gy γ-irradiation, ^aP<0.01 *vs.* 2 h group.

Apoptotic changes of transfected EC9706 cells after 2Gy g-irradiation

In P16 transfected EC9706 cells the apoptosis rate was 25.00, being higher than that of pcDNA3.1+ group (18.03, $P<0.05$). When exposed to 2Gy irradiation, the apoptosis rate was 33.23, higher than that in pcDNA3.1+ group (18.03, $P<0.01$) and P16 group (25.00). The differences were not significant between P16 and P16 plus irradiation groups.

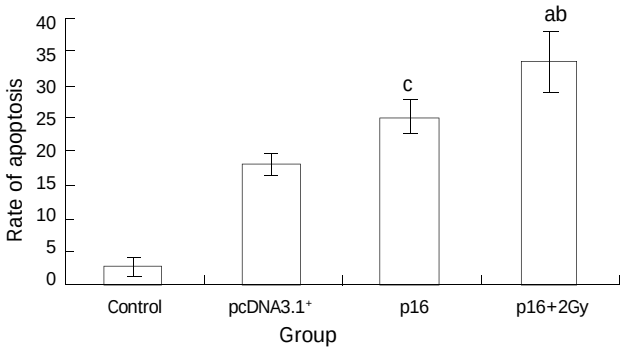

Figure 5 Apoptotic changes of transfected EC9706 cells. [a]$P<0.01$ *vs* pcDNA3.1$^+$group, [b]$P<0.001$ *vs* control group, [c]$P<0.05$ *vs* pcDNA3.1$^+$ group.

DISCUSSION

Radiotherapy is one of most important choices of the treatment for human tumors. Tumor destruction by radiation depends more on physical restriction of the radiation to a high-dose volume containing the tumor rather than a strict difference in radiosensitivity between tumor and normal cells. In fact, many tumor cells have lost the capacity for programmed cell death, resulting in radioresistance when compared with normal tissues. Vital structures are frequent within the radiotherapy volume restricting the amount of therapeutic radiation that can be safely delivered, thereby limiting tumor curability.

With the rapid development of molecular biology, gene radiotherapy has been considered as an effective way of cancer treatment. According to the mechanism that ionizing radiation could activate early Egr-1 gene promoter and induce the expression of downstream genes, Weichselbaum *et al* were the forerunners in tumor gene radiotherapy. They linked DNA sequences from the promotor region of Egr-1 with a cDNA sequence that encodes human tumor necrosis factor (TNF) alpha. The Egr-TNF construct was transfected into a human cell line of hematopoietic origin, HL525 (clone 2). The latter was injected into human xenografts of the radioresistant human squamous cell carcinoma cell line SQ-20B. Animals treated with radiation and clone 2 demonstrated an increase in tumor cures compared with animals treated with radiation alone or unirradiated animals given injections of clone 2 alone[6]. Thereafter, a variety of downstream genes were introduced to Egr-1 promoter to treat different tumors, and similar results were obtained[9-11].

The division cycle of eukaryotic cells is regulated by a family of protein kinases known as the cyclin-dependent kinases (CDKs). P16 is a tumor suppressor gene product. Serrano *et al* demonstrated that p16 could bind to CDK4 and inhibit the catalytic activity of the CDK4/cyclin D enzymes. P16 seemed to act in a regulatory feedback circuit with CDK4, D-type cyclins and retinoblastoma protein[12]. Overexpression of P16 gene could block cell cycle progression through the G_1-to-S phase boundary in a pRB-dependent manner[13-14]. Many P16 mutants identified from human tumors have been shown to have defects in this activity[15-17]. These data suggest that the CDK4-inhibitory activity of p16 is involved in regulating cell cycle progression through the G_1/S boundary.

On the basis of the antiangiogenic action of P16, we constructed pEgr-P16 plasmid and transfected EC9706 cells to study the expression properties of the plasmid induced by ionizing irradiation. The results revealed that no P16 expression in EC9706 cells transfected with pcDNA3.1$^+$ was detected and that the P16 expression in cells transfected with pEgr-P16 induced by irradiation was higher than that of sham-irradiation group. Time-course studies revealed that the P16 expression reached its peak at the 24th h after 2Gy irradiation, and the highest level was 4 times of that at the 2nd h ($P<0.01$). The combination of pEgr-P16 and radiation could induce markedly apoptosis of EC9706 cells although pEgr-P16 alone might induce transfected cells to undergo apoptosis. Our results suggested that pEgr-P16 could enhance expression property induced by radiation in EC9706 cells.

Esophageal carcinoma is still common in the world, especially in China[18-24], and the treatment remains a big problem up to date[25-31]. Gene radiotherapy may be of potential significance in the treatment of esophageal cancer. Our work will be a ground of further studies on esophageal cancer gene radiotherapy.

ACKNOWLEDGEMENT

We especially thank Prof. Ming Rong Wang for providing us the EC9706 cells line and Dr. Di Wu for providing the P16 gene.

Abstract

AIM: To investigate the possible association of *microsomal epoxide hydrolase* (*mEH*) *Tyr*113*His* polymorphism with susceptibility to esophageal squamous cell carcinoma (ESCC) in a population of North China.

METHODS: The *mEH Tyr*113*His* genotypes were determined by polymerase-chain reaction (PCR)-restriction fragment length polymorphism (RFLP) analysis in 257 patients with esophageal squamous cell carcinoma (ESCC) and 252 healthy subjects as a control group.

RESULTS: The frequencies for *Tyr* and *His* alleles were 44.2 %, 55.8 % in ESCC patients, and 44.0 % and 56.0 % in healthy subjects, respectively. No statistic difference in allele distribution was observed between ESCC patients and controls (χ^2=0.008, *P*=0.929). The overall genotype distribution difference was not observed between cancer cases and controls (χ^2=2.116, *P*=0.347). Compared with *Tyr/Tyr* genotype, neither *His/His* genotype nor in combination with *Tyr/His* genotype significantly modified the risk of the development of ESCC, the adjusted odds ratio was 1.076 (95 % CI=0.850-1.361) and 0.756 (95 % CI=0.493-1.157), respectively. When stratified for sex, age, smoking status and family history of upper gastrointestinal cancer, *His/His* genotype alone or in combination with *Tyr/His* genotype also did not show any significant influence on the risk of developing ESCC.

CONCLUSION: *MEH Tyr113His* polymorphism may not be used as a stratification marker in screening individuals at a high risk of ESCC.

INTRODUCTION

China is one of the prevalent areas of esophageal squamous cell cancer (ESCC). Exposure to environmental carcinogens is considered as the main risk factors of ESCC[1,2]. Among them, chemical carcinogens such as polycyclic aromatic hydrocarbons (PAHs) in consumed tobacco or ingested food may contribute to the high incidence of ESCC in China[3,4]. Metabolization of PAHs involves a complex enzymatic mechanism. Microsomal epoxide hydrolase (mEH) is an enzyme that hydrolyzes epoxides such as PHA, yielding corresponding *trans*-dihydrodiols. Usually, this hydrolysis acts as a detoxifying step, although in some instances, *trans*-dihydrodiols generated from PAHs are highly toxic and mutagenic. Therefore, mEH plays a dual role in the detoxification and activation of procarcinogens, and its role in carcinogenesis may depend on exposures to different environmental substrates[5].

There are two polymorphic sites that affect the enzyme activity in human *mEH* gene. One variant is characterized by substitution of histidine for tyrosine at the amino acid position 113, the other is characterized by substitution of arginine for histidine at the position 139. The proteins encoded by polymorphic alleles demonstrated different enzyme activities *in vitro*[6]. *MEH* polymorphism has been associated with chemical carcinogen-induced cancers occurring in lung[7,8], ovary[9], colorectum[10] and liver[11]. The correlation of *mEH* polymorphism with susceptibility to ESCC has not been reported so far. Therefore, the current study investigated the *Tyr*113*His* polymorphism in *mEH* exon 3 in ESCC patients and healthy individuals from North China.

MATERIALS AND METHODS

Subjects

This study included 257 patients with histologically confirmed esophageal squamous cell carcinomas and 252 healthy individuals without overt cancer. The cancer patients were hospitalized for surgery in the Fourth Affiliated hospital, Hebei Medical University between 2001 and 2003. The healthy subjects were from the same hospital for physical examination in the same period. All of the patients and control subjects were from Shijiazhuang city or its surrounding regions. Information of sex, age, smoking habits and family history was obtained from cancer patients and healthy controls by interview following sampling. The smokers were defined as former or current smoking 5 cigarettes per day for at least two years. The individuals with at least one first-degree relative or at least two second-degree relatives having esophageal/cardiac/gastric cancer were defined as having family history of upper gastrointestinal cancers (UGIC). The smoking status and family history were available from some of the cases and controls. Informed consent was obtained from all the recruited subjects. The study was approved by the Ethics Committee of Hebei Cancer Institute.

DNA extraction

Five ml of venous blood from each subject was drawn in Vacutainer tubes containing EDTA and stored at 4 ℃. Genomic DNA was extracted within one week after sampling by using proteinase K digestion followed by a salting out procedure.

MEH genotyping by PCR and restriction fragment analysis

The exon 3 T to C variant in *mEH* gene, changing tyrosine 113 to histidine, creates an *Eco*R restriction site (GATATC), which can be exploited for genotyping by PCR and subsequent RFLP analysis[12]. PCR was performed in a 25 μl volume containing 100 ng of DNA template, 2.5 μl of 10×buffer, 1 U of *Taq*-DNA-polymerase (BioDev-Tech., Beijing, China), 200 μmol of dNTPs and 200 nmol of sense primer (5'-GATCGATAAGTTCCGTTTCACC-3') and antisense primer (5'-ATCCTTAGTCTTGAAGTGAGGAT-3'). Initial denaturation at 94 ℃ for 5 min was followed by 35 cycles at 94 ℃ for 30 sec, at 56 ℃ for 30 sec and at 72 ℃ for 1 min. Subsequently, the PCR products were digested with 10 units of *Eco*R V (TakaRa Biotechnology Co., Ltd, Dalian, China) overnight at 37 ℃ and separated on a 3 % agarose gel. RFLP bands were visualized through ethidium bromide staining under UV light. *Tyr*113 wild-type homozygote was characterized by two bands at the position of 140 bp and 22 bp, while *His*113 homozygotes were identified by a single band (162 bp) and the heterozygotes by three bands (162 bp, 140 bp and 22 bp). For a negative control, each PCR reaction used distilled water instead of DNA in the reaction system. For 10 % of the samples, the reaction was repeated once.

Statistical analysis

Statistical analysis was performed using the SPSS10.0 software package (SPSS Company, Chicago, Illinois, USA). Comparison of *mEH* genotype distribution in the study groups was performed by means of two-sided contingency tables using Chi-square test. A probability level of 5 % was considered significant. The odds ratio (OR) and 95 % confidence interval (CI) were calculated using an unconditional logistic regression model and adjusted by age and sex accordingly.

RESULTS

The mean age of all ESCC cases was 58.5±9.39 years (range 32-85) and that of controls was 49.4±8.56 years (range 29-79 years). The gender distribution in ESCC patients (66.5 % men) was comparable to that in healthy controls (58.3 % men). Moreover, the proportion of smokers in ESCC patients (52.0 %) was also not significantly different from that in healthy controls (49.5 %) (χ^2=0.283, P=0.595). In addition, the frequency of the positive family history of UGIC in ESCC patients (44.1 %) was significantly higher than that in healthy controls (14.0 %) (χ^2=49.87, P<0.0001). Thus, the positive family history of UGIC significantly increased the relative risk to develop ESCC in this population, with an age and sex adjusted odds ratio of 4.06 (95 % CI=2.46-6.69). The demographic distribution of ESCC patients and healthy controls is shown in Table 1.

MEH Tyr113His genotyping was successfully performed in all study subjects. The *mEH* genotype distribution was not

ESCC: esophageal squamous cell carcinoma, UGIC: upper gastrointestinal cancer. a. Information of smoking status was available from some of subjects, b. Positive family history of UGIC significantly increased the risk to develop ESCC. Age and sex adjusted OR=4.06 (95 % CI=2.46-6.69), χ^2=49.87, *P*<0.0001.

By using *Tyr/Tyr* as the reference genotype, neither *His/His* genotype alone nor in combination with *Tyr/His* genotype significantly modified the risk of ESCC, the adjusted odds ratio was 1.076 (95 % CI=0.850-1.361) and 0.756 (95 % CI=0.493-1.157), respectively. When stratified for sex, age, smoking status and family history of upper gastrointestinal cancer, the frequency of *His/His* and *Tyr/His* genotype in ESCC patients was not significantly different from healthy controls. Consistently, *His/His* alone, or in combination with *Tyr/His* genotype, did not show any significant influence on the risk of ESCC (Table 2).

DISCUSSION

Chemical carcinogens in consumed alcohol and tobacco, polluted water, ingested food, are in general considered as the main risk factors of ESCC in China. However, not all individuals exposed to the above exogenous risk factors will develop ESCC, indicating that the host susceptibility factors may play an important role in cancer development. In recent years, many polymorphic carcinogen metabolic enzymes, such as aldehyde dehydrogenase-2 (ALDH2)[13], cytochrome P450(CYP)[14,15], glutathione S-transferase(GST)[15,16], methylenetetrahydrofolate reductase (MTHFR)[17], NAD(P)H, quinone oxidoreductase 1 (NQO1)[18,19] have been found to be able to modify the susceptibility to chemically induced cancers including esophageal and gastric cancer. Therefore, these polymorphic genes, alone or in combination with each other or with other newly developed genetic markers, may be used as predicative parameters for screening individuals at a high risk of ESCC.

MEH is involved in the metabolism of environmental carcinogens. Polymorphisms in *mEH* gene might affect the enzyme expression and lead to different phenotypes, probably by the alteration of protein stability[6]. *Tyr113His* substitution in exon 3 could reduce the enzyme expression by about 40 %, producing a slow phenotype with a low epoxide hydrolase activity. In contrast, *Arg139 His* in exon 4 could increase the expression by about 25 %, producing a fast phenotype with an increased enzyme activity[6]. The relationship between *mEH* gene polymorphisms and susceptibility to cancers studied had inconsistent conclusions due to different cancer types and populations. The *Tyr* allele in exon 3 was reported to increase the risk of several cancer types including ovarian cancer[9], oropharyngeal carcer[20] and acute leukaemia[21], whereas the *His* allele was associated with increased susceptibility to cancers occurring in colon[10], liver[11] and cervix[22]. In addition, gene-environment interaction was strongly suggested by some investigations, thus, cumulative cigarette smoking might play a pivotal role in association of *His* homozygous genotype with lung cancer development, altering the direction of risk from a risk factor in nonsmokers to a relatively protective factor in heavy smokers[8].

Recently, a slight decrease in *mEH Tyr*113 frequency was observed in esophageal adenocarcinoma (42 %) compared to controls (53 %, *P*=0.05)[23]. In the present study, the frequencies of *Tyr/Tyr*, *Tyr/His* and *His/His* genotype in healthy controls were in consistent with a recent report from a Chinese group[24]. The genotype distribution difference was not found in ESCC patients and healthy controls, as well as in stratification comparison according to the sex, age (>50 or ⩽50), smoking status (never smoking or current and ever smoking), and family history of UGIC. The result suggests that although *mEH Tyr113His* polymorphism is correlated with some cancer types, this genetic alteration may not be associated with susceptibility to ESCC in population of North China.

Abstract

AIM: Obesity has been proved as one of the main risk factors for gastric cardia adenocarcinoma (GCA) in the West. The objective of our research was to evaluate the relationship between obesity and the risk of GCA in people from North China.

METHODS: A total of 300 patients who had been diagnosed as GCA and had accepted surgical operation at Beijing Cancer Hospital from 1995 to 2002 were enrolled. Data were collected from pathology materials and hospital records. Two hundred and fifty-eight healthy people who had accepted health examination at the same hospital during the same period were enrolled as controls. Height, weight and gender of them at the time of examination were also collected. Obesity was estimated by body mass index (BMI), computed as weight in kilograms per square surface area (Kg/m^2). The degree of obesity was determined by using BMI$\leqslant$18.5, 24-27.9 and $\geqslant$28 (Kg/m^2) as the cut-off points for underweight/normal, overweight and obesity, respectively. Associations with obesity were estimated by odds ratios (ORs) and 95 % confidence intervals (CIs). All ORs were adjusted for age and sex.

RESULTS: The mean level of BMI was significantly lower in the patient group than that in the control group. The ORs for obesity in age groups 30-59 and 60-79 were 1.15 (95 % CI=0.37-3.65) and 0.16 (95 % CI=0.05-0.44) for males and 0.78 (95 % CI=0.26-2.36) and 0.28 (95 % CI=0.04-2.05) for females, respectively. The ORs for underweight were 2.42 (95 % CI=0.56-10.53) and 4.68 (95 % CI=1.13-19.40) for males in age subgroups 30-59 and 60-79 and 40.7 (95 % CI=9.32-177.92) for females older than 60 yrs. BMI was significantly associated with GCA ($P<0.01$). Underweight people were at high risk for GCA.

CONCLUSION: BMI is an independent risk factor for GCA. Underweight is positively associated with GCA.

INTRODUCTION

The incidence of gastric cardia adenocarcinoma (GCA) has been rising steadily over the past two decades in the United States and Western Europe[1-6]. Extensive studies have been conducted, trying to find its etiological reasons. Some studies showed that the risk for GCA was higher in obese people than that in normal counterparts. It has been generally accepted that obesity is one of the main risk factors for GCA[7-9]. Of all the hypotheses explaining the association between obesity and GCA, reflux theory is the widely accepted one[10-17]. Based on this theory, obesity can promote gastroesophageal reflux disease by increasing intra-abdominal pressure. Gastroesophageal reflux predisposes to Barrett' s esophagus which is a metaplastic precursor state for GCA[18-23]. But the reflux theory cannot explain every aspect of the manifestations of GCA. The real mechanism underlying the disease is still unclear.

We are still unaware if the incidence of GCA has the same pattern in China as in Western world. Based on previous studies, we know that GCA is not rare in China[24]. Great differences exist in life styles and diet habits between Chinese and the Westerners. Elucidating the association between obesity and GCA among Chinese people will be very helpful for prevention and early diagnosis of the disease. The objectives of our study were to investigate whether obesity was more prevalent in patients with GCA than in healthy people, whether the risk for GCA was greater in obese people than in non-obese counterparts, and whether obesity was a dependent/independent risk factor for GCA.

We used body mass index (BMI) to evaluate the degree of obesity. In Western world, the cut-off points of BMI for overweight and obesity are 25 kg/m^2 and 30 mg/m^2. The Chinese people are relatively lean. It is not appropriate to use the same criteria. Recently, a population-based investigation was conducted[25,26] by Zhou *et al* in China. Their results suggested that the cut-off points of BMI for underweight, overweight and obesity of the Chinese people were 18.5 kg/m^2, 24 kg/m^2 and 28 kg/m^2. We used the later criteria in our study.

MATERIALS AND METHODS

Materials

Three hundred patients were enrolled to receive radical operation for GCA in the Department of Surgery at Beijing Cancer Hospital from January 1, 1995 to December 31, 2002. All the hospital records and pathologic materials of these patients were reviewed. The inclusion criteria were listed as follows: The patients were 30 years old or older and the diagnosis of GCA was confirmed by pathologic examinations (reviewed by two independent pathologists). Classification was based on Dr. Siewert' s criteria for gastric cardia carcinoma[27].

The exclusion criteria were stipulated as follows: (1) The patients had a history of malignancies other than GCA; (2) The patients had a history of wasting disease before the diagnosis of the studied malignancy; (3) Adenocarcinoma was not diagnosed as the only histological type of the original malignancy; (4) The patients had a history of gastric cancer and received radical partial gastrectomy. The GCA arose from his/her gastric remnant.

Two hundred and fifty-eight residents who received health examination at Beijing Cancer Hospital from January 1, 2000 to December 31, 2002 were enrolled as healthy control subjects. All the healthy subjects were 30 years old or older, and had no history of any wasting disease. Pregnant women were not included in this study.

Methods

Data, including age, gender, height, weight of the patients and control subjects, were collected. For all patients who experienced weight loss during the disease, their usual height and weight before the disease were also collected. Patients whose hospital records could not provide all the information were not included in this study.

Obesity was measured by BMI, and computed as weight in kilograms per square surface area in square meters (kg/m^2). The height and weight before the disease were used to compute the BMI for patients who had experienced weight loss before the diagnosis was confirmed. The patients and control subjects of the same gender were compared with their mean values of BMI. The patients and control subjects were subdivided into five 10-year age subgroups (age 30-39, 40-49, 50-59, *etc.*). All the subjects were also divided into 2 age subgroups, age $\leqslant$60 yrs or age >60 yrs. Mean values of BMI were compared between patients and control subjects in the same age subgroup.

According to their value of BMI, all the subjects were subdivided into four subgroups (underweight, normal, overweight and obesity) using 18.5, 24 and 28 as the cut-off points of BMI for underweight, overweight and obesity. Relative risks of each group were estimated by odds ratios (ORs) and 95 % confidence intervals (CIs).

Statistic analysis of the data was performed using Chi-square test, with a level of significance at $P\leqslant0.05$. Monte Carlo estimate was used to balance the differences in age and sex structure between the two groups. Lastly, we used logistic regression to evaluate whether obesity was an independent risk factor for GCA.

RESULTS

A total of 300 patients, including 51 women and 249 men, aged 34-80 yrs (median 61.9 yrs), and 258 healthy control subjects (144 women and 114 men) aged 31-78 yrs (median 53.57 yrs), were finally enrolled. The age and sex structure of the patient group differed significantly from those of the control group ($P<0.01$).

The mean value of BMI was 22.90 kg/m^2 in the patient group and 24.85 kg/m^2 in the control group. In each coordinated sex or age subgroup, patients tended to have a low level of BMI than healthy control subjects (Table 1 and Table 2). After sex and age structures were balanced, the mean value of BMI was significantly lower in the patients group than that in the healthy control group ($P<0.01$).

Table 1 Mean levels of BMI in each age group of patients and healthy control subjects

Age	Patient group		Control group	
	Number of cases	Median level of BMI	Number of cases	Median level of BMI
30-39	8	21.94	50	24.26
40-49	27	22.37	69	25.54
50-59	84	22.64	55	24.71
60-69	134	23.46	54	24.93
70-79	47	22.25	30	24.38
Total	300	22.90	258	24.85

Table 2 Mean levels of BMI in each sex group of patients and healthy control subjects

Gender	Patient group		Control group	
	Number of cases	Median level of BMI	Number of cases	Median level of BMI
Male	249	22.88	115	24.75
Female	51	23.02	143	24.94
Total	300	22.90	258	24.85

After all the subjects were labeled as underweight, normal, overweight or obesity based on their BMI, the odds ratios and 95 % confidence intervals in each BMI subgroup were calculated. We used Monte Carlo estimate to balance the differences in age and sex between the two groups, 60 yrs as the cut-off point for age subdivision. In each coordinated subgroup, high BMI people did not show any elevated risk for GCA compared with low BMI ones. On the contrary, the relative risk for GCA rose significantly when the BMI of the subject reached the underweight criteria, especially in women older than 60 yrs ($P<0.05$ by Fisher' s exact test). The risk did not show significant differences only in men of 60 yrs old and younger (Table 3 and Table 4).

a. SE=standard error, b. Age group 2: The subjects were divided into 5 10-year age subgroups (30-39 yrs, 40-49 yrs, 50-59 yrs, 60-69 yrs, 70-79 yrs, *etc.*).

DISCUSSION

Firstly, we wanted to elucidate whether obesity was more prevalent in patients with GCA than in healthy people. After calculating BMI of all the subjects, using the height and weight before the disease for patients who had experienced weight loss before the diagnosis was confirmed, we found that obesity did not tend to be more prevalent in patients with GCA than in healthy control subjects. The mean value of BMI in each group was 22.90 kg/m^2 and 24.85 kg/m^2 (P<0.01). Within each coordinated sex or age subgroup, the patients always had a lower level of BMI (Table 1 and Table 2). The trend did not show any change after sex and age were balanced between the two groups.

We divided all the subjects into four subgroups according to the criteria of BMI for underweight, overweight and obesity proposed by Zhou *et al*[25,26]. After we calculated the relative risk in each group, we found that it did not rise with the elevation of BMI. The ORs for obesity in age groups of 30-59 and 60-79 years were 1.15 (95 % CI=0.37-3.65) and 0.16 (95 % CI=0.05-0.44) for males and 0.78 (95 % CI=0.26-2.36) and 0.28 (95 % CI=0.04-2.05) for females, respectively. On the contrary, underweight people had the greatest risk, ORs for underweight were 2.42 (95 % CI=0.56-10.53) and 4.68 (95 % CI=1.13-19.40) for males in age subgroup 30-59 and 60-79 and 40.7 (95 % CI=9.32-177.92) for females older than 60 yrs. No underweight subject was found in healthy female subjects of 60 yrs old or younger. So the ORs for underweight in this subgroup could not be calculated. After performing Fisher' s exact test, we found that the underweight people were more likely to get GCA (P<0.05) except for men under 60 yrs old (Table 4).

Sex and age might be the influence factors for BMI. Logistic regression was performed to investigate the relationship between BMI and GCA. As shown in Table 5 and Table 6, the association between risk of GCA and BMI was significant (P<0.01). Underweight people showed a high possibility of GCA.

Our results differed greatly from not only those in the Western countries but also those of Chow *et al*. in Shanghai, China[7,8,9,28]. The reasons behind the difference might be the genetic background, life style and cut-off points for BMI. The genetic background of the Chinese people differs greatly from those of the Westerners. It even differs in different parts of China. It has been proved that life styles, including smoking, alcohol consumption, and dietary habits could influence the incidence and prognosis of GCA[29]. Even in China, people in different areas have their particular life styles. For example, citizens of Shanghai take more fresh fruits and vegetables than residents of Beijing. Results of the correlative researches conducted in Shanghai were similar to those of the Westerners. The patients enrolled in our research were mainly from North China, which may cause the difference. Secondly, the cut-off points for underweight, overweight and obesity used in our study were different from those used in previous researches. Our study suggests that obesity should not be a risk factor for the North Chinese people.

According to Siewert' s classification, GCA is classified into three types based on its anatomy location. Yasuhiro *et al* noticed a striking difference between the East and the West in the proportion of patients who fell into each type of GCA[30]. Type I cancer, or adenocarcinoma of the lower esophagus was reported to be more prevalent in the Western countries[31] while type III cancer, or adenocarcinoma of the proximal stomach was predominant in Japan. By reviewing pathologic materials of GCA patients, we found that the distribution of GCA types in our patient group was very similar to that of Japanese (data not shown). Obesity might be a risk factor for type I cancer. GCA might have a particular mechanism in the Eastern countries[32].

GCA tended to be more prevalent in aged people[33]. In our study, the median age of the patient group was significantly higher than that of the control group. Epidemiological evidences showed that the proportion of obese people rose with increase of age. It must be clarified that whether a high proportion of aged people can lead to a high prevalence of obesity in the patients group or obesity really predisposes to GCA. Evidences that were opposed to the reflux theory have been also available[34,35]. Besides, one important precondition of the obesity-reflux-carcinogenesis theory is that reflux is the real risk factor. Our next research will be focused on how reflux influences cells at the gastric cardia.

Abstract

AIM: To verify the effectiveness of denaturing high-performance liquid chromatography (DHPLC) in detecting somatic mutation of p53 gene in gastric carcinoma tissues. The superiority of this method has been proved in the detection of germline mutations, but it was not very affirmative with respect to somatic mutations in tumor specimens. ST7 gene, a candidate tumor suppressor gene identified recently at human chromosome 7q31.1, was also detected because LOH at this site has also been widely reported in stomach cancer.

METHODS: DNA was extracted from 39 cases of surgical gastric carcinoma specimen and their correspondent normal mucosa. Seven fragments spanning the 11 exons were used to detect the mutation of p53 gene and the four exons reported to have mutations in ST7 gene were amplified by PCR and directly analyzed by DHPLC without mixing with wild-type allele.

RESULTS: In the analysis of p53 gene mutation, 9 aberrant DHPLC chromatographies were found in tumor tissues, while their normal-adjacent counterparts running in parallel showed a normal shape. Subsequent sequencing revealed nine sequence variations, 1 polymorphism and 8 mutations including 3 mutations not reported before. The mutation rate of p53 gene (21 %) was consistent with that previously reported. Furthermore, no additional aberrant chromatography was found when wild-type DNA was added into the DNA of other 30 tumor samples that showed normal shapes previously. The positivity of p53 mutations was significantly higher in intestinal-type carcinomas (40 %) than that in diffuse-type (8.33 %) carcinomas of the stomach. No mutation of ST7 gene was found.

CONCLUSION: DHPLC is a very convenient method for the detection of somatic mutations in gastric carcinoma. The amount of wild type alleles supplied by the non-tumorous cells in gastric tumor specimens is enough to form heteroduplex with mutant alleles for DHPLC detection. ST7 gene may not be the target gene of inactivation at 7q31 site in gastric carcinoma.

INTRODUCTION

Denaturing high performance liquid chromatography (DHPLC) is a relatively new technique with a high degree of sensitivity in the analysis of germline mutations in various inherited diseases[1-3]. It is known that equal amounts of wild-type and mutant DNA are required to form heteroduplexes for ideal DHPLC analysis. The pure mutant DNA could be available easily from germline mutations or tumor cell lines, but it is often not the case in actual tumor specimens because non-tumorous cells may be present in various amounts. Even using other methods, such as LCM, would not guarantee the gain of pure tumor DNA. So, there are few reports with respect to the analysis of somatic mutations in tumors. Fortunately, in more recent reports[4-6], it was proved that DHPLC had the ability to detect the heteroduplexes formed by mixing wild type alleles with homogenous mutant alleles of cell lines over a broad range of mutant allele concentrations, differing from 5 % to 95 %, which suggested that DHPLC may be well suited for the analysis of somatic mutations in tumor tissue samples in which the proportion of mutant and wild-type alleles is variable.

In our investigation about the somatic mutation of 2 genes by DHPLC, PCR amplification of DNA extracted from surgical tumor specimen was directly conducted without mixing with wild-type DNA, only if the existence of both tumor and normal cells was confirmed by pathology in a certain proportion but not strictly in equal amount. One gene we detected was p53 gene, which was reported to have a relatively high frequency of mutation in gastric carcinoma[7-10]. The other one was ST7 gene, which was cloned and mapped to chromosome 7q31.1-7q31.2, a region suspected of containing a tumor suppressor gene involved in a variety of human cancers[11-13]. Strong evidences to support ST7 as the key TSG at this locus have recently been reported by Zenklusen *et al*.[13]. LOH 7q31 in stomach cancer has also been widely reported[14-16], so we detected four exons of ST7 gene that was reported[13,17] to have mutations to clarify the role of ST7 gene in stomach cancer.

MATERIALS AND METHODS

Tissue samples and preparation of DNA

Thirty-nine cases of gastric cancer tissue and corresponding adjacent non-tumorous gastric tissue were obtained by surgical excision from patients at the Oncology Department of the First Affiliated Hospital of China Medical University, including 15

[a]Mutation that hasn't been reported previously.

cases of intestinal type (4 cases of papillary type and 11 cases of tubular type) and 24 cases of diffuse type (18 cases of poorly differentiated type, 4 cases of mucinous type and 2 cases of signet-ring cell type). Their average age was 58.5 years(from 42 to 79 years), male/female was 27/12. A portion of tissue was frozen and stored at -80 ℃ for DNA extraction, and the remaining tissue was fixed in 10 % buffered formalin for histological examination. DNA was isolated by a standard proteinase K digestion and phenol-chloroform extraction procedure.

PCR conditions

Primer pairs for the amplification are listed in Table 1. Oligonucleotide primers for exons of p53 were published before[18]. The underlying sequence was based on the NCBI database. The average fragment length ranged from 150 to 500 bp. Fragment amplification was accomplished with the UNO II PCR system (Biometra, Germany). PCR reactions were performed in a volume of 20-50 μl with 35 cycles consisting of a denaturation step at 94 ℃ for 45 s, primer annealing for 30 s and an elongation step at 72 ℃ for 1 min. The final step was extended at 72 ℃ for 5 min.

DHPLC analysis and DNA sequencing

Prior to DHPLC analysis, heteroduplex formation of the PCR products was carried out by heating for 5 min at 94 ℃ followed by cooling to 25 ℃ at a rate of 0.03 ℃ S^{-1}. DHPLC was performed using the transgenomic WAVE DNA fragment analysis system (transgenomic, Ohama, USA). Four μl of the PCR products was loaded on the DNASep column and DNA was eluted at a flow rate of 0.9 ml/min within a linear acetonitrile gradient consisiting of buffer A (0.1 M triethylammonium acetate, TEAA) and buffer B (0.1 M TEAA, 25 % acetonitrile). Elution of DNA from column was detected by absorbing at 260 nm. The optimal melting temperature for each fragment was selected by using WaveMaker 4.1 software (transgenomic) or by a software described before which is available freely at http:// insertion.Stanford.edu/melt.html. PCR amplification of the DNA extracted from surgical tumor specimen was directly conducted without mixing with wild-type DNA. The original PCR products of any tumor sample showing an aberrant DHPLC elution profile and its corresponding normal tissue sample were purified using a PCR fragment purification kit (Takara, Dalian), then sequenced directly. Sequence analysis was conducted with the same primers as those used in the original PCR using an ABI 377 automated DNA sequencer. The PCR products of those tumor samples that showed normal DHPLC chromatography were mixed with wile-type at the ratio of 2:1 prior to the reannealing step, and run again.

PCR reaction and DHPLC analysis of all the samples with positive results were repeated at least 2 times and a double direction sequencing was used.

RESULTS

p53 mutations

The results of DHPLC analysis are summarized in Table 2. Mutations of the p53 gene were investigated in 39 surgical specimens of primary gastric cancer by DHPLC. Altogether, 9 aberrant DHPLC chromatographies were found and all of them were from tumor tissues, while their normal-adjacent counterparts running in parallel showed a normal shape. Subsequent sequencing revealed nine sequence variations of 8 mutations and 1 polymorphism. The 8 mutations were localized at exons 5, 6, 7 and 8, including 5 missense mutations, 1 frameshift deletion of 1 bp, 1 in frame insertion of 3 bp and 1 in frame deletion of 24 bp (one example is shown in Figure 1). The latter 3 base pairs changes were not reported previously. Through the European Bioinformatics Institute (EBI) available

at ftp://ftp.ebi.ac.uk/pub/databases/p53/, one polymorphism was localized in intron 7. The positivity for p53 mutations was significantly higher in intestinal-type carcinoma (40 %, 6/15) than that in diffuse-type (8.33 %, 2/24) carcinoma of the stomach ($P<0.01$, χ^2 test).

ST7 mutations

All of the DHPLC chromatographies from 39 tumor tissues showed a normal single peak shape, just the same as with those from their corresponding normal adjacent tissues.

DISCUSSION

Some prescreening methods, such as single strand conformation polymorphism (SSCP) or denaturing gradient gel electrophoresis (DGGE), have been widely used for mutation analysis[19-35], but they were characterized by their lower sensitivity and more labor intensity[1,36,37]. A relatively new technique, DHPLC, is believed to be a superior method for its economic, automatic, time-saving features and higher sensitivities ranging from 95 % to 100 % for germline mutation detection[2,3,38-40]. However, with respect to somatic mutation in actual tumor specimens, one potential drawback that should be considered was that heteroduplexes formed by normal and mutant alleles were necessary for DHPLC detection. Such heteroduplexes were usually got by mixing tumor DNA with an normal equal amount of wild-type DNA when germline mutation was detected. Excitingly, some more recent reports[4-6] showed that heteroduplexes could still be detected by DHPLC when they changed the concentration of homogenous mutant alleles of cell lines from 5 % to 95 %. Their results indicated that DHPLC might also be well suitable for the analysis of somatic mutations in tumor tissue samples in which the proportion of mutants and wild-type alleles was variable. It has been demonstrated that many gastric cancers contained abundant non-neoplastic stromal cells[9]. So when somatic mutations in gastric cancer tissues were detected, it might not only be unnecessary but also laborious to mix normal wild-type alleles with tumor alleles. Further more it might yield a pseudo-negative result if the tumor cell concentration was relatively low in specimens.

In our study, the PCR products, which were amplified from the extracted DNA of surgical tumor specimens without mixing with extra wild type alleles, were directly analyzed by DHPLC. In the analysis of p53 gene mutations, 9 aberrant DHPLC chromatographies were found and all of them were from tumor tissues, while their normal-adjacent counterparts running in parallel showed a normal shape. Subsequent sequencing revealed nine sequence variations of 8 mutations and 1 polymorphism. The mutation rate (21 %, 8/39) was similar to the previously reported frequency of 20 % to 50 %[7-10]. Furthermore, no additional aberrant chromatography was found when wild-type DNA was added into the DNA of other 30 tumor samples that showed a normal shape previously. These results indicate that the amount of wild type alleles supplied by non-tumorous cells in actual gastric tumor specimens is enough to form heteroduplex with mutant alleles for the detection by DHPLC. So, DHPLC is a very convenient method for the detection of somatic mutations in gastric carcinomas.

In contrast to previous studies, p53 mutations did not follow a random distribution among different subtypes. The positivity for p53 mutations was significantly higher in intestinal-type carcinomas (40 %) than in diffuse-type carcinomas (8.33 %). This phenomenon was also observed in other reports[9,41]. Two hot spots for p53 gene mutations in gastric cancer at codon 251 and codon 173[42] were not observed in our study. Interestingly, we found three new mutations that have not been reported in the database of p53 mutations. Considering that all the patients in our study were from the northeast area of China, the above differences might be due to the different etiologies of gastric cancer in different geographical areas.

Evidence of LOH 7q31 has been found in many kinds of malignant tumors and also in gastric carcinomas[14-16], indicating that a putative tumor suppressor gene at this locus may be involved in the pathogenesis of many neoplasms. Strong evidences to support ST7 as the key TSG at this locus were recently reported by Zenklusen *et al*.[13]. Using a prostate cancer-derived cell line they showed that ST7 could suppress *in vivo* tumorigenicity. In addition, they described protein-truncating mutations of ST7 in three out of seven breast cancer derived cell lines and in four out of 10 primary colon carcinomas. But in our investigation on 39 cases of gastric carcinoma, no mutation was found. This could be due to the fact that in the previous study all the tumors were pre-screened for LOH at 7q31, thus increasing the likelihood of detecting a mutation. Other mechanisms of inactivation such as promoter hypermethylation, homozygous deletion, or genomic rearrangement that were not explored in our study were the common mechanisms of ST7 inactivation in stomach cancer. Our results were coincident with a few other recent reports[17,43-45] supporting the absence of ST7 alterations. In these studies, the researchers also failed to detect any further coding mutations in all exons of ST7 in a wide-range of carcinomas and cell lines, including that of ovarian, colon, breast, esophagus, head and neck, pancreatic and prostate. Our results extend the spectrum of malignant tumor types examined for ST7 somatic alterations, and suggest that one of the other tumor suppressor genes, or an undiscovered gene at 7q31 is the target involved in carcinogenesis of gastric carcinoma at this locus.

Abstract

AIM: Hepatocellular carcinoma (HCC) with portal vein tumor thrombosis (PVTT) is associated with poor prognosis. The aim of this prospective study was to evaluate the efficacy of hepatic arterial infusion chemotherapy (HAIC) for patients with this disease.

METHODS: Eighteen HCC patients with PVTT were treated with HAIC via a subcutaneously implanted injection port. A course of chemotherapy consisted of daily cisplatin (10 mg for one hour) followed by 5-fluorouracil (250 mg for five hours) for five continuous days within a given week. The patients were scheduled to receive four consecutive courses of HAIC. Responders were defined in whom either a complete or partial response was achieved, while non-responders were defined based on stable or progressive disease status. The prognostic factors associated with survival after treatment were analyzed.

RESULTS: Six patients exhibited partial response to this form of HAIC (response rate = 33 %). The 3, 6, 9, 12 and 18-month cumulative survival rates for the 18 patients were 83 %, 72 %, 50 %, 28 %, and 7 %, respectively. Median survival times for the six responders and 12 non-responders were 15.0 (range, 11-18) and 7.5 (range, 1-13) months, respectively. It was demonstrated by both univariate and multivariate analyses that the therapeutic response and hepatic reserve function were significant prognostic factors.

CONCLUSION: HAIC using low-dose cisplatin and 5-fluorouracil may be a useful alternative for the treatment of patients with advanced HCC complicated with PVTT. There may also be survival-related benefits associated with HAIC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide, especially in Asia and South Africa[1]. The incidence of HCC has increased over the past decade, and it has become the leading cause of death among patients with cirrhosis[2]. Despite the marked progress in diagnostic techniques and therapeutic procedures, the prognosis for HCC patients remains discouraging. Surgical resection or liver transplantation for these individuals is frequently not feasible due to poor hepatic reserve function, advanced HCC stage, and/or lack of suitable donor livers[3,4]. In past studies, the median survival period for unresectable HCC cases has been only a few months. The survival rate for patients with advanced HCC with portal vein tumor thrombosis (PVTT) was even worse[5-8]. It has been reported that patients with diffuse HCC complicated with PVTT survived only 1-2 months if effective treatment could not be delivered[9]. Transcatheter arterial embolization (TAE), microwave coagulation therapy (MCT), radiofrequency ablation (RFA), and percutaneous ethanol injection (PEI) were all of limited value for such patients[10,11]. Systemic chemotherapy has also been trialed in cases of this type, but without any appreciable survival benefit[12].

Recent advances in implantable drug delivery systems have made it possible to administer repeated arterial infusion of chemotherapy agents[13,14]. Hepatic arterial infusion chemotherapy (HAIC) has the advantages of increased local drug concentrations and a reduction in systemic side effects, making it appropriate, therefore, as a palliative treatment for patients with advanced, unresectable HCC complicated with PVTT. Several authors in this field have reported the efficacy of HAIC[15], with favorable results achieved by a regimen consisting of cisplatin and 5-fluorouracil (5-FU)[16-18]. Based on these considerations, the aim of our prospective study was to evaluate the efficacy of low-dose cisplatin and 5-FU chemotherapy for cases of advanced HCC with PVTT, and analyze the clinical results.

MATERIALS AND METHODS

Patients

From June 1, 2000 to May 31, 2003, twenty patients with unresectable HCC complicated with PVTT received HAIC at the Department of Internal Medicine, Cathay General Hospital. The treatment consisted of low-dose cisplatin and 5-FU delivered via a subcutaneously implanted injection port. Given the severity of HCC or coexisting liver cirrhosis, these patients were not suitable for either surgical resection[4] or nonsurgical treatments such as MCT[19], RFA[20], PEI[21], or TAE[22]. Of the initial 20 subjects, two withdrew due to technical difficulties associated with the indwelling catheter. These were related to the excessive size of the tumor, which hindered insertion of the catheter in one case; and stenosis of the hepatic artery in the other. In total, 18 patients were enrolled in the current study. Informed consent was obtained from all the subjects before the start of the investigation. The diagnosis of HCC was made by histopathology and/or imaging study. Of the 18 diagnoses, six were proven by histopathology and 12 were confirmed clinically using imaging studies, including ultrasonography

(US), computed tomography (CT), angiography, and magnetic resonance imaging, and/or based on a high plasma level of α-fetoprotein (AFP). There were no distant metastases at the time of commencement of the interventional therapy. Patients with any evidence of cardiac disease (congestive heart failure or history of myocardial infarction within the previous three months), severe vascular disease or uncontrolled concomitant infection were excluded. The exlusion criteria also included hepatic encephalopathy, hepatorenal syndrome, gastrointestinal bleeding, refractory ascites, serum bilirubin >5 mg/dl, serum creatinine >1.8 mg/dl, WBC count <3 000/mm^3, and platelet count <30 000/mm^3. The presence of PVTT was confirmed in all the cases by demonstration of one of the following: an intraluminal mass in the portal vein or portal branch from US or enhanced CT scan[23]; the "thread-and streaks" sign or arterioportal shunts on hepatic angiography[24]; or filling defects in the portal vein or in the portal branch as noted in an indirect portogram obtained from a venous phase angiogram of the superior mesenteric artery.

The clinical characteristics for the 18 HAIC-treated HCC patients with PVTT are shown in Table 1. The average age of the 16 male and two female patients was 56.9 (range, 43-75) years. Thirteen individuals were infected with hepatitis B virus (HBV) and five with hepatitis C virus (HCV). The Child-Pugh' s staging classification was used to estimate the degree of hepatic reserve function[25]. Ten patients had a past history of HCC treatment using surgery and/or TAE. The PVTT grading and tumor-extent rating were evaluated using the criteria of the Liver Cancer Study Group of Japan[26]. The PVTT grading was based on the location of the tumor thrombus in the portal vein as follows: Vp1, tumor thrombus in a third or more of the peripheral branch of the portal vein; Vp2, tumor thrombus in a second branch of the portal vein; and, Vp3, tumor thrombus in the first branch or trunk of the portal vein. Tumor-extent rating was estimated from imaging study. The rating system was based on the tumor-extent percentage (E): E1, less than 20 % of the whole liver; E2, 20-40 % of the whole liver; E3, 40-60 % of the whole liver; and, E4, greater than 60 % of the whole liver.

Catheter-implantation technique

The hepatic artery was catheterized using a femoral approach. The tip of the catheter was placed in the proper hepatic artery after HCC localization. The other end of the catheter was connected to the injection port which was implanted in a subcutaneous pocket in the right lower abdominal quadrant[16]. The gastroduodenal artery was occluded using steel coils to prevent injury to the gastrointestinal tract from exposure to the chemotherapy agents[15,16]. Heparin solution was infused regularly via the injection port to keep the catheter from occluding.

Chemotherapeutic regimen

After the set up of drug delivery system, the patients began to receive repeated arterial infusions of chemotherapy agents via the injection port. One course of chemotherapy consisted of cisplatin (10 mg per day) followed by 5-FU (250 mg per day) for five continuous days, with the patients resting on days 6 and 7. Both the cisplatin and 5-FU were administered by a mechanical infusion pump set at a rate of 10 mg for 1 hour and 250 mg for 5 hours, respectively[16]. Basically, the patients were expected to undergo four consecutive courses of chemotherapy, and then they were deemed to have completed HAIC. HAIC was considered incomplete for patients whose chemotherapy was suspended before the completion of the four consecutive courses because of adverse reactions or complications. Maintenance therapy based on the above regimen (cisplatin 10 mg and 5-FU 250 mg for one day) was continued every two weeks after the completion of the initial four courses of the HAIC, with duration depending on tumor response, hepatic function, adverse reactions, and complications.

Assessment of therapeutic response

Abdominal US and CT were performed regularly (every 2-3 and 4-6 months, respectively) to measure the size of the tumor. Local response to treatment was classified according to World Health Organization criteria[27]. Complete response (CR) was defined as the complete disappearance of all known disease, and no new lesions, as determined from two observations no less than four weeks apart. Partial response (PR) was deemed to have occurred where there was a greater than 50 % reduction in total tumor load for all measurable lesions, as determined by two observations no less than four weeks apart. Stable disease (ST) did not qualify for CR/PR or progressive disease (PD) status, with the latter defined as a greater than 25 % increase in the size of one or more measurable lesions or the appearance of new lesions.

Statistical analysis

The Kaplan and Meier method was used to plot the estimated survival curves from the first day of treatment to the last day of follow-up. The results of the univariate analysis were compared to those from the log-rank test to identify predictors of survival. The results of the multivariate analysis were then investigated using Cox' s proportional hazards model. A *P* value less than 0.05 was considered to be statistically significant.

RESULTS

Therapeutic response and patient survival

The salient clinical characteristics for the patients are presented in Table 1. Fifteen patients completed HAIC, while three did not complete the initial four courses series because of deteriorating liver function, sepsis, and gastric ulcer bleeding, respectively. Overall the CR, PR, ST, and PD in response to chemotherapy were zero (0 %), six (33 %), seven (39 %), and five (28 %) in the 18 patients respectively. The response rate (CR and PR/all patients) was 33 %.

Table 1 Clinical characteristics of the 18 patients with hepatocellular carcinoma

Characteristics	*n*
Gender (male / female)	16 / 2
Age (younger than 60 yrs / 60 yrs and older)	9 / 9
HBV / HCV	13 / 5
Child-Pugh's stage (A / B / C)	7 / 7 / 4
Previous treatment (yes / no)	10 / 8
Serum AFP (<1 000 ng.ml^{-1} / ⩾1 000 ng.ml^{-1})	6 / 12
Tumor location (unilobe / bilobe)	10 / 8
Tumor type (nodular / massive / diffuse)	7 / 6 / 5
Maximum tumor size (<5 cm / ⩾5 cm)	13 / 5
Tumor extent (E1 / E2 / E3 / E4)[a]	1 / 6 / 7 / 4
Grade of portal vein invasion (Vp1 / Vp2 / Vp3)[bc]	0 / 5 / 13
Completion of protocol (yes / no)	15 / 3
Therapeutic response (CR / PR / ST / PD)	0 / 6 / 7 / 5

HBV: hepatitis B virus; HCV: hepatitis C virus; AFP: α-fetoprotein; Vp: portal vein tumor thrombosis; CR: complete response; PR: partial response; ST: stable disease; PD: progressive disease. [a]Tumor extent. Tumor replacement of liver parenchyma: E1, <20 %; E2, 20-40 %; E3, 40-60 %; E4,>60 %. [bc]Portal vein invasion. Vp1: in a third or more of the peripheral branch; Vp2: in the second branch; Vp3: in the first branch or trunk.

The cumulative survival for the 18 patients is shown in Figure 1. The 3, 6, 9, 12, 15 and 18-month cumulative survival rates for all the 18 patients were 83 %. 72 %, 50 %, 28 %, 14 %, and 7 %, respectively. While for the six responders (CR and PR), the 3, 6, 9, 12, 15 and 18-month cumulative survival rates were 100 %, 100 %, 100 %, 67 %, 44 %, and 22 %, respectively. The median survival time for the 18 HAIC-treated patients was 9.5 (range, 1-18) months.

The median survival times for the six responders (CR and PR) and the 12 non-responders (ST and PD) were 15.0 (range, 11-18) and 7.5 (range, 1-13) months, respectively. Based on hepatic reserve function, the median survival times for Child-Pugh' s stages A, B, and C were 13.0 (range, 11-18), 8.0 (range, 2-15), and 3.5 (range, 1-9) months, respectively.

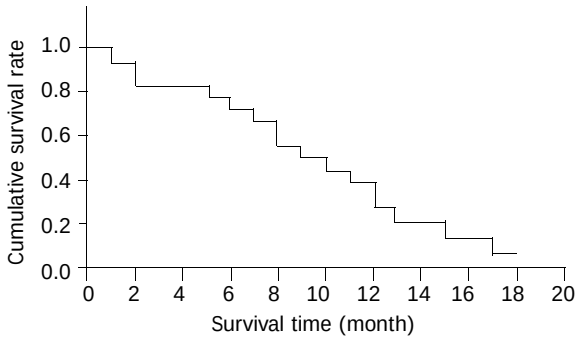

Figure 1 Cumulative survival for 18 hepatocellular carcinoma patients with portal vein tumor thrombosis undergoing hepatic arterial infusion chemotherapy. The 3, 6, 9, 12, 15 and 18-month cumulative survival rates for the 18 patients were 83 %, 72 %, 50 %, 28 %, 14 %, and 7 %, respectively.

Prognostic factors related to survival

Two of the 13 factors was demonstrated to have prognostic significance using univariate analysis: Child-Pugh' s stage (P=0.001) and therapeutic response (P<0.001; Table 2). Multivariate analysis also confirmed these two variables as independent predictors of survival (P=0.005 and 0.001, respectively). None of the other factors were significantly related to patient survival.

Serial computed tomography (CT) revealed progressive improvement in a 55-year-old male patient with HCC complicated with PVTT who presented with a good partial response to HAIC (Figure 2). The huge tumor was decreased markedly from 14×10×9 cm initially to 5×5×3 cm after four months of HAIC.

Table 2 Factors associated with cumulative survival of patients by univariate analysis (log-rank test)

	P value*
Gender (male / female)	0.950
Age (younger than 60 yrs / 60 yrs and older)	0.948
HBV / HCV	0.825
Child-Pugh's stage (A / B / C)	0.001
Previous treatment (yes / no)	0.753
Serum AFP (<1 000 ng.ml^{-1} / ⩾1 000 ng.ml^{-1})	0.994
Tumor location (unilobe / bilobe)	0.938
Tumor type (nodular / massive / diffuse)	0.541
Maximum tumor size (<5 cm / ⩾5 cm)	0.761
Tumor extent (E1 / E2 / E3 / E4)[ac]	0.429
Grade of portal vein invasion (Vp1 / Vp2 / Vp3)[bd]	0.309
Completion of protocol (yes / no)	0.155
Therapeutic response (CR / PR / ST / PD)	<0.001

HBV: hepatitis B virus; HCV: hepatitis C virus; AFP: α-fetoprotein; Vp: portal vein tumor thrombosis; CR: complete response; PR: partial response; ST: stable disease; PD: progressive disease. [ac]Tumor extent. Tumor replacement of liver parenchyma: E1,<20 %; E2, 20-40 %; E3, 40-60 %; E4,>60 %. [bd]Portal vein invasion. Vp1: in a third or more of the peripheral branch; Vp2: in the second branch; Vp3: in the first branch or trunk.

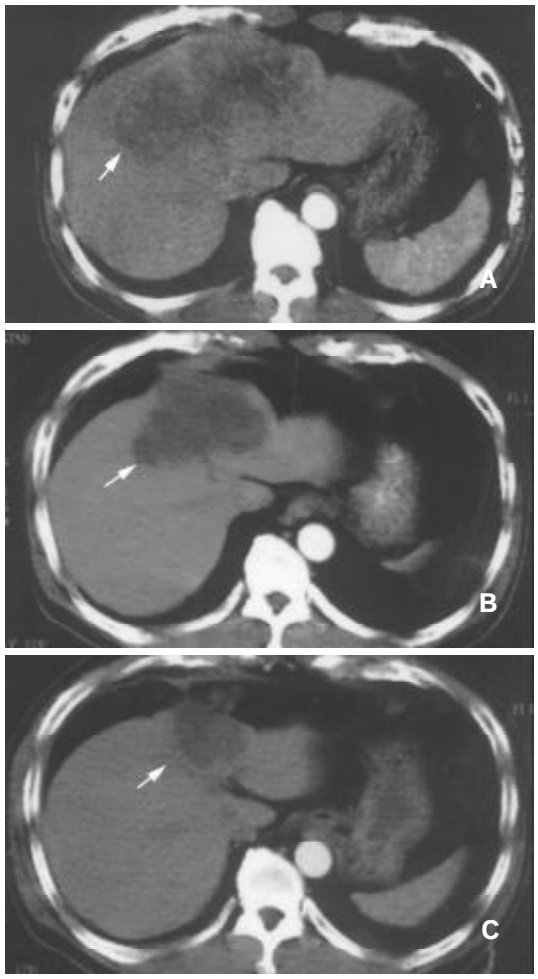

Figure 2 Image study using abdominal computed tomography (hepatic artery phase) of an HCC patient with good partial response to hepatic arterial infusion chemotherapy (HAIC) shows a marked decrease in tumor size from 14×10×9 cm (A: before HAIC) to 9×8×7 cm (B: 1.5 months after initiation of HAIC) and 5×5×3 cm (C: 4 months after initiation of HAIC).

Side effects and complications

The most common adverse reactions to HAIC were nausea and loss of appetite (five cases, 28 %). Two patients (11 %) experienced leukopenia and thrombocytopenia, with one of them unable to continue the chemotherapy due to severe leukopenia. Peptic ulcer was a complication in one case and renal damage in another. Deterioration of liver function occurred in two individuals, causing one of them to quit therapy. Most of these side effects were managed using medical treatment and were not considered serious.

Complications associated with the indwelling catheter were obstruction (n=2), infection (n=2), dislocation of the catheter tip (n=1), and hematoma around the injection port (n=1). All these technical problems were overcome by medical treatment, infusion of heparin solution, or implantation of a new catheter.

Causes of death

Two patients survived the follow-up period. The remaining 16 patients expired, ten (63 %) due to cancer-related causes.

Of these, seven were as a result of tumor extension and three due to tumor rupture. Three individuals (19 %) died of gastrointestinal bleeding; of the rest, three (19 %) died of sepsis related to pneumonia (*n*=2) or urinary tract infection (*n*=1).

DISCUSSION

A standard optimal therapy for advanced unresectable HCC is still lacking[28] . HCC has a high predilection for portal vein invasion, which has been shown to be a poor prognostic factor[5-8]. Although surgery may be considered for some HCC patients with PVTT[6], most are not suitable for this invasive treatment because of dissemination of the tumor throughout the liver, or the coexistence of cirrhotic change. The presence of tumoral portal invasion precludes most potential curative interventions such as TAE, PEI, MCT, and RFA[7]. Further, liver transplantation is not indicated for such patients. Additionally, systemic chemotherapy, hormonal therapy, and IFN therapy are all reported to be of limited value[1,11].

Most of the blood supply to HCC is derived from the hepatic artery, whereas the portal vein supplies the normal liver parenchyma. It is reasonable to assume, therefore, that intra-arterial administration of cytotoxic agents may facilitate delivery of a higher therapeutic concentration to the tumor tissue[29]. Both cisplatin and 5-FU have an anti-tumor effect[30]. In addition, cisplatin plays a synergistic role as a modulator of 5-FU, inhibiting the transport of neutral amino acids, including L-methionine, into tumor cells, and resulting in enhancement of its antitumor effects[31]. Additionally, the combination of cisplatin and 5-FU allows low-dose administration with an associated reduction in adverse reactions. Hepatic extraction of chemotherapeutic agents can result in minimal systemic concentrations of these agents and, thus, minimize systemic toxicity[32] .

In comparison to analogous research, more patients were enrolled in the study of Ando *et al*., (2002), with an HAIC response rate and median survival duration of 48 % and 10.2 (range, 1.7-76.9) months, respectively for their 48 patients with PVTT[18] . By comparison, our response rate and median survival time was 33.3 % and 9.5 (range, 1-18) months, respectively. Moreover, the median survival time for our six responders and 12 non-responders were 15.0 (range, 11-18) and 7.5 (range, 1-13) months, respectively. In the above larger study, the median survival times for the 23 responders and 25 non-responders were 31.6 (range, 9.3-76.9) and 5.4 (range, 1.9-29.0) months, respectively[18]. The longest follow-up for a survivor in their study was 76.9 months, whereas it was only 18 months in our investigation. This variation in the follow-up period may account for the difference in the results outlined above. More cases are needed to continue this study and deliver a more comprehensive and accurate result. Even in our non-responder group, however, the median survival time was 7.5 months, which is still longer than analogous reports[5,7]. The reason that some tumors responded to HAIC, and others not, was not determined in the current study, however. This critical piece of information awaits further investigations, including immunological and/or molecular biological study of tumor cells, to reveal the underlying causes.

In an evaluation of HCC prognosis conducted by the Liver Cancer Study Group of Japan, the severity of any associated cirrhosis, and the size and number of lesions were independent predictive factors[33]. In our study, however, only hepatic reserve function and the patient' s therapeutic response were associated with survival. This difference may result from variations in the patient-enrollment criteria. Our subjects were confined to cases of unresectable HCC with PVTT. In such advanced-stage patients, the influence of lesion size and number on survival is no longer significant. Cirrhosis-related complications (e.g. hepatic failure, variceal bleeding, and spontaneous bacterial peritonitis) were known to play key roles in HCC mortality[34]. The patients with more-favorable Child-Pugh' s classifications have fewer complications and may thus have better and more-favorable outcomes.

Kupffer cells and polymorphonuclear cell function are depressed in liver cirrhosis. The serum also shows a reduction in factors such as fibronectin, opsonins and chemo-attractants, including members of the complement system[35,36]. The hepatic cellular-immune responses, which involve natural killer cells, cytotoxic T lymphocytes and macrophages (Kupffer cells), and their cytotoxic reactions against tumor cells are important as a defense mechanism against hepatocarcinogenesis[37]. In cases of poor residual liver function, the complex molecular and cellular mechanisms, which prevent tumor formation and further development and spread of established tumors, are impaired[38]. Therefore, the prognosis for advanced HCC occurring in such patients is inevitably bleak and dismal.

Chemotherapeutic toxicity was infrequent in our study. Myelosuppression was noted in two cases, and deterioration of liver function also diagnosed in two individuals. The most common adverse reaction, nausea or loss of appetite, was related to the gastrointestinal tract.

Although the survival of HCC patients with PVTT can be improved using HAIC, the results remain unsatisfactory. Further research and investigation is still necessary. Combined therapy, consisting of an intra-arterial infusion of a cytotoxic agent and systemic administration of interferon-α was reportedly useful as a palliative treatment for HCC patients with major vascular involvement[1]. Additional therapy following HAIC, including surgery, MCT, PEI, and extra chemotherapy, might be another option for the prolongation of survival in advanced HCC patients[18,39]. Moreover, the identification of tumors which are more sensitive to cytotoxic agents, and the reason for this are also important areas for future research.

In conclusion, the use of HAIC improves the survival of HCC patients with PVTT. Further, most of the side effects are transient and well tolerated. Hepatic reserve function and therapeutic response are the most important survival-related prognostic factors. Based on our findings, therefore, it seems reasonable to suggest that HAIC is a safe and effective alternative for the treatment of advanced HCC.

Abstract

AIM: To study the expression and serum level of HBxAg, Fas and FasL in tissues of HCC patients, and to assess the relationship between HBxAg and Fas/FasL system.

METHODS: Tissues from 50 patients with HCC were tested for the expression of HBxAg, Fas and FasL by S-P immunohistochemistry. Serum levels of sFas/sFasL and HBsAg/HBeAg were measured by ELISA assay. HBV X gene was detected by PCR in serum and confirmed by automatic sequencing. Fifty cases of liver cirrhosis and 30 normal controls were involved in serum analysis.

RESULTS: The expression of HBxAg, Fas and FasL in carcinoma tissues was 96 %, 84 % and 98 %, respectively. Staining of HBxAg, Fas and FasL was observed predominately in cytoplasms, no significant difference was found in intensity between HBxAg, Fas and FasL ($P>0.05$). HBxAg, Fas and FasL might express in the same area of carcinoma tissues and this co-expression could be found in most patients with HCC. The mean levels of sFas in serum from HCC, cirrhosis and normal controls were 762.29±391.56 $\mu g \cdot L^{-1}$, 835.36±407.33 $\mu g \cdot L^{-1}$ and 238.27±135.29 $\mu g \cdot L^{-1}$. The mean levels of sFasL in serum from HCC, cirrhosis and normal controls were 156.36±9.61 $\mu g \cdot L^{-1}$, 173.63±18.74 $\mu g \cdot L^{-1}$ and 121.96±7.83 $\mu g \cdot L^{-1}$. Statistical analysis showed that both sFas and sFasL in HCC and cirrhosis patients were significantly higher than those in normal controls ($P<0.01$). Serum HBV X gene was found in 32 % of HCC patients and 46 % of cirrhotic patients. There was no significant relationship between serum level of sFas/sFasL and serum X gene detection ($P>0.05$). Eight percent of HCC patients with negative HBsAg and HBeAg in serum might have X gene in serum and HBxAg expression in carcinoma tissues.

CONCLUSION: Our data suggest that HBxAg and Fas/FasL system plays an important role in the development of human HCC. Expression of HBxAg can leads to expression of Fas/FasL system which and reverse apoptosis of hepatocellular carcinoma induced by FasL.

INTRODUCTION

Chronic infection with hepatitis B virus (HBV) is a major risk factor for the development of hepatocellular carcinoma (HCC). The pathogenesis of HBV-induced malignant transformation is incompletely understood[1-3]. HBV X gene encodes a 154 amino acid protein called HBV X protein (HBxAg)[4]. This protein is suspected as an oncogenic molecule responsible for hepatocarcinogenesis because of its multifunctional activities affecting gene transcription, intracellular signal transmission, cell proliferation and apoptotic cell death[5-7]. Of these activities, the best known is its promiscuous transactivation activity[8], which is subjected to complex mechanisms such as protein-protein interaction, regulation of phosphorylation, mRNA stablization and alteration of nucleocytoplasmic translocation[9-11]. Several transgenic mice experiments indicate that mice harboring HBV X gene either develop liver cancer or have accelerated development of neoplasms when they are exposed to other carcinogens[12,13]. HBxAg inhibits the function of tumor suppressor protein P^{53}, which is thought to be an early event in hepatocyte transformation before the later accumulation of inactivating P^{53} point mutations[14]. HBxAg inhibits apoptosis but also exerts pro-apoptotic effects[15,16]. In addition, HBxAg activates cell signaling cascades involving mitogen-activated protein kinase (MAPK) and Janus family tyrosine kinase (JAK) signal transducer and activators of transcription (STAT) pathways[17,18].

The signaling pathway mediated by "death factors" including TNFR1, Fas and TRAILR1 and their cognate ligands is an important mechanism to regulate apoptosis[19]. Fas is the first identified member of "death receptors" and the crosslinking of Fas by its ligand FasL binding leads to conformational changes of Fas, which result in formation of DISC (death induced signaling complex) followed by activation of Caspase-8 and finally induce apoptosis by cleaving their substrates. The Fas/FasL system is likely to play an important role in the regulation of apoptosis including apoptosis of tumor cells[20]. Up-regulation of Fas in the liver has been demonstrated in active viral hepatitis[21]. Human HCC cell lines have been shown to be resistant to Fas-mediated apoptosis[22], but very limited data are available on FasL expression in HCC tissue and its relationship with HBxAg. We investigated the immunohistochemical expression of HBxAg, Fas and FasL in specimens of HCC. The serum level of sFas, sFasL and HBV X gene was also determined.

MATERIALS AND METHODS

Tissue and blood samples

Tumor samples were randomly collected from 50 patients undergoing hepatic resection at the Affiliated Union Hospital

of Fujian Medical University from 1999-2001. Formalin-fixed and paraffin embedded tissues from these samples were used for immunohistochemical analysis. The diagnosis of each tumor was confirmed by pathologists. Blood samples of the tumor patients were taken from the cubital vein on day 3 of hospital admission before the tumor resection. Serum was separated within 30 minutes in a refrigerated centrifuge at 4 ℃, centrifuged at 1 000 g for 5 minutes and stored at –70 ℃ until analysis of sFas/sFasL and HBsAg/HBeAg. Anti- HCV analysis was also performed in order to exclude HCV-positive HCC. The sera of 50 patients with hepatic cirrhosis and 30 normal controls from the blood donators were enrolled in this study. Diagnosis of cirrhotic patients was made on the basis of clinical history, clinical examinations, laboratory findings, gastroscopy and ultrasonography. All the patients had decompensated cirrhosis complicated with ascites, variceal bleeding, or hepatic encephalopathy without infection. All the cirrhotic patients had no HCV infection and alcoholic cirrhosis.

Immunohistochemical analysis

Immunohistochemical staining of HBxAg, Fas and FasL was performed by S-P method. Paraffin embedded sections of 4 μm thickness were cut from the resected tumor samples and transferred onto glass slides. The slides were dewaxed and re-hydrated through a graded descending alcohol series (100 %, 90 %, and 70 %). The slides' endogenous peroxidase activity was blocked by covering the sections with freshly prepared 0.5 % H_2O_2 in methanol, the slides were incubated with horse serum (Vector Laboratories) to block non-specific binding of antibodies. Then, the slides were incubated with a 1:100 dilution of mouse anti-HBx monoclonal antibody, a 1:100 dilution of rabbit polyclonal anti-Fas and anti-FasL antibodies (Maixin-Bio) respectively, washed and incubated with secondary antibody. The slides were subsequently incubated with a freshly prepared 0.1 % v/v diaminobenzidine/TBS solution and counter-stained with haematoxylin. Stained slides were differentiated in acid alcohol prior to blueing in Scott' s solution (Sigma), followed by a wash in running tap water. Finally, the sections were dehydrated through a graded ascending (70 %, 90 %, and 100 %) alcohol series and mixed xylenes on the resulting slides, the sites of immunoperoxidase activity were stained brown and nuclei were blue. As a negative control for HBxAg immunohistochemistry, we used nonimmune mouse serum instead of HBxAg antibody. As negative controls of Fas and FasL, we used nonimmune sera of rabbits. The reaction for immunohistochemistry was evaluated as strong (3+), moderate (2+), weak (+) or negative (-).

DNA extraction and PCR amplification

DNA was extracted from the serum by using phenol-chloroform extracting method. In brief, the serum was mixed with phenol-chloroform-iso-pentanol (volume fraction 25:24:1). After centrifugation at 10 000 g for 10 minutes at 4 ℃. The supernatant was stored in 0.1 M sodium citrate and 100 % ethanol for 30 mintues at -20 ℃. The resulting pellet was dissolved in sterilized water. The sequences of oligonucleotide primers optimized to X region were 5' -ACGGAATTCATGGCTGCTAGGCTGTG-3', 3' -ATCCTGCAGAGGTGAAAAAGTTGCAT-5', respectively. PCR was carried in a final volume of 50 μl containing 5 μl of DNA solution, 20 pmol of each primer, 50 mM of each dNTP, PCR buffer (10 mmol· L^{-1} Tris-HCl, 50 mmol· L^{-1} KCl, 1.5 mmol· L^{-1} $MgCl_2$, 0.001 % gelatin), and 2.5 units of Taq DNA polymerase. Each PCR was as follows: 35 cycles of at 93 ℃ for 30 seconds, at 55 ℃ for 1 minute and at 72 ℃ for 1 minute. The resulting PCR products were separated in a 1 % agarose gel. Assessment of the positive results of PCR was essentially performed on ethidium bromide-stained gel. To confirm the results, PCR products of a positive sample were analyzed by automatic sequencing (Shanghai Shenggong).

Enzyme-linked immunosorbent assay

Serum level of sFas, sFasL, HBsAg and HBeAg was measured using a sandwich enzyme-linked immunosorbent assay (ELISA). Commercially available ELISA kits of sFas, sFasL, HBsAg and HBeAg (MBL) were used. ELISA was performed according to the manufacturer' s instructions. Briefly, diluted serum samples were added in duplicate to 96-well plates coated with antibody and incubated at 37 ℃ for 2 hours. After each well was washed five times with washing buffer (saline containing 0.05 % Tween20), peroxidase-labeled secondary antibody was added to each well and the plate was incubated at 37 ℃ for 1 hour. After each well was washed in a similar manner, the plate was incubated with tetramethylbenzine at room temperature for 20 minutes. The reaction was stopped by adding 1 N sulfuric acid. Optical density was measured at 450 nm using a spectrophotometric microtiter plate reader. The concentration of sample was determined from a standard curve.

Statistical analysis

The expression of HBxAg, Fas and FasL was analyzed using Redit analysis. The sFas and sFasL levels were expressed as mean ±SD, and analyzed using *t*-test. *P* value less than 0.05 was regarded as significant.

RESULTS

Expression of HBxAg and Fas/FasL system

HBxAg, Fas and FasL were detected in the majority of specimens from HCC patients. The results are summarized in Table 1. In most specimens HBxAg, Fas and FasL were detectable in a large number of carcinoma cells(Figures 1-3). No significant differences were found in the expression degrees of HBxAg whether the HCC patients were sero-positive in HBsAg/HBeAg or not ($P>0.05$). Staining of HBxAg, Fas and FasL was observed predominantly in cytoplasms, but no significant difference was found in intensity between HBxAg and Fas/FasL system ($P>0.05$). HBxAg could also express in membrane of carcinoma cells. Surprisingly, we found that HBxAg, Fas and FasL might express in the same area of HCC tissues and this co-expression could be found in most patients with HCC.

Table 1 Expression of HBxAg, Fas and FasL in HCC (n=50)

Expression	HBxAg (%)	Fas(%)	FasL(%)
-	2 (4)	8 (16)	1 (2)
+	5 (10)	9 (18)	4 (8)
++	11 (22)	9 (18)	12 (24)
+++	32 (64)	24 (48)	33 (66)

Table 2 Serum levels of sFas and sFasL in patients with HCC and Cirrhosis (μg· L^{-1})

Group	n	sFas	sFasL
HCC	50	762.29±391.56[a]	158.36±9.67[a]
Cirrhosis	50	835.63±407.33[a]	173.63±18.74[a]
Control	30	238.27±135.29	121.96±7.83

[a]$P<0.01$, *vs* control.

Serum level of sFas and sFasL

Concentrations of sFas and sFasL in HCC, cirrhotic patients and normal controls are shown in Table 2. The serum levels of

sFas and sFasL in both HCC and cirrhotic patients were significantly higher than those of normal controls ($P<0.01$), but there was no significant difference between cirrhosis and HCC patients in serum level of sFas and sFasL ($P>0.05$). In addition, we did not find a correlation between sFas/sFasL concentrations and serum HBV X gene detection ($P>0.05$).

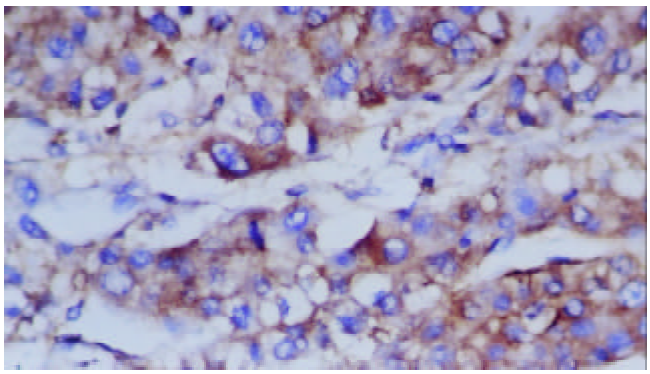

Figure 2 Positive expression of Fas in plasma of hepatocellular carcinoma (S-P stain, ×400).

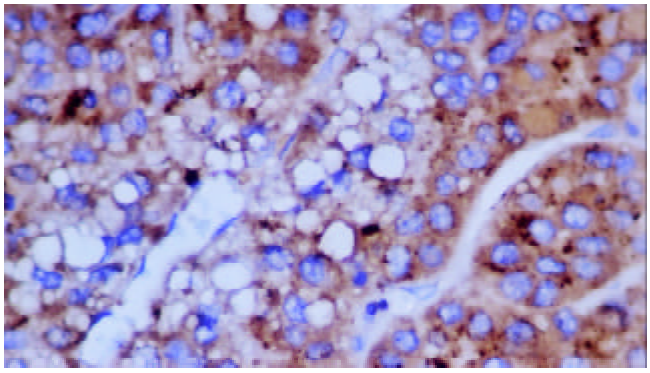

Figure 3 Positive expression of FasL in plasma of hepatocellular carcinoma (S-P stain, ×400).

Table 3 Positive rates of HBV X gene, HBsAg and HBeAg in HCC and cirrhotic patients (%)

Group	HBV X gene	HBsAg	HBeAg
HCC	32	86	34
Cirrhosis	46	82	38

Determination of X gene and HBsAg/HBeAg

The positive rates of HBV X gene, HBsAg and HBeAg in HCC and cirrhotic patients are shown in Table 3. Serum HBV X gene was found in 32 % of HCC patients and 46 % of cirrhotic patients. Eight percent of HCC patients with negative HBsAg and HBeAg in serum might have X gene in serum and HBxAg expression in carcinoma tissues.

The PCR products of X gene positive samples were analyzed by automatic sequencing and the resulting sequence was proved by Genebank.

DISCUSSION

HBV is one of the several agents causing infectious hepatitis, such as acute and chronic viral hepatitis. A strong association was found between chronic HBV infection and the development of HCC in our study. Multiple factors including damage caused by inflammatory cytokines, integration of viral DNA into host cell genomes, host genomic instability, activation of cellular oncogenes, and induction of cell survival pathways have been implicated as causes leading to HCC. However, HBV X gene and HBxAg play a major role in viral infection and carcinogenesis. X gene was the most frequently integrated protein of HBV DNA found in hepatocyte chromosomes during the development of HCC[23]. HBxAg was expressed in these integrated fragments, although no other viral proteins were present in most tumor cells. Recent studies using cDNA microarray analysis revealed that HBxAg expression in HepG2 cells could up- or down-regulate the expression of 39 genes[24]. These genes have a variety of cellular functions including oncogenesis, cell cycle regulation and cell adhesion. Our results demonstrated high levels of HBxAg expression in cirrhotic and HCC cells. Intracellular localization showed that HBxAg was predominant in cytoplasms. Serum levels of sFas and sFasL in both HCC and cirrhotic patients were significantly higher than those in controls. This could be explained by previous observations that X gene was greatly correlated with the development of cirrhosis and integrated into host chromosomes during chronic infection. It seems likely that HBxAg contributes to the initiation of tumor formation in the liver during the process of chronic active hepatitis and cirrhosis. However, whether this process is induced by Fas/FasL system remains to be elucidated.

With PCR detection, we found that some HBsAg and HBeAg negative HCC patients were X gene positive. These results were consistent with a previous report that circulating HBV X gene was detectable in a high proportion of Japanese HCC patients without HBsAg[25]. It could be explained as follows: First, a low level of viremia might exist and hardly result in expression[26]. Second, variant HBV clones might predominantly emerge, the variant HBV might have lost its common "A" determinant of HBsAg and result in loss of HBsAg[27]. Third, disrupted form of HBV was integrated into cellular chromosomes, resulting in failure to produce viral protein translated from deleted DNA[23]. Our results suggested that negative HBsAg and HBeAg HCC patients were required to examine HBV DNA in serum or in liver tissues in order to better understand HBV involvement in the etiology.

Our results indicated that HCC cells could strongly express both Fas and FasL in the same area of carcinoma. What is the target of this ligand? There are some hypotheses. First, because HCC cells can co-express Fas and FasL, they may undergo apoptosis induced not only by activated FasL-positive lymphocytes but also by their own FasL in an autocrine or paracrine manner. Such a fratricide mechanism may be involved in chemotherapeutic drug-induced death of HCC cells, as evidenced by the observations that bleomycin upregulated the expression of Fas and FasL in $HepG_2$ cells, and that apoptosis induced by this drug was almost completely inhibited by antibodies that interfere with Fas/FasL interaction[28]. Second, FasL expressed on HCC cells might be important in their

infiltration as well as dissemination into the liver[29], as has been demonstrated in the hepatic metastasis of colon cancer cells[30]. The third possibility is the so-called "counterattack" hypothesis. FasL expressed on tumor cells may be engaged with Fas receptors expressed on the surfaces of antitumor immune cells, causing them to undergo apoptosis. Strand *et al*[31] reported that HepG2 cells, expressing FasL after treatment with cytostatic drugs, could kill Fas-positive Jurkat lymphocytes, providing the first evidence that FasL is functional on HCC. Although the idea that tumor cells counterattack immune cells and escape from antitumor immunity has attracted popular attention, several investigators reported that the presence of surface FasL might be only an inflammatory response. The presence and function of FasL on HCC cells have become the subject of hot debate[32,33]. But why this happened only in HCC? Ito *et al*[34] examined the expression of Fas/FasL system in human HCC tissues and found that FasL expressing HCCs were moderately or poorly differentiated carcinomas. But FasL expression was not a critical factor in determining intrahepatic tumor spread. Fukuzawa *et al*[35] reported some conflicting results. They examined the expression of Fas and FasL in human HCC tissues, and found that Fas/FasL expression decreased in proportion to the malignancy of tumor cells. According to the concept that tumor cells become resistant to apoptosis during disease progression, their observation implies that FasL expressed on HCC may be involved in a self-regulatory mechanism of apoptosis, rather than being involved in a counterattack against immune cells or infiltration into the liver. Indeed, so far, HCC cells have often been found to be resistant to Fas-mediated apoptosis, despite their expression of Fas receptors[36]. Thus, there is no clinical evidence to directly support the idea that FasL expressed on HCCs was involved in their immune escape or infiltration into the liver. Because the mitochondrial death pathway was predominantly involved in Fas-mediated apoptosis in liver cells[37], overexpression of HBxAg might contribute to FasL-resistance in HCC. We found that Fas, FasL and HBxAg might express in the same area of HCC tissues. The precise mechanism of the co-expression of HBxAg and Fas/FasL system remains to be established. Recently Terradillos *et al*[38] reported that the proapoptotic activity of HBxAg could overcome or bypass the inhibitory effect of Bcl-2 against Fas cytotoxicity. The inability of Bcl-2 to protect HBxAg-expressing hepatocytes against Fas cytotoxicity might be resulted either from inactivation of Bcl-2 or from execution of a Bcl-2-independent death pathway. These indicate that the dominant function of HBxAg upon Bcl-2-regulated apoptosis might play an important role in carcinogenesis. It is known that HBxAg could activate various cellular transcription factors such as AP-1 and NF-kB[39]. In addition, HBxAg may induce FasL expression through activation of cellular transcription factors. Although there is no confirmative report of transcription factors regulating FasL expression, it has been found that the enhancer region of FasL gene has a putative binding site of NF-kB[40] and the important role of NF-kB has been reported in FasL gene activation. Because HBxAg could activate NF-kB, it is possible that HBxAg might induce FasL expression through NF-kB activation[41,42]. Our results also suggest that the expression of HBxAg can lead to expression of Fas/FasL system, which might not reflex apoptosis of hepatocellular carcinoma induced by FasL. This implies that Fas/FasL expression by itself, cannot be used as a reliable marker of apoptosis in HCC.

Abstract

AIM: To evaluate and compare the effect of combined transarterial chemoembolization (TACE) and arterial administration of *Bletilla striata* (a Chinese traditional medicine against liver tumor) *versus* TACE alone for the treatment of hepatocellular carcinoma (HCC) in ACI rats.

METHODS: Subcapsular implantation of a solid Morris hepatoma 3 924A (2 mm^3) in the liver was carried out in 30 male ACI rats. Tumor volume (V1) was measured by magnetic resonance imaging (MRI) on day 13 after implantation. The following different agents of interventional treatment were injected after retrograde catheterization via gastroduodenal artery (on day 14), namely, (A) TACE (0.1 mg mitomycin + 0.1 ml Lipiodol) + *Bletilla striata* (1.0 mg) (n=10); (B) TACE + *Bletilla striata* (1.0 mg) + ligation of hepatic artery (n=10), (C) TACE alone (control group, n=10). Tumor volume (V2) was assessed by MRI (on day 13 after treatment) and the tumor growth ratio (V2/V1) was calculated.

RESULTS: The mean tumor volume before (V1) and after (V2) treatment was 0.0355 cm^3 and 0.2248 cm^3 in group A, 0.0374 cm^3 and 0.0573 cm^3 in group B, 0.0380 cm^3 and 0.3674 cm^3 in group C, respectively. The mean ratio (V2/V1) was 6.2791 in group A, 1.5324 in group B and 9.1382 in group C. Compared with the control group (group C), group B showed significant inhibition of tumor growth (P<0.01), while group A did not (P>0.05). None of the animals died during implantation or in the postoperative period.

CONCLUSION: Combination of TACE and arterial administration of *Bletilla striata* plus ligation of hepatic artery is more effective than TACE alone in the treatment of HCC in rats.

INTRODUCTION

HCC is a highly malignant tumor with a very high morbidity and mortality rate worldwide, carrying a poor prognosis due to its rapid infiltrating growth and complicating liver cirrhosis[1,2].

Surgical resection, liver transplantation and cryosurgery are regarded as potentially curative treatment for HCC[3-5], but most patients are not suitable candidates[6-9]. Thus, the local interventional therapy of liver tumor has been rapidly evolving currently, which includes transarterial chemoembolization (TACE), percutaneous ethanol injection (PEI), radiofrequency ablation (RFA), laser-induced thermotherapy (LITT) and microwave coagulation therapy (MCT)[10-19]. TACE is one of the most common forms of interventional therapies and seems most effective against encapsulated small HCCs without extracapsular invasion, whereas in large HCCs, viable residual tumor cells remain and the tumor frequently recurs[20-22]. Moreover, in patients with large lesions, multiple TACE sessions are necessary to control tumor growth but may increase the risk of worsening hepatic function through damage to noncancerous liver parenchyma[8,21,23].

In the past years, locoregional Chinese medicinal therapy for treating unresectable HCC has been reported with encouraging results, especially for inhibiting arterial collaterals of liver tumor and recurrence of HCC[24,25]. Such an adjuvant treatment in conjunction with TACE has the potential to enhance the therapeutic effect of TACE alone in experimental and clinical studies. However, no experimental study to assess the value and efficacy of this combined therapy in an animal model of HCC has been performed.

The current prospective randomized study was designed to compare the effect of combined TACE and arterial administration of *Bletilla striata* (a Chinese traditional medicine against liver tumor) *versus* TACE alone for the treatment of HCC in ACI rats.

MATERIALS AND METHODS

Tumor

The hepatoma cell line (Morris hepatoma 3924A), a rapidly growing, poorly differentiated hepatocellular carcinoma[26], was used in ACI rats in this study. The hepatoma specimens were obtained from the German Cancer Research Center (DKFZ; Heidelberg, Germany).

Animal

Thirty inbred male ACI-rats (Harlan Winkelmann; Borchen, Germany) weighing 220-260 g were used. The animals were kept under conventional conditions with a temperature of 22±2 ℃, a relative humidity of 55±10 %, a dark-light rhythm

of 12 hr, and had free access to laboratory chow and tap water. All of the experiments on animals were approved by the German government.

Agents

The original material of *Bletilla striata* microspheres is the stem tubers of *Bletilla striata*. *Bletilla striata* microspheres were kindly provided by Tongji Medical College (Wuhan, China). A dose of 1.0 mg *Bletilla striata* microspheres (50 μm) was suspended in 0.5 ml 0.9 % NaCl for 10 minutes before administration.

Anesthesia

The animals were anesthetized with intraperitoneal injection of ketamine hydrochloride (Ketanest, Parke-Davis, Germany; 100 mg/kg), Xylazinhydrochloride (Rompun, Bayer, Germany; 15 mg/kg) and atropine sulfate (Atropinsulfat Braun, Braun, Germany; 0.1 mg/kg) in all interventional and imaging procedures.

Tumor implantation (on day 1)

The technique for tumor implantation was basically similar to that described by Yang *et al*[26] with minor modifications[27-29]. The Morris hepatoma 3924A tumor tissue, recovered from the passaged animals 2 weeks after subcutaneous implantation (corresponding to 5×10^6 tumor cells), was cut into small cubes about 2 mm^3.

A small subcapsular incision on the left lateral lobe of the liver was made in the recipient ACI-rats under anesthesia. The tumor fragment was gently placed into the pocket with a small cotton swab on the liver surface and the abdominal wall was then closed.

Interventional therapy (on day 14)

For interventional studies a second laparotomy was performed. By using a binocular operative microscope (M651, Leica; Wetzler, Germany), a PE-10 polyethylene microcatheter (inner diameter 0.28 mm, outer diameter 0.61 mm; Wenzel; Heidelberg, Germany) was retrogradely inserted into the gastroduodenal artery. Different agents were then injected (20 minutes a duration time) through the microcatheter via hepatic artery using sandwich technique. Administration was as follows:

Group A (*n*=10): Mitomycin (0.1 mg) + Lipiodol (0.1 ml) + *Bletilla striata* (1.0 mg)
Group B (*n*=10): Mitomycin (0.1 mg) + Lipiodol (0.1 ml) + *Bletilla striata* (1.0 mg)+ligation of A. hepatica propria
Group C (*n*=10): Mitomycin (0.1 mg) + Lipiodol (0.1 ml) (*control group*).

MR imaging and analysis (on day 13 and 27)

A 1.5 Tesla Sonata (Siemens; Erlangen, Germany) supplemented by a wrist coil (Small field of view) was used for MRI before and after therapy (on day 13 and 27). T1-weighted (SE: TR/TE, 460/15 ms) and T2-weighted (TSE: TR/TE, 3170/99 ms) transverse images with a section thickness of 2 mm and 184×256 matrix were acquired. There was no gap between sections and no contrast medium was administered. The tumor volume was determined and evaluated in T2-weighted image according to the formula[30]:

$$\text{Tumor volume } (mm^3) = \frac{\text{Largest diameter (mm)} \times [\text{smallest diameter (mm)}]^2}{2}$$

The mean tumor growth ratio (V2/V1) was analyzed by using *t* test for comparing the effect of each therapeutic group with control group respectively. A *P*-value less than 0.05 was considered to indicate a significant difference.

RESULTS

The rate of tumor implantation reached 100 % in all the rats receiving tumor implantation with Morris hepatoma 3924A. None of the animals died during implantation or interventional therapy. A total of 30 individual HCC tumors were seen with unenhanced MR imaging in the livers of 30 rats (100 %) before treatment. The tumors showed homogeneously hypointense on the T1-weighted images and hyperintense on the T2-weighted images. T2-weighted sequences provided significantly higher tumor-liver contrast than T1-weighted sequences, and improved the detectability of intrahepatic metastasis. Intrahepatic metastasis occurred in two of 10 rats (20 %) in group C.

The mean tumor volume before (V1) and after (V2) therapy was 0.0355 cm^3 and 0.2248 cm^3 in group A, 0.0374 cm^3 and 0.0573 cm^3 in group B, 0.0380 cm^3 and 0.3674 cm^3 in group C, respectively. The mean ratio of V2/V1 was 6.2791 in group A, 1.5324 in group B and 9.1382 in group C. Compared with the control group (group C, TACE alone), group B (TACE + *Bletilla striata* + ligation of hepatic artery) showed significant inhibition of tumor growth ($P<0.01$), while group A (TACE + *Bletilla striata*) did not ($P>0.05$).

The tumor volume ratio (V2/V1) in different groups (*n*=30) is shown in Table 1.

Table 1 Tumor volume rate (V2/V1) in different groups (*n*=30)

Rat No.	Group A (BS)	Group B (BS+Lig.)	Group C (control)
1	6.4810	0.8556	5.6284
2	5.7038	1.4565	9.5091

10	3.2015	1.8054	12.7182*

BS: *Bletilla striata*. Lig.: Ligation of hepatic artery; *: tumor with intrahepatic metastasis.

In group B (TACE + *Bletilla striata* + ligation), relative small tumors with the size of 0.52×0.37 mm^2 and 0.44×0.38 mm^2 in diameter were shown in two treated rats, respectively, indicating a minimal response but no tumor growth after therapy compared with that before therapy (Figure 1).

In group C (control group), the tumor volume was generally markedly increased in treated rats compared to untreated. Two rats appeared to be accompanied with intrahepatic metastasis (Figure 2).

DISCUSSION

Since TACE was introduced as a palliative treatment in patients with unresectable HCC, it has become one of the most common forms of interventional therapies[11,31]. TACE with iodized oil has been shown to result in regression of HCC and reduction of systemic toxicity, thus improving the therapeutic effects[21,32,33]. However, prolongation of the overall survival of patients remains questionable[34]. TACE might ablate a significant portion of the tumor but had a high rate of recurrence[35]. In patients with focal HCC, TACE was well tolerated and provided a survival benefit. However, no apparent benefit of it has been found for patients with diffuse HCC[36,37]. TACE using various embolizers has been well documented to include

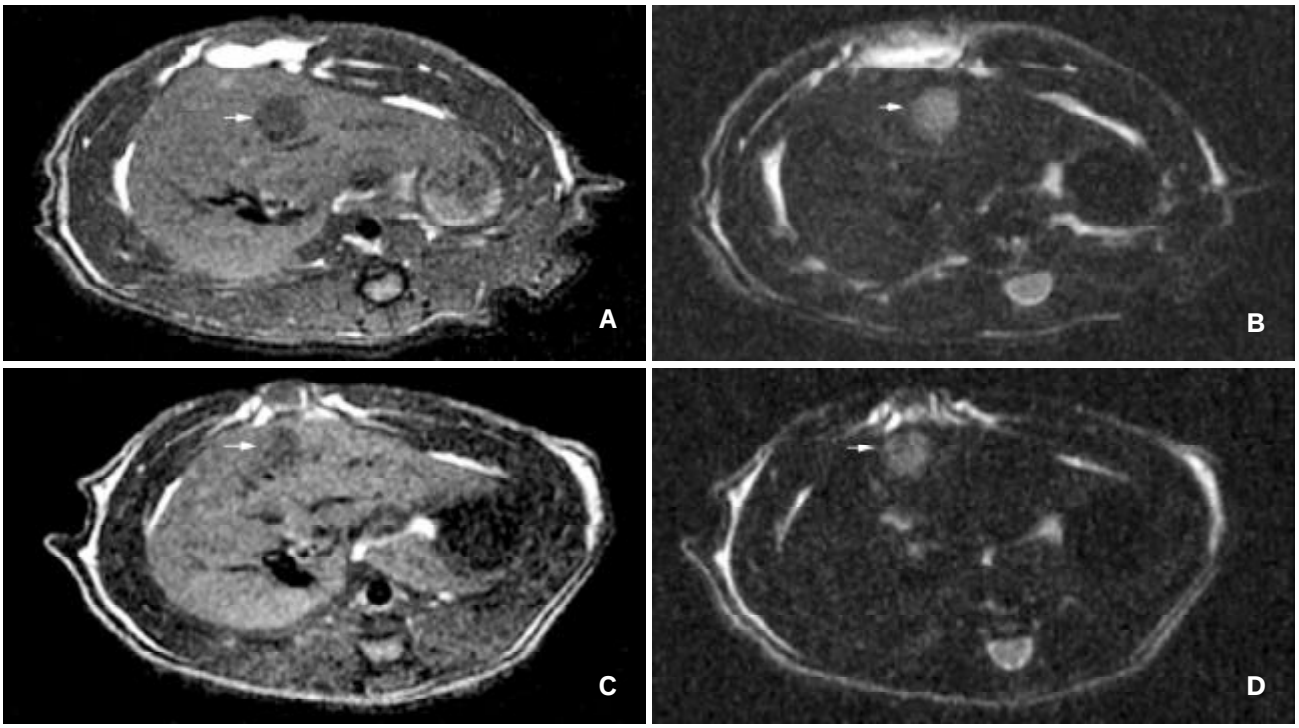

Figure 1 A: Images in a ACI rat with a solid HCC in group B. (a) Pretherapy did not enhance T1-weighted MR imaging with SE sequence (460/15). It shows a small hypointense tumor (arrow) in the left lateral lobe of liver; B: Pretherapeutic unenhanced T2-weighted MR imaging with TSE sequence (3170/99). The hyperintense lesion with a size of 0.44×0.40 mm^2 (arrow) is well discernible from the surrounding liver tissue. C: Images in a ACI rat with a solid HCC in group B. (a) Posttherapy did not enhance T1-weighted MR imaging with SE sequence (460/15). It shows a small hypointense tumor (arrow) in the left lateral lobe of liver. D: Unenhanced T2-weighted MR imaging with TSE sequence (3170/99) after therapy. It shows the inhomogeneous hyperintense lesion with a size of 0.44×0.38 mm^2 (arrow) and demonstrates that there is no difference between the tumor volume before and after therapy.

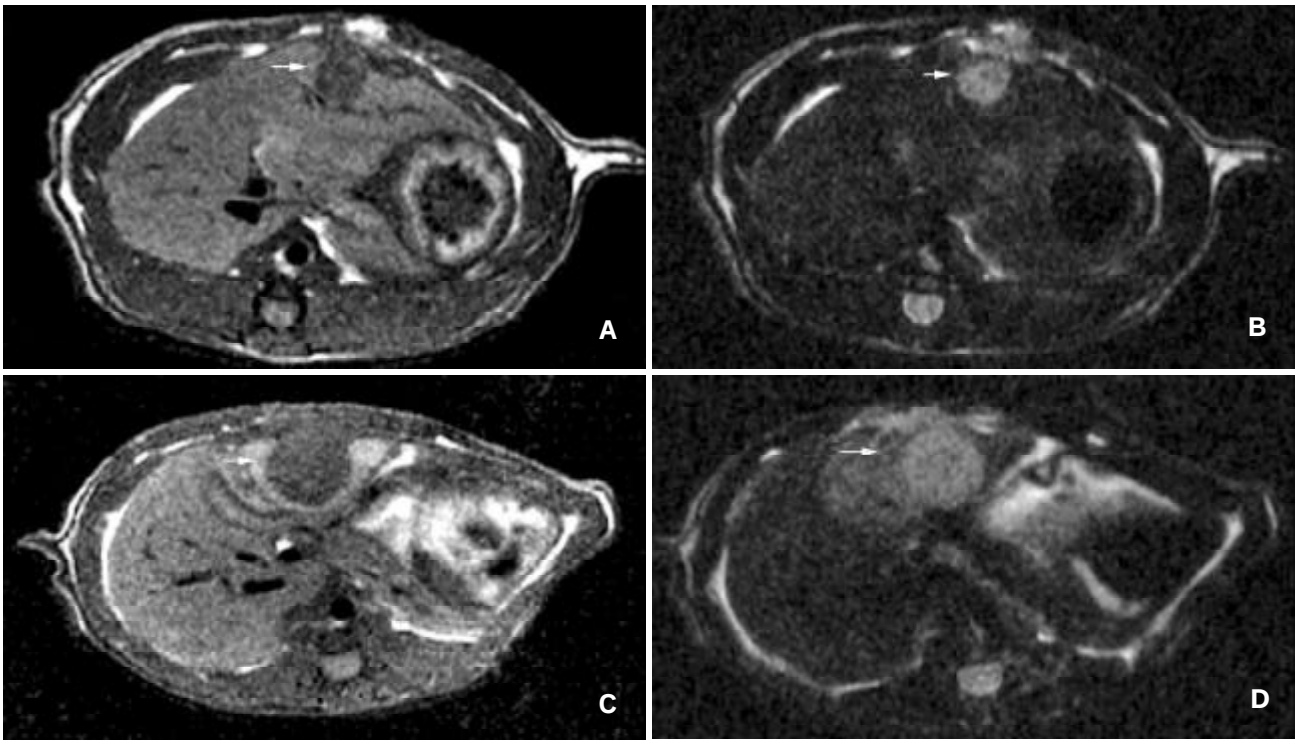

Figure 2 A: Images in a ACI rat with a solid HCC in group C. (a) Pretherapy did not enhance T1-weighted MR imaging with SE sequence (460/15). It shows a small hypointense tumor (arrow) in the left lateral lobe of liver. B: Unenhanced T2-weighted MR imaging with TSE sequence (3170/99) after therapy. The hyperintense lesion with a size of 0.49×0.46 mm^2 (arrow) is well discernible from the surrounding liver tissues. C: Images in a ACI rat with a solid HCC in group C. (a) Posttherapy did not enhance T1-weighted MR imaging with SE sequence (460/15). It shows a large hypointense tumor (arrow) in the left lateral lobe of liver. The lesion is surrounded by an iregular hypointense area. D: Unenhanced T2-weighted MR imaging with TSE sequence (3170/99) after therapy. The tumor with a size of 0.96×0.96 mm^2 had a rapid growth compared with that before therapy. It also shows the unhomogeneous hyperintense area (arrow) corresponding to the intrahepatic metastasis.

controlled studies. However, it is not indicated for patients with thrombosed main portal veins. Its therapeutic effect was also doubtful when the tumor was infiltrative in nature or hypovascular, too large or too small[38,39]. The rapid development of arterial collaterals after these treatments might reduce this therapeutic effect and thus, inhibition of the development of arterial collaterals might be important in enhancing the therapeutic efficacy of these treatments[40]. In addition, in patients with large lesions, multiple TACE sessions were necessary to control tumor growth but might increase the risk of worsening hepatic function through damage to noncancerous liver parenchyma[23]. Moreover, the types and doses of embolic agents have been extremely variable in several reported studies. The major problem with embolic agents were twofold[41]. First, they could often completely obstruct the hepatic artery, leading to difficulties in administration of subsequent courses of hepatic artery chemotherapy. With a relative short half-life of embolic agents, the effectiveness of TACE was not significantly improved. Second, it was easy to aggravate the liver cirrhosis and lead to hepatic failure after repeated TACE. The optimal treatment modality of TACE is still unknown[42].

Today, it is well known that improvement of the overall therapeutic effect of liver malignancies depends on the combined therapies. In the past years, locoregional Chinese medicinal therapy has gained wide acceptance as a safe, palliative and effective treatment even in patients with large HCC and liver cirrhosis in China. *Bletilla striata* (BS) is a common Chinese traditional medicinal herb and is usually used as an embolic material in TACE for HCC. Its compositions are mucilage, starch, and a little volatile oil. In a previous study, Zheng *et al*[24] used BS to embolize the hepatic artery in order to induce ischemic necrosis and shrinkage of tumor. It mainly blocked the trunk of the blood-supplying artery of tumor with a "vascular cast-like appearance". The embolization was extensive and lasted longer, hence a better therapeutic effect[24]. The mechanisms of embolization by BS are attributable to the following factors: non-absorbent property, total mechanical obstruction, no influence on coagulative and anticoagulative systems and secondary obstruction due to injury of the wall of blood vessels[43, 44]. Zheng *et al*[25] have confirmed that BS has an adherent function and can expand slowly in blood flow, leading to mechanical blockade of vessels. It was also hypothesized that BS could slowly diffuse into the liver parenchyma around the tumor as a colloidal form, leading to prolonged anticancer effect and inhibition of collateralisation and metastasis of tumor[25]. Compared with gelfoam embolus, BS had the following characteristics. It could produce extensive and permanent vascular embolization, while it could not be absorbed by body tissue. After embolization, tumor necrosis and shrinkage were significant with less collateral circulation that formed later. The mucilage component of BS is a wide-spectrum anticancer element that might inhibit tumor occurrence and development[45]. The 1, 2 and 3 year survival rates were 44.9 %, 33.6 % and 33.6 % in BS group while the rates were 48.9 %, 31.1 % and 16.0 % in gelfoam group, suggesting that BS is superior to gelfoam as an embolic agent, and transarterial administration of BS might provide a beneficial therapeutic modality for HCC[45]. In our experimental study, the best therapeutic effect was the combined therapy of BS+TACE+ligation of hepatic artery. There was almost no significant difference between the tumor volume before and after therapy (Figure 1). No intrahepatic metastasis was observed in this group. This approach of central- and peripheral chemoembolization is able to increase the inhibition of tumor growth more completely, resulting in local control of tumor growth in rats and has a promising prospect for treating patients with HCC in the future.

In summary, by combining TACE and arterial administration of *Bletilla striata* plus ligation of hepatic artery for treating HCC in ACI rats, an encouraging result can be obtained compared with TACE alone. However, the detailed therapeutic mechanisms, therapeutic indications, optimal strategy for the use, monitoring, and validation of these combined therapies remain unclear and more randomized experimental and clinical studies are required.

Abstract

AIM: To investigate the systemic availability of budesonide in a patient with Child A cirrhosis due to autoimmune hepatitis (AIH) and primary hepatocellular carcinoma, who developed serious side effects.

METHODS: Serum levels of budesonide, 6β-OH-budesonide and 16α-OH-prednisolon were measured by HPLC/MS/MS; portosystemic shunt-index (SI) was determined by 99mTc nuclear imaging. All values were compared with a matched control patient without side effects.

RESULTS: Serum levels of budesonide were 13-fold increased in the index patient. The ratio between serum levels of the metabolites 6β-OH-budesonide and 16α-OH-prednisolone, respectively, and serum levels of budesonide was diminished (1.0 *vs*. 4.0 for 6β-OH-budesonide, 4.2 *vs*. 10.7 for 16α-OH-prednisolone). Both patients had portosystemic SI (5.7 % and 3.1 %) within the range of healthy subjects.

CONCLUSION: Serum levels of budesonide vary up to 13-fold in AIH patients with Child A cirrhosis in the absence of relevant portosystemic shunting. Reduced hepatic metabolism, as indicated by reduced metabolite-to-drug ratio, rather than portosystemic shunting may explain systemic side effects of this drug in cirrhosis.

INTRODUCTION

Autoimmune hepatitis is a chronic necroinflammatory liver disorder of unknown etiology associated with interface hepatitis, hypergammaglobulinemia and circulating autoantibodies, which was first described by Waldenström in 1950[1] and termed "autoimmune hepatitis" by the International Autoimmune Hepatitis Group in 1992[2]. The identification and characterization of serum autoantibodies led to differentiation of three different types characterized by antinuclear antibodies (type I), liver-kidney microsomal antibodies (type II) and soluble liver antigen (type III)[3,4]. The distinction between autoimmune hepatitis and other autoimmune liver diseases like primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC) is based on characteristic clinical, histological, biochemical and immunological features but overlap and variant syndromes may occur[5].

Primary hepatocellular carcinoma (HCC) is thought to be a consequence of the progression from chronic hepatitis to cirrhosis, although this sequence appears to be rare in autoimmune hepatitis[6]. In many patients who develop HCC hepatitis C virus infection has been found to be a complicating condition[7]. However, HCC also occurs in the absence of risk factors like hepatitis C infection and corticosteroid therapy[8].

Autoimmune hepatitis is generally responsive to corticosteroid therapy despite its striking heterogeneity[1]. Corticosteroids alone or in combination with azathioprine are the treatment of choice and result in remission induction in over 80 % of patients[9,10]. Early clinical trials with prednisolone documented improvement of liver function tests, amelioration of symptoms and prolonged survival, thereby establishing corticosteroids as the "standard therapy"[11-13]. Azathioprine has no role in inducing remission but may be used for maintenance of remission induced by initial corticosteroid therapy or their dose reduction in combination therapy[9]. The potential usefullness of other immunosuppressives like cyclosporine and tacrolimus has been shown but has not yet been clinically established[9]. Since about 70 % of patients with AIH require lifelong immunosuppressive therapy, long-term use of corticosteroids is often accompanied by numerous systemic side effects, such as osteoporosis, diabetes mellitus, systemic hypertension, psychiatric disorders and altered steroid metabolism[14].

The search for new corticosteroids with a more favourable risk-to-benefit ratio led to the discovery of a new class of corticosteroids with high receptor affinity and particularly high first-pass effect in the liver resulting in lower systemic side effects. Budesonide, a nonhalogenated glucocorticoid derivative of the second generation exhibits a receptor affinity 15-20 times that of prednisolone and a 90 % first-pass metabolism in healthy liver[9]. Two major metabolites, 6β-OH-budesonide and 16α-OH-prednisolone, have been identified which lack glucocorticoid activity making the original compound virtually devoid of systemic side effects[15]. Budesonide has been evaluated in patients with primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC) at a dose of 9 mg/day with contradicting results concerning additional benefit to the standard therapy with ursodeoxycholic acid (UDCA)[16-19]. In autoimmune hepatitis only two small uncontrolled trials with a limited number of patients and rather disappointing results have been published[20,21]. In one study including 10 patients who were dependent on continuous

treatment to prevent exacerbation budesonide failed to induce clinical and biochemical remission in 7 patients who either deteriorated or became drug intolerant[21]. In a second study with 13 patients budesonide has been found to lower transaminase levels significantly while causing a low frequency of systemic side effects and only a marginal reduction in plasma cortisol in noncirrhotic patients[20]. However, the majority of patients did not reach full biochemical remission defined as normal ALT values. Patients with cirrhosis experienced higher serum cortisol levels and a partial suppression of the hypothalamic-pituitary-adrenal (HPA) axis suggestive for at least a latent systemic activity of budesonide[20].

An explanation for a variable and so far unpredictable extent of systemic side effects in patients with early liver disease treated with budesonide may be either a reduced metabolic function or the presence of latent portosystemic shunts bypassing the liver. However, no data are presently available on the metabolism of budesonide in cirrhotic livers and the incidence of side effects in these patients. Thus, there are no recommendations for therapy with budesonide in cirrhotic patients with AIH to date.

To our knowledge, treatment of patients with coexisting HCC or other malignancies has so far not been reported in literature. Systemic immunosuppression exposes such patients to an increased risk of tumor recurrance after curative surgical treatment of the malignant disorder. A risk stratification for systemic effects of budesonide by assessment of the portosystemic shunt-index (SI) and the metabolic activity of the cirrhotic liver is of major importance in these patients. We report the first case of successfull treatment of a patient with AIH after resection of a HCC and show a predominance of hepatic metabolism over portosystemic shunting on sytemic availability and side effects of budesonide in this patient with Child A cirrhosis.

MATERIALS AND METHODS

Clinical data

A 65-year-old caucasian woman (patient 1) with a 27-year history of unclassified chronic hepatitis was referred to our liver unit with a newly diagnosed liver mass during regular ultrasound screening. She experienced icteric episodes 27 and 14 years ago and a known asymptomatic cholecystolithiasis. Physical examination of the anicteric patient was unremarkable despite liver enlargement without a palpable mass. Clinical chemistry on admission showed mild signs of hepatic inflammation (AST 24 U/L, GGT 53 U/L) without elevation of further liver function tests or pancreatic enzymes. Biochemical tests revealed type I autoimmune hepatitis with antinuclear (titer 1:320), anticytoplasmatic (titer 1:320) and anti-smooth muscle antibodies (titer 1:640) as well as elevated gamma-globulins (29 % of total proteins, IgG 25.7 g/L). Quantification of alpha-1-antitrypsin, ceruloplasmin, serum iron, ferritin, transferrin saturation, serum copper and urinary copper excretion were within normal limits, and serologic tests for anti-HAV, anti-HBs, anti-HBc, HBs-antigen and anti-HCV were all negative. On ultrasound the liver appeared cirrhotic with a 4.5×3.9 cm mass in the right lobe. Computed tomography (CT) depicted a 4 cm mass in segment VI of the right lobe of the liver with contrast enhancement. Alpha-1-fetoprotein (AFP) was not elevated. A CT-guided Tru-cut biopsy confirmed the diagnosis of a primary HCC in a cirrhotic liver. Tumor staging revealed no signs of metastasis in thoracic CT, ^{19}fluor deoxyglucose positron emission tomography. Preoperative staging of the liver disease led to a grade A cirrhosis according to the Child-Pugh classification. Endoscopy of the upper GI tract did not detect obvious varices of the esophagus and gastric fundus.

The patient underwent atypical resection of segment VI liver without further complications. Follow-up in our liver outpatient clinic showed functional liver tests at the preoperative level with mild AST and GGT elevation. Three months after resection of the HCC, transaminase levels sharply increased over a period of 4 months with peak transaminases of ALT 247 U/L and AST 312 U/L. No signs of tumor recurrance were detectable by abdominal CT and AFP levels. In order to prevent further progression of the Child A cirrhosis, we initiated a therapy with budesonide which was favoured over systemic immunosuppressive treatment with respect to the antecipated lower risk of tumor recurrance. Transaminase levels dropped rapidly to the normal range during a daily dose of 9 mg budesonide. Remission was achieved within two months after starting budesonide, but systemic side effects such as facial swelling, leg edemas and weight gain occurred. To minimize these adverse effects and systemic immunosuppression, we tapered the dose to 6 mg/day for maintenance therapy. Follow-up for potential tumor recurrance with corticosteroid therapy revealed normal CT-scans and AFP levels so far. Almost four years after tumor resection, the patient is still in remission in regard to AIH at a daily dose of 6 mg budesonide. In this index patient we assessed the determinants of systemic effects of budesonide in comparison with another AIH patient matched for age, sex and functional Child-Pugh stage (patient 2, caucasian female, 67 years of age, Child A cirrhosis diagnosed by liver biopsy) with steroid dependency, no apparent varices) and historic healthy controls.

Budesonide and its metabolites

Levels of budesonide, 6β-OH-budesonide and 16α-OH-prednisolone were determined in serum 3 hours (allowance ± 60 minutes) after intake by a validated HPLC/MS/MS assay. Serum was extracted by solid phase extraction and the reconstituted extract was analyzed by HPLC/MS/MS on a Micromass Quatro LC using reversed phase chromatography and the negative electrospray ionization mode. The limit of detection was defined as 100 pg/ml for all analytes. All determinations have been performed by H.W. Moellmann (Medical Clinic Bergmannsheil, Bochum, Germany) and funded by Falk Pharma (Freiburg i.B., Germany). Falk Pharma had no involvement in analysis, interpretation and publication of the data.

Cortisol levels

Basal cortisol levels and cortisol levels in response to 100 μg corticotropine releasing hormone (CRH) were measured with routine clinical chemistry. Both tests were performed at 8 A. M. and stimulated cortisol levels were determined over 90 minutes after intravenous application of CRH.

Portosystemic shunt-index (SI)

Portosystemic SI was determined by nuclear imaging after rectal application of ^{99m}Technetium pertechnetate (Tc) as described[22]. Briefly, the rectum was emptied by administration of a laxative and a polyethylene tube was inserted. After positioning of a large-field scintillation camera over the patient 340 MBq of ^{99m}Tc pertechnetate was given over the tube and time-activity curves for the areas of the liver and heart were obtained. After normalization portosystemic SI was calculated from the activity of the liver and heart.

Cortisol and portosystemic shunt-index was measured at the time of the first serum analysis on budesonide and metabolites. All measurements were determined with informed consent by both patients.

RESULTS

Serum levels of budesonide and its metabolites

Serum budesonide levels were determined 3 h after intake of 6 mg at 4 different time points during five months (Figure 1). At all time points serum budesonide levels were markedly elevated in the index case (mean 1.9 ng/ml) when compared with the control patient (mean budesonide level 0.15 ng/ml) and historic healthy controls without liver disease (0.4-0.7 ng/ml)[23]. Systemic availability in patient 2 was remarkably lower even with a higher dose of 9 mg budesonide. However, serum levels of this control patient was in close comparison with the historic healthy controls, further supporting a potential clinical relevance of the elevated serum budesonide levels in the index patient. To determine whether elevated serum budesonide levels resulted from impaired hepatic metabolism, 6β-OH-budesonide and 16α-OH-prednisolone as its major inactive metabolites were measured in both patients (Figure 2). Although both metabolites were detectable in both the index and control patient, the mean ratio of metabolites to drug serum levels were significantly lower for both 6β-OH-budesonide (1.0- *vs*. 4.0-fold) and 16α-OH-prednisolone (4.2- *vs*. 10.7-fold) in the index compared with the control patient (Figure 2).

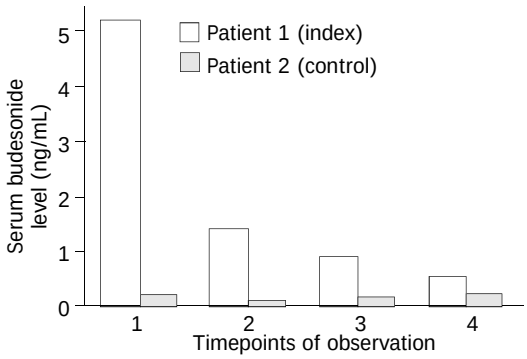

Figure 1 Serum concentration of budesonide. Serum levels of budesonide were analyzed 3 hours after intake of 6 mg 4 times during a 5-month period of follow-up. Budesonide levels were largely elevated in the index case compared to the control patient 2 with average drug levels of 1.9±2.1 ng/mL and 0.15±0.07 ng/mL, respectively. The dashed line indicates serum levels of heathy controls.

Effect of budesonide on cortisol levels

To further determine the potential systemic effects of budesonide, serum cortisol levels were measured at baseline and after stimulation by 100 μg corticotropine releasing hormone (CRH). Whereas basal and stimulated serum cortisol levels were within the normal range in the control patient, the index patient showed marked suppression of serum cortisol [<6 nmol/L (normal range 119-618 nmol/l)] and no significant stimulation by CRH within 90 min after application (maximum level 63 nmol/L at 60 min).

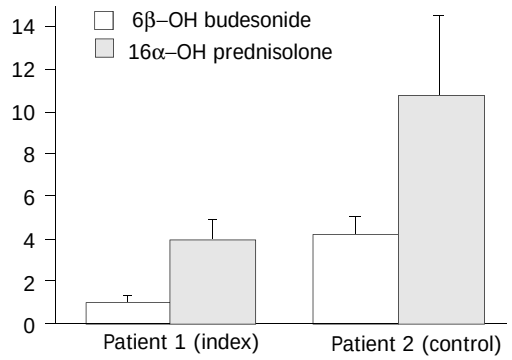

Figure 2 Ratio of metabolites to budesonide. 6β-OH-budesonide and 16α-OH-prednisolone serum levels were determined at the same time points as given in Figure 1. Metabolite-to-drug ratios were calculated and data are given as average ± SEM.

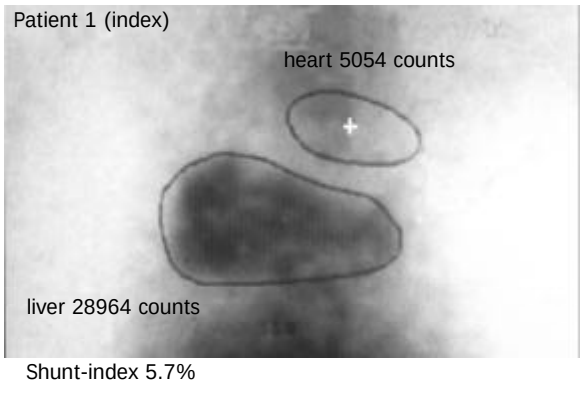
Portosystemic shunt index

To differentiate whether elevated serum budesonide levels were caused by increased portosystemic shunting due to liver cirrhosis, portal hemodynamics were assessed by per-rectal portal scintigraphy with ^{99m}Tc pertechnetate in both patients. In both the index and the control patient measurement of the portosystemic shunt index was 5.7 % and 3.1 %, respectively, which was in the range of healthy subjects (median 4.1 %; 25th percentile 2.8; 75th percentile 6.3 %)[22]. Thus, these data confirmed that no significant portosystemic shunting occurred in both patients (Figure 3).

DISCUSSION

Autoimmune hepatitis is currently treated with systemic administration of prednisolone, which has been shown to improve liver function tests and prolong survival[11-13]. These first-generation glucocorticoids may cause marked side effects in long-term therapy. In order to minimize the systemic bioavailability, a new class of corticosteroids with greater topical anti-inflammatory activity and particularly high first-pass effect in healthy liver was synthesized[24]. Budesonide, a member of this second generation, has a 90 % first pass metabolism in the healthy liver and its metabolites are virtually devoid of systemic side effects[9]. Therefore, it does not reduce peripheral cortisol levels as a measure of systemic effect on adrenal function to the same extent as prednisolone in



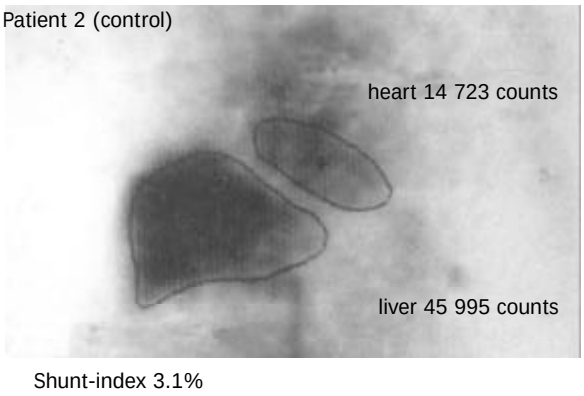


Figure 3 Portosystemic shunt index. Summed images with regions of interest over heart and liver of patients 1 (A) and 2 (B) after per rectal scintigraphy using 340MBq Tc-99m petechnetate.

noncirrhotic patients[24]. However, in a double-blind crossover study in healthy volunteers ileal release budesonide had a greater effect on plasma cortisol levels compared with placebo[25]. In patients with Crohn's disease budesonide reduced the median plasma cortisol concentrations at doses of 9-15 mg/day, whereas median cortisol values in the group given 3 mg/day were not different from placebo[26].

In patients with liver disease, systemic side effects are variable. In patients with primary biliary cirrhosis treated with 9 mg budesonide per day (in addition to UDCA) changes in bone mineral density were not significantly different as compared with pretreatment data and placebo over 2 years in the study by Leuschner *et al*.[16], whereas Angulo and coworkers found a significant loss of bone mass with the same treatment regimen over one year[17]. This difference may be related to the number of patients with PBC stage IV of disease who experienced a significantly greater loss of bone mass in the Angulo study compared with non-cirrhotic patients. Leuschner and coworkers enrolled only patients of PBC stages I to III in this study. Similar findings were obtained in patients with primary sclerosing cholangitis in whom budesonide appears to be of minimal if any benefit and is associated with a significant worsening of osteoporosis[18,19]. Although the drug is considered to be a promising candidate for treatment, only two small uncontrolled studies on budesonide in patients with autoimmune hepatitis have been published to date[20,21]. In parallel with findings in PBC and PSC therapeutic efficacy of budesonide on AIH appeared to be limitied and systemic side effects shown as decreased plasma cortisol levels were noted predominantly in those patients with cirrhosis[15,20]. Although there are no published data on a possible decrease in first pass hepatic metabolism in patients with cirrhosis and consecutive higher incidence of systemic adverse effects, indirect findings such as increased osteoporosis in budesonide-treated patients with more advanced liver disease support this hypothesis[17]. This could be due to reduced hepatic metabolism in the cirrhotic liver or, alternatively, due to increased spontaneous portosystemic shunting in these patients who may have a substantial bypass of the liver.

Portosystemic collaterals develop as chronic hepatitis and cirrhosis progress. Several methods for measurement of portosystemic shunting have been established, of which radio-isotopic imaging after per-rectal ^{99m}Tc administration with determination of the heart-liver ratio (shunt index) is most common[22,27-30]. A cross sectional study using this method has shown an increasing portal shunt index (SI) with progression of various liver diseases[22]. In this study, healthy controls and patients with chronic hepatitis showed shunt indices with medians between 5.9 % and 10 %, respectively. Patients with cirrhosis without esophageal varices had only moderatly increased portosystemic shunt indices with a median of 15 % (25^{th} percentile 9 %, 75^{th} percentile 28 %) whereas those cirrhotics with varices appeared to have dramatically increased shunting with a median SI of 70 % (25^{th} percentile 52 %, 75^{th} percentile 82 %).

Hepatic metabolism and the extent of the portosystemic shunting largely affects the bioavailability of drugs with high first-pass metabolism such as budesonide. To date, there are no data about systemic availability of the drug and its determinants in patients with advanced liver disease. To address this question and to distinguish between reduced hepatic metabolism and portosystemic shunting as the cause of higher bioavailability, we determined the serum levels of budesonide, its two major metabolites and the portal shunt index in two patients. The index patient 1 was compared with an age and sex matched AIH-patient with the same stage of cirrhosis but absent systemic effects as control. Serum levels of budesonide were largely elevated in the index case (1.9±2.1 ng/mL, n=4) compared with the control patient 2 (0.15±0.07 ng/mL, n=4) and historically healthy controls without liver disease (0.4-0.7 ng/mL)[23] (Figure 1). Although 6β-OH-budesonide and 16α-OH-prednisolone serum levels were also elevated 3-fold and 4.4-fold in the index patient as against patient 2, we detected 4-fold decreased metabolite-to-drug ratios for both 6β-OH-budesonide and 16α-OH-prednisolone in the index patient 1 compared with the control patient 2 (Figure 2). Both patients had similar shunt indices which were in the range of healthy subjects (Figure 3). These data demonstrate that an increased systemic bioavailability of budesonide may be rather due to a reduced hepatic metabolizing capacity in patients with early stages of liver disease than portosystemic shunting of an undetectable volume.

In these patients with coexisting malignancies, there is major concern about corticosteroid-related systemic immunosuppression which imposes a substantial risk of recurrance or progression of malignancy on these patients. To our knowledge, there is no report available on steroid therapy in a patient with autoimmune hepatitis and coexisting hepatic malignancy. The present case is the first reported patient with successfull treatment of AIH complicated by HCC. The substantial inflammatory activity in this patient, who had already developed liver cirrhosis, made an anti-inflammatory therapy unevitable to halt progression. In this complex situation between progression to end stage cirrhosis and recurrance of the carcinoma, budesonide seems to be the only therapeutic alternative to minimize both risks. Although low bioavailability and high first pass metabolism of budesonide are observed in healthy volunteers, systemic availability in patients with liver cirrhosis seems to be associated with decreased hepatic metabolism after exclusion of significant portosystemic shunting (Figure 3). In order to minimize systemic immunosuppression with a concommitant risk of recurrant malignancy, we tapered the daily dose from 9 mg to 6 mg per day after systemic side effects appeared. Our present study identified increased systemic budesonide levels due to reduced hepatic metabolism as a risk factor of tumor recurrance in this patient. Therefore, we closely monitored the recurrance of the HCC in short intervals by ultrasound, computed tomography and AFP levels without any signs of recurrant malignancy under budesonide for 36 months.

Whether budesonide becomes standard therapy in autoimmune hepatitis remains to be determined in larger clinical trials. In patients with concommitant malignant disorders, this drug may have the best benefit-to-risk ratio of all immunosuppressants and may be helpful even in patients with reduced hepatic metabolism due to liver cirrhosis. However, these patients have a substantial risk of systemic side effects even in the absence of detectable portosystemic shunting and need to be monitored carefully.

Abstract

AIM: To evaluate the effectiveness and safety of percutaneous hepatic cryoablation in combination with percutaneous ethanol injection (PEI) in patients with unresectable hepaocellular carcinoma (HCC).

METHODS: A total of 105 masses in 65 HCC patients underwent percutaneous hepatic cryoablation. The cryoablation was performed with the Cryocare system (Endocare, Irvine, CA, USA) using argon gas as a cryogen. Two freeze-thaw cycles were performed, each reaching a temperature of -180 ℃ at the tip of the probe. PEI was given in 36 patients with tumor masses larger than 6 cm in diameter 1-2 weeks after cryoablation and then once per week for 4 to 6 sessions. The efficacy was evaluated with survival, change of tumor size and alpha-fetoprotein (AFP) levels.

RESULTS: During a follow-up duration of 14 months in average with a range of 5 to 21 months, 33 patients (50.8 %) were free of tumors, 22 patients (33.8 %) alive with tumor recurrence: two had bone metastases, three were found to have lung metastases, and the remaining 17 recurrences occurred in the liver, of whom only 3 developed a cryosite recurrence. Among the 41 patients who were followed up for more than one year, 32(78 %) were alive despite of tumor recurrence. Seven patients (10.8 %) died due to disease recurrence. Three patients (4.6 %) died due to some noncancer-related causes. Among the 43 patients who had a CT scan available for review, 38 (88.4 %) had a shrinkage of tumor mass. Among the 22 patients who received biopsies of cryoablated tumor mass, all biopsies except one, showed only dead or scar tissues. Of the patients who had an increased AFP preablatively, 91.3 % had a decrease of AFP to normal or nearly normal levels during postablative 3-6 months. Complications of cryoablation included liver capsular cracking in one patient,transient thrombocytopenia in 4 patients and asymptomatic right-sided pleural effusions in 2 patients. Two patients developed liver abscess at the previous cryoablation site at 2 and 4 months, respectively, following cryoablation, and was recovered after treated with antibiotics and drainage.

CONCLUSION: Percutaneous cryoablation offers a safe and possibly curative treatment option for patients with HCC that cannot be surgically removed, and its integration with PEI, may serve as an alternative to partial liver resection in selective patients.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common and lethal cancers. Curative surgical resection of HCC is considered to be the optimal treatment. Unfortunately, only about 10 % of newly diagnosed HCC patients are eligible candidates for resection[1]. Therefore, alternative treatment modalities have been developed, including localized ablative techniques involving either freezing (cryoablation) or chemical desiccation (ethanol ablation)[2].

Cryoablation uses extremely low temperature to destroy tumor tissues, and has been shown to be as effective as surgical resection for treatment of primary or metastatic liver cancer[3]. Percutaneous ethanol injection (PEI) has been reported to be effective against small HCC, but is not eligible for advanced HCC[4]. We employed percutaneous cryoablation in combination with ethanol injection following cryoablation for treatment of unresectable HCC and yielded better results. This paper reports our experience using the combined therapy in 65 HCC patients and evaluates the effectiveness and safety.

MATERIALS AND METHODS

Subjects

Between March 2001 and January 2003, 65 HCC patients underwent combined treatment of percutaneous hepatic cryoablation and PEI. There were 47 men and 18 women. Their ages ranged from 32 to 78 years, with a mean age of 51 years. Sixty patients had histories of heapatitis B infection, and 4 had hepatitis C infection. Informed consents were obtained from all patients undergoing combined therapy.

The diagnosis of HCC in 43 patients was proven by liver pathology, and the remaining cases had HCC diagnosed by classical imagings, including computed tomography (CT), magnetic resonance and ultrasonography, and biochemical markers, such as increased alpha-fetoprotein (AFP). Forty-four patients had only one mass in the liver, being 4.8 cm to 15 cm in diameter with an average of 7.3 cm. Twenty-one patients had 2-4 masses from 6 cm to 14 cm in diameter. There were a total of 105 masses in 65 patients and the average number of masses per patient was 2.6.No patient had evidence of extrahepatic metastases.

All except 2 cases had cirrhosis. Using Child-Pugh' s score in assessing the severity of cirrhosis, 39 patients were classified as class A, and 25 as class B.

Cryoablation procedure

The cryoablation was performed with the Cryocare system (Endocare, Irvine, CA, USA) using argon gas as a cryogen.

Cryoprobes (3, 5 or 8 mm) were inserted into the center of tumor mass under ultrasonographic guidance, and two freeze-thaw cycles were performed, each reaching a temperature of -180 ℃ at the tip of the probe. The time of freezing was dependent on the achievement of an "ice ball", visible as a hypoechoic region by ultrasonography. Generally, the tumor was frozen at a maximum flow rate for about 15 minutes, thawed for 5 minutes and then refrozen for another 15 minutes. A margin of at least 1 cm normal hepatic tissue was frozen circumferentially around the tumor. For the mass larger than 5 cm in diameter, two or three cryoprobes were placed within the center and periphery of tumor respectively, to insure freezing of the entire tumor. Finally, the cryoprobe was removed when the tip temperature reached above 0 ℃, and the tract formed was sealed off with fibrin glue immediately after removal of the cryoprobe to ensure haemostasis.

Alcohol ablation

PEI was administered in 36 patients with tumor masses larger than 6 cm in diameter and was given 1-2 weeks after cryoablation and then once a week for up to 4-6 sessions. Absolute alcohol (100 %) was slowly injected into the peripheral zone of cancerous tissues in liver through a 20-gauge needle under ultrasonographic guidance. The goal of this procedure was to achieve a "black stain" shown by ultrasonography in the tumor tissues. A maximum of 5 ml alcohol was injected per site, with a maximum of 20 ml per session.

Postoperative follow-up

All patients were followed up at monthly intervals. The serum α-fetoprotein (AFP) levels were assayed during each visit. The first CT scanning was performed within one month after cryoablation to detect residual tumor, and then CT scan study was done every 3 months in the initial six months and every 6 months subsequently to detect recurrence.

RESULTS

Disease status and survival

All patients were followed up for a median duration of 14 months with a range of 5-21 months. The disease status of the patients is shown in Table 1. Thirty-three patients (50.8 %) were currently free of tumor with an average follow-up of 13.8 months. Twenty-two patients (33.8 %) were alive with disease recurrence: two had bone metastases, three were found to have lung metastases, and the remaining 17 had recurrences in the liver, of whom only 3 developed a cryosite recurrence. Among the 41 patients who were followed up for more than one year, 32 (78 %) were alive despite of tumor recurrence. Seven patients (10.8 %) died from their tumors, and had recurrence of tumor in the liver remnant at a mean of 7.8 months with an overall survival of 13.2 months. Three patients (4.6 %) died of noncancer-related causes. One died of myocardial infarction,1 died of pneumonia, and 1 died of liver failure,respectively.

Table 1 Disease status

	Number of patients	Percent of patients	Follow-up (months)
Alive free of tumor	33	50.8	16.8
Alive with tumor recurrence	22	33.8	17.2
Died of tumor recurrence	7	10.8	13
Died of noncancer-related diseases	3	4.6	4

Tumor size

Among the forty-three patients who had a CT scan available for review, 38 (88.4 %) had a shrinkage of tumor mass, with an average size of the dominant tumor changing from a preablative size of 7.9 cm (3.7-13.2 cm) to a 3-month postablative size of 5.6 cm (2.1-8 cm). Twenty-two received biopsies of their cryoablated tumor mass under ultrasonography guidance. All biopsies except one, showed only dead or scar tissues.

Serum AFP levels

An increased serum AFP, with a median level of 367 ng/L, ranging from 68 to 1 210 ng/L, was detected in 46 patients preablatively. The AFP levels were lowered to normal or nearly normal range in 42 patients (91.3%) during postablative 3-6 months, and the median AFP level was 59 ng/L with a range of 12-365 ng/L.

Complications

Complications of cryoablation included liver capsular cracking in one patient and recovered after blood transfusion. Transient thrombocytopenia occurred in 4 patients within 1 week following cryoablation, 2 of whom received platelet transfusion. Two patients developed asymptomatic right-sided pleural effusions, both had cancer in the right lobe which was close to the dome of the diaphragm. The pleural effusions disappeared spontaneously within 2-3 weeks. Two patients developed liver abscess at the previous cryoablation site 2 and 4 months respectively following cryoablation, and were recovered after antibiotics and drainage treatment.

The majority of patients receiving PEI had pain at injection site, fever and a feeling of alcohol intoxication, which were transient and subsided with conservative management. No patient experienced an appreciable risk.

DISCUSSION

Prognosis of unresectable HCC is very poor. In Japan, the median survival for 229 patients receiving no specific treatment was 1.6 months[5]. Although chemoembolization is associated with good objective responses in the tumor, a recent controlled trial showed that by itself, chemoembolization offered no improvement in survival compared with supportive therapy alone[6]. During the past years, great efforts have been made to improve the survival of patients with this disease[7]. In this trial, percutaneous cryoablation in combination with PEI showed more satisfactory therapeutic efficacy. Among the 65 HCC patients receiving this combined therapy and followed up for a median duration of 14 months, 50.8 % of the patients are currently free of tumor and 33.8 % are alive with tumor recurrences. Among the 41 patients who were followed up for more than one year, 78 % are alive despite of tumor recurrence. Only 10.8 % died from tumor recurrence with an overall survival for 13.2 months. Of the patients who had CT scan available for review, 88.4 % had a shrinkage of tumor masses. Of the 22 patients who received biopsies of their cryoablated tumor masses, all but one showed only dead tumor cells or scar. Of the patients who had an increased AFP preablatively, 91.3 % had a decrease of AFP to normal or nearly normal levels during postablative 3-6 months.

The present result is comparable with those by other authors. Crews *et al*[8] reported that forty patients with hepatic malignancy underwent cryoablation and the estimated 18-month survival was 60 % and 30 % for patients with HCC and with colorectal metastasis, respectively. Lam *et al*[9] treated 4 patients with recurrent HCC after previous curative hepatectomy with cryoablation. All their patients are still alive with a survival after cryoablation ranging from 12 to 23 months. Sheen *et al*[10] have demonstrated that the median survival for HCC patients after cryoablation was 36 months. Zhou *et al*[11,12]

reported 1-, 3- and 5-year survival rates of 78 %, 54 % and 40 %, respectively in 235 HCC patients who received cryoablation. It should be noted that the cryoablation reported by these authors was mainly performed through intraoperative approach with a large invasion, while in the present trial, cryoablation was performed percutaneously, being minimally invasive and allowing for a rapid recovery.

Cryoablation is a method of *in situ* tumor ablation. A circulated cryogen is used to target tumors to induce irreversible tissue destruction at a temperature below 40 ℃. Tumor cell death is caused by both direct and indirect mechanisms. The direct cellular damage is a result of intra- and extra-cellular ice crystal formation and solute-solvent shifts, which induce cell dehydration and rupture. The indirect effect was found to be resulted from the vessel obliteration which would result in ischemic hypoxia[13,14].

As a local therapy, cryoablation has been found to carry certain advantages over other forms of HCC treatment[15]. First, it is able to destroy only the tumor tissue in liver sparing more noninvolved tissues, which is of important significance to HCC patients, because the majority of these patients would been found to have cirrhosis and decreased reserve of liver function[16]. Second, because of the warming effect of flowing blood, large blood vessels, such as inferior vena cava and portal vein, are somewhat imperious to the effect of freezing. Therefore, tumors close to these venous systems could safely undergo cryoablation, whereas resection of tumors close to large vascular structures would be very difficult[17].Third, it is known that liver cirrhosis is a basis of HCC development, if the entire liver is cirrhotic, any part of the liver can develop new tumors. Liver cryoablation has been found to be more effective than surgical resection in treating multiple new tumors[13]. Forth,in contrast with other local ablations, such as radiofrequency, which are difficult to reliably destroy tumors greater than 5 cm in diameter, cryoablation would be a promising means for the treatment of this larger form of tumor[2]. Lastly, the rapid freeze-thaw process could enhance necrosis and help induce an immune response against the surviving tumor cells[18].

During cryoablation, freezing would occur in three main areas: (1) The center of iceball near the cryoprobe, where freezing would be rapid and the temperature would be lowest. (2) The middle of the iceball, where the tissue experienced intermediate cooling rate. (3) The periphery of the iceball, where slow rates of cooling would occur[18]. The cytotoxic effect from rapid cooling was the greatest in the center of the iceball, while cells at the periphery of the iceball might survive, particularly if the tumor abutted a large intrahepatic blood vessel that abrogated the effects of tissue cooling. The surviving tumor cells would result in recurrence of the disease. PEI has been used extensively for treatment of HCC. Ethanol could diffuse into the tumor cells and cause nonselective protein denaturation and cellular dehydration, leading to coagulated necrosis. Subsequent fibrosis and small vessel thrombosis would also contribute to cellular death. Therefore, after cryoablation which could destroy the majority of tumors, PEI used at periphery of tumor could destroy residue tumor tissues. It is obvious that cryoablation in combination with PEI had a complementary effects on preventing recurrence[18]. In this series, PEI was given to 36 patients with tumor masses larger than 6 cm in diameter 1-2 weeks after cryoablation, that might be contributory to a better outcome. Moreover, among the 17 patients who had recurrent tumors, only 3 had recurrence at the original cryosite, suggesting that the effectiveness of this combined therapy was good.

Cryoablation has been considered as a safe modality[10]. Transient intra-ablative hypothermia is the most common side effects. The use of warming blankets and fluid warmers has been proven beneficial. Transient thrombocytopenia and hypoglycemia have been observed. Patients should be observed for possible coagulopathy when large tumor (greater than 5 cm) has been frozen. Pleural effusions may occur in tumor mass treated close to the dome of the diaphragm. Cracking of the hepatic capsule might occur during the thawing process[13,17,19], which was seen in one patient in this series. It is one of the most serious complications of hepatic cryoablation, and could be controlled with conservative therapies for most of the cases. Cryoshock manifested as varying degrees of acute renal failure, disseminated intravascular coagulation and adult respiratory distress syndrome, was reported[15]. It has been shown that cryoshock occurred in greater than 40 % of the volume of tissue treated, and lesions over 6 cm were associated with a greater risk[17]. However, lesions up to 10 cm in size were treated safely in the present series. This complication might be related more to the total duration of cryoablation than to the volume of tumor tissue treated[10]. Nevertheless, it is necessary to prevent the disastrous complication. Diuresis with mannitol and alkalinization of urine should be used in all patients to avoid myoglobinuria and subsequent renal damage[8]. PEI has been proven safe, and no significant complication was associated with this modality in the present series.

In conclusion, this technique offers the curative treatment option for HCC that cannot be surgically removed due to the anatomic location of the tumor, and the presence of other comorbid conditions that would otherwise preclude a major liver resection. Percutaneous approach has the advantage of a minimal invasion and allows for a rapid recovery and does not produce appreciable complications. The integration of this technique with other adjuvant regional modalities, especially PEI, may be used as an alternative to resection, so as to improve a long-term disease-free survival in selected patients.

Abstract

AIM: The study of immune response of open *versus* laparoscopical total mesorectal excision with anal sphincter preservation in patients with rectal cancer has not been reported yet. The dissected retroperitoneal area that contacts directly with carbon dioxide is extensive in laparoscopic total mesorectal excision with anal sphincter preservation surgery. It is important to clarify whether the immune response of laparoscopic total mesorectal excision with anal sphincter preservation (LTME with ASP) in patients with rectal cancer is suppressed more severely than that of open surgery (OTME with ASP). This study was designed to compare the immune functions after laparoscopic and open total mesorectal excision with anal sphincter preservation for rectal cancer.

METHODS: This study involved 45 patients undergoing laparoscopic (n=20) and open (n=25) total mesorectal excisions with anal sphincter preservation for rectal cancer. Serum interleukin-2 (IL-2), interleukin-6 (IL-6), tumor necrosis factor α (TNF_α) were assayed preoperatively and on days 1 and 5 postoperatively. $CD3^+$ and $CD56^+$ T lymphocyte count, $CD3^-$ and $CD56^+$ natural killer cell (NK) count and immunoglobulin (IgG/IgM/IgA) were assayed preoperatively and on day 5 postoperatively. The numbers of $CD3^+$ and $CD56^+$ T lymphocytes and $CD3^-$ and $CD56^+$ NK cells were counted using flow cytometry. An enzyme-linked immunosorbent assay (ELISA) was used for IL-2, IL-6 and TNF_α determination. And IgG, IgM, and IgA were assayed using immunonephelometry.

RESULTS: The demographic data of the two groups had no difference. The preoperative levels of $CD3^+$ and $CD56^+$ T lymphocyte count, $CD3^-$ and $CD56^+$ NK count, serum IgG, IgM, IgA, IL-2, IL-6 and TNF_α also had no significant difference in the two groups (P>0.05). The $CD3^+$ and $CD56^+$ T lymphocyte counts had no obvious changes after surgery in laparoscopic (d=-0.79±3.83 %) and open (d=0.42±2.09 %) groups. The $CD3^-$ and $CD56^+$ NK counts were decreased postoperatively in both laparoscopic (d=-7.23±11.33 %) and open (d=-9.21±13.93 %) groups. The differences of the determined values of serum IgG, IgM and IgA on the fifth day after operation subtracted those before operation were -2.56±2.14 g/L, -252.35±392.94 mg/L, -506.15±912.24 mg/L in laparoscopic group, and -1.81±2.10 g/L, -282.72±356.75 mg/L, -252.20±396.28 mg/L in open group, respectively. The levels of IL-2 were decreased after operation in both groups. However, the levels of IL-6 were decreased after laparoscopic surgery (d_1=-23.14±263.97 ng/L and d_5=-40.08±272.03 ng/L), and increased after open surgery (d_1=27.38±129.14 ng/L and d_5=21.67±234.31 ng/L). The TNF_α levels were not elevated after surgery in both groups. There were no significant differences in the numbers of $CD3^+$ and $CD56^+$ T lymphocytes and $CD3^-$ and $CD56^+$ NK cells, the levels of IgG, IgM, IgA, IL-2, IL-6 and TNF_α between the two groups (P>0.05).

CONCLUSION: There are no differences in immune responses between the patients having laparoscopic total mesorectal excision with anal sphincter preservation and those undergone open surgery for rectal cancer.

INTRODUCTION

General anesthesia, major surgery, and severe trauma are all known to cause significant inhibition of the immune response[1]. The immunosuppression associated with major surgery is believed to contribute to the increased risk of metastasis and sepsis in the postoperative period[1]. In order to improve the immune response of postoperative patients, minimally invasive surgery has been performed. Reduced hospital stay, less wound pain, earlier resumption of diet and recovery of bowel function are recognized as benefits of laparoscopic cholecystectomy or colectomy[2]. The effects of laparoscopic colorectal surgery on the immune system varied from study to study. Meanwhile, study on immune response of open *versus* laparoscopical total mesorectal excision with anal sphincter preservation in patients with rectal cancer has not been reported yet. The dissected retroperitoneal area that contacts directly with carbon dioxide is extensive in laparoscopic total mesorectal excision with anal sphincter preservation surgery. It is important to clarify whether the immune response of laparoscopic total mesorectal excision with anal sphincter preservation (LTME with ASP) in patients with rectal cancer is suppressed more severely than that of open surgery (OTME with ASP). The aim of this nonrandomized prospective study was to compare the effects of LTME and OTME on immune response.

MATERIALS AND METHODS

Patients selection

From October 2001 to July 2002, 49 patients admitted to the General Surgery Department of West China Hospital with the diagnosis of rectal cancer confirmed by pathology were prospectively evaluated. The criterion for inclusion in the study was patients diagnosed with biopsy as adenocarcinoma of the rectum localized below 15 cm from the anal margin. The criteria for exclusion included age older than 80 years and younger than 18 years, presence of a fixed palpable mass or cancer infiltrating adjacent organs, evidence of metastatic disease, neoadjuvant chemoradiotherapy, severe cardiovascular (New York Heart Association class 3 or more) or respiratory dysfunction, patients with previous abdominal operation, acute intestinal obstruction or perforation, any malignancy within the recent 5 years, synchronous multiple adenocarcinomas and pregnancy, any contraindication to pneumoperitoneum, and patients with unresectable tumor.

Preoperative examinations including flexible endoscopy as well as biopsy, ultrasonography, computed tomography scan, radiography of the chest, etc. were routinely performed. All patients underwent preoperative bowel preparation (1L 10 % mannite electrolyte solution). Prophylactic antibiotics of ciprofloxacin and metronidazole were routinely given orally for three days before operation. A urinary catheter and a nasogastric tube were routinely used.

Data collection

The parameters measured were demographic data, operating time, distance of the tumor from the anal margin, time of first passing flatus, time removing urinary catheter, duration of hospital stay, postoperative complications and death. Demographic data included age, sex, serum total protein (TP), albumin (Alb), hemoglobulin (Hb), weight, and underlying diseases.

Operation techniques

All patients were administrated general anesthesia and operations were carried out in lithotomy position with 15° head-down tilt. Premedication and anesthetic techniques were standardized. Induction was made by intravenous injection of 3-5 mg/kg thiopentone together with fentanyl. Anesthesia was maintained by ventilation with an O_2/N_2O mixture and isoflurane. Operations were performed by surgeons experienced in both laparoscopic and conventional surgeries. The rectal surgery was performed according to the principle of total mesorectal excision (TME)[3,4]. Our laparoscopic techniques were reported previously[5].

Pneumoperitoneum was introduced through subumbilical incision to maintain the pressure at 12-14 mmHg (1 mmHg= 0.133 kPa). Camera port with subumbilical trocar was first created, then one operative port in the right midclavicular line at the level of umbilicus, and other two operative ports in the left and right McBurney point were also created respectively under the guidance of laparoscopic view to facilitate dissection. A laparoscope with 25 or 30 curvy degree was inserted into the abdominal cavity via a subumbilical trocar, following the no-touch technique. Routine exploration was performed to ascertain whether the tumor metastasized to the organs in the abdominal cavity and infiltrated the serosa or implanted in the abdominal cavity. With the operation proceeding of total mesorectal excision, division was moved downward into the pelvis along the anatomic space between visceral and parietal endopelvic fascia. In order to extract the bowel loop of the tumor, the port at the left McBurney' s point was extended to about 3.5 cm long, the tumor was routinely isolated by inserting it into a sheath-shaped bacteria-free plastic bag through the incision, and the tumor as well as the proximal colon were extracted through the bag, and then the bowel was transected at the level of 10-15 cm above upper margin of the tumor. After the anvil of a 29 mm-sized circular stapler was inserted into the end of the proximal bowel and secured with 2/0 prolene purse-string suture, the proximal bowel was internalized and the extended incision was closed. Pneumoperitoneum was then induced again, and laparoscopic colo-anal or colo-rectal anastomosis was performed using a CDH 29 circular stapler.

Immunological studies

Seven milliliters of venous blood were taken by peripheral venipuncture before surgery and on days 1 and 5 after surgery into one plain vacutainer and one heparin vacutainer. The specimens were centrifuged and the collected serum was stored at -20 ℃ for the assay of interleukin-2 (IL-2), interleukin-6 (IL-6) and tumor necrosis factor α (TNF_α). IL-2, IL-6 and TNF_α were assayed preoperatively and on days 1 and 5 postoperatively. $CD3^+$ and $CD56^+$ T lymphocyte count, $CD3^-$ and $CD56^+$ natural killer cell (NK) count and immunoglobulin (IgG/IgM/IgA) were determined preoperatively and on day 5 postoperatively. The numbers of $CD3^+$ and $CD56^+$ T lymphocytes and $CD3^-$ and $CD56^+$ NK cells were counted using flow cytometry (Elite-Esp, Beckman-Coulter, USA). An enzyme-linked immunosorbent assay (ELISA) was used for IL-2, IL-6 and TNF_α determination (Bio-Rad system, Immune Company, France), and immunoglobulin (Ig) G, IgM, and IgA were assayed using immunonephelometry (Immage analyzer, Beckman-Coulter, USA).

Statistics analysis

All the data were collected on designed forms, and analyzed with SPSS version 10.0 software. The differences of the determinated values on fifth or first postoperative day subtracted those before operation were compared between laparoscopic and open groups. Student' s *t* test was used for quantitative variables and chi-square test for qualitative variables. All *P* values were two sided. Statistical significance was established as $P<0.05$. The data were expressed as mean ± standard deviation (SD).

RESULTS

A total of 49 patients were entered into the study. Four patients did not meet the eligibility criteria for the trial (three in laparoscopic group and one in open). Three were found to have hepatic metastasis and one did not receive resection because the cancer infiltrated several adjacent organs.

Patient characteristics

The demographic features of the patients are shown in Table 1. The two groups had no differences with respect to age, gender, TP, Alb, Hb, weight and Duke' s classification ($P>0.05$).

Surgical treatment

Table 2 shows the results of the two treatments. All the 45 patients received the curative anterior resection with total mesorectal excision, and the low/ultralow/colo-anal anastomosis was performed by laparoscopic or open surgery. In laparoscopic group, no one required conversion to open surgery.

There was no surgical death in both groups. Operation time was significantly longer in the laparoscopic group than that in the open group (226.75±46.15 min *versus* 146.40±38.09 min, $P<0.05$). The time of first passing flatus in laparoscopic group was significantly shorter than that in the open group (3.15±1.14 min *versus* 4.36±1.19 min, $P<0.05$). There were

no differences in time of removing urinary catheter, duration of hospital stay and distance of tumor from anal margin between the two groups (P>0.05).

The two groups of patients had comparable preoperative underlying diseases. As for the postoperative complications, one patient in the open group had anastomotic leakage and one in the same group experienced wound infection, both of them were successfully treated conservatively. There was no postoperative complication in the laparoscopic group. There were no local recurrence, port site recurrence, and mortality in any patients observed during follow-up ranged from 8 to 17 months.

Immune response

As expected, the preoperative levels of $CD3^+$ and $CD56^+$ T lymphocyte count, $CD3^-$ and $CD56^+$ NK count, serum IgG, IgM, IgA, IL-2, IL-6 and TNF_α had no difference in the two groups (Table 3, P>0.05).

Table 3 Preoperative immune indicators of two groups (mean ±SD)

	LTME n=20	OTME n=25	P value
$CD3^+$ $CD56^+$ T (%)	4.56±5.08	3.74±4.19	0.556
$CD3^-$ $CD56^+$ NK (%)	20.87±13.76	25.41±16.79	0.335
IgG (g/L)	11.50±2.41	12.61±2.90	0.178
IgM (mg/L)	1 407.40±420.27	1 582.40±735.41	0.350
IgA (mg/L)	2 726.40±2 048.28	2 380.16±928.99	0.454
IL-2 (ng/L)	85.20±303.81	128.30±387.12	0.686
IL-6 (ng/L)	88.70±231.52	49.06±81.63	0.429
TNFα(ng/L)	7.69±5.71	12.99±26.61	0.387

Table 4 shows the differences of the values of IL-2, IL-6 and TNF_α on the fifth or first postoperative day subtracted those before operation, respectively. The TNF_α levels were not elevated after surgery, and there were no significant differences between the two groups (P>0.05). However, the levels of IL-6 were decreased after laparoscopic surgery (d_1=-23.14±263.97 ng/L and d_5=-40.08±272.03 ng/L), but there were no significant differences between the laparoscopic and open groups (P>0.05). The levels of IL-2 were decreased after operation in both groups, the differences were no significant in postoperative days between the two groups (P>0.05).

Table 4 Changes of IL-2, IL-6 and TNF_α after surgery in two groups (mean ±SD)

		LTME n=20	OTME n=25	P value
IL-2(ng/L)	d_1	-80.54±304.30	-98.82±412.38	0.869
	d_5	-27.55±344.29	-33.59±560.20	0.967
IL-6(ng/L)	d_1	-23.14±263.97	27.38±129.14	0.405
	d_5	-40.08±272.03	21.67±234.31	0.418
TNFα (ng/L)	d_1	2.23±12.78	-1.01±7.82	0.301
	d_5	1.84±12.84	0.56±9.86	0.705

(d_1=the differences of the values of IL-2, IL-6 and TNF_α on the first postoperative day subtracted those before operation, respectively. d_5= the differences of the values of IL-2, IL-6 and TNF_α on the fifth postoperative day subtracted those before operation, respectively).

Table 5 shows the differences of the values of $CD3^+$ and $CD56^+$ T lymphocyte count, $CD3^-$ and $CD56^+$ NK count, and serum IgG, IgM, and IgA on the fifth postoperative day from those before operation, respectively. There were no significant differences of $CD3^+$ and $CD56^+$ T lymphocyte count, $CD3^-$ and $CD56^+$ NK count, and serum IgG, IgM, and IgA levels after surgery between the two groups (P>0.05).

Table 5 Changes of $CD3^+$ $CD56^+$ T lymphocyte count, $CD3^-$ $CD56^+$ NK count, and serum immunoglobulin after surgery in two groups (mean ±SD)

	LTME n=20	OTME n=25	P value
$CD3^+$ $CD56^+$ T lymphocyte (%)	-0.79±3.83	0.42±2.09	0.214
$CD3^-$ $CD56^+$ NK (%)	-7.23±11.33	-9.21±13.93	0.609
IgG (g/L)	-2.56±2.14	-1.81±2.10	0.248
IgM (mg/L)	-252.35±392.94	-282.72±356.75	0.787
IgA (mg/L)	-506.15±912.24	-252.20±396.28	0.216

Numbers listed were the differences of the values of $CD3^+$ $CD56^+$ T lymphocyte count, $CD3^-$ $CD56^+$ NK count, and serum IgG, IgM, IgA on the fifth postoperative day subtracted those before operation, respectively.

DISCUSSION

Rectal cancer is the common malignance in our country. Studies on rectal cancer have made great progresses both in clinical practice[6-15] and in theoretical basis[16-26] during the latest years. Multiple clinical studies have demonstrated the correlation of high pelvic recurrence with the degree of mesorectal excision[27]. Residual mesorectum, especially inadequate excision of distal mesorectum (DMR), contributed to poor oncologic outcomes. In order to reduce the rate of local recurrence in the pelvis of rectal carcinoma, total mesorectal excision (TME) has been performed in many colorectal surgery centers. TME has been applied in clinical practice, and the local recurrence rate has decreased dramatically to 5-7.1 %[28,29],

while the mean local recurrence rate of conventional operative procedure for treatment of rectal cancer remained 18.5 %. TME has been claimed to improve not only local recurrence rate, but also long term survival[30-34]. With the improvement of laparoscopic technique, laparoscopic colorectal surgery has been attempted in many countries[4,35-39]. The laparoscopic colorectal surgery has been proposed to be less traumatic than open surgery. It has been demonstrated that laparoscopic-assisted colectomy has many advantages during immediate postoperative period over the open colectomy with regard to the disappearance of postoperative ileus, fewer analgesia, early ambulation, less postoperative complications, and shorter hospital stay[4,35-39]. In this study, the time of first flatus in the laparoscopic group was significantly shorter than that in the open group.

Some randomised clinical trials of open versus laparoscopically assisted colectomy on systematic immunity in patients with colorectal cancer have been performed. Delgado *et al*[40] found that the plasma levels of cortisol and prolactin were higher in postoperative period, but no significant differences were observed between both groups of the patients. The level of interleukin-6 was higher with significant differences at 4, 12 and 24 hours in the patients undergone open colectomy than that in laparoscopic group. The plasma level of C-reactive protein (CRP) was significantly lower at 72 hours in patients receiving laparoscopic-assisted colectomy than that in patients receiving open one. They suggested that acute phase systematic response was attenuated in patients undergone laparoscopic-assisted colectomy in comparison with those undergone open colectomy. Leung *et al*[41] clarified tissue trauma as reflected by systematic cytokine response, such as interleukin-1β, interleukin-6 and CRP, was less after laparoscopic resection than after open resection of rectosigmoid carcinoma. Nishiguchi *et al*[42] showed that interleukin-6 and CRP levels were significantly higher in the open group than those in the laparoscopic group one day and two days after surgery, respectively. Lymphocyte counts were significantly higher in the laparoscopic group than those in the open group two days after surgery. They concluded that laparoscopic surgery for colorectal carcinoma led to less postoperative stress than conventional open surgery. Some researchers verified that the levels of serum IL-2, CRP, and TNF_α were significantly lower after surgery in the laparoscopic group than those in the open group[43-45]. Braga *et al*[46] also found that laparoscopic colorectal surgery was associated with less pronounced immunosuppression and inflammatory response and lower consumption of analgesic drugs than open surgery. But Tang *et al*[47] and Mehigan *et al*[48] showed that there was no difference in the systematic immune response in patients having laparoscopically assisted colectomy compared with those undergone conventional open surgery for colorectal cancer. Sandoval *et al*[49] also revealed that the laparoscopic surgery did not affect natural antitumoral cellular immunity in an animal model. Moreover, Fukushima *et al*[50] found that serum IL-6 after surgery was significantly higher in laparoscopic sigmoid colectomy than in the open group. They proposed that early IL-6 response after surgery be associated with operation time.

Previous immune response studies were only performed in colorectal surgery. However, the study on immune response of open *versus* laparoscopical total mesorectal excision with anal sphincter preservation in patients with rectal cancer has not been reported yet. The dissected retroperitoneal area that contacted directly with carbon dioxide was extensive in laparoscopic total mesorectal excision with anal sphincter preservation surgery. It is important to clarify whether the immune response of laparoscopic total mesorectal excision with anal sphincter preservation in patients with rectal cancer is suppressed more severely than that of open surgery or not. In this study, TNF_α levels were not elevated after surgery, and there were no significant differences between the two groups (P>0.05). However, the levels of IL-6 were decreased after laparoscopic surgery (d_1=-23.14±263.97 ng/L and d_5=-40.08±272.03 ng/L), but there were no significant differences between the laparoscopic and open groups (P>0.05). The levels of IL-2 were decreased after operation in both groups, and the differences were not significant in postoperative days between the two groups (P>0.05). There were no significant differences in $CD3^+$ and $CD56^+$ T lymphocyte count, $CD3^-$ and $CD56^+$ NK count, and serum IgG, IgM, and IgA levels after surgery between the two groups (P>0.05). Based on the results of our study, it is concluded that there is difference in immune responses in patients having laparoscopic total mesorectal excision with anal sphincter preservation compared with those undergone open surgery for rectal cancer.

Abstract

AIM: To investigate the association of hepatitis B virus (HBV) genotype and HBeAg seroconversion after nucleotide analogue treatment.

METHODS: Chronic hepatitis B patients receiving lamivudine followed up for at least 6 months post-treatment were studied. Consecutive treatment-naïve patients who were prospectively followed up in the clinic for at least 18 months were studied as controls. HBeAg seroconversion was defined as loss of HBeAg, appearance of anti-HBe and normalization of alanine aminotransferase for at least 6 months.

RESULTS: Thirty-five patients on lamivudine and 96 control patients followed up for 39 (18-49) months were studied. Lamivudine was given for 12 (10-18) months, and patients were followed up for 15 (6-34) months after drug cessation. Genotype B and C HBV were found in 43 and 88 patients and HBeAg seroconversion occurred in 12 (28 %) and 16 (18 %) patients, respectively (P=0.30). There was no difference in HBeAg seroconversion between patients infected by genotype B and C HBV in the control (35 % *vs* 21 %, P=0.25) and lamivudine-treated (14 % *vs* 10 %, P=1.00) groups.

CONCLUSION: HBeAg seroconversion after treatment by lamivudine was not influenced by the HBV genotype.

INTRODUCTION

Hepatitis B virus (HBV) has 7 different genotypes (A-G) according to the homogeneity of the viral sequence[1,2]. In Southeast Asia including Hong Kong, genotype B and C HBV are the predominant species[3-6]. There are increasing evidences showing that genotype C HBV is associated with a more aggressive disease as compared with genotype B HBV[3,7-10]. A recent Japanese study suggests that HBV genotype is not associated with the development of lamivudine resistance after a median of 1.8 years of treatment[11]. However, data on the association of HBV genotype and HBeAg seroconversion response to anti-viral treatment is scanty. This information is potentially important in the selection of patients for anti-viral treatment and development of future therapeutic regimens as in the case of chronic hepatitis C.

Previous studies suggest that genotype B HBV is associated with a higher rate of HBeAg seroconversion versus genotype C HBV among patients receiving interferon treatment[12,13]. This finding, however, cannot be extrapolated to nucleos(t)ide analogues which have completely different mechanisms of action as compared with interferon. A study including 31 Taiwanese HBeAg-positive chronic hepatitis B patients treated by lamivudine does not show any difference in HBeAg seroconversion between patients infected by genotype B and C HBV[14]. This study is limited by the small number of patients and the absence of control group. Phase III, multi-centered studies on adefovir dipivoxil reveal no difference in viral load reduction among patients infected by different HBV genotypes, but both HBeAg-positive and HBeAg-negative patients are included and HBeAg seroconversion has not been studied[15]. In this study, we aimed to investigate the association of HBV genotype and HBeAg seroconversion after treatment by lamivudine, and a control group of untreated HBeAg-positive chronic hepatitis B patients was included for comparison.

MATERIALS AND METHODS

Patients on anti-viral treatment

Clinical data and stored serum samples of patients on lamivudine treated in Prince of Wales Hospital from 1998 to 2000 were included for analysis. These patients had positive hepatitis B surface antigen (HBsAg) for at least 6 months and positive hepatitis B e antigen (HBeAg), HBV DNA >1 000 000 copies/ml by DNA cross-linking assay (NAXCOR XLnt™, NAXCOR, Menlo Park, CA) or branched DNA assay (bDNA, Chiron Diagnostic, Emeryville, CA) before treatment[16]. None of these patients had evidence of liver cirrhosis complications, hepatocellular carcinoma (HCC) or co-infection by hepatitis C or human immunodeficiency viruses. All patients received lamivudine 100 mg daily. HBeAg seroconversion was defined as loss of HBeAg, appearance of antibodies to HBeAg (anti-HBe) and normalization of ALT at the end of anti-viral treatment and the response sustained for at least 6 months after cessation of treatment till the last follow-up visit.

Control patients

Consecutive chronic hepatitis B patients with positive HBeAg at the initial clinic visit recruited since 1997 in our hospital were studied as controls[3,17]. Patients who had previously received interferon or anti-viral treatment, liver cirrhosis complications and HCC were excluded from the study. To match the follow-up duration of patients treated by nucleoside analogues, patients who were followed up for less than 18 months were also excluded. All patients were followed up every 6 months, or more frequently as clinically indicated, with monitoring of HBeAg status and liver biochemistry. HBeAg

seroconversion was defined as sustained loss of HBeAg, appearance of anti-HBe and normalization of ALT during the follow-up period lasting for at least 6 months till the last visit.

HBV genotyping

The baseline samples of patients in clinical trial before starting anti-viral treatment and the serum samples at the first clinic visits of control patients were studied for HBV genotyping by restriction fragment length polymorphism as described previously[7,18]. In short, extracted HBV DNA was amplified by polymerase chain reaction (PCR) using primers flanking the HBV genome between nucleotide 256 to 796 (sense primer 5' -GTGGTGGACTTCTCTCAATTTTC and anti-sense primer 5' -CGGTA(A/T)AAAGGGACTCA(A/C)GAT). PCR product was then mixed and incubated with restriction enzymes *Tsp 5091* (New England Biolabs, Beverly, MA) and *HinfI* (Boehringer Mannheim, Mannheim, Germany) respectively. The samples were run on agarose gel and DNA was visualized by ethidium bromide staining. The restriction pattern was read accordingly.

Statistical analysis

Results were expressed as median (range). Data were analyzed using SPSS version 11.0 software package. Categorical variables were compared by Chi-square test and continuous variables were compared by Mann-Whitney U test. Proportion of patients developing HBeAg seroconversion in different HBV genotypes were also compared after adjustment of potential confounding variables with P value <0.1 by logistic regression analysis. All tests were two-tailed. Statistical significance was taken as $P<0.05$.

RESULTS

Thirty-five patients on lamivudine and 96 control patients were identified. The clinical data and viral genotype of the studied patients of two groups of patients are shown in Table 1. Lamivudine was given for 12 (10-18) months and the treated patients were followed up for 15 (6-34) months after the cessation of lamivudine. Only 1 of 35 lamivudine-treated patients had been treated for 10 months whereas the remaining patients had treatment for at least 12 months. All patients who did not achieve HBeAg seroconversion after lamivudine treatment developed biochemical relapse with ALT elevation after cessation of lamivudine. The 24 control patients who achieved sustained HBeAg seroconversion were followed up for 24.5 (8-40) months after the development of HBeAg seroconversion. Patients on lamivudine were significantly older with higher initial ALT levels and shorter follow-up duration as compared with the controls. There was no difference in the distribution of HBV genotypes and the percentage of HBeAg seroconversion between the treated and control patients.

Table 1 Clinical characteristics of patients on anti-viral treatments and controls

	Overall (n=131)	Controls (n=96)	Lamivudine (n=35)	P value
Age	30 (12-68)	29 (12-68)	38 (22-47)	0.007
Male gender (n, %)	75 (57 %)	50 (52 %)	25 (71 %)	0.074
Initial ALT (IU/l)	73 (17-1122)	57.5 (17-753)	135 (36-1122)	<0.001
Follow-up (months)	39 (18-49)	39 (19-49)	27 (18-46)	0.009
Genotype				0.40
B (n, %)	43 (33 %)	29 (30 %)	14 (40 %)	
C (n, %)	88 (67 %)	67 (70 %)	21 (60 %)	
HBeAg seroconversion (n, %)	28 (21 %)	24 (25 %)	4 (11 %)	0.15

Forty-three (33 %) and 88 (67 %) patients were infected by genotype B and C respectively. The clinical characteristics of patients infected by genotype B and C HBV are shown in Table 2. There was no difference in the age, gender ratio, initial ALT levels, follow-up duration and drug treatment between patients infected by the two HBV genotypes. There was no difference in HBeAg seroconversion among patients infected by the 2 HBV genotypes, and the overall trend was confirmed after adjusted for age, gender ratio, initial ALT level and the follow-up duration (Table 3).

Table 2 Clinical characteristics of patients infected by genotype B and C HBV

	Genotype B (n=43)	Genotype C (n=88)	P value
Age	34 (13-67)	29 (12-68)	0.14
Male gender (n, %)	28 (65 %)	47 (53 %)	0.28
Initial ALT (IU/l)	70 (17-1094)	77 (18-1122)	0.60
Follow-up (months)	38 (18-49)	39 (18-49)	0.49
Treatment (n, %)			0.40
Nil	29 (67 %)	67 (76 %)	
Lamivudine	14 (33 %)	21 (24 %)	

Table 3 Comparison of HBeAg seroconversion among patients infected by genotype B and C HBV

HBeAg seroconversion	Genotype B	Genotype C	P value 1	P value 2
Control	10/29 (35 %)	14/67 (21 %)	0.25	0.41
Lamivudine	2/14 (14 %)	2/21 (10 %)	1.00	0.51

P value 1: unadjusted comparison of genotype B versus genotype C; P value 2: comparison of genotype B versus genotype C after adjustment for age, gender, initial ALT levels and follow-up duration.

DISCUSSION

The results of this study concurred with previous data that HBV genotype could not predict HBeAg seroconversion after 1 year treatment of lamivudine. The percentages of patients infected by genotype B and C HBV undergoing HBeAg seroconversion were similar among the treatment and control groups.

In the previous study in Taiwan, the proportion of patients achieving HBeAg seroconversion after lamivudine treatment was similar between genotype B and C HBV[14]. However, genotype B HBV was reported to associate with earlier spontaneous HBeAg seroconversion by several series[9,10]. It was therefore uncertain whether there was really no difference in lamivudine response between the 2 HBV genotypes or the improved response of genotype C HBV has closed up the existing difference. In this study, a control group of untreated patients was included in the analysis. As the control group was not recruited together with the treated patients in a randomized manner, it was not surprising that untreated patients were generally younger and had lower ALT levels than the treated ones. In this study, the absence of association between HBV genotypes and HBeAg seroconversion among patients treated by nucleotide analogues was confirmed as there was no difference in HBeAg seroconversion between the 2 HBV genotypes in both the treated groups and the control group after adjustment for all the differences between the two groups.

The earlier age of spontaneous HBeAg seroconversion associated with genotype B HBV reported by recent longitudinal studies was not shown in this study[9,10]. Patient recruitment in the previous studies may be biased as one of them was a retrospective study and the other included only

patients who have consented for liver biopsy. The consecutive patient recruitment and prospective follow-up in our series has minimized the bias of sampling. Although the age of spontaneous HBeAg seroconversion did not differ between the 2 HBV genotypes, our previous studies agreed with others that genotype C HBV is associated with a more aggressive disease course than genotype B HBV[3,7].

In this study, the rate of HBeAg seroconversion was comparable between the treated and untreated patients. The rate of HBeAg seroconversion after 1 year of lamivudine treatment was comparable to that reported in the previous multicenter Asian lamivudine trial[19]. The rate of spontaneous HBeAg seroconversion (25 % in 3 years) was also comparable to previous reported Asian series after taken into consideration the young age and relatively lower ALT level of the control patients in this study[20,21]. As patients in the control group were followed up for longer duration and some of these patients might have milder disease as compared with the treated patients, the effect of treatment could not be concluded by the results of this study. This study was also not designed to assess the predictive factor of treatment response to the nucleoside analogues.

In conclusion, the results of this study did not support a role of HBV genotype in response to lamivudine among HBeAg-positive patients. Further studies are required to probe into the association of HBV genotypes and treatment response in other geographical locations where other HBV genotypes prevail.

Abstract

AIM: To investigate the effect of N-acetyl cysteine (NAC) on acute viral hepatitis (AVH).

METHODS: We administered 200 mg oral NAC three times daily (600 mg/day) to the study group and placebo capsules to the control group. All patients were hospitalized and diagnosed as AVH. Blood total and direct bilirubin, ALT, AST, alkaline phosphatese, albumin and globulin levels of each patient were measured twice weekly until total bilirubin level dropped under 2 mg/dl, ALT level under 100 U/L, follow up was continued and then the patients were discharged.

RESULTS: A total of 41(13 female and 28 male) AVH patients were included in our study. The period for normalization of ALT and total bilirubin in the study group was 19.7±6.9 days and 13.7±8.5 days respectively. In the control group it was 20.4±6.5 days and 16.9±7.8 days respectively ($P>0.05$).

CONCLUSION: NAC administration effected neither the time necessary for normalization of ALT and total bilirubin values nor duration of hospitalization, so we could not suggest NAC for the treatment of icteric AVH cases. However, our results have shown that this drug is not harmful to patients with AVH.

INTRODUCTION

Acute viral hepatitis (AVH) is an infectious disease that occurs as liver cell necrosis and inflammation as a result of the infection of liver cells by various viruses[1,2]. Its significant symptoms and alterations occur in the liver and its functions[3,4]. It is accepted that AVH is a liver disease with the highest incidence in the world and that it is a major cause of jaundice[5]. It is a public health problem in developing countries which include our country as well. Moreover, hepatitis B and C may lead to chronic hepatitis, cirrhosis and cancer, and also constitute an endemic health problem for the society and is a cause of serious economic loss[6,7]. Various medications have been tried in the treatment of acute viral hepatitis, but no superiorities to placebo was demonstrated in most of these medications and they were not recommended for routine use[8-9].

NAC (N-acetyl cysteine) is frequently used as a mucolitic and as an antidote in paracetamol intoxication[10-11]. NAC may maintain cell integrity by increasing the amount of glutathione within the cell or coming into direct reaction with spontaneous conjugation and/or reduction[12]. Recently, some studies have shown good results and absence of side effects in patients treated with interferon and NAS in chronic hepatitis C patients[13-15]. In addition, treatment of HBV-producing cell lines with NAC resulted in an at least 50-fold reduction of viral DNA in the tissue culture supernatant within 48 hours[16]. The need for a treatment to shorten duration of AVH is obvious, but it has not been found yet. We thought this problem might be solved with NAC which protects the cellular architecture by increasing the amount of intracellular glutathione that reacts with toxic free oxygen radicals[17].

We could not find any study that focused on the effects of NAC on acute viral hepatitis. For this reason, we aimed to determine the effect of NAC on acute hepatitis in this study.

MATERIALS AND METHODS

In this study, 41 acute viral hepatitis A or B cases were included. These cases were hospitalized and monitored in the Infectious Diseases Department Cerrahpasa Faculty of Medicine, Istanbul University.

Those aged 14-60 years, with transaminase values more than 10 times of the upper limit of the normal value (>400 U/L), total bilirubin values above 3 mg/dl and positive antiHBc-IgM or antiHAV-IgM detected in serological examinations and negative serologic tests for hepatitis C virus, hepatitis D virus and HIV were included. Serological tests were done for HBsAg, HBcIgM, antibody to Hepatitis C virus (Abbott Lab.) and antibody to hepatitis delta virus (Anti-HDV, Wellcozyme, Wellcome Diagnostic, England) using the EIA method.

The cases who were hospitalized and monitored in the clinic were randomized into study group (20 patients) and control group (21 patients). Randomization was carried out according to age, gender and etiological agents. In the study group, 200 mg NAC was given orally 3 times a day (600 mg/day). In the control group, placebo was given orally 3 times a day.

The study protocol was approved by the local ethics committee. All patients were informed to participate in by an inscription form in the study.

Levels of the biochemical parameters [total and direct bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase, albumin and globulin levels and prothrombine activities] were monitored in both drug and control groups. This monitoring process continued until the level of total serum bilirubin reached 2 mg/dl and the ALT level fell below 100 U/L. Then the patients were discharged from the hospital. All patients were followed up for six months after discharge.

In evaluating the results of the study, Student' s *t* test was used for average age, gender, values concerning the etiologic agents and covariate analysis tests were used for biochemical

parameters, averages of hyperbilirubinemia, ALT, and time needed before they reached normal values.

RESULTS

A total of 41 patients (28 female /13 male) were included in the study. The median age was 24 (range: 15-52). The median age of hepatitis A patients was 17 (range: 16-28) and that of hepatitis B patients was 26 (range: 15-52).

The median age was 23 (range: 15-48) in the study group and was 24 (range: 16-52) in the control group (P>0.05). Patients with HAV infection were younger than those with HBV infection. In the serological distinction of the cases, type A was detected in 9 (22 %) and type B in 32 (78 %). In study group type A was detected in 4, type B was detected in 16. In control group type A was detected in 5 (23 %) and B in 16 (76 %).

In our study, the most important finding was the time needed for ALT and total bilirubin to reach normal. The criteria used to include a case in our study was ALT value that was ten times higher than the normal and the criteria used to end the surveillance of a case was its falling below 100 U/L. Jaundice was defined as the situation in which the serum total bilirubin level was higher than 3 mg/dl. Period of jaundice was defined as the duration that ended when the increasing bilirubin decreased to 2 mg/dl.

The period for normalization of ALT in study group was 19.7±6.9 days (type A 11.2±6.1 days, type B 21.8±6.1 days), while in the control group it was 20.4±6.5 days (type A 16±7.4 days, type B 21.8±6.7 days). The period for normalization of total bilirubin in the study group was 13.7±8.5 days (type A 7.9±4.9 days, type B 15.2±8.6 days), in control group was 16.9±7.8 days (type A 7.9±4.9 days, type B 18.4±8.1 days). No significant difference could be found between the two groups (P>0.05). These data are summarized in Table 1.

As a conclusion, the hospitalization duration and time to normalization of ALT and total bilirubin of the patients did not get shorter or longer (as an adverse effect) with the use of NAC.

Table 1 Comparison of study and control groups

	Study group	Control group
Case number	20	21
Median Age (min -max) (year)	23 (15-48)	24 (16-52)
Genus (M / F)	12 / 8	16 / 5
ALT (U / L)	1 730±628	2 129±1 278
AST (U / L)	987±545	1 397±1 002
ALP (U / L)	488±201	410±149
Total bilirubin (mg / dL)	7.75±4.36	10.1±3.04
Direct bilirubin (mg / dL)	5.29±3.14	7.17±3.26
Activity of prothrombin (%)	72.6±22.7	74.1±18.9
Albumin (g / dL)	3.95±0.54	3.98±0.40
Type of hepatitis (A / B)	4 / 16	5 / 16
Time consumption for ALT <100 U / L	19.7±6.9	20.4±6.5
Time consumption for total bilirubin <2 mg / dl	13.7±8.5	16.9±7.8

DISCUSSION

Virus hepatitis is an important health problem in the world. Hepatitis A is a common infection in our country, so is in the world and 50 % of the population aged up to 15 and 90 % of the adults are exposed to this disease[18]. Annual disease reporting was approximately 25 000 according to the data of the Ministry of Health in Turkey[19]. However it was believed that the real number of the cases was at least 250 000-500 000 per year, when the unreported cases and anicteric and subclinical cases were added[20,21].

When AVH displays a symptomatic presentation, it is generally cured at the end but after a long course. It is a public health problem in developing countries which include our country as well. Hepatitis B, C, D viruses causing AVH may lead to cirrhosis and cancer, and also constitute an endemic health problem for the society and are the cause for serious economic losses[22,23]. Various medications including steroids, interferon, vidarabine, levamizol, ursodeoxicolic acids, *ribavarine* have been tried in the treatment of acute viral hepatitis, but advantages over placebo offered by most of these medications were not found to be good enough to be recommended for routine use[24,25]. Thus the gap in the treatment of AVH has not been filled yet. We thought that this gap could be filled by NAC.

NAC is frequently used as mucolitic and as an antidote for paracetamol intoxication. It was used in paracetamol intoxication as it could fill the mitochondrial and cytosolic glutathione stocks consumed by N acetyl benzoquinoneimine, which is a paracetamol metabolite, by stimulating glutathione synthesis[26]. Under physiological conditions, there is basal glutathione outrun from the liver into the blood. It has been observed that intracellular glutathione participated in some critical physiological activities such as provision of membrane and cell skeleton unity, arrangement of enzyme activities and biosynthesis of protein and nucleic acids[8,13]. It might also lead to serious decreases in the intracellular and tissue glutathione and heavy pathological transformations in this tissue[9,10].

Recently, some studies have shown good results and absence of side effects in patients treated with NAC in hepatitis B and chronic hepatitis C patients[13]. Addition of NAC which is a glutathione precursor, to 14 patients with chronic hepatitis C and high ALT level, caused a regular decrease of ALT in all patients and after a combined treatment it helped 41 % of the cases to heal completely after 5- 6 months. Consequently, it was reported that NAC increased interferon response in patients with hepatitis C[14]. Recently Neri *et al*. reported the presence of oxidative stress in patients with chronic hepatitis C, earlier relapse in patients treated with interferon alone. They obtained significant results in patients treated with interferon plus NAC compared to those with interferon alone[13]. Weiss *et al*. showed that NAC was able to inhibit hepatitis B virus (HBV) replication, by a mechanism independent of the intracellular level of reactive oxygen intermediates. Treatment of HBV-producing cell lines with NAC resulted in an at least 50-fold reduction of viral DNA in the tissue culture supernatant within 48 h. This decrease of viral DNA and thus of virions in the tissue culture supernatant was caused by a disturbance of the virus assembly, rather than by a reduction of viral transcripts. Their data strongly suggested a potential use of this well-established, non-toxic drug for the treatment of HBV infection. They found that NAC, in contrast to interferon, exerted its anti-HBV activity at a posttranscriptional level, a combination of NAC with the established interferon therapy could also be suggested.

We conducted a comparative study to examine the effects of NAC on the functions of liver in AVH. Taking the disease period as the period in which the ALT value came back to normal, we measured the duration of this period in the study group and control group. We also examined the effect of NAC on the period of jaundice. AST, ALT and serum bilirubin measurements were among the tests that were not specific in the diagnosis of AVH, and these were parameters in harmony with the hepatocellular injury. In AVHs, transaminases had diagnostic value, rather than prognostic value. It was accepted that in AVH, these enzymes increased 10 times, ALT maintained to be higher than AST and then it decreased in an evident way in the first week, then it came back to normal in 2- 4 weeks.

In AVH infections, the value of total serum bilirubin increased up to 3-20 mg/dl in 1-2 weeks under normal conditions and although serum aminotransferases levels started to fall, bilirubin levels might continue to increase, then they gradually decreased. In the study and control groups, total bilirubin levels were 7.75±4.36 mg/dl and 10.1±3.04 mg/dl respectively. The average period of jaundice was 13.7±8.5 days in the study group, and 16.9±7.8 days in the control group (P>0.05).

During ALT, AST, bilirubin values came back to normal in the study and control groups, the patients with hepatitis A and B infection were evaluated separately, the difference was not statistically meaningful. The curves of AST and ALT in the study and control groups were not statistically different (Figures 1 and 2). Thus it became obvious that NAC did not change the liver enzyme activities in the patients with AVH.

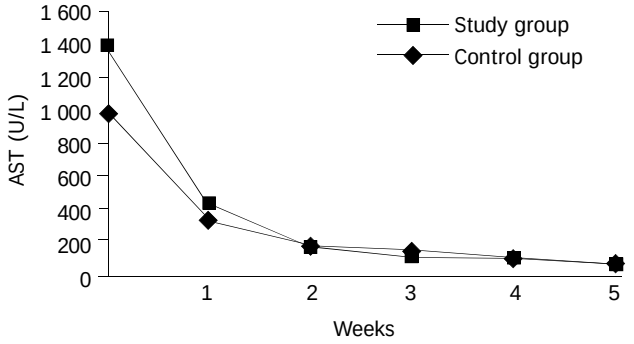

Figure 1 Changes in averages of ALT values in the study and control groups in time.

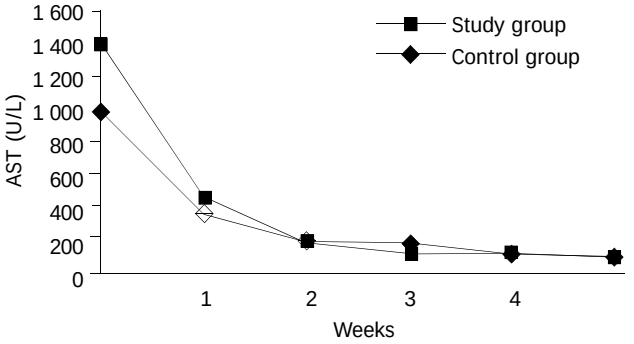

Figure 2 Changes in averages of AST values in the study and control groups in time.

This was the first study investigating the effect of NAC on AVH. In this study, it was determined that NAC had no effect on the jaundice duration in AVH infection and the period in which the ALT value came back to normal and accordingly hospitalization duration of AVH patients and the prognosis of biochemical parameters.

In conclusion, the use of NAC in acute viral hepatitis complicated by jaundice is no more effective than placebo. However, the use of NAC in AVH cases is not harmful.

Abstract

AIM: The interaction of mucosal addressin cell adhesion molecule 1 (MAdCAM-1) with integrin α4β7 mediates lymphocyte recruitment into mucosa-associated lymphoid tissue (MALT). Nodular gastritis is characterized by a unique military pattern on endoscopy representing increased numbers of lymphoid follicles with germinal center, strongly associated with *H pylori* infection. The purpose of this study was to address the implication of the MAdCAM-1/integrin β7 pathway in NG.

METHODS: We studied 17 patients with NG and *H pylori* infection and 19 *H pylori*-positive and 14 *H pylori*-negative controls. A biopsy sample was taken from the antrum and snap-frozen for immunohistochemical analysis of MAdCAM-1 and integrin β7. In simultaneous viewing of serial sections, the percentage of MAdCAM-1-positive to von Willebrand factor-positive vessels was calculated. We also performed immunostaining with anti-CD20, CD4, CD8 and CD68 antibodies to determine the lymphocyte subsets co-expressing integrin β7.

RESULTS: Vascular endothelial MAdCAM-1 expression was more enhanced in gastric mucosa with than without *H pylori* infection. Of note, the percentages of MAdCAM-1-positive vessels were significantly higher in the lamina propria of NG patients than in *H pylori*-positive controls. Strong expression of MAdCAM-1 was identified adjacent to lymphoid follicles and dense lymphoid aggregates. Integrin β7-expressing mononuclear cells, mainly composed of CD20 and CD4 lymphocytes, were associated with vessels lined with MAdCAM-1-expressing endothelium.

CONCLUSION: Our results suggest that the MAdCAM-1/integrin α4β7 homing system may participate in gastric inflammation in response to *H pylori*-infection and contributes to MALT formation, typically leading to the development of NG.

INTRODUCTION

Lymphocyte recruitment to inflammatory sites is regulated by differential expression of cell surface homing receptors and their interactions with relevant vascular adhesion molecules[1]. An immunoglobulin super family, single-chain 60-kDa glycoprotein, mucosal addressin cell adhesion molecule 1 (MAdCAM-1) is selectively expressed on the endothelium of high endothelial venules in gut-associated lymphoid tissues and vascular endothelial cells in the lamina propria of the small and large intestine[2]. Engagement of MAdCAM-1 to its exclusive ligand, integrin α4β7, on lymphocytes represents a tissue-specific homing mechanism for the intestine and gut-associated lymphoid tissue[2].

Helicobacter pylori causes one of the most common chronic infections in humans[3]. Although *H pylori* is a noninvasive pathogen[4], persistent infection causes chronic gastritis, which predisposes the mucosa to peptic ulceration, and is thought to be eventually linked to gastric cancer and primary gastric lymphoma, especially the lymphoma of mucosa-associated lymphoid tissue (MALT) type[5,6]. The histopathological features of *H pylori*-associated gastritis include intense infiltration of granulocytes and lymphocytes[7] and the formation of organized lymphoid follicles[8]. In this regard, nodular gastritis (NG), which is a unique military pattern resembling "goose flesh" on endoscopy[9], is characterized by increased numbers of lymphoid follicles with germinal center[10], in close association with *H pylori* infection[9, 10]. Although NG frequently occurs in children, there are ample evidences at present suggesting that NG is not so uncommon in adults, especially in pre-menopausal women[9,10].

Recently, Hatanaka *et al*[11] reported that expression of vascular endothelial MAdCAM-1 was enhanced in murine chronic gastritis induced by *H pylori*. Furthermore, Dogan *et al*[12] demonstrated strong expression of MAdCAM-1 protein on the vasculature in patients with *H pylori*-associated MALT type lymphoma. However, little is known about the implication of such adhesion molecules in the pathogenesis of NG. In this study, we investigated MAdCAM-1 expression on vessel endothelium in gastric mucosa of patients with NG by immunohistochemistry, along with the interaction with integrin α4β7. This could shed light on the mechanism of MALT organization in gastric mucosa in response to *H pylori* infection.

MATERIALS AND METHODS

Subjects and samples

We studied 17 patients who underwent upper gastrointestinal

endoscopy for dyspepsia and were diagnosed as having NG between April 1999 and March 2002. They included 2 men and 15 women, ranging 24 to 58 years old (mean, 43 years). As a control, age- and sex- matched 33 subjects with non-ulcer dyspepsia during the same period were recruited in the study. They consisted of 19 *H pylori*-infected patients without nodular gastritis (*H pylori*-positive controls) and 14 *H pylori*-negative ones. None of the control subjects had been treated with non-steroidal anti-inflammatory drugs, proton pump inhibitors, antibiotics, or bismuth compounds during the 4-week period prior to the present study. There were no differences in baseline characteristics such as alcohol intake, current tobacco use and body mass index among the three groups.

At endoscopy, one biopsy specimen was obtained from the antrum within 2 cm of the pyloric ring along the greater curvature. The sample was snap-frozen in OCT compound (Tissue-tek; Miles Inc., Elkhart, IN) in ethanol-dry ice bath and stored at -80 ℃ until use.

Detection of Helicobacter pylori infection

H pylori status was assessed by serology (anti-*H pylori* immunoglobulin G antibody, HEL-p TEST, AMRAD Co., Melbourne, Australia), rapid urease test (CLO test; Delta West Co., Bentley, Australia) using additional biopsy specimens obtained during endoscopy from the antrum within 2 cm of the pyloric ring and the corpus along the greater curvature. Patients were considered positive for *H pylori* infection when at least one examination yielded positive results. On the other hand, patients were defined as *H pylori*-negative if all test results were negative.

Immunohistochemical analysis

MAdCAM-1 protein expression on vascular endothelial cells was studied *in situ* by immunohistochemistry with the streptavidin-biotin-peroxidase-complex method (Histofine SAB-PO kit, Nichirei Co., Tokyo), as described previously[13]. In brief, frozen tissues were cut into 4-μm thick sections and placed on glass slides coated with 3-aminopropyltriethoxysilane (Dako Co., Glostrup, Denmark). The following steps were performed at room temperature unless otherwise specified. Sections were fixed in 4 % paraformaldehyde (Merck Co., Darmstadt, Germany) in phosphate-buffered saline (PBS, pH 7.4) for 20 minutes. After a brief washing in PBS, endogenous peroxidase activity was inhibited for 30 min with methanol containing 0.3 % H_2O_2. Sections were reacted for 20 min with 10 % normal rabbit serum (Nichirei Co.) to prevent non-specific binding, and incubated with anti-MAdCAM-1 mouse monoclonal antibody (clone 1G2)[14] at a concentration of 1:100 in PBS overnight at 4 ℃. On the next day, the sections were washed three times (10 min each) in PBS and incubated for 20 min with 10 mg/ml biotinylated rabbit anti-mouse immunoglobulins (Nichirei). After washed three times (10 min each) in PBS, the sections were re-incubated for 20 min with 100 μg/ml HRP-conjugated streptavidin (Nichirei). After washed three times (10 min each) in PBS, a color reaction was performed with 0.05 M Tris-HCl (pH 7.6) containing 3, 3' -diaminobendizine tetrahydrochloride (Dojin Chemical Co., Kumamoto, Japan) and H_2O_2. Sections were counterstained with Mayer' s hematoxylin and then dehydrated, cleared and mounted by standard procedures.

In each serial section of the same tissue specimen, vessels were immunostained with anti-von Willebrand factor monoclonal antibody (Dako Co.) in the same fashion described above, in order to assess quantitatively the difference in the extent of expression of endothelial adhesion molecules, based on the method reported by Hatz *et al*[15]. Briefly, two independent observers who were blind to the diagnosis and experimental results, counted the number of von Willebrand factor-positive vessels and then the number of MAdCAM-1-positive vessels on the section serial to that stained for von Willebrand factor. Percentage of the ratio of MAdCAM-1-positive to von Willebrand factor-positive vessels was calculated. As a negative control, each non-specific isotype antibody was used instead of the primary antibodies, or the primary antibodies were omitted. When the interobserver variability exceeded 10 %, the areas were simultaneously re-evaluated by the two investigators to reach a consensus.

Furthermore, immunoreactivity for integrin β7 on inflammatory cells infiltrating the gastric mucosa was similarly analyzed using a specific monoclonal antibody (Pharmingen Co., San Diego, CA) at a concentration of 1:10. On the section serial to that stained for β7, we also performed immunohistochemistry using anti-CD20, -CD4, -CD8 and -CD68 monoclonal antibodies (purchased from Dako Co.).

Reverse transcriptase polymerase chain reaction (RT-PCR)

Total RNA from biopsy samples that were also collected from the same location was extracted using a commercial kit according to the instructions provided by the supplier (ISOGEN, Nippon Gene Co., Toyama, Japan). Equivalent amounts of RNA were monitored by absorption at 260 nm and by monitoring the density of 28S and 18S RNA detected after electrophoresis. After 1 μg of total RNA was reverse transcribed to complementary DNA, the target sequence of MAdCAM-1 was amplified in 35 cycles, each consisting of 1 min at 94 ℃ for denaturation, 1 min at 60 ℃ for annealing and 1 min at 72 ℃ for extension, followed by a final extension for 5 min at 72 ℃ with specific primers[16], using a RT-PCR kit (Takara Shuzo Co., Otsu, Japan). Two primers designed to nucleotide positions 978-999 (TGC GGT GCT GGG ACT GCT GCT C, sense) and 1 344-1 364 (TCA GGG AGG GGC TTC AGG TCA, antisense) of human MAdCAM-1 cDNA sequence were used for amplification of a 387 bp product[16]. A 10 μl aliquot of each PCR product was analyzed by electrophoresis on 2 % agarose gel containing ethidium bromide, and the bands were examined under ultraviolet light for the presence of amplified DNA. Glyceraldehyde-3-phosphate dehydrogenase (G3PDH) gene transcript was routinely amplified as described previously[17] and used as an internal control of the processed RNA for each preparation.

All samples were obtained with informed consent in accordance with the Helsinki Declaration.

Statistical analysis

Statistical analyses were performed using Fisher' s exact, χ^2, Student' s *t*, and Mann-Whitney *U* tests, whichever appropriate. A *P* value less than 0.05 was accepted as statistically significant. Data were expressed as mean ± standard deviation (SD).

RESULTS

Clinicopathological features of NG

All 17 patients with NG were *H pylori*-positive. Among the 17 patients, no less than 9 (52.9 %) had endoscopic evidence of peptic ulcer (duodenal ulcer in 7 and gastric ulcer in 2). All except one specimen from the NG patients showed lymphoid follicle formation and/or dense lymphoid aggregates.

MAdCAM-1 expression on vessel endothelium

The MAdCAM-1antigen, recognized by the 1G2 antibody, was seen on vascular endothelial cells in gastric mucosa. In *H pylori*-negative group, MAdCAM-1 was rarely or occasionally localized in vascular endothelial cells in the lamina propria (Figure 1A). However, the relative endothelial area expressing MAdCAM-1 increased in inflammatory settings induced by *H pylori* infection (Figure 1B), particularly in association with

dense lymphocytic infiltration (Figure 1C). High endothelial venule-like vessels adjacent to the lymphoid follicle were intensely immunoreactive (Figure 1D). There was a significant difference in the percentages of MAdCAM-l-positive vessels between *H pylori*-positive and –negative controls ($P<0.001$, Figure 2). In addition, the expression of vascular MAdCAM-1 was more enhanced in patients with NG than that in *H pylori*-negative controls ($P<0.0001$, Figure 2). Of note, MAdCAM-1-positive vessels were more abundant in the antral mucosa of patients with NG, compared with *H pylori*-positive controls ($P<0.05$, Figure 2). The percentages of MAdCAM-1-positive vessels detected by the two observers were almost identical. When each non-specific isotype serum was used or primary antibodies were omitted, the specimens showed no immunoreactivity.

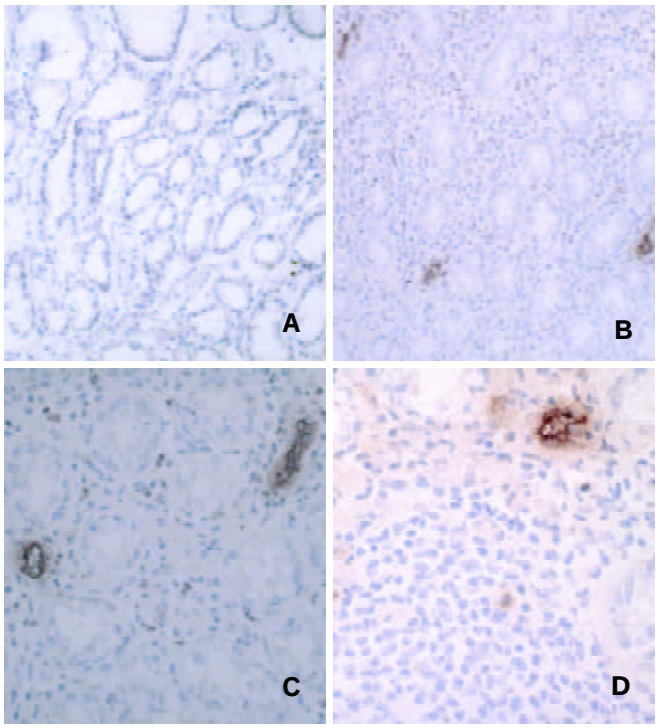

Figure 1 (A): *H pylori*-negative gastric mucosa showed little immunoreactivity for mucosal addressin cell adhesion molecule 1 (MAdCAM-1). MAdCAM-1 was expressed on the endothelium of numerous vessels within the lamina propria with *H pylori* infection (B), particularly in association with dense mononuclear infiltration (C). Strong endothelial expression of MAdCAM-1 was localized on high endothelial venule-like vessels adjacent to the lymphoid follicles D.

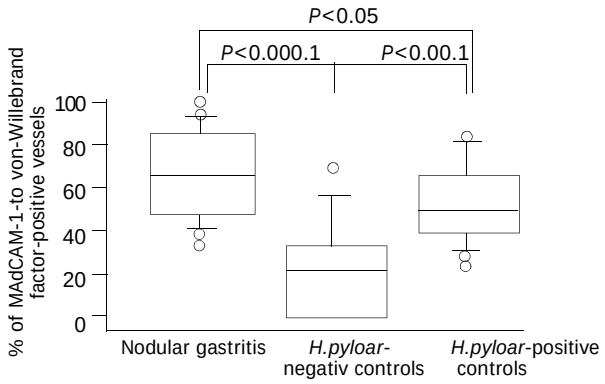

Figure 2 MAdCAM-1 immunoreactivity on mucosal vasculature of antral biopsy specimens from patients with nodular gastritis and *H pylori*-positive and –negative controls. Results were expressed as the percentage of von-Willebrand factor-positive vessels immunoreactive for MAdCAM -1 in serial sections.

Integrin β7 was expressed on increased number of mononuclear cells in the lamina propria of patients with *H pylori* infection, whereas there were few integrin β7-positive cells in the mucosa of *H pylori*-negative controls. Analysis of serial sections showed lymphocytes co-expressing anti-CD4 antibody and integrin β7 (Figure 3). Also, some CD20-positive cells also expressed integrin β7. However, the integrin β7-positive infiltrating cells showed little immunoreactivity for CD8 and CD68. The vessels lined with endothelial cells positive for MAdCAM-1 correlated well with the infiltration of integrin β7-expressing lymphocytes (Figure 4).

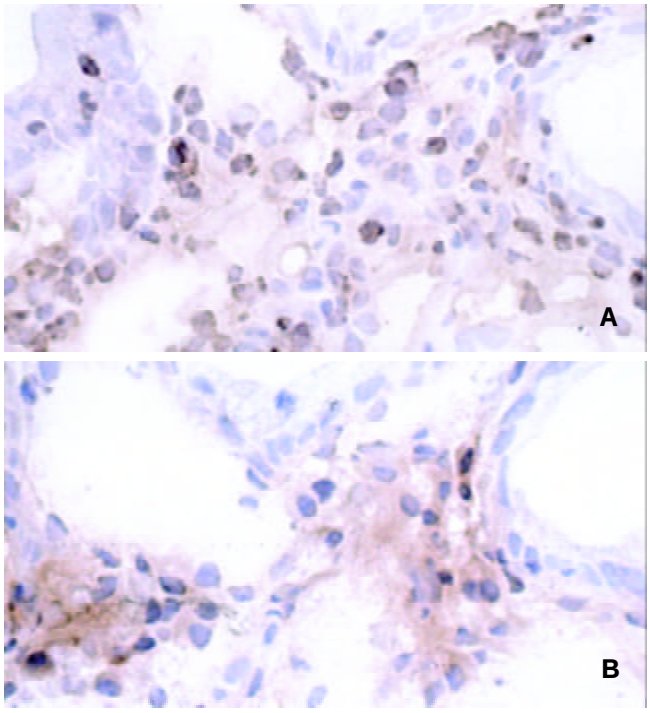

Figure 3 In simultaneous viewing of serial sections, integrin β7-expressing cells (A) consisted of CD-4-positive T lymphocytes (B).

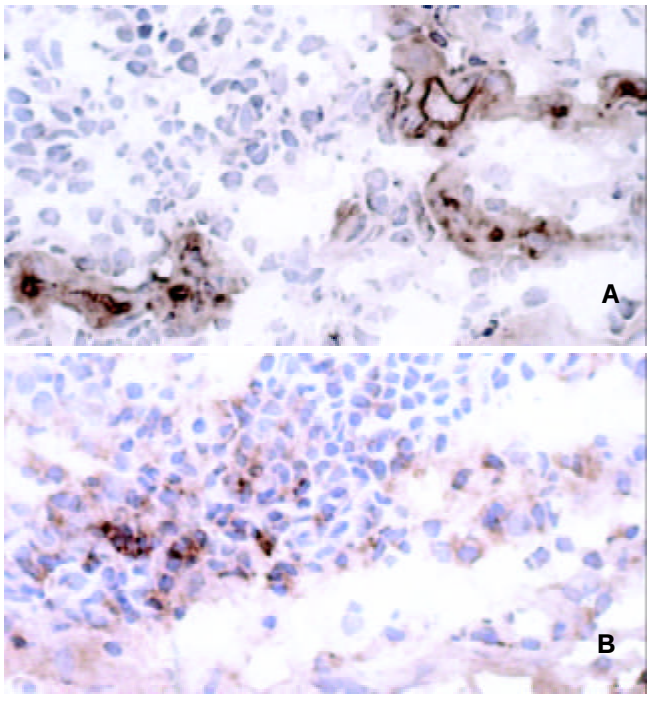

Figure 4 Vessels lined with MAdCAM-1-positive endothelium (A) were associated with infiltration of lymphocytes immunoreactive for integrin β7 (B).

Expression of MAdCAM-1 gene in antral biopsy specimens

We identified the *MAdCAM-1* gene-specific product as a 387-bp band by RT-PCR both in patients with NG and in *H pylori*-positive controls, but not in *H pylori*-negative controls despite the constitutive *G3PDH* housekeeping gene expression (Figure 5).

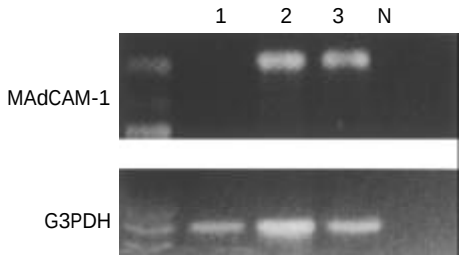

Figure 5 MAdCAM-1 and glyceraldehyde-3-phosphate dehydrogenase (G3PDH) mRNA transcripts were detected as 387 and 983 base pair-bands with reverse transcriptase-polymerase chain reaction, respectively. Lane N: negative control, lane 1: *H pylori*-negative control, lane 2: *H pylori*-positive control, lane 3: patients with nodular gastritis.

DISCUSSION

In the present study, vascular expression of MAdCAM-1 protein assessed by immunohistochemistry was more enhanced in gastric mucosa of *H pylori*-positive than in *H pylori*–negative subjects. On RT-PCR analysis, the mRNA for MAdCAM-l was detected only in *H pylori*-infected gastric mucosa, but not in the mucosa negative for the organism. In the previous *in vitro* study, MAdCAM-1 was induced on a murine endothelial cell line, by proinflammatory cytokines including interleukin 1 and tumor necrosis factor α[18], which were much more increased in human gastric mucosa with than without *H pylori* infection[19]. Considered together, these results indicate that MAdCAM-1 is selectively upregulated in the infected gastric mucosa. Integrin β7-expressing mononuclear cells were found surrounding blood vessels lined with MadCAM-1-postive endothelium, suggesting that the MAdCAM-1/integrin α4β7 pathway directs lymphocytes to the inflamed sites of *H pylori* infection, as shown in the murine model[11]. Together with other endothelially expressed adhesion molecules such as intercellular cell adhesion molecule 1 and vascular cell adhesion molecule 1[15], though more specifically, MAdCAM-1 could play a role in chronic inflammation induced by *H pylori*.

The striking finding of this study was that the percentages of MAdCAM-1-positive to von Willebrand factor-positive vessels in the lamina propria was significantly higher in patients with NG than in *H pylori*-positive controls. In addition to the prominent development of lymphoid follicles, intense mucosal inflammatory cell infiltration consisting mainly of lymphocytes was characteristic of NG[10]. The recruitment and emigration of circulating lymphocytes, on which integrin α4β7 is certainly expressed[20], may be accelerated in the gastric mucosa of NG, through, in part, the substantially enhanced expression of this vascular addressin.

MAdCAM-1 protein was strongly expressed on high endothelial venule-like vessels adjacent to lymphoid follicles and dense lymphoid aggregates within gastric mucosa. In the gut-associated lymphoid tissues such as Peyer' s patches and mesenteric lymph nodes, the homing of their constituent lymphocytes has been found to be largely dependent on the interaction of MAdCAM-1 on high endothelial venules with integrin α4β7[2]. Similarly, the vascular MAdCAM-1 localized near the lymphoid follicles may be a principal ligand for circulating lymphocytes to the specialized lymphoid sites and may contribute to the formation of MALT in *H pylori*-induced gastric inflammation, typically leading to the development of NG. This is a topic that warrants further studies, with special attention to the relationship between NG and MALT lymphoma[21], as a recent report documented the strong expression of MAdCAM-1 on the vasculature of patients with this type of lymphoma[12].

In the present study, simultaneous viewing of serial sections revealed the presence of integrin β7-expressing mononuclear cells in the infected gastric mucosa. These cells were mainly CD4-positive T and CD20-positive B cell populations, as described previously[12,20,22]. Several *in vitro* studies showed that *H pylori* antigen could induce the expression of integrin α4β7 on the surface of these cells[20,22]. In addition, employing immunomagnetic cell sorting, *H pylori* reactive circulating T lymphocytes were mainly found in the α4β7-positive cell fraction[20]. Accordingly, we believe that mucosally activated lymphocytes in response to *H pylori* infection can migrate from the inductive sites via circulation to their effector sites in the gastric mucosa, using this exclusive homing receptor as a ligand for MAdCAM-1.

In conclusion, our study demonstrated enhanced expression of MAdCAM-1 on the vascular endothelium and increased number of integrin β7-expressing T and B cells in *H pylori*-positive gastric mucosa. In NG, the proportion of MAdCAM-1-positive vessels was higher than that even in *H pylori*-positive controls. The selective MAdCAM-1/integrin α4β7 homing system is thought to play a significant role in gastric mucosal immunity in response to *H pylori* infection, especially in lymphoid follicle formation.

Abstract

AIM: Lymphocytic gastritis is commonly associated with *Helicobacter pylori* infection. The presence of glandular atrophy and foveolar hyperplasia in lymphocytic gastritis suggests abnormalities in cell proliferation and differentiation, forming a potential link with the suspected association with gastric cancer. Our aim was to compare epithelial proliferation and morphology in *H pylori* associated lymphocytic gastritis and *H pylori* gastritis without features of lymphocytic gastritis, and to evaluate the effect of *H pylori* treatment.

METHODS: We studied 14 lymphocytic gastritis patients with *H pylori* infection. For controls, we selected 14 matched dyspeptic patients participating in another treatment trial *whose H pylori* infection had successfully been eradicated. Both groups were treated with a triple therapy and followed up with biopsies for 6-18 months (patients) or 3 months (controls). Blinded evaluation for histopathological features was carried out. To determine the cell proliferation index, the sections were labeled with Ki-67 antibody.

RESULTS: Before treatment, lymphocytic gastritis was characterized by foveolar hyperplasia (P=0.001) and glandular atrophy in the body (P=0.008), and increased proliferation in both the body (P=0.001) and antrum (P=0. 002). Proliferation correlated with foveolar hyperplasia and inflammation activity. After eradication, the number of intraepithelial lymphocytes decreased in the body (P=0.004) and antrum (P=0.065), remaining higher than in controls (P<0.001). Simultaneously, the proliferation index decreased in the body from 0.38 to 0.15 (P=0.043), and in the antrum from 0.34 to 0.20 (P=0.069), the antral index still being higher in lymphocytic gastritis than in controls (P=0.010). Foveolar hyperplasia and glandular atrophy in the body improved (P=0.021), reaching the non-LG level.

CONCLUSION: In lymphocytic gastritis, excessive epithelial proliferation is predominantly present in the body, where it associates with foveolar hyperplasia and glandular atrophy. These characteristic changes of lymphocytic gastritis are largely related to *H pylori* infection, as shown by their improvement after eradication. However, some residual deviation was still seen in lymphocytic gastritis, indicating either an abnormally slow improvement or the presence of some persistent abnormality.

INTRODUCTION

Lymphocytic gastritis (LG) is an inflammatory disorder first described by Haot and his group in 1985[1]. This histopathological entity is characterized by a marked increase in the number of intraepithelial lymphocytes (IELs), most being CD8+ or CD3+ cytotoxic T-cells[2]. The amount of 25 IELs per 100 epithelial cells is usually considered diagnostic[3]. The reported prevalence of LG among patients with dyspepsia varies between 1-8 %[4,5]. Most dyspeptic patients with LG are seropositive for *Helicobacter pylori*, indicating that LG may represent an atypical host immune response to the infection[6]. Cases associated with *H pylori* infection have been reported to respond to *H pylori* eradication treatment[7-9]. Gluten is one of the other suspected trigger factors in particular cases, and the prevalence of LG is high in patients with celiac disease, reaching levels up to 45 % in some series[10,11].

LG is common in patients with gastric carcinoma and gastric MALT lymphoma, suggesting that it may be pathogenetically related to gastric malignancies[12,13]. However, mechanisms linking LG with malignancy are not known. Atrophic changes and foveolar hyperplasia in the body mucosa are common in LG, suggesting that abnormal epithelial proliferation and differentiation may be present. Without treatment these abnormalities are usually considered to be persistent[5]. Furthermore, our previous follow-up study has shown that LG is linked to a tendency of more severe progression of intestinal metaplasia than in *H pylori* gastritis without LG[5].

Since foveolar hyperplasia is a characteristic of lymphocytic gastritis, we hypothesized that this might be associated with abnormal proliferation rate. In addition to testing this hypothesis by comparing the proliferation rate with non-LG *H pylori* gastritis, we evaluated the effect of *H pylori* treatment on epithelial cell proliferation and other histopathological features of LG, including glandular atrophy, to find out whether the abnormalities are related to *H pylori* infection and whether they are irreversible.

MATERIALS AND METHODS

Subjects

Two separate series of patients were studied with some differences in the treatment and follow-up protocol. Patients with LG were collected from among the out-patients referred to one endoscopist (SN) for upper abdominal complaints. Patients with histologically proven LG and either histologically or serologically confirmed *H pylori* infection were subsequently included in the open study, in which their *H pylori* infection was treated and they were invited to take part in the post-treatment examinations to document the effects of *H pylori* eradication. An informed consent was obtained from all the

patients according to the usual clinical practice. A total of 14 patients (six men, eight women; mean age 55.2 years, range 41-70 years) who fulfilled the criteria were included. Originally all of them were seropositive for *H pylori*, while only three patients (21 %) could be confirmed as positive on histology. All of the patients had normal findings in duodenal biopsy; no subjects with celiac disease were included. Follow-up gastroscopies with gastric biopsies were performed on all the patients after the eradication. The mean follow-up time was 12 months, ranging from six to 18 months. The effect of treatment on intraepithelial lymphocyte counts in a subset of these patients has been previously reported[9].

For the control group, a series of age and gender matched *H pylori* positive subjects were selected from another treatment trial: Prospective Phase IV clinical multicenter study aiming at testing the effects of sucralfate as an adjuvant to *H pylori* eradication therapy in non-ulcer dyspepsia (F-SUC-CL-0191-FIN; Orion Corporation, Orion Pharma, Finland). Inclusion criteria included the following: age over 18 years, dyspeptic symptoms not explained by any other disease, normal upper abdominal ultrasound, no active peptic ulcer or a history of ulcer, no endoscopic esophagitis, no other severe illness, no need for continuous use of NSAID or steroids. The patients were not allowed to use any anti-ulcer drugs including antacids or H2-antagonists during the two weeks before the trial. The study was approved by the ethical committees in the participating hospitals in Northern Finland. Only subjects with a successful eradication result based on histology were selected. The control group consisted of 14 patients (seven men, seven women, mean age 53.8 years, range 38-67 years) all presenting with *H pylori* positive gastritis without either LG, celiac disease or malignancy. Biopsies taken before the treatment and three months after the eradication therapy were studied.

Histopathology

A minimum of two biopsies was taken from both the antrum and the body at the initial and follow-up gastroscopy. In addition, routine biopsies from the descending part of the duodenum were taken during the primary endoscopy. The biopsies were fixed in formalin, embedded in paraffin and stained with hematoxylin and eosin. During the collection of the patient series one pathologist (TKa) made a preliminary diagnosis of LG. The diagnosis was based on the presence of intraepithelial lymphocytes at a ratio of 30 per 100 epithelial cells, or greater, in the areas of their maximal density.

After the follow-up of the whole series was completed, the slides were coded and evaluated for IEL counts by a second pathologist (TKe), blinded for any clinical data including treatment status and the results of preliminary histopathological evaluation. The IEL number was counted at three randomly selected fields of surface and foveolar epithelium separately in the antral and body mucosa. In addition, IEL number was counted in the area of the maximal IEL density in antral and body mucosa. Around 100 to 150 cells in epithelium were counted in each field. The grade of gastritis, quantity of different types of inflammatory cells, grade of atrophy, foveolar hyperplasia and intestinal metaplasia were similarly analyzed by a blinded investigator (TKa) according to the histological criteria of the updated Sydney system. The presence and quantity of *H pylori* was evaluated from sections stained with a modified Giemsa stain.

Immunohistochemistry and determination of the Ki-67 labeling index

Sections from each gastric biopsy specimen were treated with 10 mM citrate buffer, pH 6.0, for 2 x 5 minutes for antigen retrieval. The sections were incubated with Ki-67 monoclonal antibody (clone 7B11, Zymed, South San Francisco, CA, USA; 1:50 dilution) for 60 minutes at 37 ℃. Bound antigen was detected with labeled streptavidin-biotin method using AEC as a chromogen (Histostain™ –plus, Zymed, South San Francisco, CA, USA). Hematoxylin was used as a counterstain.

Labeled and unlabeled epithelial cells were counted under a high-power microscope (×100) in the optimal, longitudinally orientated and complete foveolae. The proportion of positive cells among foveolar epithelial cells indicated the proliferation (labeling) index (LI %). The mean LI % for each biopsy was calculated as an average from several foveolae. The counting was performed by a single person (JM) blinded for all previous clinical and histopathological data.

Serology

The serological diagnosis of *H pylori* was made by testing the specific IgG antibodies with an enzyme linked immunosorbent assay (ELISA, Pyloriset®, Orion Diagnostica, Finland). Titers of 1:500 or higher were considered positive.

Eradication treatment

In the LG group, *H pylori* eradication therapy consisted of a ten day course of bismuth subsitrate (240 mg twice daily) and metronidazole (400 mg three times daily) or amoxycillin (1 g twice daily). The controls were treated for two weeks with metronidazole (400 mg three times daily) and tetracycline (500 mg three times daily). In addition they got sucralfate (2 g twice daily for 6 weeks followed by 1 g once daily for 6 weeks). No proton inhibitors were allowed in the control group.

Statistics

LG patients and controls were compared by using the nonparametric Mann-Whitney test. Temporal changes in the results were evaluated by using the Wilcoxon signed ranks test. Spearman' s two-tailed rank correlation test was used to assess the correlations between the variables. A probability of *P* less than 0.05 in two-tailed tests was considered statistically significant. Analyses were made with the Statistical Package for Social Sciences (SPSS 10.0, Chicago, IL, USA).

RESULTS

Histopathological features and cell proliferation in H pylori related lymphocytic gastritis and controls before eradication

In all the patients with LG the maximal number IELs was 30 IEL/100 epithelia in either the body or antral mucosa. The histopathological features including the IEL density (per 100 epithelial cells) in random fields. (Table 1; Figure 1) and epithelial cell proliferation (Figure 2) before eradication treatment were compared between LG and non-LG *H pylori* gastritis. The density of *H pylori* organisms was higher in the control group in the body (P=0.009) and antral mucosa (P=0.001), and showed a significant negative correlation with age in LG (body mucosa; c=-0.633, P=0.002). The pre-treatment levels of specific IgG antibody titers were lower in the control group (median 1:1 575, range 1:140-1:5 600) than in LG (1:6 000, range 1:1 000-1:17 000; P= 0.011).

In the antral mucosa the degree of atrophy did not show any significant differences between LG and non-LG *H pylori* gastritis, but the body mucosa showed significantly more severe atrophy in LG (Table 1; P=0.008). Of LG subjects 50 % (n=7) showed mild and 14 % (n=2) moderate atrophy of the body mucosa (Figure 1), while 36 % (n=5) showed no sign of atrophy. No cases with severe atrophy were found. The severity of atrophy in the body showed a trend towards a positive association with IEL count (c=0.542, P=0.069). In the control group, only 17 % (n=2) of the cases showed atrophy of the body

mucosa prior to eradication. In the antrum, gastritis was more active in the controls (P=0.034), but no significant difference was seen in the body. The eosinophilic leukocytes score in the body mucosa was higher in LG (Table 1; P=0.001), while in the antral mucosa the score tended to be higher in the control group (P=0.062). The extent of intestinal metaplasia in the body mucosa tended to be greater in LG (Table 1; P=0.095). Elongation of the foveolae was more often seen in LG (Table 1; Figure 1; body mucosa P= 0.001; antral mucosa P= 0.074.)

Due to tangential sectioning, the proliferation index based on the number of cells with nuclear expression of Ki-67 could be determined in only about 80 % of the specimen slides. The pre-treatment epithelial cell proliferation rate was higher in LG in both the body (P=0.001) and antral mucosa (P=0.002) compared to the controls (Figure 1). In LG, the proliferation index of the body mucosa showed correlation with the degree of foveolar hyperplasia (c=0.798, P=0.010), but did not correlate with atrophy or any other histologic feature, except for a trend towards correlation with the activity of gastritis (c=0.655, P=0.078). In the antral mucosa the proliferation index correlated negatively with the patient' s age (c=-0.707, P=0.050). In the controls, proliferation showed no significant correlation with any of the histological markers or age.

Table 1 Antrum and body gastritis in subjects with lymphocytic gastritis (LG) and controls (non-LG) before and after *H pylori* eradication

Antrum	LG	Non-LG
H pylori score	0 (0-2)[f]	2 (0-3)[bf]
After treatment	0 (0-0)	0 (0-0)[b]
Atrophy	2 (1-2)	2 (0-3)
After treatment	1 (1-2)	2 (0-3)
Metaplasia	0 (0-2)	0 (0-1)
After treatment	0 (0-1)	0 (0-1)
Foveolar length (μm)	340 (290-650)[a]	300 (260-370)
After treatment	300 (250-330)[a]	320 (220-480)
IEL count (mean)	9.5 (1.0-30.7)[f]	1.7 (1.0-4.0)[f]
After treatment	5.7 (0.7-11.0)	1.3 (0.3-3.7)
Activity	1 (0-2)[ad]	2 (0-3)[ad]
After treatment	0 (0-0)[ad]	0 (0-2)[ad]
Eosinophils	1 (0-2)	1 (0-2)
After treatment	0 (0-1)[d]	1.5 (0-3)[d]
Body	**LG**	**Non-LG**
H pylori score	0 (0-3)[d]	2 (0-3)[bd]
After treatment	0 (0-0)	0 (0-0)[b]
Atrophy	2 (1-3)[ad]	1 (0-2)[d]
After treatment	1 (1-2)[a]	1 (0-2)
Metaplasia	0 (0-2)[d]	0 (0-0)[d]
After treatment	0 (0-1)	0 (0-0)
Foveolar length (μm)	310 (250-800)[bf]	170 (130-210)
After treatment	210 (140-290)[b]	200 (150-320)
IEL count (mean)	26.3 (3.7-56.7)[bf]	1.7 (0.3-2.7)[f]
After treatment	5.7 (1.0-41.7)[bf]	2.0 (0.3-3.7)[f]
Activity	1 (0-2)[a]	0.5 (0-2)[a]

Eosinophils	1 (1-2)[af]	1 (0-1)[f]
After treatment	1 (0-2)[ad]	0 (0-1)[d]

Note: Median score and range are indicated except for IEL count, where mean is used. The significance of temporal changes was evaluated by Wilcoxon signed ranks test (a). LG patients and controls were compared with the Mann-Whitney test (d). c, f: P=<0.001; b, e: P=<0.005; a, d: P=<0.05 (two-tailed significance).

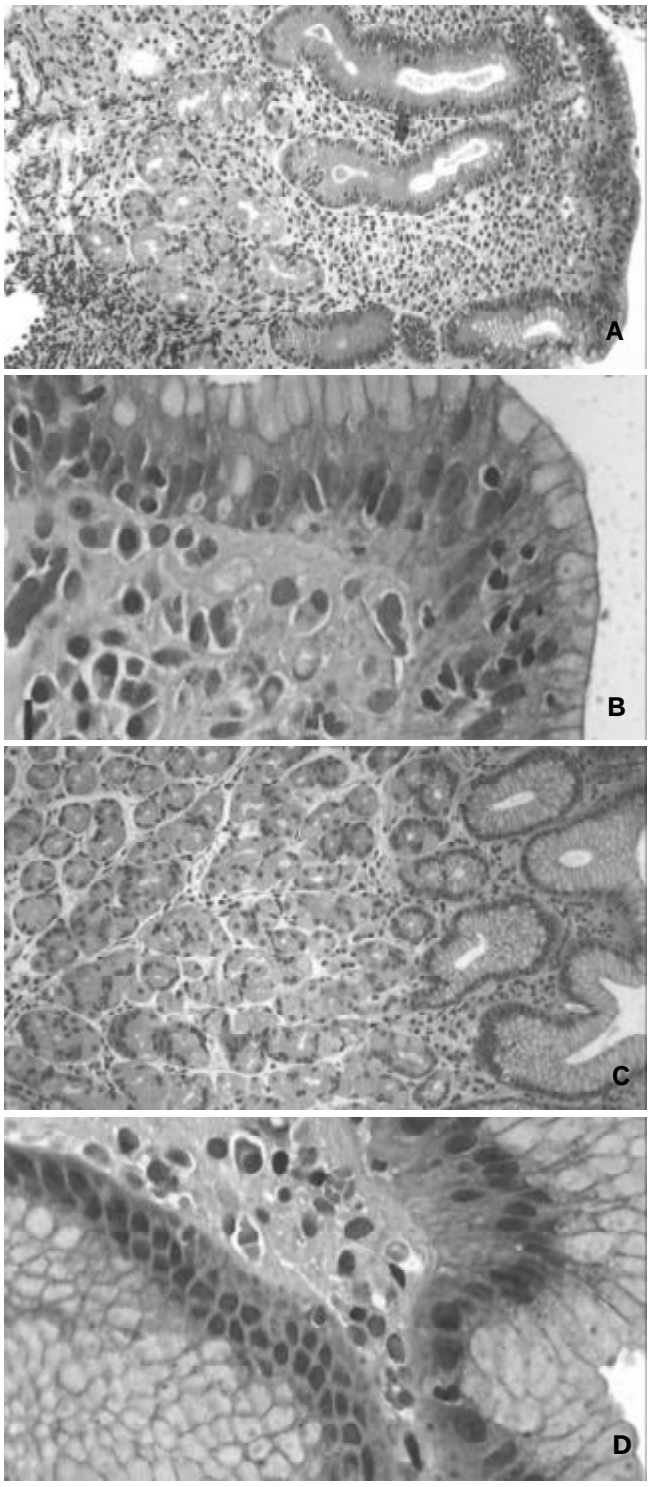

Figure 1 A,B,C,D. Hematoxylin-Eosin stained sections from gastric body mucosa in a case of lymphocytic gastritis before and after eradication treatment. Before treatment (A,B) there was a sharp increase of intraepithelial lymphocytes, moderate glandular atrophy and foveolar hyperplasia. After treatment (C,D) there were only occasional intraepithelial lymhocytes and no signs of glandular atrophy or foveolar hyperplasia. A,C, Bar=25 μm. B,D, Bar=10 μm.

Effect of eradication treatment

We then analyzed what kind of impact the eradication treatment had on cell proliferation and gastritis in LG patients and controls. In LG, successful eradication could be verified in 12 out of 14 patients. All the three patients initially positive on histology were now found to be *H pylori* negative, and showed a decrease of 50 % or more in titer of specific IgG antibodies. Nine cases initially negative on histology showed a similar

decrease in their antibody titers, thus indicating a successful eradication. In two patients, both negative on histology, the decrease in the IgG titers did not quite reach 50 %. However, on histological evaluation of the inflammation, these two patients showed a similar shift towards normal mucosal morphology as the other LG patients. In the control group, all cases were successfully eradicated and turned histologically negative. Yet on serology, only five non-LG patients showed a decrease of the IgG titer of 50 % or more.

In LG, the proliferation index decreased significantly after the eradication in the body mucosa (Figure 2; median from 0.38 to 0.15, *P*=0.043), and showed a similar trend in the antrum (from 0.34 to 0.20, *P*=0.069). In controls, no significant changes were seen (Figure 2). The post-eradication proliferation index in the antrum was nonetheless significantly higher in LG patients (*P*=0.010).

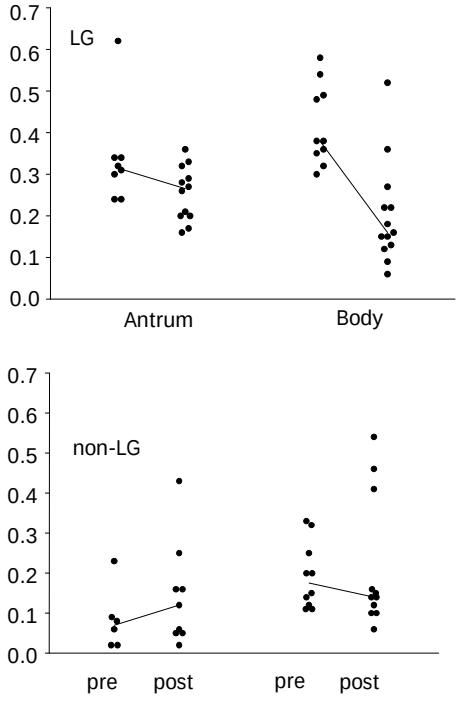

Figure 2 A scatterplot showing epithelial cell proliferation indexes in antral and body mucosa in patients with LG and non-LG *H pylori* gastritis before (pre) and after (post) treatment. The median is indicated with a solid line.

The IEL number decreased significantly in LG (Figure 1) both in areas of maximal density (data not shown) and in random fields (Table 1; body, *P*=0.004), but no change was seen among controls. The post-eradication IEL counts were still significantly higher in LG compared to the controls (Table 1; *P*<0.001). The overall score of inflammatory cells in the lamina propria decreased significantly in both groups (Table 1). In LG, glandular atrophy of the body mucosa improved significantly (*P*=0.021; Figure 1), and after the treatment most subjects (83 %) showed no atrophy at all. Two cases had mild atrophic changes at this stage. However, such a change could not be observed in the antrum. In the control group, eradication did not have any effect on the degree of atrophy in the body (Table 1; *P*=0.564) or in the antrum (*P*=0.783). In LG, a significant shallowing of the gastric pits was seen, as evidence of reduction in the foveolar hyperplasia (body, *P*=0.005; antrum, *P*=0.050). No significant changes were observed in controls.

Since both the IEL counts and proliferation remained significantly increased in LG, we searched for any correlation with inflammatory cell scores to see whether these features were related to residual inflammation, or possibly inherently abnormal. No significant correlations were seen in either antral or body mucosa between neutrophil, eosinophil or mononuclear inflammatory cell scores, but in the body the proliferation index showed a significant correlation with the IEL count (c=0.779, *P*=0.005). In controls, the proliferation index correlated similarly with the IEL number in the body mucosa (c=0.654, *P*= 0.040).

DISCUSSION

In the present study we have shown that gastric epithelial cell proliferation rate, as measured by the Ki-67 labeling index, was increased in LG associated with *H pylori* infection as compared to *H pylori* gastritis without significant increase of intraepithelial lymphocytes. Increased proliferation was predominantly present in the body mucosa, where it was correlated with foveolar hyperplasia and inflammation activity. In addition, our results suggest that in LG, the characteristic increase of IELs, abnormal proliferation, and atrophic changes of the body mucosa are all largely related to *H pylori* infection, as shown by their improvement after eradication therapy.

Increased proliferation induced by the chronic inflammation has been observed in *H pylori* associated gastritis, and the proliferation rate seems in principal to normalize after eradication therapy[14], although the antral mucosa may retain a somewhat abnormal proliferation pattern[15]. In LG, according to our findings, neither the IEL counts nor cell proliferation fell to the level observed in controls after successful treatment, even though the follow-up time was longer in LG patients (minimum six months, mean 12 months) than in controls (three months). This slow rate of normalization is likely to be related to the more pronounced initial abnormality in LG, possibly necessitating a longer period of time for full recovery. A more extended follow-up might be needed to see if these subjects show any permanent abnormality in the proliferation rate. Some intrinsic malfunction causing either a constant abnormal epithelial lymphocyte response or proliferation, or both, is also possible, but no such defects have been reported in LG. A further possible explanation is that there is some other environmental factor in addition to *H pylori* inducing these changes, the effect of which continues after eradication. In some cases, LG is associated with celiac disease[10,11]. The present study included no patients with this disorder. Other nutritional factors could be involved, as in the duodenal mucosa where an increase of IELs has been described in food allergy[16]. No such antigen related changes in the gastric mucosa are yet known.

The controversy between the negative histology and positive serology for *H pylori* in LG in the present and previous studies[5,6,13] might be explained by the fact that the bacteria are present in very small numbers, which could make them impossible to detect. In the present study, even the patients histologically positive for *H pylori* showed only a small amount of bacteria. This is likely to be related to decreased acid secretion associated with the atrophic changes in the body mucosa, which have been shown to associate with a low number of bacteria and a shift of bacteria to the body mucosa[17] in a way similar to the effect of proton pump inhibitors[18]. A significant decrease of the specific antibodies after treatment, along with the improvement of the inflammatory changes, indicates that even the cases negative on histology represent a true *H pylori* infection. It is of interest that the levels of *H pylori* specific IgG antibodies were significantly higher in LG than in non-LG *H pylori* positive gastritis. This has been noted previously[5]. Whether the intensive serological response is related to a certain bacterial strain, amount of antigen, or a matter of a genetically determined pattern of immune response, is not known.

The mechanisms behind the processes of body glandular atrophy and foveolar hyperplasia in LG are unknown. The question of whether atrophy is based on an autoimmune reaction, metaplasia, fibrosis, or on a disturbance in cell regeneration or differentiation in connection with foveolar hyperplasia, needs further study, but the last alternative is most likely the correct one. We could not see any significant change in the extent of intestinal metaplasia after eradication. No autoantibodies targeted against the gastric parietal cells have been found in LG patients (Niemelä *et al*, unpublished observation), suggesting that autoimmune mechanisms are not important in the pathogenesis of body atrophy in LG. The gastric epithelial stem cells situated in the proliferation zone are capable of differentiating into the direction of either gastric glandular cells or foveolar epithelial cells[19]. It is unknown which mechanisms are involved in the actual regulation of the direction of differentiation. We speculate that in untreated LG, the cells in the foveolar border area have a greater stimulus for differentiation towards foveolar epithelial cells than towards glandular cells, this pressure eventually leading to glandular atrophy and foveolar hyperplasia. Thus LG might provide a model for studying the mechanisms of selection of epithelial cell differentiation.

A longstanding *H pylori* infection has been shown to be associated with an increased risk of gastric malignancies[20,21], and successful eradication of this pathogen resulted in the disappearance of histologically malignant lymphomatous proliferation[22]. Mechanisms of the suggested increased risk of malignancy in LG[12,13] are unknown. The increased epithelial cell proliferation rate, as detected in the present study, might play an important part by increasing the potential for the accumulation of genetic changes. Glandular atrophy as seen in the present study, and reported previously[5,13], forms another potential link for gastric cancer, since an increased cancer risk has been documented with body atrophy[23]. Without any treatment, atrophy and foveolar hyperplasia seen in LG are generally considered to be persistent, and even to progress at a faster rate than in subjects with a non-LG *H pylori* gastritis[5], supporting the idea that LG has pre-malignant potential. However, more studies are required to find out whether patients with LG are indeed at an increased risk of a gastric malignancy, and whether *H pylori* eradication reduces the risk of gastric neoplasia in these patients.

In conclusion, we have shown that the highly increased epithelial cell proliferation, predominantly in the body mucosa, is a characteristic feature of LG. Abnormal proliferation together with atrophic changes in the body mucosa in LG provide a potential mechanism for the observed association with gastric malignancy. Furthermore, these changes in LG are largely caused by *H pylori* infection as shown by their normalization by eradication therapy.

Abstract

AIM: To express Hsp60 protein of *H pylori* by a constructed vector and to evaluate its immunogenicity.

METHODS: Hsp60 DNA was amplified by PCR and inserted into the prokaryotie expression vector pET-22b (+), which was transformed into BL21 (DE3) *E.coli* strain to express recombinant protein. Immunogenicity of expressed Hsp60 protein was evaluated with animal experiments.

RESULTS: DNA sequence analysis showed Hsp60 DNA was the same as GenBank's research. Hsp60 recombinant protein accounted for 27.2 % of the total bacterial protein, and could be recognized by the serum from *H pylori* infected patients and Balb/c mice immunized with Hsp60 itself.

CONCLUSION: Hsp60 recombinant protein might become a potential vaccine for controlling and treating *H pylori* infection.

INTRODUCTION

Helicobacter pylori (*H pylori*) infection is the major cause of chronic active gastritis and most peptic ulcer diseases[1-11], and is also closely related with gastric cancers such as adenocarcinoma, mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma[12-18]. This organism has been categorized as a class I carcinoma by the World Health Organization, and direct evidences of its carcinogenesis was recently demonstrated both in an animal model and in retrospective cohort and nested case-control studies in China[19-21]. In addition, seroprevalence studies indicated that *H pylori* infection was also associated with cardiovascular, respiratory, extra-gastroduodenal digestive, autoimmune diseases[22-24]. Successful eradication of *H pylori* is thus an important goal. Currently, its treatment involves antibiotic therapy, but this has some associated problems such as low patient compliance and increase of resistant strains[25-27]. An alternative approach is to develop a vaccine, which would not only clear the organism, but also prevent its reinfection[28-31].

Selection of antigenic targets and adjuvants is critical in developing *H pylori* vaccine. So far this area has achieved only a limited success. With most studies focusing on urease enzyme combined with cholera toxin (CT) or heat-labile toxin of *Escherichia coli* (LT), this antigen/adjuvant combination has been proved to be effective in many animal models, but some problems still exist such as toxicity of LT or CT and inadequate protection of urease enzyme, so new antigens and adjuvants should be looked for[32]. Some studies have proved that heat shock protein 60 (Hsp60) of mycobacteria was a kind of adjuvants, and could cause immune responses of priority in mouse and mankind models, so some researchers suspected *H pylori* Hsp60 might be an excellent antigen candidate[33,34]. In this study, recombinant plasmid of *H pylori* Hsp60 gene was constructed and expressed for the development of *H pylori* vaccine.

MATERIALS AND METHODS

Materials

Bacterial strain BL21(DE3) and plasmid pET-22b(+) were provided by the Institute of Biotechnology, Academy of Military Medical Sciences. *H pylori* SS1 was preserved in this research institute. Restriction enzyme Not I, Nco I and T4 DNA ligase, Vent DNA polymerase, isopropyl-β-D-thiogalactopyranoside (IPTG) were purchased from New England Biolabs Company. Goat anti-mouse and goat anti-human IgG-HRP were purchased from Huamei Bioengineering Company, China and His-Tag precolumn from Invitrogen Company. Specific-pathogen-free, female BALB/c mice were housed according to Health Research Council of China guidelines with free access to food and water. Eight *H pylori* positive sera (which were positive by urease test, pathological dying and germ culture) and three *H pylori* negative sera (which were detected negative by the above-mentioned three examinations) were from patients treated in the Endoscope Center of this institute. Other reagents were analytically pure reagents produced in China.

Recombinant DNA techniques

All restriction enzyme digestions, ligations and other common DNA manipulations, unless otherwise stated, were performed by standard procedures[31,35]. The genome of *H pylori* was prepared from cells collected from colonies on a agar plate. The gene of *H pylori* Hsp60 was amplified from the genome of *H pylori* by PCR (Techne PROGENE) using the primers Hsp601 (5' -TG GCC ATG GAT GGG CCA AGA GGC AGG AAT-3') as upstream primer and Hsp602 (5' -AG TGC GGC CGC CAT CAT GCC GCC CAT G -3') as downstream primer as described in the literature[36]. Hsp601 and Hsp602 contained *Nco* I and *Not* I sites, respectively. PCR was performed with the hot start method. PCR condition was that after initial denaturing at 95 ℃ for 30 s, each cycle of amplification consisted of denaturing at 95 ℃for 30 s, annealing at 55 ℃ for

30 s and polymerization at 72 ℃ for 60 sec and further polymerization for 10 min after 35 PCR cycles. PCR product was harvested from agarose gel, digested with *Nco* I and *Not* I, and inserted into *Nco* I and *Not* I restriction fragments of the expression vector pET-22b(+) using T4 DNA ligase. The resulting plasmid pET- Hsp60 was transformed into competent *E.coli* BL21 (DE3) cells using ampicillin resistance for selection. The alkaline lysis method was chosen for large-scale preparations of recombinant plasmid and the plasmids were identified by restriction enzymes. DNA sequence was performed with a DNA automatic sequencer.

Induced expression, purification and SDS-polyacrylamide gel electrophoresis

The recombinant strains were incubated overnight at 37 ℃ while shaking in 5 ml LB with 100 μg/mL ampicilline, 50 mL LB were inoculated and the cells grew until the optical density at 600 nm reached 0.4-0.6. Isopropyl-β-D-thiogalactopyranoside (IPTG) was added to a final concentration of 0.1, 0.2, 0.4, 0.6, 0.8, 1.0 mM, respectively.*E.coli* cells growing in 50 mL LB 3 h or 5 h after induction were harvested by centrifugation at 12 000 g for 10 min and the pellet was resuspended in 1 ml 30 mM Tris buffer (pH8.0) containing 1 mmol/L EDTA (pH8.0), 20 % sucrose. The suspension was put on ice for 10 min, and then centrifuged for 10 min at 12 000 g, and the resulting suspernatant contained proteins from periplasms. The resulting pellet was resuspended in 5 mL 50 mM Tris buffer (pH8.0) containing 2 mM EDTA, 0.1 mg/mL lysozyme and 1 % Triton X-100. The suspension was incubated at 30 ℃ for 20 min and then sonicated on ice until it became clarified. The lysate was centrifuged at 12 000 g for 15 min at 4 ℃, and then the resulting supernatant containing proteins from cytoplasms was purified with Ni-NTA column. Whole-cell lysates, sonicated supernatant, osmotic shock liquid of recombinant strains expressing *H pylori* Hsp60 genes and the purified rHsp60 were analyzed by electrophoretical analysis in a 10 % polyacrylamide gel.

Immunization of mice

Six to eight week old mice were immunized four times by hypodermic injection in the back of mice at weekly intervals. Each dose consisted of 20 μg of *H pylori* rHsp60 protein and 200 μg of adjuvant aluminum hydroxide gel. Age-matched control mice were not immunized. Four weeks after the last immunization, blood samples were taken from the retro-orbital sinus to measure anti Hsp60 systemic immune responses and stored at -20 ℃ until assay.

Serum antibody responses

Indirect ELISA as described evaluated serum samples from mice and patients for Hsp60-specific IgG previously[35]. Purified *H pylori* rHsp60 was used as the coating antigen in ELISA immunoassays.

RESULTS

PCR amplification of H pylori Hsp60 gene

According to the literature, the gene encoding Hsp60 protein was amplified by PCR with chromosomal DNA of *H pylori* Sydeny strain (ss1) as templates. The cloning products were electrophoresed and visualized on 8 g·L^{-1} agarose gel (Figure 1). It revealed that Hsp60 DNA fragment amplified by PCR contained a gene with approximately 1 548 nucleotides, which was compatible with previous reports[36].

Construction of recombinant plasmid and restriction enzyme confirmation

After PCR products and pET-22b(+) plasmid were cut by Not I and Nco I, directional cloning was performed, resulting in a recombinant plasmid named pET-22b(+)/Hsp60. The recombinant plasmids pET-22b(+)/Hsp60 were all digested by Not I or Nco I, and by Not I and Nco I simultaneously, then digestive products were visualized on 8 g·L^{-1} agarose gel eletrophoreses (Figure 2). It demonstrated that recombinant plasmid contained the objective gene.

Sequence analysis of cloned Hsp60 nucleotide

The nucleotide sequence of cloned genes inserted in pET22b (+) was analyzed by automatic sequencing across the cloning

junction, using the universal primer T7. The results were as follows the cloned genes contained 1 548 nucleotides with a promoter and a start codon coding a putative protein of 516 amino acid residues with a calculated molecular mass of Hsp60. As compared with previous reports, the homogeneity was 100 % between them[36].

Expression and purification of Hsp60 gene in Escherichia coli

Whole-cell lysates, sonicated supernatant, osmotic shock liquid of recombinant strains expressing *H pylori* Hsp60 genes and the purified rHsp60 were analyzed by electrophoretical analysis in a 10 % polyacrylamide gel for detection of fusion proteins (Figure 3). The results showed that the clearly identifiable band was 60 000 Dalton highly expressed fusion proteins, which was similar to that predicted. Gel automatic scan analysis showed that it was 0.6 at D value and the final concentration of IPTG was 0.1 mmol/L and induction for 5 hours, the expression of Hsp60 rose remarkably, which accounted for 27.2 % of total bacterial proteins. Among them, soluble substance accounted for 14.7 % of supernatant. Hsp60 was further purified with Ni-NTA column; its final purity was 80 %.

Antigenicity study of recombinant fusion protein

The positive results by ELISA had colors, but the negative results had no colors, or weak colors. The results showed that the eight mice sera immunized with rHsp60 showed positive results. In contrast, the eight mice sera in control group showed negative results. At the same time, sera from patients also showed the same results. Eight *H pylori* positive sera from patients showed positive results and three *H pylori* negative sera from patients showed negative results, it showed that anti-Hsp60 antibody existed in sera of infected patients, indicating that rHsp60 could enable the organism to generate specific humoral immunity.

DISCUSSION

Hsps exists widely in nature and is one of the most conservative proteins of biosphere. For a long time, people have researched low Hsps as a molecular partner took part in physiological activities of cells. However, their results indicate that Hsps from microorganisms are the most important protective antigens when people and animals are infected with microorganisms. The protective immune response to 20 kinds of infectious diseases, such as tuberculosis and lepra was directly aimed at Hsps as far as reported[33,34]. Especially in the model of mice infected with tubercle bacillus, specific anti-Hsp60 only produced immunoreaction with Hsp60 of tubercle bacillus, not with mice Hsp60 themselves[37]. This resolved the autoimmune problems because of high conservation, which was perplexed. Furthermore, in models of mice and monkeys infected with plasmodium, immunoreactions did not depend on adjuvants when polypeptides were combined with Hsp60[38]. It showed that Hsp60 had similar functions of adjuvants. So under the uncertainty of *H pylori* urease preventing *H pylori* infection, *H pylori* Hsp60 as a *H pylori* vaccine component is not only used to combine urease to constitute multivalence vaccine, but also used as adjuvants to resolve the disadvantages of CT or LT.

In fact, *H pylori* Hsp60 immune protection function has been confirmed by experiments *in vitro* and *in vivo*. Yamaguchi *et al* reported *H pylori* Hsp60 monoclonal antibody could significantly inhibite adhesion of *H pylori* to human gastric epithelial MKN45 cells and gastric cancer cells[39]. Yamaguchi *et al* also evaluated the protective effect of immunization with amino acids 189 to 203 (VEGMQFDRGYLSPYF) on *H pylori* Hsp60 molecules[40]. The results suggested that the immune response to the epitope (VEGMQFDRGYLSPYF) was unique and could prevent *H pylori* infection in animal models. In this study, specific antibody to Hsp60 was detected in sera from the mice immunized with purified recombinant protein Hsp60, but not in sera from the mice in control group. Sera from patients also showed the same results. These results suggest that Hsp60 of *H pylori* may be a good candidate for a vaccine. However, whether it can be used as an adjuvant and antigen needs to be further researched.

Abstract

AIM: To study the distribution and expression of non-muscle myosin light chain kinase (nmMLCK) in rabbit livers.

METHODS: Human nmMLCK N-terminal cDNA was amplified by polymerase chain reaction (PCR) and was inserted into pBKcmv to construct expression vectors. The recombinant plasmid was transformed into XL1-blue. Expression protein was induced by IPTG and then purified by SDS-PAGE and electroelution, which was used to prepare the polycolonal antibody to detect the distribution and expression of nmMLCK in rabbit livers with immunofluorescene techniques.

RESULTS: The polyclonal antibody was prepared, by which nmMLCK expression was detected and distributed mainly in peripheral hepatocytes.

CONCLUSION: nmMLCK can express in hepatocytes peripherally, and may play certain roles in the regulation of hepatic functions.

INTRODUCTION

Protein kinase plays an important regulatory role in response to both intracellular and extracellular signals[1]. Specific protein kinase is thought to control various cellular functions including glycogen metabolism, muscle contraction and growth, etc. Myosin light chain kinase (MLCK) is a Ca^{2+}/calmodulin activated enzyme in the kinase family which catalyses the phosphorylation of the 20-ku myosin light chain (MLC-20)[2]. In skeletal muscle, the phosphorylation of MLC-20 correlates with potentiated twitch tension after repetitive stimulation. In smooth muscle cells, this phosphorylation leads to an increase in actomyosin ATPase activity and contraction which appears to be required for initiation of contraction. Phosphorylation of MLC-20 by smooth muscle MLCK is a key event initiating smooth muscle contraction. Although the roles of MLCK in non-muscle cells have not been well defined, a variety of morphological changes such as cellular motility and organelle movement occur concurrently with the increased cytoplasmic Ca^{2+} levels, light chain phosphorylation and activation of MLCK. Intracellular localization studies performed in mammalian fibroblast cells have colocalized MLCK to the spindle apparatus and midbody of mitotic cells. These observations have led to the suggestion that the phosphorylation of MLC-20 by MLCK in non-muscle cells might have a role in cell division and cell motility[3]. There are at least two different stress fiber systems in fibroblasts including central stress fiber system and periphery stress fiber system and the latter system depends on MLCK[4]. And at least two distinct classes of MLCK (short and long) phosphorylate the MLC-20 of myosin in thick filaments but bind with high affinity to actin in thin filaments[5]. But which form of MLCK exists in hepatocytes? How is MLCK involved in cellular functions in hepatocytes? In order to investigate the roles of MLCK in the maintenance of liver functions and its association with some liver diseases in the future study, we prepared polyclonal antibody through expressed MLCK protein in *E. Coli* system, and the antibody was used to detect the distribution and expression of MLCK in hepatocytes with immunofluorescence microscopy. Our research provides the basis for further investigation MLCK functions of in the liver and its relation with the pathology of some hepatic diseases such as hepatocellular carcinoma and hyperlipoproteinmia.

MATERIALS AND METHODS

Reagents and instruments

Plasmid pBKcmv and *E. coli* XL1-blue were from STRATAGENE (La Jolla, CA, USA). The human-non-muscle-MLCK cDNA was a gift from Dr. Stull at University of Texas Southwestern Medical Center, USA. Concept rapid PCR purification system kit was purchased from Life Techology, GibcoBRL. pGEM-T vector system I was purchased from Promega (Madison WI, USA). Restriction endoenzyme, T_4DNA ligase, dNTPs, amplitaqe DNA polymerase, mounting media were obtained from Sigma Chemical Company. PCR primers were synthesized by BioAsia Biotechnology Co., Ltd (Shanghai, China). Other reagents were made in China and were of analytical purity. DYY-III type-2 electrophoresis and transfer system were made by Beijing Instrument Factory. UV-754 spectrophometer was made by The Third Factory of Analytical Instrument of Shanghai. Nikon eclipse E800 microscope was from Japan.

PCR of hnmMLCK DNA

The primers were designed according to human MLCK cDNA,

prime 1: 5' TGG AAT TCC ATG GGG GAC GTG AA3' containing *Eco*RI restriction site and prime 2: 5' CCA CTG CTG AAG AAG CTT AAA ATC3' containing *Hind*III restriction site. The PCR parameters were pre-denaturation at 94 ℃ for 5 min before amplification was done for 35 cycles at 94 ℃ for 1 min, annealing at 55 ℃ for 1 min and extension at 72 ℃ for 1 min, and final extension for 10 min at 72 ℃ after the last cycle. The PCR products were examined by 20 $g.L^{-1}$ agarose gel electrophoresis with TAE buffer at 80V for 40 min, visualized with ethidium bromide, and photographed under UV light.

Ligation, transformation and sequence of hnmMLCK DNA[6]

The PCR products were purified by concept rapid PCR purification system kit and inserted into the T-vector, the resulting ligation products were transferred into XL1-blue *E.coli* competent cells. The positive clone was picked up and the plasmids were prepared. The plasmid and pBKcmv vector were digested with *Eco*RI and *Hind* III and ligated before transferred into XL1-blue E *coli* competent cells. Individual recombinant white clones were picked up and recombinant DNA was prepared before digested with restrictive endonuclease. The recombinant plasmid sequence was detected with ABI377 auto analytical instrument.

Expression and purification of hnmMLCK in E. coli[7]

The positive recombinant plasmids were transformed into XL-1blue *E. coli*, the single clone was picked up and cultured overnight at 37 ℃ with shaking at 250 rpm. The media were diluted (1:100) with Luria-bertani liquid medium and isoploprl-h-D-thiogalactoside (IPTG) was added into the medium to induce protein expression when OD_{600}=0.6-0.8, and cultured for 4 h. The bacteria were harvested by centrifugation at 5 000 rpm for 10 min and the expressed protein was analyzed by SDS-PAGE. The expressed band was cut from SDS-PAGE gel and electroeluted in transfer buffer for isolation and purification.

Anti-myosin light chain kinase polyclonal antibody preparation

Polyclonal antibody to human MLCK was prepared according to the previously described method[8].

Immunofluorescence detection of MLCK in rabbit livers

The New Zealand rabbit liver tissues were embedded with O.C.T and frozen sections were prepared. The slices were incubated in 100 % acetone for 10 min at -20 ℃ and dried in air, then blocked in 5 % non-fat milk in PBS (pH7.4) overnight. The blocking solution was removed and anti-MLCK polyclonal antibody was added, and then incubated in a wet box for 2-3 h. The reactions were incubated with FITC-labeled secondary antibody for 1 h. Finally, the reactions were covered with mounting media before observation with a Nicon fluorescent microscope[9,10].

RESULTS

Amplification of human MLCK cDNA

The PCR products were detected by 20 $g\cdot L^{-1}$ agrose gel. The results showed that there was a 450 bp band in the gel (Figure 1), corresponding to the fragment of human MLCK cDNA N-terminate.

Enzymatic and sequence analysis of recombinant plasimid and cloned DNA

The recombinant plasmid was digested with *Eco*RI and *Hind*III and then run in 20 $g\cdot L^{-1}$ agrose gel, which showed that the PCR products were inserted into the pBKcmv vector (Figure 2). The DNA sequences of pBK-hnmMLCK were detected by ABI377 auto analytical instrument (Figure 3), and compared with Genbank (Figure 4).

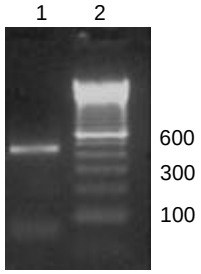

Figure 1 Amplification of hnmMLCK cDNA by PCR . 1. products of PCR amplification, 2. the 100 bp ladder.

Protein expression and purification

The expressed protein hnmMLCK in *E. coli* was induced with IPTG and bacteria were centrifuged at 5 000 rpm for 10 min. The pellet was resuspended with PBS, and an equal volume of 2×protein loading buffer was added, boiled at 100 ℃ for 5 min and analyzed by SDS-PAGE. The percentage of the expressed protein was about 21 % by scanning analysis (Figure 5).

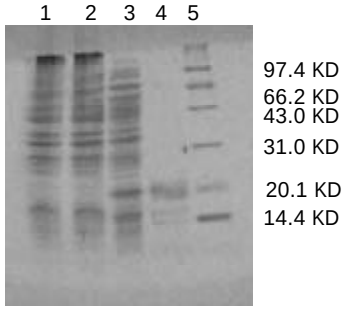

Figure 5 Analysis of pBK-hnmMLCK with SDS-PADE. 1. pBKcmv in XL1-blue, 2. pBK-hnmMLCK in XL1-blue before induced, 3. pBK-hnmMLCK in XL1-blue after induced, 4. purified expression protein, 5. protein markers.

Antiserum detection by immune double-diffusion

The ratio of antigen to antibody was at least 1:16 (Figure 6), suggesting that the polyclonal antibody could be used for immunoflouresence analysis.

Distribution of MLCK in rabbit livers

MLCK was mainly distributed peripherally in hepatocytes (Figure 7), and was hardly detected cytoplasms by immunofluorescence.

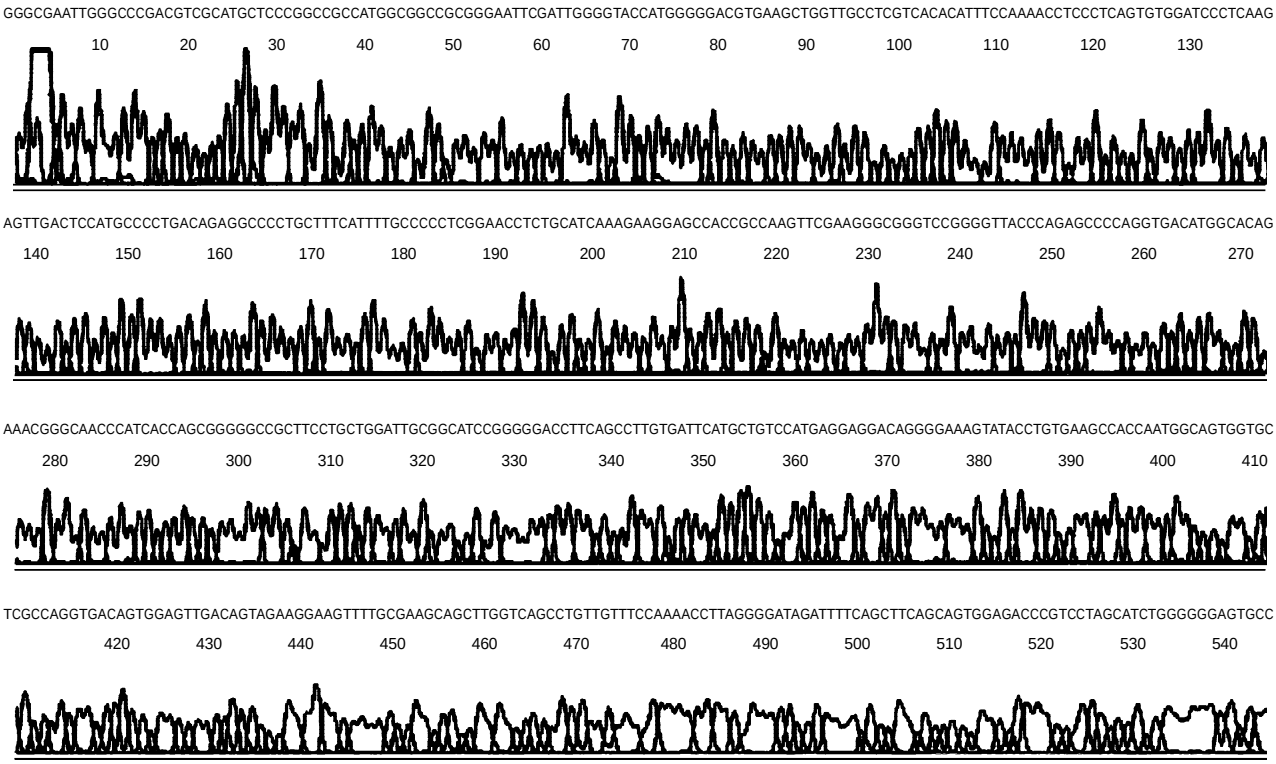

Figure 3 DNA sequences of pBK-hnmMLCK were detected by ABI377 auto analytical instrument.

DISCUSSION

MLCK is the key regulator of cell motility and smooth muscle contraction in higher vertebrates[11-13]. MLCK expression shows a complex pattern. In undifferentiated myoblasts, 220-ku long or non-muscle form of MLCK is expressed during differentiation of skeletal muscle. During myoblast differentiation, the expression of 220-ku MLCK declines and expression of this long-term is replaced by 103-ku smooth muscle MLCK and a skeletal muscle-specific MLCK. The two isoforms are products of a single gene[14], and both short and long MLCKs are expressed in embryonic and adult non-muscle as well as smooth muscle cells[15,16]. Recently, some study showed the existence of a 208-ku protein, named embryonic MLCK because its expression could be detected in early embryonic tissue stem cells and in proliferating culture cells[17]. MLCK has several well characterized domains, and they are comprised of an amino-terminal "tail" of unknown function and a central catalytic core that is homologous to the catalytic core of other protein kinases, carboxy-terminal to the catalytic core and calmodulin binding domains, which are involved in the activation of the kinase in responses to increased Ca^{2+}[18]. In this study we constructed the expression vector which could express N-terminal MLCK, and used this protein to prepare polyclonal antibody. The results showed that the antibody could react with hepatic cells and MLCK was distributed in the peripheral region of hepatic cells. In rabbit portal vein myocytes, MLCK could mediate noradrenaline-evoked non-selective cation current[19]. In the liver, agents that elevated intercellular free Ca^{2+} concentration could increase tight junctional permeability and stimulate bile canalicular contraction. Myosin phosphorylation is might be responsible for the tight junctional permeability caused by elevation of intercellular Ca^{2+} in hepatocytes. Moreover, the integrity of the phosphorylation systems of myosin is essential for normal bile flow. In addition, hepatic sinusoidal Ito cells play a regulatory role on hepatic blood flow through their contraction, while the integrity of MLCK is essential for Ito cell contractions and normal sinusoidal blood flow. However, the role of myosin phosphorylation by MLCK in non-muscle tissues has not been well characterized but correlated with important activities such as cell division, receptor capping[20,21], *etc*. It has been found that MLCK was closely associated with non-muscle cells[16,19,20]. Phosphorylation of myosin light chain by MLCK in non-muscle cells and tissues demonstrated an important physiological function[22]. For example, myosin light chain phosphorylation has been implicated in secretory vesicle movement, cellular locomotion and changes in cellular morphology[23]. MLCK activation was a critical step in cytoskeletal changes causing pseudopod formation during polymorphonuclear leukocyte phagocytosis[24]. MLCK was also associated with the gap formations and endothelial hyperpermeability of coronary venular endothelial cell monolayers[25]. The preliminary studies showed that the light chain was obviously phosphorylated when CaM was added into the reaction buffer at a suitable concentration of Ca^{2+}. The activity of MLCK in rabbit livers increased markedly when CaM was added, and the activity changed with a substrate concentration or the concentration of light chain kinase[26]. MLCK immunoreactivity was found to be colocalized with the insulin granules, suggesting that it increased insulin granules in the ready-releasable pool by acting on different steps in the secretary cascade[27]. In this study, the expressed vector was successfully constructed and MLCK was expressed in *E coli* system, which lays a good basis for the manufacture and clinical application of the enzyme. The anti-MLCK polyclonal antibody was prepared and used to detect the distribution of MLCK in the cells of rabbit liver. MLCK may play an important role in maintaining the normal functions of tissues. But in the liver, which form of MLCK was expressed, long or short? If there are both forms, which form expresses more? What are their roles in the liver? What roles will it play in liver regeneration, injury or hepatic carcinoma? And what is the mechanim of MLCK activity in the liver? All these remain to be investigated and elucidated in future studies.

Abstract

AIM: *In vivo* induced genes are thought to play an important role during infection of host. *AlkA* was identified as an *in vivo*-induced gene by *in vivo* expression technology (IVET), but its virulence in *Shigella flexneri* was not reported. The purpose of this study was to identify the role of *alkA* gene in the pathogenesis of *S. flexneri*.

METHODS: PCR was used to amplify *alkA* gene of *S. flexneri 2a* and fragment 028pKm. The fragment was then transformed into 2457T05 strain, a *S flexneri 2a* strain containing Red recombination system, which was constructed with a recombinant suicide plasmid pXLkd46. By *in vivo* homologous recombination, alkA mutants were obtained and verified by PCR and sequencing. Intracellular survival assay and virulence assay were used to test the intracellular survival ability in HeLa cell model and the virulence in mice lung infection model respectively.

RESULTS: Deletion mutant of *S. flexneri 2a alkA* was successfully constructed by λ Red recombination system. The mutant exhibited significant survival defects and much significant virulence defects in mice infection assay.

CONCLUSION: *AlkA* gene plays an important role in the infection of epithelial cells and is a virulent gene of *Shigella spp*.

INTRODUCTION

Shigella spp. is a Gram-negative facultative pathogen, which causes bacillary dysentery, a world endemic bloody diarrhea, particularly in developing countries. The disease is caused by invasion of the colorectal mucosa by *Shigella spp.*, replicating within epithelial cells and moving between cells. The interaction between epithelial cells and *Shigella spp.* plays an important role in the pathogenicity of *Shigella spp.*[1-3]. During infection of epithelial cells, genes with inducible expression are important for *Shigella spp.* to replicate and survive in the cells. Hereby, these genes are generally thought to be related to the virulence of *Shigella spp.*. Many methods could be used to isolate *in vivo* expressed genes[4].Using *in vivo* expression technology (IVET) to identify the virulence-related genes of pathogens is a flourishing field in the world[5-11]. We have employed *in vivo* expression technology with *asd* gene as a reporter to screen *S. flexneri 2a* fusion gene library. The result indicated that *alkA* gene is an *in vivo*-induced gene for *Shigella flexneri 2a*.

AlkA gene or its homologous genes have been cloned from many organisms, such as *Escherichia coli*, *Helicobacter pylori*, *Bacillus subtilis*, *Saccharomyces cerevisiae*, human, etc[12-14]. They encode 3-methyladenine DNA glycosylase, whose function is excising hypoxanthine, demethylating, and mainly taking part in the repair of damaged DNA[15,16]. Up to now researches on *alkA* have mainly focused on regulation of its expression and its role in inducing repair after DNA alkylation damage. As for its relation to bacterial pathogenesis, it is a noteworthy issue. In this experiment, based on the sequence of *E.coli alkA*, *alkA* gene of *S. flexneri 2a* 2457T was cloned. Its mutant was constructed, and its role in pathogenesis was analyzed by a HeLa cell model and a mice infection model. This study perhaps would provide insights into the pathogenicity of this pathogen.

MATERIALS AND METHODS

Materials

The strains and plasmids used in this study are listed in Table 1.

HeLa cell line was maintained in our laboratory. BALB/c mice were bought from the Laboratory Animal Center in the Academy of Military Medical Sciences, Beijing. All mice used in this study were female, specific pathogen free animals, with an age of 7-8 weeks and weight of 18-22 g. DNA endonucleases, DNA marker, T4 DNA ligase, T4 DNA polymerase, Ex *Taq* DNA polymerase, and CIAP were purchased from Takara Company. Newborn calf sera and RPMI1640 media were from HyClone, and deoxycholate sodium from Sigma. Primers (P1, P2, P3, and P4) were synthesized in our laboratory.

Methods

Culture and maintenance of strains and HeLa cells Luria-Bertani (LB) broth and agar plate were used for the growth of *S. flexneri* and *Escherichia coli* strains at 37 ℃. SOC culture medium was applied to the restoration of bacteria after electroporation. When appropriate, antibiotics were added in media as follows: 100 μg ampicillin (Ap), 100 μg streptomycin (Sm), 50 μg kanamycin (Km), 25 μg chloramphenicol (Cm), and 25 μg naladixic acid (Nal) per ml. HeLa cells were maintained in the RPMI-1640 medium supplemented with 10 % fetal bovine serum, 200 mM L-glutamine, 2 mg sodium hydrogen carbonate per ml and 100 μg penicillin-streptomycin per ml. The cells were cultured in 37.5 cm^2 or 10 cm^2 flasks at 37 ℃ in a humidified atmosphere of 5% CO_2. Confluent monolayers were split by treatment with sterile phosphate-buffered saline (PBS) and trypsin-EDTA.

Genetic techniques Plasmid DNA extraction was carried out using a Qiagen plasmid kit. Digestion, ligation, transformation, and other conventional methods of molecular biology were performed as previously described[18].

DNA amplifications For the amplification of *S. flexneri 2a alkA* gene, PCR was performed in a standard 100 μl reaction volume containing 2.5 mM Mg Cl_2, 0.25 mM of each dNTP, 100 pmol of P1 and P2 primers, 10 μl boiled *S. flexneri 2a* 2457T, and 5 U Taq DNA polymerase. Reactions were allowed to proceed in a Perkin-Elmer 2400 thermal cycler programmed for 10 min at 94 ℃, 30 cycles (for 45 s at 94 ℃, for 40 s at 55 ℃, for 3 min at 72 ℃) and an additional extension reaction for 10 min at 72 ℃. For the amplification of fragment 028pKm, PCR was carried out in 100 μl reaction volume containing 2.5 mM $MgCl_2$, 0.25 mM of each dNTP, 100 pmol of P3 and P4 primers, 2 μl plasmid pMD028pKm (about 10 ng), and 5 U Taq DNA polymerase. The program of this PCR was at 94 ℃ for 10 min, 30 cycles (for 30 s at 94 ℃, for 40 s at 58 ℃, for 1.5 min at 72 ℃) and for 10 min at 72 ℃.

Bacterial mating The donor and recipient strains were grown in LB medium containing appropriate antibiotics overnight. The liquid cultures were then washed in PBS, mixed at 1:1 ratio, and spreaded on LB agar plates. The plates were incubated at 37 ℃ for 6-8 h. After incubation, the conjugation mixture was washed in PBS and spread onto LB agar plates containing chloramphenicol (25 μg· mL^{-1}) and naladixic acid (25 μg· mL^{-1}). The plates were incubated at 37 ℃ until transconjugants were visible.

Disruption of *S. flexneri 2a alkA* gene *S. flexneri 2a* 2457T05 was grown in 5 ml LB cultures with chloramphenicol, naladixic acid and L-arabinose to an OD_{600}=0.45 and then made electrocompetent by concentrating 100-fold and washing three times with ice-cold 10 % glycerol. The gel-purified *028pKm* PCR products were digested with *DpnI*, repurified, and suspended in elution buffer (10 mM Tris, pH 8.0). Electroporation was done using a gene pulser® II with a pulse controller plus and 0.1 cm chambers according to the manufacturer's instructions (Bio-RAD) using 40 μl of competent cells and 100 ng of 028pKm fragments. The parameters for electro- transformation were resistance 200Ω, capacitance 25 μF, and voltage 2 500 V. Shocked cells were added to 1 ml SOC culture, incubated for 1 h at 37 ℃, and then one-half was spread onto agar to select Km^r and Nal^r transformants. If none grew within 24 h, the remainder was spread after standing overnight at room temperature.

Intracellular survival assay HeLa cell infection assay was routinely used to detect the intracellular replication or survival ability of the mutant[19-21]. *S. flexneri 2a* 2457T, 2457T05, mutant strain and *E. coli* MC1061 (noninvasive control) were grown in an appropriate medium overnight. The liquid cultures were then washed in PBS and resuspended in antibiotic-free medium. Approximately 10^6 HeLa cells were cultured in a 10 cm^2 flask. HeLa cells were washed three times in PBS prior to incubation with about 10^8 CFU bacteria at 37 ℃ for 3 h. The medium was removed from infected cells after 2.5 h, and the cells were washed three times in PBS. Fresh medium containing gentamicin (20 μg· mL^{-1}) was added and the flasks were incubated for 5 h to eliminate extracellular bacteria. After that, the medium was replaced by RPMI1640 containing gentamicin (20 μg· mL^{-1}) and the infected cells were cultured for another 40 h. The supernatants of culture were tested for extracellular surviving bacteria by plating them on LB agar plates. The monolayers were then washed three times in PBS and lysed by addition of 0.1 % deoxycholate sodium to liberate the intracellular bacteria. Dilutions of the lysates of HeLa cells infected with bacteria were plated on LB agar plates and cultured at 37 ℃ overnight. The CFU of the bacteria was then counted.

Competition assay To test the mutant strains for alterations in virulence relative to the wild type, a competition assay was carried out by using a murine intranasal infection model[22-24] with some modifications. The mutant or MC1061 (negative control) or 2457T (positive control) and 2457T05 grown overnight were mixed at 1:1 (v/v) ratio and washed in PBS. After concentration of the mixture was adjusted by dilutions, 20 μl mixtures containing about 10^6 CFU in PBS was used to introduce droplets into the nares of BALB/c mice that was anesthetized. The number of bacteria in each inoculum was determined by plating serial dilutions of the inoculum. After 24 h, the recovered bacteria from the lungs of mice were counted, and then the number of mutant strains and 2457T was counted. According to the method of Camilli *et al*.[25], the competitive index of each mutant was obtained.

Bioinformatics analysis The sequence of *S. flexneri 2a alkA* gene was analyzed by BLAST (http://www.ncbi.nlm.nih.gov/BLAST/). The identity and gene function were also analyzed by NCBI.

Statistical analysis

Data from the intracellular survival assay were analyzed by Dunnett *t* test, and *P* value less than 0.05 was considered as statistically significant. Data from the competition assay were analyzed by the sign test, and *P* value less than 0.0078 was

considered as statistically significant. The Dunnet *t* test and the sign test were performed using the SAS (Statistical Analysis Systems Inc., USA) program.

RESULTS

Cloning and homologous analysis of S. flexneri 2a alkA gene

In our previous work, we identified *S. flexneri 2a alkA* as an *in vivo*-induced gene, and obtained the partial sequence of *S. flexneri 2a alkA* gene which had an alignment with other bacteria. Based on the sequence of *E. coli alkA*, the primers, P1 (CGAGGAACGATTTTGGTGAT) and P2 (CTCGCT-GAAAGCGAATATGG) (Figure 3 B) were designed. Using *S. flexneri 2a* 2457T chromosome DNA as a template, PCR was performed and the PCR products were purified by agarose gel electrophoresis, and ligated into plasmid pMD18-T to produce plasmid pMD028 after the confirmation of *EcoRV* and *HindIII* digestion analysis. The recombinant plasmid pMD028 was subjected to DNA sequencing to obtain the whole length DNA sequence of *alkA*. Its open read frame was 849 bp. In the upstream there was a promoter sequence (AGCAAAGCGTAACGTCTGAATAACGTTTATGCT) and the binding site (AAAGCAAA) of Ada protein which was a regulator of *alkA* gene expression in *E. coli*. Based on the sequence of *S. flexneri 2a alkA*, homologous analysis was carried out on the NCBI website. The results are listed in Table 2. Interestingly, the sequence alignment revealed a Helix-hairpin-Helix (HhH) motif common to DNA glycosylases. *E. coli* alkA was identified as the helix-hairpin-helix DNA glycosylase[26]. Very possibly, alkA protein from *S. flexneri 2a* belonged to an HhH-GPD super family. Its hallmark was Helix-hairpin-Helix and Gly/Pro rich loop followed by a conserved aspartate and its function was presumably involved in DNA replication and repair.

Construction of S. flexneri 2a engineering strain

To delete *alkA* gene of *S. flexneri 2a*, construction of *S. flexneri 2a* engineering strain expressing *gam*, *bet*, and *exo* genes, was required. The fragment (about 4 kb) containing *gam*, *bet*, and *exo* genes was obtained by digestion of pKD46 plasmid with *Pvu I* and *Bstx I* and ligated into the *Sal I* site of suicide plasmid pXL275. Then the ligation products were then transformed into $S_{17\text{-}1}\lambda$pir. The recombinant plasmid was confirmed by *BamHI* digestion and known as pXLkd46. After bacterial mating of the donor ($S_{17\text{-}1}\lambda$pir/pXLkd46) and recipient (2457T), pXLkd46 plasmid was integrated into chromosome of *S. flexneri 2a* by homologous recombination. The process of pXLkd46 plasmid construction and chromosomal integration is showed in Figure 1. The resulting strain was verified with antibiotic selection and serum agglutination and designated as 2457T05.

Construction of deletion mutant of S. flexneri alkA gene

After 2457T05 was successfully constructed, the linear targeting DNA, *028pKm*, was required for disruption of *S.*

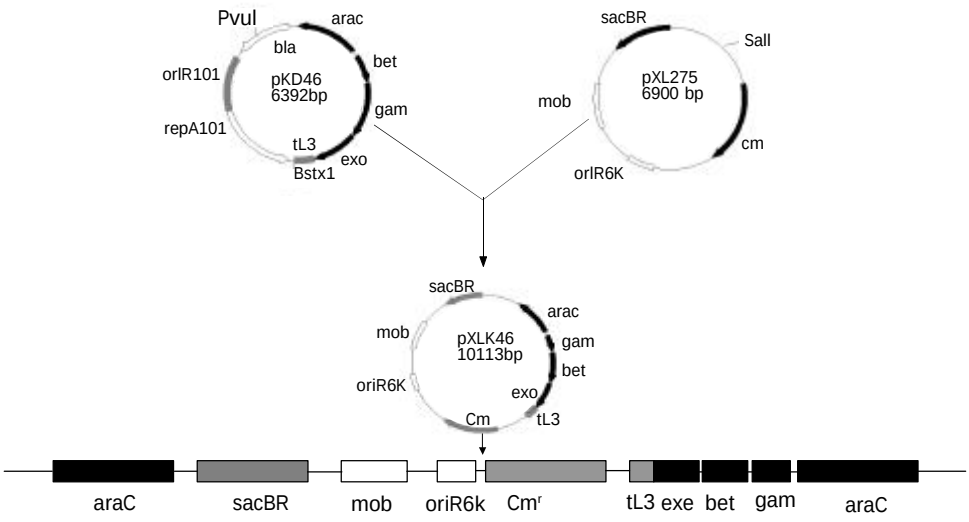

Figure 1 Construction and chromosomal integration of pXLkd46 plasmid.

Table 2 BLAST analysis of *S. flexneri 2a alkA* gene

Bacteria	Gene product	Gene function	Identities (%)
Escherichia coli K12	3-methyl-adenine DNA glycosylase II	DNA - replication, repair, restriction / modification	97 %
Escherichia coli O157:H7	3-methyl-adenine DNA glycosylase II	Macromolecule synthesis, modification: DNA-replication, repair, restriction / modification	97 %
Salmonella typhimurium	3-methyl-adenine DNA glycosylase II	Unknown	74 %
Ralstonia solanacearum	putative transcription regulator protein	Miscellaneous; not classified regulator	38 %
Pseudomonas aeruginosa	DNA-3-methyladenine glycosidase II	Unknown	37 %
Xanthomonas axonopodis	DNA methylation and regulatory protein	Unknown	35 %
Mycobacterium bovis	Methylated-DNA–protein-cysteine methyltransferase	Adaptative response	34 %
Mycobacterium tuberculosis	alkA protein	Unknown	34 %
Vibrio cholerae	ada regulatory protein	Unknown	32 %
Bacillus anthracis	DNA-3-methyladenine glycosidase	Unknown	32 %
Archaeoglobus fulgidus	3-methyladenine DNA glycosylase	DNA repair at suboptimal and maybe even mesophilic temperatures	30 %

flexneri 2a alkA gene with λ Red recombination system. To obtain the fragment *028pKm*, recombinant plasmid pMD028pKm was firstly to be constructed. Km^r gene fragment was obtained from plasmid pMDKm05 digested by *HincI I* and *Sma I* and inserted into the *alkA* gene of plasmid pMD028 digested by *EcoRV* and *StuI* and dephosphorized by CIAP. The ligation products were then transformed into *E. coli* DH5α. The recombinant plasmids were isolated from the transformants, confirmed by *EcoR I* digestion, and designated as pMD028pKm (Figure 2). Using pMD028pKm as a PCR template, P3 (TGTGCCAGTGAGGAAAGACC) and P4 (GAGAGAGCGT TTGCCCATTG) (Figure 3A) as primers, PCR was carried out. In order to reduce the interference of plasmid pMD028pKm, the second PCR was carried out at the same experimental condition except that the template was the first PCR products diluted by 1 000 times. The second PCR products (*028pKm*) did not contain the template plasmid pMD028pKm that would lead to false positive colonies in the latter electroporation experiment. The *028pKm* fragment was a cassette, 5' *alkA* end-Km^r-3' *alkA* end (Figure 3A). The concentrated *028pKm* was electroporated into *S. flexneri 2a* engineering strain 2457T05. The *alkA* gene was then replaced by kanamycin resistance gene through homologous recombination mediated by λ Red system. The positive transformants were selected on LB agar plates containing Km and Nal.

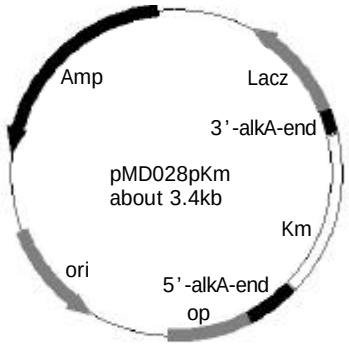

Figure 2 Construction of recombinant plasmid pMD028pkm.

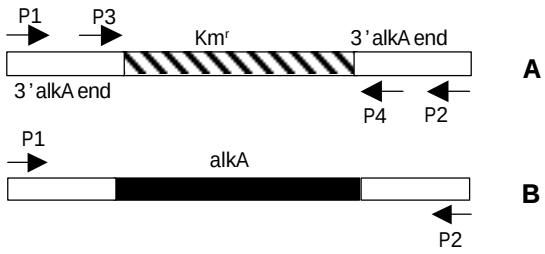

Figure 3 Location of primers P1, P2, P3 and P4 in PCR products of *alkA* and *028pKm*. A: *028pKm* (about 1.4 kb); B: *alkA* (about 1.7 kb).

To verify the replacement of *S. flexneri 2a alkA* gene, PCR and sequencing were used. PCR was performed in which 2457T05 (negative control), the transformant and pMD028pKm plasmid (positive control) were used as templates. The reaction conditions were the same as the amplification of *S. flexneri alkA* gene, and the primers were also P1 and P2. The PCR products from the transformant and pMD028pKm plasmid were about 1.4 kb and 1.7 kb from 2457T05 respectively (Figure 3, 4). Then the PCR products were sequenced and analyzed by BLAST (data not shown). The result indicated that *alkA* gene of *S. flexneri 2a* was replaced by Km^r gene. Hereby, the deletion mutant of *alkA* gene was successfully constructed and designated as 2457T028D.

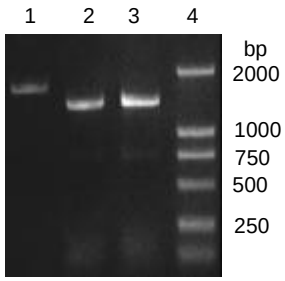

Figure 4 Verification of *alkA* gene deletion of 2457T028D mutant by PCR. 1: *alkA* PCR product (amplified from 2457T05), 2: *028pKm* PCR product (amplified from 2457T028D), 3: *028Kkm* PCR product (amplified from pMD028pKm), 4: DL2000 Marker.

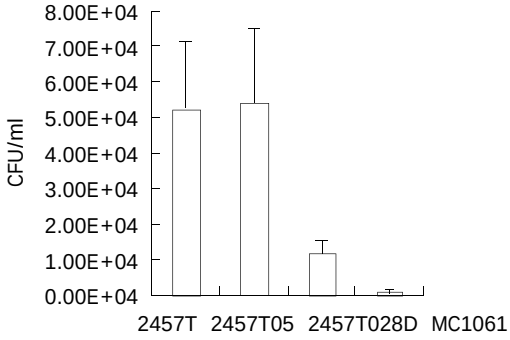

Figure 5 Comparison of HeLa cells infected by 2457T, 2457T05, 2457T028D and MC1061.

Functional analysis of deletion mutant of S. flexneri 2a alkA gene

In order to detect the role of *alkA* in the pathogenesis of *S. flexneri*, intracellular survival assay and virulence assay were respectively carried out in HeLa cells and BALB/c mice.

Mutant 2457T028D was tested for its survival ability in HeLa cells relative to the wild-type strain. Equal volume of each strain (2457T, 2457T05, 2457T028D and MC1061) was respectively used to infect the HeLa cell monolayer. Within 48 h, the integrity of the infected HeLa cell monolayer was good and the configuration of HeLa cells had no significant alterations relative to normal cells. But the growth rate of the infected cells became slow. After 48 h, CFU of bacteria recovered from HeLa cells was counted. The results of the infection assay are summarized in Figure 5. Noticeably, CFU levels of the mutant recovered from HeLa cells were five-fold lower than that of the wild type (P<0.01), indicating that the mutant had a lower capability of survival or replication. The survival probability of 2457T and 2457T05 showed no significant difference (Figure 5). In order to further confirm the survival probability of the mutant, competition assay was carried out with the HeLa cell infection model. A 1:1 (v/v) mixture of *S. flexneri 2a* 2457T05 and the mutant or 2457T or MC1061 was used to infect HeLa cells. The number of bacteria in each inoculum was determined by plating serial dilutions of the inoculum. After 48 h, recovered bacteria from HeLa cells were counted, and the number of bacteria was counted respectively. The experiment was separately repeated 3 times. Therefore, the competitive index of each strain obtained is shown in Table 3. The mutant 2457T028D whose survival probability was significantly lower in the infection assay, exhibited significant survival defects in this experiment (P<0.0078). The data strongly indicated that the mutant was much less able to survive in HeLa cells.

The mutant was also tested in a mice lung infection model for alterations in virulence relative to the wild-type parental strain. Mice that were challenged only with *S. flexneri* 2457T

showed early acute bronchiolitis at 24 h, followed by severe pneumonia at 48 h. Five mice were used for each group in the murine lung infection model. After 24 h, recovered bacteria from the lungs of mice were counted, and the number of each strain was counted. Then the competitive index of each strain obtained is summarized in Table 3. The mutant also exhibited significant colonization defects ($P<0.0078$). The data further indicated that *alkA* gene was potentially related to the virulence of *S. flexneri 2a* 2457T.

Table 3 Competitive analysis of different strains of *S. flexneri 2a*

Strains	Competitive index (CI)[a]	
	BALB/c mouse infection	HeLa cells infection
2457T05	0.96±0.27	1.07±0.35
2457T028D	0.21±0.09[b]	0.25±0.11[b]
MC1061	0.03±0.02[b]	0.02±0.01[b]

[a]Competitive index (CI) is the ratio of mutant CFU to wild-type CFU after correcting the ratios for deviations of the inoculum ratio from a value of 1. [b]$P<0.0078$.

DISCUSSION

It has been reported that *in vivo*-induced gene played an important role in the process of interaction between pathogen and host[27]. *In vivo*-induced genes are those whose expression is induced when pathogens infect their hosts. Their inducible expression is a molecular-level genetic adaptive response to special environments of host. Many virulent genes have been identified by mutational analysis of *in vivo*-induced genes. Heithoff *et al.*[28] used *purA-lacZY* as a reporter to identify *in vivo*-induced genes of *Salmonella typhimurim* utilizing macrophages or BALB/c mice as a model. They discovered some *in vivo*-induced genes, including regulatory genes (*phoP, pmrB, cadC*, etc.) and metabolic genes (*recD, hemA, mgtA, entF*, etc.). Furthermore, insertion mutants of these genes were constructed, and their virulence was detected. Seven of them exhibited significant virulence defects. In an another research on *Pseudomonas aeruginosa*, 22 genes were *in vivo*-induced during infecting BALB/c mice, including *np20*, which has been proved to be a virulence gene, and known as virulent factor FptA[29]. In our previous study, we identified *alkA* as an *in vivo*-induced gene. However, it is unknown if *alkA* gene is related to the virulence of *S. flexneri*.

In order to detect the role of *alkA* gene in the virulence of *S. flexneri 2a*, it is required to construct the deletion mutant of *alkA* gene. The mutant is conventionally constructed by twice homologous recombination mediated by suicide plasmid. Although the *asd* gene of *S. flexneri 2a* was successfully disrupted in our previous study[30], the efficiency of this method is very low and the experimental period is quite long. Recently, a new method, which depends on Red recombination system of λ phage, has been successfully established and used to speed up the knockout of genes[31,32]. However, its application was limited to *E. coli*[33-35]. It was not reported in other bacteria except that the *asd* gene was deleted with λ Red system in our laboratory[36]. In this study, the deletion mutant of *S. flexneri 2a alkA* gene was successfully constructed also with λ Red system. Importantly, an engineering strain 2457T05 of *S. flexneri 2a* was constructed, and it was confirmed that the strain could be used to study the function of *S. flexneri 2a* genes.

After the mutant of *S. flexneri 2a alkA* gene was constructed, intracellular survival and competition assays were carried out. The results showed that *alkA* mutant of *S. flexneri* could exhibit a low intracellular survival ability and a significant virulence defect, indicating that *alkA* was a virulence-related gene in *S. flexneri 2a*. However, it has not been reported before whether *alkA* was associated with the virulence of pathogens. *AlkA* is an expression-induced gene and its product, 3-methyladenine DNA glycosylase II, is involved in the SOS-dependent adaptive response. Expression of *alkA* is regulated by Ada protein. When alkylation damages bacterial DNA, *ada* gene would be induced by alkyl-DNA. The produced Ada finishes directly-repairing damage of alkyl-DNA by transferring the methyl group from alkyl-DNA to its cysteine residues. At the same time Ada loses its activity. The methyl-Ada turns into a positive regulator of *alkA, aidB, alkB*, and itself as well. Methyl-Ada could recognize and bind onto the special region (AAAGCAAA) of *alkA* promoter, start transcription of *alkA*, and further complete repairing damage of other type alkylation, avoiding bacterial death due to damage of DNA alkylation[37-40]. The base excision repair could protect against the deleterious effects of DNA alkyl lesions. However, the activities of *alkA* gene must be balanced for optimal protection against the biological consequences of damaged DNA bases because inappropriate expression of this activity might have a detrimental consequence[41]. During infection of host, *Shigella spp.* probably suffers strong damage of alkyl in host. But alkylated DNA activates the adaptive response of *Shigella spp.* to host. Expression of *alkA* effectively repairs damage of DNA alkylation so that the killing-effect resulted from DNA damage could not carry out. Therefore, from this point of view, *in vivo*-induced-expression of *alkA* provides a significant safeguard for infection of *Shigella spp.* and is an essential gene for exhibiting *Shigella spp.* virulence.

Although there has been no report about the relationship between *alkA* and virulence of pathogens, it is known that a close relation lies between DNA methylation and bacterial virulence. Heithoff *et al.*[42] discovered that DNA adenine methylase (Dam) could regulate expression of at least 20 *in vivo*-induced genes and that Dam$^-$ *S. typhimurium* as a live vaccine had a protective role with no side-effect. *S. typhimurium* with over-expressing Dam also exhibited a significant virulence defect and a protective effect as an oral vaccine[43]. Similar results have also been obtained in *Yersinia pseudotuberculosis* and *Vibrio cholerae*[44]. Hereby, during infection expression of Dam could induce the expression of *in vivo*-induced genes, but its over-expression could also lead to damage of methylation and attenuation of pathogens. Thus a suitable level of DNA methylation might play a key role for pathogens to keep the virulence. From this point of view, *alkA* may be a virulence-related gene of pathogens. The hypothesis illustrating the relationship between DNA methylation damage and *alkA* gene is shown in Figure 6. Whether a regulatory relation exists between *alkA* and *dam* remains to be further confirmed. However, we believe that *alkA* is a new target for studying on molecular pathogenesis mechanism of *Shigella spp.* and construction of attenuated live vaccines.

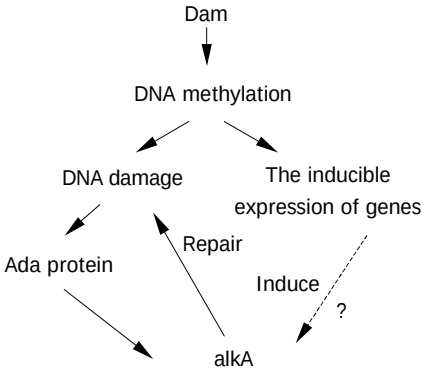

Figure 6 Hypothesis illustrating the relationship between *alkA* and damage of DNA methylation.

ACKNOWLEDGEMENTS

We thank Prof. Qi-Nong Ye and Dr Bao-Chang Fan for critical review of this manuscript. We also thank Miss Run-Yan Liu and Miss Hui-Ping Zhang for their help with experiments.

Abstract

AIM: To identify the differentially expressed proteins involved in ionizing radiation in mice and to explore new ways for studying radiation-related proteins.

METHODS: Bal B/c mice grouped as sham-irradiation, 3 h and 72 h irradiation were exposed to 9.0Gy single dose of γ-irradiation. Intestinal epithelia were isolated from mice, and total proteins were extracted with urea containing solution. A series of methods were used, including two-dimensional electrophoresis, PDQuest 2-DE software analysis, peptide mass fingerprinting based on matrix-assisted laser desorption/ionization time of flight mass spectrometry (MALDI-TOF-MS) and SWISS-PROT database searching, to separate and identify the differential proteins. Western blotting and RT-PCR were used to validate the differentially expressed proteins.

RESULTS: Mouse intestine was severely damaged by 9.0 Gy γ-irradiation. Image analysis of two-dimensional gels revealed that averages of 638±39, 566±32 and 591±29 protein spots were detected in 3 groups, respectively, and the majority of these protein spots were matched. About 360 protein spots were matched between normal group and 3 h irradiation group, and the correlation coefficient was 0.78 by correlation analysis of gels. Also 312 protein spots matched between normal group and 72 h irradiation group, and 282 protein spots between 3 h and 72 h irradiation groups. Twenty-eight differential protein spots were isolated from gels, digested with trypsin, and measured with MALDI-TOF-MS. A total of 25 spots yielded good spectra, and 19 spots matched known proteins after database searching. These proteins were mainly involved in anti-oxidation, metabolism, signal transduction, and protein post-translational processes. Western-blotting confirmed that enolase was up-regulated by γ-irradiation. Up-regulation of peroxiredoxin I was verified by applying RT-PCR technique, but no change occurred in Q8VC72.

CONCLUSION: These differentially expressed proteins might play important roles when mouse intestine was severely injured by γ-irradiation. It is suggested that differential proteomic analysis may be a useful tool to study the proteins involved in radiation damage of mouse intestinal epithelia.

INTRODUCTION

Since Wilkins and Williams first proposed the concept of "Proteome" in 1994[1], advances in the studies on proteome have made it possible to compare the total proteins of cells under different conditions on large scale. The proteomic strategy based on two-dimensional electrophoresis (2-DE) and mass spectrometry has been applied in a variety of studies[2,3].

Ionizing radiation is one of the main treatment modalities used in the management of pelvic cancer. Selective internal radiation therapy is a new method that can be used for patients given other routine therapies but without effects, and preoperative radiotherapy is effective and safe[4,5]. Although great success has been documented in cancer patients, certain side effects and complications have limited its applications in cancer radiotherapy. One of the major side effects of ionizing radiation is the depletion of normal cells along with cancer cells. For patients with pelvic cancer, a serious complication of radiotherapy is the radiation injury to small intestinal epithelium[6].

Small intestinal epithelium contains four major cell types: columnar cells, goblet cells, stem cells, and Paneth cells[7]. Intestinal stem cells, which are most sensitive to ionizing radiation, are located in the crypt portion of the intestine. The impact of ionizing radiation on intestinal stem cells can be detected at a dose as low as 0.05 Gy[8]. One of the early morphological changes that occur in mouse crypt cells upon treatment with ionizing radiation is the occurrence of apoptosis within 2-3 h after administration of the treatment. This apoptotic death can be visualized under both light and electron microscopy. Because of the emigration of crypt cells from the villi and the decreased proliferation of intestinal stem cells, the crypts become noticeably smaller 14-15 h after radiation[9]. The villous epithelial cells begin to decline from about the second day post radiation, and the villi become shorter. If a crypt contains viable clonogenic cells, the crypt begins to replenish its cellular population in the next few days.

Ionizing radiation can generate a series of biochemical events inside the cell. Free radicals produced from intercellular water interact with DNA and proteins, thus inducing inactivation of these macromolecules. It has been demonstrated that ionizing radiation can induce gene expression of intestinal epithelia[10,11]. As genes encode proteins, we can deduce that proteins of intestinal epithelia can be induced by ionizing radiation[12]. These proteins are associated with many important cellular processes including DNA repair, apoptosis, cell cycle control, and oxidative stress response[13,14]. With accumulating evidences in the literature that new proteins are implicated in

radiation response, the molecular mechanism underlying radiation response of the small intestine remains unknown. Our aim was to identify these proteins in the early stage of radiation injury. To achieve this purpose, we adopted comparative proteome approach to identify the mouse proteins whose expression was regulated by ionizing radiation. The proteomes of sham-irradiated mice were compared with those of irradiated mice 3 h and 72 h post-irradiation. The differentially displayed proteins were subjected to MALDI-TOF-MS to establish the identity. We also confirmed some differential proteins by Western blot and RT-PCR technique.

MATERIALS AND METHODS

Animal model and irradiation

A total of 15 male Bal b/c mice, 58-62 days of age, weighing 20-24 g, at the time of irradiation, were housed in conventional cages with free access to drinking water and standard chow. A pathogen-free environment with controlled humidity and temperature was maintained. These mice were randomly divided into 3 groups: one group received sham-irradiation (n=5), the other two groups received single dose of 9.0 Gy (n=5). The dose was chosen based on the data from our previous experiments. Whole-body irradiation was performed with a ^{60}Co-source at a dose rate of 0.78 Gy/min. The irradiated mice were killed 3 h and 72 h post-radiation, and intestines were removed and histological sections were made according to reference[15].

Isolation of mouse intestinal epithelia

Mouse intestinal epithelial cells were isolated according to the method described by Bjerknes[16] with slight modifications. In brief, animals were sacrificed, and the small intestine was removed and perfused with 30 ml of cold PBS. Then it was gently everted using a glass rod and flushed by PBS with its two ends enveloped. The swollen intestine was transferred to a flask, and immersed into warm PBSE solution (PBS containing EDTA 1 mmol/L), and shaken at 150 cycles per min. After shaken for 5 min, the intestine was transferred to another clean flask with warm PBSE solution, and vibrated for another 5 min. The shed intestinal epithelial cells were centrifuged at 500×g for 10 min, and prepared for protein extraction.

Protein extraction

The cell pellet harvested as described above was then washed in ice-cold PBS 3 times. Cells were resuspended in cold PBS, and counted. Total proteins were extracted from 10^7 cells with an appropriate volume (200 μl) of lysis buffer containing 7 mol/L urea, 2 mol/L thiourea, 65 mmol/L DTT, 2 % CHAPS, 2 mmol/L PMSF, 0.5 % IPG buffer, and protease inhibitor mixture. The extraction mixture was sonicated using a MSE 100 ultrasonic probe, and then centrifuged at 12 000×g for 20 min. After transferred to a clean tube, the supernatant was stored at -70 ℃ as aliquots. The protein concentration was determined using Bradford dye-binding assay with bovine serum albumin as the standard.

Two-dimensional electrophoresis

Two-dimensional electrophoresis was carried out by using the Mini-PROTEIN 2-D apparatus (Bio-Rad). For isoelectric focusing (IEF), precast IPG strips (Immobiline DryStrips, Amersham Pharmacia Biotech, Uppsala, Sweden) were used. Samples were applied via rehydration of IPG strips in sample solution for more than 12 h. Before application, the samples were diluted to a total volume of 350 μl with rehydration buffer (8 mol/L urea, 2 % CHAPS, 0.5 % IPG buffer, 0.3 % DTT, and a trace of bromophenol blue). Protein sample (1 000 μg) was loaded onto an 18 cm IPG strip (pH3-10, linear), and isoelectric focusing was run for 45 KVh at 20 ℃. To improve the sample entry, low voltage (100V) was applied for 2 h at the beginning. After IEF separation, the IPG strips were immediately equilibrated for 2×15 min with buffer (50 mmol/L Tris-HCl, pH6.8, 6 mol/L urea, 30 % glycerol, 2 % SDS, and a trace of bromophenol blue). DTT (2 %) was added in the first step, and iodoacetamide in the second step. For the second dimensional separation, the concentration of homogeneous SDS-polyacrylamide gels was 13 %. The proteins in the equilibrated strips were run at a current of 30 mA/strip for about 5 h until the bromophenol dye reached the bottom of the gels. Molecular mass marker was run on the same gel to determine the relative molecular masses of the proteins.

Image processing and analysis

After electrophoresis, the resolved proteins in 2-DE gels were fixed in ethanol/acetic acid/water (4/1/5) for at least 1 h, and then visualized by Coomassie blue R-250. The gels were scanned (Gel Doc 2000, Bio-Rad), and the images were processed with PDQuest software (Ver 7.0, Bio-Rad). To determine the variation, three gels were prepared for each sample. The computer analysis allowed automatic detection and quantification of protein spots, as well as matching between control gel and treatment. Protein spots that were new, absent, up- and down-regulated, were simultaneously displayed on the same image using the gels of sham-irradiated sample as the reference.

Protein identification by MALDI-TOF-MS

The differential protein spots were exactly excised from the gels. Gel pieces were destained with 50 % acetonitrile for several times until Coomassie blue was invisible. Then gel pieces were dried in a vacuum centrifuge. The shrinking gel pieces were re-swollen with 5 μl of protease solution (trypsin at 0.05 μg/μl in digestion buffer of 25 mmol/L NH4HCO3). Additional 50 μl of digestion buffer was added into the gel piece. Digestion was performed overnight at 37 ℃. Next, 50 μl of 5 % TFA solution was added to the gel piece, followed by incubation for 60 min at 42 ℃. The supernatant was collected and concentrated using ZipTip pipette tips (Millipore) according to the manufacturer' s instructions. The samples were mixed on the MALDI target with matrix DBA solution. Peptide mass maps were generated by applying Biosystems Voyager 6192 MALDI-TOF-Mass Spectrometry (ABI, USA). Database searching was performed using monoisotopic peptide masses obtained from MALDI-TOF-MS. The SWISS-PROT and TrEMBL database was searched with PeptIdent software (http://www.expasy.org/tools/pep-tident.html). Peptide masses were assumed to be monoisotopic masses and cystines were assumed to be iodoacetamided. The peptide mass tolerance was set to 0.2Da, and the maximum of missed cleavage site was set to 1. Species was set as mouse.

Immunoblotting

Total proteins were separated on 12 % SDS-polyacrylamide gel, and then transferred to nitrocellulose membranes. After blocked for 1 h in the Tris/NaCl (50 mmol/L Tris-HCl, 200 mmol/L NaCl, 0.05 % Tween-20, pH7.4) containing 2 % BSA, membranes were probed with the goat anti-mouse Enolase polyclonal antibody (Santa Cruz, USA). Immunoreactive bands were visualized with a solution containing 1 mg/ml DAB and 0.01 % H_2O_2.

Semi-quantitative RT-PCR

Total RNAs were isolated from mouse intestinal epithelia with

TriPure isolation reagent (Roche, USA) according to the manufacturer' s descriptions. Peroxiredoxin I, Q72VC8, and GAPDH transcripts were determined by reverse transcriptase-polymerase chain reaction (RT-PCR) with RNA PCR kit (Takara, China). The primers for peroxiredoxin I are 5' GTTCTCACGGCTCTTTCTGTTT-3' and 5' CTTCTGGCTGCTCAATGCTG-3', Q8VC72 5' TGGACAAAGCCTTCATAGCA-3' and 5' CCTGGCAGAAACCACAGTAGA-3', GAPDH 5' ACCACAGTCCATGCCATCAC-3' and 5' TCCACCACCCTGTTGCTGTA-3'. The amplification was performed with one denaturing cycle at 94 ℃ for 5 min, then 25-27 cycles at 94 ℃ for 40 s, at 55 ℃ for 40 s, at 72 ℃ for 40 s, and one final extension at 72 ℃ for 5 min. RT-PCR products were run on 1.2 % agarose gel.

RESULTS

Histological changes of mouse intestine after radiation

Mice after 9.0 Gy irradiation died within 4-6 days post-radiation, with the intestines severely injured. As shown in Figure 1, the histological changes after irradiation were in agreement with our previous experiments. Though the height of villi and crypts remained unchanged 3 h post-radiation, cell division of intestinal epithelia ceased, and the intestines were severely injured morphologically. Moreover, the height of intestinal crypts was obviously increased 72 h post-radiation, with villi decreased. This indicated that many survival epithelial cells proliferated.

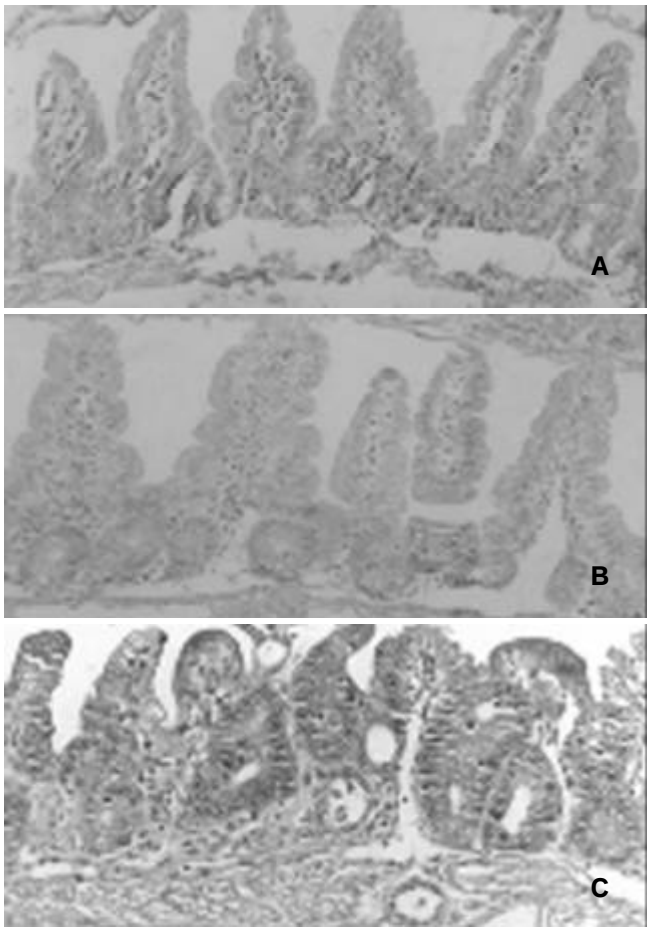

Figure 1 Histological changes in crypts following irradiation. A: Unirradiated controls (×100). B: 3 hours after a single dose of 9.0 Gy (×100). Villi and crypts remained unchanged, but cell division of intestinal epithelia ceased. C: 3 days after a single dose of 9.0 Gy (×100).

Two-dimensional electrophoresis and image analysis of mouse intestinal epithelia

To study the different proteins involved in ionizing radiation, we applied 2-DE to analyze the proteomic alteration of mouse intestinal epithelia. The 2-D patterns were highly reproducible since each experiment was performed in triplicate and produced similar results. Figure 2 showed the representative 2-D maps of the mouse intestinal epithelia. Image analysis of 2-D gels revealed that averages of 638±39, 566±32 and 591±29 protein spots were detected in 3 groups respectively, and the majority of these protein spots were matched. About 360 protein spots were matched between normal group and 3 h irradiation group, and the correlation coefficient was 0.78 by correlation analysis of gels. Three hundred and twelve protein spots were matched between normal group and 72 h irradiation group, and 282 protein spots between 3 h and 72 h irradiation groups. The unmatched spots represented those induced by irradiation as new or absent proteins, which were the main alteration of proteome.

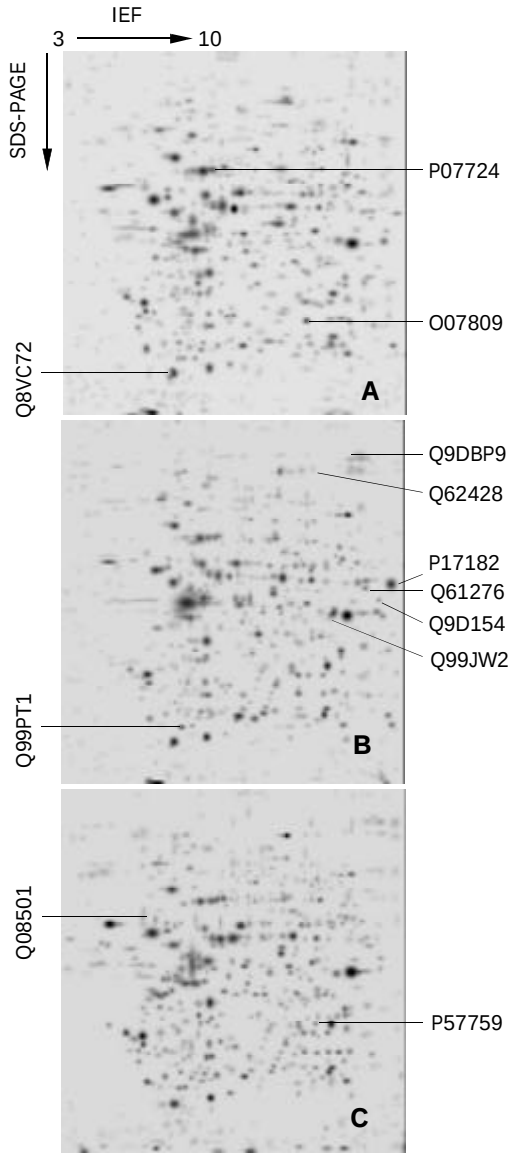

Figure 2 Two-dimensional electrophoresis maps. A: normal intestinal epithelial cells, B: 3 h irradiated epithelial cells, C: 72 h post-radiation. Number indicated proteins were summarized in Table 2.

Identification of proteins from 2-D gel spots

Out of a total of 28 spots excised from the gels, 25 spots yielded

nearly perfect MALDI spectra. A total of 19 spots were preliminarily identified by peptide mass fingerprinting. Figure 3 showed the typical peptide mass fingerprinting of Spot No. 11, whose peptides matched the mouse peroxiredoxin I. This spot was up-regulated by ionizing radiation. The identified proteins were summarized in Table 1. These proteins were involved in cellular process of anti-oxidation, metabolism, and protein post-translational processes. Other proteins, such as cellular structural proteins and hypothetic proteins derived from nucleic acid sequences, were also altered after irradiation. We also found, 6 spots with good MALDI spectra were returned with inconclusive match results, suggesting that they might be unknown proteins.

Induction of enolase by radiation

A protein spot was preliminarily identified as Enolase by

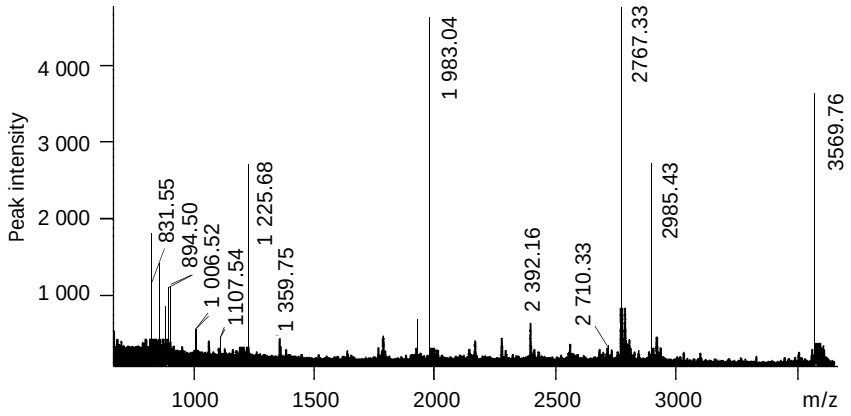

Figure 3 MALDI-TOF-MS spectrum of spot P35700 in 2-DE map. MS spectrum of peptide mixture was obtained from a typical in-gel digestion of the 2-DE separated protein.

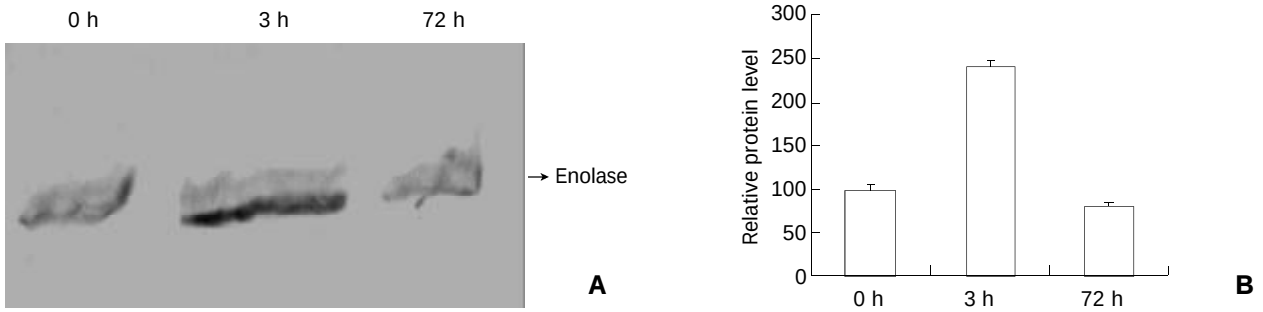

Figure 4 Western blot analysis of Enolase after radiation. A: Protein samples, obtained at indicated time after radiation, were separated by SDS-PAGE, and immunoblotted with corresponding antibody. Equal amounts of total proteins were applied to each lane. B: Relative protein level of Enolase was determined by quantitating the intensity of Enolase bands with a densitometer.

a: This protein was recorded in NCBI database.

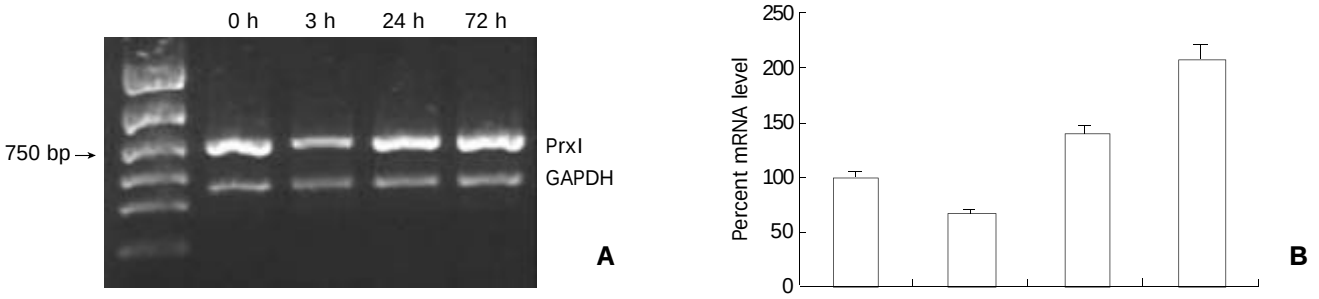

Figure 5 Semi-quantitative RT-PCR analysis of peroxiredoxin I. A: PCR product run on an agarose gel. The upper band represented peroxiredoxin I (750 bp), and the lower band represented GAPDH (450 bp). B: Relative abundance of the mRNA of peroxiredoxin I was normalized by GAPDH.

Figure 6 Semi-quantitative RT-PCR analysis of Q8VC72. RNA samples were prepared from mouse intestinal epithelia at indicated time. Left: The band represents Q8VC72 (461 bp). Right: The band represents GAPDH (450 bp). The expression of Q8VC72 remained unchanged after radiation.

MALDI-TOF-MS (Table 1), which was significantly increased in 3 h radiation group. Immunoblotting showed that Enolase was significantly up-regulated (2.1 fold more than the normal control, $P<0.01$, Figure 4). This confirmed our data of 2-D electrophoresis.

Induction of peroxiredoxin I and Q8VC72 by radiation

Semi-quantitative RT-PCR was used to detect the gene expression of peroxiredoxin I and Q8VC72. Total RNAs were isolated from normal and irradiated mouse intestine. The expression of peroxiredoxin I was markedly induced by radiation (Figure 5), using GAPDH as standard. However, the expression of Q8VC72 remained unchanged after radiation (Figure 6). This indicated that Q8VC72 might be a false-positive result.

DISCUSSION

A variety of techniques, including differential hybridization, differential display PCR, serial analysis of gene expression (SAGE), and gene array, have been used to identify the genes whose expression is selectively altered after radiation[17-19]. Recently, a new method termed gene trap strategy has also been used to predict radiation responsive genes[20]. All these methods are used to analyze the mRNA expression levels of radiation responsive genes. As mRNAs are easy to be degraded after transcription, and some are selectively translated, the quality and quantity of proteins do not correlate with that of mRNAs. Here, we applied 2-D electrophoresis to analyze the proteins involved in radiation response at protein level. As a large-scale screening of proteins, proteomics has been driven forward by the advent of the genome era[21], and it has become advantageous in analyzing total proteins of cells or tissues.

Many proteins have been demonstrated to be involved in radiation response among mammalians[22,23]. These proteins are associated with many important cellular processes such as DNA repair, apoptosis, signal transduction, and oxidative stress. Among the 19 preliminarily identified proteins, three spots belong to oxidative stress response proteins, i.e., peroxiredoxin I, glutathione S-transferase P2, and antioxidant protein 2. Radiation injuries are manifested as a result of increased production of reactive oxygen species (ROS), such as O_2, OH^-, and H_2O_2. These substances can induce the cellular antioxidant defense enzymes such as superoxide dismutase and glutathione peroxidase. In this study, peroxiredoxin I and glutathione S-transferase P2 were up-regulated by ionizing radiation, while antioxidant protein 2 was down-regulated. These proteins have been demonstrated to be involved in radiation[24-26]. Peroxiredoxin I is involved in the redox regulation of cells, such as reducing peroxides with reducing equivalents through the thioredoxin system but not from glutaredoxin. The function of glutathione S-transferase P2 has been found in conjugation of reduced glutathione to a large number of exogenous and endogenous hydrophobic electrophiles[27]. Antioxidant protein 2, also named 1-Cys peroxiredoxin, reduces H_2O_2 and phospholipid hydroperoxides. Our data confirmed the alteration of oxidative stress proteins with the exception of antioxidant protein 2. However, further studies will be performed to determine the mechanism as to why antixoxidant protein 2 does not play a critical role in ionizing radiation of small intestinal epithelial cells.

Using the proteomic strategy, we detected an interesting protein of ERP29 involved in ionizing radiation. ERP29 was first cloned from rat enamel cells, which had limited homology with protein disulfide isomerase and its cognate[28]. In this work, it was upregulated with ionizing radiation *in vivo*. ERP29 played an important role in the process of secretory proteins in the ER. Some researchers found that it played a role as a chaperone in protein folding[29,30]. The relationship between ERP29 and ionizing radiation has not yet been clarified, so it is worthy of further studying. In addition, some metabolic enzymes and hypothetical proteins, which were derived from nucleic acid sequences, were also found in this differential system. Their roles in ionizing radiation are unclear. Further researches are needed to draw precise conclusions. These data of hypothetical proteins suggest that these hypothetical proteins are expressed in intestinal epithelium indeed.

In brief, we compared the proteomics of mouse intestinal

epithelial cells with its irradiated counterparts *in vivo*. This strategy provides an efficient resolution to analyze radiation related proteins directly at protein level. The preliminarily identified proteins will be further studied in order to determine the cell signaling and molecular mechanisms of gene expression in radiation responses. This proteomic technique may contribute to the elucidation of the molecular mechanism of radiation damage, and can be applied in other research work as a useful tool.

Abstract

AIM: Human cytochrome P-450 2E1 (CYP2E1) takes part in the biotransformation of ethanol, acetone, many small-molecule substrates and volatile anesthetics. CYP2E1 is involved in chemical activation of many carcinogens, procarcinogens, and toxicants. To assess the metabolic and toxicological characteristics of CYP2E1, we cloned *CYP2E1* cDNA and established a HepG2 cell line stably expressing recombinant CYP 2E1.

METHODS: Human *CYP2E1* cDNA was amplified with reverse transcription-polymerase chain reaction (RT-PCR) from total RNAs extracted from human liver and cloned into pGEM-T vector. The cDNA segment was identified by DNA sequencing and subcloned into a mammalian expression vector pREP9. A transgenic cell line was established by transfecting the recombinant plasmid of pREP9-CYP2E1 to HepG2 cells. The expression of CYP2E1 mRNA was validated by RT-PCR. The enzyme activity of CYP2E1 catalyzing oxidation of 4-nitrophenol in postmitochondrial supernate (S9) fraction of the cells was determined by spectrophotometry. The metabolic activation of HepG2-CYP2E1 cells was assayed by *N*-nitrosodiethylamine (NDEA) cytotoxicity and micronucleus test.

RESULTS: The cloned *CYP2E1* cDNA segment was identical to that reported by Umeno *et al* (GenBank access No. J02843). HepG2-CYP2E1 cells expressed CYP2E1 mRNA and had 4-nitrophenol hydroxylase activity (0.162±0.025 $nmol \cdot min^{-1} \cdot mg^{-1}$ S9 protein), which were undetectable in parent HepG2 cells. HepG2-CYP2E1 cells increased the cytotoxicity and micronucleus rate of NDEA in comparison with those of HepG2 cells.

CONCLUSION: The cDNA of human *CYP2E1* can be successfully cloned, and a cell line, HepG2-CYP2E1, which can efficiently express mRNA and has CYP2E1 activity, is established. The cell line is useful for testing the cytotoxicity, mutagenicity and metabolism of xenobiotics, which may possibly be activated or metabolized by CYP2E1.

INTRODUCTION

Cytochrome P450 2E1 (CYP2E1) is the only member of the CYP2E subfamily in humans. Approximately 7 % of the liver CYP content consists of CYP2E1, although individual variation of the level of hepatic CYP2E1 expression can be existed by an order of magnitude. CYP2E1 is also expressed in a number of extrahepatic tissues including the lungs[1] and brain[2]. CYP2E1 takes part in the biotransformation of ethanol, acetone, and many small-molecule substrates such as halogenated hydrocarbons (1,1,1-trichlorethane, 1,2-dichloropropane, carbon tetrachloride, chloroform, ethylene dibromide, ethylene dichloride, halothane, methylchloride, methylene dichloride, vinylchloride and trichloroethylene, most of which are hepatotoxic), acetaldehyde, benzene, and styrene. It is known for its ability to metabolize volatile anesthetics such as halothane, enflurane, isoflurane, and sevoflurane, acetaminophen, phenacetin and chlorzoxazone. Another group of CYP2E1 substrates are nitrosamines. CYP2E1 is involved in chemical activation of many carcinogens, procarcinogens, and toxicants[3-5].

Genetically engineered mammalian cells expressing CYP subtypes have provided new tools for investigations of the metabolism and CYP-mediated metabolic activation of chemicals. The stable expression system of CYP in cells has made it possible to evaluate the relative risk of a chemical in toxicological testing *in vitro*[6,7]. Human CYP1A1[8], CYP2B6[8], CYP2A6[9], CYP3A4[10], CYP2C9[11], CYP2C18[12] and a phase II metabolism enzyme UDP-glucuronosyltransferase, UGT1A9[13] have been stably expressed in Chinese hamster lung CHL cells in our laboratory. Among the human hepatic cell lines, HepG2 derived from a human liver tumor has been characterized to retain many xenobiotic-metabolizing activities as compared to fibroblasts. Therefore, HepG2 cell is useful in prediction of the metabolism and cytotoxicity of chemicals in human liver[14]. But it does not produce significant amounts of CYP[15,16]. Yoshitomi *et al*[17] have established in HepG2 cells stable expression of a series of human CYP subtypes, such as CYP1A1, CYP1A2, CYP2A6, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1 and CYP3A4.

In this study, human *CYP2E1* cDNA was amplified by reverse transcription-polymerase chain reaction (RT-PCR), and a transgenic cell line HepG2-CYP2E1 stably expressing CYP2E1 was established to assess the metabolic and toxicological characteristics of CYP2E1.

MATERIALS AND METHODS

Materials

Restriction endonucleases, Moloney murine leukemia virus (M-MuLV) reverse transcriptase were supplied by MBI Fermentas AB, Lithuania. PCR primers, DNA sequence primers, random hexamer primers, and dNTPs were synthesized or supplied by Shanghai Sangon Biotechnology Corp. Expand fidelity PCR system and NADPH were from Roche Molecular Biochemicals. DNA sequencing kit was purchased from Perkin-Elmer Co. The TRIzol reagent, G418, Dulbecco' s modified Eagle' s medium (DMEM) and newborn

bovine calf sera were from Gibco. Diethyl pyrocarbonate (DEPC), MTT, and *N*-nitrosodiethylamine (NDEA) were purchased from Sigma Chemical Co. T4 DNA ligase and pGEM-T vector system were from Promega. 4-nitrophenol and *p*-nitrocatechol were from Tokyo Kasei Kogyo Co. Ltd, Japan. Other chemical reagents used were of analytical purity from the commercial sources.

Methods

Cloning of human CYP2E1 cDNA from human liver Total RNA was extracted from a surgical specimen of human liver with TRIzol reagent according to the manufacture' s instructions. RT-PCR amplifications were described before, using Expand fidelity PCR system[11]. Two specific 27 mer oligonucleotide PCR primers were designed according to the mRNA sequence of CYP2E1 reported by Song *et al*[18] (GenBank access No. J02625). The sense primer corresponding to base position -8 to 19 was 5' -AGGGTACCATGTCTGCCCTCGGAGTGA-3' , with a restriction site of *Kpn* I (underlined). The anti-sense primer, corresponding to the base position from 1 507 to 1 534, was 5' -ACAATTTGAAAGCTTGTTTGAAAGCGG-3' , with a restriction site of *Hin*d III (underlined). The anticipated PCR product was 1 542 bp in length. PCR was performed at 94 ℃ for 2 min, then 35 cycles at 94 ℃ for 60 s, at 62 ℃ for 60 s, at 72 ℃ for 2 min, and extension at 72 ℃ for 10 min. An aliquot (10 μL) from PCR was subjected to electrophoresis in a 1 % agarose gel stained with ethidium bromide.

Construction of recombinant pGEM-CYP2E1 and sequencing of CYP2E1 cDNA The PCR products were ligated with a pGEM-T vector, and transformed to *E. coli* DH5α. *CYP2E1* cDNA cloned in pGEM-T was sequenced by Perkin-Elmer-ABI Prism 310 automated DNA sequencer with primers of T7 and SP6 promoters and two specific primers of 2E1 m1 5' -GCATCTCTTGCCTATCCTT-3' (1 042-1 024), and 2E1 m2 5' -ATGGACCTACCTGGAAGGACAT-3' (353-374).

Construction of pREP9 based expression plasmid for CYP2E1 *Kpn* I/*Hin*d III fragment having the total span of human *CYP2E1* cDNA and correctly deduced amino acids sequence in pGEM-CYP2E1 were subcloned to a mammalian expression vector pREP9 (Invitrogen). The recombinant was transformed to *E. coli* Top 10, screened by ampicillin resistant, and identified by restriction mapping.

Transfection and selection[11, 19] HepG2 cells grown in DMEM containing 10 %(V/V) new born calf sera were transfected with the resultant recombinant plasmid, pREP9-CYP2E1, using a modified calcium phosphate method. The culture was split and then selected in the culture medium containing the neomycin analogue G418 (400 mg· L^{-1}). A transgenic cell line named HepG2-CYP2E1 was established.

Detection of CYP2E1 mRNA expression by RT-PCR Total RNA was prepared from G-418-resistant clones by TRIzol reagent. RT-PCR was performed as described before[11], using two primers 2E1 m1 and 2E1 m2 (200 nmol· L^{-1}), their sequence was described in above, with 20 nmol· L^{-1} primers of beta-actin as an internal control. The sense and anti-sense primers used for PCR amplification of beta-actin (GenBank access No. NM_001101) were 5' -TCCCTGGAGAAGAGCTACGA-3' (776-795) and 5' -CAAGAAAGGGTGTAACGCAAC-3' (1 217-1 237), respectively. PCR was performed at 94 ℃ for 2 min, then 35 cycles at 94 ℃ for 30 s, at 62 ℃ for 30 s, at 72 ℃ for 30 s, and extension at 72 ℃ for 7 min. The anticipated beta-actin PCR product was 462 bp in length and that of CYP2E1 was 690 bp in length. An aliquot (10 μL) from PCR was subjected to electrophoresis in a 1.5 % agarose gel stained with ethidium bromide.

Preparation of postmitochondrial supernate (S9) of HepG2-CYP2E1 The procedure of preparation of S9 fraction was described before[11]. The protein in S9 was determined by the Lowry' s method, with bovine serum albumin as standard.

4-nitrophenol hydroxylase assays[20-22] CYP2E1 4-nitrophenol hydroxylase activity of S9 was determined by spectrophotometry, 0.5 mL incubations contained 0.25 mg S9 protein, 0.2 mmol· L^{-1} 4-nitrophenol in 0.1 mmol· L^{-1} potassium phosphate buffer (pH 6.8), reactions were initiated with 1 mmol· L^{-1} NADPH and carried out in air at 37 ℃ for 60 min. Reactions were terminated by adding 0.25 mL of 0.6 mmol· L^{-1} perchloric acid and centrifuged at 10 000×g for 5 min to remove protein. The supernatant was mixed with 1/10 volume of 10 mol· L^{-1} NaOH. The absorbance of clarified supernatants was measured at 510 nm, and the amount of product was quantitated using a standard curve generated by adding known amounts of *p*-nitrocatechol to incubations without NADPH.

Cytotoxicity assay[23, 24] HepG2 and HepG2-CYP2E1 cells were seeded in 96 well cell culture plates at a density of 1×10^4 cells each well and incubated overnight. The medium was discarded, and a new medium containing NDEA 0, 1, 10, 100 mmol· L^{-1} was added to respective wells, with 6 duplications at each concentration. 72 h later, the medium was discarded and 20 μL of 50 g· L^{-1} MTT in PBS was added to each well. The MTT was discarded 4 h later and 100 μL dimethylsulfoxide was added. After formazan was dissolved, the absorbance was read at 570 nm with 630 nm as reference on the microtiter plate reader. Relative survival was represented as the relative toxicity to the control culture without NDEA. The significance of difference of relative survival between HepG2-CYP2E1 and HepG2 cells was analyzed by Student' s *t* test.

Micronucleus test[25-28] 1×10^5 HepG2 and HepG2-CYP2E1 cells were seeded in each 100 mL culture bottle and cultured overnight. The medium was discarded and 0, 5, 10, 20 mol· L^{-1} NDEA in 4 mL serum-free medium was applied to respective bottles and incubated for 4 h. Subsequently the cells were washed twice in PBS and incubated for 20 h with 4 mL completed medium containing 3 mg· L^{-1} of cytochalasin B. Then the cells were washed twice in PBS and harvested in 2 mL PBS and fixed with 0.4 mL fixed solution (methanol: acetic acid 3:1) for 30 min. The cells were centrifugated, the PBS was discarded and pelleted cells were refixed with 2 mL of fixed solution for 30 min. The cells were centrifugated, refixed and centrifugated again, and then dropped onto slides, dried in the air and stained with 10 % Giemsa solution. The scoring criteria for binucleated cells and micronucleus (MN) were based on a report of HUman MicronNucleus project[27]. The frequency of MN formation was expressed as per thousand of binucleated cells with MN. The significance of difference of MN rate between HepG2-CYP2E1 and HepG2 cells was analyzed by checking the tables for determining the statistical significance of mutation frequencies[28].

RESULTS

Construction of recombinants of pGEM-CYP2E1

The recombinant of pGEM-CYP2E1 was constructed with the human *CYP2E1* cDNA inserted into the cloning site of pGEM-T vector. Selection and identification of the recombinant were carried out by *Kpn* I/*Hin*d III endonuclease digestion and agarose gel electrophoresis (Figure 1). The cloned cDNA segment was sequenced completely. In comparison with the cDNA sequence reported by Song *et al* (GenBank access No. J02625), there was only one base difference in cloned cDNA, 105 T→C, while the encoding amino acid was 35G. But there was no sequence difference as compared with that reported by Umeno *et al*[29] (GenBank access No. J02843).

Construction of recombinants of pREP9-CYP2E1

The *Kpn* I/*Hin*d III fragment (1.54 kb) containing complete *CYP2E1* cDNA was subcloned into the *Kpn* I/*Hin*d III site

of mammalian expression vector pREP9. Selection and identification of the recombinant were carried out by *Kpn* I/ *Hin*d III endonuclease digestion and agarose gel electrophoresis (Figure 2). The resulting plasmid was designated as pREP9-CYP2E1 and contained the entire coding region, along with 8 bp of the 5' and 52 bp of the 3' untranslation region of *CYP2E1* cDNA, respectively.

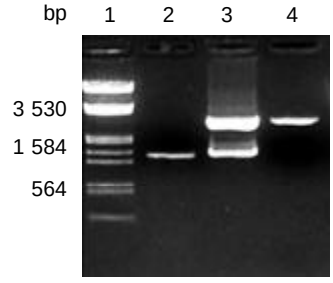

Figure 1 Electrophoretic identification of recombinant of pGEM-CYP2E1. Lane 1: Markers (λ / *Eco*R I and *Hin*d III), 2: PCR products of *CYP2E1* (1.54 kb), 3: Recombinant of pGEM-CYP2E1 digested by *Kpn* I and *Hin*d III, 4: pGEM-T vector.

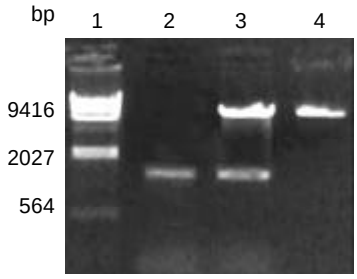

Figure 2 Electrophoretic identification of recombinant of pREP9-*CYP2E1*. Lane 1: λDNA / *Hin*d III Markers, 2: PCR products of *CYP2E1* (1.54 kb), 3: Recombinant of pREP9-*CYP2E1* digested by *Kpn* I and *Hin*d III, 4: pREP9 vector.

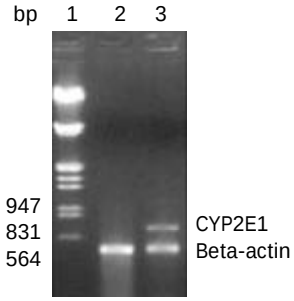

Figure 3 Identification of CYP2E1 mRNA expression in HepG2-CYP2E1 and HepG2 cells by RT-PCR with beta-actin as internal control. Lane 1: Markers (λ / *Eco*R I and *Hin*d III), 2: RT-PCR products of HepG2 cells showing only beta-actin 462 bp, 3: RT-PCR products of HepG2-CYP2E1 cells showing 462 bp of beta-actin and 690 bp of CYP2E1.

Establishment of transgenic cell line with CYP2E1 mRNA expression and 4-nitrophenol hydroxylase activity

HepG2 cells were transfected with pREP9-CYP2E1, and selected with G418. The surviving clones were propagated and a cell line termed HepG2-CYP2E1 was established. The expression of CYP2E1 mRNA could be detected in HepG2-CYP2E1 cells but not in HepG2 cells by RT-PCR (Figure 3). The 4-nitrophenol hydroxylase activity in S9 of HepG2-CYP2E1 cells was found 0.162±0.025 nmol· min^{-1}· mg^{-1} S9 protein (n=3), but not detectable in parent HepG2 cells.

HepG2-CYP2E1 cells increased cytotoxicity and MN rate by NDEA

Cells were exposed to various concentrations of NDEA. The relative survival rate of HepG2-CYP2E1 cells was lower than that of HepG2 cells in 10 and 100 mmol· L^{-1} NDEA (P<0.05 and P<0.01, respectively), as shown in Figure 4. The MN rate of HepG2-CYP2E1 was higher than that of HepG2 cells in 10 and 20 mmol· L^{-1} NDEA (P<0.05 and P<0.01 respectively) as shown in Figure 5.

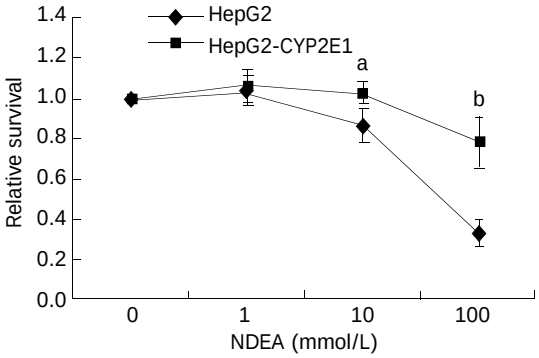

Figure 4 Cytotoxicity of NDEA against HepG2-CYP2E1 and HepG2 cells. Cells were exposed to various concentrations of NDEA. Relative survival rate was represented as the relative toxicity to the control culture without NDEA. The results presented were the average of six duplications ($\bar{x}$±s). ^aP<0.05, ^bP<0.01 *vs* HepG2 cells.

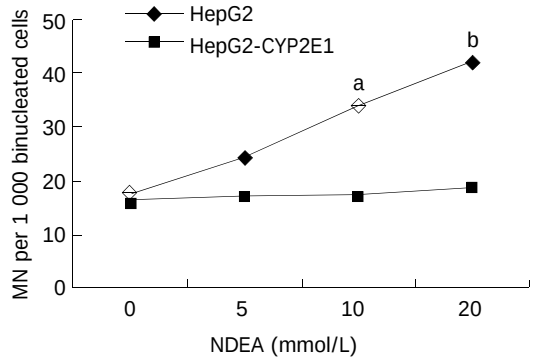

Figure 5 MN rates in HepG2-CYP2E1 and HepG2 cells induced by NDEA. Cells were exposed to various concentrations of NDEA. The data were expressed as per thousand of binucleated cells with MN. ^aP<0.05, ^bP<0.01 *vs* HepG2 cells.

DISCUSSION

Human *CYP2E1* gene is located on the chromosome 10q24.3-qter. Up to date, seven *CYP2E1* alleles have been identified (see: *CYP2E1* alleles nomenclature at: http://www.imm.ki.se/CYPalleles/cyp2e1.htm). Only 3 alleles have nucleotide substitute, resulting in amino acid change. *CYP2E1*1* is the wild type of human *CYP2E1*. *CYP2E1*2* has a 1 168 G→A point mutation in exon 2 causing an R76H amino acid substitution, and *CYP2E1*3* has a 10 059 G→A base substitution in exon 8 yielding a V389I amino acid exchange. The corresponding *CYP2E1* cDNAs were expressed in COS-1 cells by Hu *et al*[30]. The cellular levels of CYP2E1 mRNA, protein, and the rate of chlorzoxazone hydroxylation were monitored. *CYP2E1*3* cDNA variant was indistinguishable from the wild type cDNA on all variables investigated, whereas *CYP2E1*2* cDNA, although yielding similar amounts of mRNA, only caused 37 % of the protein expression and 36 % of the catalytic activity compared with the wild type cDNA. Complete screening by single-stranded conformation polymorphism of the three

populations revealed that these variant alleles were rare. Human *CYP2E1* gene was functionally well conserved compared with other CYP enzymes active in drug metabolism, which suggested an important endogenous function in humans[30]. *CYP2E1*4* has a 4 804 G→A point mutation in exon 4, resulting in V179I amino acid exchange. No significant difference in kinetic constants for chlorzoxazone hydroxylation between mutant and wild type was observed by expression of the wild type and mutated full length cDNAs in lymphoblastoid cells[31]. Our laboratory has once cloned a *CYP2E1* cDNA (GenBank access No. AF182276), which has two point mutations, i.e. 105 T→C, no amino change 35G, and 704G→T, and can result in V235A amino acid exchange. This cDNA was expressed in Chinese hamster lung CHL cells. We could not detect the *N*-nitrosodimethylamine demethylase activity in transgenic cells (data not shown). According to the homology modelling of human CYP2E1 based on the CYP2C5 crystal structure, the substrate recognition site (SRS) 1 was located at codon 100-118, SRS 2 at 200-211, SRS3 at 236-241, SRS4 at 291-305, SRS5 at 361-370, SRS6 at 470-480. The point mutations of CYP2E1*2, *3, *4 were not located on the SRS. The V235A amino acid exchange in our formerly cloned CYP2E1 was just at the front of SRS3. This might influence SRS3 and reduce the enzyme activity. Fortunately, this time we cloned a wild type CYP2E1.

It has been found that polymorphism of *CYP2E1* gene is significant for inter-individual differences in toxicity of its substrates[33], and has some effect on the development of gastric cancer[34] and colorectal cancer[35].

The expression of CYP2E1 mRNA in HepG2 cells was validated by RT-PCR. The commonly used CYP2E1 probe substrates were chlorzoxazone[36, 37] and 4-nitrophenol[38]. In this research, we used 4-nitrophenol 2-hydroxylase activity to evaluate the expression of CYP2E1, and the 4-nitrophenol hydroxylase activity of HepG2-CYP2E1 cells was found to be 0.162±0.025 nmol· min^{-1}· mg^{-1} S9 protein, a little lower than those of HepG2-CYP2E1 E43 and E47 cells (0.19 and 0.34 nmol· min^{-1}· mg^{-1} of microsome, respectively)[39], much lower than that of human liver (1.91±0.28 nmol· min^{-1}· $mg^{-1}$of microsome)[40].

The most frequently used genotoxicity test in mammals is the micronucleus test, which provides a simple and rapid indirect measure of induced structural and numerical chromosome aberrations and is a scientific and regulatory assay accepted by supranational authorities such as the Organization for Economic Cooperation and Development (OECD), International Conference on Harmonization (ICH) and European Union (EU). NDEA could induce early experimental hepatocellular carcinomas[41] and esophageal neoplasms[42]. The metabolic activation of NDEA was mediated mainly by CYP2A6 and CYP2E1[43]. This study has shown that NDEA can decrease the relative survival rate of HepG2-CYP2E1 cells and increase the MN rate in binucleated cells as compared with HepG2 cells.

cDNA of human *CYP2E1* was successfully cloned and a cell line, HepG2-CYP2E1, efficiently expressing mRNA and having the CYP2E1 enzymatic activities, was established. The cell line is useful for testing the cytotoxicity, mutagenicity and metabolism of xenobiotics and drugs, which may possibly be activated by CYP2E1.

Abstract

AIM: To investigate the hepatocellular apoptosis after hepatectomy in obstructive jaundice and biliary decompression rats.

METHODS: After bile duct ligation for 7 days, rats were randomly divided into OB group in which the rats underwent 70 % hepatectomy, OB-CD group in which the rats underwent hepatectomy accompanied by choledochoduodenostomy, CD-Hx group in which the rats underwent choledochoduodenostomy and then received 70 % hepatectomy on the fifth day after biliary decompression. The control group (Hx group) only underwent hepatectomy.

RESULTS: The level of total serum bilirubin and serum enzymes was significantly lower in CD-Hx group than in OB-CD and OB groups on day 1, 3 and 5 after hepatectomy. The apoptotic index was significantly lower in CD-Hx group than in OB-CD and OB groups on day 3 and 5. The oligonucleosomal DNA fragments and Caspase-3 activity were also lower in CD-Hx group than in OB-CD and OB groups 3 days after hepatectomy, without differences between CD-Hx and Hx groups.

CONCLUSION: Hepatocellular apoptosis plays vital roles in jaundice rats, and biliary decompression is more effective in treatment of patients with severe jaundice before operation.

INTRODUCTION

Obstructive jaundice is often a clinical manifestation of the disease of extrahepatic biliary system or pancreas. In jaundiced patients with hilar bile duct carcinoma or gallbladder carcinoma, hepatectomy is one of the surgical regimens, but surgical procedures are associated with increases of morbidity and mortality rates, mainly due to postoperative complications such as hepatic failure, sepsis, bleeding and renal failure[1,2]. The significance of biliary drainage before surgery is controversial. Preoperative biliary drainage decreased the mortality and morbidity rates in patients with obstructive jaundice in some studies but not in others[3-5]. Experimental and clinical studies have identified several etiological factors including hypotension, impaired nutritional status, depressed immune function, hepatic dysfunction and the presence of toxic bile salts in circulation[6-8]. A high serum bilirubin concentration in jaundiced patients undergoing operation has been recognized as a predictor of mortality[3].

Hepatocyte injury and progression of liver disease are due to direct chemical damage to hepatocytes by toxic hydrophobic bile salts[9]. Although toxic bile salts are known to cause hepatocyte toxicity by inducing apoptosis, the precise mechanisms responsible for bile salt-mediated apoptosis remain to be established. This information is important because it could help provide rational strategies for the treatment of cholestatic liver disorders and decreasing postoperative complications. The aim of this study was to investigate the hepatocellular apoptosis after hepatectomy in obstructive jaundice and biliary decompression rats.

MATERIALS AND METHODS

Animals and experimental design

Male Wistar rats (Shionogi Aburabi Laboratory, Shiga, Japan) weighing 190-240 g were used for this study. Animals were housed in a controlled environment with a 12 h light/dark cycle. Rats had free access to normal rat chow and water before surgery. The care and handling of the animals were made in accordance with the National Institutes of Health Guidelines for the Care and Use of Laboratory Animals. The rats were divided into four groups each containing 6 animals. Hx group in which normal rats underwent 70 % hepatectomy, OB group in which the rats underwent 70 % hepatectomy after bile duct ligation for 7 days, OB-CD group in which the rats underwent 70 % hepatectomy accompanied by choledochoduodenostomy after bile duct ligation for 7 days, CD-Hx group in which the rats underwent choledochoduodenostomy after bile duct ligation for 7 days and then received 70 % hepatectomy on the fifth day after biliary decompression, as described below.

Surgical procedures

All surgical procedures were carried out under ether anesthesia. All rats were weighed before surgery and at the end of the study.

Laparotomy was performed through an upper midline incision. After ligation of the proximal and distal bile ducts, the common bile duct was divided to prevent recanalization[10]. The ligatures were placed in the same position in all rats. The 70 % hepatectomy was done according to the method of Higgins and Anderson[11] on the seventh day after biliary obstruction in OB and OB-CD groups and on the fifth days after the biliary decompression in CD-Hx group.

Choledochoduodenostomy was performed according to the method of Ryan *et al* with minor modifications[12]. After biliary obstruction for 7 days, the abdomen was reopened through the previous incision. The dilated common hepatic bile duct was freed from its surrounding tissues and the contents were aspirated. A small incision was made in the bile duct and a silicone tube with an outer diameter of 0.9 mm was inserted and secured in position with a 7-0 silk suture. The free end of

the tube was inserted into duodenum approximately 1.5 cm from the pylorus, and then tied in position with a 6-0 PDS purse-string suture. Then the suture was carried out between the bile duct and the duodenal wall to protect the separation of the anastomosis.

Measurement of bilirubin and enzymes in blood

Blood samples were collected from the tail vein with a 27-gauge needle. Serum total bilirubin, activities of alkaline phosphatase (ALP) and aspartate aminotransferase (AST) levels were measured enzymatically using a commercial kit (Spotchem Co., Kyoto, Japan).

Quantification of oligonucleosomal (histone-associated) DNA fragments

An aliquot from the liver homogenate was centrifuged at 13 000×*g*. The supernatant was diluted 1 000-fold and subjected to a sandwich ELISA designed to detect DNA/histone fragments using a test kit from Boehringer Mannheim, according to the manufacturer' s instructions. Briefly, a 96-well microtiter plate was coated with antibody against histones. Diluted samples were then applied to the wells for 90 min, followed by incubation with peroxidase-conjugated anti-DNA antibody for 90 min. Color substrate was added and absorbance was measured at 405 nm at 5, 10, and 15 min using a 96-well microtiter plate reader.

In situ TdT-UTP nick-end labeling (TUNEL staining)

On the third and fifth day after hepatectomy, a section of liver tissue measuring approximately 5 mm in thickness was cut from the right lateral lobe and fixed in 10 % buffered formalin, processed by standard techniques and embedded in paraffin. Apoptotic change in the liver was analyzed by *in situ* TUNEL method using an apoptosis detection kit (ApopTag, Oncor S7100, Gaithersburg, MD) according to the manufacturer' s instructions. Briefly, after deparaffinization and rehydration, 4 μm thick tissue sections were incubated in PBS, and then preincubated with equilibration buffer for 15 min, and digoxigenin-labelled dUTP and dATP in TdT buffer were added to cover the section, which was then incubated in a humidified chamber at 37 ℃ for 60 min. The reaction was stopped by immersing the slides in a stop/wash buffer. Following washing in PBS, the sections were incubated in anti-digoxigenin-peroxidase for 30 min at room temperature. The slides were incubated with DAB and hydrogen peroxide and counterstained with hematoxylin. Apoptotic cells were counted from at least 10 randomly chosen high-power fields at ×400 magnification. Cells with clear brown nuclear labelling were defined as TUNEL-positive. Apoptotic index was defined as the total number of apoptotic cells seen in every ten high-power field sections.

Caspase-3-like protease activity assay

Liver tissues were immediately frozen by liquid nitrogen and stored at -80 ℃ on the third and fifth days after hepatectomy. The Caspase 3-like activity was measured using a commercially available kit (Clontech Laboratories, Palo Alto, CA) according to the manufacturer' s instructions. Caspase enzymatically cleaved the substrate and released free 7-amino-4-trifluoromethyl coumarin (AFC) that produced a blue-green fluorescence, which was measured fluorometrically. Liver samples were homogenized in 500 μl of lysis buffer. Samples were centrifuged at 16 000×g in a microfuge for 10 min at 4 ℃ and normalized to protein using the Bradford assay (Bio-Rad). Fluorescent substrate, DEVD- AFC was incubated with 50 μl supernatants for liver extracts at 37 ℃ for 60 min. The fluorescence of cleaved substrates was measured using a fluorometer (Molecular Dynamics Inc.) at an excitation wavelength of 400 nm and an emission wavelength of 505 nm. An AFC calibration curve was established by serial dilution of a pure AFC solution provided in the kit.

Statistical analysis

All data were expressed as mean ±SEM. Statistical analysis was done by statistical package of SPSS for Window release 9.0. Differences between mean were tested with the Mann-Whitney test. A probability value less than 0.05 was considered statistically significant.

RESULTS

Bilirubin and enzymes in blood

The level of total serum bilirubin reached more than 7 mg/dl after 7 days' biliary obstruction, and the high bilirubin level rapidly decreased to 0.8 mg/dl only on day 1 after biliary decompression. We therefore thought that our models functioned well for biliary decompression. The total serum bilirubin concentration on the first day after hepatectomy in OB-CD group was 1.6 mg/dl, which was higher than that in CD-Hx group. The level of bilirubin in OB group was increased, while there was no statistically significant differences among other three groups on day 5 after hepatectomy (Figure 1).

The ALP concentration of OB group was significantly higher than that of other groups, but no differences of serum ALP level were found among the other groups after hepatectomy (Figure 2).

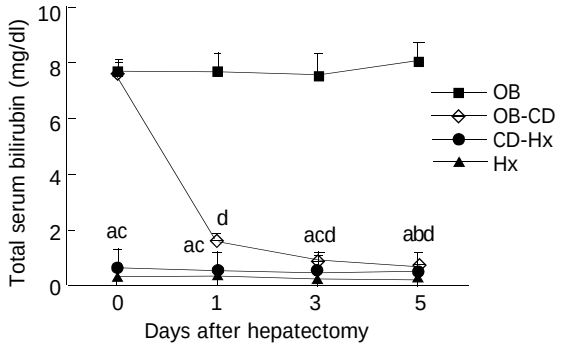

Figure 1 Changes of total serum bilirubin after hepatectomy. Blood was withdrawn from the tail vein while each rat was under ether anesthesia, and serum was obtained by means of centrifugation. Each point represents the mean ± SEM for six animals. [a]*P*<0.01 CD-Hx group *vs* OB group, [b]*P*<0.05 CD-Hx group *vs* OB-CD group, [c]*P*<0.01 CD-Hx group *vs* OB-CD group, [d]*P*<0.01 OB-CD group *vs* OB group.

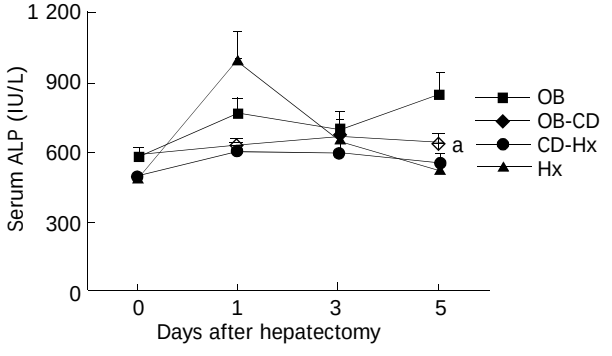

Figure 2 Changes of serum ALP after hepatectomy. Six rats were used for each group. Results were the mean ±SEM. [a]*P*<0.05 CD-Hx group *vs* OB group.

The level of serum AST peaked on the first day after hepatectomy and decreased gradually (Figure 3). There was no difference of AST concentration between CD-Hx and Hx groups on the third and fifth days after hepatectomy. The serum AST concentration in OB group on the fifth day was nearly 6 times that of the concentration in CD-Hx group.

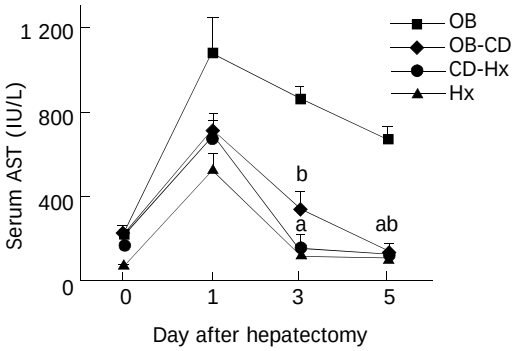

Figure 3 Changes of serum AST after hepatectomy. Six rats were used for each group. Results were the mean ±SEM. [a]*P*<0.01 CD-Hx group *vs* OB group, [b]*P*<0.01 OB-CD group *vs* OB group.

Accumulation of oligonucleosomal fragments

The cytoplasmic levels of DNA (histone-associated) oligonucleosomal fragments in hepatocytes after hepatectomy were determined. The presence of these fragments in the cytoplasm reflected the extent of DNA fragmentation and nuclear disruption that are characteristic of apoptosis. The level of DNA fragments in CD-Hx group was significantly lower than that in OB and OB-CD groups on the third day after hepatectomy (Figure 4). There was no significant difference between CD-Hx and OB groups.

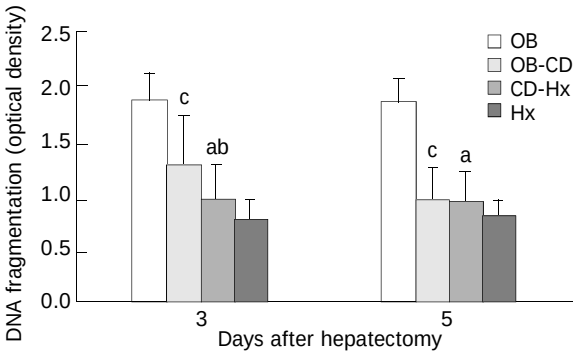

Figure 4 Quantification of oligonucleosomal DNA fragments. The supernatant from the liver homogenate was subjected to a sandwich ELISA designed to detect DNA / histone fragments. Each group consisted of 6 rats. Values were expressed as mean ±SEM. [a]*P*<0.01 CD-Hx group *vs* OB group, [b]*P*<0.05 CD-Hx group *vs* OB-CD group, [c]*P*<0.01 OB-CD group *vs* OB group.

Hepatocellular apoptosis index

TUNEL signal was defined by distinct nuclear staining. The number of hepatocellular apoptosis was high on day 3 and decreased on day 5 when the liver was harvested on days 3 and 5 from rats after hepatectomy. The data shown in Figure 5 indicate that apoptosis positive cells were significantly higher in OB group than in other groups. A very low rate of apoptosis was found in CD-Hx group, with no difference between CD-Hx and Hx groups.

Caspase-3-like protease activity

Cleavage of peptide substrate DEVD-AFC was used as an indicator of Caspase-3-like protease activity. The level of Caspase-3 activity in CD-Hx group was significantly lower than that in OB and OB-CD groups on the third day after hepatectomy. But on day 5, the level of Caspase-3 activity in OB-CD group decreased rapidly, without differences between OB-CD and CD-Hx groups (Figure 6).

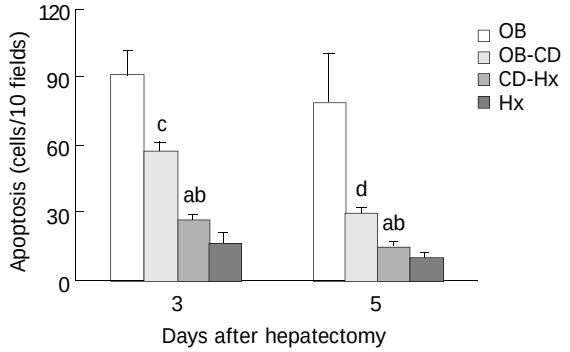

Figure 5 Changes of hepatocellular apoptotic index after hepatectomy. Morphometric analysis of the positive cells in tissue stained by TUNEL method was performed under high power magnification (×400) in a blinded fashion. Each group consisted of 6 rats. The number of positive cells was counted and expressed as the total number of apoptotic cells seen in every ten high-power fields sections. Values were expressed as mean ±SEM. [a]*P*<0.01 CD-Hx group *vs* OB group, [b]*P*<0.01 CD-Hx group *vs* OB-CD group, [c]*P*<0.05 OB-CD group *vs* OB group, [d]*P*<0.01 OB-CD group *vs* OB group.

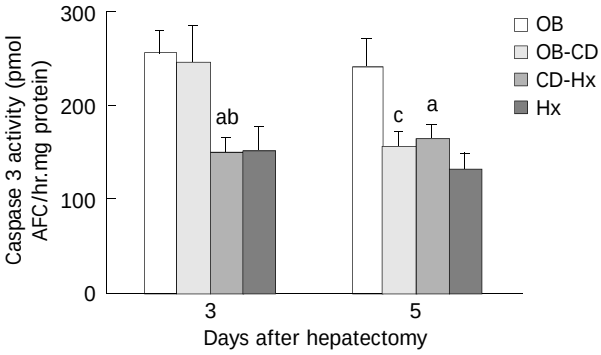

Figure 6 Changes of Caspase-3-like protease activity after hepatectomy. 50 μM DEVD-AFC was added to whole cell lysates (50 μg of total protein) for 1 h. The activity of *Caspase-3-like protease* was measured by determining the cleaved fluorogenic substrates using a spectrofluorometer at 400 / 505 nm. Each group consisted of 6 rats. Values shown represented mean ±SEM. [a]*P*<0.05 CD-Hx group *vs* OB group, [b]*P*<0.05 CD-Hx group *vs* OB-CD group, [c]*P*<0.05 OB-CD group *vs* OB group.

DISCUSSION

The perioperative mortality rate in patients with obstructive jaundice was reported to be 8 % to 28 %[13]. Perioperative complications in patients with obstructive jaundice included infections, endotoxemia, renal failure, stress ulceration, disseminated intravascular coagulation, and wound dehiscence[14,15]. Numerous reports suggested that in obstructive jaundice there was not only impairment of hepatocellular function but also depression of Kupffer cell activity and ultimately hepatic structural damage, leading to the development of portal hypertension[16,17]. In addition, it could result in depressed wound healing, significant portal and systemic endotoxaemia, decreased reticuloendothelial cell function, reduced T cell responses, depressed non-specific cell-mediated immunity, decreased bacterial clearance and increased bacterial translocation[18,19].

This animal model was designed to simulate the clinical treatment procedures used for patients with obstructive jaundice undergoing hepatectomy. Choledochoduodenal drainage was performed before or at the same time as 70 % hepatectomy. Obstruction at the choledochoduodenostomy occurred in about 2 % rats. These rats were excluded from further studies. The mortality rate was about 20 % following choledochoduodenostomy or hepatectomy in jaundice rats. No rats died during the procedure and all deaths occurred in the first 3 days postoperatively, usually secondary to bleeding.

During obstructive jaundice, the retention of biliary constituents and high biliary pressure caused hepatocellular injury[20]. This is supported by the fact that serum AST and ALP levels increased during obstructive jaundice and decreased after choledochoduodenostomy (data not shown). Kanno[21] reported that biliary obstruction for even 5 days suppressed rat liver function, as assessed with aminopyrine breath test and galactose tolerance test. These results suggested that obstructive jaundice could cause serious impairment of pivotal liver functions, consequently resulting in poor prognosis after partial hepatectomy. The present study clearly showed that biliary drainage before hepatectomy significantly improved liver functions and decreased hepatocellular apoptosis. Serum liver function tests showed that choledochoduodenal drainage was effective in both OB-CD and CD-Hx groups. Furthermore, serum enzyme levels, apoptotic index, DNA fragments and Caspase-3 activity were significantly lower in CD-Hx group than in other groups. These data suggested that biliary drainage before hepatectomy had beneficial effects in severe jaundice patients.

Accumulation of these toxic bile salts within hepatocytes has been thought to play a key role in liver injury during obstructive jaundice. Indeed, hepatic levels of toxic bile salts chenodeoxycholate and deoxycholate correlated with the degree of liver damage[22]. Because widespread necrosis was not prominent in most cholestatic liver diseases, it has become apparent that the occurrence of hepatocyte death during cholestasis was rather due to apoptosis than due to necrosis[23]. The mechanisms of apoptosis by toxic bile salts could been partially elucidated in recent years. Toxic bile salts could directly cause apoptosis in cultured rodent hepatocytes[24]. Bile acid-induced toxicity is typically characterized by hepatocyte swelling, disruption of plasma membrane integrity, and release of intracellular constituents. The apoptotic pathway in hepatocytes could be initiated by a ligand-independent activation of Fas by bile salt[25]. Apoptosis was triggered by the Fas pathway, at least in part, by the activation of intracellular enzymes called Caspases. Caspases have been found to be cysteine-containing, aspartic acid-specific proteases which exist as zymogens in the soluble cytoplasm, mitochondrial intermembrane space, and nuclear matrix of virtually all cells[26]. Upon activation of the apoptotic pathway, initiator Caspases (i.e., Caspases 8 and 9) were converted to their active forms, which in turn activated downstream Caspase 3, which could activate other Caspases and ultimately cleave various substrates[27]. One of these substrates has been found to be a Caspase-dependent endonuclease that is freed from its inhibitor by Caspase-3 in the cytoplasm, and subsequently enters the nucleus, where it cuts DNA into oligonuclesomal (180 bp) fragments[28]. Additionally, Bid, a protein responsible for the release of mitochondrial cytochrome C and amplification of the apoptotic cascade, could also be activated by Caspases[29]. Ultimately, this pathway would ensure the self-destruction of cells with the characteristic morphological features of apoptosis, including nuclear fragmentation, cellular shrinkage, and acidophilic staining of the cytoplasm[30]. Bile acid induced apoptosis also appeared to require an activation and translocation of protein kinase C, which then could lead to an increase of intracellular magnesium[31,32]. This would cause an activation of Mg^{2+}-dependent endonucleases, leading to DNA cleavage.

In conclusion, hepatocellular apoptosis plays a vital role in jaundice rats. Biliary drainage is preferable, as evidenced in rats by significantly better liver function and decrease of hepatocellular apoptosis. Biliary decompression is an effective preoperative treatment for patients with severe jaundice.

ACKNOWLEDGEMENTS

Abstract

AIM: To investigate the effects of long-term tea polyphenols (TPs) consumption on hepatic microsomal drug-metabolizing enzymes and liver function in rats.

METHODS: TPs were administered intragastrically to rats at the doses of 833 mg· kg^{-1}· d^{-1} (n=20) and 83.3 mg· kg^{-1}· d^{-1} (n=20) respectively for six months. Controlled group (n=20) was given same volume of saline solution. Then the contents of cytochrome P450, b5, enzyme activities of aminopyrine N-demethylase (ADM), glutathione S-trasferase (GST) and the biochemical liver function of serum were determined.

RESULTS: The contents of cytochrome P450 and b_5 in the livers of male rats in high dose groups (respectively 2.66±0.55, 10.43±2.78 nmol· mg MS pro^{-1}) were significantly increased compared with the control group (1.08±1.04, 5.51±2.98 nmol· mg MS pro^{-1}; P<0.01, respectively). The enzymatic activities of ADM in the livers of female rats in high dose groups (0.91±0.08 mmol· mg MS $pro^{-1}min^{-1}$) were increased compared with the control group (0.82±0.08 mmol· mg MS pro^{-1}· min^{-1}; P<0.05). The GST activity was unchanged in all treated groups, and the function of liver was not obviously changed.

CONCLUSION: The antidotal capability of rats' livers can be significantly improved after long-term consumption of TPs. There are differences in changes of drug-metabolizing enzymes between the sexes induced by TPs and normal condition.

INTRODUCTION

Tea polyphenols (TPs) are a large and diverse class of compounds extracted from tea. These polyphenolic compounds, specifically catechins epigallocatechin-3-gallate (EGCG), epigallocatechin (EGC), and epicatechin-3-gallate (ECG), account for 30-40 % of the extractable solids in green tea leaves[1]. Many health benefits are associated with consumption of tea and such effects are mainly attributed to the polyphenolic constitutes of tea[2-8]. We are more concerned about the beneficial effect of TPs on cancer[9-13].

Primary liver cancer (PLC) is a very prevalent form of cancer in the world. The incidence of PLC in China is high. Guangxi Zhuang Autonomous Region is a high mortality and morbidity region of PLC. Unfortunately, its curative effect is disappointed no matter what therapy is used. How to improve the prevention and treatment of PLC is a long-term goal of our research work. There are some evidences indicating that TPs may play a positive role in PLC prevention and treatment[14-16]. However, the mechanism of the action is not fully understood. It is known that the risk factors of PLC are intake of AFB_1, pollution of drinking water and HBV infection[17-20]. The factors are closely related to the activity of hepatic microsomal drug metabolizing enzymes and function of the liver. Because bioactivation of precarcinorgens and detoxification of ultimate carcinogens are mainly carried out by drug metabolizing enzymes in the liver, to explore the effects of TPs on these enzymes and the liver function will be helpful to understanding the mechanism of TPs in prevention and treatment of PLC, and the safety of TPs. Further more, this work will provide some useful information for the application of TPs in PLC chemoprevention and chemotherapy.

MATERIALS AND METHODS

Chemicals and reagents

TPs were purchased from Shili Natural Food Co. Ltd (Guilin, China), NADPH from Lizhudongfang Biological Technology Co. (Shanghai, China), aminopyrine from Shanghai Chemical Co., glutathione S-transferase (GST) and protein assay kits from Jiancheng Biological Technology Institude (Nanjing, China), serum biochemical tests of liver function kits from Shenneng Co. (Shanghai, China).

Animals

Five-week-old Wistar rats weighing from 80 to 130 g provided by Experimental Animal Center of Guangxi Medical University were used in the study. The rats were randomly divided into high dose, low dose, and control groups, 20 each group. The animals in high dose and low dose groups were administered intragastrically with TPs at doses of 833 mg· kg^{-1}· d^{-1} and 83.3 mg· kg^{-1}· d^{-1} respectively six times each week for six months. Same procedures were also performed in the control rats except feeding equal amount of normal saline (1.0 ml· 100 g^{-1}· day^{-1}) instead of TPs. The animals were housed in a temperature-controlled room at 22 ℃-24 ℃ and fed with standard rat chow. At the end of six months experimental period, all the rats were anesthetized with intramuscular injection of sodium pentobarbital (30 mg/kg) before sacrificed. Blood was collected

from the heart and serum obtained through centrifugation to measure liver function. The livers were removed immediately, perfused with cold 0.15M KCl and homogenized in 4 volumes of 0.15M KCl solution containing 10 mM EDTA using a Potter-type Teflon glass homogenizer. The homogenate was centrifuged, 10 000×g for 15 min at 4 ℃ in a refrigerated centrifuge (OM 3593 IEC Co. Ltd.USA). The supernatant was then centrifuged 105 000×g for 60 min at 4 ℃ in a preparative ultracentrifuge (20PR-52D; Hitachi, Tokyo). The pellet of microsomes was suspended in the homogenization solution in the homogenizer and centrifuged again as described above. The resulting pellet was suspended in 20 mM potassium phosphate buffer (PH7.4) containing 15 % glycerol until analysis.

Microsomal enzyme assays

The content of cytochrome P450 was determined by the method of Omura and Sato[21,22]. The content of cytochrome b5 was assayed as described by Omura and Takesue[23]. The activities of ADM were determined as described by Imai *et al*[24]. The content of liver microsomal protein and the activities of GST were measured as described in the booklet of kits. All the microsomal enzymes were assayed by using a spectrophotometer (DU-64; Beckman, Fullerton, CA, USA).

Biochemical liver function tests

Biochemical liver function tests (ALT, AST, TP, and ALB) were performed by using an automatic biochemical analyzer (7170A, Hitachi, Tokyo).

Statistical analyses

Data were counted separately in male and female rats and expressed as $\bar{x}\pm s$. Statistical significances were analyzed by *t*-test. The difference was considered significant in case of a two-tailed *P* value less than 0.05, and $P<0.01$ as very significant.

RESULTS

Effects of TPs on contents of P450, b5 and activities of ADM and GST

In high dose group, the contents of P450 and b5 were significantly increased in male rats (respectively 2.66±0.55, 10.43±2.78 nmol· mg MS pro^{-1}) compared with those in the control group (1.08±1.04, 5.51±2.98 nmol· mg MS pro^{-1}; $P<0.01$, respectively). The enzymatic activities of ADM in female rats (0.91±0.08 mmol· mg MS $pro^{-1}min^{-1}$) were higher than those in the control group (0.82±0.08 mmol· mg MS $pro^{-1}\cdot min^{-1}$; $P<0.05$). But the activities of GST were unchanged in all treated groups. In control group, the contents of b5 and the activities of ADM in male and female rats were significantly different (5.51±2.98, 13.42±1.85 nmol· mg MS pro^{-1}; 0.92±0.11, 0.82±0.08 mmol· mg MS $pro^{-1}min^{-1}$, respectively, $P<0.05$). The results indicated that there was a difference of hepatic microsomal drug-metabolizing enzymes under normal conditions in different sex rats (Table 1).

Effects of TPs on biochemical liver functions

TPs did not damage rat liver function after used for a long-term, and it indicated that TPs were a quite safe agent, even at a high dose of 833.3 mg· $kg^{-1}\cdot d^{-1}$, for six months (Table 2).

DISCUSSION

Hepatic drug metabolizing enzyme is called mixed-function oxidase or monooxygenase containing many enzymes including phase I enzymes such as cytochrome P450, cytochrome b5 and NADPH-cytochrome P450 reductase and phase II enzymes such as GST, sulfatase and UDP-glucuronyl transferase[25]. AFB1, one of the risk factors of PLC, damages DNA after conversion to the reactive compound AFB1-epoxide, by the action of cytochrome P450-dependent enzymes[26]. Sufficient evidences have shown that tea and TPs possessed anticarcinogenic effects[27-32]. Some works have been done in the field of TPs modulated or interacted with drug metabolizing enzymes. Maliakal *et al* reported that treating with green tea from different sources could markedly increase cytochrome P450 1A2 activity in rats, and green tea from certain sources could increase cytochrome P450 1A1 and cytosolic GST activities[33]. However, *in vitro* experiment, Mukhtar *et al* and Wang *et al* reported that TPs had an inhibitory effect on microsomal cytochrome P450 enzyme system[34,35]. Until now, no one could give a clear explanation of the different results. We tried to make clear what would happen in these enzyme activities in rats treated with TPs. Considering PLC chemopreventive and chemotherapic effects could not be achieved in a short term of TPs administration, and a long-term experiment has not been carried out in this aspect, so the rats were treated for 6 months. At the end of treatment, we determined the contents of cytochrome P450 and b5, the activities of ADM and GST, and the liver function in the rats. The results showed that the contents and activities

of drug metabolizing enzymes and the antidotal capability of liver were significantly improved in the high dose group. It shortened the time of carcinogen staying in the body and reduced DNA damages. Therefore, TPs could protect human against the risk of chemically induced PLC and other cancers.

Gender differences in drug metabolism in rats have been known for more than 60 years since it was reported that the much shorter duration of drug action in the male was due to the effects of testicular androgens[36]. The activities of hepatic drug-metabolizing enzymes, especially cytochrome P450 and sulfotransferase, were regulated through the sex-related secretion pattern of growth hormone[37]. Some studies reported the sex-related effect on drug -metabolizing enzymes[38,39]. In our study, a marked sex difference in the effects of long-term treatment with TPs on hepatic drug-metabolizing enzymes in rats was observed. In control groups, there were differences between male and female rats. The results indicated that there was a sex difference in activities of hepatic drug-metabolizing enzymes and ability of liver detoxification in normal rats. Epidemiological studies of PLC showed that there was a sex difference in human (male>female). But it is not known whether this difference is related to the difference of hepatic drug-metabolizing enzymes.

Abstract

AIM: To explore the mechanisms of effects of oil A on apoptosis of human pancreatic cancer cells.

METHODS: Cellular DNA content was analyzed by flow cytometry. Western blotting was used for caspase-3 and PARP, caspase-7, caspase-9, cytochrome c, Bcl-2, Bax, Mcl-1, cyclinA, cyclin B1, cyclin D1, cyclin E, CDK2, CDK4, CDK6, P21, P27,GADD45, GADD153.

RESULTS: The caspase-3, caspase-7, and caspase-9 activities were significantly increased as well as the cleavage of caspase-3, downstream substrate poly-ADP ribose polymerase (PARP) was induced. The amount of cytochrome c in the cytosolic fraction was increased, while the amount of cytochrome c in the mitochondrial fraction was decreased after oil A treatment. The anti-apoptosis proteins Bcl-2 and Mcl-1 were decreased in parallel and Bax increased, indicating that Bcl-2 family proteins-mitochondria-caspase cascade was responsible for oil-induced apoptosis. The proportion of cells in the G0/G1 decreased in MiaPaCa-2 and AsPC-1 cells after the treatment of oil A for 24 hours. The number of cells in S phase was increased in two cancer cell lines at 24 hours. Therefore, cells were significantly accumulated in G2/M phase. The cells with a sub-G0/G1 DNA content, a hallmark of apoptosis, were seen at 24 hours both in MiaPaCa-2 and AsPC-1 cells following exposure to oil A. The expression of cyclin A and cyclin B1 was slightly decreased and cyclin D1 levels were markedly lowered in MiaPaCa-2 cells. The expression of cyclin A and cyclin B1 was markedly decreased and cyclin D1 levels were slightly lowered in AsPC-1 cells, while cyclin E was not affected and the levels of CDK2, CDK4, and CDK6 were unchanged in MiaPaCa-2 and AsPC-1 cells. In response to oil A, P21 expression was increased, but P27 expression was not affected. The expression of both GADD45 and GADD153 was increased in two cell lines following oil A treatment.

CONCLUSION: Oil A induces apoptosis of pancreatic cancer cells via activating caspase cascade, modifying cell cycle progress and changing cell cycle-regulating proteins and GADD expression.

INTRODUCTION

It is reported that oil A appears to exert anti-cancer effect by activating apoptosis. It should be speculated that oil A may be broadly active against pancreatic cancer cells. However, whether the use of oil A can be extended to pancreatic tumors is still uncertain. The alternative mechanisms of oil A effect need to be further studied. Our previous experiments showed the inhibition of proliferation and the induction of apoptotic effect by treatment of oil A in pancreatic cancer cells[1]. However, to date, no further information is available regarding the mechanism of effects of oil A on pancreatic cancer cells. In the present study, the mechanism of oil A effect on induction of apoptosis was investigated through activating caspase cascade, inducing cytochrome c release from the mitochondria, Bax, Bcl-2, and Mcl-1 expression, the distribution of cell cycle, changes of cycle-regulating proteins, P21 and P27 expression, and GADD expression in pancreatic cancer cells.

MATERIALS AND METHODS

Reagents

The human pancreatic cancer cell lines, MiaPaCa-2 and AsPC-1 were purchased from the American Type Culture Collection (Rockville, MD, USA). Oil A (Coastside Research Chemical Co., USA) was dissolved in 1:2 DMEM as a stock solution. The stock solution was diluted to appropriate concentrations in serum-free medium prior to experiments. Mitochondria/ Cytosol Fractionation Kit was purchased from BioVision (Mountain View, CA, USA). Enhanced chemiluminescence system (ECL) was obtained from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA, USA). Mouse monoclonal antibodies against PARP, Bcl-2, Bax, Mcl-1, cyclin B1, cyclin D1, cyclin E, CDK2, CDK4, CDK6, P21, P27, GADD45, GADD153 and rabbit polyclonal antibodies against caspase-3, caspase-7, caspase-9, cytochrome c and cyclin A were purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA, USA). All other chemicals were purchased from Sigma (St Louis, MO, USA).

Cell culture

Cells were cultured in DMEM medium supplemented with penicillin G (100 U/mL), streptomycin (100 U/mL) and 10 % FBS at 37 ℃ in humidified air with 5 % CO_2. The cells were harvested by incubation in trypsin-EDTA solution for 10-15 minutes. Then cells were centrifuged at 300×g for 5 minutes and cell pellets suspended in fresh culture medium prior to seeding into culture flasks or plates[1].

Analysis of cellular DNA content by flow cytometry

The cells were grown to 50-60 % confluence in T75 flasks, serum-starved for 24 hours and then treated with or without 1:32 000 oil A for 24 hours. At the end of treatment, the cells were harvested with trypsin-EDTA solution to produce a single

cell suspension. The cells were then pelleted by centrifugation and washed twice with PBS. Cell pellets were then suspended in 0.5 ml PBS and fixed in 5 mL ice-cold 70 % ethanol at 4 ℃. The fixed cells were centrifuged at 300×g for 10 minutes and the pellets were washed with PBS. After resuspension with 1 ml PBS, the cells were incubated with 10 μL of RNase I (10 g/L) and 100 μL of propidium iodide (400 mg/L; Sigma) and shaken for 1 hour at 37 ℃ in the dark. Samples were analyzed by flow cytometry. The red fluorescence of the single events was recorded using a laser beam at 488 nm excitation λ with 610 nm as emission λ to measure the DNA index.

Preparation of cytosolic and mitochondrial extract

Collect cells (5×10^7) were centrifuged at 600×g for 5 minutes at 4 ℃ from control and oil A-treated MiaPaCa-2 and AsPC-1 cells. Wash cells with ice-cold PBS twice, and centrifuge at 600×g for 5 minutes at 4 ℃. Remove supernatant. Resuspend cells with 1.0 mL of 1×cytosol extraction buffer mix containing DTT and protease inhibitors. Incubate on ice for 10 minutes. Homogenize cells in an ice-cold dounce tissue grinder (45 strokes) until 70-80 % of the nuclei did not have the shiny ring. Transfer homogenate to a 1.5 mL microcentrifuge tube, and centrifuge at 700×g for 10 minutes at 4 ℃. Transfer the supernatant to a fresh 1.5 mL tube, and centrifuge at 10 000×g for 30 minutes at 4 ℃. Collect the supernanant as cytosolin fraction. Resuspend the pellet in 0.1 mL mitochondrial extraction buffer mix containing DTT and protease inhibitors, vertex for 10 seconds and save as mitochondrial fraction. Both cytosolic fraction and mitochondrial fraction were stored at -80 ℃ until ready for Western blotting.

Preparation of proteins

Cells were seeded into flasks and grown to 50-60 % confluence, then seeded in serum-free medium for 24 hours. Cells were then placed in serum-free medium with or without 1:32 000 oil A for a period of 24 hours. In the end, proteins were extracted from attached and floating cells in lysis buffer [20 mM Tris-HCl (pH 7.4), 2 mM sodium vanadate, 1.0 mM sodium fluoride, 100 mM NaCl, 2.0 mM phosphate substrate, 1 % NP40, 0.5 % sodium deoxycholate, 20 mg/L each aprotinin and leupeptin, 25 mg/L pepstatin, and 2.0 mM each EDTA and EGTA] for further analysis. Protein concentrations were determined using the bicinchoninic acid assay with BSA as standard.

Western blotting

Western blotting was carried out using standard techniques. In brief, equal amounts of proteins in the cell lysates were separated on SDS-PAGE and the proteins then transferred onto nitrocellulose membranes. After blocking non-specific sites with fat free dried milk, membranes were incubated with the appropriate dilution of primary antibody. Then, membranes were incubated with a horseradish peroxidase conjugated secondary antibody. Proteins were detected using an enhanced chemiluminescence detection system, and light emission was captured on Kodak X-ray films.

RESULTS

Effect of oil A on activation of caspase 3 and cleavage of PARP, caspase 7 and caspase 9

The expression and activation of caspase 3 by cleavage as well as the specific cleavage of its downstream substrate, PARP during apoptosis were observed by Western blotting. The 32 kDa procaspase 3 was cleaved into products of lower molecular weight, including a band corresponding to the 17 kDa active form. The uncleaved 116 kDa pro-form of PARP was only seen in untreated controls while in oil A treatment resulted in appearance of the active 85 kDa cleaved fragments. Caspase 7 and 9 degradation activation were also induced, and coincident with the induction of apoptosis (Figure 1).

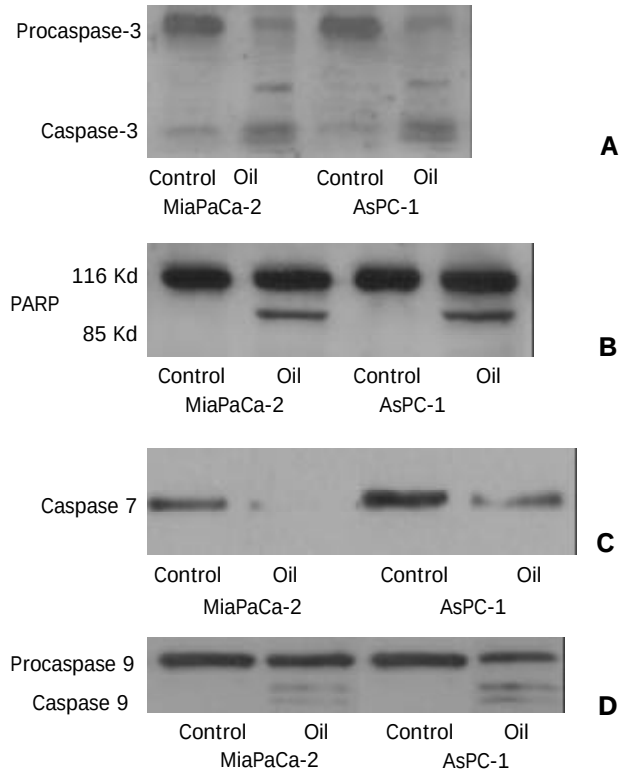

Figure 1 (A, B, C, D) Western blotting of the caspase-3, poly-ADP ribose polymerase (PARP), caspase 7 and caspase 9 in MiaPaCa-2 and AsPC-1 cells treated with 1:32 000 oil A for 24 hours. Proteins in whole cellular lysates were electrophoresed in SDS-PAGE gels and transferred to nitrocellulose membranes. Caspase-3, PARP, caspase 7 and caspase 9 were identified using specific antibodies.

Oil A induces cytochrome c release

Cytochrome c is a mitochondrial protein released from the mitochondria to cytosol during apoptosis when mitochondrial membrane permeability is disrupted. An increase in the amount of cytochrome c in the cytosolic fraction was seen in both cell lines after oil A treatment. Meanwhile, the amount of cytochrome c in the mitochondrial fraction was decreased also in both cell lines after oil A treatment (Figure 2).

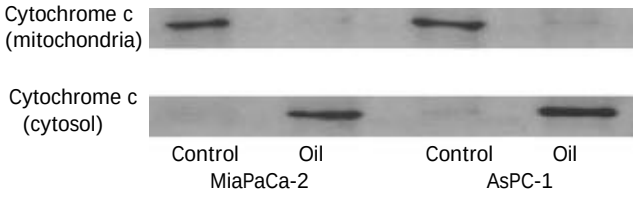

Figure 2 Western blotting of the cytochrome c protein in MiaPaCa-2 and AsPC-1 cells treated with 1:32 000 oil A for 24 hours. Proteins in cytosolic fraction and in mitochondria fraction were extracted. Proteins extracted from each sample were electrophoresed on an SDS-PAGE gel and transferred to nitrocellulose membrane. Cytochrome c was identified using a monoclonal cytochrome c antibody.

Effect of oil A on expression of Bax, Bcl-2, and Mcl-1 proteins

Expression of the anti-apoptosis proteins Bcl-2 and Mcl-1 was decreased and Bax increased following oil A treatment (Figure 3).

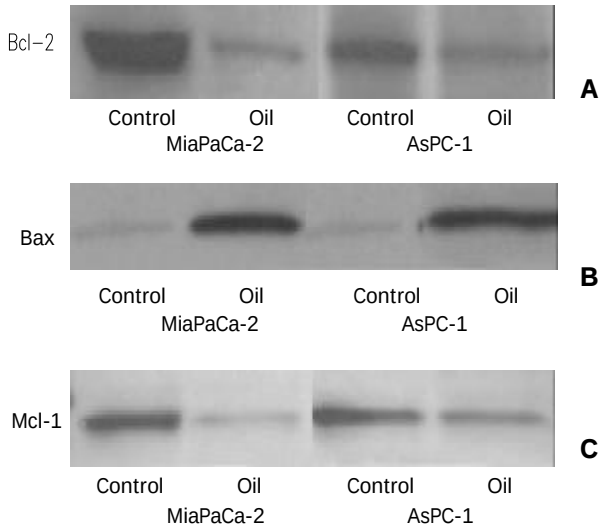

Figure 3 (A, B, C) Western blotting of the Bcl-2, Bax and Mcl-1 proteins in MiaPaCa-2 and AsPC-1 cells treated with 1:32 000 oil A for 24 hours. Whole cellular lysates were electrophoresed in SDS-PAGE gels and proteins were transferred to nitrocellulose membranes. Bcl-2, Bax and Mcl-1 were identified using specific antibodies.

Effect of oil A on cell cycle phase distribution

To understand the mechanism of induction of cell apoptosis, the redistribution of cell cycle phases were analyzed after the treatment with 1:32 000 oil A for 24 hours. The proportion of cells in the G0/G1 phase decreased in MiaPaCa-2 and AsPC-1 cell lines. Therefore, cells were significantly accumulated in the G2/M-phase in these two cancer cell lines. The number of cells in S-phase was increased also in both cell lines when compared with control. The cells with a sub-G0/G1 DNA content, a hallmark of apoptosis, were seen following 24-hour exposure to oil A in both cell lines (Figure 4).

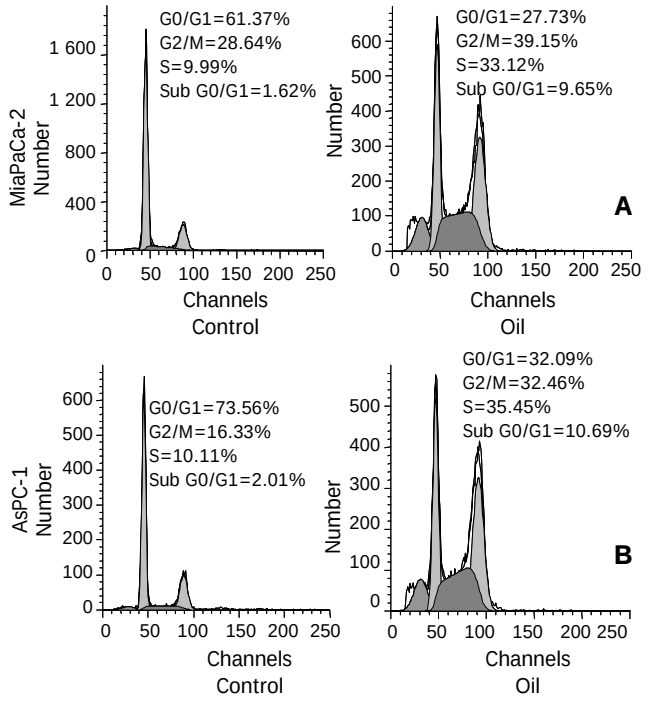

Figure 4 (A, B) Flow-cytometric analysis of cellular DNA content in control and oil A-treated MiaPaCa-2 and AsPC-1 cells, stained with propidium iodide. The cells were treated with 1:32 000 oil A in serum-free conditions for 24 hours. The distribution of cell cycle phases is expressed as % of total cells.

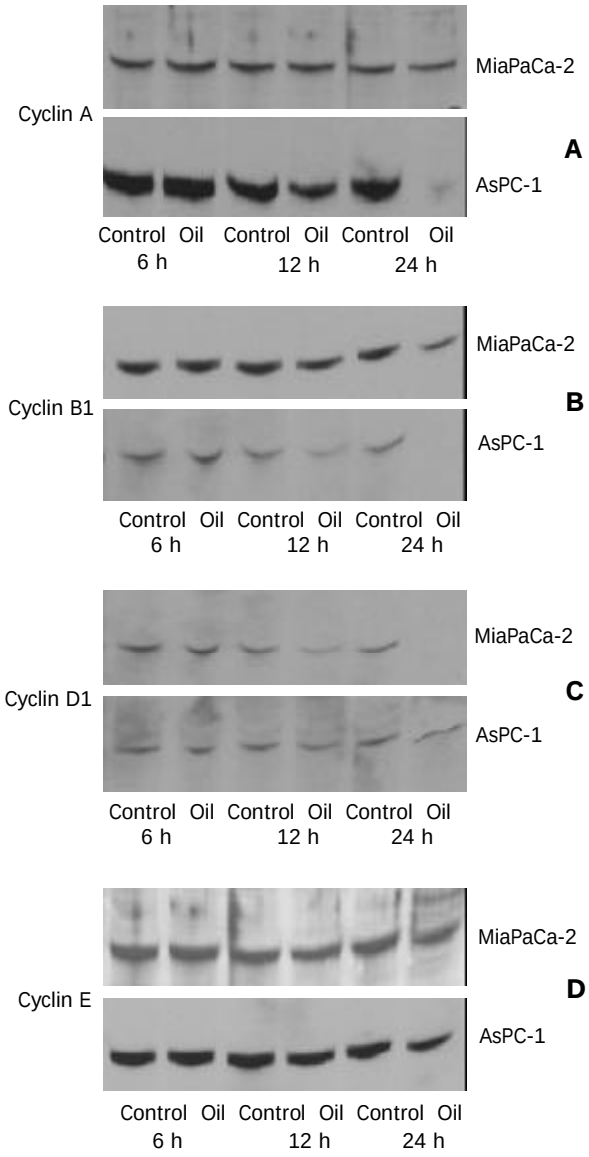

Figure 5 (A, B, C, D) Western blotting of the cyclin A, cyclin B1, cyclin D1 and cyclin E proteins in MiaPaCa-2 and AsPC-1 cells treated with 1:32 000 oil A for 24 hours. Whole cellular lysates were electrophoresed in SDS-PAGE gels and proteins were transferred to nitrocellulose membranes.

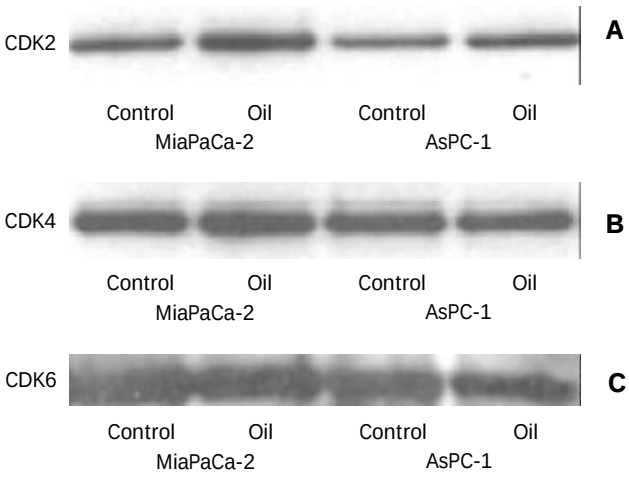

Figure 6 (A, B, C) Western blotting of the CDK2, CDK4 and CDK6 proteins in MiaPaCa-2 and AsPC-1 cells treated with 1:32 000 oil A for 24 hours. Whole cellular lysates were electrophoresed in SDS-PAGE gels and proteins were transferred to nitrocellulose membranes.

Effect of oil A on expression of cyclin proteins

The expression of cyclin A and cyclin B1was slightly decreased and cyclin D1 levels were markedly decreased in MiaPaCa-2 cell line. The expression of cyclin A and cyclin B1 was markedly decreased and cyclin D1 levels were slightly decreased in AsPC-1 cell line, while cyclin E was unaffected and the levels of CDK2, CDK4, and CDK6 remained unchanged in MiaPaCa-2 and AsPC-1 cell lines (Figures 5 and 6).

Effect of oil A on expression of P21 and P27 proteins

In response to red oil A, P21 expression was increased, but P27 expression was not affected (Figure 7).

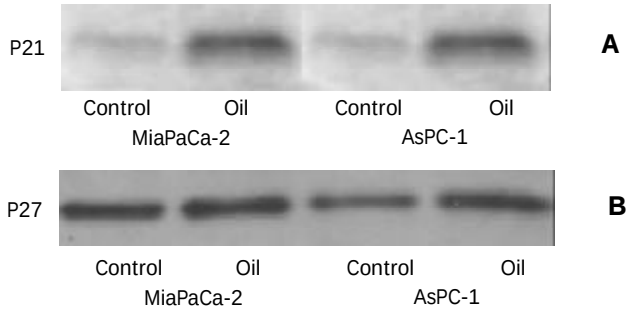

Figure 7 (A, B) Western blotting of the P21 and P27 proteins in MiaPaCa-2 and AsPC-1 cells treated with 1:32 000 oil A for 24 hours. Whole cellular lysates were electrophoresed in SDS-PAGE gels and proteins were transferred to nitrocellulose membranes. P21 and P27 were identified using specific antibodies.

Effect of oil A on expression of GADD

The expression of GADD 45 and GADD153 was enhanced in both pancreatic cancer cell lines following oil A treatment (Figure 8).

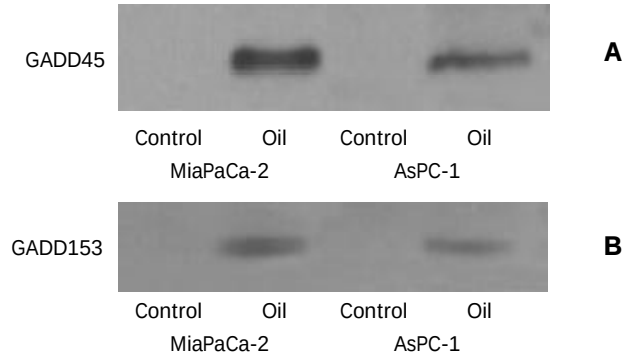

Figure 8 (A, B) Western blotting of GADD45 and GADD153 proteins in MiaPaCa-2 and AsPC-1 cells treated with 1:32 000 oil A for 24 hours. Whole cellular lysates were electrophoresed in SDS-PAGE gels and proteins were transferred to nitrocellulose membranes. GADD was identified using specific monoclonal antibodies.

DISCUSSION

Because of its significant medical properties, fish oil has been used for many years.

Recent studies indicate that diets containing a high proportion of long-chain n-3 polyunsaturated fatty acids were associated with inhibition of the growth and metastasis of human cancer including pancreatic cancer[1-3]. Diets rich in linoleic acid (LA), an n-6 fatty acid, stimulate the progression of human cancer cell in athymic nude mice, whereas supplement of fish oil components, docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) exerts suppressive effects. Fish oil has been shown to reduce the induction of different cancer in animal models by a mechanism which may involve suppression of mitosis, increased apoptosis through long-chain n-3 polyunsaturated fatty acid EPA[1,2,4-6]. In parallel, dietary supplementation with DHA is accompanied by reduced levels of 12- and 15-hydroxyeicosatetraenoic acids (12- and 15-HETE), suggesting that changes in eicosanoid biosynthesis may have been responsible for the observed decrease in tumor growth[2,7-9]. Previous studies also have shown that the anti-cancer effect of fish oil is accompanied by a decreased production of cyclooxygenase and lipoxygenase metabolites[10-13]. The efficacy of fish oil which we have found exhibits particularly potent anticancer effects that appear to be related to its content of lipoxygenase inhibitors rather than its EPA or DHA contents.

Oil A is lipid isolates from the epithelial layer of the echinoderm. Little attention of the mechanism of apoptosis induced by oil A has been paid to pancreatic cancer, which is a major cause of cancer death. The results from the present study indicate that oil A induces apoptosis on pancreatic cancer cells via caspase activities, release of cytochrome c from mitochondria, decreased expression of Bcl-2 and Mcl-1 proteins, increased expression of Bax, redistribution of cell cycle phases, increased expression of P21, GADD45 and GADD153, in association with different expression of cyclins[14-21].

Caspases are cysteine proteases produced as inactive forms and activated during apoptosis. Caspase 3 is a major executioner protease, responsible for initiating in the apoptotic program[22-24]. Caspase 3 plays an important role in the apoptotic program of cells[22-28]. As a result, the caspase 3 and caspase 9 were activated, caspase 7 was decreased following oil A treatment. As a major executioner protease, the sequence alignment among caspase 3, 7 and 9 reveals the different structural basis of functions of caspase 3, 7 and 9. Caspase 3 and caspase 7 share the same sequence by 54 % and the backbone structures are nearly identical[29]. The activation of an effector, caspase 3, is performed by an initiator, caspase 9 through proteolytic cleavage at specific internal asp residues and caspase 3 is responsible for initiating the apoptotic program[22-24,30,31].

PARP cleavage could serve as a sensitive parameter for identification of early apoptosis[32,33]. In parallel, PARP provided further evidence that this apoptotic pathway is activated.

Oil A induced cytochrome c release from the mitochondria to cytosol. Once cytochrome c is released from the mitochondria, it complexes with apoptotic protease-activating factor 1 to activate caspase 3[34-37].

Also, the increase of Bax and the decrease of Bcl-2 and Mcl-1 indicate that Bcl proteins-mitochondria-caspase cascade play an important role in oil-induced apoptosis. To better understand the effect of oil A on apoptosis of pancreatic cancer cells, flow cytometric analysis of propidium iodide-stained cells was carried out. Cytometric analysis showed significant changes of cell cycle distribution in MiaPaCa-2 and AsPC-1 cells following oil treatment for 24 hours. At first (control), the proportion of cells was arrested in the G0/G1. The G2/M phase and S phase of cell cycle were accumulated after oil treatment. In the present study, we demonstrated that the distribution of cell cycle underwent changes from G0/G1 phase arrest to G2/M phase and S phase arrest following oil A treatment. The changes of cell cycle distribution suggest that apoptosis of pancreatic cancer cells may be related to some underlying mechanism, which may trigger an apoptosis signal. Thereafter, the cells with a sub-G0/G1 DNA content, a hallmark of apoptosis, were accumulated in both cell lines MiaPaCa-2 and AsPC-1 at 24 hours following exposure to oil A. The effects

of oil A persist throughout the course of cell growth, cells with DNA damage increase progressively and develop apoptosis successively. The typical peak of a sub-G0/G1 population of cells indicates oil-induced apoptosis of pancreatic cancer cells.

The cyclins and cyclin-dependent kinases (CDKs) are key components of the cell cycle machinery that is responsible for the progression through the G1/S and G2/M phases[38]. In our experiments, the differential expression of cyclins and CDKs were observed in pancreatic cancer cells. During oil A treatment, no detectable changes of CDK2, 4, 6 were observed. When the cell cycle procession was arrested in G0/G1 phase at 24 hours of treatment, the expression of cyclins remained unchanged. Thereafter, when the cell cycle procession was arrested in G2/M phase at 24 hours of treatment, expression of cyclins was different between MiaPaCa-2 and AsPC-1 cells. Cyclin A and cyclin B1 levels were slightly decreased and cyclin D1 was markedly decreased in MiaPaCa-2 cells, whereas cyclin A and cyclin B1 levels were markedly decreased and cyclin D1 was slightly decreased in AsPC-1 cells. At the same time, expression of cyclin E was still constantly expressed. These changes of cyclins suggested underlying mechanism of cell cycle distribution in pancreatic cancer cells response to oil stress. How the cyclins are regulated remains unclear.

It has been reported that P21 mediated a significant response to DNA-damaging agents[39,40]. The results show that oil induced an increased expression of P21, whereas the expression of P27 protein was not changed following oil treatment in the present work. These results suggested that P21 protein may play a key role in G0/G1 to G2/M phase arrest leading to apoptosis of pancreatic cancer cells.

The cell cycle is regulated by inhibitory proteins, such as GADDs, which are responsible for the maintenance of the cell cycle checkpoint that prevents inappropriate mitosis[41-44]. GADDs expression played an important role in signal transduction pathway in response to DNA damage[34,42-45]. Pancreatic cancer cells might respond to oil stress by activating signal transduction leading to cell cycle arrest. As an extracellullar stress signal, oil A induced expression of GADDs in pancreatic cancer cells, which may be related to cell cycle arrest through G0/G1 to G2/M phases. The experimental findings suggest that GADD expression may modulate the sensitivity to oil-induced DNA damage leading to apoptosis. The GADD45 is considered to be functionally p53-dependent or p53-independent and GADD153 to be p53-independent. The increase in GADD45 and GADD153 along with a decrease in Bcl-2 and Mcl-1 were seen in pancreatic cancer cells that underwent growth arrest and apoptosis, which may provide clues concerning the mechanism of the effects of oil A. Although GADD expression with cell cycle redistributions are responsive to oil stress, the underlying mechanisms remain obscure. Further studies are required to elucidate how oil modulates the GADD proteins expression.

Abstract

AIM: Activated pancreatic stellate cells (PSCs) have been implicated in the pathogenesis of pancreatic fibrosis and inflammation. Primary PSCs can be subcultured only several times because of their limited growth potential. A continuous cell line may therefore be valuable in studying molecular mechanisms of these pancreatic disorders. The aim of this study was to establish a cell line of rat PSCs by spontaneous immortalization.

METHODS: PSCs were isolated from the pancreas of male Wistar rats, and conventional subcultivation was performed repeatedly. Telomerase activity was measured using the telomere repeat amplification protocol. Activation of transcription factors was assessed by electrophoretic mobility shift assay. Activation of mitogen-activated protein (MAP) kinases was examined by Western blotting using anti-phosphospecific antibodies. Expression of cytokine-induced neutrophil chemoattractant-1 was determined by enzyme immunoassay.

RESULTS: Conventional subcultivation yielded actively growing cells. One clone was obtained after limiting dilution, and designated as SIPS. This cell line has been passaged repeatedly more than 2 years, and is thus likely immortalized. SIPS cells retained morphological characteristics of primary, culture-activated PSCs. SIPS expressed α-smooth muscle actin, glial acidic fibrillary protein, vimentin, desmin, type I collagen, fibronectin, and prolyl hydroxylases. Telomerase activity and p53 expression were negative. Proliferation of SIPS cells was serum-dependent, and stimulated with platelet-derived growth factor-BB through the activation of extracellular signal-regulated kinase. Interleukin-1β activated nuclear factor-κB, activator protein-1, and MAP kinases. Interleukin-1β induced cytokine-induced neutrophil chemoattractant-1 expression through the activation of nuclear factor-κB and MAP kinases.

CONCLUSION: SIPS cells can be useful for *in vitro* studies of cell biology and signal transduction of PSCs.

INTRODUCTION

Chronic pancreatitis as well as pancreatic cancer are accompanied by progressive fibrosis that is characterized by loss of functional tissue and its replacement by extracellular matrix rich connective tissues[1,2]. In contrast to liver fibrosis, the molecular mechanisms of pancreatic fibrogenesis remain to be elucidated. In 1998, star-shaped cells in the pancreas, namely pancreatic stellate cells (PSCs), were identified and characterized[3,4]. They are morphologically very similar to the hepatic stellate cells that play a central role in fibrosis of the liver[5]. In normal pancreas, stellate cells are quiescent and can be identified by the presence of vitamin A-containing lipid droplets in the cytoplasm. In response to pancreatic injury or inflammation, they are transformed ("activated") from quiescent phenotype into highly proliferative myofibroblast-like cells which express the cytoskeletal protein α-smooth muscle actin (α-SMA), and produce type I collagen and other extracellular matrix components. Many of the morphological and metabolic changes associated with the activation of PSCs in animal models of fibrosis also occur when these cells are grown in culture on plastics in serum-containing medium. Therefore, culture of primary PSCs on plastics has been accepted as an established model that mimics the phenotypic changes that occur during the process of PSC activation following pancreatic injury. There is accumulating evidence that PSCs, like hepatic stellate cells, are responsible for the development of pancreatic fibrosis[3,4,6]. Furthermore, PSCs might participate in the pathogenesis of acute pancreatitis through the expression of monocyte chemoattractant protein-1 and intercellular adhesion molecule-1[7,8]. The activation of signaling pathways such as p38 mitogen-activated protein (MAP) kinase[9] is likely to play a key role in PSC activation. However, the precise intracellular signaling pathways in PSCs are largely unknown.

Although primary stellate cell culture is a useful tool for studying molecular mechanisms of pancreatic fibrosis and inflammation *in vitro*, their isolation is time-consuming, yields are relatively low, and there is considerable heterogeneity between preparations. Several weeks in culture are required to obtain sufficient cells to perform experiments. In addition, primary cells can be subcultured only several times because of their limited life span *in vitro*. Because rat cells are known to be immortalized by spontaneous transformation, this study aimed to establish a rat PSC line by spontaneous immortalization.

MATERIALS AND METHODS

Materials

[γ-^{32}P]ATP was obtained from Amersham Biosciences UK, Ltd. (Buckinghamshire, England). Rat recombinant platelet-derived growth factor (PDGF)-BB was from R&D Systems (Minneapolis, MN). Recombinant human interleukin (IL)-1β was from Roche Applied Science (Mannheim, Germany). Rabbit antibodies against phosphorylated MAP kinases, total MAP kinases, and inhibitor of nuclear factor κB (NF-κB)-α (IκB-α) were purchased from Cell Technologies, Inc. (Beverly,

MA). Rabbit polyclonal antibody against p53 was from Santa Cruz Biotechnology (Santa Cruz, CA). Rabbit antibodies against rat type I collagen and prolyl hydroxylases (α, β) were from LSL Cosmo Bio (Tokyo, Japan). Rabbit anti-rat fibronectin antibody was from Chemicon International (Temecula, CA). Rabbit antibody against glyceraldehyde-3-phosphate dehydrogenase (G3PDH) was from Trevigen (Gaithersburg, MD). SP600125, U0126 and SB202190 were from Calbiochem (La Jolla, CA). All other reagents were products of Sigma-Aldrich (St. Louis, MO) unless specifically described.

Cell culture and immortalization

All animal procedures were performed in accordance with the National Institutes of Health Animal Care and Use Guidelines. Rat PSCs were prepared from the pancreas tissues of male Wistar rats (Japan SLC Inc., Hamamatsu, Japan) weighing 200-250 g as previously described[3]. Isolated stellate cells were cultured in Ham' s F-12 containing 10 % heat-inactivated fetal bovine serum (FBS; ICN Biomedicals, Aurora, OH), penicillin sodium, and streptomycin sulfate. When reaching confluent, the cells were trypsinized with 0.05 % trypsin/0.01 % EDTA. Initially, cells were passaged at a ratio of 1:3. After the 10th passage, cells were split at 1:5. A homogeneous population of cells, designated as SIPS, was cloned by limiting dilution, and expanded. SAM-K is another rat PSC line established by retrovirus-mediated introduction of simian virus 40 large T antigen[10]. SAM-K cells and primary PSCs were maintained in Ham' s F-12 containing 10 % FBS, penicillin sodium, and streptomycin sulfate.

Immunostaining

SIPS cells were grown directly on slides, serum-starved for 24 hours, and immunostaining for α-SMA was performed using a streptavidin-biotin-peroxidase complex detection kit (Histofine Kit; Nichirei, Tokyo, Japan) as previously described[11]. Briefly, cells were fixed in 100 % methanol at -20 ℃, and then endogenous peroxidase activity was blocked by incubation with hydrogen peroxide in methanol for 5 minutes. After immersion in normal rabbit serum, the slides were incubated with mouse anti-α-SMA antibody (at 1:200 dilution) at 4 ℃ overnight. The slides were incubated with biotinylated anti-mouse immunoglobulin antibody, and peroxidase-conjugated streptavidin. Finally, color was developed by incubating the slides with diaminobenzidine (Dojindo, Kumamoto, Japan). Expression of glial acidic fibrillary protein, vimentin, desmin, type I collagen, fibronectin, and prolyl hydroxylases (α, β) was examined in a similar manner.

Western blotting

The levels of activated, phosphorylated MAP kinases were determined by Western blotting as previously described[12]. Briefly, cells were lysed in sodium dodecyl sulfate buffer (62.5 mM Tris-HCl at pH 6.8, 2 % sodium dodecyl sulfate, 10 % glycerol, 50 mM dithiothreitol, 0.1 % bromphenol blue) for 15 minutes on ice. The samples were then sonicated for 2 seconds, heated for 5 minutes, and centrifuged at 12 000×g for 5 minutes to remove insoluble cell debris. Cellular proteins (approximately 100 μg) were fractionated on a 10 % sodium dodecyl sulfate-polyacrylamide gel. They were transferred to a nitrocellulose membrane (Bio-Rad, Hercules, CA), and the membrane was incubated overnight at 4 ℃ with rabbit anti-phosphospecific MAP kinase antibodies (at 1:1 000 dilution). After incubation with peroxidase-conjugated goat anti-rabbit secondary antibody for 1 hour, proteins were visualized using an ECL kit (Amersham Biosciences UK, Ltd.). Levels of total MAP kinases, p53, G3PDH, and IκB-α were determined in a similar manner.

Telomerase activity

Telomerase activity was measured using the telomere repeat amplification protocol (TRAP) with the Telo TAGGG Telomerase PCR ELISAkit (Roche Applied Science). Briefly, SIPS, SAM-K, and primary PSCs (passage 3) were harvested separately, and the cell number was counted. The cell extracts were prepared from an equal number of cells, and used in telomerase-mediated elongation, adding the telomeric repeats to the 3' end of the biotin-labeled synthetic P1-TS-primer. These elongation products were amplified by PCR using the primers P1-TS and P2, generating PCR products with the telomerase-specific 6-nucleotide increments. An aliquot of the resulting PCR product was denatured, hybridized to a digoxigenin-labeled, telomeric repeat-specific detection probe, and immobilized to a streptavidin-coated microtiter plate. Then, peroxidase-conjugated anti-digoxigenin antibody was added to detect the immobilized PCR product, and the telomerase activity was determined, after the addition of 3,3', 5,5' -tetramethylbenzidine (substrate), as O.D.450-O.D.690. Ribonuclease A-treated cell extracts were used as negative controls. The mean of the absorbance readings of the negative control was subtracted from those of the samples, and the samples were regarded as telomerase positive if the O.D. difference was higher than 0.2.

Senescence-associated *b*-galactosidase (SA-*b*-Gal) staining

Senescence of SIPS, SAM-K, and primary PSCs (passage 20) was examined by SA-β-Gal staining[13]. Cells were grown directly on slides, fixed, and stained with β-Gal staining solution (β-galactosidase staining kit; Mirus, Madison, WI), pH adjusted to 6.0, for 16 hours at 37 ℃. After washed with phosphate-buffered saline, the slides were viewed under light microscope.

Cell proliferation assay

Serum-starved SIPS cells (approximately 80 % density) were treated with FBS at various concentrations or PDGF-BB (at 25 ng/ml). Cell proliferation was assessed using a commercial kit (Cell proliferation ELISA, BrdU; Roche Applied Science) according to the manufacturer' s instructions. This is a colorimetric immunoassay based on the measurement of 5-bromo-2' -deoxyuridine (BrdU) incorporation during DNA synthesis[14]. After 24-hour incubation with experimental reagents, cells were labeled with BrdU for 3 hours at 37 ℃. Cells were then fixed, and incubated with peroxidase-conjugated anti-BrdU antibody. The peroxidase substrate 3,3' ,5,5' -tetramethylbenzidine was added, and BrdU incorporation was quantitated by O.D.370-O.D.492.

Electrophoretic mobility shift assay

Following 1-hour-incubation, approximately 5×10^6 cells were harvested and nuclear extracts were prepared, and electrophoretic mobility shift assay was performed as previously described[15]. Double-stranded oligonucleotide probes for NF-κB (5' -AGTTGAGGGGACTTTCCCAGGC-3'), and activator protein-1 (AP-1) (5' -CGCTTGATGAGTCAGCCGGAA-3') were end-labeled with [γ-^{32}P]ATP. Nuclear extracts (approximately 5 μg) were incubated with the labeled oligonucleotide probe for 20 minutes at 22 ℃, and electrophoresed through a 4 % polyacrylamide gel. Gels were dried and autoradiographed at -80 ℃ overnight. A 100-fold excess of unlabelled oligonucleotide was incubated with nuclear extracts for 10 minutes prior to the addition of the radiolabeled probe in the competition assays.

Enzyme immunoassay

After a 24 hour-incubation, cell culture supernatants were

harvested and stored at -80 ℃. CINC-1 levels in the culture supernatants were measured by enzyme immunoassay (Panapharm Laboratories, Udo, Japan) according to the manufacturer's instructions.

Statistical analysis

The results were expressed as mean ± standard deviation (mean ± SD). Luminograms and autoradiograms are representative of at least three experiments. Differences between experimental groups were evaluated by two-tailed unpaired Student' s *t* test. A *P* value of less than 0.05 was considered statistically significant.

RESULTS

Establishment of an immortalized rat PSC line

PSCs were isolated from the pancreas of male Wistar rats, and conventional subcultivation was performed repeatedly. This procedure yielded actively growing cells. After limited dilution, one clone was obtained and designated as SIPS. SIPS cells were myofibroblast-like shaped, and morphologically very similar to primary, culture-activated PSCs. The characteristic fiber-like pattern of positive α-SMA staining was observed throughout the cytoplasm in SIPS cells (Figure 1A). In addition, SIPS cells showed positive staining for cytoskeletal proteins glial acidic fibrillary protein (Figure 1B), vimentin

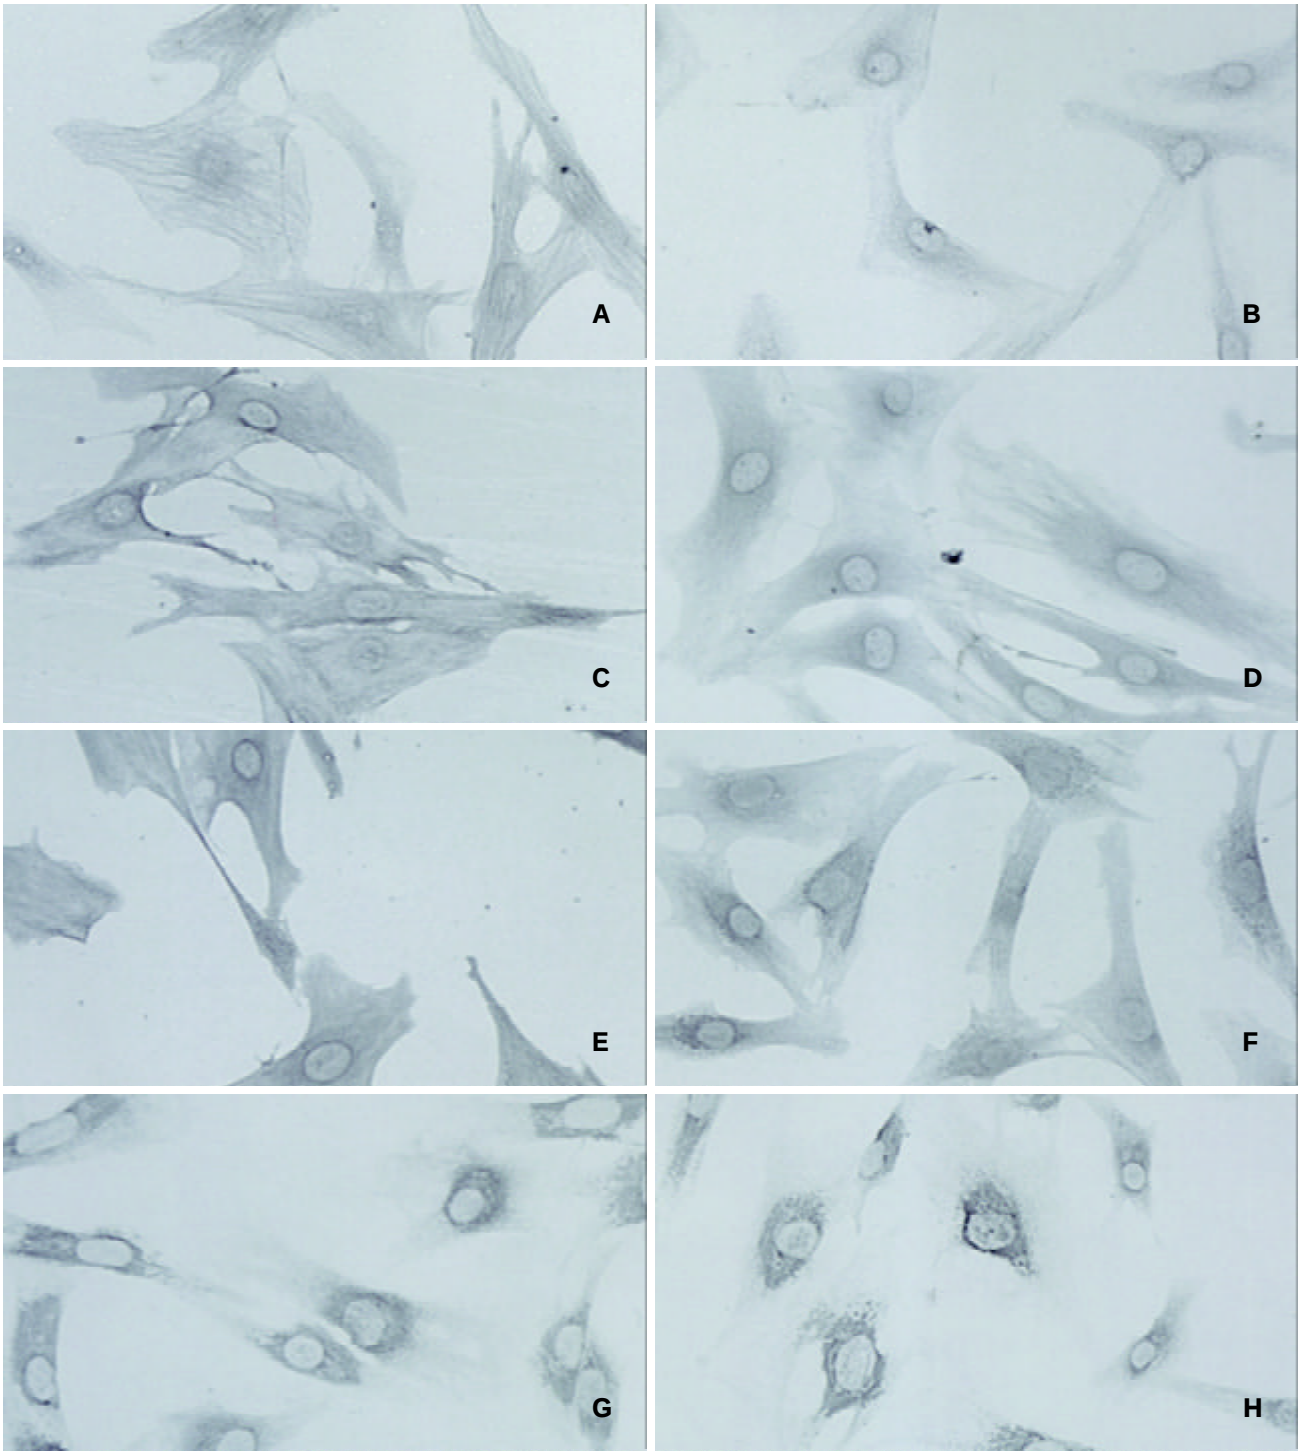

Figure 1 SIPS expressed cytoskeletal proteins and extracellular matrix proteins. Cells were grown directly on slides. Immunostaining for α-SMA (A), glial fibrillary acidic protein (B), vimentin (C), desmin (D), type I collagen (E), fibronectin (F), and prolyl hydroxylases (α) (G) and (β) (H) was performed using a streptavidin-biotin-peroxidase complex detection kit. Original magnification: ×20 objective.

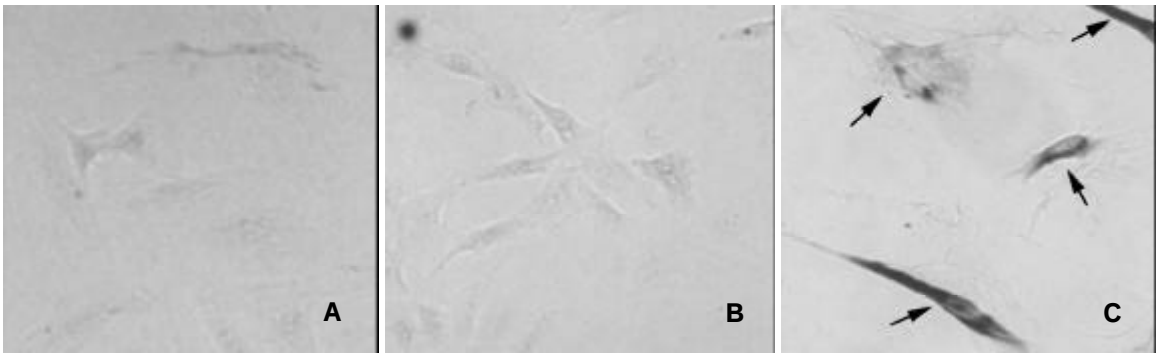

Figure 2 SIPS cells were negative for SA-β-Gal. SIPS cells (A), SAM-K cells (B), and late-passage (passage 20) PSCs (C) were grown directly on slides, fixed, and stained with β-Gal staining solution, adjusted to pH 6.0, for 16 hours at 37 ℃. After washed, the slides were viewed under light microscope. SA-β-Gal was not detected in SIPS and in SAM-K cells, but was detected in late-passage PSCs (arrows). Original magnification: ×20 objective.

(Figure 1C), and desmin (Figure 1D). SIPS cells also expressed extracellular matrix proteins type I collagen (Figure 1E) and fibronectin (Figure 1F). SIPS cells expressed prolyl hydroxylases (α, β) (Figure 1G, H), that are key enzymes in the hydroxylation of the proline residues in procollagen and are useful markers of collagen synthesis[7]. These results suggest that SIPS cells shared many phenotypical and functional characteristics with primary, culture-activated PSCs. During the two years of culture, SIPS cells have been passaged repeatedly over 100 population doublings without showing any evidence of senescence. Indeed, SA-β-Gal, a biomarker of senescent cells[13], was not detected in SIPS and in SAM-K cells (Figure 2A, B). In contrast, SA-β-Gal was detected in late-passage (passage 20) primary PSCs (Figure 2C). The phenotypic characteristics of SIPS remained unaltered, suggesting that they have acquired an immortalized phenotype. SIPS cells have conserved the characteristics of non-transformed cells since they did not form foci, and did not grow on soft agar (data not shown).

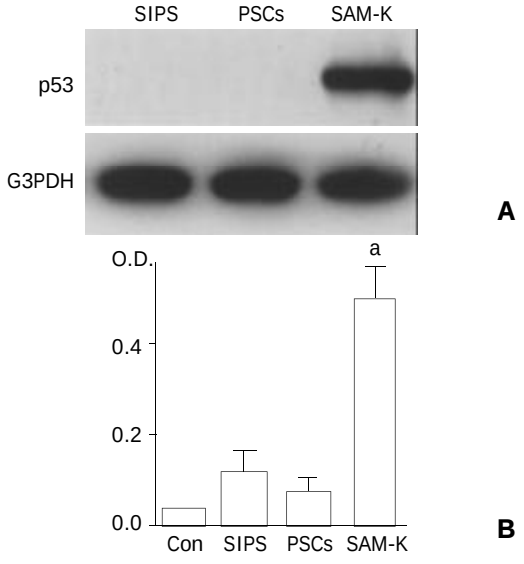

Figure 3 p53 expression and telomerase activity were negative in SIPS cells. (A) Total cell lysates (approximately 100 μg) were prepared from SIPS, primary PSCs (passage 3), and SAM-K cells. The level of p53 was determined by Western blotting. The level of G3PDH was also determined as a loading control. (B) Telomerase activity was measured utilizing the TRAP by enzyme-linked immunosorbent assay. The telomerase activity was determined by differences in absorbance at O.D.450-O.D. 690. Negative control was prepared by incubating the total cell extracts with ribonuclease A. The mean of the absorbance in negative control was subtracted from those of the samples, and the samples were regarded as telomerase positive ("**a**") if the difference in absorbance was higher than 0.2. Data are shown as mean ± SD (n=6).

Negative p53 expression and telomerase activity in SIPS cells

We next examined telomerase activity and p53 expression, potentially important factors in cellular immortalization[16,17]. p53 expression was not detected in SIPS cells and primary PSCs (passage 3), whereas the p53 level was very high in SAM-K cells (Figure 3A). As measured by the TRAP assay, SIPS cells and primary PSCs were negative for telomerase activity, whereas SAM-K cells were positive (Figure 3B).

Proliferation of SIPS stimulated by serum and PDGF

Previous studies have shown that proliferation of primary PSCs was stimulated by growth factors such as serum and PDGF-BB[18-20]. Especially, PDGF-BB has been shown to be the most potent mitogen for PSCs, and is likely to be an important mediator of the increased proliferation of the cells both *in vivo* and *in vitro*[18,19]. We examined whether proliferation of SIPS cells were also stimulated by serum and PDGF-BB. Treatment of the cells with FBS stimulated proliferation in a dose-dependent manner; serum-induced proliferation was significant at as low as 1 % (P<0.05) (Figure 4). In addition, PDGF-BB stimulated proliferation of SIPS cells; PDGF-BB (at 25 ng/ml) induced proliferation by approximately three fold in serum-free medium (Figure 4).

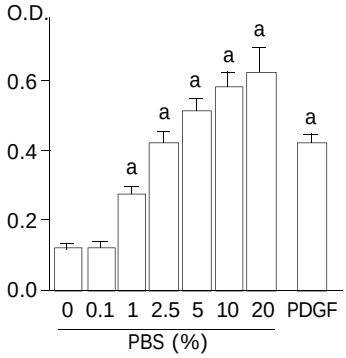

Figure 4 Proliferation of SIPS cells was serum-dependent and stimulated with PDGF-BB. SIPS cells were treated with FBS (at the indicated concentrations) or PDGF-BB (at 25 ng / ml. After 24-hour-incubation, cells were labeled with BrdU for 3 hours. Cells were then fixed, and incubated with peroxidase-conjugated anti-BrdU antibody. Then the peroxidase substrate 3,3', 5,5'-tetramethylbenzidine was added, and BrdU incorporation was quantitated by differences in absorbance at wavelength 370 minus 492 nm ("O.D."). Data are shown as mean ± SD (n=6). [a]P<0.01 *vs.* serum-free medium only. O.D.: optical density.

IL-1b activated NF-kB and AP-1

We have previously shown that proinflammatory cytokines IL-1β and tumor necrosis factor-α activated transcription factors NF-κB and AP-1 in primary PSCs[7, 8]. We examined whether IL-1β activated these transcription factors in SIPS cells. Nuclear extracts were prepared from SIPS cells treated with IL-1β for 1 hour, and specific binding activities of NF-κB and AP-1 were assessed by electrophoretic mobility shift assay. IL-1β increased NF-κB and AP-1 binding activities (Figure 5A, B). The specificity of these binding activities was confirmed by competition assays using 100-fold excess of unlabeled oligonucleotides (data not shown). Phosphorylation and degradation of IκB-α is necessary for the activation of NF-κB[21]. We examined the effects of IL-1β on the cellular IκB-α levels by Western blotting. IL-1β induced transient degradation of IκB-α, further supporting that IL-1β activated NF-κB (Figure 5C).

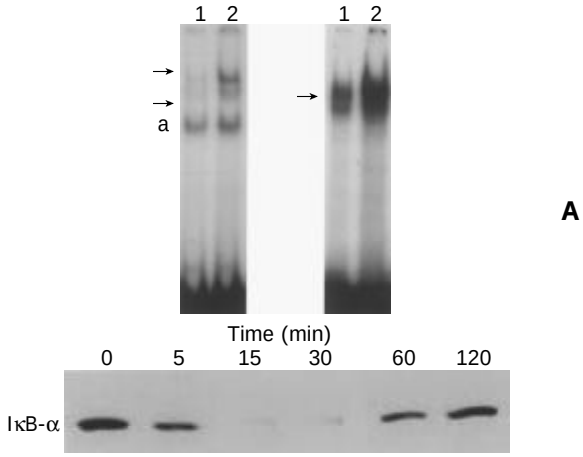

Figure 5 IL-1β activated NF-κB and AP-1 in SIPS cells. (A, B) SIPS cells were treated with IL-1β (at 2 ng / ml, lane 2) for 1 hour. Nuclear extracts were prepared, and specific binding activities of NF-κB (panel A) and AP-1 (panel B) were assessed by electrophoretic mobility shift assay. Arrows denote specific inducible complexes competitive with cold double-stranded oligonucleotide probes. Lane 1: control (medium only). a: non-specific band. (C) SIPS cells were treated with IL-1β for indicated times. Total cell lysates (approximately 100 μg) were prepared, and the level of IκB-α was determined by Western blotting.

IL-1b activated MAP kinases

Induction of the expression of AP-1 components c-Fos and c-Jun by a variety of stimuli such as growth factors and cytokines was mediated by the activation of three distinct MAP kinases: extracellular signal-regulated kinase (ERK) 1/2, c-Jun N-terminal kinase (JNK), p38 MAP kinase[22]. Because the activation of these kinases occurred through phosphorylation, we examined whether IL-1β activated these MAP kinases in SIPS cells by Western blotting using anti-phosphospecific MAP kinase antibodies. These antibodies recognized only phosphorylated form of MAP kinases, thus allowing the assessment of activation of these kinases. IL-1β activated these three classes of MAP kinases in a time-dependent manner, peaking from 5 to 15 minutes (Figure 6). The levels of total MAP kinases were unaffected by the treatment, indicating that the lanes had been equally loaded.

PDGF-BB induced proliferation of SIPS cells through ERK pathway

We and others have shown that activation of ERK plays key roles in the PDGF-induced proliferation of PSCs[20,23]. We examined whether PDGF-BB activated ERK in PSCs. PDGF-BB activated ERK1/2 in a time-dependent manner (Figure 7A). U0126, a specific MAP kinase kinase inhibitor[24], inhibited PDGF-induced proliferation in a dose-dependent manner (Figure 7B). Thus, activation of ERK plays a central role in the proliferation of SIPS, as is the case for primary PSCs.

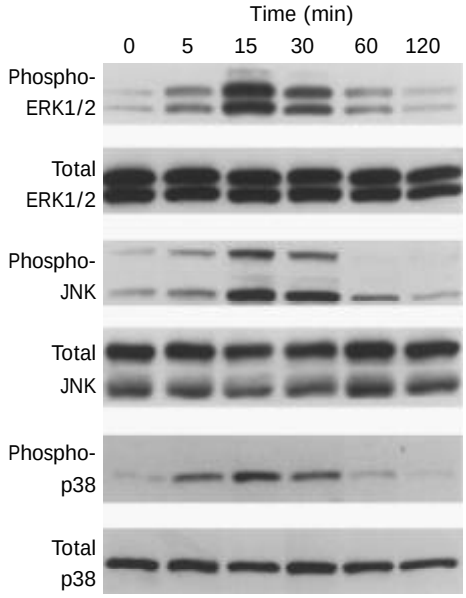

Figure 6 IL-1β activated MAP kinases. SIPS cells were treated with IL-1β (at 2 ng / ml) for the indicated time. Total cell lysates (approximately 100 μg) were prepared, and the levels of activated, phosphorylated MAP kinases were determined by Western blotting. The levels of total MAP kinases were also determined.

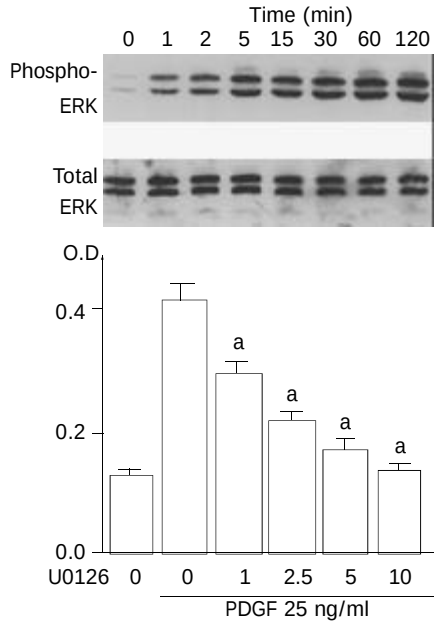

Figure 7 PDGF-BB induced proliferation of SIPS cells through ERK pathway. (A) SIPS cells were treated with PDGF-BB (at 25 ng / ml) for the indicated time. Total cell lysates (approximately 100 μg) were prepared, and the level of activated, phosphorylated ERK was determined by Western blotting. The level of total ERK was also determined. (B) SIPS cells were treated with PDGF-BB (at 25 ng / ml) in the presence of U0126 at the indicated concentrations (at μM). After 24-hour-incubation, cells were labeled with BrdU for 3 hours. Cells were fixed, and incubated with peroxidase-conjugated anti-BrdU antibody. Then the peroxidase substrate 3,3',5,5'-tetramethylbenzidine was added, and BrdU incorporation was

quantitated by differences in absorbance at O.D.370-O.D.492. Data are shown as mean ± SD (n=6). [a]P<0.01 versus PDGF only. O.D.: optical density.

IL-1b induced CINC-1 expression

Activated PSCs acquire the proinflammatory phenotype; they may modulate the recruitment and activation of inflammatory cells through the expression of monocyte chemoattractant protein-1[7] and intercellular adhesion molecule-1[8]. Monocyte chemoattractant protein-1 is a C-C chemokine and potent mononuclear cell chemoattractant. CINC-1, a C-X-C chemokine, is a rat homologue of IL-8, and a potent neutrophil attractant[25]. It remained unknown whether primary PSCs expressed CINC-1. We examined whether SIPS cells express CINC-1 in response to IL-1β by enzyme immunoassay. SIPS cells constitutively produced CINC-1 at very low levels. IL-1β significantly induced the production of CINC-1 (Figure 8). Ethanol and acetaldehyde at clinically relevant concentrations failed to induce CINC-1 production. To elucidate the roles of NF-κB and MAP kinases for the expression of CINC-1 in SIPS cells, we used specific inhibitors to block these pathways. First, we treated SIPS cells with IL-1β in the presence of pyrrolidine dithiocarbamate (PDTC), a specific inhibitor of NF-κB activation[26]. As shown in Figure 8, PDTC decreased the IL-1β-induced CINC-1 production to near the basal levels. SP600125 is a reversible ATP-competitive inhibitor of JNK that inhibits c-jun phosphorylation and the expression of proinflammatory genes such as IL-2, and tumor necrosis factor-α[27]. SP600125 at 10 μM decreased the IL-1β-induced CINC-1 production approximately by 75 %. We next examined the effects of U0126[24], a specific inhibitor of MAP kinase kinase activation, which prevents the activation of ERK1/2. U0126 at 10 μM partially inhibited inducible CINC-1 expression. A selective p38 MAP kinase inhibitor, SB202190[28], at 25 μM also partially inhibited inducible CINC-1 production. Similar results were obtained with tumor necrosis factor-α-induced CINC-1 expression (data not shown). In these experiments, the inhibitors at the indicated concentrations did not affect the cell viability during the incubation as assessed by trypan blue exclusion test (data not shown). However, at higher concentrations, some cytotoxic effects were observed during the incubation. These results suggested that activation of NF-κB and JNK plays a key role in inducible CINC-1 expression in SIPS cells. Activation of ERK and p38 MAP kinase pathways is partially required for optimal CINC-1 expression.

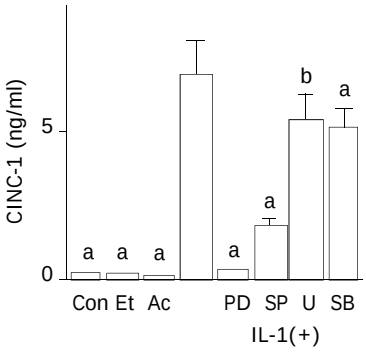

Figure 8 IL-1β induced CINC-1 expression. SIPS cells were left untreated, or treated with IL-1β (IL; at 2 ng/ml) in the absence or presence of PDTC ("PD" at 10 μM), SP600125 ("SP" at 10 μM), U0126 ("U" at 5 μM), or SB202190 ("SB" at 25 μM). After 24 hours, CINC-1 levels in the culture supernatant were determined by enzyme immunoassay. The effects of ethanol ("Et" at 50 mM) and acetaldehyde ("Ac" at 200 μM) were also examined. Con: control (medium only). Data shown are expressed as means ± SD (n=6). [a]P<0.01, [b]P<0.05 versus IL-1β only.

DISCUSSION

In response to pancreatic injury or inflammation, PSCs undergo a transformation from quiescent cells to activated, proliferating myofibroblast-like cells, which produce cytokines and extracellular matrix proteins. It has been established that activated PSCs play an important role in the pathogenesis of pancreatic fibrosis and inflammation[3,4,8]. Although primary stellate cell culture is a useful tool for studying molecular mechanisms of pancreatic fibrosis and inflammation *in vitro*, their isolation is time-consuming, yields are relatively low, and there is considerable heterogeneity between preparations. In addition, primary cells can be subcultured only several times because of their limited growth potential. To circumvent these problems, we have established and validated a new rat PSC line, named SIPS. This SIPS cell line has been developed through spontaneous immortalization, and can be passaged indefinitely compared with the limited number of passages for primary PSCs. SIPS cells have been passaged repeatedly without showing any evidence of senescence. Indeed, SA-β-Gal, a biomarker of senescent cells[13], was not detected in SIPS cells. SIPS cells retained the morphologic characteristics of primary PSCs as well as the expression of the cytoskeletal proteins α-SMA and glial acidic fibrillary protein. SIPS cells maintained the functional characteristics of primary PSCs; SIPS cells showed positive staining for type I collagen, fibronectin, and prolyl hydroxylases. Proliferation of PSCs was stimulated by FBS and PDGF-BB. SIPS cells responded to IL-1β, resulting in the activation of NF-κB, AP-1, and MAP kinases. In addition, SIPS cells exhibited proinflammatory response; SIPS cells expressed CINC-1 in response to IL-1β. Thus, SIPS cells retain several aspects of the primary and culture-activated PSCs.

We have previously established an immortalized cell line of rat PSCs, named SAM-K, by the introduction of the simian virus 40 T antigen[10]. Although SAM-K cells were found to be useful for establishment of stable transfectants, it was also shown that large T antigen led to the alternation of genome such as p53 expression[10]. The resulting genetic manipulations might limit the use of SAM-K cells for studies like defining genetic changes that occur during cell differentiation and transformation. In this study, we examined the expression of p53 and telomerase activity, both of which are shown to be associated with immortalization of mammalian cells[16,17]. We found that p53 expression and telomerase activity was negative in SIPS cells as is the case for primary PSCs. This is in striking contrast to SAM-K cells, where p53 expression and telomerase activity were high. These results suggest that different mechanisms involved for immortalization of SIPS and SAM-K cells, and that SIPS cells have more similar phenotype to primary PSCs than SAM-K cells do. Obviously, further studies are necessary to clarify the molecular mechanisms responsible for immortalization of SIPS cells.

To our knowledge, this is the first report describing the establishment of stellate cell line of the pancreas by spontaneous immortalization. In culture, PSCs are morphologically very similar to the hepatic stellate cells. To date, several hepatic stellate cell lines have been established by spontaneous immortalization. Greenwel *et al*[29] reported the characterization of two rat hepatic stellate cell lines, one from normal and the other from cirrhotic liver. Although both cell lines resembled primary cultures of hepatic stellate cells, significant differences in cell proliferation and IL-6 production between the two cell lines were found. Sauvant *et al*[30] reported that immortalized rat hepatic stellate cells were able to convert retinol into retinoic acid. Rodent cells are known to undergo spontaneous immortalization with a frequency of 10^{-5}–10^{-6} that makes isolation of immortal cell lines from rodent populations experimentally practical even without transfer of an oncogene, whereas the spontaneous immortalization of human cells is a

very rare event; the frequency is thought to be less than 10^{-12}[31]. Schnabl *et al*. reported immortal activated human hepatic stellate cells generated by ectopic telomerase expression[32]. They showed that activated human hepatic stellate cells had little, if any, detectable telomerase activity. Telomerase-induced hepatic stellate cells did not undergo oncogenic transformation and showed morphologic characteristics of activated stellate cells. In addition, mRNA expression in telomerase-positive cells and -negative cells were very similar. It would be of particular interest to see if human PSC line could be established by the introduction of ectopic telomerase expression.

Proliferation of PSCs is a fundamental feature of pancreatic fibrosis. PDGF has been shown to be the most potent mitogen for PSCs *in vitro*[18,19]. PDGF-BB stimulated proliferation of SIPS, and the stimulation was abolished in the presence of U126, a MAP kinase kinase inhibitor[24]. This is in agreement with the previous studies showing that ERK is a key mediator of mitogenic signals in rat PSCs[20,23].

Activated PSCs acquire the proinflammatory phenotype; they may modulate the recruitment and activation of inflammatory cells. We have shown that proinflammatory cytokines such as IL-1β and tumor necrosis factor-α induced expression of monocyte chemoattractant protein-1 and intercellular adhesion molecule-1 in primary PSCs[7,8]. In addition, we here showed for the first time that IL-1β induced CINC-1 expression in SIPS cells. CINC-1 production in response to IL-1β was also observed in primary PSCs (Satoh *et al*. manuscript in preparation). Although it has been shown that hepatic stellate cells express CINC-1 both *in vivo* and *in vitro*[33], whether PSCs expressed CINC-1 and its regulatory mechanisms remained unknown. In this study, inducible CINC-1 production was abolished by PDTC, a specific inhibitor of NF-κB activation, and strongly decreased by SP600125, an inhibitor of JNK. Inhibition of ERK pathway by U0126 and of p38 MAP kinase by SB202190 partially inhibited IL-1β-induced CINC-1 production. Collectively, activation of NF-κB and JNK plays a key role, and that of ERK and p38 MAP kinase plays a partial role for optimal CINC-1 expression in SIPS cells. This is in agreement with the regulatory mechanisms of IL-8, a human homologue of CINC-1[34]. Maximal IL-8 amounts are generated by a combination of three different mechanisms: first, de-repression of the gene promoter; second, transcriptional activation of the gene by NF-κB and JNK pathways; and third, stabilization of the mRNA by the p38 MAP kinase pathway. In addition, activation of ERK pathway contributes to IL-8 expression[34]. Similar to PSCs[35], ethanol and acetaldehyde at clinically relevant concentrations activated ERK, JNK and p38 MAP kinase (data not shown), but failed to induce CINC-1 expression in SIPS cells. Thus, activation of MAP kinases is required, but not sufficient for optimal CINC-1 expression in SIPS cells. We have previously shown that ethanol and acetaldehyde induced type I collagen gene expression through p38 MAP kinase in primary PSCs[35]. Further studies are necessary to clarify whether ethanol and acetaldehyde induce the collagen gene expression in a similar manner.

In summary, SIPS cells are a newly established PSC line morphologically, phenotypically and functionally similar to primary, activated PSCs. Unlike SAM-K cells, immortalization was not associated with elevated p53 expression or telomerase activity. SIPS cells can be used for both transient and stable transections (Masamune *et al*. unpublished observation), facilitating the overexpression of ectopic genes. Its phenotypic characteristics as well as its responsiveness to proinflammatory cytokines and growth factors make it a useful tool for investigation of the pathogenesis of pancreatic inflammation and fibrosis and thereby for future therapeutic development.

Abstract

AIM: Pancreatic cancer in the head is frequently accompanied by jaundice and high bile acid level in serum. This study focused on the direct effects of bile acids on proliferation and ultrastructural alteration of pancreatic cancer.

METHODS: Pancreatic cancer cell lines PANC-1, MIA PaCa-2 and PGHAM-1 were explored in this study. The cell lines were cultured in media supplemented with certain bile acids, CA, DCA, LCA, TCDC, TDCA and GCA. Their influence on cell growth was measured with MTT assay after 72 h of incubation. Cell cycles of PANC-1 cells in 40 μM of bile acids media were analyzed by flow cytometry. Ultrastructural alteration of PANC-1 cells induced by DCA was observed using scanning and transmission electron microscope (SEM and TEM).

RESULTS: At various concentrations of bile acids and incubation time, no enhanced effects of bile acids on cell proliferation were observed. Significant inhibitory effects were obtained in almost all media with bile acids. DCA and CA increased the percentage of G_0+G_1 phase cells, while GCA and TDCA elevated the S phase cell number. After 48 h of incubation in DCA medium, PANC-1 cells showed some structural damages such as loss of their microvilli and vacuolization of organelles in cytoplasm.

CONCLUSION: Bile acids can reduce proliferation of pancreatic cancer cells due to their direct cytotoxicity. This result implies that elevation of bile acids in jaundiced serum may inhibit pancreatic cancer progression.

INTRODUCTION

Pancreatic cancer is the fourth leading malignancy in terms of incidence in Western countries. Chemotherapy and radiotherapy could only produce minimal benefit. Extensive surgery is not boundless, either[1]. Pancreatic cancer has been investigated in many institutes[2-5], a great improvement of prognosis will only depend on clarifying molecular-biology of this grim tumor[6]. Obstructive jaundice is the most common symptom of pancreatic cancer, especially in developing countries and regions. Pancreatic cancer patients are always complicated with profound jaundice. About 70 % of pancreatic cancer patients already have obstructive jaundice at the time of diagnosis. Obstructive jaundice is a very life threatening pathophysiological disorder because elevation of bile acids in serum may attack many vital organs. Only two days after bile duct ligation, bile acids in serum have been reported to increase 30 fold compared to that of sham operated animals[7]. Bile acids are amphiphilic compounds that behave as detergents in aqueous solution. The hydrophobicity-hydrophibicity determine the cytotoxicity of bile acids by destroying bio-membrane specifically. No specific cytotoxicities of bile acids have been proved in hepatocytes, erythrocytes[8] and intestinal mucous epithelium[9] culture systems. However, proliferation of colonic epithelium stimulated by bile acids has been reported to occur with or without obvious cell surface damage[10,11]. TUDC has been reported recently to enhance intrahepatic bile duct carcinogenesis in the hamster model. Although obstructive jaundice is very closely related to pancreatic cancer and both the pathophysiology of obstructive jaundice and biology of pancreatic cancer have already been investigated respectively, we know little of interaction between bile acids and biology of pancreatic cancer. In treatment of pancreatic cancer, the main purpose of surgery is to eliminate jaundice, and sometimes it is also a way to access extensive resection. If the biological effect of bile acids in serum on pancreatic cancer is clarified, it will be very helpful for treating pancreatic cancer with jaundice. In this study, three typical pancreatic cancer cell lines and six kinds of common bile acids were used to explore the direct effects of bile acids on proliferation and morphological changes of pancreatic cancer cells.

MATERIALS AND METHODS

Cell culture and treatment

Human pancreatic cancer cell lines PANC-1, MIA PaCa-2 (purchased from American Type Culture Collection) and hamster pancreatic cancer cell line PGHAM-1(induced by BOP in the laboratory of First Department of Surgery, Nippon Medical School[12]) were used in this study. PANC-1, MIA PaCa-2 were primarily cultured in a 75 cm^2 flask with the cell concentration of about 2.0×10^3/ml in RPMI 1640 (GIBCO BRL, New York) medium. PGHAM-1 was incubated in Dulbeccon' s modified eagle medium (MEM: GIBCO BRL, New York) in the same way. Both media were supplemented with 10 % fetal bovine serum (FBS), 100 u/ml penicillin-streptomycin and 100 g/ml kanamycin and 100 g/ml amphotericin B (GIBCO, New York). Four days later, PANC-1, MIA PaCa-2 and PGHAM-1 cells were harvested and re-suspended in media supplemented with or without certain concentrations of bile acids including cholic acid (CA), deoxycholic acid (DCA), lithocholic acid (LCA), taurochenodeoxycholic acid (TCDC), taurodeoxycholic acid (TDCA) and glycocholic acid (GCA) (Sigma Chemical Co. USA). PANC-1, MIA PaCa-2 and PGHAM-1 cells in each group were treated and continuously cultured according to the protocols that the concentration of bile acid in each medium ranged from 10 μmol/L to 60 μmol/L. Cell density in the

suspension was adjusted to 6.0×10^3/ml. In the 96-well plates, 100 μl of cell suspension was added to each well, 6 wells for each group. The cells were incubated for 72 h and the viability of cells was measured by MTT assay. In another 96-well plate, PANC-1 cell suspension at very low concentration of bile acids (from 2 μmol/L to 8 μmol/L) was incubated for 144 h and tested by MTT assay. The medium was changed every 2 days at the same concentration of bile acids. PANC-1 cell suspension was incubated in normal or 40 μmol/L of bile acids (DCA, CA, GCA and TDCA) media in 25 cm^2 flasks for 72 h for cell cycle analysis. For scanning and transmission electron microscopic (SEM and TEM) investigations, 4 ml of PANC-1 cell suspension was incubated in normal or 20 μmol/L or 40 μmol/L DCA modified media in 25 cm^2 flasks for 48 h.

MTT assay

After 48 h or 96 h incubation, the viability of cells in each group was measured by 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) (Chemicon International Inc. Temecula, CA, USA) assay[13]. Each group had six samples. With this method, 10 μl of (5 mg/ml) MTT was added to each cell suspension and the cells were incubated for 4 h. The purple formazan product formed by the action of mitochondrial enzymes in living cells was solubilized by the addition of acidic isopropanol. The absorbency of each cell suspension was measured using a microplate reader (Model 3550, Bio-Rad, CA, USA) at a test wavelength of 560 nm and a reference wavelength of 655 nm. The inhibitory rates were calculated according to the following formula: inhibitory rate=(1-tested MTT viability/mean of control MTT viability)×100 %.

Flow cytometry

The cell cycles of PANC-1 cells incubated in 40 μM of bile acids added media for 24 h were measured by the following method. Cells were washed, permeabilised and exposed for 30 min at 4 ℃ to 800 μl of DNA-staining solution in 0.1 % Nonidet P-40 (Sigma-milan, Italy) and 25 ug/ml propidium iodide (Sigma-Aldrich). The cellular DNA content was analysed by fluorescent activated cell sorter (FACS) can (Bencton Dickinson Immunocytometry Systems, San Jose, CA, USA) using cell Quest software system for histograms of cell frequency *versus* propidium iodide fluorescence intensity.

SEM and TEM

PANC-1 cells in 25 cm^2 flasks were harvested by trypsinization after 24 h and 48 h of incubation. The cells were fixed with 2.5 % glutaraldehyde and 1 % osmium tetroxide (TAAB Laboratories Equipment Ltd. Berkshire, UK). The dehydration was carried out with an ethanol series. SEM specimens were dried using a critical point dryer (Hitachi Hcp-2), and the sputter was coated with Pt+Cd using an ion sputtering device (Hitachi Oie-102). The cell surface alteration was observed under a SEM device (Hitachi S-570). The dehydrated TEM samples were mixed with proplylene oxide and Epok 812, which were embedded and proymerilizated. The semithin sections were stained with touluidine blue. Ultrathin sections were made using the ultra-microtome (Porter-Blum MTZ-B) and then were stained with uranyl acetate and lead critrate. The inner ultrastructure of the cells was investigated using the TEM Device (Hitachi H-500).

Statistical analyses

The digital data in this study were represented by $\bar{x}\pm s$ and assessed by the analysis of variance (ANOVA). Student' s *t*-test (SPSS/PC7.5) was also used for cross comparison between different groups and different incubation times. Probabilities of less than 0.05 were considered as significant.

RESULTS

Inhibitory effects of bile acids on cultured pancreatic cancer cell lines

PANC-1 cell growth in 50 μmol/L-1 000 μmol/L of bile acids added RPMI-1640 medium was significantly inhibited in only 24 h compared with control (data not shown). When PANC-1 cells were cultured in 0.05 mmol/L to 1.0 mmol/L bile acid modified medium for 48 h, including unconjugated bile acids CA, DCA over the concentration of 0.5 mmol/L, LCA over 1.0 mmol/L and conjugated bile acids GCA over 1.0 mmol/L greater than 50 % growth inhibition was obtained (Figure 1). While PANC-1 treated with very low bile acid concentration of 2 μmol/L to 8 μmol/L for 96 h also produced certain inhibitory effect, but only exceeding 6 μmol/L did DCA show significant effect (Figure 2). All of three cell lines: PANC-1, MIA PaCa-2 and PGHAM-1 were incubated in 10 μmol/L-60 μmol/L bile acid supplemented media for 72 h, cell proliferation was inhibited to a certain degree. But the unconjugated bile acids CA, DCA and LCA showed powerful inhibitive capacity (Figures 3, 4, 5).

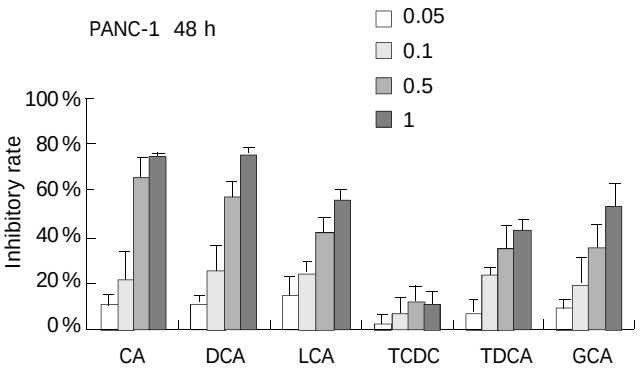

Figure 1 Bile acids (mmol/L) on PANC-1 for 48 h.

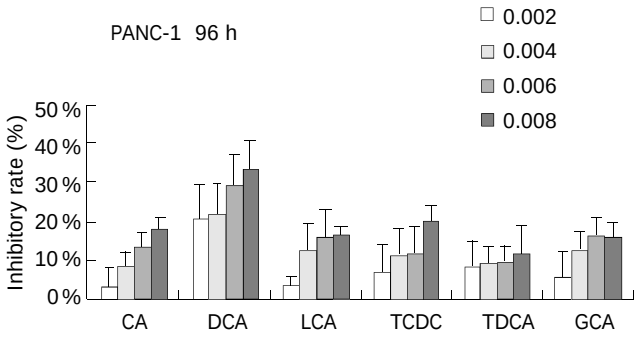

Figure 2 Bile acids (mmol/L) on PANC-1 for 96 h.

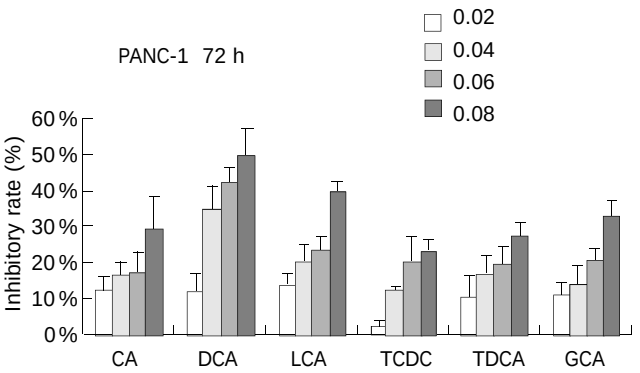

Figure 3 Bile acids (mmol/L) on PANC-1 for 72 h.

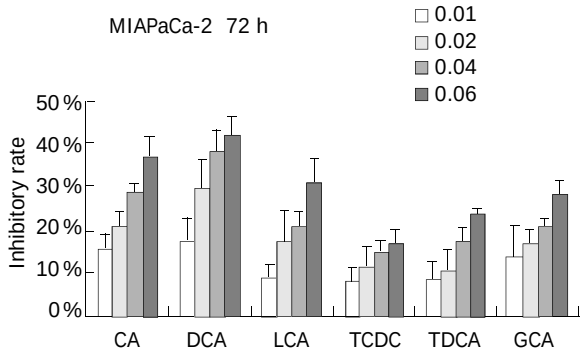

Figure 4 Bile acids (mmol/L) on MIA PaCa-2-1 for 72 h.

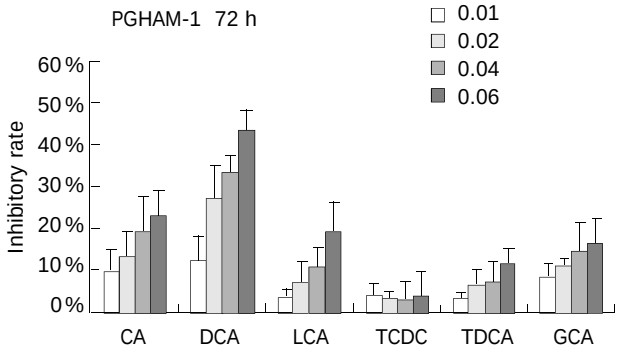

Figure 5 Bile acids (mmol/L) on PGHAM-1 for 72 h.

The inhibitive effects of all six bile acids were ranked in the following order: DCA>CA>LCA> GCA>TDCA>TCDC. Bile acid inhibition on the growth of three pancreatic cancer cells all showed a dosage dependent pattern. Among these bile acids, DCA produced the most powerful and obvious dosage-dependent inhibitory effect. Meanwhile PANC-1 cells were incubated in DCA (10-60 μmol/L) added medium supplemented with dexamethasone (50 μg per well), DCA' s inhibitive effects could not be reversed by supplement of membrane stabilizer dexamethasone (data not shown).

Ultrastructural alteration of PANC-1 cells incubated in DCA added medium

The untreated PANC-1 cells, as viewed by SEM, were characteristic of spherical in shape with plentiful microvilli which could be described as floss, spherical and leaf like microvilli (Figure 6A×7 500). When PANC-1 cells were cultured in 20 μmol/L DCA modified medium for 48 h, the majority of microvilli turned into spherical villi and the density of microvilli decreased obviously (Figure 6B×13 000). When PANC-1 cells were kept in 40 μmol/L DCA treated medium for 48 h, some cell surfaces were dotted with huge leaf-like microvilli or big microhills. Most cells lost their microvilli, becoming a bear ball with only some microvilli remnants, micro-trench and prominences (Figure 6C×20 000).

Observation of intracellular ultrastructure with TEM showed the cells in control group had normal distribution of organelles, with the integrity of mitochondria and other organelles preserved. The nuclei were surrounded by double

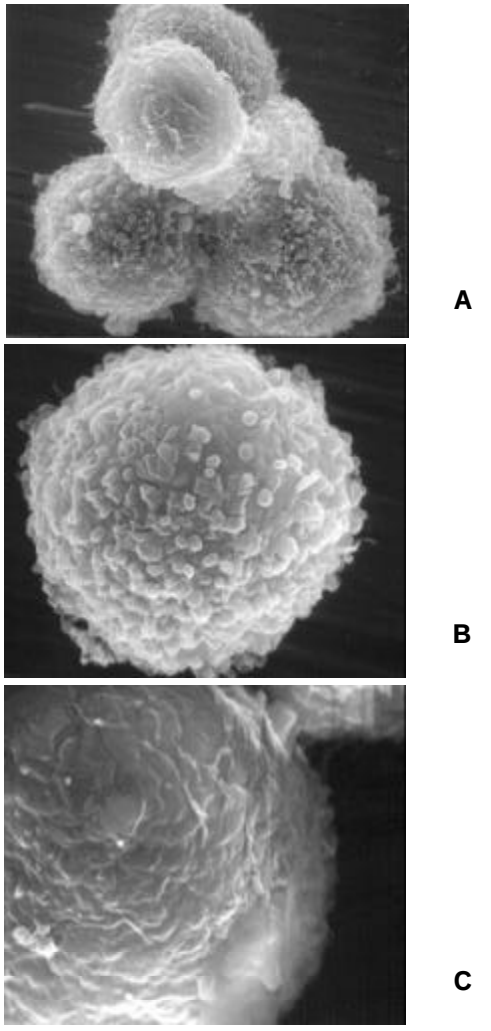

Figure 6 Ultrastructural alteration of PANC-1 viewed by SEM.

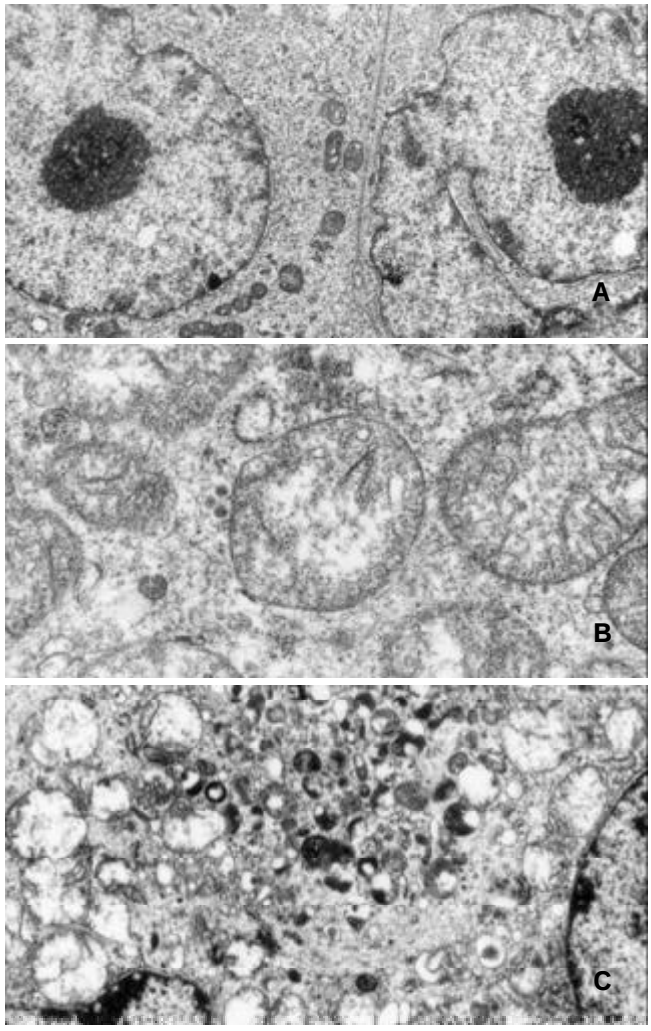

Figure 7 Ultrastructural alteration of PANC-1 viewed by TEM.

membrane envelope (Figure 7A×9 600). The cells growing in 20 μmol/L DCA modified medium for 48 h exhibited greatly extended mitochondria and dilated rough endoplasmic reticulum. All the organelles located in cells disorderly and the obviously dilated mitochondria contained twisted and broken cristae. Injured organelles were frequently seen in plasm (Figure 7B×30 000). When DCA concentration was increased to 40 μmol/L and incubated with cells for 48 h, exceedingly dilated mitochondria and vesicles formed by endoplasmic reticulum could be observed, some mitochondria lysed in cytoplasm were also seen. The lysosomes were also damaged and broken, which caused other surrounding organelles lysed in cytoplasm. The major portion of cytoplasm was occupied by vacuoles. The nuclear membrane double layer structure turned into indistinct and disconnected envelope. Rough granular masses against the inner surface of nuclear membrane could easily be observed (Figure 7C×12 000).

Cell cycles of PANC-1

The cell cycles of PANC-1 cells incubated in 40 μM of bile acids added media for 24 h were shown as follows. DCA and CA increased the percentage of G_0+G_1 phases cells, while GCA and TDCA elevated the S phase cell number compared with the control ($P<0.05$) (Figure 8).

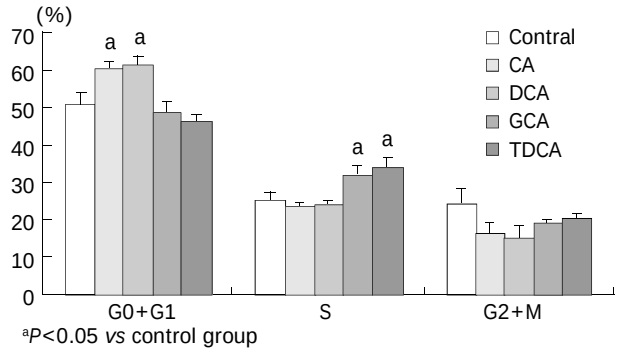

Figure 8 Cell cycles of PANC-1 cells incubated in 40 μM of bile acids added media for 24 h.

DISCUSSION

Pancreatic cancer frequently causes obstructive jaundice and elevates bile acid level in serum. For example, in non-pruritic jaundiced serum GCA concentration was 33.44±16.90 μmol/L[14]. Bile acids are steroid metabolites of cholesterol functioning as trophic factors for gut epithelium and as detergents for absorption of cholesterol and fat-soluble vitamins. The cytotoxicity of bile acids on various normal human cells[15,16] and a few malignant cells[17,18] has been demonstrated. It has been previously confirmed that bile acids could stimulate the growth of colonic epithelial cells but not that of colonic cancer cell lines[19]. While Debruyne *et al*. found recently that bile acids such as CA, chenodeoxycholic acid (CDCA), DCA, LCA could stimulate the invasion of HCT-8/E11 and PCmsrc human colorectal cancer cells into collagen type I gels[20]. Is there any interaction of elevated bile acids on human pancreatic cancer progression? However, how bile acids influence pancreatic cancer remains a subject of controversy. In order to investigate the direct effects of bile acids on pancreatic cancer, three typical pancreatic cancer cell lines(PANC-1, MIA PaCa-2 and PGHAM-1) and six common bile acids were selected and used in this study. Cultured pancreatic cancer cells have provided a model of pancreatic cancer free of other probable influencing factors such as immunoreaction and serum albumin in combination with bile acids in the body. MTT colorimetric assay is a very useful method for evaluating cell survival and proliferation. The reliability and sensitivity of MTT assay have been demonstrated to be comparable to that of tritiated thymidine incorporation in cell proliferation and cytotoxicity assays[21]. To a certain extent, the results of MTT reflect the final effects of cell proliferation or cytotoxicity instead of only earlier events detected by tritiated thymidine incorporation.

In this study, PANC-1 cells were incubated in 50 μmol/L to 1.0 mmol/L bile acid supplemented medium for 48 h, cell growth was inhibited to some extent at low concentration of bile acids and was also significantly inhibited by the higher concentration of bile acids. When bile acids concentration was reduced to only 2-8 μmol/L and the incubation time was prolonged to 96 h, cell proliferation was also observed. In 6-8 μmol/L of DCA supplemented medium significant inhibition could be obtained. Cell proliferation of PANC-1, MIA PaCa-2 and PGHAM-1 was significantly inhibited by bile acids supplemented media at certain concentrations for 72 h. The inhibitive effects of all six bile acids were ranked in the following order: DCA>CA>LCA> GCA>TDCA> TCDC. The inhibition exhibited a dosage-dependent manner, especially for DCA. Among these three cell lines, MIA PaCa-2 seemed to show the most sensitive response to all of the bile acids. The concentrations of bile acids resembled the elevation of some bile acids in jaundiced serum. Our investigation indicated that free bile acids in jaundiced serum might inhibit pancreatic cell growth and proliferation. Furthermore, we found that when PANC-1 cells were incubated in 40 μM of DCA or CA added media for 24 h, the percentage of G0+G1 phase cells was significantly increased compared with the control group ($P<0.05$). This implied that DCA and CA could induce cell cycle arrest, resulting in reduced proliferation and apoptosis of PANC-1 cells. Concerning its mechanism, Martinez *et al*. believed that cytotoxicity of DCA might be produced through induction of apoptosis via a protein kinase C-dependent signaling pathway[22].

According to our ultrastructural findings, the membrane and organelles were definitely damaged by supplement of bile acid DCA in medium, the inhibitory effects of bile acids on these pancreatic cancer cell lines might mainly depend on their cytotoxicity. Usually, cytotoxicity of bile acid is resulted from its hydrophobic features and hydrophobic-hydrophilic balance in serum. Lipophilic unconjugated bile acids have been shown to flip-flap rapidly across artificial lipid bilayers, so that unconjugated bile acids might enter the cytosol of every kind of cells even at a low concentration[23]. It has also been demonstrated that DCA or CDCA administration in rat colon could enhance cell membrane phospholipid turnover[24]. Hydrophobic bile acids, such as DCA, could damage cells by lysing membranes[25] and impairing mitochondrial function as well as increasing the generation of reactive oxygen radicals which can cause membrane lipid peroxidation and attack nucleic acids[26]. Velardi *et al* have demonstrated that the cytotoxicity of bile acids is partially dependent on the cell membrane composition. Because cell membrane components such as glycolipids, receptors, and transport proteins vary in different cell lines depending on cell origin and differentiation, cell lines may also differ in regard to their response to bile acids. The over susceptibility of MIA PaCa-2 to bile acids might be due to their unique membrane lipid components. Under SEM, we also found that DCA could reduce microvilli density of PANC-1 cells. The microvilli on the surface of malignant cells could contribute to movement, attachment and invasion of malignant cells[27]. Reduction of microvilli might potentially inhibit PANC-1 cell invasion.

Biliary drainage has been shown to be an appropriate, definitive therapy for biliary obstruction due to unresectable pancreatic and peripancreatic malignancies. Some surgeons preferred to choose billiary drainage as a preoperative treatment

to reduce the level of jaundice. They expected patients to get a better operation tolerance before the radical cure. However, patients with jaundice had a higher risk of bleeding complications while those with preoperative biliary drainage (PBD) had more infective complications[28]. Some researchers demonstrated that preoperative biliary drainage increased the risk of developing intraoperative infectious morbidity and postoperative infectious morbidity and mortality following pancreaticoduodenectomy. Preoperative biliary drainage should be avoided whenever possible in patients with potentially resectable lesions. Consequently, the effect of bile acids on pancreatic cancer should be evaluated. It is concluded that bile acids could inhibit proliferation of PANC-1, MIA PaCa-2 and PGHAM-1 cell lines *in vitro*[29]. This may imply that bile acid can inhibit the growth of pancreatic cancer. Although the observation that bile acids inhibited proliferation of cultured cell lines could not completely reflect the complex pathophysiology of pancreatic cancer patients accompanied with obstructive jaundice, this study, at least, provides a clue that bile acids in jaundiced serum may have potentially inhibitory effects on pancreatic cancer progression. However, our investigation is an *in vitro* one, further studies are needed.

ACKNOWLEDGEMENT

We would like to express our thanks to Mr. Masahiko Onda and Mr. Eiji Uchida, from the First Department of Surgery, Nippon Medical School, Tokyo, Japan, for their valuable help in the work.

Abstract

AIM: DPC4 is a tumor suppressor gene on chromosome 18q21.1 that has high mutant frequencies in pancreatic carcinogenesis. The purpose of this study was to investigate the role of DPC4 alterations in tumorigenesis and progression of pancreatic carcinomas.

METHODS: We studied the immunohistochemical markers of DPC4 in 34 adenocarcinomas and 16 nonmalignant specimens from the pancreas. The 16 nonmalignant specimens from the pancreas included 8 non-neoplastic cysts and 8 normal pancreatic tissues. The relationship between DPC4 alterations and various clinicopathological parameters was evaluated by chi-square test or Fisher's exact test. Survivals were calculated using Kaplan-Meier method (by a log-rank test).

RESULTS: All the 16 nonmalignant cases of the pancreas showed expression of DPC4 gene. Loss of DPC4 expression was seen in 8 of 34(23.5 %) pancreatic adenocarcinomas. The frequency of loss of DPC4 expression was higher in poorly differentiated adenocarcinoma (G3) than in well and moderately differentiated adenocarcinoma (G1 and G2) histologically (P=0.037). Loss of DPC4 expression of the patients at TNM stage IV was also higher than that of the patients at TNM stages I, II and III (60.0 % at stage IV, *versus* 14.3 % at stage I, 18.2 % at stage II, and 18.2 % at stage III) (P=0.223). The mean and median survival in patients with DPC4 expression was longer than those in patients with loss of DPC4 expression. Kaplan-Meier survival analysis demonstrated patients with DPC4 expression had a higher survival rate than patients with loss of DPC4 expression, but the difference did not reach statistical significance (P =0.879).

CONCLUSION: This study suggests that DPC4 is involved in the development of pancreatic carcinoma and is a late event in pancreatic carcinogenesis, DPC4 expression may be a molecular prognostic marker for pancreatic carcinoma.

INTRODUCTION

The incidence of pancreatic carcinoma has increased in recent decades in the world, and this cancer has the lowest five-year survival rate among all cancers. The dismal survival of patients with pancreatic carcinomas is caused by the late diagnosis and low resection rates[1,2]. However, understanding the molecular pathogenesis of pancreatic carcinomas may be the foundation upon which to develop novel strategies for identifying genetic markers useful for the early diagnosis and treatment. An association has been demonstrated between pancreatic carcinomas and various genetic alterations including genes K-ras[3,4], Her-2/neu[5], p16[6], and p53[7]. Recently, DPC4 (deleted in pancreatic carcinoma, locus 4; Smad4) located on chromosome 18q21.1, has received special attention as its alterations may play a role in activation of pancreatic carcinogenesis[8].

DPC4 gene is a tumor suppressor gene, which has been shown to mediate the downstream effects of TGF-β superfamily signaling, resulting in growth inhibition[9]. Inactivation of DPC4 tumor-suppressor gene is relatively specific for pancreatic carcinoma, although it has been shown to occur in a small percentage of primary carcinomas of the esophagus[10,11], stomach[11,12], head and neck[13], breast, ovary[14], colon[15], and biliary tract[16]. DPC4 can be inactivated by one of the two identified mechanisms: intragenic mutation of one allele coupled with loss of the other allele, or deletion of both alleles (homozygous deletions). Both mutations and homozygous deletions of DPC4 gene have been observed in a high proportion of pancreatic carcinomas[8]. In contrast, the role of DPC4 in human pancreatic carcinoma remains less well defined. Recently, immunohistochemical labeling for the DPC4 gene product has become an extremely sensitive and specific marker for DPC4 gene alterations in pancreatic carcinomas, and has been shown to mirror the DPC4 genetic status of pancreatic carcinomas, because most mutations of DPC4 could result in a loss of the protein. Therefore, immunolabeling for DPC4 could provide a useful tool to examine genetic status in pancreatic adenocarcinomas[17,18].

In the present study, we examined DPC4 expression in 34 adenocarcinomas and 16 nonmalignant specimens from the pancreas using a monoclonal antibody to human DPC4 protein by means of immunohistochemistry and studied the relation between expression of DPC4 and various clinicopathological parameters in order to elucidate whether altered DPC4 expression played a role in the tumorigenesis and progression of pancreatic carcinomas.

MATERIALS AND METHODS

Patients and samples

Thirty-four specimens of pancreatic adenocarcinomas were retrieved from the pathology archives of China-Japan Friendship Hospital between 1984 and 2000. There were 22 males and 12 females with pancreatic carcinomas, and the average age of the patients was 55.18±11.29 years (mean±SD), with a range of 30-75 years. Twenty-eight patients were followed up until death or until the time of this study.

Histopathological grade and clinical staging were evaluated according to the criteria by Klöppel for pancreatic tumors[19] and the International Union Against Cancer (UICC) TNM classification[20]. Histopathologic examination revealed well differentiated adenocarcinoma in 10 patients, moderately differentiated adenocarcinoma in 15 patients, and poorly differentiated adenocarcinoma in 9 patients. Seven patients were at UICC stages I, 11 at stages II, 11 at stage III, and 5 at stage IV. In addition, 16 nonmalignant specimens from the pancreas including 8 non-neoplastic cysts and 8 normal pancreatic tissues were used as controls.

Immunohistochemistry

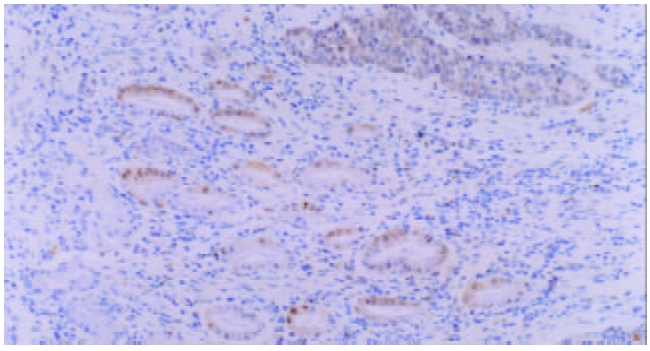
Tissues were routinely fixed in neutral formalin, embedded in paraffin, and 5 μm thick consecutive sections were cut. After deparaffinized, the slides were placed in a solution of 3 % hydrogen peroxide (1:1) for 10 minutes to block the activity of endogenous peroxidase, and then heated in a microwave for 5 minutes at 100 ℃. After the slides were cooled for 30 minutes, nonspecific binding was blocked with a protein solution for 10 minutes, and then each slide was labeled with a 1:100 dilution of monoclonal antibody to DPC4 (clone B8, Santa Cruz, CA). Anti-DPC4 antibody was detected by adding biotinylated secondary antibodies, avidin-biotin complex, and 3,3' -diaminobenzidine. The sections were counterstained with hematoxylin. Positive cells were stained dark brown in the nuclei and/or cytoplasms, and the staining was graded into four categories: 0, no staining, 1+, weak staining, 2+, moderate staining, 3+, heavy staining. Positive staining was considered as expression of DPC4. Normal pancreatic ducts, islets of Langerhans, acini, lymphocytes, and stromal fibroblasts showing moderate to strong expression of DPC4 gene, served as positive internal controls for each section. For negative controls, the primary antibody was replaced with phosphate buffered solution (PBS).

Statistical analysis

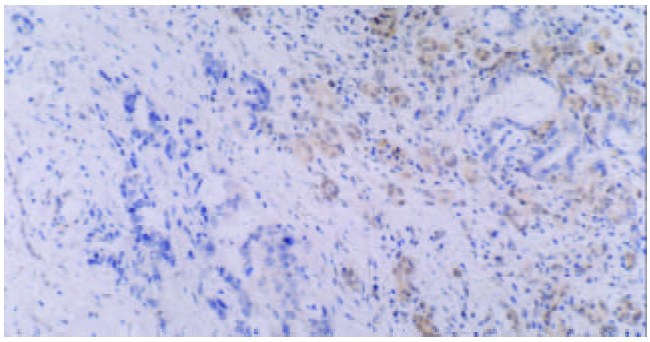
The data were analyzed with chi-square test or Fisher' s exact test to compare the differences between the two subgroups of patients based on the results of DPC4 staining. All of the tests were two-tailed. Survivals were calculated using Kaplan-Meier method (by a log-rank test).

RESULTS

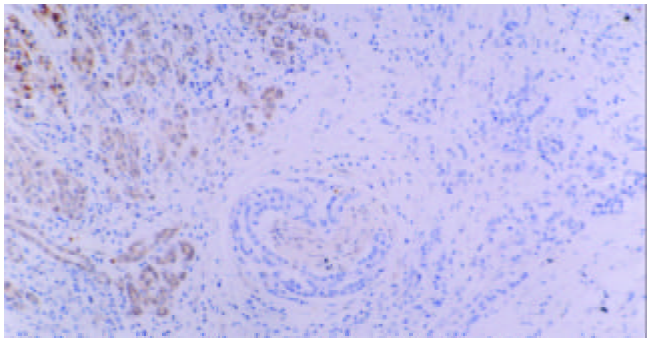
The results of DPC4 protein immunohistochemistry are summarized in Table 1, and typical examples of the positive and negative groups are shown in Figure 1 (A-E). It was observed that pancreatic carcinoma showed loss of DPC4 expression, whereas the adjacent normal pancreatic tissue had DPC4 expression (Figures 1B and C).



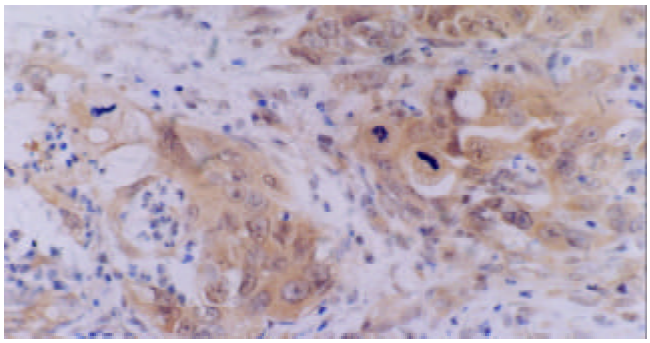
A: Well-differentiated pancreatic carcinoma showed DPC4 expression. hematoxylin counterstain. original magnification, ×100.



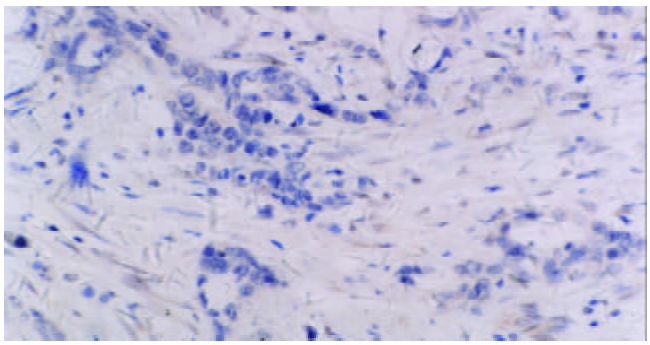
B: Well-differentiated pancreatic carcinoma showed loss of DPC4 expression (left), whereas the adjacent normal pancreatic tissue had DPC4 expression (right). hematoxylin counterstain. original magnification, ×200.



C: Moderately-differentiated pancreatic carcinoma showed loss of DPC4 expression (right), whereas the adjacent normal pancreatic tissue had DPC4 expression (left). Vortex in the middle shows invasion of pancreatic nerve. hematoxylin counterstain. original magnification, ×160.



D: Poorly-differentiated pancreatic carcinoma showed DPC4 expression. Hematoxylin counterstain. original magnification, ×400.



E: Poorly-differentiated pancreatic carcinoma showed loss of DPC4 expression. hematoxylin counterstain. original magnification, ×400.

Figure 1 Representative immunostaining results of DPC4 in pancreatic carcinoma (A-E). Positive cells were stained dark brown in the nuclei and/or cytoplasms (A-D).

All the 16 nonmalignant cases of the pancreas showed expression of DPC4 gene products. Loss of DPC4 expression was seen in 8 of 34 (23.5 %) pancreatic adenocarcinomas. The results of immunostaining of DPC4 expression in 34 pancreatic carcinomas and the correlation with various clinicopathological parameters are shown in Table 2. A significant difference was found in the frequency of loss of DPC4 expression between well and moderately differentiated adenocarcinomas (G1 and G2) and poorly differentiated adenocarcinoma (G3) histologically (P =0.037). Although loss of DPC4 expression in the patients at TNM staging IV was higher than that in those at stages I, II and III (60.0 % at stage IV, versus 14.3 % at stage I, 18.2 % at stage II, and 18.2 % at stage III), the difference did not reach any statistical significance (P=0.223). In addition, a higher frequency of loss of DPC4 expression in patients with lymph node-metastasis was also revealed, however the difference was not significant (P=0.228). The mean and median survival in patients with DPC4 expression was longer than that in patients with loss of DPC4 expression (Table 3). Kaplan-Meier survival analysis demonstrated patients with DPC4 expression had a higher survival rate than those with loss of DPC4 expression, but the difference did not reach any statistical significance (P=0.879) (Figure 2).

Table 1 Loss of DPC4 expression in pancreatic tissues (%)

Tissues	*n*	Loss expression of DPC4 (%)
Normal pancreas	8	0 (0)
Non-neoplastic cysts	8	0 (0)
Pancreatic carcinoma	34	8 (23.5)

IV	5	3 (60.00)	

G1, well differentiated; G2, moderately differentiated; G3, poorly differentiated.

Table 3 Mean and median survivals in pancreatic carcinomas

	Mean survival (days)	Median survival (days)
DPC4 expression	329.94±41.54	319.00±30.32
Loss of DPC4 expression	300.00±61.88	206.00±88.39

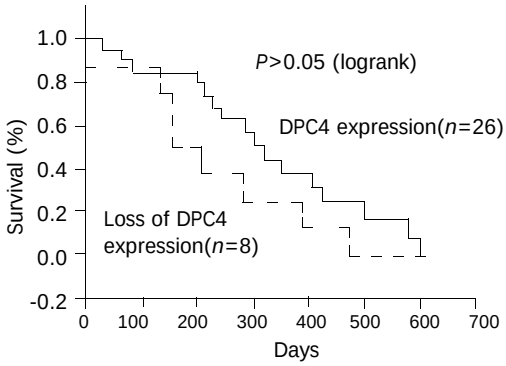

Figure 2 Kaplan-Meier survival curves comparing patients with DPC4 expression and patients with loss of DPC4 expression. Although patients with DPC4 expression had a higher survival rate than those with loss of DPC4 expression, the difference did not reach ang statistical significance.

DISCUSSION

This study aimed to clarify the role of DPC4 in the development of pancreatic carcinoma. The product of DPC4 gene belongs to the evolutionally conserved family of Smad proteins which are linked to TGF-β superfamily of cytokines. Smad proteins are involved in the regulation of cell differentiation as well as the inhibition of cell proliferation, and their alterations could confer resistance to TGF-β and thereby contribute to tumorigenesis[21,22]. DPC4 gene produces a 64-KD protein that influences gene transcription and growth arrest. In fact, DPC4 protein has three distinguishable domains, and mutations in each of these domains could lead to the loss of DPC4 function[8,23,24].

There were different findings about the frequency of DPC4 alterations in pancreatic carcinomas in previous reports (9 %-55 %)[8,25]. The discrepancies between studies might be due to differences in the study populations, techniques, or the statistical method. In our study, eight of the 34-pancreatic carcinoma specimens were immunohistochemically labeled for the loss of DPC4 protein (23.5 %). However, DPC4 immunohistochemical staining was found in all of the 16 nonmalignant specimens from the pancreas. This finding suggested that DPC4 might be involved in the tumorigenesis and development of pancreatic carcinoma.

Our study showed loss of DPC4 expression was correlated with the histological grade in patients with pancreatic carcinoma. Loss of DPC4 expression in those with poorly differentiated adenocarcinomas was significantly higher than that in those with well and moderately differentiated adenocarcinomas, which implied that DPC4 gene might preserve phenotypic characteristics under normal conditions and control the malignant progression of pancreatic carcinomas.

There was a trend toward a higher frequency of loss of DPC4 expression in patients at TNM staging IV in this study. When stratified by stage, the highest percentage of loss of DPC4 reactivity was found in carcinomas at stage IV (60.0 %), compared with 14.3 % at stage I, 18.2 % at stage II, and 18.2 % at stage III carcinomas. A higher frequency of loss of DPC4 expression in patients with lymph node-metastasis was also revealed. Survival analysis demonstrated patients with DPC4 expression had a higher survival rate than those with loss of DPC4 expression.

The data in our study were correlated fairly well with what has been reported. The results from Wilentz *et al* showed that DPC4 expression in duct lesions with a histologically low-grade (PanIN-1 and -2) was significantly higher than that in those with a histologically high-grade (PanIN-3)[26]. Another study showed that DPC4 expression in PanIN could be

predictive of DPC4 expression in the subsequent invasive ductal adenocarcinoma. Additionally, DPC4 expression could be used to differentiate recurrent or persistent adenocarcinomas from a second primary adenocarcinoma. A recent study found that survival of patients whose tumors expressed DPC4 protein was significantly longer (19.2 months) as compared with 14.7 months of those without DPC4 protein expression, and DPC4 expression was correlated with a better prognosis of pancreatic carcinomas[18]. Biankin *et al* also found DPC4/Smad4 expression had a potential as a prognostic indicator in patients with pancreatic carcinoma, and loss of DPC4 expression was associated with improved survival after resection, whereas resection did not improve the survival in patients whose tumor expressed DPC4.

These findings suggest that loss of DPC4 expression occurs biologically late in the neoplastic progression leading to the development of infiltrating pancreatic carcinoma, and indicates a poor prognosis for patients. It is reasonable to postulate that DPC4 plays a pivotal role in regulating all TGF-β superfamily signal pathways. Abrogation of DPC4 function might cause a breakdown in this signaling pathway and loss of transcription of genes critical to cell-cycle control. Cells might therefore become TGF-β resistant and escape from TGF-β-mediated growth control and apoptosis. Experimental evidences indicated that DPC4 could regulate an angiogenic switch by decreasing the expression of vascular endothelial growth factor (VEGF) and increasing the levels of angiogenesis inhibitor thrombospondin-1 (TSP-1).

In conclusion, our study shows that loss of DPC4 expression is involved in the carcinogenesis and development of pancreatic carcinoma and is a late event in pancreatic carcinogenesis. DPC4 expression may be a molecular prognostic marker for pancreatic carcinoma.

ACKNOWLEDGEMENTS

We thank Dr. Gonghua Zhao for her critical suggestions regarding this work and Mr. Jing Zhang for helping perform the immunohistochemical staining.

Abstract

AIM: To investigate the gastrin secreting cells (G cells) and the somatostatin secreting cells (D cells) of antral mucosa in rats at the ultrastructural level.

METHODS: Revised immunoelectron microscopic technique was used to detect the G cells and D cells in rat antral mucosa through gastrin and somatostatin antibodies labeled by colloidal gold. Also the relevant quantitative analysis regarding the granular number of colloidal gold in G cells and in D cells was conducted.

RESULTS: Immunological granules of colloidal gold were distributed in G cells and D cells. Gastrin labeled golden granules or somatostatin labeled ones presented mainly as lobation-like or island-like congeries. Most of the golden congeries were observed dissociated in cytoplasms of G cells or D cells, near the basement membrane. A few golden congeries were located in nuclei. The number of golden granules in one G cell was around 107.04±19.68 and was 83.36±17.58 in one D cell.

CONCLUSION: Gastrin secreting granules are located in cytoplasms and nuclei of G cells, and somatostatin secreting granules both in cytoplasms and in nuclei of D cells. The number of golden granules can be quantitatively analyzed to determine the relative amount of gastrin secreting granules or somatostatin secreting granules.

INTRODUCTION

Gastrointestinal hormones such as gastrin and somatostatin, regulate the secretion, motility, absorption, blood flow and cell nutrition of the digestive tract. Abnormality of their secretion often affects the normal functions of digestive tract, even cause clinical symptoms or syndromes. Pathological impairment of gastrointestinal tract could also result in changes of the level of gastrointestinal hormones. Gastrin is mainly secreted from gastrin secreting cells (G cells) in antrum mucosa or upper small intestine. Medulla oblongata and dorsal nuclei of vagus nerve in central nervous system also have gastrin. Somatostatin is distributed in the body, hypothalamus and at other sites of the brain, peripheral nerve and gastrointestinal tract. In digestive system, for example, somatostatin is secreted from somatostatin secreting cells (D cells). D cells are distributed mainly in intestinal nerve plexus, stomach and pancreas[1-4].

Although there are some methods to observe the shape of G cells and D cells, microscope or electron microscope could not decide G cells or D cells alone. Immunohistochemical method could not demonstrate G cells or D cells at ultrastructural levels. Thus investigations at the ultrastructural level by immunoelectron microscopy are effective[5-8]. This study was to demonstrate G cells and D cells at the ultrastructural level by colloidal gold labeled immunoelectron microscopy technique.

MATERIALS AND METHODS

Guinea pigs and antral tissue processing

Seven healthy male Wistar rats weighing 230-250 g from the Center of Experimental Animals in Sun Yat-sen University of Medical Sciences (Guangzhou, China) were used. All rats received no special treatment before sacrificed. The rats were fasted overnight with free access to water. Four days later, the rat' s abdomen, anesthetized with 3 % of sodium pentobarbital intraperitoneally at a dosage of 30 mg/kg, was cut open and its stomach was split from the greater curvature. The antral tissue of about 0.5 mm×0.5 mm was separated using ophthalmic scissors. Then the specimens were immersed into a mixture of 0.1 % glutaraldehyde and 3 % paraformaldehyde in 0.1M PBS, pH7.4, for 2 hr at room temperature for fixation.

Specimen preparation for immunoelectron microscopy

Two hours after fixation, the antral tissue specimens were washed four times for 15 min in 0.1M PBS, pH7.4, and then postfixed for 1 hr in solution of 1 % osmium tetroxide (1 % potassium dichromate, pH 7.2, 1 % osmium tetroxide, 0.85 % NaC1) at room temperature. The specimens were washed three times for 10 min in 0.1M PBS, pH7.4, and dehydrated at room temperature in 50 % acetone (15 min), 70 % acetone (15 min), 90 % acetone (15 min), and 100 % acetone (three times for 15 min each). The specimens were then infused in an open desiccator containing 50 % acetone: 50 % Spurr resin (1 hr), 33 % acetone: 67 % Spurr resin (2 hr), and 100 % Spurr resin overnight. When the resin was infused in the specimens, it was polymerized at 40 ℃ for 4 days. To orientate the samples, 1 μm thick sections were cut, put on an objective glass, and stained with 0.1 % teluidin blue. Appropriate regions were chosen, and the pyramids were further trimmed, cut on a Leica Rechert ultramicrotome into 60-80 nm ultrathin sections, put onto 300 nickle mesh grids. All ultrathin sections were divided into G cells group, D cells group, and control group.

Postembedded antibody incubation and immunoelectron microscopy

All the ultrathin sections were oxidized in H_2O_2 for 10 min,

washed three times for 5 min in water. Osmium tetroxide was removed in 1 % sodium periodate, washed three times for 5 min in 0.05 M TBS, pH7.4. The ultrathin sections were incubated for 30 min at room temperature in 1.5 % BSA (Sigma, USA) in PBS for blocking. The sections of G cells group were then incubated with rabbit anti-gastrin polyclonal antibody (Sigma, USA) at a concentration of 1:80 in PBS, the sections of D cells group were incubated with rabbit anti-somatostatin polyclonal antibody (ZYMED, USA) at a concentration of 1:80 in PBS, and the sections of control group were incubated with PBS only. All sections were incubated in a wet box at 4 ℃ overnight and then at 37 ℃ for 1 hr. The sections were washed three times for 10 min in 0.05M TBS, pH7.4, then one time for 10 min in 0.02 M TBS, pH7.4. The sections were again incubated for 30 min at room temperature in 1.5 % BSA in PBS for blocking and then incubated with a gold-conjugated secondary antibody, colloidal-gold/staphylococcic-protein-A 1:80 (10 nm, Boster Biological Technology Co, Wuhan, China) in PBS, for 1 hr at 37 ℃. The sections were washed three times for 5 min in water and stained with 5 % uranyl acetate (in water) at room temperature for 60 min, and with lead citrate for 60 min. At last the specimens were examined and photographed under an electron microscope (Philips CM10).

Image analysis of colloidal gold granules

A total of 50 cells in either G cells group or D cells group were randomly photographed from sections of their photos. They were input into the Quantimet-500 image analysis system (Leica Co. German) for calculation of the average number of colloidal gold granules. The data thus obtained were expressed in $x \pm s$.

RESULTS

Immunoelectron microscopy of G cells

No immunological granules of colloidal gold in most antral mucosa cells were found, except those in G cells. Immunological granules of colloidal gold were well distributed in G cells, with the cells' ultrastructure clearly fixed. While the membrane of G cells was intact, rough endoplasmic reticules were increased, and mitochondria decreased. The nuclei of G cells were normal, and the chromatin was equally distributed. The gastrin labeled golden granules in G cells were clear, either round-shaped or oval-shaped, with a high electro-density. The granules presented mainly as lobation-like or island-like congeries, which were dispersed in cytoplasms of G cells, directing toward the basement membrane. A few golden congeries in the nuclei of G cells were mainly located in euchromatin area. No golden congeries were observed in heterochromatin area. There were immunological granules of colloidal gold in the nuclei of G cells as island-like congeries and penetrating nuclear pore in cytoplasms (Figure 1). The number of golden granules in a G cell was 107.04±19.68.

Immunoelectron microscopy of D cells

No immunological granules of colloidal gold were found in most antral mucosa cells, except those in D cells. Immunological granules of colloidal gold were found well distributed in D cells, with the ultrastructure clearly fixed. The membrane of D cells was intact, rough endoplasmic reticules were increased, and mitochondria decreased. The nuclei of D cells were normal, with their chromatin well distributed. The somatostatin labeled golden granules in D cells were clear, either round-shaped or olive-shaped, with a high electro-density. The granules presented mainly as lobation-like or island-like congeries, a few of them were dispersed in D cells while most of them were dissociated in cytoplasms of D cells, directing toward the basement membrane. Again, a few golden congeries in the nuclei of D cells were mainly located in euchromatin area (Figure 2). No golden congeries were found in heterochromatin area. The number of golden granules in a D cell was 83.36±17.58. No colloidal gold-labeled cell was observed in control group.

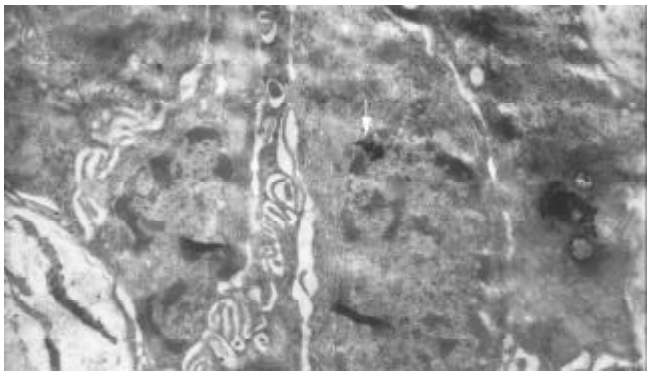

Figure 1 Immunological granules of colloidal gold located in nuclei of G cell as island-like congeries (↑), and penetrating nuclear pores into cytoplasms. ×21000.

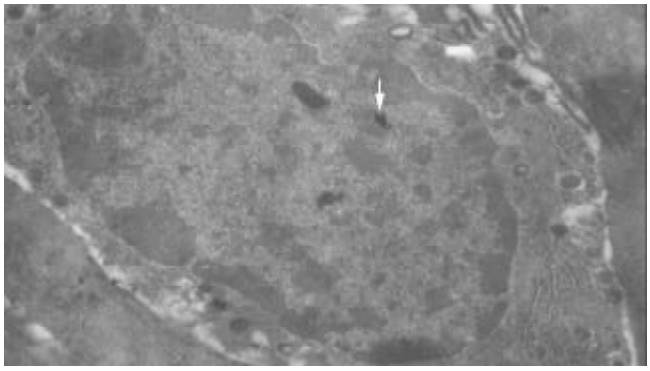

Figure 2 Immunological granules of colloidal gold locate in nuclei of D cell as island-like congeries (↑). ×8900.

DISCUSSION

Gastric mucosa consists of highly organic multi-functional glands. In a single gastric gland there are at least five kinds of cells. They are the parietal cell, chief cell, endocrine cell, superficial epithelial cell and mucous cell. The stem cells of all these kinds of cells are in the neck area near the surface of the gland. When migrating upward to the surface of gland, they changed into the surface mucous cells. When migrating downward deeper into the gland, the proliferative stem cells changed into cells in forms of parietal cells, chief cells, and endocrine cells[9-11].

The features of gastrin can be briefly summarized as follows. There are gastrin receptors both in parietal cells and in ECL cells. As the main regulating hormone of gastric acid secretion, gastrin stimulates parietal cells to secrete gastric acid directly via the gastrin receptors in parietal cells and also stimulates ECL cells to secrete histamine via the gastric receptors in the cells. Then histamine stimulates parietal cells to secrete gastric acid via H_2 receptors in parietal cells in a paracrine style. While accelerating the secretion of pepsin, secretin, pancreatic juice, and the secretion of water and salt in bile, gastrin also speeds up the releasing of insulin and calcitonin. It has both nutritional and accelerating effects on gastric mucosa. It also has a growth factor producing the similar effect. In the same way, the increase of gastrin would lead to the increasing number of both parietal cells and ECL cells.

Apart from all these, gastrin is also closely related with the occurrence of carcinoid tumor. Gastrin enhances the motion of gastrointestinal tract, thus increasing the contraction effect of the stomach, intestine and gall bladder. In addition, there are reports that G cells should be taken as the fourth histamine source in stomach besides chief cells, ECL cells, and intestinal nerve plexus. Increase of pH, intake of meal, increase of pressure in the stomach, and excitation introduced by vagus nerve or mucosa nerve plexus could make G cells secrete more gastrin. Decrease of pH stimulated by somatostatin or other gastrointestinal hormones, and excitation of sympathetic nerve could inhibit the secretion of gastrin[12-17].

What characterizes somatostatin is presented as follows. The main physiological effect produced by somatostatin on digestive system is inhibition. Somatostatin could inhibit peristalsis of stomach, intestine, gall bladder and proliferation of mucosal cells, reduce blood flow of gastrointestinal tract and small intestine to absorb water, electrolyte, glucose, amino acid, and triglycerides, depress the secretion of gastric acid, pepsin, hepatic bile, small intestinal juice, and secretion of gastrin and other gastrointestinal hormones. Excitation of sympathetic nerve could inhibit D cells to secrete somatostatin, but that of vagus nerve could stimulate D cells to do so. Gastrin has a unique regional regulatory effect on secretion of somatostatin in stomach. Gastrin could directly stimulate D cells to secrete somatostatin. In some species, gastrin receptors have been detected in D cells of stomach. As shown in some investigations, endogenous histamine inhibited the secretion of somatostatin via paracrine effect on H_3 receptor. Others showed that endothelins inhibited the secretion of somatostatin via endothelin receptors[18-23].

In histocyte, there are often different granules that are important symbols of classification. This includes neurosecretory granule of 80-600 nm with an electron-densed core, highly electron-densed zymogen granule of 1-2 μm, large and light mucus granules and endocrine secretory granules. Although some endocrine secretory granules in endocrine cells had definite characteristics and are somewhat significant to evaluate the type of such endocrine cells, it was difficult to differentiate the features of endocrine simply according to endocrine cells and their secretory granules[24-28].

Colloidal gold immunoelectron microscopic technique is the advanced method for microcosmic morphology. The colloidal gold probe is of high specification, high resolution, accurate localization and accurate quantity. The significance of colloidal gold immunoelectron microscopy is similar to common immunohistochemistry in testing specific antigens expressed in target cells. But it could not be more useful for immunoelectron microscopy to study the localization or the quantitative analysis of antigens at the ultrastructural level. There are many intervening factors in immunoelectron microscopy, the most important one is to protect the activity of antigen. In this aspect, improvement has been made in manipulating the integrating of samples, the fixative and embedding medium, the time of fixation, the temperature of aggregation, the purity and diluting ratio of antibody and colloidal gold, as well as the time of incubation[29-32].

On the whole, the result was satisfactory. The ultrastructure of G cells and D cells was well protected. The ultrastructures of secretory granules of both gastrin and somatostatin were definitely localized. The secretory granules of gastrin in cytoplasms of G cells were also found in the nuclei of G cells. The secretory granules of somatostatin in cytoplasms of D cells were also found in the nuclei of D cells. Therefore, the conclusion is thus made that there are secretory granules of gastrin or somatostatin in nuclei of G cells or D cells. After they are gradually matured, the secretory granules penetrate the nuclear pores into cytoplasms. At last, gastrin or somatostatin is secreted through the basement membrane into intercellular substances, playing their physiological roles. The lobe-like or island-like congeries of colloidal gold observed in G cells and D cells are in coincidence with the existing patterns of the secretory granules of gastrin or somatostatin. In our opinion, the size of secretory granules in congeries of colloidal gold could be subjected to quantitative analysis, though the quantitative scale of each piece of colloidal gold to bind gastrin or somatostatin has not been exactly decided. In this sense, the specific significance of colloidal gold number in congeries of G cells or D cells remains to be precisely interpreted.

Abstract

AIM: To investigate the effect of complex amino acid imbalance on the growth of tumor in tumor-bearing (TB) rats.

METHODS: Sprague-Dawlley (SD) rats underwent jejunostomy for nutritional support. A suspension of Walker-256 carcinosarcoma cells was subcutaneously inoculated. TB rats were randomly divided into groups A, B, C and D according to the formula of amino acids in enteral nutritional solutions, respectively. TB rats received jejunal feedings supplemented with balanced amino acids (group A), methionine-depleted amino acids (group B), valine-depleted amino acids (group C) and methionine- and valine-depleted complex amino acid imbalance (group D) for 10 days. Tumor volume, inhibitory rates of tumor, cell cycle and life span of TB rats were investigated.

RESULTS: The G_0/G_1 ratio of tumor cells in group D (80.5±9.0) % was higher than that in groups A, B and C which was 67.0±5.1 %, 78.9±8.5 %, 69.2±6.2 %, respectively ($P<0.05$). The ratio of S/G_2M and PI in group D were lower than those in groups A, B and C. The inhibitory rate of tumor in groups B, C and D was 37.2 %, 33.3 % and 43.9 %, respectively ($P<0.05$). The life span of TB rats in group D was significantly longer than that in groups B, C, and A.

CONCLUSION: Methionine/valine-depleted amino acid imbalance can inhibit tumor growth. Complex amino acids of methionine and valine depleted imbalance have stronger inhibitory effects on tumor growth.

INTRODUCTION

Malnutrition is encountered everyday in cancer patients and is associated with severe protein-amino acid metabolic disorder, uncorrectable negative nitrogen balance and low immune function[1-6]. Enteral nutrition (EN) and parenteral nutrition (PN) are both safe and effective methods of administering nutrients in cancer patients[7-9]. But PN with amino acid balanced solutions may prompt tumor growth[10-12]. Based on Harper's concept of amino acid imbalance, EN/TPN preparations with depleted or enriched specific amino acids produce tumor growth inhibition[13-18]. Previously, we found methionine/valine-depleted (0), low tyrosine (0.5 g/L) and arginine-enriched (6 g/L) complex amino acid imbalance solutions were the most rational formula in tumor-bearing (TB) rats[19]. In this study, we aimed to investigate the effect of complex amino acid imbalance on the growth of tumor.

MATERIALS AND METHODS

Animals

SD rats weighing 170±20 g were purchased from the Experimental Animal Center of Wuhan University (Wuhan, China) and fed with a stock rat diet *ad libitum*. The animals were maintained on a 12-hour light/12-hour dark cycle at ambient temperature of (23±2) ℃ and housed for 7 days before the experiment.

Catheterization of jejunostomy

After fasted for 12 hours, the rats (n=60) were anesthetized by intraperitoneal administration of 40 mg· kg^{-1} pentobarbital. They were then undergone catheterization during jejunostomy (day 0). A silicone rubber catheter with an internal diameter of 2 mm and an external diameter of 3 mm was inserted into the proximal jejunum. The catheter passed through a subcutaneous tunnel and emerged between the scapulae. The catheter was then mounted on a harness, passed through a protective coil, and connected to a swivel so that the animals could move without any restrictions in individual metabolic cages. The cannulation system consisted of a microinfusion pump, a swivel, rat-harness and a silicone-tube-jejunostomy. The rats were fasted for 48 hours after operation but were provided with water *ad libitum*, and then given normal rat diet.

Preparation of TB rats

Walker-256 carcinosarcoma cells were purchased from Chinese Center of Culture Preservation. On day 0, the rats were subcutaneously inoculated in the right flank with 10^7 tumor cells of approximately 0.1 ml of cell suspension.

Tumor weights and inhibitory rates of tumor

Tumors were palpable 7 days after transplantation. Measurements were made at the tumor site. The lengths of the major, minor axes and depth were measured with calipers. Growth of the tumor was evaluated every 3 days. Tumor volumes during experiments were calculated according to the following equation: $V=LWDp/6$. Where V is the tumor volume (mm^3), L is the length, W is the width and D is the depth of a solid tumor (mm). Inhibitory rates of tumor = (tumor volume of control group- tumor volume of experimental group)/tumor volume of control group×100 %.

Experimental groups and jejunal feeding

On day 8, 48 TB rats were randomly divided into four groups

(12 rats per group) according to the solutions administered: an amino acid balance solution (group A), methionine-depleted amino acid solution (group B), valine-depleted amino acid solution (group C), and methionine and valine-depleted complex amino acid solution (group D). They were administered enteral nutritional solutions (jejunal feeding) for 10 days. During EN, the rats were individually housed in metabolic cages. The compositions of EN solution infused to each rat are summarized in Table 1.

Administration methods

TB rats received continuous jejunal tube infusion for nutritional support at a daily dose of 330 ml· kg^{-1}, by means of a microinfusion pump (Sino-Swed Pharmaceutical Corp. Ltd. China). Non-protein calorie per day was approximately 1 104 K J· kg^{-1}. TB rats were not fed during the entire infusion experiment, however, they had free access to water.

Compositions of amino acid solutions

Table 1 lists the components of amino acid solution in four groups.

Table 1 Compositions of amino acid solution ($g \cdot L^{-1}$)

Amino acids	Group A	Group B	Group C	Group D
Isoleucine	5.5	5.5	5.5	5.5
Leucine	7.5	7.5	7.5	7.5
Lysine	7.0	7.0	7.0	7.0
Methionine	6.0	–	6.0	–
Phenylalanine	4.0	4.0	4.0	4.0
Threonine	5.0	5.0	5.0	5.0
Tryptophan	1.5	1.5	1.5	1.5
Valine	6.0	6.0	–	–
Arginine	6.0	6.0	6.0	6.0
Histidine	3.0	3.0	3.0	3.0
Proline	4.0	4.0	4.0	4.0
Tyrosine	1.0	1.0	1.0	1.0
Alanine	20.0	20.0	20.0	20.0
Glycine	7.5	7.5	7.5	7.5
Aspartic acid	4.0	4.0	4.0	4.0
Total amino acid	88.0	82.0	82.0	76.0
Total nitrogen	14.1	13.1	13.1	12.2

Compositions of EN solution

1 000 ml EN solution was composed of 350 ml of amino acid preparation (Table 1) supplemented with 300 ml of 50 % glucose, 100 ml of 20 % Intralipid (Sino-Swed Pharmaceutical Corp. Ltd. China), 20 ml of Soluvit, 20 ml of Vitalipid, 20 ml of Addamel and 190 ml of 0.9 % saline.

Specimen sampling

At the end of an administration period, 6 rats per group were respectively killed by cervical dislocation. The whole tumor was dissected and examined.

Cell cycle position measurement

Sections about 50 μm thick were cut from tumor tissues and washed 3 times in phosphate-buffered saline. Cell kinetics were measured by flow cytometry (FCM, PASIII, Partec Company, Germany).

Life span of TB rats

The remaining 6 rats per group were given solid food (Experimental Animal Center of Wuhan University, Wuhan, China) and water *ad libitum* according to their body weight until they died of advanced cancer. The life span of each rat in terms of median survival time (MST) was observed.

Statistical analysis

All results were presented as mean ±SD. Comparisons of the four groups were made using Uni-variate ANOVA test. The difference was considered significant when *P* value was less than 0.05.

RESULTS

Animals

Two rats in groups A, C and two rats in group D died of intestinal fistula, diarrhea, infection of abdominal cavity during enteral nutrition, respectively.

Changes in tumor cell cycle

Tumor-selective cell cycle arrest occurred in the S-G_2 phase during methionine depleted enteral nutrition. The distribution of cancer cell cycle was not obviously affected during valine starvation. The percentages of tumor cells in G_0G_1 phase in groups B and D were significantly higher than that in group A while the percentages of S phase cells in groups B and D were obviously lower than that in group A ($P<0.05$). There was no statistical difference between the percentages of G_2M cells in groups B and D and that in group A ($P>0.05$, Table 2).

Table 2 Distribution of cancer cell cycle after EN treatment (%)

Phase	Group A	Group B	Group C	Group D
G_0G_1	67.0±5.1	78.9±8.5[ac]	69.2±6.2[b]	80.5±9.0[ac]
S	20.1±1.8	11.8±2.9[ac]	19.9±3.0[b]	10.2±2.1[ac]
G_2+M	12.9±3.2	9.2±3.1	10.9±2.5	9.4±3.8
PI(S+G_2+M)	33.0±4.3	21.0±5.0[ac]	30.8±5.6[b]	20. 5±2.8[ac]

[a]$P<0.05$, *vs* group A, [b]$P<0.05$, *vs* group B, [c]$P<0.05$, *vs* group C.

Tumor volumes and inhibitory rates of tumor

Tumor volume had no statistical difference among each group before treatment. On day 10 of enteral nutrition, tumor growth in amino acid imbalance groups (groups B, C and D) was significantly lower than that in control group. The most remarkable inhibitory effect on tumor growth was found in complex amino acid imbalance group (group D) ($P<0.05$). The inhibitory rate of tumor (IRT) in groups B, C and D was respectively 37.2 %, 33.3 % and 43.9 % (Table 3).

Table 3 Changes in tumor volumes, IRT and MST before and after treatment

Group	Tumor volumes		IRT(%)	MST(d)
	Before	After		
Group A	0.028±0.015	2.85±0.43	...	26.8±1.5
Group B	0.039±0.010	1.79±0.56[a]	37.2	32.0±2.6[a]
Group C	0.033±0.020	1.90±0.30[ab]	33.3	35.6±3.2[a]
Group D	0.031±0.011	1.60±0.40[abc]	43.9	39.4±3.0[abc]

[a]$P<0.05$, *vs* group A, [b]$P<0.05$, *vs* group B, [c]$P<0.05$, *vs* group C.

Life span of TB rats

The median survival time (MST) in complex amino acid imbalance group was (39.4±3.0) days, as compared with (32.0±2.6) days in methionine-depleted group and (35.6±3.2) days in valine-depleted group (Table 3).

DISCUSSION

Influence of balanced amino acids on tumor growth

Compared with normal cells, the metabolism of tumor cells is significantly accelerated. *In vivo*, cancer cells have been known to have higher levels of protein synthesis, accompanied by a more active uptake of glucose and amino acids (nitrogen trap), and undergo more rapid differentiation and proliferation than healthy cells[20]. Amino acids are important materials of protein synthesis, Supplement of balanced amino acids results in the greatest increase of tumor cell cycles, thus tumor tissues compete with host tissues for nitrogen substrates. Nucleic acid and protein synthesis are increased, and tumor growth is accelerated. Table 3 indicates the experimental results of the anticancer effects of various amino acid imbalance solutions. As clearly shown in this table, tumor volume was especially large, and the median survival time was short after TB rats were administrated with balanced amino acid solutions (group A).

Influence of methionine/valine-depleted amino acid imbalance on tumor growth

Methionine dependency of many malignant tumor cells has been demonstrated in previous studies. That is to say, these cells were arrested in late S/G_2 phase in methionine free cell culture media, and tumor cellular proliferation was inhibited, and normal cells were methionine independent after methionine was replaced by hemocysteine[21-26]. Methionine is the principal biological methyl donor via S-adenosyl-L-methionine (SAM). SAM can easily transfer its methyl group to a large variety of acceptor substrates including rRNA, tRNA, mRNA, DNA, proteins, phospholipides, biological amines, and a long list of small molecules. Methionine dependency might be due to overutilization of methionine for transmethylation reactions resulting in a low free methionine pool and a low S-adenosylmethionie/S-adenosylhomocysteine ratio[27-31]. This directly inhibits the activity of transmethylase, thereby methionine depleted enteral nutrition can decrease methylation reaction of tumor tissues and lead to further reduction in nucleic acid synthesis and inhibition of cancer growth at molecular levels.

Our study demonstrated that tumor growth in group B was significantly slower than that in control group, the liver and peritoneum metastasis of cancer was much less in group B. It suggested that the invasive ability for metastasis be suppressed during methionine starvation. Breillout *et al* considered that methionine depletion disturbed the membrane lipids of tumor cells and inhibited their metastatic ability[32].

It was also found that valine depleted imbalance solution (group C) had a great inhibitory effect on Walker-256 carcinosarcoma cells. One possible mechanism was the alterations of intracellular protein synthesis due to deprivation of essential amino acids (Valine)[33-35]. Another possible mechanism seemed to be the inhibitory effect on the production of prolactin, which was likely to participate in tumor growth[20].

Influence of complex amino acid imbalance on tumor growth

As shown in Table 3, the most remarkable inhibitory effect on cancer growth was seen in the methionine/valine depleted complex amino acid imbalance group, followed by the methionine depleted imbalance group and then the valine depleted group. It suggested that complex amino acid imbalance solutions had the most strong anticancer effects. However, are we able to prevent the development of side effects of complex imbalance due to starvation of essential amino acids? This still needs further studies.

Abstract

AIM: Gastrointestinal dysfunction is a common complication in patients with traumatic brain injury (TBI). However, the effect of traumatic brain injury on intestinal mucosa has not been studied previously. The aim of the current study was to explore the alterations of intestinal mucosa morphology and barrier function, and to determine how rapidly the impairment of gut barrier function occurs and how long it persists following traumatic brain injury.

METHODS: Male Wistar rats were randomly divided into six groups (6 rats each group) including controls without brain injury and traumatic brain injury groups at hours 3, 12, 24, and 72, and on day 7. The intestinal mucosa structure was detected by histopathological examination and electron microscopy. Gut barrier dysfunction was evaluated by detecting serum endotoxin and intestinal permeability. The level of serum endotoxin and intestinal permeability was measured by using chromogenic limulus amebocyte lysate and lactulose/mannitol (L/M) ratio, respectively.

RESULTS: After traumatic brain injury, the histopathological alterations of gut mucosa occurred rapidly as early as 3 hours and progressed to a serious state, including shedding of epithelial cells, fracture of villi, focal ulcer, fusion of adjacent villi, dilation of central chyle duct, mucosal atrophy, and vascular dilation, congestion and edema in the villous interstitium and lamina propria. Apoptosis of epithelial cells, fracture and sparseness of microvilli, loss of tight junction between enterocytes, damage of mitochondria and endoplasm, were found by electron microscopy. The villous height, crypt depth and surface area in jejunum decreased progressively with the time of brain injury. As compared with that of control group (183.7±41.8 EU/L), serum endotoxin level was significantly increased at 3, 12, and 24 hours following TBI (434.8±54.9 EU/L, 324.2±61.7 EU/L and 303.3±60.2 EU/L, respectively), and peaked at 72 hours (560.5±76.2 EU/L), then declined on day 7 (306.7±62.4 EU/L, $P<0.01$). Two peaks of serum endotoxin level were found at hours 3 and 72 following TBI. L/M ratio was also significantly higher in TBI groups than that in control group (control, 0.0172±0.0009; 12 h, 0.0303±0.0013; 24 h, 0.0354±0.0025; 72 h, 0.0736±0.0105; 7 d, 0.0588±0.0083; $P<0.01$).

CONCLUSION: Traumatic brain injury can induce significant damages of gut structure and impairment of barrier function which occur rapidly as early as 3 hours following brain injury and lasts for more than 7 days with marked mucosal atrophy.

INTRODUCTION

Gastrointestinal dysfunction occurs frequently in patients with traumatic brain injury (TBI)[1]. Dysfunction of the different segments of gastrointestinal tract leads to corresponding symptoms such as gastrointestinal bleeding[2-4], gastric reflux[5,6] and decreased intestinal peristalsis[7,8], mainly due to mucosal damage and alteration of gastrointestinal motility[9]. Studies on gastrointestinal dysfunction associated with head injury in the literature concentrated on the gastric mucosa, gastric emptying and lower esophageal sphincter tone[2-8]. However, the effect of TBI on intestinal mucosa has not been studied to date. Therefore, the alterations of intestinal mucosa morphology and barrier function following TBI remain unclear.

It is generally accepted that the intestine may serve as an important organ in the development of severe complications under critically ill conditions, including trauma, burns, shock, *etc*.[10-12]. Major trauma and shock may initiate a cascade of intestinal events such as intestinal cytokine response[13], increased intestinal permeability[14,15], translocation of intestinal bacteria and endotoxin[10,16], leading to systemic inflammatory response syndrome (SIRS) and sepsis with subsequent multiple organ failure[12]. TBI is a severe pathological stress and critically ill condition usually complicated with gastric stress ulcer[17]. Therefore, we hypothesized that TBI could also lead to significant gut structural alterations and barrier dysfunction as mentioned above in the same mechanism as trauma, hemorrhagic shock and burns. Additionally, brain-gut axis[18,19] and hypothalamic-pituitary adrenal axis[20] may also play a certain role in the development of gut dysfunction following TBI, but the potential mechanism underlying this action is not clear.

Studies have shown that cerebral inflammation following TBI occurs frequently and is associated with adverse outcomes[21,22]. Bacterial endotoxin (lipopolysaccharide, LPS) may exacerbate the inflammatory response of injured brain, leading to invasion of granulocytes into the brain and breakdown of the blood-brain barrier[23-26]. Severe extracerebral trauma can induce the expression of TNF-α mRNA in the brain of mice[27]. Therefore, we suggest that intestinal cytokine, translocation of bacteria and endotoxin secondary to gut barrier dysfunction into the injured brain through blood circulation should activate the cerebral inflammatory response. Because enteral nutrition and enterogenous sepsis are two of the important factors affecting the outcomes of comatose patients with TBI, the maintenance of normal gut integrity is

believed to be beneficial in improving the outcomes of head-injured patients[28,29].

Considering the important role of intestinal function in the rehabilitation of patients with TBI and no study reported previously on the intestinal aspects following TBI, additional studies need to be carried out to clarify the degree of mucosal damage and gut barrier dysfunction induced by TBI, and if possible, to explore the potential mechanisms that have not been interpreted yet. Therefore, we performed a series of studies on intestines of TBI rats. The purpose of this study was to explore the alterations of intestinal mucosa morphology and barrier function, and to determine how rapidly impairment of gut barrier function occurred and how long it persisted following TBI.

MATERIALS AND METHODS

Rat models of TBI

Male Wistar rats, weighing 220 g to 250 g, were purchased from Animal Center of Chinese Academy of Sciences, Shanghai, China. The rats were fed on rodent chow with free access to tap water and housed in temperature- and humidity-controlled animal quarters with a 12 hour light/dark cycle. All procedures were approved by the Institutional Animal Care Committee.

The rats were randomly divided into six groups (6 rats each group) including control group with right parietal bone window alone and no brain injury, and traumatic brain injury groups at hours 3, 12, 24, and 72, and on day 7, respectively. Following intraperitoneal anesthesia with urethane (1 000 mg.kg^{-1}), animal head was fixed in the stereotactic device. A right parietal bone window of 5 mm diameter was made under aseptic conditions with dental drill just behind the cranial coronal suture and beside midline. The dura was kept intact. Right parietal brain contusion was adopted using the impact method described by Feeney *et al*.[30] and severe traumatic brain injury was made by dropping weight with a 4 mm impact diameter, a 5 mm depth and total impact energy of 1 000 g.cm. The control animals were killed for sample collection at 72 hours, and TBI group rats were decapitated at corresponding time points. Blood samples were obtained by right ventricle puncture and centrifuged with the plasma stored at -40 ℃ before the animals were sacrificed at each time point. A 3 cm segment of the jejunum 12 cm distal to Treitz ligament was taken for histopathological studies and 1 mm^3 mucosa for ultrastructural observations.

Histopathological and ultrastructural examination

The 10 % buffered formalin-fixed jejunum was embedded in paraffin, sectioned at 4 μm thickness with a microtome and stained with hematoxylin and eosin. The sections were examined under light microscope. Villous height, diameter of middle villous segment and crypt depth in all tissues were determined using the HPIAS-1000 colorful image analysis system (Champion Image Engineering Company, Wuhan, China). Villous surface area was calculated according to the following formula: surface area=πdh, (d: diameter, h: villous height). At least 10 well-oriented crypt-villous units per small intestinal sample were measured and averaged by a pathologist who was blind to animal groups.

Samples for electron microscopy were fixed in phosphate-buffered glutaradehyde (2.5 %) and osmium tetroxide (1 %). Dehydration of the mucosa was accomplished in acetone solutions at increasing concentrations. The tissue was embedded in an epoxy resin. Semithin (1 μm) sections through the mucosa were then made and stained with toluidine blue. Then 600 angstrom-thin sections were made from a selected area of tissue defined by the semithin section, and these sections were stained with lead citrate and uranyl acetate. Ultrastructures of mucosa were observed under a transmission electron microscope (JEM-1200X).

Plasma endotoxin determination

The endotoxin content in plasma samples was assayed by the chromogenic limulus amebocyte lysate (LAL) test with a kinetic modification according to the test kit procedure.

Intestinal permeability

Intestinal permeability was quantified using the lactulose/mannitol (L/M) test as previously described[19]. Six hours before the animals were sacrificed at each time point, the rats with their bladders emptied were given the test solution of 2.5 ml by gastric tube feeding, containing 60 mg lactulose and 30 mg mannitol. All urine was collected for 5 hours through the metabolic cage and stored at -40 ℃ for further analysis. Urinary lactulose and mannitol were measured using high-performance liquid chromatography (Waters Co., USA). Results were expressed as a ratio of percentage of the administered dose of the two molecules excreted.

Statistical analysis

Software SPSS 11.0 was used in the statistical analysis. Each parameter was expressed as mean ± SD, and compared using one-way ANOVA analysis of variance, followed by Tukey test. The level of significance was $P<0.05$.

RESULTS

Histopathology

Histopathological examination showed that the morphology of jejunal mucosa was approximately normal in control rats. After TBI, mucosal damage occurred as early as 3 hours and was maximal at 72 hours, then progressed to mucosal atrophy on day 7. The type of jejunal mucosa damages induced by TBI is shown in Table 1. Representative histopathologic sections of jejunal mucosa are shown in Figures 1-4.

Table 1 Main histopathological changes of jejunal mucosa after traumatic brain injury

Type of mucosal damages	Group of TBI
Shedding of epithelial cells from the top of villi	3 and 12 hours
Epithelial cell necrosis and disarrangement of villi	24 and 72 hours
Focal mucosa ulcer with exposure of submucosal interstitium	72 hours
Fusion of adjacent villi into piece	72 hours and 7 days
Dilation of central chyle duct	72 hours and 7 days
Inflammatory cell infiltration in intestinal wall	72 hours and 7 days
Mucosal atrophy	7 days
Vascular dilation, congestion and edema in villous interstitium and lamina propria	3 hours throughout 7 days

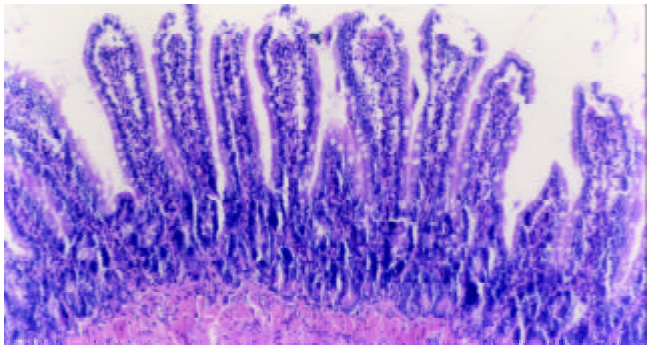

Figure 1 Epithelial cells shed from the top of villi with almost normal villous height and well defined arrangement of villi at 3 hours following TBI. H-E, magnification ×100.

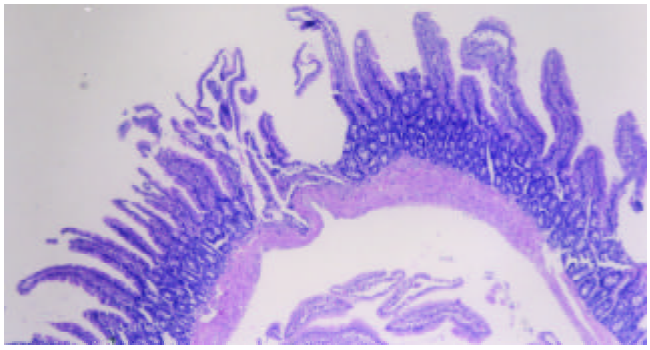

Figure 2 Markedly altered villous morphology and decreased height at 72 hours following TBI. Note the focal mucosa ulcer with exposure of submucosal interstitium and disarrangement of villi. H-E, magnification ×100.

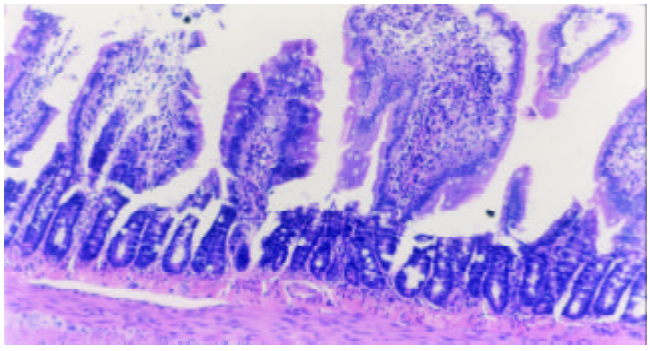

Figure 3 Marked alterations of villous morphology occurred 7 days following TBI, including mucosal atrophy, fusion of adjacent villi, inflammatory cell infiltration, and vascular dilation, congestion and edema in the villous interstitium and lamina propria. H-E, magnification ×100.

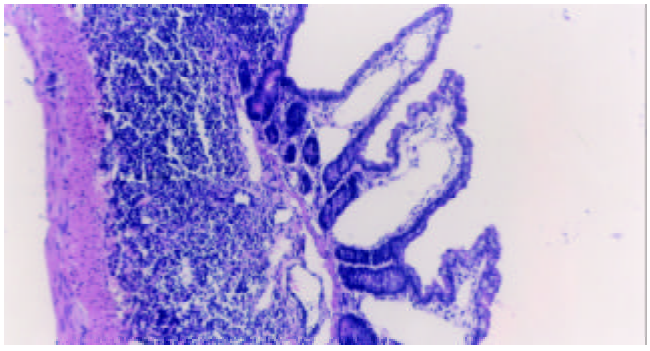

Figure 4 Dilation of central chyle duct of jejunal mucosa. H-E, magnification ×100.

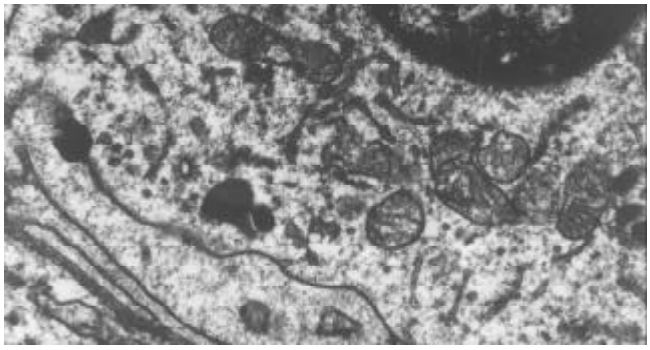

Figure 5 Reduction of mitochondrial matrix and disruption of its cristae at 72 hours following TBI. TEM, magnification ×15 k.

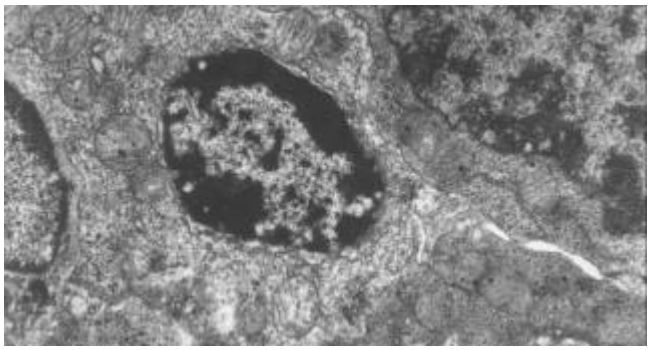

Figure 7 Apoptosis bodies in epithelial cytoplasms of jejunum following TBI. TEM, magnification ×8000.

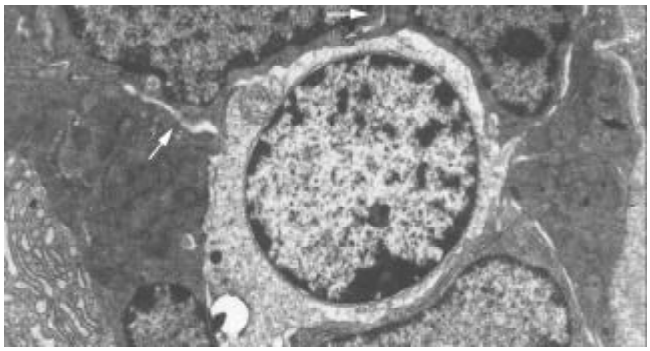

Figure 8 Disrupted and wider tight junction between epithelial cells at 72 hours and 7 days following TBI, shown as blank arrow. TEM, magnification ×5000.

Histomorphometric studies

Villous height, crypt depth and villous surface area were determined as specific indices for the evaluation of mucosal

Table 2 Changes in villous height, diameter, crypt depth and surface area of mucosa

Groups	Villous height (μm)	Villous diameter (μm)	Crypt depth (μm)	Surface area (mm^2)
Control	229.2±18.1	37.4±5.5	79.3±9.6	0.0259±0.0048
TBI 3 hours	219.5±21.2	37.6±6.1	78.9±9.4	0.0258±0.0035
TBI 12 hours	214.5±22.5	35.6±3.1	74.0±6.9	0.0241±0.0037
TBI 24 hours	189.2±13.6[b]	32.7±3.2	67.0±7.6[bc]	0.0195±0.0012[bc]
TBI 72 hours	150.8±10.4[bc]	32.1±4.2	34.8±5.6[bc]	0.0151±0.0010[bc]
TBI 7 days	136.7±15.7[bc]	30.8±5.8	38.3±6.1[bc]	0.0130±0.0015[bc]

Note: Values were expressed as mean ±SD. [b]P<0.01 *vs* control, [c]P<0.01 *vs* group of 3 hour TBI.

damages. The alterations of these parameters following TBI are shown in Table 2. Qualitative analyses of the villi demonstrated that the villous height, crypt depth and surface area were significantly decreased at 24 hours after TBI as compared with control group and further declined to the degree of mucosal atrophy on day 7 following TBI.

Ultrastructural observations

Within 24 hours of TBI, the nuclei of epithelial cells appeared irregular, but their membranes were still intact. At 72 hours and on day 7 following TBI, obvious ultrastructural alterations were found, including reduction of matrix of mitochondria and disruption of their cristae (Figure 5), ruptured, distorted and sparse microvilli (Figure 6), apoptosis bodies in cytoplasms (Figure 7), disrupted and wider tight junction between epithelial cells (Figure 8), swollen and degenerated vascular endothelial cells.

Changes in plasma endotoxin concentration

As shown in Figure 9, plasma endotoxin was significantly increased at 3 hours following TBI, and peaked at 72 hours, then declined on day 7, but was still significantly higher than that of controls (P<0.01). A marked correlation was noted between the changes in plasma level of endotoxin and intestinal permeability throughout 12 hours and 7 days following TBI (r=0.765, P<0.01).

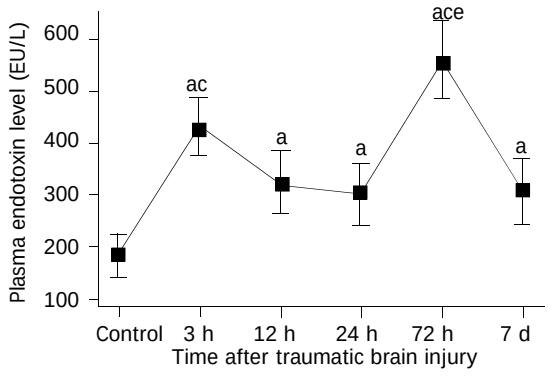

Figure 9 Significant increase of level of plasma endotoxin following TBI compared with control. Two peaks of plasma endotoxin existed at 3 h and 72 h postinjury, respectively. [a]P<0.05 *vs* control; [c]P<0.05 *vs* 12 h, 24 h and 72 h following TBI, [e]P<0.05 *vs* 3 h following TBI. Mean ± SD of six animals, control: 183.7±41.8 EU/L, 3 h: 434.8±54.9 EU/L, 12 h: 324.2±61.7 EU/L, 24 h: 303.3±60.2 EU/L, 72 h: 560.5±76.2 EU/L, 7 d: 306.7±62.4 EU/L.

Intestinal permeability and L/M ratio

As shown in Figure 10, intestinal permeability was significantly increased at 12 hours after TBI, peaked at 72 hours, and declined gradually afterward, but was still higher on day 7 following TBI than that of control group.

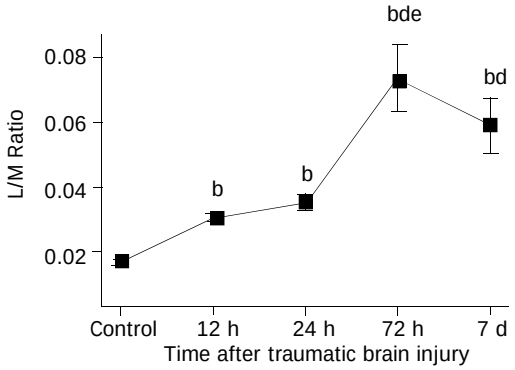

Figure 10 Significant increase of L/M ratio at 12 h, 24 h and 72 h following TBI compared with control and significant decline on day 7 compared with group at 72 h. The L/M ratio on day 7 was still significantly higher than that at 12 h and 24 h. [b]P<0.01 *vs* control, [d]P<0.01 *vs* 12 h and 24 h, [e]P<0.01 *vs* 7 d. Mean ± SD of six animals, control: 0.0172±0.0009, 12 h: 0.0303±0.0013, 24 h: 0.0354±0.0025,72 h: 0.0736±0.0105, 7 d: 0.0588±0.0083.

DISCUSSION

Major changes of gastrointestinal function following traumatic brain injury could be summarized in four aspects. The first was gastrointestinal mucosa ischemia, which usually resulted in stress ulcer and gastrointestinal bleeding[3,4]. The second was motility dysfunction, which manifested as abdominal distention, diarrhea, gastric retention, and even toxic intestinal paralysis[5-7,31]. The third was disruption of gut barrier, which led to bacterial and endotoxin translocation contributing to the development of SIRS and sepsis. The fourth was alteration of intestinal mucosal absorption of nutrients, which played an important role in malnutrition. Studies on stress ulcer and gastrointestinal bleeding after brain injury have been reported extensively[2]. Stress ulcer was one of the most common gastrointestinal complications following head trauma with a reported incidence of 74-100 %[3,4]. Endoscopic evidences of gastric mucosal lesions could appear within 24 hours, and 17 % of these erosions would progress to clinically significant gastrointestinal bleeding after severe brain injury.

Studies on intestinal mucosa structure and barrier function following TBI have not been found to date. In this study, we found that severe damage of intestinal mucosa occurred following TBI. The morphologic alterations of gut mucosa included shedding of epithelial cells, fracture of villi, focal ulcer, fusion of adjacent villi, dilation of central chyle duct, mucosal atrophy, and edema in the villous interstitium and lamina propria. Apoptosis of epithelial cells, fracture and sparseness of microvilli, disruption of tight junction between enterocytes, damage of mitochondria and endoplasm, were found by electron microscopy. These lesions occurred rapidly as early as 3 hours following TBI and lasted for more than 7 days. At the early stage (within 72 hours following TBI), it manifested as acute damages of intestinal epithelium, such as

epithelial necrosis and focal mucosa ulcer. On day 7 after TBI, the intestinal lesions were dominated by mucosal atrophy and edema of villous interstitium and lamina propria. Inflammatory cell infiltration in the small intestine was found 24 hours after TBI. Mucosal atrophy was considered to be associated with the necrosis and apoptosis of gut epithelium, which were induced by relative hypoperfusion (ischemia-reperfusion injury) and interaction of inflammatory mediators with their receptors located on the gut epithelial cells[13].

Intestinal mucosal injury could also be assessed by measuring the permeability of mucosal barrier to small or large solutes. Lactulose and mannitol have previously been used to assess intestinal mucosal permeability in burn and critically ill patients[12,14,15]. Mannitol, a smaller sugar, passes through aqueous pores in the cell membranes. Lactulose, a larger molecule, is absorbed paracelluarly through tight junctions. Increased absorption of lactulose can reflect mucosal leakiness, and decreased absorption of mannitol can reflect decreased functional absorptive area. The current study demonstrated that the L/M ratio was significantly greater at 3 hours following TBI, and reached its peak at 72 hours, then declined on day 7 with the value still markedly higher than that of control group and 24 hour TBI group. Additionally, the results showed that increased intestinal permeability might persist for 7 days in rats with TBI, which conformed highly to the histopathological alterations, i.e. mucosal atrophy and disruption of tight junction between epithelial cells.

The level of plasma endotoxin was positively related to L/M ratio, and manifested as two peaks at 3 hours and 72 hours after TBI, respectively. The first peak might be the result of acute gut mucosal damage mainly induced by splanchic ischemia due to the excited sympathetic nerve. With the resumption of liver anti-toxic function and the advent of specific antibodies to lipopolysaccharide, the plasma level of endotoxin was declined to some extent[34]. The second peak of plasma endotoxin might be related to severe mucosal damages such as focal ulcer and epithelial necrosis which usually occurred at 72 hours following TBI. High L/M ratio and plasma level of endotoxin following TBI implied that the gut barrier function was disrupted.

The potential mechanism underlying the alterations of gut structure and impairment of barrier function following TBI might be related to several factors, including ischemia-reperfusion, intramucosal acidosis[32], cytokines and inflammatory mediators[13,33]. Splanchnic hypoperfusion is a common finding in trauma. In systemic pathological stresses such as TBI, an adaptive response mediated by neuro-endocrine exists, which leads to selective splanchic vascular spasm in order to maintain the normal supply of vital organs such as the heart, lung and brain. The gut is highly susceptible to the consequent reduction in oxygenation, particularly mucosa of the stomach and intestine. This might induce increased gut permeability, alteration of enteral immune function, mucosal edema, epithelial necrosis and apoptosis, and even focal mucosa ulcer, which would contribute to bacterial and endotoxin translocation[13,14,20]. Brain-gut axis and hypothalamus-pituitary-adrenal axis might play a potential role in gut mucosal damages[18-20]. It may arise from the actions of parasympathetic centers of the hypothalamus with their connections to vagal nuclei in the medulla. Cytokines and inflammatory mediators such as TNF-α, IL-1, oxygen free radicals and nitric oxide could induce damages of microvilli, tight junction between enterocytes and paracelluar junction, which would lead to increased intestinal permeability[33].

Increased intestinal permeability has been implicated in the pathogenesis of both SIRS and progression to MODS[10,11,14,15]. The gut origin hypothesis suggests that a failure of gut barrier function as a result of a major stress insult permits bacterial and endotoxin translocation, which triggers systemic immunoinflammatory response to release cytokines and inflammatory mediators. These cytokines and mediators might exacerbate SIRS, sepsis and multiple organ failure[10-13]. This concept was supported by the data from animal studies in experimental models, including surgical trauma[14], malnutrition, jaundice, pancreatitis, hemorrhagic shock, and thermal injury[28]. Results of the current study showed that gut barrier dysfunction occurred with high plasma level of endotoxin and increased intestinal permeability following TBI. Therefore, we suggest that SIRS and MODS secondary to traumatic brain injury be possibly related to the disruption of gut barrier. Otherwise, translocated endotoxin and gut-derived cytokines may enter the injured brain with circulating blood, which was assumed to activate or exacerbate the inflammation of brain, and cause "two-hit" insult[22-26]. Circulating lipopolysaccharide and cytokines may stimulate the hypothalamic-pituitary-adrenal axis and sympathetic nervous system to affect the function of multiple organs. MODS is one of the common fatal complications following severe TBI.

Abstract

AIM: To determine the regulatory effects of recombinant human growth hormone (rhGH) on dipeptide transport (PepT1) in normal and severe scald rats.

METHODS: Male Sprague-Dawley rats with 30 % total body surface area (TBSA)IIIdegree scald were employed as the model. In this study rhGH was used at the dose of 2 IU.kg^{-1}d^{-1}. An everted sleeve of intestine 4 cm long obtained from mid-jejunum was securely incubated in Kreb's solution with radioactive dipeptide (^{3}H-glycylsarcosine, ^{3}H-Gly-Sar, 10 μCi/ml) at 37 ℃ for 15 min to measure the effects of uptake and transport of PepT1 of small intestinal epithelial cells in normal and severe scald rats.

RESULTS: Abundant blood supply to intestine and mesentery was observed in normal and scald rats administered rhGH, while less supply of blood to intestine and mesentery was observed in rats without rhGH. Compared with controls, the transport of dipeptide in normal rats with injection of rhGH was not significantly increased (P=0.1926), while the uptake was significantly increased (P=0.0253). The effects of transport and uptake of PepT1 in scald rats with injection of rhGH were significantly increased (P=0.0082, 0.0391).

CONCLUSION: Blood supply to intestine and mesentery of rats was increased following injection of rhGH. The effects of uptake and transport of dipeptide transporters in small intestinal epithelial cells of rats with severe scald were markedly up-regulated by rhGH.

INTRODUCTION

Small intestine is the major site of dietary protein absorption, the main route of absorption protein is transport of protein in the form of small peptides (di/tripeptide) across the small intestinal wall. H^+-coupled dipeptide transporter, PepT 1, is known to be located in the intestine and kidney, and plays an important role in the absorption of di/tripeptide. In addition, it mediates the intestinal absorption of β-lactam antibiotics, angiotension–converting enzyme inhibitors, and other peptide–like drugs[1].

Knowledge about the regulation of PepT 1 activity is limited. A number of studies have shown that dietary protein load causes an increase in di/tripeptide transport in small intestine of rats and mice[2,3]. Recent studies have shown that PepT1 in rat intestine is upregulated after a short period of fast via an increase in gene expression[4-6]. Another interesting regulation of PepT 1 expression is that PepT1 in rat' s small intestine is resistant to tissue damage induced by 5-flourouracil, whereas other markers such as sucrase activity, D-glucose uptake are significantly decreased[7]. This suggests that expression of PepT 1 is robust towards cellular damage.

Studies showed that some hormones metabolically regulated the expression of intestinal dipeptide transporter[8,9]. For example, insulin could increase the membrane population of PepT 1 by increasing its translocation from a preformed cytoplasmic pool[9]. Our previous study[10] showed that rhGH markedly stimulated the uptake and transport of cephalexin in Caco-2 cells with normal or anoxia/reoxygenation management. These results indicate that rhGH greatly upregulates the physiological functions of dipeptide transporters (PepT1) of human cell line. Although rhGH has been shown to be a major regulator of peptide transport activity[10], little is known about rhGH in regulation of peptide absorption *in vivo*, especially in rats with severe scald.

In this study, we determined whether rhGH could stimulate uptake and transport of small intestinal epithelial cells in normal or severe scald rats. We also investigated the *in vivo* application of 3H-glycylsarcosine (3H-Gly-Sar) as an ideal substrate for PepT1.

MATERIALS AND METHODS

Materials

[3H]-glycysarcosine (special activity of 1Ci (37GBq)/mmol, radiochemical purity >=97 %, work concentration in this study: 10 μCi/ml) was purchased from Moravek Biochemicals,USA. Recombinant human growth hormone (rhGH, 2 IU.kg^{-1}d^{-1}) was from Serono, Switzerland, Temperature-controlled surge culture device from Taicang Medical Instrument Co. Ltd, China. All other reagents were of analytical grade at least.

Animals

Adult male Sprague–Dawley (SD) rats (weighing 200±20 g) were housed in individual stainless steel cages in an air–conditioned room at 23±2 ℃ with a 12: 12-h light schedule and were fed normally. The weight of rats was measured daily during an experiment. The animals were treated in accordance with European Community Standards concerning the care and use of laboratory animals (INSERM and Ministere de 1' Agriculture et de la Foret, Paris, France).

Experimental groups

Rats were randomly divided into groups A, B, C and D. Group A(control group): normal feed rats, Group B: normal feed + injection of rhGH (2 IU.kg^{-1}d^{-1}) rats, Group C: scald rats and Group D: scald + injection of rhGH (2 IU.kg^{-1} d^{-1}) rats. The indices were observed on postburn days (PBDs) 0, 1, 3, 5 and 7 (n=4), respectively. Rats were killed by decapitation at every time point.

Scald injury models

Rats were anaesthetized with 2 % pentoburbite (30 mg.kg^{-1} body weight) and scald on the back to 30 % total body surface area (TBSA) III degree, and 30 min later, they were resuscitated with Ringer' s solution (2 ml.kg^{-1} per 1 % body surface area).

Preparation of everted sleeve of rat small intestine

The rats were fasted overnight and water was available ad libitum throughout the study. The rat was killed by decapitation, a laparotomy was performed. We defined the region approximately 6 cm below the ligament of Treitz, then a 4-cm long segment of small intestine (mid-jejunum) was removed, ringed immediately with Kreb' s buffer. One end of the intestinal fragment was ligated, an everted process was securely made by small tweezers, then an intact everted sleeve was formed after another terminal ligation. Each sleeve was weighed.

Uptake and transport measurement

We measured 3H-Gly-Sar taken up into intestinal epithelial cells of the everted sleeve across the brush–border membrane. The everted sleeve was rinsed with Kreb' s buffer, 0.2 ml Kreb' s buffer was injected slowly into the lumen of the everted intestinal sleeve. The whole segment was then immersed into a 50 ml flask containing dipeptide (3H-Gly-Sar) solution (10 μCi) while 5 % CO_2 and 95 % O_2 were filled into the flask. The uptake and transport experiments were performed when the device was surged continually with a frequency of 100 r/min at 37 ℃ for 15 min, then the everted sleeve was rinsed immediately with cold (4 ℃) Kreb' s buffer to stop subsequent transport and uptake of PepT1 in epithelial cells. The transport sample was harvested from the lumen of the sleeve, a 0.5 cm×0.5 cm segment was removed from the middle of the sleeve, weighed and digested with HCl_4 to obtain the uptake sample. All samples were mixed with 10 ml of scintillation cocktail and the radioactivity was determined by liquid scintillation counter.

Statistical analysis

Data were expressed as mean ±SD. Differences between groups were assessed by analysis of variance. Values less than 0.05 were considered statistically significant.

RESULTS

Blood Supply in bowel of rats

After killed by decapitation, a laparotomy was performed immediately at the different time point (0, 1, 3, 5 and 7 days) in rats (normal or scald) with or without injection of rhGH. Direct appearance of blood supply was observed in mesentery and the wall of intestine of rats. Abundant blood supply was shown in rats after injection of rhGH, while less blood supply was observed in rats without injection of rhGH (Figure 1, 2).

Uptake and transport in everted sleeve of normal rats after injection of rhGh

In comparison with the control, the transport of dipeptide (3H-Gly-Sar) in normal rats after injection of rhGH was not significantly increased (P=0.1923) while the uptake were markedly increased (P=0.0253) (Figure 3, 4).

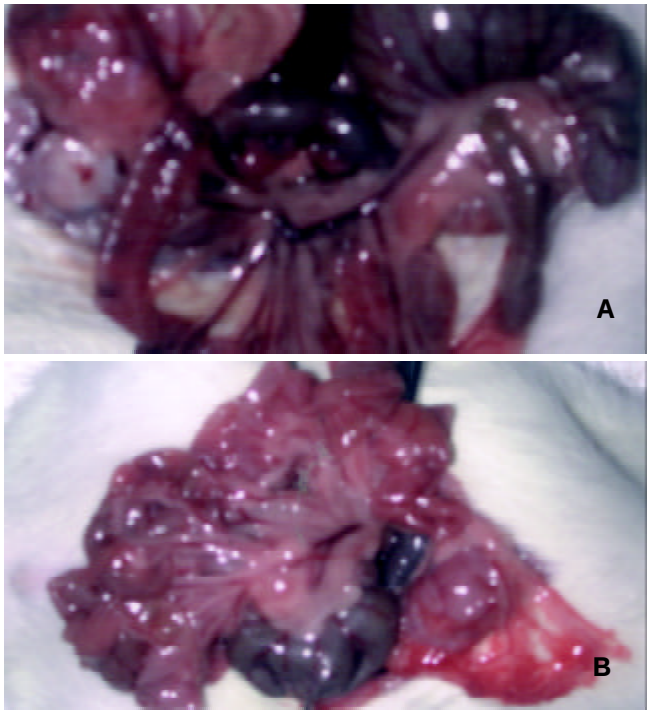

Figure 1 Blood supply to intestine and mesentery of rats 7 days after injection of rhGH was significantly abundant compared with controls. (A: rhGH group, B: control).

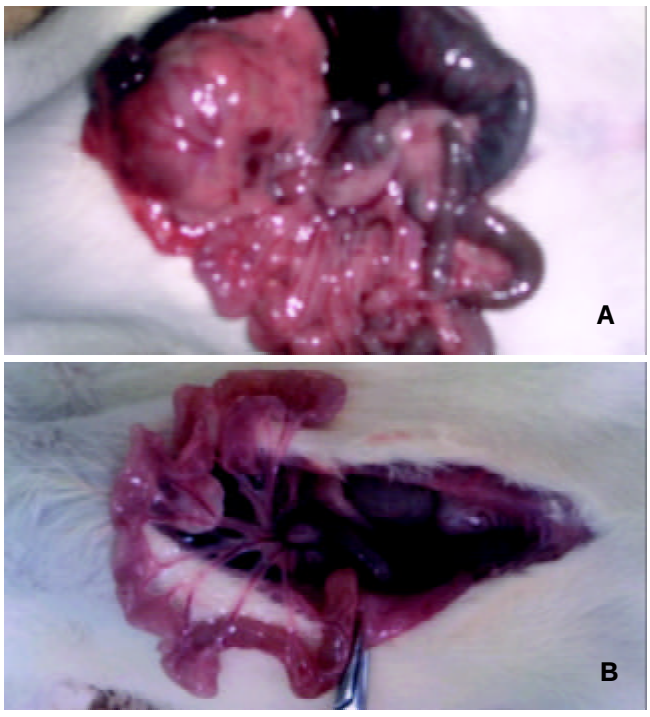

Figure 2 Blood supply to intestine and mesentery of rats with severe scald 7 days after injection of rhGH was significantly abundant compared with controls. (A: rhGH group, B: control).

Uptake and transport in everted sleeve of severe scald rats after injection of rhGH

The effects of transport and uptake of PepT1 in everted sleeve of severe scald rats after injection of rhGH were greatly increased compared with controls (P=0.0082, 0.0391) (Figure 5, 6).

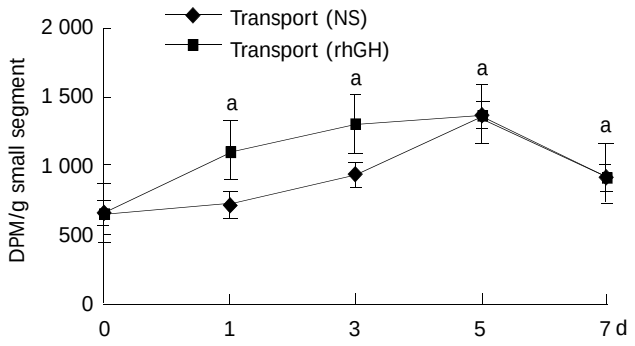

Figure 3 Transport of PepT1 in normal rats administered rhGH. Each point represents mean ±s, n=4, ^aP>0.05 *vs* control.

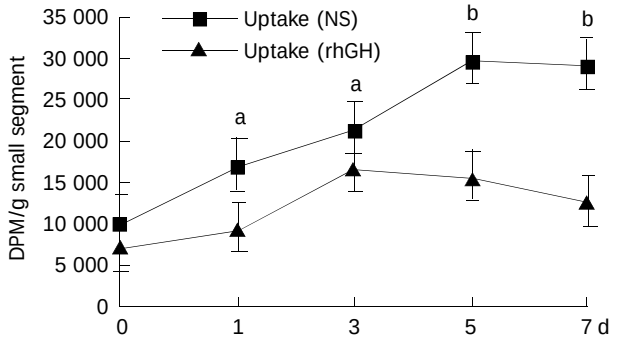

Figure 4 Uptake of PepT1 in normal rats administered rhGH. Each point represents mean ±s, n=4, ^aP<0.05, ^bP<0.01 *vs* control.

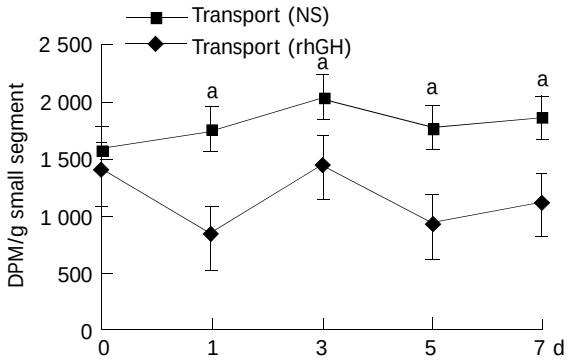

Figure 5 Transport of PepT1 in scald rats administered rhGH. Each point represents mean ±s, n=4, ^aP<0.05 *vs* control.

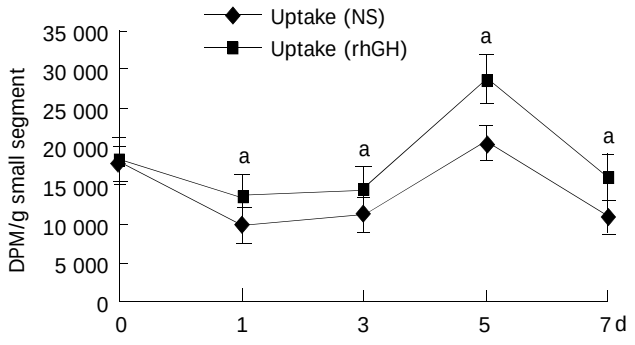

Figure 6 Uptake of PepT1 in scald rats administered rhGH. Each point represents mean ±s, n=4, ^aP<0.05 *vs* control.

DISCUSSION

We found in this study that rhGH could significantly increase the transport and uptake of peptides across intestinal epithelial barrier via proton–dependent transporter PepT1, suggesting that rhGH might be an important parameter in hormonal regulation of this transporter. It is well known that dietary proteins are absorbed as di – and tripeptides rather than free amino acids[11-14]. This absorption process is carried out by intestinal brush board transporter PepT1, which transfers peptides from a region with low dipeptidase activity (intestinal lumen) to a region with high dipeptidase activity (enterocyte cytoplasm)[15]. As a member of a family of transport proteins, PepT1 is located at the brush-border membranes of absorptive epithelial cells along the small intestine but absent in crypt and goblet cells[16,17]. PepT1 allows the use of small peptides as a source of nitrogen for enteral feeding and the route for delivery of peptidomimetic drugs such as β-lactam antibiotics. Therefore, PepT1 appears to be essential for the efficient absorption of dietary proteins[18]. Most studies on PepT1 have focused on its fundamental kinetic properties and its functional and structural characterization[19-21].

Previous studies have shown that the functions of intestine (including PepT1) were changed under the influence of many factors[22,23]. However, few reports have dealt with the hormonal regulation of PepT1. Insulin could stimulate dipeptide transport by increasing membrane insertion of PepT1 from a preformed cytoplasmic pool[9], and choleratoxin could decrease dipeptide transport by inhibiting the activity of PepT1 through an increase in intracellular concentration of adenosine 3', 5'-cyclic monophosphate[24]. Strong evidences have demonstrated that growth hormone (GH) was an important growth factor for intestine[25]. Complete GH depletion due to hypophysectomy could cause pronounced hypoplasia of small intestinal mucosa with decreased villus height and reduced crypt cell proliferation[26]. Simple replacement of GH could restore mucosal proliferative activity[27], rhGH could promote normal growth and development in the body by changing chemical activity in cells. It activates protein production in muscle cells and release of energy from fats. rhGH could significantly improve anabolism in parenteral feeding[28]. It has been typically used to stimulate growth of children with hormone deficiency, or to treat people with severe illness, burns or sepsis where destruction of human tissues and muscle occurs[29-31]. It remains unclear, however, whether the key hormone, human growth hormone (hGH) also shows some significant importance in transport and uptake of PepT1. To examine the functional changes of PepT1, everted sleeves of small intestine were used as *in vivo* intestinal model, and severe scald (30 % TBSA III degree) rats with or without injection of rhGH were employed as animal model. The results in this study indicated that the blood supply in mesentery and the wall of rat's intestine (normal or severe scald) with injection of rhGH was abundant compared with the controls. It was suggested that rhGH could increase blood supply of animal bowel, therefore, upregulate directly the physiological functions of PepT1 of small intestine.

The data in this study confirmed that both transport and uptake of PepT1 in everted sleeves of severe scald rats administered rhGH were significantly increased compared with controls. It indicated that rhGH upregulated the biological functions of PepT1. This result was in accordance with our previous research[10]. In our study, however, the transport of dipeptide in normal rats treated with rhGH was not markedly increased, while the uptake was greatly increased compared with controls. It might be due to the cytoplasmic level of dipeptidases, or a short period of experiment.

In conjunction with previous results[10], the present study further testified the enhancement effect of peptide transport by rhGH. The biological mechanism might involve increased translocation of the cytoplasmic pool of PepT1 to the apical membrance, or increased level of PepT1 mRNA. Clearly,

further study on physiology and biology of PepT1 is required to clarify the mechanism of rhGH in upregulating the functions of PepT1.

Abstract

AIM: To study the effect of angelica sinensis polysaccharide (ASP) on immunological colon injury and its mechanisms in rats.

METHODS: Immunological colitis model of rats was induced by intracolon enema with 2, 4, 6-trinitrobenzene sulfonic acid (TNBS) and ethanol. The experimental animals were randomly divided into normal control, model control, 5-aminosalicylic acid therapy groups and three doses of ASP therapy groups. The 6 groups were treated intracolonically with normal saline, normal saline, 5-aminosalicylic acid (100 mg·kg^{-1}), and ASP daily (8: 00 am) at the doses of 200, 400 and 800 mg·kg^{-1} respectively for 21 days 7 d following induction of colitis. The rat colon mucosa damage index (CMDI), the histopathological score (HS), the score of occult blood test (OBT), and the colonic MPO activity were evaluated. The levels of SOD, MDA, NO, TNF-α, IL-2 and IL-10 in colonic tissues were detected biochemically and immunoradiometrically. The expressions of TGF-β and EGF in colonic tissues were also determined immunochemically.

RESULTS: Enhanced colonic mucosal injury, inflammatory response and oxidative stress were observed in colitis rats, which manifested as significant increases of CMDI, HS, OBT, MPO activity, MDA and NO contents, as well as the levels of TNF-α and IL-2 in colonic tissues, although colonic TGF-β protein expression, SOD activity and IL-10 content were significantly decreased compared with the normal control (P<0.01). However, these parameters were found to be significantly ameliorated in colitis rats treated intracolicly with ASP at the doses of 400 and 800 mg·kg^{-1} (P<0.05-0.01). Meantime, colonic EGF protein expression in colitis rats was remarkably up-regulated.

CONCLUSION: ASP has a protective effect on immunological colon injury induced by TNBS and ethanol enema in rats, which was propably due to the mechanism of antioxidation, immunomodulation and promotion of wound repair.

INTRODUCTION

Angelica sinensis polysaccharide (ASP) possesses a variety of pharmacological effects including immunoregulation, anti-oxidation, anti-tumor, anti-irradiation injury, promotion of hematopoiesis[1-6]. ASP not only has regulatory effects on cytokines, complements, immunocompetent cells such as lymphocyte, macrophage but also shows manifold immunoregulation according to different organism immunological status, drug dose and drug administration surroundings; In addition, ASP has been recently found to be effective in preventing gastrointestinal injury induced by a neutrophil-dependent lesion model in rats, to promote gastrointestinal wound healing in rats *in vitro* and *vivo*[7-9].

Immunoregulation dysfunction plays a central role in the pathogenesis of inflammatory bowel disease (IBD) including Crohn' s disease and ulcerative colitis, although their etiology and pathophysiology remain to be elucidated. Immunoregulation dysfunction is mainly manifested as increased pro-inflammatory cytokines and decreased anti-inflammatory cytokines, which introduce the generation of "inflammation cascade", result in overproduction of oxygen and nitrogen reactive species, thus leading to intestinal and/or colonic injury[10-15]. Numerous studies have demonstrated that modulation of immunological disorders is an effective target for the treatment of IBD[15-19].

Based on ASP' s immunomodulatory feature with manifold efficacies, anti-oxidation property, promotion of gastrointestinal wound healing and safety in use, we therefore assumed that ASP might contribute to the treatment of IBD. To the best of our knowledge, there has been no report so far concerning the effect of ASP on IBD. The present study was to observe the effect of ASP on immunological colon injury in experimental colitis rats to test the hypothesis.

MATERIALS AND METHODS

Animals and reagents

Healthy Sprague-Dawley rats of both sexes, weighing 250±30 g, and C57BL/6J mice, weighing 20±2 g, supplied by the Animal Center of the Academy of Hubei Preventive Medical Sciences. The rats were allowed to take food and tap water *ad libitum*. ASP was isolated from angelica sinensis from Minxian County of China by water extraction and ethanol precipitation as described in the literature[4,10] and dissolved in normal saline, sanitized by high pressure before use. TNBS (Lot. 51K5001), ConA, MTT were all purchased from Sigma Co (USA). 5-aminosalicylic acid (5-ASA) was provided by Guoyi Pharmaceutical Ltd (Lot. 20029477, China). Occult blood test paper was provided by Tonyar Biotech Co (USA). Bovine serum and RPMI-1640 medium were purchased from Gibco Co (USA). Recombinant human TNF-α was provided by BangDing Biotech Co (China). Actinomycin D was provided by HuaMei Biotech Co (China). L929 cells were provided by Biological Classic Culture Store Centre of Wuhan University in China. IL-10 radioimmunoassay kits were provided by Radio-immunity Institute of PLA General Hospital in Beijing. Polyclonal rabbit anti-rat-TGF-β and EGF were purchased

from Santa Cruz Co. and Zymed Co., respectively. S-P kits were supplied by Zhongshan Biological Technology CO. Ltd in Beijng. MPO, SOD, MDA, NO detection kits were purchased from Nanjing Jiancheng Bioengineering Institute. Other reagents used in the present study were all of analytical grade.

Experimental protocol

According to the references[19,20], the rats were anesthetized with ether, then a flexible plastic rubber catheter with an outside diameter of 2 mm was inserted rectally into the colon, its tip was 8 cm proximal to the anus. TNBS (100 mg· kg^{-1}) dissolved in 50 % ethanol (v/v) was instilled into the colon lumen through the rubber cather (the final volume was 0.25 mL), saline was instilled as control. The experimental animals were randomly divided into 6 groups: normal group, model group, 5-ASA therapy group and three doses of ASP therapy groups. The 6 groups were treated intracolicly with normal saline, normal saline, 5-ASA (100 mg· kg^{-1}), and ASP daily (8:00 am) at the doses of 200, 400 and 800 mg· kg^{-1} respectively for 21 days 7 d following induction of colitis in rats. Then the colon mucosa damage index (CMDI) and the histopathological score (HS) were evaluated and the colonic tissue was sampled for a variety of determinations after the animals were sacrificed by decapitation.

Assessment of CMDI, HS and OBT

The tissue of colon 10 cm proximal to anus of the sacrificed rats was excised, opened longitudinally, washed in saline buffer, and pinned out on a wax block. The colonic tissue samples for HS were prepared according to the reference[19]. CMDI and HS in each colon were evaluated respectively by two independent observers. The assessment criteria of CMDI and HS were reported in previous literature[19]. CMID was as following: 0: normal mucosa, no damage on mucosal surface; 1: mild hyperemia and edema, no erosion or ulcer on mucosal surface; 2: moderate hyperemia and edema with erosion on mucosal surface; 3: severe hyperemia and edema with necrosis and ulcer on mucosal surface, the major ulcerative area extended less than 1 cm; 4: severe hyperemia and edema with necrosis and ulcer on mucosal surface, the major ulcerative area extended more than 1 cm. HS: (1) Infiltration of acute inflammatory cells: 0, without; 1, mild; 2, severe. (2) Infiltration of chronic inflammatory cells: 0, without; 1, mild; 2, severe. (3) Fibrin deposition: 0, negative; 1, positive. (4) Submucosal edema: 0, without; 1, focal; 2, diffuse. (5) Necrosis of epithelial cells: 0, without; 1, focal; 2, diffuse. (6) Mucosal ulcer: 0, negative; 1, positive. At the end of experiment, rat feces was collected for occult blood test (OBT) according to the instructions.

Determination of MPO, SOD activities and MDA and NO contents

The colon tissue samples taken for MPO detection were homogenized (50 g· L^{-1}) in ice-cold potassium phosphate buffer 50 mmol· L^{-1} (pH 6.0) containing 0.5 % hexadecyltrimethyl-ammoninm bromide. The homogenates were frozen and thawed three times, then centrifuged at 4 000 rpm for 20 min at 4 ℃. The level of MPO in supernatant was measured using a commercial kit according to its instructions. Other colon tissue samples were homogenized (50 g· L^{-1}) in ice-cold PBS (pH 7.4). The homogenates were centrifuged at 3 000 rpm for 10 min at 4 ℃, and the supernatant was stored at -20 ℃ until determination for SOD, MDA and NO using corresponding commercial kits according to the instructions.

Measurement of TNF-α, IL-2, IL-10 levels

The colon tissue samples were homogenized (100 g· L^{-1}) in ice-cold phosphate buffer saline (pH 7.4) containing penicillin 100 u· ml^{-1} and streptomycin 100 ug· ml^{-1}. The homogenates were centrifuged at 40 000 rpm for 10 min at 4 ℃, and the supernatant was stored at - 80 ℃ until determination for TNF-α, IL-2 and IL-10. The activity of TNF-α and IL-2 were measured by L929 cell cytotoxicity and C57BL/6J mice splenocytes using MTT colorimetry respectively as described in the literatue[19,21]. The content of IL-10 was detected by using a radioimmunoassay kit following the manufacturer's instructions.

Detection of colonic TGF-β and EGF expression

Immunohistochemical detection was performed using S-P technique. The experiment procedures were performed following the manufacturer's recommendations. Polyclonal rabbit anti-rat-TGF-β and EGF were diluted in PBS to 1:100, 1:150, and used as primary antibodies respectively. The dewaxed sections were incubated with polyclonal primary antibodies overnight at 4 ℃ after antigen repair. Biotinylated goat-anti-rabbit IgG was added as second antibody. Horseradish peroxidase labeled streptomycin-avidin complex was used to detect second antibody. Sections were stained with diaminobenzidine. Negative control sections were prepared by substituting primary antibodies with PBS. The bluely stained nucleus was considered as negative while the brown or dark brown stained cytoplasm and/or cell membrane were considered as positive. Expressions of these target proteins were semiquantitated respectively with an automatic image analyzer (Nikon, Japan) and HPIAS-2000 image analyzing program, in which the average value of positive cell's absorbance (A) in ten randomly selected high power fields (400×) for each section was used to compare the target protein expression.

Statistical analysis

Experimental results were analyzed by ANOVA and *t*-test for multiple comparisons between the groups. Data were finally expressed as mean ±SD. *P* value less than 0.05 was considered statistically significant.

RESULTS

Protective effect of ASP on colon injury

Results are shown in Table 1. CMDI, HS, OBT and MPO activity were regarded as main parameters that reflected the degree of colon injury and inflammation in inflammatory gut tissue. Compared with normal group, these parameters were significantly increased in model group ($P<0.01$). Both ASP (400, 800 mg· kg^{-1}) and 5-ASA (100 mg· kg^{-1}) could remarkably decrease these elevated parameters ($P<0.05$-0.01). Furthermore, the therapeutic effect of 800 mg· kg^{-1} ASP was as effective as that of 5-ASA (100 mg· kg^{-1}).

Table 1 Effect of ASP on CMDI, HS, OBT and MPO activity in colonic tissue of colitis rats (n=8, $\bar{x}\pm s$)

Group	Dose (mg·kg^{-1})	CMDI	HS	OBT	MPO (U·g^{-1})
Control	-	0.0±0.0	0.7±1.1	0.0±0.0	29±18
Model	-	3.1±1.1[d]	5.6±0.8[d]	2.2±0.8[d]	194±32[d]

Effect of ASP on colonic oxidation of colitis rats

Compared with normal group, the contents of MDA and NO

were significantly elevated while SOD activity was significantly decreased in model group (P<0.01). ASP (400, 800 mg· kg^{-1}) not only obviously decreased MDA content but also evidently increased SOD activity (P<0.05-0.01). Furthermore, ASP (200, 400, 800 mg· kg^{-1}) remarkably reduced the elevated NO content in a dose-dependent manner (P<0.05-0.01) (Table 2).

Table 2 Effect of ASP on activity of SOD and contents of MDA and NO in colonic tissue of colitis rats (n=8, $\bar{x}\pm s$)

Group	Dose (mg·kg^{-1})	SOD (kU·g^{-1})	MDA (nmol·g^{-1})	NO (nmol·g^{-1})
Control	-	23.16±5.13	27.41±9.66	294±73
Model	-	8.41±3.17^{d}	83.47±22.53^{d}	568±65^{d}

Effect of ASP on colonic TNF-α, IL-2 and IL-10 levels

Compared with normal group, the levels of TNF-α, IL-2 were significantly increased while the content of IL-10 was obviously reduced in model group (P<0.01). ASP (400, 800 mg· kg^{-1}) not only obviously decreased the levels of TNF-α, IL-2 but also significantly increased the content of IL-10 in model group (P<0.05-0.01) (Table 3).

Table 3 Effect of ASP on levels of TNF-α, IL-2, IL-10 in colonic tissue of colitis rats (n=8, $\bar{x}\pm s$)

Group	Dose (mg·kg^{-1})	TNF-α (kU·g^{-1})	IL-2 (A)	IL-10 (ng·g^{-1})
Control	-	30.6±12.6	0.176±0.028	43±8
Model	-	82.8±18.6^{d}	0.381±0.069^{d}	15±5^{d}
5-ASA	100	45.3±21.9^{b}	0.264±0.042^{b}	22±10

ASP	800	51.7±21.5^{b}	0.285±0.031^{b}	26±10^{a}

^{a}P<0.05, ^{b}P<0.01, *vs* model group; ^{d}P<0.01 *vs* normal group.

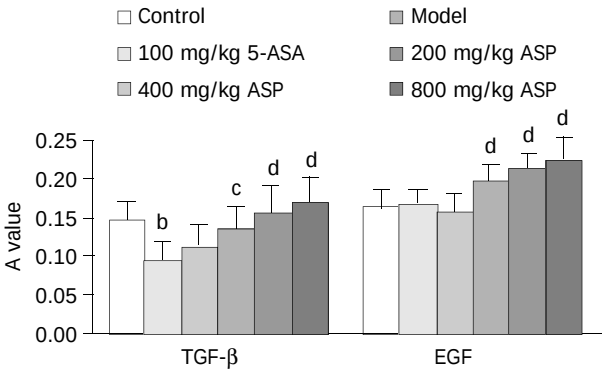

Figure 1 Effect of ASP on expressions of TGF-β and EGF in colonic tissue of colitis rats. n=8, $\bar{x}\pm s$, ^{b}P<0.01, *vs* normal control; ^{c}P<0.05, ^{d}P<0.01, *vs* model control.

Effect of ASP on colonic TGF-b and EGF expressions

As shown in Figures 1, 2 and 3, compared with normal group, TGF-β expression in model group was significantly decreased (0.096±0.021 *vs* 0.145±0.025, P<0.01) and EGF expression was hardly changed. ASP (200, 400, 800 mg· kg^{-1}) remarkably up-regulated the expressions of TGF-β and EGF in a dose - dependent manner (TGF-β: 0.132±0.031, 0.154±0.036, 0.169±0.032 *vs* 0.096±0.021; EGF: 0.197±0.021, 0.212±0.023, 0.225±0.029 *vs* 0.166±0.024, P<0.05-0.01), whereas 5-ASA (100 mg· kg^{-1}) had no obvious effect on the expressions of TGF-β and EGF.

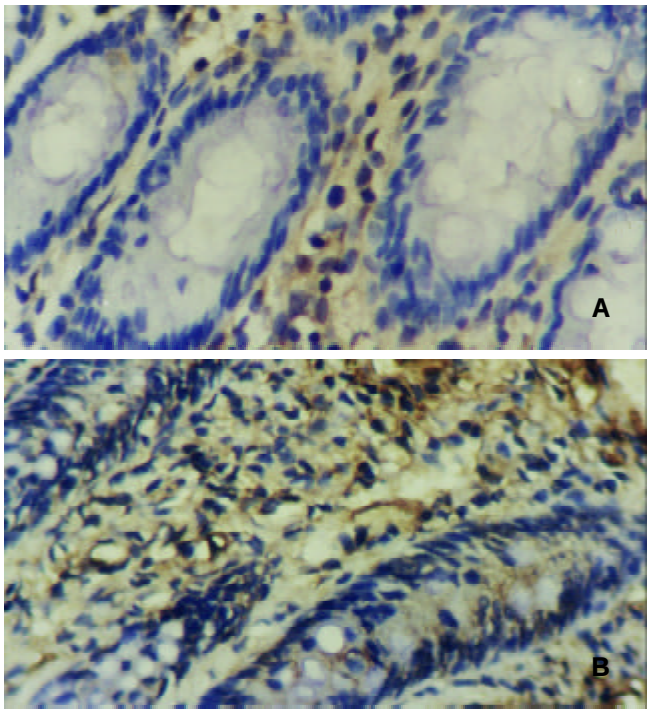

Figure 2 Expressions of TGF-β (A) and EGF (B) in inflammatory areas of colonic tissue from rats with colitis induced by TNBS and ethanol, respectively. Weakly positive signals were found. SP stain ×400.

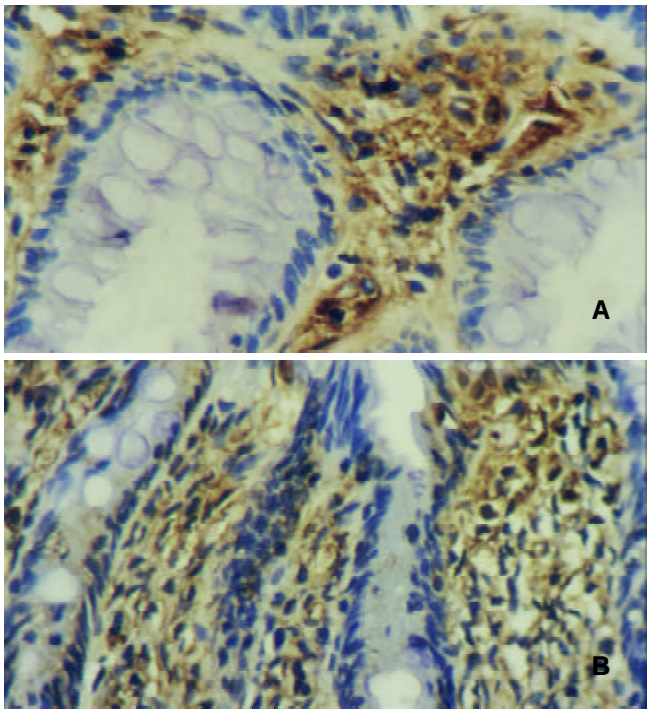

Figure 3 Significantly increaed expressions of TGF-β (A) and EGF (B) were in colonic tissue from rats with colitis induced by TNBS and ethanol after treated with 800 mg·kg^{-1} ASP. Strongly positive staining could be found. SP stain ×400.

DISCUSSION

TNBS-induced rats colitis model established by Morris *et al*

was regarded as a classic model for immunological colon injury which shares many of the histopathological and clinical features and pathogenesis of human IBD. The whole process was summarized as following: after destruction of mucosa integrity by ethanol, hapten TNBS was bound to colon tissue proteins, and changed into a modified protein compound, which was recognized by macrophages as an abnormal antigen and presented quickly to the sensitized T lymphocytes. So a series of immunoresponsiveness and severe colon inflammation were initiated subsequently[19,20]. In this study, an IBD model was successfully established, and intracolon enema with ASP showed obviously protective effects on immunological colon injury, which might be related with ASP's antioxidation property and function of balancing cytokine generation and modulating immune.

Many studies have revealed that reactive metabolites of oxygen and nitrogen were a notable characteristic of IBD, which led to the pathological aggravation of a series of free radicals chain reactions and strongly attack DNA, proteins, enzymes, biological membrances as well as disruption of the integrity and function of intestinal mucosa barrier, activaton of inflammatory mediators[22-25]. Besides direct and severe impairment of the function of intestinal barrier, excessive NO participated in complicated web system between inflammatory cells and immunocytes in IBD[12,15,22-25]. Our study showed that ASP, an anti-oxidant agent which can directly scavenge oxygen-derived free radicals, could not only remarkably decrease the elevated contents of MDA and NO, but also evidently increase the reduced SOD activity in colonic tissues of colitis rats. Reduction of NO by ASP might be related with its inhibition of nitric oxide synthase activity, which was proven by recent researches[3,4].

As the most important cytokine in "inflammation cascade" of IBD, TNF-α could directly impair gut mucosa, promote production of inflammatory mediators and oxygen free radicals, up-regulate the expression of adhesive factors. Moreover, TNF-α is also a main activator for NF-κB, a critical transcription factor, thus up-regulating many genes involved in proinflammatory and immune responses[12,15,16,26]. In this article, ASP, an immunomodulatory reagent, obviously decreased the elevated colonic TNF-α level in colitis rats. As it is known, TNF-α and NO mainly came from activated macrophages in inflammatory gut[12,19,26]. It deserves further investigation that whether inhibition of TNF-α and NO by ASP is related with its regulation of macrophage activation through the polysaccharide receptors on the surface of macrophages such as β-glucan receptor and mannose receptor[27,28].

As it is known, imbalance of type 1 helper T lymphocyte (Th1) and Th2 in IBD could promote excretion of important pro-inflammatory cytokines including TNF-α, INF-γ, and activate macrophages, which mediate inflammatory and immunological injury. Moderate IL-2 level is important for keeping the dynamic balance of Th1 and Th2 in normal gut mucosa, whereas excessive IL-2 could up-regulate the activity of Th1[29-31]. As a major anti-inflammatory cytokine mainly secreted by Th2, IL-10 could suppress inflammation by decreasing Th1 activation, reducing HLA class II expression, and diminishing production of pro-inflammatory cytokines from activated macrophages such as IL-1α, IL-1β, TNF-α and IL-8[12,32-34]. Data obtained in this study indicated that ASP could not only significantly reduce the markedly elevated IL-2 level but also increase the reduced IL-10 level in colonic tissue of colitis rats, thus partly correcting the aberrant immunological status, which might be related with the marked induction of TGF-β by ASP. As a strong immunosuppressant and anti-inflammation cytokine mainly secreted by macrophages, TGF-β plays an important role in gut local immunity in IBD. TGF-β could not only suppress the immunoresponse of Th1 in intestine, depress the activity of activated macrophages but also induce production of IL-10[12,18,34]. Investigations have demonstrated that deficiency of TGF-β in the intestine contributed to the development of IBD, whereas maintenance of TGF-β might be important in regulating immune homeostasis in the intestine[18, 35].

Besides modulating immune response, TGF-β could control cell growth, differentiation and migration, stimulate synthesis of extracellular matrix proteins, and promote angiogenesis, thus promoting wound repair and tissue reconstruction. Its functions are similar to those of cytokine EGF[36-41]. In addition, EGF could induce production of TGF-β and they showed cooperative effects[40-42]. Reseaches have proven that TGF-β and EGF were crucial for maintaining the integrity and functions of intestine mucosa barrier, and could effectively prevent and ameliorate its injury and dysfunction induced by oxidants, thus contributing to the treatment of intestinal inflammation[42-45]. Our study showed that ASP significantly increased the levels of EGF and markedly reduced TGF-β in colon tissue of colitis rats, thus accelerating repair of colon lesions, which agreed with investigations of Ye *et al*[8,9]. The underlying mechanism might be that ASP has pharmacological properties similar to heparin which can interacts with a variety of proinflammatory chemokines and growth factors, thus promoting production of many growth factors[7-9,42,47,48].

To sum up, the results of this study showed that intracolonic treatment with ASP at the doses of 400 mg·kg^{-1} and 800 mg·kg^{-1} could obviously attenuate experimental immunological colon injury in rats, suggesting that ASP in combination with well-established drugs, may contribute to the optimal therapy of IBD.

Abstract

AIM: Irritable bowel syndrome (IBS) is a functional bowel disorder characterized by visceral hypersensitivity and altered bowel motility. There is increasing evidence suggesting the role of inflammation in the pathogenesis of IBS, which addresses the possibility that formerly established rat model of colitis could be used as an IBS model after the inflammation subsided.

METHODS: Colitis was induced by intracolonic instillation of 4 % acetic acid in male Sprague-Dawley rats. The extent of inflammation was assessed by histological examination and myeloperoxidase (MPO) activity assay. After subsidence of colitis, the rats were subjected to rectal distension and restraint stress, then the abdominal withdrawal reflex and the number of stress-induced fecal output were measured, respectively.

RESULTS: At 2 days post-induction of colitis, the colon showed characteristic inflammatory changes in histology and 8-fold increase in MPO activity. At 7 days post-induction of colitis, the histological features and MPO activity returned to normal. The rats at 7 days post-induction of colitis showed hypersensitive response to rectal distension without an accompaning change in rectal compliance, and defecated more stools than control animals when under stress.

CONCLUSION: These results concur largely with the characteristic features of IBS, visceral hypersensitivity and altered defecation pattern in the absence of detectable disease, suggesting that this animal model is a methodologically convenient and useful model for studying a subset of IBS.

INTRODUCTION

Irritable bowel syndrome (IBS) is defined as a group of functional bowel disorders in which abdominal discomfort or pain is associated with defecation or a change in bowel habit in the absence of an identifiable disease process[1]. Clinical observations have revealed that patients with IBS show a disturbed colonic motor function and hypersensitivity to luminal distension, and these symptoms are generally accepted as cardinal features of IBS[2].

Although IBS is known as one of the most common disorder encountered in clinical practice[3], progress in the study of IBS in the basic scientific research fields has been hindered largely due to the lack of useful animal models that mimic the features of IBS[4]. Since the pathophysiological processes involved in IBS are multifactorial, researchers have employed various kinds of symptom-generating stimulus to establish animal models of IBS. These include a stressful event in adult animals[5], a chemical or mechanical irritation of colon in early life[4], and neonatal maternal separation[6].

Recently, attention has been directed to the role of inflammation in the pathogenesis of IBS[3,7], and IBS after enteric infection, namely post-infectious IBS has begun to be studied using rodent models experimentally infected with *Nippostrongylus brasilensis*[8] or *Trichinella spiralis*[9]. The infected animals underwent jejunitis and showed altered intestinal motor function or hypersensitivity to luminal distension even after the pathogens were eliminated. These inspiring reports addressed the possibility that the well-characterized rodent models of colitis could also exhibit some features of post-infectious IBS after resolution of colitis or, at least, in a certain period of time during the recovery course.

In the present study, we examined this possibility using one of the extensively studied rodent models of acute colitis, the rat model of acetic acid-induced colitis. Specifically, we aimed to find out whether the animal could show visceral hypersensitivity to rectal distension and altered defecation pattern under stress after the subsidence of colitis.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats (270-310 g) were housed individually in an access-restricted room with controlled temperature (23 ℃) and light-dark cycles (12:12 h). All the experimental protocols in this study were reviewed and approved by the Animal Care and Use Committee of Seoul National University.

Induction of colitis

After an overnight fast, the rats were lightly anesthetized with ether, and colitis was induced by intracolonic instillation of 1 ml 4 % acetic acid (Fluka, Buchs SG, Switzerland) at 8 cm proximal to the anus for 30 s. Then, 1 ml phosphate buffered saline was instilled to dilute the acetic acid and flush the colon. Control animals were handled identically except that 1 ml saline was instilled instead of 4 % acetic acid.

Myeloperoxidase (MPO) activity assay

MPO activity assay was performed to quantify the inflammation in distal colon according to the procedure described previously[10]. Sixteen rats (4 animals at 2 and 7 days post-

enema in each group) were used for this study. These two time-points were selected according to previous reports[10,11] to represent the overt inflammatory phase and the subsiding phase, respectively. Briefly, an 8 cm segment of distal colon was collected via laparotomy, minced in 1 ml of 50 mM potassium phosphate buffer (pH 6.0) containing 14 mM hexadecyltrimethylammonium bromide (Fluka), homogenized and sonicated. The lysates were frozen and thawed three-times, then centrifuged for 2 min in cold at 15 000 g. Aliquots of the supernatants were mixed with potassium phosphate buffer containing *o*-dianisidine-HCl (Sigma-Aldrich, St. Louis, MO, USA) and 0.0005 % H_2O_2. The change in absorbance at 460 nm was spectrophotometrically measured. MPO activity was expressed as units/g of wet tissue. The enzyme unit was defined as the conversion of 1 μmol of H_2O_2 per min at 25 ℃.

Histological examination of inflammation

To examine the extent of colonic inflammation, histological samples were collected at the selected time points. Sections with a thickness of 5 μm were cut and processed for hematoxylin-eosin staining. The coded slides were analyzed by a pathologist blinded with regard to the treatment group and the time points.

Rectal distension procedure

At 7 days post-enema, eight rats from each group were used for studying visceral sensitivity to rectal distension. A disposable silicon balloon-urethral catheter for pediatric use (6 Fr, Sewoon Medical Co., Seoul, Korea) was used for this purpose. The maximal inflation volume for the balloon was 1.0 ml and the length of the maximally inflated balloon was 1.2 cm. After an overnight fast, the animals were lightly anesthetized with ether, and the balloon was carefully inserted into the rectum until the pre-marked line on the catheter (2 cm distal from the end of the balloon) was positioned to the anus, then the catheter was taped to the base of the tail to prevent displacement. After this procedure, the rats were placed in a transparent cubicle (20 cm×8 cm×8 cm) on a mirror-based elevated platform while still sedated, and were allowed to recover and acclimate for a minimum of 30 min before testing. The catheter was connected to a pressure transducer (RP-1500, Narco Bio-systems Inc., USA) via a 3-way connector, and a non-invasive pulse transducer (MLT125R, AD Instruments, Castle Hill, Australia) was attached so that the active site of the transducer was located on the ventral surface of the tail, directly below the caudal artery. The signals from both transducers were processed through PowerLab/400 (AD Instruments) and recorded on an IBM-compatible computer.

After the animals were fully awaken and acclimatized, ascending-limit phasic distension (0.1, 0.2, 0.3, 0.4, 0.6, 0.8 and 1 ml) was applied for 30 s every 4 min. The balloon was distended with pre-warmed (37 ℃) water. We chose this protocol as hypersensitivity was reported to be best elicited by rapid phasic distension[2]. In this experiment, the abdominal withdrawal reflex (AWR) was semiquantitatively scored as previously described[4] and the concomitant change in arterial pulse rate was measured. The AWR score was assigned as follows: 0=no behavioral response to distension, 1=brief head movements followed by immobility, 2=contraction of abdominal muscle without lifting of abdomen, 3=lifting of abdomen, 4=body arching and lifting of pelvic structure.

After the experiments, the balloon was withdrawn and immersed in 37 ℃ tap water. Since the compliance of balloon was not infinite, we measured intraballoon pressure at each distension volume in 37 ℃ water, and digitally subtracted the value from that recorded during the rectal distension experiment to calculate the intrarectal pressure.

Restraint stress procedure

Fifteen animals of each group were used for this experiment. The rats were housed individually with no restrictions on food intake before testing. At 7 days post-enema, ten rats of each group were placed in restraint cages (5 cm×5 cm×20 cm) for 1 hr at room temperature. The feces excreted during restraint stress were divided into three types: hard pellet, soft pellet and formless stool, and counted separately. In another experiment, five rats of each group were left to be unrestrained for 1 hr and served as unstressed control. All the experiments were performed between 1 000 and 1 200 h.

Statistical analyses

Data were expressed as mean ± SD. Significant difference between the two groups in MPO activity at the selected time-points and in the values (AWR score and the pulse rate change) at each distension volume was statistically analyzed using Mann-Whitney U-test with P value set at <0.05 significance level. The relationship between AWR score and the extent of pulse rate change was determined by linear regression analysis, and the estimated slope coefficients and intercepts were compared between groups using Student' s t-test at 2N-4 (N=the number of data points) degrees of freedom (*d.f.*). The intraballoon volume-intrarectal pressure relationship of each group was also analyzed as above. The number of fecal output was compared using ANOVA and further analyzed using Newman-Keuls multiple comparison test, and considered significantly different from others when $P<0.05$.

RESULTS

Histological features and MPO activity

Figure 1 represents the histology of the distal colon in control (A), at 2 days (B) and at 7 days (C) post-induction of colitis (PIC). At 2 days PIC, mucosal hemorrhage with an inflammatory infiltrate in lamina propria and the edematous submucosa was observed. On the other hand, there was no remarkable inflammatory feature at 7 days PIC. Similar result was obtained from the MPO activity assay of colonic tissue. As shown in Figure 2, the enzyme activity was dramatically increased (8-fold) at 2 days PIC (P=0.0015, n=4), however it was not significantly different from the control value at 7 days PIC ($P>0.5$, n=4). These results indicated that at 7 days PIC, acute colonic inflammation was in subsiding phase.

Rectal distension-induced visceral nociception

Animals awaken in the cubicle showed regular arterial pulse after about 30 min acclimation. The pulse rate was 345.6±6.2 beat per minute (BPM) in control group (n=8) and 329.7±7.3 BPM in the 7 days PIC group (n=8), and the resting pulse rates of the two groups were not significantly different from each other. Pulse rate was instantly increased as the balloon inflated in the rectum and returned to nearly the resting level as it deflated. Animals at 7 days PIC showed hypersensitive response to the ascending-limit phasic rectal distension. The nociceptive threshold (distension volume that produced the AWR of score 2, i.e., abdominal contraction) was about 0.6 ml in the control group, and it was lowered to around 0.3 ml in the 7 days PIC group. The AWR score in rats at 7 days PIC was generally higher than that in control animals, which shifted the distension volume-response curve to left (Figure 3A). In addition, the extent of rectal distension-induced tachycardia was also significantly increased in the 7 days PIC group (Figure 3B).

We further analyzed these results by determining the relationship between the AWR score and the extent of pulse rate change (D pulse rate). The mean value with its standard error of D pulse rate at a given AWR score was plotted in

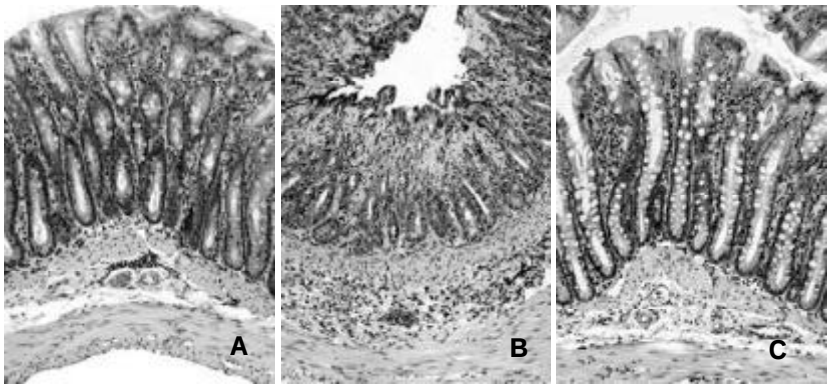

Figure 1 Photomicrographs of distal colons from control (A), at 2 days (B) and at 7 days (C) post-induction of colitis (PIC). At 2 days PIC, histological inflammatory features including mucosal hemorrhage, submucosal edema, and inflammatory infiltration in the lamina propria and the submucosa were observed. At 7 days PIC, there was no remarkable inflammatory feature compared with control.

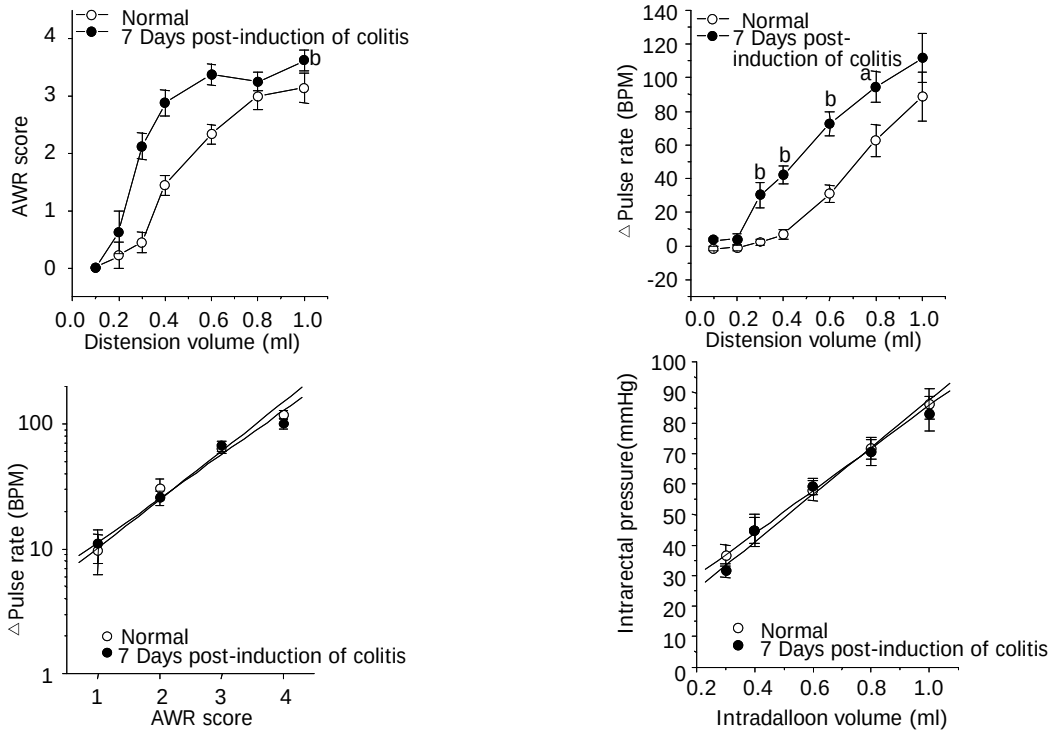

Figure 3 Summarized plots representing the rectal distension-induced AWR (A) and concomitant pulse rate change (B), the relationship between the AWR score and the extent of pulse rate change (C), and the relationship between intraballoon volume and intrarectal pressure (D) in each group. At 7 days PIC, AWR and tachycardia were exaggerated in response to rectal distension. Note the good linear correlation between the AWR score and the logarithmic D pulse rate, which was not significantly different between groups. Intrarectal pressure was linearly increased as the balloon inflated, and the fitted functions of two groups were not significantly different from each other. ($^aP<0.05$, $^bP<0.01$).

logarithmic scale for a linear fit. As shown in Figure 3C, there was a good linear correlation between the AWR score and the logarithmic D pulse rate (r=0.99, P<0.008 in control; r=0.99, P<0.007 in the 7 days PIC group). The fitted functions of two groups were not significantly different from each other (slope coefficient: 0.39±0.03 in control *vs*. 0.35±0.01 in the 7 days PIC group (P>0.45, *d.f.*=4), intercept: 0.62±0.07 in control *vs*. 0.69±0.06 in the 7 days PIC group (P>0.43, *d.f.*=4)). This implied that scoring the AWR in the present study was a reliable method to quantify the animal' s nociceptive response to rectal distension.

In order to examine whether the visceral hypersensitivity in rats at 7 days PIC was related to changes in rectal compliance, we compared the intraballoon volume-intrarectal pressure relationship of the two groups. The distension volume from 0.3 ml to 1.0 ml and the corresponding value of calculated intrarectal pressure (refer MATERIALS AND METHODS) were plotted for regression analysis (Figure 3D). Intrarectal pressure was linearly increased as the balloon inflated (r>0.99, P<0.0001 in control; r=0.99, P=0.0015 in the 7 days PIC group). The fitted functions of the two groups were not significantly different from each other (slope coefficient: 69. 83±0.99 in control *vs*. 77.46±6.81 in the 7 days PIC group (P>0. 3, *d.f.*=6), intercept: 15.94±0.64 in control *vs*. 10.15±3.67 in the 7 days PIC group (P>0.17, *d.f.*=6)).

Restrain stress-induced defecation

As shown in Figure 4, the number of fecal pellet output for 1 hr was negligible in unrestrained animals regardless of the treatment. However, restraint stress significantly increased defecation. The restrained control rats defecated 2.1±0.9 hard pellets, 1.9±0.4 soft pellets, 1.2±0.4 formless stool and a total

of 5.2±0.5 feces in 1 hr (n=10). Comparatively, animals at 7 days PIC group defected 4±0.9 hard pellets, 3±0.6 soft pellets, 2.7±0.6 formless stool and 9.7±0.8 feces in total during the 1 hr restraint stress (n=10). The number of formless stool and the total number of fecal output during 1 hr restraint stress in the 7 days PIC group were significantly larger than the corresponding values in control rats, which implied that the stress-induced increase in colonic motor function was enhanced in rats at 7 days PIC group.

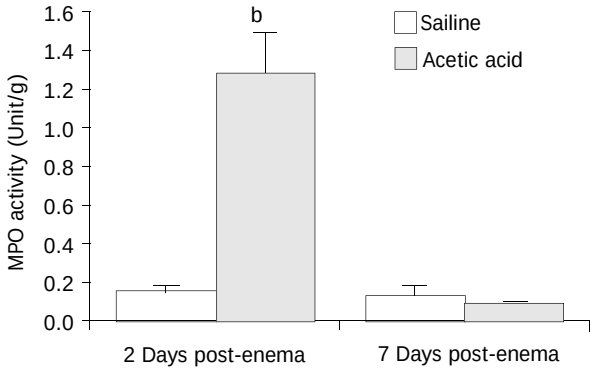

Figure 2 Tissue MPO activity at 2 and 7 days post-induction of colitis (PIC). MPO activity was increased about 8-fold at 2 days PIC. No statistically significant difference was detected between the saline-instilled and the acetic acid-instilled groups at day 7. (^bP<0.01).

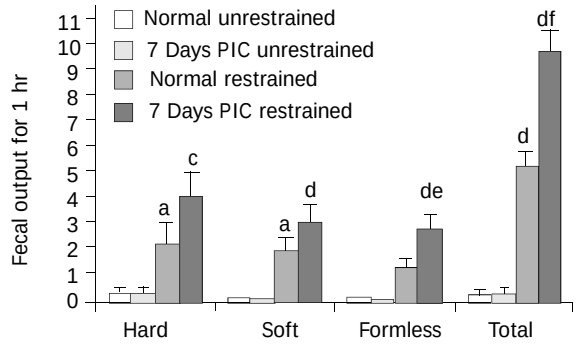

Figure 4 Restraint stress-induced defecation. The number of formless stool and the total number of defecation during 1 h restraint stress in the 7 days PIC group were significantly larger than the corresponding values in control rats. (^aP<0.05 restrained *vs*. unrestrained in control; ^bP<0.01; ^cP<0.05 restrained *vs*. unrestrained in 7 days PIC group; ^dP<0.01; ^eP<0.05 restrained 7 days PIC group *vs*. restrained control group; ^fP<0.01).

DISCUSSION

In human study, patients with ulcerative colitis were reported to show visceral hypersensitivity even when their disease was in quiescent state[12]. In the present study, we found that 7 days after the acetic acid-induced colitis subsided, the rats still showed visceral hypersensitivity, a generally accepted common feature of patients with IBS. Moreover, the rats at 7 days PIC defecated more stools in response to restraint stress than control animals, which was in good accordance with the clinical observations reporting the higher incidence of urgency to defecate and altered stool pattern under stress in IBS patients[13]. These results suggested that along with the previously reported parasite-infected rat models, acetic acid-induced colitis model could be used for the study of a subset of IBS that developed from intestinal inflammation (post-inflammatory IBS).

Indeed, it was well documented that colitis caused motility alteration and visceral hypersensitivity in various models. For instance, trinitronbenzene sulfonic acid (TNBS)/ethanol-induced colitis lowered the threshold for colorectal distension-induced visceromotor reflex at 3 days post-enema[14], and progressively altered colonic muscle function[15]. Similarly, acetic acid-induced colitis increased visceromotor response to colorectal distension at 6 and 24 h post-enema[16], and decreased colonic circular muscle contractility[17]. However, these studies mainly dealt with the alterations in acute or overt inflammatory phase, and few studies focused on the response of the animals with ‘ once’ inflamed colon.

Advantages of our model as a post-inflammatory IBS model include not only a relatively short period required for the subsidence of inflammation but also an easy access to the affected sites, i.e., rectum and colon, which make it possible to measure behavioral and pseudoaffective responses in the awake animals. In the nematode-infected IBS models, the affected site is jejunum to which anesthesia and surgical procedures are required to access for experiments. Another potential advantage is a large body of literatures reporting the pathophysiological mechanisms of alterations occurred during active colitis. Scrutinizing those reports might help to find the pivotal inflammatory changes that induce the IBS symptoms.

The reasons for the exaggerated responses to rectal distension and restraint stress in our model have been unclear, but at least, it seemed not related to changes in rectal compliance since the intraballoon volume-intrarectal pressure relationship was not different between the groups. It was noteworthy that mast cells were found to be increased in a group of IBS patients[3], and partially mediate functional disorder in the *N. brasiliensis*-infected rat model of post-infectious IBS[8]. We are currently investigating whether mast cell also plays a role in the post-colitis IBS features in rat.

In summary, we found that the rat model of acetic acid-induced colitis showed major features of IBS after subsidence of the acute inflammation in colon. The results suggest that this model has several advantages as a useful model of post-inflammatory IBS.

Abstract

AIM: To explore the relationship between clinical findings of patients with chronic liver diseases and the pathologic grading and staging of liver tissues.

METHODS: The inflammatory activity and fibrosis of consecutive liver biopsies from 200 patients were determined according to the diagnosis criteria of chronic hepatitis in China established in 1995. A comparative analysis was carried out for 200 patients with chronic liver diseases by comparing their clinical manifestations, serum biochemical markers with the grading and staging of liver tissues.

RESULTS: It was revealed that age, index of clinical symptoms and physical signs were obviously relevant to the pathologic grading and staging of liver tissues ($P<0.05$). Blood platelet, red blood cells, aspartate aminotransferase (AST), N-terminal procollagen III (PIII NP) were apparently correlated with the degree of inflammation. PGA (prothrombin time, GGT, apoprotein A1) index, PGAA (PGA+△2-macroglobublin) index, albumin and albumin/globulin were relevant to both inflammation and fibrosis. Hyaluronic acid (HA) was an accurate variable for the severity of hepatic inflammation and fibrosis. The combination of serum markers for fibrosis could increase the diagnostic accuracy. It was notable that viral replication markers were not relevant to the degree of inflammation and fibrosis.

CONCLUSION: There is a good correlation between clinical findings and the pathologic grading and staging of liver tissues, which may give aid to the noninvasive diagnosis of liver fibrosis.

INTRODUCTION

Liver fibrosis is a common sequel to diverse liver injuries. It is characterized by an accumulation of interstitial collagens and other matrix components[1-4]. Chronic liver diseases usually develop into liver cirrhosis through the phase of liver fibrosis[5-8]. In recent years, researchers have been making efforts to study the noninvasive diagnostic methods of liver fibrosis[9-15]. Through a multi-center study, we carried out a comparative analysis of 200 patients with chronic liver diseases by comparing their clinical manifestations, serum biochemical markers with histopathological findings in liver biopsy, in order to appraise the relationship between clinical findings of patients with chronic liver diseases and the grading and staging of liver tissues, and to provide clues and basis for the noninvasive diagnosis of liver fibrosis.

MATERIALS AND METHODS

Patients recruitment

The study was organized and carried out by Shanghai Cooperative Group of Hepatic Fibrosis Project. The Cooperative Group was led by Renji Hospital and Changhai Hospital in Shanghai. Cases provided by the Cooperative Group were as follows: 37 from Changhai Hospital, 36 from Renji hospital, 30 from Putuo District Central Hospital, 22 from Shanghai Hepatic Disease Center of Nanjing Military Command, 20 from Changzheng Hospital, 14 from Zhongshan Hospital, 11 from Huashan Hospital, 9 from Shibei Hospital, 8 from Shanghai No. 6 People' s Hospital, 6 from Shanghai Infectious Diseases Hospital, 3 from Ruijin Hospital, 3 from Shanghai No. 9 People' s Hospital, 1 from Shanghai No. 1 People' s Hospital. A total of 200 patients between July and October 1999 were recruited, including 156 male and 44 female patients. The average age of the patients was 34 years (range 15-60 years).

Histological examination

Within 1 week after admission, all the patients received liver puncture biopsy under the guidance of B ultrasound with the 14G quick-cut needle (8-light Company, Japan) or Menghini needle. The length of liver specimens was just 1 cm or longer. The samples were fixed with 10 % formaldehyde, embedded in paraffin and sliced, stained with hematoxylin-eosin, reticular fibers and collagenous fibers. According to the prevention and

treatment program for virus hepatitis set up in 1995[16], all the patients were graded and staged for liver fibrosis and inflammatory activity. Three pathologists read the slides, respectively. The results were statistically analyzed with Kappa test. It was revealed that the consistency of the grading and staging by the pathologists was excellent. All the pathologic diagnoses of liver biopsy were performed by Department of Pathology, Medical College of Fudan University.

Clinical data

General data The general data included age (-25, 25-35, 35-), course of disease (from the time when hepatic symptoms or abnormal laboratory parameters appeared for the first time to the present study) and gender.

Degree of hepatitis The degree of hepatitis was clinically evaluated according to the criteria recommended at the meeting of prevention and treatment of viral hepatitis held in 1995.

Clinical symptoms According to the severity of clinical symptoms such as fatigue, inappetence, swelling, nausea, ache in hepatic region and gingival bleeding, it was scored as 0: no symptom, 1:with one kind of mild symptoms, 2: with one kind of symptoms between mild and severe, 3: with one kind of serious symptoms. It was further divided into 3 grades according to the totaled score: mild: 0-1, moderate: 2-3, severe: $\geqslant$4.

Physical signs According to the degree of hepatomegaly and splenomegaly, it was scored as 0: no hyperplasia (maximal oblique diameter of the right liver <14 cm, thickness of the spleen <4.0 cm); 1: with hepatomegaly (maximal oblique diameter of the right liver >14 cm); 1.5: with mild splenomegaly (thickness of the spleen was between 4-6 cm); 3: with splenomegaly above moderate degree (thickness of the spleen $\geqslant$6.0 cm). It was further divided into 4 grades according to the totaled score: 0: no hyperplasia, 1:hepatomegaly, 1.5: mild splenomegaly, and $\geqslant$2.5: splenomegaly above moderate degree or both splenomegaly and hepatomegaly.

Laboratory parameters

Routine blood test Red blood cells (RBC), white blood cells (WBC) and platelets (PLT) were counted.

Biochemical blood test Total serum bilirubin, AST, ALT, AST/ALT, GGT, albumin (A), albumin (A)/globulin (G), γ-globulin, prothrombin time (PT), apoprotein A1(ApoA1), α2-macroglobulin and α-fetoprotein(AFP) were detected. Among them, PT, GGT and Apo-A1 were integrated as PGA index. PGA and α2-macroglobulin were integrated as PGAA index.

Serum viral markers HBsAg, HBeAg, anti-HBe, anti-HBc, HBV-DNA, anti-HCV and HCV-RNA were detected.

Serum fibrosis parameters Hyaluronic acid (HA), lamilin (LN), N-terminal procollagen III(PIII NP), 7S collagen IV(7S-IV) were included.

Statistical analysis

Analysis of variance was carried out for all the data with SAS software. $P<0.05$ was considered statistically significant.

RESULTS

Relationship between general data and pathological grading and staging of liver tissues

It was revealed that there was a significant difference in inflammatory activity and fibrosis among different age groups (-25, 25-35, 35-) ($P<0.05$). With the increase of age, the degree of fibrosis became more severe. However, there was no significant difference in inflammatory activity and fibrosis between different courses of disease (-1 year, 1-5 years, 5-years) and sexes ($P>0.05$).

Relationship between clinical manifestations and pathological staging of liver fibrosis

The statistical results indicated that there was a significant difference between the severity of hepatitis and inflammatory grading, and fibrosis staging of liver tissues ($P<0.01$) (Table 1).

The symptom accumulation score at different stages of liver fibrosis was significantly different ($P<0.05$). With the increase of score, liver fibrosis tended to be more serious. However, there was no difference between symptom score and inflammatory grading. Statistical analysis of single symptom indicated that only nausea and gingival bleeding had a significant differnce at different stages of liver fibrosis ($P<0.05$ and $P<0.01$, respectively).

Among different groups of inflammatory grading and fibrosis staging, the score of physical signs differed significantly ($P<0.05$), with the increase of score, inflammatory and fibrosis became more serious.

When symptom score and physical signs were combined for a further analysis, all the subjects were divided into 6 groups (Table 1). There were correlations between the inflammatory activity and fibrosis staging, and the differences among different groups were significant ($P<0.01$).

Relationship between biochemical parameters and inflammatory grading and fibrosis staging

The relationship between each single parameter and inflammatory grading and fibrosis staging is shown in Table 2.

From Table 2 we could find that the main biochemical parameters related only to inflammatory grading were RBC, PLT, AST, and PIIINP. With inflammation becoming serious, RBC and PLT tended to decrease, while the level of AST and PIIINP tended to increase. GGT, A, A/G, HA, 7S-IV and AFP were correlated with both inflammation grading and fibrosis staging, with the inflammation and fibrosis becoming more serious. A and A/G tended to decrease, while GGT and AFP tended to increase. There was no significant difference in PT at different stages and grades.

Table 1 Relationship between clinical manifestations and pathological grading and staging of liver tissues

Groups	Symptom score+physical signs	*n*	Inflammatory grading (G) (%)				Fibrosis staging (s) (%)

PGAA+7S-IV	60.0	48.22	50.67	92.94	33.33	89.0

Relationship between PGA, PGAA index and pathological staging and grading

PGA score had a relationship with inflammation and fibrosis ($P<0.01$, $P<0.05$ respectively). Its sensitivity and accuracy for the diagnosis of liver fibrosis were 70.33 % and 67.33 %, respectively, both of which were higher than those for early liver cirrhosis (50.00 % and 57.14 %, respectively). PGAA also correlated with inflammation and fibrosis ($P<0.05$), the sensitivity and accuracy for the diagnosis of liver fibrosis were 63.74 % and 63.37 %, respectively, both of which were higher than those for early liver cirrhosis (33.33 % and 61.64 %, respectively).

Relationship between serum parameters of liver fibrosis and pathological grading and staging

With discriminatory analysis method, we evaluated the significance of assaying single or combined serum parameters of liver fibrosis, in the diagnosis of liver fibrosis and cirrhosis (Tables 3 and 4).

Relationship between viral markers and pathological staging and grading

The statistical results revealed that there was no relationship between viral replication parameters and degrees of inflammation and fibrosis.

DISCUSSION

This study suggested that age was correlated with inflammatory activity, but the course of disease did not. Maybe it is because most of the patients were unaware of the disease, but the course of disease was always calculated from the time when symptoms appeared or people saw a doctor. It could not reflect the course accurately. So it was difficult to discover the relationship between fibrosis severity and the course of the disease[9,13,15].

With the integral method, we scored the severity of symptoms quantitatively, classified the total score, which could reflect the symptom severity comprehensively. The results indicated that there was no correlation between symptom score

and inflammatory activity (P>0.05), but the score correlated with fibrosis stage significantly (P=0.0106). With the symptoms becoming more prominent, fibrosis became more serious. At the same time, it was found that the score of physical signs had a strong relationship with inflammatory activity and fibrosis severity (P<0.05). The higher the physical sign score was, the more serious the inflammatory activity and fibrosis were. When the difference became more significant, the symptoms and signs were combined (P<0.01).

This study indicated that at different fibrosis stage and inflammatory grade of liver tissues, the serum level of HA differed remarkably (P<0.01), which could serve as a sensitive and accurate parameter to identify the severity of hepatic inflammation and fibrosis[17-20]. In addition, HA was a specific and accurate parameter for the diagnosis of early liver cirrhosis, the specificity and accuracy were 90 % and 85 %, respectively. It was also found that PIIINP differed at the different inflammatory grades significantly (P<0.01), but not significantly at different fibrosis stages (P<0.05), indicating that its correlation with inflammatory severity was closer than that with fibrosis. Thus it might be of significance in determining the inflammatory severity.

One conclusion that differs from others is that this study did not agree with the significance of LN in the diagnosis of liver fibrosis. It has been claimed that the diagnostic efficiency would increase when HA was assayed in combination with other parameters, yet it needs to be proved[21-28].

Based on the relationship between a single biochemical parameter and inflammation and fibrosis, we found that PLT, RBC and AST were important in identifying inflammatory severity rather than fibrosis. They differed significantly at grades 1, 2, 3 and 4, so they could help estimate the severity of inflammation. With the inflammation becoming serious, RBC and PLT tended to decrease. Both A and A/G ratio correlated with inflammation and fibrosis, and could be used to identify the severity. Additionally, our study proved that the level of AFP differed significantly at different inflammatory grades and fibrosis stages (P<0.01), indicating that it correlated with inflammation and fibrosis closely, and could be used as an adjuvant parameter[29-32].

PGA (PT, GGT, and ApoA1) and PGAA(PGA+α2-macroglobulin) index were mainly used as liver function indicators put forward in the early 1990' s by some experts to reflect the liver function of patients with alcoholic liver disease, and to screen or diagnose liver cirrhosis[9,33-38].

In recent years, researchers in China have probed into applying PGA index or combining it with other serum parameters to the diagnosis of liver cirrhosis. To some extent, the results of our study are in accordance with the conclusion that both PGAA and PGA correlated with inflammation and fibrosis significantly. However, when the foreign criteria were used, the score of ApoA1 in most normal samples were 4, which were too high, resulting in the increase of total PGA and PGAA scores. Therefore, we considered it abnormal when PGA score was above 6. This difference might be due to the following reasons. First, there was an ethnic difference in the normal range of ApoA1, so it is necessary to set up PGA and PGAA criteria applicable in China. Second, the two parameters were mainly used in alcoholic liver diseases, but most of the patients in our study were viral hepatitis[13-15,17,35,36,39,40].

Our study indicates that, viral replication parameters such as HBeAg and HBV DNA have no correlation with the severity of inflammation and fibrosis. We compared the inflammatory and fibrotic severity in patients with positive markers of hepatitis B only (141 cases) and in those with positive markers of both hepatitis B and C (10 cases), but no statistical difference was found between them. However, as the patients suffering from co-infection of hepatitis B and C were very few in the study, the conclusion needs to be verified by larger sample studies.

Abstract

AIM: Little has been known about the pathogenesis of non-erosive reflux disease (NERD). Recent studies have implicated interleukin 8 (IL-8) in the development and progression of gastroesophgeal reflux disease (GERD). The purpose of this study was to determine IL-8 RNA expression levels in NERD patients with or without subtle mucosal changes.

METHODS: We studied 26 patients with NERD and 13 asymptomatic controls. Biopsy sample was taken from the esophagus 3 cm above the gastroesophageal junction and snap frozen for measurement of IL-8 mRNA levels by real-time quantitative polymerase chain reaction (PCR). We also examined mRNA expression of IL-8 receptors, CXCR-1 and -2 by reverse transcriptase PCR. The patients were endoscopically classified into grade M (mucosal color changes without visible mucosal break) and N (neither minimal involvement nor mucosal break) of the modified Los Angeles classification.

RESULTS: The relative IL-8 mRNA expression levels were significantly higher in esophageal mucosa of NERD patients than those of the controls. There was a significant difference in IL-8 mRNA levels between grade M and N. The CXCR-1 and -2 mRNAs were constitutively expressed in esophageal mucosa.

CONCLUSION: Our results suggest that high IL-8 levels in esophageal mucosa may be involved in the pathogenesis of NERD through interaction with its receptors. NERD seems to be composed of a heterogeneous population in terms of not only endoscopically minimal involvement but also immune and inflammatory processes.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is one of the most common chronic disorders in modern humans. In the United States, 44 % of the adult populations reported experiencing heartburn at least once a month, 14 % on a weekly basis, and 7 % daily[1]. Esophageal erosions are the characteristic lesions of GERD seen on endoscopy[2]. A small number of GERD patients develop stricture, Barrett's esophagus and adenocarcinoma of the esophagus. In fact, the majority of GERD patients have endoscopically normal-appearing esophageal mucosa; this group is termed non-erosive reflux disease (NERD) or endoscopy-negative reflux disease[2,3].

The Los Angeles (LA) classification is widely used for endoscopic assessment of GERD[4]. The slightest degree of esophagitis, i.e., grade A, is defined as one or more mucosal breaks confined to the mucosal folds, each no longer than 5 mm. Accordingly, this classification scheme ignores subtle mucosal damage in the absence of mucosal breaks. In this regard, Hoshihara *et al*.[5,6] have proposed a modified LA system, in which grade O was subdivided into M and N, based on the concept of mucosal color changes. Thus, NERD patients can be classified into two subgroups (grade M and N) based on minimal esophageal involvement during endoscopy.

Recently, several studies have shown that mucosal immune and inflammatory responses, characterized by specific cytokine and chemokine profiles, may determine the diversity of esophageal phenotypes of GERD[7-9]. Of note, Fitzgerald *et al*.[7] reported significantly higher expression levels of interleukin 8 (IL-8) messenger ribonucleic acid (mRNA) in patients with reflux esophagitis (RE), assessed by competitive reverse transcriptase polymerase chain reaction (RT-PCR), compared with subjects with non-inflamed or Barrett's esophagus. Studies from our laboratories have also demonstrated high IL-8 protein levels in esophageal biopsy samples of patients with erosive esophagitis by enzyme linked immunosorbent assay (ELISA)[8]. Furthermore, we also showed significantly high mucosal IL-8 production, which paralleled the endoscopic severity of RE[8]. However, little has been known about the role of IL-8 in NERD.

The aim of the present study was to assess esophageal expression levels of IL-8 mRNA in NERD patients by quantitative real-time PCR procedure, with special reference to the difference between grade M and N subgroups of the modified LA scheme.

MATERIALS AND METHODS

Subjects and samples

We studied 26 patients with NERD and endoscopically confirmed normal-appearing esophageal mucosa who visited

the Outpatient Department between August 2002 and July 2003. They included 19 men and 7 women, aged between 28 and 80 years (mean, 62.0 years). The diagnosis of GERD was made with more than 6 points in the questionnaire for the diagnosis of reflux disease (QUEST) described by Carlsson *et al*[10]. None of these patients had been treated with non-steroidal anti-inflammatory drugs, proton pump inhibitors, histamine H_2-receptor antagonists, anti-cholinergic agents or antibiotics within 4 weeks prior to the present study. Furthermore, patients with severe concomitant diseases, prior esophageal or gastric surgery, peptic ulcer diseases and comorbid conditions that might interfere with esophageal or gastric motility including diabetes mellitus, systemic sclerosis and neurological disorders were excluded. As a control group, we recruited 13 asymptomatic subjects with no hiatal hernia or any lesions in the esophagus, stomach and duodenum at endoscopy for a health check-up.

In each case, a biopsy specimen was obtained from the esophageal mucosa, 3 cm above the gastroesophageal junction[8], snap-frozen in an ethanol-dry ice mixture for quantitative analysis of IL-8 mRNA expression and stored at -80 ℃ until use.

Endoscopic assessment of NERD

NERD was endoscopically classified into grade M and N in accordance with the modified Los Angeles (LA) classification system proposed by Hoshihara *et al*[5,6]. The criteria were: grade M represents minimal changes (irregular redness or whiteness) without any mucosal breaks and grade N represents esophageal mucosa with neither the minimal changes nor mucosal injury. In addition, we also evaluated the presence of hiatal hernia by endoscopy[11].

Real-time quantitative PCR

Total RNA from the biopsy samples was extracted using a commercial kit according to the instructions provided by the supplier (Isogen, Nippon Gene Co., Toyama, Japan). One μg of total RNA was reversely transcribed into complementary DNA (cDNA) in a volume of 25 μl with MuLV reverse transcriptase and random hexamers (both from PE Applied Biosystems, Warrington, UK).

Real-time PCR measurement of IL-8 cDNA was performed in the ABI PRISM 7700 sequence detector (PE Applied Biosystems) with TaqMan assay. The primers and probe sequences for IL-8 were synthesized (PE Applied Biosystems) as described previously[12]: IL-8 forward primer, 5' -CTCTTGGCAGCCTTCCTGATT-3' , reverse primer, 5' -TATGCACTGACATCTAAGTTCTTTAGCA-3' and probe, 5' -CTTGGCAAAACTGCACCTTCACACAGA-3' , labeled with the reporter dye 6-carboxyfluorescein at the 5' end and quencher dye 6-carboxytetramethylrhodamine at the 3' end. PCR was performed in a total volume of 50 μl of each amplification mixture containing 1 μl of each RT product, 25 μl of 2×Universal Master Mix (PE Applied Biosystems), 200 nM IL-8 forward and reverse primers, 100 nM fluorogenic probe. Thermal cycling was initiated with at 50 ℃ for 2 min, followed by a first denaturation step at 95 ℃ for 10 min, and followed by 50 cycles of at 95 ℃ for 15 s and at 60 ℃ for 1 min.

The *tubulin alpha 3* gene cDNA (internal control) was quantified in the same machinery using SYBR Green PCR Core reagents kit (PE Applied Biosystems). The primers used were: forward, 5' -AGATCATTGACCTCGTGTTGGA-3' and reverse, 5' -ACCAGTTCCCCCACCAAAG-3' , which correspond to nucleotides 437-458 and 537-519, respectively (*TUBA3*, GenBank accession number 17986282). PCR was performed in a total volume of 25 μl of each amplification mixture containing 1 μl of each RT product, 3 μl of 25 mM $MgCl_2$, 2.5 μl of 10×SYBR Green buffer, 2 μl of dNTP Mix (5 mM adenosine, deoxycytosine and deoxyguanosine triphosphate and 2.5 mM deoxyuridine triphosphate), 0.625 U AmpliTaq Gold polymerase, 0.125 U AmpErase and 100 nM tubulin alpha 3 forward and reverse primers. Thermal cycling was initiated at 50 ℃ for 2 min, followed by a first denaturation step at 95 ℃ for 10 min, and continued with 40 cycles of at 95 ℃ for 15 s and at 59 ℃ for 1 min.

Each assay included a standard curve, a no-template control and cDNA samples in triplicate. The standard curve was generated by serial 5-fold dilutions of pooled cDNA obtained from gastric tissues that were found to contain high levels of mRNAs of both genes. Contents of the tubulin alpha 3 and IL-8 cDNAs were expressed in arbitrary units calculated according to the standard curve. The relative expression level of IL-8 was expressed as the ratio of IL-8/tubulin alpha 3 in arbitrary units[13].

RT-PCR

Based on the technique described previously[14] with slight modification, the target sequence of CXCR-1 mRNA was amplified through 35 cycles, each consisting of denaturation at 94 ℃ for 30 sec, annealing at 53 ℃ for 30 sec and extension at 72 ℃ for 30 min, followed by a final extension at 72 ℃ for 5 min with specific primers (forward, 5' -CAGATCCACAGA-TGTGGGAT-3' and reverse, 5' -TCCAGCCATTCACCTTG-GAG-3') using an RT-PCR kit (Takara Shuzo Co., Otsu, Japan). Similarly, CXCR-2 mRNA expression was detected under the following conditions: amplification through 35 cycles, each consisting of denaturation at 94 ℃ for30 sec, annealing at 60 ℃ for 30 sec and extension at 72 ℃ for 30 min, followed by a final extension at 72 ℃ for 5 min with specific primers (forward, 5' -AGCTGCTCTTCTGGAGGTGT-3' and reverse, 5' -TTAGAGAGTAGTGGAAGTGTGC-3')[14]. A 10-μl aliquot of each PCR product was analyzed by electrophoresis on 2 % agarose gel containing ethidium bromide, and the bands were examined under ultraviolet light for the presence of amplified DNA. Glyceraldehyde-3-phosphate dehydrogenase (G3PDH) gene transcript was also amplified as described previously[15], and used as an internal control of the processed RNA for each preparation.

Detection of Helicobacter pylori infection

H pylori status was assessed by serology (anti-*H pylori* Immunoglobulin G antibody, HEL-p TEST, Amrad Co., Melbourne, Australia), rapid urease test (Helicocheck, Otsuka Pharmaceutical Co., Tokushima, Japan) and histopathology (hematoxylin-eosin and Giemsa staining) using additional biopsy specimens obtained during endoscopy from the antrum within 2 cm of the pyloric ring and the corpus along the greater curvature. Patients were considered positive for *H pylori* infection when at least two of these examinations yielded positive results. On the other hand, patients were defined as *H pylori*-negative if all the test results were negative[16].

All the samples were obtained with written informed consent of the patients prior to their inclusion in this study, in accordance with the Helsinki Declaration.

Statistical analysis

Statistical analyses were performed using Fisher' s exact, χ^2, Student' s *t*, Mann-Whitney U, and Kruskal-Wallis tests, whenever appropriate. A *P* value of less than 0.05 was accepted as statistically significant. Data are expressed as mean ± standard deviation (SD).

RESULTS

Patient demographics

According to the modified LA system, 14 patients were classified as grade M and 12 as grade N. There were no

significant differences in age, gender, current tobacco use, alcohol intake, body mass index, the presence of hiatus hernia and *H pylori* status among the patients with grade M and N and the controls (Table 1). None had such complications as stricture, bleeding and columnar-lined esophagus. The overall incidence of *H pylori* infection in our series was 51.3 %.

Table 1 Baseline characterisitics of the enrolled subjects

	Control group *n*=13	Nonerosive reflux disease group	
		Grade M[a] *n*=14	Grade N[a] *n*=12
Mean age, yr, (range)	61.6(39-80)	58.7(28-75)	62.5 (33-75)
Male / female	8 / 5	11 / 3	8 / 4
Smoker	53.8 %(7 / 13)	28.6 %(4 / 14)	33.3 %(4 / 12)
Alcohol drinker	46.2 %(6 / 13)	57.1 %(8 / 14)	33.3 %(4 / 12)
Hiatal hernia	0 %(0 / 13)	35.7 %(5 / 14)	50.0 %(6 / 12)
H pylori infection	53.8 %(7 / 13)	57.1 %(8 / 14)	41.7 %(5 / 12)

According to the modified Los Angeles system.

Relative expression levels of IL-8

We confirmed that both RT-PCR procedures for IL-8 and tubulin alpha 3 yielded 87- and 101-base pair (bp) specific bands, respectively (data not shown). As a whole, NERD patients had significantly higher expression levels of IL-8 than the controls (Figure 1, $P<0.05$). The expression levels of IL-8 in esophageal mucosa of grade M patients with NERD were significantly higher than those of grade N patients ($P<0.05$, Figure 2). In addition, the expression levels of IL-8 were higher in grade M than control group ($P<0.01$, Figure 2), but not significantly different between NERD-grade N and control group.

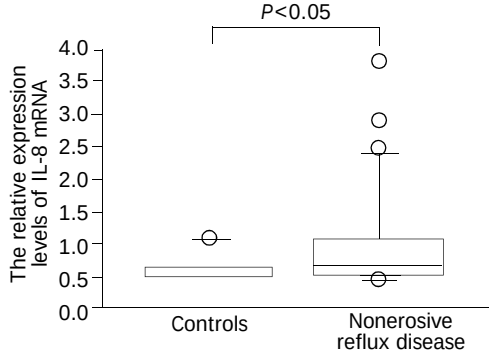

Figure 1 Relative interleukin 8 (IL-8) mRNA expression levels assessed by real-time quantitative polymerase chain reaction in patients with non-erosive reflux disease (NERD) and asymptomatic controls.

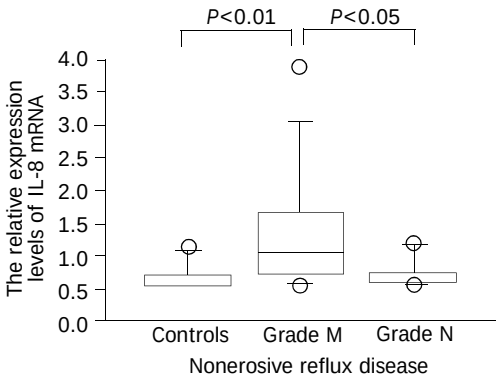

Figure 2 The expression levels of IL-8 assessed by real-time quantitative polymerase chain reaction in patients with non-erosive reflux disease (NERD) of grade M and N and asymptomatic controls.

Expression of CXCR-1 and CXCR-2 genes in esophageal mucosa

We identified the *CXCR-1* and *-2* gene-specific products as 257- and 1 154-bp bands, respectively, by RT-PCR (Figure 3). These mRNAs were constitutively expressed in each subject examined, irrespective of the presence of GERD-related symptoms or endoscopic grading. We confirmed that RT-PCR procedures for *G3PDH* housekeeping gene expression yielded 983 bp specific bands (data not shown).

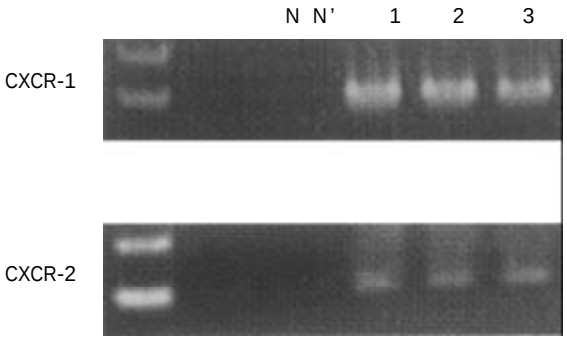

Figure 3 CXCR-1 and -2 mRNA transcripts were detected as 257 and 1 154 base pair (bp) bands with reverse transcription-polymerase chain reaction, respectively. Lane N; negative control, lane N'; RT (-) negative control, lane 1; asymptomatic normal control, lane 2; patient with NERD grade M, lane 3; patient with NERD grade N.

DISCUSSION

Several lines of evidence indicated that a prototype of CXC chemokine, IL-8, played a crucial role in the development and progression of erosive esophagitis[7,8]. In the present study, we focused on the implication of this potent inflammatory mediator in NERD. We found significantly higher expression levels of IL-8 mRNA in esophageal mucosa of patients with NERD than those in asymptomatic controls, suggesting that IL-8 is implicated in the pathogenesis of this incipient form of GERD.

The striking finding of this study was that NERD patients classified as grade M subgroup based on the modified LA system had significantly higher expression levels of IL-8 mRNA compared to those of grade N. IL-8 mediated the recruitment of neutrophils into sites of inflammation[17]. In addition, this potent chemoattractant acted on neutrophils to respiratory burst and release of a variety of reactive oxygen species (ROS), leading to tissue damage[18]. In our previous work employing ELISA, we found a significant association between the presence of intraepithelial neutrophils and increased IL-8 levels in esophageal mucosa of patients with RE[13]. Although we did not perform histopathological evaluation in the current study, elevated mucosal IL-8 expression may be involved even in such subtle mucosal changes as seen in the grade M subcategory, probably through its action on neutrophils, thus triggering chemotaxis and generating harmful ROS. This result also highlighted the possibility that NERD patients could encompass diverse subpopulations in terms of immune and inflammatory reactions. Further studies on the implication of other members of chemokines and proinflammatory cytokines can shed light on our understanding of the mechanisms underlying this poorly studied disorder.

In the present study, we demonstrated constitutive mRNA expression of CXCR-1 and -2 in esophageal biopsy samples by RT-PCR procedure. To date, CXCR-1 and -2 are two distinct receptors for IL-8[19]. It is suggested that the increased IL-8 may facilitate trafficking of neutrophils into the mucosa

affected by GERD process through the interaction with these receptors. Again, recent data from our laboratories showed a significant correlation between IL-8 protein levels and basal layer hyperplasia as well as papillary elongation in patients with RE[13]. IL-8 also exerted mitogenic actions directly or by binding to its receptors on epithelial cells[20,21]. Taken together, it is possible that IL-8, together with other cytokines as well as growth factors[14,22], could contribute to epithelial cell proliferation even in NERD, and could be eventually linked to carcinogenesis. Again, unlike CXCR-1, CXCR-2 is not specific for IL-8 and can bind to other chemokines such as growth related oncogene α, but it has 2- to 5-fold higher affinity for IL-8 than CXCR-1[19]. Further studies on the distribution of diverse IL-8 receptors and the receptor-mediated signaling pathway may help to elucidate the pathogenesis of GERD via IL-8 action.

In conclusion, our study demonstrated significantly enhanced expression of IL-8 mRNA level in NERD by real-time PCR technology. The interaction of IL-8 with CXCR-1 and -2 is likely to be involved in the pathogenesis of NERD. We also showed a significant difference in IL-8 mRNA levels between grade M and N subgroups of the modified LA classification, indicating the heterogeneity of NERD patients both immunologically and endoscopically.

Abstract

AIM: Bleeding and perforation are major and serious complications associated with endoscopic polypectomy. To develop a safe and effective method to resect hyperplastic polyps of the stomach, we employed rubber bands to strangulate hyperplastic polyps and to determine the possibility of inducing avascular necrosis in these lesions.

METHODS: Forty-seven patients with 72 hyperplastic polyps were treated with endoscopic banding ligation (EBL). At 14 days after endoscopic ligation, follow-up endoscopies were performed to assess the outcomes of the strangulated polyps.

RESULTS: After being strangulated by the rubber bands, all of the polyps immediately became congested (100 %), and then developed cyanotic changes (100 %) approximately 4 minutes later. On follow-up endoscopy 2 weeks later, all the polyps except one had dropped off. The only one residual polyp shrank with a rubber band in its base, and it also dropped off spontaneously during subsequent follow-up. No complications occurred during or following the ligation procedures.

CONCLUSION: Gastric polyps develop avascular necrosis following ligation by rubber bands. Employing suction equipment, EBL can easily capture sessile polyps. It is an easy, safe and effective method to eradicate hyperplastic polyps of the stomach.

INTRODUCTION

Bleeding is the most common complication of electrocautery snare polypectomy for upper gastrointestinal polyps, with an incidence ranging from 6.0 to 7.2 % in prospective studies[1-3]. To prevent polypectomy-elicited bleeding, epinephrine injection into the stalk[2] or placement of a metallic clip[4,5] before resection has been employed. Hachisu *et al*.[6] also reported favorable results of preventive ligation during polypectomy with placement of detachable snares at the bases of polyps. However, it is difficult to place detachable snares on sessile polyps or on polyps situated in technically difficult areas.

Endoscopic ligation using suction equipment and rubber bands or detachable snare[7-12] have been extensively applied in the management of bleeding esophageal and gastric varices. The varices are automatically eradicated through the use of ligation. In our pilot studies[13,14], we used detachable snares to strangulate gastric polyps, and demonstrated that most gastric polyps (89 %) developed avascular necrosis following ligation. Those results implied that a strangulating technique alone can achieve the bloodless transection of gastrointestinal neoplasm. However, it is important to note that a significant portion of gastric polyps (11 %) remain alive following detachable snare ligation. The aim of this study was to assess the safety and efficacy of endoscopic banding ligation (EBL) for removal of hyperplastic polyps of the stomach.

MATERIALS AND METHODS

Patients

From June 2000 to October 2001, forty-five patients (30 men and 15 women) who had 70 hyperplastic polyps documented in previous endoscopic biopsies were electively treated with EBL. Another two male patients received emergent EBL to treat bleeding gastric polyps. The mean patient age was 59.9 years (range 14 to 75 years). Written informed consent was obtained from all the subjects. The characteristics of their polyps are analyzed and illustrated in Table 1. The mean diameter of the head of polyps was 9.3 mm (range 5 to 25 mm).

EBL procedure

EBL was carried out with a GIF XQ200 endoscope (Olympus Optical Co., Tokyo, Japan) and a 19 cm flexible overtube (Sumitomo Bakelite Co., Tokyo, Japan). We set a transparent hood at the end of a scope that was equipped with a pneumoactivated esophageal variceal ligation (EVL) device set (Sumitomo Bakelite Co., Tokyo, Japan). The EVL device set consisted of an air feeding tube, a sliding tube, an inner cylinder, and a rubber band (O-ring). Pumping through an air feeding tube made a sliding tube slide on an inner cylinder and, as a result, the rubber band slipped off, thus ligating a lesion aspirated into the hood.

As premedication, 20 mg of hyoscine-N-butylbromide was given intramuscularly 5 minutes before performing EBL. The endoscope with a flexible overtube attached to its base was inserted and the overtube was inserted gently over the

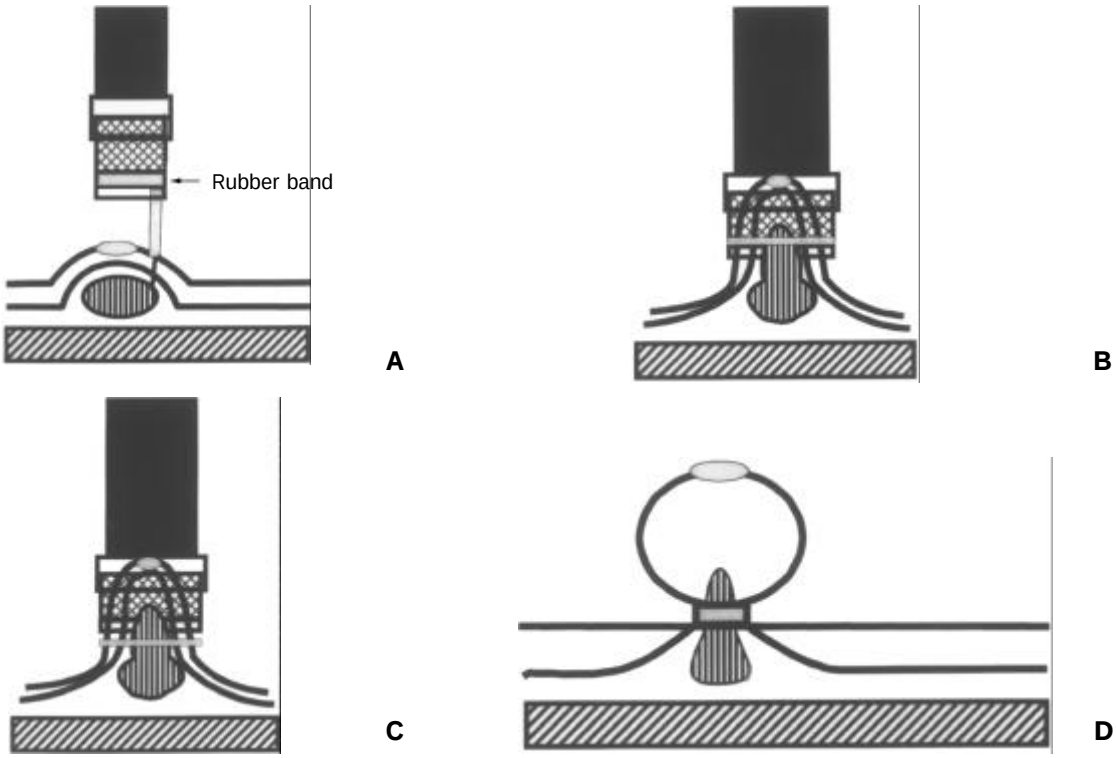

Figure 1 A: One to 4 ml of distilled water was injected locally into the submucosa adjacent to the polyp to lift the lesion from the muscle layer. B: The raised lesion was aspirated into the hood. C: The polyp was ligated by a rubber band after the air was pumped through the air feeding tube. D: The pneumoactivated EVL device set was removed.

endoscope to avoid mechanical injury to the thorax, larynx, and cervical esophagus. Before banding ligation, one to 4 ml of distilled water was injected into the submucosal layer near the lesion to tear and lift it off the muscle layer (Figure 1A). The endoscope was removed, and the pneumoactivated EVL device set was assembled on the instrument, which was then reinserted through the overtube. The raised lesion was aspirated into the hood (Figure 1B) and ligated with the rubber band after air was pumped through the air feeding tube (Figure 1C). Also, the polyp was observed for 5 minutes to investigate the sequential macroscopic changes of the strangulated lesion after EBL and biopsies were conducted later.

After the procedure, the patient was allowed to consume a liquid meal for a 24 hour period, and then issued a regular diet. An H2-receptor antagonist was administered orally for 4 weeks. A follow-up endoscopy was performed 14 days after initial endoscopic ligation to assess the outcome of the strangulated polyp.

RESULTS

Table 1 summarizes the results of 47 patients treated with EBL. EBL was performed easily and safely in each case. Following strangulation with detachable snares, all of the polyps immediately became congested (100 %), and then developed cyanotic change (100 %) approximately 4 minutes later. Figure 2 displays the typical sequential changes of a strangulated polyp. Following ligation, biopsies were conducted, and almost no bleeding was induced by biopsy procedures from the strangulated polyps. Pathological examination revealed severe venous congestion in the lamina propria of the lesions (Figure 2F). In the case of the two patients with bleeding gastric polyps above the antrum, EBL achieved successful hemostasis. The biopsies of polyps following EBL disclosed that they were hyperplastic lesions.

The follow-up endoscopy 2 weeks later revealed that all the polyps except one had dropped off, and EBL-related ulcers were found at the sites of the original lesions. The only one residual polyp shrank with a rubber band at its base. An additional follow-up endoscopy was performed for this lesion 1 month later, revealing that both the ligated polyp and rubber band had disappeared. No complications, such as bleeding or perforation, occurred during or after EBL and biopsies.

Table 1 Clinical characteristics and treatment results of endoscopic banding ligation in patients with hyperplastic gastric polyps

Variables	Number
Number of cases (M/F)	47 (32/15)
Age (years±SD)	59.9±15.1
Number of polyps	72
Mean size of polyps	9.3 mm (5-25 mm)
Morphology of polyps	
Sessile	70 (97.2 %)
Pedunculated	2 (2.8 %)
Location of polyps	
Cardia (superior, inferior, anterior, posterior)	(0, 1, 0, 2)
Fundus (superior, inferior, anterior, posterior)	(1, 4, 4, 1)
Antrum (superior, inferior, anterior, posterior)	(4, 5, 9, 7)
Body (superior, inferior, anterior, posterior)	(5, 10, 4, 15)
Initial endoscopic findings after ligation	
Congestion	72 (100 %)
Cyanosis	72 (100 %)
Endoscopic findings at second look	
Shrunken polyps	1 (1.4 %)[a]
Ligation-related ulcer	71 (98.6 %)

[a]The polyp dropped off spontaneously in subsequent follow-up.

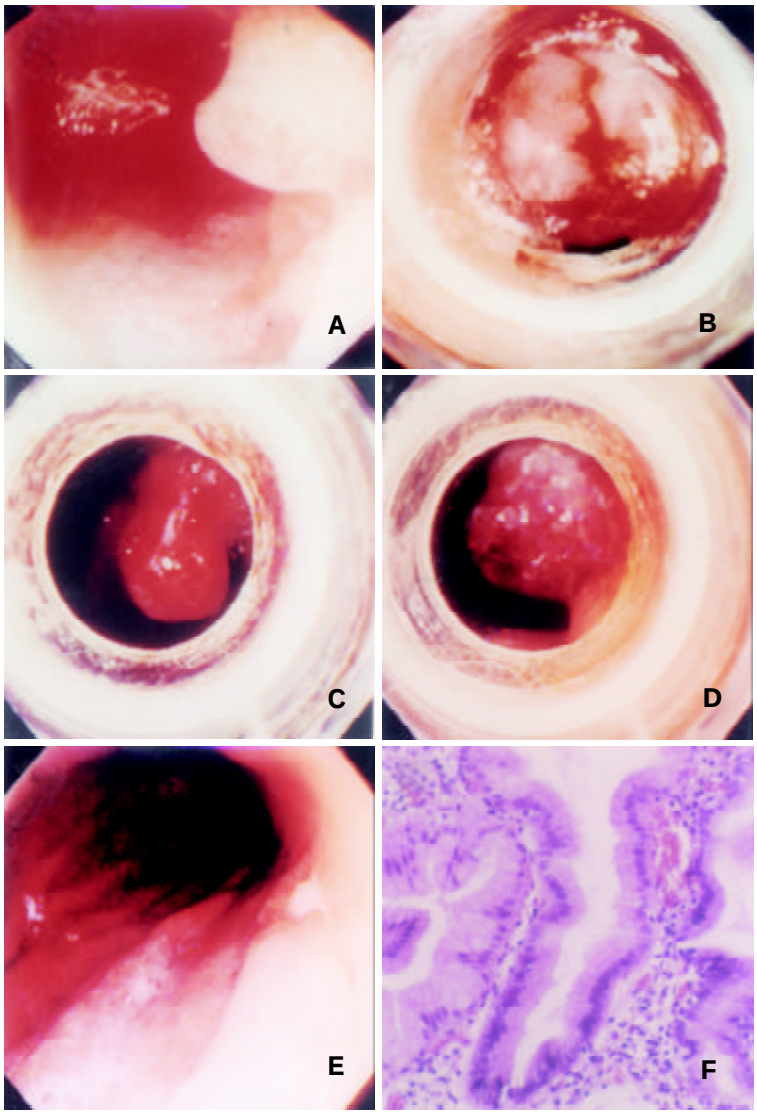

Figure 2 EBL for a hyperplastic polyp. A: A polyp over the posterior wall of corpus. B: The polyp was aspirated into the hood and ligated with a rubber band after local injection of distilled water into the submucosa. C: The polyp congested immediately after ligation. D: The polyp developed cyanotic change about 4 minutes later. E: An artificial ulcer presented at the previous ligation site. F: Pathological examination of the strangulated polyp revealed both foveolar hyperplasia of the gastric mucosa and severe venous congestion in the lamina propria.

DISCUSSION

The current study has confirmed that gastric hyperplastic polyps developED avascular necrosis following EBL. A strangulated polyp became congested immediately after ligation, and developed cyanotic changes within a few minutes. These important findings herein have not been documented before. Our study also reveals that EBL can be applied not only in the elective treatment of asymptomatic hyperplastic polyps, but also in the management of bleeding lesions. A strangulated polyp was bloodlessly transected without complications following the banding ligation.

Hyperplastic polyp is the most common polyp in the stomach, comprising 75 to 90 % of gastric polyps[15-17]. Most of the hyperplastic gastric polyps are asymptomatic. However, malignant transformation of hyperplastic polyps has been reported in several long-term follow-up studies[18,19]. They therefore should be resected when incidentally detected. Bleeding is a common complication of electrocautery snare polypectomy for gastric polyps. In a well-conducted prospective study[2], bleeding was observed in 16 of 222 snare polypectomies (7.2 %). Recently, various endoscopic mucosal resection (EMR) techniques have been developed. They included strip biopsy[20], double snare polypectomy[21] and cap-fitted panendoscopy[22]. However, complications (bleeding and perforation) of these new techniques were also high with an incidence ranging from 2.7 % to 23.9 %[23-25]. These studies underscored the importance of proficiency in endoscopic hemostatic techniques by the endoscopic team as a prerequisite for performing polypectomy in the stomach.

To prevent hemorrhage following polypectomy, preventive ligation could be conducted before the procedure[6]. However, bleeding can be encountered if a polyp is resected by electrocautery in cases where the distance above the detachable snare or rubber band is inadequate. According to our results, single ligation could effectively remove all the gastric polyps without requiring further electrocautery. No complications occurred during or after ligation. The low bleeding rate associated with EBL seemed to be attributed mainly to both a ligation of the vessels at the polyp bases and the avoidance of resecting polyps with a high-frequency electrocautery. Additionally, perforation was prevented by lifting the lesion from the muscle layer.

Our results further demonstrated that the ligating method could be employed to treat actively bleeding polyps. In the two patients with bleeding gastric polyps, EBL successfully achieved hemostasis for their bleeding polyps. Furthermore,

the strangulated polyps were bloodlessly transected without complications following the banding.

Conventional snare polypectomy or EMR methods encounter difficulties in effectively managing lesions located in the lesser curvature side, posterior wall and cardia of the stomach. Employing the EBL method allowed a lesion to be easily captured into the transparent hood, even in cases where it was situated tangentially.

Sessile polyps pose another dilemma for traditional electrocautery polypectomy, and it is difficult for snare to capture these polyps. EMR with cap-fitted panendoscopy[22] may solve this problem, but bleeding and perforation remain very problematic. Employing the proposed EBL procedure allowed theses polyps to be easily captured after submucosal injection with distilled water followed by suction. However, our EBL technique is not suitable for treating gastric adenoma, which has a high risk of carcinomatous conversion[16,17]. In managing such lesions, additional electrocautery is still required to assess the possibility of malignant transformation of polyps.

Previously, we also employed the endoscopic detachable snare ligation method to treat hyperplastic gastric polyps[13], and found that cyanotic change was an important predictor of the outcome of strangulated polyps. All the polyps with cyanotic changes developed avascular necrosis, but those without cyanotic changes remained alive following ligation by detachable snares. This study demonstrated that all the polyps became cyanotic following ligation by rubber bands, and that all the cyanotic polyps then developed avascular necrosis.

In conclusion, gastric polyps congest immediately following strangulation by rubber bands, and then develop cyanotic change within a few minutes. Avascular necrosis occurs in all the gastric polyps following banding ligation. Employing suction equipment, EBL can easily capture sessile polyps. It is an easy, safe and effective method to eradicate gastric hyperplastic polyps. Additionally, the new technique may be the choice of therapy for bleeding gastrointestinal polyps.

ACKNOWLEDGEMENTS

The authors would like to express their deep appreciation to Dr. Chang-Bih Shie, Jeng-Jie Pzeng, Miss Yu-San Chen, and Hsuan-Chun Huang for their invaluable support to this study.

Abstract

AIM: To investigate the incidence of CD117-positive immunohistochemical staining in previously diagnosed GI tract stromal tumors (GIST) and to analyze the tumors' clinical manifestations and prognostic factors.

METHODS: We retrospectively reviewed 91 cases with a previous diagnosis of GI stromal tumor, leiomyoma, or leiomyosarcoma. Tissue samples were assessed with CD117, CD34, SMA and S100 immunohistochemical staining. Clinical and pathological characteristics were analyzed for prognostic factors.

RESULTS: CD117 was positive in 81 (89 %) of 91 tissue samples. There were 59 cases (72.8 %) positive for CD34, 13 (16 %) positive for SMA, and 12 (14.8 %) positive for S100. There was no gender difference in patients with CD117-positive GIST. Their mean age was 65 years. There were 44 (54 %) tumors located in the stomach and 29 (36 %) in the small intestine. The most frequent presenting symptoms were abdominal pain and GI bleeding. The mean tumor size was 7.5±5.7 cm. There were 35 cases (43.2 %) with tumors >5 cm. The tumor size correlated significantly with tumor mitotic count and resectability. Tumor size, mitotic count, and resectability correlated significantly with tumor recurrence and survival. There was recurrent disease in 39 % of our patients, and their mean survival after recurrence was 16.6 months. Most recurrences were at the primary site or metastatic to the liver. Twenty-six percent of our patients died of their disease.

CONCLUSION: Traditional histologic criteria are not specific enough to diagnose GIST. This diagnosis must be confirmed with CD117 immunohistochemical staining. Prognosis is dependent on tumor size, mitotic count, and resectability.

INTRODUCTION

Leiomyoma of the gastrointestinal (GI) tract has a typical pathologic picture with parallel spindle cells arranged in a fascicular pattern[1,2]. However, a number of tumors have atypical findings, with epithelioid cells or pleomorphic cells instead of spindle cells or even characteristics of neurons that stain for neuron-specific enolase. Therefore, pathologists used the umbrella term "stromal tumor" to refer to such atypical mesenchymal tumors. It has been thought that these tumors might originate from mesenchymal or stromal cells within the muscle layer of the GI tract[3-5]. Molecular biochemical studies have revealed expression of kit protein (CD117) in the primitive mesenchymal cells. CD117 can be demonstrated by immunohistochemical staining using anti-kit antibodies[6]. It has been found that most mesenchymal or stromal cell tumors of the GI tract are positive for CD117[7]. Leiomyoma or leiomyosarcoma of the GI tract with typical pathologic features also stain positive for CD117. There is therefore now a consensus that these tumors originate from a common cell and that the term gastrointestinal stromal tumors (GIST) be reserved for CD117-positive neoplasms[8].

These tumors arise from primitive cells with dual characteristics of muscle and neural cells, similar to interstitial cell of Cajal[9]. Cytogenetic analysis shows that most of these tumors have a mutation of the c-kit gene. Oncogenic mutations enable the kit protein, a transmembrane tyrosine kinase receptor, to phosphorylate various substrate proteins, leading to activation of signal transduction cascades which regulate cell proliferation, apoptosis, chemotaxis, and adhesion[9]. Additional chromosomal derangements in 22q or 24q may promote GIST development[10,11]. C-kit gene mutation and kit protein over-expression appear to be essential for the pathogenesis of GIST. Imatinib is a tyrosine kinase inhibitor that has resulted in remarkable myxoid degeneration and fibrosis of GIST in clinical trials[12]. Since specifically targeted therapy is thus becoming available, it is important to know if tumors with histology consistent with GIST in fact express the kit protein[13]. We retrospectively reviewed cases in our hospital in the past 13 years with a tissue diagnosis of leiomyoma, leiomyosarcoma, or GIST to assess their immunohistochemical staining patterns, clinical manifestations, and prognostic factors.

MATERIALS AND METHODS

Patients

Using our hospital database, we collected records with a pathologic diagnosis of leiomyoma or leiomyosarcoma or stromal cell tumor of the GI tract from 1988 until 2001. There were 91 such cases. All the patients had undergone surgical resection of their tumor. We recorded the patients' age, gender, clinical manifestations, tumor site, maximal tumor diameter, duration of surgery, resectability of the tumor, the presence and date of local recurrence or distance metastasis, and the outcome, including date of death. The data of patients who were still alive in January 2002 were censored.

Immunohistochemistry

The tumor samples from all the 91 cases were examined for

various markers by using immunohistochemistry with commercially available antibodies against CD117 (1:50 dilution), S-100 protein (1:1 500), desmin (1:50), and SMA (1:100) (Dako, Carpinteria, CA). Immunoreaction was detected according to the manufacturer' s instructions (Ventana Medical Systems, Tucson, AZ). The risk of aggressive behavior of the tumors was calculated according to the NIH consensus statement of 2001[13]. Briefly, a tumor size <2 cm and mitotic count <5/50 high power fields (HPF) was graded as very low risk, a tumor between 2 and 5 cm and a mitotic count <5/50 HPF as low risk, a tumor <5 cm and mitotic count between 5/50 HPF and 10/50 HPF or a tumor between 5 and 10 cm and a mitotic count less than 5/50 HPF as intermediate risk, and a tumor >10 cm or mitotic count >10/50 HPF or a tumor >5 cm and mitotic count >5/50 HPF as high risk.

Statistic analysis

Statistic analysis was performed with SPSS software (SPSS for Window 9.0). Student' s *t* test was used to compare continuous variables. And a χ^2 test was used for dichotomous variables. Survival was calculated from the day of diagnosis until death or the last day of a patient' s visit to the outpatient clinic. The disease-free survival was calculated from the first diagnosis until tumor recurrence or distant metastases were found. Kaplan Meier analysis with a log rank test was used to compare survival and disease-free survival. The Cox proportional hazard method was used to evaluate prognostic factors.

RESULTS

Of the 91 tissue samples tested, 81 (89 %) were positive for CD117 staining. There were no significant differences in the distribution of previous pathologic diagnoses between CD117-positive and –negative samples. The highest incidence of CD117 positivity was in samples previously diagnosed as malignant GIST (Table 1). Of the 10 cases negative for CD117, 6 tumors were located in the stomach, 2 in the small bowel, and 1 each in the colon and retroperitoneum. Three of these tumors were positive for CD34, 3 for SMA, and 3 S100 (Table 2). These 10 cases were excluded from further analysis.

Table 1 Immunohistochemical staining for CD117 in tumors with a previous pathologic diagnosis of leiomyoma, leiomyosarcoma or GIST

Previous pathologic diagnosis	CD117-positive (*n*)	CD117-negative (*n*)
Leiomyoma	6 (86 %)	1 (14 %)
Leiomyosarcoma	14 (78 %)	4 (22 %)
Benign GIST	10 (77 %)	3 (23 %)
Malignant GIST	51 (96 %)	2 (4 %)
Total	81 (89 %)	10 (11 %)

Table 2 Previous pathologic diagnoses, tumor site, and other immunohistochemical markers in CD117-negative patients

Previous pathologic diagnosis	*n*	Site	CD34	SMA	S100
Leiomyoma	1	Stomach	+	-	-
Leiomyosarcoma	1	Stomach	-	-	-
	1	Small bowel	-	-	+
	1	Colon	-	-	-
	1	Other	-	+	-
Benign GIST	2	Stomach	-	-	+
	1	Stomach	+	+	+
Malignant GIST	1	Stomach	+	-	-
	1	Small bowel	-	+	-

Of the 81 patients with CD117-positive tumors, there were 42 males and 39 females. Their ages ranged from 21 to 91 years (mean 65.2±13.6 years), with over half (44/81, 54 %) between 60 and 79 years of age (Table 3). Additional immunohistochemical staining showed that the tissue samples were positive for CD34 in 59 cases (73 %), for SMA in 13 (16 %), and for S100 in 12 cases (15 %).

Table 3 Age distribution of patients with CD117-positive GIST

Age range	No. of cases (*n*)	Percentage (%)
<30	1	1
30-39	2	3
40-49	7	9
50-59	15	19
60-69	19	24
70-79	26	32
80-89	10	12
>90	1	1
Total	81	100

The tumors were located in the stomach in 44 cases (54 %), the small intestine in 29 (36 %), the colon in 5 (6 %), and the retroperitoneum or mesentery in 3 (4 %). The most frequent presenting symptoms were GI tract bleeding and abdominal pain in 27 cases (33 %) each, abdominal fullness and discomfort in 14 (17 %). Four patients had anemia on presentation, 7 had a palpable abdominal mass, and 1 presented with vaginal bleeding due to a rectal GIST involving the uterus. One patient was asymptomatic and was incidentally found to have a 3.5 cm GIST in her stomach on routine physical examination.

On pathology of the resected tumors, the mean size was 7.5±5.7 cm, 10 (12 %) were <2 cm, 25 (31 %) between 2 and 5 cm, 27 (33 %) between 5 and 10 cm, and 19 (24 %) >10 cm. Mitotic counts were <5/50 HPF in 38 cases (47 %), between 5 and 10/50 HPF in 21 (26 %), and >10/50 HPF in 22 (27 %). There was a significant correlation between tumor size and mitotic count (Pearson correlation coefficient = 0.541, $P<0.001$, Table 4). There was ulceration of the tumor in 47 % (38/81), hemorrhage in 53 % (43), tumor necrosis in 54 % (44), and tumor perforation in 25 % (20). Sixty-two (77 %) of the tumors were completely resected. There was a significant correlation between tumor size and resectability (Pearson correlation coefficient = 0.505, $P<0.001$, Table 5).

Table 4 Correlation between tumor size and mitotic count in CD117-positive GIST

Tumor size	Mitotic counts/50 HPF[a]		
	<5	5-10	>10
≤2 cm	10 (100 %)	0	0
2 to 5 cm	14 (56 %)	8 (32 %)	3 (12 %)
5 to 10 cm	12 (44 %)	8 (30 %)	7 (26 %)
>10 cm	2 (11 %)	5 (26 %)	12 (63 %)

Pearson correlation = 0.541, $P<0.001$, [a]HPF=High power fields.

Table 5 Correlation between tumor size and resectability in CD117-positive GIST

Tumor sizes	Complete resection	Incomplete resection
≤2 cm	10 (100 %)	0
2 to 5 cm	25 (100 %)	0
5 to 10 cm	18 (69 %)	8 (30.8 %)
>10 cm	9 (47 %)	10 (52.6 %)

Pearson correlation = 0.505, $P<0.001$.

There were 31 patients (39 %) with local recurrence or distant metastasis, which was statistically associated with tumor size (P<0.001, Figure 1). The 31 included 3 of 25 (12 %) whose primary tumor had been between 2 and 5 cm, 13 of 27 (48 %) whose tumor had been between 5 and 10 cm, and 15 of 19 (79 %) whose tumor had been greater than 10 cm. Recurrence was also significantly associated with mitotic count, occurring in 5 of 38 (13 %) with counts <5/50HPF, 10 of 21 (48 %) with counts between 5 and 10/50HPF, 16 of 22 (73 %) with counts >10/50HPF (P<0.001, Figure 2).

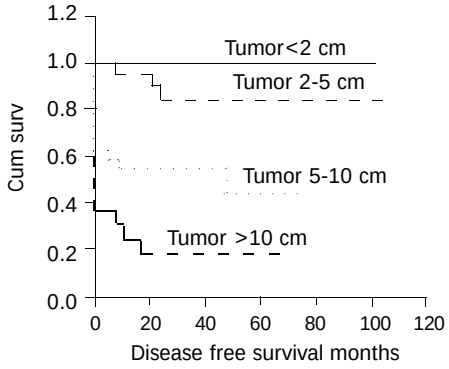

Figure 1 Cumulative disease-free survival for patients with CD117-positive GIST based on tumor size.

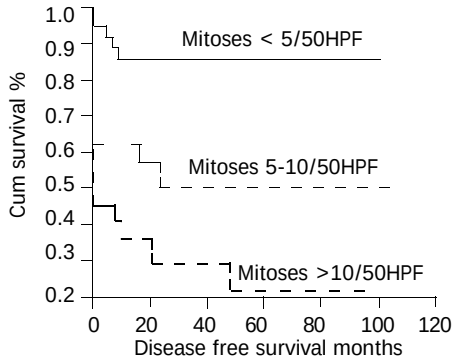

Figure 2 Cumulative disease-free survival for patients with CD117-positive GIST based on mitotic count.

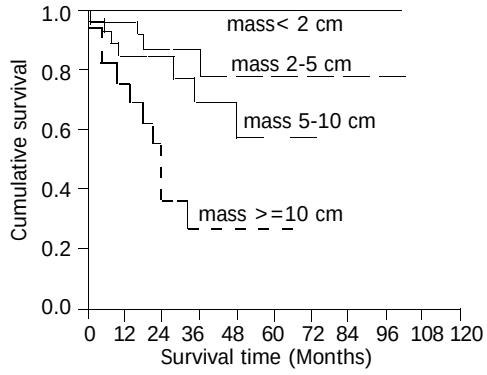

Figure 3 Cumulative survival for patients with CD117-positive GIST based on tumor size.

Twenty-one patients (26 %) died during follow up. The mean survival time after recurrence was 16.6±14.5 months. Tumor size, mitotic count, and resectability were significantly associated with survival (Figures 3,4,5). The 5-year survival was 78 % (mean survival 85.5±8.13 months) for patients with tumors between 2 and 5 cm, 57 % (mean survival 53.8±6.09 months) for those with tumors between 5 and 10 cm, and 27 % (mean survival 30.0±6.41 months) for those with tumors larger than 10 cm (Figure 3, log rank test, P<0.001). The 5-year survival was 76 % (mean survival 80.7±6.77 months) for patients with mitotic counts <5/50HPF, 73 % (mean survival 80.9±10.5 months) for those with counts between 5 and 10/50HPF, and 31 % (mean survival time 44.2±9.53 months) for those with counts >10/50HPF (Figure 4, P<0.02). Patients whose tumors were completely resected had a 5-year survival of 73 % (mean survival 82.0±5.78 months) while those without complete resection had a 5-year survival of 26 % (mean survival 27.0±5.23 months) (Figure 5, P<0.05).

The survival was also significantly correlated with the score for risk of aggressive behaviors (Figure 6, P<0.0001).

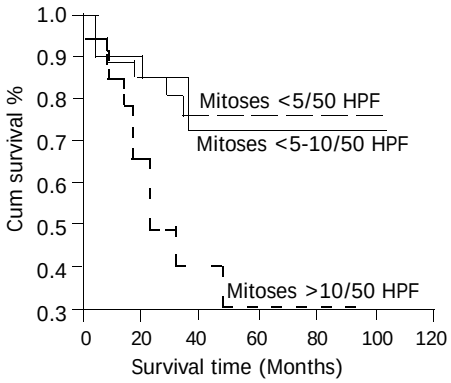

Figure 4 Cumulative survival for patients with CD117-positive GIST based on mitotic count.

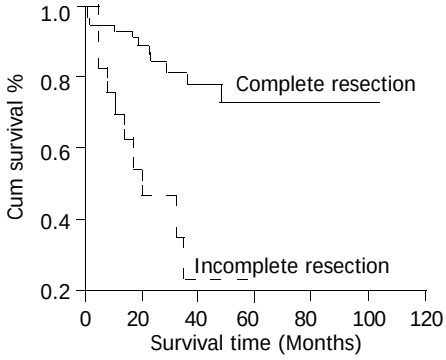

Figure 5 Cumulative survival for patients with CD117-positive GIST based on resectability.

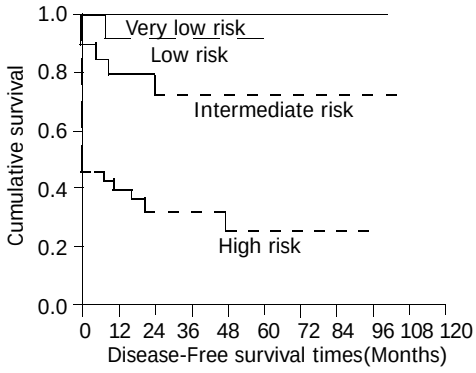

Figure 6 Cumulative disease-free survival for patients with CD117-positive GIST based on risk of aggressive behaviors.

DISCUSSION

Before the development of imatinib, surgical resection was the only treatment for tumors classified pathologically as GIST[14,15]. Tumor size was an independent prognostic factor, with tumors >10 cm having a disease-specific 5-year survival

of only 20 % after resection[16]. The tumors are often soft and fragile and prone to rupture or intraperitoneal dissemination during resection. The primary goal of surgery is complete resection of the disease, because rupture at surgery is another poor prognostic factor[17]. A number of other pathologic features have also been correlated with survival, including mitotic index, aneuploidy, cellular morphometry, proliferative index, and percent S-phase fraction[18]. Most patients with malignant stromal tumor or leiomyosarcoma have had either local recurrence or metastasis to the liver[14]. Locally recurrent tumors were usually not amenable to complete resection because of peritoneal implantation[19], nor has chemotherapy been very effective[20]. Solitary liver metastasis could be surgically resected[21], but multiple liver metastases are difficult to manage. Transcatheter arterial embolization has been used, but the partial response rate was low.

Our study confirms the contention that pathology alone is inadequate to confirm GIST by the current diagnostic criterion of CD117 immunohistochemical staining. Of the 91 tissue samples in our series, only 81 (89 %) were CD117-positive. Of the 10 negative samples, 2 were positive for SMA but negative for CD34 and S100 and therefore may be leiomyosarcomas. Another 3 were positive for S100 but negative for CD34 and SMA and therefore may be schwannomas. One case was positive and 2 were negative for all the 3 markers (that is, CD34, SMA and S100). The diagnosis in these cases is still unclear. A search for a gene mutation other than in the C-kit gene, for example PDGFR, might be helpful to clarify the diagnosis.

Among the 81cases positive for CD117, 73 % were also positive for CD34, 16 % for SMA, and 15 % for S100. These data are similar to that of previous reports.

Esophagogastroduodenoscopy is usually performed in Taiwan for any patient complaining of abdominal discomfort. As a result, we can, on occasion, find small submucosal tumors in the stomach. Most of our cases with a tumor less than 5 cm were located in the stomach. This accounted for 43 % of our patients with tumors less than 5 cm in size, all of whom had completely resectable lesions. None of our patients with tumors less than 4 cm in size died (data not shown). Our findings confired that complete resection of the tumor is one of the most important factors related to survival[16]. In our analysis, tumor size was significantly correlated with mitotic count and resectability, with larger tumors usually having higher mitotic counts and being more likely to be unresectable. Most of our patients with small intestinal GIST had lesions larger than 5 cm and a poorer outcome than those with gastric tumors. At the present time it is probably unwise to characterize any GIST benign[13]. This diagnosis mandates treatment.

Tumor grade was correlated, as expected, with mortality. No patients with very low grade tumors died, but the mortality increased as tumor grade increased, 14 % for low grade tumor, 30 % for moderate grade, and 35 % for high grade. Thirty-nine percent of our patients had recurrence, with a mean survival of 16.6 months after recurrence. Twenty-six percent of our patients died of their diseases.

We have done a clinical trial using imatinib 800 mg daily for 3 months in 11 patients with recurrent GIST. There was partial response in 3 cases and stable disease in 6 cases (unpublished data).

In conclusion, two recent developments are important with regard to GIST. The first is the ability to diagnose the tumor based on immunohistochemical staining. Our study confirms that traditional histologic criteria alone are not specific enough. The second is the development of imatinib, which specifically targets CD117, providing us a new tool to combat GIST. Early diagnosis and complete resection remain the ideal, as surgical removal provides the best prognosis. However, specific molecular diagnosis and treatment are expanding our ability to manage this disease.

Abstract

AIM: To evaluate the clinic features of eosinophilic gastroenteritis and examine the diagnosis, treatment, long-term outcome of this disease.

METHODS: Charts with a diagnosis of eosinophilic gastroenteritis from 1984 to 2002 at Mackay Memorial Hospital were reviewed retrospectively. There were 15 patients diagnosed with eosinophilic gastroenteritis. The diagnosis was established in 13 by histologic evaluation of endoscopic biopsy or operative specimen and in 2 by radiologic imaging and the presence of eosinophilic ascites.

RESULTS: All the patients had gastrointestinal symptoms and 12 (80 %) had hypereosinophilia (absolute eosinophil count 1 008 to 31 360/cm^3). The most common symptoms were abdominal pain and diarrhea. Five of the 15 patients had a history of allergy. Seven patients had involvement of the mucosa, 2 of muscularis, and 6 of subserosa. One with a history of seafood allergy was successfully treated with an elimination diet. Another patient improved spontaneously after fasting for several days. The remaining 13 patients were treated with oral prednisolone, 10 to 40 mg/day initially, which was then tapered. The symptoms in all the patients subsided within two weeks. Eleven of the 15 patients were followed up for more than 12 months (12 to 104 months, mean 48.7), of whom 5 had relapses after discontinuing steroids (13 episodes). Two of these patients required long-term maintenance oral prednisolone (5 to 10 mg/day).

CONCLUSION: Eosinophilic gastroenteritis is a rare condition of unclear etiology characterized by relapses and remissions. Short courses of corticosteroids are the mainstay of treatment, although some patients with relapsing disease require long-term low-dose steroids.

INTRODUCTION

Eosinophilic gastroenteritis is a rare disease characterized by eosinophilic infiltration into one or more layers of the gastrointestinal (GI) tract. It affects adults as well as children. The pathogenesis is poorly understood. Up to 40 % of cases were reported to have an underlying allergic basis[1]. It might involve any area of the gastrointestinal tract from the esophagus to the rectum[2,3], although the stomach and proximal small bowel were most commonly affected. Klein *et al*.[4] suggested a classification, based on the histology of the lesion: mucosal, muscularis, and subserosal disease. Clinical features depend on which layer and site are involved. Mucosal involvement leads to protein-losing enteropathy, fecal blood loss, and mal-absorption, muscularis disease often causes gastric outlet or small bowel obstruction, and subserosal involvement manifests as eosinophilic ascites. The disease often waxes and wanes in severity. Only a few studies have described the long-term outcome[5] and none have evaluated risk factors for relapse. In this study, we described the clinical manifestations of 15 patients with eosinophilic gastroenteritis.

MATERIALS AND METHODS

Charts with a diagnosis of eosinophilic gastroenteritis from 1984 to 2002 at Mackay Memorial Hospital were reviewed retrospectively. The diagnostic criteria included 1) the presence of gastrointestinal symptoms, 2) an eosinophilic infiltrate on a biopsy or operative specimen from the GI tract or else a high eosinophil count in ascitic fluid, 3) absence of parasite infestation, 4) no eosinophilic disease outside the GI tract, and 5) exclusion of intestinal lymphoma, Crohn' s disease or other tumors. As peripheral blood hypereosinophilia was not a universal finding in eosinophilic gastroenteritis, hypereosinophilia was not required for the diagnosis. Data collected from the charts included age, sex, presenting symptoms, allergy history (drug or food allergy, atopy, asthma, hay fever, etc), absolute eosinophil count, endoscopic, sonographic and radiological findings, operative records, histology of biopsies or operative specimens, response to medication, length of follow-up, and number of relapses.

An eosinophilic infiltrate was defined as at least 20 eosinophils per high power field. Klein' s criteria were followed: 1) mucosal disease was defined as infiltration of the mucosa without involvement of the muscularis or serosa, 2) muscular disease was defined as complete or incomplete intestinal obstruction and eosinophilic infiltration of the muscularis without eosinophilic ascites, and 3) subserosal disease was defined as eosinophilic infiltration of the GI tract with eosinophilic ascites.

RESULTS

Fifteen patients (6 men, 9 women), with a mean age of 38.4±14.2 (3 to 58) years, were diagnosed as eosinophilic gastroenteritis according to the above criteria. The patients are listed in Table 1 according to Klein' s classification. Hypereosinophilia (1 008 to 31 360/cm^3) in peripheral blood was noted in 12 (80 %) cases. The most common symptoms and signs in our series are shown in Table 2.

Endoscopic biopsies were performed in 12 patients from 30 different sites in the gastric antrum, duodenum, and colon. Sixteen specimens were positive, yielding the diagnosis in 12. Another 20-year-old female underwent endoscopic laparotomy for refractory ascites and was diagnosed as subserosal eosinophilic gastroenteritis based on a biopsy. The other two patients had general bowel wall thickening on CT scan and

eosinophils in their ascitic fluid. Although eosinophilic ascites might also be seen in parasitic disease and abdominal lymphoma, these entities were excluded by the clinical findings and response to treatment.

Table 1 General characteristics of patients with eosinophilic gastroenteritis according to histologic classification

Group / Patient		Sex	Age	WBC / cm^3	Eos count	% of Eos
I	1	M	43	13 800	1 380	13
	2	F	65	12 720	2 540	18

Group I: mucosal, group II: muscular and group III: subserosal disease. Eos=eosinophil.

Table 2 Presenting symptoms and signs of the 15 patients

Symptoms and signs	*n*=15
Abdominal pain	12
Diarrhea	11
Bloating / fullness	10
Nausea / vomiting	9
Hypoalbuminemia (<3.5 g / dL)	11
Fecal blood loss	6

Table 3 Characteristics of patients with and without relapse

No.	Sex	Age	Klein classification	Followed up >12 m	Allergy
			Relapsing (number of episodes)		
4	F	57	Mucosal (3)	+	+
9	F	58	Muscular (4)	+	+
10	M	17	Subserosal (1)		+
12	F	20	Subserosal (3)		+
15	F	3	Subserosal (4)		+
			Non-relapsing		
1	M	43	Mucosal	+	
2	F	65	Mucosal	+	
3	F	38	Mucosal	+	+
5	F	34	Mucosal		
6	M	45	Muscular	+	
7	F	64	Muscular		
8	M	31	Muscular		+
11	F	38	Subserosal	+	+
13	M	35	Subserosal		
14	M	53	Subserosal	+	

The endoscopic findings were nonspecific, with most patients having only hyperemic mucosa, although 2 patients had ulcers in the antrum and duodenum. A barium study of the small intestine showed thickening of the duodenal wall in 1 patient with subserosal disease and ischemic changes in the proximal ileum in 1 patient with muscular disease. CT scan or sonography were performed on all the patients with muscular and subserosal diseases (Figures 1 and 2). Intestinal wall thickening was noted in the 2 with muscular disease and in 3 of 6 with subserosal disease. Ascites was present in all the 6 who had subserosal disease.

Figure 1 Abdominal computed tomography with intravenous contrast medium showing general thickening in the small bowel wall (white arrows), characteristic of the distribution of eosinophilic gastroenteritis.

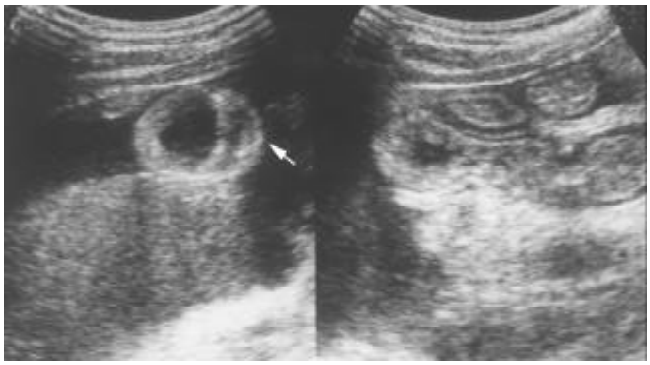

Figure 2 Transverse sonography of the proximal small bowel in the right subcostal area showing general thickening of the wall (white arrow) and ascites.

A history of allergy was noted in 5 of the 15 (34 %) patients (1 mucosal, 1 muscular, and 3 subserosal). One patient with mild mucosal disease and allergy to shellfish was successfully treated with an elimination diet. The mucosal disease in another patient (who had no history of allergy) remitted spontaneously after a fast of several days. Symptoms in both of these patients resolved within one week, and neither patient had a relapse over more than three years of follow up. Thirteen patients were treated with prednisolone, 10 to 40 mg/day initially, which was then gradually tapered over 4 to 6 weeks. Of these 13, 11 had relief of symptoms within one week, while 2 patients with subserosal disease improved within two weeks. The average hospital stay was 14.8 days (5 to 27 days).

Eleven of our patients have been followed up for more than one year (12 to 102 months). Of them, 5 (1 with mucosal, 1 with muscular and 3 with subserosal disease) had a total of 13 relapses after discontinuing steroids. A 58-year-old female with muscular disease had a relapse after discontinuing steroids and had an ileal perforation associated with ischemia. She underwent ileal resection. In general, an additional short course of steroids resulted in resolution, although 2 patients maintained on low-dose prednisolone (5 to 10 mg/day) to prevent relapses. Patients with and without relapse are compared in Table 3.

DISCUSSION

The pathogenesis of eosinophilic gastroenteritis is still unknown, but speculation has focused on the selective release

of eosinophil major proteins leading to intestinal epithelial damage. Keshavarzian *et al* demonstrated that the number of activated degranulated eosinophils in the mucosa correlated with the severity of eosinophilic gastroenteritis[6]. The disease was reportedly more prevalent in patients with seasonal allergies, food sensitivities[7], eczema, allergic rhinitis, and asthma[8]. There have been a few cases related to exposure to medications[9,10] The evidence of elevations in IgE suggested that atopy might be involved in the pathogenesis of the disease[11,12], however a history of allergy may be of little help in establishing the diagnosis. In our study 34 % of patients had a history of allergy, a proportion similar to that of other studies[1], but there was no correlation between an allergy history and the histologic type of disease.

Hypereosinophilia in the peripheral blood was absent in at least 20 % of the cases[1]. In our series, the results were similar. Therefore, the absence of hypereosinophilia should not exclude consideration of the diagnosis of eosinophilic gastroenteritis in patients with unexplained GI symptoms. Eleven of our patients had hypoalbuminemia (serum albumin <3.5 g/dl). Such a finding in patients with vague symptoms may be a hint to this disease, a chronic, organic rather than a transient, functional character.

Radiologically, the hallmark of eosinophilic gastroenteritis on CT is nodular and irregular thickening of the folds in the distal stomach and proximal small bowel[13,14]. However, similar thickening may also be seen in Menetrier' s disease, lymphoma, *scirrhous* carcinoma, Crohn' s disease, and granulomatous disease. It is thus not a specific sign of eosinophil gastroenteritis. Mesenteric inflammation as well as ascites are not uncommon but are still nonspecific. Sonography is a useful tool for detecting non-mucosal eosinophilic gastroenteritis in patients without peripheral hypereosinophilia. It may reveal generalized thickening of the intestinal wall as well as ascites, which prompted us to do cytological examination of ascitic fluid or endoscopic biopsy. Based on these sonographic abnormalities, we were able to diagnose eosinophilic gastroenteritis in 3 patients who had a normal serum eosinophil count (396 to 621/cm^3). In our series, all the 6 patients with subserosal disease had ascites on sonography, and 5 patients (3 with subserosal and 2 with muscular disease) had a thickened wall. Sonography could also evaluate the response to treatment by measuring the thickness of the affected layer[15].

The endoscopic appearance in eosinophilic gastroenteritis is nonspecific, including erythematous, friable, nodular, and occasional ulcerative changes. In our study, 10 patients had only nonspecific gastritis or colitis, while 2 had shallow gastric or duodenal ulcers. These were most likely peptic ulcers, because no eosinophilic infiltrate was found on biopsy.

Definitive diagnosis requires histological evidence of eosinophilic infiltration. Eosinophilic infiltrates are usually patchy in distribution and may be present in otherwise normal, non-inflamed bowel wall. Therefore, multiple biopsies may be required to avoid missing the diagnosis. In our study, the definitive diagnosis was established by endoscopic biopsy in 12 patients. Several different examinations, such as gastroduodenoscopy and colonoscopy, and multiple deep biopsies may be necessary to establish the diagnosis. Even then it may be difficult to evaluate accurately the degree and extent of disease in most patients, given the patchy distribution of the infiltrates. A new technique using Tc-99m HMPAO-labeled WBC SPECT may be useful in assessing the extent of disease and response to treatment. Lee *et al*, have proposed a grading system using this technology[16].

Eosinophilic gastroenteritis may present with symptoms suggesting an acute abdomen. There have been reports of the disease mimicking acute appendicitis, an obstructing cecal mass, pancreatitis, giant refractory duodenal ulcer, and intussusception[17-25]. If such patients have peripheral hypereosinophilia, the correct diagnosis of eosinophilic gastroenteritis might be suspected, avoiding an unnecessary operation. Surgery in eosinophilic gastroenteritis should be reserved for obstruction or perforation. One 53-year-old male with subserosal disease in our series underwent surgery twice, once for a refractory ulcer that had perforated, and again for an acute abdomen without definitive etiology, before the diagnosis of eosinophilic gastroenteritis. It is possible that the acute symptoms at the second time were a manifestation of eosinophilic gastroenteritis.

Once the diagnosis has been made, it is useful to look for specific food allergies, as an elimination diet may be successful if a limited number of food allergies are identified. One of our patients with mucosal disease had improvement after elimination of seafood. Katz *et al* reported that an elimination diet might fail to prevent recurrence[26], but our patient has remained well for more than 3 years. In general, patients responded quickly and well to steroids[27,28], as was true in our series. The appropriate duration of steroid treatment has been unknown, but short courses followed by a repeat course for a relapse have been described[29]. Patients with refractory relapsing disease are usually placed on long-term low-dose steroids or immunosuppressive therapy. Some authors have described the use of sodium cromoglycate (a stabilizer of mast cell membranes)[30] or montelukast (a selective, competitive leukotriene receptor antagonist)[31] as steroid-sparing agents.

We were able to follow 11 of our patients for more than one year and found that 5 of them had relapses. Three of the 5 relapse patients were all younger than 20 years old in our series. Our numbers are too small to draw firm conclusions, but this observation does raise the possibility that young age may be a risk factor for relapse. Larger series or a meta-analysis would be needed to investigate this possibility.

We found the incidence of subserosal disease (6/15=40 %) to be higher than in other studies, for example, 4.5 % to 9 % in Japan and 13 % in the USA[32,1]. Ascites as a manifestation of subserosal disease may be a more worrisome symptom, leading to a more aggressive approach to diagnosis. This in itself would not explain regional differences, but it might be that we under-diagnosed cases of mucosal and muscular disease, attributing vague symptoms to functional GI disease.

The diagnosis of eosinophilic gastroenteritis is problematic because the final diagnosis requires histological confirmation. However, this entity should be considered in the patient with unexplained chronic and relapsing gastrointestinal symptoms.

Abstract

AIM: To investigate the relationship between the expression of P-glycoprotein (P-gp) and the degree of vascularization in gallbladder carcinomas.

METHODS: P-gp was stained with streptavidin-peroxidase complex immunohistochemical method in routine paraffin-embedded sections of gallbladder carcinomas. Microvessel counts (MVC) were determined using factor-VIII-related antigens.

RESULTS: The average MVC in 32 cases of gallbladder carcinomas was (34±10)/HP. The value of MVC was closely correlated with Nevin staging and tumor differentiation ($P<0.01$ and $P<0.05$). The total expression rate of P-gp was 62.5 %. The P-gp expression rate in cases of Nevin staging S1-S3 (78.6 %) was higher than that of S4-S5 (50.0 %) with no statistical significance. The P-gp expression rate was not correlated with tumor differentiation or pathologic types. The value of MVC in P-gp (+) cases was markedly lower than that in P-gp (-) cases ($P<0.01$). The positive rate of P-gp was significantly higher in cases of smaller MVC than those of bigger MVC ($P<0.05$).

CONCLUSION: MVC may be used as one of the important parameters to reflect the biological behaviors of gallbladder carcinomas. As a major cause of drug resistance, the overexpression of P-gp is closely correlated with the poor vascularization in gallbladder carcinomas.

INTRODUCTION

Because the rate of neovascularization (angiogenesis) frequently fails to keep pace with tumor growth, tumor vasculature is often insufficient in supplying the tumor mass, therefore many solid tumors contain subpopulation of hypoxic cells. Some researches showed that the drug resistance was partially due to the poor tumor vascularization in reducing the influx of cytotoxic agents. Additionally, the hypoxic environment due to poor vascularization could also inhibit tumor cell proliferation, yet noncycling cells would be expected to be less sensitive to many agents. In recent years, some biochemical mechanisms of drug resistance have been identified; one of them is the overexpression of transmembrane transport protein and P-glycoprotein. We therefore linked angiogenesis assessed by microvessel counts with the expression of P-gp in human gallbladder carcinomas. The aim of the present study was to investigate whether MVC could be used as an important parameter to reflect the biological behaviors of gallbladder carcinomas and to illustrate the relationship between P-gp expression and vascularization.

MATERIALS AND METHODS

Clinical materials

Thirty-two cases of gallbladder carcinomas were randomly selected and diagnosed histologically. All the patients were treated surgically in our hospital. No chemotherapy or anti-angiogenesis therapy was used prior to surgery. There were 17 males and 15 females with an average age of 56 years. Histological types included 4 cases of papillary adenocarcinoma (12.5 %), 25 cases of tubal adenocarcinoma (78.1 %) and 3 cases of mucous adenocarcinoma (9.4 %). Twelve cases had well-differentiated gallbladder carcinomas (37.5 %), 9 cases moderate-differentiated gallbladder carcinomas (28.1 %) and 11 cases poor-differentiated gallbladder carcinomas (34.4 %). The Nevin staging (Table 1) was determined based on clinical features: 14 cases at stages S1, S2 and S3, and 18 cases at stages S4 and S5. All available hematoxylin and eosin-stained sections in each case were reviewed.

Table 1 Nevin staging system for gallbladder cancer[1]

Stage	Definition
1	Tumor invades mucosa only
2	Tumor invades muscularis and mucosa
3	Tumor invades subserosa, muscularis and mucosa
4	Tumor invades all layers of gallbladder wall plus cystic lymph node
5	Tumor extends into liver bed or distant spread

Immunohistochemical stains

Four micrometer-thick sections from formalin-fixed and paraffin-embedded tissues were placed on poly-L-lysine-coated slides for immunohistochemistry study. The expression of P-gp was assessed by SP immunohistochemical method using a mouse-anti-human P-gp monoclonal antibody (JSB1) and a UltraSensitive™ S-P kit (kit 9710). Blood vessels were highlighted by staining endothelial cells for factor VIII-related antigens. The deparaffinized sections were boiled in citrate buffer at high temperature and high pressure for antigen retrieval for staining of P-gp, pepsin digestion for factor VIII-related antigen staining, and then incubated with each antibody

at 4 ℃ overnight. Immunohistochemical staining was then performed according to the UltraSensitive™ S-P kit manual. All reagents were supplied by Maixin-Bio Co, Fuzhou, China. The cells with brown-yellow granules in cytoplasms or on cytomembranes were considered as positive for P-gp expression.

Immunostaining

P-gp Stained slide was examined by two independent observers and scored semi-quantitatively. Staining intensity was assessed in comparison with positive slide of colon cancer, supplied by Maixin-Bio Co, Fuzhou, China. The staining intensity was scored as none (0), weak (1), moderate (2) and strong (3). The slides were classified as negative (0), positive (1), strong positive (2) and strongest positive (3) with corresponding rates of positive cells at <10 %, 10-20 %, 20-40 %, and >40 %, respectively. When the mean score in each group was 3 or more, the slide was considered as positive. Negative controls were stained without primary antibody.

Microvessel counts

MVCs were assessed according to Weidner *et al*[2]. The hot spots were selected under a microscope (40x), then individual counts were made under 200x field (Olympus BH-2 microscope,0.74 mm^2 per field). The average counts in 5 fields were recorded. Any single highlighted endothelial cell or endothelial cell cluster clearly separated from adjacent microvessel, and distinct clusters of brown-staining endothelial cells were counted as separate microvessels. Vessel lumens were not the sole criteria in identifying a microvessel.

Statistical analysis

Statistical analysis was performed using the Chi-square test and *t* test with SPSS software (Ver.10.0). $P<0.01$ or $P<0.05$ was considered as significant.

RESULTS

Expression of P-gp and MVC

The microvessels in malignant tissues were heterogeneously distributed. These highly neovascularized areas distributed within the tumor and dominated around the tumor margins (Figure 1). The P-gp was stained in cytoplasms and on the cytomembranes of gallbladder carcinoma cells (Figure 2).

Clinicopathologic characteristics of MVC and P-gp expressions

The average MVC in 32 cases of gallbladder carcinoma was (34±10)/HP. The number of MVC was markedly higher in cases of Nevin stages S4-S5 than in those of Nevin stages S1-S3 ($t=2.833$, $P=0.008$). MVC in moderately or poorly differentiated group was higher than that in well-differentiated group ($t=2.581$, $P=0.015$). The differences of MVC among the different pathologic types were not statistically significant ($P=0.313$, 0.822, 0.168) (Table 2).

The P-gp expression rate was 62.5 % in these 32 cases. The positive rate of P-gp was higher in cases of Nevin stages S1-S3 (78.6 %) than in those of Nevin stages S4-S5 (50.0 %) with no statistical significance ($\chi^2=2.743$, $P>0.05$). The expression rate of P-gp was not correlated with tumor differentiation or pathologic types ($P>0.05$) (Table 3).

Relationship between expression of P-gp and MVC

The value of MVC in P-gp (+) cases was 30±9/HP which was significantly lower than that in P-gp (-) cases (40±8/HP) ($t=2.987$, $P=0.006$). The P-gp expression rate was significantly higher in cases with less median MVC (33.6/HP) than in those with MVC over median MVC (81.3 % *vs* 43.8 %, $\chi^2=4.800$, $P<0.05$).

DISCUSSION

In 1971, Folkman proposed that tumor growth be dependent on angiogenesis, and then considerable evidences showed that tumor growth was angiogenesis dependent, and the neovascularization was closely associated with the growth, invasion, metastasis, staging and prognosis of tumors[2-15]. Our study indicated that MVC was correlated to Nevin staging and tumor differentiation. The case at later stage and with poorer differentiation had higher level of MVC in gallbladder carcinomas. MVC might be one of the most important parameters in reflecting the biologic behaviors of gallbladder carcinomas.

Though tumor growth depends on the angiogenesis, its rate often fails to keep pace with tumor growth, as tumor vasculature is inadequate for the tumor mass. Therefore, many solid tumors have subpopulations of hypoxic cells. Studies showed that the hypoxic tumor cells were relatively resistant to certain cytotoxic drugs[16]. In the past, authors proposed that drug resistance be partly caused by poor tumor vascularization in reducing the influx of cytotoxic agents. Additionally, the hypoxic environment due to poor vascularization inhibited proliferation of tumor cells, yet noncycling cells would be expected to be less sensitive to many agents. In recent years, the identified biochemical mechanism of drug resistance was the overexpression of the transmembrane transport protein, P-glycoprotein (P-gp). P-gp is an ATP-binding-cassette transporter that is ubiquitously expressed, and often has high concentrations on plasma membrane of cancer cells, where it causes multidrug resistance by pumping lipophilic drugs out of the cell. The expression of P-gp influenced the efficacy of postoperative chemotherapy[17-24]. In our study, P-gp expression rate was 62.5 % which was similar to the result of another report on hepatocellular carcinoma[25]. Our result showed that overexpression of P-gp in gallbladder carcinoma tissue might be an important cause of drug resistance.

Recent studies showed that hypoxia-induced resistance to doxorubicin and methotrexate was attributed to an amplification of the P-gp gene and the dihydrofolate reductase gene[26-29]. Recently, it has also been shown that poor vascularization in lung carcinomas correlated with an up-regulation of drug-resistance enzymes, such as glutathione S-transferase-Ï, metallothionein and thymidylate synthase[30]. In another study on rectal cancer, poor angiogenesis was also linked to an expression of glutathione S-transferase and metallothionein[31]. Moreover, lung tumors with low vessel density and low VEGF expression have been found to be more frequently resistant to doxorubicin *in vitro* than tumors with high vessel counts and high expression of VEGF[32]. In our study, the value of MVC was markedly lower in P-gp (+) cases than in P-gp (-) cases. The positive rate of P-gp was significantly higher in cases with small MVC than in cases with big MVC.

In conclusion, the finding that poor vascularization links to overexpression of the most important multidrug resistance enzyme—P-gp provides us an additional insight into drug resistance in gallbladder carcinomas.

Abstract

AIM: To evaluate the relationship between clinical information (including age, laboratory data, and sonographic findings) and severe complications, such as gangrene, perforation, or abscess, in patients with acute acalculous cholecystitis (AAC).

METHODS: The medical records of patients hospitalized from January1997 to December 2002 with a diagnosis of acute cholecystitis were retrospectively reviewed to find those with AAC, confirmed at operation or by histologic examination. Data collected included age, sex, white blood cell count, AST, total bilirubin, alkaline phosphatase, bacteriology, mortality, and sonographic findings. The sonographic findings were recorded on a 3-point scale with 1 point each for gallbladder distention, gallbladder wall thickness >3.5 mm, and sludge. The patients were divided into 2 groups based on the presence (group A) or absence (group B) of severe gallbladder complications, defined as perforation, gangrene, or abscess.

RESULTS: There were 52 cases of AAC, accounting for 3.7 % of all cases of acute cholecystitis. Males predominated. Most patients were diagnosed by ultrasonography (48 of 52) or computed tomography (17 of 52). Severe gallbladder complications were present in 27 patients (52 %, group A) and absent in 25 (group B). Six patients died with a mortality of 12 %. Four of the 6 who died were in group A. Patients in group A were significantly older than those in group B (mean 60.88 y *vs*. 54.12 y, P=0.04) and had a significantly higher white blood cell count (mean 15 885.19 *vs*. 9 948.40, P=0.0005). All the 6 patients who died had normal white blood cell counts with an elevated percentage of band forms. The most commonly cultured bacteria in both blood and bile were *E. coli* and *Klebsiella pneumoniae*. The cumulative sonographic points did not reliably distinguish between groups A and B, even though group A tended to have more points.

CONCLUSION: Older patients with a high white cell count are more likely to have severe gallbladder complications. In these patients, earlier surgical intervention should be considered if the sonographic findings support the diagnosis of AAC.

INTRODUCTION

Acute acalculous cholecystitis (AAC) is rare, occurring in only 5 % to 10 % of patients with acute cholecystitis[1]. It is more likely to be found in patients with recent severe trauma, critical illness, cardiovascular surgery[2,3] or severe burns. AAC has also been found in association with total parenteral nutrition[4], mechanical ventilation, and the use of narcotic analgesics. Major cardiovascular disorders, complicated diabetes mellitus, autoimmune disease[5-8], and AIDS[9] have all been recognized as possible inciting factors for AAC.

AAC is a surgical emergency. Without immediate treatment, there may be rapid progression to perforation or gangrenous cholecystitis, with a mortality as high as 65 %[10]. With early diagnosis and intervention, the mortality drops to 7 %[11]. Therefore, it is important to understand the clinical variables that may assist in making an early diagnosis of this condition. The aim of the present retrospective study was to assess what clinical information might accurately predict AAC.

MATERIALS AND METHODS

We retrospectively reviewed the charts of patients in a medical center from January1997 to December 2002 and found 1395 cases of acute cholecystitis. Gallstones were present in 1234 cases. We excluded patients with carcinoma of the gallbladder, pancreas, or biliary tract, common bile duct stones, intrahepatic stones, and patients who recovered without surgery, leaving 52 cases of AAC confirmed surgically or histologically. We divided the patients into two groups based on the presence (group A) or absence (group B) of severe complications involving the gallbladder, defined as perforation, gangrene, or abscess. We recorded the following data: age, sex, white blood cell count, AST, total bilirubin, alkaline phosphatase, sonographic findings, bacteriology, and mortality. The sonographic findings were scored, with 1 point each given for gallbladder distention, wall thickness greater than 3.5 mm, and sludge.

Student' s *t*-test was used to analyze differences in means between the two groups. Sonographic scores for the severity of gallbladder condition were analyzed using the χ^2 test. A P value <0.05 was considered significant.

RESULTS

The 52 cases of AAC in our study accounted for 3.7 % of the totally 1 359 cases of acute cholecystitis seen during the study period. Males predominated, with 37 cases. The mean age of males was 56.5 years and of females, 60.5 years (Table 2). Most of our cases were diagnosed by ultrasonography (48 of 52) or computed tomography (17 of 52), with 13 patients having both examinations. Severe complications of the gallbladder were encountered in 27 (52 %) patients (group A). Six patients (12 %), all men, died, of whom 4 were in group A. The underlying conditions in these 4 patients were major surgery in 2, sepsis in 1, and bacteremia caused by *Salmonella gr. D* in 1. Of the 2 patients in group B who died, 1 had severe burns and 1 had *Aeromonas* bacteremia. The predisposing conditions for all

the patients are shown in Table 1.

There were no significant differences between the two groups in terms of liver biochemistry, length of hospital stay, or thickness of the gallbladder wall. The white blood cell count and age were significantly higher in group A ($P<0.05$, Table 2). In 10 patients in both groups, the percentage of band forms was over 10 %, including the 6 patients who died. Blood cultures were positive in 24 % and bile cultures in 66 % (Table 3). *E. coli.* and *Klebsiella pneumoniae* were the most frequently cultivated organisms in both blood and bile (Tables 4 and 5).

Most patients had a score of at least 2 points for sonographic findings. There was a tendency for group A to have higher scores, but the difference was not statistically significant (Table 6).

DISCUSSION

Most of our patients had multiple conditions that probably predisposed them to AAC (Table 1). Bile stasis, gallbladder ischemia, cystic duct obstruction, and systemic infection have been considered to be the most important factors in the pathogenesis of AAC[12].

The bacteria we cultured from blood and bile were similar to those reported by others. Gastrointestinal flora such as *E. coli* and *Klebsiella pneumoniae* were most commonly cultured, as was true in our series. However, uncommon microorganisms have also been isolated from the bile, including *Leptospira spp*[13,14], *Salmonella spp*[15], *Vibrio cholerae*[16], or *Listeria monocytogenes*. We had two patients with *Salmonella group D* infection, one of whom died of gangrene of the gallbladder with sepsis.

Rapid and accurate diagnosis is essential because ischemia may progress rapidly to gangrene and perforation. If an operation was performed within 48 hours from the onset of symptoms, severe complications would be reduced[17]. AAC should be considered in every patient who is critically ill or injured and who has clinical findings of sepsis with no obvious source. Fever, right upper quadrant pain, and leukocytosis are common manifestations but are very nonspecific. However, our study revealed that a high white blood cell count and older age were associated with a higher incidence of gallbladder gangrene and perforation. More aggressive management should be considered in these patients. Patients with greater than 10 % band neutrophils might have an especially poor outcome.

Abdominal ultrasonography is the primary diagnostic modality for AAC. The most significant ultrasonographic findings are thickening of the gallbladder wall of more than 3.5 mm, gallbladder distention, a positive sonographic Murphy's sign, pericholecystic fluid, and a sonolucent intraluminal layer[18,19]. We did not find the 3 sonographic findings we used were adequate to predict those patients likely to have severe gallbladder complications, although there was a trend toward higher scores in the group with complications. It may be that a study with a larger sample might find this to be a useful criterion.

In a discussion of diagnostic strategies for AAC, Kalliafas *et al* reported that morphine cholescintigraphy had the highest sensitivity (9 of 10, 90 %), followed by computed tomography (8 of 12, 67 %) and ultrasonography (2 of 7, 29 %). They reported a mortality of 41 % and a morbidity (that is, gangrene, perforation, or abscess) of 82 %[20]. However, in our series, the mortality was only 11.5 % and morbidity 52 %. Why are the results so different? We diagnosed most of our cases by ultrasonography (48 of 52) or computed tomography (17 of 52), only two patients had cholescintigraphy. Further studies are needed to elucidate the relationship between the diagnostic modality and prediction of the morbidity and mortality of AAC.

The mainstay of therapy for AAC is cholecystectomy, which was traditionally performed by open laparotomy[21]. Recently, laparoscopic cholecystectomy was performed in a small study with no complications from the procedure[22]. Cholecystostomy has be come a potentially lifesaving alternative in patients too weak to undergo general anesthesia[23]. Percutaneous cholecystostomy by computed tomography or echo guidance is gaining acceptance as an alternative to an open procedure[24]. In the future, laparoscopy for early diagnosis and treatment may be further developed as a useful method to decrease the mortality of AAC.

Finally, early diagnosis and early operation are the key to managing acute acalculous cholecystitis. Older patients with a high white cell count are more likely to have severe gallbladder complications. In these patients, earlier surgical intervention should be considered if the sonographic findings support the diagnosis of AAC.

Abstract

AIM: To evaluate the clinical value of various imageological methods in diagnosing the pancreato-biliary diseases and to seek the optimal procedure.

METHODS: Eighty-two cases of pancreato-biliary diseases confirmed by surgery and pathology were analyzed. There were 38 cases of cholelithiasis, 34 cases of pancreato-biliary tumors and 10 other cases. The imageological methods included B-US, CT, ERCP, PTC, cross-sectional MRI and MR cholangiopancreatography (MRCP).

RESULTS: The accuracy rate of MRCP in detecting the location of pancreato-biliary obstruction was 100 %. In differentiating malignant from benign obstruction, the sensitivity of the combination of MRCP and cross-sectional MRI was 82.3 %, the specificity was 93.8 %, and the accuracy rate was 89.0 %. The accuracy rate for determining the nature of obstruction was 87.8 %, which was superior to that of B-US (P=0.0000) and CT (P=0.0330), but there was no significant difference between direct cholangiopancreatography and the combination of MRCP and conventional MRI (P=0.6666).

CONCLUSION: In most cases, MRCP can substitute direct cholangiopancreatography for diagnosis. The combination of MRCP and cross-sectional MRI should be considered as an important means in diagnosing the pancreato-biliary diseases, pre-operative assessment and post-operative follow-ups.

INTRODUCTION

Pancreato-biliary disorders are common diseases that often involve the biliary system to produce the symptom of obstructive jaundice. It is the precondition to investigate the obstructive location and causes of pancreato-biliary diseases. In this study, 82 cases of pancreato-biliary diseases confirmed by surgery and pathology were analyzed. The aims of the prospective study were to evaluate the clinical value of various imageological methods in diagnosing the pancreato-biliary diseases and to seek the optimal examination procedure.

MATERIALS AND METHODS

Patients

The study subjects included 82 patients (54 men and 28 women, mean age 60.0 years, range 11-82 years), 67 (81.7 %) cases had the symptom of obstructive jaundice. All patients underwent B-US, MR cholangiopancreatography (MRCP) and cross-sectional MRI examination. Fifty-seven patients underwent enhanced or un-enhanced CT scan. In addition, 48 patients had undergone direct cholangiopancreatography (41 ERCP and 7 PTC). However, direct cholangiopancreatography was unsuccessful in 4 cases due to difficult cannulation (2 ERCP), post-gastroenterostomy (1 ERCP) and sick patient (1 PTC). ERCP was incomplete in another 4 cases because only the pancreatic duct could be demonstrated and the biliary tree was not opacified. Therefore, 40 direct cholangiopancreatographies (34 ERCP and 6 PTC) were performed in all 82 cases, 1 patient had complication of acute pancreatitis after ERCP. All patients with pancreat-biliary diseases were confirmed by surgical findings and pathology, including 12 by laparoscopic cholecystectomy (LC), 6 by endoscopic sphincter tenotomy (EST) and 1 by PTC drainage (PTCD). Among the 82 cases, 38 were diagnosed as cholelithiasis, 34 as pancreato-biliary tumors and 10 as other diseases (Table 1).

Table 1 Pancreato-biliary diseases (n=82)

Pancreato-biliary diseases	No. of cases
Cholelithiasis[a]	38
Gallbladder stone	14
Intrahepatic bile duct stone	7

Choledochal cyst	2
Sclerosing cholangitis	2
Chronic pancreatitis	4

[a]Gallbladder stone mixed with intra-or extra-hepatic stone 15, Mirizzi syndrome 2; [b]Hepatic invasion or metastasis 5, lymphadenectasis 3.

Techniques

MR imaging was performed with a 1.0T superconductive unit (Philips Gyroscan T10-NT, software version 4.6.2) containing a body coil. The patients were examined in the supine position, quiet breathing and abdominal band compression. The routine upper abdominal axial T1WI, T2WI and coronal T2WI MR examinations with Turbo Spin-Echo (TSE) sequence were performed first, and followed by the additional axial T2WI and/or T1WI fat-suppressed sequence (spectral saturation

inversion recovery, SPIR). The routine axial images served as guides to locate the MR cholangiopancreatography (MRCP). MRCP was performed with coronal, multislices, heavily T2-weighted TSE sequence (TR=2 000 ms, TE=700 ms). A non-breath-hold, respiratory-triggering technique was used to decrease the respiratory motion artifact. The MRCP source images were three-dimensionally (3D) reconstructed using a maximum-intensity-projection (MIP) algorithm. The total imaging time was approximately 30 min.

Computed tomography (CT) used a whole body CT scan unit (Picker PQ-2000). All CT examinations were performed after the patients had fasted for 4-8 hours and took 5 00-1 000 ml oral contrast (0.5-1 % Meglumine Diatrizoate) before CT scanning. Enhanced CT examination used 80-100 ml non-ion intravenous contrast agents injected through anecubital vein in a bolus at the rate of 2-3 ml/s.

Direct cholangiopancreatography (ERCP and PTC) was performed with a digital imaging unit (Philips Diagnost 93).

Imaging analysis

All image data of 82 cases were carefully reviewed to observe the enlargement or stricture of pancreato-biliary tract. The study protocol included detecting the obstructive locations, distinguishing the malignant from benign causes and evaluating the clinical value of various imaging methods (including B-US, CT, MRCP, ERCP/PTC) in diagnosing the pancreato-biliary diseases. *SAS* software was used for all statistical analyses.

The diagnostic principles and evaluating criteria for direct cholangiopancreatography and MRCP were identical, but in MRCP it was more important to carefully review both the source images and the MIP reconstructed images. According to the findings of the dilatation or stricture of pancreato-biliary tree and gallbladder, the obstructive locations of pancreato-biliary duct were divided into three parts: intra-hepatic or extra-hepatic bile duct and main pancreatic duct. Normal gallbladder was 7-10 cm in length and 3-4 cm in width. Dilatation of the common bile duct was defined as larger than 8 mm in maximal diameter in patients without histories of cholecystectomy and 10 mm in patients with prior cholecystectomy. Dilatation of the intra-hepatic bile duct and main pancreatic duct was defined as larger than 3 mm in maximal diameter[1-4].

The cause of pancreato-biliary abnormality was evaluated using a five-point scale to assign a confidence level: 1. definitely benign, 2. probably benign, 3. indeterminate, 4. probably malignant, and 5. definitely malignant[5]. If the cause of pancreato-biliary abnormality was assumed to be malignant, the reasons were chosen from the following findings: visualization of tumor, double duct sign, abrupt obstruction of bile duct, irregularity of obstructed margin, or asymmetric obstruction of the distal margin of the dilated bile duct. Receiver operating characteristic (ROC) curve analysis was performed to compare the results of readings of MRCP images versus the results of readings of the combination of MRCP images and routine MR images and versus the results of readings of ERCP images. Binormal ROC curves were fitted using *ROCKIT 0.9B* software. The diagnostic capability was determined by calculating the area under the ROC curve (Az). Ratings of 1 or 2 indicated a reading of a benign lesion, ratings of 4 or 5 indicated a rating of a malignant lesion. Ratings of 3 were considered to indicate an indeterminate diagnosis. Sensitivity, specificity and accuracy of ERCP, MRCP and the combination of MRCP and routine MR imaging in differentiating malignant from benign causes of pancreato-biliary tract obstruction were calculated.

RESULTS

MRCP image quality

MR cholangiopancreatography was successfully performed in all 82 patients and the images of MRCP were similar to those of direct cholangiopancreatography. MRCP studies of diagnostic quality were obtained in 79 (96.3 %) subjects with fine contrast between the pancreato-biliary structure and the surrounding background. In the remaining 3 patients with pancreato-biliary tumor, the presence of ascitic fluid in the upper abdomen and the fluid-containing organs due to gastrointestinal obstruction obscured visualization of the pancreato-biliary tree and degraded the quality of the MRCP image. In 8 (16.7 %) patients in whom direct cholangiopancreatography was unsuccessful or incomplete, MRCP examinations all succeeded and the MRCP images were satisfactory.

Diagnosis of obstructive location

Among the 82 patients with pancreato-biliary diseases, 8, 60 and 21 cases had pancreato-biliary obstructive locations in intra-hepatic, extra-hepatic bile duct and main pancreatic duct, respectively (totally 89 locations). MRCP could clearly visualize the dilation of pancreato-biliary ducts above the obstructive level in their native state, thus being more suitable for demonstrating the extra-hepatic bile duct obstruction. The total accuracy of MRCP in detecting the location of pancreato-biliary obstruction was 100 %, which was superior to that of B-US (P=0.0002) and CT (P=0.0422), but there was no significant difference between MRCP and direct cholangiopancreatography (P=0.1487) (Table 2).

Table 2 Accuracy of pancreato-biliary obstruction level (%) by different imageological methods

Level	Intra-hepatic	Extra-hepatic	Main pancreatic	Total
B-US	100.0 (8/8)	81.7 (49/60)	90.5 (19/21)	85.4 (76/89)
CT	100.0 (4/4)	93.0 (40/43)	100.0 (19/19)	95.5 (63/66)
ERCP/PTC	100.0 (5/5)	96.7 (29/30)	100.0 (8/8)	97.7 (42/43)
MRCP	100.0 (8/8)	100.0 (60/60)	100.0 (21/21)	100.0 (89/89)

Differentiation of malignant from benign obstruction

The sensitivity, specificity and accuracy of MRCP in distinguishing malignant from benign causes of pancreato-biliary obstruction were 64.7 %, 81.2 % and 74.4 %, respectively, while those of ERCP/PTC were 77.8 %, 86.4 % and 82.5 %, respectively. The difference was not significant between MRCP and ERCP/PTC in Az area under the ROC curve (P=0.4590). The combination of MRCP and routine MR imaging could obviously improve the diagnostic capability of differentiating the causes of pancreato-biliary obstruction with a sensitivity of 82.3 %, a specificity of 93.8 % and an accuracy of 89.0 %. The difference was significant between MRCP and the combination of MRCP and routine MR imaging (P=0.0489) (Table 3 and Figure 1).

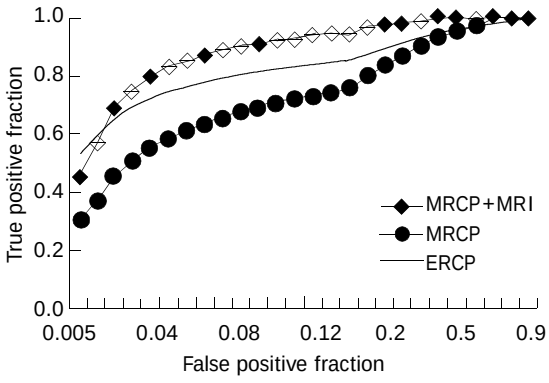

Figure 1 ROC curve analysis of differentiation between malignant and benign causes of pancreato-biliary obstruction.

Table 3 ROC analysis of pancreato-biliary obstruction

	ERCP / PTC (*n*=40)	MRCP (*n*=82)	MRCP+MRI (*n*=82)
True-positive	14	22	28
True-negative	19	39	45
False-positive	3	9	3
False-negative	4	12	6
Sensitivity (%)	77.8	64.7	82.3
Specificity (%)	86.4	81.2	93.8
Accuracy (%)	82.5	74.4	89.0
A_Z Values±SD	0.9281±0.0455	0.8833±0.0400	0.9687±0.0168

Diagnosis of obstructive causes

The total accuracy of MRCP in diagnosing the causes of pancreato-biliary obstruction was 75.6 %, which was similar to that of direct cholangiopancreatography (ERCP/PTC) (*P*=0.2345) and CT (*P*=0.7970), but superior to that of B-US (*P*=0.0131). The combination of MRCP and routine MR imaging significantly improved the clinical diagnostic ability with an accuracy of 87.8 %, which was superior to that of CT (*P*=0.0330) and US (*P*=0.0000).

The diagnostic rate by the combination of MRCP and routine MR imaging was 92.1 % and 94.1 %, for cholelithasis and choledocholithiasis respectively, which was superior to that of CT (*P*=0.0428) and US (*P*=0.0049). But the difference between ERCP/PTC and the combined MRCP and routine MR imaging was not significant (*P*=0.6445). The accuracy of CT, ERCP/PTC, MRCP and the combined MRCP and routine MR imaging in distinguishing the various pancreato-biliary tumors was significantly higher than that of US (*P*=0.0002) (Table 4).

Table 4 Accuracy of diagnosis of obstructive causes (%)

	B-US	CT	ERCP / PTC	MRCP	MRCP +MRI
Cholelithiasis					
Gallbladder stone	71.4	75.0	80.0	78.5	92.9
Intrahepatic bile duct stone	85.7	100.0	100.0	71.4	85.7

Total	57.3	73.7	85.0	75.6	87.8

DISCUSSION

US or CT examination (including endoscopic US and spiral CT) has been the first choice in diagnosing the pancreato-biliary diseases[6-9]. Direct cholangiopancreatography obtained through ERCP or PTC has served as "golden standard" in pancreato-biliary imageology.

Magnetic resonance cholangiopancreatography (MRCP), advocated by German researcher Wallner BK and his group in 1991[10], has offered a new imaging modality for diagnosing pancreato-biliary system disorders[10-15]. In the present study, MRCP was successfully performed in all 82 patients and the images of MRCP were similar to those of direct cholangiopancreatography. MRCP studies of diagnostic quality were obtained in 79 cases (96.3 %), including 8 (16.7 %) in which direct cholangiopancreatography were unsuccessful or incomplete. Therefore, MRCP might provide an efficient alternative to direct cholangiopancreatography when diagnostic ERCP and PTC were unsuccessful or inadequate[1,16].

In our study, the accuracy of MRCP in detecting the location of pancreato-biliary obstruction was 100 %, which was superior to that of B-US and CT, but was not significantly different between MRCP and direct cholangiopancreatography. Compared with ERCP/PTC examination, the noninvasive MRCP could exhibit the whole pancreato-biliary duct system and demonstrate the level, degree and range of obstruction as well as morphological characteristics. In addition, MRCP could provide a plenty of valuable imageological information and help determine the best approach for palliative drainage and other interventional treatment for the patients with unresectable tumors[17,18].

In pancreato-biliary system imageology, it is very important in diagnosing and differentiating malignant from benign causes of pancreato-biliary obstruction. The combined MRCP and routine MR imaging could significantly improve the clinical diagnostic capability by exhibiting the pathological changes of the surrounding structures[19-22]. For pancreato-biliary tumors, MRCP could define the location and morphological characteristics of pancreato-biliary obstruction, and evaluate the range of tumors involvement and the surgical resectability. Furthermore, with the advantages of both CT and direct cholangiopancreatography examination, the combined routine MR imaging and MRCP might exhibit the pertinent surrounding structures and raise the clinical diagnostic accuracy[17,23,24].

US and CT techniques are most frequently used in the initial evaluation of patients with cholelithiasis and both have a high accuracy in diagnosing gallbladder and intrahepatic duct stones. The sensitivity of MRCP in diagnosing gallbladder and intrahepatic duct stones varied with the size, number and location of the stones and MRCP being more suitable for the diagnosis of choledocholithiasis. In summary, the MRCP could mainly detect the stones in common bile duct and exclude other pancreato-biliary obstructive diseases[25-27].

With the development of laparoscopic technique, laparoscopic cholecystectomy (LC) and endoscopic sphincter tenotomy (EST) have been widely used in the biliary surgery[28]. MRCP can depict the whole anatomic structure of biliary tree and help guarantee the success of laparoscopic cholecystectomy. Before surgical dissection, to identify the anatomic variants of the biliary tree with MRCP could result in a decreased risk of bile duct injury during laparoscopic cholecystectomy[29]. Now, ERCP is no longer the routine examination in patients with choledocholithiasis, and endoscopic sphincter tenotomy is chiefly used instead to remove stones in common bile duct.

As to the benign strictures, due to cholangitis, surgical injury or chronic pancreatitis, MRCP may have some difficulties in showing the mini-changes of pancreato-biliary duct. But the use of dynamic MRCP with secretin stimulation might be useful for diagnosing pancreatic papillary stenosis or dysfunction and for detecting reduced pancreatic exocrine reserve[30-32]. In addition, the literature indicates that MRCP could be used initially in evaluating choledochal cyst[33].

In conclusion, in recent optimal imageological procedures of diagnosing the pancreato-biliary diseases, B-US is still the first choice for evaluation. The combination of MRCP and routine MR imaging provides an efficient method to diagnose various pancreato-biliary obstructions, differentiate malignant from benign causes and carry out post-operative follow-ups. Cross-sectional MR imaging and CT are complementary modalities for pre-operative diagnosis and

assessment of pancreato-biliary tumors. Direct diagnostic cholangiopancreatography (ERCP/PTC) is chiefly used for difficult cases and combined with other interventional treatment, including EST or PTCD (Figure 2).

Abstract

AIM: To identify the expression of Caspase-1(interleukin-1β converting enzyme) and its role in adenoma of the pancreas and chronic pancreatitis.

METHODS: The expression of Caspase-1 was assessed in 42 pancreatic cancer tissue samples, 38 chronic pancreatitis specimens, and 9 normal pancreatic tissues by immunohistochemistry and Western blot analysis.

RESULTS: Overexpression of Caspase-1 was observed in both disorders, but there were differences in the expression patterns in distinct morphologic compartments. Pancreatic cancer tissues showed a clear cytoplasmatic overexpression of Caspase-1 in tumor cells of 71 % of the tumors, whereas normal pancreatic tissues showed only occasional immunoreactivity. In chronic pancreatitis, overexpression of Caspase-1 was found in atrophic acinar cells (89 %), hyperplastic ducts (87 %), and dedifferentiating acinar cells (84 %). Although in atrophic cells a clear nuclear expression was found, hyperplastic ducts and dedifferentiating acinar cells showed clear cytoplasmic expression. Western blot analysis revealed a marked expression of the 45 kDa precursor of Caspase-1 in pancreatic cancer and chronic pancreatitis (80 % and 86 %, respectively). Clear bands at 30 kDa, which suggested the p10-p20 heterodimer of active Caspase-1, were found in 60 % of the cancer tissue and 14 % of the pancreatitis tissue specimens, but not in normal pancreatic tissues.

CONCLUSION: Overexpression of Caspase-1 is a frequent event in pancreatic disorders and its differential expression patterns may reflect two functions of the protease. One is its participation in the apoptotic pathway in atrophic acinar cells and tumor-surrounding pancreatitis tissue, the other is its possible role in proliferative processes in pancreatic cancer cells and hyperplastic duct cells and dedifferentiating acinar cells in chronic pancreatitis.

INTRODUCTION

Caspase-1 was the first described member of a group of cysteine proteases called Caspases. It was formerly designated as interleukin-1β converting enzyme, and was originally characterized by its ability to cleave the inactive precursor of interleukin-1β to generate the active 17.5 kDa proinflammatory cytokine IL-1β[1]. It has been found to express in many tissues as an inactive 45 kDa precursor protein (p45) from which the active enzyme is generated by an autocatalytic cleavage process[2]. Caspase-1 was first isolated from human monocytic cell line THP 1. Because of its similarity in sequence to the death gene product CED-3 of nematode Caenorhabditis elegans, it has been regarded as a key enzyme of the apoptotic pathway[3]. Today, more than 10 Caspases have been identified and their roles in apoptosis are well known[4-6].

Several new members of the group of Caspases have been identified and described. Similar to Caspase-1, overexpression of any of these enzymes would lead to apoptosis in a variety of cell types[7-9]. We investigated the expression of apoptosis-related enzyme Caspase-1 in pancreatic cancer and chronic pancreatitis. Interestingly, we found a clear overexpression of Caspase-1 in pancreatic cancer tissue as well as in chronic pancreatitis specimens.

MATERIALS AND METHODS

Tissue samples

Pancreatic tissue samples were obtained from 42 patients with pancreatic cancer and 38 patients with chronic pancreatitis who underwent surgery at the Department of General Surgery, University of Ulm. The median age of the patients with pancreatic cancer (20 women and 22 men) was 61.8 years (range 38 to 78 years). The group of patients with chronic pancreatitis was composed of 13 women and 25 men. The median age of this group was 52.2 years (range 22 to 73 years). The main indication for pancreatic head resection was long-lasting pain (36 of 38 patients) and obstruction of the common bile duct (19 of 38 patients). In all patients, duodenum-preserving pancreatic head resection was performed.

Tissues were collected after surgical removal, immediately snap-frozen in liquid nitrogen, and stored at -80 ℃, or fixed in 4 % formalin for 24 hours at room temperature, processed, and embedded in paraffin. All 42 pancreatic cancer tissue and 38 chronic pancreatitis tissue samples were used for immunohistochemical analysis. Five normal pancreatic tissue samples from organ donors and four normal pancreatic tissue samples from patients undergoing surgery for pancreatic cancer served as control specimens. Twenty pancreatic cancer tissues, 14 chronic pancreatitis tissues, and seven normal pancreatic tissues underwent Western blot analysis.

Immunohistochemistry

Paraffin-embedded tissues were cut into 5 μm-thick sections and adhered to silanized slides, deparaffinized, and hydrated. Endogenous peroxidase activity was blocked with 3 % hydrogen peroxide in methanol. The tissue sections were covered with 5 % normal goat serum (DAKO, Glostrup, Denmark) in Tris-buffered saline for 60 minutes and incubated overnight with polyclonal rabbit antihuman caspase-1 antibody (Upstate Biotechnology, Lake Placid, NY, USA.) in a dilution

of 1:100. For each case, a corresponding section was incubated in Tris-buffered saline without the primary antibody as a control for nonspecific staining. Further negative controls consisted of normal rabbit serum instead of specific antiserum. Biotinylated pig anti-rabbit secondary antibody was added for 45 minutes, followed by avidin-biotinylated peroxidase complex for an additional 45 minutes. Staining was achieved using 3,3' -diaminobenzidine. The sections were then counterstained with Mayer' s hemalum and mounted.

Grading of immunohistochemical findings

Immunohistochemical findings were scored depending on the extent and intensity of staining. Both intensity and extent were assessed in regions with hyperplastic ducts and atrophic acinar cells. All sections were graded by two experienced investigators who had no knowledge of the clinical data. At least 10 randomly selected high-power fields were scored. The intensity of staining was graded on a four points scale of 0=no staining, 1=weak, 2=moderate, and 3=strong. The extent of positive immunoreactivity was graded by the percentage of stained cells in the region of interest: 0 point=0 %, 1 point$\leqslant$20 %, 2 points=20-50 %, and 3 points$\geqslant$50 %. An overall score was obtained by the product of intensity and extent of positive staining. Cases with 0 points were considered to be negative, cases with a final score of 1-3 were considered to be weakly positive, cases with a score of 4-7 were considered to be moderately positive, and cases with a final score greater than 7 were considered to be strongly positive.

Western blot analysis

Frozen pancreatic samples were finely diced with a surgical blade and washed twice with ice-cold phosphate-buffered saline. After swelling on ice for 60 minutes, the samples were dissociated by sonication. The lysates were centrifuged and the protein fraction was aliquoted and stored at -80 ℃ until further analysis. For immunoblotting, the lysates were boiled in sodium dodecyl sulfate-gel sample buffer for 5 minutes. Thirty micrograms of protein were electrophoretically resolved on denaturing 15 % polyacrylamide gels with a 3 % stacking gel. Proteins were transferred to nitrocellulose membranes using a transblot apparatus (Phase, Lubeck, Germany). Nonspecific interactions were blocked by preincubation of the membranes with a milk powder suspension overnight at 4 ℃. After incubation of the membranes with monoclonal antibodies, the binding of antibodies was detected using the ECL-system (Amersham Pharmacia Biotech, Piscataway, NJ, USA). The autocleavage experiments of the monocytic cell line THP1 were performed as previously described[10].

RESULTS

Immunohistochemical findings

Staining of pancreatic tissue specimens with a polyclonal rabbit antiserum recognizing Caspase-1 revealed a marked overexpression of Caspase-1 in pancreatic cancer and chronic pancreatitis. Although normal pancreatic tissue showed only occasional slight staining (Figure 1A), we found predominantly cytoplasmic immunoreactivity of cancer cells in 71 % of the pancreatic tumors (Figure 1B). In primary chronic pancreatitis tissue samples, Caspase-1 overexpression was found in atrophic acinar cells, hyperplastic ducts, and acinar cells that appeared to dedifferentiate to form tubular structures. Hyperplastic ducts showed clear cytoplasmic staining in 87 % (Figure 1C). Atrophic acinar cells with pyknotic nuclei were stained positive in 89 % of the pancreatitis tissues, but the immunoreactivity was predominantly nuclear (Figure 1D). Dedifferentiating acinar cells showed positive cytoplasmic immunostaining with Caspase-1 antiserum in 84 %. In chronic pancreatitis tissues, which often surrounded pancreatic carcinoma because of tumor obstruction, we also found strong Caspase-1 expression, but immunoreactivity differed from that of chronic pancreatitis tissue specimens from patients without malignancy. The staining in tumor-surrounding pancreatitis tissues was generally stronger than that in non-tumor-related pancreatitis tissues, and the distinct distribution pattern found in primary chronic pancreatitis could not be observed. In addition to this tissue-specific staining, a positive immunoreactivity of tissue-infiltrating lymphocytes was found in 73 % of the tissues.

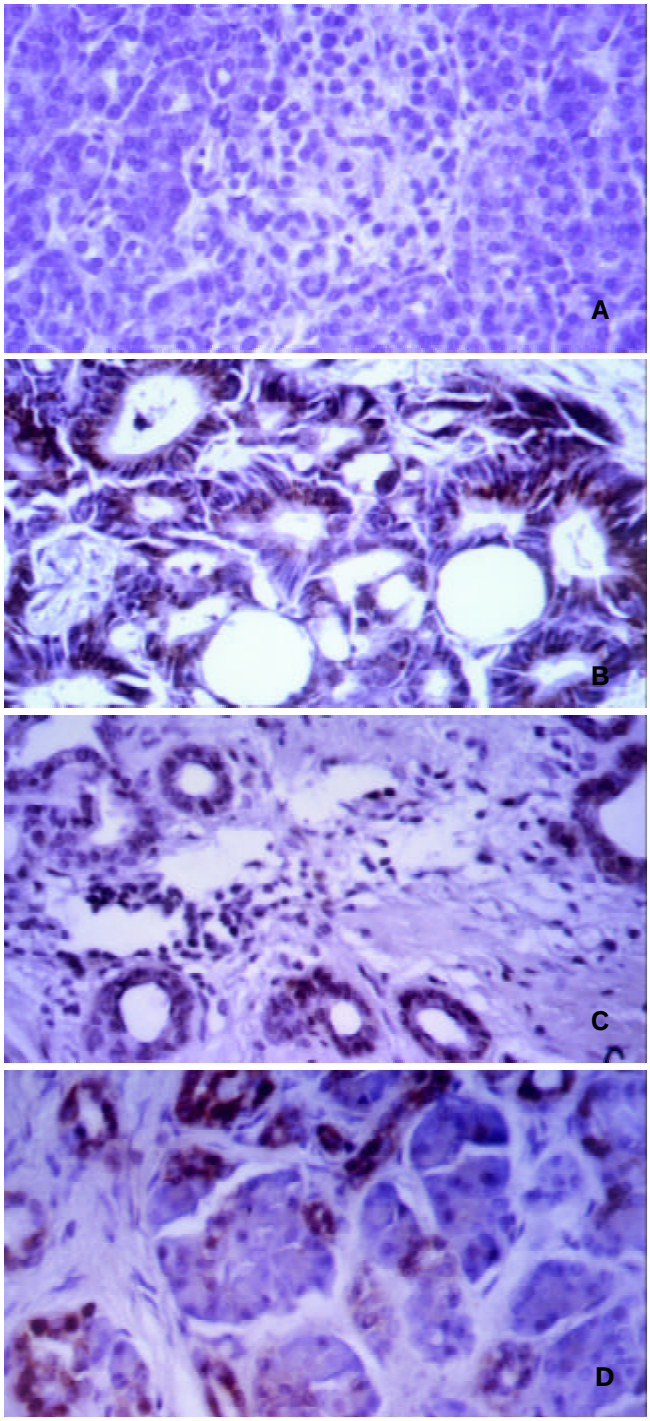

Figure 1 Immunohistochemical staining of pancreatic tissues using antiserum against human Caspase-1. A: Normal pancreas showed only occasional slight staining. B: Pancreatic cancer cells showed a clear cytoplasmatic immunoreactivity in 71 %. C: Hyperplastic ducts in chronic pancreatitis tissues also showed cytoplasmatic staining in 87 % of the tissues, whereas in atrophic acinar cells (D) a predominantly nuclear staining could be observed in 89 %.

Western blot analysis

To confirm the overexpression of Caspase-1 seen in immunohistochemical staining, Western blot analysis was performed with monoclonal antibody CAL against human Caspase-1. This antibody was developed to detect the 20 kDa subunit of active Caspase-1[11], but also detect the p45 precursor. Pancreatic cancer tissue as well as chronic pancreatitis tissue specimens showed specific bands migrating at 45 kDa (Figure 2) which suggested the p45 precursor protein of Caspase-1. This band was found in 80 % of cancer tissues and 86 % of chronic pancreatitis tissues.

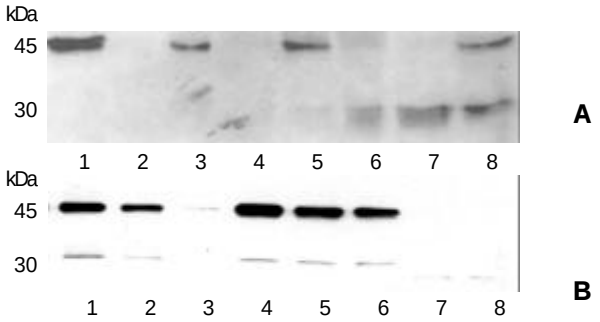

Figure 2 Western blot analysis of pancreatic tissues with anti-Caspase-1 antibody. The 45 kDa precursor of Caspase-1 was found in 86 % of chronic pancreatitis samples (A, Lanes 3-8) and 80 % of pancreatic cancer samples (B, Lanes 1-8). In 60 % of cancer specimens and 14 % of chronic pancreatitis tissue samples, the active 30 kDa p10-p20 heterodimer was found. In normal pancreatic tissues (A, lane 2), neither p45 precursor nor active Caspase-1 could be detected. Lane 1 (A) shows the positive control of THP 1 cells.

Lysates from THP-1 cells served as control specimens for active Caspase-1. In monocytic THP1 cells, p45 Caspase-1 precursor has been known to be cleaved by an autocatalytic process to the active Caspase-1 enzyme when kept at room temperature for 24 hours[11]. In 60 % of the cancer probes and 14 % of the pancreatitis lysates, and in lysates from the autocleavage experiments of THP1 cells, a further band at 30 kDa was detectable, which was suggested the active p10-p20 heterodimer of active Caspase-1. In pancreatic tissue of healthy organ donors, no signal was obtained using monoclonal antibody against human Caspase-1, suggesting an overexpression of Caspase-1 protein in pancreatic cancer and chronic pancreatitis. Since lysates from pancreatic cancer tissue and chronic pancreatitis specimens also showed the 30 kDa band, it was plausible that Caspase-1 was at least partly activated in these disorders.

Correlation with clinicopathological features

To assess the clinical importance of Caspase-1 overexpression in pancreatic cancer, we correlated the immunohistochemical findings with age, sex, tumor extent, lymph node metastasis, and grading. As a result, no correlation was found between Caspase-1 expression and any of these clinicopathologic features. In addition, no statistical difference was found with regard to postoperative survival. In patients with chronic pancreatitis, we correlated the expression of Caspase-1 with age, sex, onset of disease, need for analgesic drugs, and endocrine and exocrine pancreatic function. As in patients with pancreatic cancer, no correlation with any of the tested features could be found.

DISCUSSION

Caspases play an important role in the apoptotic pathway in a variety of cell types. However, little is known about the physiologic roles of different homologues during apoptosis. We assessed the expression of Caspase-1 in pancreatic cancer and chronic pancreatitis. Interestingly, immunohistochemical analysis revealed a clear overexpression of this enzyme in both disorders, but also differences in the expression patterns in distinct morphologic compartments. Furthermore, Western blot analysis of pancreatic cancer tissues and chronic pancreatitis tissues showed that Caspase-1 was at least partially activated in these diseases.

Caspase-1 is described as a cytosolic protein. However, in our experiments we found a clear nuclear staining with the antibody against human Caspase-1 in atrophic acinar cells in chronic pancreatitis specimens. Interestingly, most of the known substrates for Caspases in apoptosis were structural or catalytic nuclear proteins, the cleavage fragments of which were found in apoptotic bodies[12] . The nuclear immunoreactivity of atrophic acinar cells in chronic pancreatitis may, therefore, be an indication of ongoing apoptotic processes. In contrast, the marked cytoplasmatic overexpression of Caspase-1 in tumor cells could hardly be explained by apoptosis, since some tumors showed Caspase-1 overexpression in nearly all cancer cells. Furthermore, we found a clear correlation between Caspase-1 overexpression in pancreatic carcinoma and cyclin D1, which has been known to be involved in cellular proliferation and to contribute to an aggressive behavior in many tumors[13-16]. EGF and EGF-R have been shown to play a crucial role in autocrine stimulation of human pancreatic carcinoma[17]. In the pancreatic cancer tissues we investigated, the cytoplasmatic expression of Caspase-1 in pancreatic cancer cells also correlated significantly with the expression of EGF and EGF-R. Interestingly, it has recently been shown that EGF was also able to inhibit cell growth and induce apoptosis via Caspase-1 induction[18]. However, with regard to the fact that cyclin D1, EGF, and EGF-R overexpression was associated with poor prognosis in human pancreatic cancer[13,19], it is hard to believe that these factors could be an indication for the apoptotic state of these tumors.

Chronic pancreatitis is histologically characterized by the destruction of the pancreatic parenchyma, irregular sclerosis, and focal duct cell proliferation. Besides the predominantly nuclear staining with the antibody against Caspase-1 in atrophic acinar cells, we found a clear cytoplasmatic overexpression in two other distinct morphologic compartments in chronic pancreatitis—in hyperplastic ducts and in areas with tubularily dedifferentiating acinar cells. Cyclin D1, EGF, and EGF-R were also altered in chronic pancreatitis[20,21], which lend support to the hypothesis that chronic pancreatitis is a progressive process. Furthermore, we have recently found that positive nuclear MIB-1 (Ki67) expression in pancreatitis tissues might be an indication for proliferative processes[22,23]. Tumor surrounding pancreatitis tissues from patients with pancreatic cancer showed a strong positive immunoreactivity with antiserum against Caspase-1, but the differential expression pattern seen in primary chronic pancreatitis could not be observed. Nuclear and cytoplasmatic expression of Caspase-1 was found in atrophic acinar cells and in duct cells as well. One explanation for this overexpression might be the dramatic course of pancreatitis due to tumor obstruction. Another explanation might be that Caspase-1 was upregulated through paracrine stimulation with tumor-derived EGF in these cells. Nevertheless, destruction of pancreatic parenchyma due to tumor growth and invasion was likely to be associated with apoptosis of normal pancreatic cells.

In summary, Caspase-1 is overexpressed in atrophic acinar cells of chronic pancreatitis and tumor-surrounding pancreatitis tissues and is markedly expressed in cytoplasm of pancreatic cancer cells and hyperplastic duct cells and dedifferentiating acinar cells in chronic pancreatitis.

Abstract

AIM: To investigate whether vascular endothelial growth factor (VEGF) and basic fibroblastic growth factor (bFGF) are associated with spider angiomas in patients with liver cirrhosis.

METHODS: Eighty-six patients with liver cirrhosis were enrolled and the number and size of the spider angiomas were recorded. Fifty-three healthy subjects were selected as controls. Plasma levels of VEGF and bFGF were measured in both the cirrhotics and the controls.

RESULTS: Plasma VEGF and bFGF were increased in cirrhotics compared with controls (122±13 *vs*. 71±11 pg/mL, *P*=0.003 for VEGF; 5.1±0.5 *vs*. 3.4±0.5 pg/mL, *P*=0.022 for bFGF). In cirrhotics, plasma VEGF and bFGF were also higher in patients with spider angiomas compared with patients without spider angiomas (185±28 *vs*. 90±10 pg/mL, *P*=0.003 for VEGF; 6.8±1.0 *vs*. 4.1±0.5 pg/mL, *P*=0.017 for bFGF). Multivariate logistic regression showed that young age and increased plasma levels of VEGF and bFGF were the most significant predictors for the presence of spider angiomas in cirrhotic patients (odds ratio [OR]=6.64, 95 % confidence interval [CI]=2.02-21.79, *P*=0.002; OR=4.35, 95 % CI=1.35-14.01, *P*=0.014; OR=5.66, 95 % CI=1.72-18.63, *P*=0.004, respectively).

CONCLUSION: Plasma VEGF and bFGF are elevated in patients with liver cirrhosis. Age as well as plasma levels of VEGF and bFGF are significant predictors for spider angiomas in cirrhotic patients.

INTRODUCTION

Liver cirrhosis is a major disease in Asian countries and causes marked morbidity and mortality. Spider angioma is a common presentation of liver cirrhosis[1,2]. It appears frequently in alcoholic cirrhotics or when liver function deteriorates[2-4] and may be associated with esophageal variceal bleeding[5]. However, the exact pathogenesis has been unclear.

Angiogenesis is a possible mechanism in the pathogenesis of spider angiomas and has not been well investigated. Serum vascular growth factors, such as vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (bFGF), have been found to be elevated in cirrhotic patients[6-9]. These vascular growth factors may play a role in the neovascularization and formation of spider angiomas in patients with liver cirrhosis.

The aim of this study was to evaluate the predictive value of plasma VEGF and bFGF for the presence of spider angiomas in patients with liver cirrhosis.

MATERIALS AND METHODS

Study patients

Eighty-six consecutive liver cirrhotic patients from Taipei Veterans General Hospital were enrolled into this study. Fifty-three age- and sex-matched subjects from apparently healthy adults who were admitted to our hospital for routine physical checkups were randomly selected as healthy controls. The etiologies of liver cirrhosis included hepatitis B in 37 patients (43 %), hepatitis C in 18 patients (21 %), alcoholism in 12 patients (14 %), primary biliary cirrhosis in 2 patients (2 %), hepatitis B and alcoholism in 7 patients (8 %), hepatitis C and alcoholism in 6 patients (7 %), and being cryptogenic in 4 patients (5 %). The diagnosis of cirrhosis was confirmed by liver biopsy or peritoneoscopy in 8 patients, and based on typical clinical findings (splenomegaly, ascites, and/or esophageal varices), imaging studies (abdominal sonography[10], computerized tomography, and/or angiography), and characteristic laboratory findings in the remaining 78 patients. The severity of cirrhosis was categorized according to the Child-Pugh classification[11]. Patients with hypertension, diabetes mellitus, atherosclerosis, uremia, and peripheral vascular occlusive diseases were excluded. None of these patients had received antibiotics or vasoactive drugs in the previous week before blood sampling. All the subjects gave informed consent to participate in this study, which was approved by the Hospital Ethics Committee. This study also conformed to the provisions of the World Medical Association Declarations of Helsinki.

All the patients received a complete physical examination to reveal the number and size of the spider angiomas. Serum albumin (reference range 3.7-5.3 g/dL), bilirubin (0.2-1.6 mg/dL), aspartate transaminase (AST, 5-45 U/L), alanine transaminase (ALT, 0-40 U/L), creatinine (0.7-1.5 mg/dl), and blood urea nitrogen (7-20 mg/dL) concentrations were measured in each patient using standard laboratory methods (Hitachi Model 736 automatic analyzer, Tokyo, Japan) on the same day the blood was sampled for assays of plasma vascular growth factors. Each cirrhotic patient underwent an upper GI endoscopy (Olympus GIF-XQ240; Olympus Corp., Taipei, Taiwan) to

document the presence of esophageal varices. The severity of varices was graded F1: small straight varices, F2: enlarged tortuous varices, and F3: largest-sized coil-shaped varices, as suggested by Beppu *et al*[12].

Determination of plasma levels of VEGF and bFGF

All the plasma samples were centrifuged at 3 000 rpm for 10 minutes at 4 ℃ and stored at -80 ℃ until tested. Samples from all the patients and controls were coded so that the technicians running the assays were blind to the sources of the samples. Plasma levels of VEGF and bFGF were measured by using commercially available enzyme-linked immunoabsorbent assay kits (R&D Systems Inc., Minneapolis, MN) according to the manufacturer's instructions. Standard curves were constructed using serial dilutions of recombinant VEGF and bFGF. Optical densities were determined using a micro-titer plate reader (Bio-Kinetics Reader, Bio-Tek Instruments, VT). Tests were performed in duplicate. The intra- and inter-assay variations of these assays were less than 10 %.

Statistical analysis

Results were expressed as mean ± SD. Unpaired Student *t*-test was used to analyze continuous variables between groups. Chi-square test or Fisher's exact test was used for comparison of categorical variables. Pearson correlation coefficient was used to determine the relationship between numerical variables, such as plasma levels of VEGF and the size of spider angiomas. Cut-off values were determined for each serum angiogenic factor according to the best discrimination between patients with or without spider angiomas regarding optimal values of sensitivity and specificity using the receiver operating characteristics (ROC) curve analysis. Logistic regression was used to assess the relationship of independent variables with the presence of spider angiomas in cirrhotic patients. Statistical analyses were performed using the SPSS software (SPSS 10. 0, SPSS Inc., Chicago, IL, USA). Results were considered statistically significant at $P<0.05$.

RESULTS

Plasma angiogenic factors in patients with liver cirrhosis

Plasma VEGF and bFGF levels in patients with liver cirrhosis are listed in Table 1. Plasma levels of VEGF and bFGF were increased in patients with liver cirrhosis compared with healthy controls ($P<0.05$). There was no difference in age, sex, and serum levels of creatinine between the two groups (data not shown).

Table 1 Plasma levels of VEGF and bFGF

Parameters	Healthy controls (n=53)	Cirrhotics (n=86)	P Value
VEGF (pg/mL)	71±11	122±13	0.003
bFGF (pg/mL)	3.4±0.5	5.1±0.5	0.022

VEGF=vascular endothelial growth factor, bFGF=basic fibroblast growth factor.

Patient characteristics

Characteristics of the 86 patients with liver cirrhosis are listed in Table 2. Plasma VEGF and bFGF were increased in the 31 cirrhotic patients with spider angiomas compared with the 55 patients without spider angiomas (185±28 pg/mL *vs*. 90±10 pg/mL, $P=0.003$ for VEGF; 6.8±1.0 pg/mL *vs*. 4.1±0.5 pg/mL, $P=0.017$ for bFGF). Plasma VEGF was also higher in the 26 patients with alcohol-related liver cirrhosis compared with the 60 patients with non-alcoholic liver cirrhosis (167±29 pg/mL *vs*. 103±13 pg/mL, $P=0.04$).

Table 2 Characteristics of patients'

	No. of patients	VEGF (pg/ml)	bFGF (pg/ml)
Sex			
Male	67	121±14	4.8±0.5
Female	19	123±27	6.1±1.5
Age			
≤60 years	36	149±24	5.2±0.8
>60 years	50	103±13	5.1±0.6
Etiology			
Alcohol-related	26	167±29*	4.6±0.7
Non-alcoholic	60	103±13	5.4±0.6
Albumin (g/dL)			
≤3.6	48	132±15	5.1±0.7
>3.6	38	109±21	5.2±0.7
Creatinine (mg/dL)			
≤1.5	83	122±13	5.2±0.5
>1.5	3	125±73	4.5±2.6
ALT (U/L)			
≤40	37	136±22	4.1±0.6
>40	49	111±15	5.9±0.7
Total bilirubin (mg/dL)			
≤1.6	54	115±16	5.2±0.6
> 1.6	32	133±20	5.0±0.9
Child-Pugh score			
A	47	98±19	5.5±0.7
B, C	39	141±16	4.8±0.7

Spider angioma			
Yes	31	185±28[b]	6.8±1.0[a]
No	55	90±10	4.1±0.5

Data were presented as mean ±SD. [a]$P<0.05$, [b]$P<0.005$. VEGF=vascular endothelial growth factor, bFGF=basic fibroblast growth factor.

Plasma angiogenic factors and clinical features

Table 3 summarizes the clinical features of cirrhotic patients with spider angiomas and those without. Cirrhotic patients with spider angiomas were younger (54±2 years *vs*. 66±1 years, $P<0.001$) and had higher serum bilirubin (3.1±0.5 mg/dL *vs*. 1.7±0.2 mg/dL, $P=0.03$), longer prothrombin time (16.6±0.7 sec *vs*. 14.8±0.4 sec, $P=0.015$), and higher proportion of alcoholism (45 % *vs*. 20 %, $P=0.014$) than those without. Sex, serum albumin, creatinine, AST, ALT, platelet count, size of esophageal varices, and Child-Pugh score did not differ between the two groups.

In the cirrhotics, plasma VEGF was significantly correlated with the size of spider angiomas ($r=0.38$, $P<0.001$). Plasma VEGF level also showed correlation with serum bilirubin level ($r=0.3$, $P=0.006$) and platelet count ($r=0.5$, $P<0.001$).

Univariate analysis of predictive factors for spider angiomas

Univariate analysis of factors predicting the presence of spider angiomas in patients with liver cirrhosis by using logistic regression is shown in Table 4. The cut-off values of 134 pg/mL

for VEGF and 4.8 pg/mL for bFGF obtained by the ROC analysis were used in the univariate analysis. Young age, elevated serum AST and bilirubin, prolonged prothrombin time, elevated plasma VEGF and bFGF, and alcoholism were associated with the presence of spider angiomas in cirrhotic patients.

Table 3 Clinical features of cirrhotic patients with and without spider angiomas

Parameters	Spider (+) (n=31)	Spider (-) (n=55)	P Value
Age (years)	54±2	66±1	<0.001
Sex (male / female)	27 / 4	41 / 14	0.17
Albumin (g / dL)	3.4±0.1	3.5±0.1	0.69
Creatinine (mg / dL)	1.0±0.1	1.1±0.1	0.24
AST (U / L)	91±9	89±13	0.93
ALT (U / L)	59±9	72±11	0.36
Platelet count (/ uL)	108 097±12 379	94 762±7 541	0.33
Esophageal varices (nil / F1 / F2 / F3)	7 / 6 / 12 / 6	18 / 12 / 14 / 11	0.88
Child-Pugh score	8.2±0.5	7.3±0.3	0.99
Bilirubin (mg / dL)	3.1±0.5	1.7±0.2	0.03
Prothrombin time (s)	16.6±0.7	14.8±0.4	0.015
Alcoholism	14 (45 %)	11 (20 %)	0.014

AST=aspartate transaminase, ALT=alanine transaminase.

Table 4 Univariate analysis of predictive factors for spider angiomas

Parameters	Odds ratio	95 % Confidence interval	P Value
Age (≤60 years)	5.12	1.97-13.28	0.001
Albumin (≥3.7 g / dL)	0.66	0.27-1.64	0.369
Creatinine (>1.5 mg / dL)	0.58	0.06-5.81	0.642
AST (>45 U / L)	5.76	1.56-21.3	0.009
ALT (>40 U / L)	1.24	0.51-3.02	0.634
Bilirubin (>1.6 mg / dL)	2.71	1.09-6.74	0.031
Platelet count (>150 000 / uL)	1.41	0.44-4.52	0.563
Prothrombin time prolongation (>4 s)	2.96	1.15-7.58	0.024
Child-Pugh score C	1.64	0.59-4.53	0.344
VEGF (≥134 pg / mL)	5.33	1.93-14.74	0.001
bFGF (≥4.8 pg / mL)	4.38	1.67-11.5	0.003
Alcoholism	3.29	1.25-8.67	0.016

AST=aspartate transaminase, ALT=alanine transaminase, VEGF=vascular endothelial growth factor, bFGF=basic fibroblast growth factor.

Table 5 Multivariate analysis of predictive values of VEGF, bFGF, and age for spider angiomas

Parameters	Odds ratio	95% confidence interval	P Value
Age (≤60 years)	6.64	2.02-21.79	0.002
VEGF (≥134 pg / mL)	4.35	1.35-14.01	0.014
bFGF (≥4.8 pg / mL)	5.66	1.72-18.63	0.004

VEGF=vascular endothelial growth factor, bFGF=basic fibroblast growth factor.

Multivariate analysis of plasma VEGF and bFGF, age and their predictive values for spider angiomas

Multivariate analysis with logistic regression showed that young age and elevated plasma levels of VEGF and bFGF were the most independent predictive factors for spider angiomas in cirrhotic patients, as shown in Table 5. The predictive values of plasma VEGF for spider angiomas were the following: sensitivity, 53 %; specificity, 82 %; positive predictive value, 64 %; and negative predictive value, 75 %. The predictive values of plasma bFGF for spider angiomas were: sensitivity, 60 %; specificity, 75 %; positive predictive value, 58 %; and negative predictive value, 76 %.

DISCUSSION

Spider angioma has been commonly seen in patients with liver cirrhosis[1,2]. The pathogenesis is still unknown. Neovascularization is a likely mechanism, but has not been proved. In the current study, we found significantly elevated plasma levels of VEGF and bFGF in cirrhotic patients compared with healthy controls. Elevated plasma VEGF was correlated with the size of spider angiomas. To our knowledge, this is the first study to demonstrate that age and plasma VEGF and bFGF are the most significant independent predictors of spider angiomas in cirrhotic patients.

VEGF has been found to be a glycoprotein that selectively induces endothelial proliferation, angiogenesis, and capillary hyperpermeability[13-15]. VEGF gene was expressed in a wide variety of normal human tissues, including the liver[16,17]. Blood levels of VEGF in patients with cirrhosis remain controversial[6,18]. Our results showed that plasma VEGF was elevated in patients with liver cirrhosis. In addition, plasma VEGF levels were negatively correlated with liver function reserve in patients with liver cirrhosis. The elevated VEGF might be due to ischemic or damaged liver cells, which released cellular VEGF to facilitate damage repair by stimulating angiogenesis[19]. Increased production of VEGF by the cirrhotic liver has also been reported[20], and may subsequently lead to the formation of spider angiomas.

bFGF has also been found to be a potent stimulator of endothelial cell proliferation, migration, and angiogenesis[21]. Our results showed that plasma bFGF was elevated in patients with liver cirrhosis which was consistent with previous reports[7-9]. The elevated bFGF might be due to a release from damaged liver cells[22] or increased production by the cirrhotic liver[9]. bFGF could also stimulate the production of VEGF and enhance angiogenesis[23].

The presence of spider angiomas has been reported to be associated with esophageal variceal bleeding[5]. The pathophysiological mechanism has been unclarified. Spider angiomas originate from arterioles, while esophageal varices are one kind of veins. They are different in nature. In this study, there was no relationship between the presence of spider angiomas and the degree of esophageal varices. In addition, there was no association between esophageal varices and these angiogenic factors.

A positive correlation was also found between serum VEGF level and the platelet count. This result was in accordance with the findings reported by others[24]. Platelets release a variety of vasoactive substances, including VEGF, and promote angiogenesis, endothelial permeability, and endothelial growth[25]. Although there was a positive correlation between the serum VEGF level and platelet count, there was no significant association between platelet count and spider angioma in the present study. Serum VEGF level was an independent predictor of spider angioma.

Plasma VEGF was increased in alcoholic cirrhotics compared with non-alcoholic cirrhotics in our study. Ethanol could induce expression of vascular endothelial growth factor and stimulate angiogenesis[26]. This may lead to the high prevalence of spider angiomas in alcoholic cirrhotic patients.

Young age was a significant predictor for the presence of spider angiomas in cirrhotics in our study. This was in

conformity with previous reports[1]. The underlying mechanism is unknown. A decline in angiogenic capacity in the aged[27,28] may cause impaired neovascularization and formation of spider angiomas in cirrhotic patients.

In summary, plasma VEGF and bFGF are elevated in patients with liver cirrhosis, especially in those with spider angiomas. Age-related angiogenic capacity as well as VEGF and bFGF may play important roles in the formation of spider angiomas in cirrhotic patients.

Abstract

AIM: Liver transplantation is indicated for Wilson's disease (WD) patients with the fulminant form and end-stage liver failure. The aim of this study was to review our experience with living-related liver transplantation (LRLT) for WD.

METHODS: A retrospective review was made for WD undergoing LRLT at our hospital from January 2001 to Febuary 2003.

RESULTS: LRLT was carried out in 15 patients with WD, one of them had fulminant hepatic failure and the others had end-stage hepatic insufficiency. The mean age of the patients was 14.5±2.5 years (range 6 to 20 years). All the recipients had low serum ceruloplasmin levels with a mean value of 126.8±34.8 mg/L before transplantation. The serum ceruloplasmin levels increased to an average of 238.6±34.4 mg/L after LRLT at the latest evaluation, between 2 and 27 months after transplantation. A marked reduction in urinary copper excretion was observed in all the recipients after transplantation. Among the eight recipients with preoperative Kayser-Fleischer (K-F) rings, this abnormality resolved completely after LRLT in five patients and partially in three. All the recipients are alive and remain well, and none has developed signs of recurrent WD after a mean follow-up period of 15.4±9.3 months (range 2-27 months) except one who died of severe rejection. The donors were 14 mothers and 1 father. The serum ceruloplasmin levels were within normal limits in all the donors (mean: 220±22.4 mg/L). The mean donor age was 35.0±4.0 years (range, 30 to 45 years). Two donors had biliary leakage and required reoperation. Grafts were harvested as follows: four right lobe grafts without hepatic middle vein and eleven left lobe grafts with hepatic middle vein. The grafts were blood group-compatible in all recipents. Two patients had hepatic artery thrombosis and underwent retransplantation.

CONCLUSION: LRLT is a curative procedure in Wilson's disease manifested as fulminant hepatic failure and/or end-stage hepatic insufficiency. After liver transplantation, the serum ceruoplasmin level can increase to its normal range while urinary copper excretion decreases. Grafts chosen from heterozygote carriers do not appear to confer any risk of recurrence in recipients.

INTRODUCTION

Wilson's disease (WD) is an autosomal recessive disease. Its clinical and pathological manifestations are the consequence of an excessive accumulation of copper in tissues, particularly in the liver, brain, cornea, and kidneys. Liver transplantation is indicated for fulminant form and end-stage liver disease of WD[1,2].Cadaveric liver transplantation has been reported to normalize copper metabolism in recipients[3,4]. Recently, LRLT has also been used for WD[5-14]. Asonuma *et al*[8] reported that LRLT from heterozygous carriers of the WD gene could also resolve clinical signs and symptoms of WD and correct the parameters of copper metabolism. In this study, we reported our experience with LRLT for hepatic complications of WD from January 2001 to February 2003.

MATERIALS AND METHODS

Clinical and laboratory data were obtained from a review of the files of patients from 2001 to 2003 at Liver Transplantation Center of Jiangsu Province. All treatments had an informed consent of the children' s parents and the approval of the Ethics Committee of Nanjing Medical University. Donors were selected based on blood type, liver function, negative serological test results(hepatitis B virus, hepatitis C,HIV),physical examination, psychosocial evaluation including alcohol abuse and liver volumes assessed by Doppler ultrasound equipment and computed tomography. The donors were 14 mothers and 1 father. The serum ceruloplasmin levels were within the normal limits in all donors (mean: 220±22.4 mg/L). The mean donor age was 35.0±4.0 years (range, 30 to 45 years). Serum ceruloplasmin and copper level were also normal in all donors who gave an informed consent.

The diagnosis of WD was maded on the basis of a combination of the findings, including hepatic and/or neurological clinical abnormalities ,the presence of Kayser-Fleischer rings (KFR), elevated 24-hr urine copper (>100 μg/24 hr), low cerulopasmin level (reference range 200-500 mg/L). The above mentioned routine laboratory data were obtained by using standard methods. No patient received any chelating agent and presented clinical signs of WD after LRLT.

Among the 15 patients with WD, one had fulminant hepatic failure and the others had end-stage hepatic insufficiency. Their mean age was 14.5±2.5years (range 6 to 20 years). Before transplantation, all recipients had a low serum ceruloplasmin level with a mean value of 126.8±34.8 mg/L and a high urinary copper excretion with a mean value of 1 825.6±187.4 μg/24 h. Eight recipients had preoperative Kayser-Fleischer (K-F) rings. Grafts were harvested as follows: four right lobe grafts without hepatic middle vein and eleven left lobe grafts with hepatic middle vein. The grafts were blood group-compatible in all recipents.

RESULTS

Donors

All the donors were discharged from the hospital after a mean hospital stay of 9-14 days, and then resumed their normal life without any significant adverse sequelae. Two complications of bile leaks occurred, and required reoperation.

Recipents

Two patients had hepatic artery thrombosis and underwent retransplantation. All the recipients enjoyed normal health with a good quality of life, and none had signs of recurrent WD after a mean follow-up period of 15.4±9.3 months (range 2-27 months). One patient died of severe rejection. Copper metabolism of the WD recipients and the presence of K-F rings were compared before and after transplantation. After LRLT, all the recipients had normal serum ceruloplasmin concentrations in the first month. Marked reduction of urinary copper excretion occurred in the first three months, which became normal 6-9 months after operation. Kayser-Fleischer (K-F) rings were resolved completely after LRLT in five patients and partially in three.

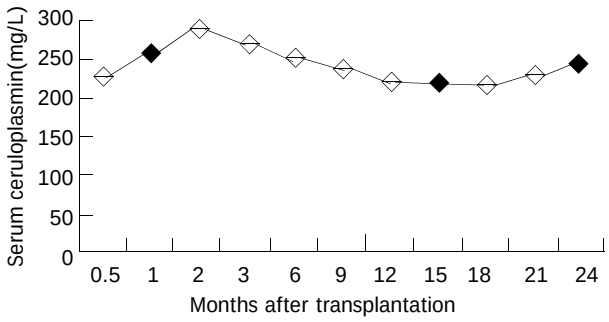

Figure 1 Changes in serum ceruloplasmin of postoperative recipients (Normal: 200-500 mg/L).

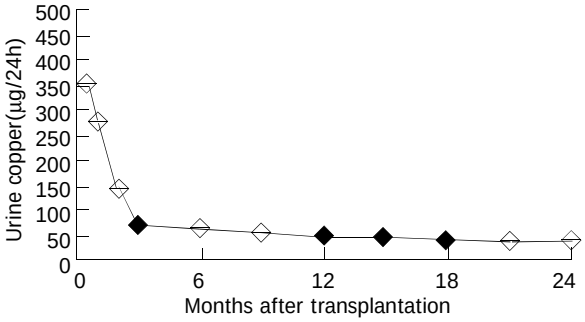

Figure 2 Changes in urine copper of postoperativ recipients (Normal: <50 μg/24 h).

DISCUSSION

Wilson's disease, first described by Kinnear Wilson in 1912, is an autosomal recessive condition with a prevalence in one of 30 000[15]. Its clinical and pathological manifestations are the consequence of an excessive accumulation of copper in tissues, particularly in the liver, brain, cornea, and kidneys. The WD gene is localized on the long arm of chromosome 13 and was recently cloned by several different research groups[16-19]. The gene product ATP7B is a copper transporting type ATPase. Establishing the diagnosis of Wilson's disease is usually straightforward if the major clinical and laboratory features are manifested as: typical hepatic and/or neurological symptoms and signs, Kayser-Fleischer rings, low serum caeruloplasmin concentrations, and increased urinary copper excretion.

It has been reported that the prognosis of fulminant WD is extremely poor and liver transplantation is currently the only available form of curative therapy when penicillamine therapy has failed or is no longer appropriate[20-22]. Cadaveric liver transplantation has been reported to normalize copper metabolism in recipients[3,4]. As scarcity of cadaveric donors is a serious problem in many countries, LRLT represents a critical form of rescue therapy in endstage liver disease. Recently, because of the shortage of donors for cadaveric liver transplantation, LRLT has also been indicated for WD[5-14]. Asonuma *et al*[8] reported that LRLT from heterozygous carriers of the WD gene could also resolve clinical signs and symptoms of WD and correct the parameters of copper metabolism.

The advantage of LRLT is that the donor liver can be obtained in an urgent situation when conservative therapy has failed. A successful transplantation of a liver from a living donor was performed in Australia in 1989 by Strong and colleagues[23], and the technique had been practised worldwide now, particularly in countries where cadaveric organs are not available. In general, the most important ethical dilemma with LRLT is that the process subjects a healthy person to a major operation. More than 1500 such surgeries in children have been performed throughout the world. Only two donors died. One died from pulmonary embolism, and the other died from an anesthetic accident. The patient with pulmonary embolisms was probably a poor surgical candidate. In neither case were there any technical complications related to the procedure. Both cases showed the importance of donor evaluation and selection in preventing living donor mortalities. In this study, 15 donors were discharged from the hospital and all resumed their normal life style without any significant adverse sequelae after a mean hospital stay of 15 days after the operation. Two complications of bile leakage occurred, and required a relaparotomy. The results, along with those from other centers, confirmed the general safety of the donor operation[24,25]. Hepatic arterial reconstruction is one of the most difficult procedures in living-donor liver transplantation (LDLT) because the artery used is generally small in diameter and has a short stalk. If hepatic artery thrombosis (HAT) occurred, the recipient clinical course would be unstable[26-30]. The introduction of microvascular hepatic arterial reconstruction has significantly decreased the incidence of HAT. In our group, HATs were recognized in 2 cases (13 %), retransplantations saved the patients. So surgeons who perform hepatic arterial reconstruction in LDLT should be well trained in microvascular techniques to decrease the incidence of HAT.

In this study, Copper metabolism in the WD recipients and the presence of K-F rings were compared before and after transplantation. After LRLT, all the recipients had a normal serum ceruloplasmin concentration and marked reduction in urinary copper excretion. All the donor ceruloplasmin levels were within the normal range, as were the post-transplant levels in the recipients. In addition to normal laboratory profiles of copper abnormalities, five out of eight patients with Kayser-Fleischer rings had a complete resolution and the remaining three showed improvement following transplantation. Despite these results, it is important to remember that about 10 % of WD heterozygotes would have low ceruloplasmin levels, so that they might be unsuitable as donors[31]. Based on the findings of this study, living related liver transplantation can be used safely in WD when appropriate cadaveric organs are unavailable. Despite the excellent results of the reported cases, there are some questions to be studied ,such as screening of potential WD heterozygote donors for uncommon abnormalities of copper metabolism, *etc*.

Furthermore, it is still unclear whether de-coppering after LRLT from heterozygote donors is slower than de-coppering after cadaveric transplantation from non-related donors. We

are reassured, however, by the fact that none of our transplanted recipients had persistent neurological abnormalities after LRLT, and K-F rings disappeared in most of the recipients, indicating that LRLT was indeed an effective and safe modality of therapy for patients with Wilsonian fulminant hepatic failure and end-stage hepatic insufficiency. After liver transplantation, serum ceruoplasmin level increased to normal range and urinary copper excretion decreased. Grafts chosen from heterozygote carriers did not appear to confer any risk of recurrence in the recipients, at least in the short term. Long-term follow-up should be continued to evaluate this specific therapy.

Abstract

AIM: To investigate the mutation of EDNRB gene and EDN-3 gene in sporadic Hirschsprung's disease (HD) in Chinese population.

METHODS: Genomic DNA was extracted from bowel tissues of 34 unrelated HD patients which were removed by surgery. Exon 3, 4, 6 of EDNRB gene and Exon 1, 2 of EDN-3 gene were amplified by polymerase chain reaction (PCR) and analyzed by single strand conformation polymorphism (SSCP).

RESULTS: EDNRB mutations were detected in 2 of the 13 short-segment HD. One mutant was in the exon 3, the other was in the exon 6. EDN-3 mutation was detected in one of the 13 short-segment HD and in the exon 2. Both EDNRB and EDN-3 mutations were detected in one short-segment HD. No mutations were detected in the ordinary or long-segment HD.

CONCLUSION: The mutations of EDNRB gene and EDN-3 gene are found in the short-segment HD of sporadic Hirschsprung's disease in Chinese population, which suggests that the EDNRB gene and EDN-3 gene play important roles in the pathogenesis of HD.

INTRODUCTION

Hirschsprung' s disease (HD) is a congenital malformation with an incidence of one in 5 000 live newborns. The absence of intramural intestinal ganglia of Meissner and Auerbach results in poor coordination of propulsive movement, and hence functional intestinal obstruction. Patients were treated surgically with removal of the affected intestine[1-4]. In 1994, two major genes associated with HD were recognized. First, in the RET (receptor tyrosin kinase) gene, there are inactivating mutations in isolated HD. RET accounts for up to 20 % of sporadic and 50 % of familial cases[5-11]. The second major gene is the EDNRB (endothelin receptor B) gene. EDNRB accounts for 5-10 % of all HD cases. Heterozygous mutations in the EDNRB gene were reported in nonsyndromic HD[12-16]. The preferred ligand for the G-protein coupled transmembranous receptor EDNRB was EDN-3 (endothelin-3). The interaction between EDN-3 and EDNRB was reported to be essential for normal development of enteric ganglia. The importance of the EDN-3-EDNRB interaction in promoting the normal development of neural crest cells has been clearly demonstrated. Human mutations in the EDN-3 gene have been reported recently: heterozygous missense mutations in two cases of sporadic HD[17-19]. However, there are fewer reports about mutations of EDNRB gene and EDN-3 gene in HD in Chinese population. In order to further investigate the pathogenic mechanism of HD, we examined mutations on exon 3, 4, 6 of EDNRB gene and exon 1, 2 of EDN-3 gene in 34 sporadic HD cases with the single strand conformation ploymorphism analysis of polymerase chain reaction products (PCR-SSCP).

MATERIALS AND METHODS

Tissue preparation and extraction of DNA

Thirty-four specimens of sporadic HD cases were collected after operation in the Second Hospital of Xi' an Jiaotong University between 1999 and 2001, and the pathological statement was approved pathologically. There are four cases of long-segment HD, seventeen cases of common HD, and thirteen cases of short-segment HD based on Romen' s division. At the same time, normal recta and sigmoid flexure tissues were collected, serving as a control group. All specimens were put into liquid nitrogen to freeze quickly after cut off in 15 minutes, and stored at a temperature of -80 ℃. DNA was extracted according to the standard protocols.

PCR amplification

The designed primers were synthesized by Bioasia Company. The specific primer sequences of exon 3, 4, 6 of EDNRB gene and exon 1, 2 of EDN-3 gene are summarized in Table 1. The PCR mixture (total volume: 30 μL) contained 2 μL of template-DNA, 3 μL of 10×PCR buffer, 3 μL of 2.5 mmol/L $MgCl_2$, 3 μL of 2.5 mmol/L dNTPs, 1 μL each of two fragment-specific primers, 17 μL of triplex distilled water, and 1 unit of Taq DNA polymerase. Thirty-five PCR amplification cycles were performed with the following condition of temperature: 94 ℃ for 35 seconds, 55 ℃ for 50 seconds and 72 ℃ for 1 minute. Amplifications were performed with a final extension for 10 minutes at 72 ℃. The amplified fragments were run in 15 g/L agarose gel, and were confirmed to be in existence.

SSCP analysis

A conventional electrophoresis apparatus (PC-3000 Mini Electrophoresis Unit; Bio-Red Company, USA) was used with a constant temperature of 10 ℃ for SSCP. For SSCP, the PCR products were heated for 10 min at 94 ℃, transferred into an ice-cold water bath for 3 min, and then run on 60 g/L polyacrylamide gel for 3 hours. The gel was stained by ethidium bromide for 10 - 20 min to visualize DNA band patterns.

Table 1 EDNRB and EDN-3 primer sequences

Gene	Exon		Primer	bp
EDNRB	3	Forwoard	ATCTTCAGATATCGAGCTGTT	223 bp
		Reverse	TGAAATTTACCTGCATGAAAG	
	4	Forwoard	ATCCCTATAGTTTTACAAGACAGC	170 bp
		Reverse	ATTTTCTTACCTGCTTTAGGTG	
	6	Forwoard	ACAGAAGCTACAATGACTAC	240 bp
		Reverse	GAAAGGCTTATATTTGAGCC	
EDN-3	1	Forwoard	CAAGCGGCCGTCCTCCTGGTCCGGT	180 bp
		Reverse	CTTCTCCGCGCCTCGGTCC	
	2A	Forwoard	CCCTCCTCAGGTGTTTGGG	239 bp
		Reverse	TCGGCCGCCTGCTCCTGC	
	2B	Forwoard	TGGCGAGGAGACTGTGGCT	218 bp
		Reverse	TGGCGAGGAGACTGTGGCT	

RESULTS

Analysis of PCR products

EDNRB gene PCR products The increment of all DNA samples from HD patients was a single strand with a length of 223 bp, 170 bp and 240 bp and so was the normal control, which indicated that a large fragment insertion and deletion did not exist in the region of EDNRB gene exon 3, 4 and 6 among 34 HD patients.

EDN-3 gene PCR products The increment of all DNA samples from HD patients was a single strand with a length of 180 bp, 239 bp and 219 bp and so was the normal control, which indicated that a large fragment insertion and deletion did not exist in the region of EDN-3 gene exon 1, 2A and 2B among 34 HD patients.

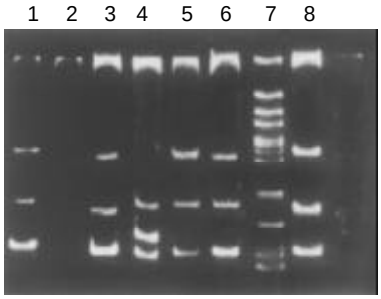

Figure 1 The abnormal shifted SSCP band in exon 3 of EDNRB. 1, 3, 5, 6: Normal shifted SSCP bands; 7: PGEM-3zf / *Hae* III marker; 8: Positive control; 2: Negative control; 4: Abnormal shifted SSCP band.

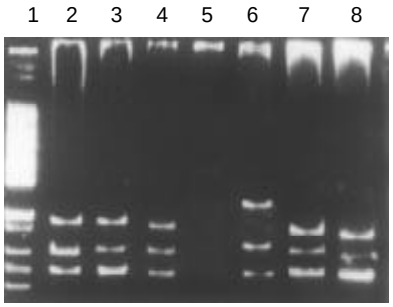

Figure 2 The abnormal shifted SSCP band in exon 6 of EDNRB. 1: PGEM-3zf / *Hae* III marker; 2: Positive control; 5: Negative control; 6: Abnormal shifted SSCP band. 3, 4, 7, 8: Normal shifted SSCP bands.

Results of SSCP

Among the 34 HD patients, abnormal SSCP migration patterns were found in 2 unrelated HD. EDNRB mutations were detected in 2 of the 17 short-segment HD. One mutant was in the exon 3 (Figure 1), the other was in the exon 6 (Figure 2). EDN-3 mutation was detected in 1 of the 17 short-segment HD and in the exon 2 (Figure 3). Both EDNRB mutation and EDN-3 mutation were detected in one short-segment HD (Figure 4). The mutation was absent in the ordinary, long-segment HD and normal control group samples.

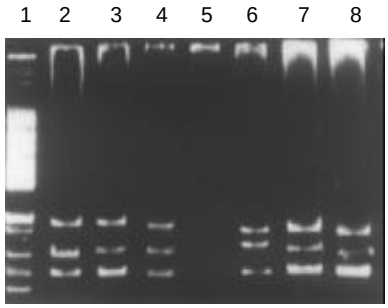

Figure 3 The abnormal shifted SSCP band in exon 2A of EDN-3. 1: PGEM-3zf / *Hae* III marker; 2: Positive control; 5: Negative control; 6: Abnormal shifted SSCP band. 3, 4, 7, 8: Normal shifted SSCP bands.

DISCUSSION

The endothelin peptide family of secreted peptides comprises four members to date: EDN-1, EDN-2, EDN-3, and VIP (vasoactive intestinal polypeptide)[20,21]. A diverse set of pharmacologic activities with different potencies are exerted by endothelin family peptides, suggesting the existence of

endothelin receptor subtypes.

The EDNRB gene encodes a heptahelical receptor that is involved in the G-protein-mediated intracellular signaling pathway. The human EDNRB gene lies on chromosome band 13q22 and comprises 7 exons, with a length of about 24 kb[22-27]. The predicted protein had 442 amino acids with a transmembrane topology similar to that of other G protein-coupled receptors which, when activated by a ligand, induce a calcium flux into the cells. Activation of EDNRB may result in upregulation of secretion of the endothelins, thereby amplifying their effects.

The EDN-3 gene encodes a large inactive preproendothelin-3 precursor which yields a biologically active 21 amino acid peptide containing four cysteines involved in two disulphide bonds. The human EDN-3 gene lies on chromosome band 20q13.3 and comprises 5 exons[28-30]. The EDN-3 is produced by a two-step proteolytic cleavage of a larger precursor molecule, preproendothelin. This molecule is enzymatically processed to an inactive progenitor (big endothelin) which is subsequently converted to the active peptide by a specific endothelin-converting enzyme 1. The mature peptide mediates its effect through two receptors, one of which is the EDNRB.

We have examined mutations on exon 3, 4, 6 of EDNRB gene and exon 1, 2 of EDN-3 gene in 34 sporadic Chinese HD patients with PCR-SSCP. The PCR result revealed that the increment of all DNA samples from HD patients was a single strand with a length of 223 bp, 170 bp and 240 bp and so was that from normal control, which indicated that a large fragment insertion and deletion did not exist in the region of EDNRB gene exon 3, 4 and 6 among 34 HD patients. And the increment of all DNA samples from HD patients was a single strand with a length of 180 bp, 239 bp and 219 bp and so was that from normal control, which indicated that a large fragment insertion and deletion did not exist in the region of EDN-3 gene exon 1, 2A and 2B among 34 HD patients. Among the 34 HD patients, we found abnormal SSCP migration patterns in 2 unrelated HD. EDNRB mutations were detected in 2 of the 17 short-segment HDs. One mutant was in the exon 3, the other in the exon 6. EDN-3 mutation was detected in 1 of the 17 short-segment HD and in the exon 2. Both EDNRB and EDN-3 mutations were detected in one short-segment HD. The mutation is absent in the ordinary, long-segment HD and normal control group samples. Due to the mutation of EDNRB, there would be no upregulation of secretion of the endothelins and amplification of endothelin effect, and the total amount of endothelin produced would be too small to initiate migration. Alteration of the structure of the preproendothelin by the mutation may conceivably result in a less efficient cleavage, or even a complete failure of cleavage of the preproendothelin, resulting in EDN-3 deficiency during development. This might lead to an incomplete colonization of the bowel by ganglion cells. We should bear in mind that EDNRB is the receptor for EDN-3, so it is reasonable to assume that the mutations of EDNRB and EDN-3 caused the maldevelopment of the enteric nervous system.

Similar to the receptor-ligand relationship between RET and GDNF observed in the etiology of some HD patients, in human fetuses, both EDNRB and EDN-3 have been demonstrated on enteric neurons and gut mesenchyme cells[31], suggesting that EDN-3 and EDNRB may regulate interactions between neural crest and gut mesenchyme cells, necessary for normal migration. There are reports on HSCR patients with GDNF-RET or NTN-RET gene mutation combinations, as well as a case with mutations in both RET and EDNRB[32-39]. So far, there has been no report on an EDN-3 mutation in combination with a mutation in other HSCR genes. In the present study, we found an EDN-3 mutation in combination with an EDNRB mutation in one short-segment HD patient.

To date, at least 16 different mutations or alterations of the EDNRB gene and 4 different mutations or alterations of the EDN-3 gene have been identified in HD patients. A variety of frameshift, nonsense, or missense mutations scattered along EDNRB gene and EDN-3 gene has been identified in HD patients[40, 41]. The combined results of our study for mutations in EDN3 and EDNRB may indicate the contributions of these genes to the HD phenotype. EDNRB and EDN3 mutations seem to account for a minority of cases. The majority of HSCR cases cannot be explained by mutations in any of the genes analysed so far, suggesting that other genes or additional factors may contribute to the occurrence of HD phenotype and that HD is a multifactorial disease.

Abstract

AIM: Overexpression of mucosal metalloproteinases (MMP) have been demonstrated recently in inflammatory bowel disease. Their activity can be counterbalanced by the tissue inhibitor of metalloproteinases (TIMP). The aim of this study was to evaluate the effect of ulcerative colitis (UC) on MMP-1 and TIMP-1 plasma concentrations, as two possible biomarkers of the disease activity.

METHODS: MMP-1 and TIMP-1 plasma concentrations were measured with an enzyme immunoassay in 16 patients with endoscopically confirmed active UC.

RESULTS: Plasma concentrations of both MMP-1 (13.7±0.2 ng/ml) and TIMP-1 (799±140 ng/ml) were significantly elevated in UC patients in comparison to healthy controls (11.9±0.9 ng/ml and 220±7 ng/ml respectively). There was no correlation between TIMP-1 and MMP-1 concentrations (r=-0.02). TIMP-1 levels revealed significant positive correlations with scored endoscopic degree of mucosal injury, disease activity index and clinical activity index values as well as C-reactive protein concentration. There was no correlation between MMP-1 and laboratory, clinical or endoscopic indices of the disease activity.

CONCLUSION: These results confirm the role of both MMP-1 and TIMP-1 in the pathogenesis of ulcerative colitis. However only TIMP-1 can be useful as a biomarker of the disease activity, demonstrating association with clinical and endoscopic pictures.

INTRODUCTION

Pathogenesis of ulcerative colitis (UC) is focused on abnormal immune response and diminished ability of mucosal protection and regeneration. These processes are controlled by signaling between epithelial cells involving complex network of cytokines, growth factors and other bioactive substances, responsible for cell proliferation and differentiation, as well as regulation of immune response[1-3]. Alterations in synthesis and breakdown of extracellular matrix components are known to play a crucial role in tissue remodeling during inflammation and wound healing. Inflammatory bowel disease (IBD) is sometimes complicated by stricture formation and muscle hypertrophy resulting from extracellular matrix (ECM) changes related to matrix metalloproteinases (MMPs) activity[4]. Overexpression of mucosal MMPs have been demonstrated recently in inflammatory bowel disease[5-7]. Effects of MMPs activity can be counterbalanced by the tissue inhibitor of metalloproteinases-1 (TIMP-1)[8]. The MMP/TIMP ratio imbalance plays an important role in many diseases including not only inflammatory bowel disease but also chronic liver injury[8] and carcinogenesis[9]. As we demonstrated recently, elevated plasma concentration of TGF-β_1, known as TIMP-1 stimulator, was related to inflammation activity and should be considered as a possible biomarker in UC patients[11,12]. According to Sch ppan and Hahn[10] blockade of certain MMPs could be a novel th rapeutic approach, and therefore some novel mucosa derived parameters, such as MMP-1 and TIMP-1, may prove useful to assess prognosis, disease activity, and treatment response in inflammatory bowel disease.

The aim of this study was to evaluate effect of ulcerative colitis on MMP-1 and TIMP-1 plasma concentrations, as two possible biomarkers of the disease activity.

MATERIALS AND METHODS

Patients

MMP-1 and TIMP-1 concentrations were measured in the plasma of 16 patients (6 females and 10 males) with active ulcerative colitis (UC), and age ranging from 25 to 68 years (mean: 42.5±3.8). All the patients had a history of diagnosed ulcerative colitis that required typical clinical and endoscopical signs of distal part of bowel involvement. MMP-1 and TIMP-1 plasma concentrations were compared with endoscopic picture scored according to Meyers *et al*.[13], the disease activity index (DAI) according to Schroeder *et al*.[14], clinical activity index (CAI) as previously described[11] and laboratory indices of UC activity such as C-reactive protein (CRP), sedimentation rate (SR), white blood count (WBC) and hemoglobin concentration. Plasma MMP-1 and TIMP-1 concentrations were also compared with those of 12 healthy controls (mean age: 40.8±2.7 years). The study was approved by the Bioethical Committee of the Medical University in Bialystok. Informed consent was obtained from each patient.

MMP-1 and TIMP-1 measurement

Venous blood was collected on ice using vacutainer tubes with EDTA as an anticoagulant and centrifuged at 1 000×g within 30 minutes of collection. Obtained plasma was additionally centrifuged at 10 000×g for 10 minutes at 2-8 ℃ for complete platelet removal and stored at -20 ℃. The samples were diluted 1:40 with 0.1M phosphate buffer before assay and then incubated in duplicate in microtitre wells precoated with anti-TIMP-1 or anti-MMP-1 antibodies (Amersham Pharmacia Biotech, Little Chalfont, Buckinghampshire, England). Any TIMP-1 or MMP-1 remained in the microtitre wells after four cycles of washing and aspiration were detected by peroxidase

labelled specific antibodies. The amount of peroxidase bound to each well was determined by the addition of tetramethylbenzidine substrate. The reaction was stopped by acidification and optical density was read with a microtitre plate photometer Stat Fax® 2100 (Alab/Poland) at 450 nm. The concentration of MMP-1 or TIMP-1 in the sample was determined by interpolation from a standard curve prepared with standard samples supplied by the manufacturer.

Statistical methods

Values were expressed by their mean and standard error of the mean (±SEM). The significance of the difference was calculated by two-tailed Student' s *t* test. Correlation analysis was calculated by the non-parametric Spearman rank order correlation test. Values of $P<0.05$ were considered to be significant.

RESULTS

Plasma mean concentration of MMP-1 measured in patients with active UC was significantly elevated (13.7±0.2 ng/ml) in comparison to that of healthy controls (11.9±0.9 ng/ml) (Figure 1). Mean TIMP-1 plasma concentration in UC patients (799±140 ng/ml) also exceeded normal values significantly (220±7 ng/ml), and the difference was much more apparent (Figure 2). Even the lowest TIMP-1 value (456 ng/ml) doubled the mean concentration from the controls. As demonstrated in Table 1, the majority of patients had CRP and SR values exceeding the upper limit of normal range. Moreover evaluation of the disease activity through CAI, DAI and endoscopic score demonstrated severe course of the present relapse (Table 1). There was no correlation between TIMP-1 and MMP-1 plasma concentrations (r=-0.02, P=0.95). As shown in Table 2 plasma TIMP-1 levels analyzed in UC patients revealed significant positive correlations with scored endoscopic degree of mucosal injury, DAI and CAI values as well as CRP concentration. There was no correlation between MMP-1 and laboratory, clinical or endoscopic indices of the disease activity (Table 2).

Table 1 Laboratory and clinical indices of ulcerative colitis activity in the patients

	Normal range	Mean	±SEM	Minimum	Maximum	Median
CRP (mg/dl)	0-5	17.7	4.6	6	62	6
SR (mm/h)	0-12	22.7	4.7	2	68	17
WBC (×10³/μl)	4-10	6.8	0.5	3.5	11.5	6.2
HGB (mg/dl)	12-16	13.3	0.3	10.5	14.9	13.4
CAI	0	10.6	0.75	7	15	9
DAI	0	6.4	0.7	3	10	5
Endoscopic score	0	11.6	0.8	8	16	10

CAI: clinical activity index, DAI: disease activity index.

Table 2 Correlation between plasma TIMP-1 or MMP-1 concentrations and values of selected laboratory indices, demonstrated through "r" values. Statistically significant correlation: [a]$P<0.05$; [b]$P<0.01$

	TIMP-1 (r)	MMP-1 (r)
CRP (mg/dl)	0.60[a]	0.05
SR (mm/h)	0.17	-0.07
WBC (x10³/ml)	0.24	-0.10
HGB (mg/dl)	-0.19	-0.10
CAI (clinical activity index)	0.55[a]	-0.18
DAI (disease activity index)	0.66[b]	-0.27
Score	0.66[b]	-0.11

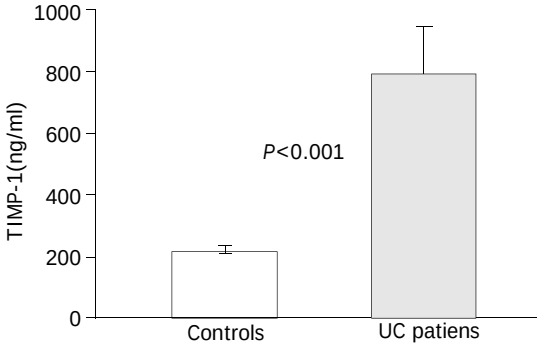

Figure 1 Comparison of mean (±SEM) TIMP-1 plasma concentrations in group of patients with ulcerative colitis and controls.

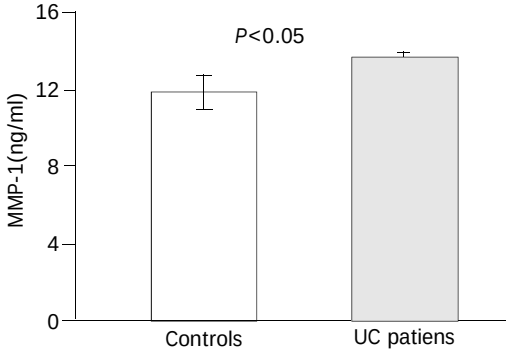

Figure 2 Comparison of mean (±SEM) MMP-1 plasma concentrations in group of patients with ulcerative colitis and controls.

DISCUSSION

Matrix metalloproteinases are involved in mucosal degradation causing tissue remodelling and ulcerations related to inflammatory bowel diseases. Enhanced expression of MMP-1, MMP-2 and MMP-3 has been demonstrated recently in inflammed mucosa from patients with UC and Crohn disease[5,6]. According to Arihiro *et al*.[15] in both UC and CD, MMP-1, MMP-9 and TIMP-1 were expressed by inflammatory cells, fibroblastic cells as well as by vascular smooth muscle cells most prominently in actively inflamed areas in ulcer bases. Stimulation of T lymphocytes in inflammatory lesions seemed to be responsible for activation of several MMPs[7,16,17]. TNF-α released by T lymphocytes was a powerful inducer of fibroblasts that were the prime source of MMPs[19,20]. This created link between mucosal inflammation and destruction of the subepithelial matrix, and MMP-1 expression in the mucosa might be related to the initial step of ulceration in UC[14]. According to Baugh *et al*.[20] the expression of matrix metalloproteinases 1, 2, 3 and 9 was significantly higher in inflamed areas of UC patients mucosa compared with noninvolved regions. In the study carried out by von Lampe *et al*.[5] MMP-1 and -3 correlated well with the histological degree of acute inflammation resulting in more than 15-fold increased levels in inflamed versus normal colon samples from patients with UC. In another study MMP-1 and -2 concentrations measured (using sandwich ELISA) in samples from pouchitis and active UC doubled the values obtained in samples of uninflamed mucosa. Mesenchymal cells were identified as major producers of MMP-1 and -2[6]. MMPs were implicated in the tissue destruction associated with inflammatory diseases and the role of MMPs in the pathogenesis of inflammatory bowel disease was also confirmed through improvement of experimentally induced colitis after treatment with a matrix metalloproteinase inhibitor[21].

Apart from protease-inhibitory action TIMP-1 serves

additional functions. Several investigators have demonstrated its growth-promoting properties and stimulation of tumor growth by inhibiting apoptosis indicating the role of TIMP-1 in cancer progression[22,23]. According to Holten-Andersen *et al*.[24] plasma TIMP-1 levels could be used to identify patients with colorectal cancer with a sensitivity of 63 % and a specificity of 98 %, so it was suggested as a marker for early identification of this cancer.

According to Heuschkel *et al*.[25] TIMP-1 measured in biopsies from patients with active IBD remained unchanged. In the study of Louis *et al*.[26] the production of TIMP-1 was undetectable in the majority of uninflamed biopsy samples from controls, UC and CD patients. However in inflamed mucosa, the production of TIMP-1 was increased significantly in both UC and CD. Its elevated plasma concentration, demonstrated in our study, can reflect situation in bowel mucosa. Enhanced expression of TIMP-1 can be a result of the stimulatory effect of transforming growth factor TGF-β_1. As we demonstrated recently, enhanced production of TGF-β_1 could be related to inflammation activity in UC patients[11]. This profibrogenic cytokine accelerated healing but during chronic inflammation might lead to excessive collagen deposition and eventually fibrosis[4]. In our recent study successful treatment of the disease resulted in decrease of its levels both in plasma and rectal mucosa, but better response has been achieved in patients with higher baseline TGF-β1 concentrations[12].

MMP-1 is the main enzyme responsible for degradation of fibrillar collagen and therefore we decided to use it as a possible biomarker in our study[6]. We demonstrated a significant increase of both MMP-1 and TIMP-1 plasma concentrations in UC patients, which could reflect their over-expression in the bowel mucosa. However significant correlation with clinical and endoscopical signs of UC activity was proved only for TIMP-1. Moreover the only laboratory parameter that showed any association with TIMP-1 was C-reactive protein.

In conclusion, our data confirm the role of both MMP-1 and TIMP-1 in the pathogenesis of ulcerative colitis. However only TIMP-1 may be useful as a biomarker of the disease activity, demonstrating association with clinical and endoscopic pictures.

Abstract

Microvesicular pneumatosis intestinalis, also called "pseudolipomatosis" for resembling fatty infiltration, is characterized by the presence of small gas voids in the gastrointestinal wall, especially in mucosa. These voids are not lined with epithelia. There are few reported cases about colon, duodenum and skin. Because there is only one case report about pseudolipomatosis in the stomach, we re-evaluated 909 endoscopic biopsies taken from gastric corpus to check the presence of pseudolipomatosis. We determined pseudolipomatosis foci in 3 percent (n=27) of biopsies. In two cases there were pseudolipomatosis foci in endoscopic biopsies having otherwise normal histologic findings, while there were pseudolipomatosis foci in endoscopic biopsies of 25 patients with gastritis. *Helicobacter pylori* was found in 85 % of biopsies having pseudolipomatosis foci. In this study, we presented some histopathologic characteristics of pseudolipomatosis seen in gastric mucosa.

INTRODUCTION

Microvesicular pneumatosis intestinalis which is also called "pseudolipomatosis" for resembling fatty infiltration, is characterized by the presence of small gas voids in the gastrointestinal wall, especially in mucosa[1]. These gas voids are not lined with epithelial cells. Since we came across only one letter about gastric mucosa while searching literature for our previous case report, in which we presented a case of pseudolipomatosis in the stomach, duodenum and colon, although recently in gastrointestinal system pseudolipomatosis was defined particularly in the colon, duodenum and skin, we investigated endoscopic biopsies with regard to pseudolipomatosis[1-8].

MATERIALS AND METHODS

In this study, 909 endoscopic gastric biopsies were investigated at the Department of Pathology of Düzce Medical Faculty Abant Ýzzet Baysal University, between December 1998 and June 2003. Biopsies taken from the corpus for various reasons other than cancer were included in this study. Biopsies were fixed in 10 % formaldehyde and subjected to automatic tissue follow-up procedures. We re-examined the 4-5 micron thick samples stained with hematoxylene eosin and modified Giemsa by a light microscope. When pseudolipomatosis was found, the presence and grade of inflammation, the presence of intestinal metaplasia, and the presence and concentration of *Helicobacter pylori* were determined. The absence of inflammation was designated as (0), and the presence of inflammation was classified as mild (1), moderate (2) and severe (3). The absence of *Helicobacter pylori* was designated as (0), and the presence was classified as scarce (1), moderate (2) and diffuse (3). Intestinal metaplasia was evaluated as present or absent, and atrophy as present or absent, if present as mild, moderate or severe. Three hundred and sixty-four (40 %) subjects were female and 545 (60 %) were male. The ages of patients ranged between 19 and 78 years with a mean of 46 years.

RESULTS

Pseudolipomatosis was found in 27 of 909 re-evaluated cases. Of these 27 patients, 15 were male and 12 were female. Male patients were between 28 and 56 years old, with a mean of 39 years, female patients were aged between 22 and 65 years, with a mean of 41 years. Mucosal vacuolation was characterized by empty spaces, 30-250 micron in diameter, associated with neither fibrosis/sclerosis nor a lymphocytic infiltrate. There was no evidence of true adipocyte differentiation, vascular markers, e.g. S-100 protein, F-VIII and F-XIII were negative. Vacuoles were found in different parts of the mucosa, although they could be seen beneath epithelia, in a few cases they were detected within muscularis mucosa as well (Figures 1-2). Twenty five of the patients with pseudolipomatosis had gastritis. Of these patients 23 were *Helicobacter pylori* positive. Among the *Helicobacter pylori* positive patients, five had scarce, ten had moderate, and eight had diffuse bacteria. Among the 25 patients with gastritis, 5 had mild, 13 had moderate, and 7 had severe chronic inflammation. In 8 cases with gastritis, intestinal metaplasia was encountered. In all the cases with metaplasia goblet cells and in 4 cases Paneth cells were noticed. Two cases of gastritis had severe atrophy, and one case had mild atrophy. Four patients with gastritis had prior endoscopy for gastric complaints. The previous biopsy results were *Helicobacter pylori* gastritis with severe inflammatory activity in three cases, and *Helicobacter pylori* gastritis with moderate inflammatory activity in one case. Pseudolipomatosis was not found in previous endoscopic gastric biopsies of these four patients. However, in one of these patients, pseudolipomatosis was detected in duodenal and colonic biopsies[8]. Two other patients had undergone colonoscopy while being searched for malignancy. In samples taken from the colon pseudolipomatosis was not detected.

The patients who were *Helicobacter pylori* positive were given a course of treatment for *Helicobacter pylori* eradication composed of lansoprazol 30 mg daily for 15 days, clarithromycin

bid 500 mg and amoxicilin bid 1 000 mg for 10 days. One month later control biopsies were performed for 5 patients whose complaints were not fully resolved. We found that in two of them pseudolipomatosis continued while in the other three biopsies pseudolipomatosis was not found. In those cases in which pseudolipomatosis continued, we noticed that although *Helicobacter pylori* was decreased, it was not completely eradicated, and in the other three patients we saw that *Helicobacter pylori* was eradicated and the gastritis continued though decreased. Control biopsies were not performed for the remaining patients. In two patients with pseudolipomatosis, a 45-year-old female and a 39-year-old man, biopsies taken for non-specific abdominal pain showed no *Helicobacter pylori*, inflammation or metaplasia. In these patients no pathologic finding except mild edema could be demonstrated. These patients had no previous endoscopies. Vacuoles were seen in small foci in lamina propria, and were considered as pseudolipomatosis.

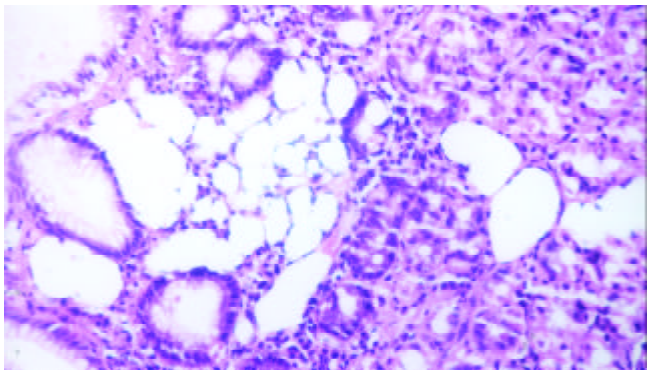

Figure 1 Presence of many vacuoles beneath epithelium in gastric mucosa (H & E ×200).

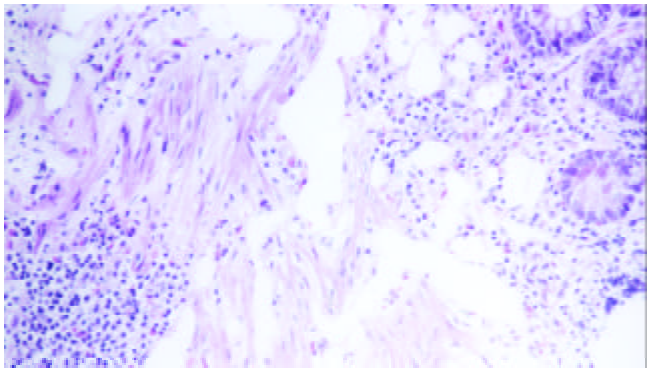

Figure 2 Presence of many vacuoles in muscularis mucosa and lamina propria as well (H & E ×200).

DISCUSSION

Mucosal pseudolipomatosis is a recently described endoscopic finding, most likely caused by intramucosal air. Because of their gross and microscopical similarity to fat, however, the term "pseudolipomatosis" is proposed. Although the etiopathogenesis of pseudolipomatosis is not so clear yet, some probable causes of it in the colon, duodenum and skin have been mentioned[1-8]. We could find only one case-report about gastric pseudolipomatosis except our one[6]. For this reason we searched how often pseudolipomatosis, yet its rate in colon increased contionusly, was found in gastric mucosa.

Pneumatosis coli is a rare condition characterized by multiple gas-filled cysts within the bowel wall. Mechanical, bacterial and biochemical theories have been availabe to explain the pathogenesis of pneumatosis in the colon[5]. Pneumatosis cyctoides intestinalis has been reported to be present together with other conditions such as pseudomembranous enterocolitis, necrotizing enterocolitis, bowel infarction, chronic obstructive pulmonary disease, intestinal obstruction, collagen vascular diseases (scleroderma, dermatomyositis, mixed connective tissue disease), systemic amyloidosis and iatrogenic conditions (after surgery or endoscopy), late-stage AIDS with cryptosporidial diarrhea, and Crohn' s disease[5]. Gagliardi *et al*. detected mucosal pseudolipomatosis foci in colon of 5 cases among 25 pneumatosis coli patients in their study[5]. Micropneumatosis was reported to be caused by disinfectant hydrogen peroxide solution[3]. It might also be a result of colonoscopy application and usually disappeared three weeks after the procedure[4]. Commercially available endoscope disinfecting hydrogen peroxide solution could cause the unique form of colitis referred as pseudolipomatosis[3]. It was also reported in asymptomatic patients as an air pressure- related colonoscopy complication[4]. Mucosal pseudolipomatosis of the colon is an infrequent condition that occurs mainly in elderly males, usually involves the left colon, and is manifested clinically by passage of blood per rectum. Colonoscopy showed solitary or multiple whitish-yellowish plaques, which were localized or involved several segments[1]. Superficial dermal vacuoles resembling fatty infiltration of the skin have also been reported as pseudolipomatosis cutis[2]. Dermal vacuoles likely represent an artifact of tissue fixation or processing and are unrelated to the underlying pathologic process. Trottor *et al*. suggested the name pseudolipomatosis cutis, analogous to insufflation-induced colonic vacuolation, to distinguish this phenomenon from true dermal fatty infiltration and to emphasize its incidental, likely artifactual nature[2]. As in colon and duodenum, histologic studies in the stomach demonstrated microscopic cavities in mucosa, measuring 20 to 300 micron in diameter. Histochemical stains showed that these cavities contained no lipids, suggesting that they were filled with gas. In the study of Gagliardi *et al*, 14 patients were treated with antidiarrhoeals and anti-inflammatory drugs, improvement was detected in 9 cases. There was a high recurrence rate, but with further courses of continued therapy remission was achieved in five patients. According to Gagliardi *et al*, the associations of pneumatosis coli with psychiatric disorders and mucosal pseudolipomatosis were new and of possible pathogenetic[5].

In our study, 23 out of 27 patients had *Helicobacter pylori*. In our previous case report, one patient was diagnosed as micropneumatosis on the first and second colonoscopy specimens at a four week interval[8]. After another four weeks during the first half of *Helicobacter pylori* gastritis treatment of the patient, colonoscopy was repeated for the third time, and micropneumatosis foci were not observed on pathological sections. In the present study, when control biopsy was performed one month later for 5 patients whose complaints were not resolved it was noticed that pseudolipomatosis continued in two of them while pseudolipomatosis was not seen in the other three in control biopsies. In those cases with persistent pseudolipomatosis, it was noticed that although *Helicobacter pylori* was decreased, it was not completely eradicated, and in the other three patients it was seen that *Helicobacter pylori* was eradicated and the gastritis findings were decreased. It is also possible that the control endoscopic biopsies may be taken from sites that are free of pseudolipomatosis. Since the conditions of some patients improved after the eradication therapy for *Helicobacter pylori*, this finding implicates that *Helicobacter pylori* may be one of the causative factors for micropneumatosis and pneumatosis cyctoides intestinalis. It can also be speculated that micropneumatosis grows with time and may lead to pneumatosis

cyctoides intestinalis. The fact that micropneumatosis foci are also reported in most pneumatosis cyctoides intestinalis cases is supportive for this suggestion. The pseudolipomatosis type changes seen in mucosal biopsies should not be ignored by just considering them as artifacts. We think that, in order to determine the etiopathogenesis and significance of gastric mucosal pseudolipomatosis, more case reports are required.

Abstract

AIM: Several neural and hormonal factors are known to affect motility of sphincter of Oddi (SO). The major roles of SO are to regulate the flow of bile and pancreatic juice into the duodenum and to prevent the reflux of duodenal contents into the biliary and pancreatic duct. After pancreas transplantation, graft SO was denervated and graft pancreatitis might have relations to SO motility. The motility of SO after canine pancreas transplantation with bladder drainage was investigated.

METHODS: Normal canine SO manometry and pancreas graft SO manometry after pancreas transplantation with bladder drainage were performed in seven dogs respectively before and after cholecystokinin (CCK) administration. Data of SO basal pressure, contraction frequency, amplitude and motility index after transplantation and CCK administration were compared with that in controls and before CCK administration.

RESULTS: SO showed regular contractions with a certain basal pressure in control dogs. After transplantation, the graft SO basal pressure and contraction frequency were higher than that in controls, but the amplitude decreased ($P<0.01$). There was no great difference in SO motility index. CCK administration could relax normal SO but stimulate graft SO after pancreas transplantation with bladder drainage. After CCK administration, SO basal pressure, frequency and motility index were increased significantly ($P<0.05$), in comparison with that before administration. The amplitude remained unchanged ($P>0.05$), in comparison with that before CCK administration.

CONCLUSION: After auto-pancreas transplantation with bladder drainage, canine SO motility was inhibited. Basal pressure and frequency increased but amplitude decreased. CCK administration after transplantation had an inhibitory effect on canine SO instead of a relaxation effect observed in normal canine SO. This will increase the resistance of SO to the pancreatic juice flow and induce pancreatic juice stagnation and can not prevent reflux of urine and duodenal contents when the bladder pressure is increased to a certain extent, which may cause graft pancreatitis.

INTRODUCTION

The major roles of the sphincter of Oddi (SO) are to regulate the flow of bile and pancreatic juice into the duodenum and to prevent the reflux of duodenal contents into the biliary and pancreatic duct. SO motility is composed of tonic contraction and phasic contraction. Neural factors, hormones and some drugs play important roles in the control of SO motility. SO motility is related to migrating motor complex (MMC) of the duodenum. Graft pancreatitis is one of the factors for graft dysfunction with bladder drainage. Reflux of urine and pancreatic juice can cause graft pancreatitis. After transplantation, the graft was denervated and graft duodenum lost its MMC. Little is known about the function of SO and its effect on the graft function after pancreas transplantation with bladder drainage. The aim of this paper was to study canine SO function after pancreas transplantation with bladder drainage and its effect on the graft.

MATERIALS AND METHODS

Preparation of animal

Fourteen healthy adult mongrel dogs, weighing 13-18 kg were anesthetized with 35 mg/kg intravenous pentobarbital sodium, and maintained under adequate anesthesia with 15 mg/kg intravenous pentobarbital sodium as required. System blood pressure was monitored through a catheter placed into the femoral artery. The femoral vein was cannulated and used for systemic administration of solutions and drugs.

Normal canine SO manometry

After an upper medium laparotomy using aseptic technique, the biliary tree was identified. A small longitudinal incision was made in the common bile duct. A triple lumen catheter was cannulated and tied in the bile duct to avoid any leakage and occlusion of the orifice of the catheters. The triple lumen catheter, measuring 1.7 mm of outer diameter and 0.5 mm of inner diameter, with three holes at 2-mm intervals, was perfused with sterile water at a rate of 0.25 ml/min per channel by means of a low-compliance pneumohydraulic pump, and connected via transducers to a computerized recording system. The catheter was sent into the duodenum. Intraduodenal pressure was taken as zero reference. By 1-mm station pull through technique, the catheter was placed just at the site of SO. After a stable basal recording for at least 2 min was obtained at the level of SO high pressure zone, 20 mg/kg cholecystokinin (CCK) diluted in 5 ml saline was injected intravenously and registration continued for a few more minutes until 2 min of stable recording was obtained during drug infusion. SO basal pressure above duodenal zero, amplitude above basal pressure, and frequency of phasic contractions before and after CCK

injection were calculated as well as the motility (amplitude per frequency).

Pancreas graft SO manometry

The dogs were fasted and anesthetized the same as the control group. After a midline celiotomy with aseptic techniques, the tail of the pancreas was mobilized by division of the veins which drain the distal pancreas into the spleen vein. The head of the pancreas was then mobilized without cutting the pancreaticoduodenal vessels. After the common bile duct at its entry into the duodenum was ligated and divided, the lessen omentum was opened. At least I cm of gastroduodenal artery and vein were dissected from the bifurcation. The proximal duodenum was cut 1 cm distal to pylorus and closed. After inferior pancreaticoduodenal vessels were cut out, the distal duodenum was divided at the end of the second part of duodenum. Thus the donor was skeletonized with intact vascular connections. Finally, the gastroduodenal artery was ligated and divided as far as possible from the bifurcation of proper hepatic arteries, and the gastroduodenal vein was removed with a cuff of portal venous wall. The graft was immediately immersed in and flushed with cold ringer solution while the portal vein wall was repaired. Reconstruction of vascular connections to the autograft was accomplished by an end-to-side anastomosis of the gastroduodenal vein to the right common iliac artery and end-to-end anastomosis of the accompanying artery to the internal iliac artery. After reperfusion, the distal pancreas was resected. Gastrointestinal continuity was restored by the Roux-en-Y technique with cholecystojejunal, gastrojejunal and graft-duodenal-host bladder anastomosis. Average graft ischemia time was 30-40 min. The bile duct residual of graft was placed under the skin. Fluid and antibiotics were given for 5 days. Oral alimentation was started on the second postoperative day. Serum and urinary amylase, free blood sugar and insulin were determined on days 1, 3, 5 postoperatively. Five days after operation, the same manometry procedure from the residual bile duct before and after CCK injection was performed as for the control dogs.

Statistical analysis

All values were expressed as mean ±SD. Comparison of values between the two groups was made with analysis of variance and paired *t* tests. Differences were regarded as significant when *P* value was less than 0.5.

RESULTS

1.Changes of SO activity before and after transplantation are shown in Table 1.

Table 1 SO activity in control and transplanted dogs

	Basal pressure (mmHg)	Amplitude (mmHg)	Frequency (min^{-1})	Motility index
Control	18.5±2.8	47.1±5.5	9.7±1.5	235.6±56.1
Transplant	27.8±2.8	7.2±1.4	13.1±1.9	211.3±33.2

SO showed regular contractions with a certain basal pressure in control dogs.

After transplantation, the graft SO basal pressure and contraction frequency increased as compared with that in controls, but the amplitude decreased (P<0.01). There was no great difference in SO motility index.

2.Changes of SO activity before and after administration of CCK in normal dogs are shown in Table 2.

Table 2 SO activity before and after CCK administration in normal dogs

	Basal pressure (mmHg)	Amplitude (mmHg)	Frequency (min^{-1})	Motility index
Before CCK	18.5±2.8	47.1±5.5	9.7±1.5	235.6±56.1
After CCK	10.2±2.2	18.7±5.3	5.0±1.2	49.6±16.9

CCK administration could relax SO motility. SO basal pressure, contraction frequency and amplitude decreased significantly after CCK administration in comparison with controls (P<0.01).

3.SO activity of grafts before and after CCKadministration is shown in Table 3.

Table 3 SO activity of grafts before and after CCK administration

	Basal pressure (mmHg)	Amplitude (mmHg)	Frequency (min^{-1})	Motility index
Before CCK	27.8±2.8	7.2±1.4	13.1±1.9	211.3±33.2
After CCK	35.5±5.1	9.7±2.1	18.9±1.9	515.4±42.3

CCK administration stimulated graft SO motility. After CCK administration, SO basal pressure, frequency and motility index increased significantly in comparison with those before administration (P<0.05),while the amplitude remained unchanged (P>0.05).

4.After transplantation, there was no great difference in serum amylase, blood sugar and blood insulin as compared with those on day 0 (P<0.05).Urine amylase that reflects graft function increased significantly. These data showed a good pancreas graft function (Table 4).

Table 4 Pancreas graft function after transplantation

	Day 0	Day 1	Day 3	Day 5
Serum amylase (IU/L)	22±5	30±11	26±7	24±4
Urine amylase (IU/L)	80±38	25 400±12 100	45 100±1 780	14 900±2 100
Blood sugar (mmol/L)	4.5±1.2	5.1±0.7	3.8±1.3	3.6±0.4
Blood insulin (IU/L)	8.5±2.2	7.3±3.2	7.0±2.4	5.5±1.0

DISCUSSION

Canine segmental pancreas auto-transplantation and pancreaticoduodenal allotransplantation were often carried out in other studies. In order to investigate the SO motility after pancreas transplantation, we excluded the effect of rejection on the graft and also the graft must have intact SO. So, we established a canine auto-pancreaticoduodenal transplantation model. The results of serum and urine amylase, free blood sugar and insulin level after transplantation showed that the endocrine and exocrine functions of the pancreas graft were both good enough for SO manometry. The transplantation model was stable and suitable for SO manometry.

Canine SO plays an important role in controlling the flow of bile and pancreatic juice into the duodenum and acts as a variable resister to prevent the reflux of duodenal contents[1-4]. SO is a complex neuromuscular structure located at the choledocho-pancreaticoduodenal junction. Canine SO exhibits regular phasic contractions superimposed on a low basal pressure under neurohormonal control. After pancreas transplantation with bladder drainage, the graft was denervated. Little was known about the SO motility after pancreas

transplantation. Several reports suggested that SO dysfunction played an important role in acute recurrent pancreatitis[5-7]. Graft pancreatitis was a serious complication after pancreas transplantation with bladder drainage. The late graft pancreatitis might be related to SO dysfunction caused by graft SO denervation. Our present study on canine SO motility after auto-pancreas transplantation with bladder drainage showed: (1)Canine SO exhibited regular contractions with a certain basal pressure. After transplantation, graft SO basal pressure and contraction frequency increased and amplitude decreased significantly. But there was no great difference in SO motility index. (2) CCK administration could relax normal canine SO, but stimulate graft SO after canine pancreas transplantation with bladder drainage. The denervated graft duodenum lost its normal migrating motor complex (MMC). These data suggested that the tonic contraction of SO remained and created a higher basal pressure than that before transplantation, and phasic contraction decreased significantly. This resulted in the obstruction of pancreatic juice flowing into the graft duodenum. Furthemore, when bladder pressure increased to a certain extent because of urine stasis, the urine would reflux into pancreatic duct and induce acute pancreatitis.

The role of extrinsic nerves in the control of SO motility has not been fully investigated. The SO was richly innervatd by cholinergic, adrenergic and peptidegic neurons[8]. Direct neural pathways couple the duodenum with the gallbladder and SO, and the SO with the gallbladder. Several surgical procedures,such as gastrectomy[9], vagotomy[10] and cholecystectomy[11,12] have been known to alter SO motility by disrupting certain aspects of the innervations. Numerous reports described SO motility after transection or electrical stimulation of extrinsic nerves,such as the vagal and splanchnic nerves[13-16]. Different effects of innervation on SO motility reflect the difference both in species and in experimental designs. Complete denervation using tetrodoxtoxin increased tonic pressure and amplitude of SO phasic contraction in the cats[10]. Ohtsuke reported increased biliary sphincter basal pressure and amplitude after neural isolation of the pancreatoduodenal region by surgical procedure in conscious dogs[17]. The present study showed that extrinsic innervation to the pancreatoduodenal region had an inhibitory effect on SO motility. The main role of extrinsic nerves was to regulate phasic contraction and relax SO. Under normal condition, the relaxing effect of extrinsic nerve on canine SO motility was better than the stimulation effect. But the amplitude decreased significantly after transplantation instead of increasing observed in Ohtsuke' s study. This is probably because the motility of graft SO was not affected by duodenum MMC. Furthermore, the effect of gastrointestinal hormone on SO motility may be different from that in normal canines because of its anastomosis to system vessels. Further investigations are needed to identify this guess.

CCK is the major physiological hormone regulating tone and motility of biliary system. It normally inhibited biliary sphincter motor activity in human and dogs but stimulated SO under various circumstances, which is known as a paradoxical response[18,19]. It is believed that these SO relaxant responses to CCK were induced via nonadrenergic, noncholinergic inhibitory neurons since cholenergic and adrenergic antagonists could not inhibit these relaxant responses[20]. Our present study showed that CCK could relax canine SO and lower SO basal pressure. But denervated SO after transplantation apparently produced paradoxical response of SO to CCK, which was likely caused by the direct effect of CCK on the smooth muscle of SO. Based on these data, we could consume that the paradoxical response of SO to CCK in SO dysfunctional patients might also be caused by the direct stimulation of CCK to SO smooth muscle because of injury of inhibitory nerves of SO.

Gancio reported that reflux pancreatitis was chemically induced by reflux of urine through SO into pancreatic duct during the voiding phase with high detrusor pressure (over 70 cmH_2O)[21]. Others hypothesized that this could be caused by an incompletent SO or by either pressure exerted on the pancreatic duct due to a large volume bladder or micturition narrowing the duodenocystostomy and obstructing it[22,23]. The current study showed that canine SO lost its normal contraction rhythm , increased basal pressure causing an obstruction of pancreatic juice into graft duodenum. When bladder pressure overrided the basal pressure, SO probably could not prevent the reflux of urine and duodenal contents into pancreatic duct. All these would contribute to graft pancreatitis.

In conclusion, after auto-pancreas transplantation with bladder drainage, canine SO motility was inhibited. Basal pressure and frequency increased but amplitude decreased. CCK administration after transplantation showed an inhibitory effect on canine SO instead of a relaxation effect to normal canine SO. This will increase the resistance of SO to the pancreatic juice flow and induce pancreatic juice stagnation and can not prevent reflux of urine and duodenal contents when the bladder pressure is increased to a certain extent, which may cause graft pancreatitis.

Abstract

AIM: To investigate the incidence and treatment of hepatic artery complications after orthotopic liver transplantation.

METHODS: From February 1999 to May 2002, orthotopic liver transplantations (OLT) were performed in 72 patients with end-stage liver diseases with an average age of 40.2±13.6 years (ranged from 11 to 68 years), 56 were males and 16 females. The preoperative evaluation for the 72 patients was performed using duplexsonography, abdominal CT scan, and angiography of the hepatic artery. All donor grafts were perfused and preserved in University of Wisconsin solution at 4 ℃. OLT was performed with standard techniques with or without a veno-venous bypass. Reconstructions of hepatic artery were performed between the branch patches of gastroduodenal/hepatic or splenic/common hepatic artery confluence of the donors and recipients, and an end-to-end anastomosis between other arterial vessels of the donors and recipients was done. Arterial anastomosis was performed with interrupted 7-0/8-0 monofilament polypropylene suture under 3.5 x loupe magnification. Diagnosis of the complications of hepatic artery after OLT was based on the clinical presentations, ultrasound findings and arterial angiography. All patients were followed up regularly for duplex ultrasound scan after discharge.

RESULTS: The overall incidence of arterial complications in 72 patients after OLTs was 1.4 % (1/72). One 3 cm pseudoaneurysm at the side of anastomotic site of hepatic artery was found by urgent arteriogram due to hemoperitoneum secondary to bile leakage after OLT. Subsequently the pseudoaneurysm was successfully embolized and the blood flow toward the donor liver in hepatic artery remained. The overall postoperative 30-day mortality rate was 8.33 %. The one-year survival rate was 83.72 % in 50 patients with benign diseases and was 71.43 % in 22 patients with malignant diseases following OLT. No death associated with complications of hepatic artery occurred.

CONCLUSION: Careful preoperative evaluations and intraoperative microsurgical technique for hepatic artery reconstructions are the keys in prevention of hepatic artery complications after OLT.

INTRODUCTION

Vascular complications after orthotopic liver transplantation (OLT) ranges from 2 % to 25 % in most publications[1,2]. The most frequent complications involve the hepatic artery (2 % to 12 % in adults)[3-5], in which the hepatic artery thrombosis (HAT) is most common[6,7]. The complications of hepatic artery are usually associated with technical, hemodynamic, immunological and infectious factors[2,8,9], which may result in biliary tract complications or sepsis[10,11], and even a retransplantation may be required[12,13]. In the present study, we report the incidence and treatment of hepatic artery complications in 72 patients with end-stage liver diseases after OLT from February 1999 to May 2002.

MATERIALS AND METHODS

Patients

From February 1999 to May 2002, OLTs were performed in 72 patients with an average age of 40.2±13.6 years (range 11 to 68 years, and 56 males, 16 females). Indications for OLT included post-inflammatory liver cirrhosis complicated with hepatitis B and liver function failure (34 cases), primary hepatocellular carcinoma (19 cases), end-stage liver hydatid cyst disease complicated with liver function failure (4 cases), Caroli' s disease (3 cases), cholestatic liver cirrhosis complicated with hepatolithiasis (2 cases), polycystic liver disease complicated with liver function failure (2 cases), primary sclerosing cholangitis (2 cases), Budd-Chiari syndrome complicated with liver function failure (2 cases), cholangiocarcinoma (2 cases), alcoholic cirrhosis (one case) and secondary hepatic maligancy (gallbladder cancer) (one case).

Methods

The preoperative evaluation for the 72 patients was performed using duplexsonography, abdominal CT scan, and angiography of the hepatic artery. All donor grafts were perfused and preserved in University of Wisconsin solution at 4 ℃. OLT was performed with standard techniques and a veno-venous bypass was used in 61 patients, and no veno-venous bypass was used in 5 patients. Retro-hepatic vena cava was resected in 66 patients, and an end-end interposition of donor vena cava together with donor liver was performed. Hepatectomy was performed according to the classical technique with preservation of retrohepatic vena cava (piggy back) in the remaining 6 patients. Reconstruction of the portal vein was performed by an end-to-end veno-venous anastomosis. The reconstruction of hepatic artery was variable and dependent on hepatic artery anatomy of the donors and recipients. Arterial anastomosis was performed between the branch patches of gastroduodenal/hepatic or splenic/common hepatic artery

confluence of the donors and recipients in 22 out of the 72 cases. End-to-end anastomosis was done between the proper hepatic artery of the donors and recipients in 18 out of the 72 cases, and the remaining anastomosis was performed between the proper hepatic artery of the donors and the right hepatic artery or the common hepatic artery of the recipients respectively in 6 and 5 out of the 72 cases. Anastomoses were performed between the proper hepatic artery of the donors and the splenic artery, between the left gastric artery and the left hepatic artery of the recipients in one case each, and between the splenic artery of the donors and the proper hepatic artery, the common hepatic artery or the left hepatic artery of the recipients in 6, 4 and one case respectively, between the common hepatic artery of the donors and the proper hepatic artery or the left hepatic artery of the recipients in 3 and one case respectively, and between the coeliac trunk of the donors and the common hepatic artery of the recipients in 3 cases. Arterial reconstruction was performed by microsurgical techniques with interrupted 7-0/8-0 monofilament polypropylene suture under 3.5 x loupe magnification, interposition grafting with same donor' s part of common hepatic conduit was used selectively in one case with end-to-end anastomosis between the proper hepatic arteries of the donors and recipients when anastomotic thrombosis was suspected before closure of the abdominal incision[14,15]. Diagnosis of complications of hepatic artery after OLTs was based on the clinical presentations, ultrasound findings and arteriography of hepatic artery. The hepatic artery was detected with routine duplex sonography intraoperatively after completion of hepatic artery reconstruction and daily in the first week after OLTs[16,17]. When the patients had elevated hepatic enzymes, cholestasis, bile leakage and high fever in the absence of acute rejection and drug toxicity, spiral CT scan or angiography of hepatic artery should be considered. No anticoagulable pharmacotherapy to maintain arterial patency was used intraoperatively and postoperatively in this group, but laboratory examination of coagulation state should be done regularly. All the patients received immunosuppressive therapy including cyclosporine or FK506 regimens and were followed up from 3 to 34 months. Hepatic artery of liver transplant patients was detected regularly by duplex ultrasound scan three or six months after discharge.

Statistical methods

The Kaplan-Meier method was used to calculate survival rate, and statistical calculations for mean values and standard deviations were performed using the SPSS software package.

RESULTS

The overall incidence of arterial complications in the 72 patients after OLTs was 1.4 % (1/72) and no HAT and hepatic artery stenosis were found after OLTs. A 3 cm anastomotic pseudoaneurysm of hepatic artery was found in 1 case by urgent arteriogram due to hemoperitoneum secondary to bile leakage about one month after OLT. The pseudoaneurysm at the side of anastomotic site of hepatic artery was successfully embolized, and blood flow toward the donor liver in hepatic artery remained. This patient was fully recovered and discharged one month later when bile leakage was stopped. The patient was doing well 1 year after OLT. The overall postoperative 30-day mortality rate was 8.33 % (6 deaths in 72 patients). The one-year survival rate was 83.72 % in 50 patients with benign diseases and was 71.43 % in 22 patients with malignant diseases after OLTs. No death occurred due to complications of hepatic artery.

DISCUSSION

Vascular reconstructions are critical to a successful outcome in orthotopic liver transplantation (OLT), complications associated with hepatic artery reconstructions are one of the major causes of graft loss and mortality after OLT. Hepatic artery complications after OLT include HAT, hepatic artery stenosis, hepatic artery pseudoaneurysm (HAP) and hepatic artery fistula. The early complications of hepatic artery were usually caused by technical problems[1-3]. The late complications of hepatic artery were usually associated with hypercoagulable state, over transfusion of platelets and fresh-frozen plasma during the surgery, severe rejection and bile leakage[11,18,19]. The hepatic artery is relatively small (3 to 6 mm in diameter in adults) during the vascular reconstructions of OLT with a very fragile intima that requires highly careful atraumatic manipulating technique during the reconstruction of hepatic artery. The anatomical variations[20-22], diameter and length of hepatic artery, and injury to vessels including prolonged clamping of hepatic artery, kinking of a long artery, and hematoma of artery wall from improper flushing after clamping during operation, and the quality of recipient vessels and mismatch between donor and recipient arterial vessels should be carefully considered and managed preoperatively and intraoperatively[2,15]. The incidence of arterial complications after OLTs varied between 2 % and 25 % among the liver transplant patients[2], HAT was most common[6,7], and caused irreversible graft damage and often required immediate revascularization of hepatic artery, even retransplantation of the liver[12,13]. HAP occurred in less than 1 % patients after OLT[23,24]. The incidence of hepatic artery complications was low in this group. The technique of microsurgical hepatic artery reconstruction contributed greatly to the reduction of incidence of HAT and hepatic stenosis[6,15,25]. Current HAT rate reported after hepatic arterial reconstruction was 1.44 % via the branch patch technique using the hepatic-gastroduodenal bifurcation and interrupted suture of 7/0 monofilament polypropylene suture[6,20]. We found a single case of hepatic artery pseudoaneurysm whose openning was at the side of anastomotic site of hepatic artery as the complication following OLT and the pseudoaneurysm was embolized successfully. The reported incidence of pseudoaneurysm of hepatic artery was low, but this complication could be devastative with a high mortality rate due to massive bleeding that often required immediate revascularization[26,27], and even retransplantation[12,13]. Extrahepatic pseudoaneurysms of hepatic artery were associated with local infection, bile leakage while intrahepatic pseudoaneurysms were caused by liver punctures[2,5]. The most frequent presentations of hepatic artery pseudoaneurysm were hemorrhages including gastrointestinal hemorrhage, hemoperitoneum and hemobilia[5,19], which often occurred within the first two months after liver transplantation, and might lead to death due to massive bleeding or loss of the donor graft[5,28,29]. Although ultrasound and CT scanning were useful in the diagnosis of hepatic artery pseudoaneurysms[30-32], arteriography was more accurate[10,33], and might demonstrate clearly an anastomotic pseudoaneurysm of the hepatic artery with bleeding into peritoneum cavity or bile tract[23,29,33]. The treatment for hepatic artery pseudoaneurysm remains a challenging problem. The current treatment options include ligation or embolization, excision and immediate revascularization of hepatic arterial pseudoanurysm with or without a donor illiac artery or autogenous saphenous vein, and retransplantation. However, ligation resulted in an extremely high morbidity and mortality[12,26,34,35], especially at the early stage after liver transplantation. The excision and immediate revascularization of hepatic arterial pseudoanurysm appeared to be the best choice[26,27]. At the time of revascularization, bile leakage should be also repaired[26], and the donor iliac artery or autogenous saphenous vein was often used for arterial revascularization[34,35]. If an adequate donor

iliac artery or autogenous saphenous vein was not available, an autogenous radial artery could be used[36]. Embolization therapy of hepatic artery pseudoaneurysm after OLT was seldom reported. In our study, pseudoaneurysm at the side of the anastomotic site of hepatic artery was embolized successfully and the patency of the hepatic artery toward the donor liver remained, which salvaged the donor liver as well as the the recipient by the mini-invasive percutaneous endovascular techniques. This case provides a good example of safe and effective approach in the management of pseudoaneurysm of hepatic artery, but more experience is expected.

Abstract

AIM: Choledocholithiasis is present in 5 to 10 percent of patients who have cholelithiasis. In the area of laparoscopic cholecystectomy (LC), laparoscopic common bile duct exploration (LCBDE) and intraoperative endoscopic sphincterotomy (IOES) have been used to treat choledocholithiasis. The purpose of this study was to compare the clinical outcomes and hospital costs of LCBDE with IOES.

METHODS: Between November 1999 and October 2002, patients with choledocholithiasis undergoing LC plus LCBDE (Group A, *n*=45) were retrospectively compared to those undergoing LC plus IOES (Group B, *n*=57) at a single institution.

RESULTS: Ductal stone clearance rates were equivalent for the two groups (88 % versus 89 %, *P*=0.436). The conversion rate was higher for Group B (8.8 % versus 4.4 %, *P*=0.381), as was the morbidity (12.3 % versus 6.7 %, *P*=0.336). There were no other significant differences between the two groups. The complications were mainly related to endoscopic sphincterotomy (ES), and the hospital costs were significantly increased in this subset of Group B (median, 23 910 versus 14 955 RMB yuan, *P*=0.03). Although hospital stay was longer in Group A (median, 7 versus 6 days, *P*=0.041), the patients in Group A had a significantly decreased cost of hospitalization compared with those in Group B (median, 11 362 versus 15 466 RMB yuan, *P*=0.000).

CONCLUSION: The results demonstrate equivalent ductal stone clearance rates for the two groups. LCBDE management appears safer, and is associated with a significantly decreased hospital cost. The findings suggest LCBDE for choledocholithiasis is a better option.

INTRODUCTION

Laparoscopic cholecystectomy (LC) has become the standard method for cholecystectomy, but the same cannot be said of the management of choledocholithiasis. There is still no standard algorithm. Laparoscopic common bile duct exploration (LCBDE) and intraoperative endoscopic sphincterotomy (IOES) have been used to treat choledocholithiasis for many years in clinical practice[1-6]. The purpose of this study was to determine the most cost-effective approach for patients with choledocholithiasis.

MATERIALS AND METHODS

Between November 1999 and October 2002, patients with choledocholithiasis undergoing LC plus LCBDE (Group A, *n*=45) were retrospectively compared to those undergoing LC plus IOES (Group B, *n*=57) at a single institution.

The clinical demographic details and the pretreatment biochemical findings are shown in Table 1. There were no significant differences between the groups. Preoperative investigations included liver function tests and external ultrasound examination of the gallbladder and bile duct. Four patients in Group A underwent preoperative ERCP. Endoscopic sphincterotomy (ES) was unsuccessful in three patients, and another ERCP was performed but no stones were found. Five patients in Group B underwent preoperative ERCP. ES was not performed in two patients. The three other patients underwent ERCP but no stones were found.

Table 1 Clinical and demographic details in patients of groups A and B

	Group A	Group B
Total no.	45	57
Age range (yr)	29-79	18-75
Male patients	17	20
Female patients	28	37
Abnormal LFTa	40	38
Jaundice	18	19
Acute cholecystitis	19	12
Pancreatitis	11	6
Preoperative ERCP	4	5

a: Liver function test.

Laparoscopic ductal stone clearance was performed either by the transcystic duct route (*n*=10) or by direct CBDE with placement of T-tube (*n*=35). Intraoperative cholangiography (IOC) was done in all patients. Complete clearance of the ductal stones was determined by the end of IOC. The necessity to convert to a different technique or the presence of an unexpected retained stone was considered as a failure. LCBDE was performed at the same institution by experienced surgeons. Two experienced gastroenterologists performed IOES [5,6]. The exact technique was left up to the individual physician.

All hospital cost data were obtained from the hospital admission department. The cost of complications the patients

incurred was included in the cost data. If LCBDE or IOES failed and the patient required postoperative ES or chledochoscopy through the sinus tract, the cost of that intervention was included. The cost of additional anesthesia or IOC was also included.

Data and statistical analysis

Statistical analysis was performed using chi square test with a likelihood ratio and Mann-Whitney test for nonparametric data. Significance was set at the 5 % level.

RESULTS

Outcome of Group A (LCBDE)

Ductal stone clearance was successful in 40 out of 45 patients (88 %). There were two cases of conversions to open surgery (4.4 %)(Table 2). One patient had large impact stones, the other had multiple stones. Two patients (4.4 %) had unexpected retained stones, one requiring ES at readmission, the other choledochoscopy through the sinus tract.

Postoperative complications occurred in 3 patients (6.7 %) (Table 3). Two patients had infection around the T-tube, and the other had bile leak after the T-tube was removed.

The cost ranged from 6 979 to 23 813 RMB yuan with a median 11 362 RMB yuan (Table 2). Of the 42 patients having uncomplicated hospital stays, the median cost was 11210 RMB yuan compared with a cost of 15121 RMB yuan for the three patients with complications (Table 4). The hospital stay ranged from four to eighteen days with a median stay of seven days. The median postoperative stay was four days (range, 2-14) (Table 2).

Outcome of Group B (IOES)

Ductal stone clearance was successful in 51 out of 57 patients (89 %). There were five cases of conversions to open surgery (8.8 %) (Table 2). One had a microperforation of the duodenum, one had bleeding at the sphincterotomy, and the other three patients had unsuccessful ES. One patient (1.8 %) had an unrecognized retained stone and required ES at a second admission.

Seven cases had complications (12.3 %)(Table 3). Three patients developed pancreatitis, two of them had severe pancreatitis, and the other required open surgery for an abdominal abscess that resulted in a 51-day hospital stay with a cost of 133 239 RMB yuan. Two patients developed postoperative pneumonia.

The cost ranged from 8 823 to 133 239 RMB yuan with a median of 15 466 RMB yuan (Table 2). Of the 50 patients having uncomplicated hospital stays, the median cost was 14 955 RMB yuan compared with a cost of 23910 RMB yuan for the seven patients with complications (Table 4). The hospital stay ranged from 2 to 51 days with a median stay of six days. The median postoperative stay was three days (range, 1-51)(Table 2).

Table 3 Morbidity of two groups

	Group B	Group A

Microperforation	1	
Pancreatitis	3	
Pneumonia	2	
Infection with t-tube		2
Bile leak		1

Comparison of clinical outcome and hospital costs of two groups

Statistical analysis and comparison between Groups A (LCBDE) and B (IOES) are presented in Table 2.

The ductal stone clearance rates were equivalent in the two groups (88 % versus 89 %, P=0.436). The conversion rate was higher in Group B (8.8 % versus 4.4 %, P=0.381), as was the morbidity (12.3 % versus 6.7 %, P=0.336). The operating time was shorter in Group B (median, 155 min versus 180 min, P=0.661). But there were no significant differences between the two groups. Although the hospital stay was longer in Group A(median,7 versus 6 days, P=0.041), the patients in Group A had a significantly decreased cost of hospitalization compared with those in Group B (median, 11 362 versus 15 466 RMB yuan, P=0.000), and the hospital costs significantly increased in complicated Group B (Table 4).

DISCUSSION

The presence of common bile duct stones (CBDS) significantly increases the morbidity, mortality, and cost of patients with gallstones. The potential complications of choledocholithiasis,

cholangitis, and pancreatitis could be life-threatening[7,8]. The safest and most cost-effective approach for patients with CBDS could decrease suffering and disability and save millions of heath care us dollars each year[9,10].

ES was first described in 1974. Today, ES for choledocholithiasis remains the most difficult and dangerous procedure routinely performed by endoscopists. The application of ES to CBDS was advocated for patients with cholangitis, acute biliary pancreatitis, and for elderly high-risk patients[11]. Gong *et al* from China reported a ductal stone clearance rate of 91.7 % and a complication rate of 8.8 %[12]. In our experience, the ductal stone clearance rate was 89 %, the morbidity was 12.3 %. Although IOES was performed by experienced gastroenterologists, it still resulted in procedure-related complications that could be life-threatening[13-16]. The cost was significantly increased in complicated Group B (IOES) (median, 23 910 versus 14 955 RMB yuan, P=0.03)(Table 4), and the hospital stay was much longer.

Successful LCBDE has been reported in several large series in 57 to 98 percent of cases[17]. Our experience compared favorably with these results. LCBDE was used in our recent management of choledocholithiasis for the vast majority of patients, whereas early IOES was more commonly performed in the past two years. The clearance rate in Group A (LCBDE) was 88 %, and the complication rate was 6.7 %. With the experience and new instrumentation, the limiting factor in successful LCBDE was not the CBD access but the CBD pathologic alterations such as large impact stones or multiple stones[17].

On the other hand, Group A was associated with a significantly decreased cost of hospitalization compared with Group B (median, 11 362 versus 15 466 RMB yuan, P=0.000) (Table 2). The total hospital cost of Group B included two parts, and was higher even for uncomplicated patients (median, 14 955 versus 11 210 RMB yuan, P=0.000). The cost of complicated patients was significantly increased (Table 4). Therefore, a thorough evaluation and consideration of management options would reduce the risk of complications and the cost of CBDS management.

Although the hospital stay was longer in Group A (LCBDE), it was mainly related to postoperative stay (median, 4 versus 3 days, P=0.024) with placement of T-tube. Therefore, primary closure of CBD without T-tube would be more cost-effective.

The operation time was shorter in Group B (IOES) (median, 155 min versus 180 min, P=0.661). In most situations, we had to wait for gastroenterologists, and the waiting time was not included in the operation time. The actual procedure time was delayed, which partially contributed to an increased hospital cost[18].

The results demonstrate that the ductal stone clearance rate was equivalent in the two groups. The conversion rate and morbidity were higher in Group B (IOES), and mainly related to ES. The hospital cost was significantly increased in complicated Group B patients. LCBDE management appears safer, and has no life-threatening complications, and can significantly decrease the hospital cost. The findings suggest LCBDE for CBDS is a better option.

Abstract

AIM: To investigate the effect of liver nonparenchymal cell infusion combined with cyclosporin A (CsA) on rejection of heterostrain rat small bowel transplantation.

METHODS: The liver nonparenchymal cell suspension was prepared by density gradient centrifugation method with Percoll centrifugal solution. Heterotopic small bowel transplantation was performed. Then the rats were divided into four groups. Group one: homogenic transplantation (F344/N→F344/N), group two: allotransplantation (F344/N →Wistar), group three: allotransplantation (F344/N→Wistar) + CsA, with CsA 10 mg· kg^{-1}· d^{-1} after transplantation, group four: allotransplantation + CsA (F344/N→Wistar) + liver nonparenchymal cell infusion + CsA (F344/N→Wistar), in which recipient Wistar rats had been injected with 2×10^8 F344/N liver nonparenchymal cells 20 days before transplantation, and treated with CsA after transplantation. Finally, the survival time after small bowel transplantation, gross and histopathological examination, and IL-2 levels in serum were observed.

RESULTS: The survival time after small bowel transplantation was 7.14±0.33 d, 16.32±0.41 d and 31.41±0.74 d in group 2, 3, and 4, respectively. The survival time was significant longer (P<0.01) in group 4. The gross and histopathological examination showed that the rejection degree in group 4 was lower than those in groups 2 and 3. Serum IL-2 level in group 4 was also lower than those in groups 2 and 3 (P<0.01).

CONCLUSION: Liver nonparenchymal cell infusion combined with CsA can prolong the survival time of rat small bowel transplantation, and the anti-rejection effect is good.

INTRODUCTION

In clinical practice, rejection responses induced by organ transplants necessitate the use of potent immunosuppressive drugs. It should be noted, however, that excessive dosage of immunosuppressive agents may result in severe side effects such as hypertension and hepatic and/or renal toxicity. Moreover, prolonged usage of immunosuppressants often leads to severe infection and increased susceptibility to malignant tumors, thus critically affecting the health of recipients[1-5]. It is therefore imperative to assess, as an alternative to immunosuppressants, the protective effect of induced immune tolerance on organ transplantation. The ideal strategy is to induce a immune tolerance state or a low reactive state toward donors' grafts in the recipients, while preserving normal immunological functions for the recognition of tumor antigens and prevention of infection. Thus immunosuppressive agents can be avoided or used at a dramatically reduced dosage. The key steps toward a successful transplantation therefore include either attenuated immune reactions or induced immune tolerance to grafts[6-10].

Small bowel transplantation is an ideal method to treat short bowel syndrome and other end stage small bowel dysfunctions, and thus can free the patients from total parenteral nutrition, returning to normal life pattern[11,12]. But because of the rich lymphatic tissue in small bowel and its mesentery, the mesenteric lymph nodes and lymphatic plexus are transplanted along with small bowel transplantation. So small bowel transplantation has more severe immune rejection compared with other organ transplantation, which is the main cause leading to failure of small bowel transplantation[13-16]. The liver is an immunologically privileged organ, and after liver transplantation, the incidence rate and degree of rejection are much lower than other solid organ transplantations. Liver transplantation can also induce tolerance in recipients to organs, such as the heart, kidneys, skin, etc, which are susceptible to be rejected[17-19]. Both in experimental study and in clinical practice of recent years, liver nonparenchymal cells (including lymphocytes, dendritic cells, Kupffer cells, *etc*) play an important role in immune tolerance induction[20-22]. In the present study, we took the advantage of liver nonparenchymal cell infusion combined with cyclosporin A (CsA) on rat small bowel transplantation. Some parameters were tested in order to confirm the anti-rejection effect of liver nonparenchymal cell infusion combined with CsA.

MATERIALS AND METHODS

Animals

Male FK344/N rats weighing 230-260 g as donors and male Wistar rats weighing 200-240 g as recipients were obtained from the Laboratory Animal Center of Beijing Medical University, and fed with standard rat chow.

Preparation of rat liver nonparenchymal cells from donor liver

Rats were anaesthetized with intraperitoneal pentobarbital and the abdomens were shaved and cleansed with betadine solution. The peritoneal cavity was widely exposed, with the inferior vena cava cannulated, the portal vein divided, and the suprahepatic vena cava ligated. The liver was perfused at a rate of 3-4 ml/min at 37 ℃ *in situ* with a Hank' s calcium-free solution for 5 min followed by perfusion with a 0.05 % collagenase (Sigma, type V) solution for 15 min. Hepatic

attachments were divided and the liver was transferred to a Petri dish, where the liver substance was gently minced and filtered (100 μm) to remove large aggregates, followed by incubation for 45 min in 50 ml of Hank's containing 0.05 % collagenase at 37 ℃ with continuous stirring. 0.5 mg DNAase in 1.0 ml of PBS was added 20 and 40 min after this incubation period. The cell suspension was filtered (40 μm) and nonparenchymal cells were separated by discontinuous density gradients of Percoll (Pharmacia Biotech) at 1.044 g/ml and 1.07 g/ml. The final cell suspension was prepared in PBS/15 % FCS at a concentration of 5×10^8/ml. Cell viability counting (usually greater than 95 %) was done using trypan blue exclusion test, the cell suspension was used for infusion within 4 hours of preparation[23,24].

Rat small bowel transplantation

Donor rats were fasted for 24 hours. All procedures were performed under inhalation anesthesia with ether. The entire small bowel from the ligament of Treitz to the ileocecal valve was isolated with the superior mesenteric artery on a segment of aorta and portal vein. After donor systemic heparinization (300 U), the graft was perfused with 20 ml of cold lactated Ringer's solution via the aorta. The lumen was also washed in 20 ml of the same solution. In the recipient, end-to-side vascular anastomoses were performed between the graft aorta and recipient infrarenal aorta and between the graft portal vein and recipient inferior vena cava with 10-0 sutures using the standard microsurgical technique. Superior extremity of transplanted small bowel was ligated and distal small bowel stoma was performed on left abdominal wall. Animals that died within 3 days were considered as technical failures and excluded from data collection[25-28].

Experimental groups and postoperative care

The rats were divided into the following four groups. Group 1: homogenic transplantation group (F344/N→F344/N), Group 2: allotransplantation group (F344/N→Wistar), Group 3: allotransplantation group +CsA group (F344/N→Wistar), in which recipient rats received CsA 10 $mg\cdot kg^{-1}\cdot d^{-1}$ after transplantation, Group 4: allotransplantation +CsA+ nonparenchymal cells infusion group (F344/N→Wistar), in which nonparenchymal cell infusion was performed 20 days prior to transplantation, and CsA applied after transplantation. Animals were fasted with access to water on the day of surgery, fed with only sugar water (7 g/day) on day 1, and rat chow and water on day 2 and thereafter. The rats' psyche status, appetite and ejection liquid of small bowel stoma were observed.

Graft histology

Rats' small bowel allografts were excised from stoma or by laparotomy and fixed in 10 % formalin. The fixed tissue was paraffin embedded, and tissue sections were stained with hematoxylin and eosin (H-E). Rejection was evaluated according to the following scoring system: grade 0, intact mucosa with complete villi; grade 1, mucosa with shortened villi and initial cellular infiltration; grade 2, mucosa with incomplete and damaged villi or complete loss of villi, usually with cryptitis and lymphocyte infiltration; grade 3, no mucosa with extensive necrosis and fibrosis[29-31].

Detection of interleukin-2 (IL-2)

The serum samples were collected on days 3, 5, and 7 after transplantation. Serum concentration of IL-2 was measured with ELISA kits (Beijing East Asia Immunological Technique Institute).

Graft survival

All recipients were followed by visual inspection, and submitted to autopsy as soon as they died. Graft survival time was defined as death of recipient due to acute rejection.

Statistics

All the data were analyzed by Student's *t* test and expressed as mean ± SD. The statistical difference $P<0.05$ was considered significant and $P<0.01$ as very significant.

RESULTS

Gross observation

The rats awaked soon after operation, then reactivated. In homogenic transplantation group (group 1), the psyche of rats was good with normal diet and activity. Mucosa of abdominal wall stoma was ruddy, and secretion was mucous. Exploratory laparotomy showed that intestinal graft was rubicund, mesentery blood vessel pulsated obviously, and the intestinal adhesion was seldom. In allotransplantation group (Group 2), the rats presented various degrees of lethargy, anorexia hair disorder, unresponsive to outside stimulation and body weight loss, until died. Exploratory laparotomy showed that intestinal graft was hoar, intestinal luminal amplificated with massive adhesion and gradually aggravated, accompanying mass purulent discharge, intestinal perforation occurred in some severe cases. In allotransplantation +CsA group (Group 3), the rats were vigorous, sensitive to outside stimulation, and low-grade adhesion occurred 7 days after transplantation. In allotransplantation +CsA+ nonparenchymal cell infusion group (Group 4), the manifestations were similar to those in Group 1.

Histopathologic examination

In group 1, the rats represented rejection of grade 0, with no rejection pathological finding but a few of lymphocytic infiltration in stroma. In group 2, rejection of grade 1 was found 3 days after transplantation, rejection of grade 2 was found 5 days after transplantation, and rejection of grade 3 was found 7 days after transplantation. In group 3, rejection of grade1was found 5 or 7 days after transplantation. In group 4, histopathologic examination showed similar results as in group 1.

Detection of IL-2

Expression level of IL-2 was low in group1, and increased in group2 on days 5 and 7 after transplantation. IL-2 level in group3 was mildly increased, but was lower than that in group 2 on days 3, 5 and 7 after transplantation. IL-2 level in group 4 was significantly lower than those in group 2 and group 3 ($P<0.01$), and was slightly increased on days 5 and 7 after transplantation.

Table 1 IL-2 level after small bowel transplantation in rats ($\bar{x}\pm s$, ng / ml)

Group	IL-2 level		
	3 d	5 d	7 d
Group 1	1.46±0.02	1.73±0.01	1.61±0.05
Group 2	2.44±0.07	5.15±0.31	5.83±0.52
Group 3	1.72±0.11	2.17±0.09	2.43±0.06
Group 4[b]	1.62±0.08	1.81±0.05	2.06±0.13

[b]$P<0.01$ *vs* group 2 and group 3

Survival time after transplantation

The survival time after small bowel transplantation was 7.14±0.33 d in group 2, 16.32±0.41 d in group 3, 31.41±0.74 d in group 4 which was significantly longer than that in other groups ($P<0.01$).

DISCUSSION

Small bowel transplantation is the ultimate therapy for patients with short-bowel syndrome or end stage intestinal function failure. But the small bowel is the maximal immunological organ in human body, the mesenteric lymph nodes and lymphatic plexus are transplanted along with the small bowel transplantation, thus the rejection of small bowel transplantation is much more fiercer than that of other organ transplantations. The failure of small bowel transplantation was more often due to severe rejection[32-34]. So rejection induced by small bowel transplantation necessitates the use of large potent immunosuppressive drugs. It should be noted, however, that excess dosage of immunosuppressive agents may result in severe side effects such as hypertension and hepatic and/or renal toxicity. Moreover, prolonged usage of immunosuppressants often leads to severe infection and increased susceptibility to malignancy, thus critically affecting the health of recipients. The ideal strategy is to induce a low responsiveness or irresponsiveness in recipients toward grafts from donors, while preserving normal immunological functions for the recognition of tumor antigens and prevention of infection. Thus immunosuppressive agents can be avoided or used at a dramatically reduced dosage. The key steps toward successful transplantation therefore should include either attenuated immune reactions or induced immune tolerance to grafts[35-38].

The liver is an immunologically privileged organ, the rejection incidence rate and degree of liver transplantation are much lower than other solid organs. Liver transplantation can also induce tolerance of other organ transplantations, such as the heart, kidneys, skin, *etc*. Experimental and clinical researches also showed that liver combined with small bowel transplantation could alleviate the rejection of small bowel transplantation. Investigations in recent years showed that liver nonparenchymal cells (including lymphocytes, dendritic cells, Kupffer cells, *etc*.) played an important role in inducing tolerance. Donor rat' s intrahepatic leucocytes were eliminated by rays before transplantation, acute rejection would happen after liver transplantation, and the recipients' survival time was shortened. Yet after intrahepatic leucocyte infusion to recipients with rays treated donor liver, the recipients' survival time was obviously prolonged[39-41]. So in our experiment, liver nonparenchymal cell transfusion combined with ciclosporin A was used to suppress the rejection of rat small bowel transplantation. It was observed that the rejection was effectively suppressed, indicating the feasibility of tolerance induction by this method. Compared with small bowel associated with liver transplantation, the method of donor liver nonparenchymal cell transfusion has the advantage of less demanding on manipulation and technique requirements. Its postoperative complications are relative less, yet the suppressive effect on rejection of small bowel transplantation is good. So the donor liver nonparenchymal cell transfusion is a simple and practical method, which has the prospect of becoming a new way to suppress rejection of small bowel transplantation in clinical practice. Further work is needed to reveal if chimerism is induced by liver nonparenchymal cells transfusion, and its possible influence on the immune system of graft recipients such as graft versus host reaction.

Abstract

AIM: To investigate the expression of proliferating cell nuclear antigen (PCNA) and CD44mRNA in colorectal cancer with venous invasion and its relationship with liver metastasis.

METHODS: Reverse transcriptase-polymerase chain reaction (RT-PCR) was used to detect the expression of PCNA and CD44mRNA in 31 cases of colorectal cancer with venous invasion.

RESULTS: Positive expression rates of PCNA and CD44mRNA in colorectal cancer were higher than those without liver metastasis ($P<0.05$ and $P<0.01$). In case of colorectal cancer with liver metastasis, strongly positive rates of PCNA and CD44mRNA were 94.1 % and 70.6 %, respectively, significantly higher than those without liver metastasis. There was a positive relationship between the expressions of PCNA and CD44mRNA ($r=0.67$, $P<0.05$).

CONCLUSION: Detection of PCNA and CD44mRNA expression in colorectal cancer may be useful for evaluating liver metastasis of cancer cells.

INTRODUCTION

Many mechanisms are involved in liver metastasis of colorectal cancer, of which venous invasion is considered to be the chief process[1-6]. Previous studies showed that the degree of venous invasion was positively related to the rate of liver metastasis. But it is unknown which factors participate in liver metastasis of colorectal cancer. PCNA is a chief marker reflecting the activity of cell proliferation, which is closely related to invasion and metastasis of malignant neoplasms and their prognosis[7-10]. Cell adhesion molecules (CAMs) correlate to the invasion and metastasis of tumor cells, and play an important role in occurrence, development and metastasis of neoplasms[11,12]. The goal of this study was to test the expression of PCNA and adhesion molecule CD44mRNA in colorectal cancer with venous invasion by RT-PCR and its relationships with liver metastasis.

MATERIALS AND METHODS

Materials

According to the pathological diagnosis standards, the severity of venous invasion was classified as V0- V3[13]. Thirty-one patients with severe venous invasion of colorectal cancer in V3 stage were chosen as study subjects (male 20, female 11), aged 44-82 years (average 66 years), of them 17 cases had liver metastasis. After operations, neoplasm samples were kept in liquid nitrogen. RNA extract reagent was purchased from Gibco Co., Taq enzyme from Takara Co., PCNA, CD44mRNA and β-actin primer were synthesized by BoYa Shanghai Co.. PCNA' s sequence of up-stream primer was 5' -GCCGAGATC-TCAGCCATATT-3' , that of down-stream primer was 5' -ATGTACTTAGAGGTACAAAT -3' . CD44' s sequence of up-stream primer was 5' -CTTCATCCCAGTGACC-3' , that of down-stream primer was 5' -TGCCACTGTTGATCAC-3' . β-actin' s sequence of up-stream primer was 5' -CACCATGTA-CCCTGGCATTG-3' , that of down-stream primer was 5' -TAACGCAACTAAGTCATAGT-3' . The size of anticipatively amplified products was 452 bp, 446 bp and 243 bp, respectively.

Methods

Using TRIzol reagent kit, total RNA was extracted according to the method previously described[14-20]. The purity and content of RNA were measured by a spectrophotometer, and kept at -80 ℃. Total RNA 5 μg, 5×reaction buffer 10 μl, 10 mmol· L^{-1} dNTPs 5 μl, RNasin 20 U, oligo$(dT)_{12-18}$ 0.25 μg, reverse transcriptase (M-MLV, Gibco) 200 U and 0.1 mol· L^{-1} DTT 0.5 μl were added to reaction volume of 50 μl, incubated at 37 ℃ for 1 h, then heated at 65 ℃ for 5 min to stop reaction. cDNA 0.1 μg, 10×PCR buffer 2.5 μl, 2 mmol· L^{-1} dNTPs 2.5 μl, 25 mmol· L^{-1} $MgCl_2$ 2.5 μl, PCR primer 20 pmol and Taq DNA polymerase (Takara) 5 U were added to reaction volume of 25 μl. Using PTC-100 equipment (MJ Research), PCR conditions were as follows: pre-denaturing at 93 ℃ for 1 min, then 35 cycles at 93 ℃ for 30 s, at 52 ℃ for 30 s and 72 ℃ for 1 min, followed by extension at 72 ℃ for 8 min. Each amplified product of 10 μl was detected via 3 g· L^{-1} sepharose electrophoresis, bromide staining, and analyzed by using a UVP gel imaging system and Labworks software. The ratio of density of positive PCNA and CD44 to that of β-actin was considered to be PCNA and CD44 relative expression quantity[21-28]. Expression intesity was classified into 3 grades: +: 1-30 % β-actin density, ++: 31-65 %, +++: 66-100 %.

Statistics

All the data were analyzed by χ^2-test, and a value of $P<0.05$ was considered significant and $P<0.01$ very significant.

RESULTS

Expression of PCNA and CD44mRNA in colorectal cancer tissue

PCNA, CD44 and β-actin gene expressions were detected in colorectal cancer tissues by RT-PCR, the size of amplified fragment was coincident with that of anticipation (Figure 1). All cases had expression of PCNA, the positive rate was 100 %,

but the expression levels were different among different cases (Figure 1A). Twenty cases had positive expression of CD44 mRNA, the positive rate was 64.5 %. The expression levels were different among different cases. As an inter-control, the expression level of β-actin was basically coincident among different cases (Figure 1C).

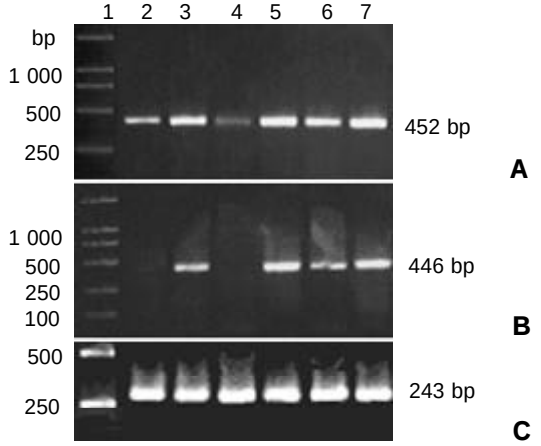

Figure 1 Expression of PCNA (A), CD44 (B) and β-actin (C) in colorectal cancer by PCR amplification. 1: DL2000 DNA marker (Takara), 2-7: Colorectal cancer tissues at various venous invasion stages.

Relationship between expression of PCNA and CD44mRNA and liver metastasis

In 17 cases of liver metastasis, 16 cases had strongly positive expression of PCNA mRNA (++, +++) (94.1 %), significantly higher than those without liver metastasis (28.6 %, $P<0.01$). There was a positive relationship between the expression of PCNA and colorectal cancer with liver metastasis ($r=0.82$, $P<0.01$). In 17 cases of liver metastasis, 12 cases had strongly positive expression of CD44mRNA (70.6 %), significantly higher than those without liver metastasis (21.4 %, $P<0.01$). There was a positive relationship between the expression of CD44mRNA and colorectal cancer with liver metastasis ($r=0.82$, $P<0.01$).

Relationship between expressions of PCNA and CD44mRNA in colorectal cancer

Of the 16 cases with strongly positive expression of CD44mRNA, 12 cases had strongly positive expression of PCNA (75.0 %). Of the 15 cases with weak or negative expression of CD44mRNA, 7 cases had strongly positive expression of PCNA (46.7 %), and there was a significant difference ($P<0.05$). There was a positive relationship between the expressions of PCNA and CD44mRNA ($r=0.67$, $P<0.05$).

DISCUSSION

Venous invasion of cancer cells was the first step of neoplasm' s liver metastasis[29]. However, in clinical cases, venous invasion by histological detection was not definitely related to liver metastasis. It implies that, besides venous invasion, other factors might also participate in the process of liver metastasis[30-32].

PCNA is a kind of non-histone nuclear polypeptide with 36 000 molecular weight, as an assistant protein to DNA polymerase, its content could reflect the degree of cell proliferation[33-37]. Previous studies showed that there was a significant relationship between PCNA labelling and degree of malignancy, vessel invasion, distant metastasis and prognosis[38-42]. In this study, we found that under the condition of venous invasion, the strong expression rate of PCNA mRNA in venous invasion of colorectal cancer with liver metastasis, was significantly higher than that without liver metastasis. This showed that there was a positive relationship between the strong expression of PCNA and colorectal cancer with liver metastasis. All these indicate that colorectal cancer cells with higher proliferating activity are much more easier to proceed liver metastasis.

CD44 is a kind of cell adhesion molecules. Under normal conditions, CD44 acts as the receptor of hyaluronic acid, and chiefly participates in infra-cells and cell-stroma specific adhesion[43-46]. Recent studies showed that CD44 could be expressed in different neoplasm tissues. Bhatavdekar *et al* found that over-expression of CD44 was associated with clinical staging of colorectal cancer. Furthermore, positive expression of CD44 is an important prognostic factor associated with colorectal cancer patients' relapse and total survival time. Further studies found that CD44 could make cancer cells be able to metastasize, adhere to vessel endothelium, accelerate cancer metastasis. We found that the strong expression rate of CD44 mRNA in colorectal cancer with liver metastasis was significantly higher than that without liver metastasis, further suggesting that CD44 might play an important role in colorectal cancer with liver metastasis. But it is still in argument whether CD44 can be taken as an independent marker for progress and metastasis of colorectal cancer.

We also found that under the condition of venous invasion in colorectal cancer patients with liver metastasis, the expression of PCNA and CD44mRNA was strong at the same time. All these indicate that there is a positive relationship between colorectal cancer with liver metastasis and expression of PCNA and CD44mRNA ($r=0.82$, $P<0.01$). Moreover, in colorectal cancer tissue with strong expression of CD44mRNA, PCNA mRNA was significantly higher than that with weak or negative expression, showing that there was a positive relationship between the expressions of CD44 and PCNA ($r=0.67$, $P<0.05$). Taken together, we conclude that detection of PCNA and CD44 expression in colorectal cancer may be useful for evaluating liver metastasis of cancer cells.

Abstract

AIM: Angiogenesis is an important step in the growth of solid malignant tumors. A number of angiogenic factors have been found such as transforming growth factorβ1 (TGF-β1) and vascular endothelial growth factor (VEGF). However, the roles of TGFβ1 and VEGF in gastrointestinal carcinogenesis are still unclear. This study was to investigate the expressions of TGF-β1 and VEGF in gastrointestinal tract malignant tumors, as well as their association with microvessel density (MVD). At the same time, we also observed the localization of TGF-β1 and its receptor CD105 in gastric malignant tumors.

METHODS: The expressions of TGF-β1 and CD105 were detected in 55 fresh specimens of gastric carcinoma and VEGF and CD105 in 44 fresh specimens of colorectal carcinoma by immunohistochemical staining (S-ABC). TGF-β1 and CD105 in 55 gastric carcinoma tissues on the same slide were detected by using double-stain Immunohistochemistry (DS-ABC).

RESULTS: Among the 55 cases of gastric carcinoma tissues, 30 were positive for TGF-β1 (54.55 %). The MVD of TGF-β1 strong positive group (++~+++ 23.22±5.8) was significantly higher than that of weak positive group (+17.56±7.2) and negative group (- 17.46±3.9) (q=4.5, q=5.3207, respectively, P<0.01). In the areas of high expression of TGF-β1, MVD and the expression of CD105 were also high. Among the 44 cases of colonic carcinoma tissues, 26 were positive for VEGF (59.1 %). The expressions of both VEGF and CD105 (MVD) were related with the depth of invasion (F=5.438, P<0.05; F=4.168, P=0.05), lymph node metastasis (F=10.311, P<0.01; F=20.282, P<0.01) and Dukes stage (F=6.196, P<0.01; F=10.274, P<0.01), but not with histological grade (F=0.487, P>0.05). There was a significant correlation between the expression of VEGF and CD105 (MVD) (r=0.720, P<0.01).

CONCLUSION: Over-expression of TGF-β1 and VEGF acts as stimulating factors of angiogenesis in gastrointestinal tumors. CD105, as a receptor of TGF-β1, can regulate the biological effect of TGF-β1 in tumor angiogenesis. MVD marked by CD105 is more suitable for detecting newborn blood vessels.

INTRODUCTION

Angiogenesis occurs in diverse physiological and pathological situations and particularly in tumour growth. The development of a new blood vessel is a complex phenomenon and the result of a sequence of events, among which the release of growth factors of interstitial cells is the most important step. At present, many growth factors have been identified including transforming growth factor (TGF)-β1 and endothelial cell growth factor (VEGF). TGF-β1 is a potent inhibitor of endothelial cells (EC) proliferation and migration *in vitro* and an angiogenesis promoter *in vivo*. It has aroused much interests in study of the relationship between TGF-β1 and angiogenesis. In this research, we used CD105, a new EC marker, to count the intratumor microvessel density (MVD), and to detect the expression of TGF-β1 in 55 gastric carcinoma tissues. Because CD105 is one of the receptors of TGF-β1, we hoped to find out the biological effect of TGF-β1 by studying the relationship between the ligand and the receptor. We also detected the expression of VEGF and CD105 (MVD) in 44 colorectal carcinoma tissues and analyzed the effect of VEGF in angiogenesis of colorectal carcinoma tissues. Furthermore we demonstrated the confidence level and superiority of CD105 in studying tumor angiogenesis.

MATERIALS AND METHODS

Patients

Two groups of patients were chosen and examined. Group A: Fifty-five specimens of freshly resected malignant gastric tissues were collected from 55 patients with gastric carcinoma (median age 57.65±5.3 years, range 29-77 years) who were operated in Qingdao Municipal Hospital and the Affiliated Hospital of Medical College, Qingdao University (Shandong, China) from October 2000 to April 2001. Four cases were well-differentiated adenocarcinoma, nine moderately-differentiated adenocarcinoma and forty-two poorly-differentiated adenocarcinoma. Among the 55 cases, 36 cases had lymph node metastasis and five cases had distant metastasis. Normal tissue samples located at least 8 cm away from the margins of cancers, and 51 normal gastric tissue samples were frozen in liquid nitrogen. Group B: Forty-four freshly resected malignant intestinal tissue samples were collected from 44 patients with intestinal carcinoma (median age 62.5±6.2 years, range 31-79 years) who were operated in Qingdao Municipal Hospital and the Affiliated Hospital of Medical College, Qingdao University from July 2001 to March 2002. The group included one case of well-differentiated adenocarcinoma, thirty-eight cases of moderately-differentiated adenocarcinoma and five cases of poorly- differentiated adenocarcinoma. Among the 44 tumor patients, 20 cases had lymph node metastasis. 20 normal

intestinal tissue samples taken at least 8 cm away from the margins of cancers were frozen in liquid nitrogen.

None of the patients in groups A and B received any chemotherapy or radiation therapy prior to surgery. Fresh tissue samples were collected within 4 hours after resection. The pathological diagnosis was made on the basis of the size, infiltrating depth, histological grade, lymph node and distant metastasis. The grading standard was in accordance with "Practical and surgical pathology"(Chen-Zhong Nian, published by ShangHai Medical University, first edition). Written informed consent was obtained from each patient.

Methods

Immunohistochemistry Biopsy specimens were snap frozen in liquid nitrogen and serial cryostat sections were cut into 7 μm thick. Paraffin-embedded sections were cut into 4 μm thick. Immunohistochemical staining (S-ABC) and immunohistochemical double staining (DS-ABC) were performed in accordance with the introduction of the kit. PBS was used as the negative controls instead of Mab.

Identification of immunohistochemical staining results TGF-β1/VEGF staining was classified into four grades. +++, most carcinoma cells were stained with a very strong intensity, and distributed in clusters. ++, a large number of carcinoma cells were stained with a moderate intensity, and distributed in clusters occasionally. +, a few carcinoma cells were stained with a slight intensity. -, no staining of carcinoma cells.

Counting of MVD in carcinoma tissues was in accordance with Weidner' s standards with a minor modification. The slide was searched for the hot spots rich in vessels, which were located in or near the area of tumor tissues under a low power microscope (100×). MVD was counted under a high power (400×) or low power (100×) microscope according to the standards that any stained endothelial cell or cells were identified as an independent vessel. These vessels must be clearly separated from each other. However, apparent vasa or vasa with red blood cells could be regarded as vessels. Five different HP vision fields were chosen on each of the slides, and the stained vessels were counted simultaneously by two doctors under a multi-ocular len microscope. The results were averaged, which was the relative value of the amount of vessels per unit area.

Statistic analysis

The relation between MVD and expression of TGF-β1 was studied with analysis of variance and Q-test. The analysis of variance and χ^2-test were used for statistical analysis of the relation between MVD and expression of VEGF.

RESULTS

Results of TGF-b1 staining in gastric carcinoma tissues

Among the 55 specimens in group A, 30 were positively stained and 25 negatively stained, with a positive rate of 54.55 %. TGF-β1 was mainly existed in cytoplasms of carcinoma cells. In the 51 specimens of normal gastric tissues, TGF-β1 was mainly expressed in gastric mucosa epithelial cells.

Results of VEGF staining in colorectal carcinoma tissues

Among the 44 cases in group B, 26 were positively stained and 18 negatively stained, with a positive rate of 59.1 %. VEGF was mainly existed in cytoplasms of colorectal carcinoma cells.

Expression of CD105 and counting of MVD in carcinoma tissues

In both group A and group B CD105 was mainly expressed in cytoplasms and plasmalemma of newborn endothelial cells in cryostat section. CD105 was weakly expressed or absent in native blood vessels with thick walls and large lumina. MVD of gastric carcinoma tissues is listed in Figure 1.

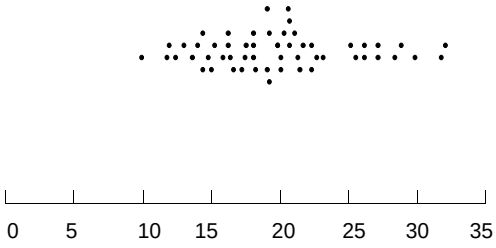

Figure 1 MVD marked by CD105 in 55 cases of gastric carcinoma tissues.

C and D	25	27.31±12.16		167.7±30.3	

expressed and so was CD105 in the same area. It was also found that newborn vessels were present around carcinoma nests whereas TGF-β1 was observed mainly in cytoplasms of carcinoma cells. The relation between MVD and TGF-β1 is shown in Table 1. Analysis of variance and *Q*-test were used to analyze the difference of MVD counting among the three different TGF-β1 staining groups. It showed that MVD of TGF-β1 strong positive group was significantly higher than weak positive group and negative group, and the MVD between the two groups of TGF-β1 staining weak positive "+"and negative "-" had no significant difference.

Relation between VEGF/MVD and clinical pathological parameters in colorectal carcinoma

Analysis of variance showed the expression of VEGF was correlated with infiltrating depth (F=5.438, P<0.05), lymph node metastasis (F=10.311, P<0.01) and Duke' s staging (F=6.196, P<0.01), but had no relation with histological stage (F=0.487, P>0.05). MVD was correlated with infiltrating depth (F=4.168, P=0.05), lymph nodes metastasis (F=20.282, P<0.01) and Duke' s staging (F=10.274, P<0.01), but had no relation with histological stage (F=0.006, P>0.05), (Table 2).

DISCUSSION

Angiogenesis refers to the formation of new blood vessels from native blood vessels, which is essential for the unrestricted growth and metastasis of solid tumors[1]. Thus, highly hyperplastic microvessels are usually recognized as a marker of malignant tumor development. At present, many growth factors have been identified including TGF-β1 and VEGF. These factors could be paracrined by tumor cells[2]. However, the potential roles of these factors, especially TGF-β1, are not clearly known.

Human TGF-β is a large family consisting of 3 isomers: TGF-β1, TGF-β2 and TGF-β3. TGF-β1, the most widely studied protein of the three TGF-β isomers, derived from a 390-amino acid precursor cleaved to produce a 112-amino acid carboxy-terminal peptide, is the predominant form in humans. TGF-β1 influences the proliferation rate of many cell types, acting as a growth inhibitor in most but not all cases. In addition, TGF-β1 controls the processes of epithelial cell differentiation. In normal cells, TGF-β1 generally enhances adhesion through increased matrix production and decreased proteolysis. Resistance to the negative growth regulating properties of TGF-β1 has been observed in epithelial and mesenchymal tumors. In addition to a stimulator of angiogenesis, TGF-β1 also influences the growth of tumor cells directly or indirectly. Tumor cells can escape the inhibiting effect of TGF-β1 on normal cells at post- transcription level, receptor level or post-receptor level. When tumor cells are insensitive, TGF-β1 also can promote tumor metastasis through enhancing angiogenesis, adjusting the character of matrix, or adjusting the body' s immune response to tumor growth. TGF-β1 seems to affect tumor angiogenesis and play an important role in tumor progression in non-small cell lung carcinoma and lung adenocarcinoma. A significant correlation between TGF-β1 protein level and prognosis was detected by multivariate analysis[3]. Maehara[4] found that TGF-β1 was closely related to the invasion and metastasis of gastric cancer, and production of TGF-β1 in the tumor did not contribute to the total amount of TGF-β1 in the blood circulation. TGF-β1 might be associated with tumor progression by modulating angiogenesis in colorectal cancer and it could be used as a possible biomarker[5].

In the present study, 55 cases of gastric carcinoma tissues were stained for TGF-β1. 54.55 % of these tissues were positively stained including 21 strong positive cases "+++~++", 9 positive cases "+", 25 negative cases "-". MVD between the two groups of "+" and "-" staining had no significant difference (P>0.05), but MVD of the group of "+++~++" was significantly higher than the groups of "+" and "-" (P<0.01). Therefore, we propose that overexpression of TGF-β1 be positively correlated with MVD in tumors and one of the bio-effects of TGF-β1 act as a stimulating factor of angiogenesis *in vivo*. In our other studies, TGF-β1 was highly expressed in gastric carcinoma tissues with lymph node metastasis and distant metastasis.

TGF-β1 exerts its functions through binding its receptors. Receptors for TGF-β family include type I, type II, type III and CD105. CD105 could act as an auxiliary protein in the ligand-receptor compound and regulate the function of TGF-β1[6]. It has been found to mainly localize in vascular endothelial cells in normal or tumor tissues. Calabro[7] detected soluble TGF-β1 and CD105 (sCD105) in hematopoietic malignancies, and showed that high levels of sCD105 were present in myeloid malignancies characterized by a high cellular proliferation rate, and suggested that an altered balance between sCD105 and sTGF-β1 might favor disease progression and clinical complications.

In this study we used double staining to detect the expression of CD105 and TGF-β1 in one gastric carcinoma section, and found that CD105 was highly expressed around these cancer cells with more TGF-β1.

VEGF, also named vascular permeability factor, can specifically direct to endothelial cells and is one of the most important factors to induce, up-regulate and migrate angiogenesis. VEGF is a kind of dimer glycoproteins, with a molecular weight of 34-50 kD. VEGF specifically promotes the mitosis and proliferation of endothelial cells by paracrine. Furthermore, VEGF can induce angiogenesis, increase the permeability of vessels and stimulate endothelial cells to produce protease and other low molecule proteins. In addition, VEGF can significantly prolong the life span of endothelial cells, increasing the mitosis to 15-20 fold. Further studies showed VEGF could improve the function of vesicles in endothelial cells, thus increasing the permeability of vessels, which facilities tumor cells to invade the vessels and distant migration. Therefore, VEGF can effectively promote angiogenesis and maintain its existence.

Kaio[8] found that lymph node metastasis and VEGF expression were significant risk factors in advanced colorectal carcinoma patients. Song[9] noticed VEGF was closely related to gastric carcinoma angiogenesis, and involved in tumor progression and lymph node metastasis. Some other studies showed that high VEGF expression or high MVD would indicate a poor prognosis in breast carcinoma patients[10] or high VEGF could be a marker of metastasis and invasion in squamous cell carcinomas[11]. In our study, VEGF and MVD marked by CD105 were highly expressed in colorectal carcinoma tissues. The expression of VEGF and MVD in colorectal carcinoma tissues was closely related to infiltrating depth, lymph node metastasis and Duke' s staging but not related to histological staging. These observations suggested that the expression of VEGF and MVD in colorectal carcinoma tissues was important in monitoring tumor invasion, lymph node metastasis and Duke' s staging.

Our previous correlation analysis showed that the expression of VEGF was positively related to MVD, further proving the causality of VEGF and MVD, i.e., VEGF could stimulate angiogenesis through paracrine in colorectal carcinoma tissues and thus promoting the growth, infiltration and metastasis of tumors.

Newborn blood vessels have their own construction features. For example, the new vessels in tumor tissues do not further differentiate or rebuild corresponding arteries and veins, which means that newborn vessels have no smooth muscle and cannot contract. Newborn vessels in tumors are highly winded, sinusoid and slender. Functionally, blood stream in new vessels is irregular, tending to result in thrombosis or

hemorrhage spontaneously. In this case, tumor cells invade into new vessels and are carried to other organs, continuing to grow and become a metastasis. The more the newborn blood vessels are, the greater the possibilities of metastasis are. Because of the important effects of newborn vessels, great attention has been paid to the studies of angiogenesis.

While counting newborn blood vessels, most researchers selected several normal endothelial cell markers, such as CD31, CD34 and von Willerbrand (vWF). VWF, a factor VIII related antigen (VIII-RA), is a kind of EC marker that exists on EC of normal tissues. Many experiments showed that VIII-RA mainly existed in completely mature vessels, and the chapter restricts its utilization in angiogenesis of tumor tissues. CD31, a member of cell adhesion molecules, often participates in the adhesiveness of platelets in inflammation and wound. Parums pointed out that anti-CD31 monoclonal antibody could also bind normal blood vessels. CD34 is a transmembrane glycoprotein with a MW of 110 kD, and can express on endothelial cells. Ewoto[12] found that it was difficult to identify native or newborn vessels by using CD34. For this reason, CD34 is not an ideal marker of endothelial cells in the research of newborn vessels. Because of the heterogeneity of endothelial cells, the markers of normal endothelial cells are apparently unfit for the studies of angiogenesis in tumor tissues.

CD105, also called endoglin, is a new kind of cell adhesion molecules, first found by Quackenbush in pre-B cell line HOON[13]. CD105 mainly locates in EC and has become a new marker of EC[14]. CD105 is an endothelial homodimeric membrane antigen with 633 amino acid residues and its molecular mass is 180 kD. The gene of CD105 is located on 9q34, which is the target gene of HHT-I. Therefore, the expression of CD105 in EC showed it was highly related to the structure and function of EC[15]. Although CD105 can express in normal vessels, many studies showed CD105 could be detected more easily and reacted more strongly in tissues with angiogenesis.

Mab E9, a new murine anti-human monoclonal antibody, was produced by the Experimental Pathology Institute, Manchester University in early 1990's. It belongs to immunoglobulin G (IgG). Mab E9 does not react with large vessels but with microvessels in tumor tissues strongly. The series of responses of Mab E9 showed its uniqueness from other antibodies. Wang stained the vessels in breast carcinoma tissues with antibody Mab5.6E (anti-CD31) and Mab E9 (anti-CD105), and found blood vessels in or around tumor tissues stained intensely for Mab E9, whereas the same blood vessels were either weakly positive or did not stain at all for CD31. Furthermore, in most cases, unlike Mab 5.6E, Mab E9 failed to stain (a) some apparently normal blood vessels in tumor tissues and (b) a few apparently normal blood vessels in normal tissues were entrapped within a tumor mass. In several normal breast tissues, Mab E9 alone stained only a proportion of blood vessels (-20 %) that were positive for Mab 5.6E. Kumar stained CD34 and CD105 in series cryostat sections with Mab QBEND-10 and Mab E9, and found there was no relation between the two groups of MVD. The group of MVD marked with CD34 was only related to the size of tumors, while the group marked with CD105 could be the independent prognostic marker for patients with breast cancer. Further observation showed, in the same sites the native vessels were CD34 stained, and the newborn vessels were CD105 stained[16].

Because of the heterogeneity of endothelial cells, the markers of normal endothelial cells are apparently unfit for the studies of angiogenesis in tumor tissues. The growth of tumors includes not only the increase of blood vessels in number but also the change of protein molecules in structure of ECs. An ideal EC marker for angiogenesis should detect the newborn vessel quality as well as its quantity. Only in this way can we improve the sensitivity and credibility in detecting angiogenesis. From the above, it is reasonably believed that CD105 is a better marker of angiogenesis compared with CD34, CD31 and VIII-RA. Mab E9 increases the credibility in detecting angiogenesis. In our study, we used Mab E9 to stain MVD in malignant tumors of the gastrointestinal tract, so the credibility was high. We were able to prevent the possibility of mistaking native vessels for newborn vessels.

Abstract

Carcinoid tumors generally appear as yellow/gray or tan submucosal nodules. We experienced a case of pedunculated rectal carcinoid showing a mushroom-like appearance. The case was a forty years old woman who was admitted to our hospital due to rectal bleeding. Colonoscopy revealed a pedunculated polyp presenting a mushroom-shaped appearance measuring 13 mm in diameter in the rectum. The histological diagnosis of specimens obtained by biopsy was adenocarcinoma and transanal ultrasonography revealed the tumor localization within the submucosal layer in the rectum. Endoscopic mucosal resection (EMR) was performed. Histopathological examination established the diagnosis of carcinoid tumor in the rectum. Frequencies of the pedunculated type in rectal carcinoids were reported to be 2.4 % to 7.1 % in the literature. Because of its rarity, pedunculated configuration may confuse the endoscopic diagnosis of carcinoids. Treatment for carcinoids of 1 to 1.5 cm in size remains controversial. Although such tumors are technically respectable by EMR, careful attention must be paid in dealing with these tumors because there may be unexpected behaviors of the tumors.

INTRODUCTION

Carcinoid tumors characteristically appear as yellow/gray or tan submucosal nodules, but they are occasionally polypoid or sessile. However, there have been few reports describing a pedunculated type of carcinoid. We presented here an extremely rare case with a pedunculated rectal carcinoid showing a mushroom-like appearance, and referred to the diagnosis and treatment of this rare tumor.

CASE REPORT

A 40 years old woman was admitted to our hospital due to rectal bleeding. Physical examination and laboratory data including serum tumor markers and hormones such as urinary 5-hydroxyindoleacetic acid (5-HIAA) were normal. Barium enema contrast examination showed a fungiform polyp in the rectum. Colonoscopy revealed a pedunculated polyp presenting a mushroom-shaped appearance in the rectum (Figures 1A, B). There was a hemispherical protrusion with a shallow central erosion in the top, surrounded by a marked mucosal bulge of the edge. Magnifying endoscopy (OLYMPUS CF-type XQ240ZI, Olympus, Tokyo, Japan) revealed no absence of the pit pattern in the center and enlarged pits at the edge, corresponding to the non-structure type of the pit pattern classification proposed by Kudo *et al*[1] (Figure 1C). Endoscopic ultrasonography (EUS), using a miniature probe (12-20 Hz) with a water-filling method, demonstrated a homogeneous hypoechoic mass, but the structure deeper than the third layer of the rectal wall was unclear (Figure 2). Therefore, we employed a soft-balloon technique using an ultrasonic probe with a balloon filled with deaerated water, which provided a clear ultrasonographic picture of the deeper part of the rectum. Judging from findings on EUS, abdominal computed tomography and chest roentgenography, there were no signs of metastasis in the regional lymph nodes or distant organs. Histology of the biopsy specimens suggested an adenocarcinoma, yielding a diagnosis of polypoid type of early rectal cancer. The depth of mural invasion was estimated to be limited to the submucosa by magnifying endoscopy and EUS. After an injection of saline in the submucosa, the lesion was excised by EMR. Macroscopically, the lesion was located in the submucosal layer. The mass was white-yellowish and solid, measuring 13 mm in diameter (Figure 3). Microscopically, the tumor was composed of small uniform cells, arranged in small nests and cords and with an anastomosing ribbon-like pattern in the submucosal layer (Figure 4). There were no atypical histopathologic features such as mitosis or nuclear atypism. Histochemically, the tumor cells possessed an argyrophil but not an argentaffin nature. Immunohistologically, the tumor cells were positive for neuron specific enolase (NSE) and chromogranin A, but were negative for p53 and Ki67. These findings established the diagnosis of carcinoid tumor in the rectum.

DISCUSSION

Carcinoid tumors are enigmatic slow growing malignancies

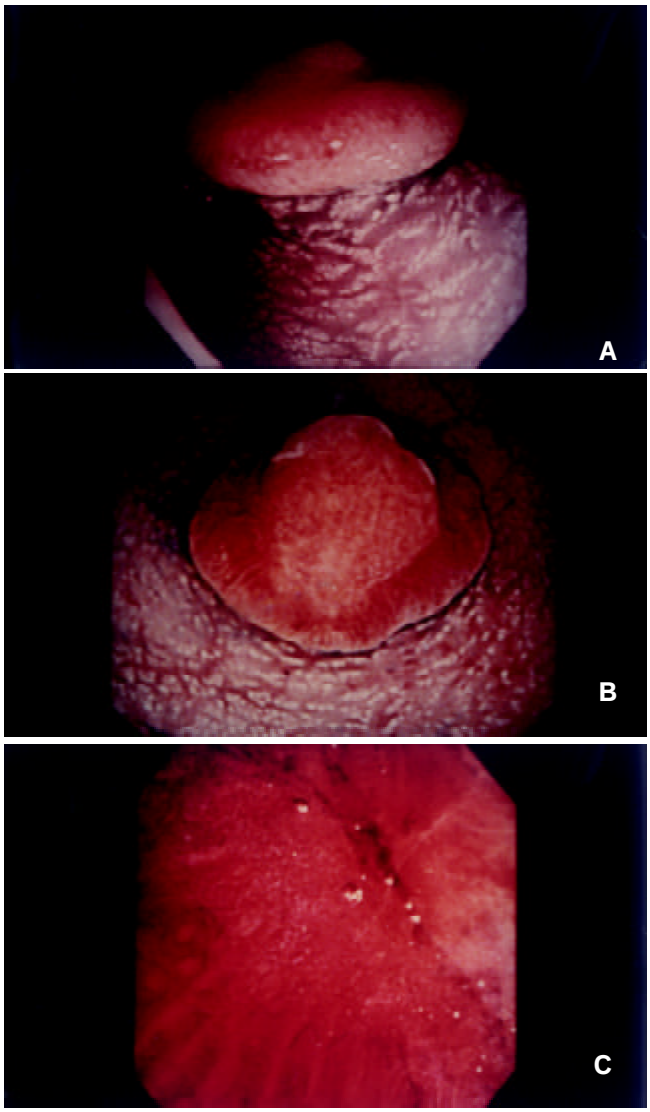

Figure 1 A: Pedunculated polypoid lesion presenting a mushroom appearance in the rectum; B: A round and shallow erosion in the center and a marked mucosal bulge at the edge of polyp; C: A non-structural pit pattern in the center with elongated pits at the edge revealed in magnifying endoscopy.

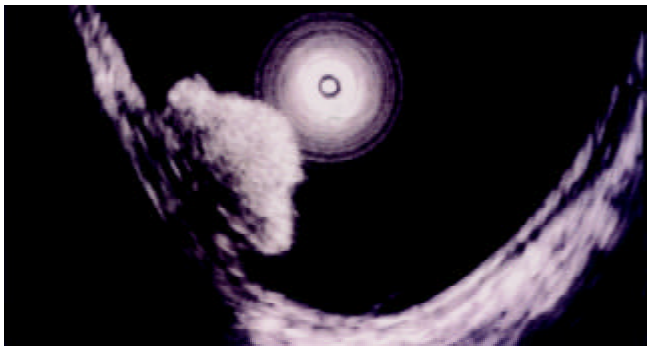

Figure 2 An endoscopic ultrasonography demonstrated homogeneous hypoechoic mass.

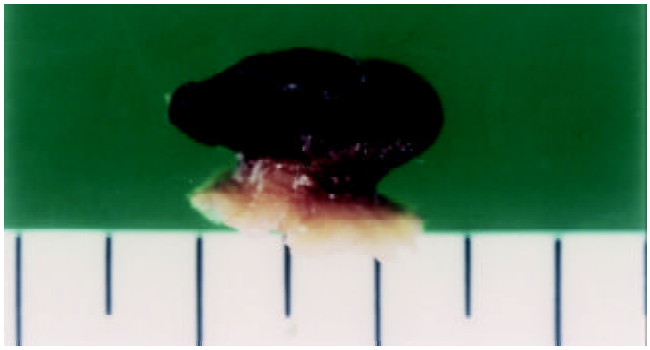

Figure 3 Gross appearance of excised polyp showing a white-yellowish and solid tumor, measuring 13×10 mm with a pedicle.

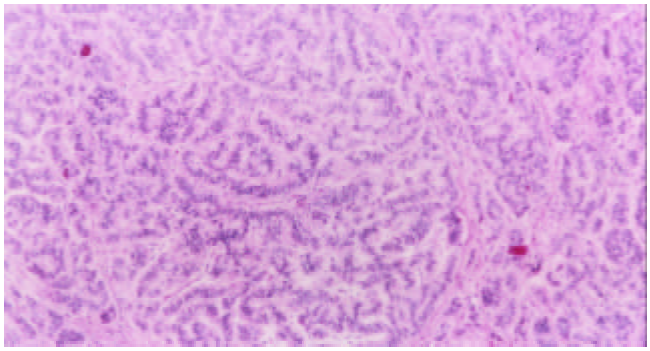

Figure 4 Histology of tumor showing small uniform cells arranged in small nests and cords with an anastomosing ribbon-like pattern in the submucosal layer.

and controversy remains as to their origin[2]. Gastrointestinal carcinoid is regarded as a tumor arising from subepithelial neuroendocrine cells or the totipotential crypt cells in the deep mucosa, usually presenting as a submucosal tumor. Therefore, endoscopic diagnosis is difficult unless biopsy provides a correct histological diagnosis. Macroscopically, a gastrointestinal carcinoid tumor appears as a yellow-gray tan nodule beneath the mucosa and develops a round or oval, sessile polyp as it grows[3]. A pedunculated polyp of carcinoid tumor is extremely rare in the rectum. To our knowledge, only nine cases of rectal carcinoid, including the present case, have been reported[4-9]. Frequencies of the pedunculated type in rectal carcinoids were reported to be 2.4 % to 7.1 % in the literature[5,6]. Because of its rarity, pedunculated configuration may confuse the endoscopic diagnosis of carcinoids.

Recently, Kudo *et al*. reported the usefulness of the pit pattern observation using magnifying endoscopy and stereomicroscopy in the diagnosis of epithelial neoplasms of the large intestine[1]. They classified the pit patterns into five types based on fine morphology of the surface, histology and size. Type V pit pattern showed an irregular or nonstructural surface, which was frequently seen in carcinomas[1]. In this case, we misdiagnosed this tumor as carcinoma because it showed the V pit pattern and pathological diagnosis of biopsy specimens was not correct. It was suggested that the carcinoid in the present case showed non-structural pit patterns because overlying mucosa of the tumor disappeared. It appears inappropriate, therefore, to use pit pattern analysis for evaluation of nature of the tumor in this case.

The size of carcinoid has been accepted as an important factor predicting its prognosis. Several surgical studies have shown that tumors less than 1 cm seldom metastasize, whereas tumors greater than 2 cm have a high incidence of metastasis[2,3,10]. As for the risk of metastasis from rectal carcinoid, Bates *et al*. reported an incidence of 1.7 % for tumors less than 9 mm in size, 10 % for tumor of 10 to 19 mm and 82 % for tumors larger than 20 mm[11]. It is uncertain whether gross appearance of the carcinoids is a predicting factor, although Haraguchi *et al*[12] reported that no metastasis was observed in pedunculated carcinoid in a review of 496 cases of rectal carcinoid.

These reports indicated that the most effective therapy for

rectal carcinoid was a complete surgical excision, particularly in tumors greater than 2 cm[3,13]. Recently, endoscopic treatment has been applied for gastrointestinal tumors including carcinoids. Ishikawa *et al.* suggested the following indications of conventional endoscopic polypectomy for rectal carcinoid tumors. They were tumors less than 15 mm in diameter, flat tumors with normal or yellow color, tumors consisting of nodular nests or trabecular or ribbon-like structures in histology[14]. This guideline of endoscopic treatment for rectal carcinoid may remain controversial. We do not recommend a conventional endoscopic polypectomy for common rectal carcinoid because there was a high incidence of tumor residue after treatment[15]. Recently, endoscopic mucosal resection (EMR) has been generally accepted as a choice of treatment for rectal carcinoid tumors less than 1 cm[9,14,16,17]. Treatment for carcinoids of 1 to 1.5 cm in size remains controversial. Although such tumors have been technically respectable by endoscopic aspiration mucosectomy using the hood technique or a ligating device[18], careful attention must be paid to these tumors because there may be unexpected behaviors of the tumors.

The carcinoid in the present case was negative for p53 and Ki-67. Hasegawa *et al*. reported that carcinoid tumors expressing p53 and Ki-67 had a high malignant potential and metastatic activity[4]. In future, the induction of molecular biology may be helpful in predicting the prognosis of carcinoid tumors[19, 20].

Abstract

AIM: Gastric outlet obstruction caused by duodenal impaction of a large gallstone migrated through a cholecystoduodenal fistula has been referred as Bouveret's syndrome. Endoscopic lithotomy is the first-step treatment. However, surgery is indicated in case of failure or complication during this procedure.

METHODS: We report herein an 84-year-old woman presenting with features of gastric outlet obstruction due to impacted gallstone. She underwent an attempt of endoscopic retrieval which was unsuccessful and was further complicated by distal gallstone ileus. Physical examination was irrelevant.

RESULTS: Endoscopy revealed multiple erosions around the cardia, a large stone in the second part of the duodenum causing complete obstruction, and wide ulceration in the duodenal wall where the stone was impacted. Several attempts of endoscopic extraction by using foreign body forceps failed and surgical intervention was mandatory. Preoperative ultrasound evidenced pneumobilia whilst computerized tomography showed a large stone, 5×4×3 cm, logging at the proximal jejunum and another one, 2.5×2×2 cm, in the duodenal bulb causing closed-loop syndrome. She underwent laparotomy and the jejunal stone was removed by enterotomy. Another stone reported as located in the duodenum preoperatively was found to be present in the gallbladder by intraoperative ultrasound. Therefore, cholecystoduodenal fistula was broken down, the stone was retrieved and cholecystectomy with duodenal repair was carried out. She was discharged after an uneventful postoperative course.

CONCLUSION: As the simplest and the least morbid procedure, endoscopic stone retrieval should be attempted in the treatment of patients with Bouveret's syndrome. When it fails, surgical lithotomy consisting of simple enterotomy may solve the problem. Although cholecystectomy and cholecystoduodenal fistula breakdown is unnecessary in every case, conditions may urge the surgeon to perform such operations even though they carry high morbidity and mortality.

INTRODUCTION

Gallstones are completely asymptomatic in the majority of patients (60 %-80 %)[1]. When they become symptomatic, biliary colic is the most frequently encountered manifestation. Patients with mild symptoms have a higher risk of developing gallstone-related complications such as acute cholecystitis, choledocholithiasis with or without cholangitis, gallstone pancreatitis or gallstone ileus[2]. Biliary fistula occurs in 3 % to 5 % of the cases[3]. Gallstones can migrate into the terminal ileum through a cholecystoduodenal fistula and cause an intestinal obstruction at this level but they may also anchor at the duodenum and produce the symptoms of gastric outlet obstruction in rare cases as first described by Bouveret in 1893[4]. Since this syndrome is usually observed in older patients with poor medical status, a non-surgical approach such as endoscopic stone removal has been used as the first-line treatment. This may be performed by simple endoscopic lithotomy with snare or specific stone baskets designed for endoscopic retrograde cholangio-pancreatography. When feasible, stones are attempted to fragment into small pieces followed by endoscopic removal. Laser lithotripsy either with percutaneous or transendoscopic routes and extracorporeal shock-wave lithotripsy (ESWL) are the alternative treatment modalities[5-7]. In the case of unsuccessful stone removal or its distal migration resulting in mechanical intestinal obstruction, particularly with larger stones, these techniques may be ineffective and surgery may be needed. The main purpose of surgical intervention should be to remove the obstructing stone by enterotomy without cholecystectomy and cholecystoduodenal fistula breakdown to minimize the risks of surgery. However, when it is necessary as the case presented hereby, gallbladder excision can be performed successfully.

CASE REPORT

An 84-year-old woman presenting with 5 days of nausea and vomiting, hematemesis, loss of appetite, and a severe upper abdominal pain located to the periumbilical region was admitted to the emergency unit of the Marmara University Institute of Gastroenterology and referred to Acibadem Hospital according to her will. The physical examination did not show remarkable abdominal distention or any changes in bowel sounds. Abdominal ultrasound evidenced pneumobilia but the gallbladder was not visualized due to excess gas related to gastric and duodenal dilatation. Upper gastrointestinal endoscopy revealed multiple erosions around the cardia, ascribed to Mallory-Weiss syndrome, a large stone in the second part of the duodenum causing complete obstruction, and wide ulceration in the duodenal wall where the stone was

impacted (Figure 1). Although, no clear cholecystoduodenal fistula was demonstrated endoscopically, the typical appearance of the stone indicated its gallbladder origin. Attempts for mechanical fragmentation and retrieval of the stone at the same endoscopic session were unsuccessful. Computerized tomography of the abdomen showed pneumobilia, remarkable distention of stomach, and a 5 cm mass with a calcified rim in the jejunum (Figure 2A). Another mass of 2.5 cm in diameter, sharing similar radiologic features at the right upper abdominal quadrant (Figure 2B) was reported by radiologists as a second gallstone obstructing the duodenal lumen and resulting in a closed-loop syndrome.

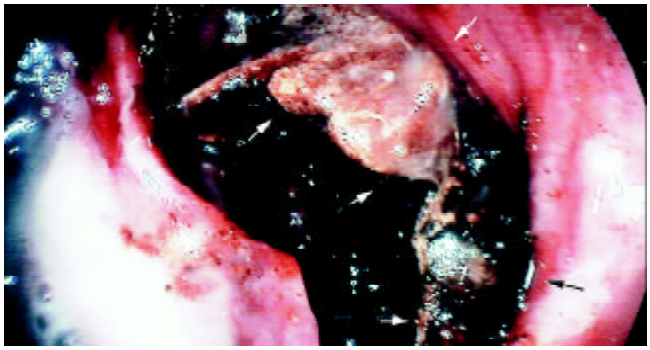

Figure 1 Endoscopic appearance of a large duodenal stone (black arrows) causing complete obstruction. Note the irregular edges of the stone (white arrows), which indicate its fragmentation.

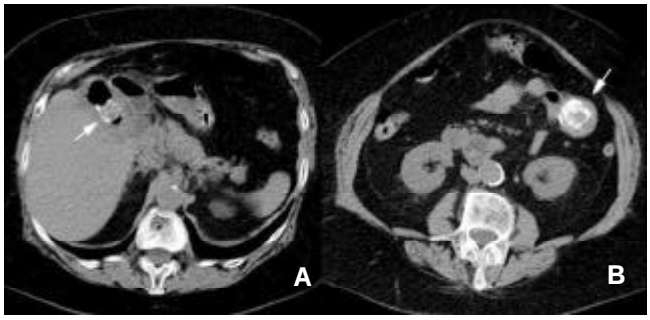

Figure 2 CT shows: A: A large, 5×3×3 cm, intraluminal stone (arrow) in the proximal jejunum, B: Another stone in the duodenal bulb (arrow).

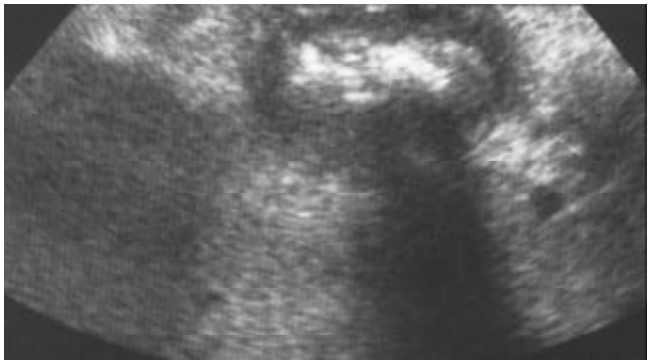

Figure 4 After the adhesions between the gallbladder (arrow) and the adjacent organs were dissected, cholecystoduodenal fistula (arrow head) was broken down and then the retained stone was removed.

The features of the stone, the failure of endoscopic retrieval and the general status of the patient urged to undertake a surgical lithotripsy by laparotomy and enterotomy. At laparotomy, the stone was palpated in the jejunum about 15 cm distal to the ligament of Treitz with a complete mechanical obstruction which was easily diagnosed with the presence of remarkable dilation of the proximal jejunal segment (Figure 3A). There were dense adhesions between the gallbladder and the duodenum, greater omentum, and right part of the transverse colon. The jejunum was opened and the large stone was removed (Figure 3B). Two small pieces of the stone were also removed from the proximal lumen (Figure 3C).

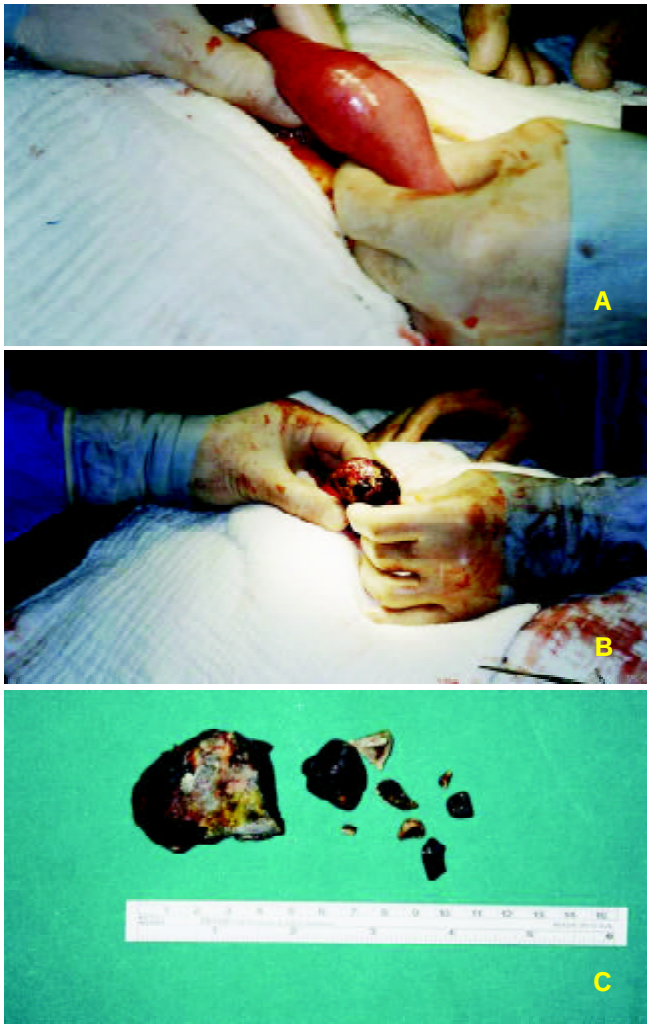

Figure 3 Intraoperative views: A: The obstructed proximal jejunal segment, note a large intraluminal stone causing complete intestinal obstruction at this level, B: Removal of the stone with enterotomy, C: Macroscopic view of the fragmented gallstone which had a very hard outer shell with a soft core.

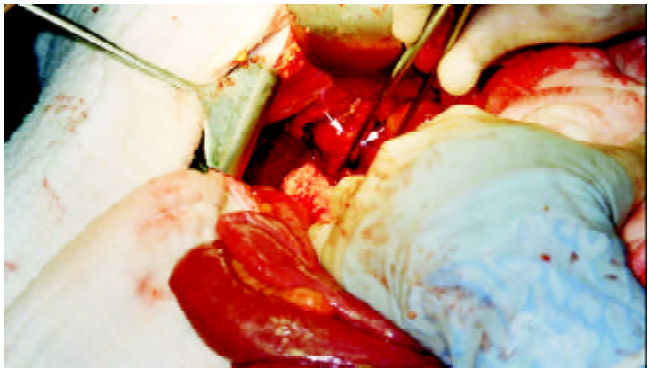

Figure 5 Intraoperative ultrasound revealed that the suspicious stone was in the gallbladder instead of the duodenal lumen.

Then the jejunum was primarily closed with double-layer running stitches of an absorbable material. Since the location of the other stone could not be detected by palpation and the subsequent operative strategy was dependent on its site, an intra-operative ultrasound was performed (Figure 4). Once the other stone was shown to be located in the gallbladder lumen, a cholecystectomy and a duodenal repair was undertaken to avoid further migration of the retained large fragment of the stone which would result in intestinal obstruction. Hence the gallbladder was opened, cholecystoduodenal fistula was broken down, and the stone was retrieved from the lumen followed by antegrade cholecystectomy (Figure 5). Duodenal lumen was also cleared from small stone fragments (Figure 3C) then the duodenal opening was closed by a transverse single-layer running stitch of an absorbable material. The post-operative period was uneventful and the patient was discharged on the eighth postoperative day. She has been symptom-free in the 3-month period of follow-up.

DISCUSSION

Bouveret' s syndrome as described by gastric outlet obstruction caused by a large gallstone passing into the duodenal bulb through a biliogastric or bilioduodenal fistula usually develops in older patients with poor medical conditions and surgical treatment consisting of cholecystectomy and duodenal repair following extraction of the stone through the broken-down cholecystoduodenal fistula or a separate duodenotomy results in considerable morbidity and mortality[8]. Developments in surgical techniques have reduced the reported mortality rate of 30 % before 1968 to 12 % in recent years. Accordingly, surgical aim has gradually shifted from a radical procedure in which the gallbladder is removed and the cholecystoduodenal fistula is repaired to a simple approach consisting of enterotomy and stone extraction. Alternatives to surgical lithotomy such as simple endoscopic lithotomy and laser or ESWL have been reported with successful outcomes in some cases[5].

Bouveret' s syndrome was reported to occur more frequently in females (65 %) with a median age of 69 years. Diagnosis is made usually during the upper GI endoscopy further supported by abdominal ultrasound findings. Computerized tomography is helpful in demonstrating the exact level of obstruction, the biliary site of duodenal fistula, and the status of gallbladder especially in cases of gallbladder rupture. Endoscopic lithotomy is the first line approach to treatment; however, it may be unsuccessful in some cases particularly with impacted large stones. Stones, usually larger than 2.5 cm in diameter, have been reported in cases with Bouveret' s syndrome[3]. Smaller stones generally pass through the duodenum and do not cause gastric outlet obstruction. Endoscopic extraction of stones up to 3 cm in size has been reported[3]. However, larger stones usually get impacted in the duodenum and cause an ischemic ulceration on its wall. On the other hand, large gallstones of mixed type tend to have a very hard outer shell, even though their core may be softer[5]. This feature may hamper their mechanical fragmentation with endoscopic forceps. Although these large stones can be broken down by ESWL, the irregular shape and the relatively large sizes of the fragments may hinder their passage to distal bowel, especially in the case of impacted stones. Percutaneous laser lithotripsy or Holmium: YAG laser via a flexible optic fiber through the working-channel of the endoscope, as recently reported by Alsolaiman *et al*.[5], do not always result in success. In addition, the non-availability of these expensive equipments in most centers restricts their wide-spread use.

Many cases have been reported with migration of the stone after unsuccessful attempts of endoscopic stone extraction or alternative lithotripsy methods. When un-fragmented stone migrates into the small bowel, its removal by a simple enterotomy is easily done. Enterotomy carries less morbidity rate when compared to duodenotomy particularly in patients with duodenal ulcer due to the erosion of duodenal wall by an impacted large stone. When the stone is broken down into several pieces by non-surgical methods and pieces are removed endoscopically, larger fragments which migrate distally can cause obstruction and require surgery. Intraoperative endoscopy may facilitate recognition and removal of remaining stones in the proximal gastrointestinal lumen. However, the presence of any remaining stone fragments in the gallbladder may critically raise the question whether the cholecystectomy is necessary or not. In the present case, the large piece of the gallstone was removed by enterotomy, but the presence of a remaining fragment, which was 2.5 cm in diameter in the gallbladder, necessitated cholecystectomy and cholecystoduodenal fistula breakdown in order to avoid any further attack as it has been reported in similar cases in the literature.

Intraoperative ultrasound is advised in cases where the surgeon is unable to localize exactly the site of the remaining stone fragments. In our case, although radiologists preoperatively reported the second stone fragment as situated in the duodenum causing closed-loop syndrome with a larger one located more distally, intraoperative ultrasound showed the remaining fragment still in the gallbladder. This finding changed our operative strategy from a simple enterotomy and stone extraction to a more complicated procedure such as cholecystectomy and duodenal wall repair.

In summary, endoscopic lithotripsy and stone extraction should be performed as a first-step treatment in patients with Bouveret' s syndrome. When it fails, surgical lithotomy consisting of simple enterotomy may solve the problem. Although cholecystectomy and cholecystoduodenal fistula breakdown is not recommended routinely, especially when the patient' s age and clinical status limit a more aggressive approach, they can be performed successfully when conditions force the surgeon to undertake such a decision.

Abstract

A 95-year old gentleman developed fatal icteric flare of chronic hepatitis B despite lamivudine treatment. This article highlights the atypical presentations of chronic hepatitis B in elderly patient and the need to consider this possibility for acute fulminant hepatitis in endemic areas.

Wong WS, Leung WK, Chan HLY. Icteric flare of chronic hepatitis B in a 95-year old patient. *World J Gastroenterol* 2003; 9(12): 2876-2877
http://www.wjgnet.com/1007-9327/9/2876.asp

CASE REPORT

A 95-year old gentleman was admitted in July 2003 for decreased appetite and reduced mobility. He enjoyed good past health and had no history of hepatitis or jaundice. Two weeks prior to admission, family members noted that he became drowsier and refused food. He was living at home with family and had no history of percutaneous exposure before admission. He had never had tattooing, blood transfusion, casual sex or illicit drug use. There was no traveling history for more than twenty years. The patient was not on any medication or herbs.

On admission, the patient was barely arousable. He could only answer simple questions. He was in deep jaundice and dehydrated. There was no stigma of chronic liver disease. Abdominal examination did not reveal any tenderness, organomegaly or ascites. Flapping tremor could not be demonstrated because the patient was in grade 3 hepatic encephalopathy.

Blood test results were compatible with the picture of severe hepatitis. The serum bilirubin level was 188 μmol/l, alkaline phosphatase was 76 IU/l (normal 40-100 IU/l), and alanine aminotransferase was 825 IU/l (normal <58 IU/l). The prothrombin time was prolonged at 18.1 seconds. Platelet count was 86×10^9/l. Renal function was normal. Urgent ultrasound scan showed normal liver echotexture and normal size spleen. The biliary trees were normal. There was no gallstone.

His hepatitis B surface antigen (HBsAg) was positive, IgM anti-hepatitis B core antigen (anti-HBc) was equivocal, hepatitis B e-antigen was negative, and antibodies to hepatitis B e-antigen (anti-HBe) was positive. Hepatitis B virus DNA was 97.9×10^6 copies/ml by TaqMan real-time polymerase chain reaction[1]. The serology tests for hepatitis A, C, D and E viruses were negative.

Lamivudine 100 mg daily was commenced on the fourth day of admission, and supportive treatment with vitamin K, lactulose and intravenous fluids replacement were prescribed. While the level of alanine aminotransferase was on decreasing trend, serum bilirubin and prothrombin time gradually increased (Figure 1). He developed progressive liver failure with worsening hepatic encephalopathy and eventually succumbed sixteen days after admission.

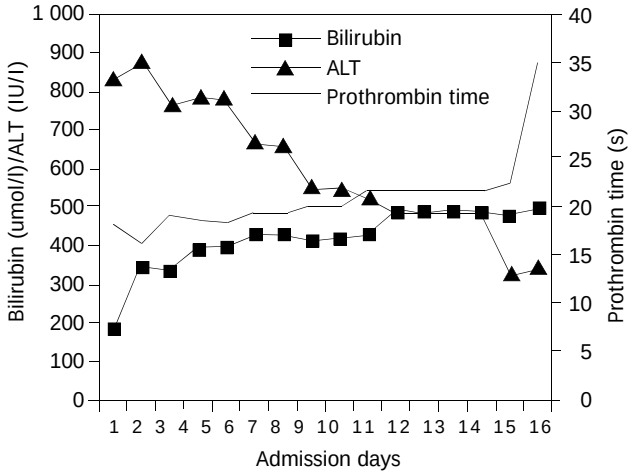

Figure 1 Serial blood results of the patient with acute flare of chronic hepatitis B. The serum bilirubin, alanine aminotransferase and prothrombin time are shown.

DISCUSSION

This case illustrates an unusual presentation of severe hepatitis B virus infection at an advanced age. Although liver biopsy has not been performed, other causes of acute hepatitis have been excluded by negative drug history and negative serology tests for other hepatitis viruses. The absence of risky percutaneous exposure renders the possibility of acute hepatitis B very unlikely. As a majority of chronic hepatitis B patients are asymptomatic and most people in Hong Kong do not have regular health check-up, it is most likely that this patient was suffering from chronic hepatitis B with HBsAg first discovered to be positive at this presentation. Equivocal IgM anti-HBc test is not diagnostic of acute hepatitis B but could also be detected in severe reactivation of chronic hepatitis B[2].

According to most prospective series, reactivation of chronic hepatitis B typically occurred at around the second and third decades[3-5]. Once a patient develops HBeAg seroconversion to anti-HBe, the durability reaches eighty percent. Patients often have quiescent disease afterwards, and the risks of complications, such as hepatocellular carcinoma and liver cirrhosis, are considerably reduced. Our patient probably has achieved sustained HBeAg seroconversion and disease remission several decades before this admission as he had negative HBeAg and no sign of liver cirrhosis at the age of 95. Reactivation of chronic hepatitis B causing jaundice and liver failure at this advanced age is uncommon. This case illustrates the importance to consider chronic hepatitis B as a cause of liver function derangement in endemic areas such as Asia.

Icteric reactivation of chronic hepatitis B carries a poor prognosis even with lamivudine treatment. In a series of 46

patients with severe reactivation of chronic hepatitis B with jaundice a quarter of patients died or required liver transplantation[6]. When both independent predictors of liver-related mortality including thrombocytopenia (platelet count below 143×10^9/l) and hyperbilirubinemia (serum bilirubin greater than 172 μmol/l) are present, as in our case, the mortality rate is up to 69.2 %.

In conclusion, despite atypical presentation and atypical age group, chronic hepatitis B should be considered in cases of acute fulminant hepatitis in endemic areas.

Abstract

We report a rare case of a postoperative pseudoaneurysm of the gastroduodenal artery following radical gastrectomy. Surgical trauma to the gastroduodenal artery during regional lymphadenectomy was considered the cause of the postoperative pseudoaneurysm. The pseudoaneurysm was successfully managed by ligating the bleeding vessel. We should consider the possibility of pseudoaneurysm formation in a patient with gastrointestinal bleeding in the postoperative period following radical gastrectomy with regional lymph node and perivascular lymphatic dissection.

http://www.wjgnet.com/1007-9327/9/2878.asp

INTRODUCTION

The causes of pseudoaneurysms include infection, trauma, and surgical procedures[1]. The development of pseudoaneurysms after upper abdominal surgery is rare, and most occur after biliary and pancreatic surgery[2-5]. There have been only a few reported cases of postoperative pseudoaneurysm of an artery following abdominal surgery. We recently encountered a patient with a ruptured pseudoaneurysm of the gastroduodenal artery following radical gastrectomy for gastric carcinoma.

CASE REPORT

A 73-year-old male was admitted with a two-month history of epigastric discomfort and weight loss. An upper gastrointestinal series, endoscopy, and abdominal CT scan suggested gastric carcinoma. The preoperative laboratory work-up was normal.

Laparotomy revealed an advanced gastric carcinoma involving the adjacent lymph nodes. No peritoneal dissemination or hepatic metastasis was found. The patient underwent a successful radical gastrectomy and the regional lymph nodes, and perivascular lymphatics surrounding the gastroduodenal artery were dissected.

Macroscopically, a curative resection was performed. Postoperative microscopic examination revealed poorly differentiated adenocarcinoma involving the serosal layer of the stomach, and metastasis in one of the twenty-eight lymph nodes dissected.

On postoperative day eight, a wound infection with moderate fever developed, and examination of the anastomotic site revealed no leakage. Twenty-five days after the operation, he suddenly developed abdominal distention with hypovolemic shock. A tentative diagnosis of hemoperitoneum was made and an emergency angiography was performed. An emergency celiac trunk arteriogram revealed a pseudoaneurysmal sac originating from the gastroduodenal artery (Figure 1). To obliterate the pseudoaneurysm transcatheter embolization with steel coils was attempted (Figure 2), but failed. We performed an emergent laparotomy. There was a large hematoma around the gastroduedenal artery. The gastroduodenal artery was allegedly ligated. The patient recovered and was discharged from the hospital two weeks later. He had no subsequent bleeding episodes and was doing well two months following discharge.

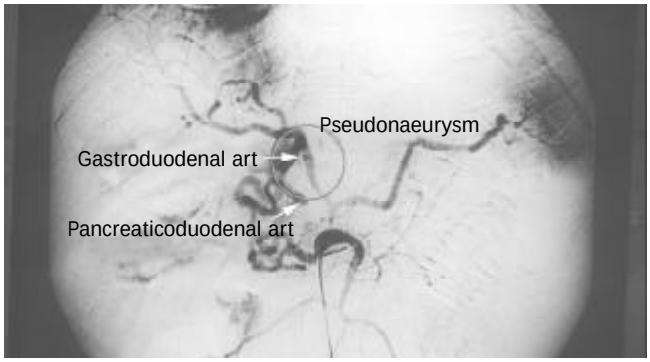

Figure 1 Anterior-posterior view of the superior mesenteric arteriogram showing a pseudoaneurysmal sac originating from the gastroduodenal artery.

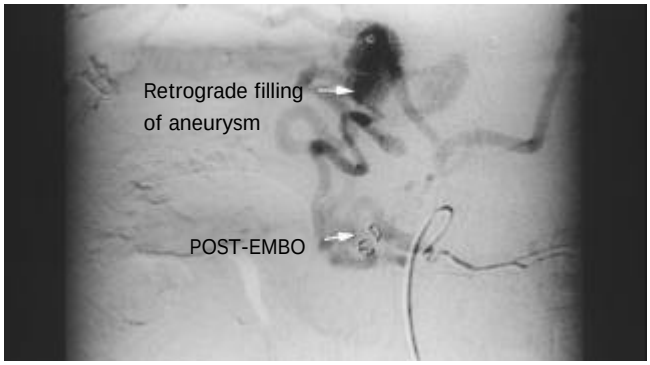

Figure 2 Superior mesenteric arteriogram after embolization shows the pseudoaneurysmal sac by retrograde filling.

DISCUSSION

Pseudoaneurysms result from a variety of mechanisms,

including infection, trauma, and surgical procedures[1]. All have in common disruption of arterial continuity with extravasation of blood into the surrounding tissues. This ultimately results in the formation of a fibrous tissue capsule that progressively enlarges due to the unrelenting arterial pressure[1]. Gastroduodenal artery aneurysms account for 1.5 % of all splanchnic artery aneurysms, but the true incidence of postoperative pseudoaneurysm of the gastroduodenal artery is unknown[6]. Postoperative pseudoaneurysm formation is uncommon, but can follow surgical trauma during gastrointestinal surgery or perioperative local infection[2,7,8]. There is usually a history of massive bleeding and perioperative local infection when the pseudoaneurysm develops[2]. Our patient had a local wound infection and massive intra-abdominal bleeding.

Our review of the literature revealed no reported cases of postoperative pseudoaneurysm of the gastroduodenal artery following radical gastrectomy. We assumed that the pseudoaneurysm formation had been caused by a weakness in the arterial wall according to skeletonization resulting from lymphadenectomy.

When an intra-abdominal pseudoaneurysm is suspected, angiography is useful for determining the exact location of the pseudoaneurysm. In addition, it can save time and prevent the danger of an emergency laparotomy to locate the source of bleeding without angiography[9]. In our case, emergent angiography was performed after the episode of massive intra-abdominal bleeding and demonstrated a pseudoaneurysm arising from the gastroduodenal artery. Many authors[4,6,9-11] have recommended transcatheter occlusion or selective embolization as a useful method in high-risk patients. Basile *et al*.[12], Bulut *et al*.[13] and Furukawa *et al*.[14], reported successful transcatheter arterial embolization in a patient who developed pseudoaneurysm after abdominal surgery. We tried transcatheter arterial embolization, but failed to control the bleeding.

Although it is impossible to know the true incidence of postoperative pseudoaneyrysm of the gastroduodenal artery, it may develop due to iatrogenic injury during surgery[4,15].

We should consider the possibility of pseudoaneurysm formation in a patient with inta-abdominal bleeding during the postoperative period following radical gastrectomy with regional lymph nodes and perivascular lymphatic dissection.

This report describes the successful management of a pseudoaneurysm of the gastroduodenal artery following radical gastrectomy, by ligation of the bleeding vessel.

Abstract

Intestinal lymphangiectasia, characterized by dilatation of intestinal lacteals, is rare. The major treatment for primary intestinal lymphangiectasia is dietary modification. Surgery to relieve symptoms and to clarify the etiology should be considered when medical treatment failed. This article reports a 49-year-old woman of solitary duodenal lymphangiectasia, who presented with epigastralgia and anemia. Her symptoms persisted with medical treatment. Surgery was finally performed to relieve the symptoms and to exclude the existence of underlying etiologies, with satisfactory effect. In conclusion, duodenal lymphangiectasia can present clinically as epigastralgia and chronic blood loss. Surgical resection may be resorted to relieve pain, control bleeding, and exclude underlying diseases in some patients.

http://www.wjgnet.com/1007-9327/9/2880.asp

INTRODUCTION

Intestinal lymphangiectasia (IL) is a rare condition with widely variable symptoms and signs. Patients may be asymptomatic or present as vague abdominal pain, chronic diarrhea, steatorrhea, edema, chylous pleural effusion, ascites, hypoproteinemia, lymphocytopenia or protein-losing enteropathy[1,2]. IL usually occurs in children or young adults, and is suspected to be caused by a congenital abnormality in the lymphatic system[1-3]. Occasionally, IL can be seen in the aged people, which may be secondary to disorders causing lymphatic obstruction, such as lymphoma, carcinoma, tuberculosis, constrictive pericarditis, retroperitoneal fibrosis, post-radiation effects, and repeated parasite infestation[1,4-6]. Diagnosis depends on characteristic endoscopic findings and pathological features[7-9]. However, it is sometimes difficult to differentiate primary from secondary IL. Surgical intervention may be a final resort to make a definite diagnosis and to relieve symptoms. Herein, we present a case with a solitary duodenal lymphangiectasia presenting as epigastralgia and chronic blood loss. The patient finally received surgical intervention and the symptoms resolved.

CASE REPORT

A 49-year-old woman was admitted to our hospital in February 1999 with progressive epigastralgia and malaise for 2 months. She had been well in the past and denied family history of systemic disorders. Physical examination showed mild anemic conjunctivae and tarry stool. There was no evidence of significant enteric protein loss.

Complete blood count revealed mild normocytic normochromic anemia (hemoglobin 10.5 g/dL). Stool examination disclosed positive occult blood (+++). Serum biochemistries as well as serum concentrations of immunoglobulins and tumor markers, including α-fetoprotein, carcinoembryonic antigen, carbohydrate antigen 19-9, and carbohydrate antigen-125, were all within normal limits. Urinary excretion of 5-hydroxyindoleacetic acid (5-HIAA) was normal. Upper gastrointestinal endoscopy showed a 3 cm irregular elevation with bulging border, superficial whitish spots, as well as hemorrhagic and friable mucosa in the second portion of duodenum (Figure 1a). Histological examination showed prominent, dilated lymphatic vessels in the mucosal and submucosal layers (Figure 1b). Upper gastrointestinal barium radiography demonstrated a cluster of polypoid filling defects, 3×3 cm in size, in the second portion of duodenum (Figure 1c). Abdominal sonography and computerized tomography (CT) showed no obvious abnormalities. Small intestine series and barium enema did not disclose any lesion. Antacids and a low-fat, high-protein diet supplemented with medium-chain triglycerides were prescribed for one month with no obvious improvement.

For treating refractory epigastralgia and chronic bleeding and excluding underlying diseases, the modified Whipple's operation with pylorus preservation was carried out in March 1999. A polypoid lesion in the second portion of the duodenum, 3×3 cm in size, was found 1 cm lateral to the papilla of Vater (Figure 1d). Pathological examination confirmed it to be an idiopathic lymphangiectasia. No underlying etiologies could be identified. After operation, the patient recovered well. Epigastralgia resolved and the blood hemoglobin returned to normal after surgery and during the later four-years' follow-up.

DISCUSSION

Intestinal lymphangiectasia has been well recognized as a disorder characterized by dilated lymphatic vessels of the gastrointestinal tract, especially the small intestine[1-3]. It is a

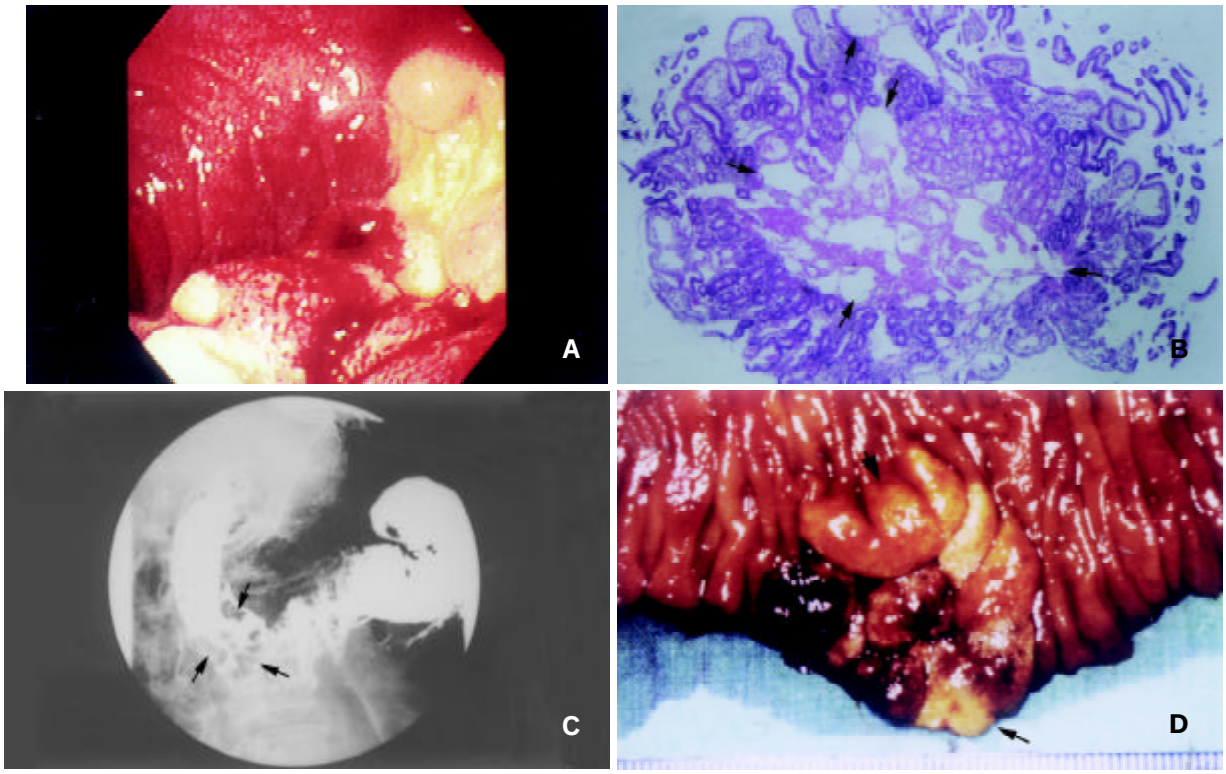

Figure 1 (a) Panendoscopy revealed a 3 cm irregular elevated lesion with whitish spots on the surface and a central crater with blood-coating in the second portion of duodenum. (b) Histology of the endoscopic biopsy showed prominent dilatation of intramucosal and submucosal lymphatic ducts (arrows), a picture of intestinal lymphangiectasia (Hematoxylin and eosin, ×40). (c) Upper gastrointestinal series demonstrated a cluster of polypoid filling defects, 3×3 cm in size, in the second portion of the duodenum (arrows). (d) Gross appearance of the surgical specimen revealed a sessile polypoid lesion, 3 cm in diameter, in the second portion of the duodenum (arrows).

rare condition related to fat malabsorption and protein-losing enteropathy. Distribution of IL can be segmented, multifocal or diffuse. The pathogenesis is believed to be due to obstruction of lymphatic drainage[1-3]. According to the etiologies, IL can be classified into primary and secondary forms[1,2]. Primary IL is usually associated with many genetic syndromes, such as Turner' s syndrome[2,10]. On the contrary, secondary IL is acquired, due to several kinds of gastrointestinal diseases and intra-abdominal or retroperitoneal pathologies, such as carcinoma, lymphoma, tuberculosis or constrictive pericarditis[1,4-6].

Clinical manifestations are similar in both forms of IL, but with variable severity according to the extent of involvement. Some patients can be completely asymptomatic, while at the other extreme, some may be associated with protein-losing enteropathy, growth retardation, or recurrent gastrointestinal tract bleeding[1,2,11]. The protein loss is suspected to be due to rupture of the dilated intramucosal or submucosal lacteals, or exudation from the epithelium[3]. The hemorrhage may be due to rupture of the dilated lacteals, which have potential communications with blood vessels[11].

Diagnosis depends on clinical suspicion. Specific endoscopic findings, accompanied by typical histological pictures can draw into the diagnosis[7]. These endoscopic findings include white-tipped villi, scattered white spots, white nodules, and submucosal elevations[7-9]. Typical histological pictures consist of dilated intramucosal and submucosal lacteals[7-9]. CT scan can help to find the underlying causes of secondary IL[12].

Treatment of IL depends on the severity and extent of involvement. For most patients with primary IL, due to generalized abnormalities and diffuse distribution, dietary modification with a low-fat, high-protein diet and supplementation of medium-chain triglycerides (MCT) is the mainstay of treatment[1, 2]. As MCT is absorbed from the portal venous system directly rather than via lymphatics, it may avoid engorgement of the lymphatics, and thus reduce the opportunity for rupture[2]. On the other hand, for patients with secondary IL, the underlying diseases should be treated. Surgical resection can be chosen when IL is confined to a segment of the intestine and has successfully treated protein-losing enteropathy, anemia or abdominal pain in intestine lymphangiectasia[2,13-15].

In this case, an irregularly elevated lesion in the second portion of the duodenum combined with epigastralgia and chronic blood loss was found. Biopsies showed a picture of IL, however, secondary IL could not be excluded. Due to segmental involvement and to rule out underlying causes, surgical resection was performed. The symptoms were relieved and a definite diagnosis of idiopathic duodenal IL was made. In conclusion, surgical resection may be chosen to relieve symptoms and exclude underlying diseases in patients with solitary duodenal IL.

Abstract

Hemobilia is one of the causes of obscure gastrointestinal haemorrhage. Most cases of hemobilia are of iatrogenic or traumatic origin. Hemobilia caused by a hepatic artery pseudoaneurysm due to ascending cholangitis is very rare and its mechanism is unclear. We report a 74-year-old woman with a history of surgery for choledocholithiasis 30 years ago, suffering from a protracted course of life-threatening gastrointestinal bleeding. A small intestines series and endoscopic retrograde cholangiopancreatography revealed a chronic cholangitis with marked contrast reflux into the biliary tree. Angiography confirmed the bleeding from a pseudoaneurysm of the middle hepatic artery. Coil embolization achieved successful hemostasis. We discussed the mechanism and reviewed the literature.

INTRODUCTION

Hemobilia, a phenomenon of bleeding into the biliary tree, is an unusual cause of obscure upper gastrointestinal bleeding. Most of the etiologies of hemobilia are iatrogenic or traumatic in origin[1]. An hepatic artery aneurysm is a rare vascular lesion that accounts for nearly 10 % of hemobilia cases[2], and is mostly due to atherosclerosis or trauma[3,4]. A hepatic artery aneurysm due to biliary inflammation is less frequent and usually attributed to parasites or stone obstruction in the biliary tract[5]. Inflammatory causes of hemobilia in the Far East are mainly due to parasitic infections, such as ascariasis or clonorchiasis, which have the tendency to invade the bile ducts and induce bleeding. Impacted stones may also erode the biliary mucosa and lead to bleeding. Severe hemobilia is rare, but can occur when a large stone erodes vessels of the hepatoduodenal ligament or the cystic artery[6]. In contrast, hemobilia caused by reflux cholangitis without stones or parasitic infection, has not yet been reported and its mechanism is unclear. We present a case of life-threatening hemobilia from an hepatic pseudoaneurysm, complicated by reflux cholangitis due to previous biliary surgery.

CASE REPORT

A 74-year-old woman had a history of biliary stones and received a cholecystectomy, hepatic lateral segmentectomy and sphincterotomy over 30 years ago. In March 2001, she developed intermittent tarry stools and dizziness for one week and came to our hospital. At the emergency room, her blood pressure was 99/35 mmHg and her pulse rate was 93/minute. Physical examination showed a pale conjunctiva and mild epigastric tenderness. A hemogram showed microcytic hypochromic anemia with a hemoglobin level of 7.6 g/dl. An emergent gastro-duodenal endoscopy disclosed gastric ulcers near the angularis. Proton pump inhibitor therapy was started. On the third hospital day, massive hematemesis with hypovolemic shock occurred. An emergent endoscopy did not disclose any evidence of recent bleeding from the gastric ulcers, but a lot of fresh blood in the duodenal bulb and beyond was observed. An immediate angiography, Tc-99m-RBC scan, and colonoscopy all returned negative findings. An abdominal CT did not display any abnormal lesions. A small intestines series did not disclose any abnormal lesions, except an obvious contrast medium reflux from the duodenum into biliary tree (Figure 1).

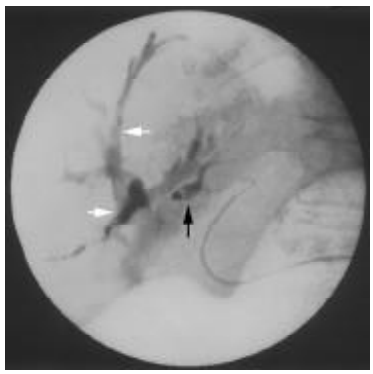

Figure 1 Small intestines series show chronic cholangitis with obvious contrast medium reflux into the biliary tree (arrow).

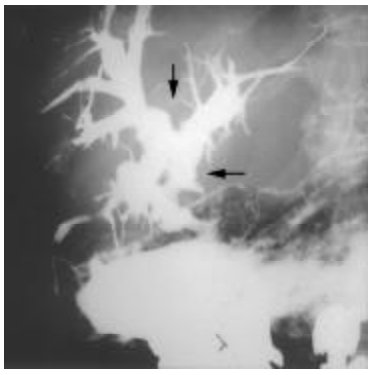

Figure 2 Angiography shows a small pseudoaneurysm (arrow) over the middle hepatic artery. Injecting the contrast medium into the middle hepatic artery opacified the intrahepatic biliary duct (arrowheads).

In the following days, intermittent tarry stools continued to pass. She suffered from upper abdominal pain before every bleeding episode. On the 16th day of admission, she had another massive hematochezia with hypovolemic shock. This time, the emergent endoscopy showed fresh blood flowing from the orifice of the ampulla of Vater. Endoscopic retrograde cholangiopancreatography found widening of the papillary orifice and amorphous filling defects of blood clots retained in the irregular and dilated biliary trees. An angiography showed a small pseudoaneurysm over the middle hepatic artery. Injection of a contrast medium into the middle hepatic artery also opacified the intrahepatic biliary ducts (Figure 2). A coil embolization was performed smoothly and no more event of hemobilia has been reported after this procedure.

DISCUSSION

There were many etiologies for hemobilia such as iatrogenic and accidental trauma, gallstones, inflammation, vascular malformations and tumours[1]. Because interventional procedures and laparoscopic cholecystectomy were used more to manage hepatobiliary disorders, iatrogenic origins were the more frequent etiology for hemobilia[1].

Hemobilia due to a hepatic artery aneurysm only accounted for 10 % of cases[2], and was mostly due to atherosclerosis or trauma[3,4]. Hepatic artery aneurysms due to biliary inflammation were usually attributed to parasites or stone obstruction in the biliary tract[5], and rarely due to non-obstructive inflammations, as in this case. After sphincterotomy, biliary reflux of the duodenal chyme was observed in most patients, aerobilia in half and bactibilia in all[7,8]. Infected bile may lead to cholangitis in more than 1 % of them[9]. Although such a reflux might not always produce clinical symptoms, the biochemical changes suggested that there might be some degree of continuing low-grade damage within the liver parenchyma. Twenty percent of asymptomatic patients undergoing an endoscopic sphincterotomy for biliary stones still had persistent subclinical injury to the biliary tract[10]. Liver biopsy showed periportal fibrosis and inflammation[10]. The bile ducts were richly supplied by the hepatic artery, which forms a peri-biliary vascular plexus[11]. As the inflammation proceeds and involves the collateral hepatic artery, a pseudoaneurysm forms and raises the risk of hemobilia.

The most common symptoms of hemobilia are upper gastrointestinal haemorrhage, upper abdominal pain, and jaundice. These occurred in 73 %, 52 %, and 30 % of cases, respectively, although the complete triad occurred in only 22 % of the them[1]. For patients with upper gastrointestinal bleeding, an endoscopy is the first step. If blood or clotting is seen at the ampulla of Vater, hemobilia is the likely cause of the haemorrhage. However, only 12 % of these endoscopies might be diagnostic[12]. The choice of subsequent investigations depends on the history and the level of suspicion. Abdominal sonography or computed tomography can detect common bile duct obstruction and identify intrahepatic lesions, such as stones or tumors. Endoscopic retrograde cholangiopancreatography may be helpful. Blood may be seen at the ampulla of Vater and contrast studies may show filling defects in the biliary tree. Angiography could detect significant hemobilia in over 90 % of patients[13], and allow the localization of vascular lesions and therapeutic embolization.

The management of hemobilia is aimed at stopping the bleeding and relieving biliary obstruction. Transarterial embolization is now the first line of intervention to stop the bleeding of hemobilia, which returned a high success rate of around 80 % to 100 %[1], and lower morbidity or mortality rates than surgery[14]. Surgical interventions, such as ligation of the bleeding vessel or excision of the aneurysm, should be considered if embolization fails or is contraindicated.

In conclusion, hemobilia is one of the causes of obscure gastrointestinal hemorrhage. Although iatrogenic cases have replaced traumatic ones as the major type of hemobilia, one should keep in mind that ascending cholangitis is a possibility and may sometimes be complicated by life-threatening hemobilia. In particular, the rupture of a hepatic artery aneurysm should be taken into consideration in patients with a remote history of endoscopic or surgical sphincterotomy.
