Sample preparation The sample used in our experiments was obtained within 2 hours after human normal small intestine tissue resection from one subject. The sample was rinsed briefly in saline to remove excess surface blood, and peeled off surface fats. The sample was cut with scissors along its direction of axis and stored at -70 ℃ until the experiments. For the thin tissues, two-faces of sample were not cut by microtome in order to keep integrity of the sample. Because the area of a slice of sample cut by microtome was large, the cytoplasmic liquid exuded severely, which increased the excessive liquid on the surface of the sample. Consequently, the measured results were influenced. The tissue-sample holder was designed and made from a black piece of opacity that was rounded with scissors. The piece was drilled two holes, and its inside radius and outside radius were respectively equal to 6 mm and 12 mm, as shown in Figure 1. The sample was spread out on the tissue-sample holder and nipped. The sample area and thickness were respectively 16.1 mm×16.4 mm and 1.42×0.16 mm, and then it was put in the sample-pool of a double-integrating-sphere system to be measured. The whole experimental process took 4 hours, including sample preparation and taking the sample.

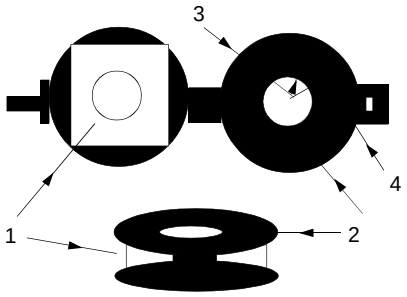

Figure 1 Exhibition map of the tissue- sample holder. 1. Tissue-sample, 2. Tissue- sample holder, 3. R_a=6 mm 4. R_b=12mm.

Methods

Measurement of diffuse reflectance and transmittance The double-integrating-sphere system was a traditional technique to obtain the diffuse reflectance and transmittance of a sample[26-28]. A double-integrating-sphere system shown in Figure 2 consisted of Ti: S ring laser (COHERENT, model 899-05), an argon ion laser (COHERENT, model: INNOVA 70), light attenuator, mirror, 2 mm pinhole, 6 mm pinhole, beam expander of 25 times, two integrating-spheres and two detectors and two optical traps (Anhui Institute of Optics and Fine Mechanics, Academia Sinica, China, model: F4). A Ti:S ring laser emitted at 532 nm and 808 nm wavelengths of laser. An argon ion laser emitted at 476.5 nm, 488 nm, 496.5 nm and 514.5 nm wavelengths of laser. The structures of the two integrating-spheres were the same, the diameter of the sphere was 0.05 m. The diameter of entrance and exit port of the integrating-spheres was equally 0.012 m. The laser beam was passed through two light attenuators, and reflected by the mirror. It was passed through a 2 mm pinhole, and expanded into a collimated laser beam by the beam expander of 25 times. It was passed through a 6 mm pinhole, and perpendicularly incident on the sample. The integrating-sphere I was only used to measure the diffuse reflectance R_d of the sample, not including the specularly reflected light of the sample. The optical trap backed of sample was used for light extinction, including the transmitted light and the diffusely transmitted light. The other optical trap backing the integrating-sphere II was used for light extinction, including all exiting light. The integrating-sphere II was only used to measure the diffuse Transmittance T_d of the sample, not including the collimatedly transmitted light. In this experiment, the diffuse reflectance and transmittance of the wall and the ektexine of the thin sample at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm, 532 nm, 808 nm wavelengths of laser were measured.

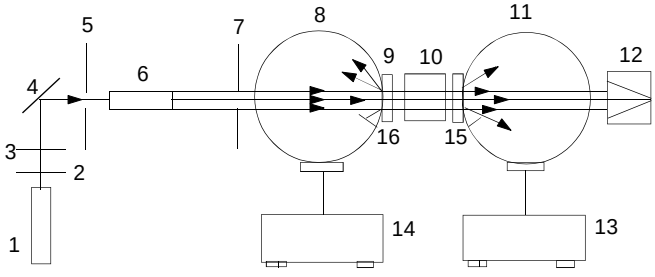

Figure 2 A double-integrating-sphere system was used to determine the optical properties of biological tissues. 1. Laser, 2. Attenuator, 3. Attenuator, 4. Mirror, 5. 2 mm pinhole, 6. Beam expander, 7. 6 mm pinhole, 8. Intergrating sphere I, 9. Sample, 10. Optical trap, 11. Intergrating sphere II, 12. Optical trap, 13. Detector system, 14. Detector system, 15. Baffle, 16. Baffle.

The measuring method of diffuse reflectance was the same as reported[24]. The diffuse reflectance of the sample was given by

$$R_d = \left(\frac{K_S}{K_P} \right) r \qquad (5)$$

where K_p is the diffuse reflection value of the standard target, K_s is the diffuse reflection value of the sample, ρ is the reflection coefficient of the standard target. The diffuse transmittance of the sample was given by

$$T_d = \frac{I_s}{I_0} \qquad (6)$$

where I_s is the diffuse transmission value of the sample, I_o is the total transmission value. Figure 3 shows the arrangement to measure the total transmission value. The half-angle subtended by this aperture from the sample was 3°, and the standard target was placed at the exit port of integrating-sphere II. The wall and ektexine of the sample were respectively radiated at laser and measured.

Measurement of specular reflectance and collimated transmittance

Figure 3 shows the arrangement and method to measure the specularly reflected light, collimated light and the total transmitted light. The half-angle subtended by this aperture from the sample was 3°, and the standard target was placed at the exit port of integrating-sphere II. The other was the same as Figure 2. The integrating-sphere I was used to measure the diffusely and specularly reflected light of the sample. The integrating-sphere II was used to measure the diffusely and collimatedly transmitted light of the sample, and the sum of the diffusely and collimatedly transmitted light of the sample was the totally transmitted light of the sample. The specular reflectance of the sample was given by

$$R_m = \left(\frac{K'_S}{K'_P} \right) r - R_d \qquad (7)$$

where K_p' is the diffuse reflection value of the standard target, K_s' is the diffuse reflection value of the sample, R_d is the diffuse reflectance of the sample, R_m is the specular reflectance of the sample. The collimated transmittance of the sample was given by

$$T_c = \frac{I'_s}{I'_0} - T_d \qquad (8)$$

where T_d is the diffuse transmittance of the sample, T_c is the collimated transmittance of the sample, I_s' is the diffuse transmission value of the sample, I_o' is the total transmission value.

Statistical analysis

Experimental data were shown as mean and standard deviation (X±SD). The SPSS10 for Windows was used for statistical analysis. The difference between each group was analyzed by *t* test. Significant difference was set at $P<0.05$.

RESULTS

In this experiment, 476.5 nm, 488 nm, 496.5 nm, 514.5 nm, 532 nm, 808 nm wavelengths of laser radiation were respectively used for radiating the wall and ektexine of the thin sample. Each datum was the mean of at least ten measurements of human normal small intestine tissue, and each wavelength of laser in the same way. Each time the sample was measured, the position of incident light spot on the sample was changed. The data had very good repetition. There were no significant differences in the diffuse reflectance and transmittance, the specular reflectance and collimated transmittance of the wall and ektexine of the sample at each wavelength of laser radiation ($P>0.05$). Consequently, the measured results of the wall and ektexine of the sample at the same wavelength of laser radiation were estimated by arithmetical average.

Optical parameters of the tissue in Kubelka-Munk two-flux model

The absorption coefficients, scattering coefficients, total attenuation coefficients and effective attenuation coefficients of human normal small intestine tissue in Kubelka-Munk two-flux model at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm, 532 nm, 808 nm wavelengths of laser radiation are given in Table 1 and shown in Figure 4.

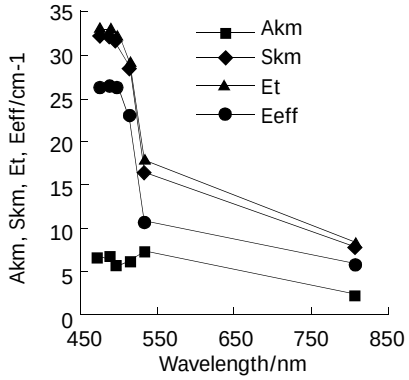

Figure 4 Broken line graphs of A_{KM}-λ, S_{KM}-λ, E_t-λ, S_{eff}-λ of human normal small intestine tissue.

Light distribution of the tissue in Kubelka-Munk two-flux model along the tissue thickness

Light distribution of i(x), j(x), I(x) of human normal small intestine tissue in Kubelka-Munk two-flux model that changed with tissue thickness at six different wavelengths of laser radiation are shown in Figure 5. Light distribution was automatically created by using the experimental data in Table 1 and Mathcad2001 for Windows.

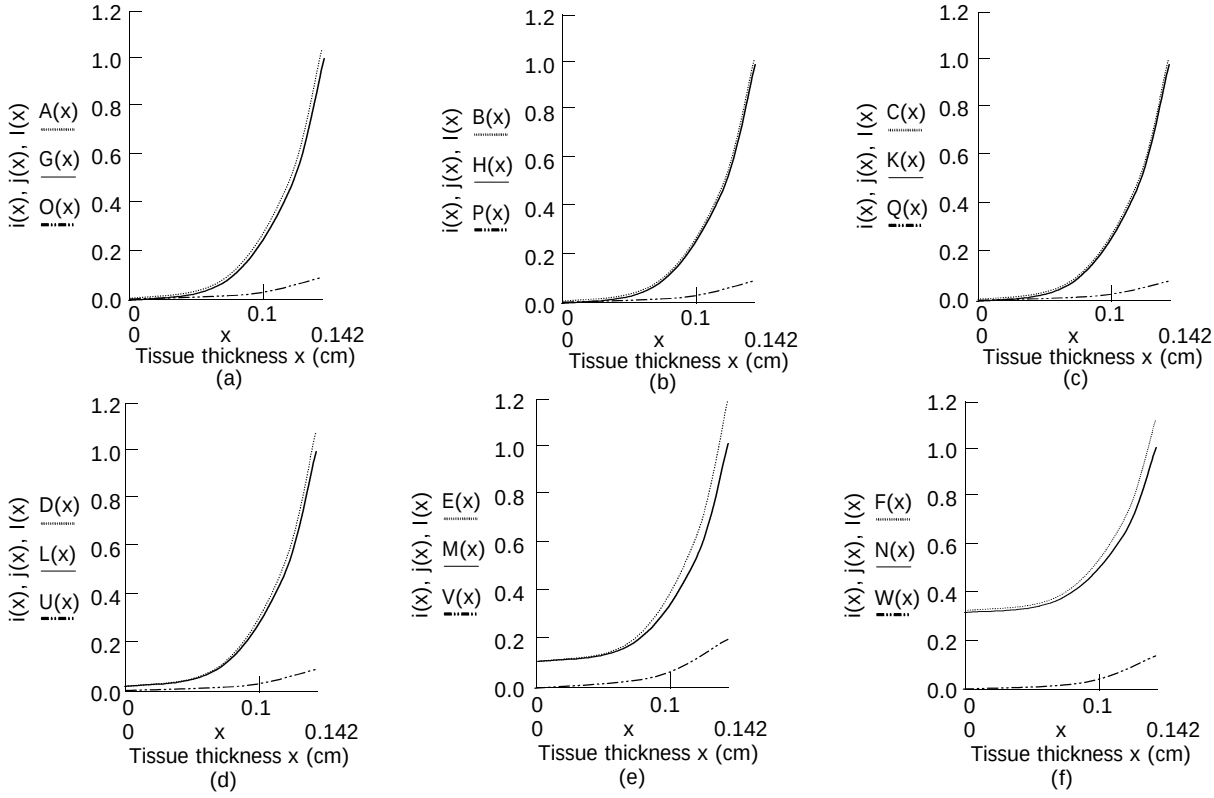

Figure 5 Light distribution of i(x), j(x), I(x) of human normal small intestine tissue in Kubelka-Munk two-flux model changed with tissue thickness at six different wavelengths of laser radiation. (a) A(x), G(x) and O(x) respectively represented the forward and backward, and the total scattered photon fluxes of the tissue at 476.5 nm laser irradiation. (b) B(x), H(x) and P(x) respectively represented the forward, backward and the total scattered photon fluxes of the tissue at 488 nm laser irradiation. (c) C(x), K(x) and Q(x) respectively represented the forward, backward and the total scattered photon fluxes of the tissue at 496.5 nm laser irradiation. (d) D(x), L(x) and U(x) respectively represented the forward, backward and the total scattered photon fluxes of the tissue at 514.5 nm laser irradiation. (e) E(x), M(x) and V(x) respectively represented the forward, backward and the total scattered photon fluxes of the tissue at 532 nm laser irradiation. (f) F(x), N(x) and W(x) respectively represented the forward, backward and the total scattered photon fluxes of the tissue at 808 nm laser irradiation.

The results showed that there were differences both in optics properties of the tissue at six different wavelengths of laser radiation in Kubelka-Munk two-flux model, and in light distribution of i(x), j(x), I(x) of the tissue in Kubelka-Munk two-flux model which changed with the tissue thickness at six different wavelengths of laser radiation.

DISCUSSION

Table 1 and Figure 4 show that there were no significant differences in the absorption coefficients of human normal small intestine tissue in Kubelka-Munk two-flux model at 476.5 nm, 488 nm, 496.5 nm laser radiation (P>0.05). The absorption coefficients of the tissue at 514.5 nm, 532 nm, 808 nm laser radiation obviously increased with decrease of these wavelengths. The scattering coefficients of the tissue at 476.5 nm, 488 nm, 496.5 nm laser radiation increased with decrease of these wavelengths. And the scattering coefficients of the tissue at 496.5 nm, 514.5 nm, 532 nm laser radiation obviously increased with increase of these wavelengths. The scattering coefficient of the tissue at 532 nm laser radiation was bigger than that of the tissue at 808 nm laser radiation. There were no significant differences in the total attenuation coefficients of the tissue at 476.5 nm and 488 nm laser radiation (P>0.05). The total attenuation coefficients of the tissue at 488 nm, 496.5 nm, 514.5 nm, 532 nm, 808 nm laser irradiation obviously increased with decrease of these wavelengths, and their effective attenuation coefficients revealed the same trend. It is suggested that the optical parameters of human tissues in Kubelka-Munk two-flux model can be measured by using the measuring technology of light radiation, and the optical parameters of human tissues with pathological changes and normal human tissues can be compared and analyzed. The results provide a new method of information analysis for clinical diagnosis. Figure 5 shows there were no obvious differences in the forward, backward and the total scattered photon fluxes of the tissue at 476.5 nm, 488 nm, 496.5 nm laser irradiation. All of them obviously increased with attenuation of the tissue thickness. Attenuations of the forward, backward and the total scattered photon fluxes of the tissue at 514.5 nm laser radiation were slightly slower than those at 476.5 nm, 488 nm, 496.5 nm laser radiation. And attenuations of the forward, backward, and the total scattered photon fluxes of the tissue at 532 nm laser radiation were obviously slower than those at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm laser radiation. Attenuations of the forward, backward, and the total scattered photon fluxes of the tissue at 808 nm laser radiation were all obviously slower than those at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm, 532 nm laser radiation. Consequently light attenuation of human normal small intestine tissue at six different wavelengths of laser radiation increased with decrease of these wavelengths, and the change of light attenuation of the tissue accorded completely with the changing rule of penetrability of biological tissues at light radiation of different wavelengths, namely the penetrability of biological tissues from visible light to Infrared light, a range of wavelengths from 400 nm to 900 nm, increased with the increase of wavelengths. It was obvious that penetrability of biological tissues at 808 nm laser was better than the other five wavelengths of laser radiation. 808 nm laser may be used to treat the deep disease

focus in organisms by photodynamic therapy[29-32]. The results of measurement provide useful references and data to laser therapy that is used in clinics, and help improve the effectiveness of photodynamic therapy[33-35].

Abstract

AIM: To understand the effect of low concentration of N-methyl-N'-nitro-nitrosoguanidine (MNNG), which is a widely distributed environmental mutagen and carcinogen especially for human gastric cancer, on DNA damage and to study its possible pathway in regulating cell cycle arrest.

METHODS: The DNA damage effect was measured by Comet assay. A specific phospho-(Ser/Thr) ATM/ATR substrate antibody was used to detect the damage sensor by Western blot. p38 kinase activity was measured by direct kinase assay, and immunoprecipitation for the possible connection between ATM/ATR and p38 MAPK. Flow cytometry analysis and p38 MAPK specific inhibitor SB203580 were combined to detect the possible cell cycle arrest by p38 MAPK.

RESULTS: With the same low concentration MNNG exposure (0.2 μM 2.5 h), Comet assays indicated that strand breaks accumulated, Western blot and kinase assay showed ATM/ATR and p38 kinase activated, immunoprecipitation showed phospho-ATM/ATR substrate antibody combined with both p38 MAPK antibody and phospho-p38 MAPK antibody. p38 MAPK pathway was involved in the G1-S arrest.

CONCLUSION: Activation of ATM/ATR by MNNG induced DNA damage leads to activation of p38 MAPK, which involves in the G1 checkpoint in mammalian cells.

INTRODUCTION

Human beings are exposed to a multitude of carcinogens in their environment, and most cancers are considered to be chemically induced. Monofunctional alkylating agents like N-methyl-N'-nitro-Nitrosoguanidine (MNNG) are widely distributed environmental mutagens and carcinogens that, on activation, react with DNA and proteins and generate adducts. The main target of MNNG is believed to be chromosomal DNA damage, which in turn would provide the primary signal, triggering the DNA damage response that involves coordinate control of multiple signal transduction pathways[1-4]. MNNG is responsible for human gastric cancer, and thus MNNG-induced signal transduction should be most relevant to human gastric carcinogenesis. Since the concentration we used was close to the actual environment concentration, the results would be of much practical significance.

The complex network of DNA damage sensors, signal transmitters, and effectors (checkpoints) is evolved in all eukaryota[5]. The top level of sensors/transmitters in the signal transduction cascade that responds to DNA strand breaks is the members of the phosphatidylinositol 3-kinase family: ataxia-telangiectasia-mutated protein (ATM), ATM- and Rad3-related protein (ATR), and DNA-dependent protein kinase (DNA-PK)[6-8]. Recent findings indicate that ATM activation is not limited to the ionizing radiation-induced response and potentially plays an important role in response to DNA alkylation[9] .

Some evidences have shown that ATM-dependent p53 and c-Jun N-terminal kinase (JNK) pathways are linked to UVA-induced apoptosis. On the other hand, UVC-induced apoptosis occurs through ATR-dependent p53 phosphorylation as well as the JNK pathway[10]. Recently, other data suggest a model in which activation of ATM by gamma irradiation leads to the activation of MKK6, and p38 gamma, and is essential for the proper regulation of the G(2) checkpoint in mammalian cells. But there is no report about the effect of alkylating agents on the possible ATM/ATR-p38MAPK cascade[11].

Based on the above findings, we wanted to know whether low dose of MNNG could damage DNA, what possible function of DNA damage sensor ATM/ATR was in the damage reaction, what the relationship was between ATM/ATR and p38 MAPK, and what effect was on cell cycle.

MATERIALS AND METHODS

Cell culture and MNNG treatment

African green monkey kidney Vero cells cultivated as monolayer in DMEM with 10 % (v/v) heat inactivated fetal calf serum and 100 U/ml penicillin, 100 mg/ml streptomycin in a humidified 5 % CO2 incubator at 37 ℃. For MNNG treatment, the medium was replaced by serum-free DMEM containing 0.2 μmol/L MNNG with 0.2 % solvent DMSO in the medium for indicated period of time (2.5 h). Cells treated in the same way with 0.2 % (v/v) DMSO served as solvent control.

Comet assay

A base layer of 1.0 % agarose was placed on microscope slides and allowed to harden. 75 μl of 1 % low melting point agarose (37 ℃) diluted in deionized H_2O was mixed with 1.0×10^4 treated or untreated cells (5-10 μl in volume) and applied to the coated slide. A glass coverslip was then overlaid on the cell layer, and the agarose was allowed to solidify. The coverslip was then removed, and a third layer of low melting point agarose (75 μl) was added to the slide. Again, a coverslip was overlaid, and the agarose was allowed to solidify. After this, the coverslip was removed, and the slides were placed in a lysis solution (10 mM Tris, pH 10.0, 2.5 M NaCl, 100 mM EDTA, 1 % Triton X-100, 10 % Me_2SO) at 4 ℃ overnight.

The slides were then transferred to an electrophoresis apparatus containing an alkaline solution consisting of 300 mM NaOH and 1 mM EDTA. The slides remained in this solution for 1 h to promote DNA unwinding and were finally subjected to electric current (200 mA) for 1 h. Then the slides were removed, washed three times for 5 min in neutralizing buffer (0.4 M Tris-HCl, pH 7.5) at room temperature, and stained in 50 μl 20μg/ml dilution of EB. The stained nuclei were subsequently examined and photographed.

Western blotting

Protein bands in gels were transferred to nitrocellulose (NC) membranes for 90 min under 100 voltages. After that, all performances about the membranes including washing, primary antibody and horseradish peroxides (HRP) conjugated antibody interactions, enhanced chemiluminescence (ECL) and exposure to films were carried out according to the instruction manual provided by the manufacturer. Bands emerged on films were scanned with a scanning densitometer and quantitated with Kodak 1 D Analysis 2.0 software. Assuming the absorbance of band of DMSO control as 1, the ratio between band of MNNG treatment group and DMSO treatment group of the same kinase on the film was calculated by comparing the relative absorbances of these two bands.

Assay for p38MAPK activity

p38 kinase assay was carried out as described by the protocol of cell signaling technologies. In brief, the Vero cells were washed twice with ice-cold phosphate-buffered saline and exposed to 0.2 μmol/L MNNG for 2.5 h. Then, the cells were washed once with ice-cold phosphate-buffered saline and lysed in 500 μl of lysis buffer per sample (20 mmol/L Tris, pH 7.5, 150 mmol/L NaCl, 1 mmol/L EDTA, 1 mmol/L EGTA, 1 % Triton, 2.5 mmol/L sodium pyrophosphate, 1 mmol/L β-glycerophosphate, 1 mmol/L Na_3VO_4, 1 mg/ml leupeptin, 1 mmol/L PMSF). The lysates were sonicated and centrifuged and the supernatant (which contained 200 μg total protein) was incubated with an immobilized phospho-p38 kinase antibody (Thr 180/Tyr 182) with gentle shocking overnight at 4 ℃. The beads were washed twice with 500 ml of lysis buffer and twice with 500 μl of kinase buffer (25 mmol/L Tris, pH 7.5, 5 mmol/L β-glycerophosphate, 2 mmol/L DTT, 0.1 mmol/L Na_3VO_4, 10 mmol/L $MgCl_2$). The kinase reactions were carried out in the presence of 200 μmol/L ATP, and 2 μg of ATF-2 at 30 ℃ for 30 min. ATF-2 phosphorylation was selectively measured by Western immunoblotting using a chemiluminescent detection system and specific antibodies against phosphorylation of ATF-2 at Thr[71].

Immunoblot analysis

The cells were harvested by trypsinization, and the extracts were prepared by resuspending cell pellets in lysis buffer per sample (20 mmol/L Tris, pH 7.5, 150 mmol/L NaCl, 1 mmol/L EDTA, 1 mmol/L EGTA, 1 % Triton, 2.5 mmol/L sodium pyrophosphate, 1 mmol/L β-glycerophosphate, 1 mmol/L Na_3VO_4, 1 mg/ml leupeptin, 1 mmol/L PMSF). The lysates were sonicated and centrifuged and the supernatant (which contained 200 μg total protein) was incubated with a specific phospho-(Ser/Thr) ATM/ATR substrate antibody with gentle shocking overnight at 4 ℃. Followed by adding 20 μl protein A agarose at 4 ℃ 2 h, the lysates were centrifuged at 1 500×g for 1 min at room temperature. The bands were washed five times with 500 ml of lysis buffer. The protein concentrations were determined using the Bradford assay. Prior to electrophoresis, an appropriate volume of 20 μl 3×SDS sample buffer (150 mM Tris-HCl, pH 6.8, 10 % β-mercaptoethanol, 20 % glycerol, 3 % SDS, 0.01 % bromphenol blue, 0.01 % pyronin-Y) were boiled for 3 min, then it was subjected to SDS-PAGE on 10 % polyacrylamide gels and electrotransferred onto nitrocellulose membranes. The membranes were probed with antibodies against total p38MAPK, phospho-p38MAPK (cell signaling technology). Quantitation of immunoblot signals was performed by densitometry of exposed X-ray films.

Flow cytometry analysis

Was carried out according to the instruction manual provided by the manufacturer.

RESULTS

Accumulation of strand breaks indicated by Comet assays

After treatment with 0.2 μM MNNG 2.5 h, Comet assay (single cell gel electrophoresis, SCGE) showed significant Comet tail formation, similar to the positive control group (4NQO 2.5 mM 30 min). While the control group, both the DMSO treatment group and PBS treatment group, showed no Comet tail formation (Figure 1). Evidently even low concentration of MNNG (0.2 μM) could cause DNA strand broken.

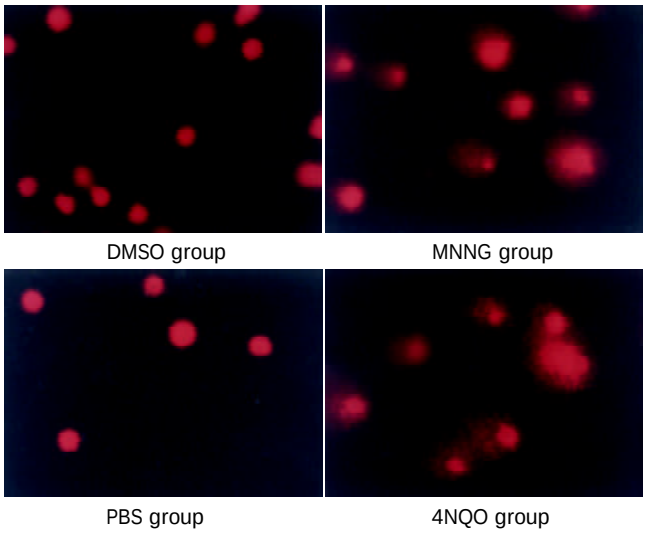

Figure 1 Comet assays indicated accumulation of strand breaks. With low concentration MNNG 0.2 μM 2.5 h treatment, SCGE showed significant comet tail formation, just like the positive control group (4NQO 2.5 mM 30 min). While the control group, both the DMSO treatment group and PBS treatment group, showed no comet tail formation.

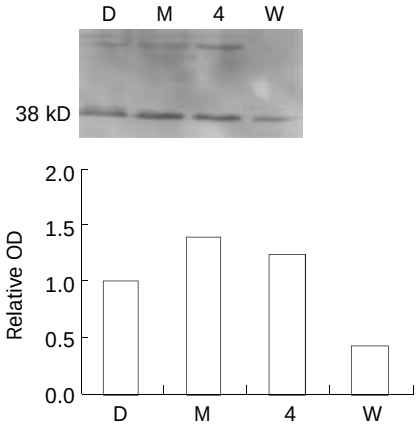

Figure 2 MNNG exposure activates ATM / ATR in Vero cells. Increased phosphorylation of ATM / ATR was observed after 0.2 μM MNNG 2.5 h exposure. One activated substrate molecular weight is about 38 Kda. Pretreatment with 100 μM

wortmannin abrogated the upregulation. Positive control 4-NQO 2.5 mM 30 minutes.

ATM/ATR activated by low concentration MNNG exposure

To test if ATM/ATR was activated in Vero cells following 0.2 μM MNNG exposure, we selected specific phospho-(Ser/Thr) ATM/ATR substrate antibody. We observed increased phosphorylation of ATM/ATR substrate after 2.5 h treatment. The molecular weight of one activated substrate was about 38 Kda. Pretreatment with 100 μM wortmannin abrogated the upregucation. Positive control 4-NQO 2.5 μM for 30 minutes showed similar activated band as the MNNG treatment group (Figure 2). ATM/ATR up-regulation/phosphorylation suggested that DNA strand breaks arising during the repair process activate ATM. These findings indicated that ATM activation was not limited to the ionizing radiation-induced response and potentially played an important role in response to DNA alkylation.

p38 kinase activated by MNNG treatment

Results showed the exposure to 0.2 μmol/L MNNG for 2.5 h, p38 kinase in Vero cells was activated by about 1.47 fold (Figure 3).

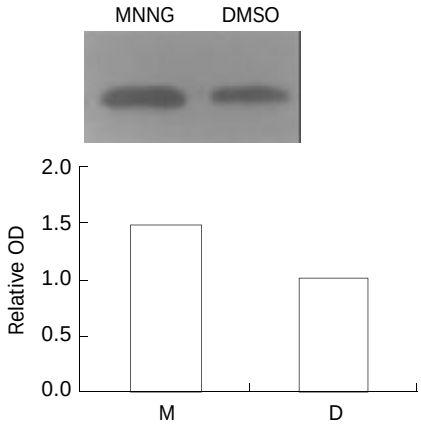

Figure 3 MNNG treatment activated p38 kinase. p38 kinase in Vero cells was activated by about 1.47 fold after the exposure to 0.2 μmol/L MNNG for 2.5 h.

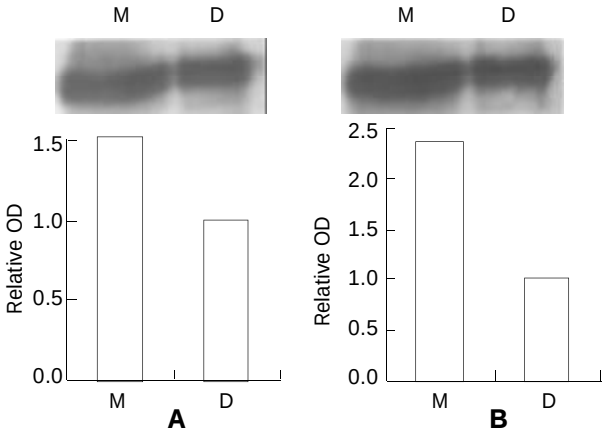

Figure 4 ATM/ATR-P38MAPK pathway is activated by MNNG. Immunoprecipitation showed phospho-ATM/ATR substrate antibody connected with both the p38 MAPK antibody and the phospho-p38MAPK antibody. The band of MNNG group is 1.78 fold (p38MAPK) and 2.37 fold (phospho-p38MAPK) stronger than DMSO group. Combined with the result that P38MAPK was activated by the same treatment, we conclude that ATM/ATR-P38MAPK pathway is activated by MNNG.

ATM/ATR-P38MAPK pathway activated by MNNG

With same treatment (0.2 μM MNNG 2.5 h), immunoprecipitation (IP) showed phospho-ATM/ATR substrate antibody combined with both p38 MAPK antibody and phospho-p38MAPK antibody. The band of MNNG group was 1.78 (p38MAPK) and 2.37 fold (phospho-p38MAPK) stronger than that of DMSO group (Figure 4). Combined with the result of P38MAPK activated by the same treatment, we concluded that ATM/ATR-P38MAPK pathway was activated by MNNG.

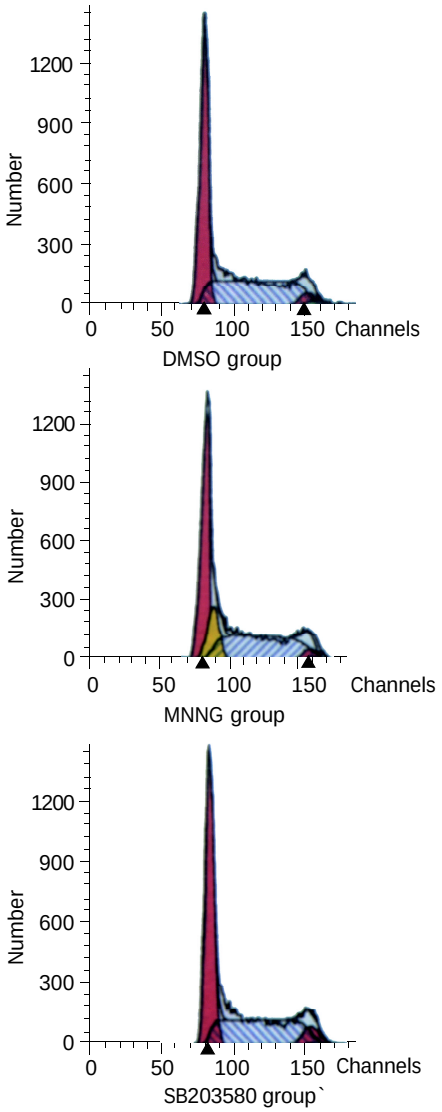

Figure 5 P38MAPK joined G1-S arrest. In the flow cytometry analysis work, it was found that the population of S phase of cell cycle in MNNG treatment group was decreased as compared with the controls (DMSO group). Pretreatment with p38MAPK specific inhibitor SB203580 for 1 h, the G1-S arrest disappeared after the same MNNG treatment.

Table 1 Cell cycle analysis by flow cytometer

Cell	Cell cycle phase fraction (%)		
	G_0-G_1	S	G_2-M
DMSO group	50.22	42.24	4.54
MNNG group	90.36	0.00	9.64
SB203580 group	51.78	41.79	6.43

P38MAPK involved in G1-S arrest

In the flow cytometry analysis (Figure 5), it was found that the population of S phase of cell cycle in MNNG treatment group was decreased as compared with the controls (DMSO group). Pretreatment with p38MAPK specific inhibitor SB203580 for 1

h, the G1-S arrest disappeared after the same MNNG treatment (Table 1). It implied that P38MAPK was involved in the G1-S arrest.

DISCUSSION

Genotoxic events activate a number of signaling pathways that serve, for example, to activate DNA repair mechanisms, halt cell cycle progression and/or trigger advancement into apoptosis. Although all genotoxins produce such general responses, the mechanisms governing response to divergent forms of DNA damage are potentially diverse themselves. γ-irradiation produces double and single strand breaks as well as numerous oxidative changes to bases and deoxyribose moieties, whereas MNNG alkylates (methylates) several nucleophilic centers in bases but does not directly induce strand breaks. MNNG exposure produces mutagenic and cytotoxic O^6-methylguanine (O^6MeG) adducts that can force O^6MeG-T mispairing following replication. In addition to O^6MeG, MNNG causes base alkylation at numerous nucleophilic centers within DNA, such as the N^3 position of adenine. The presence of such adducts triggers DNA glycosylases to generate apurinic/apyrimidinic sites during repair. Apurinic/apyrimidinic sites, in turn, activate an apurinic/apyrimidinic-specific endonuclease resulting in cleavage of DNA.

MNNG can activate JNK/SAPK in human 293 cells at concentrations as high as 70 μmol/L[12]. By our experience, MNNG at concentration of 20 μmol/L is enough to kill over 80 % Vero cells while at concentration of 0.2 μmol/L the highest nontargeted mutation frequency is induced without remarkable mortality[13]. Although it has been verified that with ultraviolet and high concentration of chemical DNA damaging agents, signal transduction is activated not only by damaged but also by undamaged DNA pathways. Insufficient knowledge has been obtained on details of cellular response to low concentration of chemicals especially MNNG. Comet assay (Single cell gel electrophoresis assay, SCGE) is a new and sensitive test for DNA damage studies[14-19]. In our study, with low concentration of MNNG 0.2 μM 2.5 h treatment, Comet assay showed significant Comet tail formation, indicating that strand breaks are accumulated. So even with very low concentration of 0.2 μM of MNNG, DNA strand can also be broken.

It is widely believed that it is the presence of broken DNA strands that activates the catalytic activity of ATM. The ATM gene is mutated in ataxia-telangiectasia, a pleiotropic autosomal recessive disorder characterized by progressive cerebellar degeneration, oculocutaneous telangiectasia, immunodeficiency, cancer predisposition, and an extreme sensitivity to ionizing radiation (IR). Cells derived from ataxia-telangiectasia patients exhibit chromosomal instability and a profound defect in all cellular responses to DNA double strand breaks (DSBs). ATM is a serine/threonine protein kinase that is located mainly in the cell nucleus. Upon infliction of DSBs, ATM mediates the rapid induction of numerous cellular responses that lead to damage repair, and activation of cell cycle checkpoints and other survival pathways[20,21]. To test if ATM/ATR was activated in Vero cells following 0.2 μM MNNG exposure, we selected specific phospho-(Ser/Thr) ATM/ATR substrate antibody. We observed increased phosphorylation of ATM/ATR substrate after 2.5 h treatment. The molecular weight of one activated substrate was about 38 Kda. Pretreatment with 100 μM wortmannin abrogated the upregulation while in positive control it showed similar activated bands as in the MNNG treatment group. ATM/ATR up-regulation/phosphorylation suggested that DNA strand breaks activated ATM/ATR. These findings also indicate that ATM activation is not limited to the ionizing radiation-induced response and potentially plays an important role in response to DNA alkylation.

Downstream targets of ATM/ATR kinase activity that partially delineate DNA damage-activated cell cycle checkpoint signaling pathways have been recently described. The best characterized checkpoint pathways involve p53, Chk1, Chk2, c-Abl, and BRCA1[22-28], but the participating signaling pathways are less clear[29,30]. The complex phenotype of AT cells suggests that it must have other cellular substrates as well[31,32]. Our Western blot result showed that the molecular weight of one activated phosphorylated ATM/ATR substrate was about 38Kda. To identify the possible substrates for ATM and the related kinases ATR, we selected immunoprecipitation test and found that phospho-ATM/ATR substrate antibody was connected with both p38 MAPK antibody and phospho-p38MAPK antibody. By *in vitro* kinase assays, with the same MNNG treatment, p38 MAPK was activated. Taken together, we conclude that ATM/ATR- P38MAPK pathway is activated by MNNG.

MAPKs (mitogen-activated protein kinase) are evolutionarily conserved enzymes connecting cell surface receptors to critical regulatory targets with in cells. MAPKs respond to chemical and physical stresses, thereby controlling cell survial and adaptation. It is becoming clear that MAPKs regulate almost all cellular processes, from gene expression to cell death[33-36]. Mammals express at least four distinctly regulated groups of MAPKs, extracellular signal related kinase (ERK)-1/2, C-Jun N-terminal kinase (JNK1/2/3), p38 MAPK and ERK5. Among MAPKs, both JNK/SAPK and p38MAPK play important roles in cellular stress signal transduction. The involvement of MAP kinases in cell cycle arrest has been studied in a number of organisms. Perhaps due to differences in substrate specificity and regulation among the MAP kinases, their roles in cell cycle regulation appear to be different. Activation of $p42^{MAPK}$ is required for the G_2/M transition in the maturation of Xenopus oocytes[37]. BMK1 (ERK5) was reported to be required for epidermal growth factor-induced progression through S phase[38]. p38α has been reported to be involved in Cdc42-induced G_1 arrest as well as the spindle assembly checkpoint[39,40]. In our experiment, treatment of Vero cells with SB203580, a selective inhibitor of the p38 MAPK pathway, effectively inhibited the G1-S arrest which could be induced by MNNG. These data support an important interplay between the p38 pathway and G_1 cell cycle checkpoint control.

In conclusion, low concentration of MNNG can damage DNA, activate ATM/ATR-p38MAPK cascade and induce G1-S arrest. To our knowledge, this is the first report about the involvement of the ATM/ATR-p38MAPK cascade in the G1-S arrest induced by monofunctional alkylating agent MNNG.

Abstract

AIM: To identify the susceptible gene (s) for type 2 diabetes in the prevously mapped region, 1p36.33-p36.23, in Han population of North China using single nucleotide polymorphisms (SNPs) and to analyze the haplotypes of the gene (s) related to type 2 diabetes.

METHODS: Twenty three SNPs located in 10 candidate genes in the mapped region were chosen from public SNP domains with bioinformatic methods, and the single base extension (SBE) method was used to genotype the loci for 192 sporadic type 2 diabetes patients and 172 normal individuals, all with Han ethical origin, to perform this case-control study. The haplotypes with significant difference in the gene (s) were further analyzed.

RESULTS: Among the 23 SNPs, 8 were found to be common in Chinese Han population. Allele frequency of one SNP, rs436045 in the protein kinase C/ζgene (*PRKCZ*) was statistically different between the case and control groups ($P<0.05$). Furthermore, haplotypes at five SNP sites of *PRKCZ* gene were identified.

CONCLUSION: *PRKCZ* gene may be associated with type 2 diabetes in Han population in North China. The haplotypes at five SNP sites in this gene may be responsible for this association.

INTRODUCTION

Type 2 diabetes is a highly heterogeneous multifactorial disease with both genetic and environmental determinants and an uncertain mode of inheritance. It is characterized by hyperglycaemia due to defects in insulin secretion and action[1]. Now there are 143 millions people with the disease and more than 15 millions diabetic patients in China. In addition, the prevalence of diabetes is still increasing. The belief that type 2 diabetes has strong genetic determinants is based on several lines of evidence, including the high concordance rate among MZ twins[2,3], the marked difference in disease rate between populations[4-6], and the close correspondence between admixture rate and disease prevalence in hybrid populations[7,8]. In addition, there are evidences for major gene (s) influencing diabetes or its specific clinical manifestations, such as glucose concentration, 2-h postprandial insulin level, and age at onset of diabetes[9-11]. However, the mode of inheritance of type 2 diabetes appears to be variable across populations, suggesting a complex genetic mechanism underlying the disease.

In our previous genome-wide screening, we detected the possible susceptibility gene loci located on chromosomes 1, 12, 18 and 20 in Han population of North China. The 4 regions on chromosome 1 (1p36, 1p31, 1q22, 1q42-43) showed strong evidences of linkage with type 2 diabetes. Interestingly, there are 5 serial makers in the p terminal region, 1p36.33-36.23, showed the linkage, which strongly suggests that there might be susceptible genes residing in this region[12].

In order to clone the susceptible genes in the 1p36.33-36.23 region, we conducted a linkage relative study by using single nucleotide polymorphism (SNP), and observed that three SNPs might be associated with the disease. One of these was the SNP rs43605 in protein kinase C/ζ (PRKCZ) gene, which showed a significantly different frequency between patients and normal controls, implying a possible association with the disease.

Then a set of SNPs located in the upstream and downstream from rs436045 in PRKCZ gene were selected to conduct a case-control study with the linkage disequilibrium (LD) analysis. The results suggested that five SNPs extending about 7kb were in the same haplotype block and there was a significant difference in their haplotype frequencies between case and control groups, which further proves that the PRKCZ gene is a susceptible gene for type 2 diabetes.

MATERIALS AND METHODS

Samples

One hundred and ninety two unrelated type 2 diabetes patients from North China together with 172 controls, matched both

for sex and age, were enrolled in a case-control study. The criteria for diagnosis of diabetes mellitus conformed to those of World Health Organization. Informed consent was obtained from each subject, and the study was performed with the approval of the Ethical Committee of Peking Union Hospital. Genomic DNA was isolated from the blood samples by conventional phenol and chloroform methods. Their final concentrations were all adjusted to 20 ng/μl.

SNP-searching in the 1p36.33-36.23 region

23 SNPs in 10 genes located in or near the 1p36.33-36.23 region were selected from the NCBI SNP database (www.ncbi.nlm.nih.gov/SNP) for genotyping. All these genes were either glucose metabolism-related or lipid metabolism- related or involved in signal transduction pathways.

Primer design

The Primer3.0 program (http://zeno.well.ox.ac.uk:8080/gitbin/primer3_www.cgi) was used to design three primers to every SNP site. One pair of primers was used to amplify the fragments including the SNP site from genomic DNA. The third primer was designed to carry out the single base extension (SBE) reaction[13], and this primer should be near the upstream of the SNP site, and could be used to anneal with the template. We then carried out a multiplex polymerase chain reaction (PCR). We designed eight different SBE primers according to different SNPs. The primers' lengths were 18, 22, 26, 30, 34, 38, 42 and 46 bp, respectively, with Tm between 60 ℃-80 ℃.

PCR and purification of the products

The touch-down PCR was carried out. The reaction system was 10 μl mixture containing 50 ng genomic DNA, 3 mmol/L Mg^{2+}, 0.3 mmol/L dNTP, 1 U AmpliTaq Gold. The reaction conditions were denaturation at 94 ℃ for 12 min, then 15 cycles of denaturation at 94 ℃ for 30 s, annealing at 63 ℃ for 30 s, extension at 72 ℃ for 40 s, with the annealing temperature being decreased 0.5 ℃ every cycle. After 15 cycles, the reaction conditions were denaturation at 94 ℃ for 30 s, annealing at 56 ℃ for 30 s, extension at 72 ℃ for 40 s, for 25 cycles, then extension at 72 ℃ for 10 min. The excess primers and dNTPs were removed by adding exonuclease I (1 U, USB, OHIO, USA) and calf intestine alkaline phosphatase (1.5 U, Boehringer Mannheim, Germany) to the PCR reaction mixture and incubating it at 37 ℃ for 1 hour, and then at 95 ℃ for 15 min to inactivate the enzymes.

SBE reaction and identification of genotypes

SBE reaction was carried out on the purified PCR products using SBE primer (100 nM), Joe-ddATP (30 nM), Fam-ddGTP (30 nM), Tamra-ddCTP (30 nM), Rox-ddUTP (150 nM) and Thermosequenase (1 U, Amersham Pharmacia, USA). The reaction conditions were denaturation at 95 ℃ for 30 s, annealing at 50 ℃ for 30 s, extension at 60 ℃ for 40 s, for a total of 35 cycles, followed by extension at 60 ℃ for 3 min.

One μl of SBE products in loading buffer (2 μl) was electrophoresed in the ABI377 sequencers. The length of the products was compared with differently colored luciferin marking a DNA complex with different lengths (i.e.19, 23, 27, 31, 35, 39, 43 and 47 bp). The SNP's genotype was determined by the color and length of each line. Then the PCR products were sequenced to check the SBE genotypes.

Statistical analysis

Hardy-Weinberg equilibrium[14] was tested for each genotyped locus. Using SPSS10.0 program, we compared the difference in allele frequency between cases and controls with χ^2 test.

SNP genotype in PRKCZ gene and haplotype analysis

The SNPs in PRKCZ gene were found from the NCBI SNP database according to gene name and 16 SNPs upstream and downstream of rs436045 were selected and genotyped. For SNP genotyping in *PRKCZ* gene and analysis of the haplotypes, the association analysis was carried out as follows: (1) Hardy-Weinberg equilibrium analysis; (2) The allele association analysis using SPSS10.0 program; (3) The linkage disequlibrium analysis and haplotype analysis were performed to find the haplotype related to type 2 diabetes. Genotyping results were chosen from the 24 normal controls to calculate the number of individuals with different haplotypes using the Phase program. The above results were transformed into a FASTA file analyzed using DnaSP3.5 program (http://www.bio.ub.es/~julio/DnaSP.html). The degree of linkage disequlibrium between each SNP pair (D' and r^2) and the minimum number of recombination events and their locations were calculated in order to determine the haplotype block structure of these loci. The number of haplotypes and the number of individuals with different haplotypes in each haplotype block in both case and control groups were calculated by the DnaSP3.5 program again to search for the disease-associated haplotypes.

RESULTS

Results of 23 SNPs in both case and control groups analyzed by SPSS program

Of the 23 candidate SNPs tested, one was failed to be amplified from genomic DNA (rs586965) and three were heterozydous in all the samples tested (rs5251, rs15431 and rs15854). We deduced that these three were false SNPs due to paralogous sequences. In the remaining 20 candidates, 7 SNPs were homozygous in all the samples (rs91350, ss91351, rs9117, rs5259, rs228691, rs228677 and rs170633), suggesting that they might not be true polymorphisms. Four SNPs (rs1801131, rs14311, rs5254 and rs609805) had minor allele frequencies of less than 15 % and thus were discarded. The remaining 8 SNPs (rs1801133, rs436045, rs228648, rs11740, rs262669, rs228669, rs170629 and rs161825) were genotyped in both case and control groups. Their minor allele frequencies ranged from 26.3 % to 43.16 % and all belonged to the transition type. All the SNPs were studied in the Hardy-Weinberg equilibrium. SPSS analysis showed that the allele frequency of one SNP, namely rs436045 in an intron of PRKCZ gene, was statistically different between case and control groups (Table 1).

Results of SNP genotype in PRKCZ gene and haplotype analysis

Sixteen SNPs in the upstream and downstream of rs436045 in PRKCZ gene were selected, and genotyped. Then the results were analyzed. (1) Hardy-Weinberg equilibrium analysis. (2) The allele frequencies analysis, χ^2 analysis showed the difference between the case and controls (Table 2). (3) Linkage disequlibrium analysis and haplotype analysis were used to find the haplotype related to type 2 diabetes.

To search for the disease-associated haplotypes, haplotypes were constructed by linkage disequlibrium mapping in the region. The results were analyzed using DnaSP3.5. The recombination analysis showed that the minimum number of recombination events was three and they were detected between [rs1878745, rs1467217], [rs1467217, rs1401126], [rs1401126, rs411021]. From the results, we believed that 10 SNPs from rs411021 to rs262642 in 13 loci were in the linkage disequlibrium. They were in the same haplotype block. Further analysis on the frequencies of haplotypes formed by alleles of the 10 loci in case and control groups showed that a more

significant difference existed in the frequencies of different haplotypes (Table 3). There were mainly 4 haplotypes in the control group, accounting for 98.3 % of the total, suggesting that these loci were in the same haplotype block. But there were many more different haplotypes with variable frequencies in the case group. Analysis using the DnaSP3.5 program showed that recombination events existed between [rs809912, rs262669], [rs262669, rs262662], [rs262662, rs381664], [rs381664, rs262650] and [rs262650, rs262642], suggesting that only rs411021, rs436045, rs427811, rs385039 and rs809912, were in the same haplotype block in the case group (Figure 1). The haplotypes containing these five loci were further analyzed in the two groups. The results showed that there were mainly two haplotypes and their frequencies were significantly different in the two groups (Table 4).

Table 1 SPSS analysis results of genotyped SNPs in case and control group

CGTAG	72.1	81.0	0.007	1.652
TAGGA	27.0	17.3		
CGGAG	0.4	1.0		
CAGAG	0.4	0		
TAGAT	0	0.3		
CAGGA	0	0.3		

DISCUSSION

In our previous genome-wide screening, we detected the possible susceptible gene loci located on chromosomes 1, 12, 18 and 20 in Han people of North China. Especially, the four regions on chromosome 1 (1p36, 1p31, 1q22 and 1q42-43) showed evidences of linkage with type 2 diabetes[12]. Interestingly, five serial makers in the p terminal region, 1p36.33-36.23, showed the linkage, strongly suggesting that there may be susceptible

genes residing in this region. Eight SNPs from six genes in the region were genotyped for 192 unrelated type 2 diabetic patients and 172 normal controls. The results showed that one SNP (rs436045) in *PRKCZ* gene was statistically different, suggesting that the SNP may be associated with type 2 diabetes. So we suggested that *PRKCZ* might be a susceptible gene for type 2 diabetes.

Protein kinase C zeta (PRKCZ) is a member of the PKC family of serine/threonine kinases, which consists of at least 10 structurally related enzymes that have been implicated in a variety of cellular processes. *PRKCZ* gene belongs to the aPKC subfamily and is thought to function downstream of phosphatidylinositol 3-kinase (PI 3-kinase) in the insulin signal pathway and to contribute to the translocation of the protein encoded by *GLUT4*. The activated PRKCZ products can accelerate glucose transport during insulin action on rat skeletal muscle and adipocytes[15-18]. In addition, PRKCZ may participate in a negative feedback pathway by phosphorylating insulin receptor substrate-1 (IRS-1) and impairing its ability to activate phosphatidylinositol 3-kinase in response to insulin[19,20]. Insulin-stimulated glucose transport is defective in type 2 diabetes, and this defect is ameliorated by thiazolidinediones and lowering of blood glucose by chronic insulin therapy or short-term fasting. Rosiglitazone treatment, insulin treatment, and fasting can reverse the defects in PRKC-zeta/lambda activation by insulin in GK rat muscles and adipocytes and increase glucose transport in GK rat adipocytes, suggesting that insulin-sensitizing modalities may similarly improve defects in insulin-stimulated glucose transport at least partly by correcting defects in insulin-induced activation of PRKC-zeta/lambda[21]. The above may explain our results.

It is the essential prerequisite for localizing genes associated to disease on the base of the multitude to study linkage disequlibrium (LD) model in detail of the multitude. Now there are still some controversies on the LD capacity. The computer imitating[22] and the experience data[23] all showed that the LD would elongate several kilo basepair near some common SNP, while some other data showed that the LD would elongate more sometimes beyond 100 kilo basepairs[24-26]. Some new research data showed that the LDs would exist in the genomic DNA as the block structure, they would be broken up by the recombination spot[27-30]. Understanding the LD structure is very important for LD analysis, and for carrying out studies on disease-related mutations, population genetics, and the human genomes project. Haplotype blocks are very important for LD. Once a haplotype block is identified in some sequences, different alleles based on it can be selected for LD analysis. So, haplotype block is a very effective method to test the genomic DNA fragments associated with diseases.

Blocks are defined according to the genetic content, not according to how the information is produced and why it exists. Thus, there is no strictly limit in the definition of blocks, which may be different according to different aims. Now there are no very accurate methods to construct haplotype blocks. When we constructed the blocks, we classified a series of SNPs, which have a high linkage disequlibrium but have no recombination, into one block under the condition of the capacity of LD and the recombination spots for every two SNPs.

In order to further study PRKCZ associated with diseases, a set of SNPs located in the upstream and downstream from rs436045 in PRKCZ gene were selected to conduct a case-control study and LD analysis. The results showed that the frequencies of many sites' alleles were significantly different between case and control groups. LD analysis and recombination analysis were further carried out, and the results showed that there was a slight difference between case and control groups. The LD capacity was very high between rs411021 to rs262642 among about 50 kilobasepairs region, and the recombination frequency was very low, suggesting that these SNPs existed in one haplotype block. In cases, however, the LD capacity was very high only in five SNPs from rs411021 to rs809912, within the about 7 kilo basepaires region. The haplotypes containing these five loci were further analyzed in the two groups. The results showed that there were mainly two haplotypes with frequencies very different between the two groups. The frequency of CGTAG haplotype was significantly increased while that of TAGGA haplotype decreased in the case group ($P<0.01$), suggesting that CGTAG and TAGGA might be disease-associated haplotyps. In conclusion, *PRKCZ* gene may be associated with type 2 diabetes in Han population of North China. The haplotypes at five SNP sites in this gene may be responsible for this association.

Abstract

AIM: To study the expression of enhanced green fluorescent protein (EGFP) gene in retrovirally transduced variant HT-29 cells.

METHODS: The retroviral vector p*rkat* EGFP/neo was constructed and transfected into the 293T cell using a standard calcium phosphate precipitation method. HT-29c cells (selected from HT-29 cells) were transduced by a retroviral vector encoding the GEFP gene. The fluorescence intensity of colorectal carcinoma HT-29c cells after transduced with the EGFP bearing retrovirus was visualized using fluorescence microscope and fluorescence activated cell sorter (FACS) analysis. Multiple biological behaviors of transduced cells such as the proliferating potential and the expression of various antigens were comparatively analyzed between untransduced and transduced cells *in vitro*. EGFP expression of the fresh tumor tissue was assessed *in vivo*.

RESULTS: After transduced, HT-29c cells displayed a stable and long-term EGFP expression under the nonselective conditions *in vitro*. After cells were successively cultured to passage 50 *in vitro*, EGFP expression was still at a high level. Their biological behaviors, such as expression of tumor antigens, proliferation rate and aggregation capability were not different compared to untransduced parental cells *in vitro*. In subcutaneous tumors, EGFP was stable and highly expressed.

CONCLUSION: An EGFP expressing retroviral vector was used to transduce HT-29c cells. The transduced cells show a stable and long-term EGFP expression *in vitro* and *in vivo*. These cells with EGFP are a valuable tool for *in vivo* research of tumor metastatic spread.

INTRODUCTION

The detection of tumor invasion and micrometastasis in fresh tissues is necessary for critical understanding of tumor progression and its control. The real-time visualization of tumor cells, micrometastasis and their progression during the course of the disease is not easy to study in current models of metastasis. The green fluorescent protein (GFP) from the jellyfish *Aequorea victoria* has attracted widespread interest and has become an important reporter gene since heterologous expression of the cloned gene was found to be able to generate striking green fluorescence[1,2]. GFP is a relatively small polypeptide consisting of 238 amino acid residues, and is able to produce green fluorescence when excited with a blue light. So far, it has been used as a reporter of gene expression, tracers of cell lineage, and fusion tags to monitor protein localization within living cells in a broad spectrum of model organisms[3]. No additional substrates are required to detect GFP and it can be monitored in living cells. But the sensitivity of wild type GFP is below that of standard reporter proteins, such as β-galactosidase, which utilizes enzymatic amplification. Wild type GFP exhibits lower fluorescence intensity which is hard to detect in several mammalian cells[4]. To improve the detection of GFP in transduced mammalian cells, a unique GFP variant, which contains a chromophore mutation making the protein 35 times brighter than wild type GFP, and is codon-optimized for high level expression in mammalian cells has been constructed[5,6]. These changes in the GFP coding sequence provide an enhanced GFP (EGFP) that greatly increases the sensitivity of the reporter protein[7, 8].

GFP has demonstrated its potential for use as a marker for gene expression in a variety of cell types[9,10]. Numerous studies have proven the usefulness of GFP as a reporter molecule in the setting of transient gene expression[11,12]. However, it remains unclear whether colorectal carcinoma cell lines are able to stably express and maintain high level of EGFP expression over many passages in the absence of selective growth conditions. In this study, we assessed the expression of colorectal carcinoma cells after transduced with EGFP gene, and evaluated their biological behaviors *in vitro*. Moreover, to develop an experimental animal model of colorectal carcinoma that improves the visualization of fresh tissue, we injected EGFP-expressing human colorectal carcinoma cells subcutaneously into rats. This model involves the stable transduction of HT-29c tumor cells *in vitro* with the EGFP gene that could be stably and highly expressed *in vivo*.

MATERIALS AND METHODS

Materials

Cell lines and cell culture HT-29 cell line, a gift of Dr. Dippold (Mainz, Germany), was established from a human colon adenocarcinoma with moderate differentiation, HT-29c with increased metastatic activity was a variant cell line after three cycles of selection of liver metastases from injected HT-29 cells[13]. All cell lines were grown in 75 cm^2 cluture flasks in RPMI-1640 medium supplemented with 10 % fetal bovine serum, 2 mM L-glutamine and 1 mM sodium pyruvate (Life

Technologies) in a humidified atmosphere of 5 % CO_2 and 95 % air at a 37 ℃ incubator (Heraeus, Germany).

Plasmids For subcloning the HSV-TK gene and modifying the restriction sites on the 5' and 3' ends, the pSP72 cloning vector was obtained from Promega Corp., Madison, WI. The gene coding for humanized EGFP of Aequorea victoria contained in the plasmid pEGFP-C was obtained from Clontech Laboratories (Heidelberg, Germany). prkat, a retroviral vector backbone derived from the Moloney murine leukemia virus (MMLV) was provided by Cell Genesys Corp. The expression vector for the vesicular stomatitis virus G protein, pCMV VSV-G, was generously provided by Dr. Ted Friedman.

Construction of retroviral vector General molecular biological cloning techniques and the necessary solutions used to generate this plasmid vector were found in standard protocols[14]. A 0.7 kb EcoR I/BamH I fragment containing the coding region of EGFP gene was isolated and ligated into the prkat to generate prkat EGFP/neo. In this construct, the MMLV long terminal repeat (LTR) controled the expression of EGFP gene and an internal IRES sequence drived the expression of the neomycin resistance marker.

Experimental animal Three-week-old male athymic Rowett nude rats (Hsd: RH-nu/nu) were obtained from Harlan/ Winkelmann (Borchen, Germany). All the rats were housed in cages with filter bonnet under special pathogen-free conditions in a laminar flow cabinet (EHRET, DIPL.-ING. W. EHRET GmbH, Germany) at constant temperature (24-26 ℃), humidity (40-50 %) and 12-hour light/12-hour dark cycle. The rats were fed on standard rat food (Altromin, Lage/Lippe, Germany) and water *ad libitum*. Operative equipments, all cages and bedding were autoclaved at 121 ℃ for 30 minutes. All animal manipulations were done aseptically in a transverse laminar flow hood (BDK, Luft-und Reinraumtechnik GmbH, Germany).

Methods

Production of retrovirus particles and transduction of HT-29c cells with rkat EGFP/neo retroviruses 1.5×10^6 293T cells were seeded onto 10 cm^2 Primaria™ dishes. The next day, fresh medium was added 4 hours prior to transduction. 10 μg of prkat EGFP/neo, 5 μg of prkat gag/pol and 5 μg pCMV-VSV were co-transfected into the 293T cells using a standard calcium phosphate precipitation method. 24 hours later fresh medium (DMEM high glucose with 10 % FCS plus 2 mM glutamine, 1 mM sodium pyruvate and 1X non essential amino acids) was added. 48 hours after the cells were washed, the supernatant containing VSV-G pseudotyped recombinant retroviruses was harvested from the plate and filtered using a 0.45 μm low protein binding Acrodisc™ filter (Gelman Sciences, Ann Arbor, MI). 3 ml of the retroviral supernatant was then added to a 6 cm^2 dish seeded with 1×10^5 HT-29c cells containing 8 μg/ml polybrene. 24 hours later, the transduced HT-29c cells were placed under geneticin (G418, Life Technologies) selection (700 μg/ml). After two weeks, individual clones were generated by limited dilution. 96 well plates were seeded using cell densities of 3, 5 and 10 cells per well. Within 3-4 weeks, 12 separate clones were generated and expanded into 6 well plates. To analyze the expression of EGFP in the individual clones, 5×10^5 cells from each clone were fixed in 2 % formaldehyde and the fixed cells were analyzed by FACS. The two clones with the most intense fluorescence, HT-29cEGFPclone #1 and #7 were selected and used for *in vitro* or *in vivo* studies.

Cell culture of transduced HT-29c cells HT-29cEGFP, HT-29cEGFPclone#1 and clone#7 cells were grown in supplemented RPMI-1640 medium. The cultures were incubated at 37 ℃ in a humidified atmosphere of 5 % CO_2. G418 was added to cell medium at a final concentration of 600 mg/ml from first till 15th passage for selection. After passage 15, the cells were grown in the absence of G418 and cells were passaged twice per week.

Microscopic and FACS analysis of EGFP expressing cells *in vitro* HT-29c EGFPclone#1 and clone#7 cells were seeded onto chamber slides. When cells grown in monolayer became confluent, the fluorescence of the cells were visualized with an Axioskop fluorescence microscope (Carl Zeiss, Germany) equipped with a FITC filter set (UV light exciter BP 546 nm, FT 580 nm, emitter LP 590 nm). Cultivated cells were harvested by trypsinization and were fixed in 0.4 ml 2 % formaldehyde. The fluorescence intensity of samples was analyzed using fluorescence activated cell sorter (FACS, Epics XL, Hamburg, Germany).

Comparative analysis of biological behavior between transduced and untransduced cell lines *in vitro* Growth rate determination: HT-29, HT-29c, HT-29c EGFPclone#1 and clone#7 cells were seeded in six-well plastic culture plates, in triplicate at a density of 1×10^5 in supplemented medium. The cells were harvested by trypsinization and counted every 24 hours using a hemocytometer. The test was repeated three times. The mean number of cells in each interval for each cell line was determined. The growth curve of each cell line was constructed. The doubling time of tumor cell growth was calculated from the cell growth curve over 5 days according to the formula: Doubling time=(T_2-T_1) In 2/(In N_2-In N_1), in which N_1 and N_2 are the number of tumor cells at time points of T_1 and T_2, respectively.

Three-dimensional spheroid culture of cell lines: Three-dimensional spheroid culture of HT-29c and HT-29cEGFPclone cells were performed as follows: six-well culture plates were pre-coated with 2 ml 1% (w/v) agarose gel/per well. The single-cell suspension containing 1×10^5 tumor cells in supplemented medium was seeded onto each well and incubated in a humidified 5 % CO_2 at a 37 ℃ incubator. Cell aggregation was monitored daily using a phase-contrast microscope (Carl Zeiss, Germany).

Expression of different antigens: Cells were seeded onto 10-well mask slides and incubated for 48 hours as described above. Cells on the slides were fixed in cold acetone (Merck, Darmstadt, Germany) for 5 minutes. Immunohistochemical staining (IHC) was performed using the standard ABC method with VECTASTAIN ABC-kit and monoclonal antibodies (mAbs) KL-1 (Keratin), IT-ks20.10 (Cytokeratin 20), C1P83 (CEA), CA19-9 (CA19-9), MiB-1 (Ki-67) and Do7 (p53). All mAbs were commercially available except for C1P83 which was provided by Prof. Kalthoff H. The percentage of positive tumor cells was determined by calculating 1 000 tumor cells in 5 random vision fields of one section under microcope.

EGFP expression of HT-29c cells *in vivo* All the rats were stabilized for one week in the laboratory before the experiments. 0.5 ml single-cell suspension containing 2×10^7 cells of HT-29cEGFPclone#7 was injected subcutaneously into both flanks of the rat. The rat was monitored daily. When the tumor reached 15 mm in diameter, the rat was killed. The fresh tumor tissues were sliced at 0.7-1.0 mm thickness and sliced at 60 μm cryosections, then observed directly under the fluorescence microscope.

Statistical analysis

Statistical analyses were performed using the *F* test.

RESULTS

Expression of EGFP in transduced HT-29c cells in vitro

HT-29c cells could be transduced by retroviral vector with EGFP and then selected in G418. Transduced HT-29c cells with EGFP (HT-29cEGFP, HT-29c EGFPclone#1 and clone#7)

were grown *in vitro* in G418 (600 μg/ml). Untransduced HT-29c cells did not survive in G418, suggesting all cells within the transduced pools contained at least one copy of a transcriptionally active neomycin phosphotransferase gene. Under fluorescence microscope, the selected neomycin-resistant HT-29cEGFP and HT-29cEGFPclone cells all displayed strong fluorescence (Figure 1). HT-29cEGFPclone cells exhibited stronger fluorescence than HT-29cEGFP cells, no significant difference was found between fluorescence levels of HT-29cEGFPclone#1 and clone#7 cells by FACS analysis (Table 1). After 8 weeks in culture, G418 was removed from the growth medium. The expression of EGFP fluorescence of HT-29cEGFP clone cells was still stable for over six months *in vitro*. No significant difference was found between passage 5 and passage 50 of HT-29cEGFPclone#1 in fluorescence intensity by FACS (Table 2).

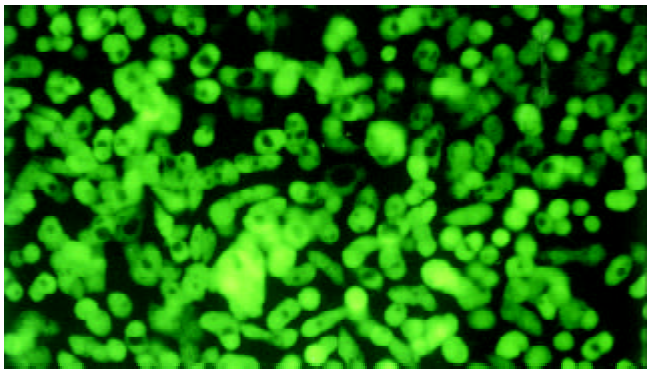

Figure 1 Stable high level of EGFP expression of transduced HT-29c EGFP clone cells *in vitro*. ×100.

Table 1 FACS analysis of EGFP expression in cell lines

Cell lines	Fluorescence intensity
HT-29c	2.5±0.9[a]
HT-29cEGFP pool	64.6±7.4[b]
HT-29cEGFPclone#1	206.5±39.9[c]
HT-29cEGFPclone#7	203.4±46.4[d]

The fluorescence intensity refers to fluorescence of 10 000 cells according to standard software supplied by the FACS cytometer manufacturer. a: $P<0.001$ *vs* b, c or d, respectively. b: $P<0.001$ *vs* c or d, c: $P=0.818$ *vs* d.

Table 2 EGFP expression in different passages of transduced HT-29c cells by FACS

Clone #1	Fluorescence intensity
Passage 5	217.8
Passage 17	198.1
Passage 31	193.4
Passage 40	212.1
Passage 50	208.8

Table 3 Doubling times of parental HT-29 cells and EGFP transduced HT-29 cells

Cell line	Doubling time (h)[a]
HT-29	25.3±5.5
HT-29c	26.0±3.3
HT-29cEGFPclone #1	26.3±4.7
HT-29cEGFPclone #7	27.7±5.3

a: *F* test $F=0.62$, $P>0.05$.

Comparison of biological behavior between untransduced and transduced cells in vitro

Comparison of cell proliferation rate The results indicated that there was no significant difference in the cell proliferation rates of parental cells and selected transfectants as determined by comparing their doubling time (Table 3).

Table 4 Phenotypical comparison of HT-29cells, HT-29c cells and EGFP transduced cells

mAb	Percentage of positive cells (%)		
	HT-29	T-29c	HT-29c EGFPclone
KL-1	100	100	100
IT- Ks20.10	100	100	100
C1 83	33.9	34.6	36.5
CA19-9	48.0	49.3	47.2
MiB-1	96.7	97.8	97.2
Do-7	96.8	97.1	98.3

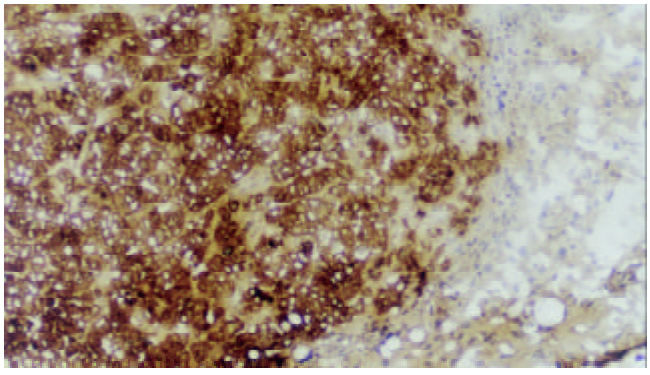

Figure 3 Immunostaining of the s.c. tumor with mAb KL-1 (c) ×100.

Comparison of aggregation potential To compare cell aggregation potential between untransfected and transfected cells *in vitro*, HT-29c and HT-29cEGFPclone cells were monitored under three dimensional culture conditions. At 4 hours after incubation, cell aggregation began. Most of the cell clumps were formed by 8-15 cells. The membranes of single cells in the clumps could be distinguished under phase-contrast microscope. At 24 hours after incubation, the cells aggregated together to form 1-3 larger elliptic cell spheroids in each cell line. The cell spheroids consisted of more than 100 cells. There were still several cell clumps formed by 10-30 cells besides a few larger cell spheroids. Moreover, a lot of cells remained as single cells. After incubation for 1 week, most of the cell clumps remained the same size as at 24 hours. No significant difference was observed in cell aggregation capability between untransduced and transduced cells *in vitro*.
Comparison of cell antigen expression by IHC The ratio of positive cells of antigen expression in HT-29, variant HT-29c and transfected HT-29cEGFPclone cells are shown in Table 4. No significant difference was observed in the positive ratios of HT-29, HT-29c and HT-29cEGFPclone cells.

EGFP expression in vivo

Five days after injection of HT-29cEGFPclone#7 cells, a rat s.c. tumor could be found. Two weeks after injection the rat was sacrificed. The rat had a s.c. tumor that ranged from 13.0-15.3 mm in diameter. The fresh tumor tissues were sliced at 0.7-1.0 mm and at 60 μm cryosections, then observed directly under fluorescence microscope. The tumor tissue displayed strong fluorescence (Figure 2), thereby demonstrating stable, high level EGFP expression *in vivo* during tumor growth. The rat s.c. tumor was also diagnosed by immunostaining with mAb KL-1 (Figure 3).

DISCUSSION

Previous studies have demonstrated the effectiveness and sensitivity of EGFP gene as a marker to visualize micrometastases in live tissue[15,16]. To use EGFP as a marker for *in vivo* experiments, it is necessary to establish very stable transfectants that can express EGFP constantly under nonselective conditions. In this study the retroviral vector expressing EGFP gene was transduced into HT-29c cells and the transduced cells were selected under G418. The present study showed HT-29cEGFPclone cells had stable and long-term EGFP expression under nonselective conditions *in vitro*. When passaged successively to passage 50 *in vitro*, EGFP expression was still high and stable.

The distinct metastatic potential of tumor cell is one of the most important factors in determining the outcome of metastasis. Many biological characteristics of tumor cells are associated with their metastatic ability such as proliferating potential, cell surface adhesion molecule expression, expression of oncogenes or tumor suppressor genes[17] and cell-cell junctions and active cell separation[18]. Spheroidal aggregates of malignant cells may serve as *in vitro* model of tumor microregions and of an early, avascular stage of tumor growth. The similarities between the original tumor and the respective spheroids include volume growth kinetics, cellular heterogeneity, e.g. induction of proliferation gradients and quiescence, differentiation characteristics, development of specific histological structures or expression of antigens[19]. Some research using cell aggregates has focused on mechanisms involved in the control of distribution, spread, invasion and metastasis of tumors[20]. Cellular heterogeneity, which is a general property of solid tumors may occur in multicellular spheroids rather than in conventional monolayer cultures. In the present study some biological behaviors were compared between transduced and parental cells *in vitro*. No differences were found in the expression of antigens. There was no difference in the cell proliferation rate determined by comparing their doubling times. And there was no difference in the cell aggregation capability either, which correlated with the metastatic potential.

In the present study, EGFP gene-transduced HT-29c cells were successfully used to visualize s.c. tumors in rat. The fresh tumor tissues could be analyzed directly under fluorescence microscope. The tumor tissue showed strong fluorescence, demonstrating stable, high level of EGFP expression *in vivo* during tumor growth. Other studies also demonstrated that EGFP gene transduced tumor cells were successfully used to visualize extensive peritoneal seeding[21], lung metastasis[22], skeletal metastasis[23] and bone metastasis[24,25], brain tumor[26,27] and liver metastasis[28]. Using EGFP fluorescence, diagnosis of tumor metastasis can be detected down to the single-cell level. This method has a higher resolution and is much more feasible than the traditional cumbersome pathological examination procedures, such as histology and immunohistochemistry. It is possible that when EGFP-expressing cells undergo apoptosis, they could be engulfed by macrophages. However, when EGFP-expressing cells die, they lose their fluorescence, such as in necrotic areas of tumors, suggesting that these macrophages will not interfere with the detection of metastases[29]. Studies have shown that EGFP transfectants should also be useful with new techniques such as intravital videomicroscopy, which previously involved labeling of tumor cells with dyes[30]. Flotte *et al*.[31] reported gene transfer and expression could be detected by a fluorescence video-endoscopy technique. This method could be used to reliably track transfer in living animals or patients. Other results also showed all intravital imaging, that is, imaging of an intact primary tumor in a living animal was carried out on the laser scanning confocal microscope using the whole-animal platform in animal models with EGFP-expressing tumor cells[32]. Recent studies showed whole-body optical imaging, in real time, of genetically EGFP-expressing tumor growth and metastases. The whole-body optical imaging system is external and noninvasive. It affords unprecedented continuous visual monitoring of malignant growth and spread within intact animals[33,34]. A major advantage of EGFP-expressing tumor cells is that they do not need any preparation and can be seen in fresh living tissues at the microscopic level, and it allows direct observations of metastasis in an intact orthotopically growing primary tumor in a living animal.

ACKNOWLEDGEMENT

We sincerely thank Dr. Zhu Kejian in the Department of Dermatology of the Second Affiliated Hospital of Medical College, Zhejiang University, Hangzhou, Zhejiang Province for performing the FACS analysis.

Abstract

AIM: To investigate the clinical pathologic features of gastrointestinal leiomyoma and the diagnostic value of endoscopic ultrasonography (EUS) on gastrointestinal leiomyoma.

METHODS: A total of 106 patients with gastrointestinal leiomyoma diagnosed with EUS were studied. The location, size and layer origin of gastric and esophageal leiomyomas were analyzed and compared. The histological diagnosis of the resected specimens by endoscopy or surgery in some patients was compared with their results of EUS.

RESULTS: The majority of esophageal leiomyomas were located in the middle and lower part of the esophagus and their size was smaller than 1.0 cm, and 62.1 % of esophageal leiomyomas originated from the muscularis mucosae. Most of the gastric leiomyomas were located in the body and fundus of the stomach with a size of 1-2 cm. Almost all gastric leiomyomas (94.2 %) originated from the muscularis propria. The postoperative histological results of 54 patients treated by endoscopic resection or surgical excision were completely consistent with the preoperative diagnosis of EUS, and the diagnostic specificity of EUS to gastrointestinal leiomyoma was 94.7 %.

CONCLUSION: The size and layer origin of esophageal leiomyomas are different from that of gastric leiomyomas. Being safe and accurate, EUS is the best method not only for gastrointestinal leiomyoma diagnosis but also for the follow-up of patients.

INTRODUCTION

With the development and popularization of endoscopic ultrasonography (EUS) in clinical diagnosis, great progress has been made in diagnosis and treatment of gastrointestinal leiomyoma[1-3]. We collected 106 patients with gastrointestinal leiomyoma diagnosed by EUS from the First Affiliated Hospital, School of Medicine, Zhejiang University, in China from August 2000 to September 2002. This report is to summarize and analyze the clinical pathologic features and results of diagnosis and treatment of gastrointestinal leiomyoma and to evaluate the clinical diagnostic value of EUS for gastrointestinal leiomyoma.

MATERIALS AND METHODS

Patients

The patients with submucosal protruding lesions in gastrointestine by conventional endoscopy were examinated by EUS. Before making EUS, physical examinations were performed. One hundred and six patients (63.8 %) were diagnosed having gastrointestinal leiomyoma by EUS among 166 patients with true submucosal lesions, their mean age was 51 years, ranging from 2 to 88 years. There were 52 men and 54 women. Including 66 cases of esophageal leiomyoma, 35 cases of gastric leiomyoma, 2 cases of duodenum leiomyoma and 3 cases of colon leiomyoma.

Instrument

Instruments of EUS included Fujino EG-410D double-cavity electronic gastroscope, Olympus CF-VL electronic colonoscope and Fujino SP-70 high-frequency echoprobe system. The frequency of probe is between 7.5 MHz to 20 MHz.

Methods

According to the information of the location and size of lesion in gastrointestine shown by the conventional endoscopy examination, we chose different frequency microprobes and examination methods (water-ballon method, water-soak method or water-pour method) to scan the lesion[4]. Then a diagnosis was made for the size, origin, invasion field and nature of the lesion. Some patients were treated by endoscopic resection or surgical excision after EUS, the postoperative histological results were compared with the preoperative diagnoses of EUS. In addition, a follow-up with EUS was made for a few patients without endoscopic or surgical resection because of different reasons.

RESULTS

Ninety-eight patients (92.5 %) showed no related symptoms and were found by conventional endoscopic examination occasionally among 106 patients with gastrointestinal leiomyoma diagnosed by EUS. Only 8 patients (7.5 %) had fixed symptoms, of them, 6 cases had esophageal leiomyoma and 2 cases had gastric leiomyoma. The size of tumor was > 2.0 cm, and major symptoms were dysphagia, feeling of foreign body, pain behind chest bone, upper abdominal indisposition, etc. The distribution, layer of origin, size and number of esophageal or gastric leiomyoma were summarized in Tables 1 and 2. The majority of esophageal leiomyoma were located in the middle and lower part of the esophagus, and their size was <1.0 cm, and 62.1 % of the esophageal leiomyomas originated from the muscularis mucosae. Most of the gastric

leiomyomas were located in the body and fundus of stomach, their size was 1-2 cm. Almost all gastric leiomyomas (94.2 %) originated from the muscularis propria. Duodenal leiomyomas in two patients were derived from the muscularis propria, being 0.5-0.8 cm in size. Colon leiomyomas in three patients were located in cecum, transverse colon and sigmoid colon, respectively. The lesions were originated from the muscularis propria, 1.1-1.6 cm in size. One hundred and one of 106 patients just had single leiomyoma. After EUS examination, 35 patients with leiomyoma originating from muscularis mucosa were treated with endoscopic resection (Figure 1A,B,C). The other group of 22 patients received surgical excision because their lesions appeared to be in the proper muscle layer. The size, number and layer-origin of the lesions in 57 patients treated with endoscopic or surgical resection were completely consistent with the preoperative diagnosis of EUS. However, postoperative histological results of only 3 patients were carcinoid, esophageal cyst gland hyperplasia and tubercle, respectively, which were not in agreement with the preoperative diagnosis of EUS. The diagnostic accuracy of EUS for leiomyoma was 94.1 % (54/57). The remaining 49 patients were not treated with endoscopic or surgical resection due to various reasons. They were observed and followed up. Fifteen of 49 patients were examined with EUS at three, six and twelve months later, the results of examination showed that the position, shape and structure of their lesions were unchanged. In our study, all the patients could well tolerate EUS without serious complications such as bleeding, perforation, shock and asphyxia except a few patients who felt disorder in throat, and abdominal distension. No complication occurred in 35 patients treated by endoscopic resection.

Lower part (27)		>2.0 cm (10)	

DISCUSSION

Gastrointestinal leiomyoma is a common kind of benign submucosal tumor in gastrointestine[1,5], because it originates from muscularis mucosa or muscularis propria, the conventional endoscopy can not diagnose it accurately. Since EUS was used in clinical diagnosis, the diagnostic situation of gastrointestinal leiomyoma has changed greatly[6-9]. The five-layered structure of gastrointestinal wall can be shown clearly, and gastrointestinal leiomyoma presents homogeneous and hypoechoic lesion with clear margin, and the lesion is around the hyperechoic wrapping area under endosonography (Figures 2,3). According to these features of ultrasonography, leiomyoma is easy to be distinguished from hemoangioma, cyst and lipoma in digestive tract wall[10-15]. Thus we can define not only the nature of leiomyoma, but also its size, number and the layer of origin by EUS. Our clinical study showed that

gastrointestinal leiomyoma mainly occurred in esophagus and stomach. The incidence in duodenum and colon is markedly lower than that in esophagus and stomach. The partial reason of the lower incidence of colon leiomyoma may be that the number of patients undergoing colonoscopic examination was significantly less than that of gastroscopic examination (the ratio of gastroscopy to colonoscopy was 3:1 in this study). The incidence of esophageal leiomyoma was higher than that of stomach leiomyoma, the size and layer origin of esophageal leiomyoma were different from gastric leiomyoma. The reason is still unknown. Although leiomyoma was located in different positions of gastrointestine, almost all the patients (101/106) only had single lesion, which conformed with other reports[16,17]. With regard to the diagnosis of gastrointestinal leiomyoma, our clinical data indicated that most cases (92.5 %) were occasionally found by endoscopic examination, these patients showed no related symptoms and signs, and no positive change in blood examination. The diagnosis of leiomyoma mainly depends on EUS, which combines the function of endoscope and ultrasonic, by which we can not only inspect the surface shape of gastrointestinal lesion, but also gain the image of the layer of origin, the invasive scope and the structure of the lesion. According to the literature[18-20], the diagnostic specificity of EUS to gastrointestinal leiomyoma is superior to other imaging techniques such as B type ultrosonophy, gastrointestinal radiography and computed tomography. In our clinical study, the size, number and the layer of origin of the resected lesions were completely consistent with the diagnosis of EUS in 57 patients treated by endoscopic resection or surgical excision, The nature of the lesions in 54 of 57 patients was in agreement with the diagnosis of EUS, the diagnostic accuracy of EUS for leiomyoma was 94.7 %. Our study indicated that EUS had a very important diagnostic value for gastrointestinal leiomyoma[21]. However, we are still possible to make a mistake in the diagnosis of gastrointestinal leiomyoma, because the image of ultrasonophy of a few other lesions is the same as that of gastrointestinal leiomyoma, e.g, the gastrointestinal carcinoid and tubercle. For these diseases, we should depend on other clinical information to differentiate them. Furthermore, when EUS finds that the size of leiomyoma is bigger than 4 cm, or the surface of leiomyoma has erosion or ulceration, or internal echo being unhomogeneous, we should consider the possibility of leiomyosarcoma[22]. Presently, EUS is considered the best method for the diagnosis of submucosal lesion[7,8,23], Which can not only diagnose leiomyoma correctly, but also help us work out scientific and rational therapeutic strategies. EUS can clearly show the origin of gastrointestinal leiomyoma, either from the muscularis mucosae or the muscularis propria. Usually, leiomyoma originating from the muscularis mucosae can be treated by endoscopic resection[24-27], whereas leiomyoma originating from the proper muscle layer contraindicates endoscopic resection. Unwell-planned resection will bring about perforation of gastrointestine. Thirty-five patients with leiomyoma originating from muscularis mucosae were treated by endoscopic resection in our study. No complications such as bleeding, perforation occurred, showing that EUS has a very important value to the selection of therapeutic methods for gastrointestinal leiomyoma[28-31]. It makes the therapy of gastrointestinal leiomyoma more rational, safe and economic. In addition, for those patients with gastrointestinal leiomyoma who refused to receive or could not be treated by endoscopic resection or surgical excision, we followed up them by EUS periodically. The results showed that gastrointestinal leiomyoma grew slowly and showed no marked change in a short time. Thus, we can choose observation and follow-up for the patients with small lesions, and lesions originating from the muscularis propria, or the special position of lesion.

In conclusion, EUS is a safe and effective diagnostic method for gastrointestinal leiomyoma.

Abstract

AIM: Our research attempted to evaluate the overall functional reserve of cirrhotic liver by combination of hepatic functional blood flow, liver volume, and Child-Pugh's classification, and to discuss its value of clinical application.

METHODS: Ninety two patients with portal hypertension due to hepatic cirrhosis were investigated. All had a history of haematemesis and hematochezia, esophageal and gastric fundus varices, splenomegaly and hypersplenia. A 2-year follow-up was routinely performed and no one was lost. Twenty two healthy volunteers were used as control group. Blood and urine samples were collected 4 times before and after intravenous D-sorbitol infusion. The hepatic clearance (CL_H) of D-sorbitol was then calculated according to enzymatic spectrophotometric method while the total blood flow (Q_{TOTAL}) and intrahepatic shunt (R_{INS}) were detected by multicolor Doppler ultrasound, and the liver volume was measured by spiral CT. Data were estimated by *t*-test, variance calculation and chi-squared test. The relationships between all these parameters and different groups were investigated according to Child-Pugh classification and postoperative complications respectively.

RESULTS: Steady blood concentration was achieved 120 mins after D-sorbitol intravenous infusion, which was (0.358±0.064) mmol· L^{-1} in cirrhotic group and (0.189±0.05) mmol· L^{-1} in control group (P<0.01). CL_H=(812.7±112.4) ml· min^{-1}, Q_{TOTAL}=(1280.6±131.4) ml· min^{-1}, and R_{INS}=(36.54±10.65) % in cirrhotic group and CL_H=(1248.3±210.5) ml· min^{-1}, Q_{TOTAL}= (1362.4±126.9) ml· min^{-1}, and R_{INS}=(8.37±3.32) % in control group (P<0.01). The liver volume of cirrhotic group was 1057±249 cm^3, 851±148 cm^3 and 663±77 cm^3 in Child A, B and C group respectively with significant difference (P<0.001). The average volume of cirrhotic liver in Child B, C group was significantly reduced in comparison with that in control group (P<0.001). The patient, whose liver volume decreased by 40 % with the CL_H below 600 ml· min^{-1}, would have a higher incidence of postoperative complications. There was no strict correspondent relationship between CL_H, liver volume and Child-Pugh's classification.

CONCLUSION: The hepatic clearance of D-sorbitol, CT measured liver volume can be reliably used for the evaluation of hepatic functional blood flow and liver metabolic volume. Combined with the Child-Pugh's classification, it could be very useful for further understanding the liver functional reserve, therefore help determine reasonable therapeutic plan, choose surgical procedures and operating time.

INTRODUCTION

Accurate evaluation of the hepatic functional reserve is very important in the development of hepatobiliary surgery. Hepatic functional reserve means the whole functions of all hepatic parenchyma cells, which depend on the interaction between relatively healthy hepatic cells and blood perfusion. Based on Child-Pugh' s classification, we have established a new method to evaluate the liver functional reserve by D-sorbitol clearance rate indicating hepatic functional blood flow and CT measured liver volume indicating normal hepatic metabolic volume.

MATERIALS AND METHODS

Materials

Ninety two patients with portal hypertension due to hepatic cirrhosis, were selected in our hospital from March 1999 to January 2001, including 57 males and 35 females aged between 20-66 years, with a mean age 43.5±11.8 years. All of them had a history of haematemesis and hematochezia, and moderate esophageal varices were found in 41 patients and severe ones in 51 patients by gastroscopy. Porta-azygous devascularization was applied to all patients and the pathological diagnosis was confirmed by biopsy during the surgical procedure. According to Child-Pugh' s classification, 36 cases were scored as A, 39 as B and 17 as C. A 2-year follow-up was routinely performed. The healthy control group consisted of 20 volunteers, 11 males and 9 females, who had no abnormality in CT scan and related history of liver disease.

The postoperative data of operative complications and hepatic functions were carefully recorded and a routine follow-up was given. There was no operative mortality, severe complications occurred in 31 cases because of liver function deterioration after the operation, including 13 cases of long standing jaundice, 7 hepatic coma, 13 severe ascites, and 6 recurring hemorrhage of upper GI tract.

Methods

Intravenous infusion of D-sorbitol and collection of blood and urine samples Controlled by the peristalsis pump, 5 % D-sorbitol solution was continuously infused intravenously for 3 hours at a rate of 1 ml· min^{-1} (a dose of 50 mg· min^{-1}). The

samples of blood (3 ml), urine and the volumes at the same time were collected and recorded once before infusion and 3 times at 120,150,180 min after infusion.

Determination of D-sorbitol concentration and calculation The enzymatic spectrophotometric method was used to determine the D-sorbitol concentration in blood and urine[1, 2]. The total D-sorbitol clearance rate (CL_{TOTAL}), renal D-sorbitol clearance rate (CL_{REN}) and liver D-sorbitol clearance rate (CL_H) were calculated according to the formula reported[3,4] as $CL_{TOTAL}=R \div Css$ and $CL_{REN}=U \div Css$. (R: D-sorbitol infusion rate; Css: homeostatic plasma concentration; U: average urinary excretion rate, ($C_{LH}=CL_{TOTAL}- C_{LREN}$).

Hepatic total blood flow (Q_{TOTAL}) and intrahepatic shunt rate (R_{INS}) and liver extraction rate (E) assay and calculation The angle between blood flow and Doppler ultrasound wave direction was controlled below 60 degrees, the mean blood flow rates of three main liver veins (left, middle, right hepatic vein) were carefully detected by ultrasonic equipment. Then, the accurate blood flow of each vein was calculated according to the formula as $Q=1/4\pi D^2\times 60\times V_{mean}$[5, 6], and their sum was the total blood flow (Q_{TOTAL}). The D-sorbitol hepatic clearance rate equaled to the liver functional blood flow (Q_{FUNC}), and $R_{INS}=(Q_{TOTAL}-Q_{FUNC})/Q_{TOTAL}$. According to Fick' s rule[7, 8], the hepatic extractive rate $E=CL_H/Q_{TOTAL}$.

Method for measuring liver volume change by CT Guided by the reported method[9], the cirrhotic liver volume was measured by CT (PQ6000), at the same time the expected "normal" liver volume of the patient was calculated according to the reported formula[10]. The volume change rate (R) was then calculated according to the formula : (CT measured LV-expected LV)/expected LV×100 %.

Statistical analysis

The relationship between liver functional blood flow, liver volume change rate, Child-Pugh' s classification, postoperative complication rate was investigated.Data were expressed as mean ±S. Statistical significance was estimated by *t*-test. The multiple means between various groups were estimated by variance calculation. The difference of percentage was estimated by chi-squared test.

RESULTS

Changes of D-sorbitol clearance index in two groups

Table 1 Indexes of D-sorbitol clearance (mean ±s)

Groups	*n*	Css (mmol·L^{-1})	R_{INS} (%)	$CL_H(Q_{FUNC})$ (ml·min^{-1})	E (%)	Q_{TOTAL} (ml·min^{-1})
Control	20	0.189±0.05	8.37±3.32	1248.3±210.5	91.6±6.5	1362.4±126.9
Cirrhotic	92	0.385±0.064[a]	36.54±10.65	812.7±112.4[a]	63.5±9.4[a]	1280.6±131.4

[a]P<0.01 in comparison between the two groups.

Table 1 shows that the D-sorbitol plasma concentration of each group could come to a stable level after continuous intravenous infusion for 120 minutes. The homeostatic plasma concentration of control group was (0.189±0.05) mmol· L^{-1}, and that of hepatic cirrhotic group was (0.358±0.064) mmol· L^{-1}. The difference between the two groups was significant (P<0.01). The total liver blood flow between the two groups had no significant difference. The D-sorbitol liver extraction rate and hepatic clearance rate decreased significantly while intrahepatic shunt flow increased significantly in the cirrhotic group. All reached statistical significance compared with that of the control group.

Relationship between Child-Pugh' s classification and D-sorbitol liver clearance rate and liver volume change rate

Table 2 Relationship between Child-Pugh' s classification and D-sorbitol liver clearance rate and liver volume change rate

Child-Pugh' s classification	*n*	CL_H (ml·min^{-1})	Q_{INS} (%)	Mean cirrhotic liver volume (cm^3)
A	36	995.8±174.8	22.2±4.2	1057±249
B	39	783.4±120.6[a]	38.8±7.3[a]	851±148[a]
C	17	548.6±32.8[b]	57.8±6.6[b]	663±77[b]

[b]P<0.01, [a]P<0.05 in comparison between the two groups.

Table 2 shows that there was a clear correlation between each Child-Pugh' s classification group and D-sorbitol liver clearance rate and liver volume,respectively. The higher the Child-Pugh' s classification degree, the lesser the liver functional blood flow, the more the intrahepatic shunt flow, and the smaller the mean liver volume. The difference had statistical significance between each group (P<0.05).

Table 3 Correlative relationship between hepatic D-sorbitol clearance rate and liver volume change rate and Child-Pugh' s classification

Child-Pugh' s classification	CL_H (mL·min^{-1})			Liver volume change rate		
	>800	600-800	<600	R≥-20 %	-40 %<R<-20 %	R ≤-40 %
A(case)	21	11	4	20	13	3
B(case)	8	24	7	9	26	4
C(case)	0	6	11	2	5	10

Table 3 shows in view of individual patient, there was not any complete correlation between the D-sorbitol liver clearance rate and liver volume change rate or liver function status in cirrhotic patients. Even in the same Child-Pugh' s classification group, the D-sorbitol clearance rate and liver volume change rate varied remarkably. It was found that a mild Child' s classified patient could have a low D-sorbitol clearance rate and a small liver volume, and *vice versa*.

Relationship between postoperative complications and D-sorbitol clearance rate and liver volume change rate

Table 4 shows that severe postoperative complications increased steadily as the D-sorbitol clearance rate and/or liver volume decreased. When the CL_H was below 600 /ml· min^{-1}, R below -40 %, the incidence of severe complications was higher than 70 % (P<0.05).

Table 4 Relationship between hepatic D-sorbitol clearance rate and liver volume change rate and postoperative complications

Postoperative complications	CL_H / mL·min^{-1}			Liver volume change rate		
	>800	600-800	<600	R≥-20 %	-40 %<R<-20 %	R ≤-40%
Case number	29	41	22	31	44	17
Complication cases	1	14	16	3	16	12
Rate (%)	3.4	34.2[a]	72.7[b]	9.7	36.4[a]	70.6[b]

[b]P<0.01, [a]P<0.05 in comparison between each groups.

Table 5 shows that 22 cases had a D-sorbitol clearance rate lower than 600/ml· min^{-1}. 8 of them had their liver volume change rate between -20 % and -40 %, 14 below -40 %, and the incidences of postoperative complications were 62.5 % (5/8), and 78.6 % (11/14), respectively.

Table 5 Correlation between hepatic D-sorbitol clearance rate and liver volume change rate and operation complications

CL_H(ml·min^{-1})	-40 %<R<-20 %			R≤ -40%		
	Number	Complication case	Complication rate	Number	Complication case	Complication rate
600-800	35	12	34.3(%)	3	1	33.3(%)
<600	8	5	62.5(%)	14	11	78.6(%)

DISCUSSION

It is essential in the surgical treatment of portal hypertension, to evaluate accurately the patient' s preoperative liver functional reserve and to make a reasonable peri-operative therapeutic plan in order to choose the best surgical procedures and to increase its efficacy. The Child-Pugh' s classification is still the most important method to determine the type and time of operation, and is widely accepted for the patients who are in stage I or II. But there are relatively high-risks for post-operative complications and mortality[11-13]. This is because the present classification cannot completely reflect the injured and whole hepatic function, besides the technical factors[14-16]. What condition would go worse with the operative burden is another factor that is difficult to tell. It is therefore necessary to find more objective criteria for the evaluation of hepatic functional reservation.

The liver inherent metabolic volume and blood flow determine its functions in most occasions, which also depend on the relative ratio and mutual influence of the two factors[17-20]. When cirrhosis and portal hypertension occur, necrosis of liver cells, hyperplasia of fibrous tissue, formation of pseudo lobules and abnormality of liver microcirculation will result in decrease of liver inherent metabolic volume, increase of anatomical and physiological intrahepatic shunt and change of their relevant ratio[21]. Therefore, measurement of liver inherent metabolic volume and functional blood flow can provide more information on the understanding of physiological changes and functional reserve of the cirrhotic liver, and help to make individualized and reasonable therapeutic decisions.

Liver functional blood flow is a part of total liver blood flow that enters the hepatic sinusoid involved in the metabolic process[1]. Currently it can only be measured by assay of its clearance rate. D-sorbitol is the first substance suitable for noninvasive evaluation of hepatic blood flow, and is widely used to observe the normal and pathologic perfusion of the liver outside China[22]. Molino, Susanne *et al*, reported that the normal liver had a very high D-sorbitol extraction rate of around 94 %, and CL_H could be used to represent the liver total blood flow (Q_{TOTAL}), and its variation could reflect the change of liver blood flow[8,23]. In our research, D-sorbitol clearance rate and color Doppler ultrasonography were used to study the liver blood flow. It was found that D-sorbitol plasma concentration of the healthy control group always came to homeostasis by continuously intravenous infusion after 120 minutes (0.189±0.05 mmol/l), CL_H was 1 248.3±210.5/ml.min^{-1}, Q_{TOTAL} was 1 362.4±126.9/ml· min^{-1} and the D-sorbitol extraction rate of the liver was 91.6±6.5 %. The D-sorbitol extraction rate decreased dramatically to 63.5±9.4 % in the cirrhotic group, which was statistically significant compared with that of control group (P<0.01). The CL_H, reflecting the liver functional blood flow[1,11,24], was 812.7±112.4/ml.min^{-1} significantly different from that of the control group (P<0.01). The R_{INS} was 8.37±3.32 % in control group and was 36.54±10.65 % in cirrhotic group (P<0.01). The intrahepatic shunt consisted of anatomical shunt and physiological shunt, and the latter had no help to hepatic function even passing through hepatic sinusoid[25]. Therefore, the combination of D-sorbitol clearance rate and color Doppler ultrasonography can show the liver functional blood flow and the conditions of intrahepatic shunt which are so meaningful for the evaluation of liver blood flow in the liver functional reserve before proper medication is given[26, 27]. Our conclusion is that D-sorbitol clearance rate can be widely used in clinical practice, which is safe, economical, practicable, and noninvasive.

The liver inherent metabolic volume and liver functional blood flow are complementary to each other, especially their matching. It is a mature and repeatable method to use CT in measuring liver volume[28-30]. Liver volume is considered as a liver function index as important as the Child-Pugh' s classification because it can partly represent the hepatic parenchyma cell volume[31-33]. Combining liver volume measured by CT scanning and an expected "normal" liver volume calculated according to a standard liver volume formula[8], the cirrhotic liver volume change rate has been measured quantitatively. The Child-Pugh' s liver function classification is a classic liver function index and is widely used in clinical practice. Our research results demonstrated that the indexes for liver inherent metabolic volume and liver functional blood flow could be used as a complement to Child-Pugh' s classification to gain overall and objective data of liver functional reserve. The CL_H, R_{INS} and liver volume change rate had some correlations with the Child-Pugh' s classification. The higher the Child-Pugh' s classification, was the less the liver functional blood flow existed, the more the intrahepatic shunt occurred, the smaller the liver volume was. This result is comparable with other reports[34, 35]. It was also found that variation of CL_H and liver volume change rate did not always correlate with each other even the Child-Pugh' s classification was the same. There was an overlap among different groups, indicating that a patient classified as Child A might have a smaller CL_H and liver volume than a patient classified as Child B or C. This may explain why some deadly complications such as severe ascites or hepatic coma might occur in Child-Pugh' s A patients but not in Child-Pugh' s B or C patients after operation. In conclusion, the functional blood flow and cirrhotic liver volume are two critical indexes which are complementary to Child-Pugh' s classification and can help the evaluation of the overall status of cirrhotic liver and the establishment of individualized therapeutic plan[17,18,30,31].

The CL_H and liver volume change rate had a close relationship with the postoperative complications in cirrhotic patients. The complication incidence increased as the CL_H or liver volume change rate decreased. The complication rate exceeded 70 % (P<0.05) when CL_H was below 600/ml.min^{-1} or R below 40 %. This can be explained by the theory that the liver can not stand anesthesia and operative risks when decreased metabolic volume and functional blood flow have already put the liver at the edge of collapse. The CL_H and liver volume change rate could be complementary to each other when postoperative complications were to be predicted. 22 cases had D-sorbitol clearance rate lower than 600/ml· min^{-1}. 8 of them had their liver volume change rate between -20 % and -40 %, 14 below -40 %. The incidence of postoperative complications was 62.5 % (5/8) and 78.6 % (11/14), respectively. Therefore, the Child-Pugh' s classification complemented by CL_H and liver volume change rate should be used to determine the surgical time and type. When the liver has a better functional blood flow with liver volume compensated, the portal-systemic shunt

or combination operation can be performed. When the functional blood flow and /or liver volume are decreased dramatically, the treatment of perioperative period should be strengthened to increase the tolerance of the cirrhotic liver, and porta-azygous devascularization would be more suitable. When CL_H <600/ml· min^{-1}, R<-40 %, conservative therapy should be recommended. If no improvement of these indexes is achieved after that, the patients should be considered as the end stage of liver cirrhosis and liver transplantation should be possibly considered.

Abstract

AIM: To investigate the efficiency of continuous high volume hemofiltration (HVHF) in the treatment of severe acute pancreatitis (SAP) complicated with multiple organ dysfunction syndrome (MODS).

METHODS: A total of 28 SAP patients with an average of 14.36±3.96 APACHE II score were involved. Diagnostic criteria for SAP standardized by the Chinese Medical Association and diagnostic criteria for MODS standardized by American College of Chest Physicians (ACCP) and Society of Critical Care Medicine (SCCM) were applied for inclusion. HVHF was started 6.0±6.1 (1-30) days after onset of the disease and sustained for at least 72 hours, AN69 hemofilter (1.2 m^2) was changed every 24 hours. The ultrafiltration rate during HVHF was 4 000 ml/h, blood flow rate was 250-300 ml/min, and the substitute fluid was infused with pre-dilution. Low molecular weight heparin was used for anticoagulation.

RESULTS: HVHF was well tolerated in all the patients, and lasted for 4.04±3.99 (3-24) days. 20 of the patients survived, 6 patients died and 2 of the patients quited for financial reason. The ICU mortality was 21.4 %. Body temperature, heart rate and breath rate decreased significantly after HVHF. APACHE II score was 14.4±3.9 before HVHF, and 9.9±4.3 after HVHF, which decreased significantly ($P<0.01$). Partial pressure of oxygen in arterial blood before HVHF was 68.5±19.5 mmHg, and increased significantly after HVHF, which was 91.9±25 mmHg ($P<0.01$). During HVHF the hemodynamics was stable, and serum potassium, sodium, chlorine, glucose and pH were at normal level.

CONCLUSION: HVHF is technically possible in SAP patients complicated with MODS. It does not appear to have detrimental effects and may have beneficial effects. Continuous HVHF, which seldom disturbs the hemodynamics and causes few side-effects, is expected to become a beneficial adjunct therapy for SAP complicated with MODS.

INTRODUCTION

Acute pancreatitis is an inflammatory process of the pancreas with multiple etiologies and a physiopathology that is still unclear. It has a nonspecific clinical presentation, varying from moderate to severe forms, including MODS. The latter is associated with SAP and evolves with high morbidity, mortality and costs[1,2]. MODS has become the primary cause of death in SAP. From Jan 1997 to May 2002, we accepted 283 patients involved in acute pancreatitis. 11 of 31 cases complicated with MODS died, accounting for 91.7 % of the death toll in acute pancreatitis.

Evidences accumulated over the last years demonstrate that many soluble inflammatory molecules of the systemic inflammatory (and anti-inflammatory) response syndrome (SIRS) can be removed by hemofiltration[3-5]. This has led to the hypothesis that hemofiltration could play a major role in sepsis therapy as immunomodulatory treatment, in addition to being a blood purification technique. Particular attention has been paid to HVHF to remove inflammatory molecules as compared to standard volume hemofiltration[6]. HVHF might be of more benefits for amelioration of severe SIRS or MODS, but the clinical feasibility and safety are noticeable. The present study was therefore to investigate the clinical efficacy of continuous HVHF on SAP complicated with MODS.

MATERIALS AND METHODS

Patient population

A total of 28 patients with SAP complicated with MODS, including 7 women and 21 men, with an average age of 51.43±12.96 years were admitted to the study. SAP was diagnosed according to the criteria of Chinese Medical Association for SAP (2001), and MODS was diagnosed according to the criteria of ACCP and SCCM for MODS (1992)[7]. All the patients had complications such as SIRS, systemic infection, shock, etc (Table 1). The average of APACHE II score was 14.36±3.96. SAP was caused by alcohol in 5 patients, hyperlipidemia in 3 patients, high fat diet in 3 patients and biliary disease in 17 patients. The CT scan on admission revealed that necrosis of the body of the pancreas was below 33 % in 6 patients, 33-67 % in 12 patients and 67-100 % in 10 patients. The average CT severity score was 8.5±1.4, and 9 patients were in grade B and 19 in grade C according to Balthazar CT grading criteria of SAP[8].

Conventional treatment for SAP

Seven patients had accepted surgical treatment in other hospitals before admission to our hospital due to severe complications. All the patients were allocated to ICU and underwent following conventional treatments such as fasting and fluid resuscitation, gastrointestinal decompression, drainage of pancreatic (or bile) duct, and abdominal cavity, oxygen therapy, in which 3 patients underwent mechanical ventilation by non-invasive method and 24 patients underwent mechanical ventilation by tracheotomy, gut cleaning (enema

by taking magnesium sulfate orally), somatostatin, prostaglandin E1, nutritional support (enteral nutrition), antibiotics. 12 patients underwent drainage of peripancreatic abscess and necrosis, and 5 patients who suffered from pancreatitis secondary to biliary disease underwent cholecystectomy.

Table 1 Incidence of complications before HVHF

Complications	Case	Incidence (%)
SIRS*	28	100
Systemic infection	10	35.7
ARDS*	20	71.4
Shock	14	50.0
Renal failure	7	25.0
Pancreatic encephalopathy	6	21.4
Bleeding in alimentary tract	12	42.8
Cardiac arrhythmia	4	14.3
Heart failure / pulmonary edema	2	7.1
Dysfunction of coagulation	4	14.3
Liver function failure	2	7.1
Fungal infection	7	25.0

SIRS: systemic inflammatory response syndrome; ARDS: acute respiratory distress syndrome.

HVHF technique

For vascular access, a double coaxial lumen 14-Fr catheter was inserted percutaneously either through the right internal jugular or the femoral vein using the Seldinger technique. A Baxter BM25 machine (Baxter, USA) was used for HVHF with a polyacrylonitrile AN69 hemofilter (1.2 m^2 surface area, 35-kD limit; Hospal, USA). Blood flow was set at 250-300 ml/min and ultrafiltrate flow at 4 000 ml/h, transmembrane pressure was maintained between 300-500 mmHg, and the substitute fluid was infused with pre-dilution. Low molecular weight heparin served as the anticoagulant, patient-activated clotting time was adjusted to 60-70 seconds, a strictly neutral balance was maintained using a digital balance system (Baxter). Elapsed time was expressed in hours from the beginning of HVHF as a T value. T_0 was the beginning of HVHF at zero hours, T_{24} was 24 hours after T0, *et al*. These values were recorded for each patient.

Clinical variables

Vital signs, including body temperature, breath rate, blood pressure and heart rate were recorded every half an hour. Blood samples were collected every 24 hours to observe blood cell count, serum amylase and electrolyte, hepatic and renal function, and arterial blood gas. The APACHE II score was applied to evaluate the state of the patients.

Statistical calculations

Results were expressed as mean ±SD and analyzed using pair-matching *t* test. The difference was considered significant at $P<0.05$.

RESULTS

Outcome

20 patients were cured and discharged from hospital, 6 patients died and 2 patients quit for financial reason. One patient died of pulmonary embolism secondary to the exfoliation of cardiac valve emboli, four of fungal sepsis and one of septic shock. The mortality rate was 21.4 %.

Clinical symptoms and signs

During HVHF the hemodynamics and mean arterial pressure (MAP) were stable, while body temperature, heart rate and breath rate decreased eventually after the beginning of HVHF with amelioration of the symptoms (Table 2). 6 patients suffering from pancreatic encephalopathy secondary to SAP were administrated with 50-100 mg chlorpromazine each day simultaneously, and state of awareness recovered during the procedure with amelioration of dysphoria and delirium. Three of four patients complicated with acute renal failure recovered after HVHF.

Table 2 Changes of vital signs after HVHF

	T_0	T_{24}	T_{48}	T_{72}	T_{96}	T_{120}
Case	28	28	28	28	28	28
BT (℃)	37.8±0.8	37.3±0.8[a]	37.2±0.7[a]	37.2±0.8[a]	37.3±0.9	37.5±0.9[b]

[a]$P<0.01$, *vs* T_0; [b]$P<0.05$, *vs* T_0; BT: body temperature (℃); HR: heart rate (beats per minute); BR: breath rate (times per minute); MAP: mean arterial pressure (kpa).

Severity and homeostasis

APACHE II score before HVHF was 14.4±3.9, and decreased significantly after HVHF, which was 9.9±4.3 ($P<0.01$, Table 3). Hyperkalemia in two patients and metabolic acidosis in eleven patients were redressed after 24 hours of HVHF. During HVHF the serum potassium, sodium, chlorine, glucose and pH were at normal level.

Table 3 Changes of laboratory parameters after HVHF

Index	Pre HVHF	Post HVHF
Case	28	28
APACHE II score	14.4±3.9	9.9±4.3[a]
PaO_2	68.5±19.5	91.9±25[a]
CRP	187±39	87.4±112
White cell count	15.5±5.8	14.9±6.9
Serum amylase	392±517	103±184[a]
Blood urea nitrogen	9.9±10.1	5.0±2.9[b]
Serum albumin	33.0±5.4	31.8±4.8

[a]$P<0.01$, *vs* pre-HVHF; [b]$P<0.05$, *vs* pre-HVHF.

Side-effects correlated with HVHF

Two patients got a high fever caused by infection of intravenous catheter, and recovered after the catheter was removed. Hypophosphatemia occurred in four patients and was redressed by transvenous recruit of compound phosphate solution. The drainage fluid of abdominal cavity of two patients who suffered from intraabdominal hemorrhage became bloody after the beginning of HVHF. Bleeding was controlled following reducing the administration of anticoagulant.

DISCUSSION

With patho-morphological, pathophysiological, biochemical, immunologic and real time imaging observations, adequate evidences have revealed that SAP is a systemic rather than a local critical condition[9]. Extensive peripancreatic necrosis of fat tissue in the omentum and retroperitoneum may induce a SIRS that extends beyond the pancreas. Hemorrhage is caused

by tissue necrosis or rupture of surrounding blood vessels[10]. Associated complications include sepsis, MODS, acute respiratory distress syndrome (ARDS), acute renal failure, disseminated intravascular coagulation (DIC), hypovolemic shock, and acute liver failure. MODS has become the primary cause of morbidity and mortality in SAP. Systemic lymphocyte activation (triggered by local release of mediators) causes the distant organ complications in SAP[11]. Utilizing proteolytic enzymes and toxicant, neutrophils injure the infiltrated vital organs, causing cellular damage and dysfunction of vital organs distant from the pancreas. Multiple organ failure in acute pancreatitis with septic complications can develop, at least in part, by proinflammatory cytokine release and neutrophil activation[12]. Recent studies have established the critical role played by inflammatory mediators such as TNFα, IL-1β, IL-6, IL-8, CINC/GROα, PAF, IL-10, C5a, ICAM-1 and substance P in acute pancreatitis and the resultant MODS[11-18]. Potentially, there is a therapeutic window between symptom onset and the development of distant organ damage, when anti-inflammatory therapy may be of use. Strategies have been used to target cytokines, such as cytokine antibody, transfection of human anti-inflammation gene and blood purification. Method targeting only one inflammatory mediator is far from combating with complicated cytokines network. Blood purification, such as plasmapheresis, hemadsorption, hemofiltration, can remove nonselective inflammatory mediators, which may make it possible to develop clinically effective anti-inflammatory therapy. Among them, hemofiltration is used widely in clinic.

In 1977, hemofiltration was applied in clinic for the first time to cure the over-hydrated patients resistant to diuretics[19]. Hemofiltration has been widely applied to patients with MODS as an artificial support such as an artificial kidney or an artificial liver[20,21]. Recent advances in medical engineering have made it possible to apply hemofiltration continuously (i.e., 24 hours a day, 7 days a week, if necessary) even to critically ill patients, such as MODS patients with renal and hepatic failure[22]. Continuous hemofiltration (CHF), especially continuous venovenous hemofiltration (CVVH), was developed as continuous renal replacement therapy (CRRT) for patients with severe conditions and has been widely performed mainly in critical care, taking the place of intermittent hemodialysis (IHD). The membrane pore size of a hemofilter used for CHF allows passage of substances ranging from 30 000 to 50 000 Daltons, and the method for solute removal in CHF employs the principle of convection, which is advantageous for removing middle- to high-molecular-weight substances[20]. Many inflammatory mediators, such as TNF, IL-1, IL-6, sIL-2R, IL-8, IL-2 and IL-10, can be removed by CHF for their molecular weights are under 50 000 Daltons[6]. Since 1990s, CHF has been employed in treatment of SIRS and MODS secondary to SAP. In 1999, Yekebas[23] performed experiments in pigs to investigate the effects of CHF on SAP. It was found that effective removal of tumor necrosis factor, phospholipase, and kinin by CHF significantly improved survival time. Animals that received prophylactic CHF had a longer survival period than those in which HVHF was started after clinical onset. Bellomo *et al*.[24] reported that CHF could remove cytokines from the circulation of septic patients.

There are a large amount of soluble inflammatory mediators in circulation in severe sepsis, so the low intensity therapy, such as standard CRRT at 1 000 ml/h of ultrafiltration rate, would be inadequate. For this reason, many investigators have long felt that if we wish to tackle blood purification therapy in sepsis, we need to move "renal dose" CRRT to "sepsis dose" CRRT. HVHF represents the logical response to these observations[6]. Rogiers *et al*[25] studied the effect of hemofiltration at various levels of intensity and varying times of intervention in dogs made septic by the infusion of endotoxin. The results suggested that, even at ultrafiltration rates of 3 000 ml/h (close to 7 000-8 000 ml/h in humans), one could achieve clinically important and beneficial hemodynamic effects. Lonnemann *et al*.[26] were able to demonstrate a beneficial effect of HVHF on macrophage function with restoration of the ability to produce TNF in response to exposure endotoxin. This is the first demonstration that HVHF has an effect on cell function. In the present study we have reported the effects of zero-balanced continuous HVHF on 28 patients suffering SAP complicated with MODS. Body temperature, heart rate, breath rate and APACHE II score decreased significantly and partial pressure of oxygen in arterial blood increased significantly after HVHF. During HVHF the hemodynamics parameters were stable, and serum electrolytes, glucose and pH were at normal level. This investigation established the fact that HVHF was well tolerated in SAP patients complicated with MODS and might be of potential benefits.

Furthermore, hemofiltration might be able to improve organ functions. The study performed by Roman Ullrich[27] demonstrated that high-volume CVVH improved arterial oxygenation and lung function in endotoxin-induced acute lung injury in pigs. This improvement in arterial oxygenation with CVVH might be due to the removal of interstitial edema, improvement in the microcirculation and uptake of oxygen by parenchymal cells, or it might be due to removal of humoral mediators that depressed oxygen uptake by parenchymal cells. The results clearly indicate that hemofiltration can effectively improve tissue oxygen metabolism. More and more evidences have shown that gut barrier dysfunction is related to multiorgan system failure in sepsis and immune dysregulation[28,29]. Gut endothelial barrier dysfunction probably plays a central role in the development of the complications of SAP[30,31]. Pancreatitis-induced hypovolemia due to endothelial barrier leakage and gut arteriovenous shunting could cause intestinal ischemia and reperfusion injury with concomitant gut barrier dysfunction[32-34]. Hemofiltration can improve the splanchnic vascular infusion, so we might conclude that hemofiltration is helpful to improve the gut barrier function. Improvement of the splanchnic vascular infusion could also decrease the content of endotoxin and the rate of intestinal bacterial translocation in SAP[35]. Moreover, hemofiltration might play an important role in maintaining the hydrate, electrolyte and acid-base balance and homeostasis, especially when renal function was injured.

In summary, HVHF is technically possible in patients suffering from SAP complicated with MODS. It does not appear to have detrimental effects and may have beneficial effects. Continuous HVHF, which seldom disturbs the hemodynamics and causes few side-effects, offers therapeutic options for SAP complicated with MODS. The mechanisms underlying HVHF in SAP are thus complex and yet not fully elucidated.

Abstract

AIM: To study the correlation between pancreatic phase CT enhancement, intratumor microvessel density (MVD) and pathologic grading of pancreatic carcinoma and to evaluate the relationship between the degrees of CT enhancement and malignancy of pancreatic carcinoma.

METHODS: Thirty four patients with pancreatic carcinoma underwent CT scanning before resection. The enhancement degrees and forms of tumor were observed in pancreatic phase. The operative sample was stained with HE and CD34 marked by immunohistochemistry. MVD and histopathological grades of pancreatic carcinoma were examined. CT enhancement of the tumor, MVD counting in hot spot areas of neoplastic parenchymal cells and pathological grades of pancreatic carcinoma were comparatively analyzed.

RESULTS: Highly differentiated pancreatic adenocarcinoma was identified in 16 patients, moderately-differentiated tumor in 7 and poorly-differentiated in 11. Isodensity CT enhancement was demonstrated in 13 cases, slightly low density enhancement in 9, slightly low density enhancement with small cystic lesions in 9 and slightly low density enhancement with large cystic lesions in 3. The counting of MVD with CD34 marked by immunohistochemistry in hot spot areas of neoplastic parenchyma cells was small in 10 cases, medium in 16 and large in 8. The pathological grades correlated well with CT enhancement of the tumor (r=0.7857, P<0.001) and with MVD counting of tumor (r=0.3613, P<0.05). The CT enhancement of tumor correlated with MVD(r=0.6768, P<0.001).

CONCLUSION: There is an obvious and significant correlation between CT enhancement, pathological grades and MVD number in the hot spot areas of tumor. The extent of CT enhancement is inversely proportional to the malignant degree of pancreatic carcinoma, and to the MVD number in the hot spot areas of neoplastic parenchyma. The MVD in the hot spot areas of neoplastic parenchyma cells can also reflect the prognosis of the patients, and is directly proportional to the malignant degree of pancreatic carcinoma.

INTRODUCTION

Pancreatic carcinoma is a common malignant tumor. Patients with pancreatic carcinoma have a high mortality rate and short survival time[1-10]. The resection rate of the tumor is only 10-25 %[1,3,6,7]. Early diagnosis is of great clinical significance for pancreatic carcinoma. Some authors reported[11-17, 23-32] that tumor angiogenesis was closely correlated with the growth, metastasis and malignancy degree of the tumor. CT enhancement of pancreatic carcinoma in pancreatic phase, intratumor MVD and tumor malignancy degree were assessed in this article.

MATERIALS AND METHODS

Patients

Thirty four patients with pancreatic carcinoma (26 men, 8 women; age range 31-76 years, mean age 55.5 years) were evaluated retrospectively. All the patients underwent CT enhancement and surgery from June 1997 to May 2002. The tissue samples available were studied with CD34 marker by immunohistochemistry in our hospital.

CT scaning

Somatom plus spiral CT scanner (Siemens Company, Germany) and electron beam CT (EBCT) (Imatron Co, America.) were used. Before examination, the patients took 1 000 ml water containing a few iodinated contrast materials (Iodinated degree less than 5 %). The section thickness was usually 10 mm in liver and 5mm in pancreas. The scanning time was 1 s. Iodinated non-ionic contrast material? (iopamidol 300; Bracco, Milan, Italy) was injected at a rate of 2.5-3 ml/S for a total of 100 ml by a high pressure autoinjector. General scanning was done at first. CT enhancement was performed in the pancreatic phase, and the scanning time was 35 s after injection of the contrast agent.

Pathologic study

Tumor specimens obtained from resected pancreatic carcinoma were fixed with 10 % formalin and embedded in paraffin. The specimens were stained with hematoxylin-eosin. Four-micron-thick sections were mounted on silanized slides. The histopathologic grades of pancreatic carcinoma were observed by microscopy. The neoplastic parenchyma cells, fibrotic stroma, necrotic tissuse and residual pancreatic tissue were also examined. The sections were then incubated with mouse monoclonal antibody of CD34 for 24 h at room temperature. After being washed with phosphate-buffered solution (PBS), the sections were incubated with avidin-biotin-peroxidase complex (Histofine) for 30 min and washed once more with PBS. The sections were finally incubated with 3,3-

diaminobenzidine (Simplestain DAB; Nichirei). To assess the intratumor MVD, we used the counting methods of intratumor MVD reported by Weidenr[17] . We assessed delineated CD34-positive cells as microvessels (size 0.02-0.10). Stained vessels were counted in a ×200 microscopic field in hot spot areas of neoplastic parenchyma cells. To count the immunohistochemical anti-CD34 antibody stained vessels in hot spot areas of tumor parenchymal cells, the average MVDs were calculated in three hot spot areas. The tumor MVD was categorized into four grades: "+" the average number of MVD <10, "++" between 10 and 20, "+++" between 20 and 40, "++++" >40.

Statistical analysis

Methods of evaluating extent of CT enhancement The enhancement effects of pancreatic parenchymal tissue were the same in the pancreatic-phase and dual-phase enhanced scanning[18-20,33-36]. Therefore, the extent of CT enhancement of pancreatic carcinoma was only assessed in the pancreatic phase. The degree and form of the tumor in CT enhancement compared to normal pancreatic tissue could be classified as follows: I-isodense enhancement, indicating the degree of tumor CT enhancement was the same as that of the surrounding normal pancreatic tissues; II-slightly low density enhancement, indicating the degree of tumor CT enhancement was slightly lower than that of the surrounding normal pancreatic tissue, with few blood vessels in the tumor; III-slightly low density enhancement with small hypodense cystic lesions, indicating the tumor enhancement was the same as II, but with small cystic density regions in the tumor; IV-cystic low density lesion with slight enhancement of surrounding tumor tissue, indicating large necrotic lesions in the central area and slight enhancement in the surrounding tumor tissue.

Statistical methods The degree of CT enhancement of the tumor, pathological grading of pancreatic carcinoma and the average number of MVD in hot spot areas of neoplastic parenchymal cells were assessed by SPSS software. We used Spearman correlation test with two unpaired samples, a level of significance was set when P value <0.05.

RESULTS

The results of the patients' CT scanning, HE staining and immunohistochemistry were calculated. Well-differentiated pancreatic carcinoma was identified in 16 cases, one with solid cystic-papillary tumor. Moderately-differentiated pancreatic carcinoma was identified in 7, among which one was highly moderately-differentiated. Poorly differentiated pancreatic carcinoma was identified in 11, among which one was highly poorly-differentiated and 2 were moderately poorly-differentiated. The tumor was localized in pancreatic head in 19 cases, pancreatic head and body in 2, pancreatic body in 6, pancreatic body and tail in 1, pancreatic tail in 4, upper edge of pancreas with involvement of ligamentum hepatoduodenale in 1, pancreatic groove with involvement of second part of horizontal duodenum in 1. Immunohistochemical study of tumor specimens' showed MVD count in hot spot areas of tumor parenchymal cells was least in 10 cases, medium in 16 and most in 8. Its routine histopathological results, CT enhancement, MVD and pathological grading are shown in Tables 1 and 2 and Figures 1-4.

CT enhancement degree of tumor, pathological grading of pancreatic carcinoma and the average count of MVD in hot spot areas of neoplastic parenchyma cells were comparatively assessed by Spearman correlation test. The pathological grades correlated well with CT enhancement of tumor (r=0.7857, t=7.1851, P<0.001), and with MVD count of tumor(r=0.3613, t=2.1917, P<0.05).

Table 1 CT enhancement, pathologic grades and MVD number in hot spot areas of neoplastic parenchymal cells of pancreatic carcinoma

Pathologic grades	No of cases	CT enhancement degree of tumor				MVD in hot spot area in neoplastic parenchymal cells			
		I	II	III	IV	+	++	+++	++++
Well differentiated	16	12	3	1	0	8	5	3	0
Moderately differentiated	7	1	4	2	0	1	5	1	0
Poorly differentiated	11	0	2	6	3	1	6	4	0
Total	34	13	9	9	3	10	16	8	0

Table 2 CT enhancement degree in pancreatic phase and MVDs in hot spot areas of tumor parenchyma in pancreatic carcinoma

CT enhancement degree		MVDs in hot spot areas in tumor parenchyma			
Enhanced type	n	+	++	+++	++++
I	13	9	4	0	0
II	9	1	5	3	0
III	9	0	6	3	0
IV	3	0	1	2	0

There was a significant correlation between CT enhancement degree in pancreatic phase and MVDs in hot spot areas of neoplastic parenchyma in pancreatic carcinoma (r=0.6768, t=5.2006, P<0.001).

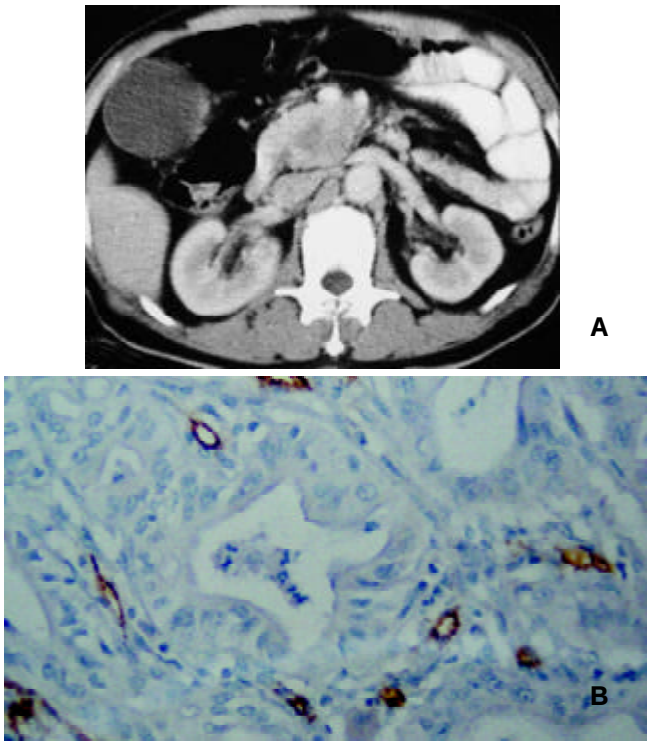

Figure 2 A 52-year-old man with moderately-differentiated pancreatic head carcinoma. A: Pancreatic-phase helical CT enhancement imaging 35 s after administration of contrast agent revealed that CT enhancement of mass in pancreatic head was slightly lower than that of normal pancreatic tissues. Scarce blood vessel area appeared in the central region of the mass; B: Showing immunohistochemical staining of anti-CD34 antibody (200×). CD34-positive cells were counted as microvessels (tan color), moderate MVDs in hot spot area of the neoplastic cells in moderately-differentiated pancreatic carcinoma.

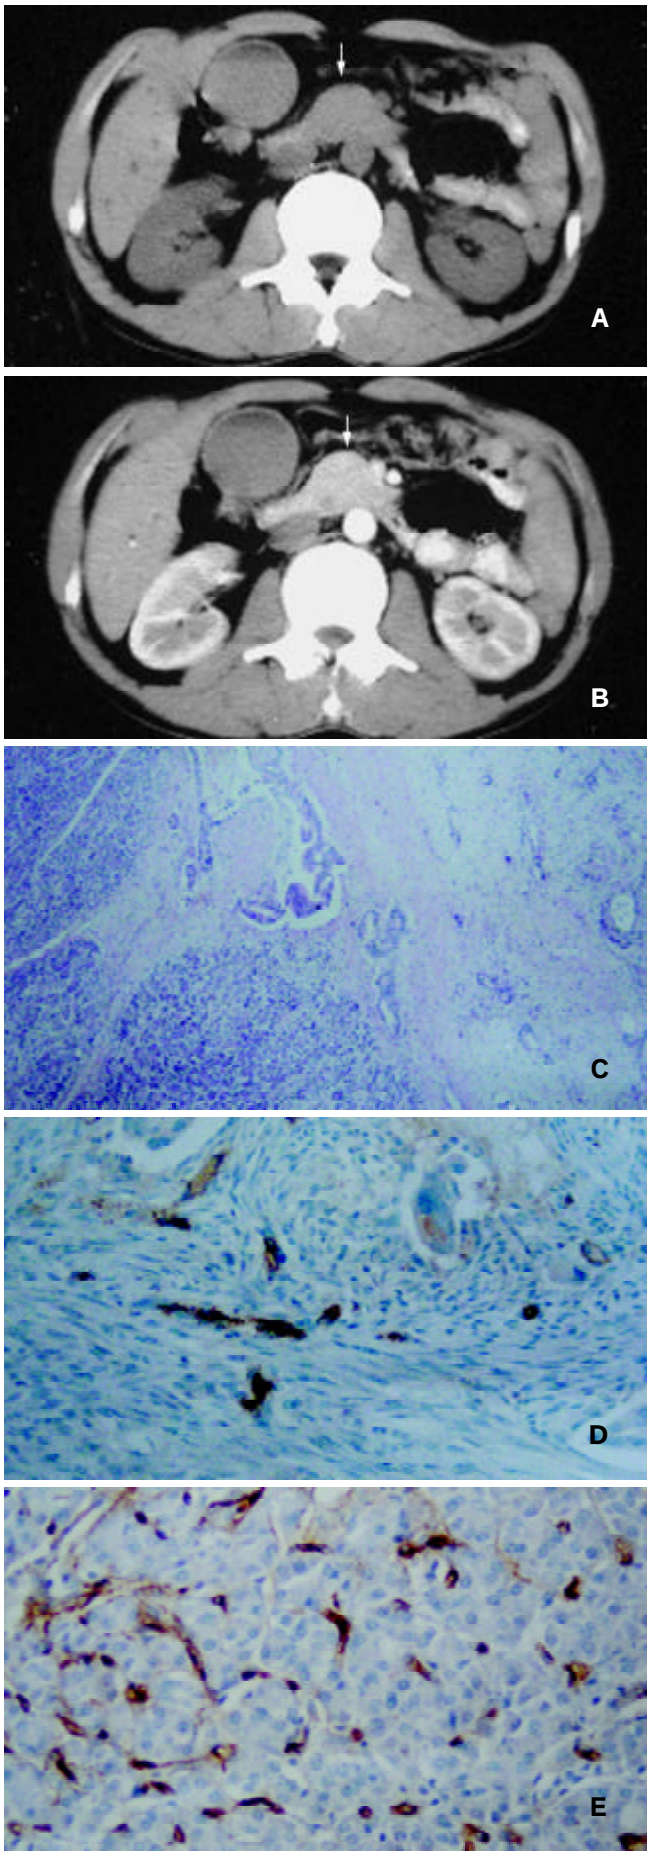

Figure 1 A 52-year-old man with well-differentiated pancreatic head carcinoma. A: EBCT imaging revealed that bulging pancreatic head (white arrow), density of mass in head and neck were the same as that of pancreatic body; B: EBCT enhancement imaging was 35 s after administration of contrast agent revealed that enhancement of mass in pancreatic head (white arrow) was the same as that of normal pancreatic tissue; C: Hematoxylin-eosin-stained specimen (100×) demonstrated the irregularity around tumor cell adeno-tubula structure and residual pancreatic tissue; D: Showing immunohistochemical staining of anti-CD34 antibody (200×). CD34-positive cells were counted as microvessels (tan color), MVDs in hot spot area of the neoplastic cells in well- differentiated pancreatic carcinomal; E: High MVDs of residual pancreatic tissue in well differentiated pancreatic carcinoma (200×).

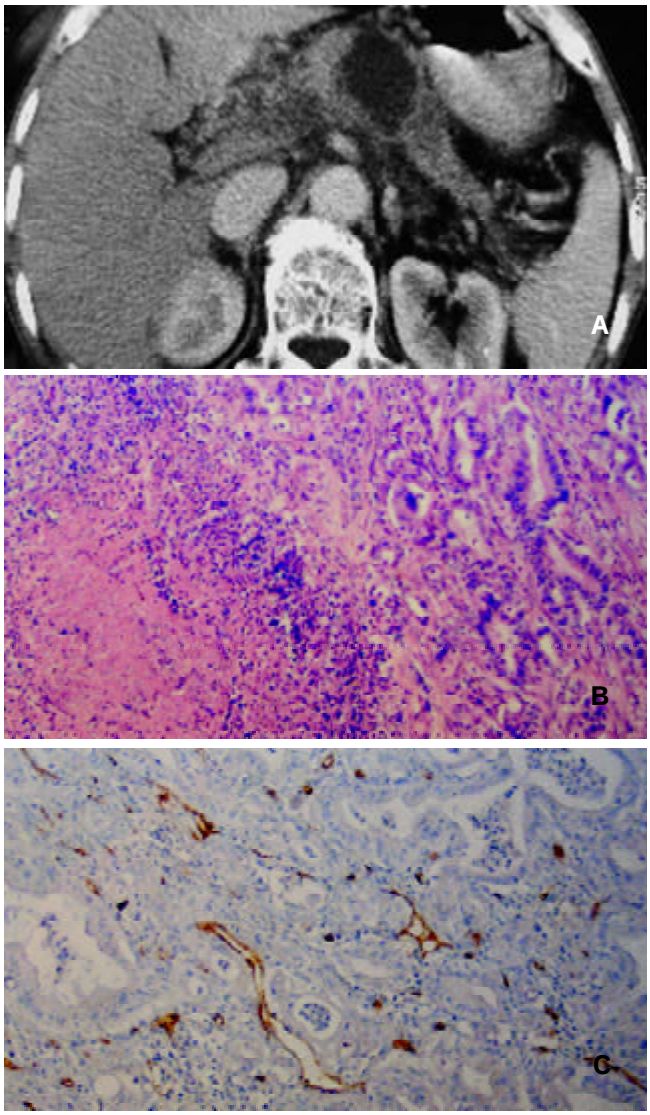

Figure 3 A 59-year-old man with poorly differentiated pancreatic body carcinoma. A: Helical CT enhancement imaging 35 s after administration of contrast agent revealed that pancreatic-phase CT enhancement of mass in pancreatic body was lower than that of surrunding normal pancreatic tissues. Necrotic tissue in the center of the mass was not enhanced. Tumor tissue around the necrotic tissue was slightly enhanced; B:Hematoxylin-eosin-stained specimen (100×) demonstrated massive necrosis and decreased residual pancreatic tissue; C: Showing immunohistochemical staining of anti-CD34 antibody (200×). CD34-positive cells were seen as microvessels (brown yellow color), more MVDs in hot spot area of the neoplastic cells in poorly-differentiated pancreatic carcinoma.

DISCUSSION

The grading of the tumor, its occurrence, progression and metastasis, were all dependent on tumor angiogenesis[13,17,23-25].

Tumor angiogenesis was first proposed by Folkman[11,13]. In recent years, study of intratumor angiogenesis has become a hot spot in neoplastic research[11-17,23-25]. Tumor angiogenesis mainly includes an increase of newly grown microvessels and their permeability change. Histopathology usually reflects an increase or decrease of intratumour MVDs. CT enhancement can also indirectly reflect the situation of intratumor angiogenesis because the enhancement degree of tumor is dependent upon the number of blood vessels within the tumor[12,21,22].

The result of our study showed that the pathological grades of pancreatic carcinoma and CT enhancement of the tumor were significantly correlated (r=0.7857, P<0.001). Table 1 shows isodensity in 75 % (12/16) of well-differentiated pancreatic cancer, 14.3 % (1/7) in moderately-differentiated, and 0 % (0/11) in poorly differentiated. Slightly low density or low density was 25 % (4/16) in well-differentiated tumour, 85.7 % (6/7) in moderately-differentiated tumour, 100 % (11/11) in poorly differentiated tumour. This indicated that the malignant degree of pancreatic carcinoma was inversely proportional to its CT enhancement degree, i.e., the higher the malignant degree, the lower the CT enhancement.

It is agreed that the pathological grades of pancreatic carcinoma are directly proportional to the number of intratumor MVD[21], but Table 2 shows that CT enhancement was inversely proportional to the number of MVD in hot spot areas of neoplastic parenchymal cells (P<0.001). The reason was that the microvessel and its tissue composition of pancreatic carcinoma were different from malignant tumors of other organs such as lung cancer and renal cancer. Pancreatic carcinoma has its own distinct characteristics, usually diffuse fibrosis[23]. Therefore, the CT enhancement is decided by the combination of the total number of intratumor MVD, the fibrous stroma and residual normal pancreatic tissue. A small number of tumor parenchymal cells, a medium number of fibrosis and a large number of residual normal pancreatic tissue constitute well-differentiated pancreatic carcinoma shown in its histopathology. The MVD of the residual pancreatic tissue stained CD34 by immunohistochemistry was abundant (Figure 1D), and the MVD in hot spot areas of neoplastic parenchymal cells was scarce in well-differentiated pancreatic cancer. So the total number of intratumor MVD was mainly decided by the number of MVD within the residual pancreatic tissue (Figure 1E). As we could see that the total number of MVD within the well-differentiated pancreatic cancer was almost the same as that of the surrounding normal pancreatic tissue, hence, the CT enhancement degree of well-differentiated pancreatic carcinoma in pancreatic phase was similar to that of the surrounding normal pancreatic tissue. Whereas in the moderately and poorly-differentiated pancreatic carcinoma, the volume of tumor parenchymal cells increased and the residual pancreatic tissue was relatively decreased. Therefore, CT enhancement degree in these pancreatic carcinoma was lower than that in the well-differentiated pancreatic carcinoma. One could see the scarce microvessel showed slightly-low density enhancement (Figure 2A). Some small cyst and large cystic or low density regions within the tumor were necrosis lesions (Figure 3A).

Linder and others belivered that MVD count of tumor cells was larger than that of the tumor matrix, the former was closely related to the degree of malignancy[23]. According to our data, the pathological grades of pancreatic carcinoma were to some extent correlated with the intratumor MVD count (P<0.05), but significantly correlated with the CT enhancement degree in the pancreatic-phase. This indicated that CT enhancement could effectively evaluate the malignant degree of pancreatic carcinoma before operation. However, pancreatic-phase CT enhancement of pancreatic carcinoma has its own particular features (Figure 4).

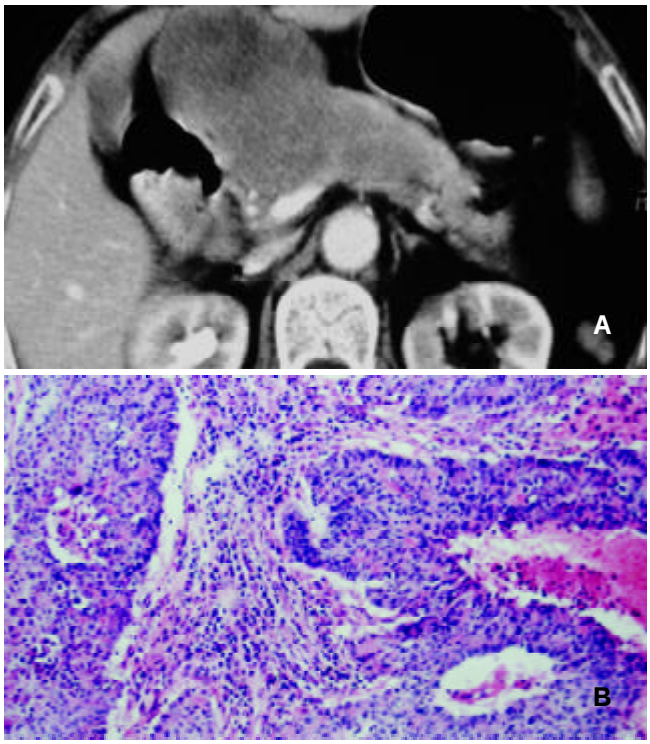

Figure 4 A 70-year-old woman with solid-cystic-papillary well-differentiated pancreatic carcinoma with involvement of ligamentum hepatoduodenale. A: Helical CT enhancement imaging 35 s after administration of contrast agent revealed that CT enhancement of mass was heterogenously slight low density with low density necrotic region; B: Hematoxylin-eosin-stained specimen (100×) demonstrated massive necrosis tissuse and irregular tubula structure in well-differentiated pancreatic carcinoma.

To sum up, if CT enhancement degree of pancreatic carcinoma is as high as that of the surrounding normal pancreatic tissues, it would reflect a high MVD in the residual pancreatic tissue and a small count of intratumoral MVD indicating pancreatic carcinoma is well-differentiated. If CT enhancement degree is slightly lower than that of the normal pancreatic tissue with a vessel voided area, with or without low-density cystic areas, it would reflect a moderately-differentiated pancreatic cancer. The appearance of heterogeneously slight-low density areas with a large low density necrotic lesion might reflect a highly malignant and poorly-differentiated pancreatic carcinoma.

ACKNOWLEDGEMENT

I wish to express our sincere and hearty thanks to Professor Li Jieshou, academician of the Chinese Academy of Engineering. We are deeply indebted to his careful and enlightening advice.

Abstract

AIM: To investigate the effect of nutritional support therapy on severe acute pancreatitis (SAP).

METHODS: A total of 96 patients with severe acute pancreatitis were divided randomly into control and treatment groups. The former group received total parenteral nutrition (TPN) via central venous infusion, while parenteral nutrition (PN) and enteral nutrition (EN) therapies were applied in different phases for the latter group. The nutrition status, acute phase responses, pancreas lesions, enteric mucosa penetrability and immune functions were monitored.

RESULTS: Body weight and prealbumin concentration were increased in treatment group, compared to those in the control group, but albumin concentration did not change significantly. Acute physiology and chronic health evaluation II (APACHE II) scores decreased after 7 d of treatment, whereas the scores of the control group decreased on the 11th day. Concentrations of tumor necrosis factor-α (TNF-α), interleukine-6 (IL-6) and serum C reactive protein (CRP) dropped earlier in the treatment group (on the 4th day) than that in the control group (on the 7th day). No difference was observed in pancreatic lesions between the control and treatment groups. Concentration of endotoxin and lactulose/manicol (L:M) ratio of urine did not change in treatment group, but those in the control group were elevated markedly. Compared with the treatment group, CD4:CD8 T cells ratio and immunoglobulin G (IgG) concentration in the control group decreased significantly.

CONCLUSION: Compared to TPN, the combined therapy of EN and PN could improve the nutrition status and moderate the acute phase response obviously. Moreover, the integrity of enteric mucosa and immune function were protected more effectively in treatment group than in the control one. On the other hand, EN did not simulate the excretion of pancreas and avoid exaggerating the inflammation of pancreas. Thus, appropriate application of PN and EN appears to be more effective for patients with SAP.

INTRODUCTION

Severe acute pancreatitis (SAP) is characterized by a diffuse inflammatory process of the pancreas with variable involvement of adjacent tissues and dysfunction of remote organs[1]. The metabolic alterations of SAP are involved in a classical stress state, as proposed for sepsis, including hyperdynamic changes, hypermetabolism and hypercatabolism. Thus, artificial nutritional support should be a suitable treatment[2-4]. The clinical nutritional management of pancreatitis has changed from total parenteral nutrition (TPN) to enteral nutrition (EN). However, it remains to be clarified whether EN is the best approach or not[5-8]. The purpose of this observation was to evaluate different nutrition therapies for SAP.

MATERIALS AND METHODS

Patients

A total of 96 patients with SAP admitted to the Pancreatic Surgery Center of Union Hospital (Wuhan, China) between February 2000 and October 2002 were recruited to the randomized study. The severity of pancreatitis was defined according to the Atlanta classification system for acute pancreatitis. Criteria for this observation were the acute physiology and chronic health evaluation II (APACH II) score higher than 8, and no indication for operation temporarily[9, 10]. These patients consisted of 58 males and 38 females with a mean age of 47.8 years (range 24-68 years). After 48 hours of common management including active liquid resuscitation and organ function protection[11,12], the patients were divided randomly into control and treatment groups. No significant differences of male:female ratio (15.6:16.7) and average age (48.2 and 46.7) were found between the two groups.

Study protocol

The 41 patients in control group were commenced on TPN via central venous infusion. In the treatment group, PN and EN were carried out by three stages for 55 patients. At first, the patients of treatment group only received glutamine-supplemented PN. When the paralysis was relieved, EN and PN were applied at the same time. EN was administrated via a nasojejunal feeding tube under endoscopy or X-ray. Following the study period, the volume and speed of enteral feeding were adjusted depending on the individual tolerance. Deficiency of energy was compensated through glutamine-supplemented PN. At last, the enteric feeding reached approximately 2 000 ml in 5-7 d, and PN was ceased.

Nutrition formulas

Conventional TPN was based on an amino acid solution providing 0.25 g nitrogen/(kg· d) with lipid emulsion and glucose. Half of the non-protein calories were provided by lipid. The total calorie was 30 kcal/(kg· d) and the calorie to nitrogen ratio was 120:1 in each patient. Electrolytes, trace elements and vitamins were added to maintain requirements [13].

PN in treatment group was based on the same elements as TPN but with supplement of 0.22 g glutamine/kg. EN formula was Peptide-2000 (Nutricia, Holland) semi-elementary diet

(2.9 g nitrogen and 500 kcal non-protein calorie/500 ml), with supplement of glutamine tablets to increase the intake of glutamine[14,15].

Experimental protocols

Body weight, albumin and prealbumin concentrations were determined to evaluate the nutrition status once of a week. APACH II scores, serum C reactive protein (CRP), tumor necrosis factor-α (TNF-α) and interleukine-6 (IL-6) were quantified every three days to assess the acute phase response. Pancreatic and peripancreatic necrosis were detected by contrast-enhanced CT scan once a week. These results of CT scan were scored with a modified Balthazar scoring system. Permeability of gastrointestinal mucosa was evaluated by concentration of endotoxin and lactulose/manicol (L:M) ratio of urine. CD4:CD8 ratio of T cell and concentration of immunoglobulin G (IgG) were quantified to assess immunological function.

Statistical analysis

All data were expressed as the mean ± standard deviation. Student' s *t* test was used to analyze the difference. A value of $P<0.05$ was considered statistically significant.

RESULTS

Nutrition status

Compared to the control group, body weight and plasma prealbumin concentration were increased in the treatment group after two weeks of treatment ($P<0.05$), whereas plasma albumin concentration did not change (Table 1).

Table 1 Changes of body weight, plasma albumin and prealbumin concentrations in two groups

[a]$P<0.05$ *vs* control.

Acute phase responses

APACH II scores decreased earlier in the treatment group (on the 4th day) than those in the control group (on the 7th day). Moreover, the concentration of serum CRP, TNF-α and IL-6 in treatment group decreased earlier too (Table 2).

Pancreas lesions

The concentrations of serum and urine amylase in both groups decreased on the 7th day, and there were no significant differences between these two groups. Similar changes were observed in the CT scores (Table 3).

Enteric mucosal permeability

Few endotoxins were detected in the treatment group on the 7th day, and the urine L:M ratio remained unchanged. Endotoxin concentration and urine L:M ratio in control group elevated gradually and were much higher than those in the treatment one ($P<0.05$) (Table 4).

Immune function

CD4:CD8 T cell ratio and serum IgG concentration did not change in the treatment group. In control group, CD4:CD8 T cell ratio and serum IgG concentration decreased continuously and were markedly lower than those in the treatment group ($P<0.05$) (Table 5).

DISCUSSION

Infected pancreatic necrosis is the most severe complication in patients with SAP. Its occurrence is associated with systemic inflammatory response syndrome (SIRS), sepsis, and multiple organ failure (MOF). Failure of intestinal barrier function is probably responsible for the occurrence of these phenomena[16-19]. Experimental models have shown that infection of necrotic pancreas is caused by translocated intestinal bacteria. Bacterial endotoxins and antigens invade the portal circulation and generate cytokines, causing multiple organ failure syndrome (MODS). Enteral feeding has been proved to be beneficial in burn patients and major trauma victims. Theoretically, EN should help preserve intestinal barrier function in patients with SAP[20-23].

It is worth considering which factors contribute to the failure of gut barrier function in acute pancreatitis. Some of these factors are consequences of the disturbance of peristalsis caused by paralysis and disturbance of perfusion caused by hypotension. The most important factor is the deficiency of oxygen and substrate supply for enteric mucosae. Atrophy and apoptosis of intestinal mucosae occur after several days of PN, and the permeability of intestinal wall increases[24-26]. The increased permeability of intestinal wall allows macromolecules, bacteria, endotoxins, and antigens to enter into the portal circulation and adjacent tissues. This invasion elicits an inflammatory response by stimulating the macrophages and neutrophil granulocytes and by inflammatory cytokines (IL-1, 2, and 6 and TNF). These inflammatory mediators may be responsible for the development of SIRS and MODS[27-29]. Our study indicated that inflammatory mediators (CRP, IL-6 and TNF-α) in the treatment group decreased earlier (on the 4th day) than those in the control group (on the 7th day). Similarly, APACH II scores in the treatment group declined earlier (on the 7th day) than those in the control group (on the 11th day). These results suggest that the combined therapy of EN and PN could avoid the excess production of inflammatory mediators, and then alleviate SIRS and acute phase response.

Glutamine is an amino acid rich in the plasma and intracellular free amino acid pool. It is essential for a wide variety of physiologic processes, in particular, the growth and function of enteric mucosae and immune cells including lymphocytes and macrophages[30-32]. In SAP, glutamine is in condition of excess utilization and endogenous glutamine production may not adequate. In our present study, glutamine was added into the elements of PN and EN. The results showed that endotoxin concentration and urine L:M ratio in the treatment group did not have any change, but elevated markedly in the control group. It was indicated that intestinal epithelial cells and immune cells received nutrients especially glutamine from the gut and reins in the treatment group. Furthermore, intestinal motility adjusted the secretion of enteral hormones and enhanced blood flow. Therefore, the combined therapy of PN and EN can prevent mucosae from atrophy and apoptosis effectively. Meanwhile, the results of CD4:CD8 ratio of T cells and serum IgG concentration indicated that the immune function in the treatment group was protected effectively. The combined therapy of PN and EN protected mucosal barrier and immune function, which could prevent the translocation of bacteria effectively.

Several investigations have emphasized that early EN should be beneficial to patients with SAP. However, too early EN or intragastric nutrition would increase the exocrine of pancreas, which aggravates pancreatitis. Our criteria for the enteral feeding are to alleviate the acute phase response, stabilize the organs function and limit the local necrosis tissue and exudates. Nutritional tube must be placed in the superior segment of jejunum, so enteric feeding will not increase the amount of pancreatic secretions[33, 34]. Because the gut failed to function in patients with SAP and the nutritional tube couldnot peristalsize, the tube should be pushed with endoscopy or under X-ray to the superior segment of the jejunum[35]. In this study, CT scores and the concentration of amylase indicated that EN did not simulate the excretion of pancreas, and thus could avoid exaggerating the inflammation of pancreas.

In summary, the results of our study provide evidences that combined therapy of EN and PN can significantly modulate acute phase response and improve the mucosal barrier and immune defense. Thus, appropriate application of PN and EN appears to be more effective for patients with SAP.

Abstract

AIM: To determine the efficacy and long-term outcome of biofeedback treatment for chronic idiopathic constipation and to compare the efficacy of two modes of biofeedback (EMG-based and manometry-based biofeedback).

METHODS: Fifty consecutive contactable patients included 8 cases of slow transit constipation, 36 cases of anorectic outlet obstruction and 6 cases of mixed constipation. Two modes of biofeedback were used for these 50 patients, 30 of whom had EMG-based biofeedback, and 20 had manometry-based biofeedback. Before treatment, a consultation and physical examination were done for all the patients, related information such as bowel function and gut transit time was documented, psychological test (symptom checklist 90, SCL90) and anorectic physiological test and defecography were applied. After biofeedback management, all the patients were followed up. The Student's *t*-test, chi-squared test and Logistic regression were used for statistical analysis.

RESULTS: The period of following up ranged from 12 to 24 months (Median 18 months). 70 % of patients felt that biofeedback was helpful, and 62.5 % of patients with constipation were improved. Clinical manifestations including straining, abdominal pain, bloating, were relieved, and less oral laxative was used. Spontaneous bowel frequency and psychological state were improved significantly after treatment. Patients with slow and normal transit, and those with and without paradoxical contraction of the anal sphincter on straining, benefited equally from the treatment. The psychological status rather than anorectal test could predict outcome. The efficacy of the two modes of biofeedback was similar without side effects.

CONCLUSION: This study suggests that biofeedback has a long-term effect with no side effects, for the majority of patients with chronic idiopathic constipation unresponsive to traditional treatment. Pelvic floor abnormalities and transit time should not be the selection criteria for treatment.

INTRODUCTION

Chronic constipation is a common and distressing complaint, which may be secondary to many diseases, or may also be of functional origin. In the United Stats, it is more common in blacks (17 %), women (18 %), elderly over 60 years (23 %), and in those who are inactive, low income, or poorly educated[1]. In Tianjin, China, 4.43 % of the general population had this complaint according to a study in 1994.

Chronic idiopathic functional constipation is a severe type of constipation and has poor response to the traditional management. Many such patients could not live without the use of laxatives, suppositories or enemas and experience major physical, social, and psychological impairments from the condition.

Biofeedback has been used for a long time to strengthen pelvic floor muscles in patients with fecal incontinence[2]. In recent years, biofeedback has been used for retraining of the pelvic floor with paradoxical sphincter contraction[3]. The reported results varied and the successful rate ranged from 0 to over 90 %[5,6]. Although most groups restricted the use of biofeedback to patients with normal transit and paradoxical pelvic floor contraction during straining[6-9], the technique has a wide therapeutic benefit.

Behavioral techniques were applied to patients with three kinds of constipation (pelvic floor dysfunction, slow transit, and mixed) in order to assess prospectively the effects of biofeedback, to evaluate factors that might be helpful in selecting patients or the optimal method of biofeedback, and to explore the mechanism of this treatment.

MATERIALS AND METHODS

Patients

From October 1998 to October 1999, 50 patients with chronic idiopathic functional constipation from Tianjin Binjiang hospital and Tianjin Medical University Hospital were offered biofeedback. The duration of constipation of the patients was more than 2 years. All the 50 patients failed to respond to first-line therapy, including dietary advice, bulk-forming agents, and use of laxatives. Operation was performed on 4 patients. There were 36 females and 14 males, their mean age was 52.6 years (range, 16-71), mean duration of constipation was 4.6 years (range, 2.5-30). Detailed information is shown in Table1.

Table 1 Common features of the patients

No. of cases	50 (36, female)
Average age	52.6 (10-71)years
Average history	4.6 (2.5-30)years
Average onset age	34 (1-60)years
Complaint in childhood	4
Average follow-up period	18 (12-28)months
Times of biofeedback treatment	1
Failed treatment prior to BF	
Normal traditional conservative treatment	50
Operation	4

All the patients had constipation as defined by the Rome II criteria, complaining of either decreased bowel frequency (less than three times per week), a sensation of incomplete emptying or a history of difficult evacuation on at least a quarter of occasions, or a need to strain. According to the criteria, we divided the patients into pelvic floor dysfunction (n=36), slow transit (n=8) and mixed (n=6). The algorithm for clinical approach in this study is showed in Figure 1.

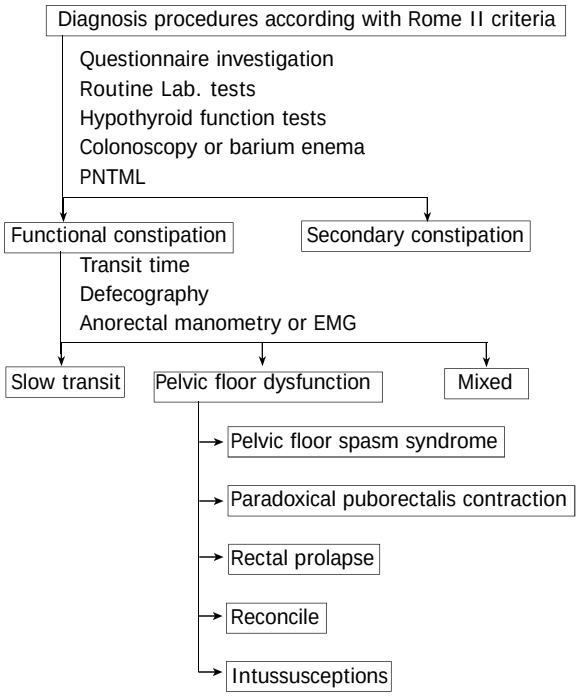

Figure 1 Algorithm for clinical approach.

Methods

Physical examination and thyroid function test were done to exclude constipation secondary to other causes. Moreover, an initial series of tests, including colonoscopy or barium enema failed to detect organic lesions in all patients. Patients were assessed clinically using a specially designed questionnaire that was filled out by a specialist, physician or a medically qualified researcher. The questionnaire included history of age at onset, bowel frequency, precipitation factors, use of laxatives, major and secondary syndromes, family history, urinary syndromes, gynecologic history, and other relevant diseases. A series of tests of colonic and pelvic floor functions were performed before and after biofeedback treatment as described below.

Whole gut transit study We used the method previously reported[10]. Patients ingested twenty radiologically distinguishable radio-opaque markers on day one, and no laxatives or enemas were allowed for five days. In women, the investigation was performed in the nonmenstrual phase. A single plain abdominal radiograph was taken 120 hours after ingesting of the markers. We interpreted more than 8(>40 percent) markers left in the colon as abnormal, which were divided into two kinds: slow transit of whole colon, slow transit of sigmoid colon and rectum.

Anorectal manometry We used an open-tip perfused catheter system (Medtronic Synectics Ltd). The catheter had a four-channel flexible probe with an outside diameter of 4.8 mm. Rectal sensory function to distension was assessed using an intrarectal balloon, according to previously published techniques. The initial sense, a sense of urgency, and the maximum tolerated volume were recorded. Rectal sensation to an electrical stimulus was also assessed using a bipolar electrode placed in the rectum 6 cm above the upper limit of the anal canal. The length of the anal canal was also measured. This technique had been previously validated. Manometric studies were performed with the patient lying on the left side.

Electromyography of the external sphincter muscle We used surface EMG electrode to measure the electromyographic activity of the anal sphincter as described by Abdullhakim and Gerger. The study was performed with the patient in the right lateral position. We repeatedly assessed the myoelectric activity during resting, squeezing, and straining. A reproducible increase in myoelectrical activity during straining was considered as the paradoxical puborectalis contraction.

Defecography Cinedefecography was a dynamic study of anorectal function, and was described before. Evacuation was started from the beginning of straining to completion of rectal emptying, and measured in seconds on a video counter. Subjective evaluation of rectal emptying was then undertaken to determine completeness and speed of evacuation. Prolonged (>35 seconds) emptying or incomplete emptying or both were considered as abnormal pelvic floor function. A rectocele that failed to empty the evacuation was considered as significant pelvic floor dysfunction. Paradoxical puborectalis contraction, rectal prolapse and intussusception were diagnosed with defecography.

Psychological questionnaire Symptom Checklist 90 (SCL-90) was used to evaluate the psychological state of patients[11]. Nine factors could be described, which were somatization, obsessive-compulsive, interpersonal sensitivity, depression, anxiety, hostility, photic anxiety, padanoid ideation and psychoticism. We could also get the general symptomatic index.

Telephone interview Each patient was interviewed over telephone by an investigator who had not been the patient's biofeedback therapist. Data were obtained using a questionnaire containing the same questions as those before treatment. Using these pretreatment and post-treatment data, an assessment was made regarding the age of constipation onset of the patient, and whether there were any precipitating factors, including vaginal delivery, hysterectomy, or other surgery. Bowel function before and after biofeedback, and at the time of interview was assessed, including use of bowel evacuants (oral laxatives, enemas, and suppositories), bowel frequency without laxatives, need of strain, need of dig with finger, and a sense of incomplete evacuation. Enquiries were also made about the presence and subjective severity of abdominal pain or bloating. To establish the possible subjective benefits of the treatment as a whole, in addition to the effect on constipation, benefit of biofeedback, improvement of constipation and compliance with practice of biofeedback techniques were asked.

Questionaire A special questionaire including listing symptoms and daily use of laxatives or enemas during and after treatment was designed, and was filled out by patients and was checked by doctors in charge.

Biofeedback therapy Patients were subjected to biofeedback twice per week for five sessions. All the patients were treated as outpatients. At the first session, the anatomy and physiology of the gut and the pelvic floor were explained to the patients using diagrams and their own tests results. The objectives of biofeedback therapy were carefully explained to the patients.

In the pressure-based training, we used the same four-lumen catheter as described above. The side holes were placed in the distal rectum and the anal canal, and the balloon attached to the tip of the catheter was used for training expulsion. During training, the catheter was inserted in the same way as during diagnostic studies, and the subjects were allowed to view the manometric recordings. They were instructed to look for changes in the pressure tracing, thereby visualizing the location and function of the pelvic floor muscles, with specific attention to the responses of the anal sphincter during squeezing and

straining. Patients were told that the sphincter should relax during expulsion of the rectal balloon at the urge threshold, indicated by a decrease in basal pressure, and they should learn how to relax the pelvic floor muscles and to push down slowly using their abdominal muscles. Straining and relaxing were repeated until a normal pattern of expulsion occurred. The exercise was repeated several times during an one-hour session.

For EMG feedback, the subjects were seated on a toilet-like chair. Disposable bilateral prenatal surface EMG electrodes were connected to the EMG recording device, which provided auditory and visual signals to aid the patient in observing muscle activity. Resting EMG was noted, then the subject recorded a squeeze, bore down as defecation and tried to relax the pelvic floor and to lower the straining records below the resting recording. Afterward, the patients were trained to expel the rectal balloon connected to a catheter on lateral position and were instructed to pratise expulsion of rectal contents and relax without straining at home.

Polygraf ID (Medtronic Synetics Ltd) was used in this study. The patients were consulted on normal defecography behavior and bowel habits, such as adjusting the number of visits to the toilet, amount of time spent, and posture in toilet. At each biofeedback session the therapist tried to have a good understanding and collaboration with patients. An attempt was made to get patients off laxatives, enemas, and suppositories. When the course of biofeedback was completed, the patients were encouraged to continue practicing the techniques.

Prognostic factors To determine whether certain patient characteristics may predict a response to biofeedback treatment, the patients who benefited from biofeedback were compared with those who did not. Parameters used for comparison were the objective findings of slow or normal transit, the presence or absence of pelvic floor paradoxical contraction on straining, the presence of previous psychological factors, and the compliance of practice the biofeedback at home after the treatment. Difference between EMG-based and Manometry-based biofeedback was compared.

Assessment of symptoms A questionnaire was used to assess the manifestation of patients, it detailed the number of bowel movements, failed attempts of bowel movement, the use of laxatives and enemas, presence of bloating, severity of abdominal pain (0=no pain, 1=mild pain, 2=moderate pain, 3=severe pain) for each day during one week. The score of one-week abdominal pain was calculated as the sum of seven consecutive daily scores of pain severity.

Patients were investigated with anorectal manometry, EMG, and the one-week bowel habit questionnaire before and after biofeedback retraining. After treatment and 6 months following treatment, a global assessment for the treatment was evaluated by patients through filling the questionnaire, including the degree of improvement of bowel movement.

Statistical methods Non-normal data were expressed as median and full range. Normal data were expressed as mean ±standard deviation. Student' s *t*-test was used to compare the treatment results, and the chi-square test was used for comparison of proportions. Prognostic factors were analyzed by logistic regression.

RESULTS

All the 50 patients agreed to participate in the study. Table 1 shows characteristics of the patients. The vast majority of patients were female. Each patient had only one course of biofeedback. Almost 10 % of the patients had experienced constipation since childhood. Almost all the patients believed they could not identify a precipitating factor of their constipation. One fifth of patients were recorded as having possible relevant psychological factors.

The median time of follow up was 18 months (12-28 months).

At the end of treatment, 31 of the 50 patients reported a subjectively overall improvement. The overall successful rate was 62 %, the successful rate was 72.2 % for patients with pelvic floor dysfunction constipation.

Table 3 shows the prevalence of symptoms in the study group. The most common findings were difficult evacuation, hard stools, distention or bloating and laxative dependence.

All the patients underwent both a transit study and physiological study, 8 had slow colonic transit, 36 showed pelvic floor dysfunction constipation, 6 had both slow transit and pelvic floor dysfunction (Table 2).

Two methods of biofeedback were applied in this study. We used EMG-based biofeedback for 30 patients, and manometry-based biofeedback for 20 patients.

Table 2 Symptoms Changes before and after Biofeedback (BE)

Symptoms	No. of patients before BF	No. of patients 10 days after BF	No. of patients 1 year after BF
Difficult evacuation	50	16[a]	13[a]
Hard stools	40	18[b]	16[b]
Loose stools at onset of abd. Pain	39	19(NS)	22(NS)
No sense of defecate in 1 week	35	20(NS)	16(NS)
Need for digitations	21	11(NS)	11(NS)
Sense of incomplete emptying	31	18(NS)	16(NS)
Distention or bloating	42	15[b]	13[b]
Laxative dependence	48	12(P<0.01)	14[a]
Need of enema	31	9[b]	9[b]
Perianal pain at defecation	30	16(NS)	11(NS)

[a]P<0.01 *vs* before BF, [b]P<0.05 *vs* before BF.

Table 3 Successful rate in patients with different types of constipation

Types	*n*	Successful rate (%)
Slow transit	8	3
Pelvic floor dysfunction	36	26 (72.2 %)
Paradoxical puborectalis contraction	20	16 (80 %)
Pelvic floor spasm syndrome	9	6 (66.7 %)
Intussusception	7	4 (55.6 %)
Mixed	6	2

Symptoms

At the end of treatment, 31 of 50 patients reported a subjectively overall improvement in their symptoms. The need for enema, difficult evacuation, hard stools, distention or bloating and use of laxatives were all significantly improved immediately after biofeedback or after a long-term follow up (Table 3). The proportion of patients with loose stools at onset of pain, no feeling to defecate, need for digitations, feeling of incomplete emptying and perianal pain at defecation were also reduced, but these did not reach statistical significance, probably due to the small number of patients with these symptoms.

Physiological investigations

Whole gut transit Before biofeedback: 14 of 50 constipated patients were identified as having slow transit. Of them, seven had marker retention predominantly in the rectosigmoid as defined by more than half of the excessively retained markers present in the rectosigmoid, the remaining 7 patients with slow transit had excessive marker retention throughout the colon.

After biofeedback: 5 of 14 slow transit constipation patients reported subjective improvement after biofeedback. 26 of 36 patients with normal transit reported a similar improvement. The difference between the two groups was not significant. Similarly, there was no difference between patients with slow and normal transit.

Among the 7 patients with slow transit, 3 patients with only rectosigmoid delay and 2 with slow transit were due to a more generalized holding up of markers, and reported a subjective improvement.

Defecography Before biofeedback: 42 of 50 constipated patients were identified as having pelvic floor dysfunction constipation. Of them, 22 were complicated with paradoxical puborectalis contraction, 7 with pelvic floor spasm syndrome, 9 with major intussusception.

After biofeedback: 28 of 42 patients reported a subjective improvement after biofeedback. Among them, 15 were complicated with paradoxical puborectalis contraction predominantly, 8 with pelvic floor spasm syndrome and 5 with intussusception. The difference in outcome between the three groups was not significant.

Anorectal manometry There were significant reductions in the index of "initial sense" and "average rest pressure" before and after biofeedback. On the other hand, there was no difference in other results concerning the type of biofeedback (Table 4).

Table 4 Changes of anorectal manometry index before and after BF

Manometry index	Volume before BF	Volume after BF	Statistic value
Anal canal(mmHg)			
Average rest pressure	49.7±7.7	19.4±10.1	$P<0.05$
Voluntary squeeze	112.5±18.5	164.4±40.6	NS
Rectum			
Initial sense(ml)	95.4±39.1	41.4±19.2	$P<0.05$
Maximum tolerable(ml)	195.7±42.5	412.6±235.3	NS
Compliance(ml/mmHg)	5.1±1.5	6.3±2.9	NS

Table 5 Prognostic factors (1 year after BF therapy)

Factors	Percent of success (31)	Percent of failure (19)	Statistic value
Gender			
Female (36)	22(72.8 %)	14(73.7 %)	NS
Male (14)	9(28.1 %)	5(26.3 %)	NS
Methods of BF			
EMG-based (30)	20(64.5 %)	10(52.6 %)	NS
Manometry-based(20)	11(36.1 %)	9(47.3 %)	NS
Types of constipation			
Slow transit(8)	3	5	
Pelvic floor dysfunction(36)	26(83.9 %)	10(52.6 %)	$P<0.05$
Mixed (6)	2	4	
Psychological state			
High-level group [a](25)	15 (49.43 %)	10(52.6 %)	NS
low-level group [a](25)	16 (51.6 %)	9(47.3 %)	NS

[a]Limitation to measure high and low group was half of total number.

Psychological state

The general symptomatic index was significantly reduced after biofeedback therapy (from 44.80±33.34 before BF to 24.05±20.62 after BF, $P<0.01$). All the factors were improved after BF, and except photic anxiety, all the factors had a significant difference between before and BF ($P<0.05$-0.01, Table 6).

Prognostic factors

No practice of biofeedback techniques after treatment was significantly associated with poor outcome immediately after biofeedback treatment (practised: 76 % in the success group versus 43 % in the failure group, $P<0.01$, χ^2 test), however, this difference at long-term follow up was no longer significant. Patients with slow transit gained more benefit than those with normal transit, but the number of patients with slow transit was too small to draw conclusion. Patients with normal pelvic floor contraction gained less benefit than those with abnormal one. Different methods of biofeedback did not predict outcome.

Table 6 Symptomatic factors index of SCL-90

Factors	Before BF	After BF
Somatization	0.5	0.2
Obsessive-compulsive	0.6	0.3
Interpersonal sensitivity	0.9	0.4
Depression	0.7	0.1
Anxiety	0.8	0.2
Hostility	0.7	0.3
Padanoid ideation	0.7	0.2
Psychoticism	0.5	0.2
Photic anxiety	0.1	0.1

DISCUSSION

This study showed that biofeedback was a successful treatment for patients with constipation unresponsive to other treatments. 62 % of patients reported a subjective improvement in long-term follow up. This was objectively supported by their decreased use of laxatives. Symptom improvement was related not only to bowel frequency, but also to symptoms such as bloating.

The biofeedback component was important. Similar training without biofeedback from the sphincter was not effective, as was shown in a recent study by Bleijenberg and Kuijpers[12]. They compared the efficacy of EMG biofeedback with that of retraining defecation using an intrarectal balloon only. In the former group, 8 of 11 patients improved as opposed to only 2 of 9 in the latter group. The efficacy of biofeedback over other treatments was also demonstrated by Loening-Baucke[13], who studied children with constipation and encopresis. Nineteen patients were treated with conventional therapy combined with EMG feedback, 7 months later, 77 % of the biofeedback-treated children improved as opposed to only 13 % of those treated conventionally.

Our selection of patients for biofeedback was based on international criteria for functional constipation-Roma II criteria. Organic lesions were excluded by colonoscopy or barium enema, as Hirschsprung's disease and megarectum by anorectal manometry. According to the criteria, the patients were divided into slow transit, pelvic floor dysfunction and mixed. Others had their own opinions on classification. Another type associated with irritable bowel syndrome (IBS) that was defined as combination of normal transit and normal pelvic floor function was reported, Pemberton reported 71.1 % of constipated patients (n=277) had IBS (n=197). Nyam reported 59.2 % (597) of 1009 patients belonged to this type. Glia A and Lindberg G found that 35 % of the constipated patients complained of constipation but had no detectable disturbance of anorectal or colonic function, and thought that the methods were too crude to detect clinically relevant disturbances of

colorectal function. The patients with normal transit constipation more often reported normal stool frequency, alternating diarrhea and constipation, urgent need for defecation, history of previous anorectal surgery, and looser stools at onset of pain. In the absence of a quantifiable abnormality, patients with normal-transit constipation previously diagnosed as IBS. Our data showed that the International Working Team criteria for IBS did not discriminate between different diagnostic groups. Further studies are needed to determine if a modification of the IBS criteria works well.

This prospective study shows that biofeedback is an effective behavioral treatment for chronic idiopathic constipation with slow transit and normal transit. Five of 14 patients with slow transit were normal by the end of treatment. This study has also shown that the changes in transit occurred in patients with excessive retained markers are distributed around the colon. The effect may relate to whole colon function or innervations and not just the distal large bowel. Treatment also significantly speed up transit in those with normal transit pretreatment, with 18 % reduction in the number of markers present on the follow up transit study.

For such a labor intensive treatment it is important to determine which patients are likely to respond to treatment. In our research, the gender of patients, and the type of constipation, physiological factors and the method of biofeedback could not predict response to treatment.

This study demonstrated that patients with idiopathic constipation had significantly greater psychological morbidity than age matched healthy controls. They had higher levels of depression, anxiety, psychoticism and hostility. This finding was partly reproduced in studies[14,15] which suggested that psychological factors influenced gut function via autonomic efferent neural pathways.

In the meantime, after biofeedback therapy, the general symptomatic index was significantly reduced, and except photic anxiety, all the factors fell down. So it is possible that the biofeedback therapy improved the psychological state.

The mechanism of action of biofeedback treatment is complicated. It was as effective in patients with slow transit as it was in those with paradoxical contraction, 82 % of those with paradoxical contraction and 50 % of those without paradoxical contraction reported subjective improvements after treatment. Previous studies showed that patients with and without animus, with both slow and normal transit benefited equally from biofeedback[16-18].

There are several mechanisms by which behavioral treatment may have altered gut function and blood flow. Cerebral autonomic control of the gut and its microcirculation may have been changed. Alternatively, it is possible that the observed increases in rectal mucosal blood flow are due to improvement in psychological or social functioning brought about by behavioral treatment.

ACKNOWLEDGMENTS

We are indebted to Drs. Shu-Ling Yuan, Ying-Chao Hu, and Zhang-Rong Jiang for assistance in performing the biofeedback treatment.

Abstract

AIM: To observe the binding activity of beta-2-glycoprotein I (β_2GPI) to hepatitis B surface antigen (HBsAg) and the possible roles of β_2GPI in hepatitis B virus (HBV) infection.

METHODS: The rationale of ELISA methods and ELISA-based research method and ligand-blotting technique were used to detect the specific interaction of β_2GPI with HBsAg.

RESULTS: With the increase of rHBsAg, the binding of β_2GPI to rHBsAg elevated, and these changes had statistic significance. When we added non- biotinlyated β_2GPI, the OD value significantly decreased though they still were positively relevant to rHBsAg, suggesting non- biotinlyated β_2GPI competed with biotinlyated β_2GPI to saturate the binding sites on rHBsAg. Meanwhile BSA was used as negative control to substitute for rHBsAg coating the plates. The results indicated no interaction between β_2GPI and BSA, suggesting the affinity of β_2GPI to rHBsAg was specific. The ligand blotling indicated that β_2GPI might bind to rHBsAg no matter whether it was under reduced condition or not.

CONCLUSION: The binding of β_2GPI to HBsAg suggests that β_2GPI may be a carrier of HBV and that β_2GPI may play important roles in HBV infection.

INTRODUCTION

β_2GPI (beta-2-glycoproteinI) is a plasm glycoprotein circulating as a free protein and is associated to lipoproteins. This protein is also referred to as apolipoprotein H(Apo H). Human β_2GPI is a single-chain molecule consisting of 326 amino acid residues and 5 carbohydrate chain and has a molecule mass of approximately 55 kDa[1-3]. The amino acid sequences of β_2GPI in human, bovine, mouse, and rat appear to be highly conserved[4-6]. The protein contains 5 internal repeat unit of 60 amino acid residues, each with 2 internal disulfide bonds, known as Sushi domain[7].

Although quite a lot is known about the structure of β_2GPI, its biological function remains unclear. It is known that β_2GPI can bind to negatively charged substances such as DNA and heparin and negatively charged phospholipids etc *in vivo*[8,9], but the meaning of such interaction is still unclear. It is known that β_2GPI may serve as a major factor in clearing the plasma liposome[10] as well as an anticoagulant in blood[11]. β_2GPI may also modulate the function of kidney and placenta. The abnormality of plasma β_2GPI level has been shown to be associated with many diseases such as arterial and venous thrombosis, recurrent abortion and alcoholic liver disease[12,13]. In addition, it has been found that, in diabetes or atherosclerosis patients, the concentration of plasma β_2GPI increases and distribution of the protein among different types of lipoprotein is perturbed[14,15]. Recent research on β_2GPI has given a further impetus to the discovery that lipid- associated β_2GPI can bind to some pathogenic antigens or proteins such as HBV Dane particles, protein p18, p26, gp160 of HIV and so on[16], and perhaps hepatitis virus antigen[17,18]. These findings highlighted a potentially critical role of β_2GPI in the mechanism of hepatitis B, AIDS, and systemic lupus erythematosus, etc.

The lipid-binding and transportation functions are considered as a basic mechanism related to its physiological and pathogenic functions. It has been demonstrated by several labs that β_2GPI prefers to bind negatively charged phospholipids[9,19-21]. It was reported that β_2GPI could be removed from the membranes with a weakly acidic buffer and it was partly associated with chylomicrons and high-density lipoproteins, both of which were targeted to hepatocytes during the normal course of lipid metabolism[22]. In the present paper, the characteristics of β_2GPI interacting with HBsAg were further examined by several measurements. As a result, the standpoints that β_2GPI might participate in HBV infection were held out accordingly. Our results may also help to explain how β_2GPI facilitates HBV transportation, location and the important roles of β_2GPI in HBV infection.

MATERIALS AND METHODS

Reagents

TEMED, APS, PMSF, and aprotinin purchased from Sigma Chemical Co., acrylamide and biacrylamide purchased from Serva, human β_2GPI provided by Prof. Zhang GR from Jilin University, rHBsAg offered by Zhang HY from Jilin Institute of Family Plan, Hybond obtained from Amersham, SDS, NP-40, Coomasie brilliant blue obtained from Fluka (Finland). The other chemicals used were of analytical grade made in China.

ELISA-based determination of b_2GPI-rHBsAg interaction

rHBsAg was diluted into 0.125 μg/ml, 0.5 μg/ml and 2 μg/ml in 0.05 $NaHCO_3$ (pH 9.4) and added to 96-well plates respectively at 4 ℃ overnight (8 wells/group). Non-specific sites were blocked with PBS containing 1 % BSA for 1.5 h at 37 ℃. Plates were washed three times between the different incubation steps. Biotinylated β_2GPI was added to every well followed by adding HRP-Avidin and substrate consequentially. Simultaneously, 40 ng of non-labeled β_2GPI was added to

4well/group as a competitor. OPD was used to develop color and the intensity of color was quantified at 492 nm with Model 550 Microplate Reader (Bio-Rad). In addition, BSA was used as negative control (2 ug/ml, 1 ug/ml, 0.2 ug/ml), to observe its binding to β_2GPI.

SDS-PAGE and ligand blotting

The β_2GPI protein was performed by SDS-PAGE using the vertical electrophoritic apparatus (Bio-Rad) on 12 % acrylamide under reduced and non-reduced condition. The gels were stained with Coomassie brilliant blue to visualize the proteins. The proteins separated were transferred onto nitrocellulose using an electric transfer system at 50 V for 16 min, followed by immunoblot analysis employing biotinylated rHBsAg as a detecting probe and DAB as a developing system. The blotting buffer consisted of phosphate-buffered saline (10 mM phosphate, pH7.5, 138 mM NaCl, 2.7 mM KCl) containing 5 % dried skimmed milk powder and 1 % Tween 20 detergent (Sigma). Biotinylated rHBsAg was used at a dilution of 1/200 and HRP-avidin (Huamei Company), a dilution of 1/200. The density was analyzed with Luzex-F Image-analysis System.

Statistical analysis

Results from quantitative parameters were presented as mean ±SD and comparisons of which were performed using the Student' s *t* test.

RESULTS

ELISA-based determination of b_2GPI- rHBsAg interaction

rHBsAg was diluted into 0.125 μg/ml, 0.5 μg/ml and 2 μg/ml and used as capture antibody to coat the plates, then biotinlyated β_2GPI was added to interact with rHBsAg, simultaneously we used non- biotinlyated β_2GPI to observe the competitive binding interaction. The following figure indicated that with the increase of rHBsAg the binding of β_2GPIto rHBsAg elevated and these changes had statistic significance (*vs* 0.125 μg/ml group, $P<0.05$). When we added non- biotinlyated β_2GPI, the OD value significantly decreased though they still were positively relevant to rHBsAg, suggesting that non-biotinlyated β_2GPI competed with biotinlyated β_2GPI to saturate the binding sites on rHBsAg (Figure 1). Meanwhile BSA was used as negative control to substitute for rHBsAg coating the plates, the results indicated no interaction between β_2GPI and BSA, (Figure 2) suggesting the affinity of β_2GPI to rHBsAg was specific.

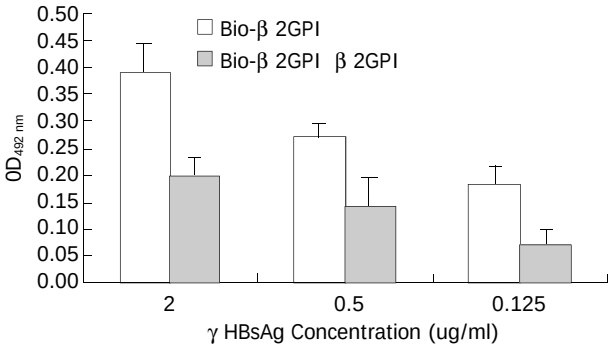

Figure 1 Comparative binding reaction of β_2GPI to rHBsAg by ELISA-based determination of protein interaction.

Binding of b_2GPI to rHBsAg observed by ligand blotting

The discrepancy between ligand blotting and Western blotting was that the former made use of ligand-receptor reaction, while the latter, the antigen-antibody interaction. The image showing -50 kDa protein bands in both lane 1 and lane 2 represented reduced (with DTT) and non-reduced (without DTT) condition, respectively (Figure 3). The results indicated that β_2GPI might bind to rHBsAg no matter whether it was under reduced condition or not, which manifested difference from that reported by Mehdi *et al*[17]. The subsequent digital scaning by Luzex-F Imager confirmed no quantitative changes in density between lane1 and lane 2.

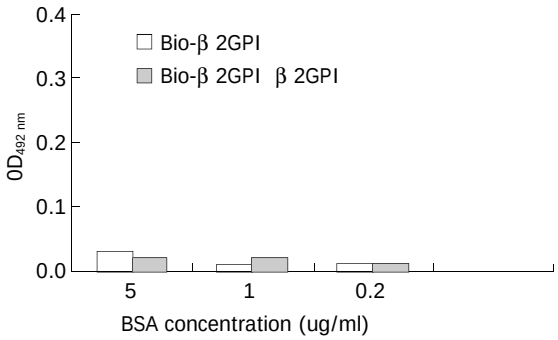

Figure 2 Comparative binding reaction of β_2GPI to BSA by ELISA-based determination of protein interaction.

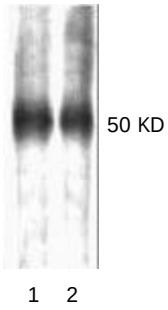

Figure 3 Reduced (lane1) and non-reduced (lane2) human β_2GPI (1 μg/lane) was separated with 12 % SDS-PAGE and applied to Hybond nitrocellous membrane, blocked with 5 % skimmed milk, then probed with biotinylated rHBsAg, color was developed with HRP-avidin in DAB solution. Single band at -50 kDa was observed, no significant diference in color density was observd, which was further confirmed by digital scaning.

DISCUSSION

Hepatitis B virus (HBV) is a member of the hepadnavirus family, which includes duck HBV, woodchuck hepatitis virus and ground squirrel hepatitis virus. These viruses are highly infectious for their host animals, targeting primarily, though not exclusively, the liver. Although many researches have been done, it is not clear which of these virus' components is in responsible for its attachment to a target cell[23]. As a step toward identifying the mechanism of HBV targeting hepatocytes, Haider Mehdi reported that a 50 kDa protein known as β_2GPI, which could be removed from the membranes with a weakly acidic buffer, might participate in the infection of HBV. Examination of human serum revealed that β_2GPI was a serum protein. Isolation of plasma lipoproteins revealed that β_2GPI was in part associated with chylomicrons and high-density lipoproteins, both of which are targeted to hepatocytes during the normal course of lipid metabolism[21]. In this study, we further examined the possible roles of β_2GPI in HBV infection. A ligand-blotting system was used to identify and partially characterize a rHBsAg-binding protein associated with hepatocyte membrane, plasma and lipoproteins. Immunoassay was performed to characterize the properties of rHBsAg binding to β_2GPI and to demonstrate the specificity of this

interaction.

β_2GPI is a glycoprotein with four N-linked carbohydrate chains[2,3] present at concentrations of approximately 200 μg/ml in serum[17]. The 326-residue mature protein is composed of a 61 amino acid motif repeated four times, followed by one longer, modified repeat. Each of the first four repeats contains four cysteines in conserved positions, at least one of which is critical for its rHBsAg-binding activity. This pattern of disulfide bonds is similar to the short consensus repeat units found in a family of approximately 20 proteins which includes many of the complement control proteins. It is interesting that the measles virus receptor, CD46[24,25] also belongs to this short consensus repeat family.

The work described in the present report was to reveal the possible roles of β_2GPI in HBV infection. As we have known that β_2GPI may target to hepatocytes in the form of chylomicrons and high-density lipoproteins. The result of the present paper suggested that β_2GPI might specifically bind to HBsAg no matter whether it was under reduced condition or not. We might well reckon that β_2GPI might contribute to transportation of HBV to hepatocytes as a kind of carrier. Since β_2GPI is associated with lipoproteins, particularly chylomicrons and HDL, it is possible that HBV binds to β_2GPI on the surface of these lipoprotein particles. In the bloodstream, chylomicrons are partially degraded by lipoprotein lipase, resulting in chylomicron remnants, which are taken up by hepatocytes. HDLs are also taken up by hepatocytes in the process of "reverse cholesterol transport". They may have been associated with the process of HBV infection. It is tempted to speculate that infectious HBV might bind to chylomicron or HDL particles by interacting with β_2GPI and be taken into hepatocytes as a "hitchhiker" along with these lipoproteins. Our results showed that β_2GP I might bind to rHBsAg no matter whether it was under reduced condition or not manifested difference from that reported by Mehdi *et al*[17]. In Mehdi experimental system, they used human serum to observe the relationship between β_2GPI and HBsAg, while we used purified β_2GPI. There might exist differences between the two kinds of β_2GPI sources in their first, second or third structure, which might lead to the differences of sensitivity to reduced-agents. Moreover, the genetic heterogeneity of β_2GPI could also cause mutations of sequences of some domains, which eventually affect the binding of β_2GPI to rHBsAg. Related issues should be further investigated.

To sum up, if HBV infection to hepatocytes involves β_2GPI on chylomicrons and /or HDL, it is a novel mechanism for virus attachment and entry.

Abstract

AIM: To study the inhibitory effect of all-trans retinoic acid on human hepatocellular carcinoma cell line SMMC-7721 and to explore the mechanism of its effect.

METHODS: SMMC-7721 cells were divided into two groups, one treated with all-trans retinoic acid (ATRA) for 5 days and the other as a control group. Light microscope and electron microscope were used to observe the morphological changes. Telomerase activity was analyzed with silver-stained telomere repeated assay protocal (TRAP). Expression of Caspase-3 was demonstrated with western blot.

RESULTS: ATRA-treated cells showed differentiation features including small and pyknotic nuclei, densely stained chromatin and fewer microvilli. Besides, ATRA could inhibit the activity of telomerase, promote the expression of Caspase-3 and its activation.

CONCLUSION: Telomerase activity and Caspase-3 expression are changed in human hepatocellular carcinoma cell line SMMC-7721 treated with all-trans retinioc acid. The inhibition of telomerase activity and the activation of Caspase-3 may be the key steps through which ATRA inhibits the proliferation of SMMC-7721 cell line.

INTRODUCTION

Several isomers have been found for retinoic acid (RA), an oxidative product of vitamin A, including all-trans retinoic acid (ATRA) and 9-cis retinoic acid (9C-RA). ATRA has been used successfully in treatment of acute promyelocytic leukemia and other hematologic diseases[1-3]. It can induce cellular differentiation of many malignant tumors and inhibit their growth[4-11]. Morphological and biological changes were also observed in the human hepatocellular carcinoma (HCC) cell line SMMC-7721, treated with ATRA[12,13], but the mechanism remains obscure. For this reason, the changes in telomerase activity and Caspase-3 expression induced by ATRA were analyzed in SMMC-7721 in this study.

MATERIALS AND METHODS

Cell culture

The hepatocellular carcinoma cell line SMMC-7721, was kindly provided by the Hematology Institute of the First Hospital of Norman Bethune University of Medical Sciences, and cultivated in Iscove' s modified Dulbecco' s medium (IMDM, Gibco) containing 10 % fetal bovine serum at 37 ℃ in an incubator with 5 % CO_2. During the exponential stage, ATRA was added to the medium (10^{-5} mmol/L). Cells growing in the ATRA-free medium were used as the control group.

Morphological observation

The ATRA-treated cells and the control cells were observed everyday. After 5 days, the cells were collected, stained and observed under the light microscope. About 10^7 cells were collected, washed with cold saline, and fixed with 4 % glutaral and 1 % osmium acid. After dehydration, embedding, sectioning and staining, the cells were observed under transmission electron microscope.

Activity of telomerase assayed by TRAP silver staining

About 2.5×10^5 cells were collected, washed and homogenized. The telomerase activity was detected using a TRAP kit following instructions of manufacturer (Beijing Tiangekangning biotech institute). The reaction system, containing 25 μl TRAP agent, 0.2 μl Taq enzyme and 1 μl cell extract, was incubated for 30 min at 25 ℃. Then 0.5 μl of primer was added and PCR was conducted for 30 cycles with denaturing at 94 ℃ for 30 s, annealing at 60 ℃ for 30 s, extending at 72 ℃ for 30 s. 15 μl PCR products was loaded onto a 9 % non-degenerative SDS gel, resolved through the SDS-PAGE, demonstrated by a reaction in 0.2 % silver nitrate for 15 min, and visualized by incubation in 30 g/L anhydrous sodium carbonate containing formaldehyde (1 ml/L). The activity of telomerase was indicated by the presence of a 6 bp-DNA ladder. The cell extracts inactivated by incubation at 75 ℃ for 10 min were used as the negative control.

Expression of Caspase-3 assayed by western blot

About 10^6 SMMC-7721 cells were harvested, washed, and lyzed in the 5 volumes extract buffer (5 mM Tris-Cl (pH8.0), 150 mM NaCl, 5 mM EDTA, 1 mM DTT, 100 μg/ml PMSF, 2 μg/ml aprotinin, 1 % NP-40) in the iced bath for 20 min. The supernatant was stored at -70 ℃. After protein quantification, 80 μg of the extraction was subjected to SDS-PAGE. Proteins resolved on the gel were transferred to a nitrocellulose filter (Amersham) in the buffer containing 48 mmol/L Tris, 39 mmol/L glycocol, 0.037 % SDS and 20 % methanol. After being blocked in phosphate buffer saline containing 5 % defatted milk, the blots were incubated with goat antibody against Caspase-3 (Santa Cruz). After being washed three times, the filter was incubated with HRP-labeled rabbit anti-goat immunoglobulin, and the reaction was visualized by incubation with a buffer containing DAB and H_2O_2.

RESULTS

Morphological changes

ATRA-treated cells appeared spindle-shaped, rather than polygon-shaped as under normal conditions. Their nuclei became smaller and pyknotic. The cytoplasma was also stained densely. Cell shrinkage, loss of microvilli, chromatin clumps and reduction of the nuclear/cytoplasmic ratio were noted under the electron microscope. The mitochondria proliferation, enlargement of Golgi complex, cytoplasmic vacuolation and glycogen accumulation, as well as lipofuscin and tonofilaments were also observed (Figure 1).

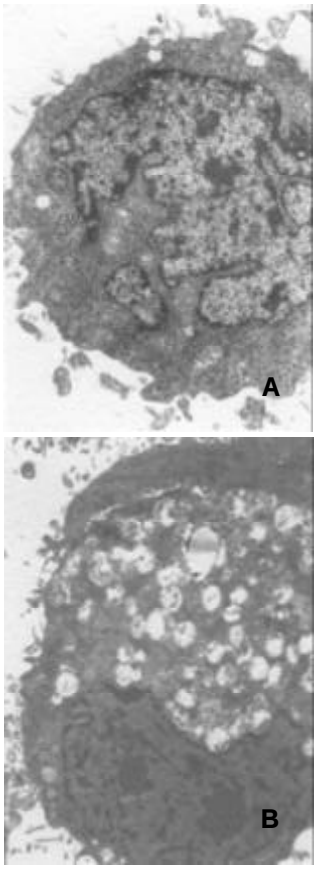

Figure 1 Morphology of SMMC-7721 observed under transmission electron microscope. Untreated-cells have many microvilli, and their nuclei have a great of incisure (A). ATRA-treated cells have smaller volume, fewer microvilli on the surface, densed chromatin and increased heterochromatin. With the plasma increased, the nuclear/cytoplasmic ratio decreased. The mitochondria also increased. The Golgi complex became bigger. More vacuole and glycogen were seen. There were also many lipofuscin and tonofilaments (B).

Activity of telomerase

The untreated cells showed a 6 bp ladder pattern, suggesting the active telomerase, so it served as the positive control. The negative control did not show the pattern, the samples were inactivated at 75 ℃. Similarly the ATRA-treated cells did not show the DNA ladder. We considered that ATRA could inhibit the telomerase activity (Figure 2).

Expression of Caspase-3

All the control groups showed a weak signal at the position of 32 kD, suggesting the presence of Caspase-3 expression at a low level. For the ATRA-treated cells, the 32 kD signal was shown to be strong. In addition, another signal at the position of 20 kD was detected. The latter represented the p20 subunit of Caspase-3, an active form of the molecule (Figure 3).

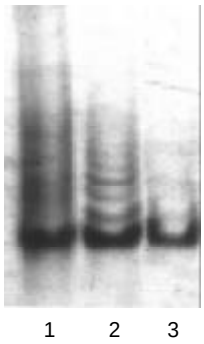

Figure 2 Telomerase activity of SMMC-7721. The untreated cells showed 6bp ladder pattern, suggesting the active telomerase. So it served as the positive control (Lane 2). The negative control did not show the DNA ladder because the sample was inactivated at 75 ℃ (Lane 3). The ATRA-treated cells showed no ladder as the negative control (Lane 1).

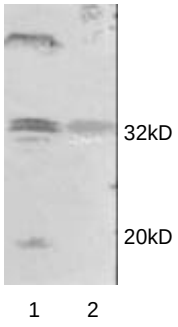

Figure 3 The expression of Caspase-3. All the control groups showed weak signals at the position of 32kD, suggesting the presence of Caspase-3 (Lane 2). For the ATRA-treated cells, the 32kD signal was shown to be stronger. In addition, another signal at the position of 20kD was detected. The latter represented the p20 subunit of Caspase-3, an active form of the molecule (Lane 1).

DISCUSSION

It is estimated that about 437 000 people die of HCC every year worldwide, and that their 5-year survival rate is below 3 %. It is believed that development of HCC is associated with many factors[14-18]. Several gene mutations have been proven to play some roles during this process[19]. Eukaryotic chromosomes are capped with repetitive telomere sequences that appear important for maintaining chromosomal integrity. In all normal somatic cells, each cycle of cell division and DNA replication results in the loss of 50-200 terminal nucleotides from each chromosome. This gradually results in instability of the chromosomes and cell death[20,21]. Telomerase is a type of reverse transcriptase being essential in many cases for telomere stability and cell proliferation, immortalization and transformation[22-35].

Recently, more than ten types of proteases with homology to ICE/CED-3 that is specific to aspartic acid have been found. The Caspase family plays key biological roles in inflammatory responses and in regulation of apoptosis of mammalian cells. Among them, Caspase-3 is known as a key protease whose activation can induce apoptosis of mammalian cells[36-42]. It lies in the upper stream of a series of cascade reactions. Therefore, it may be of some help to delineate Caspase-3 expression during the ATRA-associated cell differentiation and death for further understanding of its mechanism.

In the present study, a reduction of telomerase activity, upregulation of Caspase-3 expression and the activation of this molecule were linked to the ATRA-induced differentiation of

SMMC-7721 cells. A few mechanisms have been proposed for the growth inhibition of HCC cells by ATRA. For example, ATRA can inhibit telomerase activity and shorten telomere length of cancer cells and disrupt the stability of the chromosomes. Alternatively, Caspase may also be involved in this process. ATRA activates Caspase-3, stimulating a series of apoptotic signals and resulting in cell death. It is presumed that ATRA may directly or indirectly affect the function of Caspase-3 at the following three levels: 1) up-regulating the expression of Caspase-3; 2) indirectly acting on the upper stream regulator of Caspase-3; and 3) directly acting on Caspase-3 itself and promoting its activity. In conclusion, inactivation of telomerase and activation of Caspase-3 may be important pathways for the inhibition of HCC cell proliferation by ATRA.

Abstract

AIM: To study the therapeutic effectiveness of intra-tumor injection of Xiao-Zhi-Ling(XZL) on transplanted hepatoma in rats.

METHODS: Sixty rats were divided into 3 groups (groups S, X and E), 20 in each. Different drugs were injected into the implanted hepatoma (Group S with 0.2 ml saline as control, group X with 0.2 ml XZL, group E with 0.2 ml ethanol). After 3 days and 8 days respectively, we detected the hepatoma volume (HV), the level of albumin, alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase (ALP) in serum, and the expression of proliferating cell nuclear antigen (PCNA) in hepatoma.

RESULTS: The results were obtained after 3 days, the HVs in groups X and E were smaller than those in group S (group X *vs* S P=0.010*, group E *vs* S P=0.002*, P<0.05). The levels of ALT and AST in group S and X were lower than those in group E (ALT Group S *vs* E P=0.019*, group X *vs* E P=0.003*, P<0.05; AST group X *vs* E P=0.002*, P<0.05). The levels of ALP and PCNA labeling index in group X were lower than those in group S and E (ALP group X *vs* S P=0.000*, group X *vs* E P=0.000*. P<0.05; PCNA group X *vs* S P=0.008*, group X *vs* E P=0.048*, P<0.05). The levels of creatinine in group S were lower than those in group E (group S *vs* E P=0.017, P<0.05). The degree of tumor necrosis in group S was lower than those in groups X and E (group S *vs* X P=0.006*, group S *vs* E P=0.006*, P<0.05). After 8 days, the HVs in groups X and E were smaller than those in group S (group X *vs* S P=0.007*, group E *vs* S P=0.004*, P<0.05). The difference of HVs between groups X and E was not significant. The levels of albumin, ALT, AST and creatinine in group X were not higher than those in other groups, the levels of ALP and PCNA in group X were lower than those in groups S and E (ALP group X *vs* E P=0.006* P<0.05; PCNA group X *vs* S P=0.044*, group X *vs* E P=0.021*, P<0.05). The degree of tumor necrosis in group S was lower than that in groups X and E (group S *vs* X P=0.001*, group S *vs* E P=0.002*, P<0.05).

CONCLUSION: The therapeutic effectiveness of intra-tumor injection of XZL and ethanol on implanted hepatoma is obvious, but the toxicity of XZL on liver function is markedly lower than that of group E, at the same time XZL can inhibit the growth of tumor. XZL is relatively better and safer than ethanol in intra-tumor injection therapy.

INTRODUCTION

The resection rate of hepatocellular carcinoma (HCC) is only about 20 %. Percutaneous ethanol injection therapy (PEIT) and transcatheter arterial chemoembolization (TACE) can be used in patients who have lost the chance of surgical operation. Both could be used easily and widely. But to small HCC, they cannot treat it thoroughly. To huge HCC, repeated use can cause liver function failure and biliary tract injury, so the application in clinic is limited. Xiao-Zhi-Ling (XZL) is a traditional Chinese drug, it can cause vascular embolization and tissue fibrosis. In this research XZL was used in the treatment of implanted hepatoma in rats in order to find its therapeutic effectiveness.

MATERIALS AND METHODS

Tumor implantation

Walker-256 tumor cells were injected into the abdominal cavity of Wistar rats, tumor ascites were removed from the abdominal cavity 7 days later. After diluting them subcutaneous vaccination was given in right forefoot axillary fossa of healthy Wistar rats[1]. 8 days later we obtained the subcutaneous tumor which grew quickly, then cut it into pieces of 1×1×1 mm^3, put them into RPMI medium 1640[2,3]. A small subcapsular incision on the left lateral lobe of the liver of healthy Wistar rats was made. Tumor fragments were gently put into the pocket and abdominal wall was then closed. After that rats were maintained on the previous diet[4,5].

Experimental procedures

8 days after tumor cells were implanted, 60 rats were divided into 3 groups (groups S, X and E), 20 rats in each group. Different drugs were injected into the implanted hepatoma of each rat, group S with 0.2 ml saline as control, group X with 0.2 ml XZL (obtained from Ji-an Pharm Corp in Jilin province, China), group E with 0.2 ml ethanol.

After 3 days and 8 days respectively, 10 rats were sacrificed in each group at random. Tumors in the left lobe of liver were removed and fixed in 10 % formalin. The respective blood samples were centrifuged, then the level of albumin, alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase (ALP) in serum were detected[6,7].

Immunohistochemistry analysis

The implanted liver tumor tissues were paraffin-embedded and sectioned, sections were made for standard histological detection using hematoxylin and eosin[8,9]. The expression of proliferating cell nuclear antigen (PCNA) in hepatoma was detected in each case[10,11].

Statistical analysis

The data were expressed as $\bar{x}\pm s$. Statistical differences were

analyzed by *t*-test, a value of $P<0.05$ was considered significant. The difference between groups was compared by LAD method.

RESULTS

Comparison of hepatoma volume (HV) between different groups (Table 1 and 2)

After 3 and 8 days, the HVs in group X and E were smaller than those in group S ($P<0.05$).

By the 3rd day, the differences of hepatoma volume between different groups were as follows: group S *vs* X $P=0.010$*, group S *vs* E $P=0.002$*, group X *vs* E $P=0.443$.

By the 8th day, the differences of hepatoma volume between different groups were as follows: group S *vs* X $P=0.007$*, group S *vs* E $P=0.004$*, group X *vs* E $P=0.771$.

Comparison of hepatoma necrosis between different groups

After 3 days the difference of hepatoma necrosis between groups X and S, and groups E and S was significant ($P<0.01$). After 8 days group S was significantly different from groups X and E. But there was no difference between groups X and E.

By the 3rd day, the differences of hepatoma necrosis between different groups were as follows: group S *vs* X $P=0.006$*, group S *vs* E $P=0.006$*, group X *vs* E $P=1.000$.

By the 8th day, the differences of hepatoma necrosis between different groups were as follows: group S *vs* X $P=0.001$*, group S *vs* E $P=0.002$*, group X *vs* E $P=0.690$.

Rate of tumor inhibition (RTI)

Tumor volume was calculated by the formula ($\pi/6\times$length$\times$width$\times$height). The rate of tumor inhibition (RTI) could be calculated by the formula: (volume of control group -volume of test group)/volume of control group$\times$100 %; 3 and 8 days after injecting drug, RTIs in groups X and E were 45.86 %, 57.73 % and 62.47 %, 68.24 %. MDDT stands for multiplication diameter time, which indicates the growth rate of tumor. Table 3 shows different growth rates in the 3 groups.

Table 3 MDDT of the tumor in groups S, X and E

Group	MD (3 days)	MD (8 days)	MDDT
Group S	4.56	9.62	4.51
Group X	4.6	6.74	10.75
Group E	3.54	6.5	5.9

Comparison of hepatic and renal function (Table 1 and 2)

Serum albumin After 3 and 8 days the level of serum albumin in group X was higher than those in groups S and E, but there was no statistical significance ($P=0.13$).

Serum ALT After 3 days, the level of serum ALT in groups S and X was lower than that in group E, there was statistical significance ($P<0.01$). After 8 days, the level of serum ALT showed no statistical difference among three groups ($P>0.05$). By the 3rd day, the differences between every two groups were as follows: group S *vs* X $P=0.309$, group S *vs* E $P=0.019$*, group X *vs* E $P=0.003$*.

Serum AST After 3 days, the level of serum AST showed statistical difference among three groups ($P<0.05$). After 8 days, the level of serum AST showed no statistical difference among three groups ($P>0.05$). By the 3rd day, the differences between every two groups were as follows: group S *vs* X $P=0.077$, group S *vs* E $P=0.067$, group X *vs* E $P=0.002$*.

Serum ALP After 3 days the level of serum ALP in group X was lower than those in groups S and E, there was statistical significance ($P<0.01$). After 8 days the level of serum ALP in group X was lower than that in group E, there was statistical significance ($P<0.01$). By the 3rd day, the differences between every two groups were as follows: group S *vs* X $P=0.000$*, group S *vs* E $P=0.649$, group X *vs* E $P=0.000$*. By the 8th day, the

PCNA	56.20±8.67	41.40±10.00	58.80±12.10	4.063	0.045

differences between every two groups were as follows: group S *vs* X, *P*=0.846, group S *vs* E, *P*=0.004*, group X *vs* E, *P*=0.006*.

Serum creatinine After 3 days the level of serum creatinine in group E was higher than that in group S. There was statistical significance among three groups ($P<0.05$). After 8 days there was no statistical difference among three groups ($P>0.05$). By the 3rd day, the differences between every two groups were as follows: group S *vs* X *P*=0.054, group S *vs* E *P*=0.017*, group X *vs* E *P*=0.543.

PCNA expression in tumor tissue (Table 1 and 2)

After 3 and 8 days fine positive expression existed in the remnant tumor tissue in every group. PCNA labeling index among 3 groups was statistically different ($P<0.05$). PCNA labeling index in group X was lower than that in groups S and E, but there was no statistical significance between groups S and E ($P>0.05$). By the 3rd day, the differences between every two groups were as follows: group S *vs* X *P*=0.008*, group S *vs* E *P*=0.350, group X *vs* E *P*=0.048*. By the 8th day, the differences between every two groups were as follows: group S *vs* X *P*=0.044*, group S *vs* E *P*=0.700, group X *vs* E *P*=0.021*.

DISCUSSION

Primary liver carcinoma is one of the most popular malignancies in China, and its incidence has been increasing in recent years. The reported mortality of primary liver carcinoma in China is higher than that of other malignant tumors. Because of difficulty in early diagnosis, 75 % of the clinically diagnosed are large ones when the patients lose the opportunity of operation. Non-operation therapy becomes more and more important, and many basic researches have been done[12,13]. In some experiments, massive proliferation of donor-derived normal hepatocytes was observed in the liver of rats previously given retrorsine (RS). Suicide gene therapy based on ganciclovir (GCV) metabolism by transgene herpes simplex thymidine kinase (HSV-1 TK) has been used to selectively kill proliferating cells in hepatic tumor. Effect of Avemar and Avemar + vitamin C on hepatic tumor growth was observed in experimental animals. Through various experiments, some encouraging results have been reported[14,15]. In the nude mice hepatoma model, the antitumor effects of pDR2-TK/GCV system on tumor growth were evaluated. Through MTT method, they found that the pDR2-TK/GCV had cytotoxic effect and about 70 % SMMC-7721 cells were killed when GCV was at 1 000 umol/L. *In vivo* experiment showed that the tumor size in nude mice with transferred pDR2-TK gene was significantly smaller than that in control group. PEIT was used clinically, because this method of intra-tumor injection was easy, cheap and could be used repeatedly, it has been widely used. But both of these methods cannot treat the patients thoroughly. Repeated use can cause liver function failure and biliary tract injury. Therefore researches on drugs which can be used in intra-tumor injection therapy become more and more important. Some kinds of traditional Chinese drugs were purified and the immunosuppressive function was examined[16].

XZL is mainly composed of Wu-Bei-Zi extracts and alum, both of which have the function of astringing, antidiarrheal, hemostasis and antisepsis. The vascular vessels would astringe immediately after injection of XZL. Then inflammatory reaction and hyperplasia would occur in the local artery. Endoangiitis and intravascular coagulation would occur in arteries and veins. All the above finally lead to fibrinoid necrosis of local tissue. These changes perhaps are the reason why XZL has antineoplasitc activity.

From this research we conclude that the therapeutic effects of intra-tumor injection of XZL on implanted hepatoma is obvious. XZL can evidently inhibit the growth of tumor. The inhibition of XZL on implanted hepatoma is no better than that of PEIT according to statistical analyses. But in terms of MDDT, XZL is much better than PEIT, perhaps because the toxicity of XZL on liver function is markedly lower than that of ethanol.

Based on the results of liver and renal function, the toxicity of XZL on liver function is relatively less severe than that of ethanol. For patients with disorder of liver function, PEIT could not be used, we can try XZL instead. The dose of ethanol is very important in treatment, high-dose of ethanol can lead to liver function failure and systemic toxicity to the patient, but low-dose can not kill the edge cells of the tumor thoroughly. Many experiments have shown that high-dose therapy of common drugs can lead to hepatic function failure, but if low-dose of drug is given, tumor cells cannot be killed thoroughly, because the tumor cells are supplied by duplicated vessels (liver artery and portal vein) and grow rapidly than before[17]. The patients' prognosis could be influenced and the tumor perhaps would recur and metastasize quickly. So we could use XZL to resolve this problem. We can inject XZL into the edge of the tumor to kill the tumor cells, thus to improve the therapeutic effectiveness, reduce recurrence and metastases of the tumor. This study revealed that 3 and 8 days after injection of drug (saline, XZL and ethanol), fine positive expression of PCNA occurred in the remnant tumor tissue of every group. PCNA labeling index among 3 groups was significantly different. PCNA labeling index in Group X was lower than that in groups S and E ($P<0.05$), but there was no statistical significance between groups S and E ($P>0.05$). This result implies although injection of ethanol can lead to necrosis of tumor tissue, it cannot influence proliferation activity of the remnant tumor tissues. Intra-tumor injection of XZL into implanted hepatoma can reduce the expression of PCNA labeling index, suggesting XZL can inhibit the proliferation activity of tumor cells. This might be the reason why XZL has the antineoplasitc activity.

Abstract

AIM: To introduce combined liver-small bowel transplantation in pigs.

METHODS: Eighteen transplantations in 36 large white pigs were performed. Three modifications in combined liver-small bowel transplantation model were applied: Veno-venous bypass was not used. Preservation of the donor duodenum and head of pancreas in continuity with the combined graft to avoid biliary reconstruction. The splenic vein of donor was anastomosed end-to-end with the portal vein of recipients by the formation of a "cuff".

RESULTS: Without immunosuppressive therapy, 72-hour survival rate of the transplanted animals was 72 % (13/18). Five of 18 pigs operated died of respiratory failure (3 cases) and bleeding during hepatectomy (2 cases). The longest survival time of animals was 6 days.

CONCLUSION: Our surgical modifications are feasible and reliable, which have made the transplantation in pigs simpler and less aggressive, and thus these can be used for preclinical study.

INTRODUCTION

Despite intestinal transplantation technique for the treatment of irreversible failure of the intestine has been improved, clinical intestinal transplantation still remains at an experimental stage. Compared with other solid organ transplantations, attempts at human small bowel transplantation had disappointed results in terms of survival of patients and grafts[1-4]. Bowel transplant can also be performed as a part of a multivisceral graft[5]. Even though total parenteral nutrition (TPN) and home parenteral nutrition (HPN) allow many patients with intestinal failure to live with a high life quality, it has some severe and even fatal complications, such as catheter sepsis, severe cholestasis, and chronic secondary hepatopathy[6-8]. Many institutions have performed combined liver-small bowel transplantations in human and small animals, but few studies were conducted in large animals[9]. Pigs are one of the standard models for large animal transplantation due to the anatomic features. In order to improve clinical prognosis of liver-small bowel transplantation (LSBT), we investigated the modifications of the experimental model.

MATERIALS AND METHODS

Large white pigs weighing 25±5 kg were used for LSBT under general anesthesia[10]. Animals were fasted with free access to water for 24 hours prior to surgery. The size of donor pigs was the same as or smaller than that of recipients.

Donor operation

After vascular cannulation for venous and hemodynamic monitoring, the abdomen was entered at middle line xipho-pubic incision. After transection of transverse colon, the whole intestine tract was inspected thoroughly. Total colon including the ileocecal valve was transectioned. Hepato-gastric and spleno-gastric ligaments including splenic and left gastric arteries were ligated. The splenic vein was prepared for perfusion, and the ligaments around the liver were mobilized. Then the abdominal aorta was dissected from infrarenal aorta until one centimeter cranially to celiac axis. Lymphatic vessels were tied carefully to avoid lymphorrea after transplantation. And the vena cava was also dissected from infrarenal until suprahepatic cava. Before systemic heparinization, blood was drawn and saved for use in recipient operations. Before clamping the cranial aorta upper the celiac axis, the distal aorta was cannulated and 1.5 liter of UW solution was perfused through the infrarenal aorta and splenic venous *in situ* and venting from the supra diaphragm vena cava and infrarenal vena cava. To ameliorate cooling of the graft, the abdominal cavity was filled with cold saline and melting ice. Then the liver-small bowel was *en bloc* harvested in continuity with duodenum and pancreas.

Bench surgery

The *en block* liver-small bowel was preserved in cold UW solution with melting ice. The proximal aorta and the thoracic vena cava were ligated. The vascular pedicles for vascular anastomoses were prepared. Diaphragm veins were ligated and a continuous hemostatic suture was performed. The subtotal pancreas was transected, leaving the head and uncinate processing attached to the duodenum. The stump of the pancreas was stapled and then over-sewn with a continuous suture using 0/4 polypropylene.

Recipient operation

During the recipient operation, the end-tidal carbon dioxide, electrocardiogram and arterial, central vein, and pulmonary artery pressure were monitored.

The abdomen was accessed at a middle line xipho-pubic incision. Firstly a cystostomy was performed using a Foley's

catheter. The small bowel was resectioned except for short segments of proximal jejunum and distal ileum. The recipient' s infrarenal aorta and the vena cava were dissected and encircled for anastomosis. The hepatic hilum was transected with the portal vein preserved. Then hepatectomy was performed with preservation of hepatic part encircling the vena cava. In this period, transfusion was necessary. Three vascular anastomoses between the recipient and the donor were performed as followings: The recipient' s infrarenal vena cava side-to-end anastomosis with donor' s infrahepatic vena cava with continuous 4/0 polypropylene suture, the recipient' s infrarenal aorta side-to-end anastomosis with the donor' s infrarenal aorta with continuous 4/0 polypropylene suture, and the recipient' s distal portal vein end-to-end anastomosis with donor' s splenic vein by the formation of a "cuff". The gut continuity was established proximally between allograft jejunum and native jejunum and distally between allograft ileum and native ileum. A loop enterostomy was performed for endoscopies after transplantation. At last, a gastrostomy was performed to reduce the gastric pressure.

RESULTS

Mean operation time in the donor and recipient was 3.5 hours±10 minutes and 4.5 hours±15 minutes, respectively. During the recipient operation, there was no obvious hemodynamic alteration. Survival rate at 72 hours was 72 % (13/18). Three pigs died of respiratory failure and two of bleeding during hepatectomy. The longest survival time was 6 days without immunosuppression.

DISCUSSION

Multivisceral transplantation was firstly performed for the treatment of short bowel syndrome complicated with liver failure due to long-term hyperalimentation[11]. Starzl reported the first study in dogs in 1960s. Investigations with large animals have shown that multivisceral transplantation is a technically complicated procedure with high mortality[12]. We have been studying on improving surgical techniques of the transplantation for more than 6 months and performed 18 consecutive operations with three innovations.

Firstly, veno-venous bypass, necessary in the conventional experiments[9], was avoided, and thus made the operation simple and less aggressive. It also reduced the incidence of bleeding due to heparinization in operation. Considering the anatomic features of pigs, bleeding in hepatectomy in recipients is unavoidable. But based on our experiences in many preliminary operations, we could control this operative bleeding with the new techniques. In order to keep the recipient hemodynamicaly stable during this period, transfusion and solution were necessary. With this modification the duration of unhepatic period was also shortened.

Secondly, preservation of the donor duodenum and head of pancreas in continuity with the combined graft avoided the need for biliary reconstruction. The standard technique involved an obligatory reconstruction of the biliary system with a defunctionalized loop of proximal allograft jejunum[13]. Consequent limitations of this technique were biliary leaks, obstructions and strictions[14]. In our surgical technique, we eliminated hilar dissection, leaving the hepatoduodenal ligament undisturbed by including the intact duodenum and a rim of pancreatic tissue in the allograft. Apart from obviating biliary anastomotic complications and potential vascular torsion of the small bowel graft[14, 15], surgical modifications also made bench surgery simpler. This modification was applied in human transplantation with satisfaction[14,15]. Debera *et al*[15] reported that the remaining head of the pancreas on the combined liver-small bowel allograft was not associated with a high incidence of pancreatic complications.

The third modification was that the donor splenic vein was end-to-end anastomosed to the recipient' s distal portal vein by the formation of a "cuff". In the standard technique, the recipient' s portal vein was end-to-side anastomosed with the donor portal vein or supra mesenteric vein to avoid portal hypertension in native remnant viscera[9,15,16]. This innovation shortened the operation time, simplified the surgical procedure and also reduced venous stagnation of the allograft and native viscera.

Our technical refinements have made combined liver-small bowel transplantation in pigs simpler and less aggressive. And the technique of this model is feasible and can be used for preclinical study. However, animals experienced with this operation were faced with life threatening respiratory failure, infection, GVHD and rejection[17-27]. Much more work should be done to improve the outcomes of both experimental and clinical combined liver-small bowel transplantations.

Abstract

AIM: To investigate the presence of M2 antibodies specific for primary biliary cirrhosis (PBC) in asymptomatic Chinese and identify patients with early PBC.

METHODS: Enzyme-linked immunosorbent assay (ELISA) tests for M2 antibodies to recombinant protein were performed in 5 011 subjects (age range, 26-85 years; mean age: 45.81±15.02 years) who took an annual physical examination. M2-positive subjects were further analyzed for immunoglobulin (Ig) classes and subclasses of M2 antibodies. Clinical, biochemical and immunological data were obtained for M2-positive subjects. In addition, ultrasonography (US) or endoscopic retrograde cholangio-pancreatography (ERCP) was performed to exclude any disorders other than PBC.

RESULTS: M2 antibodies were detected in 8 (0.16 %) of the 5 011 subjects studied. Of the 8 subjects, 7 were female and 1 was male (age range: 40-74 years). An unexplained increase of serum alkaline phosphatase (ALP) and gamma glutamyl transpeptidase (γ-GT) values, often to striking levels, was detected in 4 M2-positive subjects, 3 of them accorded with the diagnostic criteria recommended by the American Association for the Study of Liver Diseases, even though they had no symptoms of PBC (such as fatigue, pruritus or jaundice). Liver biopsy was performed in two M2-positive subjects and the histology was compatible with PBC in both cases.

CONCLUSION: Our data, while not assessing the true prevalence of asymptomatic PBC in the general population, suggest that asymptomatic PBC is much more common in China than has been supposed.

INTRODUCTION

Primary biliary cirrhosis (PBC) is a chronic progressive cholestatic liver disease with autoimmune basis. Patients are typically females aged 35-65[1, 2]. Many patients with PBC have no specific symptoms, rather, they have unexplained liver function abnormalities. Progression occurs over years or decades. The end stage is an established biliary cirrhosis[1].

A hallmark feature of PBC is the presence of high titer antimitochondrial antibodies (AMA) in patients sera. AMA are divided into nine subgroups termed M1-M9 according to the autoantigens they recognize. It has been established that only those antibodies known as M2 are specific for PBC. M2 antibodies are detectable years or decades before the presence of clinical and histological features of PBC[3-7].

The major autoantigens recognized by M2 antibodies are members of the 2-oxo-acid dehydrogenase complex, including pyruvate dehydrogenase complex E2 (PDC-E2), branched chain 2-oxo-acid dehydrogenase complex E2 (BCOADC-E2) and 2-oxo-glutarate dehydrogenase complex E2 (OGDC-E2). The immunodominant epitopes of PDC-E2, BCOADC-E2 and OGDC-E2 have been mapped within the lipoyl domains. Antibodies to these corresponding autoantigens have been reported to appear in PBC patients with a positive rate of 95 %, 53-55 % and 39-88 % respectively[8-10]. Using the above three immunodominant lipoyl domains, 92-100 % of patients with PBC can be verified[9-12]. In contrast, there is no report that M2 are found in diseases other than PBC[13-18]. We have designed a triple hybrid clone, designated as BPO, that coexpresses the three immunodominant lipoyl domains of PDC-E2, BCOADC-E2 and OGDC-E2 from human sources. We established and then used clinically specific immunological methods with purified BPO to detect the M2 antibodies[19,20].

According to some research, there is a wide spread impression that the number of patients with PBC is on the rise, many of whom, thanks to the application of the immunological diagnostic methods, are diagnosed at a stage of asymptomatic PBC in recent years[21-23]. However, the M2-positive rate in Chinese general population has not yet been determined. In the present research, we investigated the prevalence of M2 antibodies which are specific for PBC in asymptomatic Chinese population and identified patients with early diseases.

MATERIALS AND METHODS

Establishment of the immunological method

Recombinant fusion protein fragments of human BCOADC-E2, PDC-E2, OGDC-E2 and the triple-expression hybrid clone (BPO) were expressed in *Escherichia coli*, and then purified with Ni-NTA affinity chromatography under denaturing conditions. Enzyme-linked immunosorbent assay (ELISA) method for detecting M2 antibodies was established using purified recombinant proteins. The cut-off O.D. value for positive ELISA was defined as 0.303[19,20].

Subjects

Sera were collected from subjects aged over 26 years who took an annual physical examination in 85 Hospital the Chinese PLA in Shanghai, China from January 1, 2000 to August 30, 2001. A total of 5 011 adults including 3 108 females and 1 903 males,

aged between 26-85, with a median age of 45.81±15.02 years were enrolled in this investigation. ELISA method was used for screening M2 antibodies. M2-positive sera were verified using the kit provided by the Euroimmun Research Center (Germany) which used purified porcine heart mitochondrial protein as antigen. Clinical, biochemical and immunological data were obtained for M2-positive persons. In addition, ultrasonography (US) or endoscopic retrograde cholangiopancreatography (ERCP) was performed to exclude any disorders other than PBC.

In 2000, the American Association for the Study of Liver Diseases (AASLD) recommended a guideline to aid the practicing physicians in diagnosing PBC: the diagnosis of PBC can be made with confidence in a patient with high-titer AMA (>1:40) and elevation of serum ALP and γ-GT in the absence of an alternative explanation (normal bile ducts on ultrasound)[24].

RESULTS

Immunology

Of the 5 011 subjects tested, 8 (0.16 %) had detectable titers of M2 antibodies using the ELISA containing the purified BPO. The reactivities were confirmed using the Euroimmun' s kit. Of the 8 M2-positive subjects, 7 were females and 1 was male (age range: 40-75 years). 6 M2-positive subjects were also AMA positive tested by indirect immunofluorescence (IIF) at a titer of >1:100. Antinuclear autoantibodies (ANA) were present in subjects 2, 5 and 8. Anti-smooth-muscle antibodies (SMA) were found in subject 5. Elevated IgM was found in 5 of 8, 4 had elevated IgG, and 2 had elevated IgA (Table 1). Of the 8 reactive sera, 2 recognized PDC-E2, 2 recognized BCOADC-E2, 2 recognized both PDC-E2 and BCOADC-E2, and 2 recognized BCOADC-E2 and OGDC-E2. Each positive serum was analyzed for the identification of the reactive classes and subclasses of Ig: 2/8 had detectable IgM antibodies against BCOADC-E2 and 3/8 against PDC-E2, 2/8 contained IgA antibodies to BCOADC-E2 and 1/8 against PDC-E2, 4/8 contained IgG antibodies to BCOADC-E2, 3/8 against PDC-E2 and 2/8 against OGDC-E2. The active IgG subclass of M2 antibodies were mostly in the IgG1 and IgG2 subclasses (Table 2).

Table 2 Class and subclass of reactive M2 antibodies

BCOADC-E2	PDC-E2	OGDC-E2
IgM 2/8[a]	3/8	0/8
IgA 2/8	1/8	0/8
IgG13/8	0/8	2/8
IgG21/8	2/8	0/8
IgG30/8	1/8	0/8
IgG40/8	0/8	0/8

[a]Positive samples/total samples.

Biochemistry

An unexplained increase of serum ALP and γ-GT values, often to striking levels, was detected in 4 subjects (subjects 4, 5, 6, 8). These subjects were previously unaware of the rise in serum ALP and γ-GT. The types of clinical conditions of these subjects (such as cardiac, respiratory diseases) did not explain their high serum ALP and γ-GT levels. Other aetiological studies for viral hepatitis, haemochromatosis, α_1 antitrypsin deficiency and Wilson' s disease were also excluded. Subjects 4, 5 and 6 accorded with the AASLD' s guideline, even though they had no symptoms of PBC (such as fatigue, pruritus or jaundice).

Histology

With written consent, a percutaneous liver biopsy was obtained in two patients (Patients 5 and 6). Biopsies were routinely examined by two different pathologists. Both biopsies showed the presence of lymphoid aggregates within the portal areas and were thought to be consistent with the diagnosis of PBC.

Table 1 Clinical and laboratory data of M2-positive subjects

	M2-positive subjects No.							
	1	2	3	4	5	6	7	8
Age (y)	52	42	40	62	47	67	53	74
Sex	F	F	F	F	F	F	F	M
Laboratory parameters								
AMA titer	1:160	1:640	Negative	1:1 000	1:640	1:100	1:640	Negative
M2 (O.D.)	0.544	0.578	0.583	0.602	0.655	0.673	0.987	2.157
M2 reactivity	P	B,P	B	B	B,O	B,O	P	B,P,
Other autoantibodies	Negative	ANA	Negative	Negative	ANA,SMA	Negative	Negative	ANA
IgG (g/l)	12.12	13.73	22.95	10.57	19.30	11.65	16.35	15.66
IgM (g/l)	2.37	4.32	4.17	4.78	3.98	2.80	2.73	9.52

ALT (U/l)	24	36	24	55	56	61	33	65
AST (U/l)	28	35	30	22	42	35	37	47
Ultrasonography	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal
ERCP	ND	ND	ND	ND	Normal	Normal	ND	Normal
Liver histology	ND	ND	ND	ND	Compatible	Compatible	ND	ND
Accorded with the AASLD's guideline	No	No	No	Yes	Yes	Yes	No	No

Upper limits of normal for IgG<15.5 g/L, IgM<2.8 g/L, IgA<4.0 g/L, ALP<112 U/L, γ-GT <54 U/L, T-Bil<21 umol/L, ALT<40 U/L, AST<40 U/L; T-Bil: total serum cholesterol; ND: not done.

Clinical data

Of these 8 subjects, three were considered to be healthy (Subjects 1, 4 and 5), subject 2 had thyroid disease, subject 3 had rheumatoid arthritis who had taken rifampicin for one year, subject 6 had hypertension and non-insulin-dependent diabetes, subject 7 had pain and effusion in her knees and ankles, and subject 9 had lung cancer. None of the 8 M2-positive persons had symptoms of liver diseases.

DISCUSSION

In this study, we took advantage of the recombinant protein: BPO to investigate the prevalence of M2 antibodies in asymptomatic Chinese population and identified patients with early diseases. We revealed 8 M2-positive cases in 5 011 subjects who took an annual physical examination. All these 8 M2-positive persons had no symptoms attributed to liver diseases. Three (Subjects 4, 5 and 6) of the 8 fulfilled the AASLD' s guideline. Liver biopsy was performed in subjects 5 and 6 and the histology was compatible with PBC in both cases.

One M2-positive subject (subject 8) had an unexplained increase of serum ALP, γ-GT levels asympatomatically, but AMA was negative using IIF method. According to the guideline recommended by AASLD in 2000 and the standards recommended by other researchers, AMA have long been used as an important marker for the diagnosis of PBC[21,23], but AMA is inferior to M2 in sensitivity and specificity. Among AMA, only M2 antibodies are specific for PBC. Other sub-types of AMA have been found in diverse conditions, including drug-induced disorders, cardiomyopathies, systemic lupus erythematosus, rheumatoid arthritis, tuberculosis, syphilis and hepatitis C. Using IIF, AMA cannot be sub-classified, indicating the nonspecific nature of AMA in diagnosis of PBC[25]. About 5-17 % of patients with liver biochemcal and histological features compatible with the diagnosis of PBC had no detectable AMA using IIF method. Autoimmune cholangitis (AIC) has been proposed as a better term for these patients[26-28]. In recent years, some researches have indicated that no difference was found between AMA-positive PBC and AIC, with respect to age, liver function tests, serum IgA, IgG and IgM, T-cell oligoclonality, laparoscopic features or pathologic stage(detection)[29-34], while the detection of M2 antibodies could be achieved by ELISA or Western-blot using recombinant antigen of PDC-E2, BCOADC-E2 and OGDC-E2[11,14,15,35]. Therefore, this subject should also be diagnosed as asymptomatic PBC.

In this research, we also found that 4 M2-positive subjects with normal liver biochemistry were women over 40 years old. Many studies indicated that the presence of AMA (M2 antibodies more accurately), the hallmark of PBC, preceded the clinical manifestations of the disease for many years. In 1986, Mitchison *et al*. reported 29 patients with AMA detected at a titer of at least 1:40 by IIF when screened for an autoimmune disease. None had any symptoms of a liver disease and all had normal liver biochemistry. An 18-year follow-up of this cohort revealed that 83 % developed persistent abnormal liver biochemistry and 76 % developed symptoms of PBC[3]. In 2001, Kisand *et al*. performed ELISA tests for antibodies to PDC-E2 in 1 961 persons, then identified 14 (0.71 %) asymptomatic persons with antibodies to PDC-E2. Eight of the 14 were followed-up. Three of the 8 persons with high levels of anti-PDC-E2 developed abnormal liver biochemical test results by the ninth year of follow-up[4]. Also in 2001, Koizumi *et al*. tested sera from 1 145 corporate workers who took an annual physical examination and evaluated the liver of AMA-positive subjects. AMA were detected in 5 of 1 145 (0.44 %) workers. AMA-positive people were all females aged over 40. All of the AMA-positive sera were also positive for M2 antibodies. Liver biopsy was performed in two M2-positive cases and the histology was compatible with PBC in both cases[5]. The authors of these studies concluded that, before the advent of any clinical or biochemical indications, individuals positive for M2 did have PBC.

In several autoimmune diseases, autoantibodies are detectable in the sera of patients several years before the onset of the disease. A better example is PBC. The appearance of M2 antibodies early in the course of the disease raises the possibility that they may precede and perhaps contribute to target organ damage. That M2 antibodies are present after transplantation in the presence of normal allograft histology is consistent with this suggestion. Recent evidences have shown that M2 antibodies to intracellular targets may act directly by penetrating the biliary epithelial cells, the target of PBC and interfering with cellular function[1,36].

According to James *et al*.[21], there is a widespread impression that the number of patients with PBC is increasing, although its prevalences vary widely. The prevalence of PBC rose from 201.9 per 10^6 in the adult population and 541.4 per 10^6 women over 40 in 1987 to 334.6 per 10^6 adults and 939.8 per 10^6 women over 40 in 1994 in northern England. Due to a lack of available diagnostic equipments, there are no reliable data relating to the epidemiology of PBC in China at present, and it is presumed that PBC is rare in China. However, we checked 10 patients with cirrhosis of liver hospitalized in January, February and April of 2000 whose serum immunological studies showed there was not any sign of viral infections, and the reason for their liver cirrhosis seemed unclear. But 7 of the 10 patients were found to be M2 positive by the detailed studies of the Euroimmun Research Center (Germany). In the past two years since we established the specific immunological methods for the diagnosis of PBC, over 300 patients have been assayed,125 of them have been determined to be M2-positive. Our recent research and related domestic reports in 2001 indicate PBC is probably not so rare in China as it was thought before[19,20,37].

The three major autoantigens of M2 antibodies, i.e, BCOADC-E2, PDC-E2 and OGDC-E2 have no cross-reactivity. The M2 antibodies in serum from a confirmed patient may be reactive with one or more of them. There does not appear to be any clinical correlation with the pattern of M2 reactivity. Consequently, the use of recombinant hybrid molecule offers a rapid, simple, and sensitive ELISA for the immunodiagnosis of PBC. AMA screening using standard IIF method in a population of several thousand patients is not possible because of the economic costs. On the contrary, our methodology allows the screening of a large series of population at a minimal cost. In summary, this is one of the first studies aimed at assessing the prevalence of asymptomatic PBC in a large sample of Chinese population. Our data suggest that asymptomatic PBC in a certain Chinese population is much more common than has been supposed.

Abstract

AIM: Hepatic cavernous hemangioma (HCH) is the most common benign tumor of the liver and its management is still controversial. Recent success *in situ* radiofrequency ablation of hepatic malignancies has led us to consider using this technique in patients with HCH. This study was to assess the efficacy, safety, and complications of percutaneous radiofrequency ablation (PRFA) under ultrasonography guidance in patients with HCH.

METHODS: Twelve patients (four men and eight women, age ranged 33-56 years, mean age was 41.7 years) with 15 hepatic cavernous hemangiomas (2.5 cm to 9.5 cm) were treated using the RF-2000 generator and 10-needle LeVeen electrode percutaneously guided by B-ultrasound. Lesions larger than 3 cm were treated by multiple overlapping ablations that encompass the entire lesion as well as a rim of normal liver tissue (approximately 0.5 cm).

RESULTS: All the patients who received PRFA therapy had no severe pain, bleeding or bile leakage during and after the procedures. Nine to 34 months' follow-up (mean, 21 months) by ultrasound and/or spiral CT scan demonstrated that the ablated lesions in this group were shrunk remarkably, and the shrunken range was 38-79 % (mean, 67 % per 21 months). The contrast enhancement was disappeared within the tumor or at its periphery in all cases on spiral CT scans obtained 3 to 6 months after treatment.

CONCLUSION: The results of this study suggest that PRFA therapy is a mini-invasive, simple, safe, and effective method for the treatment of selected patients with HCH.

INTRODUCTION

Hepatic cavernous hemangioma (HCH) is the most common benign tumor of the liver, its incidence in necropsy series ranges from 0.4 % to 7.4 %. It occurs at all ages and affects women predominantly,the sex ratio is 1.5-6:1, and may increase in size with pregnancy or with administration of estrogens. The majority of HCHs are small, single and asymptomatic. About 20 % are large (>5 cm) and 10 % to 29 % are multiple[1-5]. The largest HCH reported in the literature was 63 cm×48.5 cm×40 cm in size and 18 kg in weight[5]. They are often discovered incidentally on routine abdominal ultrasonography or at the time of laparotomy and necropsy. The widespread use of ultrasound (US) and computerized topography (CT) scanning nowadays has made the diagnosis of HCH easier. HCHs usually become symptomatic as they reach a certain size. Abdominal pain or discomfort is the most common complaint. Rarely, large HCHs sequester and destroy platelets, causing symptomatic thrombocytopenia, known as Kasabach-Merritt syndrome. Occasionally, these vascular lesions rupture spontaneously, or with minimal trauma, and present as hemoperitoneum[1-6].

The management of HCHs is still controversial. *In situ* radiofrequency ablation (RFA) of hepatic malignant tumors[7-21] has led us to consider using this minimally invasive technique in patients with HCH. On the basis of our successful experience in controlling hepatic malignances, we applied the percutaneous RFA (PRFA) guided by B-US to the treatment of patients with HCH and the initial results were promising[22,23]. This article describes our preliminary experiences and evaluates the efficacy, safety, and complications of PRFA therapy for HCHs.

MATERIALS AND METHODS

The study was performed at the RFA center of our department with the approval from the hospital authority. Written informed consent was obtained from each patient prior to treatment.

Twelve consecutive patients with 15 cavernous hemangiomas of the liver were treated with PRFA from May 2000 to June 2002. There were four males and eight females. Age ranged from 33 to 56 years (mean, 41.7 years). Eleven patients had a single lesion (4.8 cm to 9.5 cm), and one patient had four lesions (2.5 cm to 7.0 cm). The tumors were located in the right lobe of the liver in nine patients, left lobe in five, and both lobes in one. Nine patients had discomforts in the right upper quadrant of abdomen, while the remaining three were asymptomatic. The definite histologic diagnosis of HCHs was established by means of enhanced spiral CT scan and B-US guided percutaneous biopsy with 16-gauge biopsy needles in all cases.

The patients were fasted for 4 hours and under conscious sedation and analgesia induced by administering promethazine hydrochloride 25 mg, pethidine hydrochloride 50 mg and morphine hydrochloride 10 mg intravenously. An intercostal or subcostal approach was selected according to the location of hemangiomas in the liver. Local anesthesia was achieved by using 5 ml to 8 ml of 1 % lidocaine. The 10-needle LeVeen electrode, which was connected to the RF-2000 generator (Radio Therapeutics Corp., Mountain View, CA, USA), was inserted percutaneously into and fully deployed within the target tumor under real-time B-US guidance. Grounding was achieved by attaching two dispersive pads on the thighs of patients. The power was set at 30 watts initially and increased by 10 watts per minute until 90 watts were delivered via the needle electrode. The tissue impedance was monitored

automatically by using circuitry incorporated within the generator and the treatment was stopped at roll off. The ablation overlaps were intended so as to destroy HCHs completely. For tumors larger than 3 cm in diameter, the tip of LeVeen needle electrode was readjusted repeatedly under real-time B-US guidance until the entire lesion as well as a rim of normal liver tissue (approximately 0.5 cm) were encompassed and destroyed. The vital signs of patients were monitored continuously during the procedure. The patients were allowed to have a light diet six hours after PRFA therapy. Prophylactic antibiotics and liver protectives were given intravenously for 2 to 3 days. To evaluate the response of hemangiomas to PRFA therapy, B-US and enhanced spiral CT scan were performed regularly by using the same parameters as used for the pretreatment examination. Tumor size was observed, and complete tumor necrosis was considered when no focal enhancement was seen within the tumor or at its periphery on spiral CT scans obtained 3 to 6 months after the treatment.

RESULTS

All treatments were technically successful. When the patients were treated under sedation and analgesia, they experienced a mild pain during the procedure, which disappeared immediately following cessation of PRFA. As radiofrequency energy was applied to the treatment probes, a hyperechoic focus was observed by B-US around the uninsulated portion of the electrodes, which was attributed to the tissue vaporization, microbubble formation and tissue necrotic coagulation. There was a single treatment session in one tumor which was 2.5 cm in diameter, and 2-7 treatment sessions in 14 tumors which were 4.8 cm to 9.5 cm in diameter. The duration of the treatment sessions was quite different from patient to patient, and even from lesion to lesion in the same patient. The average treatment duration was 39 minutes (8-125 minutes). The liver function study showed that serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels were increased two to three times above the baseline values, and normalized 2-5 days posttreatment. No change was observed in other serum element levels. No PRFA-related complications including bleeding or bile leakage occurred, and no repeated PRFA treatment was needed. The post-PRFA course was uneventful, and the patients were discharged on the third to fifth day postprocedure. The fact that the hospital stay was longer than that in Western countries was largely due to our local preferences and social reasons.

All the patients were followed up for 9 to 34 months (mean, 21 months). Nine patients' discomforts in the right upper quadrant of abdomen were ameliorated, the symptoms were significantly or completely controlled in 7 patients for a mean of 2 months (range 1-4 months). B-US and CT scan showed that the ablated lesions were swollen within 2 to 4 weeks after PRFA and started to shrink thereafter. The shrunk range was 38-79 % (mean, 67 % per 21 months). The contrast enhancement was disappeared within the tumor or at its periphery in all cases on spiral CT scans obtained 3 to 6 months after treatment.

DISCUSSION

Traditionally, surgical resection has been considered the choice of treatment for HCHs including those of symptomatic, larger than 10 cm in diameter, and manifested as Kasabach-Merritt syndrome. Steroid therapy and external radiation have provided relief for a few patients[1-5]. The transcatheter arterial embolization (TAE), an effective interventional therapy for hepatic malignancies, has also been advocated for the treatment of HCHs[24,25]. However, there are some differences of hepatic hemodynamics between hepatic malignancies and HCHs[26,27]. The value of TAE as well as its disadvantages have not been fully evaluated. Though TAE has the advantages of avoiding operative intervention and prolongation of hospitalization, TAE may result in disastrous consequences including complications of severe destructive biliary damages and ectopic embolizations[28-30].

Recent successes in local treatment of malignant tumors of the liver have led us to consider using the minimally invasive PRFA in patients with HCHs. In the procedure, the needle-electrode with an insulated shaft and an uninsulated distal tip is inserted directly into hepatic tumor through percutaneous approach under local anesthesia and conscious sedation by the guidance of ultrasonography. Energy is transferred from the uninsulated distal tip of the needle to the tissue as current rather than as direct heat. As the alternate current flows to the grounding pads, it agitates ions in the surrounding tissue of the needle tip, resulting in frictional heat exceeding 80-100 ℃. The local tissue is heated and dried, creating a 3.5 cm to 5.0 cm oval or spherical thermal coagulative necrosis. Thus the tumors are ablated and destroyed *in situ*. The dead cells are not removed, but they eventually shrink and become scar tissues[7-17].

On the basis of our successful experience in controlling hepatic malignances with PRFA therapy, we applied this technique to the treatment of HCHs with a considerable success, and our initial experience was reported in 2001[22, 23]. To our knowledge, this is the first publication on the use of percutaneous radiofrequency ablation therapy for hepatic cavernous hemangiomas. We observed that the patients who accepted PRFA recovered quickly, the ablated lesions were remarkably shrunk after treatment, and no minor or major complications occurred. PRFA has an additional advantage of being easily repeated, so large HCHs can be retreated and the benefits of it to HCHs are definite, which is quite different from the repeat PRFA for hepatic malignancies in which local tumor control is greatly influenced by its size[7-12]. In this group, we managed to adjust LeVeen needle electrode repeatedly under real-time B-US guidance, and large HCHs were completely ablated, and repeat treatment was not needed. Our study showed that this technique was safe and effective for the treatment of HCHs in selected patients. An important limitation of PRFA is related to location of HCHs, in which the near-hilum, near-gallbladder and submembranous HCHs should not be heated lest the tumor' s surrounding tissues or organs be damaged. The interference with the ribs, lung, and adjacent bowel may also affect the procedure.

It is well documented that HCHs should not be disturbed by attempts at biopsy or aspiration, lest serious bleeding occurs, so percutaneous biopsy is contraindicated[1-3]. But several studies have also shown that percutaneous fine needle biopsy with ultrasound guidance is safe for HCH diagnosis[31-35]. We performed percutaneous biopsy successfully in patients with HCHs unexpectedly in our early diagnostic liver biopsies. Along with the experience with recent practice of PRFA for hepatic malignances, we performed both B-US guided biopsy with 16-gauge biopsy needle and PRFA therapy with 15-gauge LeVeen electrode needle in patients with HCHs. There was no hemorrhage or other complications, indicating that both percutaneous biopsy and PRFA therapy under ultrasonography guidance can be performed safely for the diagnosis and treatment of HCHs.

In conclusion, the results of this study suggest that PRFA is a promising and minimally invasive technique for the treatment of HCHs. Long-term studies to assess the clinical outcome of PRFA for HCHs are ongoing. We believe that by virtue of its mini-invasion, effectiveness, simplicity, safety, and easy repeatability, PRFA therapy can be the choice of treatment for HCHs in selected patients.

Abstract

Gastroesophageal reflux disease (GERD) has been an area of active research in the Asia-Pacific region in the recent years. This article outlines some of the interesting research findings. It comprises three parts. The first part dealt with recent data on the changing epidemiology of GERD in Asia. The second part summarized published studies on the relationship between GERD and *Helicobacter pylori*, relevant to the Asia-Pacific region. The last part discussed some of the recent advances in the treatment of GERD.

INTRODUCTION

Gastroesophageal reflux disease (GERD) has been an area of dynamic research in the Asia Pacific region in the last few years. This article outlines some of the interesting research findings.

CHANGING EPIDEMIOLOGY OF GERD IN THE ASIA PACIFIC REGION

There was little information on GERD in the Asia Pacific region until recently. A cross-sectional survey of randomly selected adults in Singapore provided evidence that reflux-type symptoms were uncommon in the Asian population in the early 90' s[1]. Of 700 persons evaluated, only 2 % reported having heartburn more than once a month. A similar study among a random sample of 5 000 adult residents in Shanghai and Beijing showed a point prevalence of symptomatic GERD of 6 %[2].

These prevalence rates were lower than those of Western populations. Endoscopic esophagitis was also less common among Asians than their Western counterparts. One of the evidences came from a comparative study of consecutive English patients and Singaporean patients seen for upper abdominal discomfort[3]. Reflux *esophagitis* was found in 25 % of the English patients and only 6 % of the Singaporean patients ($P<0.005$). The most important risk factor for *esophagitis* was race. An endoscopic study conducted among 16 606 patients in Southern China supported the Singaporean finding, showing a similarly low frequency of endoscopic esophagitis of 4 %[4]. It also showed that esophagitis, when present, was often mild with the vast majority of cases being Los Angeles grade A or B. Severe esophagitis and large hiatal hernia were rare in Asians.

In the past few years, there has been an increase in the frequency of GERD in Asia. In a re-survey[5] of community residents who were interviewed in an earlier study in 1994[1], there was a more than 4-fold increase in the frequency of heartburn. This trend could not be explained by genetic factors *per se*. It also did not appear to be related to lifestyle changes such as smoking, alcohol consumption, or changes in body weight. Among a consecutive series of 9 000 patients who had diagnostic esophagogastroduodenoscopy, the frequency of endoscopic *esophagitis* was also increasing ($P<0.001$) while that of duodenal ulcer was decreasing ($P<0.005$), from 1992 to 1999[6].

The lower frequency of GERD in Asian populations in the early 90' s was unlikely to be solely caused by the known extrinsic risk factors. Genetic factors were probably involved as Asians have a smaller parietal cell mass and a lower acid output compared with Caucasians. The lower prevalence of *hiatus hernia* and smaller body mass index in the Asian population might also have accounted for the lower prevalence of GERD in Asia[7]. The cause of the opposing time trend of GERD and duodenal ulcer disease in Asia was unclear but might be related to the declining rate of *Helicobacter pylori* (*H pylori*) infection, or lifestyle changes, such as increased dietary fat intake.

However, similarities exist in Asian and Western patients with GERD. Interestingly, pathogenic factors of reflux esophagitis in Asians were found to include lower esophageal sphincter competence, esophageal peristaltic contractility, and esophageal acid exposure[8], which were identical to results in Western studies. Elderly Chinese patients were found to have more severe gastroesophageal reflux and esophageal lesions compared with their younger counterparts[9].

GERD AND *HELICOBACTER PYLORI*

Although the relationship between *H pylori*, peptic ulcer disease and gastric malignancy is well established, the link between *H pylori* and GERD remains controversial.

In a systemic review of 20 studies[10], the prevalence of *H pylori* infection in subjects with GERD was significantly lower than that in those without GERD. Geographical location was a strong contributor to the heterogeneity between studies. Although the prevalence of *H pylori* in the general population was found to be higher in the East, patients from the Far East with reflux disease had a lower prevalence of *H pylori* infection than patients from Europe and North America.

Since associations do not prove causality, a more pertinent question is whether eradication of *H pylori* increases the risk of GERD. Hamada and colleagues[11] addressed this question by comparing the prevalence of new onset reflux *esophagitis* among 286 patients who underwent *H pylori* eradication therapy with that of 286 age- and disease-matched *H pylori*-positive controls who did not undergo eradication therapy. Within 3 years of follow-up, 18 % of those who had successful eradication of *H pylori* developed reflux *esophagitis* and this prevalence was higher than the 0.3 % recorded among those without therapy. Reflux esophagitis, when present was mild in most cases. The presence of *hiatal hernia* and severe corpus gastritis was closely related to the development of reflux esophagitis after *H pylori* eradication therapy. The data suggested that increased gastric acid secretion after *H pylori* eradication might only be one of the several factors responsible

for the increased risk of GERD following *H pylori* eradication. On the other hand, in a post hoc analysis of 8 prospective double blind US trials of *H pylori* therapy for patients with active duodenal ulcers or a history of duodenal ulcers[12], no difference was found in the likelihood of developing new GERD symptoms or *esophagitis* in individuals cured of *H pylori* infection compared with those with persistent infection. There was no association of *H pylori* eradication with worsening symptoms in those with preexisting GERD. The likelihood for patients who were successfully cured of their *H pylori* disease to experience a worsening of their GERD symptoms was less than that for those with persistent infection (odds ratio: 0.47, 95 % confidence interval: 0.24-0.91). However, this study had its limitations. Although the overall number of subjects included in the analysis was large, the numbers of patients in some of the subgroup analyses were small. In addition, follow-up was less than 2 months in 7 of the 8 studies included in the analysis. Nevertheless, this study suggested that *H pylori* eradication should not be withheld for fear of causing or worsening GERD. The findings in this study that patients with preexisting GERD were less likely to develop worse symptoms must not be taken to mean that patients with GERD improved after *H pylori* eradication. At present, the treatment of *H pylori* in patients with GERD remains controversial.

TREATMENT OF GERD

In a study investigating the healthcare-seeking behavior of Asian subjects with heartburn, the decision to medicate and to seek medical advice was linked to symptom severity, but not to ethnicity[13].

The mainstay of treatment for GERD is acid suppression. Proton pump inhibitors provide the most rapid symptomatic relief and the highest healing rates for *esophagitis*. Omeprazole, lansoprazole, pantoprazole, rabeprazole and esomeprazole had all been demonstrated to improve GERD symptoms and to heal *esophagitis*. Interestingly, antireflux therapy has been shown to decrease bronchial hyper-responsiveness and improve pulmonary function in asthmatic patients with GERD[14].

For patients with GERD who do not like the idea of taking long-term proton pump inhibitors, Nissen fundoplication, which was modified to the laparoscopic technique in 1991, is an option. However, its association with significant morbidity and its mortalilty rate of 0.2 % prompted the birth of innovative endoscopic techniques.

The Stretta procedure, which involves radiofrequency induction of localized thermal energy to lower *esophageal sphincter* or *cardia*, has been shown in a multicentre randomized double-blind sham-controlled trial[15] to improve heartburn symptom scores and physical quality of life scores. There was no bleeds, perforations or deaths in this study. Another technique, known as the gatekeeper system, has the unique advantage of allowing addition or removal of implants as necessary and was shown to improve symptoms and decrease requirement for anti-reflux medication[16]. A third option, transesophageal endoscopic plication, resulted in significant improvement in lower *esophageal sphincter* pressure and post-procedure 24-hour *esophageal* pH[17]. Finally, endoscopic implantation of inert materials such as Enteryx has been shown to improve symptom scores, quality of life and 24-hour *esophageal* pH, with reduction in the use of acid suppression 6 months after treatment[18].

Abstract

It is known that deficiencies of micronutrients due to infections increase morbidity and mortality. This phenomenon depicts itself conspicuously in developing countries. Deficiencies of iron, vitamins A, E, C, B12, *etc* are widely prevalent among populations living in the third world countries. *Helicobacter pylori* (*H pylori*) infection has a high prevalence throughout the world. Deficiencies of several micronutrients due to *H pylori* infection may be concomitantly present and vary from subtle sub-clinical states to severe clinical disorders. These essential trace elements/ micronutrients are involved in host defense mechanisms, maintaining epithelial cell integrity, glycoprotein synthesis, transport mechanisms, myocardial contractility, brain development, cholesterol and glucose metabolism. In this paper *H pylori* infection in associaed with various micronutrients deficiencies is briefly reviewed.

INTRODUCTION

Helicobacter pylori (*H pylori*) is a gram negative, microaerophilic human pathogen which colonizes the gastric mucosa. Infection with *H pylori* leads to gastritis and is associated with the development of peptic ulcer disease, gastric carcinoma and lymphoma[1]. *H pylori* may be acquired at any age, and the infection persists for years once acquired. The age specific prevalence of *H pylori* infection is higher in developing countries and particularly in lower socioeconomic group[2]. In developing countries *H pylori* infection occurs early in life, and hypochlorhydria commonly seen in the malnourished predisposes them to repeated gastrointestinal infection, persistent diarrhea and malnutrition[3]. *H pylori* infection usually causes both acute and chronic inflammatory cell infiltration, leading to an increase in reactive oxygen species (ROS) which have been shown to accumulate in *H pylori* gastritis[4]. Excessive production of reactive oxygen metabolites (ROMs) by phagocytic cells is thought to contribute to mucosal lesions produced by *H pylori* infection. These are highly reactive compounds capable of combining with DNA in a number of potentially genotoxic ways[5]. Reactive oxygen species can react with the lipid-bilayers releasing peroxidation products such as malondialdehyde. These processes could lead to alterations in the structure of DNA facilitating mutations and carcinogenesis.

Nutrition is a critical determinant of the outcome of host microbe interactions through a modulation of the immune response. "Micronutrient" or "trace elements" are generally defined as constituting less than 0.01 % of body mass and are needed in much smaller amounts. Trace minerals and vitamins are essential for life and include iron (Fe), zinc (Zn), copper (Cu), nickel (Ni), *etc*. They act as essential cofactors of enzymes and as organizers of the molecular structures of the cell, e.g. mitochondria and its membrane. Deficiencies of micronutrients influence immune homeostasis and thus affect infection-related morbidity and mortality. Micronutrients like β carotene, vitamin C, selenium, copper and others are powerful antioxidants and have a significant impact on infection related morbidity in humans. Subclinical deficiencies are known to impair biological and immune functions in the host. Antioxidants play a part in gastric mucosal defense by protecting against damage caused by excessive oxygen derived free radicals. β-carotene and α-tocopherol are lipophilic and have been shown to suppress the oxidation induced by either lipophilic or hydrophilic radical species[6]. In addition, they could act as anti-carcinogens through their ability to prevent the formation of N-nitrosamines which are important in the development of gastric carcinoma[7]. These vitamins are the major oxidant scavengers in biomembranes in contrast to vitamin C, which is mainly responsible for scavenging free radicals in the aqueous phase. However, compensatory mechanisms may become defective while gastric inflammation develops from normal to chronic gastritis and finally to gastric atrophy/intestinal metaplasia, perhaps due to reduced infiltration of inflammatory cells, loss of gastric gland cells and increased ROM production.

IRON

Iron deficiency anemia affects all groups of the under privileged population in most developing countries. Iron is an essential growth factor for *H pylori*, which contains Fe in their outer membrane protein and a system for intracellular storage of iron, consisting of ferritin like molecules pfr and napA[8]. Patients with *H pylori* associated iron deficiency anemia (IDA) would have involvement of both antral and corporal mucosa when compared with controls (90 % *vs* 42.7 %; P=0.0001)[9]. Iron deficiency anemia associated with *H pylori* gastritis is characterized by a concomitant increase in median intragastric pH value >3 and lowering of intragastric concentrations of ascorbic acid. A significant percentage (43 %) of *H pylori* positive IDA patients presented atrophic changes in the gastric body, and the remaining had a superficial gastritis extended to the fundic mucosa, in contrast with *H pylori* positive controls[10]. *H pylori* eradication has also been shown to improve the absorption of other nutrients besides iron, and produce more rapid and complete clinical responses in patients with iron deficiency anemia[11].

COPPER

Copper is involved in the function of several enzymes. It is required for infant growth, host defense mechanisms, bone strength, red and white cell maturation, iron transport, *etc*. Acquired deficiency is mainly seen in infants. However, it has been diagnosed also in malnourished children and adults[12]. A

gene, copA, associated with copper transport, has been isolated from *H pylori* UA802. The adenosine triphosphatase-derived copper-transporting mechanism is employed by various *H pylori* strains[13]. As a cofactor in various redox enzymes and an essential trace metal required for the synthesis of metalloproteins, copper plays a role in the pathogenesis of *H pylori*. *H pylori* has a differential effect on some gastric mucosal scavenger enzymes of ROMs, namely mitochondrial and cytoplasmic superoxide dismutases reflected by a large increase in the cytokine inducible manganese superoxide dismutase and a decrease in the constitutive copper/zinc superoxide dismutase[14].

VITAMIN B12

The mechanisms of vitamin B12 malabsorption caused by *H pylori* infection are unclear but following are the possibilities: a) The diminished acid secretion in *H pylori* induced gastritis may lead to a failure of critical splitting of vitamin B12 from food binders and its subsequent transfer to R binder in the stomach. b) A secretory dysfunction of the intrinsic factor. c) Decreased secretion of ascorbic acid from the gastric mucosa and increased gastric pH[15,16]. Annibale *et al*, studied the prevalence of *H pylori* infection in pernicious anemia patients and have demonstrated that almost two thirds of pernicious anemia patients had evidence of *H pylori* but only those with an active *H pylori* infection had distinctively functional and histological features[17]. These findings support the hypothesis that *H pylori* infection could play a triggering role in a subgroup of pernicious anemia patients, and suggest the possibility that *H pylori* is involved in the early stages of PA that lead to severe corpus atrophy. The later progress of gastritis seems to be dependent on factors other than *H pylori*, most likely "autoimmune" mechanisms[18]. *H pylori* may also be involved in the pathogenesis of pernicious anemia via antigenic mimicry as antibodies directed against the H+, K+- adenosine-triphosphate protein that has been found in high numbers of patients with *H pylori* infection[19]. Food cobalamin malabsorption may occur without gastric atrophy or achlorhydria. Malabsorption can respond to antibiotics, but only in some patients[20].

VITAMIN A

Vitamin A has effects on important determinants of immune function and epithelial cell integrity such as gene expression, cellular proliferation and differentiation and also glycoprotein synthesis. Loss of integrity of the epithelial lining of mucus membranes in a vitamin A deficient state could explain its close association with increased susceptibility to infections particularly of gastrointestinal, respiratory and genitourinary tracts especially in children and pregnant women[21]. Even mild or subclinical vitamin A deficiency could induce keratinizing metaplasia of the epithelium and depletes goblet cells from mucosal linings thus causing xerosis of the membrane[22]. The xerotic surfaces form potential sites for increased bacterial adherence thus leading to bacterial colonization. The antimicrobial enzyme lysozyme depends on vitamin A for its synthesis. A decrease in T cell number with no change in proliferative activity has been demonstrated in children suffering from mild xerophthalmia due to vitamin A deficiency. *H pylori* infection and low β-carotene in plasma contribute to the increased risk of gastric atrophy, indicating that *H pylori* infection might be associated with low plasma β-carotene[23].

VITAMIN E

Vitamin E is composed of a group of compounds termed tocopherols and tocotrienols. α-tocopherol is the major active form in the human body, accounting for 95 % of vitamin E and is the most effective lipid soluble anti-oxidant in biomembranes. It acts as the major chain breaking antioxidant and is able to interfere with the propagation of lipid peroxidation. It plays an immune modulatory part and is capable of increasing natural killer cell activity. Concentrations of α-tocopherol in *H pylori* negative subjects were higher in the corpus than in the antrum or duodenum[6]. This distribution of α-tocopherol is reversed in the presence of antral *H pylori* infection. These findings may reflect a mobilization of antioxidant defenses to the sites of maximal inflammation in the stomach.

VITAMIN C

Vitamin C exists as ascorbic acid (AA) or dehydroascorbic acid. The stomach secretes ascorbic acid across the gastric mucosa into the gastric juice against a concentration gradient. Ascorbic acid is the reduced form of the vitamin and can act as a potent antioxidant, and is able to scavenge ROS in gastric mucosa. This has been proposed as one means by which it exerts an anti-carcinogenic effect. Ascorbic acid may also prevent formation of N-nitroso compounds in gastric juice by scavenging nitrite. It has been observed that diets poor in foods containing AA were associated with an increased risk of gastric cancer[24]. Wei-cheng *et al* showed that presence of *H pylori* infection at the baseline and smoking were strongly associated with progression to dysplasia or gastric cancer, whereas the risk of progression was decreased by 80 % among subjects with baseline ascorbic acid levels in the highest tertile compared with those in the lowest tertile[25]. A number of studies have demonstrated that gastric juice but not gastric mucosal AA levels were reduced in the presence of *H pylori* gastritis and that successful eradication restored the juice/plasma AA ratio[23, 26]. The lower plasma AA concentration in *H pylori* positive subjects could be due to reduced bioavailability, active secretion from plasma to gastric juice in attempts to restore the positive gastric juice/plasma ratio or both[27]. In some studies no difference was found in the gastric juice AA concentration between patients with antral-limited gastritis and *H pylori* negative healthy controls, while lower AA levels were observed in patients with gastric body involvement and increased pH[28]. These observations suggest that AA, which is very unstable in the presence of increased pH, is converted to the less active form of dehydroascorbic acid, in the presence of gastric damage extending to the corporal mucosa with consequent hypochlorhydria[29,30]. It has been demonstrated that eradication of *H pylori* could lead to a reduction in ROS activity in gastric mucosa[31]. Ascorbic acid has also been shown to inhibit *H pylori* urease activity and growth *in vitro*[32]. *H pylori* infection associated low gastric juice-ascorbic acid levels return to normal after successful eradication of the infection[33]. A study of antibiotic treatment failure showed that compliant patients in whom *H pylori* infection did not clear had lower baseline plasma and gastric juice vitamin C concentrations than patients whose infection was cleared[26].

In developing countries micronutrient deficiencies facilitated by *H pylori* infection are a clinical and public health problem. It is essential to define the precise extent of the problem. Several micro and macronutrient deficiencies could be concomitantly present in the population with several other deficits. They will require correction to achieve significant effects on the over all health of the population.

Abstract

Colonic diverticular disease (diverticulosis) is one of the most common gastrointestinal disorders in Western countries. This disorder is strictly related to aging and fibre intake, and still bears a discrete amount of morbidity. Numerous etiological co-factors have to date been implicated in the pathogenesis of the disease, yet the supporting evidence is still far from absolute. The present review considers the pathophysiology of colonic diverticular disease, with a special emphasis on factors related to abnormal colonic motility.

INTRODUCTION

Diverticular disease of the colon (diverticulosis) is the most common disease affecting the large bowel in the Western world[1]. This disease is correlated with the aging process and a low-fiber diet and bears a considerable amount of morbidity[2]. The continuous aging process of the population also leads to an increase of this disease.

It is commonly thought that an altered motility of the large bowel may have a major pathophysiological role, even though it is probable that multiple factors (anatomic features intrinsic to the colon, alterations in colonic wall with aging, dietary fiber, motor dysfunction, abnormal intraluminal pressures, and possibly genetic influences) interact in ill-defined relationships to play a greater or lesser role in the genesis of colonic diverticul[3,4].

This article will review the pathogenetic factors of colonic diverticular disease (diverticulosis), with an emphasis on those related to large bowel motility.

ANATOMIC FACTORS

Diverticul are usually found in the left (sigmoid, descending) colon on either mesenteric side of the antimesenteric teniae in Western countries[5], and occur at weak points in the circular muscle layer, where the blood vessels supply the mucosa[6], suggesting that increased intraluminal pressure might play a role in their formation. The presence of right-sided diverticula is conversely more frequently seen in Eastern populations[7]. An impaired structure of the colonic wall has been described in patients with diverticular disease. In fact, both *in vitro*[8] and *in vivo*[9] studies showed that these patients displayed an increased colonic compliance in the affected segments. This might be due to a pathological accentuation of the physiological differences among colonic segments[10], that has been ascribed to qualitative than quantitative changes in collagen[11], since the content of the latter remained unaltered, with respect to controls, in the entire colonic wall[12] and in the muscle layers[13]. However, the available studies measured colonic compliance by means of latex balloons that constitute a suboptimal method for this measurement. More precise studies with up to date systems (i.e., polyethylene bags, which intrinsic compliance is negligible) are needed. Colonic diverticula were also prevalent in young patients with connective tissue disease[14,15].

Previous studies showed that a consistent anatomic finding in colonic diverticular disease was the presence of thickening of the bowel wall muscle layers[16,17]. However, no evidence of hyperplasia or hypertrophy of the muscle cells has been found (although this finding has been challenged[18]). There is an enormous increase in elastin deposition in the teniae, that leads to shortening of this layer with thickening of the circular muscle layer and produces the concertina-like folds in the inner muscle layer[12,19]. This deformity (also called myochosis) would narrow the lumen, allowing muscle contractions to obliterate the lumen and divide the bowel into isolated segments[4].

Unfortunately, available neurophysiopathological data are remarkably few in colonic diverticulosis. A study investigating the myenteric plexus in such patients was unable to demonstrate any morphological abnormality[20]. Another more recent study showed that cholinergic nerves were dominant in the left-sided diverticular colon, and that a decreased action of non-adrenergic non-cholinergic nerves by nitric oxide might be related to the high intracolonic pressures by colonic segmentation observed in such portions of the viscus[21]. Moreover, *in vitro* cholinergic stimulation of colons of patients with diverticular disease yielded increased low frequency and uncoordinated smooth muscle contractions in response to acetylcholine, compared with controls[22].

AGING

Colonic diverticular disease showed a striking correlation with advancing age[23], and it was estimated that 50 % of the Western population approximately 70 years of age were affected[24], an important consequence of aging was that the properties of the colon wall changed with a decrease of the tensile strength[25]. The reason of this decrease is unknown, but it might be related to an increased cross-linking of collagen fibrils with age, which also became smaller, more numerous and more tightly packed in the left colon[9]. These changes seemed to be accentuated in diverticular disease[26]. Moreover, since elastin deposition continued throughout life in all layers of the colonic wall[27] (with predominance in the teniae in diverticular disease), the fibers lost some mechanical properties and became more distensible in diverticulosis[28].

DIET

There is substantial evidences that colonic diverticulosis was related to civilization, industrialization, and a Western lifestyle and diet[29]. Dietary factors, and in particular low fiber intake,

have been considered as main pathogenic factors[30,31], as also shown by the observations that populations moving from rural to urban environments displayed an increased prevalence of the disease[32], and that vegetarians had a lower incidence of diverticular disease of the colon[33]. In addition, an interesting observation in rats showed that the animals whose mothers were fed on a fiber-deficient diet had an increased incidence of colonic diverticulosis[34].

The "protective" action of dietary fiber would make the stools bulkier, thereby increasing the colon size and decreasing intraluminal pressures (since according to Laplace's law, the pressure required to distend the wall is the greatest where the radius is small)[35], and reducing colonic transit time[36]. These hypotheses have been indirectly confirmed by the observations that typical African diets yielded rapid colonic transit times, bulkier stools and no need to strain[37], whereas those of Europeans resulted in almost double colonic transit times[38] and firmer and more viscous stools that increased intraluminal pressures and the need to strain. Of course, other dietary factors are likely to play a role in this area, as shown by the fact that a Western-type diet was implicated in the increased proline intake from the gut, that led to elastosis of the sigmoid colon[39], and that the prevalence of right-sided diverticular disease displayeds a strongly positive association with past meat consumption frequency[40].

COLONIC MOTILITY

Abnormal intraluminal pressure and disordered colonic motility have been implicated as pathogenic factors in diverticulosis. The evidence for this belief (as discussed below) is far from absolute, however, there are several data suggesting that abnormal colonic motility may be considered as an important pathophysiologic mechanism. It is worth noting that most studies on colonic motility and myoelectrical activity were biased by poor patient selection, small numbers of patients recruited, heterogeneity of clinical conditions, recording techniques (only the rectosigmoid or even rectal motor activity was often obtained) and duration of recording periods (at best, less than two hours, whereas colonic motility displayed wide and important fluctuations around-the-clock[41]).

Concerning right-sided colonic diverticular disease, there is paucity of studies facing the motor aspects. Two investigations, featuring very brief recording periods, reported that patients with diverticulosis displayed higher motility indices with respect to controls, both basally and after pharmacologic stimulation[42, 43]. An increased motor activity was also observed in the segment with diverticula with respect to the non affected sigmoid colon.

Looking at studies in patients with "traditional" diverticulosis, most manometric investigations, as already stated, were carried out in the rectum and (at best) very distal sigmoid area. Therefore, it was possible that the portion of the viscus harboring diverticula might have not been studied at all. This might justify the fact that increased pressures were documented[44-47] or not found[48-51] with respect to controls and in response to pharmacological stimulation. Similar contrasting results were reported from myolectrical studies of the rectosigmoid area[52, 53]. However, more recent studies, carried out in the true sigmoid and descending colon (and, therefore, investigating colonic segments actually bearing diverticula) are available, which showed an increased motor activity in such patients (both symptomatic and asymptomatic) with respect to controls[54,55]. This abnormal motility was reduced following surgery[56]. More recently, we investigated colonic motility in patients with symptomatic uncomplicated diverticular disease, by means of a 24-hour manometric technique that allows studying most of the viscus, its daily fluctuations[57], and detection of the motor equivalents of mass movements, the so-called high-amplitude propagated contractions (HAPC)[58]. With respect to controls, patients with diverticulosis displayed a significantly overall increase of daily motor activity, except in the transverse colon (the segment not involved by diverticula), and of propulsive activity[59]. Interestingly, patients had several retropropagated HAPC (never observed in controls), and the motor activity of the affected segments, especially the sigmoid, was significantly higher than that of the unaffected ones (the transverse).

All the above observations seem to support a discrete role of colonic motility (with the probable concourse of other factors) as a pathophysiological mechanism in diverticular disease. Colonic motility is influenced by the aging process, as shown by the decrease of HAPC frequency with age, whereas segmental contractile activity increases[60]. Anatomical studies in experimental animal models showed that these changes might be related to aging of colonic smooth muscle[61].

The muscle thickening observed in affected bowel segments was thought to be obstructive, and to contribute to the delayed transit of feces[18]. Studies with intracolonic displacement tools suggested that an accentuation of segmentary motor activity (as observed in diverticular disease) might abolish oro-aboral progression of contents[62], thereby facilitating retropropulsion and drying of the semiliquid fecal matter. Moreover, reverse peristalsis, as observed in animal studies, might be a general response to distal obstruction associated with a narrowed terminal colon segment[63]. We have shown that a similar mechanism is present in diverticulosis, and this might have some pathophysiological relevance (for instance, a local nondominant pacemaker might take over in the "spastic" region, initiating an oral spreading of contractions along the less active proximal colonic segments).

CONCLUSIONS

Although many evidences suggest that colonic diverticular disease is related to low-residue diet, the scarce effectiveness of dietary manipulations[64] and the complex relationships with other factors, among which abnormal colonic motility might play an important role, still make this disease a fascinating pathophysiological puzzle. Further studies are needed to understand the intrinsic mechanisms better and possibly, to give us useful insights for a better and more targeted therapeutic approach.

Abstract

AIM: To separate and identify differentially expressed nuclear matrix proteins (NMPs) between the immortalized human esophageal epithelial cell line (SHEE) and the malignantly transformed esophageal carcinoma cell line (SHEEC), and to provide new ways for finding specific markers and the pathogenesis of esophageal carcinoma.

METHODS: SHEE and SHEEC cell lines were used to extract NMPs. The quality of NMPs was monitored by Western blot analysis including DNA topoisomerase IIα, proliferation cell nuclear antigen (PCNA) and histone. NMPs of SHEE and SHEEC were analyzed by two-dimensional electrophoresis (2-DE), silver staining and PDQuest6.2 image analysis software. Three spots in which the differentially expressed NMPs were more obvious, were selected and analyzed with matrix-assisted laser desorption/ionization time of flying mass spectrometry (MALDI- TOF-MS) and database search.

RESULTS: Western blot analysis revealed that DNA topoisomerase IIα and PCNA were detected, and the majority of histones were deleted in NMPs of SHEE and SHEEC. After 2-DE image analysis by PDQuest6.2 software, the 2-DE maps were detected with an average of 106±7.1 spots in SHEE and 132±5.0 spots in SHEEC. Most of them were matched one another (r=0.72), only 16 protein spots were found differing in intensity. Three NMPs including cytoskeletal tropomyosin, FK506-binding protein 6, similar to retinoblastoma binding protein 8 were preliminarily identified by MALDI- TOF-MS.

CONCLUSION: These differentially expressed NMPs may play an important role during malignant transformation from SHEE to SHEEC. Their separation and identification will contribute to searching for specific markers and probing into the pathogenesis of esophageal carcinoma.

INTRODUCTION

Nuclear matrix (NM) represents the insoluble structural framework of nucleus which removes membrane lipid, soluble protein and chromatin. According to many investigations, nuclear matrix has been shown to play an important role not only in maintaining the structure of nucleus, but also in chromatin/chromosome construction, DNA replication, gene expression and regulation (RNA synthesis, RNA splicing and RNA transportation)[1]. Recently changes of the composition, structure and function of NMPs in the generation and development of tumors have been more and more concerned. Separation and identification of tumor associated NMPs have been a new way to search for tumor specific markers and to study tumor pathogenesis. Nowadays several tumor specific NMPs have been separated and identified from hepatocellular carcinoma[2], colon cancer[3] and prostate cancer[4], etc. Some of them (such as NMP22) have been applied to clinical diagnosis and therapy[5], but studies of the separation and identification of esophageal carcinoma specific NMPs have not been carried out.

Esophageal carcinoma is one of the most common malignant tumors in China[6-27]. In recent years, it has been increasingly concerned about the roles of human papilloma virus (HPV) in esophageal carcinogenesis[28-32]. In our previous work, we transfected human embryonic esophageal mucosal cells with HPV18 E6E7 genes, and established an immortalized epithelial cell line SHEE[33,34]. The SHEE cells were further exposed to the tumor promoter (12-O-tetradecanoyl-phorbol-13-acetate, TPA) to induce malignant transformation from which a human embryonic esophageal epithelial carcinoma cell line SHEEC was then established[35,36]. These studies not only provided the evidence for the close relationship between HPV and esophageal carcinogenesis, but also established a reliable model for studying the molecular mechanisms of esophageal carcinogenesis. In the present study, the differentially expressed NMPs between SHEE and SHEEC were investigated by Western blot, 2-DE and MALDI-TOF-MS, and three esophageal carcinoma associated NMPs were preliminarily identified. The separation and identification of these proteins may contribute to searching for specific markers and studying the pathogenesis of esophageal carcinoma.

MATERIALS AND METHODS

Cell culture

SHEE and SHEEC were cultured in MEM medium (Gibco) supplemented with 100 ml/L fetal bovine serum (100 u/ml penicillin, 100 u/ml streptomycin) and incubated at 37 ℃ in humidified atmosphere of 50 ml/L CO_2. Cells were harvested when they grew into a full monolayer and kept at -70 ℃ until use.

Extraction of NMPs

The method used was modified from Fey *et al*[37]. Cultured cells were extracted by cytoskeleton (CSK) buffer (100 mM KCl, 3 mM $MgCl_2$, 1 mM EGTA, 10 mM PIPES pH6.8, 300 mM sucrose, 0.5 % triton X-100, 1.2 mM PMSF) for 5 min at 4 ℃. After centrifugation at 650 g for 5 min, the supernatants contained cytoplasmic proteins. The pellets were resuspended in digestion buffer (same as CSK buffer except with 50 mM NaCl instead of KCl) containing 400 μg/ml DNase I and 100 μg/ml RNase A. Enzyme digestion was carried out for 20 min at room temperature and terminated by adding cold ammonium sulfate to a final concentration of 0.25 M. After centrifugation at 1 000 g for 10 min, the pellets were then solubilized in disassembly buffer (8 M urea, 20 mM Mes pH6.6, 0.1 mM $MgCl_2$, 1 mM EGTA, 1 % 2-mercaptoethanol, 1 mM PMSF) and dialyzed overnight at 4 ℃ against 1 000 volumes of assembly buffer (150 mM KCl, 5 mM $MgCl_2$, 0.125 mM EGTA, 25 mM imidazole hydrochloride pH7.1, 2 mM dithiothreitol, 0.2 mM PMSF). The samples were centrifuged at 200 000 g for 100 min. The protein concentration of supernatants containing NMPs was determined by Bradford method and then precipitated in 5 volumes of absolute ethanol. The dried pellets were resuspended in electrophoresis sample buffer. The sample aliquots were stored at -70 ℃ until use.

Western blot

The experimental procedures were referred to *Molecular cloning*[38]. Briefly, the proteins were separated by SDS-PAGE and then transferred onto nitrocellulose membranes. Nonspecific reactivity was blocked by incubation overnight at 4 ℃ in buffer (10 mM Tris-HCl pH7.5, 150 mM NaCl, 2 % Tween-20, 4 % bovine sreum albumin). The membrane was then incubated with primary antibody including mouse anti-human histone (Roche), mouse anti-human DNA topoisomerase IIα. (Roche) and mouse anti-human PCNA (Dako). The secondary antibody (Zymed) was used to detect bound primary antibody. Reactive protein was detected by Western blot luminol reagent (Santa Cruz) and exposed to X-films (Kodak). The X-films were scanned and analyzed with Kodak 1-D 3.5 software (Kodak).

Two-dimensional electrophoresis

To separate NMPs, the 2-DE procedures were referred to Xiong *et al*[39]. Briefly, 2-DE was carried out by using the Mini-PROTEAN II 2-D apparatus (Bio-Rad). 90 μg of the NMPs was mixed with the rehydration solution to a total volume of 125 μl. After rehydration, the isoelectric focusing (IEF) and equilibration, and the IPG strips (pH4-7, 7 cm) were placed on a 1.0 mm thick, 10 % SDS-PAGE gel. On electrophoresis, the SDS-PAGE gels were stained with PlusOne™ silver staining kit (Phamacia).

Image acquisition and analysis

Image scanning for the silver-stained 2-D gels was performed with EDAS290 digital camera system (Kodak) and image analysis with the PDQuest 6.2 software (Bio-Rad). To obtain reliable results, three gels were employed for each cell line. After the background subtraction, spot detection and match, one standard gel for each cell line was obtained. These standard gels were then matched to yield information about the spots of differentially expressed NMPs.

Protein identification by MALDI-TOF-MS

Three spots in which the differentially expressed protein was more obvious in each cell line were cut out from the gel. The gel pieces were treated by a series of steps including silver-removal, reduction, alkylation and in-gel digestion with trypsin. The peptide mass maps were generated by Applied Biosystems Voyager System 6192 MALDI-TOF-mass spectrometry (ABI, USA). Peptide masses were analyzed using the MS-Fit search program (http:// prospector.ucsf.edu/ucsfhtml4.0u/ msfit.htm).

RESULTS

Evaluation of NMPs quality

The NMPs extracted from SHEE and SHEEC were evaluated by Western blot, and the aim of evaluation was to monitor whether some NMPs were lost and whether other non-NMPs components were mixed. In recent years, many studies proved that DNA topoisomerase IIα and PCNA were the major components of NMPs[40,41], the existence of histone in nucleosome was the major soluble protein of nucleus. In our study, 170 kD DNA topoisomerase IIα was detected in the nuclear protein fraction of SHEE and SHEEC at the same position of NMPs fraction, but the density in NMPs fraction was weaker than that in the nuclear protein fraction (Figure 1). This agreed with other reports[40]. PCNA (36kD) was detected in the NMPs fraction of SHEE and SHEEC, and this showed PCNA was the major protein of NMPs (Figure 2). Moreover, histone was seen at 23 kD and 12-15 kD in the nuclear protein fraction (Mw of histone: H1:23 kD, H2A:14.5 kD, H2B: 13.8 kD, H3:15 kD, H4:11.8 kD) and almost no histone was detected at the same position of NMPs (Figure 3). This showed majority of histone was removed during extraction and there was almost no histone in the NMPs fraction of SHEE and SHEEC. According to these results, the NMPs fractions extracted from SHEE and SHEEC almost deleted the histone and retained the major NMPs components including DNA topoisomerase IIα and PCNA, so the NMPs were pure in high quality.

2-D map and image analysis

To obtain a higher electrophoretic resolution, IPG strips (pH4-7) were selected to separate the NMPs of SHEE and SHEEC in our study because the p*I* range of NMPs was mainly in acid pH. Three pairs of gels from different batches of SHEE and SHEEC were analyzed by using the software PDQuest6.2. There were 106±7.1 and 132±5.0 protein spots observed in SHEE and SHEEC respectively. Most of them were matched one another (r=0.72), only 16 protein spots were found differing in intensity. These 16 protein spots belonged to 4 types. Namely A: one protein spot was detected in SHEE (No.2). B: Seven protein spots were detected only in SHEEC (No.3, 4, 9, 11, 12, 14, 16), C: One protein spot was expressed higher in SHEE (No.1), D: Seven protein spots were expressed higher in SHEEC (No.5, 6, 7, 8, 10, 13, 15). According to the standard molecular weight and pH gradient of IPG strips, the positions of these 16 protein spots were estimated with the software PDQuest6.2 (Table 1). Three protein spots (No.4, 14, 16) which belonged to type B and had a higher intensity were selected and analyzed with MALDI-TOF-MS (Figure 4).

MALDI-TOF-MS analysis and protein identification

These three protein spots (No.4, 14, 16) were cut out from the gels and analyzed with MALDI-TOF-MS. Peptide mass fingerprint (PMF) of each protein spot was then generated (Figure 5). By searching the NCBInr protein database with the MS-Fit search program, we identified these three proteins combined with the searching results. The characteristics of the protein, the number and intensity of peptide matching peak, the sequence coverage of matching peptide, as well as the theoretical and approximate values of M_r and p*I*, the identified protein names, accession numbers, as well as the sequence coverages, the theoretical M_r and p*I* values for each protein spot are listed in Table 2.

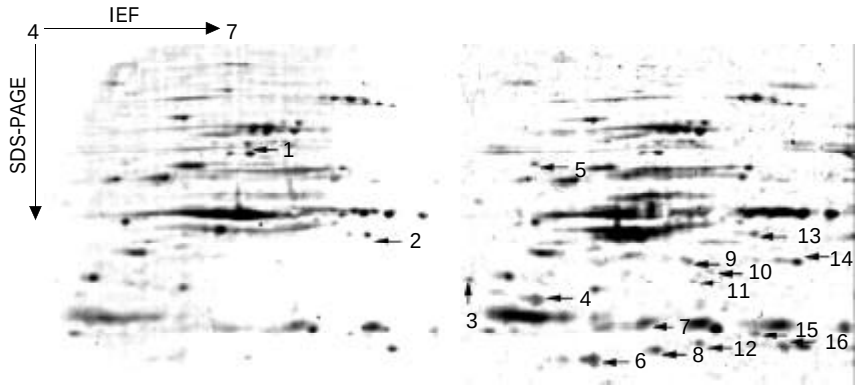

Figure 4 Differentially expressed NMP spots observed in SHEE (left) and SHEEC (right) two-dimensional gels (IPG dry strips: pH 4-7, 7 cm). The arrows show differentially expressed protein spots. Three protein spots (No.4, 14, 16) were selected and analyzed with MALDI-TOF-MS.

DISCUSSION

In the present study, we studied the differentially expressed NMPs extracted from SHEE and SHEEC by Western blot, 2-DE and MALDI-TOF-MS, and preliminarily identified three differentially expressed NMPs. According to their characteristics, these three proteins were connected with diseases such as colon carcinoma and myofibroblastic tumor, etc, but they were not related to esophageal carcinoma.

Cytoskeletal tropomyosin (tropomyosin 3, cytoskeletal (TPM3)) belongs to the tropomyosin family. There were at least 5 isoforms in tropomyosins including TPM1, TPM2, TPM3, TPM4, TPM5 which were produced by a tissue-specific alternative mRNA splicing mechanism[42]. The tropomyosins were a group of actin-binding proteins which served to mediate the effect of Ca^{2+} on the actin-myosin interaction[43]. Actin is one of the major components of NMPs. Owing to active cell division during the course of malignant transformation, cytoskeletal tropomyosin connected with actin in the nucleus becomes overexpressed. Zeng and his associates[44] found that tropomyosin was localized in the nuclear matrix and chromosome scaffold, and dispersively distributed in the interphase nuclei and metaphase chromosomes. Many studies have proved that cytoskeletal tropomyosin is related to the generation and development of tumors. Martin-Zanca and his associates[45] found the oncogene-Onc D (named later "trk" (tropomyosin(t)-receptor(r) -kinase(k)) in colon carcinoma. Sequence analysis for the oncogene Onc D found that it was generated by a somatic rearrangement of two genes, one of which coded for cytoskeletal tropomyosin (TPM3) and the other for a tyrosine-specific protein kinase. The amino end of TPM3 has been found to be fused with tyrosine protein kinase domain and has become a new oncogenic protein. These results indicate that cytoskeletal tropomyosin is related to the generation and development of colon carcinoma. Furthermore, Lawrence and his associates[46] reported that TPM3-ALK (anaplastic lymphoma kinase, ALK) and TPM4-ALK fusion genes occurred in inflammatory myofibroblastic tumors. In our study, cytoskeletal tropomyosin (TPM3) showed overexpression in the NMPs fraction of SHEEC cells, indicating that cytoskeletal tropomyosin as a oncoprotein might be related to esophageal carcinoma. But its characteristics and functions in esophageal carcinoma remain to be further studied.

FK506-binding protein 6 (FKBP6) is one member of FKBP family. The FKBP family proteins were those directly binding to the immunosuppressant drug FK506[47]. So far there are several FKBP family members, namely FKBP6, FKBP12, FKBP13, FKBP25 and FKBP52. These FKBP family members differ in their subcellular localization. FKBP12 and FKBP52 are localized in the cytosol, FKBP13 in the endoplasmic reticulum, and FKBP25 in the nucleus. Like other FKBP members, FKBP6 had some peptidyl-prolyl cis-trans isomerase activity and a drug binding site[48]. Owing to its possession of cis-trans isomerase activity, FKBPs are thought to be essential for protein folding during protein synthesis. FKBP6 gene is localized in chromosome 11 and consists of nine exons. Meng and his associates[49] found FKBP6 gene was deleted in Williams syndrome (WS), and this might contribute to certain defects such as hypercalcemia and growth delay in WS. In our study, FKBP6 was overexpressed in the NMPs fraction of SHEEC. This indicated that FKBP6 as an active NMP might play a role during malignant transformation of the immortalized human esophageal epithelial cells.

Similar to retinoblastoma binding protein 8 (STRBP8), it contains 230 amino acid residues. Its sequences are the same as residues 668-897 of retinoblastoma binding protein 8 (RBP8), and so it is named STRBP8. So far there are not any reports about the function of STRBP8. Moreover, RBP8 is localized in the nucleus. It might interact with some tumor suppressive factors including CtBP1, Rb1 and BRCA1, and was involved in transcription regulation and tumor suppression[50,51]. The interaction with CtBP1 requires a short amino acid motif PLDLS (residues 490-494) of RBP8, whereas the Rb1 tumor suppressor binding to a LXCXE motif is located within the N-terminal region of RBP8 (residues 153-157). Unlike RBP8, STRBP8 has no Rb1 binding motif (sequence LXCXE) and CtBP1 binding motif (sequence PLDLS). The results indicate that STRBP8 possibly loses the function of tumor suppression and on the contrary possesses carcinogenetic effect. The fact that STRBP8 was overexpressed in SHEEC in our study, showed that STRBP8 as a new oncoprotein might

be involved in the malignant transformation of SHEE.

Although three NMPs have been found to be associated with esophageal carcinoma in the present study, but whether they would become specific markers of esophageal carcinoma needs to be further studied. In addition, the generation and development of tumors are the extraordinary pathological complex phenomena, and the process of coordinated interaction and programed development of many proteins. It will help elucidate the process of tumor generation and development to study the network relationship of these tumor associated proteins. Therefore, the network functional relationship of these differentially expressed NMPs needs to be further studied.

Abstract

AIM: To investigate the influence of peroxisome proliferator-activated receptor γ (PPARγ) ligand, 15-deoxy-△12, 14-prostaglandin J_2 (15dPGJ$_2$) on the proliferation and apoptosis of MCG-803 human gastric cancer cell lines.

METHODS: Cell proliferation was measured by ^{3}H-TdR assay. Apoptosis was determined by ELISA and TUNEL staining. Protein and mRNA level of bcl-2 family and COXs were measured by Western blotting and Northern blotting respectively. PGE_2 production was examined by RIA.

RESULTS: 15dPGJ$_2$ inhibited cell growth and induced apoptosis of MCG-803 cells. The COX-2 and bcl-2/bax ratios were decreased following 15dPGJ$_2$ treatment. The PGE_2 production in supernatants was also decreased. These changes were in a dose-dependent manner.

CONCLUSION: 15dPGJ$_2$ may be a useful therapeutic agent for the treatment of gastric cancer.

INTRODUCTION

Peroxisome proliferator-activated receptor γ (PPARγ), a nuclear hormone receptor, provided a strong link between lipid metabolism and the regulation of gene transcription[1,2]. Recent studies showed that PPARγ was expressed at high levels in human colon cancer cells[3-5]. Ligand activation of PPARγ in human colon cancer cells caused a reduction of growth[3,4]. In contrast, two independent groups demonstrated that activation of PPARγ promoted the development of colon tumors in mice[6,7]. Thus the roles of PPARγ activation in the growth of colon tumors are controversial. In addition to colon cancer, PPARγ activation induced growth arrest in human liposarcoma, prostate cancer and breast cancer[8-10]. These results suggest that PPARγ activation may be implicated in the proliferation and apoptosis of malignant tumor cells.

Gastric cancer is the most common malignant tumor of gastrointestinal tract in the world. The survival rate in gastric cancer is poor. Although PPARγ expression has been studied in various epithelial cancer cell lines such as colon, prostate and breast, no information is available as to whether PPARγ is involved in the regulation of gastric cancer cell survival. In the present study, we investigated the effect of natural PPARγ ligand, 15dPGJ$_2$ on the growth and apoptosis of gastric cancer cell lines. We have further examined the role of bcl-2 family in the regulation of 15dPGJ$_2$-induced apoptosis. In addition, the change of cyclooxyenase (COXs) and the rate-limiting enzyme in the synthesis of prostaglandins (PGs) have been investigated in the process since COXs is recently considered as a promoter of human gastrointestinal cancer.

MATERIALS AND METHODS

Cell line and reagents

MCG-803 gastric cancer cell was kindly provided by Cancer Institute, Zhongshan University. Cells were maintained in RPMI-1640 medium and supplemented with 10 % new fetal bovine serum. Antibodies used in this study were obtained from Santa Cruz Biotech. The apoptosis ELISA kit and RIA kit were purchased from Sigma.

[^{3}H] Thymidine incorporation

Cells were planted in 96-well plates and grown for 24 h after they were serum starved for 48 h. They were treated with 15dPGJ$_2$ for 48 h and pulsed with 5 μCi of [^{3}H] thymidine for 4 h. We counted the radioactivity in Beckman L5 counter after washing the cells and stopping the reaction with 5 % trichloroacetic acid and solubilizing the cells in 0.5 % of 0.25 N sodium hydroxide. Each experiment was done in quadruplicates and repeated at least three times.

TUNEL

TUNEL assay was performed using the apoptosis detection system.15dPGJ$_2$ (0, 10, 30 μM) was added to the culture medium for 48 h. Cells were fixed with 4 % paraformaldehyde in PBS overnight at 4 ℃. The samples were washed three times in PBS and permeabilized by 0.2 % Triton X-100 in PBS for 15 min on ice. After washed twice, cells were equilibrated at room temperature for 15-30 min in equilibration buffer (200 mmol/L potassium cacodylate, 0.2 mmol/L dithiothreitol, 0.25 g· L^{-1} bovine serum albumin, and 2.5 mmol/L cobalt chloride in 25 mmol/L Tris-HCL, pH 6.6) and incubated in the presence of 5 μmol/L pluorescein-12-dUTP, 10 μmol/L dATP, 100 μmol/L ethylenediaminetetraacetic acid (EDTA), and terminal deoxynucleotidyl transferase at 37 ℃ for 1.5 h in dark. The tailing reaction was terminated by 2×standard saline citrate (SSC). The samples were washed three times in PBS and analyzed by fluorescence microscopy. At least 1000 cells were counted, and the percentage of TUNEL-positive cells was determined.

Detection of apoptotic DNA fragmentation

MCG-803 cells were grown in 96-well culture plates. The cells

were incubated with various doses of $15dPGJ_2$ for 24 h. Apoptotic DNA fragmentation was determined using a commercially available enzyme-linked immunosorbent assay (ELISA) kit from Sigma. This assay was based on a quantitative Sandwich enzyme-immunoassay directed against cytoplasmic histone-associated DNA fragments. Briefly, the cells were incubated in 200 μL lysis buffer provided with the kit, the lysates were centrifuged, and 20 μL supernatant containing cytoplasmic histone-associated DNA fragments were reacted overnight at 4 ℃ in streptavidin-coated microtitrator wells with 80 μL immunoreagent mixture containing biotinylated anti-histone antibody and peroxidase-conjugated anti-DNA antibody. After washED, the immunocomplex-bound peroxidase was probed with 2, 2' -azino-di [3-ethylbenzthiazoline sulfonate] for spectrophotometric detection at 405 nm.

RIA for PGE2

The amounts of immunoreactive PGE_2 in supernatants were determined by radioimmunoassay (RIA) using a commercially available RIA kit according to the manufacturer' s instructions. Briefly, to each polypropylene RIA tube were added 100 μL each of anti-PGE_2, ^{125}I-PGE_2 , and PGE_2 or the sample. Immune complexes were precipitated 24 h later with 1 ml of 16 % polyethylene glycol solution, and a gamma counter determined the radioactivity in the precipitate. There was no nonspecific interference of the assay by the components of the sample. Determinations were carried out in triplicate and the means and standard deviations were obtained.

Western blot analysis

The cells were lysed in lysis buffer containing 25 mM Hepes, 1.5 % Triton X-100, 1 % sodium deoxycholate, 0.1 % SDS, 0.5 M NaCl, 5 mM EDTA, 50 mM NaF, 0.1 mM sodium vanadate, 1 mM phenylmethylsulfonyl fluoride (PMSF), and 0.1 g/L eupeptic (pH7.8) at 4 ℃ with sonication. The lysates were centrifuged at 15 000×g for 15 min and the concentration of the protein in each lysate was determined with Coomassie brilliant blue G-250. Loading buffer (42 mM Tris-HCl, 10 % glycerol, 2.3 % SDS, 5 % 2-mercaptoethanol and 0.002 % bromophenol blue) was then added to each lysate, which was subsequently boiled for 3 min and then electrophoresed on a SDS-polyacrylamidel gel. Proteins were transferred to nitrocellulose and incubated respectively with antibodies against COX-1, COX-2, PPARγ, Bcl-2, bax, bcl-x_l and β-actin, and then with peroxidase-conjugated secondary antibodies. Detection was performed with enhanced chemiluminescence reagent.

Northern blot

Total mRNA was isolated and stored at -80 ℃ until use. The synthetic DNA oligonucleotide probes complemented to COX-1, COX-2, PPARγ, Bcl-2, bax, bcl-x_l and β-actin mRNA were labeled using terminal deoxynucleotidyltransferase [Boehringer]. Thirty mg of RNA per sample was separated on 1 % agarose-formaldehyde gels and transferred to nylon membranes. The blots were hybridized overnight at 42 ℃, washed in 0.2×SSC containing 0.1 % SDS at 50 ℃ for 10 min, and subjected to autoradiography.

Statistical analysis

Data were presented as the mean ± standard error of the mean, unless otherwise indicated. Multiple comparisons were made for significant differences using analysis of variance, followed by individual comparisons with the Bonferroni post-test. Comparisons between two groups were made with the Student *t* test. *A P*<0.05 was considered significant.

RESULTS

15dPGJ2 inhibited growth of MCG-803 cells

To evaluate the effect of $15dPGJ_2$ on the growth of MCG-803 cells, $15dPGJ_2$ (1,10,30 μM) was added to the culture medium for 48 h. Cell growth was determined by ^{3}H-dRT assay (Figure 1). $15dPGJ_2$ inhibited MCG-803 cell growth in a dose-dependent manner.

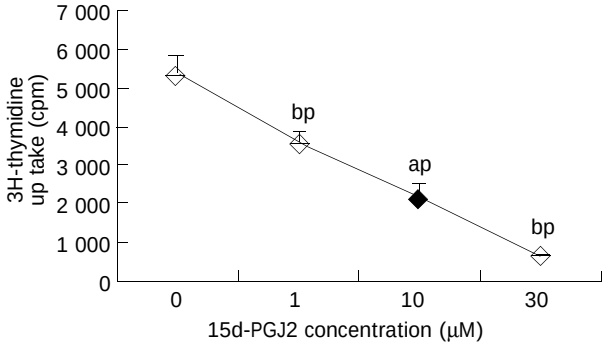

Figure 1 Effect of 15d-PGJ_2 on cell growth by H^3-TdR assay (48 h). MCG-803 cells were incubated with various concentrations of 15d-PGJ_2 for 48 h. The value is represented as mean±SEM (n=3). ^aP<0.05, ^bP<0.01 *versus* control group.

15dPGJ2 induced apoptosis in MCG-803 cells

There are several methods to evaluate apoptosis. In this study, we used ELISA and TUNEL to check for apoptosis of MCG-803 cells after 24 h treatment with $15dPGJ_2$. The percentage of TUNEL-positive cells increased from 13.7±1.5 % to 48.3±2.9 % (Table 1). The same results were obtained by ELISA. The effect of 15dPGJ2 at concentrations from 1 μmol/L to 30 μmol/L on DNA fragmentation in MCG-803 cells is shown in Figure 2. 15dPGJ2 was found to significantly induce DNA fragmentation after the onset of incubation and this effect was in a dose-dependent manner.

Table 1 TUNEL assay performed using apoptosis detection system

15d-PGJ_2 (μM)	Control	10	30
Percentage of TUNEL-positive cells	13.7±1.5 %	34.9±2.7 %^{bp}	48.3±2.9 %^{bp}

$15dPGJ_2$ (0, 10, 30 μM) was added to the culture medium for 48 h. The percentage of TUNEL-positive cells was determined. ^aP<0.05, ^bP<0.01 compared with respective controls. The value is represented as mean ±SEM (n=3). ^bP<0.01 *versus* corresponding control groups.

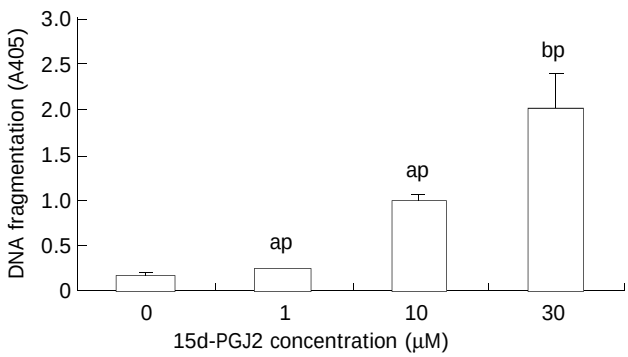

Figure 2 Effect of 15d-PGJ2 on DNA fragmentation in MCG-803 cells. Cytoplasmic histone-associated DNA fragments were determined using a commercial ELISA kit. Culture of MCG-803 cells for 24 h in the presence of 15d-PGJ2 resulted in dose

dependent DNA fragmentation. $^aP<0.05$, $^bP<0.01$ compared with the controls. The value is represented as mean±SEM (n=3).

PPAR mRNA and protein expression in MCG-803 cells increased by 15dPGJ2

Since 15dPGJ$_2$ is a potent PPAR agonist in the events leading to cell apoptosis, we have investigated its effects on the expression of PPARγ mRNA and protein. MCG-803 cells were treated with 15dPGJ$_2$ in the range of 1-30 μM for 6 h. Figure 4 shows that PPARγ mRNA expression was significantly increased in a dose-dependent manner. A Western blot analysis further showed that the mRNA levels encoding PPARγ upon treatment with 15dPGJ$_2$ could be related to the variation of the corresponding protein (Figure 3).

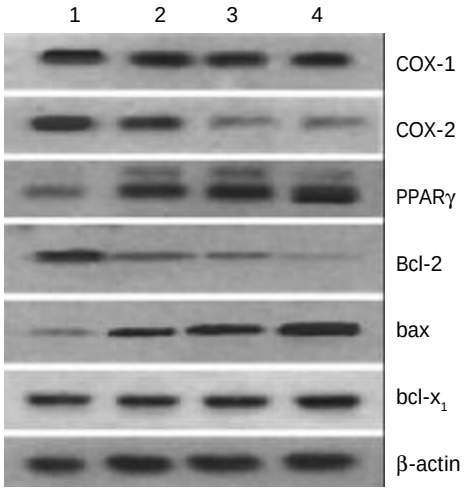

Figure 3 COX-1, COX-2, PPARγ, bcl-2, bax, and bcl-XL protein levels in MCG-803 cells treated with 15d-PGJ2. Cell lysates were collected and processed at 6 h. The whole cellular protein was electrophoresed in SDS-PAGE gel. Western blot was performed using antibodies against COX-1, COX-2, PPARγ,bcl-2, bax, bcl-XL. β-actin was used as a lane-loading control. (1) control, (2) 1 μM, (3) 10 μM, (4) 30 μM.

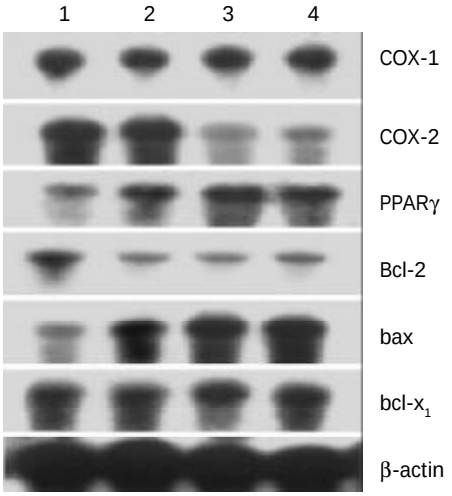

Figure 4 COX-1, COX-2, PPAR-γ, bcl-2, bax, bcl-XLmRNA levels in MCG-803 cells treated with 15d-PGJ2 for 6 h by Northern blot. (1) control, (2) 1 μM, (3) 10 μM, (4) 30 μM.

Effect of 15dPGJ2 on bcl-2, bcl-XL and bax expression in MCG-803 cells

To further elucidate the mechanism of 15dPGJ$_2$ induced apoptosis in MCG-803 cells, we evaluated the involvement of bcl-2 family in the apoptosis process by Western blot and Northern blot analysis. The protein and mRNA of bax were increased and bcl-2 decreased in a dose-dependent manner 6 h after 15dPGJ$_2$ treatment (Figures 3, 4). No change was observed in protein and mRNA expression of bcl-X$_L$ (Figures 3, 4).

Effect of 15dPGJ2 on COXs expression and PGE2 production in MCG-803 cells

To assess the role of COXs in 15dPGJ$_2$ induced apoptosis, we first examined the changes of COX-1 and COX-2 in MCG-803 cells treated with 15dPGJ$_2$. As shown in Figures 3 and 4, the COX-2 protein increased 6 h after 15dPGJ$_2$ treatment and no change was observed in protein expression of COX-1. In Northern blot analysis, similar results were obtained. The expression of COX-1 mRNA was not changed and COX-2 mRNA was not regulated by 15dPGJ$_2$ in dose dependent manners. We used specific RIA to measure the production of PGE$_2$ as COX$_s$ catalyzed the rate-limiting step in the biosynthesis of prostaglandins. Parallel to the inhibition of COX-2, decrease of PGE$_2$ was found in culture medium of HCG-803 cells stimulated by 15dPGJ$_2$ (Figure 5). These results further confirmed that COX-2, not COX-1 activity was changed by 15dPGJ$_2$.

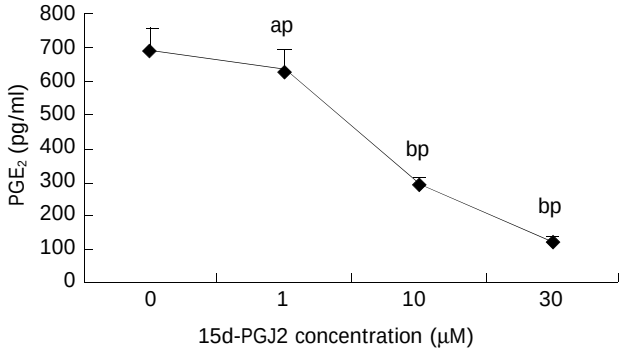

Figure 5 Effect of 15d-PGJ$_2$ on PGE2 production by RIA (24 h). MCG-803 cells were incubated at various concentrations of 15d-PGJ$_2$ for 24 h. The value is represented as mean ±SEM (n=3). $^aP<0.05$ and, $^bP<0.01$ *versus* corresponding control groups.

DISCUSSION

Peroxisome proliferator-activated receptor (PPAR) γ, a member of the steroid nuclear hormone receptor superfamily[11], has been known to trigger adipocyte differentiation and lipid storage by regulating the expression of genes critical for adipogenesis[12]. PPARγ functioned as a ligand-dependent transcription factor[13], which upon heterodimerization with the retinoid X receptor (RXR)[14], bound to specific response elements termed peroxisome proliferator response elements (PPRE). This in turn regulated the expression of target genes[15,16]. Activation of this receptor has been implicated in tumor promotion, cellular differentiation and apoptosis[17]. There are a number of naturally occurring agents that activate PPARγ. Some J-series prostaglandins have been found to bind to PPARγ in low micromolar range[18,19]. The PGD2 derivative, 15-deoxy-12, 14-PGJ2 (15d-PGJ2) was a high affinity ligand (*K*d=300 nM) that demonstrated anti-inflammatory[20,21] and anti-neoplastic activity[22].

The anti-neoplastic activity of PPARγ ligand prompted us to determine whether 15dPGJ$_2$ would trigger MCG-803 cells to undergo apoptosis. The results from Western blotting and Northern blotting have demonstrated that the PPARγ gene and protein expression were clearly observed in MCG-803 cells. 15dPGJ$_2$ stimulated the expression of PPARγ mRNA and its product. Coincubation of MCG-803 cells with 15dPGJ$_2$ potently inhibited cell growth and induced apoptosis in a dose-

related fashion. The dose-dependent suppression of cell growth in cancer cells was also reported after a number of synthetic PPARγ ligands such as thiazolidinediones (TZDs) and non-steroidal anti-inflammatory drugs (NSAIDs) treatment[9]. These results suggest that activation of the PPARγ pathway by $15dPGJ_2$ induces MCG-803 cells to undergo apoptosis.

In this study, the well-known important mediator of apoptosis, bcl-2 family was examined in MCG-803 cells treated with $15dPGJ_2$. In bcl-2 family, bcl-2 and bcl-X_L were anti-apoptotic, whereas bax, bad and bak were pro-apoptotic[23]. The ratio of anti-apoptotic factor to pro-apoptotic factor in the cells was assumed to be a critical mechanism in maintaining normal homeostasis. A higher concentration of bax compared with bcl-2 enhanced susceptibility to apoptosis. Nevertheless, the cell continued to survive if bcl-2 predominated over bax. One of the most significant problems in the treatment of cancer was the resistance of cancer cells to chemotherapy-induced apoptosis. Of gastric cancers, 72 % bcl-2 overexpression and 33-40 % bax frameshift mutation were observed[24-26]. A higher ratio of bcl/bax strongly blocked gastric cancer cell apoptosis by inhibiting cytochrome C release from mitochondria and Caspase-3 activation[27-31]. Our data indicated that $15dPGJ_2$ led to a dramatic decrease in bcl-2 and increase in bax. The bcl-X_L remained unchanged after $15dPGJ_2$. In addition, the decreased ratio of bcl/bax was detected prior to commencement of cell apoptosis after 6 h treatment. These results suggested a direct effect of PPAR pathway on bcl/bax expression. Therefore we concluded that the change of bcl-2 family might play a key role in $15dPGJ_2$-induced apoptosis in MCG-803 cells.

Cyclo-oyxgenase (COX) was the rate-limiting enzyme that catalyzed the initial step in biosynthesis of prostaglandins (PG) from arachidonic[32,33]. COX is encoded by two separate genes, COX-1 and COX-2, both of which participate in formation of a variety of eicosanoids. COX-1 is expressed constitutionally in most tissues and has been proposed to be a housekeeping gene involved in cytoprotection of gastric mucosa, vasodilation in the kidney, and control of platelet aggregation. In contrast, COX-2 is an inducible immediate early gene that is upregulated by various stimuli including mitogens, cytokines, growth factors, and tumor promoters. Accumulating evidence has shown that increased PGE_2 levels via overexpression of the inducible COX-2 isoform were important in the development of human cancer[34]. Previous studies have demonstrated that COX-2 expression was aberrantly increased in various human epithelial cancers, including those of colorectal[35,36], esophageal[37], gastric[38], lung[39] and bladder origin[40]. Data in this study also showed apparent COX-2 expression in MCG-803 cells. These findings suggest that cellular upregulation of COX-2 and PGE_2 may be a common mechanism in epithelial carcinogenesis.

In gastrointestinal system, it has been reported that COX-2 overexpression led to the inhibition of apoptosis or altered cell cycle kinetics in epithelial cells[41,42]. Numerous epidemiological studies suggested that non-steroidal anti-inflammatory drugs (NSAIDs) decreased incidence of gastrointestinal cancers and COX-2 was recognized as a major target of NSAIDs. Inhibition of COX-2 by NSAIDs or COX-2-specific inhibitors caused cell death in cancer cells[43-49], indicating that COX-2 was an important molecular target for prevention and treatment in gastrointestinal cancers. In this study, a crucial issue yet to be resolved was whether COX-2 inhibition played a role in the induction of apoptosis by $15dPGJ_2$ in human gastric carcinoma. We found decreased expression of COX-2 mRNA and protein as well as PGE_2 production in MCG-803 after $15dPGJ_2$ treatment. Our current study demonstrated that the decrease in COX-2 expression occurred prior to apoptosis, suggesting that down-regulation of COX-2 might be an upstream event of $15dPGJ_2$-induced apoptosis. These changes may imply that $15dPGJ_2$ interferes with the expression of COX-2 and PGE_2 production, thereby contributing to induced apoptosis in MCG-803 cells.

The premise is that COX-2 inhibitor has antitumor effect is based on the assumption that prostaglandins and other COX-2 generated downstream mediators promote tumor cell proliferation, survival, and angiogenesis in an autocrine and/or paracrine manner[50-53]. It was also reported that selective cyclo-oxygenase-2 inhibitor induced apoptosis and down-regulated bcl-2 expression in cancer cells[54]. Sheng H also found modulation of apoptosis and Bcl-2 expression by PGE_2 in human colon cancer cells[55]. However, Hsu AL reported that the cyclo-oxygenase-2 inhibitor celecoxib induced apoptosis by blocking Akt activation in human prostate cancer cells independent of Bcl-2[56]. In this study no data proved that Bcl-2 was one of the downstream mediators when COX-2 was inhibited by $15dPGJ_2$. The precise mechanisms on the molecular interaction of COX and bcl-2 expression in $15dPGJ_2$ induced gastric apoptosis should be established by more profound analysis.

In summary, our data demonstrate that 15dPGJ2 inhibited the growth of human gastric cancer cells (MCG803). It is proposed that the decrease of bcl-2/bax ratio and COX-2 be responsible for the apoptotic process in MCG803 cells. Furthermore, PPARγ ligand is a new strategic approach to provide new anticancer therapies.

Abstract

AIM: Ets1 proto-oncogene is a transcription factor involved in the activation of several genes of tumor invasion and metastasis. We aimed to determine the relationship between the extent and intensity of Ets1 expression and patients' clinicopathological factors in gastric carcinoma.

METHODS: Immunohistochemical analysis was performed for gastric tumor paraffin-embedded sections, followed by image analysis.

RESULTS: Ets1 was not expressed in the normal gastric epithelium and its surrounding cells. The percentage of Ets1 expressing cells detected increased significantly in both epithelial tumor and stromal cells from high T classification, lymph node metastasis positive, clinical advanced-stage groups ($P<0.001$). The level of Ets1 staining in epithelial tumor cells also reflected the degree of cell differentiation. The percentage of epithelial and stromal cells expressing Ets1 was significantly correlated with the presence of lymph node metastasis ($P=0.014$ and $P<0.001$ respectively). Ets1 expression was not observed in tissue samples from patients with benign gastric ulcers.

CONCLUSION: Ets1 protein expression in epithelial tumor cells reflects the degree of differentiation, and the percentage of Ets1 positive tumor and stromal cells correlates with lymph node metastasis. Thus Ets1 is a valuable marker of malignant potential in terms of invasiveness and metastasis of gastric carcinoma. It is also possible that inhibition of Ets1 is a potential avenue for therapy in gastric cancer.

INTRODUCTION

Gastric cancer is a leading cause of cancer death in the world. The pathological stage of gastric cancer, including the depth of tumor penetration and the presence of metastases to lymph nodes or distal organs, remains the most important determinant in its prognosis. Usually, these parameters can be determined by microscopic examination of tissue sections from the primary neoplasm and lymph nodes. However, where only primary gastric carcinoma specimens are available for histopathological examination cannot always accurately predict metastasis and disease progression. Recently, from microarray gene expression profiling data[1], the occurrence and progression of cancer were suggested to be related to a series of genetic events affecting the structure and expression of a number of genes. These genes include potential oncogenes, tumor suppressors and those involved in angiogenesis and extracellular matrix (ECM) remodeling. The factors regulating these genes could thus be important markers for disease prognosis and potential therapeutic targets. Since most transcription factors are expressed at very low levels (-10 copies/cell), sensitive assays are required. One suitable approach is to use a specific antibody to detect these factors by immunohistochemical analysis. This allows analysis of the epithelial tumor cells and its surrounding stromal cells. In addition, this approach will enable further understanding of the molecular mechanisms of gastric carcinoma invasion and metastasis.

The Ets family of transcription factors is defined by a conserved DNA binding domain of approximately 85 amino acids. These proteins bind to specific purine-rich DNA sequences, with a core motif of GGAA/T, and have been shown to transcriptionally regulate a number of viral and cellular genes. Ets factors have been shown to be important in a number of biological processes, including cellular proliferation, differentiation, development, transformation, and apoptosis[2-6]. Indeed the Ets1 protein has recently been shown to regulate genes such as vascular endothelial growth factor(VEGF), urokinase plasminogen activator (uPA), matrix-metallopteases (MMPs) and integrin in a variety of cancer cell lines and tissues[7-12]. Many of these genes are involved in angiogenesis and extracellular matrix (ECM) remodeling, important events in the processes of cancer invasion and metastasis.

Microarray analysis from a number of epithelial tumor tissues or cell lines indicate that alterations in Ets1 expression are associated with lung carcinoma[13], breast carcinoma[14], pancreatic carcinoma[15], thyroid carcinoma[16] and oral squamous cell carcinoma[17]. However, it is not clear from these data which cells in the tumor expressed Ets1 or whether this expression was associated with invasive growth. Thus the purpose of this study was to analyze the relationship between Ets1 expression and the malignant behavior in gastric carcinoma, in particular to determine whether Ets1 may have a role in breaking through the muscularis mucosae by invasive tumors and metastasis. This will determine whether Ets1 has potential as a credible marker in predicting the metastatic potential of gastric cancer and assisting in elucidating its role in gastric carcinoma's malignant progression.

MATERIALS AND METHODS

Samples and patients

Since January 2001 to June 2002, we collected biopsies from 43 patients who underwent surgery for gastric neoplasia in the General Surgery Department of Xinhua Hospital, Shanghai Second Medical University. The data set for each patient

included sex, age, histological classification, clinical grade, depth of infiltration (T classification), presence of lymph node metastasis (N classification), distant metastasis (M classification), and clinical stage. Pathological assessments were determined by clinical pathologists according to WHO standards. T1 indicated infiltration of the *lamina propria* or submucosa, T2 infiltration of muscularis propria or the subserosa, T3 penetration of the serosa (visceral peritoneum), and T4 penetration of the serosa and infiltration of adjacent structures. Lymph node (N) classification was divided into no metastasis (N0) and metastasis in 1-6 (N1), 7-15 (N2) or >15 (N3) regional lymph nodes. M classification was M1 for presence or M0 for absence of distant metastasis. Clinical stage was determined by combination of these parameters as stage IA (T1N0M0), stage IB (T1N1M0), stage II (T1N2M0, T2N1M0 or T3N0M0), stage IIIA (T2N2M0, T3N1M0 or T4N0M0), stage IIIB (T3N2M0) and stage IV (TxN3M0, T4NxM0, TxNxM1). In addition, two samples of both benign gastric ulcer and breast cancer were used as controls.

Samples were fixed in formalin immediately after the operation and specially prepared for immunohistochemistry. Briefly, samples of no more than 2×1.5×0.2 cm were dehydrated at 4 ℃, and low temperature paraffin wax (<60 ℃) was used for embedding. 3 μm thick sections were de-waxed immediately before use with xylene (4 ℃) and rehydrated for immunohistochemistry.

Immunohistochemistry

Endogenous peroxidase activity was quenched with 3 % hydroperoxide followed by incubation with 1 % bovine serum albumin to block any nonspecific binding. Primary antibodies used were anti-human Ets1 monoclonal antibody (Transduction Laboratories, Lexington, KY), rabbit anti-human Ets1 polyclonal antibody (Santa Cruz Biotechnology, CA) or rabbit anti-human cytokeratin polyclonal antibody (DAKO, Copenhagen, Denmark). Amplification of the primary antibody reaction was achieved by incubation with an appropriate secondary antibody [Goat anti-Rabbit or anti-mouse IgG, Gene Tech] conjugated to peroxidase. The binding was visualized by DAB and the sections were counterstained with hematoxylin. All incubations and washing were performed at room temperature.

Image analysis

Intensities, percentages, and patterns of immunohistochemical staining for each sample slide were analyzed by KS4000 image analysis system (Zeiss Company, Germany) and recorded individually. For each sample, six representative images were collected at high magnification (×400). Image analysis determined the proportion of epithelial or stromal cells within the tumor expressing Ets1 and the percentage of cells with moderate and intense staining. The data were expressed as proportion of tumor.

Statistic analysis

The data were presented as the mean ± standard deviation (SD) for each group. Statistical analysis was performed using analysis of variance (ANOVA) and Mann-Whitney non-parametric test. Intergroup difference was evaluated by Fisher' s test. $P<0.01$ was considered statistically significant.

RESULTS

Patients characteristics

Samples were obtained from 41 patients, 30 males and 10 females. The age range was from 37 to 87. The 41 patients were diagnosed with malignant tumor. The histological classification included adenocarcinoma (30), signet ring cell carcinoma (6), undifferentiated carcinoma (4) and gastrointestinal stromal tumor (GIST) (1). The samples were divided into two groups according to their depth of infiltration (WHO classification): 15 of T1 or T2, and 25 of T3 or T4. Specimens were also divided according to histological grade: grade I (highly differentiated carcinoma) for 7 samples, grade II (moderately differentiated carcinoma) for 19 samples, grade III (poorly differentiated carcinoma) for 14 samples. 26/40 patients demonstrated lymph node metastasis and only one patient had known distant metastasis (liver).

Expression of Ets1 in gastric carcinoma

In our study, staining of Ets1 was observed in all malignant gastric tumor cells, including adenocarcinoma, signet ring cell adenocarcinoma and undifferentiated carcinoma, and the results are summarized in Table 1. Epithelial tumor cells stained for Ets1 were mainly in the nucleus and only rarely was staining observed in the cytoplasm (Figure 1A). No staining for Ets1 was observed in the non-neoplastic tissue or in tissues from a patient with benign gastric ulcer (Figure 1G). In contrast, antibodies to another Ets factor which is known to be epithelium-specific (Elf5), stained normal gastric epithelium, but lost its expression in gastric cancer (data not shown). Ets1 staining was also observed in newly formed blood vessel endothelial cells (Figure 1B) and interstitial cells in surrounding tissue (Figure 1C). Ets1 protein was localized in both cytoplasm and nucleus of the stromal cells. Furthermore intense staining for Ets1 was observed in invasive cells at the junction of normal tissue and malignant tissue (Figure 1D). Increased Ets1 protein expression observed by immunohistochemistry was confirmed by quantitation of Ets1mRNA levels by RT-PCR and Northern blot (data not shown). Immunohistochemistry of a breast cancer specimen also detected Ets1, but it was predominantly expressed in the cytoplasm (Figure 1E).

Relationship between percentage of Ets1 expressing cells and pathological assessment in gastric carcinoma

Age, sex and histological grade Statistical analysis determined that there was no significant correlation between the expressions of Ets1 in gastric cancer and age, sex or WHO histopathological classifications. Although there was a trend in proportions of Ets1 positively stained epithelial cells from 26.9 % in grade I, increasing to 39.5 % in grade II and 32.8 % in grade III (Table 1), there was no significant correlation ($P=0.366$). A similar trend was also observed for staining of tumor stromal cells ($P=0.486$).

Depth of infiltration (T) classification Considering the importance of breaking through muscularis mucosae, we compared the groups with tumors confined to the mucosa/submucosa (15 samples, T1 or T2) and those tumors which had penetrated the serosa (25 samples, T3 or T4). Our data demonstrated that Ets1 was detected in a higher proportion of both epithelial and stromal cells in tumors from patients with more advanced disease. For example, 17.2±12.0 % of tumor epithelial cells from T1 or T2 tumors were positive for Ets1, whereas 45.6±17.9 % were positive for T3 or T4 tumours ($P<0.001$, Table 1). The proportion of Ets1 expressing tumor stromal cells also significantly correlated with the presence of more advanced disease T classification ($P<0.05$).

Lymph node and distant metastasis Similarly, grouping of patients according to the presence (N123) or absence (N0) of lymph node metastasis showed an increase in Ets1 positive tumor epithelial cells from 24.1±17.4 % (N0) to 40.8±20.8 % (N123, $P<0.05$). In addition, the proportion of Ets1 expressing tumor stromal cells was also significantly higher in patients with lymph node metastasis ($P<0.001$). Only one patient in our samples had known distant metastasis, but Ets1 was detected in both epithelial and stromal cells in tumor sections from this patient (71 % and 61 % respectively).

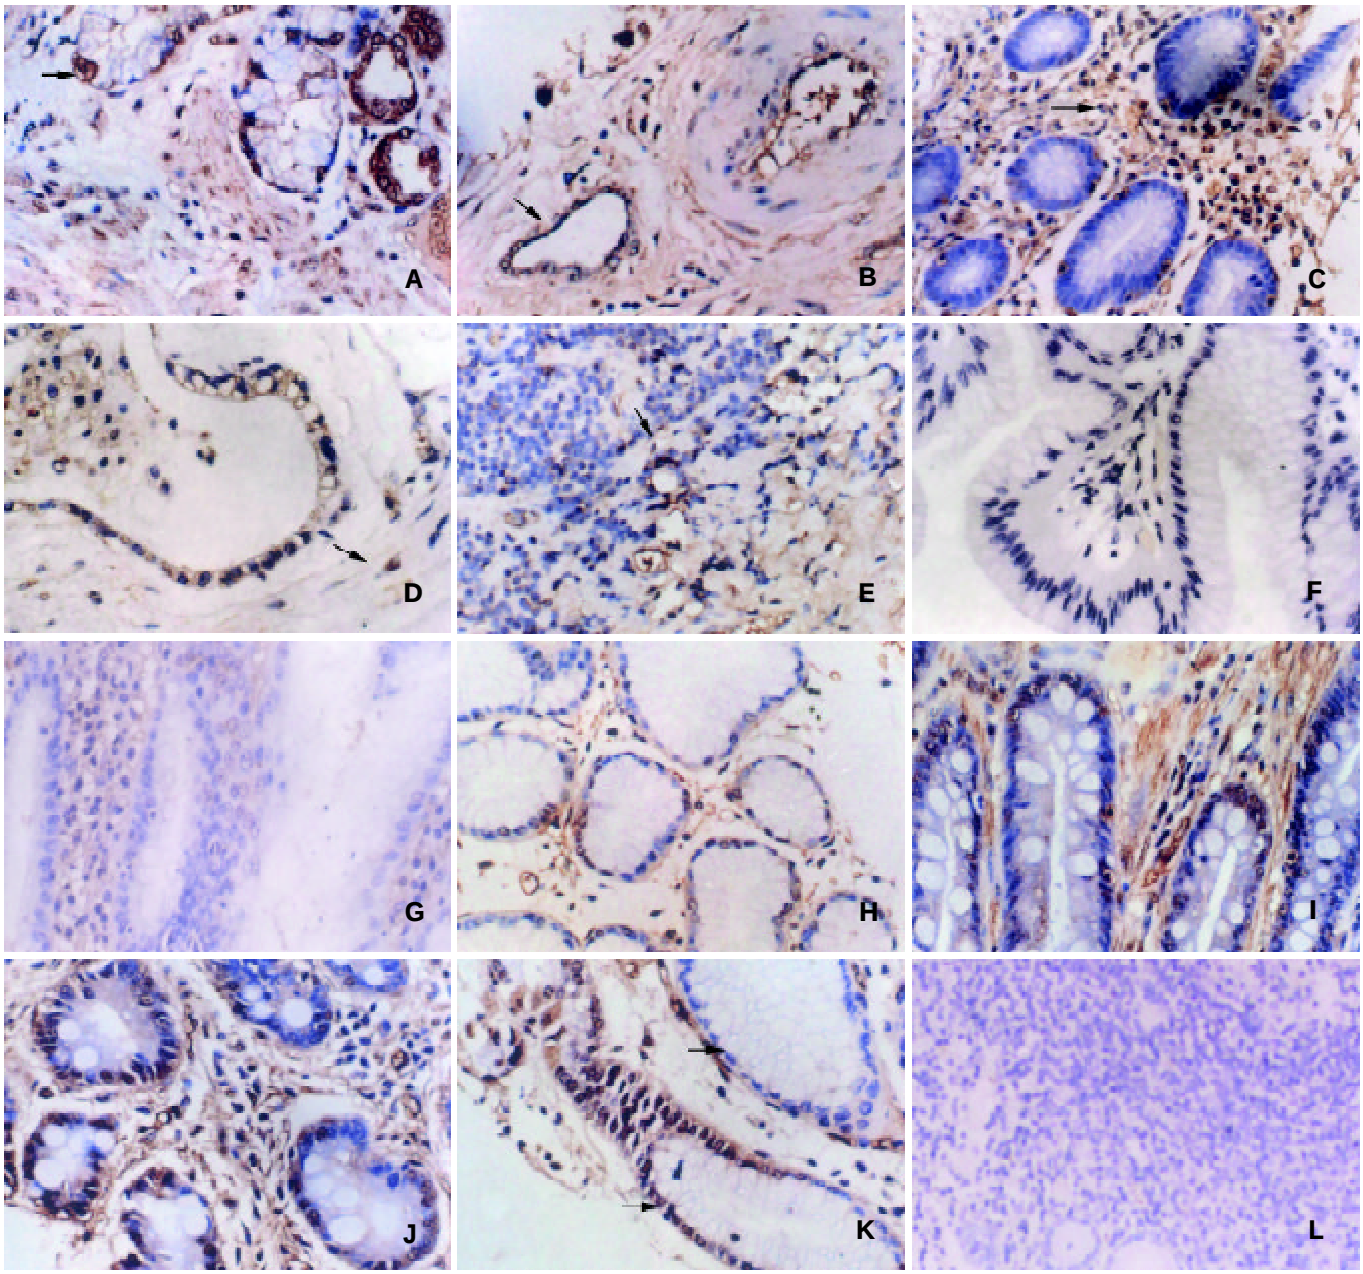

Figure 1 A: Ets1 immunohistochemical stain in gastric cancer cells. The arrowed cell is a typical Ets1 positively stained cell. The area of stain was mainly, located in the nucleus of epithelial tumor cells. Ets1 protein was localized in both cytoplasm and nucleus of the stromal cells. B: Ets1 expression in vascular endothelial cells. This was an example of pooly differentiated gastric adenocarcinoma. Ets1 was present in endothelial cells of blood vessels (arrowed). C: Ets1 is expressed in interstitial cells. Photomicrograph of a typical gastric carcinoma. Ets1 positive stromal cells were detected in the interstitial tissue. D: The expression of Ets1 in polarity. Image of gastric cancer cells infiltrating to the muscular layer. Intense staining of Ets1 was observed at the junction of the infiltrating tumor cells and the serosa. We termed it the polarity expression. E: Ets1 expression in breast carcinoma. Example of breast carcinoma, Ets1 positive cells arrowed. F: Ets1 negative control staining. G: Ets1 is not expressed in glandular cells of benign gastric ulcer. H-J: Ets1 expression in tissues with different histopathological grades. Section of grade I(H), grade II(I) and grade III(J) gastric cancer showing increased positive cells and intensity of Ets1 staining with advanced disease. K: Ets1 expression is high in undifferentiated tumor cell. The image contained well differentiated and poorly differentiated tumor tissues. The number of positive cells and the intensity of the Ets1 staining were increased in undifferentiated tumor cells. L: Ets1 is not expressed in GIST. Photomicrograph of gastrointestinal stromal tumor (GIST). No Ets1 positive cancer cells were observed. (A, H, I, J, K original magnification ×400), (B, C, D, E, F, G original magnification ×100), (L, original magnification ×50).

Clinical stage When the T, N and M classifications were combined into the WHO defined clinical stages, there was a significant correlation between Ets1 staining in epithelial and stromal cells with the presence of more advanced disease ($P<0.001$ and $P<0.005$ respectively).

Relationship between Ets1 levels and clinical disease

Our image analysis also enabled us to compare the signal intensity of Ets1 staining (Table 2-1,2), which reflected the levels of Ets1 (confirmed by RT-PCR, data not shown). When all the patients were considered together, the majority (24/40, 60 %) displayed moderate staining levels in tumor epithelial cells whereas 10/40 (25 %) displayed intense staining. Of these 10 patients with intense staining, however, 9 had tumors penetrating the mucosa (T3 or T4) and 8 had metastasis into the regional lymph nodes. The single patient with distant metastasis also displayed intense staining for Ets1. Similar high levels of Ets1 labelling were observed in stromal cells from

patients with advanced disease. In stromal cells 16/40 (40 %) displayed intense staining. These 16 patients with intense staining included a single patient with distant metastasis, while 11 of these 16 patients had tumors penetrating the mucosa (T3 or T4) and metastasis into the regional lymph nodes. Thus it appeared both the level of Ets1 and the proportion of positive cells were correlated with advanced gastric carcinoma.

DISCUSSION

Gastric cancer is the most frequent malignancy of the gastrointestinal tract in China and the second most common cause of cancer-related death in the world[18]. The prognosis of patients with gastric cancer has been improving owing to the progress in diagnostic techniques and treatment methods for gastric cancer, but peritoneal dissemination is the main cause of recurrence after curative resection of advanced cancer. The prognosis of gastric cancer which has invaded as far as the gastric serosa was still poor with a 5-year survival of less than 35 %[19]. Among these malignant characteristics of gastric cancer cells, metastasis to the peritoneum is an especially complex phenomenon, which requires the involvement of many different genes in multiple steps for tumor cells. Although many aspects of gastric cancer metastasis await further clarification, adhesion molecules, apoptosis-related genes, and others have been reported to play an important role in peritoneal dissemination of gastric cancers[20], but details of the mechanism involved remain unclear. Since Ets1 has been shown to regulate many genes involved in angiogenesis and extracellular matrix (ECM) remodeling, events important in cancer metastasis, we analyzed the relationship between Ets1 expression and the malignant behavior in gastric carcinoma. This demonstrated that Ets1 expression was related to the pathological stage of gastric cancer, including tumor infiltration and presence of metastases to lymph nodes or distal organs. These data are consistent with other studies that have shown significant correlation between Ets1 expression in tumor cells and the presence of lymph node metastasis. But our data also demonstrated that Ets1 expression in cancer associated stromal cells was significantly correlated with the presence of lymph node metastasis. The proportion of Ets1 expressing cells was also associated with metastasis kinetics, expression of Ets1 within a few epithelial tumor cells in early disease, then expression in stromal, endothelial and other cells in advanced malignant disease where cancer has broken through muscularis mucosae. This suggested that Ets1 had a specific role in the regulation of genes involved in gastric invasion and metastasis, rather than carcinogenesis[2,3] in gastric carcinoma. It also indicated that Ets1 was a promising marker of malignant potential and a potential avenue for therapeutic intervention in gastric cancer.

The level of Ets1 expression in epithelial tumor cells was correlated with the progression of disease, perhaps associated with the degree of cancer cell differentiation. In addition, Ets1 expressing cells were located at the invasive front of the tumor. This is consistent with previous observations that Ets1 was associated with branching morphogenesis and organ formation in embryos[21] and embryonic stem cell differentiation (Xu *et al*.,

unpublished data). Other cell types in gastric cancer, such as stromal cells, significantly increased Ets1 expression which was correlated with penetration through the muscularis mucosae and the presence of lymph node metastasis. These data are important observations since the key approach for advancing our treatment of gastric carcinoma is to clarify the mechanism of infiltration, especially for the first step, namely penetrating the muscularis mucosae. Previously, the interrelated elements concerned with gastric carcinoma' s penetration of the extracellular matrix (ECM), angiogenesis and the surrounding microenvironment have not been connected.

Increased expression of genes encoding enzymes involved in degradation of the extracellular matrix (ECM), such as MMP-1 (collagenase-1), MMP-3 (stromelysin-1), MMP-7 (matrilysin), and MMP-9 (type IV collagenase/gelatinase) has been identified in cancer from recent microarray data[22]. Hence, Ets1 is likely to contribute to tumor invasion and progression through activation of these enzymes. Indeed, expression of these ECM remodeling enzymes was detected concomitant with Ets1 mRNA in tumor cells and/or stroma cells.

Ets1 is also involved in angiogenesis, which is essential for tumor progression. In a non-vascularized tumor the growing tumor becomes hypoxic, thus the observation that Ets1 was induced by hypoxia via hypoxia-inducible factor-1 (HIF-1)[23] is important. VEGF and bFGF also induce Ets1 in endothelial cells. Ets1 was believed to confer an angiogenic phenotype to the endothelial cells through induction of the urokinase-type plasminogen activator (u-PA))[24-26] and MMPs, and also to regulate N-acetylglucosaminyl-transferase V (GnT-V), which has been associated with metastasis of tumors[27]. Thus the microenvironment of a growing tumor may induce Ets1 in tumor cells and/or stroma cells, which subsequently induces angiogenesis-related genes and ECM remodeling enzymes required for tissue invasion and metastasis. It is interesting to note that expression of Ets1 in both tumor and stroma was correlated with poor prognosis in human ovarian carcinoma[28].

Recent development in microarray technologies has resulted in extensive profiling of cancer and cancer metastases[29]. These approaches have generated a vast amount of new data to investigate the molecular mechanisms of cancer metastasis, however, many of these studies have not identified Ets1 as significantly increased. This is surprising given both our data and other data demonstrating increased Ets1 in lung carcinoma, breast carcinoma, pancreatic carcinoma, thyroid carcinoma, and oral squamous cell carcinoma[7-12]. We suggest that this anomaly is due to the sensitivity of microarray analysis, which is commonly used to detect genes with altered expression of more than 2 fold. As a transcription factor, 1-2 fold increased expression could have significant biological effects. It is interesting to note that one microarray study of gastric cancer cell lines reported that it did not find any transcription factor more than 2.0 fold upregulated from 20 k genes examined. However this study identified increased levels of defined Ets regulated genes, such as MMP and VEGF. It is also possible that mRNA status was not consistent with protein expression status or perhaps variation in cell types and Ets1 expression in the tumor sample concealed a more localized Ets1 increase. Thus we believe that our results from immunohistochemistry do not conflict with these microarray data.

In addition to the potential of Ets1 as a diagnostic marker, there is also potential for Ets1 as a potential therapeutic target for metastasis in gastric carcinogenesis. Since increased expression of Ets1 and subsequently its downstream target genes (MMPs, VEGF and HIF) contribute to invasiveness and metastasis of gastric carcinoma, inhibition of its expression is potentially therapeutic. Recently, we reported that inhibition of Ewing' s sarcoma associated EWS/FLI-1 transcription via sequence-specific transcriptional suppressor was sufficient to inhibit the transformed phenotype[30]. Thus specific inhibition of Ets1 function (or induction of Ets1) has potential for reducing metastasis in gastric carcinoma[31].

Abstract

AIM: To investigate the expression of c-myc target from laryngeal cancer cells (MTLC) gene in gastric carcinoma (GC) tissues and the effect of MTLC over-expression on gastric carcinoma cell line BGC823.

METHODS: RT-PCR was performed to determine the expression of MTLC mRNA in GC and matched control tissues. BGC823 cells were transfected with an expression vector pcDNA3.1-MTLC by liposome and screened by G418. Growth of cells expressing MTLC was observed daily by manual counting. Apoptotic cells were determined by TdT-mediated dUTP nick-end labeling (TUNEL) assay.

RESULTS: The expression of MTLC mRNAs was down-regulated in 9(60%) of 15 cases of GC tissues. The growth rates of the BGC823 cells expressing MTLC were indistinguishable from that of control cells. A marked acceleration of apoptosis was observed in MTLC-expressing cells.

CONCLUSION: MTLC was down-regulated in the majority of GC tissues and could promote apoptosis of GC cell lines, which suggests that MTLC may play an important role in the carcinogenesis of gastric carcinoma.

INTRODUCTION

Gastric carcinoma (GC) is one of the most common malignant tumors in the world[1,2]. Numerous data have shown that some genes such as p53, c-myc, bcl-2, COX-2 and PTEN[3-6] might be associated with the gastric carcinogenesis. However, the exact molecular mechanism underlying GC remains to be fully elucidated. Therefore, it is necessary to look for novel genes to obtain a thorough understanding about gastric carcinogenesis.

c-myc target from laryngeal cancer cells (MTLC) gene, a putative target of c-myc, was recently cloned in our laboratory (GenBank access number AF527367). MTLC was located in 6q25, a chromosome region involved in various kinds of cancers[7-11]. Previous studies have shown that its protein product expressed in nuclei and might take part in the regulation of cell cycle[12], suggesting that MTLC was potentially related to the carcinogenesis. In this study, we therefore performed RT-PCR and eukaryotic transfection to reveal the relationship between MTLC and GC.

MATERIALS AND METHODS

Tissues and cell line

All the gastric cancer and matched control tissues confirmed pathologically were obtained from the First Affiliated Hospital of China Medical University. Tumor tissues were dissected from the resected specimens. The normal tissue block was taken from the distal resection margin and was apart from cancer at least 1 cm. Gastric carcinoma cell line BGC823 was kept in our laboratory.

RT-PCR

Total RNAs were extracted from cancer tissues by TRIZOL reagents (GibcoBRL, Grand Island, NY, USA), and were reverse-transcripted to the first strand of cDNA using reverse transcriptase system (Promega, Madison, WI, USA). MTLC cDNA was amplified by PCR under the following condition: first at 95 ℃for 1 min, 30 cycles at 95 ℃for 30 s, at 60 ℃for 1 min, at 72 ℃for 1.5min, and finally at 72 ℃for 10 min. PCR primers consisted of the sequences of forward: 5-ATGGATCCCTGCACTGGCTGATGAGTGTGTA-3 and reverse: 5-GTAAGCTTGAACAGTGCCTTCACCCTCG AGGT-3. β-actin gene was used as internal control.

Construction of MTLC expression vector

MTLC segment amplified by PCR was ligated to pMD-18T vector (Takara, Dalian, China) by TA cloning. The recombinant was digested by *BamH I* and *EcoR I*, and then the target fragment was recollected and cloned into pcDNA3.1 vector (Invitrogen, Carlsbad, CA, USA). Both PCR product and the expression vector pcDNA3.1-MTLC were confirmed by sequencing to avoid mutation.

Transfection and screening of BGC823 cells

BGC823 cells in logarithmic phase were seeded in 35 mm plates and cultured with DMEM containing 10 % serum overnight. Cells were transfected with 1 μg expression vector or empty parental vector by Lipofectamin 2000 (Invitrogen, Carlsbad, CA, USA) and subsequently screened by G418 at a final concentration of 5 g/L after cultured for 24 h.

Observation of cell growth

Cells transfected by pcDNA3.1-MTLC or empty parental vector were plated in 35 mm plates at a concentration of 1×10^5 cells/plate with DMEM culture containing 10 % serum. Individual plates were trypsinized daily and the total number of viable cells per plate was determined by manual counting.

Detection of apoptosis

DeadEnd™ Fluorometric TUNEL System (Promega, Madison, WI, USA) was used to determine the apoptosis of cells. 1×10^5 cells transfected by pcDNA3.1-MTLC or empty parental vector were seeded into a plate with a poly-L-lysine-coated slide on its center and grown for 24 h in DMEM culture containing 10 % serum. The cells were then maintained for additional

18 h in serum-free culture and then detected according to the protocol provided by the manufacturer. The samples were stained with propidium iodide (PI) to make a red background and then observed under fluorescence microscope.

RESULTS

Expression of MTLC mRNA in GC tissues

RT-PCR was performed in 15 paired tissues to reveal the expression levels of MTLC mRNA. The result of electrophoresis showed that the PCR product was a single band on agar gel (Figure 1). MTLC was down-regulated in cancer tissues in 9(60 %) of 15 cases after normalization by comparing the band intensities with software UVP Gelworks ID advanced version 2.5 (Figure 1).

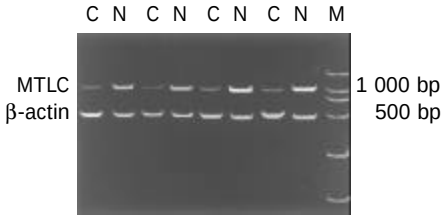

Figure 1 RT-PCR products were electrophoresed on 1 % agarose gel containing ethidium bromide. The level of β-actin was used as internal control. M: DL2000 DNA marker; C: gastric cancer tissue; N: adjacent normal gastric tissue.

Effects of MTLC expression on cell growth

One of the effects of c-myc on cells is to affect their growth properties. Therefore, we determined whether over-expression of MTLC could recapitulate this character. As seen in Figure 2, the growth rates of MTLC-expressing cells were indistinguishable from those of control cells transfected with the empty parental vector.

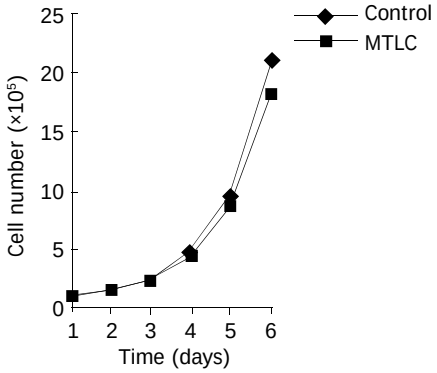

Figure 2 Cells were determined by manual counting daily. The data was analyzed by Microsoft Excel.

Promotion of apoptosis by MTLC

We studied the response of MTLC-expression BGC823 cell line to avoid its growth factors. Compared with the control

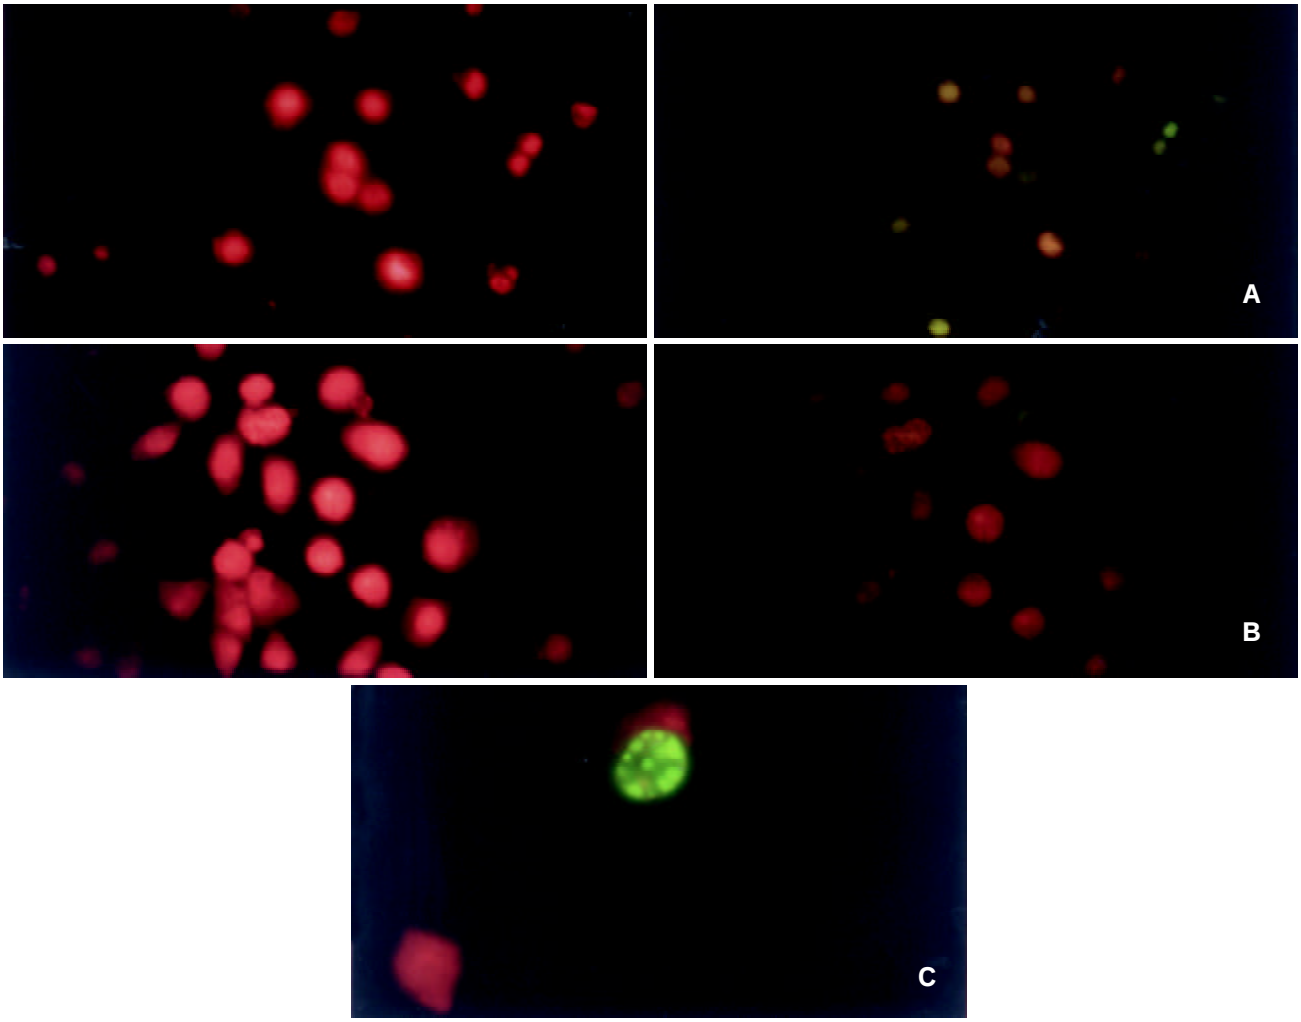

Figure 3 Apoptosis of cells were detected by TUNEL (TdT-mediated dUTP Nick-End Labeling) assay. Green fluorescence of fluorescein-12-dUTP was detected in apoptotic cells, whereas red fluorescence of PI was observed in all cells. Both signals in a same field were photographed respectively. A: MTLC-expressing cells (×400); B: control cells (×400). C: a single apoptotic cell (×1000).

cells, MTLC-expression cells showed a marked acceleration of apoptosis (Figure 3).

Table 1 Relative expressions of MTLC / β-actin in GC tissues and control tissues

Case No.	GC	Control	Ratio[a]
1	0.27	2.56	0.10
2	0.16	3.78	0.04
3	0.56	2.64	0.21
4	0.93	1.56	0.59
5	1.25	1.17	1.06
6	0.52	2.31	0.22
7	0.35	1.75	0.20
8	0.35	1.21	0.29
9	0.64	0.73	0.87
10	1.21	0.98	1.29
11	0.39	2.35	0.16
12	0.57	1.54	0.37
13	0.47	1.56	0.30
14	0.69	0.76	0.90
15	0.83	0.93	0.89

[a]The ratios less than 0.5 were defined as down-regulation.

DISCUSSION

MTLC is a novel gene cloned in our laboratory recently and has no known function. Previous studies showed that it was located in 6q25, a chromosome region involved in a variety of human malignancies, including gastric cancer. Analysis of the 5' flanking sequence also demonstrated two E-boxes on the promoter region of MTLC, suggesting that MTLC may be a target of oncogene c-myc. C-myc, a helix-loop-helix leucine zipper transcription factor, can exert considerable control over transformation, differentiation, apoptosis, and cell cycle progression through a number of target genes, including CAD[13], ODC[14,15], LDH-A[16,17], cyclin E[18], MrDb[19], telomerase/hTERT[20-25], rcl[26], IRP2[27], cdc25A[28], and JPO1[29]. It was also shown that c-myc could contribute to gastric carcinogenesis[30-36], but the exact mechanism is still not clear.

In this study, therefore, we detected the expression of MTLC mRNA in gastric cancer tissues and the effects of MTLC over-expression in gastric carcinoma cell line BGC823 to reveal the relationship between MTLC and gastric cancer. Results of RT-PCR showed that MTLC was down-regulated in 60 % (9/15) cases of gastric cancer tissues, a considerable frequency approximating to other genes suppressed in gastric cancer[37-40], suggesting that MTLC may play an important role in carcinogenesis. Furthermore, we performed gene transfection to reveal the possible function of MTLC in gastric carcinogenesis. MTLC did not affect cell growth but remarkably promoted apoptosis in response to growth factor deprivation, although we could not yet explain how this occurred. Over-expression of some other c-myc targets such as p21[41-45] and GADD45[46-51] has been reported to exhibit similar effects through p53 pathway. However, the mechanism of MTLC promoting GC cells apoptosis needs to be further studied. It is also necessary to verify the down-regulation of MTLC in GC tissues by detecting more samples with various types or clinical stages.

Abstract

AIM: To clone and express the antigen of monoclonal antibody (MAb) PD4 for further investigation of its function.

METHODS: MGC803 cDNA expression library was constructed and screened with PD4 as probes to clone the antigen. After failed in the library screening, immunoprecipitation and SDS-polyacrylamide gel electrophoresis were applied to purify the antigen for sequence analysis. The antigen coming from *Mycoplasma hyorhinis (M. hyorhinis)* was further confirmed with Western blot analysis by infecting *M. hyorhinis* -free HeLa cells and eliminating the *M. hyorhinis* from MGC803 cells. The full p37 gene was cloned by PCR and expressed successfully in *Escherichia coli* after site-directed mutations. Immunofluorescence assay was used to demonstrate if p37 protein could directly bind to gastric tumor cell AGS.

RESULTS: The cDNA library constructed with MGC803 cells was screened by MAb PD4 as probes. Unfortunately, the positive clones identified with MAb PD4 were also reacted with unrelated antibodies. Then, immunoprecipitation was performed and the purified antigen was identified to be a membrane protein of *Mycoplasma hyorhinis (M. hyorhinis*) by sequencing of N-terminal amino acid residues. The membrane protein was intensively verified with Western blot by eliminating *M. hyorhinis* from MGC803 cells and by infecting *M. hyorhinis*-free HeLa cells. The full p37 gene was cloned and expressed successfully in *Escherichia coli* after site-directed mutations. Immunofluorescence demonstrated that p37 protein could directly bind to gastric tumor cell AGS.

CONCLUSION: The antigen recognized by MAb PD4 is from *M. hyorhinis,* which suggests the actions involved in MAb PD4 is possibly mediated by p37 protein or *M. hyorhinis.* As p37 protein can bind directly to tumor cells, the pathogenic role of p37 involved in tumorigenesis justifies further investigation.

INTRODUCTION

Gastric cancer is common in China[1-14]. For decades, a goal of cancer researchers is to be able to immunize patients with their own tumor tissues or tumor associated antigens after surgical operation to stimulate their immune response. The benefits of this aim include host immune surveillance to eliminate the metastatic cells and prevent its relapse. Many tumor associated antigens defined by monoclonal antibodies have been successfully applied clinically in detecting different tumors[15,16]. However, only a few of the genes for these markers have been cloned[17,18], primarily because the epitopes usually are not protein or not linear in amino acid sequence.

MAb PD4 has been derived from mouse immunized with human gastric cell line MGC803 and could specially react with some tumor cells[19]. Our previous studies showed that MAb PD4 could induce apoptosis of MGC803 cells[20], inhibit both the growth of ras transformed cell line Rat3-3 and the tumorigenesis in nude mice[21], suggesting that the antigen recognized by MAb PD4 could be associated with cancerous development. Obviously the critical step in investigating the molecular mechanisms involved in the antigen is to isolate its cDNA.

As it was shown previously that PD4 worked well in Western blot in which the recognized protein was around 40 kilo-Dalton in molecular weight[21]. First, we screened the cDNA library constructed with MGC803 cells by MAb PD4 as probes. Unfortunately, the positive clones identified with MAb PD4 were reacted with unrelated antibodies. We tried with other different tumor expression cDNA libraries and also did not get any specific clones. Then, immunoprecipitation was performed and the target molecule was identified to be a membrane protein of *M. hyorhinis* by N-termial amino acid residues sequencing. The membrane protein was intensively verified with Western blot by eliminating *M. hyorhinis* from MGC803 cells and by infecting *M. hyorhinis*-free Hela cells. Therefore, the actions involved in MAb PD4 were possibly mediated by p37 protein or *M. hyorhinis.*

p37 is a membrane protein of *M. hyorhinis* located on the outside of the cell membrane. It contains 1209 nucleotides and encodes 403 amino acid residues[22]. An analysis of the protein sequence has revealed that p37 has a 41 % similarity to a periplasmic binding-protein-dependent transport system found in Gram-negative bacteria[22]. Thus, p37 is thought to be part of a high affinity transport system from *M. hyorhinis*. Also, there are lines of evidence indicating the linkage between p37 or *M. hyorhinis* and cancer[23-25]. For example, antibodies against p37 could inhibit the invasive potential of FS9 cells and cause malignant cells to revert to a more normal behavior.

In this study, we identified the antigen recognized by MAb PD4, which was previously considered as an antibody against cancer. The full gene encoding the antigen was cloned and expressed successfully in *Escherichia coli (E. coli)* after site-directed mutation of the seven codes tryptophan TGA into universal codes tryptophan TGG and demonstrated that p37 could bind directly to tumor cell AGS. Considering the association between p37 and tumor development and invasion, this work provides a basis for further investigation of the pathogenic role of p37 involved in *M. hyorhinis* infection.

MATERIALS AND METHODS

Cell culture and regents

Human gastric cancer cell lines MGC803 and AGS, human ovarian cancer cell line HeLa, expression plasmid pGEX-4T-1, *E. coli* BL21(DE3) and MAb PD4 were all kept in our laboratory. Site-directed mutation kit was purchased from Promega Corp. Anti-glutathione-S-transferase (GST) mouse antibody, goat anti-mouse antibody conjugated with tetramethyl rhodaine isothiacy-anate (TRITC), 3,3'-diaminobenzidine (DAB), isopropylthiogalactoside (IPTG) were from Sigma. All primers for PCR and site-directed mutation were synthesized by Sangon Corp. (Shanghai, China). Various restriction endonucleases were products of New England BioLabs (NEB). RPMI1640 and F12K medium were from GIBCO BRL. RNA extraction kit was from Invitrogen Corp.

cDNA library construction, screening and clone identification

mRNA purification and poly(A)+ mRNA enrichment were processed with a messenger RNA isolation kit (Strategene Corp.) from 5×10^7 MGC803 cells. A cDNA library was prepared and packaged with ZAP Express cDNA Gigapack III gold cloning kit (Strategene Corp.) according to the manufacture's instruction. The library quality was determined with its diversity and the average size of the inserted cDNA fragments. The non-amplified library was plated and transferred to nitrocellulose filters. Initial screening was performed with 1 $\mu g\cdot mL^{-1}$ MAb PD4 (diluted in phosphate-buffered saline containing 1 % bovine serum albumin). The filters were then washed in phosphate-buffered saline (PBS) and bound MAb PD4 was detected by alkaline phosphatase coupled to sheep anti-mouse antibodies followed by the mixture solution of nitro blue tetrazolium and bromochloroindolylphosphate. The positive bacteriophages were subcloned and the positive individual clones were checked with unrelated antibodies for its specificity.

Preparation of MGC803 cell membrane proteins

2×10^8 MGC803 cells were frozen and thawed repeatedly for 4-5 times in phosphate-buffered saline containing 1 $mmol\cdot L^{-1}$ PMSF, then centrifuged at 4 000×g for 30 min at 4 ℃. The supernatant was collected, centrifuged at 100 000×g for 1 h at 4 ℃. The precipitated membrane debris was suspended with 1-2 ml lysis buffer (20 mM Tris-HCl pH 7.5, 150 mM NaCl, 2 mM EDTA, 1 % NP-40, 5 % sodium deoxycholate, 1 mM PMSF, 2 $\mu g\cdot mL^{-1}$ aprotinin), shaken for 30 min at 4 ℃, then centrifuged at 100 000×g for 1 h at 4 ℃. The supernatant was analyzed by Western blot with MAb PD4.

Purification and identification of the antigen protein

The lysates from MGC803 cells were immunoprecipitated for overnight at 4 ℃ by MAb PD4 coupled with protein A-sepharose 4B beads (Sigma). The normal mouse IgG was used as control. The immunoprecipitated beads were washed three times with lysis buffer and subjected to 12 % SDS-polyacrylamide gel electrophoresis (SDS-PAGE). The gel-separated proteins were transferred onto PVDF membranes. A piece cut off from the membrane was used for Western blot with MAb PD4 and the left transferred membrane was stained with ponceau S. After the identification, the corresponding band with the Western blot was cut off and the sequence of N-terminal amino acid residues was performed in Life Science Center of Peking University.

Further identification of the antigen from mycoplasma infected cells

When *M. hyorhinis*-free HeLa cells grew to appropriate confluence, the conditional medium from cultured MGC803 cells, which reacted with MAb PD4, was added into the cultured HeLa cells system. After 72 h incubation, total proteins were extracted from HeLa cells with lysis buffer (1 % Triton X-100/PBS, 1 $mmol\cdot L^{-1}$ PMSF) and Western blot was performed with MAb PD4 as first antibody. Moreover, cultured MGC803 cells were treated with BM cyclin antibiotics for 3 weeks (Roche, Mannheim, Germany) which were recognized as the most effective against mycoplasma infection[26]. Then the total proteins of MGC803 cells were extracted, followed by Western blot as above.

Cloning, site-directed mutations and sequencing of p37 gene

3 mL supernatant from cultured MGC803 cells infected with *M. hyorhinis* was collected, centrifuged at 12 000×g for 5 min, rinsed once with PBS, dissolved in 30 μl ddH2O, then boiled for 5 min, centrifuged for 5 min at 10 000×g. 2 μl supernatant was used as the template for PCR to amplify p37 gene. Upstream primer 5'-aatcggatcc gaggtagcttttatgctc-3' (including *Bam*H I site) and downstream primer 5'-aaagaattctcatttaatggcttttt c-3' (including *Eco*R I site) were synthesized by Sangon Co. (Shanghai. China). The PCR program was consisted of 30 cycles at 94 ℃ for 1 min, at 48 ℃ for 1 min, at 72 ℃ for 90 s, and at 72 ℃ for 10 min for the final extension. The PCR product was inserted into a pBluescript vector after digestion with endonucleases *Bam*HI and *Eco*R I. The seven tryptophan TGA codes were mutated into universal codes tryptophan TGG using mutation vector pALTER-1 according to the instructions of the site-directed mutation kit (Promega) and verified by DNA sequencing. The 5' phosphated mutated primers were as follows: (1) 5'-p(A GGTCAATG**G**G ATAAAAGTA)-3', (2)5'-p(GCAAGTTG **G**ACTGATGA AAATC A TAAGTG**G**AATGGTAATG)-3', (3)5'-p (GGAATGATTTG**G**ATAAAAGGTAAT G)-3', (4)5'-p (AAAAAGCTTG**G**AATGATA AAGATTG**G**AATAC ATTTAGAAA TTTT)-3', (5)5'-p(GG T TCTTTTGCTTG**G**A CACATAAC A)-3'. The bold letters were changed from A.

Expression, purification and identification of GST-P37 fusion protein

The recombinant vector pGEX-4T-p37 was constructed through inserting the mutated p37 into plasmid pGEX-4T-1, then it was introduced into *E. coli* BL21(DE3). The transformed bacteria were induced with 0.1 mM IPTG to express the fusion protein at 30 ℃ overnight. Then the induced bacteria were collected and lysed by ultrasonocation. After centrifugation, the supernatant was incubated with glutathione-sepharose-4B and binding protein was eluted with elution buffer (50 mM Tris-HCl, pH 8.0, 15 mM reduced glutathione). The GST-p37 protein in elution buffer was tested by SDS-PAGE and identified by Western blot after concentrated with sucrose and dialyzed with PBS.

Binding assay with immunofluorescence microscopy

AGS cells were seeded into 6-well culture plates in F-12K medium and crept on cover slides for 24 h. Then the cells were washed twice by PBS. The GST-p37 and GST proteins (10 $\mu g\cdot mL^{-1}$) dissolved in serum-free F-12K medium were added respectively. After incubation for 1 h, cells were gently washed 3 times by PBS and fixed for 15 min with freshly prepared 4 % paraformaldehyde. Then the cells were washed twice by PBT buffer (PBS with 0.1 % bovine serum albumin and 0.01 % Tween 20) and blocked with 10 % normal goat serum for 1 h at 37 ℃. Anti-GST antibodies were added as the first antibody and incubated for 1 h at 37 ℃. After the cells were washed twice for 5 min each by PBT buffer, TRITC-conjugated goat anti-mouse IgG antibodies were used as secondary antibody to detect bound GST-p37 and GST

proteins. The cells were washed twice with PBT buffer and briefly rinsed with water before mounted onto slides for observation under fluorescence microscopy.

RESULTS

cDNA library construction, screening and identification

We obtained 2 μg poly(A)+ enriched mRNA for synthesizing the cDNA library. Double-stranded cDNA was generated by means of "nick-translation". *Eco*R I adapters were ligated to the double-stranded cDNA, which was then digested with *Xho*I and size selected. Only the cDNA molecules larger than 500 bp were collected and ligated into ZAP expression vectors. The diversity of the primary library was 1.2×10^6 pfu. The recombinant rate was 9/9, and the average size of cDNA inserts was about 1.5 kb. A total of 10^6 non-amplified library clones were screened with MAb PD4 and the positive clones were confirmed with unrelated antibodies as controls. Anyhow no specific positive clone reacted with MAb PD4 was obtained.

Purification of the antigen recognized by MAb PD4

First, the total membrane protein from MGC803 was analyzed by Western blot with MAb PD4, and a specific 40 kilo-Dalton band could be found (Figure 1A). Then immunoprecipitation was performed and the protein complex was subjected to 12 % SDS-PAGE. The gel-separated proteins were analyzed with Western blot, and the target band was cut off from the membrane (Figure 1B). The sequence of N-terminal amino acid residues revealed that 16 amino acid residues (CSNTGVVKQEDVSVSQ) were completely identical with protein p37 from *M. hyorhinis*, which suggested the antigen recognized by MAb PD4 was from mycoplasma, not from tumor cells, and the PD4 was a MAb against *M. hyorhinis.*

Further identification of the antigen with mycoplasma infected cells

If the antigen was really derived from *M. hyorhinis*, it should be transferred along with *M. hyorhinis* infection and also would disappear when the infected mycoplasma was cleared away from host cells. HeLa cells, which were mycoplasma-free and not reactive with PD4, were treated with conditional medium from *M. hyorhinis* infected cell MGC803. After 72 h treatment, the totally extracted cell protein could react with PD4 (Figure 2A). Meanwhile, the reacting band with PD4 disappeared after MGC803 cells were treated by BM cyclin antibiotics. This result indicated that the antigen of MAb PD4 was a protein from *M. hyorhinis.*

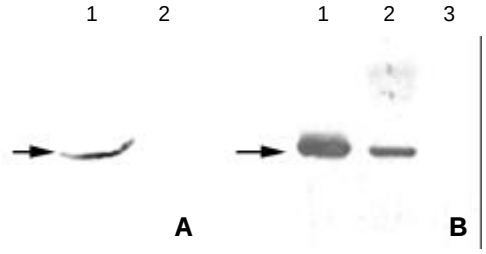

Figure 2 Further identification of the antigen from mycoplasma infection. (A) 1. Western blot analysis of the total protein from Hela cells with MAb PD4, which was treated with cultured MGC803 medium. (A) 2. Western blot analysis of the total protein from untreated HeLa cells with MAb PD4. (B) Western blot analysis of the total proteins from MGC803 cells treated with BM cyclin antibiotics differently. Lane 1: untreated, lane 2: treated for two weeks, and lane 3: treated for three weeks. As indicated by the arrow, the band reacted with MAb PD4 disappeared gradually following the treatment.

Cloning, expression and purification of GST-P37 protein

The results above suggested that the effect of MAb PD4 on tumor cells was mediated by p37 or *M. hyorhinis.* To investigate the molecular mechanisms of the effect, the gene p37 was cloned and mutated by site-directed mutagenesis successfully. After checked by DNA sequencing, the full length p37 was expressed as fusion protein GST-p37 and it could react with PD4 specifically by Western blot (Figure 3).

Binding assay

Because p37 is a dominant protein component of *M. hyorhinis* located on the outside of the cell membrane, we hypothesized that p37 was capable of mediating *M. hyorhinis* binding to host cells. In current study, we first demonstrated that p37 could directly bind to gastric cell line AGS (Figure 4), which provided the basis for further related investigation of p37.

DISCUSSION

Our study indicated that the antigen recognized by MAb PD4, which was derived from mice immunized with gastric tumor cell line MGC803, was a protein from *M. hyorhinis.* This result suggests that the actions of MAb PD4, which we showed before, are mediated possibly by p37 protein or *M. hyorhinis*. Mycoplasmas are a heterogeneous group of the smallest organisms capable of self-replication that can cause a wide variety of diseases in animals. Some mycoplasmas cause respiratory or urogenital diseases in humans[27,28], but others chronically colonize on respiratory and urogenital tracts without apparent clinical significance. There have been some discrete reports about the correlation between mycoplasma infection and cancer since last century. In 1960s, two studies reported that infection of mycoplasma (*M. orale* and one unspeciated) caused chromosomal changes[29]. Other researches in the 1980s reported that an arthropod spiroplasma could rapidly transform mouse and monkey cells[30]. However, investigating the possible association between mycoplasma infection and carcinogenesis did not become more active until Tsai *et al*. reported that continuous infection of *M. penetrans* or *M. fermentans* could lead to multiple stage of malignant transformation of murine embryonic C3H cells, accompanied by abnormal karyotypes and some oncogene upregulation[30, 31].

Also, there are documents indicating the linkage between p37 protein or *M. hyorhinis* and cancer. One is that elevated tumor invasion, as suggested by a leukocyte adherence inhibition (LAI) response, correlates with the presence of *M. hyorhinis* in patients with lung cancer, colon cancer, and breast cancer[32]. Furthermore, two independent research groups showed that p37 on the surface of FS9 mouse fibrosarcoma cells correlated with a highly invasive phenotype, as measured in an *in vitro* cellular invasion assay[22,23]. Antibodies against p37 inhibited the invasive potential of FS9 cells in the assay *in vitro*[23]. Using Abercrombie' s confronted explant assay, it was shown that antibodies against p37 caused malignant cells to revert to a more normal behavior[24]. More recently, p37 antibodies were reported to reduce the lung metastasis of colon cancer in nude mouse models[25]. These results, taken together, suggest that *M. hyorhinis* infection causes enhanced tumor invasion and correlates with tumorigenesis, and that p37 is an essential component of this phenomenon.

In order to further investigate the pathogenic role of p37 in *M. hyorhinis* infection, we cloned the full p37 gene and expressed it successfully in *E. coli*. Eighty percent of the expressed GST-p37 fusion protein was soluble at the inducing condition (IPTG 0.1 mM, 30 ℃ overnight). Western blot analysis indicated the expressed p37 protein was intact. As p37 is a dominant protein component of *M. hyorhinis* located on the outside of the cell membrane, we hypothesize that p37 may be capable of mediating *M. hyorhinis* binding to host cells. In the current study, we first demonstrated that p37 could directly bind to gastric cell line AGS, which provided the basis for further related investigation of p37.

M. hyorhinis contamination is very common in routine cell culture and mycoplasma may be more prone to stimulate immune response when mice are immunized with tumor cells infected with mycoplasma. Thus, the obtained monoclonal antibodies are possibly raised to mycoplasma, especially when the infected tumor cells are used as both immunogen and target cells for screening positive clones. This should draw more attention during preparing monoclonal antibodies. Interestingly, when we recently performed immunohistochemistry with PD4 to detect *M. hyorhinis* infection in paraffin embedded carcinoma tissues, the results indicated that positive rates in gastric carcinoma, esophageal cancer, colon carcinoma and lung cancer were around 50 %, but they were less than 25 % in other gastric diseases, such as chronic superficial gastritis, gastric ulcer and intestinal metaplasia[33]. Meanwhile, we have also isolated *M. hyorhinis* successfully from human gastric cancer tissues by direct culture (data not published). These results strongly suggest an association between mycoplasma infection and tumorigenesis. Undoubtedly, the molecular mechanism of p37 action on tumor cells needs to be intensively investigated.

Abstract

AIM: To study different approaches to caudate lobectomy with "curettage and aspiration" technique using Peng's multifunctional operative dissector (PMOD). The surgical procedure of isolated complete caudate lobectomy was specially discussed.

METHODS: In 76 cases of various types of caudate lobectomy, three approaches were used including left side approach, right side approach, and anterior approach. Among the 76 cases, isolated complete caudate lobectomy was carried out in 6 cases with transhepatic anterior approach. The surgical procedure consisted of mobilization of the total liver, ligation and separation of the short hepatic veins, splitting the liver parenchyma through the Cantlie's plane, ligation and division of the caudate portal triads from the hilum, dissection of the root of major hepatic veins, detachment of the caudate lobe from liver parenchyma.

RESULTS: The mean operative time was 285±51 min, the mean blood loss was 1 600 ml. No severe complications were observed. Among the 6 cases receiving isolated complete caudate lobectomy with transhepatic anterior approach, one case died 17 months after operation due to disease recurrence and liver failure, the other 5 cases have been alive without recurrence, with one longest survival of 49 months.

CONCLUSION: The choice of approach is essential to the success of caudate lobectomy. As PMOD and "curettage and aspiration" technique can delineate intrahepatic or extrahepatic vessels clearly, caudate lobe resection has become safer, easier and faster.

INTRODUCTION

The caudate lobe of the liver is difficult to resect because it lies deep beneath the confluence of main hepatic veins and between porta hepatis and inferior vena cava[1]. Isolated or combined caudate lobectomy is the treatment of choice for a mass originating in caudate lobe or for hepatobiliary cancer invading the hepatic hilum. Among various types of caudate lobectomy, isolated complete resection of caudate lobe is technically the most difficult one. Anterior approach is considered to be a safe, potentially curative option for isolated resection of the entire caudate lobe, especially in the presence of cirrhosis, as we can spare innocent hepatic parenchyma using this approach[2,3]. With the use of a specially designed instrument-Peng's multifunctional operative dissector (PMOD), we developed a new surgical technique called "curettage and aspiration" technique with which transection of the liver parenchyma can be carried out in a nearly bloodless field[4]. Precise anatomy of caudate lobe can be achieved with this technique and instrument. Therefore isolated complete resection of caudate lobe has become easier and faster as the liver is split into two halves by anterior approach. From 1994 to June 2003, we performed 76 cases of various types of hepatectomy with caudate lobectomy, which included 6 isolated complete caudate lobectomies by anterior transhepatic approach. This review studied different approaches to caudate lobectomy especially the anterior transhepatic approach for isolated complete caudate lobectomy with "curettage and aspiration" technique using PMOD.

MATERIALS AND METHODS

Patients

Seventy-six cases were enrolled in the study. Various types of hepatectomy with caudate lobectomy were performed in 51 cases, isolated caudate lobectomy was performed in 25 cases. Forty-five cases had hepatocellular carcinoma (HCC) originating from or invading caudate lobe, 7 cases had benign tumors and stone of caudate lobe, 17 cases had cholangiocarcinoma, 7 cases had metastatic tumor in the liver (6 cases of colonic carcinoma, 1 case of adrenal carcinoma). These 6 patients received isolated complete caudate lobectomy by anterior approach. Among them, four were male and 2 female, their age ranged from 32 to 65 years (mean 52 years); five cases had HCC accompanied by cirrhosis, and one had hemoangioma.

Surgical procedures

In the majority of cases, a reversed L-shaped skin incision from xiphoid to the tip of the twelfth right rib was used, giving an excellent exposure, which was of vital importance for caudate lobectomy. The whole abdominal cavity was explored to rule out intra-abdominal metastasis.

The choice of approach is essential to the success of caudate lobectomy. Approaches are dependent largely on the size, location of the lesion and the severity of cirrhosis. In this series, four approaches were used for various types of

caudate lobectomy. Left side approach was suitable for small tumors situated in Spiegelian lobe or when caudate lobe was to be resected combined with the left liver. Left lateral segmentectomy, left hemi-hepatectomy or left trisegmentectomy was carried out before caudate lobe was exposed and resected. Right side approach was more suitable for tumor located in the caudate process or when the caudate lobe was resected together with the right liver, mostly right hemi-hepatectomy. The combined approach was a combination of the left side and right side approach. The caudate lobe might be approached mainly from the right or left side although dissection from both sides was necessary in many cases. Anterior transhepatic approach was suitable for cases when isolated complete resection of caudate lobe was indicated and innocent liver parenchyma should not be resected due to cirrhosis of the liver (Figure 1). The characteristics of this approach were that the liver was split through the interlobar plane into two halves, so as to fully expose the caudate lobe.

The anterior transhepatic approach included 7 steps. (1) The falciform ligament was separated up to the front of suprahepatic IVC, then the incision was turned to the right and left. The coronary ligaments, triangular ligaments and hepato-renal ligament were separated, respectively. The adrenal gland was detached from the liver, and hepatogastric ligament was completely separated. (2) The short hepatic veins (SHV) were dissected and ligated caudal cranially, three to five thick short hepatic veins were separated in this process (Figure 2). (3) Tapes were used to encircle the suprahepatic and infrahepatic IVC, respectively (Figure 3). (4) The interlobar plane was split and the anterior surface of the paracaval portion and the hilar plate were explored. (5) The ascending caudate portal triads were ligated and separated (Figure 4). (6) The caudate lobe was separated from the major hepatic veins (MHV) (Figure 5). (7) The caudate lobe was detached from the neighboring liver parenchyma. No large branches here needed to be ligated, the small vessels encountered could be cauterized with PMOD. Thus isolated complete caudate lobe was resected and two halves of the liver were sutured (Figure 6).

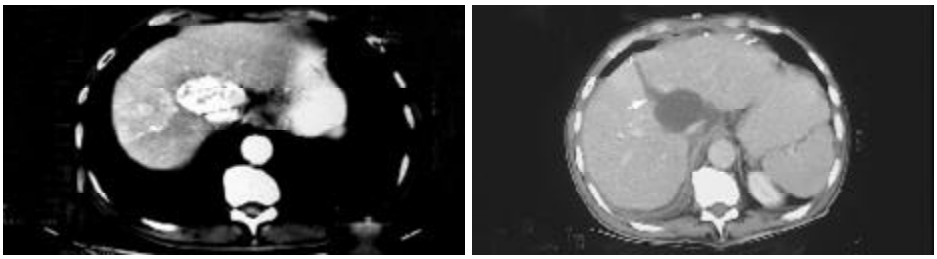

Figure 1 Pre-operative CT scan shows the tumor originating in caudate lobe, post-operative CT scan shows splitting line(arrow).

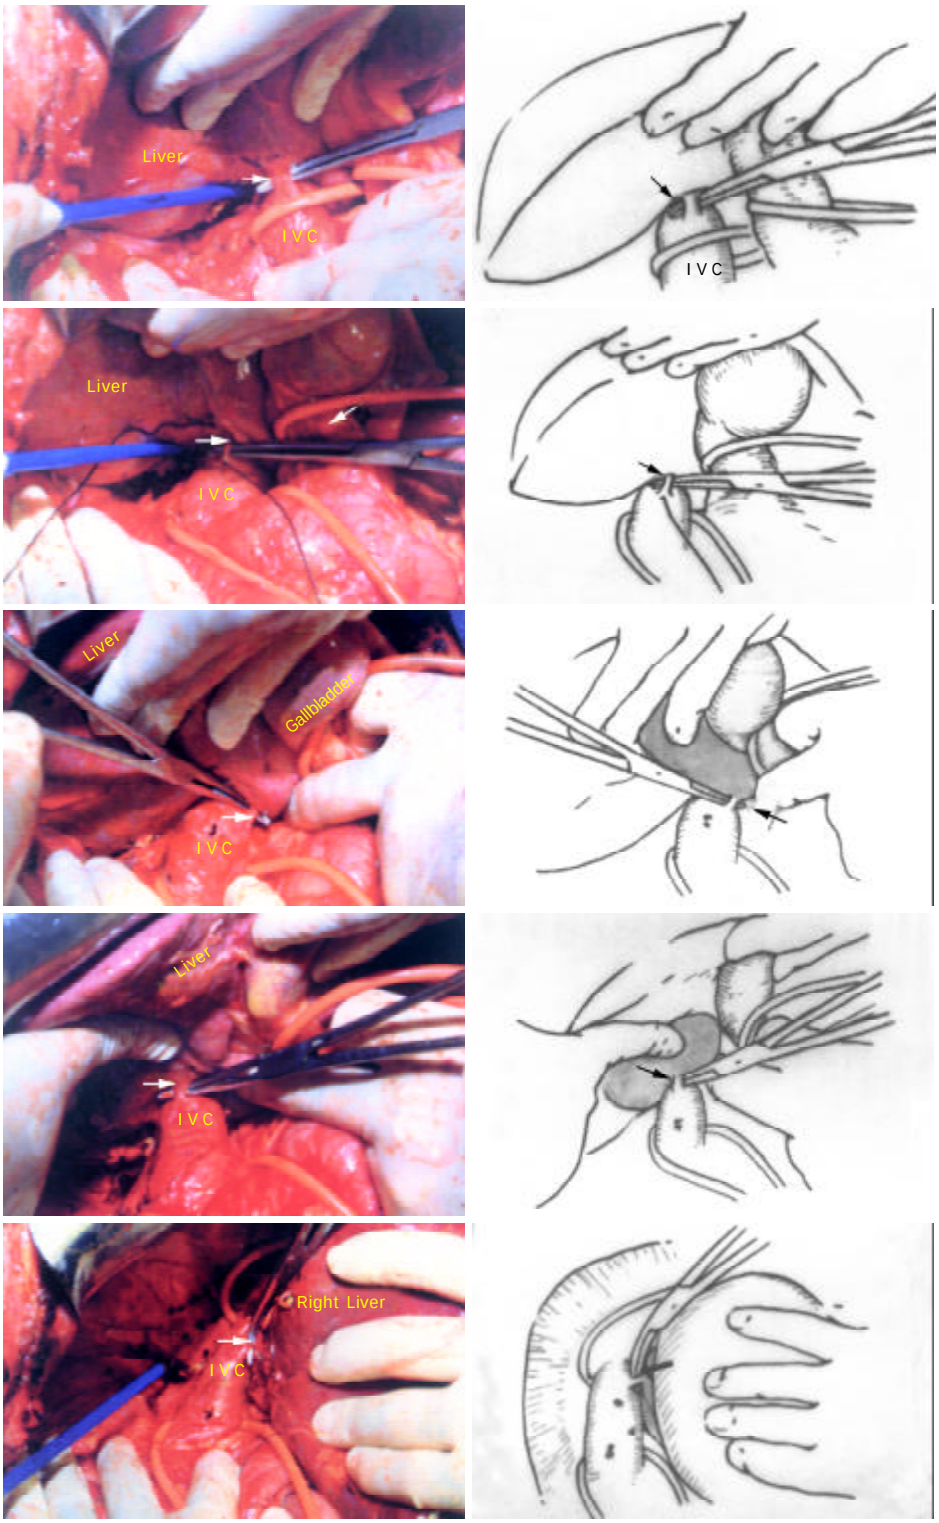

Figure 2 Five short hepatic veins ligated from caudal direction to cranial direction respestively (Arrow).

In this series, the mobilization of caudate lobe was from left side first in most of the cases. Bartlett *et al*. reported that the ligamentous attachment should be separated and the tip of caudate lobe was mobilized before separation of the caudate veins[5].

The liver parenchyma was transected by means of "curettage and aspiration" technique using PMOD with intermittent inflow occlusion at the hepatoduodenal ligament (Pringle's maneuver), the time limit was 10 min each time with reperfusion for 2 min. Total vascular exclusion was seldom necessary except that when the tumor involved IVC or major hepatic veins. PMOD is a special instrument, it has the functions of dissection, coagulation and aspiration separately or synchronously. As a result, the surgical field was nearly bloodless and the intrahepatic duct structures could be identified, isolated and treated individually.

RESULTS

Isolated or combined caudate lobectomy was successfully performed in 76 patients (Table 1). Isolated caudate lobectomy was performed in 25 cases. Of these 25 cases, isolated complete caudate lobectomy was performed in 19 cases, 6 cases (31.6 %,6/19) underwent complete resection by anterior transhepatic approach (Table 2). In these 6 cases, the size of tumor was from 3 cm to 8 cm, the mean operating time was 285±51 min, and the total occlusion time ranged from 50 to 110 min, the operative blood loss ranged from 500-3 000 ml (mean 1 600 ml).

No intraoperative death and signs of liver failure occurred in all the 6 cases, serum aspartate transaminase level recovered to normal range within one week postoperatively. One case had ascites because of liver cirrhosis, one case had right pleural effusion and was cured after aspiration two times. One case had bile leakage and was cured after two weeks' conservative treatment. Abdominal drains were placed in all the patients and removed within one week except the case with bile leakage.

All the 6 cases received a long-term follow-up. One case died in the 17th month postoperatively due to disease recurrence and liver failure, the other 5 cases have been alive without recurrence, with the longest survival of 49 months in 1 case.

DISCUSSION

The caudate lobe is a single anatomic segment that is defined by the presence of portal venous and hepatic arterial branches, which supply the lobe, drain biliary ducts and hepatic veins[6]. Three parts make up the entire caudate lobe, namely, the usual caudate lobe (Spiegelian lobe), the caudate process, and the paracaval portion[7]. Partial or complete caudate lobectomy with major hepatectomy is often necessary for extirpation of the tumor. But in China, most liver cancers occur in cirrhotic liver. The poor liver function of our cases prevented us from performing a combined or preparatory resection of major segment or other liver segments for tumors situated only in the caudate lobe.

Caudate lobectomy is classified by complete and partial resection, it is also classified by isolated and combined resection. Therefore caudate lobectomy is generally composed of four types: isolated complete resection, combined complete resection, isolated partial resection and combined partial resection. To select an appropriate surgical approach is essential for resection of caudate lobe. In our experience, right side approach is suitable for the tumor confined in caudate process or for cases when hepatectomy is indicated for cancer involvement. Left side approach is suitable for the combined resection of the left liver overlying the caudate lobe or for tumor confined in Spiegelian lobe. Isolated complete caudate lobectomy without resection

of innocent parenchyma is sometimes performed by splitting the parenchyma through interlobar plane as anterior approach. In addition, central segmentectomy is also classified as anterior approach, anterior segmentectomy together with caudate lobectomy has been considered as an appropriate treatment for hilar cholangiocarcinoma without infiltration of the posterior hepatic branch[8,9].

Some of the isolated caudate lobectomies could be performed through both left side and right side approaches when the tumor was small, but when the tumor was large or IVC and/or major hepatic veins were compressed by the tumor, the above methods might not be appropriate due to the possibility of laceration of major hepatic veins. Under such circumstances, anterior transhepatic approach is the best choice for isolated complete caudate lobectomy. In 1992, Yamamoto *et al*. described a patient with cirrhosis and a 3×3 cm HCC in the paracaval portion of the caudate lobe for whom they performed isolated caudate lobectomy by splitting the cirrhotic liver into two halves. The anterior transhepatic approach could provide a safe strategic alternative for isolated complete caudate lobectomy[10]. The separation of hepatic parenchyma overlying the caudate lobe could expose the major hepatic veins and the hilar plate to direct view, facilitating control of venous bleeding and interruption of the ascending paracaval portal branches along the hilar plate. Usually it would be associated with a significant amount of blood loss. In this series, we used PMOD to transect the liver parenchyma by means of "curettage and aspiration" technique, all of the intrahepatic ducts could be identified and isolated before it was transected. Asahara *et al*. reported that the minor operative time and blood loss were 355 min and 1 100 ml[2]. Because PMOD could facilitate the transection of cirrhotic liver, the minor operation time and blood loss were 234 min and 500 ml respectively. In our series with "curettage and aspiration" technique, not only the blood loss was decreased obviously, but also no atrophy of the medial segment was observed on postoperative computed tomography. So the benefit exceeded the risk of splitting the medium hepatic plane. For selective caudate lobectomy, the most dangerous part is the parenchyma division of its anterosuperior portion, where the roots of major hepatic veins are running next to the line of dissection. Without an outflow occlusion, any inadvertently deep cleavage could result in sudden and massive hemorrhage from a hepatic vein. Although total vascular exclusion could limit blood loss from the hepatic venous system and decrease the risk of air embolism. Such a maneuver would result in hemodynamic instability in up to 40 %[11]. In our series, Tapes were used to encircle the suprahepatic and infrahepatic IVC for precautions. The author usually isolated the common trunk and the right hepatic vein to pre-place the tapes for controlling the three major hepatic veins. In case massive hemorrhage occurred from a hepatic vein, we could control the hepatic vein to substitute the total vascular exclusion. In addition, during hepatic transection, usually dissection was carried out along the section plane, but when large vessels were shown, curettage was proceeded in parenchyma in parallel with the vessels in deep cleavage plane by altering direction, so sudden and massive hemorrhage occurred rarely, and we could treat vessels in direct view even if there was hemorrhage. In fact, we did not use tapes in all the 6 cases.

The anterior transhepatic approach for isolated complete caudate lobectomy is a curative procedure for primary or metastatic hepatobiliary neoplasm originating from caudate lobe, especially in the presence of cirrhosis when the tumor is large and involves IVC and/or the major hepatic veins. As PMOD and "curettage and aspiration" technique can delineate intrahepatic or extra hepatic vessels clearly, caudate lobe resection has become safer, easier and faster.

ACKNOWLEDGMENT

We are deeply grateful to Professor Fang Zheng (Department of Anatomy, School of Medicine, Zhejiang University) for producing the figures of this paper.

Abstract

AIM: To study the inhibitory effects of antisense RNA of HAb18G/CD147 on invasion of hepatocellular carcinoma (HCC) cells *in vitro*.

METHODS: Antisense RNA of HAb18G/CD147 vector PCI-asHAb18G was constructed by reversely inserting HAb18G/CD147 cDNA to eukaryotic expression vector PCI-neo. The HCC cell line HHCC was transfected by PCI-asHAb18G via cation liposome. Expression of HAb18G/CD147 of transfected cells selected by G418 (geneticin) was observed by immunohistochemical SP staining and FACS (fluorescence activated cell sorting). Gelatin zymography was used to determine the effect of PCI-asHAb18G on reducing secretions of MMP-2 and MMP-9 of the transfected cells. Boyden chamber was employed to test the invasion of HCC cells *in vitro*.

RESULTS: The construction of antisense RNA vector PCI-asHAb18G was verified correct by partial nucleotide sequencing and restricted endonuclease digestion. The expression of HAb18G/CD147 in transfected HHCC was inhibited by PCI-asHAb18G. Secretions of MMP-2 and MMP-9 of transfected HHCC were reduced and the invasion of transfected HHCC was inhibited compared to HHCC, respectively.

CONCLUSION: Invasion of HCC cells can be inhibited by antisense RNA of HAb18G/CD147. HAb18G/CD147 may be used as a potential target of drugs for anti-invasion and metastasis of HCC.

INTRODUCTION

Invasion and metastasis are malignant characteristies of HCC and the main mortal reason for patients[1,2]. In the invasive and metastatic process of malignant tumor, molecules existing in extracellular matrix (ECM) and receptors or ligands existing on the surfaces of tumor cells play critical roles[3,4]. HAb18G is such a molecule obtained by screening cDNA library with HAb18 specific monoclonal antibody (mAb) against HCC[5-7]. The gene sequence of HAb18G is homologous to that of CD147. CD147, also named extracelluar matrix metalloproteinase inducer (EMMPRIN), is originated from human lung cancer cell line LX-1, firstly found in human HCC tissue in our laboratory. Previous studies demonstrated that EMMPRIN, a member of the immunoglobulin superfamily, concentrated on the surfaces of most tumor cells, promoted invasion of tumor cells by stimulating stromal cells to produce elevated levels of several matrix metalloproteinase (MMPs)[8,9] which play very important roles in several aspects of tumor progression, including growth, invasion, metastasis, and angiogenesis[10-12]. To study the relationship between HAb18G/CD147 and metastasis of HCC, we constructed a vector of antisense RNA of HAb18G/CD147 and investigated its inhibitory effects on invasion of HCC cells *in vitro*.

MATERIALS AND METHODS

Plasmid, bacteria strain and cell line

Plasmid pBluescript ks(+/-)/HAb18G including full length cDNA of HAb18G/CD147 was constructed by our laboratory. Eukaryotic expressing vector PCI-neo was purchased from Promega. *E.Coli* strain JM109 was purchased from Huamei Co, Ltd. Human HCC cell line HHCC was purchased from Type Culture Collection of Chinese Academy of Sciences, Shanghai, China. Human embryo dermal fibroblast cell line (fb) was kindly presented by Dr. Han (Department of Plastic Surgery, Fourth Military Medical University).

Construction and identification of antisense vector

Full length cDNA fragment of HAb18G/CD147 was obtained from pBluescript ks(+/-)/HAb18G by cutting with *Xba*I and *Xho*I and inserted reversely into eukaryotic expressing vector PCI-neo by cutting with the same restriction endonucleases. The antisense vector of HAb18G/CD147, named as PCI-asHAb18G, was transformed into *E.coli* stain JM109 and identified by restricted endonuclease digestion and DNA sequences analysis by an automatic fluorescence sequenator using T_3 sequencing primer.

Cloning of cell transfected with antisense RNA vector

Empty vector PCI-neo and antisense vector PCI-asHAb18G were transfected into human HCC cell line HHCC via cation liposome Lipfectinamine^{2000} (Gibco) respectively. The two kinds of transfected cells were named as HHCC/neo and HHCC/asHAb18G respectively. All transfection procedures were performed according to the product manual. After two days of transfection, cells were selected by culture medium containing G418 (400 mg/L) for 4 weeks. The single clone was picked out by using limiting dilution method and cultured constantly in the culture medium containing G418 (100 mg/L).

Immunohistochemical staining of transfected cells

Transfected cells were plated on glass slides overnight, fixed with cold acetone, and stained with SP (streptomycin avidin-peroxidase) according to the manufacturer' s instructions.

Briefly, mAb HAb18 was used as primary antibody and the goat anti-mouse mAb coupled with biotin as secondary antibody followed by indirect immunohistochemical staining with the mixture of streptomycin-avidin peroxidase and its substrate DAB. HHCC/neo served as the control.

FACS analysis

HHCC/asHAb18G suspension was prepared by adding primary antibody and secondary antibody coupled with fluorescein into 10^8 cells per liter. Then the cells were fixed and analyzed by flow cytometer.

Gelatin zymography

Five experimental groups of cells were HHCC, fb, HHCC/neo+fb, HHCC/asHb18G +fb and HHCC+fb, which were plated into 100 mL culture flasks respectively. The ratio of HCC cells/fb cells was 1:1. After cultured in completed DMEM medium for 24 hours, all the groups of cells were washed three times with serum free DMEM and cultured for 2-3 days in DMEM with 20 mL/L bovine serum. Subsequently, the supernatants were collected and centrifuged to remove the cell debris. Proteins were precipitated with 800 g/L saturated $(NH_4)_2SO_4$. Precipitations were dissolved in 10 mmol/L Tris-HCl, pH 7.5 and dialyzed. Dialyzed samples were determined with SDS-PAGE that was modified in four points. Gelatin (Sigma) was added into the separating gel with 1.0 g/L, concentration of the stacking gel was 5 %, samples were not boiled and sample buffers did not contain DTT. After electrophoresis, the gel was washed with 0.1 mol/L NaCl and incubated for 24 hours at 37 ℃. Finally, the gel was dyed and decolorized.

Reconstituted basement membrane invasion detection

Matrigel (main component was type IV collagen, purchased from Cell-biology Department of Pecking University) was added onto the inner surface of Boyden chambers (Millipore) to form the reconstituted basement membrane. Three groups of cells were HHCC+fb, HHCC/asHAb18G+fb, HHCC/neo+fb (the ratio of HCC cells/fb cells was 1:1), which were added on the reconstituted basement membrane respectively. Then the chambers were put in the 24-well plates and cultured overnight. Cells infiltrated through the reconstituted basement membrane and appeared on the outer surfaces of the membrane were stained with HE. The numbers of the cells were counted under high-power microscope.

RESULTS

Construction and identification of PCI-asHAb18G

Two fragments were obtained by digesting HAb18G/CD147 antisense vector with *Xho*I and *Xba*I , one was human HAb18G/CD147 cDNA fragment about 1.7 kb and the other was 5.5 kb fragment. Two fragments of 1.1 kb and 6.1 kb were also obtained with *Sma*I digestion (both MCS of vector and 1.1 kb site of HAb18G/CD147 cDNA respectively have a *Sma*I site). The construction of the vector was verified correct by endonuclease digestion (Figure 1) and nucleotide sequencing. The vector was named as PCI-asHAb18G.

Immunohistochemical staining and FACS

HHCC/as HAb18G was negative, HHCC/neo and HHCC groups were positive (Figures 2-4). Average value of the fluorescence intensities of HHCC/asHAb18G cells was 5, and that of HHCC/neo cells was 500 (Figure 5).

Gelatin zymography and cell invasion

The secretions of MMP-9 and MMP-2 in the transfected cells HHCC/asHAb18G co-cultured with fb were inhibited compared to those in the HHCC/neo and intact HHCC. The cells of HHCC/asHAb18G infiltrated through the reconstituted basement membrane were less than those of HHCC/neo and intact HHCC (Figure 7).

DISCUSSION

Matrix metalloproteinases (MMPs) play an important part in tumor progression and tumor cell survival, with a positive correlation between MMP expression and the invasive and metastatic potential of malignant tumors, including colon, lung, head and neck, basal cell, breast, thyroid, prostate, ovarian, and gastric carcinomas. CD147 is a heavily glycosylated transmembrane glycoprotein containing two immunoglobulin superfamily domains, which induces MMPs production in the adjacent stromal cells. Some results implied that a CD147 counter-receptor might existed on the fb cell surface, but such a counter- receptor has not been identified[13]. Other studies[14] showed that CD147 also acted in an autocrine fashion to increase productions of MMPs and invasiveness in tumor cells themselves. CD147 enriched in HCC tissue was first reported by our laboratory and might be a potential target for anti-invasion and metastasis therapies. Our previous studies showed that HAb18G/CD147 was highly expressed in HCC tissues and lowly expressed in normal tissues. HAb18G/CD147, not only participated adhesion of cell-cell or cell-matrix but also enhanced metastatic potentials of human hepatoma cells by disrupting the regulation of store-operated Ca(2+) entry by NO/cGMP[15,16].

The principle of antisense technology is the sequence-specific binding of an antisense oligonucleotide to target mRNA, resulting in the prevention of gene translation. The specificity of hybridisation makes antisense treatment an attractive strategy selectively modulating the expression of genes involved in the pathogenesis of diseases. In 1998, the first antisense drug (fomivirsen) was approved by the US Food and Drugs Administration (FDA) for the treatment of cytomegalovirus-induced retinitis in patients with AIDS[17]. Now, several antisense oligonucleotides have been under clinical trials, including oligonucleotides targeting the mRNA of Bcl-2[18,19], protein-kinase-C alpha[20,21], RAF kinase[22,23], H-ras[24,25], C-myb [26], DNA methyltransferase[27] and RI-alpha regulatory subunit of protein kinase A (PKA)[28,29]. Antisense oligonucleotides are well tolerated and might have therapeutic activities.

Our experimental findings showed that the expression of HAb18G/CD147 on HCC cells transfected by PCI-asHAb18G was decreased by analysis of immunohistochemical staining and FACS. Gelatin zymography demonstrated that secretions of MMP-2 and MMP-9 of HHCC/asHAb18G were lower than those of HHCC/neo and HHCC. Matrigel invasion assay indicated that invasion of HHCC/asHAb18G cells was inhibited significantly. All of the results confirm that antisense RNA targeting HAb18G/CD147 mRNA interfered with translation and expression of HAb18G/CD147, weakened the productions of MMPs, and inhibited the invasion of HCC cells through reconstituted basement membrne *in vitro*.

We suggest that HAb18G/CD147 be used as a novel target for anti-hepatoma metastatic therapy. Intervention in HAb18G/CD147 function by agents, such as antisense RNA, may have potential therapeutic value in the prevention of hepatoma invasion and metastasis.

Abstract

AIM: This study was designed to evaluate the clinical application of serum total sialic acid (TSA) in the diagnosis of cholangiocarcinoma (CCA).

METHODS: Serum TSA was determined by periodate-resorcinol microassay in 69 patients with CCA, 59 patients with hepatocellular carcinoma (HCC), 37 patients with cirrhosis, 61 patients with chronic hepatitis and 50 healthy blood donors.

RESULTS: The mean serum TSA concentration in CCA (2.41±0.70 mmol/L) was significantly higher than those of HCC, cirrhosis, chronic hepatitis and healthy blood donors (1.41±0.37 mmol/L, 1.13±0.31 mmol/L, 1.16±0.26 mmol/L, and 1.10±0.14 mmol/L, respectively; $P<0.001$). Based on ROC curve analysis, a cut-off point of 1.75 mmol/L discriminated between CCA and HCC with a sensitivity, specificity and accuracy of 82.6 %, 83.1 %, and 82.8 %, respectively.

CONCLUSION: Based on our results, serum TSA would be a useful marker for the differential diagnosis of CCA from HCC.

INTRODUCTION

Cholangiocarcinoma (CCA) constitutes a common primary liver cancer in Southeast Asia where the liver fluke, *Opisthorchis viverrini*, is endemic[1]. Most patients with CCA are diagnosed at advanced stages, therefore, treatment of the cancer is usually palliative and the prognosis is poor[2]. Currently, there is no ' gold standard' tumor marker for the diagnosis of CCA. This is particularly remarkable for early detection of the tumor itself, for screening of the high-risk groups, and for differentiating CCA from hepatocellular carcinoma (HCC), another primary liver cancer which is common in Southeast Asia and frequently associated with chronic hepatitis B or C[3]. Among the available serum tumor markers, the most commonly used is a high-molecular-weight glycolipid, carbohydrate antigen 19-9 (CA 19-9). CA 19-9, however, is not a sensitive or specific tumor marker for CCA. As a single diagnostic test, CA 19-9 increases in approximately 65 % of liver fluke-associated CCA[4]. Elevated concentrations of this marker have also been observed in patients with a variety of gastrointestinal cancers, as well as benign cholestasis and acute cholangitis[5]. As a result, a more sensitive and specific serum marker for the diagnosis of CCA is considered necessary.

Sialic acid, a class of important ketoses that contain nine carbon atoms, is an acetylated derivative of neuraminic acid (2-keto-5-amino-3, 5-dideoxy-D-nonulosonic acid)[6]. The unique structural features of this molecule, which includes a negative charge owing to a carboxyl group, enable it to play an important role in cellular functions, such as cell-to-cell recognition and transformation to malignancy[7]. Elevated levels of serum total sialic acid (TSA) have been reported in patients diagnosed with various cancers such as lymphoma, malignant melanoma, lung cancer and gastrointestinal cancers[8,9]. Recently, it has been shown that most patients with CCA have an elevated concentration of serum TSA, and determination of this marker yields high diagnostic values that differentiate between CCA and benign hepatobiliary diseases[10]. However, the diagnostic role of the serum marker in discriminating CCA from HCC has never been verified.

Therefore, the aim of this study was to use a simple technique (microassay) to determine the clinical application of serum TSA in the diagnosis of CCA by comparison with HCC and other chronic liver diseases including chronic hepatitis and cirrhosis.

MATERIALS AND METHODS

Subjects

Sera for the measurement of TSA levels were obtained from 5 groups of subjects who were attending King Chulalongkorn Memorial Hospital and Udonthani Hospital from January 1998 to July 1999.

Group 1 consisted of 50 adult healthy blood donors as control subjects.

Group 2 consisted of 61 patients with chronic hepatitis which was diagnosed based on histopathology.

Group 3 consisted of 37 patients with cirrhosis. The diagnosis of cirrhosis was based on histopathology and/or clinical features such as the presence of ascites, or esophageal varices.

Group 4 consisted of 59 patients with HCC. The diagnosis of HCC was based on histopathology and/or imaging techniques combined with serum alpha-fetoprotein levels above 400 ng/ml.

Group 5 comprised 69 patients with CCA. All patients in this group were residents of Thailand's northeastern provinces where *O. viverrini* was endemic. The peripheral type CCA was diagnosed based on liver tumor features detected by ultrasound/CT scan and confirmed by histology. Criteria for

diagnosis of the hilar type included findings of primary mass at the hilum and the evidence of bile duct dilatation on ultrasound/ CT scan and confirmed by characteristic features on cholangiography or histopathology.

All subjects were informed about the objective of the study, and subsequently provided their consent. Blood was obtained during investigation at the initial presentation, sera were separated by centrifugation and stored at -70 ℃ at Viral Hepatitis Research Unit until tested for TSA concentrations.

Measurement of serum TSA by periodate-resorcinol microassay

Serum TSA determination was performed as previously described[6], with some modifications. Briefly, 40 μL of samples or pure standard sialic acid solution (2-10 μg/well) was added to the wells of a 96-well microtiter plate. Then, 50 μL of 1.3 mM periodic acid (prepared from stock 0.32 M), was added to each well and mixed by shaking the plate for 5 minutes on a microplate shaker at room temperature. The plate was placed (floated) in an icebox for 60 minutes, then 100 μL of 0.6 g/dL of resorcinol reagent (prepared from stock 6 g/dL) was added and mixed by shaking as described above. The plate was covered with a glass and heated at 80 ℃ for 60 minutes in water bath, then it was removed and placed on the shaker for about 2 minutes mixing as well as cooling the contents down to room temperature. Then, 100 μL of 95 % tert-butyl alcohol was added to each well and mixed once again as described above. The absorbance at 620 nm was measured immediately by a microtiter plate reader.

The precision of the test was determined by analysis of an intra- and inter-assay coefficient variation (CV). The method described herein demonstrated an intra- and inter-assay CV of 0.79 % and 4.68 %, respectively. Furthermore, the recovery percentage of this assay was 94.25 %.

Statistical analysis

The data were expressed as mean values ± standard deviation. Statistical significance in the mean values was evaluated by the Student' s *t* test. Receiver-operating characteristic (ROC) curves were constructed to establish the diagnostic cut-off level of serum TSA in discriminating CCA from other groups. Sensitivity, specificity, positive and negative predictive values and diagnostic accuracy were calculated in accordance with standard methods. *P* value below 0.05 was considered statistically significant.

RESULTS

Comparison of the characteristics of the subjects in each group (Table 1) showed that the mean age of patients with CCA (60.2±12.6 years) was significantly higher than those with HCC and cirrhosis (53.0±12.0 and 50.0±13.3 years, respectively; P=0.001), chronic hepatitis and blood donors (42.0±13.0 and 34.6±10.3 years, respectively; P<0.001). There was no significant difference in the sex distribution in each group. Mean total bilirubin level was significantly higher in patients with CCA compared with those with HCC, cirrhosis and chronic hepatitis (P<0.05), whereas mean serum alkaline phosphatase was significantly higher in patients with CCA compared to those with cirrhosis and chronic hepatitis (P<0.05).

The distributions of serum TSA levels in each group are shown in Figure 1. The mean serum TSA concentration in patients with CCA (2.41±0.70 mmol/L) was significantly higher than that in those with HCC, cirrhosis, chronic hepatitis and blood donors (1.41±0.37 mmol/L, 1.13±0.31 mmol/L, 1.16±0.26 mmol/L, and 1.10±0.14 mmol/L, respectively; P<0.001). The mean concentration of serum TSA in patients with HCC was also significantly higher than that in those with cirrhosis, chronic hepatitis and blood donors (P=0.001). However, there was no significant difference in mean serum level of TSA among patients with cirrhosis, chronic hepatitis and blood donors.

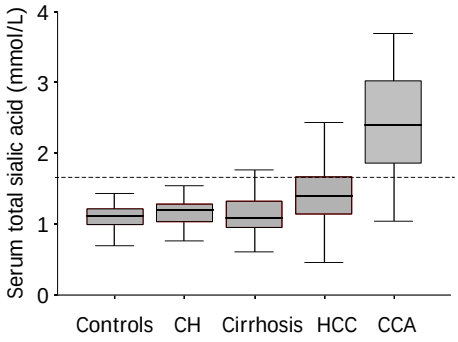

Figure 1 Serum total sialic acid (TSA) concentrations in each group. Cut-off value of serum TSA as a tumor marker was 1.75 mmol/L.

In order to discriminate CCA from HCC with an optimal accuracy, an analysis of the ROC curve was performed. As shown in Figure 2A, the area under the curve of CCA and HCC was 0.885 [95 % confidence interval (CI) 0.828-0.0.942]. This result indicated that approximately 89 % of randomly selected patients from the positive group (CCA) would have a higher TSA value than a patient randomly selected from the HCC group. Similarly, the area under the ROC curve of CCA and the other three groups (cirrhosis, chronic hepatitis and healthy controls) was 0.964 (95 % CI 0.938-0.0.989) (Figure 2B), indicating that approximately 96 % of patients with CCA would have a higher level of serum TSA than patients with cirrhosis, chronic hepatitis and healthy controls.

Based on the ROC curve analysis, a cut-off point of serum TSA concentration considered as the highest accuracy for diagnosing CCA was 1.75 mmol/L. At this concentration, the sensitivity, specificity and accuracy for differentiating CCA from HCC were 82.6 %, 83.1 %, and 82.8 %, respectively.

Table 1 Clinical characteristics of the subjects in this study

Group	No	Age (yr)	Sex (M/F)	TB (mg/dl)	ALT (IU/L)	Alb (g/l)	AP (IU/L)
Controls	50	34.6±10.3[a]	29/21	-	-	-	-
CH	61	42.0±13.0[a]	46/15	1.6±0.9[a]	98.1±72.9	3.8±0.3	201.5±106.2[a]
Cirrhosis	37	50.0±13.3[a]	26/11	2.5±1.3[a]	65.0±49.6	3.3±0.5	290.2±212.5[a]
HCC	59	53.0±12.0[a]	50/9	3.0±2.1[a]	79.9±46.1	3.4±0.3	612.9±393.7
CCA	69	60.2±12.6	46/23	7.5±7.6	71.4±68.7	3.4±0.5	894.3±850.2

Controls=healthy blood donors, CH=chronic hepatitis, HCC=hepatocellular carcinoma, CCA=cholangiocarcinoma. TB=total bilirubin, ALT=alanine aminotransferase, Alb=albumin, AP=alkaline phosphatase. Data were expressed as mean±standard deviation. Statistical analysis compared to CCA: [a]P<0.05.

Likewise, when compared to patients with cirrhosis, chronic hepatitis and healthy blood donors, the same cut-off level of serum TSA exhibited a sensitivity, specificity and accuracy for diagnosing CCA of 82.6 %, 86.0 %, and 84.8 %, respectively.

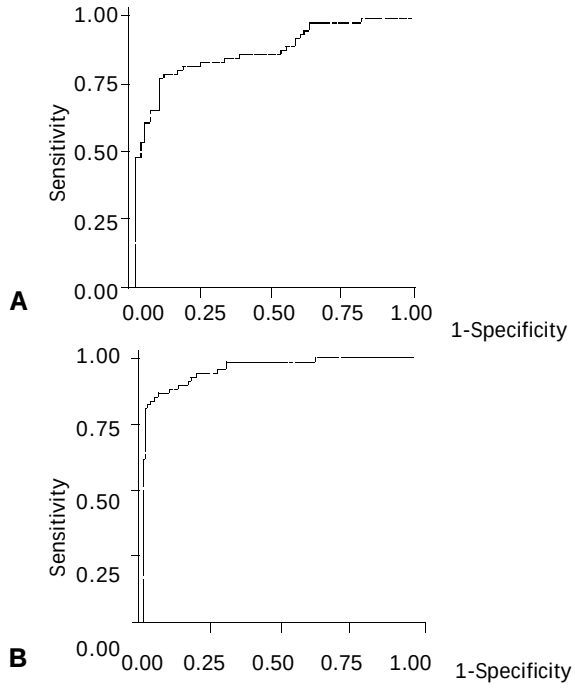

Figure 2 ROC curves of serum TSA in distinguishing CCA from other groups. A: CCA and HCC (the area under the curve was 0.885), B: CCA and cirrhosis, chronic hepatitis, blood donors (the area under the curve is 0.964).

DISCUSSION

Liver fluke-associated CCA is typically associated with its insidious onset of clinical manifestations, which frequently escapes detection until late stages. The clinical features of CCA appeared to differ according to the location of the tumor along the intrahepatic duct, whether in the hilum or periphery[11, 12]. The hilar type tends to present with progressive jaundice or ascending cholangitis due to tumor obstructtion in the confluence of the hepatic ducts, while the peripheral type usually presents with weight loss and progressive right upper quadrant pain caused by the expanding tumors. In areas where both liver flukes and chronic viral hepatitis are prevalent, it remains an essential problem to differentiate CCA from HCC. Although HCC is usually associated with cirrhosis, while conversely, CCA develops in a non-cirrhotic liver, the occurrence of CCA in cirrhosis has been increasingly recognized[13]. Moreover, approximately 10 % of patients with HCC presented with obstructive jaundice, a clinical feature that might imitate the hilar type of CCA[14]. Accordingly, a sensitive and specific serum marker of CCA would be considered as a valuable adjunct to non-invasive imaging for the diagnosis of the cancer.

Serum TSA has been reported as a diagnostic maker for patients with various cancers such as lymphoma, malignant melanoma, lung cancer and gastrointestinal cancers[8,9]. A variety of methods for the detection and estimation of free and glycosidically-bound sialic acids have been performed. These techniques could be broadly classified as colorimetric, fluorometric, enzymatic methods, as well as the highly sensitive high performance liquid chromatographic (HPLC) method[7]. Among these, the most widely used technique is the colorimetric method, which includes the Ehrlich method, the periodate-thiobabituric acid method, and the periodic-resorcinol assay. In this report, we employed a newly developed periodate-resorcinol micorassay that has several advantages over the conventional methods. These include use of smaller samples (5 μL), a larger number of samples simultaneously analyzed, and a greater speed in measuring absorbance by a microtiter plate spectrophotometer. Moreover, this method enables the direct transfer of data to a computer, or even an adaptation to an automated system.

In this study, we demonstrated that increased serum TSA concentration yielded a high sensitivity, specificity and accuracy for the diagnosis of CCA. Our data showed that the mean serum TSA level in patients with CCA was significantly increased compared to those with cirrhosis, chronic hepatitis and healthy controls ($P<0.001$). Notably, the mean concentration of serum TSA in patients with CCA was substantially higher than that in those with HCC ($P<0.001$). Based on the ROC curve analysis, a cut-off point of 1.75 mmol/L provided a satisfactorily high sensitivity, specificity and accuracy of above 80 % for the differential diagnosis of CCA from HCC. The data of the present study are in agreement with those previously reported which described an increase in serum TSA in patients with CCA[10,15]. Thus, serum TSA would be a useful marker, particularly in conjunction with radiological studies such as ultrasonography or CT scan, for the detection of CCA in patients presenting with clinical features of liver mass and jaundice.

The mechanisms underlying the substantial difference in levels of TSA between patients with CCA and HCC are unclear. One possible explanation is that, in certain cancers, increased activity of sialytransferase might lead to spontaneous shedding of aberrant sialic acid-containing cell surface glycoconjugates into the circulation[16]. Alternatively, since TSA has been well described as being associated with the acute-phase protein response[17], increased activity of serum or tissue sialidase in combination with inflammatory response could considerably elevate serum TSA levels in patients with CCA. Also, the difference between the ages of the CCA and HCC groups might be responsible for this discrepancy, since serum TSA concentration slightly increased with advancing age[18]. Nonetheless, the age-dependent difference between groups might not be sufficient to interfere with the discrimination of serum TSA values in our study. To confirm this observation, the group of age-matched patients with HCC should also be examined for serum TSA levels.

In conclusion, we have demonstrated that serum TSA concentrations, which were determined by a simple microassay, are significantly higher in patients with CCA than in those with HCC, cirrhosis, chronic hepatitis and blood donors. At a cut-off point of 1.75 mmol/L, this serum marker can yield a satisfactory accuracy for the differential diagnosis of CCA from HCC. Accordingly, the measurement of serum TSA level might be useful for the diagnosis of CCA, particularly in the regions where liver flukes are common.

Abstract

AIM: To study the immunoprotective effect of liver cancer vaccine with co-transfected IL-2 and B7-1 genes on hepatocarcinogenesis in mice.

METHODS: The murine liver cancer cell line Hepal-6 was transfected with IL-2 and/or B7-1 gene via recombinant adenoviral vectors and the liver cancer vaccines were prepared. C57BL/6 mice were immunized with these vaccines and challenged with the parental Hepal-6 cells afterwards. The immunoprotection was investigated and the reactive T cell line was assayed.

RESULTS: The immunoprotection of the tumor vaccine was demonstrated. The effect of IL-2 and B7-1 genes co-transfected Hepal-6 liver cancer vaccine (Hep6-IL2/B7 vaccine) on the onset of tumor formation was the strongest. When attacked with wild Hepal-6 cells, the median survival period of the mice immunized with Hep6-IL2/B7 vaccine was the longest (68 days, χ^2=7.70-11.69, P<0.05) and the implanted tumor was the smallest (z =3.20-44.10, P<0.05). The effect of single IL-2 or B7-1 gene-transfected vaccine was next to the IL2/B7 gene co-transfected group, and the mean survival periods were 59 and 54 days, respectively. The mean survival periods of wild or enhanced green fluorescence protein gene modified vaccine immunized group were 51 and 48 days, respectively. The mice in control group all died within 38 days and the implanted tumor was the largest (z=3.20-40.21, P<0.05). The cellular immunofunction test and cytotoxicity study showed that the natural killer (NK) cell, lymphokine activated killer (LAK) cell and cytotoxic T lymphocyte (CTL) activities were significantly increased in mice immunized with the Hep6-IL2/B7 vaccine, (29.5±2.5 %, 65.0±2.9 %, 83.1±1.5 % respectively, compared with other groups, P<0.05).

CONCLUSION: The Hep6-IL2/B7 liver cancer vaccines can induce the mice to produce activated and specific CTL against the parental tumor cells, and demonstrate stronger effect on the hepatocarcinogenesis than single gene modified or the regular tumor vaccine. Therefore, the vaccines may become a novel potential therapy for recurrence and metastasis of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary malignancy of liver in humans and the rate of incidence and mortality is very high in East Asia and China[1]. Though many approaches, such as surgical resection, transarterial chemoembolization (TACE), percutaneous ethanol injection (PEI), radiofrequency ablation (RFA), radiotherapy and liver transplantation were developed to treat it, and the effective and survival rates were increased, a large number of patients died from recurrence and metastasis[2-6].

Some studies showed immunogene modified tumor vaccines could induce effective specific active T cell immune response to prevent tumor recurrence and metastasis[7-10]. Also some reports demonstrated that specific active immunotherapy based on specific antitumor T cell immunity could be a potential modality for further improving the survival of HCC patients on preventing tumor recurrence and metastasis[11-14]. But HCC is poorly immunogenic. Poor or no immunogenicity and lack of costimulating molecules on the surface of tumor cells are some of the causes of most tumors including HCC[15].

The successful induction of an anti-tumor immune response has been reported in a number of tumor models including HCC animal models by using B7-1 (CD80) transfected tumor cells as a vaccine[16]. The rationale of B7-1 based immunotherapy is that T cells require both an antigen-specific signal delivered through the T-cell receptor and a co-stimulatory signal to be fully activated and proliferated, and secrete cytokines or generate cytotoxic T lymphocyte (CTL) to cytolyse tumor cells[17-19].

Interleukin 2 (IL-2) is a growth factor that stimulates the proliferation of cytotoxic T cells, helper T cells, natural killer (NK) cells, and lymphokine activated killer (LAK) cells, all of which can participate in the anti-tumor response[20-22]. Many HCC animal models demonstrated that local secretion of IL-2 abrogated the tumorigenicity of cytokine-producing tumor cells and inducing a long-lasting protective immune response against a subsequent tumor graft[23,24].

In this study, we compared the effect and immunological mechanism of mouse Hepal-6 liver cancer cell vaccine modified by IL-2 and/or B7-1 genes on protecting the C57BL/6 mice from challenge of wild parental Hepal-6 cells. The results provide some experimental evidences that gene modified tumor vaccine can prevent recurrence and metastasis of liver cancer.

MATERIALS AND METHODS

Cell lines

For the experiments, three tumor cell lines were used. Hepal-6 was a liver cancer cell line derived from C57BL/6 mice generously provided by Dr. Li-Xin Wei from Eastern Hepato-Biliary Surgery Hospital, Second Military Medical University,

Shanghai. P815 (NK cell resistant) and Yac-1 (NK cell sensitive) were leukemia cell lines derived from C57BL/6 mice and generous gifts from Prof. Xue-Tao Cao from Institute of Immunology, Second Military Medical University, Shanghai.

Mice

Female C57BL/6 mice, 6-8 weeks old (15-19 g), were purchased from the Animal Center of Chinese Academy of Sciences and housed in a specific-pathogen-free animal facility in Shanghai Medical University.

Replication-deficient recombinant adenoviral vectors

Recombinant adenoviruses carrying human IL-2 and B7-1 genes (AdVhIL-2 and AdVhB7-1) were obtained from Prof. Xue-Tao Cao. The control AdVEGFP (recombinant adenovirus carrying enhanced green fluorescence protein) was gifted from Dr. Gambotto from Pittsburgh University, USA.

Reagents

CD3-FITC, CD4-PE, CD8-PE and CD25-PE, monoclonal antibodies (mAbs) specific for murine CD3, CD4, CD8 and CD25 respectively,used for flow cytometry were purchased from Pharmingen Co. (USA). MTS kits used for cytolytic assay were purchased from Promega Co. (USA). CD80-FITC which was mAbs specific for human CD80 was purchased from Pharmingen Co. (USA). Human IL-2 ELISA Kits used to detect the active part p70 of IL-2 in solution were purchased from DIACLONE Co. (USA).

Preparation of gene modified Hepal-6 tumor cell vaccines

Hepal-6 cells were transfected with various recombinant adenoviruses according to the five protocols listed below, namely 200 pfu/cell AdhIL-2, 200 pfu/cell AdhB7-1, co-transfection of 200 pfu/cell AdhIL-2 and 200 pfu/cell AdhB7-1, 200 pfu/cell AdEGFP, and wild Hepal-6 cell not transfected with any gene. All of the modified Hepal-6 cells in the five groups were inactivated with mitomycin-C (80 ug/ml) to prepare tumor vaccines. These tumor vaccines were named as Hep6-IL2, Hep6-B7, Hep6-IL2B7, Hep6-EGFP and Hep6 tumor cell vaccines, respectively.

Immunization of C57BL/6 mice with various gene modified Hepal-6 tumor cell vaccines

The mice were divided into six groups with 6 mice in each. Five groups were injected 5×10^6 cell vaccines/mouse subcutaneously in the left scapula of those above 5 tumor cell vaccines, respectively. The sixth group was control group and the mice were injected culture medium. All the mice were injected twice a week.

Immunoprotection of tumor cell vaccines to mice

On the 7th day after the final immunization, the mice were injected 8×10^6/mouse of wild Hepal-6 cell subcutanously in right scapula. The mice were scored for tumor growth twice a week according to the tumor volume, and calculated as $V=L*W^2/2$ (L: length, W: width)[25]. The survival time of the mice was investigated.

Preparation of lymphocytes in spleens from mice immunized with gene modified Hepal-6 tumor cell vaccines

The mice in each group were killed by dislocating cervical vertebra on the 7th day after the final immunization, and the spleens were cut aseptically and minced into suspension of single splenocytes. Then the suspensions were centrifuged at 1 000 rpm for 5 min and RBCs in the splenocytes were lysed with sterile distilled water for 10 sec to get lymphocytes, and then the debris was filtered. The filtered cells were centrifuged, and the lymphocytes were harvested and maintained in 1 640 medium (GIBCO BRL, USA) containing 10 % FCS (HYCLONE, USA).

Immunostaining and FACS analysis

The freshly prepared spleocytes were analyzed by direct immunofluorescence staining with mAbs CD3-FITC, CD4-PE, CD8-PE and CD25-PE. Flow cytometry analysis was then performed with a FACScan (Becton Dickson Co.) in the Department of FACS, the Chinese Academy of Sciences.

Induction of the cytolytic activity of LAK cells and CTL from the lymphocytes

The harvested lymphocytes (2×10^6 cell/ml) were cultured in 1 640 containing 10 % FCS with rhIL-2 at 1 000 U/ml at 37 ℃ in a 5 % CO_2 incubator for 5 days and then cocultured with mitomycin Ctreated Hepal-6 cells (20:1 of responder to tumor cell ratio) in 1 640 containing 10 % FCS with rhIL-2 at 50 U/ml at 37 ℃ in a 5 % CO_2 incubator for 5-7 days.

In vitro cytolytic assay of NK, LAK cells, and CTL

MTS assay was employed to test the cytolytic activity of NK cell, LAK cell and CTL from stimulated lymphocytes. Target cells were Yac-1, P815 and Hepal-6 respectively and incubated with various lymphocytes at 37 ℃ in a 5 % CO_2 incubator for 2-4 hours at 100:1 of effector/target ratio. Assays were performed in triplicate wells. Cytolytic activity was calculated according to the formula provided by the MTS kits: cytolytic activity (%) =[(ODe-ODb)+(ODt-ODb)-(ODa- ODb)]×100 %/(ODt- ODb).

Statistical analysis

The data were analyzed with SAS 6.12 and STATA 6.0 software, and expressed as $\bar{x}\pm s$. The cytolytic activity of NK cell, LAK cell and CTL was determined by *t* test. The growth curves of tumor volume were analyzed with a generalized regression model and the mice survival period was analyzed with Log-Rank test.

RESULTS

In vivo immuno-protection by various tumor cell vaccines

After the immunized mice were challenged with wild Hepal-6 cells, the change of the tumor volume was assessed as is shown in Figure 1. The tumors grew progressively in Hep6-EGFP and Hep6 tumor vaccine immunized mice. The tumors in Hep6-IL2 and Hep6-B7 tumor vaccine immunized mice grew more slowly than those in Hep6-EGFP, Hep6 tumor vaccine immunized mice and the control. Compared with the above 5 groups of mice, the tumors in Hep6-IL2B7 tumor vaccine immunized mice grew most slowly and the tumor volume was the smallest (z=3.20-44.10, P<0.05) and about 50 % of the tumor disappeared 68 days after attacked by the wild Hepal-6 cell.

The survival periods of each group of mice were compared. The median survival time of Hep6, Hep6-EGFP, Hep6-B7 and Hep6-IL2 tumor vaccine immunized mice was 51, 48, 54 and 59 days, respectively and significantly longer than that of the control group (χ^2=10.61-23.81, P<0.05). The median survival period of the control mice was the shortest and all the mice died within 41 days. The median survival period of the Hep6-IL2B7 tumor vaccine immunized mice was significantly longer than that of other groups (χ^2=7.70-11.69, P<0.05) and all the mice in this group were alive for more than 68 days after attacked by the wild Hepal-6 cell.

Expression of B7-1 and IL-2 genes transduced Hepal-6 tumor vaccine

Flow cytometry analysis confirmed that the transfected tumor

vaccines Hep6-IL2B7 and Hep6-B7 expressed a higher level of CD80 (55.47 % and 59.11 %, respectively) than Hep6-IL2, Hep6 and Hep6-EGFP tumor vaccines (12.48 %, 11.87 %, and 7.93 %, respectively).

In the supernant of Hep6-B7, Hep6 and Hep6-EGFP tumor vaccines, no IL-2 was detected, while a high level IL-2 was detected in the supernant of Hep6-IL2 and Hep6-IL2B7 tumor vaccines (1 885 pg and 460 pg per $3*10^5$ cells, respectively).

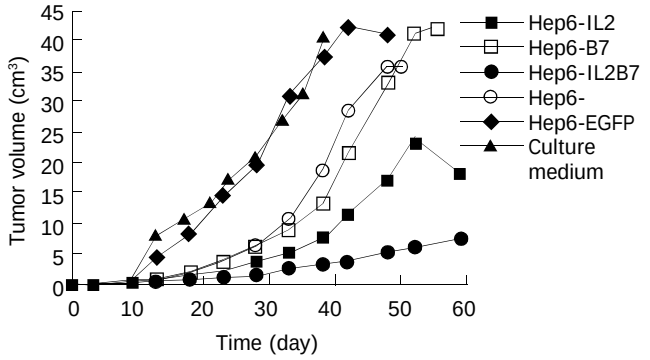

Figure 1 Change of tumor volumes after cancer vaccine immunization.

Flow cytometry analysis

The CD4/CD8 ratio in lymphocytes of the Hep6-IL2B7 tumor vaccine immunized mice was the lowest (0.91) among all the study groups and the CD25 positive rate was the highest (32.85 %). The CD4/CD8 ratios in lymphocytes of the Hep6-B7, Hep6-IL2 and Hep6 tumor vaccine immunized mice and normal mice were 1.02, 1.17, 1.24 and 1.31, respectively, while the CD25 positive rates were 28.62 %, 26.13 %, 19.32 % and 3.59 %, respectively.

Cytolytic assay of NK cell, LAK cell, CTL of spleen lymphocytes

The results are shown in Table 1. The cytolytic activities of the NK cells in each group of tumor vaccine immunized mice were all significantly higher than those in the normal mice (t=11.3-15.5, P<0.05) and it was the highest in the Hep6-IL2B7 group (29.5±2.5 %, t=10.4-15.5, P<0.05). The cytolytic activities of the LAK cells in Hep6-IL2 and Hep6-IL2B7 tumor vaccine immunized mice were significantly higher than those in the normal mice (60.9±1.7 %, 65.0±2.9 %, t=10.6-40.2, P<0.05). The cytolytic activities of the CTL induced by Hep6-IL2B7 tumor vaccine were significantly higher than those in other groups (83.1±1.5 %, t=13.7-53.3, P<0.05).

Table 1 The NK cell, LAK cell and CTL activities of each group mice against different target cells ($\bar{x}$±s %)

Effector cell	Target cell		
	Yac-1	p815	Hepal-6
Normal group	19.0±1.9	48.4±1.9[c]	29.9±1.3[e]
Hep6-IL2 cancer vaccine immunized group	32.5±2.7[a]	60.9±1.7	64.4±12.3[e]
Hep6-B7 cancer vaccine immunized group	17.0±1.7	47.7±1.2[c]	71.2±1.5[e]
Hep6-IL2B7 cancer vaccine immunized group	29.5±2.5[a]	65.0±2.9	83.1±1.5
Hep6 cancer vaccine immunized group	18.5±1.4	42.5±1.3[c]	52.8±1.2[e]

NK cell activities: [a]P<0.05 *vs* normal, Hep6-B7 and Hep6 cancer vaccine immunized group; LAK cell activities: [c]P<0.05 *vs* Hep6-IL2 and Hep6-IL2B7 cancer vaccine immunized group; CTL activities: [e]P<0.05 *vs* Hep6-IL2B7 cancer vaccine immunized group.

DISCUSSION

Hepatocellular carcinoma was poor immunogenicity partly because of poor antigen expression and lack of co-stimulatory molecules[26]. Though successful induction of anti-tumor immunity by means of B7-1 gene[11,14,16] or cytokine (IL-2, IL-4, IL-12, GM-CSF, IFN, and so on) gene[9,12-14,27] transfection has been reported in some HCC animal models, prevention of tumor recurrence and metastasis still needs to be improved.

Some animal experiments showed that IL-2 gene-modified tumor vaccine constantly secreted a relatively high level of IL-2 in local areas, induced local and systemical specific antitumor immuno-reactions and immuno-memory T cells in the body of the animals, prevented the challenge of the next parental tumor and decreased the recurrence rate[28-30]. Reports showed the locally secreted high level of IL-2 generated much less side effects than a systemically administered high dose of IL-2[31].

Double signal systems were needed in the process of inducing effective specific active antitumor T cell immune response[18]. B7-1 was an important co-stimulating molecule for tumor antigen presentation, and could provide the second signal system for T cell immune[11,32,33]. Tumors could escape from the immune surveillance of host when they were lack of it[17]. B7-1 gene-modified tumor vaccine could break the immuno-tolerance of the tumor to the host and induce effective specific antitumor immunology[32,34].

Some reports showed a single immunogene modified tumor vaccine could not induce very effective immune response because double signal systems were needed in the process[18,19] and multi-gene modified tumor vaccine could improve the immunogenicity of tumor vaccines in different ways and promote T cell immunity[18,19,35-39]. So in our experiment, we investigated the immunoprotection of single IL-2 or B7-1 gene or both IL-2 and B7-1 genes immunized mice HCC cell line Hepal-6 tumor vaccines.

In our experiment, the results showed Hepal-6 liver cancer cell line expressed a low level of B7-1 molecule and no IL-2 was secreted, and the tumorigenicity was 100 %. The vaccine prepared from wild Hepal-6 cells showed very weak protection against wild tumor cell attacking. The tumor vaccine modified with IL-2 or B7-1 gene induced a stronger immunoprotective effect than the wild vaccines, and could significantly improve the survival rate and median survival time. More excitingly, the immunoprotection induced by IL-2 and B7-1 genes co-transfected tumor cell vaccine was even better than that of either of the genes. These two genes improved the immunogenicity of the liver cancer cell vaccine synergically and induced the mice to generate stronger anti-tumor immunoreactions. The immunological analysis of spleno-lymphocytes from the mice showed that IL-2 and B7-1 genes co-transfected liver cancer cell vaccine induced lymphocytes to express a significantly higher CD25 positive level and a lower CD4/CD8 ratio. This result suggested the T cells were activated. The cytotoxic analysis showed after immunization with this vaccine, specific CTLs were induced in the mice.

The results in this mouse liver cancer model demonstrated that after immunization with IL-2 and B7-1 genes co-transfected liver cancer cell vaccine, more effective systemic anti-tumor cell immunoreactions could be induce in mice than that with either of the gene modified vaccines, and the induced immuno-memory reaction could protect against the challenge of the wild parental Hepal-6 cell. The results suggest that the co-transfected gene tumor vaccine can prevent recurrence and metastasis of liver cancer.

Abstract

AIM: To study the oxidative DNA damage to adolescents of hepatocellular carcinoma (HCC) families in Guangxi Zhuang Autonomous Region, China.

METHODS: Peripheral leukocytes' DNA 7, 8-dihydro-8-oxoguanine (8-oxoG) and repair enzyme $hOGG_1$ were quantified by flow-cytometry. $hOGG_1$-Cys326Ser single nucleotide polymorphism (SNP) was distinguished by polymerase chain reaction-single strand conformational polymorphism (PCR-SSCP) assay.

RESULTS: There was a positive correlation between 8-oxoG and repair enzyme $hOGG_1$ expression ($P<0.001$). HCC children ($n=21$) in Fusui county had a higher level of $hOGG_1$ ($P<0.01$) and a lower level of 8-oxoG ($P<0.05$) than the controls ($n=63$) in Nanning city. Children in Nanning exposed to passive-smoking had a higher $hOGG_1$ expression ($P<0.05$) than the non-exposers. 8-oxoG and $hOGG_1$ were negatively correlated with body mass index, while $hOGG_1$ was positively correlated with age. There was a peak of 8-oxoG level nearby the 12 year point. Individuals with the $hOGG_1$ 326Ser allele had a significantly marginal higher concentration of leukocyte 8-oxoG level than $hOGG_1$ 326Cys allele.

CONCLUSION: This is the first report using flow-cytometry to simultaneously quantify both the DNA oxidative damage and its repairing enzyme hOGG1. The results provide new insights towards a better understanding of the mechanisms of oxidative stress in a population highly susceptible to hepatocarcinogenesis.

INTRODUCTION

Reactive oxygen species (ROS) possess a high reactivity of a variety of biological molecules, among which, DNA is one of the most important targets[2]. Oxidative DNA damage, caused by either endogenous or exogenous source of ROS, has been linked to aging, chronic degenerative diseases, inflammatory diseases and cancers[3-6]. Among various types of DNA base modifications induced by ROS attack, 7,8-dihydro-8-oxoguanine (8-oxoG) has been the most widely studied and is considered as a key biomarker of oxidative DNA damage[7]. Leaving unrepaired, 8-oxoG is highly mutagenic because of its propensity to mispair with adenine during DNA replication, ultimately yielding GC to TA transversion[8].

To minimize 8-oxoG accumulation within genomes, this lesion is subjected to DNA repair primarily through the base excision repair pathway[9]. A key component of this pathway in eukaryotes is OGG_1, a DNA glycosylase/β-lyase that recognizes 8-oxoG opposite cytosine[10]. Inactivation of the OGG_1 gene generates a mutator phenotype characterized by GC-TA transversions in yeast[10]. Analysis of the human OGG_1 gene ($hOGG_1$) and its transcripts in normal and tumoral tissues has revealed alternative splicing, polymorphisms and somatic mutations[11]. The repair effectiveness of OGG_1 may be modulated by gene polymorphisms. A Cys326Ser substitution in exon 7 has been the most extensively studied. The Cys326 isoform is postulated to exhibit reduced 8-oxoG repair activity[12], increase susceptibility to squamous cell carcinoma of lung cancer[13,14], otolaryngeal cancer[15] and esophageal cancer[16], nevertheless, controversy still remains[17-21].

Dietary aflatoxin exposure[22,23] and hepatitis infection[24,25] are two well known risk factors in liver carcinogenesis, which involves ROS generation and oxidative DNA damage. A synergistic effect of aflatoxin B_1 (AFB_1) and hepatitis virus B (HBV) may be involved in the hepatocellular carcinoma (HCC) formation, and may be responsible for the predominance of one hotspot GC→TA transversion in the p53 gene of affected individuals[22,23].

HCC is the third most common cause of cancer death in China[26], and the main killer in a south-western province, Guangxi Zhuang Autonomous Region[27]. The age-standardized mortality of HCC for males and females in this province was 32.5/100 000 and 8.5/100 000, respectively[1], accounting for 50 % and 25 % of all the cancer deaths in this region in men and women, respectively[1]. Thus far, dietary AFB_1 exposure[28] and HBV infection[1] are the well documented risk factors

for the extraordinarily high prevalence of HCC in this area. Our earlier data[29,30] together with that of Stern *et al*[31] have highlighted a frequency of 36-73 % of p53-249 codon mutation in HCCs in this region, which is consistent with the notion that, the p53-249 hot-spot mutation is a fingerprint of AFB_1 contamination, and possibly synergistic with HBV infection in hepatocarcinogenesis[22].

In the present study, on the assumption that environmental carcinogens may impose oxidative stress on the residents living in Guangxi Zhuang Autonomous Region, we examined the level of 8-oxoG and $hOGG_1$ expression in leukocytes of a random sample of adolescents aged 4-18 in an area of Guangatxi exposed to a high level of aflatoxin and high risk of HCC, using a newly developed flow cytometry method. Furthermore, we examined the relationship between DNA damage and genetic polymorphisms of oxidative damage repair gene $hOGG_1$.

MATERIALS AND METHODS

Study subjects

This collaborative study by the Guangxi University and Fusui Cancer Institute was part of a community-based health survey in the Nanning region of Guangxi Zhuang Autonomous Region, conducted during April to June 2001. Based on the local cancer registry from 1974 to 1999, the HCC incidence rate in this region ranged from 32 to 97 per 100 000 for males and 4.27 to 17.32 per 100 000 for females, respectively. The aims of the study were explained in detail prior to the survey. From a total of 472 informed residents, 162 adults and 123 adolescents (60.4 % response rate) participated in on a voluntary basis.

After written consents were obtained from all the individuals or children' s parent/guidance. Ten-milliliter venous blood was collected with heparin as anticoagulant. Buffy-coat and plasma separated soon after collection, and kept in liquid-nitrogen during transportation, and stored at -80 ℃ till analysis. Body weight, height, age, gender, occupation, alcohol and smoking habit and family history of hepatitis infections were also recorded using a structured questionnaire approved by the Guangxi Medical University. Plasma of all subjects was screened to differentiate HBV, HCV, HDV, HEV and HGV infections. 25.6 % (73/285) subjects were positive of HV infection (63/HBV(+), 1/HBV&HCV(+), 1/HCV(+), 4/HBV&HDV(+), 2/HEV(+), 2/HBV&HGV(+)). These cases were excluded, in order to rule out the possibility of influence from hepatitis viruse infection[24,25]. Furthermore, subjects with known exposure to known environmental or occupational hazards (such as cigarette smoking, alcohol or pesticides), as well as those who were currently under medication or known to have a chronic illness were also excluded. Fifty-six boys and 28 of girls aged from 4 to 18 (mean±SD, 11.45±3.0 years) born and grown up in this region met the above mentioned criteria, and were selected for this investigation.

Determination of DNA 8-oxoguanine and $hOGG_1$ in leukocytes

Prior to the investigation, extensive experiments were conducted to optimize the antibody/probe titers and the amount of cells to be used for flow cytometry. It was found that reproducible data could be achieved with 40 μl-buffy coat (around $0.8\text{-}1.1\times10^6$ WBC). The buffy-coat was first transferred from -80 ℃ to 4 ℃, gently thawed for 4 h, and then shifted to room temperature till completely thawed. Forty micro liters buffy-coat were counted for leukocytes using a hemocytometer, and another 40 μl buffy-coat was transferred into an Eppendorf tube containing 1 ml of PBS with 1 % paraformaldehyde, stood on ice for 30 min. After washed twice with PBS, Cells were then fixed in ice-cool 70 % ethanol and kept at -20 ℃ till staining.

8-oxoG was stained by a Biotrin OxyDNA Assay Kit (Fluorescein isothiocyanate, FITC-conjugated probe, Biotrin Int. Ltd., Dublin, Ireland.) according to the manufacturer' s protocol with some minor modifications[32,33]. For $hOGG_1$ staining, first antibody (1st Ab, goat-anti-$hOGG_1$) was obtained from Santa Cruz Biotech, Inc (California, U.S.A.) (goat polyclonal antibody, against a peptide mapping at the amino terminus of OGG_1 of human origin, reacts with all OGG_1 splice variants of human origin). The second antibody (2nd Ab, R-phycoerythrin, PE-conjugated rabbit anti-goat IgG) was purchased from Sigma-Aldrich Inc., (St. Louis, MO, USA). Before staining, the cells were treated by Biotrin Blocking Solution at 37 ℃ for 60 min. After washed with Biotrin Washing Solution, the cells were first incubated with 1st Ab (goat-anti-$hOGG_1$, 1:100 in 3 % FBS/PBS), followed by a mixture of Biotrin 8-oxoG probe (FITC-conjugate, 1:10 dilution) and 2nd Ab (rabbit-anti-goat, PE conjugate, 1:400 dilution) in the Biotrin Washing Solution at 37 ℃ in the dark for 60 min per step. The cells were then re-suspended and quantified by a flow cytometer (Coulter Epics Elite Flow Cytometer, Coulter Corporation, Miami, USA), at 488 nm excitation and 525 nm (FITC), 578 nm (PE) emission, respectively. Blood from a healthy adult volunteer was included and served as an internal control. Data were analyzed using the WinMDI2.8 software (http: //facs.scripps.edu/software.html). 8-oxoG and $hOGG_1$ levels were determined as percentage of positive-staining-cells (oxoGP, $hOGG_1P$) and mean of relative fluorescence intensity (RFI for oxoGI, $hOGG_1I$) of 10 000 cells counted by the flow cytometer[34]. To eliminate possible batch-to-batch variations, all the samples were analyzed at the same batch by the same cytometer.

Genotyping of $hOGG_1$ Cys326Ser single nucleotide polymorphism (SNP)

PCR-SSCP analysis of $hOGG_1$ Cys326Ser SNP was modified from a technique described by Kohno *et al*[12]. DNA extracted from leukocytes using phenol-chloroform method was amplified by PCR. The primers used were 5' -actgt-cacta-gtctc-accag-3' (forward) and 5' -tgaat-tcgga-aggtg-cttgg-ggaat-3' (reverse) (Research Biolabs Pte., Ltd., Singapore). PCR polymerase and dNTP were from Finnzymes (ESPOO, Finland). Twenty-μl PCR reaction mixture contained 2 μl 10×PCR-buffer, 1.5 mM $MgCl_2$, 0.1 mM dNTP, 0.5 μM of each primer, 1 U Finnzyme polymerase and -100 ng of sample DNA. PCR reaction on a thermocycler (Biometra TGradient, Göttingen, Germany) began with pre-incubation at 94 ℃ for 5 min, followed by 30 cycles of denaturation at 94 ℃ for 30 s, annealing at 54 ℃ for 30 s, and elongation at 72 ℃ for 30 s. PCR products were diluted with 4 volumes of loading buffer (0.5×TBE, 0.05 % bromophenol blue, 0.05 % xylene cyanol, 20 mM methylmercury hydroxide), heat-denatured at 85 ℃ for 5 min and rapidly cooled on ice before loading. Twenty microliters of each sample were separated on 10 % non-denaturing polyacrylamide gels with or without 5 % glycerol. Electrophoresis was conducted at 200 V constant for 5 h at 4-5 ℃. Silver staining followed Forsberg *et al*[35]. Genotype of each band-pattern was confirmed by a subsequent sequencing in a commercial laboratory (Research Biolabs Pte., Ltd, Singapore) using BigDye™ Terminator kits on a ABI PRISM® 377-96 DNA Sequencer. A blank was inserted into each batch PCR to monitor PCR contamination, and for each sample, at least one independent repeat of PCR-SSCP assay was done.

Statistical analysis

All analyses were performed using the SPSS 10.0 program (Chicago, USA). Two cases were excluded from flow cytometry assays because of inadequate leukocytes. The frequency distributions of 8-oxoGP, 8-oxoGI, $hOGG_1P$ and $hOGG_1I$ skewed to the right while body mass index (BMI)

skewed to the left. In order to obtain acceptable fit to the normal distribution and stabilize the variance, 8-oxoGI, $hOGG_1I$ and BMI were log-transformed while 8-oxoGP and $hOGG_1P$ were transformed by the formula: log ((100+X)/(100-X)). Non-parameter Mann-Whitney test and one-way ANOVA were used to examine the influence of gender and $hOGG_1$ genotype on the four biomarkers, respectively. A partial correlation was calculated to examine the closeness of relationship between continuous variables (biomarkers, age and BMI). Multiple linear regressions were conducted to examine the influence of risk factors on the four biomarkers, respectively. A two-tailed *P* value <0.05 was considered significant.

RESULTS

Levels of 8-oxoG and $hOGG_1$

Figures 1a to 1d show the images of leukocytes stained for 8-oxoG and $hOGG_1$ under laser confocal microscope. The mean levels of the four biomarker parameters in male and female children are summarized in Table 1. The positive-staining cell percentage of 8-oxoG and $hOGG_1$ ranged between 45-99 % and 44-98 %, respectively. It was noted that the majority (>72 %) of cases had over 90 % positive-staining leukocytes for both 8-oxoG and $hOGG_1$. The data suggested that between male and female children, there was no significant difference in both 8-oxoG and $hOGG_1$ expressed either as percentage or fluorescent intensity.

Association between 8-oxoG, $hOGG_1$, age and BMI

Table 2 reveals that there were significant correlations between 8-oxoG level and $hOGG_1$ expression even after adjustment of age and BMI. Furthermore, a positive correlation was seen between age and $hOGG_1$ expression, either measured as percentage or intensity. In contrast, a negative correlation was noted between BMI and 8-oxoGP, and between BMI and $hOGG_1P$. These associations remained significant even when BMI or age was adjusted. These data suggested that age and BMI could independently influence the levels of oxidative damage and $hOGG_1$ gene expression.

Association between biomarkers and $hOGG_1$ Cys326Ser SNP

The median levels and 95 % confidence interval (95 % CI) of the four biomarker parameters of their respective $hOGG_1$ Cys326Ser SNP genotype are presented in Table 3. Children with $hOGG_1$ Cys326Ser heterozygote were found to have a higher level of 8-oxoG than those with Cys/Cys homozygote, although statistical significance was observed only in 8-oxoG intensity. Also, comparison of subgroup Cys/Cys *vs.* (Cys/Ser + Ser/Ser) revealed similar results (data not shown).

Multivariate analysis

To explore possible interactions of risk factors, a linear regression was then conducted for the four biomarkers, respectively (Table 4). Based on the multiple regression analysis against 8 variables, $hOGG_1$ expression level increased with aging, leaner children had a lower level of 8-oxoG, and $hOGG_1$ 326Ser allele had an increasing effect on 8-oxoG level while a reducing effect on $hOGG_1$ expression. However, the 8 factors listed in Table 4 explained only less than 50 % of the entire variations, suggesting that other oxygen radical-forming factors might be involved.

Table 1 Level of biomarkers in male and female children

DISCUSSION

Population-based researches can provide new clues to etiology of a disease. The unique epidemiology of high mortality rate of HCC in Guangxi Zhuang Autonomous Region, China has provided an ideal population model for the study of oxidative DNA damage and corresponding repair mechanism[1]. Although aflatoxin exposure was not measured in the present study, our earlier reports and others have shown that the dietary intake of aflatoxin in the local residents was high[28,36]. Furthermore, it has been well established that AFB1 causes rapid ROS formation and leads to DNA oxidative damage, which plays a critical role in hepato-carcinogenesis[22]. The subjects of the present study came from a typical HCC high risk community. In order to rule out the possibility of influence from hepatitis virus infection and other potential environmental and occupational factors, such as pesticides, cigarette smoking and alcohol, we have limited the present study to 82 children under the age of 18 with no known liver diseases or other medical history.

Methodology of quantification for oxidative DNA damage

Immunohistochemistry-based approaches have been widely used for the quantification of DNA adducts in various tissues[37], as well as in *in-situ*[38,39] or urinary[40] 8-oxoG quantification. On the other hand, flow cytometry technology allows multi-parameter analyses of heterogeneous cell population, in which immunophenotyping of both surface and cytoplasmic antigens, DNA analysis and functional evaluations are combined. Subsets of cells can be identified and characterized by patterns of maturation antigens and staining intensity[41]. This report is the first study thus far utilizing flow cytometry for simultaneous quantification of both 8-oxoG and a high risk population of HCC as a model. Compared to the immuno-quantification of 8-oxoG using visualized counting of positive-staining cells, the flow cytometry approach we used, has the following advantages. The assessment is more objective compared to other methods as the scoring is not operator dependent, both the number of positive-staining cells and fluorochrome intensity could be quantified simultaneously, the sample required (-1×10^6 cells) is much less, compared to other traditional methods, and high-throughput (it can handle as many as 100 samples per batch, thus eliminating possible batch to batch variations).

Prior to the present investigation, attention was paid during the pilot study to standardize and validate the instrumentation and methodology. Factors such as specificity and performance of the reagents, staining intensity, spectral overlap, and instrument compensation were carefully evaluated[41]. The overall indication is that the flow cytometry determinations of 8-oxoG and $hOGG_1$ are of high reliability. The reproducibility is generally over 90 % with batch-to batch variation of less than 10 %. As for the actual samples from Guangxi, a substantial proportion of leukocytes was found to be positively-stained for both 8-oxoG and $hOGG_1$. These values are much higher compared to normal healthy subjects from Singapore of about 20 % to 40 % (Tao *et al*, unpublished data). Table 2 clearly demonstrates that there were significant correlations between 8-oxoG level and $hOGG_1$ expression, either expressed as percentage or chromophore intensity. Even after confounding factors such as age and BMI were adjusted, there were still significant associations between oxidative damage and $hOGG_1$ expression in leukocytes (Table 2). This finding supports that normal cells have certain defensive mechanism against ubiquitous oxidative DNA damage[9], and $hOGG_1$ works as a housekeeping gene, ubiquitously expressed during cell cycle[42].

Although inter-individual variations of $hOGG_1$ are genetically determined, the present data and several earlier studies suggest that its expression could be influenced by endogenous formation of ROS or environmental carcinogens. Increased 8-oxoG repair activity has been shown to increase in smoker's leukocytes[43] and in lung cells exposed to asbestos[44]. Quantitative assessment of hOGG1 expression in peripheral blood cells can provide information on exposure to environmental carcinogens[45]. The present study has clearly demonstrated that hOGG1 in leukocytes, expressed either in percentage or fluorescence intensity, can indicate the oxidative damage in an HCC high risk population, suggesting that $hOGG_1$ is a useful biomarker for monitoring oxidative stress, in addition to 8oxoG.

Gender and oxidative DNA damage

Based on the epidemiological data obtained earlier in other parts of China as well as in Guangxi Zhuang Autonomous Region, the occurrence of HCC is predominant in men, the ratio of male to female is 4-6:1[1]. However, in the present study, we did not observe any difference in either 8oxoG or $hOGG_1$ level between male and female children (Table 1). According to Loft *et al*.,

adult healthy men aged 40 to 60 excreted 29 % (10-48 %) more 8-oxoG in urine than women[46]. Nevertheless, DNA damage, measured as either percentage of DNA migrated in COMET tail[47] or 8-oxoG excretion in urine[48], was not associated with gender in other two adult populations. In healthy individuals, there was no difference in $hOGG_1$ activity due to gender by means of an 8-oxoG-containing oligonucleotide assay[17]. Since this was a children-based study, further evidences from adult subjects are required to elucidate the role of gender-related factors in hepatocarcinogenesis in this population.

Age, BMI and oxidative DNA damage

An inversed relationship between BMI and urinary excretion of 8-oxoG in adults has been documented[46,49], and was postulated to be due to a higher metabolic rate in lean persons[46]. In the present study, similarly, we observed a negative correlation between BMI and 8-oxoGP, and between BMI and $hOGG_1P$ (Table 2), which was consistent with that in previous reports. There was also a positive correlation between $hOGG_1$ level and age, which was not consistent with that of 8-oxoG (Figure 2, Table 2). This age-dependent increase of $hOGG_1$ in children has never been reported elsewhere. The results indicated that, the age-dependent increase of $hOGG_1$ level can not simply be explained by metabolic rate and BMI.

Using COMET assay to study DNA damage of children in Mexico City, Calderon-Garciduenas[50] showed that there was an age-dependent increase in the percentage of nasal cells with COMET tails >10 microns, implying a dose response relationship between exposure to environment pollutants and increase of age. Drury[51] in a preliminary study of 15 children observed an increase of mean 8-OHdG excretion in urine with postnatal age (r=0.80, P<0.0001). Nevertheless, the author argued that these changes could also be due to changes in the activity of the enzyme responsible for 8-OHdG excision. According to Bogdanov[52], however, neonates of 50-60 days had a higher 8-OHdG excretion in urine (13.39±0.082 ng/mg creatinine, n=150) than children aged 3-9 (4.62±0.091 ng/mg creatinine, n=32). So far no report about hOGG1 expression in children is available. Therefore it is not known whether this age-dependency is attributed to growth-related increase of metabolism or dietary increase (accumulation) of exposure to aflatoxin or other hazards, or both. Further studies with a larger population should be able to provide more insights in this preliminary observation.

$hOGG_1$-Cys326Ser SNP and oxidative DNA damage

DNA repair enzyme OGG1 is a DNA glycosylase/AP lyase that has been hypothesized to play an important role in preventing carcinogenesis by repairing oxidative damage to DNA. Specifically, it can efficiently repair 8-oxoG, a major base lesion produced by ROS and formed by endogenous metabolism or exposure to environmental oxidizing agents or genotoxic compounds[10]. In this study we have analyzed the variants of $hOGG_1$-Cys326Ser in 84 children and the results showed that the frequency of $hOGG_1$-Cys326 allele of 54.8 % was similar to that reported by Sugimura[13] and Takezaki[53] conducted in two other Chinese populations (54.5 % to 60.7 %). In the present investigation, individuals with the $hOGG_1$ 326Ser allele rather than $hOGG_1$ 326Cys allele, had a significantly higher concentration of leukocyte 8-oxoG level (Tables 3 and 4).

Kohn *et al*. first described a reduced repair activity of $hOGG_1$-Cys326 protein in a complementation assay system[12]. Nevertheless, this observation was not supported by another study using cell homogenates-cleavage system[17]. A recent study by Janssen *et al* found that DNA repair activity of OGG1 in human lymphocytes was not dependent on the Ser326Cys variants[17]. Paralleling to the results of functional studies, population studies on $hOGG_1$-326 polymorphism and cancer susceptibility thus far were also not conclusive[17-21]. It is however important to note that the proportion of homozygous Ser-Ser individuals is the highest in Melanesians (74.5 %), and German (57.1 %), lower in Australian Caucasians (40 %), Japanese (27.7 %) and even lower in Chinese (12 %)[13].

Since the 8-oxoG level measured in a tissue at time is an integration of a number of parameters including the level of ROS, tissue redox status, cellular antioxidant defense mechanism and DNA repair system[21], our data suggest that the role of $hOGG_1$ SNP, if any, in modulating 8-oxoG level of individuals, may be diluted by other confounders. On the other hand, it is believed that $hOGG_1$ may not be the only gene associated with oxidative damage. An alternative DNA oxidative damage repair pathway to minimize the effects of 8-oxoG in genomes has also been reported recently[54]. Carefully designed studies considering these confounders however, are obviously needed to verify this observation.

From the data obtained in this study, it is concluded that, oxidative damage is significantly correlated with the DNA damage repair enzyme $hOGG_1$, there are positive associations between oxidative damage, repair enzyme $hOGG_1$ and age, while there are reverse relationships between oxidative damage and body mass indexes, and polymorphism of $hOGG_1$ variant appears to influence 8-oxoG level in peripheral leukocytes, but only at a marginal strength. These findings provide some new insights into a better understanding of the complex etiology and molecular events that could lead to the development of HCC. Further study should take into consideration of both long term environment exposure and genetic susceptibility in a larger population.

ACKNOWLEDGEMENT

We are grateful to Prof. Chia SE and Dr. Dong F for their statistical advice and critical comments on the manuscript. We are also grateful to Ong HY and Ong YB for their technical support (Department of Community, Occupational and Family Medicine, National University of Singapore, Singapore.).

Abstract

AIM: To improve the low resection rate, poor prognosis and to control the massive hemorrhage during operation, total vascular exclusion (TVE) technique was used in hepatectomies of advanced and complicated hepatocellular carcinomas (HCCs).

METHODS: Five hundred and thirty patients with HCCs were admitted in our hospital. They were divided into TVE technique group (group A: n=78), Pringle maneuver method group (group B: n=176) and unresectable group (group C: n=276). The clinical, operative, pathological parameters and outcome of the patients were statistically evaluated.

RESULTS: Group A had a significantly higher resection rate than group B (accounting for 47.92 % and 33.21 % respectively). There was no significant difference in blood loss, blood transfusion and perioperative mortality between groups A and B. Both groups had the similar median disease free survival time (14.6 *vs* 16.3 months) and 1 year survival rate (92.9 % *vs* 95.5 %). The TVE group had a medial survival time of 40.5 months and its 5-year survival rate was 34.6 %.

CONCLUSION: As compared with Pringle maneuver method, the total vascular exclusion is a safe and effective technique to increase the total resection rate of advanced and complicated HCCs.

INTRODUCTION

At present, operations including tumor resection and liver transplantation offer the only chance of cure for the patients with HCCs[1], and hepatectomy remains the normal choice when liver transplantation is not available. HCCs we met were mostly advanced with a low resection rate and had a high risk of lethal blood loss during operation as well as a high mortality after operation especially when the liver was affected by chronic hepatitis or cirrhosis[2-7]. To avoid excessive bleeding and blood transfusion, several methods to limit bleeding have been developed since hepatic portal clamping was successfully performed by Pringle in 1908, which led to the development of total vascular exclusion (TVE) of the liver by Heaney in 1966. Since then, Huguet and his colleagues have better characterized and widely advocated the use of TVE, which can greatly reduce the risk of massive hemorrhage and air embolism[8].

Pringle maneuver method is routinely used in hepatectomy to control blood loss during HCCs operation, TVE is there fore controversial. To the present, no study has documented its safety and efficacy as compared with Pringle maneuver method in resection of HCCs. This study was review our experiences with resection of HCCs by TVE and Pringle maneuver methods.

MATERIALS AND METHODS

Patients

From January 1994 to January 2002, 530 patients with HCCs were admitted in our hospital, they were divided into 3 groups. Group A: 78 patients with complicated HCCs underwent total vascular exclusive hepatectomies. Group B: 176 patients with HCCs underwent Pringle maneuver hepatectomies. Group C: 276 patients with unresectable HCCs underwent conservative treatments such as transhepatic artery embolization.

Diagnosis and vascular exclusion selection

HCCs were diagnosed by examinations such as serum tumor marker α-fetal protein, B-type ultrasound, plain or enhanced spiral computed tomography, magnetic resonance imaging before operation. The diagnosis was confirmed by pathologic examination after operation.

Pringle maneuver method was routinely used in the hepatectomy in our center, and the TVE was only used in advanced and complicated HCC patients such as massive tumors needing major hepatectomy, tumor closing or invading the major blood vessels of liver, tumor in the caudate lobe and multiple tumors.

Perioperative care and treatment

Preoperative care: A venous catheter was introduced one week before operation for routine parenteral nutrition to improve the patient' s liver function, nutritional status and coagulation condition. During perioperative care period, frozen plasma should be infused and blood transfusion must be strictly controlled. Blood loss and ascites production during the operation were balanced by infusing fresh frozen plasma. Intraoperative blood transfusion was given only if the hematocrit value was below 0.30. To prevent bleeding, hemostatic drugs such as fibrinogen and thrombinogen were always intravenously given. The main aim during the first few postoperative days was to restore the liver function and prevent hepatic failure. We used 20 % human albumin 100-200 ml/day to maintain the serum protein level. Glucose solution was given for the energy, and short-term antibiotics, histamine blockers were also administered. Appropriate oral intake was restored as soon as possible. The blood discharge from the drain was

carefully monitored. When bleeding exceeded 100 mL/h, an emergency laparotomy was performed. The patients were taken care of in an intensive care unit for the first 24 to 48 hrs with their the life signs inspected. Immediate postoperative treatments included hemostasis, prophylaxis antibiotic treatment and total parental nutritional support.

Operative technique

The surgical technique was described previously[2,8]. In general, a bilateral subcostal incision with or without an upward midline extension was used, and intraoperative ultrasound was routinely used to determine location of the tumor, or possible tumor modules in the contralateral lobe and the exact relationship between the tumor and the major liver blood vessels. In group A, all the hepatic ligaments were divided to allow complete mobilization of the liver and exposure of the whole retrohepatic vena cava. TVE was prepared by carefully dissecting the suprahepatic and infrahepatic vena cava, and right adrenal veins and accessory hepatic veins were ligated if necessary to allow complete venous control during clamping. Clamps were always applied in the following sequence: hepatoduodenal ligament, infrahepatic vena cava and suprahepatic vena cava. During transection of the liver, 5 min interval was always allowed in every 15-20 min TVE until the transection was over. After the resection was completed, the clamps were removed in reverse order of their application. Pringle maneuver method was applied in group B at the time of liver transection and consisted of cross-clamping the hepatoduodenal ligament until the liver transection was completed. If the time was more than 20 min, the clamp was released for about 5 min until the operation was completed. Hemostasis of the raw surface of the liver was assured by biological fibrin glue and exact suture. Closed drainage was routinely used before closure of the incision.

Data collection and analysis

All medical records of the patients of the three groups were reviewed retrospectively. Major hepatectomy was defined as resection of two or more liver segments according to Goldsmith and Woodburne, while minor hepatectomy was defined as resection of only one segment[2]. Tumor closing or invading the major liver blood vessels was defined as the distance between them which was less than 1 cm.

The values were expressed as median (range) and cases (percent). The overall survival after hepatic resection was calculated by the Kaplan-Meier method. Statistical evaluations were performed by using unpaired Student *t* test and chi-spuare analysis, and comparison was made by log rank analysis. Statistical significance was determined by a *P* value of less than 0.05. Calculations were made with SPSS computer software (Chicago, IL).

RESULTS

As shown in Table 1, the two groups (groups A and B) of patients were similar in terms of age, sex. Both groups had similar high HBV infectious rate. Although the operative time and blood exclusive time were long in TVE group, no significant difference was found in blood loss and blood transfusion between groups A and B. More major hepatectomies and caudate lobe hepatectomies were performed in group A than in group B.

The pathologic data are shown in Table 2. There was a significant difference in the size of tumors between groups A and B. From the data, the rate of tumor closing or invading the major liver blood vessels in group A was higher than that in group B. The patients with HCCs in group A had a higher probability in their advanced stage, about 70 % of the patients were TNM stage 3 or 4 in group A, while only about 32 % in group B. Although higher cirrhosis rate, multiple tumor possibility, more caudate lobe location and higher risk of tumor rupture were found during operation in group A than in group B, the possibilities of tumor free resection margin in the two groups were similar.

Table 1 General clinical data

Clinical parameters	Group A (*n*=78)	Group B (*n*=176)
Age (yr)	51.72 (36-71)	49.66 (14-74)
Male	69 (88.64 %)	147 (83.52 %)
HbsAg (+)	67 (85.89 %)	151 (85.79 %)
Child-Push grade		
Grade A	41 (52.54 %)[a]	124 (70.45 %)
Grade B	28 (35.90 %)[a]	38 (21.59 %)
Grade C	9 (11.53 %)	14 (8.0 %)
Total resection rate	47.92%(254 / 530)[a]	33.21 %(176 / 530)
Procedure time (min)	268 (150-325)[a]	178(128-356)
Blood exclusion time (min)	25.4 (12-55)[a]	14.2(8-28)
Blood loss (ml)	818 (250-2800)	725(180-2400)
Blood transfusion (ml)	690 (0-2400)	620 (0-2600)
Total hospital stay time (d)	29.4 (12-35)	19.8 (10-39)
Re-operation	11 (14.10 %)	16 (9.09 %)
Emergency operation	5 (6.41 %)	9 (5.11 %)
Local hepatectomy	12 (15.38 %)[a]	48 (27.28 %)
Minor hepatectomy	21 (26.92 %)[a]	96 (54.55 %)
Major hepatectomy	45 (57.69 %)[a]	32 (18.19 %)
Caudate lobe hepatectomy	4 (5.13 %)[a]	0 (0)

[a]*P*<0.05 *vs* statistically significant when compared with group B.

Table 2 Pathologic data

Clinical parameters	Group A (*n*=78)	Group B (*n*=176)
The mass		
Median diameter (cm)	11.58 (6.2-24.6)[a]	6.25 (1.8-12.7)
>or =5 cm	72 (92.30 %)[a]	118 (67.05 %)
>or =10 cm	53 (67.95 %)[a]	28 (15.90 %)
Close or invade vana cana	23 (29.49 %)[a]	17 (9.65 %)
Close or invade major hepatic vein	21 (26.92 %)[a]	13 (7.39 %)
Close or invade major bile duct	11 (14.10 %)[a]	8 (4.55 %)
Close or invade major port vein	32 (41.03 %)[a]	22 (12.5 %)
TNM tumor stage		
Stage 1	6 (7.69 %)[a]	49 (27.84 %)
Stage 2	12 (15.38 %)[a]	71 (40.34 %)
Stage 3	36 (46.15 %)[a]	32 (18.19 %)
Stage 4a	20 (25.64 %)[a]	22 (12.5 %)

Tumor rupture during operation	11 (14.10 %)[a]	13 (7.39 %)

[a]*P*<0.05 *vs* statistically significant when compared with group B.

Bleeding was most common short-term complication after hepatectomy, but there was no significant difference between the two groups, accounting for 20.5 % and 16.48 %, respectively. Although the complications in group A including bile leakage, ascites, pleural effusion, jaundice, hepatic failure were significantly higher than those in group B, the reoperation

rate within 24 h after operation and perioperative mortality were similar in the two groups. The data are shown in Table 3.

The prognostic data are shown in Table 4. As compared with Pringle maneuver technique, the hepatectomy of TVE might lead to similar median disease-free survival time and short-term survival rate (92.3 % *vs* 95.5 % of one year survival rate, $P>0.05$). The median survival time and long-term survival rate in group A were significantly lower than those in group B, but obviously higher than those in group C. The results showed that the Pringle maneuver group had a higher incidence of remote metastasis than the other two groups.

Table 3 Postoperative complications

Clinical parameters	Group A	Group B
Bleeding	16 (20.51 %)	29 (16.48 %)
Bile leakage	6(7.69 %)[a]	8 (4.55 %)
Infection (including abscess)	12 (15.38 %)	23 (13.68)
Pleural effusion	31 (39.74 %)[a]	34 (19.32 %)
Reoperation within 24 h after operation	3 (3.85 %)	6 (3.40 %)
Ascites	16 (20.51 %)[a]	20 (11.36 %)
Jaundice	6 (7.69 %)[a]	5 (2.84 %)
Hepatic failure	6 (7.69 %)[a]	5 (2.84 %)
Total morbidity	40 (51.28 %)[a]	45 (25.57 %)
Perioperative mortality	2 (2.56 %)	5 (2.84 %)

[a]$P<0.05$ *vs* statistically significant when compared with group B.

Table 4 Outcome after hepatic resection

Clinical parameters	Group A	Group B	Group C
Median disease-free survival (m)	14.6 (8-25)	16.3 (9-37)	-
Median survival (m)	40.5 (28-52)	57.6 (33-84)	8.8 (5-31)
Cumulative survival rate			
1 year survival	92.3 %[b]	95.5 %[b]	29.9 %
3 year survival	51.3 %[ab]	69.6 %[b]	2.9 %
5 year survival	34.6 %[ab]	48.0 %[b]	0
Remote metastasis rate	16.27%[a]	23.9%[b]	14.8 %

[a]$P<0.05$ *vs* statistically significant when compared with group B; [b]$P<0.05$ *vs* statistically significant when compared with group C.

DISCUSSION

With the advances in surgical technique, the mortality rate of hepatectomy today is less than 5 %[2]. Despite of the satisfactory outcome of hepatectomy for HCC[9], hepatectomy of advanced and complicated HCC remains a major surgical challenge, especially when underlying liver cirrhosis is present[10-12]. HCC is mostly resulted from hepatitis virus infection and liver cirrhosis, and the conventional approach used in hepatcetomy will always lead to excessive bleeding and high risk of perioperative mortality[13,14]. Perioperative transfusion has been found to promote recurrence of HCC and to result in short disease-free and overall survivals[15], the highlight of surgery of advanced and complicated HCC is thus to prevent massive bleeding and blood transfusion in hepatectomies[2]. HCCs we met were always in their terminal stage with a diameter larger than 10 cm. Since the Pringle maneuver method does not prevent hepatic venous bleeding or air embolism, new ways of vascular exclusion has to be devised. The TVE technique has been widely accepted in resection of advanced and complicated HCCs since it was introduced by Heaney in 1966 and modified in clinical practice[3,7,8,16]. In general, the TVE technique is used predominantly for major resections or centrally placed lesions or in cases with blood vessels involved.

TVE technique means the total vascular block of the liver during hepatectomy. Though bleeding is decreased in the operation, the TVE technique will prolong the warm ischemia time of the liver, so we must emphasize its safety. Complications were noted in the total vascular exclusive group, which was regarded to be corresponded to the higher incidence of complex resections[17]. Berney and his colleagues showed that the risk factors for postoperative complications were the duration of surgery and the amount of blood transfused[3]. The frequency of perihepatic infected fluid collections has been reported to be 2 % to 20 %, biliary fistulas occurrence was up to 8 % of patients[18]. Brancatisano showed similar perioperative mortality (2.5 %) in radical major hepatic surgery by TVE but with a lower postoperative complication rate (about 46 %) than that of ours[19].

At present, it is generally accepted that liver resection performed under intermittent warm ischema is a safe and well-tolerated modality in patients with and without cirrhotic livers[20]. Huguet and others showed that hepatocytes could tolerate normothermic ischemia in excess of 1 hour, and ischemia up to 2 hour without major detrimental effects other than transient hepatic failure has never been reported[21,22]. Others suggested that the risks related to hemorrhage were of greater concern than those related to the time of ischemia. Thus, for advanced and complicated HCC, it is safer to continue vascular exclusion, within 1 h, until complete resection is achieved, rather than take the risk of significant bleeding for the sake of a shorter period of ischemia. A prospective randomized trial showed that the postoperative outcome of patients who underwent liver resection with Pringle maneuver method was better than that of those who underwent operation with other methods[2]. The results of our data showed that although the TVE group had a high hepatic failure rate and complication occurrence than the Pringle maneuver group, but the perioperative mortality was not significantly higher, suggesting that the hepatic failure and complication occurrence might be transient and recoverable.

Another major problem of TVE is the hemodynamic change during TVE. As reported before, hemodynamic tolerance to TVE was excellent in most patients[3], and we also found that the patients could adapt well and quickly to the haemodynamic changes observed after total vascular exclusion. On the bases of the reported complications of spinal cord ischemia, renal failure or aortic injury after routine aortic clamping[23] and the excellent hemodynamic tolerance obtained without aortic occlusion, we applied the modified TVE without aortic exclusion.

Advanced and complicated HCCs were formerly regarded as contraindications of operation for their high mortality and postoperative recurrent rate, the resection rate of advanced and complicated HCCs was extremely low. It was reported that the resection rate of HCCs was 12-28 %[18, 24,25]. After the use of TVE technique, the resection rate of HCCs increased remarkably, which was also confirmed in our retrospective analysis.

Untreated patiens with HCCs had a median survival time of 6 months, no 5-year survival has been reported. But the surgical treatment prolonged the median survival to 42 months and the 5-year survival to 32 % in some center[26]. Good results could be obtained through an aggressive surgical approach for patients with advanced and complicated HCCs, even for those with tumor thrombi in the portal trunk and vena cava invasion[27]. Comparatively, our perioperative mortality of the patients with advanced and complicated HCCs by TVE was similar to the hepatectomy by Pringle maneuver method and the 5-year survival rate of TVE group after resection was similar to others[28]. The shorter long-term survival rate and median survival time of complicated HCCs by TVE compared with

Pringle maneuver group might be resulted from their poorer conditions such as inflammatory activity, hepatic reserve and tumor characteristics, advanced TNM stage, higher possibility of introgenic tumor rupture, higher rate of metachronous and multicentric liver carcinogenesis[29-31]. However, the long-term survival rate and median survival time of the TVE group were remarkably higher than those of the unresectable group. By the way, the remote metastasis rate of the Pringle maneuver group was higher than that of the TVE group and unresectable group, and this result needs to be further studied. In addition, the potentially harmful effect on the metabolic function of hepatocytes should be mentioned in future study.

In summary, hepatectomy by TVE is a safe and effective technique in surgical treatment of advanced and complicated HCC as compared with Pringle maneuver technique. It can increase the resection rate of HCCs, reduce the massive bleeding during operation and increase the survival rate of advanced and complicated HCCs. This series of HCCs demonstrate that an aggressive policy of liver resection by TVE can be adopted as a feasible therapeutic option without excess mortality.

Abstract

AIM: To evaluate the role of multiphasic scanning by multirow-detector helical CT (MDCT) in detecing small hypervascular hepatocellular carcinoma (SHCC).

METHODS: Multiphasic scanning was carried out in 75 patients with SHCC with Marconi MX8000 CT scanner. The early arterial phase (EAP), late arterial phase (LAP) and the portal venous phase (PVP) scans were started at 21 s, 34 s and 85 s respectively. The mean difference of CT values between tumor and liver parenchyma for each scanning phase was measured, and the sensitivity of detection of SHCC in each of these phases and in the combined phase was calculated and statistically analyzed.

RESULTS: The mean difference of CT values between tumor and liver parenchyma was significant in 71 lesions$\geqslant$1 cm in three phases (P<0.05). In 91 tumor foci, the detectability of SHCC was 45.1 %, 83.5 % and 92.3 % in EAP, LAP and double arterial phases (DAP), respectively. The early arterial phase plus the portal venous phase and the double arterial phase plus the portal venous phase were 94.5 %, 97.8 %, respectively. Whereas the detectability in LAP plus PVP and in DAP plus PVP had no statistical difference.

CONCLUSION: The utility of faster speed and thinner slice MDCT and multiphase scanning protocol can improve the detectability of hypervascular small hepatocellular carcinoma. Among which LAP is superior to EAP in depicting the lesions.

INTRODUCTION

It has been recognized that the majority of hepatocellular carcinomas (HCC) are hypervascular. During the hepatic arterial phase (AP), hypervascular lesions will be greatly enhanced, and become iso- or hypodense in the portal venous phase (PVP), which is a sensitive and specific feature for diagnosing SHCC. A biphasic hepatic acquisition helical CT scanning technique has become a standard method for clinical diagnosis of SHCC. Some studies and clinical applications have shown that the arterial dominant phase using a single row detector helical CT (SDCT) is effective for detection of SHCC[1-6], but by using this kind of scanner, the scanning of the whole liver takes approximately 20 s with a great difference in scanning time from subdiaphragmatic region to the right lower border of the liver. So that, some lesions are not conspicuously enhanced within the time.

Recently, a new generation of MDCT has been used in clinical practice. The scanning time can be shortened to 0.5 s. If the four-detector array CT scanner is used, the entire hepatic acquisition can be accomplished in a very short period (4-8 s). Therefore, to makes use of the advantages of faster scanning speed of MDCT, we can create a double arterial phase (DAP) scanning technique and compare the detectability of SHCC in the early arterial phase (EAP), late arterial phase (LAP) and portal venous phase (PVP).

MATERIALS AND METHODS

Patients

From September 2001 to July 2002, 75 patients (67 men, 8 women, mean age 49 years) with 91 lesions were enrolled in this study. All the patients were proved or suspected to have SHCC who had undergone imaging diagnostics as US, SDCT or MRI. Among them, 40 cases were confirmed by surgical operation or biopsy, 11 recurred cases were postoperatively diagnosed, and the other 24 cases were diagnosed by clinical data, such as history of liver diseases, evaluation of serum AFP and other imaging modalities.

Methods

Multiphasic CT scans of liver were performed with Marconi MX8000 CT scanner using the following parameters, namely 0.5-0.75 s scanning time, 6.5 mm thick section, 23.3 mm/s table speed, 120 KVp and 200-250 mA.

Before examination, 800-1 000 ml water was taken as oral contrast. The whole liver scanning was followed by nonionic contrast enhancement with a dose of 1.5 ml/kg and an injection rate of 3 ml/s via the antecubital vein. Multiphase acquisition was performed with a scanning delay set for EAP, LAP and PVP at 21 s, 34 s and 85 s, respectively. Each of the whole liver scanning by cephalad-caudal orientation was completed in 4-8 s with breath held.

Imaging analysis

CT attenuations of 71/91 tumor foci with diameter$\geqslant$1 cm were measured in all images, and the difference in density of the tumor foci and surrounding hepatic parenchyma was calculated during the enhanced three phases.

Based on the enhancement and the comparison with adjacent liver parenchyma, the tumor foci were described as hyper-, iso- and hypoattenuation, only hyper- and hypoattenuation lesions could be detected and the number of tumor foci was recorded blindly by two radiologists.

Statistical analysis

The statistical analysis was done by SPSS10.0 software, Chi-square test and analysis of variance.

RESULTS

Among the ninety-one tumor foci identified on the images, 20 of them were less than 1 cm in diameter. The size of the other 71 lesions varied from 10 mm to 30 mm (mean 21.3 mm.) The maximum contrast of tumor-to-liver of the majority lesions during the late arterial phase is shown in Table 1. The difference of tumor-to-liver contrast among the EAP, LAP and PVP was statistically significant (P<0.05).

Table 1 Mean attenuation difference of tumor-to-liver in all phases

Scanning phases	No of SHCCs	X±SD
Noncontrast	71	15.75±7.0[a]
Early arterial phase	71	11.0±9.4[a]
Late arterial phase	71	20.2±14.7[a]
Portal venous phase	71	18.0±10.68

Note: The mean attenuation difference value of each phase was an absolute value. [a]P<0.05.

The sensitivity of tumor foci detection in each scanning phase is shown in Table 2.

Table 2 Sensitivity of SHCC detection for each scanning phase

Scanning phases	Sensitivity (%) (n=91)
EAP	45.1(41/91)
LAP	83.5(76/91)
DAP	92.3(84/91)
PVP	78.0(71/91)
EAP+PVP	84.6(77/91)
LAP+PVP	94.5(86/91)
EAP+LAP+PVP	97.8(89/91)

Table 2 shows that there was a significant difference in the sensitivity of SHCCs detection between EAP and LAP (45.1 % *vs* 83.5 %). Considering the importance of different phases, the sensitivity of the combined phase was 92.3 %, 94.5 %, and 97.8 % for DAP, LAP plus PVP and DAP plus PVP, respectively, which was higher than that of each phase. (Figures 1-3).

The comparison of detectability is shown in Table 3. The EAP had a lower sensitivity for SHCCs compared with others (P<0.05). A notably statistical significance was found in LAP plus PVP and EAP plus PVP (P<0.05), but no statistical significance was observed in LAP plus PVP and DAP plus PVP.

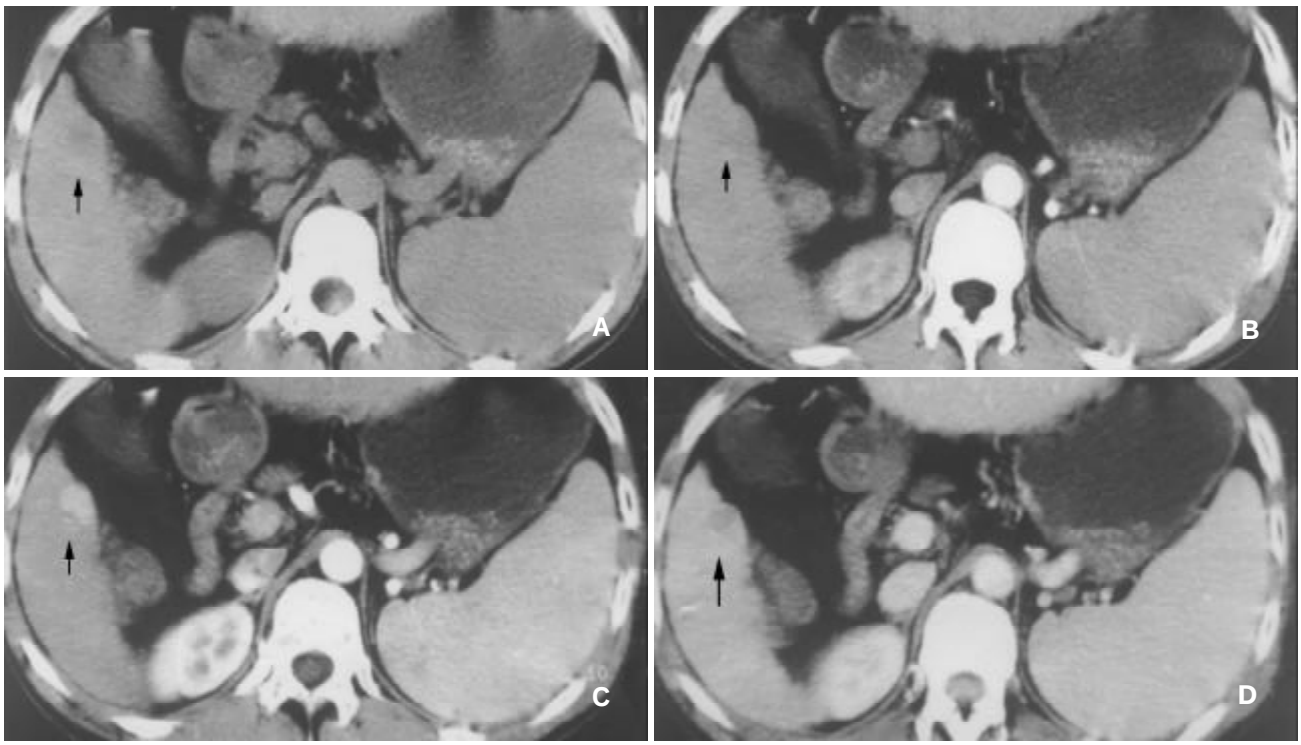

Figure 1 SHCC with size of 1.5 cm in diameter. A: Precontrast image shows hypoattenuating lesion. B:The early arterial phase image shows nonenhanced lesion. C: In the late arterial phase,the lesions enhanced. D: In the portal venous phase, the lesions enhanced dropped down.

Table 3 Comparison of X^2 value between each scanning phase

Scanning phases	LAP	ELAP	PVP	EAP+PVP	LAP+PVP	EAP+LAP+PVP
EAP	P<0.001[a]	P<0.0018	P<0.001[a]	P<0.001[a]	P<0.001[a]	P<0.001[a]
LAP		P=0.088	P=0.258	P=0.831	P=0.033[a]	P=0.006[a]
ELAP			P=0.088	P=0.135	P=0.669	P=0.285
PVP				P=0.200	P<0.001[a]	P<0.001[a]
EAP+PVP					P=0.053	P=0.010[a]
LAP+PVP						P=0.521

Note: All data represented the comparison between each scanning phase using McNemar Test. [a]P<0.05 was considered significant.

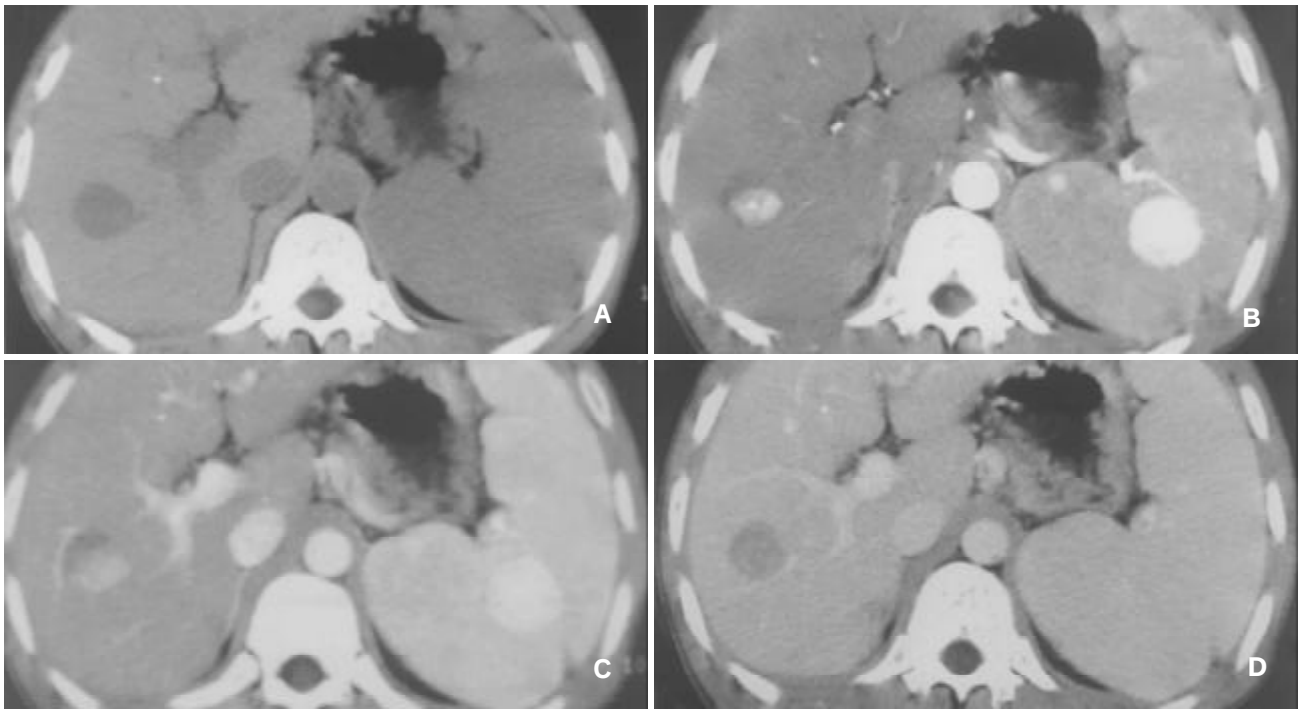

Figure 2 SHCC of 2.0 cm in diameter, A: Precontrast image shows hypoattenuating lesion. B: CT scan obtained at the same level as in the early arterial phase, Tumor intensely enhanced. C: In the late arterial phase, the lesions showed enhancement yet. D: In the portal venous phase, the lesions enhancement dropped down.

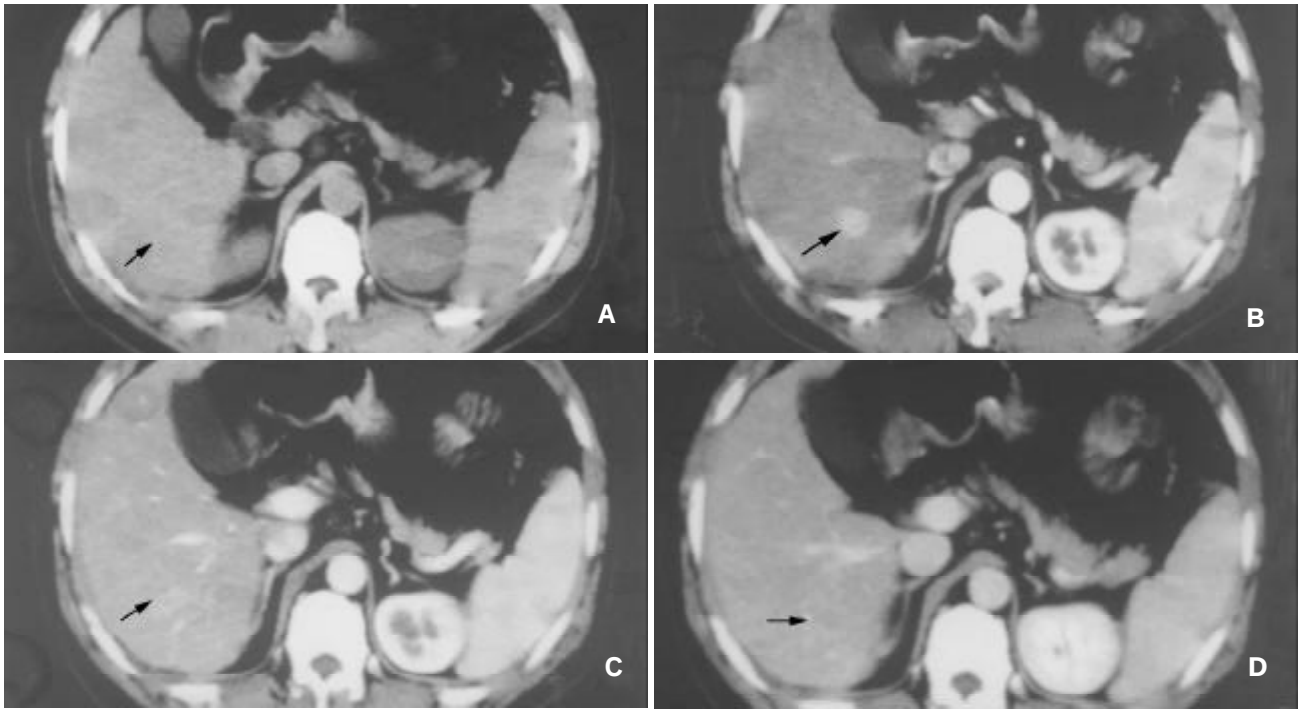

Figure 3 SHCC of 1.5 cm in diameter, A: Hypoattenuating lesion showed in plance image. B: CT scan obtained at the same level as in the early arterial phase, Tumor intensely enhanced. C: In the late arterial phase tumor becomes isodense (arrow). D: In the portal venous phase, the tumor turned to hypodense.

DISCUSSION

The biphasic acquisition helical CT scanning technique has become a standard method for the detection of suspected hypervascular hepatomas. But the single-row detector helical CT (SDCT) has a slow scanning speed (0.8-1 s) and acquires only one section of CT data with each rotation of the X-ray tube. The whole liver scanning using SDCT only takes 20-25 s. It is recognized that the liver has a dual blood supply, the duration of the virtual hepatic arterial phase equals the interval from the beginning of the contrast inflow into the liver from arteries to the beginning of the contrast inflow from the portal vein. It is so short that SDCT is impossible to cover the whole liver during the real hepatic arterial phase[1-6].

Application of MDCT technology in clinical practice has brought about a decisive breakthrough, which is an important milestone in helical CT technologic revolution. The major attribution of MDCT is faster Z-axis coverage speed and improves the longitudinal resolution. MDCT can acquire multiple sections of CT data with each rotation of the X-ray tube and scan the whole liver in 4-8 s, thus imaging of the whole liver can be completed

during the virtual arterial phase[7-13], even twice of the whole liver scanning can be accomplished during the virtual arterial phase. In our study the images in EAP showed intense enhancement of hepatic artery, and minimum enhancement of portal vein, and none of the hepatic parenchyma. The images in the late arterial phase demonstrated substantial portal vein, slight parenchyma enhancement, and no hepatic vein enhancement. The images in PVP showed hepatic veins enhancement, which were not yet enhanced during the early and late arterial phases[14-17].

Our previous studies[18] of continuously dynamic enhancement at the levels of hepatic artery, aorta and hepatic parenchyma, as well as at the level of SHCC foci showed that the arterial phase scanning was started at 16 s (12-22 s) and ended at 40 s. The mean duration of the arterial phase was 23 s. SHCCs were enhanced most markedly in the arterial phase. Due to its hypervascular nature , the mean peak time of the enhancement of SHCC foci was 45.4 s (31-56 s), and the maximum difference of the enhancement between tumor and liver parenchyma occurred at 36 s (28-48 s). Although SHCCs enhanced maximally at 45.4 s, the liver enhancement increased gradually and became quite obvious at that time. The conspicuity depended upon the enhancement difference of the tumor to the liver. Hence the optimally delayed scanning time should be the period when the maximum difference of enhancement occurred between tumor and liver and should not be at the peak time of the tumor enhancement[1,19,20]. This was the theoretical basis on which we set the EAP, LAP and PVP (or parenchyma phase) at 21 s, 34 s and 85 s, respectively. The delayed scanning time at different phases set up by us was in consistency with that reported by Murakami *et al*. They decided the delayed scanning timing for EAP (19.4s) using a mini bolus test, and for LAP (34.9 s), just a 5 s interscan delay after the end of the first pass scanning for table increment patients' movement and patients' respiration[15,16].

This study showed that SHCCs were enhanced during the arterial phase gradually and declined during the portal venous phase (Figure 1). But the mean enhancement difference was greater in LAP than that in EAP (P<0.05) (Table 1). We presume that this reflects the time interval for distribution of contrast-enhanced hepatic arterial blood into the tumor neovasculature and diffusion into the interstices of the tumor[15-22].

The results of our study showed that the sensitivity of detection of SHCC foci (n=91) was 45.1 % and 83.5 % for EAP and LAP. So the late arterial phase was very important for the detection of tumor foci. During the double arterial phase, it could reach 92.3 %, and was higher than that in the portal venous phase (P<0.05). This result indicated that the arterial phase was superior to the portal venous phase in the detectability of SHCCs and was similar to that reported by other authors using biphasic scanning of SDCT[15,16]. But the CT attenuation difference of enhancement of tumors and liver between LAP and EAP led to an extremely significant difference (P<0.001) in the detectability between LAP and EAP (83.5 % *vs* 45.1 %). Therefor, LAP is the best way for demonstrating SHCCs, which represents the advantage of triphasic scanning using MDCT. In addition, MDCT scans allow hepatic imaging with least image thickness and acquire the data in the early arterial phase, later arterial and portal venous phases and improve the sensitivity for depicting SHCC[15,16].

Since DAP combined with PVP had the highest detectability (97.8 %), but with no statistical difference when compared with LAP plus PVP (94.5 %). We consider the latter is more practical.

Abstract

AIM: To describe the correlation between innunostaining patterns of p16 and CDK4 and prognosis in colorectal carcinoma.

METHODS: Paraffin sections of 74 cases of colorectal carcinoma were analysed immunohistochemically for expression of p16 and CDK4 proteins.

RESULTS: Most carcinomas showed stronger p16 and CDK4 immunostaining in the cytoplasm than the adenomas or the adjacent normal mucosa. Strong immunostaining of p16 was a predictor for better prognosis whereas strong cytoplasmic immunostaining of CDK4 was a predictor for poor prognosis. Both p16 and CDK4 immunostainings were correlated with histological grade or Dukes' stage.

CONCLUSION: These results support the experimental evidence that interaction of expression of p16 and CDK4 may play an important role in the Rb/p16 pathway, and the expression paterns of CDK4 and p16 may be imperative in the development of colorectal carcinoma, thus becoming a new prognostic marker in colorectal cancer.

INTRODUCTION

p16 gene, an important tumor suppressor gene, regulates cell proliferation negatively through inhibition of the kinase activity of cyclin-dependent kinase 4/6 (CDK4/6), which promotes phosphorylation and therefore inactivation of a very important tumor suppressor product, the retinoblastoma (Rb) gene protein[1-4]. The Rb/p16 tumor-suppressor pathway is abrogated frequently in multiple types of human tumors, either through inactivation of Rb or p16 tumor-suppressor protein, or through overexpression of cyclin D1 or cyclin-dependent kinase 4 (CDK4) oncoproteins. But no deletion and only quite a low frequency of mutation on p16 gene have been found in colorectal cancer since this gene was identified in 1994[1,5]. CpG islands are areas rich in CpG dinucleotides, which are found within the promotors of about 60 % of human genes. These CpG islands normally lack DNA methylation, regardless of the expression status of the gene[6]. Methylation of promotor usually leads to irreversible inhibition of gene transcription[7]. It has become apparent that *de novo* methylation is an important alternate mechanism to code region mutation for inactivating tumor suppressor genes during neoplasia[8-11]. Herman *et al*.[9] previously reported that there was methylation of p16 gene in 40 % of primary colorectal cancers and 92 % of colorectal cancer cell lines, in which all the p16 genes were inactivited by Southern analysis. Gonzalez-Zulueta *et al*.[10] found the evidence of methylation of the 5' CpG island not only in cancer tissues but also in normal colonic tissues by the more sensitive PCR-based assay, in which methylation of p16 exon 1 was detected in 1 of 10 (10 %) colon carcinomas and methylation of p16 exon 2 was detected in 7 of 10 (70 %) colon cancers. It is interesting that in 50 % of the colon normal/tumor matched cases, p16 was methylated and not expressed in the normal tissues but unmethylated and highly expressed in the tumor tissues. It also suggested that methylation of exon 1, but not exon 2, of p16 was associated with transcriptional silencing although the CpG island in exon 2 of p16 underwent extensive *de novo* methylation in colorectal carcinoma. More recently, Ahuja *et al*.[12] found that 16 (34 %) of 47 colorectal cancers exhibited methylation in exon 1 of the p16 gene, which was associated with microsatellite instability. Transcriptional silencing of p16 gene could be due to either gene deletion or methylation in exon 1. In either event, there would be no expression product in the cells. Therefore, we used an immunohistochemical method to detect p16 protein level *in situ* and compared with its binding oncoprotein, CDK4, as a simple way to investigate their possible interaction in the development and prognosis of colorectal carcinoma. We also detected the mRNA levels of both p16 and CDK4 genes and checked the methylation status on the promoter region of p16 gene to confirm their expression results in immunocytochemistry.

MATERIALS AND METHODS

Colorectal carcinoma

Seventy-four cases of colorectal carcinoma were randomly and retrospectively selected from the files of the Academic Department of Pathology, St. Mark' s Hospital, London, UK and the Department of Pathology, the former West China University of Medical Sciences, China. Specimens obtained at surgery were routinely fixed in 10 % neutral formalin and embedded in paraffin. The clinical stage was determined according to the Dukes' stages A, B and C. The histological grade of tumors was also determined according to the WHO criteria as follows: grade I as well differentiated, grade II as moderately differentiated, and grade III as poorly differentiated. Follow-up data on 5-year survival rate in 32 cases were available for further analysis with variables.

Immunohistochemical staining

Immunohistochemical staining for p16 and CDK4 was performed according to the standard ABC method except that the pressure for cooking procedure was used for antigen retrieval pretreatment[13, 14]. Serial 4 μm thick sections were cut and dewaxed in xylene and rehydrated in a graded ethanol series. The sections were immersed in 3 % hydrogen peroxide in methanol for 15 minutes to block endogenous peroxidase activity. and rinsed in running water. After that, sections were immersed in boiling 1 mM EDTA-NaOH (pH 8.0) buffer in a pressure cooker. The pressure cooker was then sealed and brought to full pressure. The heating time was 2 minutes which began only when full pressure was reached. At 2 minutes, the cooker was depressured and cooled under running water. The lid was then removed, and the hot buffer was flushed out with cold water from a running tap. The cooled sections were washed twice in PBS before immunohistochemical staining, then immersed in 0.05 % avidin for 30 minutes to block any possible endogenous biotin exposed to heating. Prior to immunohistochemical staining, the sections were first incubated with 10 % horse serum for monoclonal antibody and 10 % goat serum for polyclonal antibody respectively for 15 minutes to block non-specific binding. The primary monoclonal mouse antibody against human p16 protein (Pierce, USA) and polyclonal rabbit antibody against human CDK4 protein (Santa Cruz Biotechnology, USA) were diluted in 200 with 0.01 M PBS (pH 7.2), respectively. Then the sections were allowed to react by the standard ABC method using a VECTASTAIN Elite PK-6100 kit (Vector Labratories, Inc., USA), as directed by the manufacturer. A previously known positive pancreatic carcinoma was used as a positive control. The primary antibody was replaced by 0.01 M PBS or 10 % serum as a negative control. Normal colon mucosal tissue was used as a normal control.

Evaluation of score

The slides were examined and data regarding staining positivity were recorded before the clinical outcome was available. When p16 or CDK4 protein expression was scored, both the extent and intensity of immunopositivity were considered, according to Hao *et al*[15]. The intensity of positivity was scored as follows: 0 as negative, 1 as weak, 2 as moderate, 3 as strong as normal liver. The extent of positivity was scored as follows: 0 <5, 1>5-25 %, 2>25-50 %, 3>50-75 %, and 4>75 % of the tumor cells in the respective lesions. The final score was determined by multiplying the intensity of positivity and the extent of positivity scores, yielding a range from 0 to 12. Scores 9-12 were defined as strong staining pattern (++), 5-8 as weak staining pattern (+), and 0-4 as markedly reduced or negative expression (-).

RNA extraction and RT-PCR

Total RNA was isolated from the frozen tissues of 10 paired normal and tumor samples using the total RNA isolation system (Promega) and treated with RNase-free DNase I (GeneHunter). Equal amount (0.2 μg) of total RNA from each sample was added into the access RT-PCR system (Promega) which carried on both cDNA syntheses by reverse transcription and PCR in a same tube with a total volume of 25 μl reaction solution according to the manufacturer' s directions. The primer pairs used to amplify p16 and CDK4 genes were as follows. The sequence of p16 sense primer was 5' -CCCGCTTTCGTAGTTTTCAT-3' and that of antisense primer was 5' -TTATTTGAGCTTTGGTTCTG-3' [16] and that of CDK4 sense primer was 5' -ATGGCTGCCACTCGATAT GAACCC-3' and antisense primer, 5' -GTACCAGAGCGT AACCACCACAGG-3' [17]. In addition, primers for glyceraldehyde 3-phosphate dehydrogenase (G3PDH) gene were used as an internal control to ensure the quality of the templet RNA and reagents in reactions. The sequence of sense primer was 5' -TGGTATCGTGGAAGGACTCATGAC-3' and antisense primer was 5' -ATGCCAGTGAGCTTCCCGTT CAGC-3' [16]. cDNA for each sample was synthesized at 48 ℃ for 45 min, followed by at 94 ℃ for 2 min to inactivate reverse transcriptase and was subjected to 40 cycles of amplification under the conditions described before[16,17] except for modified extension step during each cycle at 68 ℃ for 2 min according to the access RT-PCR system' s direction. Water controls, including primers and all reagents except for RNA in PCR reactions, were setup for potential DNA contamination.

Methylation-specific PCR

Samples from 24 cases of colorectal carcinoma with residual adenoma were selected for DNA extraction. DNA was extracted from these cases according to the conventional methods. The methylation status on the promoter region of p16 was assessed by methylation-specific PCR (MSP) as described previously[9] Genomic DNAs from the primary tumors were subjected to bisulfate modification using the CpGenome DNA modification kit (Intergen, New York, NY). Treatment of genomic DNA with sodium bisulfate converted unmethylated cytosines (but not methylated cytosines) to uracil, which was then converted to thymidine during the subsequent PCR step, yielding sequence differences between methylated DNA. PCR primers distinguishing these methylated and unmethylated DNA sequences were used. Primer sequences of p16 genes[9] for both the methylated and unmethylated forms were 5' -TTATTAGAGGGTGGGGCGGATCGC-3' /5' -GACCCCGAACCGCGACCGTAA-3' and 5' -TTATTAGAGGGTGGGGTGGATTGT-3' /5' -CAACCCCAAACCACAACCATAA-3' , with annealing temperature at 65 ℃ and at 60 ℃, and the expected PCR product sizes were 150 bp and 151 bp, respectively. For PCR amplification, 2 μl of bisulfate-modified DNA was added in a final volume of 25 μl PCR mixture containing 1×PCR buffer, $MgCl_2$, deoxynucleotide triphosphates, and primers (100 pmol each per reaction), and 1 unit of AmpiTaq Gold (Applied Biosystems, Branchburg, NJ). Amplification was performed at 95 ℃ for 12 min, 35 cycles at 95 ℃ for 1 min, the specific annealing temperature for both methylated and unmethylated at 65 ℃ and at 60 ℃ for 1 min, and at 72 ℃ for 1 min, followed by a final 7-min extension at 72 ℃. PCR products (15 μl) were loaded onto a 10 % nondenaturing polyacrylamide gel, stained with ethidium bromide after 2 hours of electrophoresis, visualized under UV illumination. MSP for all samples was repeated to confirm their methylation status.

Statistical analysis

Fisher' s exact test (two sided) and Pearson Chi square test for trends in proportions were used to assess the associations between Fhit expression and pathological indices. A $P<0.05$ was considered statistically significant.

RESULTS

The results are summarized in Tables 1-2.

The 5-year survival of the 32 patients according to the available data was significantly shorter in patients with Dukes' C tumors than in those with Dukes' A and B tumors ($P<0.01$).

p16 expression in colorectal carcinoma

In 61 patients in whom non-neoplastic mucosa was detected adjacent to the carcinoma, weak p16 expression was observed in the nuclei and moderate p16 expression only in the cytoplasm around nuclei. Most of the cytoplasm of goblet cells filled with

mucus was negative (Figures 1A, B). Of the 74 specimens examined, 73 (98.6 %) were p16-positive (Table 1). Expression of p16 was almost always observed in the cytoplasm but only sporadically in the nuclei. Of the p16 positive specimens, 53 showed a strong expression pattern and 20 a weak expression pattern (Figure 1C). Strong p16 expressions were detected in 15 (78.9 %) patients who survived more than 5 years, while weak p16 expressions were detected in 8 (61.5 %) patients who survived less than 5 years after operation (Table 1). The prognosis was significantly better in patients with tumors in strong expression pattern of p16 (P<0.001).

Table 1 Relationship between p16 expression and clinicopathological features

Clinicopathological features	No. of patients	p16 Immunostaining patterns		
		Strong	Weak	Negative
Dukes' stage				
A	23	16	7	0
B	22	16	6	0
C	29	21	7	1
Histological grade				
I	24	17	7	0
II	41	30	10	1
III	9	6	3	0
Total	74	53	20	1
5-year survival rate				
Alive	20	15	5	0
Dead	12	4	8	0
Total	32	19	13	0

CDK4 expression in colorectal carcinoma

In 49 of 61 non-neoplastic mucosaea adjacent to the carcinoma, CDK4 nuclear and cytoplasmic immunoreactivity was a little weaker than the p16 staining, but otherwise identical. The remaining 12 were negative. Expression of CDK4 was observed predominantly in the cytoplasm (Figure 1D). All the 74 specimens showed CDK4 expression (Table 2). Of the CDK-positive specimens, 33 showed a strong expressing pattern and 41 yielded a weak expressing pattern. Tumors with strong CDK4 expression were found in 4 (28.6 %) patients who had survived for more than 5 years after operation, whereas those with weak CDK4 expression were found only in 2 (11.1 %) patients who died within 5 years after operation. The prognosis was significantly poorers in patients with cancers in strong expression of CDK4 (P<0.001).

Table 2 Relationship between CDK4 expression and clinicopathological features

Clinicopathological features	No. of patients	CDK4 Immunostaining patterns		
		Strong	Weak	Negative
Dukes' stage				
A	23	9	14	0
B	22	10	12	0
C	29	14	15	0
Histological grade				
I	24	8	16	0
II	41	19	22	0
III	9	6	3	0
Total	74	33	41	0
5-year survival rate				
Alive	20	4	16	0
Dead	12	10	2	0
Total	32	14	18	0

Correlation between p16 and CDK4 expression

Of the 74 tumors with CDK4 expression (strong in 33, weak in 41), p16 expression was also found in all but one (strong in 53, weak in 20). There was a significantly reverse correlation between p16 and CDK4 expression patterns (P<0.001).

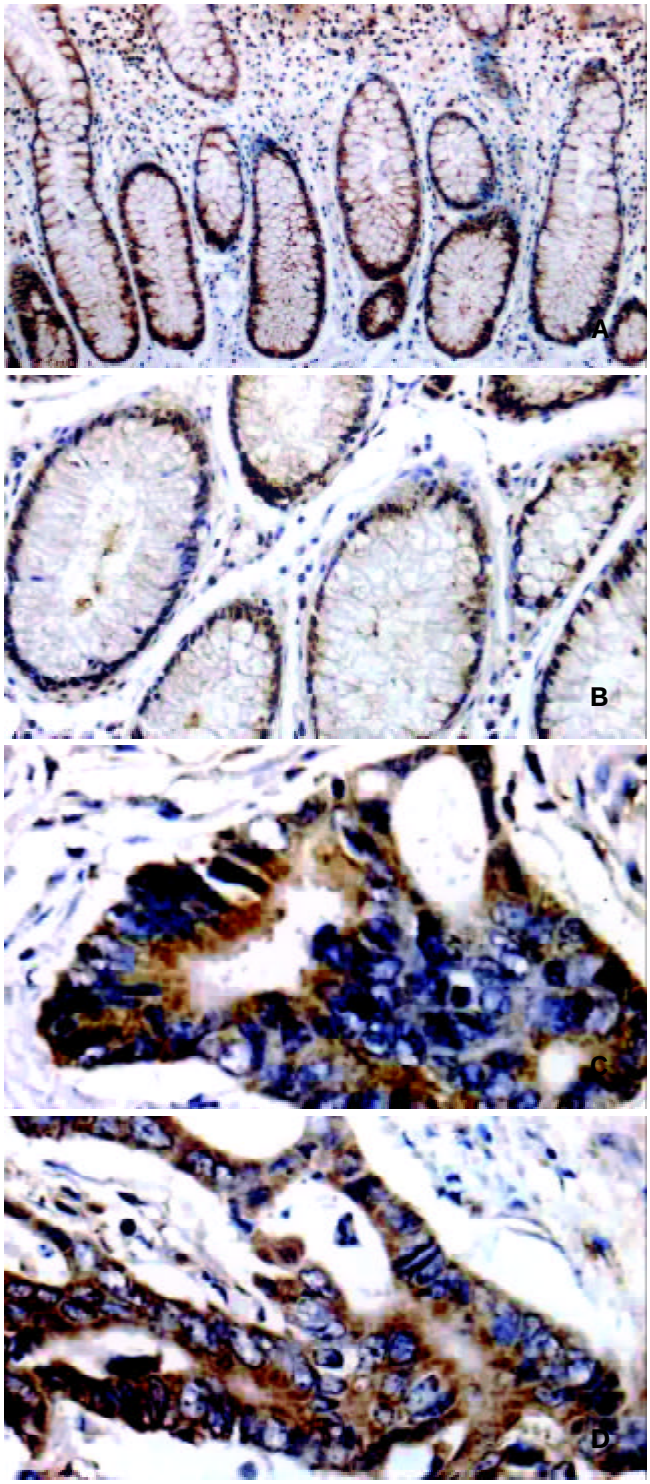

Figure 1 Expression patterns for p16 and CDK4 gene proteins. A, B: nuclear/cytoplasmic pattern of p16 protein in normal crypts (SP×100, 200), C: overexpression pattern of p16 in the cytoplasm of colon cancer cells (SP×400), D: overexpression pattern of CDK4 in the cytoplasm of colon cancer cells (SP×400).

Correlation between p16 or CDK4 expression and clinicopathological features

In our study, a significant correlation was found between p16 or CDK4 expression patterns and the tumor stage (P<0.001;

P<0.001) or the histological grade (*P*<0.001; *P*<0.001) (Tables 1, 2). The prognosis was significantly poorer in patients with weak p16 expression pattern (*P*<0.001), or with strong CDK4 expression pattern (*P*<0.001).

Results of RT-PCR and MSP

We investigated the mRNA expression of p16 and CDK4 genes in 10 frozen normal-tumor paired tissues. The results showed that the level of mRNA expressions of p16 (9/10) and CDK4 (10/10) of cancer tissues rose in accordence with that of proteins of p16 and CDK4 in immunostaining (Figures 2A, B). We also determined the frequency of promoter methylation of p16 gene by MSP-PCR, but the result showed no positively methylated signal in all the 24 cases of colorectal carcinoma with residual adenoma (Figure 2C).

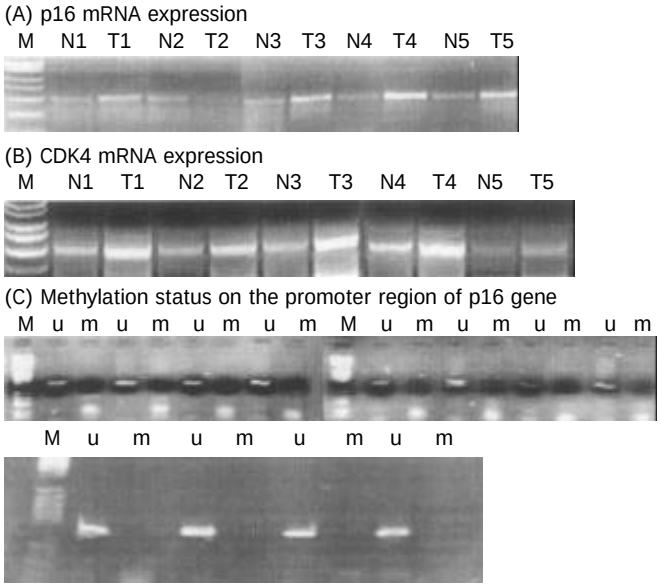

Figure 2 Results in p16 and CDK4 mRNA expressions as well as p16 gene methylation status on the promoter region. (A) and (B): mRNA levels of both p16 and CDK4 genes were elevated in colorectal carcinoma (T), compared with their matched normal (N) tissues. (C) There was no methylation detected on p16 promoter region in all 24 cases of cancer tissue with residue adenoma. u: unmethylated, m: methylated, M: molecular marker (PBR322 / Hae III).

DISCUSSION

Loss of expression of proteins such as p16 could occur as a consequence of either homozygous gene deletion or gene methylation. One aim of this study was to assess the extent to which both homozygous deletion and methylation on promoter region of p16 gene occurred with loss of gene expression in colorectal carcinoma. All carcinomas but one in this study showed the expression of p16 protein, confirmed not only by immunocytochemistry but also by RT-PCR and MSP, suggesting that loss of p16 gene expression is infrequent in primary colorectal carcinoma. The localization of p16 protein was similar to that of CDK4, almost always in the cytoplasm of adenocarcinoma cells. This indicates that the main site of interaction between p16 and CDK4 in adenocarcinoma cells is the cytoplasm. This contrasts with the localization of p16 protein in astrocytoma[18], in which nuclear expression is always more intense than any cytoplasmic expression. Based on these findings, our results indicate that CDK4 may contribute to phosphorylation of pRB, and to the loss of regulating function of p16 protein in nuclei, leading to the development of colorectal carcinoma. Induction of p16 overexpression would act as a brake at G1/S transition through pRB phosphorylation by CDK4 overexpression on the one hand, but predominant mislocation or only in cytoplasm might also imply the function of p16 in the nuclei, its ability to regulate transcriptions of other important genes related to proliferation and angiogenesis[19-21], was lost in colorectal carcinogenesis on the other hand.

The previous results[22-26] suggest that the deletion or mutational inactivity of both p16 and Rb proteins may be a rare event in cervical carcinogenesis. Moreover, overexpression of the p16 protein may be a useful diagnostic marker for cervical neoplastic lesions on routine laboratory screening. It was proposed that the expression of two viral oncogenes, E6 and E7, in epithelial stem cells be required to initiate and maintain cervical carcinogenesis and result in significant overexpression of the cellular p16 protein. Since this protein was not expressed in normal cervical squamous epithelia, screening for p16 over-expressing cells could specifically identify dysplastic lesions, and significantly reduced the inter-observer disagreement of the conventional cytological or histological tests. The similar results[28-30] have also been reported in prostate cancer, gastrointestinal stromal tumor and gastritis, in which overexpression of p16 in high grade prostate intraepithelial neoplasia (HGPIN) and cancer was correlated with, but independent of, pathological stage and was associated with early relapse in cancer patients treated with radical prostatectomy. Overexpression of p16 in HGPIN was also an independent predictor of disease relapse and increased the risk of recurrence 2.24-fold, providing the first evidence for a prognostic marker in HGPIN. The aberrant cytoplasmic expression as well as overexpression of p16 in colorectal carcinoma might be due to its binding to CDK4, CDK6 and some unknown proteins, thereby forming a larger volume of molecule which is uneasy to pass through the nuclear membrane. Nuclear expression of p16 would therefore imply extra unbound p16[5, 19], which might play other important roles in inhibiting transcription of genes related to tumor progression in the nuclei. For instance, VEGF for angiogenesis is besides or independent of binding CDK4/6[18-20]. It could be that CDK4 overexpression is an initial event, which is followed by a reactive overexpression of p16 in colorectal carcinoma, thus the oncoprotein function of CDK4 is inhibited to some extent by binding to p16. In our study, the histological grade, Dukes' stage and prognosis in colorectal carcinoma were closely related to p16 or CDK4 expression (*P*<0.001), respectively, suggesting that the expression of p16 or CDK4 protein may be a useful diagnostic and prognostic marker for colorectal neoplastic lesions. A more extended study is required to confirm the value of aberrant cytoplasmic expression or overexpression of p16 protein as a prognostic marker.

Abstract

AIM: To analyse the prognostic factors in 165 colorectal patients aged ⩾70.

METHODS: One hundred and sixty-five elderly patients with colorectal cancer diagnosed by histology were entered into the retrospective study between 1994 and 2001. Patients were given optimal operation alone, chemotherapy after operation, or chemotherapy alone according to tumor stage, histology, physical strength, and co-morbid problems. Survival rate was calculated by Kaplan-Meier method, and compared with meaningful variances by Log-rank method. Prognostic factors were analyzed by Cox regression.

RESULTS: The 1,2,3,4,5 year survival rate (all-cause mortality) was 87.76 %, 65.96 %, 52.05 %, 42.77 %, 40.51 %, respectively. The mean survival time was 41.89±2.33 months (95 % CI: 37.33-46.45 months), and the median survival time was 37 months. Univariate analysis showed that factors such as age, nodal metastasis, treatment method, Duke's stage, gross findings, kind of histology, and degree of differentiation had influences on the survival rate. Multivariate analysis showed that factors such as treatment method, Duke's stage, kind of histology and degree of differentiation were independent prognostic factors.

CONCLUSION: This study suggests that the prognosis of elderly colorectal cancer patients is influenced by several factors. Most of elderly patients can endure surgery and/or chemotherapy, and have a long-time survival and good quality of life.

INTRODUCTION

Colorectal cancer (CRC) is one of the most common malignant tumors in the world[1-5]. In China it is the fifth of malignant tumor, and the third of alimentary tract malignant tumor[6, 7]. Its incidence rises with increasing age[8,9]. Currently, the majority of colon and rectum tumors arise in patients aged 70 and over. Improvements in public health, nutrition and the prevention and treatment measures have prolonged the life of elderly individuals. The average life expectancy of a 70-year-old man can be prolonged ten years and of a 70-year-old woman 15 years. As a result, there will be a rise in the prevalence of CRC in elderly patients in the coming decades. But the elderly always have some co-morbid problems, and their clinical, pathological characteristics are different from young patients, so how to rationally treat CRC cancer of the old becomes very important.

MATERIALS AND METHODS

Clinical data

There were 205 elderly colorectal patients (aged ⩾70) in the First Hospital of Xi' an Jiaotong University from 1994 to 2001, accounting for 12.1 % of the total colorectal cancer patients. One hundred and sixty-five cases were enrolled into the study that had full histology, clinical and follow-up records. There were 105 males, and 60 females (sex ratio was 1.75:1). All patients were aged from 70 to 91 (the median 74 years), and the mean age was 74.67±0.54 years. The latent period ranged from 1 day to 4.5 years, and the mean latent time was 6.21±0.69 months. One hundred and three tumors were located in colon, and 68 in rectum, respectively, including 3 simultaneous double-tumors and 3 different time double-tumors. In the 129 resection specimens, the dimension was smaller than 5 cm in 74 and ⩾5 cm in 55. Forty-six patients had adenomatous polyps simultaneously. One hundred and forty-five had co-morbidity, among them 73 had cardiovascular diseases, 24 respiratory tract disorders, and 17 cerebral vessel disorders, 16 diabetes mellitus, and 15 other diseases.

Treatment methods

Operation 118 Duke's A, B, C, D stage patients received curative resection, 27 received palliate resection, and 4 received only emergency surgery. 16 cases received no surgery because of their reluctance or bad status.

Chemotherapy Patients who conformed with the requirements were given chemotherapy: PS 0-2 with Duke's C or D or high risk Duke's B tumors (having any characteristic such as perforated or obstructed tumors, T4 tumors, poor differentiation in histology, extra-mural vascular invasion, or mucinous differentiation). They were given 5-Fu/CF+L-OHP every 21 days, L-OHP 80-100 mg· m^{-2} >2 h iv d_1, LV 200 mg· m^{-2}· d^{-1} 2 h iv d_{1-5}, 5-Fu 400 mg· m^{-2}· d^{-1} iv d_{1-5}. Forty-seven patients with Duke's B and C tumors had 197 cycles of chemotherapy. Patients with Duke's D tumor accepted 154 cycles of chemotherapy. Among them, 15 cases received post-operation chemotherapy, and 28 cases pure chemotherapy.

Statistical analysis

Kaplan-Meier method was used to calculate survival rate, and Log rank test was used in the univariate analysis. Cox regression Model was used in the multivariate analysis. The SPSS 10.0 for windows was used for all the statistical analyses.

RESULTS

General information

In this study, the 1, 2, 3, 4, 5 year survival rate (all-cause mortality) was 87.76 %, 65.96 %, 52.05 %, 42.77 %, 40.51 %, respectively. The mean survival time was 41.89±2.33 months (95 % CI: 37.33-46.45 months), and the median survival time

was 37 months. The mortality of surgery was 2.8 % (4/145), and death occurred due to perforation, pulmonary infection, and cachexia, respectively. The rate of chemotherapy side effect was 87.3 %, but besides 1 IV^0 diarrhea and 1 IV^0 myelosupression, all others were 0-III^0.

Univariate analysis

There were several risk factors by univariate analysis as shown in Table 1. But other factors had nothing to do with prognosis, such as gender, latent period, tumor size, co-morbid problems, precancerous lesion, and bloody stool.

Table 1 Results of univariate analysis

Value: resection + chemotherapy=0, resection only=1. Duke's A+B stage=0, Duke's C+D stage=1. Other type=0, tubular adenoma=1. Low differentiation=0, middle and high differentiation=1.

Multi-variate analysis

The factors associated with the risk of colorectal cancer at $P<0.05$ were furthered tested using backward stepwise conditional Cox regression. The final model consisted of the variables having a significant association with the risk of elderly colorectal cancer at $P<0.05$. The results are shown in Table 2.

DISCUSSION

Though the number of elderly CRC patients is increasing, study about their treatment is rare, especially in China. A number of factors may account for the reluctance to receive operation and chemotherapy in elderly CRC patients. For example, family members do not want them to accept operation and chemotherapy in their old age, co-morbid problems may complicate or even preclude operation and chemotherapy, elderly patients may be more susceptible to side-effects of operation and chemotherapy which may decrease their quality of life[10], studies on the efficacy and toxicity of chemotherapy in elderly group are limited[11,12].

Treatment method is the most important prognostic index of elderly CRC in this study. Univariate and multivariate analyses showed that operation combined with post-operation chemotherapy was superior to resection only and chemotherapy only. The curative resection rate of the 165 patients was 71.52 % (118/165), and the total resection rate was 87.88 % (145/165). Operation mortality rate was 2.8 %. So it is evident that age is not the contraindication for surgery[13,14]. Resection should still be the first choice of treatment for elderly colorectal patients[15]. Patients who can endure operation after pre-operation management should receive operation in order to decrease the tumor burden. But acute abdomen is frequent in elderly CRC patients, and emergency operation is frequent accordingly, so active peri-operation preparations are necessary[16,17], such as the selection of optimal anesthesia and operation method to make them more endurable to operation, carefully nursing and supporting to reduce the opportunity of complication. Suitable chemotherapy can prolong the life of advanced patients, and improve their quality of life[18]. In this study, the patients who received chemotherapy lived longer than those who only received operation, and there were no severe side effects. It is obvious that elderly patients can survive chemotherapy and have a long-time survival and good quality of life, if an optimal chemotherapy scheme is given[19-23]. Also, because most of CRC relapse or transfer in the following 3 years of operation, it is necessary to give patients adjuvant chemotherapy[24, 25]. As to the elderly patients, several factors must be taken into consideration when chemotherapy is given, such as suitable chemotherapy regimen with good efficiency and low side effects[26,27], the importance of the first cycle[28], liver and kidney function testing and blood cell calculation before every cycle with heart and lung function evaluated if necessary, active support simultaneously, less or no anti-HT3 used to decrease the rate of constipation, long-cycle and convenient scheme to decrease the in-patient time, and changing scheme when it is inefficient[29].

In this study, univariate and multivariate analyses showed that the patients aged 70-75 years had a longer survival than those aged 75-91 years, which conformed with the study that aging was a risk factor for prognosis[30]. The elder the patient the lower of sensitivity, so older patients are always diagnosed in their late stage, which significantly influences the treatment and prognosis. But another study showed that aging had nothing to do with prognosis[31].

Lymph nodular metastasis is a negative indicator of prognosis for elderly CRC patients[30,32-34]. When cancer cells stay in the celiac lymph node, it is probable that malignant cells have transferred to liver, lung, bone, etc, through lymph

circulation and blood circulation. At last patients may become fatigue, even die of target organ' s dysfunction. However, some researchers hold that lymph nodular metastasis is not correlated with prognosis[25].

Both univariate and multi-variate analyses showed that Duke' s stage was an important prognostic factor in this study[34]. The early the stage, the easy the treatment, and the better the long-survival. Duke' s A and some B stage patients did not need to receive chemotherapy at all, but their survival time was the best at all stages. While Duke' s C and D patients needed both operation and chemotherapy, but their prognosis was always poor. Precise pre-operation staging is beneficial to the optimal treatment, which has something to do with the prognosis[35,36]. So doctors must carefully and precisely evaluate the Duke' s stage before and during operation so as to give elderly CRC patients the optimal treatment.

Univariate analysis showed that gross finding was another prognostic factor[34]. In this study, ulcer patients had a longer survival than those with infiltration, which was similar to the result of L.Roncucci' s study[37]. Infiltration type and prominence type always result in intestinal obstruction, which makes the patients have to accept emergency operation. Also, both of them can make patients emaciation, which decreases the endurance to necessary treatment, because of dysfunction of digestion and absorbance. Furthermore, infiltration type always has a poor differentiation in histology.

Univariate and multi-variate analyses showed that histology type and differentiation influenced prognosis in this study[34, 38]. Tubular adenocarcinoma had a better prognosis than mucinous adenocarcinoma. The latter had a poorer differentiation, and this kind of cancer cells had a tendency to transfer to distant sites, which leads to a poor survival. However the high and middle differentiations had a better prognosis and quality of life[30, 39].

In conclusion there are several factors influencing the prognosis of elderly CRC patients. When selecting treatment method, doctors have to take PS, Duke' s stage, age, gross finding, histology type, differentiation, lymph node metastasis into consideration. Besides the clinical characteristics that influence the prognosis of elderly CRC patients, other molecular markers such as oncogene mutation, change of chromosome and vascular endothelial growth factor are also significant prognostic factors[40-46]. Searching for new biology markers and better treatment methods will be one part of the future study.

Abstract

AIM: To transfer hepatitis E virus (HEV) ORF2 partial gene to tomato plants, to investigate its expression in transformants and the immunoactivity of expression products, and to explore the feasibility of developing a new type of plant-derived HEV oral vaccine.

METHODS: Plant binary expression vector p1301E2, carrying a fragment of HEV open reading frame-2 (named HEV-E2), was constructed by linking the fragment to a constitutive CaMV35s promoter and nos terminator, then directly introduced into *Agrobacterium tumefaciens* EHA105. With leaf-disc method, tomato plants medicated by EHA105 were transformed and hygromycin-resistant plantlets were obtained in selective medium containing hygromycin. The presence and integration of foreign DNA in transgenic tomato genome were confirmed by Gus gene expression, PCR amplification and Southern dot blotting. The immunoactivity of recombinant protein extracted from transformed plants was examined by enzyme-linked immunosorbant assay (ELISA) using a monoclonal antibody specifically against HEV. ELISA was also used to estimate the recombinant protein content in leaves and fruits of the transformants.

RESULTS: Seven positive lines of HEV-E2-transgenic tomato plants confirmed by PCR and Southern blotting were obtained and the immunoactivity of recombinant protein could be detected in extracts of transformants. The expression levels of recombinant protein were 61.22 ng/g fresh weight in fruits and 6.37-47.9 ng/g fresh weight in leaves of the transformants.

CONCLUSION: HEV-E2 gene was correctly expressed in transgenic tomatoes and the recombinant antigen derived from them has normal immunoactivity. Transgenic tomatoes may hold a good promise for producing a new type of low-cost oral vaccine for hepatitis E virus.

INTRODUCTION

Research on using plants for expression and delivery of oral vaccine has attracted much academic attention and has become a hot spot of study since 1990 when Curtiss *et al*. first reported the expression of *Streptococcus mutans* surface protein antigen A(SpaA) in tobacco, and great progress has been made since then[1]. So far, more than 10 viral epitopes and subunits of bacterial toxins have been successfully expressed in plants, mainly including hepatitis B surface antigen (HBsAg)[2-9], *E.coli* heat-labile enterotoxin B subunit (LT-B)[10-15], cholera toxin B subunit (CT-B)[16], Norwalk virus capsid protein (NVCP)[17,18], rabies virus glycoprotein[19], *etc*. The involved plant receptors are mostly mode species: tobacco, potato, *etc*., some fruits and vegetables that can be consumed raw, tomato, banana, lettuce and lupine have also been attempted. Significant breakthrough has been achieved in increasing the expression of vaccine components in plants. At present, the plant-derived oral vaccines from potato for HBsAg and LT-B are undergoing clinical trials[13,14], but there has been no report about plant-derived oral vaccine for hepatitis E virus (HEV).

HEV is the major cause of acute, enteric non-A, non-B (NANB) hepatitis in the world, and large outbreaks occur primarily in underdeveloped countries. China is one of the high epidemic areas. The highest infection rate is in young adults (15-40 years). Although only 1 % to 3 % of non-pregnant patients with HEV infection progress to fatal fulminant hepatitis, the mortality can be as high as 20 % in pregnant patients[20]. There is neither effective antiviral drugs nor vaccine against HEV available for commercial use at present. Since HEV pathogen is difficult to culture, it is not easy to develop the live attenuated strains for vaccine. A promising approach is to develop recombinant subunit vaccines. Compared with gene engineering vaccine for hepatitis B, the study of hepatitis E recombinant vaccine was only a recent endeavor, but some progress has been made.

ORF2-encoded protein of HEV is the most promising subunit vaccine candidate because it possesses good antigenicity. So far, HEV ORF2 gene or its fragments have been expressed in prokaryote cells[21-24], insect cells[25], animal cells[26], and *Pichia pastoris*[27], *etc*., and the expression products possessed immunogenicity. HEV vaccine is about to undergo clinical trials[28].

Since hepatitis E occurs primarily in developing countries and impoverished regions with poor environmental sanitation, where administration of various medicinal vaccines may be hampered by the relatively high cost. Plant-derived hepatitis

E vaccine is a promising approach that may solve the problem because of its low cost for delivery and administration, and its safety for humans.

Tomato is a nutrition-rich fruit that can be consumed raw and easily transformed, so it is an ideal plant carrier for oral vaccine. In this paper we reported that a plant expression vector of HEV antigen gene was constructed and transformed into tomato plants with *Agrobacterium tumefaciens*, and its expression in plants and immunoactivity of the expression product were examined. This study would lay the foundation for further research on the development of a new type of plant-derived hepatitis E oral vaccine or other oral vaccines, and promote their practical application.

MATERIALS AND METHODS

Plant material

Tomato (*Lycopersium esculentum* CV. "XiuNu") seeds were purchased from Xiamen Nong-You Seed Co., Ltd.

Reagents, bacteria and plasmids

Restriction endonucleases and T4 DNA ligase were obtained from Promega Co. Hygromycin and X-gluc staining solution from Calbiochem-novabiochem Co. and Amres Co., respectively. Double antibody sandwich-ELISA kit was provided by Beijing Wantai Biological Pharmaceutical Co. *Agrobacterium tumefaciens* strain EHA105 was kindly presented by Professor Zhang Qi-fa, Huazhong Agricultural University. Plasmid pBPFΩ7 containing CaMV35s promoter and nos terminator, and plant binary plasmid pCAMBIA1301 containing hygromycin-resistant gene, kanamycin-resistant gene and Gus gene, were constructed and preserved in our laboratory.

Construction of plant binary expression vector

An 810 bp DNA fragment (named E2) of HEV ORF2 region, located between amino acid residue 394 and 604[23], was obtained by a PCR-based assembly from the patient' s serum and inserted into pBPFΩ7 between CaMV35S promoter and nos terminator at *Bam*HI/*Eco*RI site to form pBE2. The fragment containing "P35S+Ω+E2+Tnos" was isolated by gel extraction from plasmid pBE2 after *Pst*I restrictive digestion and then subcloned into plasmid pCAMBIA1301 that had been digested by the same restriction endonuclease to yield the reconstructed plant binary expression plasmid p1301E2 (Figure 1). Confirmed by restriction digestion, p1301E2 was directly introduced into *Agrobacterium tumefaciens* strain EHA105 by freeze-thaw method.

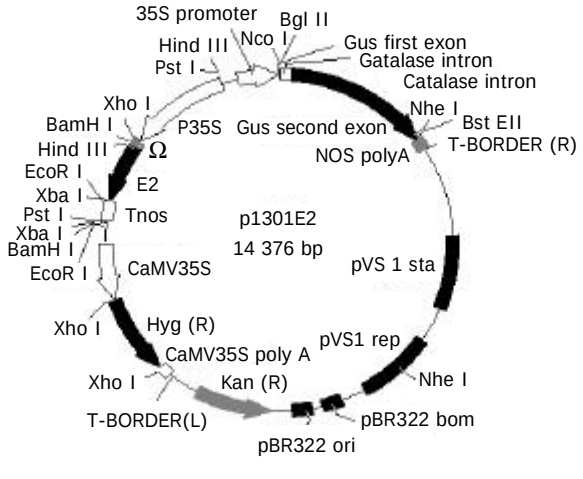

Figure 1 Structure of plasmid p1301E2.

Plant transformation and regeneration

Tomato was transformed through leaf discs mediated by *Agrobacterium tumefaciens* EHA105 with p1301E2. Shoots were generated from transformed callus after 3-4 weeks selected on medium containing 20 mg of hygromycin (Hyg) and 300 mg of cefotaxime per liter. The rooting was obtained in medium containing 20 mg of Hyg per liter, and the plantlets was transplanted to soil, and watered with 1/2 MS medium.

Analysis of Gus gene expression

Both transformed and untransformed tissues were cut from tomato plants, immerged into Gus reaction buffer (X-gluc staining solution) for 12 to 24 hours at 37 ℃, then bleached with absolute alcohol, observed and photographed under dissecting microscope.

Analysis of HEV-E2 gene integration

PCR amplification Genomic DNAs extracted from leaves of tomato plants by CTAB[29] were used as PCR templates. The forward primer HEFP and reverse primer HERP were: 5' -GGA TCC ATA TGC AGC TGT TCT ACT CTC GTC-3' and 5' -CTC GAG AAA TAA ACT ATA ACT CCC GA-3', respectively (synthesized by BioAsia Co., Shanghai). PCR reaction was performed using 50 ng of template DNA, 0.5 μM of each primer in a total volume of 30 μl. Cycling parameters were at 94 ℃ for 10 min, followed by 35 cycles at 94 ℃ for 50 s, at 57 ℃ for 50 s, and at 72 ℃ for 50 s, and a final extension at 72 ℃ for 7 min.

Southern dot blotting It was performed as reported previously[29].

Analysis of HEV-E2 gene expression

ELISA Total soluble proteins were extracted from leaf and fruit tissues as described[29], and HEV-E2 recombinant protein was detected by HEV enzyme-linked immunosorbant assay (ELISA) kit, the protocol and positive determination were performed according to the instructions supplied with the kit. The expression levels of HEV-E2 in transformants were quantified by ELISA. The extract of transformant was diluted several fold until it could reach the same OD value (measurement wavelength: 450 nm) as the standard HEV-E2 protein (1 ng/mg), then HEV-E2 expression levels in transformants could be calculated according to the sampling quantity, and diluting times.

RESULTS

Regeneration of transgenic tomato plants

The plasmids for expression of HEV-E2 in plants allowed morphogenesis of transformants on selective medium containing hygromycin. Through about 1 month of selection, 7 independent Hyg-resistant plantlets were obtained. These transformants bore fruits and the seeds were collected. The flowers and fruits of the transformants resembled those of wild-type tomato plants and the seeds were plump. Each fruit produced approximately 70 seeds. This demonstrated that the introduction of foreign gene into tomato plants did not influence the normal growth and development of the transformants (Figure 2).

Gus expression in transgenic plants

Untransformed tissues appeared colourless when stained with Gus reaction solution and bleached with absolute alcohol, whereas transformed tissues presented blue spots even after bleached with absolute alcohol, the spots were generally large in size, with a deep blue color (Figure 3). The results indicated that Gus gene was stably integrated into the genomic DNA of transformed tomatoes.

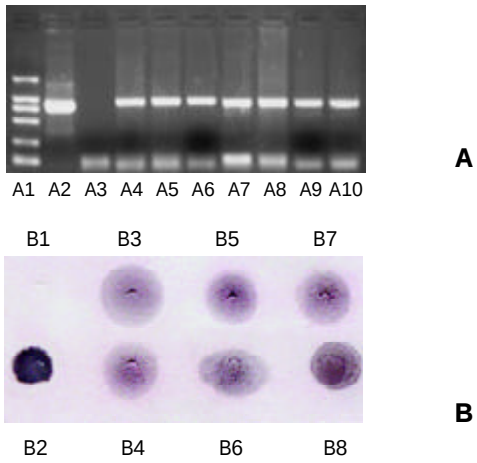

Figure 4 Analysis of HEV-E2 gene integration. A: PCR amplification of genomic DNA of tomato plants, B: Southern dot blotting of genomic DNA of tomato plants. A1: DL-2000 marker, A2: Positive control (p1301E2), A3: Total DNA of wild-type control plant, A4-A10: Total DNA of independent transformants. B1: Total DNA of wild-type control plant, B2: Positive control (p1301E2), B3-B8: Total DNA of independent transformants.

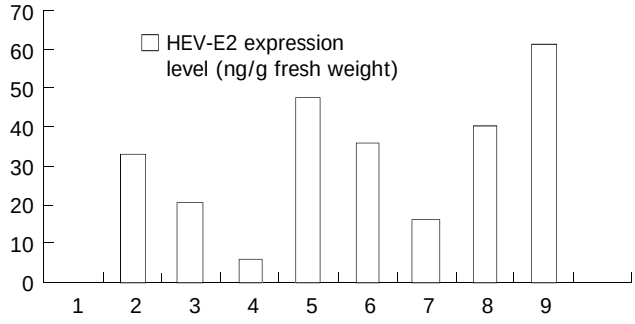

Figure 5 HEV-E2 expression levels in transgenic tomato plants. 1: Leaves of wild-type control plant, 2-8: Leaves of seven independent transformants, 9: The mixed flesh tissue of 3 independent transformant fruits.

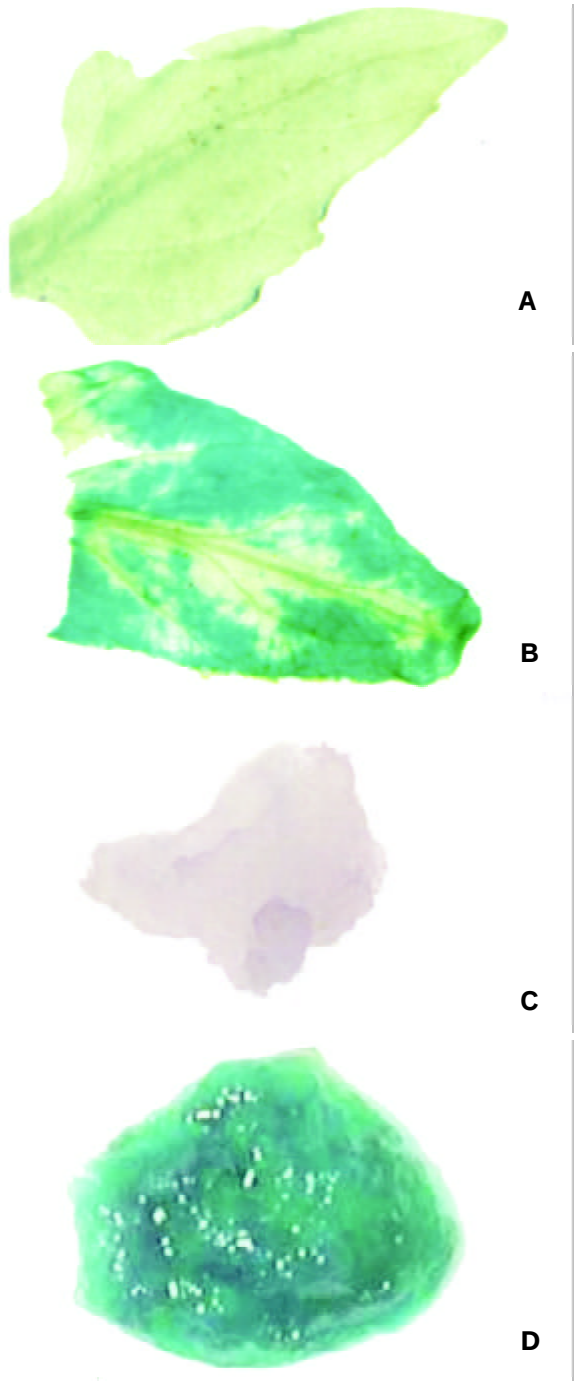

Figure 3 Analysis of Gus gene expression. A: Leaf of untransformed tomato plant, B: Leaf of transformed tomato plant, C: Flesh of untransformed tomato, D: Flesh of transformed tomato.

PCR amplification

The expected 810 bp fragments were amplified from 7 transformed lines of tomatoes, the length of the fragments was identical with that amplified from p1301E2 (positive control), whereas there was no PCR product in wild-type tomato plants (negative control). The results primarily verified that the target gene was integrated into the genomic DNA of transformed tomatoes (Figure 4A).

Southern dot blotting

To further verify the integration of foreign gene into tomato plants, the total genomic DNA of transformed tomatoes was hybridized by a DIG-labeled probe (encompassing the coding region of HEV-E2 gene) generated by PCR amplification from p1301E2 with HEFP and HERP primers, and all the

transformants gave the same hybridization spots as the positive control(p1301E2) did, whereas the untransformed plant showed no detectable hybridization signal (Figure 4B). Thus the results further confirmed that the target gene was integrated into the tomato plants.

Expression of HEV-E2 gene in transgenic tomato plants

The leaf extracts of 7 lines of transformants and the mixed fruit tissue extracts from 3 transformants were tested by ELISA for the presence of HEV-E2 expression products, and foreign protein could be detected in all of the examined samples. The reaction was specific because wild-type tomato showed no detectable expression products. The result demonstrated that HEV-E2 gene was expressed in transformed tissue. The expression level of HEV-E2 protein was lower as compared to HBsAg in transgenic tomatoes[8], the maximal expression level was only 47.9 ng/g fresh weight in leaves. The expression levels were different between different transformants and between different organs of the same plant, which indicated that the inserting site of foreign DNA into the plant genome was random. The expression in fruits (61.22 ng/g fresh weight) was higher than that in leaves, which was similar to that of HBsAg in transgenic tomatoes[8]. The higher expression of target protein in edible tissue mightbe helpful for producing oral vaccine.

DISCUSSION

The most striking advantage of using tomato as oral vaccine vector is that the plant-derived vaccine is cheap and tomato is a freshly-eaten fruit, which allows the target population to acquire immunity at the same time when they enjoy the delicious fruits. But accumulation of protein in tomato itself is low, the expression levels of foreign protein in it are much lower. This will make it difficult when administering the plant-derived vaccine. However, the expression of foreign protein in plants might be increased by several modifications, including the use of stronger promoters, the use of plant-derived leader sequences and signal peptide, and targeting the protein for retention in edible tissue and so on[1]. For example, Mason *et al*[2] increased the level of HBsAg 11 fold in transgenic tobacco by linking CaMV35S promoter to the tobacco etch virus (TEV) 5' leader sequence (acts as a translational enhancer). In 1998, Mason *et al*[12] increased the expression of LT-B in transgenic potatoes 3-14 times by designing and constructing a plant-optimized synthetic gene encoding LT-B. Tackaberry *et al*[30] reported the synthesis of recombinant glycoprotein B which expressed specifically in tobacco seeds, with expression level reaching 70-146 ng/mg extracted protein. Lauterslager *et al*[11] made a synthetic gene coding for LT-B and optimized it for expression specifically in potato tubers and accumulation in endoplasmic reticulum, which resulted in a high expression level about 13 μg/g fresh weight of LT-B in potato tubers. Besides, by using chloroplast expression system, Cosa *et al*[31] introduced foreign genes into the chromoplast genome, which enabled the foreign protein to accumulate at 46 % of the total soluble protein in leaves of transgenic plants. All these studies provided us successful experiences in improving expression level of HEV-E2 in transgenic tomatoes. In our study, we only inserted an enhancer Ω in the promoter, there were many reconstruction possibilities to achieve high expression. Currently we are engaged in researches on increasing expression level of foreign proteins, and the animal trials of oral immunization of mice with transgenic tomatoes expressing HEV-E2 are also in progress.

We have successfully introduced HEV-E2 gene into tomatoes and identified the expression protein. The expression product possessed HEV specific antigenicity in transgenic plants. Previous studies also demonstrated that plant-derived vaccines were safe and functional. It is cheap to produce and store, easy to deliver and administer, it has many advantages over other vaccines. Although this technology is not likely to produce great commercial value in the short term, the present advance in plant genetic engineering demonstrates that there is a tremendous potential to develop various low-cost recombinant vaccines by using plants.

Abstract

AIM: To determine the lethiferous effects of a recombinant vector carrying thymidine kinase (TK) suicide gene on 2.2.15 cells and the possible self-modulating mechanism.

METHODS: A self-modulated expressive plasmid pcDNA3-SCITK was constructed by inserting the fragments carrying hepatitis B virus antisense-S (HBV-anti-S) gene, hepatitis C virus core (HCV-C) gene, internal ribosome entry site (IRES) element of HCV and TK gene into the eukaryotic vector pcDNA3, in which the expression of TK suicide gene was controlled by the HBV S gene transcription. 2.2.15 cells that carry the full HBV genome and stably express series of HBV antigen were transfected with $pcDNA_3$-SCITK or vector $pcDNA_3$-SCI which was used as the mock plasmid. The HepG2 cells transfected with $pcDNA_3$-SCITK were functioned as the negative control. All the transfected cells were incubated in DMEM medium supplemented with 10 μg/ml. of ganciclovir (GCV). The HBsAg levels in the supernatant of cell culture were detected by ELISA on the 1st, 3rd and 6th day post-transfection. Meanwhile, the morphology of tranfected cells was recorded by the photograph and the survival cell ratio was assessed by the trypan blue exclusion test on the 6th day post-transfection.

RESULTS: The structural accuracy of $pcDNA_3$-SCITK was confirmed by restriction endonuclease digestion, PCR with specific primers and DNA sequencing. The HBsAg levels in the supernatant of transfected 2.2.15 cell culture were significantly decreased on the 6th day post-transfection as compared with that of the mock control ($P<0.05$). The lethiferous effect of $pcDNA_3$-SCITK expression on 2.2.15 cells was initially noted on the 3rd day after transfection and aggravated on the 6th day post transfection, in which the majority of transfected 2.2.15 cells were observed shrunken, round in shape and even dead. With assessment by the trypan blue exclusion test, the survival cell ratio on the 6th day post transfection was 95 % in the negative control and only 11 % in the experimental group.

CONCLUSION: The results indicate that suicide gene expression of $pcDNA_3$-SCITK can only respond to HBV-S gene transcription, which may be potentially useful in the treatment of HBV infection and its related liver malignancies.

INTRODUCTION

Despite the availability of efficient vaccines, chronic hepatitis B virus (HBV) infection remains a major public health problem worldwide[1-7]. The World Health Organization estimates that there are still 350 million chronic carriers of the virus who are at risk of developing chronic hepatitis, liver cirrhosis and hepatocellular carcinoma[8, 9]. This issue is also an important problem in China. The carrier rates of HBsAg are estimated to be as high as more than 10 % of Chinese population and a substantial proportion of liver cancer incidence is associated with chronic HBV infection[10-12]. Currently interferon-alpha (IFN-α), an immunomodulator, and two synthetic nucleoside analogues, lamivudine and adefovir dipivoxil, are the only licensed antiviral agents for the treatment of chronic HBV infection. However, this therapeutical modality is still problematic. In addition to the standard treatment endpoints being achievable only in approximately 20-30 % of those treated with either type of agents, interferon usually confers serious side effects, and lamivudine is associated with the occurrence of viral mutations and drug-resistant strains[13-17]. Thus, there is an urgent need for the development of more effective modalities to deal with HBV infection. As yet, several therapeutic protocols with molecular biological techniques have been tried in experimental studies of this disease in the last few years[1,18-25], although significant progress remains to be made in such kinds of explorations. In the present study, we tried to construct a recombinant vector carrying TK suicide gene and harboring a self-modulating property for gene therapy in an attempt to vanquish HBV infection in a fire-new strategy.

MATERIALS AND METHODS

Materials

Plasmid $pcDNA_3$-TK containing TK gene and $pcDNA_3$-S carrying HBV-S gene were maintained in our laboratory. Eukaryotic expression vector $pcDNA_3$ was from Invitrogen Company, Netherlands. Purification kit for PCR product was obtained from QIAGEN Company (Germany). Reverse transcriptase and PCR amplification system were purchased from Shenzhen Jingmei Company (China) and Expand PCR kit form Stratgene Company (USA). Taq and Pfu enzymes were purchased from Bio-Star Company (Canada). Restriction endonucleases such as EcoR I, BamH I and HinD III, T_4 DNA ligase and ELISA kit for detecting HBsAg were from Huamei Bioengineering Company (Luoyang,

China). All the PCR primers used in the study were synthesized by Takara Ltd (Dalian, China).

Preparation of gene fragments

The fragments of HCV-IRES element and core gene were obtained by RT-PCR. Total HCV RNA was extracted and purified from 100 μl samples of HCV-positive sera using a guanidium isothiocyanate-acid phenol extraction procedure (Jingmei Company, Shenzhen, China). Precipitated RNA was dissolved in 20 μl of diethyl pyrocarbonate-treated water and quantified by UV spectrum analysis. Specific cDNA for HCV IRES element and core gene were amplified respectively with RT-PCR kit by adding their corresponding primers according to the protocols of Reverse Transcription System (Jingmei Company, Shenzhen, China). The primers for the HCV IRES were sequenced as sense: 5' -GCGCGGATCCGGGCGACAC TCCACCATAG-3' (nucleotides [nt] 17 to 36) and antisense: 5' -GCGAATTCGTTTTTCTTTGAGGTTTAGGATTC-3' (nt 347 to 371). The primers for the HCV core gene were 5' -TAGGAATCCTGATGAGCACGAATCCTAAACCTC-3' (sense) and 5' -GCGCGGATCCTTAAGCGGAAGCTGGGA TG-3' (antisense). PCR was performed on the Real-time PCR apparatus (Roche, USA) with a program for 30 cycles at 42 ℃ for 45 min and at 94 ℃ for 5 min followed by at 92 ℃ for 30 s, at 55 ℃ for 30 s and at 72 ℃ for 30 s. After prepared by routine procedures, the PCR products were analyzed by agarose gel electrophoresis and stored at -20 ℃ until use.

The antisense fragment of HBV-S gene lack of initiating codon (ATG) was amplified with the PCR protocol using the oligonucleotide sequence 5' -GCGCGTGCAAGCTT ATAAAACGCCGCAGACACATC-3' (sense) and 5' -ATTCGTGCTCATCAGGATTCCTAGGACCCCTTC-3' (antisense) as primers, and $pcDNA_3$-S as the template. After an initial denaturation step was performed, PCR was carried out for 45 cycles at 95 ℃ for 15 s, at 70 ℃ for 5 s and at 72 ℃ for 15 s each cycle. The PCR products were identified by electrophoresis on an l % of agarose gel stained with ethidium bromide and stored at -20 ℃ until use.

TK gene segment was prepared by digestion of plasmid $pcDNA_3$-TK with EcoR I and purified with the routine procedures.

Construction of self-modulated expression vector

The construction scheme for the self-modulated expression vector that can respond to HBV infection and eliminate the infected hepatic cells is shown in Figure 1. Briefly, ligation of antisense fragment of HBV-S gene with HCV-C gene segment was performed by SOEing PCR[26-28], in which the sense sequence of HCV-C gene primer 5' -TAGGAATCCTGATGA GCACGAATCCTAAACCT**C**-3' and a truncated antisense sequence of HBV-S gene primer 5' -ATTCGTGCTCATCA GGATTCCTAGGACCCC-3' were used as primers. The major SOEing PCR round comprised of 30 cycles at 92 ℃ for 30 s, at 50 ℃ for 45 s and at 72 ℃ for 60 s each cycle, and a final extension at 72 ℃ for 10 min. The ligated PCR products were purified and analyzed by agarose gel electrophoresis and used to link with the HCV-IRES fragment by T_4 ligase after both segments were digested by BamH I. The resultant HBV antisense S-HCV C-HCV IRES (SCI) fragment was further amplified by PCR with the major round to be at 92 ℃ for 30 s, at 53 ℃ for 45 s and at 72 ℃ for 60 s for 30 cycles, and the final extension at 72 ℃ for 10 min, in which HBV-S gene sense primer, 5' -GCGCGTGCAAGCTTATAAAACGCC GCAGACACATC-3, and HCV-IRES antisense primer, 5' -GCGAATTCGTTTTTCTTTGAGGTTTAGGATTC-3' , were employed as primers. After digested by corresponding restriction endonucleases, the amplified HBV antisense S-HCV C-HCV IRES fragment was cloned into Hind III and EcoR I sites of $pcDNA_3$ to generate eukaryotic expression plasmid pcDNA3-SCI (Figure 1). In the same way, the expression plasmid $pcDNA_3$-SCITK was yielded by cloning TK fragment into EcoR I site of $pcDNA_3$-SCI. Both of the newly constructed plasmid were confirmed by restriction endonuclease digestion, PCR with specific primers and finally by DNA sequencing (Baosheng Company, Daliang, China).

Self-restricted expression of recombinant plasmid

HepG2 and its derived cell line 2.2.15 that carries the full HBV genome and can stably express series of HBV antigen were maintained in our laboratory. They were cultured in a modified Eagal' s essential medium (Sigima) supplemented with 100 $U \cdot ml^{-1}$ penicillin, 100 $U \cdot ml^{-1}$ streptomycin, and L-glutamine, nonessential amino acids and sodium bicarbonate

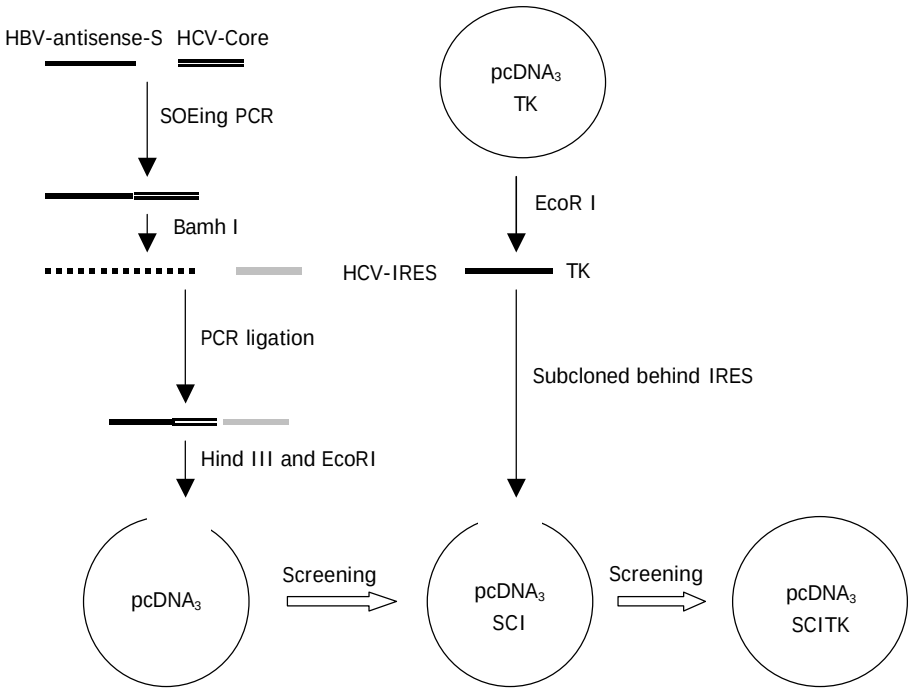

Figure 1 Construction scheme of recombinant plasmid $pcDNA_3$-SCITK.

in doses recommended by the China Type Culture Collection (Wuhan, China) at 37 ℃ in a humidified atmosphere containing 5 % of CO_2. One day prior to transfection, cells were transferred onto an 8-well plate and incubated in complete Dulbecco' s modified Eagle' s medium (DMEM) containing 10 % (v/v) fetal calf serum (FCS) and 10 μg/ml of ganciclovir. When the cells grew to 50-80 % confluence, they were transfected with $pcDNA_3$-SCITK or pcDNA3-SCI plasmid in a ratio of per 10^6 cells to 1 μg of plasmid DNA by LipofectAMINE transfection reagent following the manufacturer' s instructions. (Invitrogen Co. USA). 2.2.15 cells transfected with $pcDNA_3$-SCITK or $pcDNA_3$-SCI plasmids were designated as the experimental group or the mock group. The HepG2 cells transfected with $pcDNA_3$-SCITK plasmids were functioned as the negative control. All of the transfected cells were maintained in DMEM medium with 10 % (v/v) fetal calf serum (FCS) and 10 μg/ml of ganciclovir for at least 7 days. The HBsAg levels in the supernatant of cell culture were detected by ELISA on the 1st, 3rd and 6th day after transfection. Meanwhile, the morphology of transfected cells were recorded by the photograph and the survival cell ratio was assessed by the trypan blue exclusion test on the 6th day of posttransfection.

Statistical analysis

Experimental data were processed by analysis of variance and *t*-test for comparison between groups. Results were expressed as mean ± SE. $P<0.05$ was selected as the level of statistical significance.

RESULTS

Structural identification of constructed plasmids

The segment analysis of recombinant plasmid $pcDNA_3$-SCITK by restriction endonuclease digestion and PCR with specific primers demonstrated that the inserted gene sequences in the plasmid were completely consistent with that of the theoretical

Figure 3 Effects of $pcDNA_3$-SCITK expression on morphological alterations of 2.2.15 and HepG2 cells. Photographs a, b and c in each group exhibited respectively the cell changes on the 1st, 3rd and 6th day post transfection. Lethiferous changes of 2.2.15 cells transfected with $pcDNA_3$-SCITK were noted initially on the 3rd day of posttransfection and aggravated on the 6th day after transfection, in which the majority of cells were observed shrunken, rounded in shape and even dead. However, the negative contrl HepG2 cells grew well.

calculations as shown in Figure 2, which were further confirmed by the DNA sequencing (data not shown).

Effects of pcDNA3-SCITK expression on HBV-infected cells

The expressive efficiency of TK protein by 2.2.15 cells transfected with pcDNA$_3$-SCITK was confirmed in our previous investigations (data to be published). In the present study, the effects of pcDNA$_3$-SCITK transfection on the expression of HBsAg by 2.2.15 cells was observed. The results showed that HBsAg in the supernatant of transfected 2.2.15 cell culture was significantly decreased on the 6th day post-transfection as compared with that of the mock group (P<0.05, Table 1).

Table 1 HBsAg expression in supernants of cell culture by experimental cells

Groups	OD Value		
	1st day	3rd day	6th day
Mock group	0.32±0.13	0.61±0.23	0.61±0.25
Experimental group	0.31±0.11	0.51±0.22	0.41±0.16[a]

[a]P<0.05 *vs* Blank control.

The lethiferous effect of pcDNA$_3$-SCITK expression on 2.2.15 cells was first noted on the 3rd day after transfection and aggravated on the 6th day posttransfection, in which the majority of transfected 2.2.15 cells were observed shrunken, round in shape and even dead (Figure 3). With assessment by the trypan blue exclusion test, the survival cell ratio on the 6th day posttransfection was 95 % in the negative control and only 11 % in the experimental group.

DISCUSSION

Chronic hepatitis B infection remains a major public health problem worldwide. Hepatitis B virus belongs to the family of hepadnaviruses that replicate their DNA genome via a reverse transcription pathway. The chronicity of infection in infected hepatocytes is maintained by the persistence of the viral covalently closed circular DNA. Traditionally, the strategy to combat chronic HBV infection depends mainly on the stimulation of specific antiviral immune response or on the inhibition of viral replication, or on both. However, it has been found that prolonged administration of therapeutic agents is often associated with the production of resistant mutants and serious side effects, as well as a control of viral replication rather than eradication. To further search for effective therapeutic modalities to deal with the chronic infection of HBV is therefore urgently needed to design a brand-new strategy to clear the causative virus.

Hepatitis C virus, a member of the Flaviviridae family and an enveloped virus with a single-stranded 9.6 kb RNA genome of positive polarity[29], utilizes a cap-independent mechanism to initiate translation on its genomic RNAs. This process could involve an internal ribosome entry sites (IRES) located in the 5' nontranslated RNA (5'-NTR), and both canonical and noncanonical translation initiation factors[30-32]. The former could be constructed in some of the bicistronic systems with a higher efficiency in the initiation of protein translation and has been used to construct recombinant vectors[33-36]. It has been recently found that HCV-C protein, another functional modulator localized both in cytoplasm and in perinuclear regions, could interact with IRES and down-regulate IRES-directed translation[37-42], which has been considered to be involved in the establishment or maintenance of the virus persistence[40-43]. Based on these observations, we hypothesized that a self-modulating mechanism by the interaction of HCV-C protein with IRES element was possible to be employed in gene therapy for the eradication of chronic HBV infection.

In the present study, we constructed a recombinant plasmid pcDNA3-SCITK by cloning HCV-C gene and IRES element, partial antisense sequence of HBV-S gene, and TK suicide gene into the eukaryotic expression vector pcDNA3, in which the expression of TK gene was driven in turn by human cytomegalovirus (CMV) promoter, HBV-anti-S and HCV core-IRES sequences. The prominent feature of this plasmid was the temperate expression of effector gene in transfected cells by a self-modulating mechanism. When HBV in the infected cells began to replicate, the transcribed mRNA of HBV-S gene could be combined with its counterpart produced by HBV-antisense-S gene in the recombinant plasmid to form a mRNA dimmer prior to the initiation codon AUG of HCV-C gene, which brought about a decreased expression of HCV-C protein. The consequently reduced HCV core protein-IRES combination could enhance the IRES element to promote the expression of TK suicide gene and further to cause a lethiferous effect on HBV infected cells. In contrast, the expression of effector gene TK was inhibited in non-infected cells because of the normal level of HCV-C protein expression and its normal combination with HCV-IRES element, which would not cause any damage to the healthy cells.

In order to identify the anti-HBV efficiency of pcDNA3-SCITK, 2.2.15 cells that carry the full HBV genome and can stably express series of HBV antigen were transfected with the plasmid. The results showed that HBsAg level in the supernatant of transfected 2.2.15 cell culture was significantly decreased on the 6th day post transfection as compared with that of the mock cells (Table 1). The lethiferous effect of pcDNA$_3$-SCITK expression on 2.2.15 cells was noted initially on the 3rd day after transfection and aggravated on the 6th day posttransfection, in which the majority of transfected 2.2.15 cells were observed shrunken, round in shape and even dead. However, the negative control HepG2 cells grew well (Figure 3). With assessment by the trypan blue exclusion test, the survival cell ratio on the 6th day post transfection was 95 % in the negative control and only 11 % in the experimental group. All these observations confirmed that plasmid pcDNA3-SCITK could exert a lethiferous effect on HBV infected cells via a self-modulating mechanism, which might also be served as a potential therapeutic strategy for the liver cancers derived from chronic HBV infection.

The limitation of the present study is the neglect of anti-HBV infection by preventing the pathogen from invading target cells or by interrupting the virus replication at the beginning of the disease. How to apply our present therapeutic strategy in combination with other treatment protocols to the eradication of chronic HBV infection is to be further investigated.

Abstract

AIM: To investigate the association between the polymorphism of HLA-DRB1, -DQA1 and -DQB1 alleles and viral hepatitis B.

METHODS: HLA-DRB1, -DQA1 and -DQB1 alleles in 54 patients with chronic hepatitis B, 30 patients with acute hepatitis B and 106 normal control subjects were analyzed by using the polymerase chain reaction/sequence specific primer (PCR/SSP) technique.

RESULTS: The allele frequency of HLA-DRB1*0301 in the chronic hepatitis B group was markedly higher than that in the normal control group (17.31 % *vs* 5.67 %), there was a significant correlation between them (χ^2=12.3068, *Pc*=0.0074, RR=4.15). The allele frequency of HLA-DQA1*0501 in the chronic hepatitis B group was significantly higher than that in the normal control group (25.96 % *vs* 13.68 %), there was a significant correlation between them (χ^2=9.2002, *Pc*=0.0157, RR=2.87). The allele frequency of HLA-DQB1*0301 in the chronic hepatitis B group was notably higher than that in the normal control group (35.58 % *vs* 18.87 %), there was a significant correlation between them (χ^2=15.5938, *Pc*=0.0075, RR=4.07). The allele frequency of HLA-DRB1*1101/1104 in the chronic hepatitis B group was obviously lower than that in the normal control group (0.96 % *vs* 13.33 %), there was a significant correlation between them (χ^2=11.9206, *Pc*=0.0145, RR=18.55). The allele frequency of HLA-DQA1*0301 in the chronic hepatitis B group was remarkably lower than that in the normal control group (14.42 % *vs* 30 %), there was a significant correlation between them (χ^2=8.7396, *Pc*=0.0167, RR=0.35).

CONCLUSION: HLA-DRB1*0301, HLA-DQA1*0501 and HLA-DQB1*0301 are closely related with susceptibility to chronic hepatitis B, and HLA-DRB1*1101/1104 and HLA-DQA1*0301 are closely related with resistance to chronic hepatitis B. These findings suggest that host HLA class II gene is an important factor determining the outcome of HBV infection.

INTRODUCTION

The progression of hepatitis B virus (HBV) infection may be influenced by a number of factors including the viral genotype and the level of viremia, but these factors alone do not account for the variability in outcome. There is an increasing awareness that host factors are involved. A great deal of evidences suggest that both cellular and humoral immune responses are required for viral clearance[1-3]. Polymorphisms of human leukocyte antigen (HLA) influence immune responses. Variability in immune response is often associated with HLA polymorphism. HLA genotype of an individual may influence the progression of HBV infection. Patients who have successfully recovered from acute hepatitis B develop strong HLA classes I and II restricted T cell response, whereas these responses are weak or absent in patients with chronic hepatitis B[4, 5]. In the present study, we have analyzed the polymorphism of HLA-DRB1, -DQA1 and -DQB1 alleles in patients with chronic and acute hepatitis B and healthy controls using the polymerase chain reaction with sequence specific primers (PCR/SSP). This study aimed at investigating whether these alleles might be associated with susceptibility or resistance to chronic hepatitis B.

MATERIALS AND METHODS

Subjects

Fifty-two patients (43 males, 9 females, mean age: 33.46 years) with chronic hepatitis B and 30 patients (24 males, 6 females, mean age: 33.25 years) with acute hepatitis B, and 106 healthy blood donors (88 males, 18 females, mean age: 31.27 years) were included in this study. All the patients were from the Institute of Infectious Diseases, Southwest Hospital of Third Military Medical University. The diagnosis of all the cases was made according to the criteria established on the Viral Hepatitis Conference held in 2000. All the patients and controls were Chinese Han people without relatives from Chongqing. The subjects were divided into chronic hepatitis B group, acute hepatitis B group and healthy control group.

Primer synthesis and reagents

The polymorphisms of HLA-DRB1, -DQA1 and -DQB1 alleles were assessed by PCR/SSP technique. HLA-DRB1, -DQA1 and -DQB1 loci of specific PCR primers were designed by Olerup *et al*[6, 7], and synthesized by Shanghai Branch, Canadian Sangon Company. The primers amplifying human growth hormone gene (5' -primer: 5' -GCC TTC CCA ACC ATT CCC TTA-3' , 3' -primer: 5' -TCA CGG ATT TCT GTT GTG TTTC-3') were synthesized by Shanghai Branch, Canadian Sangon Company. Taq DNA polyenzyme and dNTP were purchased from Shanghai Branch, Canadian Sangon Company, pBR322/ Hand III marker and the ReadyPCR™ whole blood genomic DNA purification system were provided by Sino-American Biotechnology Company.

Methods

DNA extraction Genomic DNA was extracted from peripheral blood by using the Ready PCR™ whole blood genomic DNA purification system.

PCR amplification

A total amount of 25 μl PCR reaction solution contained 8 pmoles of each sequence specific primer (3.2 μl), 0.8 pmoles of each internal control primer (0.32 μl), 80-100 ng of genomic DNA (2 μl), 2.5 μl of 10×buffer, 25 mmol/L of $MgCl_2$ (2.5 μl), 10 mmol/L of dNTP (1 μl), 5 unit/μl of Taq polymerase (0.5 μl) and 13 μl of demonized H_2O. The PCR cycling parameters of HLA-DRB1 alleles were as follows: predenaturation at 94 ℃ for 5 min, denaturation at 94 ℃ for 50 s, annealing at 65 ℃ for 1 min, extension at 72 ℃ for 1 min, repetition for 30 cycles and final extension at 72 ℃ for 5 min. The PCR cycling parameters of HLA-DQA1 and -DQB1 alleles were as follows: predenaturation at 94 ℃ for 4 min, denaturation at 94 ℃ for 1 min, annealing at 65 ℃ for 1 min, extension at 72 ℃ for 1 min, repetition for 30 cycles and final extension at 72 ℃ for 2 min. In each PCR reaction a primer pair was included to amplify the human growth hormone gene, which functioned as an internal positive amplification control and gave rise to a 429 base pair fragment.

Detection of PCR products PCR products were loaded in 2 % agars gel containing 0.5 μg/ml of ethidium bromide, electrophoresed for 20 min at 15 V/cm, examined under ultraviolet light. The individual alleles were assigned for the specific pattern of appropriately sized bands.

Statistical analysis

Allele frequencies of HLA-DRB1, -DQA1 and -DQB1 were calculated by direct count. AF for the study group was compared with that for the control group using Chi-square (χ^2) test. The Fisher' s exact test was used when χ^2 value exceeded 3.84, the *P* values were corrected for the number of alleles (corrected *P*=*Pc*). Relative risk frequencies (RR) were calculated according to Wolf formula.

RESULTS

HLA-DRB1 alleles in patients with chronic and acute hepatitis B and healthy controls

The distribution of HLA-DRB1 alleles is shown in Table 1. The allele frequencies of HLA-DRB1*0301 in the chronic hepatitis B group (17.31 %) were markedly higher than those in the normal control group (5.67 %), there was a significant correlation between them (χ^2=12.3068, *Pc*=0.0074, RR=4.15). The allele frequencies of HLA-DRB1*1101/1104 in the chronic hepatitis B group (0.96 %) were significantly lower than those in the acute hepatitis B group (13.33 %), with significant correlation between them (χ^2=11.9206, *Pc*=0.0145, RR=18.55). The data of electrophoresis of HLA-DRB1 alleles amplification are shown in Figure 1.

HLA-DQA1 alleles in patients with chronic and acute hepatitis B and healthy controls

The distribution of HLA-DQA1 alleles is shown in Table 2. The allele frequencies of HLA-DQA1*0501 in the chronic hepatitis B group (25.96 %) were markedly higher than those in the normal control group (13.68 %), there was a significant correlation between them (χ^2=9.2002, *Pc*=0.0157, RR=2.87). The allele frequencies of HLA-DQA1*0301 in the chronic hepatitis B group (14.42 %) was significantly lower than those in the acute hepatitis B group (30 %), there was a significant correlation between them (χ^2=7.6781, *Pc*=0.0388, RR=3.70). The data of electrophoresis of HLA-DQA1 alleles amplification are shown in Figure 2.

DISCUSSION

Host and viral factors undoubtedly influence the clinical expression and behavior of chronic hepatitis B. Attempts to explain the clinical expression and the behavior of chronic hepatitis B by viral factors have shown the importance of viral genotypes and viraemia level for the clinical presentation. However, there remain large inconsistencies, and it is very likely that immune response to hepatitis B virus (HBV) of the host can modify disease outcome[8-10]. HLA is a critical genetic factor that determines individual variations of immune response. The ternary structure of HLA molecules and their roles in the control of immune response have been clearly elucidated. There are many reports about statistical associations between HLA and diseases. HLA gene contributes to the host response against HBV[11-28]. Individuals with different HLA types may differ in susceptibility or resistance to disease[29-35], and associations between HLA polymorphism and susceptibility or resistance to diseases have been identified.

Researches on the correlation between HLA and hepatitis B have been performed for many years. Traditional serological method was used in some investigations, but it has become obsolete and inaccurate. To have a better understanding of the disease, correlation between hepatitis B and HLA should be further studied using nucleotide-typing techniques. Therefore, in the present study, we examined the HLA-DRB1, -DQA1 and -DQB1 alleles by PCR/SSP technique in patients with hepatitis B in an attempt to investigate the association between the polymerase of HLA class II gene and hepatitis B. Fourteen HLA-DRB1 alleles, ten HLA-DQA1 alleles and thirteen HLA-DQB1 alleles were detected. The allele frequencies of HLA-DRB1, -DQA1 and -DQB1 in healthy individuals tallied with genetic characteristics of the Han people in southern region of China.

A previous study showed that the allele frequencies of HLA-B8, DR3, A30, DQA1*0501 in patients with chronic hepatitis B were markedly increased, suggesting that these alleles are associated with chronic hepatitis B[36]. Thio *et al*[37] found that HBV persistence was significantly associated with two class II alleles, DQA1*0501 (OR=2.6) and DQB1 *0301 (OR=3.9), the two-locus haplotype consisted of these same two alleles (OR=3) and the three-locus haplotype consisted of DQA1 *0501, DQB1 *0301 and DRB1 *1102 (OR=10.7). The study by Shen *et al* suggested that the susceptibility to chronic hepatitis B was strongly associated with HLA-DRB1*10 allele in northern Chinese patients[38]. In the present study, we found that the allele frequencies of HLA-DRB1*0301, -DQA1*0501 and -DQB1*0301 in the chronic hepatitis B group were markedly higher than those in the normal control group, there was a significant correlation between them (Tables 1, 2 and 3). These findings suggest that HLA-DRB1*0301, -DQA1*0501 and -DQB1*0301 are closely associated with the susceptibility to chronic hepatitis B, and may be the susceptible gene.

Cotrina *et al*[39] analyzed the HLA-DRB1 genotype in a series of patients with chronic hepatitis B and acute hepatitis B, which further confirmed that HLA-DRB1*1301 and -DRB1*1302 alleles were associated with the clearance of HBV infection and protected people against chronic hepatitis B. Diepolder *et al*[40] found that a strong virus-specific $CD4^+$ and $CD8^+$ T lymphocyte response to hepatitis B virus was associated with viral clearance, patients with acute hepatitis B carrying HLA-DR13 had a more vigorous $CD4^+$ T cell response to HBV core than patients not carrying HLA-DR13, suggesting that HLA-DR13 is associated with a self-limited course of HBV infection, and the beneficial effect of HLA-DR13 alleles on the outcome of HBV infection could be explained by a more vigorous HBV core-specific $CD4^+$ T cell response, which might be either due to a more proficient antigen presentation by HLA-

DR13 molecules themselves or due to a linked polymorphism in a neighboring immunoregulatory gene. In the present study, we found that the allele frequencies of HLA-DRB1*1101/1104 and HLA-DQA1*0301 in the chronic hepatitis B group were markedly lower than those in the acute hepatitis B group, there was a significant correlation between them (Tables 1 and 2). These findings suggest that HLA-DRB1*1101/1104 and -DQA1*0301 are closely associated with the resistance to chronic hepatitis B, and may be the resistant gene.

The results of the present study suggest that HLA-DRB1*0301, -DQA1*0501 and -DQB1*0301 may be the susceptible gene, and HLA-DRB1*1101/1104 and -DQA1*0301 may be the resistant genes to chronic hepatitis B, and that host HLA class II gene is an important factor determining the outcome of HBV infection, which will give some new clues to the study of pathogenesis of chronic hepatitis B.

Abstract

AIM: To express all three HCV structural proteins in the presence or absence of HCV 5'NCR to investigate the requirement of 5'NCR for the assembly of HCV-like particles in insect cells.

METHODS: HCV structural protein encoding sequences CE1E2 and 5'NCR-CE1E2 were amplified with PCR. Recombinant baculovirus were constructed with recombinant DNA techniques. HCV structural proteins expressed in insect cells were analyzed by immunofluorescence and SDS-PAGE. Immunoprecipitation experiment of insect cell lysates with anti-E2 monoclonal antibody (MAb) was carried out and the immunoprecipitated proteins were subjected to SDS-PAGE and immunoblotting with anti-C, anti-E2 MAbs and HCV positive serum. The virus-like particles in insect cells were visualized by electron microscopy (EM). The HCV-like particles were purified by sucrose gradient centrifugation and identified by EM and immune aggregation EM.

RESULTS: The recombinant baculovirus reBV/CE1E2 containing HCV C, E1, E2 genes and reBV/CS containing the same structural protein genes plus 5'NCR were constructed. The insect cells infected with either reBV/CE1E2 or reBV/CS expressed HCV C, E1 and E2 proteins with a molecular weight of 20 kD, 35 kD and 66 kD respectively. The results of immunoprecipitation and the immunoblotting revealed the coimmunoprecipitation of C, E1, and E2 proteins, indicating the interaction of HCV structural proteins expressed in insect cells. Electron microscopy of insect cells infected with reBV/CE1E2 or reBV/CS demonstrated spherical particles (40 to 60 nm in diameter) similar to the HCV virions from sera or hepatic tissues of HCV infected humans. The HCV-like particles were partially purified by sucrose gradient centrifugation, and the purified VLPs showed immuno-reactivity with anti-HCV antibodies.

CONCLUSION: HCV 5'NCR is not required for the assembly of HCV-like particles in insect cells, HCV core and envelope proteins are sufficient for viral particle formation.

INTRODUCTION

Hepatitis C virus (HCV) is the major causative agent of posttransfusion and sporadic non-A, non-B hepatitis. It is estimated that 170 million people worldwide are infected with HCV[1], more than 75 % of infected individuals develop a chronic infection, frequently with severe long-term pathologies such as cirrhosis and hepatocellular carcinoma[2]. Neither an effective treatment for chronic HCV infection nor a vaccine to prevent HCV infection is available at the present time.

HCV belongs to the genus *hepacivirus* of the *flaviviridae* family. Its genome is a 9.6-kb single-stranded RNA of positive polarity with a 5' noncoding region (5' NCR) that functions as an internal ribosome entry site, a single long open reading frame encoding a polyprotein of approximately 3 000 amino acids (aa) and a 3' NCR. This polyprotein is posttranslationally cleaved by host cell peptidases to yield structural proteins and by viral proteases, which generate nonstructural proteins. The three structural proteins, namely core (C) and envelope glycoproteins E1 and E2, are located within the amino-terminal region of the polyprotein. The nonstructural proteins (NS) 2 to 5B reside within the carboxyl-terminal part. By analogy with other *flaviviruses*, HCV virion is presumed to consist of a nucleocapsid or core protein and a viral genome coated by a lipid envelope containing glycoproteins E1 and E2. The study of HCV has been hampered by the low level of viral particles in infected individuals, the inability to propagate efficiently the virus in cultured cells, and the lack of a convenient animal model. Due to these obstacles, neither the structure of the virus nor the prerequisites for its assembly have been clearly defined. Synthesis of virus like particles (VLPs) in eukaryotic cells has opened up new possibilities for defining the structural requirements for viral particle assembly under natural intracellular conditions. In this way, by manipulating the sequence of the different proteins involved, it will be possible to define experimentally the essential morphogenic interactions required for the assembly process.

The assembly of VLPs has been reported for a number of viruses[3,4] with the most successful example of human *papillomavirus* (HPV). Baumert *et al*. have reported the recombinant *baculovirus* containing entire structural protein encoding sequences plus part of 5' NCR led to the expression and assembly of HCV-like particles in insect cells[5].

In the present study we reported the expression of HCV structural proteins in the presence or absence of HCV 5' NCR to investigate the requirement of 5' NCR for the assembly of HCV-like particles in insect cells.

MATERIALS AND METHODS

Cloning of cDNAs encoding HCV structural proteins

HCV cDNA was isolated from a HCV patient from Hebei Province, China, as previously described[6], and used as the amplifying template. cDNA fragments encoding HCV structural proteins were generated by PCR with the following primers: P1: 5'-ACAGATCTACCATGAGCACGAATCCTAAACC-3', P2: 5'-ACAGATCTACTCCACCATAGATCACTCCCC-3', P3: 5'-ATCAAGCTTACGCGTCTGCTAGTAGAAGGA-3',

P1 and P3, P2 and P3 were for CE1E2 and 5' NCR-CE1E2 respectively. A *Bgl*II site was introduced in P1 and P2 primers separately, a stop codon and a *Hin*dIII site were introduced in P3 primer. The correct sequences of CE1E2 and 5' NCR-CE1E2 were confirmed by DNA sequencing.

Baculovirus constructs and insect cell cultures

For the construction of recombinant *baculoviruses*, a Bac-to-Bac *baculovirus* expression system (Gibco-BRL/Life Technologies) was applied. The *Bgl*II-*Hin*dIII digestion products of PCR fragments were subcloned into *Bam*HI-*Hin*dIII site (multiple cloning site) of *baculovirus* donor plasmid pFastBacI. After identification by restriction digestion and PCR, each of the recombinant plasmids was used to transform DH10Bac. Through Tn7 transposon-mediated site-specific transposition foreign gene expression cassette was integrated into a *baculovirus* shuttle vector (bacmid). The size of inserts was confirmed by PCR with the pUC/M13 amplification primers, which were directed at sequences on either side of the mini-*att*Tn7 site in the bacmid. The recombinant bacmids were used for transfection of Sf9 cells (*Spodoptera frugiperda*). Recombinant *baculoviruses* were harvested thereafter and purified by plaque screening. The recombinant *baculoviruses* were verified by PCR with CE1E2 and 5' NCR-CE1E2 gene specific primers and amplified by subsequent rounds of Sf9 cell infection until a final titer of 5×10^7 PFU/ml was achieved. Detailed methods for *baculovirus* manipulation were referred to the instruction manual. Sf9 insect cells were maintained in spinner or monolayer cultures at 27 ℃ in Grace' s medium (Gibco-BRL/Life Technologies) supplemented with 10 % fetal bovine serum.

Protein expression assay

For all protein expression experiments, Sf9 cells in mid-log growth in monolayer cultures were infected with a multiplicity of infection (MOI) of 10. Infection of insect cells with non-recombinant *baculovirus* served as a negative control in all experiments. The expression of HCV structural proteins was analyzed at 72 h postinfection by immunofluorescence and SDS-PAGE. For immunofluorescence, cells were fixed with -20 ℃ acetone for 5 min. The primary antibody used was anti-HCV serum, and the secondary antibody was fluorescein isothiocyanate (FITC)-conjugated goat anti-human IgG antibody. Detailed methods were referred to Ausubel[7]. For SDS-PAGE, the cells were lysed by ultrasonic, the cell lysate was briefly centrifuged to remove cell debris and nuclei, and the supernatant was subjected to electrophoresis on a SDS-12 % polyacrylamide gel. Detailed methods were referred to Sambrook[8].

Immunoprecipitation and immunoblotting of HCV proteins

The Immunoprecipitation starter packthe (Amersham Pharmacia Biotech) was used for immunoprecipitation analysis, details of the experimental procedures were referred to the manufacturer' s protocols. Briefly, at 96 h postinfection, cells were lysed with RIPA buffer [50 mM Tris-HCl, 150 mM NaCl, 0.1 % Nonidet P-40 (NP-40), 5 mM EDTA (pH 7.5), 0.5 % sodium deoxycholate (DOC), 1 mM phenylmethylsulfonyl fluoride (PMSF)]. The cell lysate was cleared of cell debris and nuclei by low-speed centrifugation (15 min at 15 000×g and 4 ℃) and immunoprecipitated with anti-E2 monoclonal antibody (MAb). The immunoprecipitated proteins were analyzed by electrophoresis on a 12 % polyacrylamide gel. After gel transfer to polyvinylidene difluoride membranes, the blots were probed with anti-C, anti-E2 MAb, or anti-HCV serum followed by horseradish peroxidase (HRP)-conjugated goat anti-mouse (for anti-C and anti-E2 MAb) or anti-human (for serum) IgG antibody. Detailed methods for immunoblotting were referred to Sambrook[8].

Electron microscopy (EM) of VLPs in insect cells

A flask (25 cm^2) of infected cells (MOI=10, at 96 h postinfection) was harvested, washed in PBS and centrifuged at 1 000 r/min for 5 min. The cell pellets were fixed with 3.8 % glutaraldehyde in PBS for 24 h at 4 ℃. After fixation, the cells were washed three times in PBS (8 h each time) at 4 ℃ and post-fixed with 1 % osmium tetroxide for 2 h at 4 ℃. The samples were then dehydrated with acetone of a series of graded concentration, and embedded in 1:1 acetone-Epon 812 for 30 min at room temperature, further embedded in Epon 812 overnight at 37 ℃, and then polymerized for 24 h at 60 ℃. Ultrathin sections were cut with LKBIII ultramicrotome, mounted on copper grids, stained with uranyl acetate and lead citrate, washed, dried and finally examined under transmission electron microscope.

Purification of VLPs

Cells were harvested at 96 h postinfection, All purification steps were carried out on ice. Insect cells infected with reBV/CS or reBV/CE1E2 (approximately 5×10^7 cells, grown in suspension) were lysed in 50 mM Tris, 50 mM NaCl, 0.5 mM EDTA, 1 mM PMSF, 0.1 % NP-40. Sonication of the lysate was performed. The lysate was homogenized and subjected to low-speed centrifugation (15 min at 4 ℃ and 15 000×g), and the supernatant was pelleted over a 30 % (wt/vol) sucrose (in 20 mM Tris, 150 mM NaCl [pH 7.4]) cushion (6 h at 4 ℃ and 150 000×g). The pellet was resuspended in 50 mM Tris, 100 mM NaCl (pH 7.4), homogenized, and subjected to a second sucrose gradient centrifugation. The resuspended pellet was layered onto a 20 % to 60 % (wt/wt) sucrose (in 50 mM Tris, 100 mM NaCl [pH 7.4]) gradient and centrifuged for 22 h at 4 ℃ and 150 000×g. Fractions (0.5 ml) were collected from the top and analyzed by immunoblotting.

Electron microscopy and immune aggregation electron microscopy of purified VLPs

After the sucrose gradient centrifugation, VLPs were diluted in PBS (1:10), centrifuged for 2 h at 4 ℃ and 150 000×g, the pellet was resuspended in PBS. Anti-HCV serum (diluted 1:200 in PBS) was homogenized, incubated at 37 ℃ for 1 h, then stored at 4 ℃ overnight. Samples were centrifuged again for 1h at 4 ℃ and 150 000×g, the pellet was resuspended in PBS. Samples (3 ul) were absorbed on the surface of carbon-coated 300 mesh copper grids, and stained negatively with 2 % phosphotungustic acid for EM examination.

RESULTS

Construction and identification of recombinant baculoviruses

The fragment CE1E2 consisting of HCV C, E1, E2 encoding sequences and the fragment 5' NCR-CE1E2 containing the same structural protein genes plus 5' NCR were produced by PCR, with the size of 2 578 bp and 2 238 bp respectively (Figure 1). The correct sequences of CE1E2 and 5' NCR-CE1E2 were confirmed by DNA sequencing.

5' NCR-CE1E2 and CE1E2 were separately subcloned into *baculovirus* donor plasmid pFastBacI. The resulting recombinant plasmids pFB1-CS and pFB1-CE1E2 were verified (Figure 2) and used to transform DH10Bac. Through Tn7 transposon-mediated site-specific transposition foreign gene expression cassette was integrated into a *baculovirus* shuttle vector (bacmid). The result of PCR with M13/pUC forward and reverse primers indicted the correct insertion of 5' NCR-CE1E2 and CE1E2 fragments into bacmids (Figure 3),

and the resulting recombinant bacmids were named as bacmid/CS and bacmid/CE1E2 respectively. The non-recombinant bacmid was named as bacmid/0.

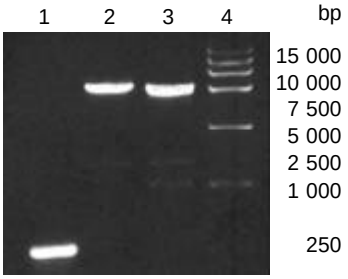

Figure 3 Confirmation of recombinant bacmids by PCR. Lane 1: bacmid / 0 control, lane 2: bacmid / CS, lane 3: bacimd / CE1E2, lane 4: DL-15000 marker.

Bacmid/CS and bacmid/CE1E2 were separately used to transfect Sf9 cells to generate recombinant *baculoviruses*, yielding reBV/CS and reBV/CE1E2, respectively. Bacmid/0 was used to generate non-recombinant *baculovirus* control, BV/Bac.

A large number of *baculoviruses* could be observed in nuclei of the Sf9 cells transfected with bacmid DNAs (Figure 4).

The recombinant *baculoviruses* reBV/CS and reBV/CE1E2 were confirmed by PCR with 5' NCR-CE1E2 and CE1E2 specific primers (Figure 5).

Immunofluorescence of HCV proteins

Either the recombinant *baculovirus* reBV/CS or reBV/CE1E2 directed the production of HCV structural proteins in insect cells, as demonstrated by immunofluorescence analysis of infected insect cells with anti-HCV antibodies (Figure 6). Immuno-staining was observed in the cells infected with recombinant *baculovirus* (Figures 6A and B). The anti-HCV antibodies used in this study did not display any cross-reactivity against insect cell or *baculovirus* proteins (Figure 6C).

HCV structural proteins expressed in insect cells

SDS-PAGE analysis of lysates from Sf-9 cells infected with either reBV/CS or reBV/CE1E2 demonstrated 3 novel bands of the size of expected HCV E2, E1 and C proteins which were 66 kD, 35 kD and 20 kD respectively, which were not present in cells infected with non-recombinant *baculovirus* BV/Bac (Figure 7).

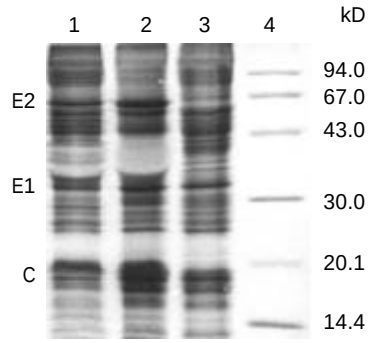

Figure 7 Identification of HCV structural proteins expressed in Sf9 cells by SDS-PAGE. Lanes 1-2: cells infected with reBV/CS and reBV/CE1E2 respectively, lane 3: control cells infected with BV/Bac, lane 4: molecular weight marker.

Coimmunoprecipitation of C and E1 with E2 protein

To further investigate the association of C, E1, and E2 proteins expressed in insect cells, cell extracts were immunoprecipitated with anti-E2 monoclonal antibody (MAb), and the precipitated proteins were separately probed with anti-C, anti-E2 MAb, or anti-HCV serum.

As shown in Figure 8, E2 protein was precipitated by anti-E2 MAb (Figure 8A), C protein could be detected in the immunoprecipitation complex when probed with anti-C MAb (Figure 8B), while C and E1 proteins could be detected together with E2 protein when probed with anti-HCV serum (Figure 8C). These results revealed the coimmunoprecipitation of C, E1 and E2 proteins.

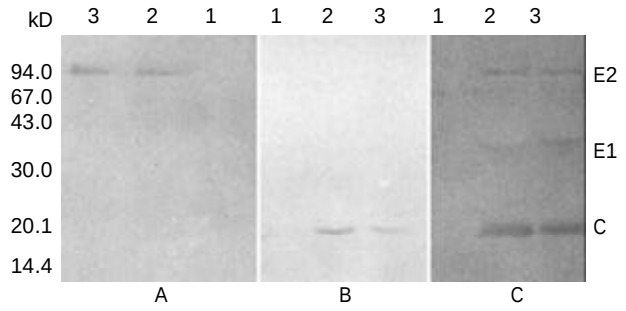

Figure 8 Immunoblotting of anti-E2 antibody immunoprecipitated proteins with anti-E2 mAb (A), anti-C mAb (B) and anti-HCV serum from HCV-infected patients (C). Lane 1: control BV/Bac, lane 2: reBV/CE1E2, lane 3: reBV/CS.

Electron microscopy of infected Sf9 cells

Transmission electron microscopy of the cells infected with either reBV/CS or reBV/CE1E2 revealed abundant virus-like particles in cytoplasm (Figures 9A and B). These particles (indicated by arrow "➡"), 40 to 60 nm in diameter, were polymorphic in appearance, many of them had unevenly distributed electron-dense structures suggestive of possible nucleocapsids. No such structures were observed in the control cells infected with BV/Bac (Figure 9C) in spite of the existence of abundant *baculoviruses* in the nuclei (indicated by arrow "▶").

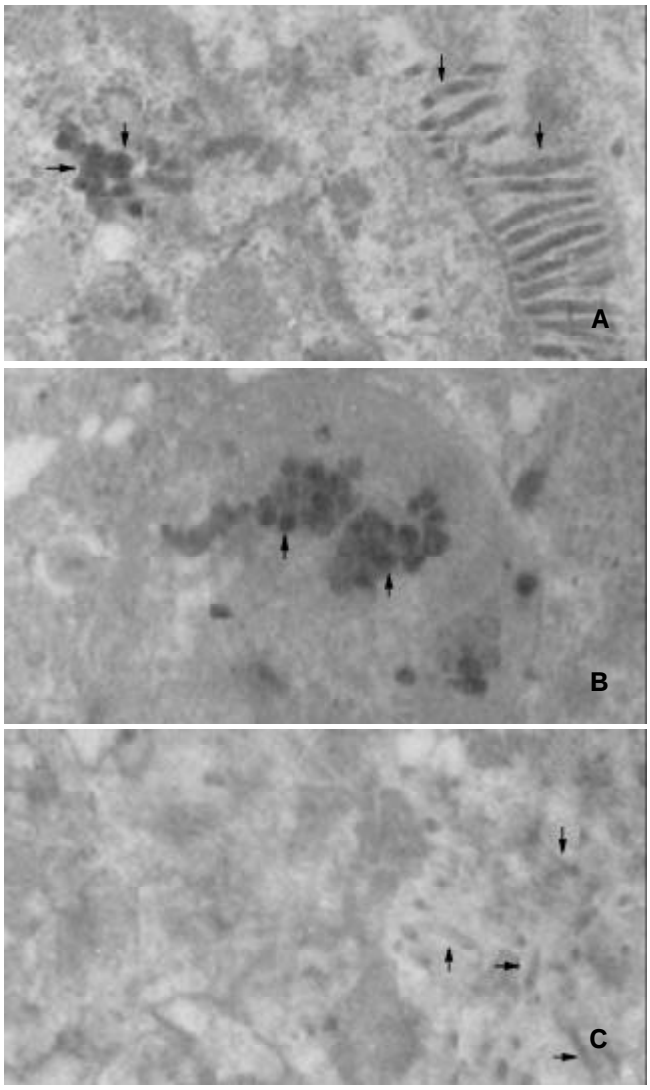

Figure 9 Electron micrographs of *baculovirus*-infected Sf9 cells (×25 000). Sf9 cells infected with A: reBV/CS, B: reBV/CE1E2, C: control BV/Bac.

Purification and identification of VLPs

VLPs were purified from large-scale cell cultures. The band corresponding to VLPs in sucrose gradient centrifugation was indicated in Figure 10. Portions of the VLPs were examined by EM which showed separate spherical particles similar to those seen in Sf9 cells infected with recombinant baculoviruses (Figures 11A and B), other portions of VLPs were examined by immune aggregation EM which revealed aggregated VLPs by anti-HCV serum (Figures 11C and D), indicating the immuno-reactivity of VLPs with anti-HCV antibodies.

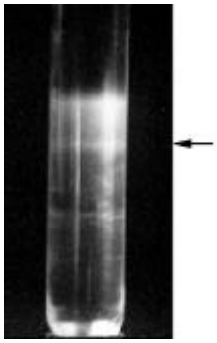

Figure 10 VLP band (indicated by arrow) in sucrose gradient centrifugation.

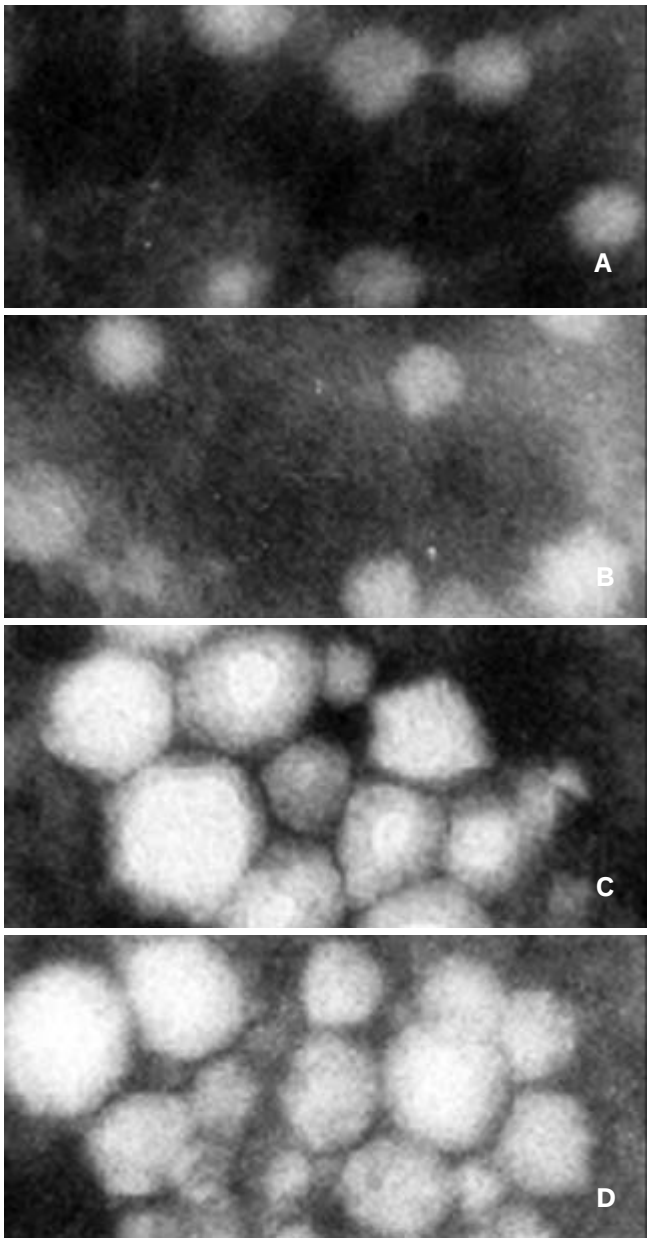

Figure 11 Electron microscopy and immune aggregation electron microscopy analysis of VLPs (negative staining). A and B (×100 000): VLPs isolated from Sf9 cells infected with reBV/CS and reBV/CE1E2, respectively. C and D (×150 000): Immune aggregation of VLPs from A and B with anti-HCV serum, respectively.

DISCUSSION

In this study, either in the presence or absence of HCV 5' NCR, the recombinant *baculovirus* (reBV/CS or reBV/CE1E2) efficiently expressed all the three HCV structural proteins, indicating the efficient cleavage of the polyproteins into individual proteins. The sizes of C, E1 and E2 proteins were 20 kD, 35 kD and 66 kD respectively, similar to those of HCV structural proteins expressed in mammalian cells[9], suggesting similar posttranslational processing of HCV structural proteins in insect and mammalian expression systems.

The interactions of HCV structural proteins expressed in insect cells were investigated by means of immunoprecipitation and immunoblotting. In addition to E2 protein, C and E1 proteins were also present in the immunoprecipitation complex (Figures 8B and C), indicating that C and E1 proteins were precipitated together with E2 protein by anti-E2 MAb. The result of immunoblotting of the immunoprecipitated proteins with anti-E2 MAb (Figure 8A) showed that the coimmunoprecipitation of the three structural proteins was not precipitated because there existed cross-reactivity between E2 MAb and C or E1 protein. So, we could conclude that the coimmunoprecipitation of C, E1 and E2 proteins was due to the association of the three structural proteins. These results extended the findings of previous studies which demonstrated interactions of E1 and E2 proteins[10] as well as C and E1 proteins[11], and provided immunological and biochemical evidences for the assembly of HCV structural proteins into VLPs in insect cells.

Detail ultrastructural features of HCV virions remain elusive since direct visualization of virus particles from infected serum and tissues has proven to be difficult. Filtration studies have estimated the virion particle size was 30 to 60 nm in diameter[12], Shimizu *et al*. detected VLPs with a diameter of approximately 50 nm in cytoplasm of the liver cells obtained during the acute phase of hepatitis C from a chimpanzee[13]. Kaito *et al*. reported visualization of 55 to 65 nm VLPs by immunogold electron microscopy with antibodies to HCV envelope protein[14]. Takahashi *et al*. observed by EM 55 nm VLPs in a gradient fraction when human plasma containing HCV was separated by potassium bromide density gradient centrifugation[15].

In our study, abundant spherical particles with the size of 40-60 nm in diameter were observed in the cytoplasm of Sf9 cells infected with either reBV/CS or reBV/CE1E2. Such particles could not be found in the cells infected with nonrecombinant *baculovirus* although the existence of abundant *baculoviruses* in the nuclei, indicating that VLPs in the infected cells were not correlated with the propagation of *baculovirus* in insect cells, but were resulted from the expression of HCV structural proteins in insect cells. Furthermore, VLPs isolated from recombinant *baculovirus* infected cells showed immuno-reactivity with anti-HCV antibodies, indicating that VLPs were derived from HCV proteins. Our data suggest that the morphology of HCV-like particles synthesized in insect cells is similar to the features described for HCV virions isolated from HCV-infected humans and chimpanzees. These results provided the morphological evidence for the assembly of HCV structural proteins into HCV-like particles.

In conclusion, either in the presence or absence of 5' NCR, the recombinant *baculovirus* containing HCV structural protein encoding sequences can direct the expression of correctly processed individual HCV structural proteins, which assemble into VLPs similar to HCV particles from sera or hepatic tissues of HCV infected humans or chimpanzees. HCV core and envelope proteins are sufficient for viral particle formation, 5' NCR is not required for the assembly of VLPs in insect cells.

Abstract

AIM: Because the presence or absence of *H pylori* infection has important implications for therapeutic decisions based on histological assessment, the reproducibility of Sydney system is important. The study was designed to test the reproducibility of features of *Helicobacter pylori* gastritis, using the updated Sydney classification.

METHODS: Gastric biopsies of 40 randomly selected cases of *H pylori* gastritis were scored semiquantitatively by three pathologists. Variables analysed included chronic inflammation, inflammatory activity, atrophy, intestinal metaplasia, *H pylori*, surface epithelial damage. κ values below 0.5 represented poor, those between 0.5 and 0.75 good and values over 0.75 excellent interobserver agreement.

RESULTS: The best interobserver agreement (κ=0.62) was present for intestinal metaplasia. The agreement was the poorest for evaluating atrophy (κ=0.31).

CONCLUSION: Although the results of this study were in accordance with some previous studies, an excellent agreement could not be reached for any features of *H pylori* gastritis. This low degree of concordance is assumed to be due to the personal evaluation differences in grading the features, the lack of standardized diagnostic criteria, and the ignorance to reach a consensus about the methods to be used in grading the features of *H pylori* gastritis before initiating the study.

INTRODUCTION

Although gastritis was first interpreted to be due to aging and lifelong exposure to various insults, it is now clear that the most common cause of this inflammatory condition is infection with *H pylori*[1]. It has been shown[2] that this organism is strongly associated with chronic active gastritis as well as gastric adenocarcinoma and MALToma.

The Sydney system for grading and classifying chronic gastritis was devised to provide a standardized approach to the histologic interpretation of gastric biopsies in 1990[3,4], and it was later updated in 1994[5,6]. Although it was reported that the Sydney systems' weakness was that it was used in complex descriptions rather than true diagnosis[7]. After the updating of the Sydney classification, several studies on interobserver variation for the assessment of *H pylori* gastritis have been reported[6,8-11]. The evaluation of interobserver agreement by using kappa (κ)-statistics has been accepted by pathologists for several years[9].

Although the histologic examination of gastric biopsy specimens is accepted as the gold standard[12,13] for the diagnosis of *H pylori* gastritis, it has not been demonstrated that histopathologic assessment is both accurate and reproducible[9].

The study was designed to test the reproducibility of the features of *H pylori* gastritis, using the updated Sydney classification by κ-statistics.

MATERIALS AND METHODS

Three pathologists participated in the study. One was a professor with primary interest in gastrointestinal pathology. The second was a 4th-year assistant professor in pathology. An other was an 18th-month pathology resident. The slides were examined independently, and also incombination with any clinical information by each of the pathologists.

Histologic evaluation

From 130 cases diagnosed as *H pylori* gastritis in our department (Department of Pathology, Medical School, Mersin University.) in a period of 17 months, 40 [22 (55.0 %) female, 18 (45.0 %) male] were randomly selected for study, their age ranged from 23 to 72 years, with a mean of 47.2. The specimens were excluded from the study because they were insufficient in mucosal thickness for proper assessment of atrophy and without surface epithelium before the selection. Slides were coded using a computer generated list of random numbers.

Biopsy samples from the antrum and body were formalin-fixed and paraffin-embedded and cut into 2-3 μm sections which were stained using hematoxylin and eosin (H&E), and alcien blue/PAS for intestinal metaplasia. Five H&E sections were examined for each case. The biopsies were scored semiquantitatively by three pathologists according to the updated Sydney classification[14].

The updated Sydney system has a scale of 0-3 for scoring the features of chronic gastritis[14]. In order to improve assessment of minor degrees of alteration, a detailed histopathological classification was used, which also provides numerical data for statistical analysis[15]. At first, each variable was divided into seven subcategories, resulting in a score on a scale of 0-6. But the κ values could not be calculated using this classification. The 6 subcategories (excluding 0, none) were then amalgamated by pairs (none, 0; mild, 1-2; moderate, 3-4; severe, 5-6), but the calculation of the κ values was again impossible for the majority of variations using this classification, and the calculated values were found to be low. So, we came to a conclusion that the agreement between pathologists could be improved when a different amalgamated 3-point scale classification was used for each variable (Table 1).

Table 1 Histologic features evaluated on each slide and score scale

Histologic features	Score	Grading
Chronic inflammation	0, none	0, none
	1, <10 cic*/HPF**	1-2-3, mild
	2, >10 cic/HPF	4-5-6, moderate to marked
	3, some areas with dense cic	
	4, diffuse infiltration with dens cic	
	5, nearly whole mucosa contains a dense cic	
	6, entire mucosa contains a dense cic infiltrate	
Inflammatory activity	0, none	0, none
	1, only one crypt involved/ biopsy	1-2, mild
	2, two crypts involved/ biopsy	3-4-5-6, moderate to marked
	3, many crypts (<25%) involved/ biopsy	
	4, 25-50% of crypts involved/ biopsy	
	5, >50% of crypts involved/ biopsy	
	6, all crypts involved	
Atrophy	0, none	0, none
	1, foci where a few gastric glands are lost or replaced by ie•	1-2, mild
	2, small areas in which gastric glands have disappeared or been replaced by ie	3-4-5-6, moderate to marked
	3, <25% of gastric glands lost or replaced by ie	
	4, 25-50% of gastric glands lost or replaced by ie	
	5, >50% of gastric glands lost or replaced by ie	
	6, only a few small areas of gastric glands remaining	
Intestinal metaplasia	0, none	0, none
	1, only one crypt replaced by ie	1-2-3, mild
	2, one focal area (1-4 crypts) in one of two biopsies	4-5-6, moderate to marked
	3, two separate foci	
	4, multipl foci in one or both biopsies	
	5,>50% of gastric epithelium diffusely replaced by ie	
	6, only a few small area of gastric epithelium are not replaced by ie	
H pylori	0, none	0, none
	1, *H pylori* found only in one place	1-2-3-4, mild
	2, only a few *H pylori* found	5-6, moderate to marked
	3, scattered *H pylori* found in separate areas/foci	
	4, numerous *H pylori* in separate areas/foci	
	5, nearly complete gastric surface covered by a layer of *H pylori*	
	6, continuous gastric surface coverage by a thick layer of *H pylori*	
Surface epithelial damage	0, none	0, none
	1, slight	1-2-3-4, mild
	2, mild deg♦ in the top of the epithelial cells	5-6, moderate to marked
	3, moderate deg with disorientation of the epithelial lining	
	4, indistinct cell borders at the surface of the epithelium	
	5, flattened epithelial cells with severe deg and enlarged nuclei	
	6, flattened to erosive epithelium of the entire surface	

*: Chronic inflammatory cells, **: High power field, •: Intestinal type epithelium, ♦: Degeneration.

Table 2 Kappa values and their 95 % confidence intervals between three pathologists for *H pylori* gastritis

Variable	Pairwise analysis between pathologists					
	1:2		1:3		2:3	
	Kappa	95 % CI	Kappa	95 % CI	Kappa	95 % CI
Chronic inflammation	0.49[a]	0.13-0.85	-0.34	NS	0.14	NS
Inflammatory activity	0.44[a]	0.13-0.71	-0.13	NS	-0.27	NS
Atrophy	0.31[a]	0.83-0.56	0.03	NS	0.14	NS
Intestinal metaplasia	0.51[a]	0.25-0.85	0.52[a]	0.20-0.80	0.62[a]	0.40-0.85
H pylori	0.40[a]	0.10-0.71	0.38[a]	0.06-0.71	0.56[a]	0.28-0.84
Surface epithelial damage	-0.01	NS	-	-	-	-

NS: Non-significant, 95 % CI: 95 % confidence interval, -: Kappa statistics could not be done because data table had less than two rows or columns; [a]$P<0.05$.

Statistical analysis

Interobserver agreement was analysed with the use of κ statistics (BMDP software: Cork, Ireland). The benchmarks suggested by Svanholm *et al*[16] were accepted. Values below 0.5 represented poor, those between 0.5 and 0.75 good and values over 0.75 excellent interobserver agreement. Only values greater than 0.5 were considered good enough for diagnostic reliability. Confidence interval was calculated for only statistically significant values.

RESULTS

κ values and their 95 % confidence intervals between three pathologists for *H pylori* gastritis are shown in Table 2. On

blinded review of the coded slides the best interobserver agreement (κ=0.62, CI: 0.40-0.85) was present for intestinal metaplasia. The good agreement was reached in the assessment of the grade of *H pylori*, with κ value of 0.56 (CI: 0.28-0.84). The interobserver agreement was the poorest for evaluating atrophy (κ=0.31, CI: 0.13-0.56). Following atrophy, the two variables with poor agreement were chronic inflammation (κ=0.49, CI: 0.13-0.85) and inflammatory activity (κ=0.44, CI: 0.13-0.71).

There was an agreement among the three observers for only evaluating intestinal metaplasia and the grade of *H pylori*. There was no interobserver agreement among the three pathologists for the assessment of surface epithelial damage. An excellent agreement could not be reached in any features of *H pylori* gastritis in our study.

DISCUSSION

Correct and reliable histological diagnosis of *H pylori* gastritis has a great influence on clinical practice as an indicator for therapy. Reliability in assessing intestinal metaplasia and atrophy in histological specimens was especially important because these changes were associated with an increased risk of gastric cancer[12,17-19]. Andrew *et al*[8] and Tepes *et al*[12] held that histopathology was a reliable diagnostic method for *H pylori* gastritis based on their results.

The best interobserver agreement was reached for intestinal metaplasia. The κ values were 0.51-0.62 (CI: 0.40-0.85). As in our study, others have also shown a good agreement for scoring intestinal metaplasia, with κ values varying from 0.54 (CI: 0.31-0.77) in the study by Tepes *et al*[12] to 0.73 in the study by Andrew *et al*[8]. However, our κ values were lower than those reported by Fiocca *et al*[20]; (κ=0.75-0.92). Although, the H&E stain has been the standard basis for recognition of intestinal metaplasia[21], we based our observations on the alcian blue/PAS in addition to H&E because of ease to identify the goblet cells.

In the present study, the grading of *H pylori* reached good reproducibility, with κ value of 0.56 (CI: 0.28-0.84). This result was consistent with the study of Fiocca *et al*[20] (κ=0.62), Andrew *et al*[8] (κ=0.74) and Tepes *et al*[12] (κ=0.43), but lower than the value reported by El-Zimaity *et al*[9] (κ=0.90). Our results have also confirmed that H&E was an adequate stain for the detection of *H pylori*. There was no need for an additional staining like Warthin-Starry to identify the organism.

The lack of explicit criteria for the diagnosis of normal gastric mucosa when mononuclear cells were present, made grading difficult[12]. Therefore, the κ value for assessment of the degree of chronic inflammation (κ=0.49, CI:0.13-0.85) using semiquantitative scoring was lower than that for intestinal metaplasia and for the grading of *H pylori* in the present study. Tepes *et al*[12], also found a κ value for chronic inflammation ranged from 0.39 to 0.53. Our result is also in accordance with those of Fiocca *et al*[20], who reported κ values ranging from 0.49 to 0.82 and Andrew *et al*[8] who reported κ value of 0.58.

The interobserver agreement was poor with κ value of 0.44 (CI: 0.13-0.71) for scoring neutrophil infiltration in gastric mucosa. This result was consistent with those of Tepes *et al*[12] (κ=0.28-0.41) and Andrew *et al*[8] (κ=0.69). But the interobserver agreements of the studies of El-Zimaity *et al*[9] (κ=0.80) and Fiocca *et al*[20] (κ=0.58-0.77) were better than ours. Inflammatory activity and *H pylori* infection were present together and when only neutrophils were discovered in the tissue specimen the pathologists should intensively search for some residual *H pylori*[22].

Recently, it has been shown in several studies that even experienced gastrointestinal pathologists had poor interobserver agreement over the assessment of gastric atrophy of *H pylori* gastritis[6,8-11]. In the present study, the interobserver agreement for the grade of atrophy was lower than that for the other gastritis features. As in our study (κ=0.31, CI:0.13-0.56), others have also shown the lowest agreement for scoring atrophy, with κ values varying from 0.42 in the study of Fiocca *et al*[20] to 0.51 in the study of Andrew *et al*[8]. Tepes *et al*[12] also found the lowest interobserver agreement for atrophy (κ=0.17-0.57). Although El-Zimaity *et al*[9] also found the poorest agreement for atrophy, with κ value ranged from 0.08 to 0.29, the agreement in our study for the evaluation of atrophy was still better.

Among the similar previous studies, the surface epithelial damage in *H pylori* gastritis has been evaluated in only the study of Chen *et al*[15]. They reached good to excellent reproducibility in grading this feature, with weighed κ values of 0.6 and 0.73. But there was no interobserver agreement between the three pathologists for the assessment of surface epithelial damage in our study. Although the Sydney classification has been used routinely, the surface epithelial damage in *H pylori* gastritis have not been evaluated in our department until the present study was designed. It is suggested that the reason of this disagreement may be the lack of our experience in evaluating epithelial damage.

The results of this study suggest that assessment of many histopathologic features of *H pylori* infection have a low degree of concordance. Interobserver variation has been rather high in this study as in some other studies[9,12,23]. This may be due to the discrepancies in the semiquantitative evaluation of the features of *H pylori* gastritis, or due to the observations of the pathologists. Essentially, a perfect agreement by pathologists was practically impossible because pathology results were based on subjective interpretation of different features and classification, and numerous studies on the reproducibility of histopathologic data have reached similar conclusion. Pathologists could usually agree in the presence or absence of a particular histological characteristic, but were seldom consistent when they estimated its degree[24-27].

In the present study, the best interobserver agreement was reached between the assistant professor and the pathology resident, suggesting that the scale of the score is more important than experiences.

Because of the level of agreement in the presence or absence of *H pylori* infection had important implications for therapeutic decisions based on histological assessment[8], reproducibility of Sydney system is important. The updated Sydney system for scoring *H pylori* gastritis is useful and reproducible, but it needs to be improved in the criteria for grading the histologic features[15]. The lack of standardized diagnostic criteria is likely to have contributed significantly to the poor interobserver agreement found in certain features such as atrophy[9] as in our study. More exact criteria will probably further improve the interobserver agreement in assessing the histologic features, but some interobserver variability will probably persist because of the subjectivity that has been part of all semiquantitative grading systems[12]. The point that where cases were reviewed and numerical parameters were established was the best strategy to improve diagnostic concordance between pathologists[28].

Although, the results of this study were in accordance with some previous studies, an excellent agreement could not be reached for any features of *H pylori* gastritis. In conclusion, this unexpectedly low degree of concordance is assumed to be due to the personal evaluation differences in grading the features, and the lack of the standardized diagnostic criteria, as well as the ignorance to reach a consensus about the methods to be used in grading the features of *H pylori* gastritis before initiating the study.

Abstract

AIM: To analyze gastric polypoid lesions in our patient-population with respect to histopathologic features and demographic, clinical, and endoscopic characteristics of patients.

METHODS: Clinical records and histopathologic reports of patients with gastric polypoid lesions were analyzed retrospectively. All lesions had been totally removed by either endoscopic polypectomy or hot biopsy forceps. The histopathologic slides were re-evaluated by the same histopathologist.

RESULTS: One-hundred and fifty gastric polypoid lesions were identified in 91 patients. There were 53 (58 %) women and 38 (42 %) men with a median age of 53 (range, 31 to 82) years. The most frequent presenting symptom was dyspepsia that was observed in 35 (38.5 %) patients. Symptoms were mostly related to various associated gastric abnormalities such as chronic gastritis or *H pylori* infection rather than polypoid lesion itself. Polypoid lesions were commonly located in the antrum followed by cardia. Out of 150 lesions, 80 (53 %) had the largest dimensions less than or equal to 5 mm and only 7 were pedunculated. The frequencies of hyperplastic polyps, foveolar hyperplasia, and fundic gland polyps were 46 %, 18 %, and 14 % respectively. We also detected gastritis varioliformis in 12 specimens, lymphoid follicles in 9, 4 adenomatous polyps in 4, polypoid lesions with edematous mucosa in 4, inflammatory polyps in 3, and carcinoid tumor in 1. Adenomatous changes were observed within two hyperplastic polyps and low grade dysplasia in one adenoma. Histopathologic evaluation of the surrounding gastric mucosa demonstrated chronic gastritis in 72 (79 %) patients and *H pylori* infection in 45 (49 %).

CONCLUSION: Hyperplastic polyps are the most frequently encountered subtype of gastric polypoid lesions. They are usually associated with chronic gastritis or *H pylori* gastritis. Contrary to the previous belief, they may harbour adenomatous changes or dysplastic foci. Therefore, endoscopic polypectomy seems as a safe and fast procedure for both diagnosis and treatment of gastric polypoid lesions at the same session. In addition, edematous mucosa may appear misleadingly as a polypoid lesion in some instances and it can be ruled out only by histopathologic examination.

INTRODUCTION

The frequency of gastric polyps is gradually increasing due to widespread use of endoscopic examinations[1,2]. Any discrete lesion protruding into the lumen of gastrointestinal (GI) tract appeared at endoscopy is called as "polypoid lesion"[3]. However, a polyp is defined as a proliferative or neoplastic lesion of gastrointestinal mucosal layer[3]. Although endoscopic appearances of some polyps may be diagnostic, the term "polyp" should not be used for every discrete protrusions identified at endoscopy unless histopathologically confirmed[4,5]. According to the classification suggested by Oberhuber and Stolte[4], gastric polypoid lesions are divided into five distinct groups: non-neoplastic polyps such as hyperplastic polyp, hamartomatous polyps such as Peutz-Jeghers polyps, heterotopic tissue polyps such as heterotopic pancreas, neoplastic polyps such as adenoma, and reactive polypoid lesions such as foveolar hyperplasia. In their series, hyperplastic polyps and fundic gland polyps are the two most common subtypes of gastric polypoid lesions[4].

In this study, the demographic, clinical, and endoscopic characteristics of patients with gastric polypoid lesions were presented. The histopathologic features of these lesions were also reported and their malignancy potential is discussed.

MATERIALS AND METHODS

Patients with gastric polypoid lesions detected by upper gastrointestinal endoscopy at the Institute of gastroenterology, Marmara University, between January 1998 and December 2002 were analyzed retrospectively. All gastroscopies were performed under sedation with intravenous midazolam and topical pharyngeal anesthesia with 10 % lidocaine. The location, shape, size, and surface appearance of each polypoid lesion were assessed. Polypoid lesions were totally removed either by endoscopic polypectomy with an attempt or by hot biopsy forceps with multiple attempts according to their size. In addition, multiple biopsies were collected from both antrum and incisura angularis for *Helicobacter pylori* (*H pylori*) urease test and from surrounding gastric mucosa to detect any associated histopathologic changes such as chronic gastritis, *H pylori* infection, or intestinal metaplasia. Endoscopic records were screened for any complication resulted from polypectomy.

An experienced pathologist (O. K-Y.) re-evaluated all the tissue samples to confirm the histopathologic subclassification of gastric polypoid lesions in our series according to the classification suggested by Oberhuber and Stolte[4].

RESULTS

Demographic features

One hundred and fifty gastric polypoid lesions were identified in 91 consecutive patients from 2 630 (3.4 %) upper GI endoscopies. There were 53 (58 %) women and 38 (42 %) men with slightly female predominance (1.4:1). The ages of patients ranged from 31 to 82 years with a median of 53.

Clinical features

The most frequent presenting symptom was dyspepsia (38.5 %) followed by epigastric pain (27.5 %), and anemia (11 %). Symptoms were usually related to the associated gastric abnormalities such as gastritis rather than polypoid lesion itself. Exceptionally, there was an antral hyperplastic polyp causing intermittent gastric outlet obstruction in one case in which the problem was solved with its removal by endoscopic polypectomy. The patient was symptom-free in the 8 months of follow-up.

Endoscopic features

Characteristics of the gastric polypoid lesions are shown in Table 1. Out of 150 gastric polypoid lesions, 61 (40.6 %) were located in the antrum followed by 40 (26.6 %) in cardia, 34 (22.6 %) in corpus, and 13 (8.6 %) in fundus. In two patients who had previously undergone partial gastrectomy, the lesions were detected around anastomoses (1.2 %). Only 7 out of 150 (4.6 %) lesions were pedunculated (Figure 1A), while the remainder was sessile.

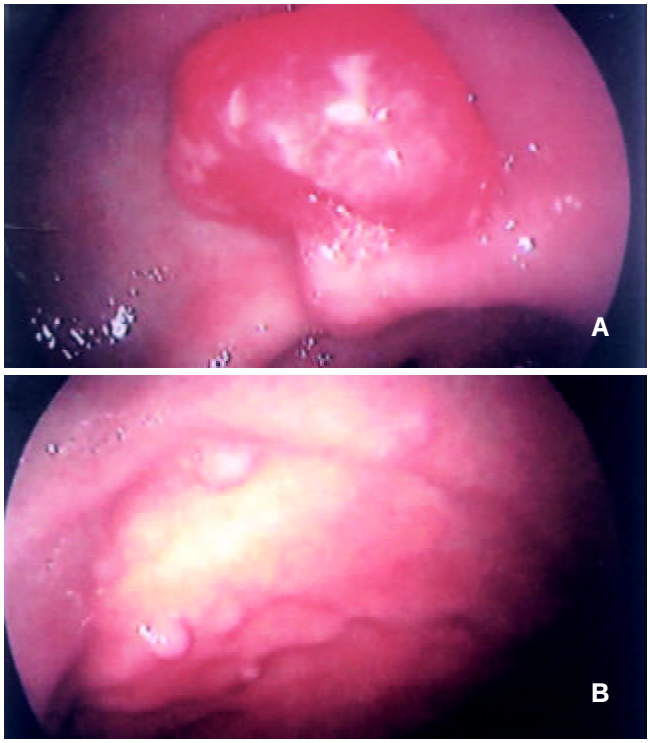

Figure 1 Endoscopic views of pedunculated gastric polyp (A) and multiple gastric polyps (B).

Eighty (53 %) gastric polypoid lesions with the largest dimensions less than or equal to 5 mm were totally removed by hot biopsy forceps. In the remainder, the largest dimension ranged from 6 to 30 mm and all lesions but one were excised by snare polypectomy. One lesion was initially evaluated by forceps biopsy because it was suspected to be a submucosal lesion. After a definite histopathologic diagnosis of carcinoid tumor was established in this patient, it was totally removed by snaring. Among 17 (11 %) polypoid lesions with surface erosion, 5 were larger than 10 mm. Multiple lesions were detected in 29 (32 %) patients (Figure 1B). No complication developed following the endoscopic procedure in any patient.

Table 1 Characteristics of gastric polypoid lesions

Characteristics	Number* (%)
Location	
Antrum	61 (40.7%)
Cardia	40 (26.7%)
Corpus	34 (22.7%)
Fundus	13 (8.7%)
Peri-anastomotic	2 (1.2%)
Shape	
Sessile	143 (95.3%)
Pedunculated	7 (4.7)
Size	
<5 mm	80 (53.4%)
5-10 mm	51 (34.0%)
10-20 mm	17 (11.4%)
20-30 mm	2 (1.2%)
Histologic subtypes	
Hyperplastic polyp	69 (46.0%)
Foveolar hyperplasia	27 (18.0%)
Fundic gland polyp	21 (14.0%)
Gastritis varioliformis	12 (8.0%)
Lymphoid follicles	9 (6.0%)
Adenoma	4 (2.7%)
Edematous mucosa	4 (2.7%)
Inflammatory polyp	3 (2.0%)
Carcinoid tumor	1 (0.6%)

*Number of lesions.

Histopathologic features of the lesions

The most frequently encountered histopathologic subtype of gastric polypoid lesions was hyperplastic polyp (Figure 2A) which was diagnosed in 46 % of the lesions, followed by foveolar hyperplasia (Figure 2B), fundic gland polyp (Figure 2C), and gastritis varioliformis (Table 2). Three of 43 patients with hyperplastic polyp had adenomas (Figure 2D) as well. Interestingly, the lesions ranging from 4 to 15 mm in diameter were observed as polypoid in 4 patients at endoscopy, but no pathologic changes except an edematous mucosa were determined in samples of endoscopic polypectomy. On the other hand, adenomatous changes were noted within two hyperplastic polyps. Out of 150 lesions, low grade dysplasia was found in one adenoma.

Table 2 Histopathologic features of surrounding gastric mucosa in patients with gastric polyp

Surrounding gastric mucosa	Type of Polyp			
	Hyperplastic	Fundic gland	Adenomatous	Inflammatory
Normal	10	3	1	-
Chronic gastritis	33	1	3	3
H pylori gastritis	19	1	1	1
Intestinal metaplasia	12	-	3	1

Evaluation of the surrounding gastric mucosa revealed that 72 (79 %) patients had chronic gastritis, 45 (49 %) associated *H pylori* infection, and 33 (36 %) intestinal metaplasia, while the remainder (21 %) had normal gastric mucosa (Table 2).

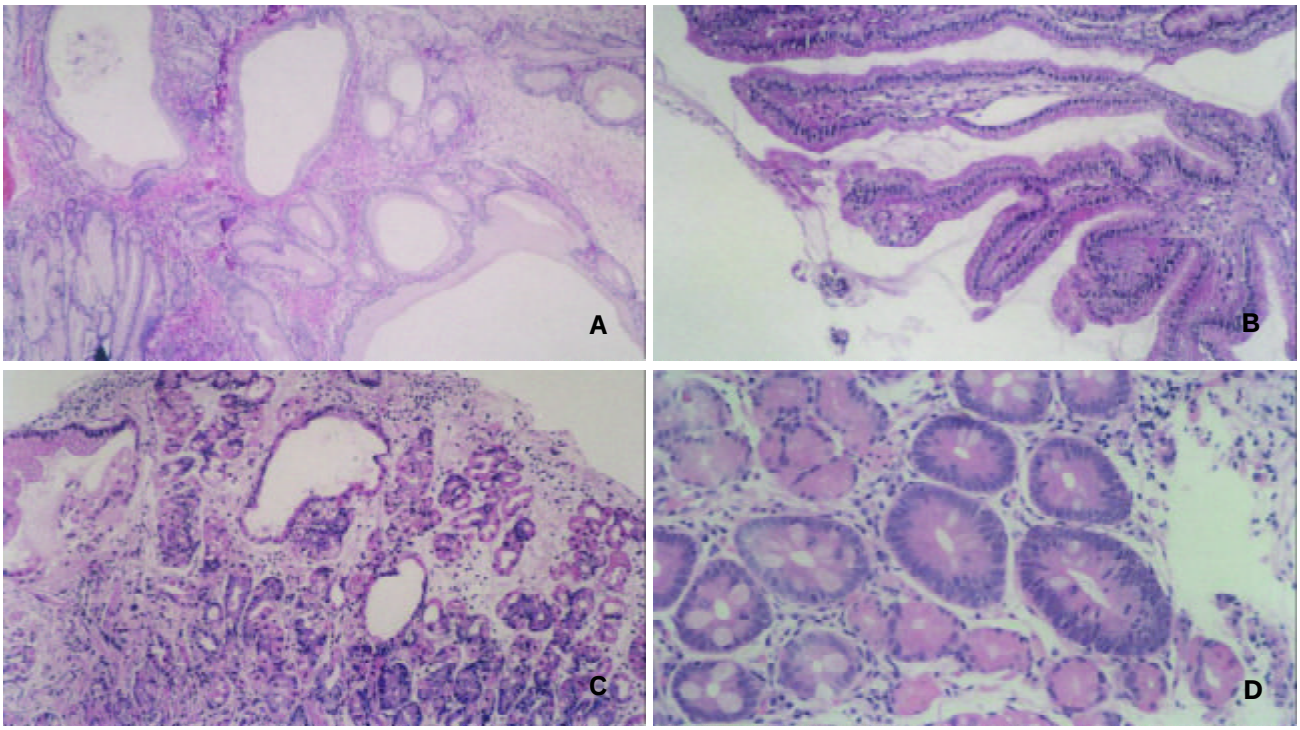

Figure 2 Microscopic pictures of gastric hyperplastic polyp, H&E, X40 (A), foveolar hyperplasia, H&E, X100 (B), fundic gland polyp, H&E, X100 (C), and tubular adenoma,H&E, X200 (D).

The average size of hyperplastic polyps was 8 mm in diameter. However, there was quite a large, hyperplastic polyp 30 mm in diameter, in one patient, and it caused gastric outlet obstruction by plugging the pyloric channel because of its antral location. They were preferentially located in the antrum (42 %) and out of 69 hyperplastic polyps, 5 (7 %) were pedunculated. Only fourteen patients (32 %) had multiple hyperplastic polyps, while all the fundic gland polyps were multiple. Coexistent gastric abnormalities such as chronic gastritis, *H pylori* infection, and intestinal metaplasia were determined in 33 (77 %), 19 (44 %), and 12 (28 %) patients, respectively.

DISCUSSION

The incidence of gastric polyps was 2 % in 2 630 patients who underwent upper GI endoscopic examination at our institution. Our rate was very similar to previously reported frequencies of 2-3 %[4]. However, the overall incidence of gastric polypoid lesions in our patient-population was 3.4 %. Gastric polyps were usually seen as small and sessile polypoid lesions at endoscopy in patients over 40 years old[6]. Although a vast majority of gastric polyps were asymptomatic, they might cause epigastric pain, gastrointestinal bleeding, and symptoms of gastric outlet obstruction[6-8]. The complication risk was generally related to polyp size. We detected only two polyps larger than 2 cm in diameter in our series. A relationship between the presenting symptom and the polyp itself was observed only in one lesion as detailed above. Our results support the fact that underlying gastric abnormalities are likely to be responsible factors for presenting symptoms in patients with gastric polyps.

While polypectomy was performed either endoscopically or surgically in the treatment of symptomatic gastric polyps, there were still no standardized guidelines concerning the management of asymptomatic ones[5,9]. Many endoscopists first took forceps biopsies from gastric polypoid lesions. After obtaining a definite histopathologic diagnosis, they performed polypectomy to these lesions[5]. However, forceps biopsies carried the risk of missing the neoplastic foci within polyp, since only a small portion of the lesion was sampled in this technique[10]. Seifert and Elster[11] compared histopathologic results of biopsy materials and polypectomy specimens of same lesions and showed a remarkable discrepancy between them in 70 % of cases. With this observation, the authors recommended to remove all gastric polyps larger than 5 mm in diameter by an experienced endoscopist[10,12]. In our study, all lesions except one, which was likely to be a submucosal lesion, were totally removed by either snare or hot biopsy forceps without any complication. Endoscopic polypectomy seems as a safe and fast procedure for both diagnosis and treatment of gastric polypoid lesions at the same session.

Some authors reported hyperplastic polyps or fundic gland polyps as the most frequently encountered subtypes of gastric polyps[13-16]. These lesions have previously been accepted as completely benign. However, some current studies showed that they might include adenomatous changes or dysplastic areas[4,7,13,17]. The reported frequencies of dysplastic foci within hyperplastic polyps showed a wide range (4-22 %)[18,19]. Hizawa[20] and Zea-Iriarte[21] found the incidence of malignancy in hyperplastic polyps was 2 % and 1.8 %, respectively. Since hyperplastic polyps were usually associated with chronic gastritis, particularly autoimmune gastritis and *H pylori* gastritis, patients with hyperplastic polyp had an increased risk of synchronous or metachronous adenocarcinomas elsewhere in the stomach[2,4,22]. In a series including 21 patients with hyperplastic polyps, chronic atrophic gastritis was found in all of them and *H pylori* gastritis in 16[16]. On the other hand, the rate of gastric cancer development in nonpolypoid mucosa was reported as 3.3 % in another study of 2 036 hyperplastic polyps[23]. In our series, the presence of chronic gastritis and *H pylori* gastritis was demonstrated in 76 % and in 45 % of hyperplastic polyps, respectively. In addition, two of 69 hyperplastic polyps contained adenomatous changes. These results support the suggestion of removing polypoid lesions instead of taking biopsy from them if feasible, when they are observed at endoscopy.

Gastric adenomas, similar to hyperplastic polyps, were usually detected in pathologically abnormal gastric mucosa

such as gastritis or intestinal metaplasia[13,16]. The malignant potential of gastric adenomas was related to their histologic features, size, shape, and surface appearance[24]. While malignancy risk of adenomas smaller than 2 cm in diameter ranged from 1 % to 5 %, it was higher than 50 % in larger ones[8]. The risk of gastric cancer in other parts of gastric mucosa in patients with adenoma varied between 8 % and 59 %[4]. Contrarily, fundic gland polyps were almost always associated with normal gastric mucosa and sometimes with long-term use of omeprazole[4,13]. They are divided into two different forms: sporadic form and syndromic form, which are associated with familial adenomatous polyposis (FAP) and attenuated variants. In a series including 319 fundic gland polyps from the John Hopkins Hospital, the FAP-associated polyps tended to include low grade dysplasia more than the sporadic ones (25 % *versus* 1 %)[25]. Furthermore, patients with fundic gland polyp might have an increased risk of harbouring a colorectal adenoma or carcinoma[4,23]. Nevertheless, prospective studies are necessary to ascertain whether fundic gland polyp is a sign for colorectal tumours or not. In our study, 75 % of patients with adenoma had chronic gastritis and intestinal metaplasia, whilst gastritis was detected solely in one patient with fundic gland polyps.

Foveolar hyperplasia was the second most common type of gastric polypoid lesions in our series. There is still a debate on whether foveolar hyperplasia is a precursor of hyperplastic polyps[4,23]. The most important distinction between the two lesions was based on the presence of neoplastic foci. Orlowska and associates[26] analyzed 751 hyperplastic lesions and did not find carcinoma in any of foveolar hyperplasia either by primer biopsy or at follow-up. It is wise to separate foveolar hyperplasia and hyperplastic polyp from each other as two distinct subtypes of foveolar hyperplastic lesions, since foveolar hyperplasia has no malignant potential.

We determined that four lesions with polypoid appearance at endoscopy were actually areas of edematous mucosa by histopathological examination. This observation showed that a lesion protruding into the gastric lumen might appear as polypoid lesion even it was not a true polyp. In order to prevent diagnostic confusion, the term "polyp" should be used after achieving exact histopathologic diagnosis as well-supported by the above instance.

In summary, hyperplastic polyp is the most frequently encountered subtype of gastric polypoid lesions. It is usually associated with chronic gastritis or *H pylori* gastritis. Hyperplastic polyps have been described as harmless lesions until recently. However, risk of their malignant transformation has been emphasized in the current literature. For this reason, endoscopic polypectomy seems to be a sensible diagnostic and therapeutic procedure of hyperplastic polyps when feasible. Finally, endoscopic surveillance in these patients may be recommended to exclude both possibility of recurrence and cancer development elsewhere in stomach.

Abstract

AIM: To clone flagellin genes A (*flaA*) and B (*flaB*) from a clinical strain of *Helicobacter pylori* (*H pylori*) and to construct prokaryotic expression systems of the genes and identify immunity of the fusion proteins.

METHODS: The *flaA* and *flaB* genes from a clinical *H pylori* isolate Y06 were amplified by high fidelity PCR. The nucleotide sequences of target DNA amplification fragments from the two genes were sequenced after T-A cloning. The recombinant expression vector *pET32a* inserted with *flaA* and *flaB* genes was constructed, respectively. The expressions of FlaA and FlaB fusion proteins in *E. coli* BL21DE3 induced by isopropylthio-β-D-galactoside (IPTG) at different concentrations were examined by SDS-PAGE. Western blot using commercial antibodies against whole cell of *H pylori* and immunodiffusion assay using self-prepared rabbit antiserum against FlaA (rFlaA) or FlaB (rFlaB) recombinant proteins were applied to the determination of the fusion proteins immunity. ELISA was used to detect the antibodies against rFlaA and rFlaB in sera of 125 *H pylori* infected patients and to examine rFlaA and rFlaB expression in 98 clinical isolates of *H pylori*, respectively.

RESULTS: In comparison with the reported corresponding sequences, the nucleotide sequence homologies of the cloned *flaA* and *flaB* genes were from 96.28-97.13 % and 96.31-97.73 %, and their putative amino acid sequence homologies were 99.61-99.80 % and 99.41-100 % for the two genes, respectively. The output of rFlaA and rFlaB expressed by *pET32a-flaA*-BL21DE3 and *pET32a-flaB*-BL21DE3 systems was as high as 40-50 % of the total bacterial proteins. Both rFlaA and rFlaB were able to combine with the commercial antibodies against whole cell of *H pylori* and to induce rabbits to produce specific antibodies with the same 1:2 immunodiffusion titers after the animals were immunized with the two recombinant proteins. Ninety-eight and zero point 4 and 92.80 % of the serum samples from 125 patients infected with *H pylori* were positive for rFlaA and rFlaB antibodies, respectively. One hundred percent and 98.98 % of the 98 tested isolates of *H pylori* were detectable for rFlaA and rFlaB epitopes, respectively.

CONCLUSION: Two prokaryotic expression systems with high efficiency of *H pylori flaA* and *flaB* genes were successfully established. The expressed rFlaA and rFlaB showed satisfactory immunoreactivity and antigenicity. High frequencies of FlaA and FlaB expression in different *H pylori* clinical strains and the general existence of specific antibodies against FlaA and FlaB in *H pylori* infected patients strongly indicate that FlaA and FlaB are excellent antigen candidates for developing *H pylori* vaccine.

INTRODUCTION

In China, chronic gastritis and peptic ulceration are two most common gastric diseases, and gastric cancer is one of the malignant tumors with high mortalities and morbidities[1-34]. *Helicobacter pylori* (*H pylori*), a microaerophilic, spiral and Gram-negative bacterium, is considered as a human-specific gastric pathogen that colonizes the stomach of at least half of the world population[35]. Most infected individuals are asymptomatic. However, in some subjects, the infection causes acute, chronic gastritis and peptic ulceration, and plays important roles in the development of peptic ulcer and gastric adenocarcinoma, mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin' s lymphoma[36-43]. This microorganism has been categorized as class I carcinogen by the World Health Organization[44], and direct evidence of carcinogenesis has been recently demonstrated in animal models[45, 46]. Immunization against the bacterium represents a cost-effective strategy to prevent *H pylori*-associated peptic ulcer diseases and to reduce the incidence of global gastric cancer[47]. Selection of antigenic targets is critical in design of *H pylori* vaccine. So far, no vaccine preventing *H pylori* infection has been commercially available. The majority of studies attempting to produce a vaccine have focused on urease enzyme, heat shock protein, and vacuolating cytotoxin[35, 48-50], but rarely on *H pylori* flagellin. *H pylori* flagellin is composed of two subunits, named as FlaA with 53KDa and FlaB with 54 KDa respectively. The flagellin plays a main role in motility and is necessary for colonization or persistence of *H pylori* infection[51]. The motility of *H pylori* is a virulent factor in the pathogenesis of gastric mucosal injury[52]. The data mentioned

above indicate that FlaA as well as FlaB may be used as antigen candidates for *H pylori* vaccine. Therefore, in this study, two prokaryotic vectors responsible for expressing recombinant FlaA (rFlaA) and FlaB (rFlaB) were constructed. Immunoreactivity and antigenicity of rFlaA and rFlaB were further examined. Furthermore, these two recombinant proteins were used for detecting specific antibodies in sera from *H pylori* infected patients, and rabbit anti-rFlaA and anti-rFlaB sera were prepared for examining the corresponding epitopes of *H pylori* clinical isolates. The results of this study may contribute to the development of *H pylori* vaccines.

MATERIALS AND METHODS

Materials

A clinical strain of *H pylori* was used in this study, which was provisionally named Y06, and well-characterized by the Department of Medical Microbiology and Parasitology, College of Medical Sciences, Zhejing University. A plasmid *pET32a* (Novagen) and an *E. coli* strain BL21DE3 (Novagen) were used as the expression vector and host cell, respectively. Primers for PCR amplification, the Pfu-Taq high fidelity PCR kit and restriction endonucleases were purchased from BioAsia (Shanghai, China). The T-A cloning kit and sequencing service were provided by BBST (Shanghai, China). Rabbit antiserum against the whole cell of *H pylori*, HRP-labeling sheep antisera against rabbit IgG and against human IgG were purchased from DAKO and Jackson ImmunoResearch, respectively. Agents used in isolation and identification of *H pylori* were purchased from Sigma and bioMérieux. Gastric biopsy specimens with positive *H pylori* isolation from 126 patients (86 males and 40 females, age range: from 6-78 years old, mean age: 40.5 years old) referred for gastroduodenoscopic examination in four different hospitals in Hangzhou were collected during the period between December 2001 and June 2002. Each of the patients gave a written informed content for this study. Of the 126 patients, 68 had chronic gastritis (CG, 48 superficial, 10 active and 10 atrophic), and the other 58 had peptic ulcer disease (PUD, 12 gastric ulcer, 40 duodenal ulcer and 6 gastric and duodenal ulcer). None of the patients had taken nonsteroidal anti-inflammatory drugs, antacids and antibiotics during the two weeks before seeking medical advice. At the same time, serum specimens were also collected from these patients.

Methods

Isolation and identification of *H pylori* Each gastric biopsy specimen was homogenized with a tissue grinder and then inoculated on Columbia agar plates supplemented with 8.0 % (V/V) sheep blood, 0.5 % (W/V) cyclodextrin, 5 mg/L trimethoprim, 10 mg/L vancomycin, 2 500 U/L cefsoludin and 2.5 mg/L amphotericin B. The plates were incubated at 37 ℃ under microaerobic conditions (5 % O_2, 10 % CO_2 and 85 % N_2) for 3 to 5 days. A bacterial isolate was identified as *H pylori* according to typical Gram staining morphology, biochemical tests positive for urease and oxidase, and agglutination with the commercial rabbit antibody against whole cell of the microbe. All of *H pylori* isolates were stored at -70 ℃ for ELISA.

Preparation of DNA template Genomic DNA of *H pylori* strain Y06 was extracted by the conventional phenol-chloroform method and DNase-free RNase treatment[52]. The obtained DNA was dissolved in TE buffer, and its concentration and purity were determined by ultraviolet spectrophotometry[52].

Polymerase chain reaction Oligonucleotide primers were designed to amplify the whole sequence of *flaA* and *flaB* genes from *H pylori* strain Y06 based on the published corresponding genomic sequences[53-56]. The sequence of *flaA* sense primer with an endonuclease site of *Eco*RV was 5' -CCG GATATCATGGCTTTTCAGGTCAA-3' . The sequence of *flaA* antisense primer with an endonuclease site of *Xho*I was 5' -CCGCTCGAGAAACTAAGTTAAAAGCC-3' . The sequence of *flaB* sense primer with an endonuclease site of *Eco*RI was 5' -CCGGAATTCATGAGTTTTAGGATAAA-3' . The sequence of *flaB* antisense primer with an endonuclease site of *Xho*I was 5' -CCGCTCGAGCTGTTATTGTAAAA GCC-3' . The total volume per PCR was 100 μl containing 2.5 mol· L^{-1} each dNTP, 500 nmol· L^{-1} each of the two primers, 15 mol· L^{-1} $MgCl_2$, 3.0 U Pfu-Taq polymerase, 100 ng DNA template and 1×PCR buffer (pH8.8). The parameters for PCR were at 94 ℃ for 5 min, ×1; at 94 ℃ for 30 s, at 52 ℃ for 30 s, at 72 ℃ for 90 s, ×10; at 94 ℃ for 30 s, at 52 ℃ for 30 s, at 72 ℃ for 100 s (10 s addition for the each of the following cycles), ×15; then at 72 ℃ for 10 min, ×1. The results of PCR were observed under UV light after electrophoresis in 15 g· L^{-1} agarose pre-stained with ethidium bromide. The expected sizes of target amplification fragments were 1 530 bp for *flaA* gene and 1 542 bp for *flaB* gene.

Cloning and sequencing The target amplification DNA fragments from *flaA* and *flaB* genes were respectively cloned into *pUCm*-T vectors (*pUCm*-T-*flaA* and *pUCm*-T-*flaB*) by using the T-A cloning kit according to the manufacturer' s instructions. The recombinant plasmids were amplified in an *E. coli* strain DH5α and then extracted by the Sambrook' s method[57]. A professional company (BBST) was responsible for nucleotide sequence analysis of the inserted fragments. Three strains of *E. coli* DH5α containing *pUCm*-T-*flaA*, *pUCm*-T-*flaB* and expression vector *pET32a* were amplified in BL medium, and the three plasmids were extracted, respectively[57]. These plasmids were digested with *Eco*RV and *Xho*I, *Eco*RI and *Xho*I, respectively. The *flaA* target fragment and *pET32a*, and the *flaB* fragment and *pET32a* were recovered and then ligased. The recombinant expression vectors *pET32a-flaA* and *pET32a-flaB* were respectively transformed into *E.coli* BL21DE3, and the expression systems were named as *pET32a-flaA*-BL21DE3 and pET32a-*flaB*-BL21DE3. The target fragments of *flaA* and *flaB* genes inserted in *pET32a* plasmid were sequenced again.

Expression and identification of fusion proteins *pET32a-flaA*-BL21DE3 and *pET32a-flaB*-BL21DE3 were rotatively cultured in LB medium at 37 ℃ induced by isopropylthio-β-D-galactoside (IPTG) at different concentrations of 1.0, 0.5 and 0.1 mmol· L^{-1}. The supernatant and precipitate were separated through centrifugation after the bacterial pallet was ultrasonically broken (300V, 5 s×3). The molecular weight and output of rFlaA and rFlaB were examined by SDS-PAGE. The two recombinant proteins were collected by Ni-NTA affinity chromatography. The commercial rabbit antiserum against whole cell of *H pylori* and HRP-labeling sheep antiserum against rabbit IgG were used as the first and second antibodies to determine the immunoreactivity of rFlaA and rFlaB by Western blot. Rabbits were immunized with rFlaA and rFlaB, respectively, for preparation of antisera. Immunodiffusion assay was applied to the determination of the antigenicity of rFlaA and rFlaB.

ELISA The specific antibodies against FlaA and FlaB in sera of the 126 patients infected with *H pylori* were detected by ELISA, by using rFlaA and rFlaB as antigens at the coated concentration of 20 μg/ml and a patient serum sample (1:400 dilution) as the first antibody and HRP-labeling sheep antibody against human IgG (1:4 000 dilution) as the second antibody. The result of ELISA for a patient' s serum sample was considered as positive if the optical density at 490 nm (OD_{490}) was over the mean plus 3 SD of five negative serum samples[58]. FlaA and FlaB expression in clinical isolates of *H pylori* was detected by ELISA using the ultrasonic supernatant of each *H pylori*

isolate (50 μg/ml) as a coated antigen, the self-prepared rabbit antisera against rFlaA and rFlaB (1:800 dilution in both) as the first antibody and HRP-labeling sheep antibody against rabbit IgG (1:3 000 dilution) as the second antibody. The result of ELISA for a *H pylori* ultrasonic supernatant sample was considered as positive if its OD_{490} value was over the mean plus 3 SD of five ultrasonic supernatant samples at the same protein concentration of *E. coli* ATCC 25922[58].

Date analysis The nucleotide sequences of the cloned *flaA* and *flaB* genes were compared for homology with the 3 published *flaA* gene sequences (NC000915, NC000921, X60746)[53-55] and the 4 published *flaB* gene sequences (NC000915, NC000921, L08907, AF479024)[53,54,56,59] by using a molecular biological analysis software.

RESULTS

PCR

Target fragments of *flaA* and *flaB* genes with expected sizes amplified from DNA template of *H pylori* stain Y06 are shown in Figure 1.

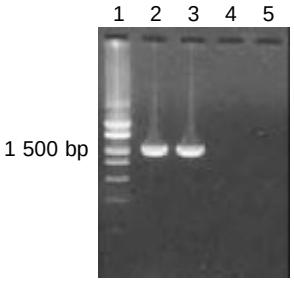

Figure 1 Target fragments of *flaA* and *flaB* genes amplified from *H pylori* strain Y06 DNA.

Nucleotide sequence analysis

The nucleotide sequences of *flaA* gene in *pUCm*-T-*flaA* and *pET32a-flaA* were completely the same and so as for *flaB* gene. The homologies of nucleotide and putative amino acid sequences of the cloned *flaA* gene compared with the published *flaA* sequences[53-55] were from 96.28 % to 97.13 % and from 99.61 % to 99.80 %, respectively (Figures 2 and 3). The homologies of nucleotide and putative amino acid sequences of the cloned *flaB* gene were 96.31-97.73 % and 99.41-100 %, compared with the published *flaB* sequences (Figures 4 and 5)[53,54,56,59].

Expression of target fusion proteins

IPTG at concentrations of 1.0, 0.5 and 0.1 mmol· L^{-1} efficiently induced the expression of rFlaA and rFlaB in *pET32a-flaA*-BL21DE3 and *pET32a-flaB*-BL21DE3 systems. The products of rFlaA and rFlaB were mainly presented in ultrasonic precipitates, and the output was 40-50 % of the total bacterial proteins (Figures 6 and 7).

Immunoreactivity and antigenicity of rFlaA and rFlaB

The commercial rabbit antibodies against the whole cell of *H pylori* combined with rFlaA and rFlaB as confirmed by Western blot (Figures 8 and 9). Both the titer of immunodiffusion assay between rFlaA and its rabbit antiserum, rFlaB and its rabbit antiserum was 1:2.

ELISA

Since the mean ±SD of OD_{490} values of the five negative serum samples were 0.338±0.036 for rFlaA and 0.102±0.051 for rFlaB in the detection of specific antibodies in patients' sera, the positive reference value was 0.446 for FlaA and 0.255 for FlaB. According to the reference values, 98.4 % (123/125, one serum sample was contaminated) of the tested patients' serum samples were positive for antibodies against rFlaA with an OD_{490} value range of 0.52-1.76, and 92.8 % (116/125) were positive for antibodies against rFlaB with an OD_{490} value range of 0.26-1.50. Since the mean ±SD of OD_{490} of the five negative bacterial controls was 0.200±0.046 for FlaA and 0.170±0.044 for FlaB in the detection of clinical *H pylori* isolates, the positive reference value was 0.338 for FlaA and 0.302 for FlaB. According to the reference values, 100 % (98/98) of the tested *H pylori* isolates were detectable for the epitope of rFlaA with an OD_{490} value range of 0.36-2.01 and 99 % (97/98) of the isolates were detectable for the epitope of rFlaB with an OD_{490} value range of 0.31-1.78.

Figure 5 Homologies of putative amino acid sequences of *H pylori flaB* gene with reported sequences. (1): the sequencing result of *H pylori* strain Y06 *flaB* gene; (2)-(5): the reported sequences from GenBank (No. NC000915, strain 26695; No. NC_000921, strain J99; No. L08907, strain 85P; No. AF479024, strain CH-CTX1).

DISCUSSION

In the present study, *H pylori flaA* and *flaB* genes were detected in genomic DNA of almost all *H pylori* isolates, and their nucleotide and amino acid sequences were considerably conserved[53,54]. The FlaA and FlaB expressed by *H pylori* rendered the organism strong motility in mucous environment, induced IL-8 secretion and facilitated inflammation in gastric tissue[51,52]. Furthermore, we observed that serum antibodies against FlaA and FlaB were present in approximate 98.4 % and 92.8 % of *H pylori* infected patients, respectively, the rates were significantly higher than those of heat shock protein (68 %) and vacuolating cytotoxin (68 %)[60]. These data indicate that *flaA* and *flaB* genes express their products in majority of *H pylori* strains and efficiently induce specific antibodies, implying a brilliant potential for developing *H pylori* vaccine.

The *flaA* gene from *H pylori* strain Y06, cloned in this study, showed high homologies of nucleotide and putative amino acid sequences compared with the published corresponding sequences (Figures 2 and 3)[53-55]. Similarly, the homologies of nucleotide and putative amino acid sequences of the cloned *flaB* gene from *H pylori* strain Y06 were quite high when compared with the published corresponding sequences (Figures 4 and 5)[53,54,56-59]. The high conservation of nucleotide and putative amino acid sequences found in the cloned *flaA* and *flaB* genes were probably due to their expression products just as the structural peptides of *H pylori*.

In the present study, SDS-PAGE demonstrated that the constructed expression systems *pET32a-flaA*-BL21DE3 and *pET32a-flaB*-BL21DE3 were able to efficiently produce the target recombinant proteins. However, rFlaA and rFlaB were mainly presented with the form of inclusion body even if they were induced by IPTG at a lower concentration. The high output of rFlaA and rFlaB (40-50 %) was beneficial to the production of a possible *H pylori* vaccine.

The rabbit antiserum against the whole cell of *H pylori* recognizes and combined with rFlaA and rFlaB as confirmed by Western blot, indicated that the two recombinant proteins had a relatively high immunoreactivity. The immunodiffusion assay performed in this study demonstrated that rFlaA and rFlaB could efficiently induce rabbit to produce specific antibodies with a higher titer, which indicated that these two recombinant proteins exhibited favorable antigenicity.

All tested *H pylori* isolates (98/98) expressed FlaA while 99.0 % (97/98) of the tested isolates expressed FlaB, as detected by ELISA. Of the *H pylori* infected patients, 98.4 % (123/125) and 92.8 % (116/125) were seropositive for the specific antibodies against rFlaA and against rFlaB, respectively. The universal existence of FlaA and FlaB in *H pylori* strains and the efficient induction of specific antibodies against FlaA and FlaB in patients were the strong favorable evidences for using these two recombinant proteins as the potential antigens in the development of *H pylori* vaccine.

In conclusion, FlaA and FlaB are excellent and ideal antigens that can be potentially used for the development of *H pylori* vaccine, and the expression systems of FlaA and FlaB with a high efficiency has been successfully constructed.

ACKNOWLEDGEMENTS

We are grateful to the four hospitals in Hangzhou that provided gastric biopsies in this study, which help us to complete the research subject.

Abstract

AIM: To construct a *vacA*-knockout *Helicobacter pylori* mutant strain, whose only difference from the wild strain is its disrupted *vacA* gene.

METHODS AND RESULTS: A clone containing kanamycin resistance gene used for homologous recombination was constructed in a directional cloning procedure into pBluescript II SK, and then transformed into *vacA*$^+$ *H pylori* by electroporation. Colonies growing on the selective media containing kanamycin were harvested for chromosomal DNA extraction, and the allelic exchange was determined by polymerase chain reactions and sequencing. Loss of vacuolating activity of the *vacA*-knockout strain was confirmed by examining the gastric cells co-cultured with cell-free supernatants from *H pylori* wild strain or the mutant.

CONCLUSION: We constructed a *vacA*-knockout strain of *H pylori* through direct mutagenesis, which creates an important precondition for the future research on virulence comparison with gene expression analysis.

INTRODUCTION

Helicobacter pylori (*H pylori*) is a Gram-negative bacterium that colonizes the gastric mucosa of humans[1], and plays an important role in pathogenesis of chronic gastritis, peptic ulcers, gastric adenocarcinomas, and gastric mucosa-associated lymphoid tissue lymphomas[2-6]. Leunk *et al* first reported in 1988 that cell-free supernatants from *H pylori* broth cultures induced striking vacuolar degeneration when added to cultured eukaryotic cells[7]. Subsequently in 1992, this effect was disclosed to be caused by a secreted toxin VacA[8].

The gene encoding the vacuolating cytotoxin has been cloned from an *H pylori* isolate, and termed *vacA*[9]. Analysis of the nucleotide sequence of the *vacA* open reading frame (ORF) suggested that *vacA* encoded a 139-kDa protoxin that has three functional domains: a 33-amino-acid N-terminal signal sequence, a mature cytotoxin domain (approximately 87kDa), and a cleaved C-terminal domain (approximately 50kDa)[10,11]. VacA could induce vacuole formation from the cell cytosol, as determined by transfection of epithelial cells with a plasmid encoding the complete 95-kDa domain of VacA[12]. These vacuoles are acidic, and their membrane contains the vacuolar ATPase proton pump and the small GTP-binding protein rab7. Therefore, they have been suggested to arise from late compartments of the endocytic pathway[13].

Over the past decade, there has been considerable effort directing toward understanding the molecular mechanisms underlying VacA action. But till now, little is known about the mechanisms of vacuole formation and other effects of VacA. In this study, using the technique of direct mutagenesis to disrupt *vacA* gene, we constructed a *vacA*-knockout *H pylori* mutant strain for the further research on virulence comparison between the *H pylori* wild strain and the mutant.

MATERIALS AND METHODS

Bacterial strain and growth conditions

H pylori NCTC 11638 as a gift from Dr. Tong Shi (Shanghai Institute of Digestive Diseases) was cultured routinely on brain heart infusion (BHI) agar plates with 5 % sheep blood in an environment containing 6 % CO_2 at 37 ℃. For the preparation of cell-free supernatants from *H pylori* broth cultures, *H pylori* was cultured in BHI broth+10 % fetal bovine serum (FBS) in an environment containing 6 % CO_2 at 37 ℃ with agitation (200 rpm) for 48 h. The cultures were centrifuged (15 000 g, 30 min, 4 ℃) and filtrated with a 0.2 μm syringe filter.

Disruption of vacA gene

The strategy for disruption of *vacA* gene by direct mutagenesis is shown in Figure 1, and genetic techniques involved were described as follows.

DNA isolation To isolate chromosomal DNA, *H pylori* cells were lysed in lysis buffer (10 mM Tris· HCl, pH 8.0, 0.1 M EDTA, pH 8.0, 0.5 % (w/v) SDS, 20 μg/ml DNase free pancreatic RNase), and then, protease K (Sangon, Shanghai, China) was added in to a final concentration of 100 μg/ml. The lysate was incubated in a water bath at 50 ℃ for 3 h. Then, the solution was cooled to room temperature, and mixed with an equal volume of phenol equilibrated with 0.1 M Tris· HCl (pH 8.0). The two phases were separated by centrifugation at 5 000 g for 15 min at room temperature, and the aqueous phase was extracted with phenol twice again. Afterwards, 0.2 volume of 10 M ammonium acetate and 2 volume of ethanol were added to the aqueous phase. The precipitate was collected by centrifugation at 5 000 g for 2 min, washed twice with 70 % ethanol, and dissolved in an appropriate volume of TE buffer (pH8.0)[14].

Polymerase chain reactions (PCR) PCR was carried out in 100 μl volume containing 100 ng of genomic DNA, 1 U of Ex Taq (Takara), 50 pmol of each primer, and 10 nmol of each deoxynucleoside triphosphate in a standard buffer. Oligonucleotide primers (5'-CGTGGAAATCTTATTACT CTTAGC-3' and 5'-TGATGCTGACTAATGCTCCT-3')

were used to amplify a 1.7 kb product from *H pylori* NCTC 11 638. Primers for amplifying kanamycin resistance gene (*kanR*) and two fragments flanking *kanR*, *LA* and *RA*, were designed as shown in Table 1.

Gel purification and enzyme digestion PCR products were electrophoresed and excised from a 1 % agarose gel, purified using a Qiaquick gel extraction kit (Qiagen, Hilden, Germany), and digested with corresponding restriction enzymes (Promega, Madison, USA) depending on different restriction sites.

Cloning of different DNA fragments Purified PCR products for sequencing were cloned into *pGEM-T* vector (Promega). Fragments *kanR*, *LA*, and *RA* with different restriction sites on both sides were digested with corresponding endonucleases (Promega), and then cloned into *pBluescript SK* II digested with the same enzymes.

Sequencing Every clone was sequenced with the ABI DNA sequencer (Bioasia Biotechnology Company, Shanghai, China).

***H pylori* DNA transformation by electroporation** *H pylori* NCTC 11 638 cells were transformed with plasmid *pLKR* by electroporation, and kanamycin-resistant (*Km*^{r}) transformants were selected by a method similar to that described by Clayton *et al*[15]. Briefly, *H pylori* cultured on plates were scraped and suspended in 30 ml cold double-distilled water. Cells were harvested by centrifugation at 4 360 g at 4 ℃ for 5 min, and the pellet was suspended in 20 ml of cold 10 % glycerol. The cells were centrifuged once, and resuspended in 2 ml ice-cold 10 % glycerol. Plasmid DNA (1 μg in 5 μl TE buffer) was mixed with 0.2 ml cell suspension. The mixture was added to a prechilled (-20 ℃) 0.2 cm electroporation cuvet (Bio-Rad, Hercules, USA), and subjected to single-pulse electroporation of initial voltage 2.5 kV, 25 μF and 600Ω in parallel. The sample was transferred onto a cold plate and incubated for 12 h at 37 ℃. Then the cells were inoculated onto selective media with 30 μg/mL kanamycin, followed by incubation for 4 d to allow the growth of transformants.

Cell culture and detection of vacuole formation

Cells of gastric cancer cell line SGC7901 as a gift from Jie Yang (Department of Cell Biology, Shanghai Second Medical University) were grown in DMEM (GIBCO-BRL, Gaithersburg, USA) supplemented with 10 % FBS, 2 mmol/L glutamine, 100 U/mL penicillin, and 100 μg/mL streptomycin in a humidified 5 % CO_2 atmosphere. SGC7901 cells were co-cultured with cell-free supernatants from *H pylori* NCTC11638 wild strain or mutant strain for 12 h, and then observed by contrast microscopy.

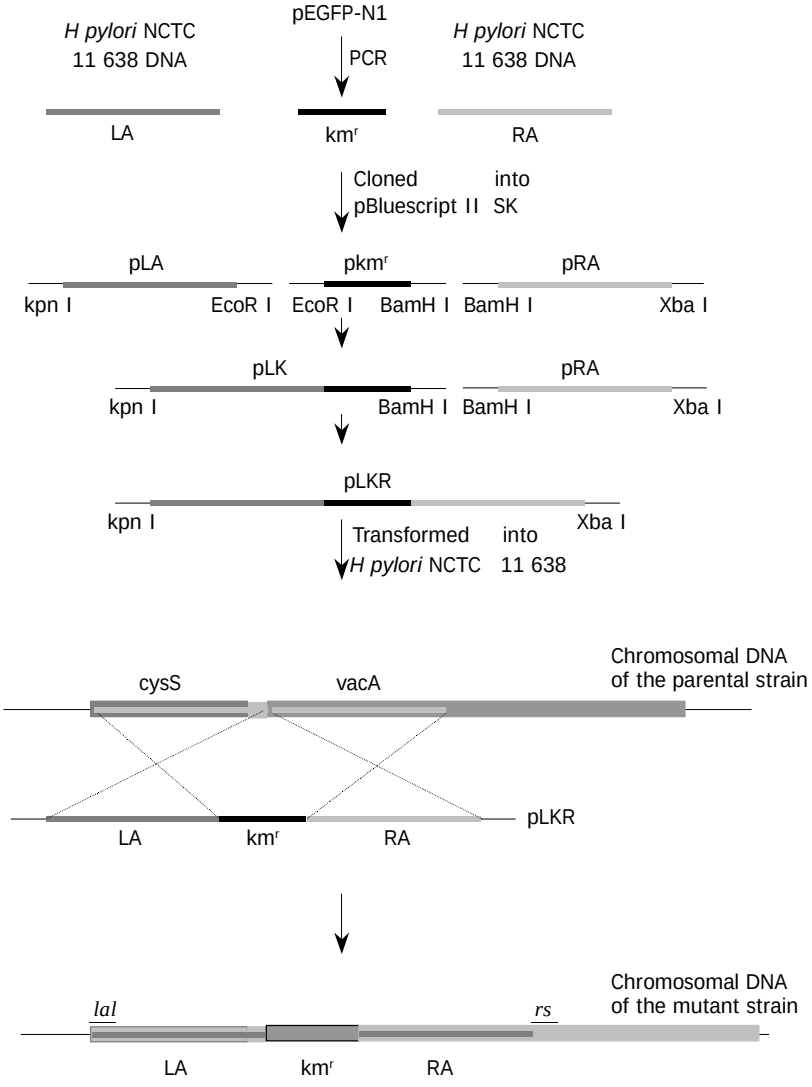

Figure 1 The strategy for disruption of *vacA* gene by directed mutagenesis. LA and RA were PCR-amplified from *H pylori* NCTC 11638 genomic DNA, and the kanamycin resistance gene, from pEGFP-N1. PCR products with different restriction sites on both sides were digested with corresponding endonucleases, and then cloned into pBluescript II SK digested with the same enzymes. Because there is an *EcoR* II site in RA, *pLA* and *pkm*^{r} were firstly joined together, resulting in *pLK*, which then was joined with *pRA*, resulting in *pLKR*. The plasmid *pLKR* was transformed into *H. pyloi* NCTC 11638, where the *Km*^{r} marked mutation was introduced into the genome by homologous recombination, resulting in the *vacA*$^-$Km^r mutant strain.

Figure 2 Nucleotide sequence of cysS gene and the downstream sequence amplified from the *vacA*$^{-}$*Km*^{r} mutant *H pylori*. The 1 398 bp *cysS* ORF and the 795 bp *km*^{r} ORF are shown. Primers *la1*, *la2*, *ra1*, *ra2*, and *rs* for amplifying LA, RA, and ASm are indicated. -35 signal, -10 signal, and rbs of *vacA* gene serving km^{r} gene in the mutant strain are also shown.

RESULTS

Upstream sequence close to vacA *gene*

Genome of NCTC 11638 was not completely sequenced, and the upstream portion close to *vacA* gene going to be used in the mutagenesis technique was not published in GeneBank. Therefore, the upstream sequences close to *vacA* gene of 26695 and J99, whose genomes were completely sequenced and published, were aligned and searched for conservative sequences. Then a 1.7-kb product was PCR-amplified from *H pylori* NCTC11638 DNA and sequenced. The sequencing result showed the complete *cysS* (cysteinyl-tRNA synthetase) gene of NCTC 11638 (Figure 2).

Cloning of pLKR for transforming H pylori

As shown in Figure 1, LA which contains the *H pylori vacA* promoter and RA were amplified from genomic DNA of NCTC11638, while *kanR* gene which has no promoter was amplified from the plasmid *pEGFP-N1* (Clontech, Palo Alto, USA). PCR-products LA, *kanR* and RA, with restriction sites incorporated at the termini, were joined together in a directional cloning procedure into *pBluescript* II *SK*, resulting in *pLKR*.

Construction of vacA-knockout H pylori mutant strain

pLKR which is unable to replicate in *H pylori*, was introduced into *H pylori* NCTC11638 by electroporation. After 4 d of growth, five Km^r single colonies were isolated. To determine whether *vacA* had been disrupted in the transformed strains through allelic exchange, DNA isolated from *H pylori* NCTC11638 wild-type strain and the Km^r mutant strain were PCR-amplified with the primers *la1* and *rs* (5' -GCGCTTGATC CTGCCAAAGCATAGC-3') annealing to *H pylori* NCTC 11638 *vacA* at bp 1808 to 1832 flanking *ra2* (Figures 1 and 2). A 3.8-kb product consistent with the expected size was PCR-amplified from Km^r mutant strain, as compared with a 3.0-kb product amplified from wild strain (Figure 3), suggesting a substitution of Km^r gene for a short fragment of *vacA* gene by homologous recombination between plasmid and chromosomal sequences. The sequencing result of the 3.8-kb product confirmed the occurrence of allelic exchange (Figure 2).

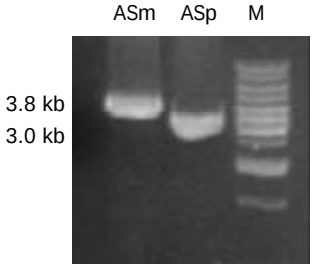

Figure 3 PCR amplification for the determination of homologous recombination in Km^r mutant strain. Genomic DNA of NCTC 11638 wild strain and Km^r mutant strain were respectively PCR-amplified for the fragments ASm and ASp using the primers *ra1* and *rs*. A single 3.8 kb product ASm was amplified from Km^r mutant strain as compared with the 3.0 kb product ASp amplified from the wild strain.

Characterization of vacA-knockout H pylori mutant

To determine the loss of vacuolating activity of the mutant strain, gastric cells SGC7901 were co-cultured with cell-free supernatants from *H pylori* NCTC11638 wild strain or mutant strain for 12 h, and then observed by contrast microscopy. Intracellular vacuoles developed in cells co-cultured with supernatant from the wild strain, while no vacuoles developed in cells co-cultured with supernatant from $vacA^-Km^r$ mutant strain (Figure 4).

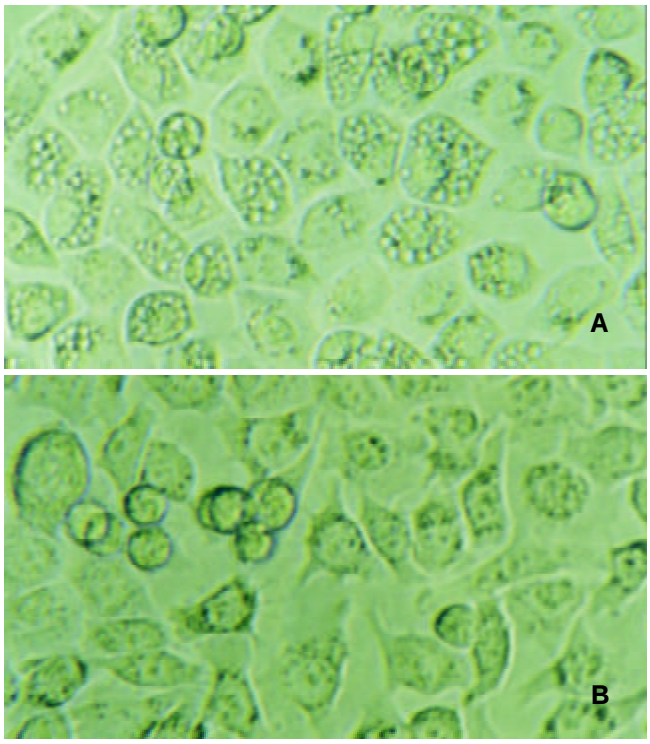

Figure 4 Gastric cancer cells SGC-7901 were co-cultured with the supernatant either from *Helicobacter pylori* NCTC 11638 or its *vacA*-knockout mutant strain. 12 h after the incubation, A: cells co-cultured with NCTC 11638 developed vacuoles in the cytosol; B: cells co-cultured with $vacA^-$ mutant strain developed no vacuoles at all.

DISCUSSION

VacA, produced by pathogenic strains of *H pylori*, was a major virulence factor in pathogenesis of gastroduodenal ulcers[8,16]. VacA induced the formation of membrane-delimited vacuoles in intoxicated cells[7], and showed many other effects on cellular functions and viability, such as causing mitochondrial depolarization[17], inducing apoptosis in gastric cells[18], affecting or interacting with various components of cytoskeleton to cause actin rearrangements[19], and even disorganizing microtubular network[20]. To study VacA machanism of action, we have tried to get purified VacA used as single virulence determinant, to study its effect on the expression profile of eukaryocyte. However, like Manetti *et al*[21], we did not successfully get the expressed VacA as a functional recombinant protein in *E. coli*, probably due to its incorrect fold. We have also considered letting VacA directly expressed in the cytosol to induce vacuole formation. In our experiments, vacuoles were induced in only 10 % of cells transfected with plasmids expressing VacA, because the efficiency of the transfection method was relatively low. In addition, when VacA acts outside the cells, the pathway by which it interacts with the cells is quite different from that when the protein is produced in the cytosol. Under natural conditions, association of VacA with the eukaryotic cell surface was the first step in the intoxication of cells[22]. The initial interaction of VacA with target cells was through high-affinity cell surface receptors, and this interaction was necessary for its biologic activity[23,24]. A 250 kDa receptor protein tyrosine phosphatase (RPTP) β served as a receptor for VacA on AZ521 cells, and another protein, p140, was also commonly detected in VacA-susceptible cells[25,26]. Increased binding of acid- or alkali-activated VacA to RPTPβ may alter its activity and possibly accelerates or inhibits dephosphorylation of tyrosine on cytosolic proteins. Moreover, VacA acting outside the cells

is a kind of exogenous antigen, having different pathways of processing and presentation from that of VacA expressed in the cytosol as an endogenous antigen. All of these processes may affect gene expression of the host cells.

Direct mutagenesis was probably the most useful technique for assessing the contribution to virulence of specific bacterial gene products[27]. In our study, *vacA* gene encoding vacuolating cytotoxin that has been identified by conventional biochemical means was disrupted by gene replacement. This technique requires a means for introducing DNA into the pathogen, as well as suitable selective markers and an inherent capacity for homologous recombination. In previous studies, the Km^r determinant often came from *Campylobacter coli*[28]. Here we introduced a simple method to get the Km^r gene from commercialized plasmids such as *pEGFP-N1*. Coding sequence of the gene without a promotor was PCR-amplified from *pEGFP-N1* and ligated downstream with the promotor of *H pylori vacA* gene. Upon insertion into chromosomal DNA of *H pylori* through homologous recombination, this gene could be efficiently transcribed because the *vacA* promoter was recognized by *H pylori* transcriptional machinery, introducing kanamycin resistance characteristics into *H pylori*. Due to the stop coden of Km^r, *vacA* would not be translated at all although most of the sequences still existed. The results of PCR and sequencing confirmed the occurrence of allelic exchange. Therefore, using the direct mutagenesis technique, we obtained the isogenic mutant strain of *H pylori*, which differed from the wild strain only in that the *vacA* gene was knocked out. Through co-culture of cell-free supernatants from the wild or mutant *H pylori* strain with gastric cells, loss of vacuolating activity of the *vacA*-knockout strain was confirmed. These results clearly show that VacA is an indispensable toxin secreted by *H pylori* for the induction of vacuole formation.

Such kind of technique has been used to yield $vacA^-$ mutant *H pylori*[9,28,29]. But no further experiment has been done to compare the virulence between the mutant and the parental strain. On the other hand, microarray analysis has been used in several studies to screen gene expression profiles in gastric epithelial cells induced by *H pylori*[30-32]. Our group has also analyzed different expression profiles of gastric cancer cells co-cultured with supernatants of $VacA^+$ or $VacA^-$ *H pylori* isolates. However, VacA has not been used as a single virulence determinant to stimulate host cells, thus one can not determine which virulent factors result in the alteration of the expression. In this study, we successfully constructed the $vacA^-$ mutant strain, using the direct mutagenesis technique, which creates an important precondition for the further research on virulence comparison with gene expression analysis.

Abstract

AIM: To determine the distribution of *cagG* gene of *Helicobacter pylori* (*H pylori*) isolates cultured from patients with various digestive diseases and its relationship with gastroduodenal diseases.

METHODS: *cagG* was amplified by polymerase chain reaction in 145 *H pylori* isolates cultured from patients with chronic gastritis (n=72), duodenal ulcer (n=48), gastric ulcer (n=17), or gastric and duodenal ulcer (n=8), and the relationship between *cagG* status and the grade of gastric mucosal inflammation was determined.

RESULTS: *cagG* was present in 91.7 % of the 145 *H pylori* isolates, with the rates were 90.3 %, 93.8 %, 88.2 % and 100.0 %, respectively, in those from patients with chronic gastritis, duodenal ulcer, gastric ulcer, and gastric and duodenal ulcer. There was no significant difference among the four groups (P>0.05). The average grade of gastric mucosal inflammation in the antrum and corpus was 1.819±0.325 and 1.768±0.312, respectively in *cagG* positive patients, whereas the average inflammation grade was 1.649±0.297, 1.598±0.278 respectively in *cagG* negative cases (P>0.05).

CONCLUSION: *cagG* gene of *H pylori* was quite conservative, and most *H pylori* strains in Chinese patients were *cagG* positive. *cagG* status was not related to clinical outcome or the degree of gastric mucosal inflammation. Therefore, *cagG* can not be used as a single marker for discrimination of *H pylori* strains with respect to a specific digestive disease.

INTRODUCTION

Helicobacter pylori is a well-recognized pathogen that chronically infects more than 50 % of the world population. *H pylori* is associated with the development of acute or chronic gastritis, peptic ulcer diseases, gastric adenocarcinoma and gastric mucosa-associated lymphoid tissue (MALT) lymphoma. Most infected subjects will remain asymptomatic throughout life with only about 20 % developing peptic ulcer diseases or gastric carcinoma[1-5]. What determines the outcome of an infection remains unclear. The reasons for these different outcomes of *H pylori* infection may be related to both bacterial factors and host responses. The major *H pylori* disease-associated genetic factor is the whole *cag* pathogenicity island (PAI), which contains 25 open reading frames and at least 30 genes. The *cag* PAI is associated with increased interleukin (IL)-8 production by gastric epithelial cells[6,7].

The cytotoxin-associated gene A (*cagA*) is located in the most downstream part of the *cag* PAI. The presence of this gene or its encoded protein, CagA, has been regarded as a marker for the *cag* PAI. Many clinical studies have demonstrated that *cagA* gene or CagA protein is associated with a more severe clinical outcome. CagA was reported to increase the risk of development of duodenal ulcer, atrophic gastritis and gastric adenocarcinoma. In contrast to the *cagA*-negative patients, gastric mucosal inflammation of *cagA*-positive patients was more severe[8-10]. *cagG* is located within the *cag* PAI upstream of *cagA*. The distribution of this gene in *H pylori* strains isolated from Chinese digestive patients and its relation with the gastroduodenal diseases remain unclear. In the present study, a set of specific primers were designed to detect the *cagG* gene in 145 clinical *H pylori* strains, and the relationship between *cagG* and different digestive diseases was determined.

MATERIALS AND METHODS

H pylori isolates

H pylori isolates obtained from 145 patients (80 males, 65 females, aged 18-69 years, mean age 42.5 years old) who underwent upper endoscopy in our department were included in this study. These patients were diagnosed endoscopically as chronic gastritis (n=72), duodenal ulcer (n=48), gastric ulcer (n=17), or gastric and duodenal ulcer (n=8). Informed consents were obtained from all patients. The standard strains CCUG17874 (NCTC11638) and Tx30a were kindly provided by the Italian IRIS Research Center.

H pylori culture

Two antral biopsy specimens taken during endoscopy were immediately cultured on the *H pylori* selective agar plates with 10 % defibrillated sheep blood and antibiotics (Merck Company, Germany) at 37 ℃ under microaerophilic conditions with 5 % O_2 10 % CO_2 and 85 % N_2 for 3-6 days. The colonies were identified as *H pylori* if Gram stain morphology and biochemical tests were positive for urease, oxidase and catalase. All stock cultures were preserved at -80 ℃ in Brucella broth with 20 % glycerol, and subcultured for genomic DNA extraction. The passage number of *H pylori* used in this study averaged six.

Histopathologic examination

Two biopsy specimens each taken from the gastric corpus and antrum endoscopically were used for histopathologic examination to grade the severity of gastritis after they were embedded in paraffin and stained with hematoxylin and eosin. The severity of gastritis (i.e. mononuclear cell and polymorphonuclear leukocyte infiltration) was evaluated, and graded on a scale of 0-3 (i.e. 0=no, 1=mild, 2=moderate, and 3=marked) according to the updated Sydney system[11].

Genomic DNA extraction

Subcultured *H pylori* cells were collected from the agar plates, then genomic DNA was extracted and purified from each *H pylori* isolate using cetyltrimethyl ammonium bromide (CTAB), phenol-chloroform-isoamyl alcohol, and ethanol precipitation.

Detection of cagG with polymerase chain reaction (PCR)

The primers to amplify *cagG* gene and give a 497 base pair (bp) product were designed based on the published gene sequence[12]. *cagG*F: 5' -GCCATGTTAACACCCCCTAG-3' , and *cagG*R:5' -TTAATGCGCTAGAATAGTGC-3' . PCR was performed in an Eppendorf thermal cycler using a PCR kit (Takara, Dalian, China) according to the manufacturer' s instructions. Briefly, the reaction was performed in a total volume of 50 μl containing 20 ng genomic DNA as a template and 200 μM each deoxynucleotide, 1.5U Taq polymerase, 0.4 μM each primer and PCR buffer. The PCR amplification program comprised at 95 ℃ for 5 min, then 35 cycles at 95 ℃ for 1 min, at 52 ℃ for 1 min and at 72 ℃ for 1 min, followed by at 72 ℃ for 7 min, then cooled at 4 ℃. The PCR products were analyzed on 1.5 % agarose gels with ethidium bromide. CCUG17874 was taken as a positive control, Tx30a as a negative control, and deionized water as a blank control.

Statistical analysis

The data were expressed as the mean ±SD. The *t* test and χ^2 test were used for statistical analysis. A *P* value <0.05 was considered to be statistically significant.

RESULTS

Amplification of cagG gene

After PCR amplification of the *cagG* gene, the products were electrophoresed on 1.5 % agarose gels, and stained with ethidium bromide. Under ultraviolet light, *cagG* appeared as a specific band with 497 bp (Figure 1).

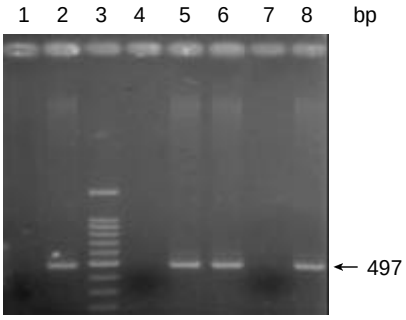

Figure 1 Electrophoresis of PCR products. Lane 3: 100 bp DNA Marker; Lanes 1, 2 and 4: controls: Tx30a, CCUG17874, and deionized water; Lanes 5, 6, 7 and 8: clinical *H pylori* isolates.

CagG status in H pylori isolates from patients with various diseases

H pylori cagG gene was detected in 91.7 % of the 145 isolates, the rate was 90.3 %, 93.8 %, 88.2 % and 100.0 % in patients with chronic gastritis, duodenal ulcer, gastric ulcer and gastric/duodenal ulcer, respectively (Table 1). There was no significant difference among the groups (*P*>0.05).

Table 1 *cagG* in *H pylori* isolates from patients with different gastroduodenal diseases

Group	Number	*cagG* positive	*cagG* negative	*cagG* positive rate (%)[a]
Chronic gastritis	72	65	7	90.3
Duodenal ulcer	48	45	3	93.8
Gastric ulcer	17	15	2	88.2
Gastric duodenal ulcer	8	8	0	100.0
Total	145	133	12	91.7

[a]*P*>0.05 between any two groups.

CagG status and gastric mucosal inflammation

The average grade of gastric mucosal inflammation in the antrum and corpus was 1.819±0.325 and 1.768±0.312 in *cagG* positive patients, respectively, whereas the average grade was 1.649±0.297, 1.598±0.278 in *cagG* negative group, respectively (*P*>0.05, both in the antrum and body).

DISCUSSION

H pylori infects human gastric mucosa which evokes a mucosal inflammatory response by neutrophil recruitment from the microcirculation. Persistent inflammation may lead to the development of digestive diseases such as chronic gastritis, peptic ulcer disease and gastric cancer. Although pathogenicity of *H pylori* infection is not well understood, there were several putative virulence factors that might contribute to mucosal damage by *H pylori* infection[13,14].

The *cag* PAI is an approximately 40-kb cluster of genes in *H pylori* chromosome, and a quite conservative entity. Many of *H pylori* strains had an intact *cag* PAI divided into two regions: *cag*I in downstream and *cag*II in upstream, and some with an insert sequence IS605 or IS606[15,16]. There were at least 14 and 16 open reading frames in *cag*I and *cag*II, several of which were virulence factors[17]. Several studies suggested that *cagA* gene could be used as a marker for *cag* PAI[16]. *cagG* is another gene in *cag*I region which is located upstream of *cagA* gene. The function of this gene is not well known. Recently, Hsu *et al*[17] reported that an intact *cag* PAI was identified in 95 % and 100 % of the strains that possessed *cagA* and *cagG* respectively, whereas the *cagA* and *cagG* genes were found in 100 % and 95 % of the strains containing a partial or complete set of *cag* PAI, indicating that *cagA* gene is not associated with a complete *cag* PAI in 5 % of the strains, and cannot be considered as an absolute marker for the presence of a complete set of *cag* PAI, but *cagG* gene may be a better indicator for the presence of an intact *cag* PAI.

Extensive studies of *cagA* gene indicated that CagA protein encoded by *cagA* gene was associated with severe clinical outcomes, such as peptic ulcer disease and gastric cancer. Therefore, it was considered as a main virulence factor of *H pylori*[16]. Some reports suggested that the presence of *cagE* gene within *cag*I might be related to more severe clinical outcomes. For example, Day *et al*[18] revealed that *H pylori* isolates containing *cagE* were associated with duodenal ulcer in Canadian children. Fallone *et al*[19] reported that *cagE*-positive isolates were more prevalent in Canadian adult patients with peptic ulcer or gastric cancer than in those with gastritis only. In the present study, we designed a set of primers to amplify *cagG* gene of 145 clinical *H pylori* isolates, and

determined the correlation of *cagG* status with endoscopic presentation, and histological findings. The results showed that *cagG* was present in 91.7 % *H pylori* isolates examined. 100 % of *H pylori* isolates from patients with gastric and duodenal ulcer were *cagG* positive, which was higher, but not statistically significant than that in other groups ($P>0.05$). Lack of difference in *cagG* positive rate might be due to patient selection or the relatively small number of patients with gastric and duodenal ulcer. Nevertheless, our study suggested that positive rate of *cagG* in *H pylori* was high and *cagG* was quite conservative in Chinese population, and that there was no difference in the frequencies of *cagG*-positive isolates among patients with gastritis, duodenal ulcer, gastric ulcer or gastric duodenal ulcer. Our results are supported by the study by Jenks *et al*[20] who demonstrated that no specific genes within the *cag* PAI could reliably predict the clinical outcome of *H pylori* infection in French patients, and also by Hsu *et al*[17] who concluded that any of the *cag* PAI genes such as *cagE* could not predict the clinical presentation in Korean patients.

Hsu *et al* reported that of the 120 clinical isolates from Korean patients with various gastrointestinal diseases, 86.7 % (104/120) were *cagG* positive[17]. Mizushima *et al*[21] used PCR and Southern blot to investigate the prevalence of *cagG* gene in 236 clinical *H pylori* isolates from Japanese patients, and found that *cagG* was present in 97 % of the isolates. These results were similar with ours. The same Japanese research group[21] further used flow cytometry to assay the ability of *H pylori* with or without *cagG* to adhere to KATOIII and ELISA to detect the IL-8 secreted from gastric epithelial cells induced by *H pylori*. They observed that in comparison with the *cagG*-positive strains, all *cagG*-deleted strains decreased adherence to KATOIII cells, and abolished IL-8 induction despite the presence of *cagE*, which was reported to be essential for IL-8 induction. *H pylori* genome is known to be diversified and may differ between geographic regions. However, there has no reports so far about *cagG* gene distribution in the Western countries.

Infection with *cagA* positive *H pylori* induces stronger gastric chemokine mRNA expression such as IL-8 in the antral mucosa, which may be relevant to the increased mucosal damage associated with *cagA* positive *H pylori* infection. The levels of the chemokines were correlated with cellular infiltration in the antrum and inflammation of the gastric mucosa[22,23]. We compared the severity of gastric mucosal inflammation in the antrum and corpus in *cagG*-positive and *cagG*-negative patients, and observed that, the average grade of inflammation was only slightly higher in *cagG*-positive group than that in *cagG* negative group both in the antrum and in the corpus ($P>0.05$). Therefore, the *cagG* status has no relation to the severity of gastritis.

In conclusion, *cagG* gene was quite conservative in clinical *H pylori* isolates from Chinese patients with different gastroduodenal diseases, since most *H pylori* isolates were *cagG* positive. There was no difference in the frequency of *cagG* -positive isolates among patients with different diseases. The *cagG* status was not related to gastric mucosal inflammation grade. Therefore, *cagG* cannot reliably predict the clinical and histological outcomes.

Abstract

AIM: To investigate the effect of epidermal growth factor (EGF) on mucosal healing in rats with duodenal ulcer.

METHODS: Male Sprague-Dawley rats were randomly divided into sham operation without EGF, sham operation with EGF, duodenal ulcer without EGF, or duodenal ulcer with EGF groups. Additionally, normal rats without operation served as the control group. Duodenal ulcer was induced in rats by 300 mL/L acetic acid. Rats with EGF were orally administered at a dose of 60 μg/kg/day in drinking water on the next day of operation (day 1). Healing of duodenal ulcer was detected by haematoxylin and eosin staining. Cell growth of damaged mucosa was determined by the contents of nucleic acids and proteins. The level of EGF in duodenal mucosa was measured by ELISA.

RESULTS: The pathological results showed that duodenal ulcer rats with EGF improved mucosal healing compared with those without EGF after day 5. Duodenal ulcer rats with EGF significantly increased duodenal DNA content compared with those without EGF on day 15 (6.44±0.54 mg/g *vs* 1.45±0.52 mg/g mucosa, $P<0.05$). Duodenal RNA and protein contents did not differ between duodenal ulcer rats with and without EGF during the experimental period. Sham operation and duodenal ulcer rats with EGF significantly increased duodenal mucosal EGF content compared with those without EGF on day 5 (76.0±13.7 ng/g *vs* 35.7±12.9 ng/g mucosa in sham operation rats, and 68.3±10.9 ng/g *vs* 28.3±9.2 ng/g mucosa in duodenal ulcer rats, $P<0.05$).

CONCLUSION: Oral EGF can promote mucosal healing of the rats with duodenal ulcer by stimulating mucosal proliferation accompanied by an increase in mucosal EGF content.

INTRODUCTION

Epidermal growth factor (EGF) is present in various body fluids and tissues, and is continuously secreted into the gastrointestinal lumen in humans by submandibular glands, mucous neck cells of the stomach, Brunner's glands of the duodenum, Paneth cells of the small intestine, and ulcer-associated cell lineage (a recently identified glandular structure induced at the sites of injury)[1-3]. EGF and EGF family of related peptides are involved as key constituents in the maintenance and repair of gastrointestinal mucosa[4]. There has been evidence that increases in the EGF receptor and EGF producing cells around acetic acid-induced gastric ulcer in rats, and a novel cell lineage in human mucosal ulceration secreting EGF adjacent to peptic ulcer[3,5]. The results suggest that EGF plays an important role in ulcer healing.

Previous studies showed that EGF administration regulated the healing of ulcers in rats[6,7] and humans[8]. Oral administration of EGF, given at 30 μg/kg/day in the drinking water for 25 or 50 days, promoted the healing of cysteamine HCl-induced duodenal ulcer in rats to the same extent as cimetidine, a H_2-receptor antagonist[6]. However, Kuwahara *et al*.[7] demonstrated human EGF, given orally twice daily at 30 and 100 μg/kg for 2 weeks or at 100 μg/kg for 4 weeks, had no effect on natural healing of acetic acid-induced gastric ulcer in rats. It has been controversial if orally administered EGF, a feasible and easy way in clinical therapy, is effective to promote the healing of duodenal ulcer. Therefore, the purpose of the study was to investigate the effect of orally administered EGF on the healing of intestinal mucosa and the content of EGF in acetic acid-induced duodenal ulcer rats.

MATERIALS AND METHODS

Animals and duodenal ulcer operation

Male Sprague-Dawley rats (-200 g) were purchased from the National Laboratory Animal Center (National Science Council, Taipei, Taiwan). The rats were housed in individual cages and had free access to food (powdered laboratory autoclavable rodent diet 5 010, PMI Nutrition International Inc., Brentwood, MO), except for the fasting period. The light cycle was 12 h and the room temperature was kept at 22-24 ℃. The rats were randomly divided into four operated groups: sham operation without EGF, sham operation with EGF, duodenal ulcer without EGF, and duodenal ulcer with EGF groups (n=10 on each sacrificed day, 6 rats for biological analysis, and 4 rats for pathological examination and photography). Additionally, normal rats (n=10) without operation served as the control group. Duodenal ulcer was induced in rats by acetic acid according to the modified method of Konturek *et al*[9]. Prior to operation, the rats were fasted overnight, anesthetized by intraperitoneal injection with 50 mg/kg body weight thiopental sodium (Abbott Australia Pty.Ltd., Kurnell, Australia), and the abdomen was then opened. A plastic tube (4.5 mm inner diameter) filled with 70 μL of 300 mL/L acetic acid was applied tightly to the surface of the duodenum for 10 sec. Due to different tolerance to acetic acid in various layers of the duodenum, it only caused immediate necrosis in the mucosal and submucosal

layers exactly within the area (4.5 mm diameter) of acetic acid application without penetration or perforation to the surrounding organs. Normal saline instead of 300 mL/L acetic acid was applied to sham operation rats. After operation, the rats were allowed to recover from anesthesia. The operated rats received only water on the day of operation (day 0), and were fed a normal chow diet *ad libitum* next day (day 1). Body weight, food intake, and water intake of the rats were routinely recorded. All protocols were conducted under the guidelines of Animal Care and Use Committee, Taipei Medical University.

Treatment and pathological observation

The next day after operation at approximately 15:00, the rats were orally administered recombinant human EGF (60 μg/kg body weight) (Biosource International, Camarillo, CA) in 35 mL (minimal intake during the adaptation period) sterile deionized drinking water, and remaining water was exactly recorded to determine actual intake of EGF. The rats without oral EGF were given the same amount of sterile deionized drinking water. The operated rats were killed on day 1 to identify the formation of duodenal ulcer, and on days 5 and 15 at 15:00 for pathological and biological analyses. The duodenum (5×5 mm) was excised, preserved in 10 % formaldehyde, and stained with haematoxylin and eosin. The diameter of ulcer size was measured in sectioned samples by microscopy. Coded mucosal specimens were evaluated under a light microscope at ×100 or ×200 magnification by a pathologist in a blinded fashion.

DNA, RNA, and protein in duodenal mucosa

The ulcer area of duodenal mucosa in duodenal ulcer rats and a similar area of intact duodenal mucosa in sham operation rats were excised. Duodenal mucosa was entirely scraped off, weighed, and immediately frozen at -80 ℃ for further analysis. DNA, RNA, and protein in duodenal mucosa were purified using a commercial TRIZOL reagent (Life Technologies, Inc., Rockville, MD) to evaluate mucosal growth[10]. Duodenal mucosa (0.2-0.5 g wet weight) was homogenized in 1 mL of TRIZOL reagent followed by the addition of 200 μL chloroform. After centrifugation, RNA remained exclusively in the aqueous phase, and DNA and protein were then recovered by sequential precipitation. RNA was precipitated with isopropanol. DNA was precipitated with ethanol from the interphase, and protein was precipitated with isopropanol from the organic phase after separation from DNA. DNA, RNA, and protein pellets were resuspended in 8 mmol/L NaOH, diethylpyrocarbonate-water, or 1 mol/L NaOH, respectively. DNA and RNA were quantitated spectrophotometrically at 260 nm. Protein content was determined spectrophotometrically at 690 nm by a Bio-Rad Dc protein assay kit (Bio-Rad Laboratories, Hercules, CA).

EGF in duodenal mucosa

Duodenal mucosal EGF content was measured by a commercial EGF immunoassay kit (Quantikine™, DEG00, Research and Diagnostics Systems, Inc., Minneapolis, MN)[11]. Duodenal mucosa (0.2-0.3 g wet weight) was homogenized with RD1 reagent. The mucosal homogenate (200 μL) was incubated with EGF antibody coated in a 96-well plate for 2 h at room temperature, washed 3 times with 400 μL wash buffer, and then incubated with 200 μL polyclonal EGF antibody conjugated to horseradish peroxidase for 2 h. After several washes, samples were incubated with 200 μL substrate (tetramethylbenzidine: H_2O_2=1:1) for 20 min. The reaction was terminated by 50 μL of 1 mol/L sulfuric acid. Mucosal EGF content was determined at 450 nm and corrected at 540 nm using an ELISA reader (Multiskan RC, Labsystems, Helsinki, Finland).

Statistical analysis

All values were expressed as mean ± SE. Data were analyzed by three-way ANOVA to determine the main effects of duodenal ulcer, oral EGF, and time using SAS 6.12 (SAS Institute, Cary, NC). *Post hoc* multiple comparisons between two groups were performed either by Fisher's least significant difference or Dunnett's test. Differences were considered significant at $P<0.05$.

RESULTS

Weight gain, EGF and food intake

Body weight of sham operation and duodenal ulcer rats with or without EGF on different sacrificed days is shown in Table 1. At the beginning of the experiment, body weight of the rats was similar in all operated groups and the control group (189.0±4.5 g). Body weight of sham operation and duodenal ulcer rats with or without EGF significantly increased ($P<0.05$) on day 15 compared with that of the control group on day 0 and the corresponding group on day 5. Oral EGF did not affect body weight.

Table 1 Body weight of sham operation and duodenal ulcer rats with or without oral EGF before operation and sacrifice

Group	Sham operation		Duodenal ulcer	
	- EGF	+ EGF	- EGF	+ EGF
	Body weight before operation (g)[2]			
Day 5	192.0±3.9	199.8±3.8	200.6±5.0	195.2±5.0
Day 15	192.4±4.8	198.9±4.2	194.9±4.7	195.9±6.0
	Body weight before sacrifice (g)[2]

[1]Data are mean ± SE (n=10). [2]Values were not significantly different ($P>0.05$) among different groups in each row by Fisher's least significant difference test. *Body weight was significantly different ($P<0.05$) from that in the control group (189.0±4.5 g, n=10) on day 0 by Dunnett's test. †$P<0.05$ compared with day 5 within the same group by Fisher's least significant difference test.

Table 2 EGF and food intake of sham operation and duodenal ulcer rats with or without oral EGF[1]

Group	Sham operation		Duodenal ulcer	
	- EGF	+ EGF	- EGF	+ EGF
	EGF intake (μg / kg / day)[2]			
Day 5	-[3]	59.9±3.8	-	57.8±0.4
Day 15	-	57.3±0.6	-	58.1±0.3
	Food intake before operation (g / day)[2]			
Day 5	24.5±1.1	25.2±0.8	26.5±0.5	25.4±0.9
Day 15	25.1±0.5	25.3±0.4	26.6±0.8	24.8±0.6
	Food intake before sacrifice (g / day)			
Day 5	27.9±4.3[a]	27.4±6.4[a]	24.2±3.6[a]	25.6±5.4[a]
Day 15	27.2±1.8[b]	26.7±1.0[b]	25.1±1.4[a]	25.2±1.8[ab]

[1]Data are mean ± SE (n=10). Values in a row not sharing a superscript letter were significantly different ($P<0.05$) by Fisher's least significant difference test. [2]Values were not significantly different ($P>0.05$) among different groups in each row and column by Fisher's least significant difference test. [3]Data were not measured.

Exact oral EGF intake of the rats was close to 60 μg/kg/day, and not significantly different between sham operation and duodenal ulcer groups, and between different days in the same group (Table 2). The initial food intake of the rats before

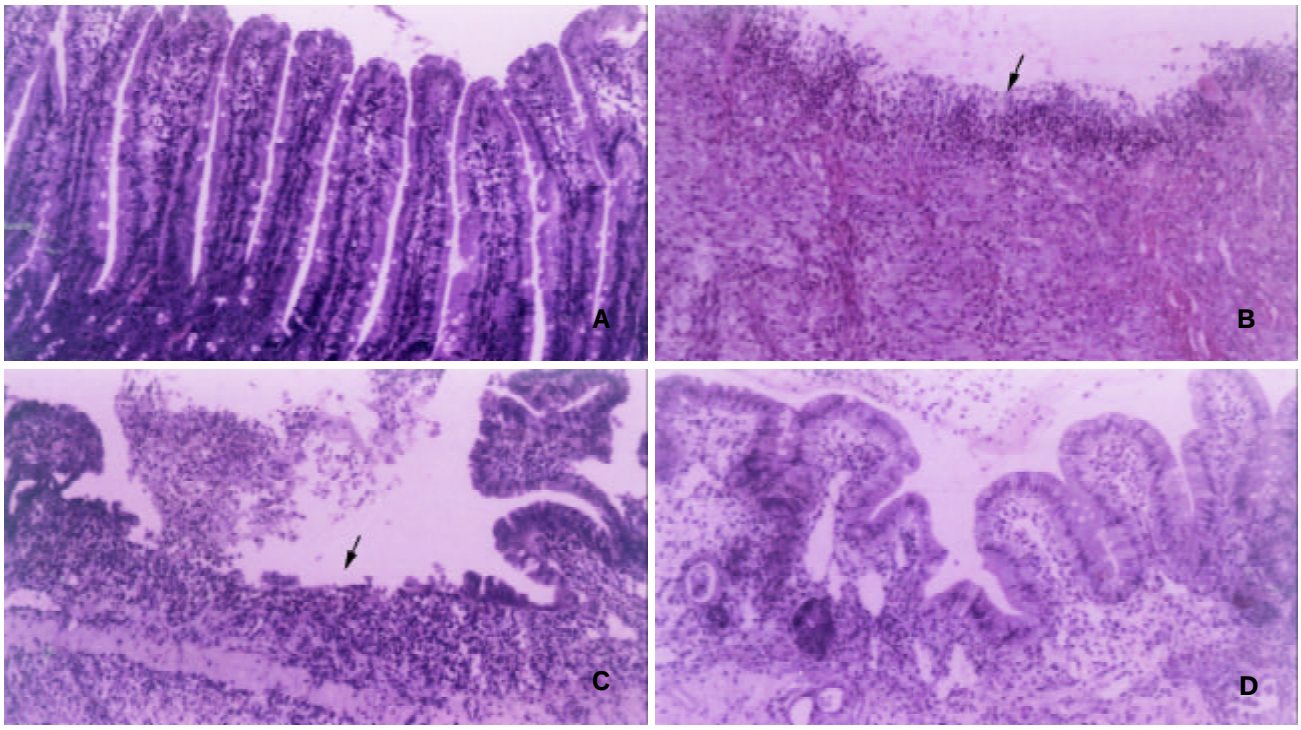

Figure 1 Representative micrographs of duodenal mucosa stained by haematoxylin and eosin were selected from 4 sectioned samples per group. A: control rats on day 0 (×200), B: duodenal ulcer rats without EGF on day 1 (×100), C: duodenal ulcer rats without EGF on day 5 (×100), D: duodenal ulcer rats with EGF on day 5 (×200). Arrow represents the discontinuous lining of the duodenal mucosa.

operation was similar to that in the control group (26.7±3.1 g/day), and not significantly different among the groups. On day 15, decreased food intake was only observed in duodenal ulcer rats without EGF compared with that in sham operation rats. Neither EGF nor time in sham operation or duodenal ulcer rats affected food intake.

Morphological appearance

To identify the formation and healing of duodenal ulcer in rats after operation, the morphological appearance magnified by ×100 or ×200 is shown in Figure 1. Compared with the control group (Figure 1A), duodenal ulcer rats on day 1 had the discontinuous lining of the mucosal and submucosal layers, and serious inflammation (Figure 1B). The mean diameter of ulcer damage was 2 mm. Sham operation rats had similar morphology as the control rats (data not shown). The morphology was not different between sham operation and the control rats on days 5 and 15. On day 5, the mean diameter of ulcer damage reduced to 1 mm in duodenal ulcer rats without EGF. Although some microvilli proliferated, but the discontinuous lining of the mucosal layer and inflammation were still observed in the ulcer area of duodenal ulcer rats without EGF (Figure 1C). Duodenal ulcer rats with EGF had obvious mucosal healing and proliferation (Figure 1D), and the mean diameter of ulcer damage was undetectable on day 5. On day 15, the morphology was not different between duodenal rats with and without EGF (data not shown).

DNA, RNA, and protein in duodenal mucosa

The results of mucosal DNA, RNA, and protein contents in the duodenum are shown in Table 3 to evaluate the growth of duodenal mucosa in rats after operation. Mucosal DNA content in the duodenum significantly increased (P<0.05) in sham operation rats without EGF (2.96±1.27 mg/g mucosa) and duodenal ulcer rats with EGF (6.44±0.54 mg/g mucosa) on day 15 compared with that in the control rats (0.86±0.06 mg/g mucosa) on day 0 and the corresponding group on day 5 (Table 3). Duodenal ulcer rats with EGF had higher duodenal DNA content (P<0.05) on day 15 compared with other groups. Three-way ANOVA showed both oral EGF and time significantly increased duodenal DNA content (P<0.05).

Mucosal RNA content in the duodenum did not change with EGF treatment and time in sham operation and duodenal ulcer rats (Table 3). However, duodenal ulcer significantly decreased mucosal RNA content (P<0.05). Duodenal ulcer rats had significantly lower RNA content (P<0.05) in duodenal mucosa on day 5 compared with the control rats (15.9±9.3 mg/g mucosa) on day 0. Sham operation rats with EGF had higher duodenal RNA content (P<0.05) than other operated groups on day 5. On day 15, duodenal RNA content did not differ among four operated groups.

Three-way ANOVA showed that oral EGF and time affected duodenal protein content (P<0.05). Duodenal protein content in sham operation rats without EGF significantly decreased (P<0.05) with time, but significantly increased (P<0.05) compared with that in the control group (25.1±1.4 mg/g mucosa) on day 0 and other operated groups on day 5 (Table 3). On day 15, duodenal protein content did not differ among four operated groups.

EGF in duodenal mucosa

Duodenal EGF content significantly increased (P<0.05) with time in sham operation rats without EGF, but significantly decreased (P<0.05) in duodenal ulcer rats with EGF (Table 4). Sham operation or duodenal ulcer rats with EGF significantly increased duodenal EGF content (P<0.05) compared with those without EGF on day 5. However, duodenal EGF content did not differ between sham operation and duodenal ulcer rats with or without EGF on day 5. On day 15, duodenal EGF content significantly decreased (P<0.05) in duodenal ulcer rats without EGF (12.9±3.9 ng/g mucosa) compared with that in the control rats (61.1±5.4 ng/g mucosa) on day 0 and sham operation rats without EGF (84.8±22.8 ng/g mucosa). However, duodenal EGF content did not differ between

sham operation or duodenal ulcer rats with and without EGF. Three-way ANOVA showed only duodenal ulcer significantly decreased mucosal EGF content ($P<0.05$).

DISCUSSION

Duodenal ulcer *per se* and oral EGF at a dose of 60 μg/kg/day did not obviously affect body weight of the rats in this study. However, Majumdar[12] found administration of EGF (20 μg/kg/day, ip. injection) to undernourished weanling rats for 7 days significantly reversed the decreased weight of whole body, small intestine, and oxyntic gland in the stomach caused by undernutrition. Similar to the results of body weight, oral EGF did not affect food intake. Because food intake was similar, body weight of the rats did not differ among four operated groups.

From the pathological observation, the mean diameter of ulcer area was undetectable in duodenal ulcer rats with EGF on day 5, and the damaged mucosa apparently recovered. However, the damaged mucosa was still found in duodenal ulcer rats without EGF on day 5. The data revealed that oral EGF reversed the damaged mucosa of duodenal ulcer on day 5, but duodenal ulcer could be self-recovered after 15 days. The results for cell growth of duodenal ulcer evaluated by mucosal DNA, RNA, and protein levels in the duodenum showed that mucosal DNA content did not significantly increase in duodenal ulcer rats with EGF until day 15 compared with those without EGF. Although we only measured DNA, RNA, and protein contents in the ulcer area of duodenal mucosa in duodenal ulcer rats and a similar area of intact duodenal mucosa in sham operation rats, these levels could be overestimated due to mixed cell types while collecting the samples. According to the results of pathological observation, the healing of damaged mucosa obviously occurred after day 5 in duodenal ulcer rats with EGF. Mucosal DNA content could reflect cell proliferation or cell division, but not measure DNA synthesis in the real time. While the pathological observation in the healing of damaged mucosa included the overall results of both cell proliferation and DNA synthesis. Oral EGF did not affect mucosal RNA and protein contents in duodenal ulcer rats. The data suggested that oral EGF had hyperplastic rather than hypertrophic effect on duodenal mucosa in duodenal ulcer rats. Although oral EGF did not influence cell proliferation in sham operation rats, EGF supplementation might temporarily cause cell hypertrophy due to increased ratio of RNA to protein caused by an increase in RNA and a decrease in protein on day 5. However, a previous study[7] demonstrated that orally administered EGF twice daily at 30 and 100 μg/kg body weight for 2 weeks had no effect on ulcer area and healing rate in Donryu rats with gastric ulcer induced by a submucosal injection of 20 mL/L acetic acid into the antrum. Different strain of animals, method of ulcer induction, severity of ulcer, and duration of EGF treatment could cause different results.

Our data showed that sham operation and duodenal ulcer rats with EGF significantly elevated mucosal EGF to 2.1- and 2.4-fold, respectively, compared with those without EGF on day 5. However, mucosal EGF did not differ between sham operation and duodenal ulcer rats with or without EGF on day 5. The results indicated that exogenous EGF increased mucosal EGF in the duodenum of both sham operation and duodenal ulcer rats to the similar extent on day 5. Therefore, exogenous EGF could be directly uptaken by the mucosa, and increased mucosal EGF in the duodenum of sham operation and duodenal ulcer rats could be derived from both exogenous and endogenous EGF. Increased mucosal EGF in sham operation and duodenal ulcer rats with EGF reduced to the similar level as in those without EGF on day 15, probably because of the adaptation to exogenous EGF through down-regulation of endogenous EGF. The EGF receptor was localized in the apical membrane of the enterocytes of rat duodenum[13,14], therefore the hypertrophic and hyperplastic effect of EGF on the mucosa of sham operation and duodenal ulcer rats, respectively, in this study could be induced via the interaction with the EGF receptor. Whereas if and how exogenous EGF regulates endogenous production of EGF or the interaction with the EGF receptor in the gastrointestinal tract of sham operation or duodenal ulcer rats, a further study to measure EGF mRNA and EGF receptors in the duodenum is required.

Our study showed that oral EGF significantly increased EGF content in the duodenal mucosa on day 5, accompanied by grossly improved healing in duodenal ulcer rats after day 5, and followed by elevated mucosal DNA content on day 15. The data suggested that oral EGF improved mucosal healing in duodenal ulcer rats by increasing EGF content in the duodenal mucosa to accelerate cell proliferation. Although EGF could be cleaved to smaller, less active forms in acidic gastric juice, the proportion of intact EGF increased to about 60 % if the pH was maintained above 4[15], which allowed it to survive passage through the intestinal tract. After administration of ^{125}I-labeled EGF, reversed-phase HPLC identified >90 % and 46-51 % of C18-extracted radioactivity from gastric and

midjejunal luminal contents as intact ^{125}I-EGF, whereas <3 % of C18-extracted radioactivity in extracts of duodenal, jejunal, and ileal luminal contents was intact ^{125}I-EGF in adult mice[16]. The result indicated that EGF, given by oral administration, in the gut lumen, more or less, was still intact. Additionally, Tsujikawa *et al*[17] suggested that the luminal EGF might play a role only under tissue damage, where enhanced permeability allowed passage of luminal EGF to its receptor on the membranes. The mechanism for the healing effect of EGF on the damaged intestine is now uncertain. Most studies have focused on the mitogenic and antisecretory actions of EGF[6,9,18-21]. Konturek *et al*.[18] suggested that the mechanism for protective and ulcer healing effects of EGF involved the activation of ornithine decarboxylase, the key enzyme in the biosynthesis of polyamines, which play a crucial role in the growth-promoting action of EGF. Additionally, EGF administration (50 μg/kg) accelerated the healing of acetic acid-induced duodenal ulcer in rats via an increase in collagen proliferation and secretion without affecting gastric acid secretion[19]. A previous study[9] reported that subcutaneous injection of EGF increased duodenal DNA and RNA contents in rats with duodenal ulcer after 7-day treatment, but oral administration of EGF did not. In addition, they indicated that oral dose (10 μg/kg) of EGF had no influence on gastric secretion in rats with chronic gastroduodenal ulcer but subcutaneous injection of EGF (10 μg/kg) decreased gastric acid output by 59 % compared with the control rats without EGF administration. They suggested that the ulcer-healing effects of EGF were mediated by factors other than the inhibition of acid secretion, because oral EGF did not have any influence on gastric secretion. However, decreased gastric acid secretion in rats with chronic duodenal ulcer was observed after intravenous administration of EGF at a dose of 36 μg/kg but not at doses of 0.36 or 3.6 μg/kg[6]. Furthermore, EGF has been reported to inhibit gastric acid and stimulate duodenal bicarbonate secretion[20]. The physiological effect of EGF on acid secretion was mediated by induction of gastric H^+, K^+-ATPase gene expression[21,22].

In conclusion, oral administration of EGF (60 μg/kg/day) can increase EGF content in the duodenal mucosa and promote the healing of the rats with duodenal ulcer by its mitogenic action.

Abstract

AIM: The generation of oxygen free radicals has been implicated in the pathogenesis of experimental pancreatitis. The aim of this study was to determine the role of oxygen free radicals in patients with acute pancreatitis.

METHODS: The plasma levels of C-reactive protein (CRP), lipid peroxide (LPO), myeloperoxidase (MPO) and superoxide dismutase (SOD) were measured in 13 patients with acute pancreatitis and 14 healthy volunteers.

RESULTS: Among the patients with acute pancreatitis, there were higher plasma levels of LPO and MPO and lower SOD activity in patients with severe pancreatitis than in those with mild pancreatitis. However, there was no significant difference in the serum marker of oxidative stress no matter what the etiology was. The LPO level was especially correlated with the concentration of serum CRP and CT severity index.

CONCLUSION: The oxygen free radicals may be closely associated with inflammatory process and the severity of acute pancreatitis. Especially, the concentration of plasma LPO is a meaningful index for determining the severity of the disease.

INTRODUCTION

Oxygen free radicals are molecules produced continuously in cells by several mechanisms. The generation of oxygen free radicals is physiologic. In most circumstances, oxygen free radicals are neutralized immediately by enzymatic scavengers. However, when formation of oxygen free radicals overwhelms radical neutralization in cells, oxidative stress occurs. As they are very reactive, they react well with all biological substances such as proteins, polysaccharides and nucleic acids, resulting in tissue injury[1-3]. It has been suggested that oxygen free radicals are responsible for a wide variety of diseases or conditions[1,4-8].

Oxygen free radicals have been known to play an important role in the pathogenesis of pancreatitis of some experimental models[6-12]. Oxygen free radicals are involved in initiation of pancreatitis[11]. Also, it was reported that oxygen free radicals acted as important mediators of tissue damage in experimental acute pancreatitis[10]. Therapeutic effects of antioxidants and radical scavengers have been shown in experimental models of acute pancreatitis[11,13,14].

However, there is doubt that experimental models of acute pancreatitis will match clinically acute pancreatitis in humans. Although there were some data that reflected enhanced oxygen stress in patients with acute pancreatitis[15-17], the role of oxygen free radicals in patients with acute pancreatitis has not been well clarified.

Therefore, this study was conducted to evaluate the role of oxygen free radicals in human acute pancreatitis and to analyze the correlation between oxygen free radicals and the severity of acute pancreatitis.

MATERIALS AND METHODS

Patients

Thirteen patients admitted to Medical Center of Yonsei University with a diagnosis of acute pancreatitis were included in this study. The diagnosis was established on the basis of acute abdominal pain, at least 3-fold elevated levels of serum amylase and computed tomography (CT). All patients had no previous history of acute pancreatitis. Fourteen healthy subjects without previous medical history were enrolled as controls. The mean age was 53.6 years in patients and 32.5 years in control group. The male to female ratio was 11:2 in patients and 10:4 in control groups.

Measurement of oxygen free radicals

Peripheral blood samples were taken on recruitment. After the blood was centrifuged, the plasma was stored at -70 ℃ until analysis. The blood samples of control group underwent the same process. C-reactive protein was measured by the routine method. Serum lipid peroxide (LPO) and myeloperoxide (MPO) as markers of oxygen free radicals were measured. Also the activity of superoxide dismutase (SOD) that diminished in oxidative stress due to its role as enzymatic scavenger was measured.

Lipid peroxidation

LPO was analyzed by measuring the amount of thiobarbituric acid reactive substances (TBARS). It was preceded that the standard solution was prepared by diluting 1 000 nmol/ml tetraethoxy propane, which was made by mixing with tetraethoxy propane and tertiary distilled water. Tertiary distilled water was used as blank solution. Plasma, blank, and standard solution 200 μL, respectively, were mixed with 20 % acetic acid. TBARS resulted from the reaction with thiobarbituric acid (TBA) 400 μL, was detected as reading fluorescence at 535 nm emission. The result was compared with standard curve.

Myeloperoxidation

MPO was analyzed as a marker of neutrophil activation by

Bioxytech®MPO enzyme immunoassay kit (OXIS International Inc., Portland, USA). This assay detects the fluorescence of solution at 405 nm emission using sandwich enzyme-linked immunosorbent assay (ELISA) against biotin-labeled goat polyclonal anti-MPO.

Superoxide dismutase

SOD activity was measured by using Bioxytech® SOD-525™ assay kit (OXIS International Inc., Portland, USA). This assay detects the fluorescence of solution at 525 nm, based on the principle that autoxidation of tetracyclic cathechol accelerates in condition of SOD.

Other parameters

To determine the severity and prognosis of acute pancreatitis, the level of C-reactive protein (CRP) in serum was used for a single indicator, Ranson' s score for multiple indicator, and CT severity index[18] for morphological indicator. Atlanta classification[19] was used as a main determining index for the severity of acute pancreatitis.

Statistical analysis

We used chi-square test and independent sample *t*-test for comparison in each group. A *P* value less than 0.05 was considered significant.

RESULTS

Levels of oxygen free radicals

The mean plasma level of LPO was 21.9±26.5 nmol/ml in acute pancreatitis and 5.7±1.7 nmol/ml in control group (*P*=0.030). Also, the mean plasma level of MPO was 12.3±11.7 nmol/ml in acute pancreatitis and 2.7±1.2 nmol/ml in control group (*P*=0.005). Oxygen free radicals significantly increased more in acute pancreatitis patients than in control group. The mean level of SOD activity was 48.2±41.4 U/dl in acute pancreatitis patients and 100.4±20.2 U/dl in control group (*P*=0.002). The decrease of SOD activity was more prominent in acute pancreatitis than in control group (Table 1).

Table 1 Laboratory parameters in patients with acute pancreatitis and control group

Parameters	Control (*n*=14)	Acute pancreatitis (*n*=13)	*P*-value
Amylase (IU / dL)	141.9±179.3	393.3±243.1	0.005
LPO (nmol / mL)	5.7±1.7	21.9±26.5	0.030
MPO (nmol / mL)	2.7±1.2	12.3±11.7	0.005
SOD (U / dL)	100.4±20.2	48.2±41.4	0.002

Values are means ± SD, LPO = lipid peroxide, MPO = myeloperoxidase, SOD=superoxide dismutase.

Oxygen free radicals according to etiology of acute pancreatitis

The etiologies of acute pancreatitis were gallstone (*n*=5), alcohol (*n*=4), hyperlipidemia (*n*=1), and unexplained (*n*=3). Comparing gallstone pancreatitis patients with alcohol induced pancreatitis, the plasma levels of CRP, LPO, MPO, and SOD showed no significant differences between the two groups (Table 2).

Association with severity of acute pancreatitis

According to the Atlanta classification, acute pancreatitis was classified as mild in 8 patients and as severe in 5 patients based on their clinical manifestations. There were no differences of age and sex between the two groups (Table 3). The mean level of serum CRP in patients with severe pancreatitis was higher than the one in patients with mild pancreatitis (12.3±9.0 mg/dl *vs* 6.7±4.5 mg/dl, *P*=0.311). The mean level of SOD activity more markedly decreased in patients with severe pancreatitis than in patients with mild pancreatitis (27.3±15.4 U/dl *vs* 65.7±49.2 U/dl, *P*=0.130).

Table 2 Laboratory parameters according to etiology of acute pancreatitis

Paramerters	Gallstone group (*n*=5)	Alcohol group (*n*=4)	*P*-value
Age (years)	55.4±19.7	44.5±14.2	0.368
Amylase (IU / dL)	364.6±271.9	366.5±252.5	0.992
Lipase (IU / dL)	10 004.0±15873.2	6 035.8±8,265.2	0.646
CRP (mg / dL)	6.0±2.5	12.3±9.8	0.296
LPO (nmol / mL)	15.6±10.5	38.7±45.1	0.385
MPO (nmol / mL)	11.3±15.3	15.5±14.3	0.689
SOD (U / dL)	59.2±49.3	21.0±17.1	0.171

Values are means ±SD, LPO = lipid peroxide, MPO = myeloperoxidase, SOD = superoxide dismutase.

Table 3 Clinical characteristics of patients with acute pancreatitis classified according to Atlanta classification

	Mild group	Severe group
No. of cases	8	5
Age (years)	53.5±17.1	53.8±15.7
Sex (M:F)	7:1	5:1
Etiology		
Gallstone	2	3
Alcohol	2	2
Others*	4	0
No. of mortality	0	0

*One case was due to hyperlipidemia and 3 cases were idiopathic.

Table 4 Laboratory parameters in patients with mild and severe pancreatitis according to Atlanta classification

Parameters	Mild group (*n*=8)	Severe group (*n*=5)	*P*-value
Amylase (IU / dL)	374.7±252.4	423.0±253.1	0.745
Lipase (IU / dL)	10 082.8±12 565.6	30 008.0±3 314.9	0.167
CRP (mg / dL)	6.7±4.5	12.3±9.0	0.311
LPO (nmol / mL)	11.5±6.8	38.7±38.1	0.068
MPO (nmol / mL)	7.5±4.1	20.1±15.4	0.053
SOD (U / dL)	65.7±49.2	27.3±15.4	0.130
Ranson's score	1.4±0.7	2.8±1.9	0.177
CT severity index	2.0±1.1	5.8±3.1	0.008

Values are means ±SD, LPO = lipid peroxide, MPO = myeloperoxidase, SOD = superoxide dismutase.

The mean plasma levels of LPO and MPO were higher in patients with severe pancreatits than those in patients with mild pancreatitis (LPO: 38.7±38.1 nmol/ml *vs* 11.5±6.8 nmol/ml, *P*=0.068, MPO: 20.1±16.1 nmol/dl *vs* 7.5±4.1 nmol/dl, *P*=0.053). The significant difference was for CT severity index between the two groups (5.8±3.1 in severe pancreatitis, 2.0±1.1 in mild pancreatitis, *P*=0.008) (Table 4). To analyze the relationship between oxygen free radicals and CT severity index, serum CRP that is widely used as an index for severity of pancreatitis, plasma LPO showed a close correlation with CT severity index and serum CRP (r^2=0.373, and 0.675, *P*=0.027, and 0.001, respectively) (Figure 1). Plasma MPO showed a close correlation

with CT severity index but not with serum CRP (r^2=0.319 and 0.202, P=0.044 and 0.143, respectively) (Figure 2). But SOD activity showed no significant correlation with either CT severity index or serum CRP (r^2=0.026 and 0.307, P=0.638 and 0.096, respectively) (Figure 3). CT severity index was correlated with serum CRP and Ranson' s score (r^2=0.334 and 0.382, P=0.049 and 0.024, respectively).

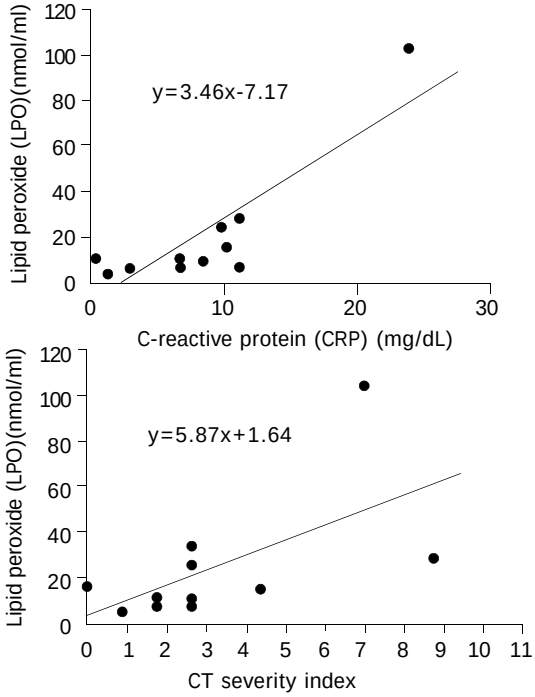

Figure 1 Relationships between serum levels of LPO and prognostic indices (CRP and CT severity index). There was a statistically significant correlation between LPO levels with CRP and CT severity index (γ2=0.675 and 0.373, P=0.001 and 0.027, respectively).

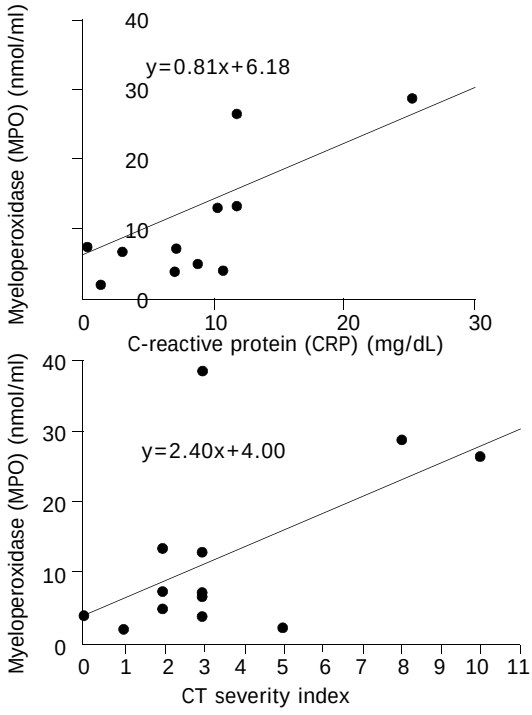

Figure 2 Relationships between serum levels of MPO and prognostic indices (CRP and CT severity index). There was no statistically significant correlation between MPO level and CRP (γ2=0.202, P=0.143). However, MPO level correlated positively and significantly with CT severity index (γ2=0.319, P=0.044).

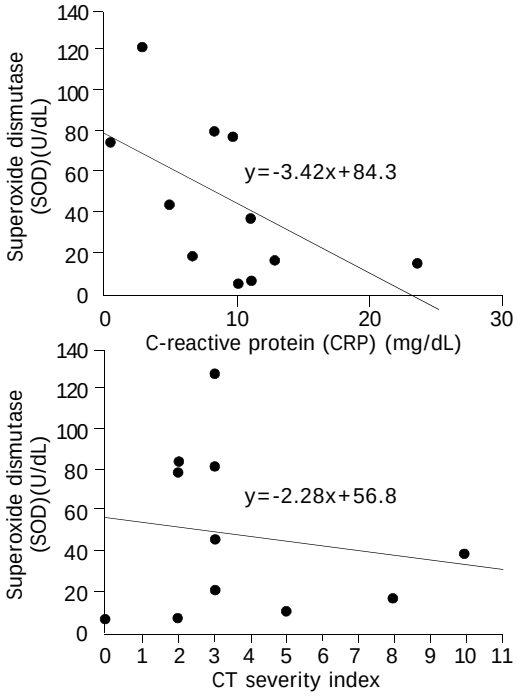

Figure 3 Relationships between serum enzymatic activity of SOD and prognostic indices (CRP and CT severity index). There was no statistically significant correlation between serum SOD concentrations and CRP and CT severity index (γ2=0.307 and 0.026, P=0.096 and 0.638, respectively).

DISCUSSION

Acute pancreatitis led to various degrees of interstitial edema, acinar cell damage, hemorrhage and necrosis[8]. Although the inflammation initiates in pancreas, the disease may lead to systemic multi-organ failure. Several factors (complement activation, cytokines, oxygen free radicals, ischemia, and autodigestion of pancreatic enzyme) have been known to be involved in the pathogenesis of acute pancreatitis. But the role of these factors remains still unclear. Among them, oxygen free radicals could damage extracellular tissue by degrading hyaluronic acid and collagen in the intercellular matrix and directly attack biological membrane through the peroxidation of structurally and functionally important lipids[20]. Furthermore, they could denature enzymes and other important proteins, and damage nucleic acid. In addition, they could indirectly trigger the accumulation of polymorphonulclear (PMN) leukocyte in the tissue. Activated PMN leukocytes could secrete various enzymes such as myeloperoxidase, protease, and elastase[21]. As a result, the inflammatory reaction accelerated. Also, oxygen free radicals could indirectly stimulate arachidonic acid metabolism with increased production of prostaglandins, thromboxane, and leukotrienes, and eventually could lead to microcircular derangement and cellular damage[2,15].

There are some reports concerning mechanisms of enhanced production of oxygen free radicals. Xanthine oxidase, PMN leukocyte, and cytochromes P-450 have been introduced as the source of oxygen free radicals[3,12]. However, the true sources of oxygen free radicals that are responsible for the pathogenesis of acute pancreatitis have not yet been identified. Since the first study by Sanfey *et al*[9], many studies have demonstrated the role of oxygen free radicals in the pathogenesis of acute pancreatitis in experimental models and patients. Oxygen free radicals have been known to mediate an important step in the initiation of acute pancreatitis[11]. But most results have been derived from experimental animal models in which acute pancreatitis was induced by stress, cerulein

injection, choline-deficient diet, or taurocholate injection into pancreatic duct. Only a few data have been derived from patients. Furthermore, there are many limitations on studying patients with acute pancreatitis in clinical settings.

Because of the nature of their high reactivity, oxygen free radicals are difficult to measure directly. Direct measurement of oxygen free radicals with electron spin resonance (ESR) technique was limited to *in vitro* studies due to short half time of free radicals and toxicity of compounds[22]. For these reasons, the alternative of measuring stable metabolites was met with broad acceptance. In most studies, measurements of the effects of radical reaction with biological substances (i.e., lipid peroxides and changes of glutathione metabolism) have replaced the assessment of oxygen free radicals.

In acute pancreatitis patients, increased production of lipid peroxidation, decreased level of vitamin C, and direct correlation between oxidative stress and severity of acute pancreatitis have been reported[15-17]. Equally, our results showed that plasma levels of LPO and MPO increased more in acute pancreatitis patients than in normal control group, and that increase of LPO and MPO was more prominent in severe pancreatitis than in mild pancreatitis, and that SOD activity, as a scavenger of oxygen free radical, was lower in acute pancreatitis patients than in normal control group. From these results, we can suggest that oxygen-derived free radicals play a pivotal role in the pathogenesis of acute pancreatitis in patients. In our study, it was probable that lipid peroxidation was correlated with severity of acute pancreatitis. There was a close correlation of lipid peroxidation with serum CRP and CT severity index. Therefore, there is some possibility that LPO could be a predictor of severity of acute pancreatitis. Similarly it was shown that lipid peroxidation was significantly increased in patients with septic shock[23]. In contrast, Abu-Zidan *et al*[16] have reported that lipid peroxidation was highly correlated with the severity of pancreatitis but not a good predictor of it. This discordance may be due to different method of measuring lipid peroxidation and study design.

In our study, the level of SOD activity, enzymatic scavenger, was significantly decreased in the plasma of patients with acute pancreatitis, and although not significant, it was related to the severity of acute pancreatitis. The effects of antioxidant, such as vitamins C and E, in experimental models have been reported[11,13,14]. However, the results have varied according to different models. Because in these most studies, antioxidant therapy was performed before acute pancreatitis was induced, the results were unlikely to be applied to clinical conditions. As well, the therapeutic effect of antioxidants and radical scavenger in patients has not been demonstrated yet.

There was no difference of oxygen free radicals between alcohol-induced pancreatitis and gallstone pancreatitis in our study. In many various experimental models and patients with acute pancreatitis, oxygen free radicals have been related to the disease[2,15,24,25]. Thus in our opinion, the role of oxygen free radicals may not be different no matter what the etiology of the disease is.

In conclusion, oxygen-derived free radicals may be closely associated with inflammatory process and the severity of acute pancreatitis, and the plasma level of LPO is a meaningful index for determining the severity of the disease.

Abstract

AIM: To evaluate the effect of early intrajejunal nutrition (EIN) on the natural course, entero-hormone secretion and its efficacy on dogs with acute pancreatitis.

METHODS: An acute pancreatitis model was induced by injecting 1 ml/kg of combined solution (2.5 % sodium taurocholate and 8 000-10 000 BAEE units trypsin/ml) into the pancreas via pancreatic duct. Fifteen dogs were divided into parenteral nutrition (PN) group and EIN group. Two groups were isonitrogenous and isocaloric. EIN was used at postoperative 24 h. Serum glucose, calcium, amylase and lysosomal enzymes were determined before and 1, 4, 7 d after acute pancreatitis was induced. All the dogs were injected 50 uCi ^{125}I-BSA 4 h before sacrificed on the 7th day. The ^{125}I -BSA index of the pancreas/muscle, pancreas/blood, and pancreas pathology score (PPS) were determined. The peripheral plasma cholecystokinin (CCK), secretin (SEC) and gastrin were measured by ELISA and RIA, and was quantitative analysis of pancreatic juice and amylase, pancreatolipase and HCO_3^-, Cl^-, Na^+ and K^+ performed by an autochemical analyzer at 30, 60, 120 and 180 min after beginning PN or EIN on the first day.

RESULTS: There was no difference between two groups in the contents of serum calcium, amylase and lysosomal enzymes, ^{125}I-BSA index of pancreas/muscle and pancreas/blood and PPS. The contents of CCK and gastrin in EIN were higher than those in PN group at 60 and 120 min (P<0.05). The content of SEC post-infusion of nutrition solution was higher than that of pre-infusion of nutrition solution in both groups, and only at 60 min SEC in EIN group was higher than that in PN group. The content of gastrin in EIN was higher than that in PN group at 120 and 180 min (P<0.05). The changes of pancreatic juice, amylase, pancreatolipase and HCO_3^-, Cl^-, Na^+ and K^+ between two groups did not reach significantly statistical difference (P>0.05).

CONCLUSION: EIN does not stimulate entero-hormone and pancreatic juice secretion, and enzyme-protein synthesis and release. EIN has no effect on the natural course of acute pancreatitis.

INTRODUCTION

Total parenteral nutrition (TPN) has been the standard practice for providing exogenous nutrients to patients with acute pancreatitis in order to improve their nutritional status and to avoid pancreatic stimulation. However, TPN is associated with certain disadvantages. In particular, there is an increased risk of central catheter infection, severe hyperglycaemia, and other metabolic and electrolyte disturbances and a possible exacerbation of metabolic disturbances. TPN may also result in gut barrier function alterations due to increasing intestinal permeability[1-10].

Benefits from the use of total enteral nutrition (TEN) have been noted in a number of other diseases, such as burns, trauma, and sepsis. In comparison with TPN, use of TEN reduces nosocomical infection, multiple organ failure (MOF), and length of hospitalization[3,4]. The use of early enteral feeding for nutritional support in patients with acute pancreatitis has not been evaluated systematically. The commonly encountered problems of gastric atony and outlet obstruction have limited the successful delivery of enteral formulas to patients with severe acute pancreatitis. In addition, many surgeons hold scrupulously that the EIN may exacerbate the clinical pathological features, and lead to recurrence of symptoms and delayed complications to be cured[11-18]. However, these problems could be overcome if enteral nutrition is delivered to the distal ileum far away from the Treitz' s ligament, to avoid stimulation of the cephalic and gastric phase, and those effects are not so pronounced as nutrients are delivered directly into jejunum[3,9-13]. Therefore, it is necessary to investigate the efficiency of early intrajejunal nutrition on pancreatitic clinicopathological changes, entero- hormone release and its efficacy on dogs with acute pancreatitis.

MATERIALS AND METHODS

Animal model

A total of 22 dogs weighing 18-22 kg, were allowed *ad libitum* intake of water. After fasted for 12-14 hours, all the dogs were induced anesthesia by intramuscular injection of ketamine 10 ml/kg, and intravenous injection of sodium pentobarbital 30 mg/kg. Under sterile conditions, a middle laparotomy and a duodenotomy were performed. The duodenum papilla was found and a silastic catheter was inserted into pancreatic tube and fixed for collecting pancreatic juice. Acute pancreatitis model was induced by injecting 1 mg/kg of combined solution of 2.5 % sodium taurocholate and 8 000-10 000 BAEF units trypin/ml into pancreas via pancreatic duct with a pressure of 30 cmH_2O, and the common biliary duct was clamped. After the model

was established, the duodenum and abdomen were closed. A catheter via jejunostomy was set at 30 cm away from the Treitz' s ligament. The neck region of the dogs was shaved and prepared in a sterile manner for catheterization. A silastic catheter (1.0 mm inner diameter and 1.5 mm outer diameter) was inserted through the external jugular vein to reach the superior vena cava. The catheter was fixed to connect the infusion solution. Fifteen dogs with acute pancreatitis survived over 7 days, and the death rate was 32 % (7/22). The trial was approved by the Institutional Animal Committee.

Experimental groups and preparation of nutritional solution

Fifteen dogs having survived over 7 days with acute pancreatitis were randomly divided into PN group (n=7) and EIN group (n=8). The two groups were isocaloric and isonitrogenous. The PN solutions were consisted of 7 % Vamin (SSPC, 9.4 g/1 000 ml) and 20 % Intralipid (SSPC) and 50 % glucose (GS). Non-protein calorie was 50 kC (209.2 kJ/kg) and nitrogen was 0.3 g/kg/d. The total volume of solution infused was 70 ml/kg/d. Energy index supported with glucose and fat emulsion was 1∶1. Multivitamins and electrolytes were also contained in TPN solutions. The normal saline was infused by 250 ml/kg during operation time and 8 h postoperation, and then infused with 125±25 ml/kg. The nutrient solution was infused at a constant infusion rate by a pump (100-120 ml/h).

The EIN solution was Nutrison (Nutricia). At the 24th h after acute pancreatitis was induced, the jejunum through jejunostomy catheter was infused 250 ml Nutrison and 500 ml NS. At the 48th h after acute pancreatitis, 500 ml Nutrison and 250 ml NS were infused for 5 days. The infusion rate was controlled by a microcomputer-pump (Nutricia). During EIN supporting, the content with insufficient calories and nitrogen were supplemented by partial parenteral nutrition[3,16,18].

Laboratory tests, ^{125}I-BSA index and pancreatic pathology

Serum glucose, calcium, amylase and lysosomal enzymes (according to Kit' s indication) were determined before and 1, 4, 7 d after the occurrence of acute pancreatitis. All the dogs were injected 50 uCi ^{125}I-BSA 4 h before sacrificed on the seventh day. The ^{125}I-BSA volume in the pancreas (/g), muscle of the right leg (/g) and blood (/ml) were tested by a r-accounter radioimmunology analyzer. The ^{125}I -BSA index of the pancreas/muscle and pancreas/blood was measured. Fixed tissues of the pancreatic head, body, tail and the total pancreas were sectioned and the histological change was observed. Pancreatitic pathological scores (PPS) were taken by the extent of pancreas tissue edema, inflammation, hemorrhage and necrosis according to scores 1, 2, 3 and 4, and PPS of the different parts of the pancreas was determined.

Entero-hormone determination

Twenty-four hours after the occurrence of acute pancreatitis, serum was used to determine the CCK and SEC (Peninsula Laboration, Inc.USA), and gastrin (Beijing Furui Bioengineer Co.) at the same time before and 30, 60, 120 and 180 min after PN or EIN. The former two samples were measured by competitive ELISA. The serum gastrin was measured by competitive binding RIA. The serum amylase, pancreaolipase and pancreatic juice, electrolytes (HCO_3^-, Cl^-, Na^+ and K^+) were determined by a 1 600 full-automatic biochemical analyser.

Statistical analysis

These data were expressed as means ± SEM, and comparison between two groups was made using χ^2 analysis of variance. A P value less than 0.05 was considered statistically significant.

RESULTS

Changes of serum glucose, calcium, amylase and lysosomal enzymes

After the acute pancreatitis model was prepared, serum glucose level in PN group was higher as compared with that in EIN group during the whole experimental period. Serum calcium was markedly decreased after acute pancreatitis was induced, and there was no difference in the changes of serum calcium in the latter days between two groups. Serum amylase and lysosomal enzymes (LE) increased and gradually decreased later during the experimental period, there was no difference between two groups (P>0.05) (Table 1).

Table 1 Effect of different nutrition support methods on serum glucose, calcium amylase and lysosomal enzymes

Groups	Time	Glu (umol/L)	Ca (mmol/L)	Amylase (SU)	LE(U)
PN group	Pre-AP	4.0±0.5	2.50±0.10	328±96	22±10
	30 min	8.3±0.8[a]	2.42±0.11	636±100[a]	53±11
	1 d	9.7±0.7[a]	2.35±0.09	1 689±298[a]	68±17
	4 d	10.3±1.0[a]	2.36±0.13	1 150±416[a]	45±14

[a]P<0.05, *vs* pre-SAP, [b]P<0.05, *vs* PN group, Pre-AP: before acute pancreatitis.

^{125}I-BSA index and pancreatitic pathological scores

^{125}I-BSA index of pancreas/muscle and pancreas/blood in EIN group (4.22±0.18 cpm/g, 0.22±0.03 cpm/ml) and PN group (3.69±0.26 cpm/g, 0.17±0.02 cpm/ml) did not reach statistical difference (P>0.05). Pancreatitic pathological scores (PPS) of different parts including head, body, tail and total pancreas in EIN group (1.40±0.24, 2.3±0.20, 2.1±0.20, 1.9±0.23) and PN group (1.30±0.38, 2.4±0.22, 2.2±0.22, 1.9±0.06) also did not reach statistical difference (P>0.05).

Entero-hormone, pancreatic juice and their components analysis

CCK The content of CCK in EIN group was higher than that in PN group at 30 and 60 min (P<0.05). There was no difference before and after nutrition liquid infusion in PN group (Table 2).

Table 2 Changes of serum CCK at different times (ng/ml)

Group	0 min	30 min	60 min	120 min	180 min
PN group	0.24±0.02	0.17±0.01	0.23±0.01	0.23±0.02	0.33±0.03
EIN group	0.22±0.02	0.29±0.06[a]	0.33±0.05[a]	0.29±0.03[a]	0.31±0.05

[a]P<0.05 *vs* PN group.

Table 3 Changes of serum SEC at different times (ng/ml)

Group	0 min	30 min	60 min	120 min	180 min
PN group	0.33±0.03	0.65±0.14	0.74±0.17	0.61±0.20	0.56±0.23
EIN group	0.35±0.06	0.61±0.17	0.88±0.25[a]	0.64±0.13	0.61±0.25

[a]P<0.05 *vs* PN group.

SEC SEC after infusion of nutrition liquid was higher than that before infusion of nutrition liquid ($P<0.05$), but it did not reach statistical difference between two groups at 30, 120 and 180 min ($P>0.05$). SEC only at 60 min in EIN group was higher than that in PN group (Table 3).

Gastrin The changes of gastrin in the PN group did no reach statistical difference before and after nutrition liquid infusion. Gastrin in EIN group gradually increased, and was higher than that in PN group at 120 and 180 min ($P<0.05$) (Table 4).

Pancreatic secretion and its component analysis

The changes of pancreatic juice, amylase, pancreatolipase, HCO_3^-, Cl^-, Na^+ and K^+ did not reach statistical difference between two groups (Table 5).

Table 5 Changes of pancreatic juice, amylase, pancreatolipase, HCO_3^-, Cl^-, Na^+ and K^+

DISCUSSION

Autodigestion of the pancreas is the main mechanism of acute pancreatitis. The conception of pancreatic rest stems from the belief that stimulation of pancreatic exocrine function in patients with acute pancreatitis releases large quantities of proteolytic enzymes that result in autodigestion of the inflammatory pancreas and peripancreatic tissues, causing a deterioration in the patient' s condition. The presence of food in the stomach and duodenum elicits gastropancreatic and duodenopancreatic reflexs that result in stimulation of pancreatic exocrine secretions. Therefore, traditionally, enteral nutrition could be adopted after parenteral nutrition support for over 2-3 weeks. That means to keep the pancreas in rest and rehabilitation for a long time. However, these effects are not so pronounced when nutrients are delivered directly into the jejunum[11-18].

Heidenhain in 1 875 first demonstrated the effect of vagal and entero- hormone stimulation on pancreatic secretion, in which hormones played a more important role than vagal stimulation. There were three classic phases, namely cephalic, gastric and intestinal phases of digestion that describe the response of the pancreas to a meal. The hormones served a major function in mediating pancreatic exocrine secretion[16,19]. Normally, during the cephalic and gastric phases, oral nutrients can stimulate the release of gastric acid, duodenum juice and pancreatic enzyme, and activation of proteins and peptide in the nutrients commences after the peptidase enters the duodenum, where mucosal enterokinase cleaves trypsinogen to trypsin, leaving trypsin to further activate the other peptidases, and then stimulates entero-hormones secretion such as cholecystokinin (CCK), secretin (SEC) and gastrin to increase pancreatic secretion. It is known that CCK and SEC are synthesized in the mucosal I and S cells of the crypts of Liberkuhn in the proximal small intestine and released in the presence of luminal acid and bile. The gastic G cell product, gastrin, which serves a major function to promote gastric acid release also serves as a weak stimulator of pancreatic enzyme secretion. CCK is one of the most important entro-hormones known to stimulate pancreatic enzyme secretion. Some authors also found that avoidance of cephalic, gastric and duodenual stimuli by jejunal tube feeding did not result in pancreatic stimulation. They concluded that bypassing the stomach, and minimizing acid secretion, played an important role in keeping the pancreas at rest[16,21,22].

Some authors[20-25] described an experience of early enteral nutrition in severe acute pancreatitis using nasoenteral feeding. No patients developed relapse, hypertri-glyceridaemia or abnormalities of liver function, indicating that jejunal feeding can be used safely in acute pancreatitis without reactivation of the inflammatory process[26-32]. Our experimental results showed that the changes of serum glucose, calcium, and amylase did not reach statistical difference between two groups. The serum lysosomal enzymes is believed to be the gold standard for reflecting the extent of pancreatic tissue necrosis and inflammation and more attention has been paid to them in international medicine. Once the pancreatic tissue necrosis stoped, the volume of systemic lysosomal enzymes discharging from pancreatitis tissue would be attenuated. Our results indicated that serum lysosomal enzymes was markedly increased after acute pancreatitis was induced, but did not reach statistical difference between two groups. In addition, the ^{125}I-BSA index of pancreas/muscle and pancreas/blood reflected the permeability of the pancreas microcirculation. If this ^{125}I-BSA index decreased, microvessal permeability would be improved. Once the ^{125}I- BSA index in pancreatic tissue increased, the microvessal permeability elevated and deteriorated pancreatitis. Our study showed that administration of EIN did not increase the content of serum lysosomal enzymes, and deteriorate the course of acute pancreatitis. As to the PPS in different parts of the pancreas, there was no difference between EIN group and PN group. Kalfarentzos *et al*[17], reported that EIN was well tolerated following acute pancreatitis, and was of comparable efficacy to PN. In fact, EIN did not deteriorate pancreatitic pathology, and might be safely adopted in dogs with acute pancreatitis[26-32].

Normally, it is known that secretion of CCK, SEC and gastrin is mainly located in the duodenum and jejunum. The number of CCK-produced cells is 11-30 per square millimeter both in duodenum and in proximal jejunum, and their amount is 52.5±8 pmol/g, and 26±5 pmol/g respectively; The number of pancreatic SEC-produced cells is >31 in duodenum, 1-10 in proximal jejunum per square millimeter respectively, and their amount is 73±7 pmol/g and 32±4 pmol/g. The number of gastrin CCK-produced cells is >31 in gastric antrum, 11-30 in duodenum and 1-10 in proximal jejunum per square millimeter respectively, and their amount is 2 342±14 pmol/g, 1 397±192 pmol/g, 190±24 pmol/g, respectively. Therefore, the secretory locations of entero-hormones are mostly in gastric antrum, duodenum and proximal jejunum, and less in the distal jejunum. Theoretically, if the nutrients were infused from proximal jejunum to distal jejunum, it would decrease stimulatory activation of pancreatic secretion to a minimum degree[16].

To further study the possibility of EIN stimulated entero-hormones and pancreatic juice release, we observed the effects of different nutrition support methods on the CCK, SEC, gastrin and pancreatic secretion and their components. Our results suggested that the serum CCK increased at 60 min after nutrient was infused in EIN group as compared with PN group.

It was interesting that SEC was elevated after nutrition infusion in both groups, but it was only higher at 60 min in EIN group than in PN group. The serum gastrin was gradually increased in EIN group at 120 and 180 min as compared with PN group. Based on pancreatic juice and its component analysis, our results suggested that the amount of pancreatic juice was higher in EIN than in PN group. But the changes of the amylase, pancreatolipase and electrolytes were not significant. The study suggested that EIN indeed stimulated entero- hormones secretion at some degrees, but did not increase enzyme-proetin and pancreatic juice secretion. The reason was not clear, maybe due to the fact that the pancreatic acinar cells swelling, hemorrhage and necrosis decreased the physiological efficiency of entero-hormones by altering the membrane receptor number and activity.

In recent years, effect of human EIN or oral feeding on the natural course and entero-hormones secretion was seldom reporte. It was well tolerable, feasible and desirable as TPN in the management of acute pancreatitis, but it failed to reveal any detrimental effect on the clinical pathologic features of AP, and increase pancreatic secretion. Therefore, EIN can contribute to the study of pancreatic natural course, and may play an important role in keeping the pancreas at rest, bypassing the stomach, and minimizing acid secretion.

Abstract

AIM: To evaluate the protective effects of transplanted and mobilized bone marrow stem cells (BMSCs) on mice with severe acute pancreatitis (SAP) and to probe into their possible mechanisms.

METHODS: A mouse model of SAP induced by intraperitoneal injections of L-arginine was employed in the present study. Two hundred female Balb/c mice weighing 18-22 g were randomly assigned into 4 groups. Group A was the stem cell mobilized group treated by injection of granulocyte-colony stimulating factor (G-CSF) into mice for 4 days at a dose of 40 μg· kg^{-1}· d^{-1} before induction of SAP. Group B was the group of BMSCs transplantation, in which the mice were given the isolated BMSCs via the tail vein 4 days prior to induction of SAP. Group C served as the model control and only SAP was induced. The mice without induction of SAP in group D acted as the normal control. At the time of animal sacrifice at 24, 48 and 72 h after induction of SAP, blood samples were obtained and prepared to detect serum amylase, while the abdominal viscera were examined both grossly and microscopically for the observation of pathological changes.

RESULTS: The mortality of mice in the model control, groups A and B was 34 %, 8 % and 10 % respectively within 72 h after induction of SAP. The serum level of amylase in the model control was significantly increased at all time points after induction of SAP as compared with that of the normal control (P<0.05-0.01). When the mice were pretreated with BMSCs' transplantation or G-CSF injection, their serum level of amylase was significantly reduced at 48 h and 72 h after induction of SAP in comparison with that of the model control (P<0.05-0.01). In accordance with these observations, both gross and microscopic examinations revealed that the pathological changes of SAP in mice pretreated with BMSCs transplantation or G-CSF injection were considerably attenuated as compared with those in the model control at all observed time points.

CONCLUSION: Both transplanted allogenic and mobilized autologous BMSCs can protect mouse pancreas from severe damage in the process of SAP.

INTRODUCTION

Severe acute pancreatitis (SAP) is a life-threatening disease with a mortality rate of 20 to 30 percent[1,2]. Despite recent improvements in our understanding of the disease process and the development of a range of supportive measures, today's treatment approaches for SAP are still less than ideal. It has been demonstrated recently that multipotent somatic stem cells in adult bone marrow can exhibit tremendous functional plasticity[3-9] and reprogram in a new environmental tissue niche to give rise to cell lineages specific for the new organ site. Stem cells from bone marrow, autologous or allogenic, have been used to treat myocardial infarction[10-13], hepatic disease[14-20], nervous system dysfunction[21-25] and severe autoimmune diseases[26, 27]. However, there have been fewer reports concerned about the treatment of SAP with BMSCs as yet. Since the two critical determinants, tissue damage and higher level of pluripotent cells, seem to be the prerequisite for the transdifferentiation of transplanted BMSCs and G-CSF has been proved to have a great potency in mobilizing both hematopoietic stem cell (HSC) and mesenchymal stem cells (MSCs) of bone marrow, we hypothesized that the transplanted allogenic BMSCs, as well as the autologous BMSCs mobilized by G-CSF would exert a protective role in the treatment of SAP. The present study is therefore designed to verify our hypothesis in attempt to develop new protocols for the improvement of SAP therapy.

MATERIALS AND METHODS

Animals and experimental protocol

Two hundred female Balb/c mice weighing 18-22 g were randomly assigned into 4 groups according to different treatment protocols with 50 mice each. Group A was the stem cell mobilized group treated by injection of sc G-CSF into mice for 4 days at a dose of 40 μg· kg^{-1}· d^{-1} before induction of SAP. Group B was the group of BMSCs transplantation, in which the mice were given BMSCs isolated from male mice bone marrow at a dose of 2×10^7 per mouse via tail vein 4 days prior to induction of SAP. Group C served as the model control and only SAP was induced. The mice in group D acted as the normal control treated only with an equal amount of saline as sc G-CSF in group A and without induction of SAP.

Mouse model of SAP was prepared in all animals except that in group D according to the scheme described elsewhere[28]. Briefly, the mice were fasted overnight but allowed to free access to water. The SAP inducer, a 20 g/L of L-arginine (Sigma) solution, was freshly prepared with saline just prior to use. In induction of SAP, the animals were injected intraperitoneally L-arginine solution at a dose of 2 g· kg^{-1} twice at an interval of 1 h.

The mice in groups A, B and C were sacrificed at 24, 48 and 72 h after induction of SAP. In the meanwhile, the mice in group D were killed at the corresponding time points. At the time of animal sacrifice, blood samples were obtained and prepared to

detect serum amylase, while the abdominal viscera were examined both grossly and microscopically for the observation of pathological changes.

Transplantation of primary BMSCs

Primary BMSCs to be transplanted to group B animals were isolated from donor male mice. The whole bone marrow cells were harvested by rinsing the thighbone and shankbone' s medullary cavities with cold DMEM (Gibco, Grand Island, NY) and then fractionated by density gradient centrifugation with lymphocytic separating medium. Mononuclear component, the constituent rich in BMSCs, was obtained from the interface after centrifugation at 2 500 r/min for 30 min. After repeatedly washed in cool D-Hanks solution, BMSCs were resuspended and adjusted to a cell density of 10^8/mL with the same solution. The transplantation of primary BMSCs into group B animals was performed via the tail vein injection at a dose of 0.2 ml cell suspension per mouse 4 days prior to induction of SAP.

The transplanted stem cells were identified at the end of the experiment (72 h post SAP induction) by examining the existence of Y chromosome Sry region in recipient female mice with a PCR scheme. Briefly, the female recipients were killed by cervical dislocation and DNA samples were extracted respectively from the pancreas, bone marrow, liver and spleen. The sequence of the sense primer was 5' -ATTTATGGTG TGGTCCCG-3' and that of the antisense primer was 5' -GCTGTAAAATGCCACTCC-3' . PCR consisted of an initial denaturation step at 96 ℃ for 6 min, followed by 35 cycles at 94 ℃ for 1 min, at 52 ℃ for 1 min and at 72 ℃ for 1 min each, and a final extension at 72 ℃ for 10 min. The resulting products were analyzed by electrophoresis on a 2 % agarose gel and stained with ethidium bromide. The expected size of amplified DNA fragment was 239 base pair.

Statistical analysis

All the data were expressed as $\bar{x}\pm s$. Comparisons between the means of different groups were performed using analysis of variance followed by Student' s *t*-test. $P<0.05$ was selected to be the level of statistical significance.

RESULTS

Animal mortality

The mortality of mice in the model control was 34 % within 72 h after induction of SAP, which was considerably decreased in the mices pretreated with BMSCs' transplantation or sc G-CSF injection. The mortality of mice in groups A and B was 8 % and 10 % respectively.

Table 1 Changes of serum amylase activity after SAP induction ($\bar{x}\pm s$, n=10)

Group	Serum amylase activity (μkat/L)		
	24 h	48 h	72 h
A	25.3±4.8	40.8±7.4[b,c]	27.6±6.2[a,c]
B	25.9±4.9	40.7±6.7[b,c]	27.3±6.3[a,c]
C	46.1±12.8[a]	78.4±15.8[b]	50.2±13.3[a]
D	17.2±6.2	16.9±2.7	19.0±3.4

[a]$P<0.05$, [b]$P<0.01$ *vs* group D; [c]$P<0.05$ *vs* group C.

Alterations of serum amylase

The serum level of amylase was significantly increased in the mice of model control at all time points after induction of SAP as compared with that of the normal control ($P<0.05$-0.01). When the mice were pretreated with BMSCs transplantation or G-CSF injection, their serum level of amylase was significantly reduced at 48 h and 72 h after induction of SAP as compared with that of the model control ($P<0.05$-0.01), although the amylase value was still significantly higher than that of the normal control ($P<0.05$, Table 1).

Pathological changes

Grossly, a typical appearance of SAP changes was observed in animals of the model control. These pathological changes were progressively aggravated after SAP induction and manifested in a time- dependent manner. Twenty-four hours after L-arginine injection, the pancreas was sprinkled with hemorrhagic spots and focal necrosis with a dark-color appearance. At the same time, a little bloody ascites was noted in the abdominal cavity. At 48 h, different sizes of more hemorrhagic and necrotic focus appeared on the pancreatic surface with the increment of bloody ascites. Seventy-two hours after induction SAP, the pancreatic necrosis and blood ascites were even more prominent with saponification of fatty tissue around. Massive necrosis of multiple organs such as the intestine, lungs and kidneys was found in the mice died from SAP (Figure 1).

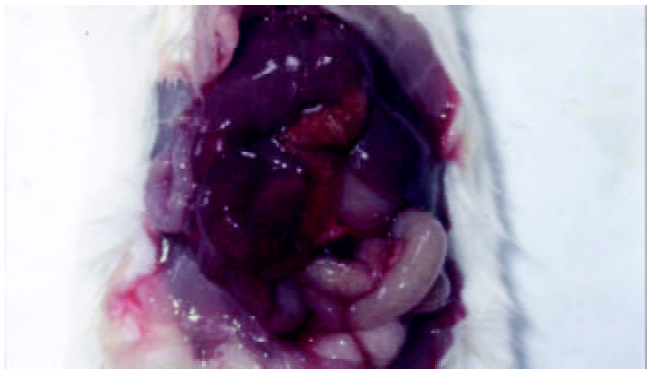

Figure 1 Gross appearance of abdominal cavity in SAP model control.

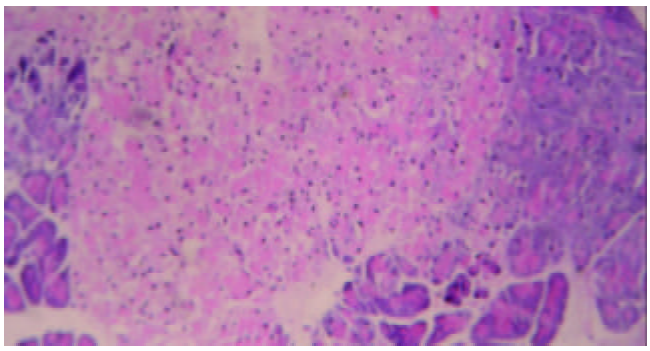

Figure 2 Pathological changes of pancreas at 24 h post SAP induction in mice of model control (HE, ×200).

Attenuated pathological lesions were noted both in group A and in group B mice, which were manifested mainly as minor pancreatic edema and congestion with less bloody or non-bloody ascites generated, no fat saponification and necrosis were observed.

In the microscopic examination, various degrees of pancreatic impairments were found in all mice injected with L-arginine. In mice of the model control, pancreatic congestion, interstitial edema, disorganized lobular architecture, as well as the focal hemorrhage and necrosis appeared at 24 h after induction of SAP, along with an obvious mesenchymal infiltration by inflammatory cells (Figure 2). The changes above were even more aggravated at 48 h and large areas of

coagulation necrosis occurred in the pancreatic parenchyma acompanied by the destroyed lobular architecture and massive inflammatory cell infiltration at the time of 72 h after induction of SAP (Figure 3).

In contrast, these pathological changes were obviously attenuated in mice pretreated with BMSCs' transplantation or G-CSF injection (Figures 4, 5). Most lobular architecture in these animals remained recognizable with alleviated hemorrhage, necrosis and infiltration of inflammatory cells, whereas some focal necrosis remained in the periphery of pancreas.

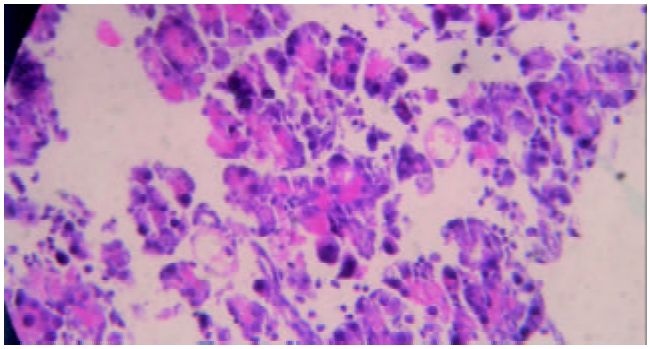

Figure 3 Pathological changes of pancreas at 72 h post SAP induction in mice of model control (HE, ×200).

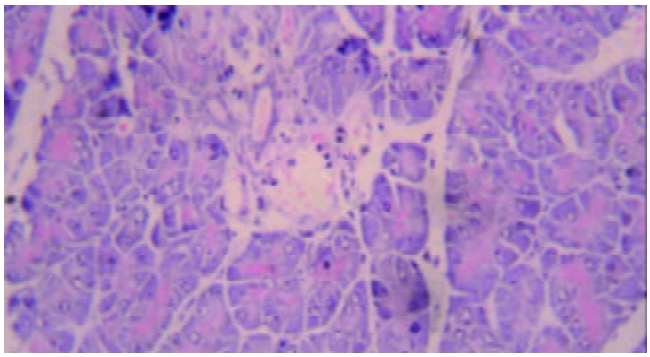

Figure 4 Microscopic changes of pancreas at 72 h after induction of SAP in mice pretreated with G-CSF (HE, ×200).

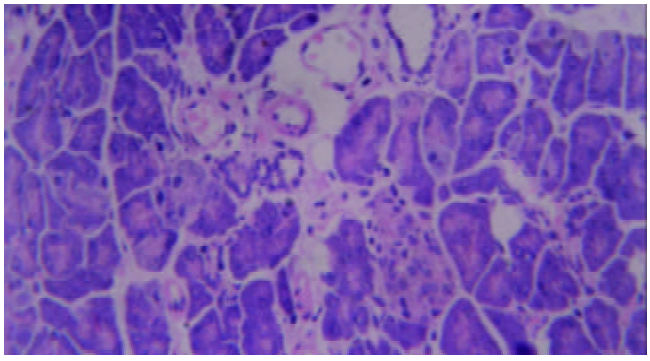

Figure 5 Microscopic changes of pancreas at 72 h post SAP induction in mice pretreated with BMSCs transplantation (HE, ×200).

Identification of transplanted BMSC

All sampled tissues from the pancreas, liver, spleen and bone marrow of the female recipients were demonstrated harboring a DNA fragment, 239 bp in length, of Y chromosome Sry region of donor mice, indicating that the engrafted BMSCs could migrate and survive in the impaired pancreas of SAP animals (Figure 6).

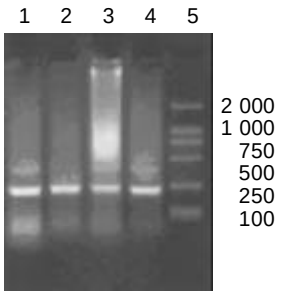

Figure 6 PCR products of Y chromosome Sry region gene existed in some organs of recipient female mice after male BMSCs transplantation demonstrated by agarose gel electrophoresis. Lane 1: pancreas, Lane 2: liver, Lane 3: liver, Lane 4: spleen, Lane 5: DNA marker.

DISCUSSION

The management of SAP has changed significantly over the past 20 years. In contrast to surgical intervention, there is now a strong tendency towards a more conservative therapy. The established treatment of SAP included aggressive fluid resuscitation, oxygen supplementation, prophylactic use of antibiotics, enteral feeding and intensive care support of any failing organ or system[29]. Nevertheless, the fact that these therapeutic modalities did not aim directly at the etiological factors made the treatment lack of specificity. Therefore, it remains a great challenge for the improvement of SAP therapy in the daily clinical practice. Recently, it has been shown that somatic stem cells were capable of regenerating injured tissue and improving the functions of involved organs[6,30-32], which might be used also as a new potential therapeutic modality for SAP treatment.

Bone marrow is an ideal source of stem cells. The multidirectional differentiation potential of BMSCs has been proved to be more than what we expected[32]. It has been reported that BMSCs could transdifferentiate into a variety of cell types derived from three embryonic layers such as endoblast-derived hepatic cells and lung alveolar epithelial cells, mesoblast-derived kidney and muscle cells, and ectoblast-derived neurons and epidermic cells. Furthermore, some authors have shown that bone marrow might serve as an extra-pancreatic hideout for the pancreatic stem cells[33,34] that contributed to the adult islet neogenesis. Transplantation with bone marrow cells has been used in several animal experiments for the treatment of types I and II diabetes mellitus, which has been achieved some promising results. All these facts indicate that BMSCs harbor a biological basis which can be used as an excellent candidate for SAP therapy.

In the present study, we observed the protective effects of BMSCs transplantation in a mouse model of SAP. It showed that a considerably reduced mortality and serum amylase activity, as well as obviously attenuated pancreatic pathological changes in the animals treated by transplantation of BMSCs or by injection of G-CSF, which presented a striking contrast to those of the model control. Regarding the mechanisms involved, these protective effects might be mediated by the rehabilitative action of BMSCs, which was partially supported by the existence of transplanted stem cells in the assaulted pancreas with a PCR scheme. The transplanted BMSCs might be ' tweaked' from the peripheral blood circulation to the injured tissues whenever SAP took place, where they exerted the function of pancreatic stem cells to regenerate the destroyed cells. As a result, gradual necrosis of impaired pancreas was effectively prevented. On the other hand, critical ill conditions such as SAP can usually caused serious injuries to multiple organs or systems, leading to a poor capability for the tissue repair. At

this time, transplanted stem cells in peripheral circulation were no doubt helpful for regeneration of injured tissues[38]. However, the direct evidence of BMSCs transdifferentiating to pancreatic cells should be further demonstrated by *in situ* hybridization and immuneohistochemistry.

An important phenomenon that deserved to note in the present study was the protective effects of autologous BMSCs mobilized by G-CSF injection in this model of SAP, whose efficiency was similar to that of alligeneic BMSCs transplantation. It implies that BMSCs, no matter autologous or allogenic, could get to and reside in the impaired tissue via blood circulation to repair the dysfunctional organs. Recently, Jensen and his associates[31] have shown that a normal physiological process of tissue regeneration and repair could be achieved by *in situ* mobilization of autologous stem cells from the bone marrow. Through the stimulation of normal stem cell migration, therapeutic benefits could be achieved with less invasive regimens than the removal and re-injection of stem cells. In this way, some obstacles in the allograft such as rejection and shortness of tissue donor supply would be also overcome easily. However, there were fewer BMSCs with weaker expansion and differentiation capacity in the peripheral circulation. Once mobilized by G-CSF, BMSCs in the peripheral circulation were estimated to be increased about 250 times higher than the baseline, along with an enhanced expansion and differentiation capacity. Thereby, autologous BMSCs transplantation could be performed safely and conveniently. Further research should be focused on the more efficient mobilization of autologous BMSCs to attract them to the injured region for tissue repair. This cell-restoring therapy may serve as a new modality in the future management of SAP and other serious diseases.

Abstract

AIM: Systemic treatment with epidermal growth factor (EGF) leads to growth of all parts of the small intestine in normal functioning rats. In this study, we investigated the effect of this growth process on morphometric and biomechanical parameters of ileum.

METHODS: Rats were treated with EGF (150 μg· $kg^{-1}day^{-1}$) or placebo via osmotic minipumps for 2, 4, 7, and 14 days. A segment of ileum was removed. The morphology at no-load state and zero-stress state was measured and passive biomechanical properties were assessed using a biaxial test machine (combined inflation and axial stretching).

RESULTS: The ileum weight increased after EGF administration. After 4 days' EGF treatment, the wall thickness was increased. Significantly smaller inner perimeters were seen in 4 day and 7 day EGF treatment groups. The opening angle and residual strain began to increase after 7 days' EGF treatment. Wall stiffness, evaluated from the stress-strain curves, showed a continuous decrease in circumferential direction during the first 7 days' EGF treatment. The longitudinal stiffness increased during the first 7 days. The stress-strain curves for both circumferential and longitudinal direction tended to shift back to normal 14 days after starting EGF administration.

CONCLUSION: EGF can cause significant changes both in the morphology and in the passive mechanical properties of the rat ileum.

INTRODUCTION

Epidermal growth factor (EGF) is a peptide growth factor belonging to the EGF family[1]. Throughout the last decade, the pharmacological potential of systemic treatment of EGF has been explored[2]. In the gastrointestinal tract, EGF causes growth, inhibits gastric acid secretion, and leads to changes in electric potentials, enzyme activity and transport of amino acids[3-6]. Due to the pronounced effects on intestinal mucosa, the therapeutic potential of systemic treatment of EGF has been explored in animal experiments. For example it has been shown that EGF accelerates adaptive growth of the small intestine in different species[7-10].

Only few studies have addressed the effect of systemic treatment of EGF on the normal small intestine. In a series of studies, we have examined its effect on the morphological and biomechanical properties of the small intestine. Vinter-Jensen, *et al*[11] used impedance planimetry to examine the tension-strain properties of the intestinal wall after EGF treatment and found that the circumferential wall stiffness decreased during EGF treatment. However, their study had limitations because the circumferential strain was referenced to the no-load state rather than to the zero-stress state and the mechanical properties were only studied for the circumferential direction.

The present study was to investigate the time-dependent effect of systemic treatment with EGF on the passive biomechanical properties of the small intestine. Segments obtained from the ileum were tested in a biaxial mechanical test machine that renders possible simultaneous inflation and longitudinal stretch. Stress and strain were computed and material constants were derived for the circumferential and longitudinal directions.

MATERIALS AND METHODS

Animals and study design

Thirty-four female Wistar rats (bred at the Department of Pathology, Aalborg Hospital Denmark) weighing 190-200 grams were included in this study. The animals were housed individually in cages on white special span wall bedding (temperature 21 ℃, humidity 55±5 %, dark/light cycle 12-h shift). They were fed on a standard laboratory diet. The study complied with Danish regulations for care and use of laboratory animals.

Twenty-two rats were allocated to four groups and treated for 2 (n=6), 4 (n=6), 7 (n=6), and 14 (n=4) days with human recombinant EGF (150 ug/kg/day, Upstate Biotechnology, New York, USA) using osmotic minipumps (ALZET 2001; ALZA, Palo Alto, California, USA). Twelve rats served as controls (n=3 for each time period). The body weights of both the control and EGF treated rats were measured at the beginning and the end of the study.

Collection of specimens

After treatment, the rats were anaesthetized (pentobarbital 50 mg· kg^{-1} intraperitoneally) and a midline laparotomy was performed. The calcium antagonist papaverine (60 mg· kg^{-1}) was injected into the lower thoracic aorta through a cannula (22 G/25 mm) in order to abolish any contractile activity in the gastrointestinal tract. A 5.5-cm-long segment from ileum was excised after the attainment of muscle relaxation (no visible contraction was observed). The residual contents in the lumen were gently cleared using saline and the *in vitro* weight and length of the segment were measured. Then the segment was placed in cold Krebs solution containing 6 % dextran aerated

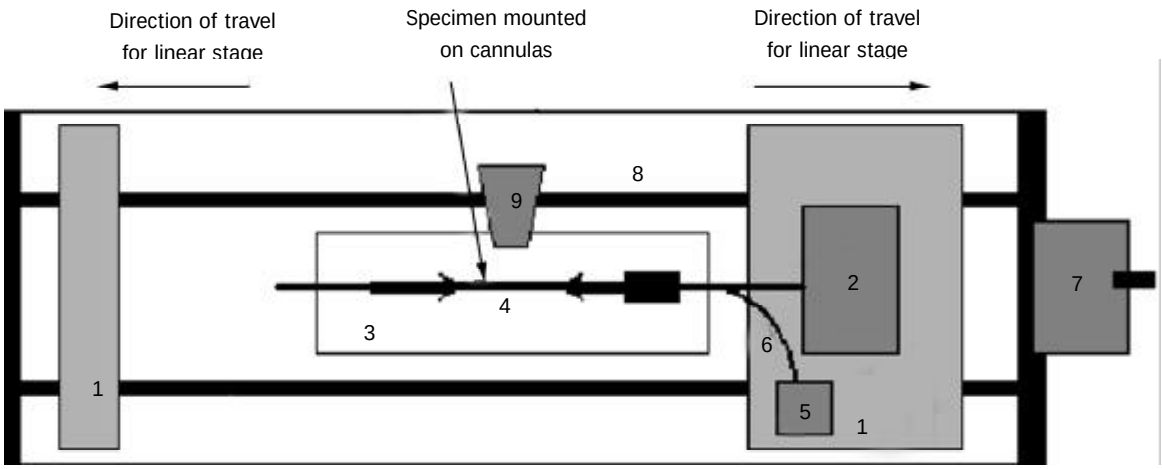

Figure 1 Legend, biaxial test machine setup. 1: Stage, 2: Force transducer, 3: Organ bath, 4: Specimen, 5: Pressure transducer, 6: Infusion channel, 7: Motor for linear stage, 8: Rails for linear stage, 9: Video camera.

with a gas mixture (95 % O_2 and 5 % CO_2, pH 7.4). Rings of 1-2 mm in length were cut at the edge of the tissue for no-load and zero-stress state measurements. The remaining part was used for the biaxial test.

Stress-strain experiment

The stress-strain test was conducted on the self-developed biaxial machine (Figure 1), which consists of the force and pressure transducers, the organ bath, motion stage and electronics. The specimen was bathed in the physiological Krebs solution. The two ends of the sample were tied with silk threads on the cannulas and the length between the threads was measured. The length *in vitro* was approximately 30 mm. Then the cannulas were mounted on the rods. The rod on the right side contained a T-connector for changing the pressure in the ileum. The rod on the right was also attached to a force transducer. The rods could be moved towards or apart from each other at controlled rates by two linear stages using a motor. The whole segment was photographed using a video camera (SONY CCD Camera, Japan) for later analysis of length and diameter.

In mechanical testing of living tissues, preconditioning was necessary to obtain repeatable results. This meant that after the specimen was installed in the test machine, the loading and unloading processes were repeated for a number of cycles until the stress-strain relationship became stabilized. The number of cycles required depended on the tissue and method of preparation. In these experiments, we preconditioned the ileum at 6 cm H_2O pressure, 4 stretch cycles to stretch ratio 1.25. The segment was then elongated to stretch ratios of 1.0, 1.08, 1.16, and 1.25. At each stretch level, we applied the pressure to the levels of 0, 2, 4, and 6 cm H_2O. The corresponding diameter and gauge length, displacement and axial force at each stress level were monitored.

Determination of no-load state and zero-stress state

The tissue rings were immersed separately in small organ baths containing the aerated Krebs solution. They were photographed in the no-load state and then cut radially on the anti-mesenteric side to obtain their zero-stress state (Figure 2). A 30-min-period was allowed for equilibration after the radial cut and the specimens were photographed again. The selection of this time period was based on pilot experiments.

Data analysis

Morphometric data were obtained from the digitalized images of the segments in the zero-stress, no-load and deformed states. The measurements were done using dedicated software (Sigmascan 4.0, Jandel Scientific, USA). The following data were measured from each specimen at the no-load and zero-stress states (illustrated in Figure 2), which were the circumferential length (*C*), the wall thickness (*h*), the wall area (*A*), and the opening angle at the zero-stress state (α). The subscripts *i*, *o*, *m*, *n*, *z* and *d* refered to the inner (mucosal) surface, outer (serosal) surface, the mid-wall, the no-load state, zero-stress state and deformed condition, respectively. The opening angle α was defined as the angle subtended by two radii drawn from the midpoint of the inner wall to the inner tips of two ends of the specimen. Furthermore, the outer diameter (*D*) and the length (L_d) were measured from the images of the deformed segments.

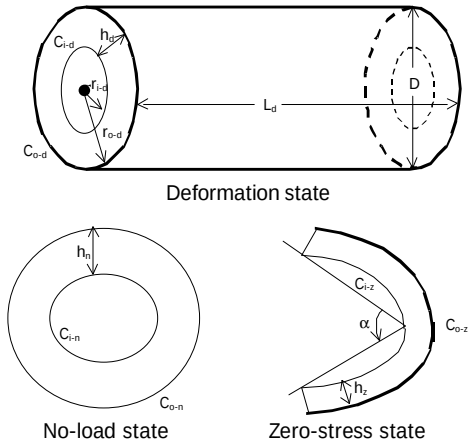

Figure 2 Legend, illustrations of intestinal small intestinal segment in the no-load, zero-stress and deformed states. C, h, α, denoted the circumference, thickness, and opening angle, respectively. The subscripts *n*, *z*, *d* denoted the no-load state, zero stress state and deformed state, respectively. The subscripts *i*, *o* referred to the inner (mucosal) surface, outer (serosal) surface, respectively.

The measured data were used for computation of the biomechanical parameters. Circumferential residual Green' s strain at the mucosal and serosal surface:

$$E_i = \frac{(\frac{C_{i-n}}{C_{i-z}})^2 - 1}{2} \quad \text{and} \quad E_o = \frac{(\frac{C_{o-n}}{C_{o-z}})^2 - 1}{2} \qquad (1)$$

The stress and strain of the intestine in the deformed state were determined under assumptions that the intestinal wall was thin and homogenous and the intestinal geometry was a circular

tube when pressurized. The circularity assumption had been verified in yet unpublished studies. The simplification we wished to make under the thin wall assumption was that the normal stress in the radial direction, s_{rr}, was negligible and that the stresses s_{qq}, and s_{ff} were approximately uniform throughout the wall thickness. Here r, q, f were polar coordinates in radial, circumferential and axial directions, respectively. The calculations were based on knowing the zero-state, no-load state dimensions, the outer diameters and lengths of the specimen at varying pressures, and assuming incompressibility of the intestinal wall. The longitudinal mid-wall stretch ratio, $l_{ff} = \frac{L_d}{L_n}$; the luminal radius, $r_{i-d} = \sqrt{r_{o-d}^2 - \frac{A_n}{p\, l_{ff}}}$; the wall thickness, $h_d = r_{o-d} - r_{i-d}$; the mucosal circumferential length, $C_{i-d} = 2p\, r_{i-d}$; the serosal circumferential length, $C_{o-d} = 2p\, r_{o-d}$; the mid-wall circumferential length, $C_{m-d} = \frac{C_{i-d} + C_{o-d}}{2}$; the mid-wall circumferential length at zero-stress state $C_{m-z} = \frac{C_{i-z} + C_{o-z}}{2}$, the circumferential stretch ratio, $l_{qq} = \frac{C_{m-d}}{C_{m-z}}$.

The longitudinal mid-wall stretch ratio was referenced to the no-load state because tissue strips were not cut for obtaining the zero-stress state in both directions. However, the longitudinal mid-wall length in rat intestine did not differ between the no-load and zero-stress states.

Kirchhoff ' s stress and Green' s strain at a given pressure were computed according to the following equations.

The circumferential and longitudinal Kirchhoff' s stress:

$$S_{qq} = \frac{\Delta \mathrm{Pr}_{i-d}}{(r_{o-d} - r_{i-d})\, l_{qq}^2}, \text{ and } S_{ff} = \frac{F + \Delta P p r_{i-d}^2}{p\, l_{ff}^2 (r_{o-d}{}^2 - r_{i-d}{}^2)} \quad (2)$$

Where ΔP was the transmural pressure difference, F was the force applied on the two ends of intestine.

The circumferential and longitudinal midwall Green' s strain:

$$E_{qq} = \frac{l_{qq}^2 - 1}{2}, \text{ and } \quad E_{ff} = \frac{l_{ff}^2 - 1}{2} \quad (3)$$

The stress and strain under each level of pressure and stretch ratio were calculated. In order to compare the stress-strain relationships among different EGF groups, one dimensional stress-strain curve was fitted, averaged and plotted: Circumferential stress-strain relationship (P=0 to P=6 cmH_2O (l_{ff}=1)) was fitted by the exponential equation: $strain = y_0 + k\exp(stress/t)$. Longitudinal stress-strain relationship (l_{ff}=1 to l_{ff}=1.25 (P=0 cmH_2O)) was fitted by another exponential equation because of different curve shapes, $stress = exp(a + b \times strain)$. Where y_0, k, and t, a, b were derived from the curve-fit regression done for each of segments. After fitting and averaging, the average curves with error bar could be obtained in different groups.

The exponential strain expression proposed by Fung[12] was applied to a set of test results on EGF treatment ileum. The stress and strain at a fixed stretch ratio of l_{ff}=1.16 and at varying pressure (P=0, 2, 4, 6 cmH_2O) were calculated and fitted to the function.

$$r_0 W^{(2)} = \frac{C}{2}\exp\left[a_1(E_{qq}^2 - E_{qq}^{*2}) + a_2(E_{ff}^2 - E_{ff}^{*2}) + 2a_4(E_{qq}E_{ff} - E_{qq}^* E_{ff}^*)\right] \quad (4)$$

where W was the strain energy per unit mass of the tissue, and r_0 was the mass density (mass per unit volume) in the initial zero-stress state. Then $r_0 W^{(2)}$ was the strain energy per unit volume of the tissue at zero-stress state for two dimensions.

From $S_{qq} = \frac{s_{qq}}{l_{qq}^2} = \frac{\partial(r_0 W^{(2)})}{\partial E_{qq}}$ and $S_{ff} = \frac{s_{ff}}{l_{ff}^2} = \frac{\partial(r_0 W^{(2)})}{\partial E_{ff}}$ (5)

We obtained $S_{qq} = C(a_1 E_{qq} + a_4 E_{ff})\exp[F(a,E)]$, and
$S_{ff} = C(a_4 E_{qq} + a_2 E_{ff})\exp[F(a,E)]$ (6)

Where

$$F(a,E) = a_1(E_{qq}^2 - E_{qq}^{*2}) + a_2(E_{ff}^2 - E_{ff}^{*2}) + 2a_4(E_{qq}E_{ff} - E_{qq}^* E_{ff}^*) \quad (7)$$

Where C (with units of stress,) and a_1, a_2, a_4 (dimensionless) were material constants, $E_{\theta\theta}{}^*$, $E_{\phi\phi}{}^*$ were strains corresponding to a selected pair of stresses $S_{\theta\theta}{}^*$, $S_{\phi\phi}{}^*$. The material constants were determined by a modified version of Marquardt' s nonlinear least-squares algorithm.

The meaning of the material constants was discussed in detail by Fung[12]. Constant a_1 would affect the curve for $S_{\theta\theta}$ *vs.* $E_{\theta\theta}$, the higher the a_1, the curve of $S_{\theta\theta}$ *vs.* $E_{\theta\theta}$ would leave the origin closer to the strain axis, and rise more rapidly, the more non-linear the curve was. Constant a_2 would affect the curve for $S_{\phi\phi}$ *vs.* $E_{\phi\phi}$ in a similar way. Constant a_4 specified the cross talk between the circumferential and longitudinal directions. The constant C fixed the scale on the stress axis. The larger the value of a_1, a_2 and a_4 was, the smaller C was[12].

Statistical analysis

Data were expressed as mean ±SEM. One-way analysis of variance was used to detect variations between treatment groups (Sigmastat 2.0™, Jandel Scientific, Germany). In case of significance (P<0.05), differences were tested between the control group and EGF-treated groups at 2, 4, 7, and 14 days treatment (Dunnet' s Test). If the normality test failed, Kruskal-Wallis one way analysis of variance on ranks was used instead.

RESULTS

Weight and morphological data

The total body weight did not change (Figure 3A). The ileum weight began to increase after 2 days' EGF treatment (Figure 3B). The wall thickness increased significantly after 4 days' EGF treatment, it did not change further (Figure 3C). A significantly larger wall area was observed in the 4 days' treatment group (Figure 3D). The luminal area did not change significantly (Figure 3E). However, a significantly smaller inner perimeter was observed in the 4 days, and 7 days' EGF treatment groups, but not in the 14 days' group (Figure 3F).

Zero-stress state data

The opening angle increased significantly after 7 days' EGF treatment and continued to increase up to 14 days (Figure 3G). The mucosal residual strain was compressive in all groups and decreased from 4 days of EGF treatment. The serosal residual strain was tensile with relatively higher values after 14 days of EGF treatment (Figure 3H).

Biomechanical data

The stress-strain relationships are shown in Figure 4. In circumferential direction, the curves representing 4 days and 7 days of EGF treatment were shifted to the right, whereas 14 days' EGF treatment curve shifted back towards normal. In longitudinal direction, the stress-strain curves representing 4 days and 7 days of EGF treatment were shifted to the left. Like the circumferential direction, the curves shifted towards normal after 14 days' EGF treatment.

The derived material constants a_1, a_2, a_4, and C from the strain energy function are illustrated in Table 1. Constant a_1 and a_2 having comparably smaller SEM values were therefore more stable than the other parameters. A significantly smaller a_1 value was found in the 7 days' and 14 days' EGF treatment groups and larger a_2 values were found in the 2 days' and 7 days' EGF treatment groups. This demonstrated that 7 days'

EGF treatment had the lowest circumferential stiffness and comparatively high longitudinal stiffness, and that the remodeling was most significant in the 7 days' EGF treatment group.

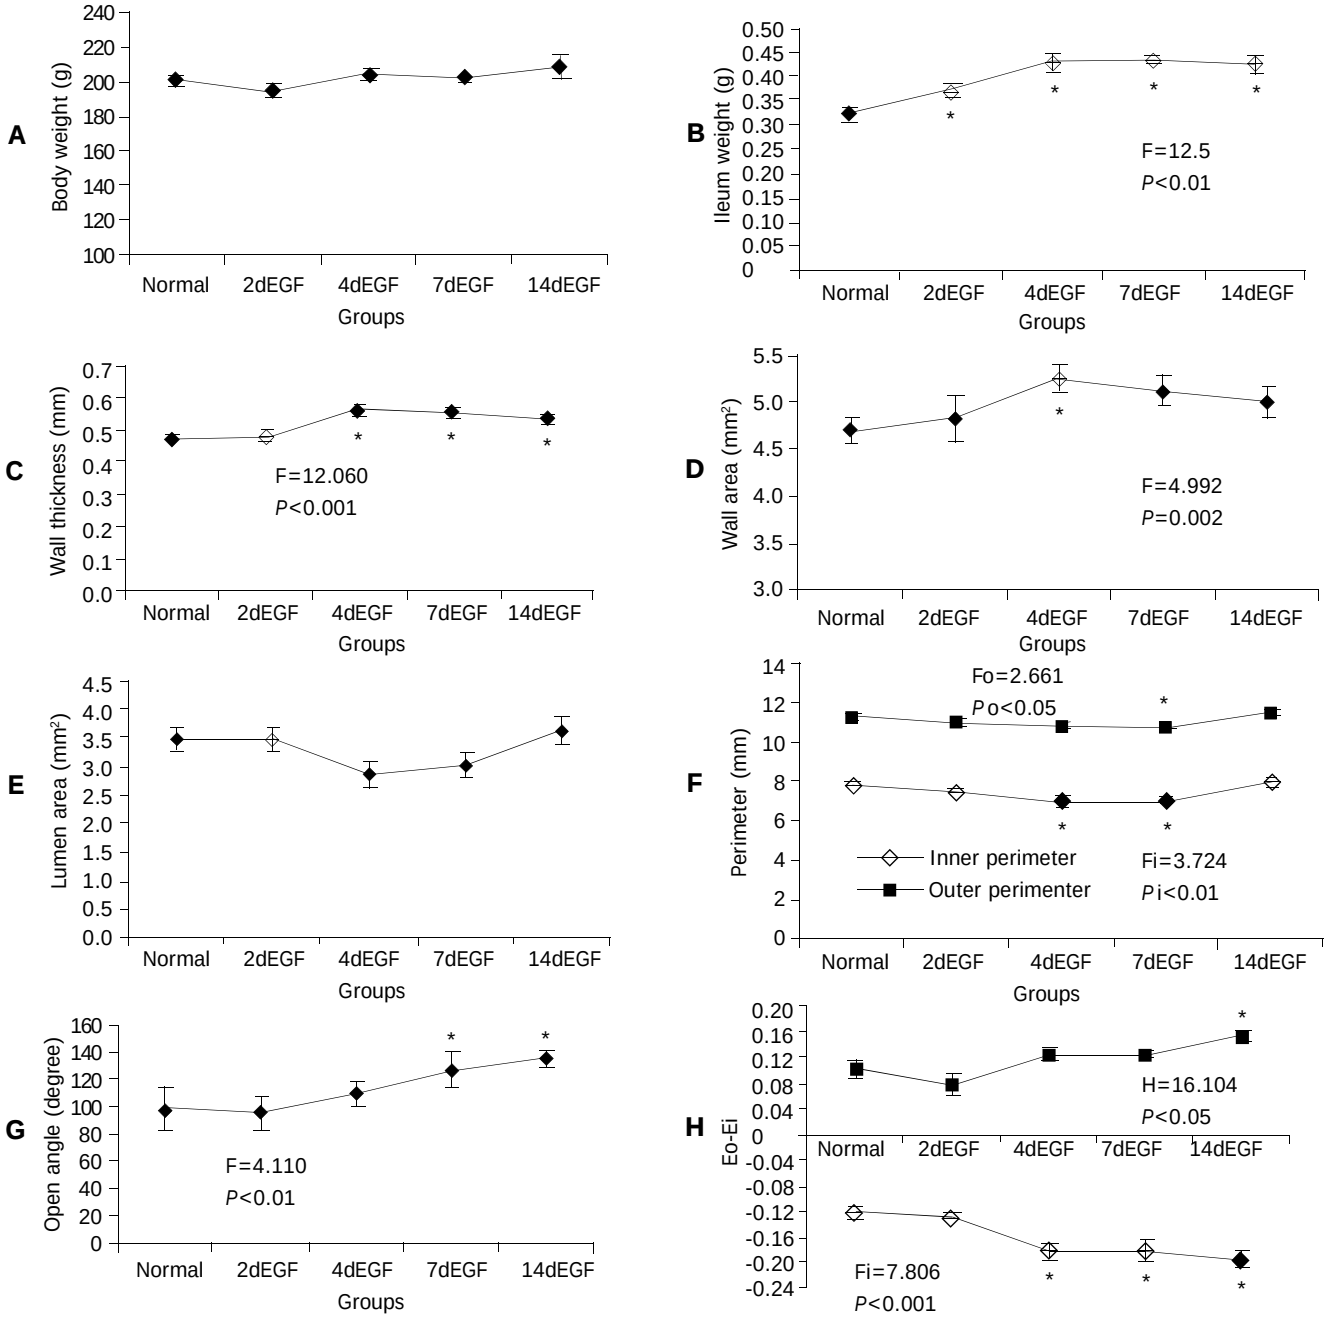

Figure 3 Legend, morphometric data of ileum in the no-load (A-F) and zero-stress states (G-H). *F* and *P* values were from one-way ANOVA for different treatment groups: If significant difference ($P<0.05$) was found using one-way ANOVA (marked with a), multiple comparisons with normal controls were done using Dunnet's test. Significantly different groups were marked with b.

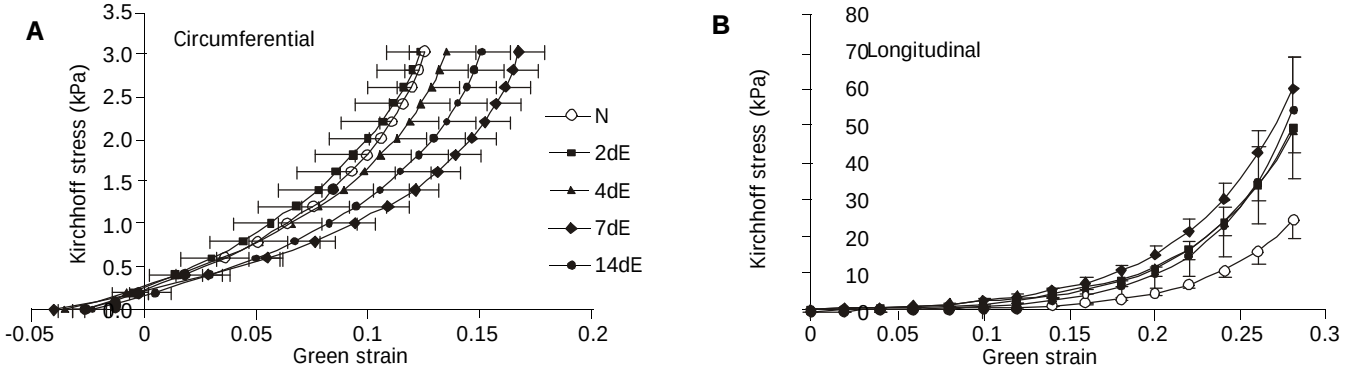

Figure 4 Legend, intestinal stress-strain curves in the EGF-treated and normal control groups. Translation of the stress-strain curve to the right in the coordinate system implied tissue softening (decreased stiffness) and *vice versa.*

Table 1 Material constants

	Normal	2dEGF	4dEGF	7dEGF	14dEGF
a_1[a]	25.42±1.91	18.19±2.80	19.32±3.91	11.57±2.04[b]	13.61±3.00[b]

A: One-way ANOVA result: $P<0.05$; B: Post analysis (Dunnet´s test) result: significantly different from normal control group ($P<0.05$).

DISCUSSION

The major findings in the present study were that EGF treatment induced time-dependent morphometric and biomechanical remodeling in the ileum. The ileum weight and wall thickness increased. The biomechanical changes were characterized by increased opening angle, inner and outer residual strains, decreased circumferential wall stiffness and increased longitudinal wall stiffness.

As the function of the GI tract is to a large degree mechanical, it has become increasingly popular to acquire biomechanical information on the GI tract[13-17]. However, many aspects of its biomechanical function are still largely left unexplored. Previous investigations were mainly conducted on uni-axial isolated strip experiments and balloon distension[18,19]. In the isolated strip studies, the structural integrity of the organ wall was not preserved and the strip was not necessarily in its zero-stress state at resting conditions since large residual strains existed in the GI tract[19]. In the balloon distension test, by means of impedance planimetry, the luminal cross-sectional area (CSA) could be measured. CSA as function of pressure provided important information on luminal dimensions during the loading but gave little information about material properties without further mechanical analysis. Furthermore, the tension-strain relationship was only computed for the circumferential direction and the strain was not referenced to the zero stress state[18].

The zero stress state of an organ is the state at which the organ is stress-free, meaning that all external and internal forces are removed. Vaishnav and Vossoughi[20] and Fung[21] independently reported respectively that the no-load state of a blood vessel was not the zero stress state. Recently, residual strains were demonstrated in the esophagus, small intestine, and large intestine[14-16, 22-28] and were found to be closely related to the growth and remodeling[24-30]. Hence the analysis of stress and strain begins with identification of the zero stress state.

This study was to explore how EGF affects geometric and biomechanical remodeling. EGF induced remodeling of the material structure, zero-stress state, and mechanical properties. The changes were quantified in terms of material constants in the constitutive equation. For computation of mechanical parameters we used video image techniques during loading and at no-load and zero-stress states. Assuming the intestine wall to be a membrane, biaxial experiments were done and a two- dimensional pseudostrain energy function was used to express the stress-strain relationship with reference to the zero-stress state. The use of pseudoelasticity to describe biological materials has been justified by Fung *et al*[12]. The vascular study by Liu and Fung[31] found that the zero stress state and the material constants changed with the development of diabetes.

Remodeling of the small intestine was evident after 4 days' EGF treatment with increased wall thickness and decreased luminal area. This was consistent with Vinter-Jensen' s study[11]. They demonstrated that EGF stimulated intestinal wall thickness growth before the surface area growth. According to the histology observation, the growth progress mainly involved the mucosa layer. The speed of growth began to decrease after 4 days' EGF treatment.

The small intestinal residual strains were negative at the mucosal layer and positive at the serosal layer. This implied that the mucosa was under compression in the no-load state and at physiological conditions in the low pressure range, whereas the muscle layers were in tension. As expected, both the residual strain and the opening angle increased in a time-dependent manner. The change of the opening angle was a result of non-uniform tissue remodeling of the organ wall. The opening angle increases when the inner layers had a higher growth rate than the outer layers or when the outer layer' atrophy was more severe than the inner layer[32]. In the present EGF study, the mucosa growth was much faster than that in the other layers, which resulted in the increased opening angle and residual strains. It has been demonstrated that residual stress reduces the stress concentration at the inner wall of the GI tract at no-load and homeostatic states[15, 16, 22]. The residual stress in the resting condition may also serve as a growth-regulation factor[33]. However, additional studies are needed to investigate whether the growth influences the residual stress distribution or *vice versa*.

The biaxial test showed that the wall stiffness changed in response to EGF treatment. After 7 days' EGF treatment, the wall stiffness decreased in circumferential direction and increased in longitudinal direction. The wall stiffness remodeled towards the normal state in both directions after 14 days' EGF treatment. In circumferential direction, the result was consistent with Vinter-Jensen' s report[11]. The different tendency of intestinal wall stiffness change in the two directions demonstrated that EGF-induced tissue remodeling was heterogeneous in the ileum. The elastic modulus of the intestine wall was closely related to the morphological wall composition and the stiffness was mainly dependent on the collagen in the submucosal layer[15, 34]. The submucosal layer did not remodel to the same degree as the mucosal layer. Therefore, the intestinal wall became softer in the circumferential direction after EGF treatment. At this point we could not explain the different remodeling in the two directions. A possible explanation is that the collagen orientation changed its direction during EGF treatment. This study did not intend to evaluate the collagen orientation angle, so this needs to be evaluated in future studies. Another noticeable result was that after 14 days' EGF treatment the curves shifted towards normal in both directions. We hypothesize that the pronounced proliferation of the intestine in the first week is due to direct stimulation by exogenous EGF. However, after one week, a negative feedback mechanism of the organ reduced the response to endogeneous EGF, resulting in reduced growth speed of the intestine. Finally, after two weeks, the remodeling might be determined by the stress in the tissue in accordance with the stress-growth law proposed by Fung[21].

Abstract

AIM: To study the effects of *Rheum tanguticum* polysaccharide$_{-1}$ (RTP$_{-1}$) on ulcerative colitis in rats induced by 2, 4, 6-trinitrophene sulphonic acid (TNBS) and their possible mechanism.

METHODS: RTP$_1$ (200 mg·kg^{-1}, ig) extracted from *Rheum tanguticum* Maxim. ex Regel was administrated to rats with colitis induced by TNBS for 5 d, 7 d, 10 d and 14 d, respectively. The effects of RTP$_1$ and dexamethasone (DX, 0.2 mg·kg^{-1}, ig) were contrastively investigated. The MPO level and SOD activity were determined by chromatometry. The expansion and protein expression of CD4$^+$T lymphocytes isolated from colon mucosae and mesenteric lymph nodes of colitis rats were performed by immunohistochemical analysis and Western-blot methods.

RESULTS: Treatments of RTP$_1$ (200 mg·kg^{-1}, ig) significantly reduced diarrhea, mortality, colon mass, ulcer areas and MPO level in colon mucosae on days 5, 7, 10 and 14 (5.2±1.4, 5.4±0.7, 5.2±1.8, $P<0.05$. 3.4±0.8, $P<0.01$. 16.1±12.1, $P<0.01$. 31.8±8.6, 17.7±5.3, 12.7±4.1, $P<0.05$). The effects of RTP$_1$ were similar to those noted above in DX group, but there were no immunosupressive effects of DX in RTP$_{-1}$ group, such as body mass loss, thymus and spleen atrophy. The decreased number and down-regulated protein levels of CD4$^+$T cells isolated from the colon of colitis rats treated with RTP$_1$ were found.

CONCLUSION: RTP$_1$ shows significantly protective effects but lower side effects on rats with colitis induced by TNBS. The mechanism may be due to the resistance to over expansion of CD4.

INTRODUCTION

Inflammatory bowel diseases (IBD), including ulcerative colitis (UC) and Cron' s disease, are complex autoimmune diseases whose etiology and pathogenesis have not been fully elucidated. IBD is related with multiple etiologic theories such as genetics, immunology and environment[1,2]. In recent years, a study of animal models of IBD pathogenesis showed that immune imbalance led to the inflammation in the gastrointestinal tract[3]. A growing number of evidences support an important role for dysregulated CD4+T cells response to the antigens, such as enteric bacterial flora, as a common disease mechanism[4-6]. Previous studies have also demonstrated an increasing number of infiltrating CD4+T cells and anti-CD4 antibodies are thought to be effective[7-9]. The fact showed that an imbalance of excessive CD4/Th1 cell response or inadequate CD4/Th2 cells response was involved in experimental colitis[10]. These studies strongly suggest that immunomodulatory drugs have a bright future in IBD therapy, and CD4 could be a potential therapeutic target of colitis drug research[11]. Many biologic therapies are being evaluated for the treatment of chronic inflammatory bowel diseases[12-15]. However, during recent years, the mainstay therapies for IBD were anti-inflammatory drugs and glucocorticosteroids (GCS)[16,17]. The incidence of IBD is increasing in Asia[18,19], some traditional Chinese medicine therapies, such as moxibustion[20] and decoction, have shown significant therapeutic effectiveness on IBD. Rhubarb which has been used for gastrointestinal disease, is a main ingredient of some decoctions administrated to patients with IBD. Our previous data showed *Rheum tanguticum* polysaccharide (RTP) extracted from *Rheum tanguticum* Maxim. ex Regel, could significantly protect against acute hepatic injury and oxidation injury[21,22]. Although there is no evidence whether IBD patients can benefit from RTP, heparin exhibits significant effects on colitis[23,24] and some plant polysaccharides exhibit immune regulative effects[25,26]. Therefore, we administered RTP$_1$ to colitis rats and investigated its therapeutical effectiveness on colitis rats-induced by TNBS and the expansion and protein level of CD4$^+$ lymphocytes, which were the potential targets of colitis immunoregulatory therapy.

MATERIALS AND METHODS

Animal

Male Sprague-Dawley rats (220-250 g) obtained from the Animal Center of Fourth Military Medical University were fed on a standard laboratory diet and free to access tap water. The rats were kept in a room at a controlled temperature (22±1 ℃), humidity (65-70 %), and a 12:12-h light-dark cycle. Forty rats were randomly divided into four groups, namely normal, model, RTP (200 mg· kg^{-1}, ig) and dexamethasone (DX, 0.20 mg· kg^{-1}, ig) groups.

Materials

Sephacryl-S400 was from Pharmacia Biotech AB, dexamethasone (DX) and 2, 4, 6-trinetrophene sulphonic acid (TNBS) were purchased from Sigma, hexadecytrimethyl-ammonium was a product of Fluka. CD4 mAb was a product

of Immunotech Co. SABC immunehistochemical kits were purchased from Boshide Co. Electrophoresis apparatus was purchased from Bio-Rad.

Preparation of polysaccharide from Rheum tanguticum Maxim. ex Regel

Rhubarb, identified by professor Ren Yi Northwest University of china, was *Rheum tanguticum* Maxim.ex Regel. *Rheum tanguticum* polysaccharide (RTP) was extracted according to the methods described previously[27]. In brief, *Rheum tanguticum* Maxim (1 kg) was fragmented and boiled 3 times,8 hours each time with absolute ethanol for 24 hours to extract the components dissolved in ethanol. The residue was boiled for another three times (8 h each time) with water to extract polysaccharide. All the water extractions were finally pooled and mixed with a finally concentrated ethanol solution of 75 ml/L to precipitate the polysaccharide-enriched fractions. After proteins removed by freezing-thawing methods, crude *Rheum tanguticum* polysaccharide (RTP) was obtained by dialysis, concentration and lyophilization. In this study, the polysaccharide (uronic acid) content of RTP_1 was 97.4 % (27.5 %), and their molecular masses were 60 Kda-80 Kda , and $RTP_1$was administered orally to rats to study the effects and mechanism on colitis.

Induction of ulcerative colitis model in rats

Male Sprague-Dawley rats were fasted for 24 hours before experimentation but with free access to drinking tap water. Colitis model was produced as before[28] (*Gastroenterology* 1989;96:795-811). In brief, the rats (except rats in normal group) were lightly anesthetized with ether. A rubber catheter (OD 2 mm) was inserted rectally into the colon so that the tip was 8 cm proximal to the anus, approximately at the splenic flexure. TNBS dissolved in 40 mL/L in ethanol was instilled into the lumen of colon through the rubber catheter. Saline, RTP and DX were administrated 6 hours after induction of colitis model. The body weight was recorded during the experimental period. The rats were anesthetized with ether and killed by cervical dislocation on d5, d7, d10, d14, respectively. Each was 10 rats. The distal colon was removed and opened by a longitudinal incision, rinsed with saline, and weighed. Mucosal damage was assessed by measurement of ulcerative areas in colon mucosae by a single observer blinded to characteristics or treatment of the animals being studied. Colon samples were then excised, snap-frozen in liquid nitrogen, and stored at -80 ℃ for later assay of myloperoxidase (MPO) and superoxide dismutase (SOD). Additional samples were preserved in formaldehyde for histological and immunohistochemical analysis. Meantime, the spleen and thymus were removed and weighed.

Determination of biochemical marker

The activity of MPO and SOD was determined by chromatometry. In brief, the colon tissue was suspended in 5 g/L hexadecytrimethyl-ammonium (pH6.0, 50 mg of tissue per milliliter) for MPO level and suspended in PBS (pH 7.2, 100 mg per milliliter) for SOD level and then homogenized for 15 s by using a polytron generator in ice bathing. The MPO and SOD levels in colon tissue were determined by using the technique described as before (*Gastroenterology* 1984;84:1344).

Immunohistochemical analysis on $CD4^+$ lymphocyte

Immunohistochemical staining was performed on paraffin embedded sections by using biotinylated anti-CD4 mAb, and then operated according to the procedure for SBC immunohistochemiacal kit.

Western-blot analysis on $CD4^+$ lymphocyte

The rats with colitis induced by TNBS ethanol were killed by cervical dislocation. The lumenal lymphoid node was separated and homogenized in 1 ml lysis buffer in ice bathing for 10 min, then centrifuged at 11 000 g for 5 min at 4 ℃, and 30 μl suspension was moved to lodding buffer 15 ml. The samples were boiled for 10 min and subjected to electrophoresis on 120 g/L SDS-acrylamide gel. The gel was then electroblotted onto a ultrocellulose membrane, and detection of CD4 protein was conducted by using anti-CD4 mAb.

Statistical analysis

Results were expressed as mean ± standard deviation ($\bar{x}\pm s$). Differences between two groups were examined by Student' s *t*-test. A probability (*P* value) of less than 0.05 was considered statistically significant.

RESULTS

Effects of RTP_1 on rats with TNBS-induced colitis

Grossly visible colon wall thicking, inflammation, and ulcers were found in the animals that received TNBS in 400 mL/L ethanol. Treatments of RTP_1 (200 $mg \cdot kg^{-1}$ ig) significantly reduced diarrhea, mortality, colon mass and ulcer area. The effect of RTP_1 on colitis was similar to that in DX group (Figure 1, Table 1).

^{a}P<0.05, ^{b}P<0.01 *vs* Model; ^{c}P<0.05, ^{d}P<0.01 *vs* Normal; ^{e}P<0.05, ^{f}P<0.01 *vs* RTP_1.

Effects of RTP_1 on SOD and MPO of colon mucosa

The MPO activity and SOD level in TNBS-induced colitis rats were much higher than those in control. Treatments with RTP_1 (200 mg·kg^{-1} ig) significantly increased SOD activity, meanwhile, decreased MPO level in colon mucosae. The effects of DX on MPO and SOD activity of colon mucosae were similar to those of RTP_1 (Table 2).

Effects of RTP_1 on body weight, thymus and spleen index

During the inflammatory period, the rats with colitis showed marked body mass loss, thymus atrophy and spleen hypertrophy. Administration of RTP_1 (200 mg·kg^{-1}, ig) significantly prevented body mass loss. But the effects of DX showed farther body mass loss, thymus atrophy compared with control and RTP_1, suggesting severe immunosuppression occurred (Table 3).

Effects of RTP_1 on $CD4^+$T lymphocytes

Evidences indicated that $CD4^+$T cells played a key role in the pathogenesis of gastrointestinal tissue damage in ulcerative colitis. According to the results of immunohistochemical and Western-blot of $CD4^+$T lymphocytes isolated from colon tissues, there were a great increase of CD4 lymphocytes in the diseased colon and a significant decrease ofter the treatment with RTP_1 (200 mg·kg^{-1} ig). (Figures 2, 3).

DISCUSSION

Some plant polysaccharides are known to posses immunorgulatory effects and wide bioactivities[29,30]. Rhubarb has traditionally been used as a folk remedy for gastrointestinal diseases for over two thousand years in China. We hypothesized that polysaccharide isolated from rhubarb might exhibit immune regulation on colitis rats. To test this hypothesis, we extracted polysaccharide from a breed of rhubarb, *Rheum tanguticum* Maxim. ex Regel., then administrated RTP to rats with colitis induced by TNBS. The results showed striking therapeutic effectiveness of RTP on the experimental colitis by attenuating the colon weight increase, decreasing the ulcer area formation, which resulted in a rapid recovery of animals from colitis induced by TNBS-enema. There was no significant difference between RTP and DX on colitis. Besides, RTP had no immunosuppressive side effects as DX.

Ulcerative colitis (UC) is considered to have a multifactorial etiology leading to intricate pathogenic mechanism that results in complex clinical manifestations. In recent years, the established animal models of immunology, genetics and biochemistry have promoted the study on pathogenic mechanism of UC[3]. The animal model of colitis induced by TNBS-enema, used in the present study, was considerated the characteristics as excessive Th1/$CD4^+$T lymphocytes response and similar to human IBD[31]. The TNBS-induced animal model, which was duplicated and cheap, was most commonly used to estimate the therapeutic effectiveness of colitis[3]. Therefore, this TNBS/ethanol-induced animal model may be suitable for investigate the therapeutic effectiveness and mechanism of RTP on colitis.

Colonic lesion and inflammation induced by TNBS-ethanol were accompanied by a drastic elevation of MPO activity in colonic tissues. This enzyme was used as an index of quantitative inflammation and a marker of neutrophil infiltration in the tissue (*Gastroenterology* 1989;96:795-811). In the present study, administration of RTP significantly attenuated the increase of colonic MPO activity, indicating its anti-inflammatory effect. SOD is an antioxidant enzyme that is cytoprotective in many tissues, because it scavenges the overproduced superoxide by stimulants. This study showed that the SOD activity in colonic tissue was significantly increased on days 5 and 7, but returned to normal level on days 10 and 14 after TNBS-enema. It is envisaged that the elevated SOD activity may be a protective reaction in the colonic tissue against the overproduction of superoxide during the early active phase of colonic inflammation. Administration of RTP markedly increased SOD activity after TNBS-enema and kept SOD at a higher level till 14 days. This result indicated that the therapeutic effectiveness of RTP on colitis might be at least in part, through its anti-oxidative effect. However, the underlying mechanisms of the therapeutic effectiveness of RTP need further studies. All these findings implicate that RTP has a very impressive therapeutic effectiveness on experimental colitis, and RTP may be the main component of *Rheum Rheum tanguticum* that is commonly used as a classic Chinese drug against inflammation in gut.

An increasing body of evidence suggests that inflammatory bowel disease (IBD) is due to abnormal function of regulatory T cells required for immunological homeostasis in gut-associated lymphoid tissue (GALT)[32]. CD4+T lymphocytes play an important role in the progressive and perpetuated inflammation of colitis[33,34]. In this study, RTP showed significant effects on resistance to the up-expression of $CD4^+$protein levels, suggesting that the mechanism of RTP on colitis is related to the modulation of $CD4^+$T cell dysfunction. $CD4^+$ T cells containing both $CD45RB^{high}$ and $CD45RB^{low}$ populations participatein as a pathogenic subset that in turn leads to inflammatory reactions selectively in the large intestine, indicating that UC can be cured by maintaining the balance between the two subunits of CD4 and the balance between the cytokines nets[35]. Therefore, $CD4^+$ T cell may be a new potential target of therapeutic drugs on UC patients.

Abstract

AIM: To investigate the effects and mechanisms of ischemic preconditioning (IPC) on the ischemia/reperfusion (I/R) injury of liver cirrhosis in rats and the effect of IPC on P-selectin expression in hepatocytes.

METHODS: Forty male SD rats with liver cirrhosis were randomly divided into sham operation group (SO group), ischemia/reperfusion group (I/R group), ischemic preconditioning group (IPC group), L-Arginine preconditioning group (APC group), L-NAME preconditioning group (NPC group), eight rats in each group. Hepatocellular viability was assessed by hepatic adenine nucleotide level and energy charge (EC) determined by HPLC, ALT, AST and LDH in serum measured by auto- biochemical analyzer and bile output. The expression of P-selectin in the liver tissue was analyzed by immunohistochemical technique. Leukocyte count in ischemic hepatic lobe was calculated.

RESULTS: At 120 min after reperfusion, the level of ATP and EC in IPC and APC groups was higher than that in I/R group significantly. The increases in AST, ALT and LDH were prevented in IPC and APC groups. The livers produced more bile in IPC group than in I/R group during 120 min after reperfusion (0.101±0.027 *versus* 0.066±0.027 ml/g liver, P=0.002). There was a significant difference between APC and I/R groups, (P=0.001). The leukocyte count in liver tissues significantly increased in I/R group as compared with SO group (P<0.05). The increase in the leukocyte count was prevented in IPC group. Administration of L-arginine resulted in the same effects as in IPC group. However, inhibition of NO synthesis (NPC group) held back the beneficial effects of preconditioning. Significant promotion of P-selectin expression in hepatocytes in the I/R group was observed compared with the SO group (P<0.01). IPC or L-arginine attenuated P-selectin expression remarkably (P<0.01). However, inhibition of NO synthesis enhanced P-selectin expression (P<0.01). The degree of P-selectin expression was positively correlated with the leukocyte counts infiltrating in liver (r=0.602, P=0.000).

CONCLUSION: IPC can attenuate the damage induced by I/R in cirrhotic liver and increase the ischemic tolerance of the rats with liver cirrhosis. IPC can abolish I/R induced leukocyte adhesion and infiltration by preventing post-ischemic P-selectin expression in the rats with liver cirrhosis via a NO-initiated pathway.

INTRODUCTION

Ischemic preconditioning (IPC) refers to a phenomenon in which a tissue is rendered resistant to the deleterious effects of prolonged ischemia and reperfusion (I/R) by prior exposure to a short period of vascular occlusion. This phenomenon was first demonstrated in the heart a decade ago[1] and has been the subject of intensive investigation ever since. Although it is clear that activation of adenosine receptors and protein kinase C (PKC) is critical to the development of the beneficial action of IPC, the downstream effectors in the signaling cascade initiated by IPC are uncertain. Akimisn *et al*[2] and Kubes *et al*[3] have demonstrated that IPC prevents intestinal and skeletal muscle I/R injury by inhibiting postischemic leukocyte-endothelial cell interaction. However, identification of the end effectors of the ant adhesive effects of IPC remains unclear. A likely candidate effector molecule that may be targeted by the signaling cascade initiated by IPC is P-selectin, because post-ischemic leukocyte rolling (and thus subsequent stationary adhesion and emigration) is critically dependent on the expression of P-selectin on venular endothelium[4]. IPC has been commonly studied in the heart, but few studies have been performed on cirrhotic liver IPC. This study was aimed to determine the effects and mechanisms of IPC on the I/R injury rats with liver cirrhosis and the effect of IPC on the expression of P-selectin.

MATERIALS AND METHODS

Reproduction of rat cirrhotic liver model

Sprague-Dawley (SD) Male rats initially weighing 200±20 g were used.

Subcutaneous injection of 60 % Ccl_4 (0.3 mg/kg) was made once every 4 days for 8 weeks and 5% ethanol was allowed for 60 days[5].

Operative procedure

At first, ligamentous attachments around the liver were dissected. The common bile duct was then cannulated and bile output was measured. Ischemia was induced in the median and left lateral hepatic lobes by clamping the corresponding hepatic arterial and portal vein, while the blood flowing to the other lobe was left intact. When the assigned period of warm ischemia was completed, the clamp was removed and the pedicles to the non-ischemic lobe were ligated[6].

Grouping of animals

Forty male SD rats with liver cirrhosis were divided into 5

groups randomly, eight rats in each group. Animals in sham Operation group (SO group) were subjected to anesthesia and laparotomy. Animals in ischemia/reperfusion group (I/R group) were subjected to 30 min of left and middle lobe hepatic ischemia, followed by 120 min of reperfusion. Animals in ischemic preconditioning group (IPC group) were same as I/R group, but subjected to 10 min of ischemia and 5 min of reperfusion prior to I/R. Animals in L-arginine preconditioning group (APC group) were same as IPC group, but treated with a continuous intravenous infusion of L-Arginine (10 mg/kg, portal vein) for 5 min before preconditioning. Animals in L-NAME preconditioning group (NPC group) were same as IPC group, but treated with a continuous intravenous infusion of L-NAME (10 mg/kg, portal vein) for 5 min before preconditioning.

The animals were killed after blood samples were collected from the inferior vena cava after 120 min of reperfusion. Liver samples were excised from the anterior edge of the median lobe before ischemia, after the induction of ischemia and 120 min after reperfusion respectively. The specimens were immersed in liquid nitrogen immediately after sampling to measure the tissue concentration of adenine nucleotides, adenosine 5'-triphosphate (ATP), adenosine 5'-diphosphate (ADP), adenosine 5'-monophosphate (AMP) and total adenosine nucleotide. At 120 min after reperfusion, livers were perfused and fixed *in situ* with 4 % para formaldehyde.

Energy metabolism

ATP and its metabolites, ADP and AMP in the liver tissue were assayed as follows. After the frozen tissue with a mortar and pestle was ground, the powder was mixed with 1 ml 6 % perchloric acid at 4 ℃. The mixture was centrifuged at 3 000 rpm for 10 min and the supernatant was stored at 4 ℃, then 0.5 ml 6 % perchloric acid was added to the precipitate and centrifuged in the same manner. The supernatant was neutralized with 3 mol/l potassium carbonate and centrifuged at 3 000 rpm for 10 min. The final supernatant was used as a sample for ATP and its metabolites. The tissue concentration of ATP and its metabolites was determined by high-performance liquid chromatography (HPLC). Energy charge (EC) was equal to (ATP+1/2ADP)/(ATP+ADP+AMP)[7].

Measurement of serum cytosolic enzymes

Serum alanine aminotransferase (ALT), aspartate aminotransferase (AST) and lactate dehydrogenase (LDH) were measured at 4 ℃ using commercially available kits (Horizon, American) by an auto-biochemistry analyzer.

Measurement of bile output

Bile output from the ischemic liver was measured through a choledochotomy tube placed in the common bile duct.

P-selectin expression in liver tissues

Immunohistochemical staining for P-selectin protein was performed using SP technique[8]. The immunostaining of P-selectin was visually classified into four groups: no staining present in any tumor cells (-), slight staining in most of the hepatocytes (+), most of the hepatocytes with moderate staining (++), and strong staining in most of the hepatocytes (+++). Two senior pathologists who did not know the clinicopathological data did the classification.

Histological examination

Liver samples were excised from the anterior edge of the median lobe 120 min after reperfusion. Small portions (0.5 cm×0.5 cm) were fixed immediately in 4 % buffered para formaldehyde (pH 7.2) and embedded in paraffin. These portions were cut into 4 μm thick sections and stained with hematoxylin and eosin (H & E). Leukocyte count in ischemic hepatic lobe could be calculated randomly under microscopy(×400).

Statistical analysis

The results were expressed as $\bar{x}\pm s$. The one-way NOVA and H test were used for statistical significance of differences between groups. Correlation analysis between two factors was made by Spearman method. $P<0.05$ was considered significant.

RESULTS

Change of ATP, ADP, AMP and EC levels in liver after ischemia and reperfusion

At 30 min of hepatic inflow occlusion, the ATP and EC levels in liver tissues were significantly decreased in I/R, IPC, APC and NPC groups ($P<0.05$). At 120 min after reperfusion, the ATP and EC levels in IPC and APC groups were significantly higher than those in I/R group ($P=0.000$, $P=0.001$). But there was no significant difference between NPC and I/R groups ($P>0.05$) (Table 1).

Change of ALT, AST and LDH in serum

Significant increases of ALT, AST and LDH levels in serum were observed in the group subjected to ischemia and reperfusion (I/R group) in comparison with the control group (SO group). When ischemia was preceded by 10 min of ischemia and 5 min of reperfusion (IPC), the increases of AST, ALT and LDH in serum were prevented ($P=0.000$). Administration of L-Arginine (APC group) resulted in the same effects on ALT, AST and LDH as above ($P=0.001$). However, infusion of L-NAME (NPC group) inhibited the beneficial effects of preconditioning (Table 2).

Results of bile output and leukocyte count in ischemic hepatic lobe

The livers produced more bile in IPC group than in I/R group during 120 min after reperfusion (0.101±0.027 *versus* 0.066±0.027 ml/g liver, $P=0.002$). There was a significant difference between APC and I/R, NPC and SO groups ($P=0.001$, $P=0.000$) respectively. However, there was no significant

Results of P-selectin expression in liver tissues

Significant promotion of P-selectin expression in hepatocytes in the I/R group was observed in comparison with the SO group (P=0.000). IPC or L-arginine attenuated P-selectin expression significantly (P=0.005). However, inhibition of NO synthesis enhanced the expression of P-selectin (P=0.001) (Table 4).

Table 4 Expression of P-selectin in liver tissues

Groups	Cases	Grade			Average rank
		(+)	(++)	(+++)	
SO	8	7	1	0	10.69
I/R	8	0	5	3	30.50[a]

APC	8	4	4	0	17.25[b]
NPC	8	0	6	2	29.00[a]

[a]P<0.01, *vs* SO group; [b]P<0.05, *vs* I/R group.

Correlation between leukocytes infiltration and P-selectin expression in liver tissues

Leukocytes infiltration was significantly correlated with P-selectin expression in liver tissues. The degree of P-selectin expression was positively correlated with the counts of leukocyte infiltration in liver (r=0.602, P=0.000).

DISCUSSION

IPC is a unique phenomenon which attenuates organ injury caused by I/R. This is accomplished through a brief preceding episode of vascular occlusion which renders these tissues resistant to the deleterious effects of prolonged ischemia and reperfusion. The protective effects of IPC have been well documented in the previous studies involving different tissues and organs. These included cardicmuscle[1,9], skeletal muscle[2], small intestines[10] and more recently the liver[11]. Although the mechanism of IPC is still unclear up to now, several potential mediators (nitrogen monoxide, adenosine, oxide radical, bradykinin and so on) have been found to play different roles in different organs[11-14]. Adenosine and protein kinase C (PKC) were critical to the beneficial actions of IPC in the heart[15]. IPC-induced adenosine A_1-receptor stimulation during the period of preconditioning ischemia increased phospholipose C (PLC) activity, an event that is coupled by pertussis toxin-sensitive G proteins[12,13]. Activation of PLC induced the formation of diacylglycerol, which in turn promotes the translocation and activation of PKC. Activation of PKC stimulated the activation of ATP-sensitive potassium (Katp) channels, and the beneficial actions of IPC in the heart were induced[15], while adenosine stimulated NO production in IPC to protect against the injury associated with I/R in liver[16]. In the case of the cirrhotic liver, our work revealed that the ATP and EC levels in IPC group were higher than those in I/R group. There was significantly more bile produced by the livers in IPC group too. However, the increase of AST, ALT and LDH release was attenuated, when IPC was performed before ischemia. This fact shows the protective effect of IPC on preventing ischemia-reperfusion damage of cirrhotic liver. In addition, we found that L-arginine administration in hepatic ischemia reperfusion attenuated the injury in a manner similar to that of IPC. Accordingly, inhibition of NO synthesis abolished the beneficial effects of IPC. Thus, our data suggest that NO is one of the potential mediators of the protective effects of IPC.

Akimisn.[2] and Kubes[3] demonstrated that IPC prevented intestinal and skeletal muscle I/R injury by inhibiting postischemic leukocyte-endothelial cell interactions. These observations are important because they indicate that in addition to protecting against the deleterious effects of ischemia and reperfusion, IPC could induce cellular changes that also prevent leukocyte recruitment to ischemic tissues. This might limit the reperfusion component of I/R injury, which was primarily leukocyte dependent in the small intestine and other organs[17,18]. Thus, in addition to K^+-ATP channels, IPC appears to target effector molecules that modulate the inflammatory response to I/R. A likely candidate effector molecule that may be targeted by the signaling cascade initiated by IPC is P-selectin, for several researches have shown that I/R injury is a leukocyte-mediated event resulted from a cascade of acute phase reactants causing leukocyte-endothelial cell interactions. The interactions progressed from rolling to saltation to firm adhesion with subsequent tissue infiltration and organ injury[19-24]. The cascade of acute phase reactants was critically dependent on the expression of P-selectin on venular endothelium[4,25]. In our study, significant promotion of the expression of P-selectin in hepatocytes in the I/R group was observed in comparison with the SO group. IPC or L-arginine attenuated P-selectin expression significantly. However, inhibition of NO synthesis enhanced the expression of P-selectin. The increase in the leukocytes count was prevented in IPC group. Administration of L-arginine resulted in the same effects as in IPC group. In the mean time, there was a significant correlation between leukocytes infiltration and P-selectin expression in liver tissues. The degree of P-selectin expression was positively correlated with the counts of leukocyte infiltration in liver.

In summary, IPC can abolish I/R induced leukocyte adhesion and infiltration by preventing postischemic P-selectin expression in rats with liver cirrhosis via a NO-initiated pathway.

Abstract

AIM: Psychological factors, altered motility and sensation disorders of the intestine can be variably associated with irritable bowel syndrome (IBS). Such aspects have not been investigated simultaneously. The aim of this paper was to evaluate gastrointestinal motility and symptoms, psychological spectrum and quality of life in a large group of IBS patients in southern Italy.

METHODS: One hundred IBS patients (F:M=73:27, age 48±2 years, mean±SE) fulfilling ROME II criteria matched with 100 healthy subjects (F:M=70:30, 45±2 years). Dyspepsia, bowel habit, alexithymia, psycho-affective profile and quality of life were assessed using specific questionnaires. Basally and postprandially, changes in gallbladder volumes and antral areas after liquid meal and orocaecal transit time (OCTT) were measured respectively by ultrasonography and H_2-breath test. Appetite, satiety, fullness, nausea, and epigastric pain/discomfort were monitored using visual-analogue scales.

RESULTS: Compared with controls, IBS patients had increased dyspepsia (score 12.6±0.7 *vs* 5.1±0.2, $P<0.0001$), weekly bowel movements (12.3±0.4 *vs* 5.5±0.2, $P<0.00001$, comparable stool shape), alexithymia (score 59.1±1.1 *vs* 40.5±1.0, $P=0.001$), poor quality of life and psycho-affective profile. IBS patients had normal gallbladder emptying, but delayed gastric emptying (T_{50}: 35.5±1.0 *vs* 26.1±0.6 min, $P=0.00001$) and OCTT (163.0±5.4 *vs* 96.6±1.8 min, $P=0.00001$). Fullness, nausea, and epigastric pain/discomfort were greater in IBS than in controls.

CONCLUSION: ROME II IBS patients have a pan-enteric dysmotility with frequent dyspepsia, associated with psychological morbidity and greatly impaired quality of life. The presence of alexithymia, a stable trait, is a novel finding of potential interest to detect subgroups of IBS patients with different patterns recoveed after therapy.

INTRODUCTION

Irritable bowel syndrome (IBS) is a common, chronic biopsychological functional disorder of unknown aetiology, affecting 10-20 % of all individuals any one time. Psychological factors, altered motility and sensation disorders of the intestine can be variably associated[1]. Dysfunctions of the gastrointestinal tract in IBS appear as altered bowel function[2], associated with pain or discomfort, without organic disease[3-5]. Besides lowered visceral perception thresholds involving the rectum[6] and more proximal districts[7], motility defects seem to develop. Thus, IBS patients may complain of a constellation of both gastrointestinal and extra-intestinal symptoms[7], and a significant proportion of patients may have disordered perception[8,9] resulting in more readily feeling of normal intestinal contractions[10]. Psychological factors, such as abnormal illness attitute[11], may also play a role in the pathogenesis of IBS[5], with a significant impact on health-related quality of life (HRQOL)[12]. More recently, revised diagnostic criteria for IBS have been proposed (ROME II criteria)[4]. Moreover, sophisticated questionnaires are now available for studying both quality of life and specific psychological aspects like the alexithymia construct. The latter includes difficulties in identifying and describing feelings, impoverishment of fantasy life and excessive preoccupation with physical symptoms and external events[13].

Such aspects have not been investigated simultaneously in IBS patients. Therefore, the aim of the present study was to evaluate gastrointestinal motility and symptoms, psychological status, including alexithymia and HRQOL in a large group of IBS patients from a referral center in southern Italy.

MATERIALS AND METHODS

Subjects

A total number of 200 adult subjects were studied prospectively and divided into 2 cohorts: 100 consecutive patients with IBS (27 males and 73 females) and 100 healthy subjects (30 males and 70 females) with their age and body size matched. The two groups were also comparable for years of education (9.3±1.5 years and 9.6±1.3 years in healthy and IBS, respectively). The characteristics of patients are depicted in Table 1. There was no difference in sex ratio, age and body size. The percentage of non-coffee drinkers and smokers was greater in IBS than in healthy subjects ($0.02<P<0.03$). The IBS group was composed of out-patients, with a firm diagnosis through positive identification of the ROME II diagnostic criteria[4]. With the inclusion criteria used in this study, the specificity of IBS diagnosis was about 98 %[14,15]. Mean years since first diagnosis have been 5.9 years with bowel habit alternating between diarrhea and constipation, according to standardized criteria[4]. During the above mentioned period, patients had tried several -albeit poorly effective- therapeutic trials with the help of their family practices. All patients were symptomatic at the time of the study, and lower abdominal discomfort or pain was the main reason for seeking medical advice, and none was on specific therapy for IBS at the time of evaluation. There was no coexistent disease and all patients had normal haematology, biochemistry, urinalysis, together with a normal colonoscopy

or barium enema if aged over 50 years. Excluded were subjects if they had a history of gastrointestinal surgery. Female subjects were excluded if they were pregnant, breast feeding, or hysterectomised and were studied during the first phase of the menstrual cycle or while taking oestrogen/progesterone contraceptive medication. Drugs and cigarette smoking were not allowed for 48 hours prior to the study while alcohol and caffeine containing drinks were stopped 24 hours prior to the study. All subjects smoked less than 5 cigarettes per day and drank below the recommended safe alcohol limit (that is less than 21 units/week).

Because lactose maldigestion-intolerance and IBS may have almost identical symptoms[16], all patients were screened by lactose H_2-breath test, which was invariably negative. Healthy volunteers were recruited from staff members and with the help of local family practices. Laboratory investigations were normal (as above) in all healthy subjects and there was a negative toxicology for substances of abuse. All subjects gave informed consent to join the study which was approved by the Ethics Committee of Bari University Hospital.

Measures

Symptomatology was assessed by focusing on an estimate of the maximum degree of lower abdominal pain or discomfort, and abdominal bloating in the previous 12 months was assessed by visual analogue scales (VAS)[17]. The weekly frequency of bowel movements over a time span of one month was estimated by a self-assessed diary. A specific stool form scale was also used based on a semi-quantitative score[18]. To carefully characterise the association between IBS and functional dyspepsia[19], the presence and severity of dyspeptic symptoms were quantified in two ways: validated semiquantitative score[20]; and self-assessed VAS of upper gastrointestinal perception monitoring appetite, satiety, nausea, abdominal fullness and upper abdominal (epigastric) pain or discomfort[21]. In the latter case, scores were obtained at baseline (*i.e.* time 0) and at 15, 30, 45, 60, 90 and 120 min postprandially. The Middlesex Hospital Questionnaire (MHQ) symptom check list was used to investigate six symptoms: anxiety, phobic behavior, obsessive-compulsive behavior, somatization, depression, and hysteria[22]. Traits of alexithymia were assessed by the Toronto Alexithymia scale based on a 20-item scale (TAS-20)[23] with the validated Italian translation[24,25]. A final score $\geqslant$61 was considered positive for alexithymia, while a score ranging from 50 to 60 was "border line"[25]. The short form check list (SF-36) was used to assess HRQOL in the following 8 domains: general health, physical functioning, role-physical, role-emotion, social functioning, mental health, body pain, and vitality[26,27].

Motility studies

After an overnight fast, subjects attended the Functional Investigations Unit. Standard criteria recently reviewed by our group[28] were used to study gallbladder and gastric emptying by functional ultrasonography in response to a liquid test meal, consisting of 200 mL solution totalling 13 g (39 %) fat, 10 g (13 %) protein and 35 g (48 %) carbohydrates, calorie content 1 270 kJ, 365 mmol /L (*Nutridrink*®, Nutricia, Milano, Italy), which was consumed within 2 min. Gallbladder emptying was assessed by monitoring fasting and postmeal course of gallbladder volumes. Sagittal and transverse scans of the gallbladder at its largest dimension were obtained at 5-15 minute intervals over 2 hours. Gastric emptying was assessed by monitoring fasting and postmeal course of antral areas[17,29]. Oro-caecal transit time was measured simultaneously with ultrasonographic studies by hydrogen breath test using 10 g lactulose and collecting the breath with a portable equipment (EC60-Gastrolyzer, Bedfont, USA)[30].

Statistical analysis

All calculations were performed with the *NCSS 2001* statistical software (Kaysville, UT, USA, see http://www.ncss.com/). Results were given as mean ± standard error (SE). Differences in emptying curves were evaluated by two way *ANOVA* repeated-measures followed by Fisher's LSD multiple comparison test. Differences of means between healthy and IBS were evaluated using the Student's *t* test for unpaired data. Linear regression analysis was performed by the method of least square. The chi-square test was used to assess associations between categorical data. A two-tailed probability (*P*) value of less than 0.05 was considered statistically significant[31,32].

RESULTS

All subjects tolerated the tests well. Table 1 also shows that VAS scores for lower abdominal pain and bloating were significantly higher in IBS patients than in healthy subjects. Whereas the frequency of bowel movements was greater in IBS patients than in healthy subjects (12.3±0.4 *vs* 5.5±0.2 evacuations/wk, *P*=0.00001) (Figure 1A), stool form was similar (Buckley score: 3.9±0.1 *vs* 3.5±0.1 in patients and controls, respectively),(Figure 1B).

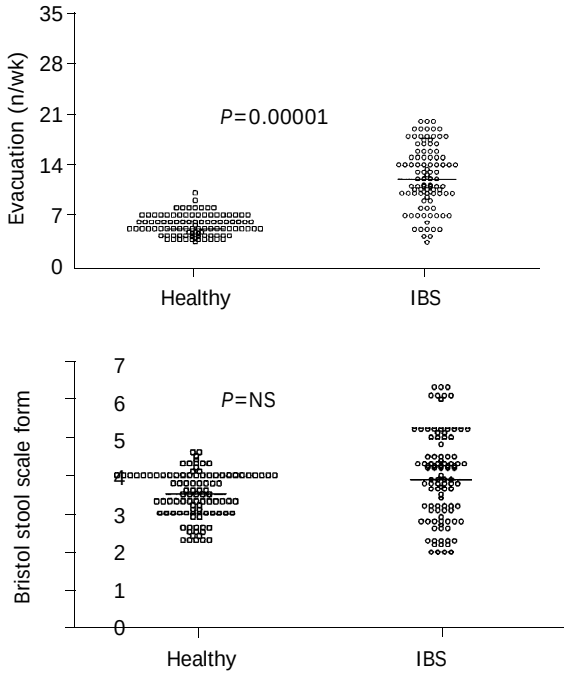

Figure 1 A: Significantly more bowel movements in IBS patients than in healthy subjects. B: Comparable score for stool form between IBS patients and healthy subjects. Results are expressed as individual data and median (horizontal line).

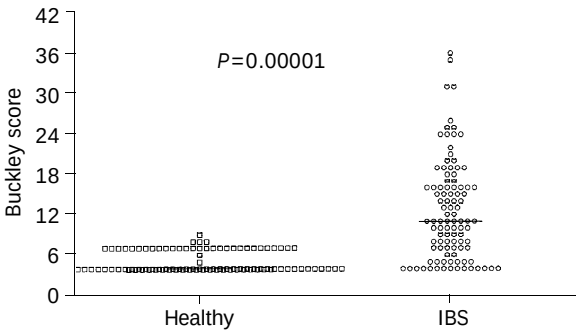

Figure 2 Significant dyspepsia in IBS patients compared with healthy subjects. Results are expressed as individual data and median.

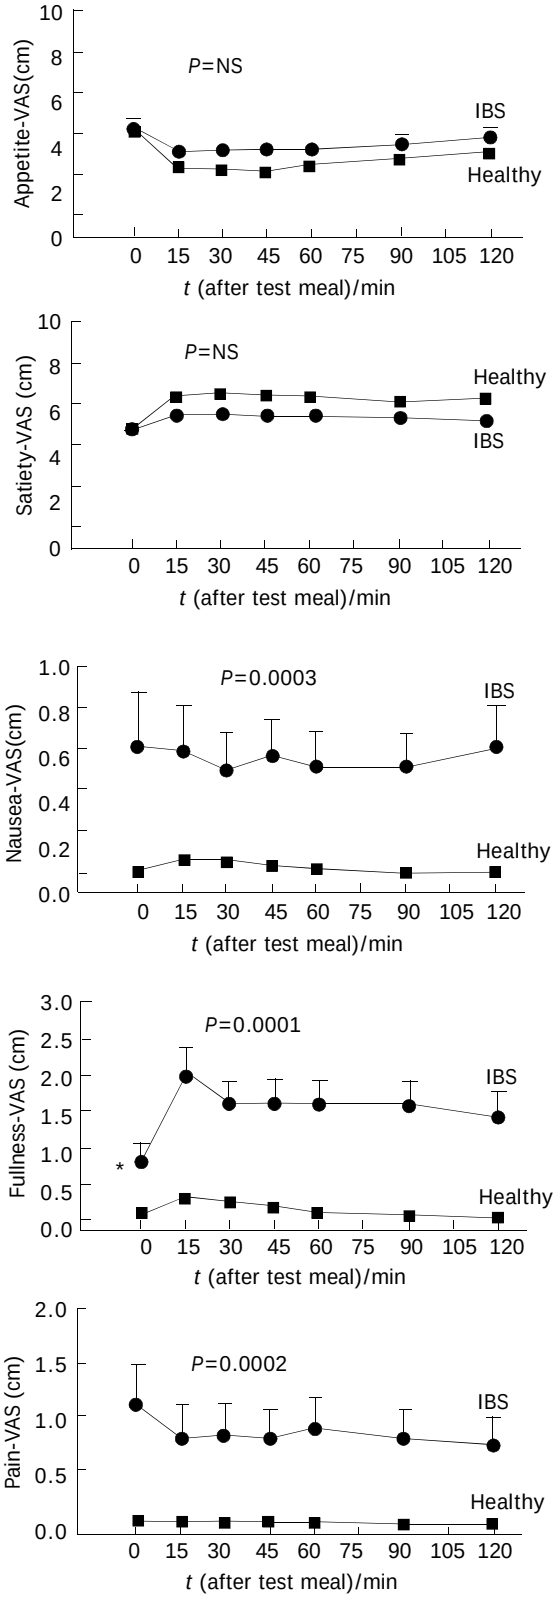

Figure 3 Time-course of visual analogue scale (VAS) for appetite, satiety, nausea, abdominal fullness and epigastric pain (or discomfort) in healthy subjects. On the X-axis time "0" is before ingestion of test meal. Asterisks indicate significant differences ($0.0001<P<0.001$) of IBS patients *vs* healthy subjects at baseline. Significant differences for nausea, fullness and epigastric pain / discomfort of IBS patients *vs* healthy subjects (area under curve).

Mean score of dyspepsia was greater in patients than in healthy subjects (12.6±0.7 *vs* 5.1±0.2, $P<0.0001$), an abnormal score was found in 75 % and 5 % of patients and healthy subjects, respectively ($P<0.0001$, Figure 2). As expected, the perception of satiety and appetite (both at fasting and as postprandial AUC) showed a strong negative correlation in IBS patients and healthy subjects ($0.91<r<0.92$, $P<0.0001$). There was no difference in appetite and satiety between IBS patients and healthy subjects (either at baseline and postprandially), By contrast, the AUC during 120 min was invariably greater in IBS than in control subjects for nausea (58.0±14.1 *vs*3.9±1.0, $P=0.002$), fullness (133.5±26.1 *vs* 17.1±1.9, $P=0.00002$) and pain/discomfort (75.1±24.2 *vs* 2.5±0.6, $P=0.002$). Time-dependent profiles for these scores are depicted in Figure 3.

Table 1 Patient characteristics in study group (mean ± SE)

	IBS	Healthy	*P**
No of subjects	100	100	
Female: Male ratio	73:27	70:30	NS
Age (yr)	48±2	45±2	NS
BMI (Kg / m^2)	23.5±0.4	22.9±0.3	NS
Coffee-drinkers No (%)			
None	43 (43%)	24 (24%)	0.03°
<1 per day	9 (9%)	22 (22%)°	
1-5 per day	48 (48%)	54 (54%)°	
Smokers No (%)	30 (30%)	15 (15%)	0.02°
Lower abdominal pain (VAS, cm)	5.8±0.1	0.04±0.01	0.0001
Abdominal bloating (VAS, cm)	6.2±0.1	0.1±0.02	0.0001

*Student's *t* test or χ^2 for comparison of proportions, VAS=visual analogue scale.

Results from the MHQ questionnaire are given in Figure 4A which shows that IBS patients had significantly higher scores for anxiety, somatization, phobia and depression than healthy subjects. Results from the TAS 20 questionnaire on alexithymia are given in Figure 4B which shows a significantly increased score in IBS patients (59.1±1.1) compared to healthy subjects (40.5±1.0). An abnormal (*i.e.*>61) score for alexithymia was found in 43 % of patients and in 2 % of healthy subjects. Mean scores of SF-36 are reported in Figure 5 which shows that HRQOL was significantly poorer for all domains in IBS patients compared with healthy subjects. There was no difference between IBS patients and healthy subjects with respect to gallbladder motility, *i.e.* fasting and postprandial volumes and half-emptying times (Table 2). Concerning gastric motility, the mean cross-sectional antral areas at fasting and immediately after the test meal were comparable between IBS patients and healthy subjects (Table 2). However, postprandial minimal antral areas were significantly larger and half-emptying time longer in IBS than in healthy subjects (Table 2, Figure 6). With respect to OCTT, basal levels of H_2 were invariably <10 p.p.m. in all subjects (*i.e.* absence of bacterial overgrowth) and did not differ between IBS patients and healthy subjects. OCTT, however, was increased by 62 % in IBS patients compared to healthy subjects (Table 2) with scattered distribution depicted in Figure 7. A value of OCTT above 130 min, representing the upper limit of normal (mean+2SDs), was found in 70 % of patients and in 2 % of healthy subjects ($P=0.000001$).

Overall, the score of dyspepsia was positively correlated with OCTT ($r=0.38$, $P=0.0001$) but not with gastric emptying speed. Also, the dyspepsia score was negatively correlated with all domains of HRQOL ($-0.34< r <-0.43$, $P<0.001$), while there was a positive correlation with somatization ($r=0.32$, $P=0.001$), anxiety ($r=0.29$, $P=0.002$) and alexithymia ($r=0.47$, $P=0.00001$). Frequency of bowel movements increased with anxiety ($r=0.39$,

P=0.00001), somatization (*r*=0.34, *P*=0.0004) and alexithymia (*r*=0.52, *P*=0.000001).

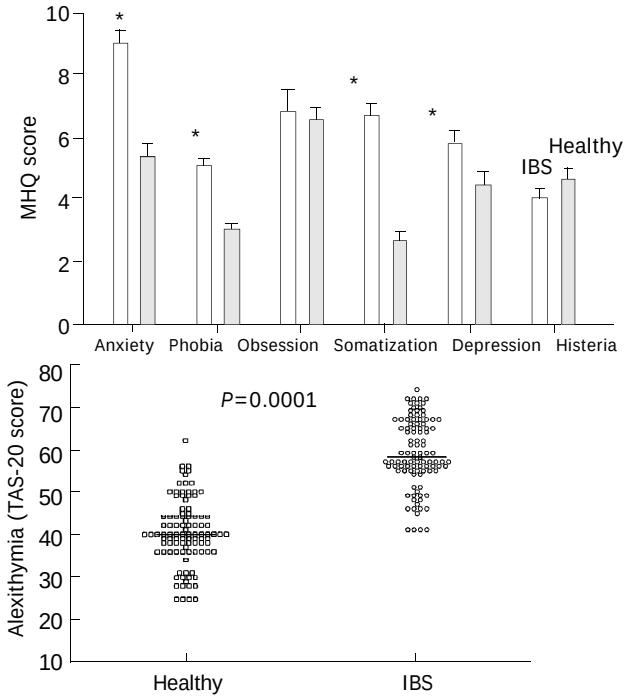

Figure 4 A: Scores of psychological disorders (mean ± SE, *0.0009<*P*<0.04). B: Scores of alexithymia (individual data and median) in IBS patients and healthy subjects.

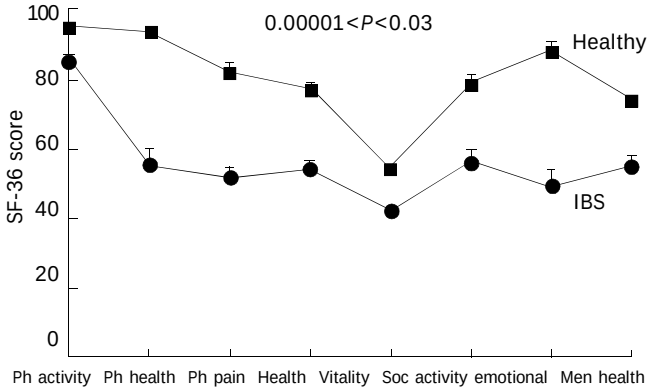

Figure 5 Profiles of health-related quality of life-HRQOL (SF-36 questionnaire) for IBS patients and healthy subjects. Data are mean±SE. Significantly poorer HRQOL for all 8 scales in IBS patients compared with healthy subjects. Legend: Ph, physical; soc, social.

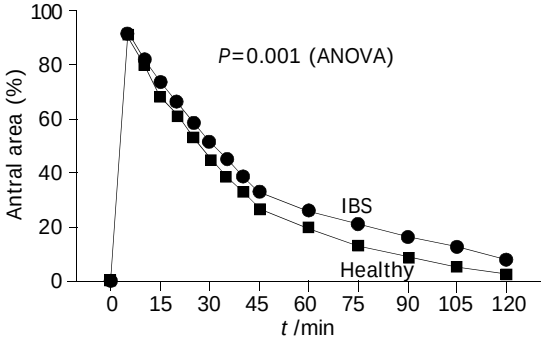

Figure 6 Time-course of gastric emptying in IBS patients and healthy subjects after ingestion of 200 mL of standard liquid meal. Symbols indicate mean (SE is very small and not visible at each time-point). IBS patients had impaired emptying with larger postprandial antral areas (expressed as % of basal area) than healthy subjects. See also Table 2 for half-emptying time differences.

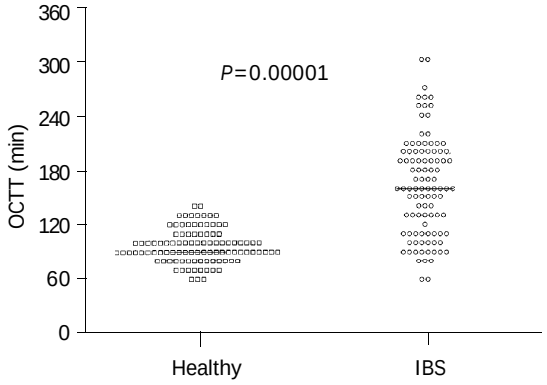

Figure 7 Significant delay of orocaecal transit time (OCTT) in IBS patients compared with healthy subjects. Results are expressed as individual data and median.

T_{50} (min.)	35.5±1.0	26.1±0.6	0.00001
Small bowel			
Orocaecal transit time (min.)	161.9±5.5	96.6±1.8	0.00001

*Student's *t* test, OCTT=orocaecal transit time, NS=not significant. Indices of gallbladder motility: fasting volume (mean of 3 measurements at -15, -5 and 0 min before test meal, expressed in mL), residual volume (minimum volume measured postprandially, in mL) and half-emptying time (T_{50}, time to achieve 50 % decrease of fasting volume). Indices of stomach emptying: fasting antral area (mean of 3 measurements at –15, -5 and 0 min before test meal, expressed in cm^2), maximal antral area at 2 min postmeal in cm^2, minimal postprandial antral area during the 2-hour observation period (expressed in %, normalized to maximal area after subtracting basal areas: i.e. $100x(A_t-a)/(A_2-a)$, where A_t=postprandial area at any given time; a=basal area; A_2=area at 2 min postprandially[37]) and half-emptying time (T_{50}).

DISCUSSION

We used an integrated approach in a large group of IBS patients to investigate gastrointestinal motility patterns in relation to symptoms, quality of life and psychological comorbidity. We believe that the present study may offer a fairly representative picture of IBS characteristics in southern Italy. The ROME II criteria[4] were chosen because they perform well in the clinic and they have greater simplicity than other less recent criteria[1]. Due to the setting where the study was performed (*i.e.* a tertiary referral center), caution must be expressed in interpreting our results, for at least two reasons. Firstly, only a minority of IBS patients were thought to consult physicians[33] and secondly,

characteristics of patients seen in a third referral center miqht differ from those of patients referred to primary or secondary care[25,34]. Nevertheless, IBS patients had multiple and simultaneous gastrointestinal motility defects involving stomach and intestine at a different extent, and were associated with diffuse gastrointestinal symptoms, abnormal psychological status, including alexythimia, and poor quality of life.

Ultrasonography was chosen as a non-invasive and validated technique to assess both gallbladder[35,36] and gastric emptying[17,29,37-40] simultaneously[28]. The protocol we employed, moreover, was further informative due to the simultaneous assessment of small bowel transit by H_2-breath test. Such a novel combined procedure allows a one-day (and time-saving) test for studying upper gastrointestinal motility in a clinical setting.

Despite "normal" feeling of appetite and satiety, IBS patients had strikingly abnormal upper gastrointestinal perception for nausea, fullness, epigastric pain/discomfort, both at fasting and postprandially. This was also the case in gastrectomized patients[21], Thus, ingestion of 200 mL of a moderately caloric, isosmotic test meal might prove useful in identifying groups of patients with dyspepsia, as also proposed in different clinical settings[41]. About 30 % of IBS patients included in this study had delayed gastric emptying, as was found in other gastrointestinal functional disorders such as dyspepsia and slow transit constipation[30,42]. Although this study was primarily focusing on patients with lower abdominal symptoms for IBS, we found that the score for dyspepsia was abnormal in about two-thirds of patients, as was also reported by Agreus *et al.* in the Swedish population[43]. Taken together, these findings suggest that dyspepsia and IBS are closely related and develop as a *continuum*[19]. No close correlation existed between delayed gastric emptying and dyspepsia. Indeed, gastric emptying was defective only in a subgroup of dyspeptic patients and this also seemed to be the case in IBS patients. Moreover, both symptoms or gastric half emptying times were poor predictors of gastrointestinal dysmotility in functional dyspepsia[44]. Also, dyspeptic symptoms might originate from an altered fundic receptive relaxation (not measured in the present study) and/ or from disorders of other organs, including duodenum under acidic stress[45].

At variance with an early study in a scant number of IBS patients[46], we found no gross evidence for impaired gallbladder motility. Differences in selection criteria might partly explain the variability. CCK played a key role in postprandial gallbladder contraction, and abnormal sensitivity of the gallbladder smooth muscle to exogenous CCK has been reported in IBS[47]. Apparently, the defect was absent postprandially, since either a high-fat[47] or a low-fat (this study) liquid meal yielded similar gallbladder contractions. Whether or not the trend we showed of faster refilling in IBS points to an abnormality of the smooth muscle in the digestive tract[47], remains to be established. Impaired gallbladder motility has been found in a subgroup of patients with functional dyspepsia[42] and delayed transit constipation[30]. Disturbed motilin and CCK release might be a potential cause of intestinal dysmotility in IBS[48].

This study also showed that OCTT was delayed in IBS. Changes in phase II and phase III components of the migrating motor complex suggested that both local (*i.e.* enteric) and central mechanisms might operate to produce intestinal dysmotility[49]. Delayed OCTT could be independent of colonic transit (as seen in patients with functional dyspepsia[42]) or might be associated with delayed colonic transit (as seen in patients with functional constipation[30]). Although accelerated small bowel and colonic transit have been reported in diarrhea-predominant IBS[50], a similar conclusion could not be drawn from this study, since patients alternated between diarrhea and constipation in their history. IBS patients had rather increased bowel habits, despite delayed OCTT. This finding pointed to a diffuse impairment of visceral sensitivity and perception, involving not only the rectum[6], but also the colon or even more proximal districts such as small bowel and stomach[7,51]. Abnormal motor patterns in the small bowel might be associated with symptoms in patients with IBS (*e.g.* clustered jejunal contractions and propagated giant ileal contractions during abdominal colic[52]). It must be stressed, however, that no motor abnormality in either small or large intestine was pathognomonic for IBS[53]. Whether or not delayed OCTT in IBS could contribute to accumulation of gas in the intestine[54,55] and/or abnormal colonic fermentation in the colon[56], remains to be determined. Interestingly, we found delayed OCTT with increased bowel movements in chronic alcoholic patients during abstinence, associated with dysfunction of autonomic nervous system[57]. This possibility deserves further attention, since a form of subclinical autonomic neuropathy might predispose to a diffuse disorder of smooth muscle,which was suggestive for the multi-organic involvement of the gastrointestinal tract[7].

It is known that visceral hyperalgesia in IBS could exacerbate symptoms due to lactose maldigestion[58]. A recent study found that 24 % of previously diagnosed IBS patients had lactose intolerance[16], this was not the case in the present study where lactose maldigestion or intolerance was an exclusion criterion. It is still controversial whether or not a subset of patients with IBS might be positive for coeliac disease[59,60]. Since the recent British Society of Gastroenterology guidelines estimated that routine antiendomysial antibodies would reveal only 1-2 % of abnormalities[3], systematic screening for coeliac disease in this study was not believed to be cost-effective and was not performed.

It is believed that up to 60 % of IBS patients seen at referral centers might have psychological morbidity[5,61-64]. An abnormal psychological profile in IBS patients emerged also from the present study. Psychological disturbances could influence aspects of bowel habit[1,65]. We found increased bowel movements to be associated with anxiety, somatisation and also with alexithymia. Alexithymia construct is one of the four syndromes in the Diagnostic Criteria for Psychosomatic Research[34]. A stronger positive association was reported between alexithymia and somatoform rather than chronic somatic disorders[25,66,67]. In the present study we employed TAS-20, the most validated questionnaire available so far[23] and found significant alexithymia in over 40 % of IBS patients (increasing to about 80 % if patients with border-line scores were included). These results are in line with those from another although smaller study conducted in a closed geographical area, investigating alexithymia in patients with IBS and other functional gastrointestinal disorders[25]. The finding may have at least two practical implications. Firstly, whether IBS patients are first seen in a gastroenterological or psychiatric setting might determine if patients are classified as suffering mainly from IBS or somatoform disturbances, respectively. Secondly, as alexithymia is seen as a stable feature, it might act as an important prognostic factor related to treatment outcomes in subgroups of IBS patients. If the IBS patients were seen within the broader spectrum of functional gastrointestinal diseases, our findings pointed to an association between alexithymia and tendency to negative affectivity[25,67].

IBS patients showed a significantly poorer HRQOL than healthy subjects. This finding was in accordance with previous studies[12,61] and pointed to related problems, namely absenteeism, the social indirect costs and, ultimately, the need for appropriate treatment of IBS patients. Interestingly, both IBS patients and healthy subjects in this setting had a HRQOL profile remarkably

similar to that derived from subjects across different cultures in the USA and UK[12]. This finding underscored the internal consistency of HRQOL questionnaires. Taken together, our findings confirmed that although IBS was not a life-threatening condition, it could lead to significant impairment of quality of life, at least in the subgroup of patients seen in a tertiary referral center.

In conclusion, these data show that IBS patients have a pan-enteric dysmotility with frequent dyspepsia, associated with psychological morbidity and greatly impaired quality of life. The presence of alexithymia, a stable trait, is a novel finding of potential interest to detect subgroups of IBS patients with different patterns of recovery after therapy.

Abstract

AIM: IBD is a systemic disease associated with a large number of extraintestinal manifestations (EIMs). Our aim was to determine the prevalence of EIMs in a large IBD cohort in Veszprem Province in a 25-year follow-up study.

METHODS: Eight hundred and seventy-three IBD patients were enrolled (ulcerative colitis/UC/: 619, m/f: 317/302, mean age at presentation: 38.3 years, average disease duration: 11.2 years; Crohn's disease/CD/: 254, m/f: 125/129, mean age at presentation: 32.5 years, average disease duration: 9.2 years). Intestinal, extraintestinal signs and laboratory tests were monitored regularly. Any alteration suggesting an EIMs was investigated by a specialist.

RESULTS: A total of 21.3 % of patients with IBD had EIM (UC: 15.0 %, CD: 36.6 %). Age at presentation did not affect the likelihood of EIM. Prevalence of EIMs was higher in women and in CD, ocular complications and primary sclerosing cholangitis (PSC) were more frequent in UC. In UC there was an increased tendency of EIM in patients with a more extensive disease. Joint complications were more frequent in CD (22.4 % *vs* UC 10.2 %, $P<0.01$). In UC positive family history increased the risk of joint complications (OR:3.63). In CD the frequency of type-1 peripheral arthritis was increased in patients with penetrating disease ($P=0.028$). PSC was present in 1.6 % in UC and 0.8 % in CD. Dermatological complications were present in 3.8 % in UC and 10.2 % in CD, the rate of ocular complications was around 3 % in both diseases. Rare complications were glomerulonephritis, autoimmune hemolytic anaemia and celiac disease.

CONCLUSION: Prevalence of EIM in Hungarian IBD patients is in concordance with data from Western countries. The high number of EIM supports a role for complex follow-up in these patients.

INTRODUCTION

Ulcerative colitis (UC) and Crohn' s disease (CD) are chronic inflammatory diseases of undetermined origin. Inflammatory bowel disease (IBD) is a multifactorial polygenic disease with probable genetic heterogeneity. In this hypothesis, the disease may develop in a genetically predisposed host as a consequence of altered mucosal barrier and disregulated immune response to environmental, in particular enteric antigens, resulting in continuous immune-mediated inflammation[1-4]. IBD predominantly affects the gastrointestinal system but it is associated with a large number of extraintestinal manifestations (EIMs)[5]. Some disorders parallel the activity of the bowel disease but for a number of these conditions, their courses run independently of the course of the intestinal disease[6,7]. Furthermore, there has been some variance in the literature as to whether these EIMs are more associated with CD or UC. In the classical study of Greenstein *et al*.[8] EIMs were classified as colitis associated, small bowel associated and none specific manifestations.

EIMs contribute significantly to morbidity and mortality. Defining specific associations of immune mediated diseases in extraintestinal sites and IBD may be helpful in the better understanding of the pathogenesis of IBD.

The pathogenesis of EIMs is also multifactorial. The role of genetic factors is supported by family and candidate (e.g. certain HLA) gene studies[9-11]. The role of humoral immunity is supported by the higher prevalence of autoantibodies in the presence of EIMs, especially pANCA in primary sclerosing cholangitis (PSC). The immunological and clinical connections between these diseases and IBD have never been fully elucidated.

In this study we aimed to define the prevalence of EIMs in a 25-year follow up study in Hungarian IBD patients. We sought to determine if any of the EIMs was more likely associated with CD or UC, with male or female gender in a follow-up study. Possible associations between EIMs and location and disease behaviour were also investigated.

MATERIALS AND METHODS

Eight hundred and seventy-three IBD patients followed-up at the Out- and Inpatient Gastroenterology Units of the Csolnoky F. Province Hospital in Veszprem Province were enrolled. This hospital is the secondary referral center for IBD patients in the province.

The data of the 619 UC patients (male/female: 317/302) are summarized in Table 1. The age at presentation varied between 9 and 80 years (average: 38.3 years). Average disease duration was 11.2 years (1-56 years). The location of UC according to the known greatest extent was proctitis in 117,

left sided colitis in 304 (including 171 patients with proctosigmoiditis), subtotal (98) and pancolitis (100) in 198 cases. Two hundred and fifty-four CD patients were included (125 males, 129 females). Average age at presentation was 32.5 years (12-80 years). According to the Vienna classification 192 patients were classified as A1, while 62 as A2. Disease duration was 9.2 years (1-40 years). Location of CD was ileal (L1) in 60, colonic (L2) in 81 and ileocolonic (L3) in 113 cases. Patients with upper GI manifestation had lower GI disease as well and they were classified according to their lower GI disease. According to the disease behavior 83 of our CD patients were defined as non-stricturing non-penetrating, 62 as stricturing and 105 as penetrating. Fifty-eight patients of the 95 penetrating cases had parallel strictures. Patients with indeterminate colitis were excluded.

Table 1 Clinical data of IBD patients

	Ulcerative colitis	Crohn's disease
Number of patients	619	254
Male / female	317 / 302	125 / 129
Mean age at diagnosis	38.3 yrs (9-80 yrs)	32.5 yrs (12-80 yrs)
Location	Proctitis: 117	L1: 60
	Left sided colitis: 304	L2: 81
	Pancolitis: 198	L3: 113
Behaviour of CD	-	B1: 87
		B2: 62
		B3: 105

In Crohn's disease (CD). Location: L1: terminal ileum, L2: colonic, L3: ileocolonic, behaviour: B1: non stricturing-non penetrating, B2: stricturing, B3: penetrating.

Patients in remission were followed-up twice per year. Patients who relapsed were followed-up or hospitalised according to the actual disease activity. Special interest was dedicated to the presence of EIM. Screening of EIMs was not performed, therefore the number of EIMs may have been underestimated. Routine follow-up consisted of assessment of patient's complaints, physical examination and laboratory testing.

Any alteration suggesting an EIMs was investigated by a specialist. In this study we did not assess the association between disease activity and the presence of EIM. Major EIMs studied in this report were axial and peripheral arthropathies (including ankylosing spondylitis), aseptic femoral head necrosis, primary sclerosing cholangitis (PSC), small duct cholangitis, autoimmune hepatitis, erythema nodosum, pyoderma gangrenosum, chronic urticaria, acute anterior uveitis, iritis, episcleritis, conjunctivitis, autoimmune hemolytic anaemia (AIHA), immune thrombocytopenic purpura (ITP), celiac disease, myositis, and glomerulonephritis.

Joint involvements were classified as peripheral and/or axial arthropathies. Peripheral arthropathies were divided into two subgroups according to the classification of Orchard *et al*[13]. Type-1 arthritis is an acute self-limiting pauciarticular (less than 5 joints) arthropathy typically affecting large joints. It is associated with other EIMs and its course parallels with the activity of the bowel disease. In contrast, type 2 arthritis is a chronic bilateral, symmetrical polyarticular arthropathy affecting five or more small joints. Its course runs independently of the course of the intestinal disease. Axial arthropathies are divided into sacroileitis and ankylosing spondylitis (SPA). Its incidence is 20-times higher than that in the normal population[14]. Rheumatologists investigated sacroileitis and ankylosing spondylitis cases. Laboratory testing (rheumatoid factor), X-ray and since 1997 MRI examinations were done.

Patients with elevated liver function tests (LFT, aminotransferases, cholestatic enzymes) were followed-up more cautiously. In patients with chronic or progressive elevation of enzyme levels liver biopsy and/or endoscopic retrograde cholangiopancreatography (ERCP) examination was done if patient gave informed consent. The diagnosis of PSC was based on elevated liver function tests, ERCP and consistent histology findings. Small duct PSC was diagnosed if histology suggested PSC, but ERCP could not verify the diagnosis[15,16]. Cholelithiasis, cirrhosis and focal nodular hyperplasia (FNH) were excluded from hepatobiliary manifestations.

In patients with verified thrombosis, blood samples were examined for hypercoagulability including in almost all cases analysis of plasminogen, proteins C and S activity and factor V Leiden mutation.

Patients with glomerulonephritis were followed-up by nephrologists as well. Diagnosis was based on clinical and chemical data and congruent histology findings. Ureteral obstruction was diagnosed by cystoscopy and urography, CT or MRI. If the alteration suggested fistulae in the urinary tract, cytography was also performed.

Statistical analysis

For statistical comparison of the data, Statistica 6.0 (Statsoft Inc, USA) was used. Normality was tested by Shapiro-Wilk's W test. χ^2 test with Yates correction was used to compare groups and odds ratios were calculated.

RESULTS

The prevalence of major (joint, hepatobiliary, ocular and cutaneous) and all EIMs determined in this study are shown in Table 2. Major EIMs were apparent more frequently in CD than in UC (36.6 % *vs* 15.0 %, $P<0.001$). EIMs were more frequent in patients with a disease duration for more than 10 years in both CD (22.1 % *vs* 48.9 %, $P=0.003$) and UC (22.1 % *vs* 10.4 %, $P<0.001$).

Table 2 Prevalence of extraintestinal manifestations (EIM) in IBD

	Total *n* (%)	Disease duration	
		⩽ 10 yrs *n* (%)	> 10 yrs *n* (%)
IBD	873	511	352
Major EIMs	186 (21.3)	86 (16.8)	102 (30.0)
All EIM signs	547 (62.7)	278 (54.4)	269 (76.4)
Ulcerative colitis	619	357	262
Major EIMs	93 (15.0)	37 (10.4)	58 (22.1)
All EIM signs	360 (58.2)	167 (46.8)	193 (73.7)
Crohn's disease	254	164	90
Major EIMs	93 (36.6)	49 (29.9)	44 (48.9)
All EIM signs	187 (73.6)	111 (67.7)	76 (84.4)

The prevalence of EIMs was higher in CD except ocular complications and PSC ($P<0.001$ for joint, hepatobiliary and cutaneous manifestations, Tables 3 and 4). In general, EIMs were more frequent in women except hepatobiliary manifestations and arthropathies in UC patients.

All major EIMs were more prevalent in more extensive UC (Table 5). There was a tendency of increased frequency of joint manifestations in CD patients with colonic involvement (L2 and L3: 23.7 %) compared to patients with only ileal disease (18.3 %, P=NS, Table 5). The prevalences of hepatobiliary, ocular and cutaneous manifestations were not different according to disease location.

Table 3 Age at presentation and prevalence of major extraintestinal manifestations in patients with IBD

	A1 *n* (%)	A2 *n* (%)
UC (*n*: 619)	369	250
Joint	32 (8.7)	20 (8.0)

Hepatobiliary	57 (22.4 %)	4 (12.9 %)
Cutaneous	26 (10.2 %)	2 (6.5 %)
Ocular	8 (3.1%)	0

Table 5 Prevalence of extraintestinal manifestations in ulcerative colitis and Crohn's disease according to location and disease behaviour

	Joint *n* (%)	Hepatobiliary *n* (%)	Cutaneous *n* (%)	Ocular *n* (%)
Location		Ulcerative colitis		
Proctitis (*n*=117)	5 (4.3)	9 (7.7)	1 (0.9)	1 (0.9)
Left sided colitis (*n*=304)	14 (4.6)	32 (15.7)	8 (2.6)	7 (2.3)
Pancolitis (*n*=198)	33 (16.7)	36 (18.2)	15 (7.6)	12 (6.1)
Location		Crohn's disease		
L1 (*n*=60)	11 (18.3)	14 (23.3)	6 (10.0)	2 (3.3)
L2 (*n*=81)	17 (21.0)	17 (21.0)	10 (12.3)	3 (3.7)
L3 (*n*=113)	29 (25.7)	26 (23.0)	10 (8.8)	3 (2.7)
Behaviour				
B1 (*n*=87)	13 (14.9)	22 (25.3)	11 (12.6)	1 (1.1)
B2 (*n*=62)	16 (25.8)	11 (17.7)	5 (8.1)	0
B3 (*n*=105)	28 (27.6)	24 (22.9)	10 (9.5)	7 (6.7)

Age at presentation (A1: <40 years, A2: =40 years) did slightly affect the prevalence of EIMs (Table 3). Joint manifestations were more prevalent in CD patients with earlier disease onset (OR: 1.96, 95 % CI: 1.01-4.21). The same tendency was observed for cutaneous manifestations.

Familial disease was seen in 3.9 % of patients with UC and 12.2 % of patients with CD (Tables 4A-B). Joint manifestations were more frequent in UC patients with familial disease (OR: 3.63, 95 % CI: 1.43-9.31) than without. The same tendency was seen in UC patients (OR: 1.9, 95 % CI: 0.87-4.14) and ocular manifestations were found in familial UC cases.

B2 (*n*=62)	16 (25.8)	8 (12.9)	6 (9.7)	3 (4.8)
B3 (*n*=105)	28 (27.6)	10 (9.5)	18 (17.1)	3 (2.9)

*One patient with proctitis and one with pancolitis had rheumatoid athritis.

Joint manifestations were more frequent in CD than in UC ($P<0.001$, Tables 6A-B.). There was a tendency of increased frequency of joint manifestations in women with CD (26.4 % *vs* 18.4 %, OR: 1.58, 95 % CI: 0.87-2.87). Axial arthritis (10.2 % *vs* 3.2 %, $P=0.0001$) and type 1(11.4 % *vs* 2.7 %, $P=0.0001$) arthritis were more frequent in CD, with equal prevalence of type-2 arthritis. In UC joint manifestations were almost three-fold more frequent in patients with pancolitis compared to proctitis and left sided colitis cases ($P<0.002$ for both, Table 5). In CD a tendency of increased frequency of joint manifestations was observed in patients with colonic involvement (L2 and L3: 23.7 %) or stricturing/penetrating disease (26.3 %) compared to patients with ileal only disease (18.3 %) or non-stricturing non-penetrating disease behavior

(14.9 %, Table 6B). An increased frequency of type 1 arthritis was observed in patients with penetrating compared to non-stricturing non-penetrating disease (P=0.028), the same tendency was observed in patients with or without colonic involvement. Type-1 arthritis affected more frequently the joints of the lower extremities (most frequently the knee and ankle), while type-2 arthritis was more common in the joints of the upper extremities.

Hepatobiliary manifestations are summerised in Table 7. PSC was diagnosed in 10 patients with UC and only 2 patients with CD. Small duct PSC was diagnosed in 8 and 6 cases, respectively. Non-alcoholic fatty liver disease (NAFLD) or non-alcoholic steatohepatitis (NASH) was diagnosed in 9.4 % of UC patients and 19.3 % of CD patients (P<0.0001). These patients had unexplained abnormal liver function tests (viral hepatitis, autoimmune, drug or alcohol induced disease, extrahepatic obstruction excluded). Liver biopsy was performed in 22/107 cases, which identified NAFLD or NASH in almost all cases. US proved hepatomegaly in 13/107 (12.1 %). Progression to cirrhosis was not observed in these patients during follow-up.

Table 7 Hepatobiliary manifestations in IBD patients

	Total *n* (%)	PSC *n* (%)	Small duct PSC *n* (%)	NAFLD / NASH *n* (%)
Ulcerative colitis				
Total (*n*=619)	77* (12.4)	10 (1.6)	8 (1.3)	58 (9.4)
Male (*n*=317)	39 (12.3)	3 (1.0)	6 (1.9)	30 (9.5)

Crohn's disease				
Total (*n*=254)	57 (22.4)	2 (0.8)	6 (2.4)	49 (19.3)
Male (*n*=125)	27 (21.6)	2 (1.6)	6 (4.8)	19 (15.2)
Female (*n*=129)	30 (23.3)	0	0	30 (23.3)

*One female patient had autoimmune hepatitis. NAFLD: non-alcoholic fatty liver disease, NASH: non-alcoholic steatohepatitis.

Cutaneous manifestations were seen in 10.2 % of the patients with CD and 3.9 % of the patients with UC (Tables 8A-B). Cutaneous manifestations were more common in women in both UC (male/female: 5.0 %/2.8 %) and CD (13.2 %/7.2 %, OR: 1.95, 95 % CI: 0.85-4.48). Erythema nodosum and pyoderma gangrenosum were the most frequent manifestations. In UC cutaneous manifestations were more frequent in more extensive disease (7.6 % in pancolitis *vs* 2.1 % in proctitis or left sided colitis, P=0.002).

Ocular manifestations were apparent in approximately 3.0 % of UC and CD patients (Table 9). The prevalence was more frequent in women in both UC (P=0.009, OR: 4.37, 95 % CI: 1.51-12.6) and CD (OR:3.0, 95 % CI=0.67-8). Conjunctivitis, acute anterior uveitis and scleritis were the most frequent manifestations. Ocular manifestations developed mostly during the early years of the disease. In UC more than half of the patients with ocular complication had pancolitis (6.1 % in pancolitis *vs* 1.9 % in left sided colitis or proctitis, P=0.01).

Iron deficiency anaemia was seen in 35.8 % of CD patients and in one fourth of UC patients (Tables 10A-C). It was more frequent in women in UC (32.1 % *vs* 19.6 %, P<0.001, OR=1.95, 95 % CI: 1.35-2.81). Chronic anaemia was more frequent in patients with CD (9.6 % *vs* 17.7 %, P<0.001). The prevalence of macrocytic anaemia was around 4 % in both diseases. It was also observed more frequently in patients with ileocolonic disease than without it (P=0.03). The same tendency was observed according to disease behaviour; chronic anaemia tended to be more frequent in patients with stricturing or penetrating disease (P=0.06, Table 10C). AIHA developed in four UC patients.

DISCUSSION

It is difficult to define the true prevalence of EIMs in IBD. If one was counting only major EIMs with common immunogenetic background the prevalence was about 20-25 %[1,5,8,17,18]. However, if all possible secondary systemic effects and/or complications of therapy are also included, then almost all patients will have "extra-intestinal manifestations". Prevalence may vary depending on the actual geographic area, IBD population, location and duration of the disease, medication and diagnostic accuracy.

Only few large cohort follow-up data are available on the prevalence of EIMs in IBD. The study of Greenstein *et al*. was one of the first reports[8]. Farmer *et al*.[19] reported a prevalence of 16.7 % during a 13-year follow-up study. EIMs were more prevalent in patients with colonic involvement or previous operations. In the Swedish epidemiology study Monsen *et al*.[20] excluded arthralgia, stomatitis and episcleritis from the EIMs. More recently, Jiang and Cui[21] analyzed the data of 10218 ulcerative colitis cases in China. The frequency of EIMs was 6.1 %, however no further data were available about the type of EIM. Bernstein *et al*.[22] investigated the prevalence of five "major" EIMs (iritis/uveis, PSC, pyoderma gangrenosum, erythema nodosum and ankylosing spondylitis) with the help of the University of Manitoba IBD Database in IBD patients with a disease history of at least 10 years. They found a single EIM prevalence of 6.2 %, which was one of the lowest rates reported. However, peripheral arthropathies were excluded from their study. There is undoubtedly a debate with the diagnosis of peripheral arthopathy, as it is sometimes difficult to distinguish arthropathy from arthralgia, especially in retrospective studies. In contrast, it is one of the most typical EIMs, observed in a high frequency of the patients. Excluding peripheral arthropathy from EIMs in one study and including it in another make the data difficult to compare. The reported overall EIM prevalence of 21.3 % in our study is in concordance with previous studies. The overall prevalence of EIMs was higher in patients with a longer disease history, but age at presentation did not affect the prevalence of EIMs.

There were gender predilections. EIMs were more frequent in femal pateints compared to males, which may support the hypothesis that autoimmune diseases are more common in female subjects.

The role of genetic factors has been implicated in the pathogenesis of IBD and EIMs[8-11]. In our study we investigated the familial occurrence in IBD. Positive family history was four times more frequent in CD compared to UC. The frequencies of joint and ocular manifestations were higher in patients with familial UC. Others have suggested high concordance of the occurrence of EIMs in affected siblings with IBD[23].

Previous studies have suggested multiple extraintestinal diseases[8,22] with certain genetic associations[10,23]. We found multiple extraintestinal diseases in 4.5 % of IBD patients, more

common in patients with CD. The most frequent associations were co-existing ocular, cutaneous and joint (type 1 arthritis) manifestations. The Canadian study reported multiple extraintestinl disease in only 0.3 % of all patients[22], however the rate of multiple EIMs was comparable to our results in most studies[17, 19].

Relation of EIMs with type, location and behaviour of IBD

Type of IBD Overall EIMs were more frequent in patients with CD than in patients with UC, in concordance with previous studies[8,24] with the exception of ocular manifestations and PSC. These two EIMs were equally prevalent in CD and UC (both occurred approximately in 3 % of the patiens) in concordance with previous data[10,16,25].

Location of IBD In UC EIMs were thought to be more prevalent in extensive disease[5], but there were some contradiction in the literature[13]. In our study the rate of EIMs increased with the increasing extent of the disease. In CD it was generally accepted, that some EIMs were associated with colonic (e.g. peripheral arthropathy) others with small bowel (e.g. cholelithiasis) location[8,19]. We also found that type-1 arthritis was twice as frequent in patients with colonic or ileocolonic disease compared to patients with only ileal disease. The difference was smaller compared to patients with axial arthritis and disappeared in patients type 2 arthritis. The prevalences of cutaneous, ocular and hepatobiliary manifestations were not associated with location.

Behaviour of CD We did not find data in the literature about the relation of EIMs and the behaviour of CD, according to the Vienna classification. Earlier studies have suggested that EIMs tended to associate with perianal (=penetrating) disease[26]. We found a higher rate of joint complications in stricturing and penetrating disease than in non-stricturing non penetrating form. All but one ocular disease developed in patients with penetrating disease, but the rate of other complications was similar in the three groups.

Extraintestinal manifestations according to affected organs

Arthritis is the most common EIM in IBD IBD related arthropaties were originally classified as axial and peripheral arthritides. Orchard *et al*. subdivided the peripheral disease into type 1 (large joint, pauciarticular, parallels with the course of IBD) and type-2 (small joint, polyarticular, the course independent of IBD) arthritides[13]. In our study joint manifestations were more frequently seen in patients with CD, first of all with the higher prevalence of axial and type-1 arthritis in these patients. Type-1 arthritis was more frequent in patients with stenosing and penetrating disease compared to patients with non-stenosing non-penetrating disease behaviour. In patients with penetrating disease bacterial infections could explain the high prevalence, the reason for the high prevalence in patients with stenosing disease is not clear, perhaps it has a genetic background.

Hepatobiliary complications PSC was diagnosed in 1.6 % in UC and even more infrequently in CD. When small duct PSC was included, the overall prevalence was 2.9-3.2 % in both diseases, in concordance with the majority of previous reports (2.4-11 %)[15,16,27]. PSC was a precancerosus condition with increased risk for cholangiocarcinoma and colorectal cancer[28]. In this study 3 patients with PSC and one patient with small duct cholangitis developed colorectal cancer and one PSC patient developed cholangiocarcinoma, which supports a role for more intensive follow-up in these subgroups of patients.

The cause of elevated LFT was found to be steatosis and/or steatohepatitis, reported in 6.3 % in UC and in 4 % in CD in previous studies[29,30]. An Italian study found that 12 % of the 474 asymptomatic IBD patients had hepatobiliary disease[31]. In non-selected or operated UC patients the prevalence of steatosis could be as high as 15-45 %[16,32,33]. In our study the rate of NAFLD was twice as high in CD than in UC, otherwise our data are in concordance with the data of previous studies. Several cutaneous diseases were diagnosed, 14 were classified as EIM. Cutaneous manifestations were more frequent in CD and in female patients. The prevalence of erythema nodosum and pyoderma gangrenosum was in the range previously reported[10,34,35] with very few psoriasis cases.

Ocular complications were equally frequent in both diseases with increased prevalence in women. Anterior uveitis was found at a frequency as previously reported[8,10,22]. We found one orbital pseudotumour in a young woman with severe ulcerative pancolitis. Ocular manifestations occurred mostly in the early few years after diagnosis. Pancolitis patients with UC were more liable to develop ocular manifestations compared to other locations. Ocular manifestations did frequently occur together with other (joint or cutaneous) extraintestinal diseases.

Haematological complications Iron deficiency anaemia is the most frequent hematological manifestation. In most of the cases its course ran parallel to the course of the intestinal disease. "Chronic anaemia" that occurs in inflammatory conditions and tumours was mostly apparent in severe, refractory cases and resolved only slowly after remission. Macrocytic anaemia was more frequent in patients with ileal and penetrating/stricturing disease than in patients with colonic involvement or non-stricturing non-penetrating disease. It was less frequent since preventive folate supplementation has been introduced in patients receiving sulfasalazine treatment.

Autoimmune haemolytic anaemia (AIHA) rarely complicates IBD, the reported prevalence rates were between 0.2 % and 1.7 %. Our observed rate (0.6 %) correlated with the previous data. In concordance with other studies AIHA occurred in patients with extensive colitis. In most of the cases AIHA could be treated successfully with steroids and/or immunosuppressive drugs[36]. In our study one patient required splenectomy, and in another case haemolysis subsided only after colectomy.

Increased risk of lymphoma has been reported in IBD, especially in patients receiving immunosupressives, but data were conflicting[37,38]. Our data do not support the notion of increased risk in these patients. In our series one 76-year old male UC patient with left sided colitis developed a high grade B-cell lymphoma in the rectum, but he did not receive immunosuppressive therapy. ITP might be true EIM, methaemoglobinaemia was associated with high dose sulfasalazine treatment, leukaemoid reaction was seen in a fulminant relapse.

Hypercoagulability was thought to be involved in the pathogenesis of IBD[39-41], and increased risk of thromboembolic complications (1-6 %) has been reported in IBD[42]. The prevalence of prothrombotic inherited and/or acquired coagulation abnormalities in patients with IBD remains controversial. Genetic thrombophilia with deficiencies in some coagulation inhibitors (antithrombin, proteins C and S), acquired thrombophilia due to inflammation, antiphospholipid syndrome and mutations of factor V Leiden and recently other genes involved in thrombogenesis (prothrombin mutation 20210A or factor V fV4070G polymorphism) have been described[39,43]. The most common cause of hypercoagulability status in Europe is resistance to activated protein C (APC). Resistance to APC and mutations that cause APC resistance (mainly factor V Leiden) have been of particular interest[42,43]. Some studies reported increased frequency of Leiden mutation in IBD[42], however others found that Leiden mutation was associated with thromboembolism with (14.3 %) or without IBD (15.5 %) but not with IBD (0 % and controls 3.6 %) itself [39,44]. In our study Leiden mutation was infrequent in IBD patients with thrombosis. The frequency was the same

that as observed in normal Hungarian population without thrombosis (5.26 %)[45]. Most thromboembolic episodes developed in the lower extremities, in some patient with pulmonary embolism as a complication. Thrombosis of the splenic vein occurred in one young female CD patient with ileocolonic disease.

Other EIMs Glomerulonephritis is a rare complication in IBD. Only case reports could be found in the literature[46]. Deposition of immune-complexes is thought to be involved in the pathogenesis. Finding 3 patients (1 UC and 2 CD) in this series was an unexpected high number. Histology revealed IgA nephropathy, membranous glomerulonephritis and focal glomerulosclerosis. Ductal changes suggesting chronic pancreatitis were common in IBD[47]. Our two pancreatitis cases developed in patients taking azathioprine.

In conclusion, in IBD a variety of EIMs may occur during the course of the disease affecting several organ systems. In Hungarian IBD patients, major EIMs develop in concordance with previous European data in approximately one fifth of the patients. The high number of EIMs supports a role for complex follow-up in these patients.

Abstract

AIM: To explore whether there was anti-*Saccharomyces cerevisiae* antibodies (ASCA) positivity in our patients with biopsy-confirmed celiac disease.

METHODS: A cohort of patients with inflammatory bowel diseases (42 patients with Crohn's disease and 10 patients with ulcerative colitis) and gluten sensitive enteropathy (16 patients) from Debrecen, Hungary were enrolled in the study. The diagnosis was made using the formally accepted criteria. Perinuclear antineutrophil cytoplasmic antibodies (pANCA) and *anti-Saccharomyces cerevisiae* antibodies (ASCA), *antiendomysium* antibodies (EMA), antigliadin antibodies (AGA) and anti human tissue transglutaminase antibodies (tTGA) were investigated.

RESULTS: The results showed that ASCA positivity occurred not only in Crohn's disease but also in Celiac disease and in these cases both the IgG and IgA type antibodies were proved.

CONCLUSION: It is conceivable that ASCA positivity correlates with the (auto-) immune inflammation of small intestines and it is a specific marker of Crohn's disease.

INTRODUCTION

Gluten-sensitive enteropathy (GSE) or, as it is more commonly called, celiac disease, is an immune-mediated enteropathic condition (specified as an autoimmune inflammatory disease of the small intestine) that is precipitated by the ingestion of gluten, a component of wheat protein, in genetically susceptible persons. Exclusion of dietary gluten results in healing of the *mucosa*, resolution of the malabsorptive state, and reversal of most, if not all, effects of celiac disease. GSE commonly manifests as "silent" celiac disease (i.e., minimal or no symptoms). Histological examination and serologic tests for antibodies against *endomysium*, transglutaminase, and gliadin identify most patients with the disease[1].

Crohn's disease (CD) and ulcerative colitis (UC) are both classified under the medical rubric of inflammatory bowel disease (IBD). It is currently accepted that the term "IBD" does not encompass just two diseases (CD or UC), but rather a group of diseases, triggered and perpetuated by a variety of diverse genetic, environmental, and immunologic factors that share similar clinical manifestations. They cause life-impaired symptoms, necessitate long-term dependence on powerful drugs, and often result in debilitating surgery and even death. Although the etiology of UC and CD remains unclear, in addition to genetic and other environmental factors (food allergens, *etc*.), microorganisms have been discussed as possibly playing an important role. The gastrointestinal (GI) tract has direct contact with the environment and therefore forms a very important protective barrier within the human's organism. The *gut mucosa* has to stop foreign materials, such as bacteria or antigens, from entering the body and also prevent excessive loss of "body material" into the lumen. If the mucosal barrier is broken, an influx of luminal antigens may result in the perpetuation of intestinal inflammation by chronically stimulating resident and recruited immunocompetent cells of the *lamina propria*. Bacteria present within the intestinal lumen or in the intestinal wall are important in the development of mucosal inflammation. Recent reports in the literature do not suggest that a specific persistent infection causes IBD (i.e. the repeatedly blamed *Mycobacterium paratuberculosis avium*), but indicate that enteric pathogens could cause initial onset of IBD and are associated with reactivation of quiescent disease. CD patients may have a heterogeneous serological response to specific bacteria and bacterial related antigens. The serologic responses seen in CD patients include antibodies to *Saccharomyces cerevisiae, Mycobacteria, Bacteriodes, Listeria,* and *E. coli*. Many of the specific organisms have been proposed to directly or indirectly contribute to the pathogenesis of CD. Despite their self-limited character, these infections initiate a cascade of inflammatory events leading to chronic, relapsing disease in a genetically susceptible host ("hit-and-run" hypothesis). So, epidemiological and microbiologic studies suggest that enteropathogenic microorganisms play a substantial role in the clinical initiation and relapses of IBD. Thus microbiologic screening might be helpful in patients with flares of IBD for optimal medical treatment and as many bacteria cannot be cultured, culture-independent techniques are expected to be of great help in identifying microorganisms in IBD. With more comprehensive knowledge of the intestinal microflora and how the latter interacts with the host's immune system, it may be possible to define specific microbial substances in specific patients that are either present or absent from the normal flora to cause disease. The diagnoses of CD, UC and GSE are based on clinical features and the results of barium X-rays, endoscopy, mucosal biopsy histology, and in some cases operative findings and resected bowel pathology and histology. Serologic disease markers are accepted in GSE but unambiguously in IBD. Serologic tests that could serve as an adjunct to these invasive and expensive diagnostic studies, or possibly replace them, would have clinical utility[2-5]. Antibodies have attracted much interest for the study of the immune response in inflammatory bowel disease (IBD) and are also used as a tool for phenotyping. Antibodies to baker's yeast and brewer's yeast (anti-*Saccharomyces cerevisiae* antibodies or ASCA) directed against cell wall oligomannoside epitopes have been proposed as a serological marker for CD[6,7].

They have a sensitivity of 60 % and a specificity of 80-95 % for differentiating CD from controls[8]. One small study also reported the production of ASCA by a fraction of unaffected relatives of Crohn's patients. The role of ASCA's in CD is completely unknown, but one hypothesis links them to increased intestinal permeability. 50-60 % of patients with CD exhibit an activity-related increase in intestinal permeability, and this increase might be predictive for relapse. A variable proportion of healthy first-degree relatives of CD patients also have abnormal permeability of the small intestine, which lead some authors to postulate a primary defect of the tight junctions as etiologic factor in CD. Increased exposure of the epithelium to common food antigens such as yeasts due to a break in the epithelial barrier may then result in an antibody response. The effect of dietary yeast (*Saccharomyces cerevisiae*) on the activity of stable CD disease was assessed in patients. The patients' mean CD activity index (CDAI) while taking baker's yeast was significantly greater than that during yeast exclusion and patients with elevated yeast antibodies tended to develop a higher CDAI while receiving baker's yeast. These results suggest that dietary yeast may affect the activity of CD[9]. Antinuclear cytoplasmic antibodies (ANCA) with a perinuclear staining pattern have been proposed as a serologic marker for UC. pANCA's were found in 60-70 % of patients with UC. There is no clear association of pANCA with severity of disease but it is predictive of pouchitis after restorative proctocolectomy with ileoanal pouch anastomosis[10]. pANCA's are also found in 15-20 % of patients with CD. These patients present diffuse left-sided colitis with symptoms such as rectal bleeding, urgency, and mucus discharge and this phenotype is labeled "UC-like CD".

Saccharomyces cerevisiae (SC) is "ubiquitous" yeast and occurs in diverse places in naturally on plants and in the ground. Mankind used in the past and use now yeast for making miscellaneous foods (i.e. beer, bread) so we can come into contact with it principally with our consumed food products and beverages. It is generally accepted that SC is not a pathogen, but it has been suggested that in case of *fungemia* with SC (in patients with damaged/defective immune system) various organs can be affected and injured. The titer of pANCA does not change with the activity of the disease, does not depend on the therapy or the surgical intervention and but persists after resection of the affected part of the bowels. Similarly, the titer of the ASCA is stable irrespective of the activity of the disease and the drug-therapy. ASCA titers correlated with small bowel involvement and occurred particularly in cases of young adults with CD.

The aim of the study was to determine the prevalence of serological markers for GSE and IBD in patients with celiac disease (16 patients), UC (10 patients) and Crohn's disease (42 patients) and to correlate the presence with the characteristics of these diseases.

MATERIALS AND METHODS

Patients

The entire cohort of patients with IBD (42 patients with CD and 10 patients with UC) and GSE (16 patients) from Debrecen, Hungary were enrolled in the study. Adult patients of both sexes were included. The diagnosis of CD, UC or GSE was made using the formally accepted criteria. The medical records for these patients have previously been reviewed by investigators and abstracted for patient characteristics. The blood samples for the study were collected between January 2000 and March 2000. Their sera were separated and stored at -70 ℃. Determination of serum values was performed by individuals blinded to the clinical data for the patients in our Regional Immunology Laboratory.

Specific antibody measurement

Gliadin Glia-test from Diagnosticum Rt.(Budapest, Hungary) was warmed up to room temperature and the dilution of the diluents solution and the buffer solution was dispensed. For the measurement of specific IgG and IgA, the samples were diluted 1:500 (v/v). Micro standardization strips were incubated with one hundred microlitres of washing buffer, negative control, IgA positive control, IgG positive control, and the samples from the patients, for 30 min at 37 ℃. After the incubation, the plate was washed three times with a Labsystems ELISA washer (Beverly, MA). Both of the anti-IgG and anti-IgA conjugate were diluted 1:200 in diluents solution (100 μL per well divided). Wells were again incubated for 30 min at 37 ℃ and washed three times with two hundred microlitres of washing buffer. Next step was incubation with 100 μL of TM B substrate buffer (protected from light) at room temperature for 30 min. Reaction was stopped with 50 μL 4N sulphuric acid per well. Optical density (OD) was determined at 450 nm. All chemical reagents were reagent grade, from Sigma unless otherwise stated.

Transglutaminase Greiner plates (N° 655180) were incubated with transglutaminase, dissolved in PBS at 10 μg per milliliters, 50 μL per well, 16 hours at +4 ℃. Binding sites were blocked by incubating with two hundred microlitres per well of 1 % (w/v) bovine serum albumin (BSA) in PBS for 2 hours at 37 ℃. 100 μL per well of each sample as incubated at room temperature for 2 hours. (For the measurement, the serum samples were diluted 1:100) Anti-human IgA/HRPO conjugate, diluted 1:4 000 (v/v) in diluents solution (1 % BSA-PBS) were incubated (100 μL per well) for 1 hour at room temperature. The color reaction was developed by adding a solution (containing 12.5 ml citrate-phosphate buffer pH 5.0, 4.25 mg OPD, 5 μL of 30 % H_2O_2). The enzymatic reaction was stopped after 15 min with 50 μL per well of 4N H_2SO_4. Optical density (OD) was determined at 492 nm. After each incubation step, wells were washed two times with PBS containing 0.05 % (v/v) Tween 20 (PBS-T) during 10 minutes. Each sample was analyzed in duplicate. All chemical reagents were reagent grade, from Sigma unless otherwise stated.

Endomysium Indirect immunofluorescent method was developed in our laboratory. The substrate (umbilical cord) was incubated in PBS with sera (diluted 1:10 in diluent), washed twice with PBS for 10 min, then incubated with anti-human IgA/FITC and IgG/FITC, washed twice with PBS for 10 min. The preparates were coated with a mixture of glycerin/PBS (1:1) and covered with cover plate. Evaluation was interpreted with fluorescent microscopy. All chemical reagents were reagent grade, from Sigma.

ASCA IgG and IgA Medizym® ASCA IgA is an enzyme immunoassay for the quantitative determination of IgA antibodies to *Saccharomyces cerevisiae* in human serum. Autoantibodies of the diluted patient samples and calibrators reacted with mannan (cell surface component of baker's yeast) immobilized on the solid phase of a microtiter plate. Following an incubation period of 60 min at 37 ℃, unbound serum components are removed by a washing step. The bound antibodies react specifically with anti-human-IgA-antibodies conjugated to horseradish peroxidase (HRPO). Within the incubation period of 30 min at 37 ℃, excessive conjugate was separated from the solid-phase immune complexes by the following washing step. Horseradish peroxidase converted the colorless substrate solution of 3, 3', 5, 5' -tetramethylbenzidine (TMB) added into a blue product. This enzyme reaction was stopped by dispensing an acidic solution (H_2SO_4) into the wells after 10 min at room temperature turning the solution from blue to yellow. The optical density (OD) of the solution at 450 nm was directly proportional to the amount of specific antibodies bound. The standard curve was established by

plotting the concentrations of the antibodies of the standards (x-axis) and their corresponding OD values (y-axis) were measured. The concentration of antibodies of the specimen was directly read off the standard curve.

ANCA The presence of ANCA was first screened by means of a fixed neutrophil enzyme-linked immunosorbent assay (ELISA). Methanol-fixed neutrophils were incubated with control and coded sera at 1:100 dilutions. Neutrophil-bound antibody was labeled by alkaline phosphatase-conjugated goat antihuman IgG. After the addition of p-nitrophenol, specific absorbance was measured at 405 nm. The cutoff for positivity was determined by positive controls from well-defined patients with UC. Indirect immunofluorescent staining was then performed on ANCA ELISA-positive samples to determine whether a predominantly perinuclear (pANCA) or cytoplasmic (cANCA) staining pattern was present. Methanol-fixed neutrophils on glass slides were incubated with the coded sera samples (1:20 dilution). Specific binding was visualized by fluorescence microscopy after the addition of fluorescein-labeled antihuman IgG. The specificity of the perinuclear staining pattern in UC was finally confirmed by its disappearance after DNase treatment of the neutrophils. Results were considered positive when both the ANCA titers were above the cutoff and the indirect immunofluorescence revealed a perinuclear binding of ANCA that disappeared after DNase treatment.

Statistical analysis

The relations were concluded from the evidences with statistical methods and summarized them in tables. Data was presented as percentages or mean values ± standard deviation (SD). The statistical package used in data interpretation (the two-tailed Student's *t*-test, Pierce regression coefficient assay) was Statistica for Windows software (StatSoft, Inc., OK, U.S.A.).

RESULTS

Results are summarized in (Tables 1-3, Figures 1-4). Twenty-seven patients with CD had only colonic localization (27/42), terminal ileitis was in 7 cases (7/42). Both the small and large bowels were affected in 8 cases (8/42). IgG type ASCA was found in 9 patients (1 colitis, 4 ileitis, 4 duodenitis-ileitis-colitis). IgA type ASCA was positive only in the patients with terminal ileitis (6/10) and in the patients with the duodenitis-ileitis-colitis type CD (10/15). The 27 patients with only colonic localization (27/42) had no IgA type ASCA positivity (Figures 1-2). All together, we detected that the increased IgG and IgA type ASCA titers, were mainly in patients with small bowel type CD (with the exception of one patient with colitis-type form with only IgG type ASCA) and celiac disease (Figure 3-4). IgG and IgA ASCA progressed together. IgA type ASCA values were between 0.35-938.19 U/ml (positive $\geqslant$20 U/ml). The prevalence of ASCA in patients with celiac disease outlined a possible role of anti-*Saccharomyces cerevisiae* antibodies in GSE. These findings outlined a noticeable startling resemblance, suggesting a possible kind of connection between CD and GSE.

Table 1 ASCA positive patients in different diseases of bowels

	ASCA IgG+	ASCA IgA+	ASCA IgG+IgA+	IgG *vs* IgA corr.*(r)*
All patients (*n*=68)	5	4	10	0.75
Crohn's disease (*n*=42)	1	2	8	0.81
Ulcerative colitis (*n*=10)	2	1	0	-0.01
Celiac disease (*n*=16)	2	1	2	0.50
Controls (*n*=20)	0	0	0	-0.18

Notes: It is clear that there was no ASCA positivity in the controls. ASCA positivity was common in patients with Crohn's disease. The ASCA IgG- and IgA-type seropositivity was concomitant.

Table 2 ASCA positive patients with different forms of Crohn's disease

Affected section of the bowels	ASCA IgG+	ASCA IgA+	ASCA IgG+IgA+
Only the colon (*n*=27)	1	0	0
Large and small bowels both (*n*=8)	0	0	4
Only small bowels (*n*=7)	0	2	4
Small bowel together (*n*=15)	0	2	8

Notes: Both the IgA and IgG type ASCA associated to the small bowels. $P<0.0004$, ASCA IgG+ *vs* small bowels; $P<0.0001$ ASCA IgA+ *vs* small bowels.

DISCUSSION

Both celiac disease and Crohn' s disease are characterized by the presence of distinct (auto) antibodies. Based upon our results, theoretically and practically it is thinkable that ASCA positivity is not only a specific marker of Crohn' s disease but correlates with the (auto-) immune inflammation of the small intestines How does it happen?

Macrophages can produce proinflammatory cytokines (i.e. TNF-α) with direct and indirect microbicide activity. Several cell-wall components of *Candida albicans* were investigated in relation with the TNF-alfa secretion of macrophages and confirmed that they all had beta-1,2-oligomannoside[11,12]. The incubation with purified oligomannoside activated macrophages and they secreted TNF-alfa (in dose and molecule-size dependently) *in vitro* and *in vivo*[13,14]. Similar observations were demonstrated with *Saccharomyces cerevisiae*: the oligomannose structures influenced per interaction the cytokine network[15-17]. It is conceivable that miscellaneous *fungus*-oligosaccharides (their signal function in phytopathology is well-known) could play a key role in the regulation of human infections[18]. Oligomannosids of *Saccharomyces cerevisiae* with modification by ASCA can change their immunopathogenicity and trigger a process that results in specific inflammation such as CD.

The human gastrointestinal tract possesses a complex ecosystem, the components of which are multifaceted and metabolically diverse. Although the presence of intestinal microflora certainly contributes to the maintenance of human health, intestinal mucosa has the task, among others, of preventing the passage of commensal microflora and occasional pathogens to other compartments. To carry out such a function, the mucosa has to behave as a physical barrier but it also has to play an active role. Oral tolerance (OT) consists of the oral administration of antigens that could alter the response of the immune system[19]. This is a form of peripheral immune tolerance in which mature lymphocytes in the peripheral lymphoid tissues are rendered non functional or hyporesponsive by prior oral administration of antigens. The mechanisms by which OT is mediated include deletion or anergy and active cellular suppression. The primary factor determining which form of tolerance will be developed after oral administration of antigen is its dosage. Thus, it is thought that low doses of antigen can induce the generation of active suppression, *via* regulatory T cells in the gut-associated lymphoid tissue (GALT), which then migrate to the systemic immune system. These regulatory T cells produce down-regulatory cytokines such as IL-4, IL-10 and TGF-β in a Th2 /Th3 cytokine pattern. Conversely, high dose of antigen favors anergy or clonal deletion. The phenomenon in which regulatory cells, as generated by oral tolerance, are primed in an antigen specific manner, but act in the respective microenvironment in a non-antigen specific manner is called bystander suppression. This phenomenon is of particular interest and can explain the use of oral/mucosal tolerance in T cell mediated autoimmune diseases such as rheumatoid arthritis and some diseases in which the autoantigen remains unknown or where there are reactivities to multiple autoantigens. T helper type 1 (Th1) lymphocytes secrete interleukin (IL)-2, interferon-γ and lymphotoxin-α, and stimulate type 1 immunity, which is characterized by intense phagocytic activity. Conversely, Th2 cells secrete IL-4, IL-5, IL-9, IL-10 and IL-13, and stimulate type 2 immunity, which is characterized by high antibody titers. Type 1 and type 2 immunity are not strictly synonymous with cell-mediated and humoral immunity, because Th1 cells also stimulate moderate levels of antibody production, whereas Th2 cells actively suppress phagocytosis. For most infections caused by large eukaryotic pathogens, type 1 immunity is protective, whereas type 2 responses assist with the resolution of cell-mediated inflammation. Severe systemic stress, immunosuppression, or overwhelming microbial inoculation causes the immune system to mount a type 2 response to an infection normally controlled by type 1 immunity. Macrophages also play a crucial role in the mucosal network as they must perform a number of diverse cellular functions that allow them to kill invading micro-organisms and neoplastic cells as well as produce growth factors involved in wound healing. Macrophages that develop these diverse functions arise from a common precursor. By a process of selective adaptation, the common precursor monocyte/ macrophage differentiates into a distinctive macrophage with a different and specific phenotype, characterized by the expression of a specific set of gene products. The local environment plays a critical role in shaping or directing the pattern or pathway of macrophage differentiation: one pathway was believed to play a role in wound repair and characterized by the induction of insulin-like growth factor-1 (IGF-I) and a second pathway was involved in macrophage cytocidal activation and characterized

by the induction of the inducible form of nitric oxide synthase (iNOS)[20,21].

IBDs are a group of diseases due to chronic inflammation of the gastrointestinal tract, but without proved etiology. IBD appears to be resulted from a dysregulated immune response with contributions from environmental, genetic, and bacterial factors. In the last decades, our understanding of the pathogenesis of IBD has greatly expanded but a better insight is needed into the environmental agents responsible for either initiation or perpetuation of IBD. The increasing attention given to the ecosystem of the gut may help define the antigens responsible for immune reactivity and provide opportunities toward application of antigen-specific therapeutic interventions such as induction of tolerance. Further investigation into probiotic agents and their mechanisms is especially appealing as a way to provide alternative therapies to decrease the inflammatory response. Antibodies to an oligomannose epitope of *Saccharomyces cerevisiae* demonstrated in 60-70 % of the patients with Crohn' s disease. The origin and clinicopathological role of ASCA have not been clarified. The sporadic information about ASCA positivity in patients suffering from gluten sensitive enteropathy in the literature suggests another occurrence.

We examined the ASCA' s occurrence in our patients and compared it with the clinical picture of the Crohn' s disease. The results supported the theory that ASCA positivity correlated with small intestinal Crohn' s disease and in these cases both IgG and IgA type antibodies were proved. The relatively high incidence of ASCA in GSE was unexplained but indicated further surveys to elucidate it as it was definitely more than accidental[22]. The antibodies in the sera of the analyzed ASCA positive cases proved a systemic immune response against *Saccharomyces cerevisiae* and suggested the end of the oral tolerance against the yeast' s antigens. The diet restriction (elemental diet, total parenteral nutrition, and fecal diversion) may ameliorate the status of the patients with Crohn' s disease. It can also be speculated that the yeast-free diet as a part of the therapy for the ASCA positive patients can be reasonable, moreover the permanent "forbidding" of the yeast can be an acceptable alternative in case of getting well.

Abstract

AIM: Capsule endoscopy has demonstrated its clinical utility in the evaluation of small bowel pathology in several Western studies. In this prospective study, we aimed to determine the clinical utility, safety and tolerability of capsule endoscopy in the evaluation of suspected small bowel disease in an urban Southeast Asian population.

METHODS: We used the given (M2A) capsule endoscopy system in 16 consecutive patients with suspected small bowel pathology. In 9 patients the indication was obscure gastrointestinal bleeding, while in 6 patients it was to determine the extent of small bowel involvement in Crohn's disease. One patient underwent capsule endoscopy for evaluation of chronic abdominal pain. Patient's tolerability to the procedure was evaluated by standardized questionnaires and all patients were reviewed at one week to ensure that the capsule had been excreted without any adverse events.

RESULTS: Abnormal findings were present in 8 patients (50 %). The cause of obscure gastrointestinal bleeding was determined in 5 out of 9 patients. Findings included 2 cases of angiodysplasia, 2 cases of jejunal ulcers and 1 case of both angiodysplasia and jejunal ulcer. One patient had small bowel erosions and foci of erythema of doubtful significance. Ileal lesions were diagnosed in 2 out of 6 patients with Crohn's disease. Capsule endoscopy was well tolerated by all patients. One patient with Crohn's disease had a complication of capsule retention due to terminal ileum stricture. The capsule eventually passed out spontaneously after 1 month.

CONCLUSION: Our study, which represented the first Asian series, further confirms the diagnostic utility, safety and tolerability of wireless capsule endoscopy.

INTRODUCTION

Small bowel imaging is important in the evaluation of obscure gastrointestinal bleeding[1], inflammatory disease of the small bowel[2] and tumours. The main methods of small bowel imaging have been either enteroscopy or small bowel barium studies in the evaluation of luminal pathology. Angiography is a diagnostic option in the context of suspected small intestinal bleeding. Push enteroscopy allows examination of only 80 to 120 cm of the small bowel beyond the ligament of Treitz, while intra-operative enteroscopy requires general anesthesia and laparotomy. Small bowel series and enteroclysis have limited sensitivity, and in particular, could not detect flat lesions such as angiodysplasia[3].

Wireless capsule endoscopy was first reported by Iddan *et al*[4] in 2000, and it represents a major advancement in the imaging of the small intestine. It is able to capture video-images of the mucosal surface of the entire length of the small intestine directly, and has been reported to be virtually pain-free since it is essentially propelled forward through the gastrointestinal tract by peristalsis, without the need for any air-insufflation.

Thus far all published data on the use of capsule endoscopy have been from Western countries, with only 2 case reports on its use from India. One was a case of ileal angiodysplasia[5] while another was that of small intestine tuberculosis[6].

In this prospective study, we aimed to determine the clinical utility, safety and tolerability of capsule endoscopy in the evaluation of suspected small bowel disease in an urban Southeast Asian population.

MATERIALS AND METHODS

Study population

Consecutive patients with suspected small bowel pathology seen at the Division of Gastroenterology, Changi General Hospital, Singapore, were recruited. Indications for capsule endoscopy included obscure gastrointestinal bleeding, assessment of extent of small intestine involvement in Crohn's disease, evaluation of chronic abdominal pain and assessment for small bowel pathology in the presence of malabsorption. Patients with the following conditions were excluded from the study: pregnant subjects, suspected small bowel obstruction, presence of cardiac pacemaker, subjects expected to undergo MRI examination before elimination of capsule and subjects with swallowing difficulty. The study was approved by the Hospital Ethics Committee. Informed consent was obtained from all patients before commencement of the study.

Given diagnostic imaging system

The given diagnostic imaging system is comprised of the 26 mm by 11 mm M2A® capsule which contains a miniscule color video-camera equipped with a localization feature, a data recorder which is a portable, battery operated external receiving/recording unit that receives data transmitted by the capsule and subsequently allows data downloading, the Rapid® Workstation, a modified personal computer which has been designed for storage, processing and presentation of captured images as well as generation of reports. The technical details have previously been described in an earlier paper[7].

M2A® capsule ingestion, data capture and follow-up

After a 12-hour fast, subjects underwent capsule examination with the M2A®capsule according to the standard procedure. Briefly it involved attaching 8 sensory arrays to the abdomen

based on a standard template. These arrays were then attached to the portable battery powered data recorder. The capsule was swallowed and subjects were advised that fluids were allowed after 2 hours and light snack after 4 hours. Subjects were then allowed to go home. After 8 hours, the subject returned and the equipment was removed and the data were downloaded into the Rapid® Workstation and the images were analyzed using the proprietary software. The subjects were asked to look for the capsule in the feces. They were also reviewed again at 1 week for any complications and to ensure that the capsule had passed out. If excretion of the capsule was not noticed by the subject, an abdominal X-ray would be done.

Assessment of tolerability and complications

All subjects were asked about tolerability of the procedure in the following areas using a standardised questionnaire, which included ease of swallowing, pain or discomfort experienced during the procedure, pain or discomfort experienced after the procedure, overall tolerability of the procedure, and overall convenience of the procedure. The subjects were also evaluated at one week after procedure for any adverse events such as pain, nausea,vomiting and capsule impaction or retention.

Capsule image interpretation

Two gastroenterologists (Drs Tay-Meng Ng and Tiing-Leong Ang) reviewed the capsule images independently and reported on the findings. Questionable findings were discussed. Positive findings were defined as detected abnormalities that were potentially related to the presenting problem.

RESULTS

Demographics

During the period from mid February to May 2003, 16 consecutive patients with suspected small bowel pathology and no contraindication to capsule endoscopy were recruited. Their mean age was 55.6 years (range: 19 to 82 years) with a male to female ratio of 9:7. Table 1 summarizes the patient profile, indication for capsule endoscopy and the results of the study.

Nine patients had obscure gastrointestinal bleeding, having presented with anaemia and melaena. All underwent both gastroscopy and colonoscopy. These investigations did not reveal significant pathology that could have accounted for the bleeding. Push enteroscopy was done in 2 of these patients, and small bowel series were done in another 4. Apart from small bowel diverticula seen on small bowel series in one patient, the rest of the small bowel imaging were normal.

Six patients were diagnosed to have Crohn' s disease on the basis of characteristic clinical, endoscopic and histologic features. Capsule endoscopy was performed to determine the extent of small bowel involvement in these patients.

One patient had a problem of recurrent abdominal pain and capsule endoscopy was performed to exclude any small intestine pathology after previous endoscopies did not reveal any significant lesions.

Findings in capsule endoscopy

Among the 9 patients with obscure gastrointestinal bleeding, capsule endoscopy was able to diagnose a clinically significant pathology in 5 of them (55.6 %). Two patients had jejunal ulcers (Figure 1). Two patients had angiodysplasia while the last patient had both angiodysplasia and jejunal ulcer. It was felt that the jejunal ulcers could have been related to NSAID usage. A sixth patient had the finding of small bowel erosions and foci of erythema, but the authors felt that these lesions could not have accounted for the gastrointestinal bleeding. Among the 6 patients with Crohn' s disease, capsule endoscopy revealed small bowel pathology in 2 cases. One patient had multiple ileal ulcers and strictures (Figure 2) while the other had erythema in the terminal ileum. These abnormalities were not detected by small bowel barium studies done prior to capsule endoscopy. Overall, abnormalities were present in 50 % (8/16) of the subjects.

Patient tolerability and complications

All the patients rated the procedure as comfortable and very convenient. Despite the size of the capsule being larger than most tablets, all the patients described swallowing as very easy. There was no complaint of pain or discomfort during or after the procedure. However, 2 of the patients commented on the weight of the portable recorder/battery pack.

The capsule was excreted in all the patients without any ill effects. One patient had retention of capsule beyond one week without developing any obstructive symptoms. It took 31 days before the capsule was noted to have passed out spontaneously. This was the patient with Crohn' s disease who had ileal ulcer and stricture. In fact, an attempt was made to retrieve it endoscopically at one week but it was unsuccessful. It was then decided to follow up the patient and wait for spontaneous passage of the capsule as he had remained asymptomatic

Table 1 Patient characteristics and results of capsule endoscopy

SN.	Age / sex	Indication for capsule endoscopy	Results of capsule endoscopy
1	66 / male	Extent of small bowel involvement in Crohn's disease	Erythema in terminal ileum
2	30 / male	Extent of small bowel involvement in Crohn's disease	Edematous small bowel
3	62 / female	Obscure gastrointestinal blood loss	Small bowel angiodysplasia
4	39 / male	Extent of small bowel involvement in Crohn's disease	Ulcers and strictures in ileum
5	28 / male	Extent of small bowel involvement in Crohn's disease	Normal small bowel
6	74 / female	Extent of small bowel involvement in Crohn's disease	Gastric erosions; normal small bowel
7	62 / male	Obscure gastrointestinal blood loss	Gastric erosion; normal small bowel
8	69 / male	Obscure gastrointestinal blood loss	Jejunal ulcer; small bowel angiodysplasia
9	59 / female	Obscure gastrointestinal blood loss	Mild gastritis and duodenitis; normal small bowel
10	82 / female	Obscure gastrointestinal blood loss	Gastritis; small bowel angiodysplasia
11	54 / female	Extent of small bowel involvement in Crohn's disease	Normal small bowel
12	69 / male	Evaluation for small intestine pathology in context of chronic abdominal pain	Normal small bowel
13	71 / female	Obscure gastrointestinal blood loss	Jejunal ulcer
14	66 / female	Obscure gastrointestinal blood loss	Bleeding jejunal ulcer
15	46 / male	Obscure gastrointestinal blood loss	Normal small bowel
16	19 / male	Obscure gastrointestinal blood loss	Small bowel erosions and foci of erythema

throughout, rather then subject him to surgery. For the remaining 15 patients, the capsule was excreted within a week, six of these patients actually did not notice the passage of the capsule, but an abdominal X-ray done at one week proved that the capsule had not been retained.

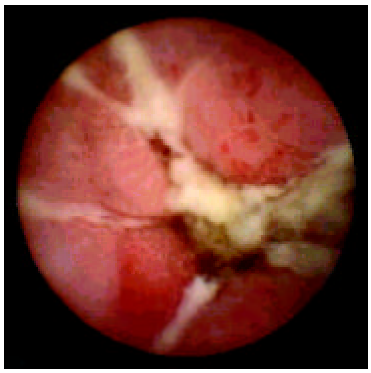

Figure 2 Terminal ileum ulcer and stricture in a patient with Crohn's disease.

DISCUSSION

Our study, which represented the first Asian series, further confirmed the diagnostic utility, safety and tolerability of wireless capsule endoscopy. In our series, it was able to reveal significant small intestine pathology in 43.8 % (7/16) of the patients. In particular, for obscure gastrointestinal bleeding, it was able to reveal the cause in 55.6 % of the patients. It was remarkably well tolerated, and apart from one patient with delayed capsule excretion, there were no complications. This complication highlighted the need to be vigilant towards the possibility of intestinal obstruction when considering the use of capsule endoscopy.

In a prospective study of 20 patients, Costamagna *et al*[7] confirmed the superiority of capsule endoscopy over small bowel radiographs in the diagnosis of suspected small bowel disease. Capsule endoscopy was able to detect abnormalities in 17 out of 20 patients, compared to 3 out of 20 using barium studies. Similarly, Scapa[8] in another prospective study found that among 35 patients with suspected small intestine pathology but normal small bowel series, capsule endoscopy was able to detect clinically significant small intestine pathology in 63 % of (22/35) patients.

For the evaluation of obscure gastrointestinal bleeding, our results were comparable to other published data. Scapa[8] was able to find a source of bleeding in 75 % (15/20) of his patients with obscure gastrointestinal bleeding. Lewis[9] had a positive yield of 55 % (11/20) in the evaluation of obscure gastrointestinal bleeding with capsule endoscopy. Ell[10] detected a definite source in 66 % of his patients.

For the diagnosis of Crohn's disease, Fireman[11], Eliakim[12] and Herrerias[13] have demonstrated the clinical utility of capsule endoscopy in diagnosis as well as in assessment of the extent of disease. It was particularly relevant where conventional endoscopic and radiological techniques have not identified pathological findings but clinical suspicion based on symptoms and laboratory tests was strong. In our series, only 33 % of the patients with Crohn's disease had abnormal findings on capsule endoscopy. This probably simply reflected the actual prevalence of small bowel involvement in our series, rather than under-diagnosis, since alternative imagings, such as barium studies when done, did not reveal any small bowel lesions either. In addition it was recognized that about 1/3 of patients with Crohn's disease had ileocolic disease, about 1/3 had colonic disease and about 1/3 had small bowel disease[14]. An important point to note was that one patient actually had ileal stricture that led to delayed excretion of the capsule. In this case, the presence of small bowel stricture was not suspected, as the patient did not have any clinical evidence of small bowel obstruction. It is therefore suggested that if Crohn's disease is a diagnostic consideration, then small bowel series or enema should precede the use of capsule endoscopy in order to minimize the risk of capsule retention. It is also worth noting that despite the stricture, the capsule was able to pass out without any ill effect after 31 days. Therefore in the absence of any signs or symptoms of capsule impaction or obstruction, a conservative approach may be adopted, with the use of high dose steroid to reduce the inflammation and oedema so as to facilitate the passage of the capsule, as occurred in this patient with Crohn's stricture.

Possible complications and limitations exist with any procedure, and capsule endoscopy is no exception, in spite of the high diagnostic yield. The key complication is that of capsule retention proximal to a stricture, and a 5 % retention rate has been reported, with the need for surgery in less than 1 % of patients[15]. Another concern is delayed passage of capsule due to slow transit time, resulting in capsule recording terminating before it has passed to the caecum, and hence incomplete data acquisition. Other limitations included difficulty in determining the exact site of the abnormality in the small bowel, inability to take tissue biopsy, problem of visual clarity due to intestinal fluids and long viewing time of the video, which could take up to 2 hours[7]. It is also costly, with the estimated cost of each capsule being greater than the cost of undergoing colonoscopy in the Singapore context. Thus it is likely that its use would remain selective, being reserved for situations when endoscopy or other imaging modalities have failed to achieve a definite diagnosis. These would include the investigation of obscure gastrointestinal bleeding, and in the context where clinical suspicion for Crohn's disease is strong but the results of all other tests have been equivocal.

In conclusion, our study affirms the diagnostic utility and safety of capsule endoscopy in clinical practice. It has the promise to become a leading method in the evaluation of small bowel pathology, but limitations and the issue of cost need to be addressed.

Abstract

AIM: To evaluate the role of three-dimensional contrast-enhanced magnetic resonance angiography (3D CE MRA) in the diagnosis of Budd-Chiari syndrome (BCS).

METHODS: Twenty-three patients with BCS underwent 3D CE MRA examination, in which 13 cases were secondary to either hepatocellular carcinoma (11 cases), right adrenal carcinoma (1 case) or thrombophlebitis (1 case) and 10 suffered from primary BCS. The patency of the inferior vena cava (IVC), hepatic and portal veins as well as the presence of intra- and extrahepatic collaterals, liver parenchymal abnormalities and porto-systemic varices were evaluated. Inferior vena cavography was performed in 10 cases. The diagnosis of IVC obstruction by 3D CE MRA was compared with that demonstrated by inferior vena cavography.

RESULTS: The major features of BCS could be clearly displayed on 3D CE MRA. Positive hepatic venous signs included tumor thrombosis (9 cases), tumor compression (2 cases), nonvisualization (4 cases) and focal stenosis (2 cases). Positive IVC findings were noted as severe stenosis or occlusion (10 cases), tumor invasion (2 cases), thrombosis (3 cases), thrombophlebitis (1 case) and septum formation (3 cases). Intrahepatic collaterals were shown in 9 patients, 2 of them with "spider web" sign. The displayed extrahepatic collaterals included dilated azygos and hemi-azygos veins (13 cases) and left renal-inferior phrenic-pericardiophrenic veins (2 cases). The occlusion of the left intrahepatic portal veins was found in 2 cases. Porto-systemic varices were detected in 10 patients. Liver parenchymal abnormalities displayed by 3D CE MRA were enlargement of the caudate lobe (7 cases), heterogenous enhancement (18 cases) and complicated tumors (13 cases). Compared with the inferior vena cavography performed in 10 cases, the accuracy of 3D CE MRA was 100 % in the diagnosis of IVC obstruction.

CONCLUSION: 3D CE MRA can display the major features of BCS and provide an accurate diagnosis.

INTRODUCTION

Budd-Chiari syndrome (BCS) is a rare disease caused by the obstruction of the hepatic venous outflow or the inferior vena cava (IVC) above the hepatic vein[1]. It often occurs secondary to intrinsic vascular thrombosis, hepatic tumor invasion/compression, or associates with an idiopathic obstructing membrane[1,2]. The clinical signs of ascites, abdominal pain and hepatomegaly are the typical triad of BCS. Since these signs are nonspecific, the clinical diagnosis of this syndrome is difficult. Conventionally, X-ray angiography and/or liver biopsy are used to confirm the diagnosis of BCS with the limitation of invasiveness. Ultrasound (US), computed tomography (CT) and magnetic resonance imaging (MRI) are the noninvasive imaging techniques currently used in the evaluation of the patency of hepatic veins, IVC and portal vein. However, some limitations are also existed in each of these modalities[2-7].

Three-dimensional contrast-enhanced magnetic resonance angiography (3D CE MRA) is a new technique and widely used in the imaging of the arterial system, portal venous system and central venous system[8-16]. However, to our knowledge, few studies have been reported so far concerning its use in the diagnosis of BCS[17]. Therefore, this study was conducted to evaluate the usefulness of this technique in the imaging of BCS and to present various findings of BCS demonstrated on 3D CE MRA.

MATERIALS AND METHODS

Patients

Twenty-three patients with BCS underwent 3D CE MRA. There were 20 men and 3 women ranging from 26 to 56 years of age (average age 38 years). In 11 patients, BCS was secondary to the invasion and occlusion of the hepatic vein and/or IVC by hepatocellular carcinoma (HCC). In 1 patient, BCS was resulted from tumor invasion of IVC by right adrenal carcinoma. In 1 patient, IVC obstruction was due to superior extension of pelvic thrombophlebitis. The above 13 patients were considered to be secondary BCS. Ten patients had primary BCS with an unknown origin. The diagnosis of BCS was confirmed by inferior vena cavography in 10 cases, percutaneous liver biopsy in 2 cases, and surgery in 5 cases. The diagnosis of the remaining 6 cases was confirmed by combined color Doppler sonography and contrast-enhanced CT.

3D CE MRA examination

All scans were performed using a 1.5T MR imager (Signa, General Electric Medical Systems, Milwaukee, WI.) and a body coil. After the localizing images were obtained, a breathhold T1-weighted fast multiplanar spoiled gradient-echo (FMPSPGR) sequence (repetition time/echo time, 150/4.2 msec; flip angle, 90°; field of view, 360 mm; matrix, 128×256; 18 slices; slice thickness, 7.0 mm; gap, 3.0 mm; one signal acquired) and a respiratory-triggered T2-weighted fast spin-echo sequence (repetition time/echo time, 2800-4200/80 msec; echo train length 8-12, field of view, 360 mm; matrix, 128×256; 18 slices; slice thickness, 7.0 mm; gap, 3.0 mm; 2 signals

acquired) were performed in the liver. For 3D CE MRA, a breath-hold 3D fast spoiled gradient-echo sequence (repetition time/echo time, 5.2-10.2/1.2-1.9 msec; flip angle, 30° or 45°; field of view, 360-480 mm; matrix, 128×256; imaging volume, 75-168 mm; number of partitions, 24-30; one signal acquired; and acquisition time, 19-28 sec) was used.

With T1-weighted and T2-weighted images as reference, the imaging volume of 3D CE MRA was acquired in a coronal plane to cover the hepatic veins, IVC, portal veins and collateral vessels. The imaging volume was determined by a radiologist depending on each patient´s abnormalities, liver size and ability of breathholding.

A gadolinium chelate called gadopentetate-dimeglumine (Magnevist; Schering AG, Berlin, Germany) was used as a contrast material for all examinations, with a concentration of 0.15 mmol per kilogram of body weight. In all cases the contrast material was injected by an experienced MR technician through an antecubital vein with an injection rate of approximately 3 ml/sec. In 2 patients, however, due to poor visualization of IVC after injection of the contrast material into an arm vein, the study was repeated and the contrast agent was injected via a pedal vein for assessment of IVC. Scanning was commenced immediately after the injection and repeated three times with a 6-second delay between each acquisition for patient' s breathing. The first acquisition was the imaging of the arterial phase, the second acquisition was the portal venous phase for demonstration of the portal vein and IVC, while the third acquisition coincided with the image of the late venous phase for visualization of the hepatic veins. Source images of each acquisition were reviewed first, and then these images were reconstructed on a workstation (Advantage windows workstation, General Electric Medical Systems, Milwaukee, WI) to produce projectional images like X-ray angiography. Both maximum intensity projection (MIP) and multiplanar reconstruction (MPR) techniques were employed to analyze the acquired image.

Image analysis

3D CE MRA images were reviewed together by two radiologists unaware of the patients' clinical statuses and other imaging findings. The patency of the hepatic veins, IVC and portal veins was assessed. The presence of intra- and extrahepatic collaterals, liver parenchymal abnormalities and porto-systemic varices were also noted. Inferior vena cavography was performed in 10 cases. The diagnosis of IVC obstruction by 3D CE MRA was compared with that demonstrated by inferior vena cavography.

RESULTS

3D CE MRA findings

Hepatic veins 3D CE MRA demonstrated tumor thrombosis of two or three hepatic veins in each of the 9 patients with HCC (Figure 1). The right and middle hepatic veins were severely compressed and distorted by HCC in 2 patients. Nonvisualization of hepatic veins occurred in 4 patients with primary BCS. Focal stenosis of the right and middle hepatic veins near the caval confluence was detected in 2 patients with primary BCS (Figure 2).

IVC Severe stenosis or occlusion of the IVC was found in 10 patients (Figure 3), 3 of them were associated with the external compression or direct invasion of IVC by HCC. Tumor thrombosis was found in 3 cases with HCC (Figure 1). Direct invasion of IVC by right adrenal tumor was observed in 1 case. Thrombosis of IVC was shown in 1 patient with pelvic thrombophlebitis. A septum or obstructing membrane was demonstrated in the IVC in 3 patients (Figure 4). Localized dilatation of the distal IVC and renal veins were shown in 2 cases with IVC obstruction. In 10 patients with inferior vena cavography, the site and extent of IVC obstruction and distribution of collaterals presented by 3D CE MRA were in agreement with those by cavography (Figure 3). The accuracy of 3D CE MRA was 100 % in the diagnosis of IVC obstruction.

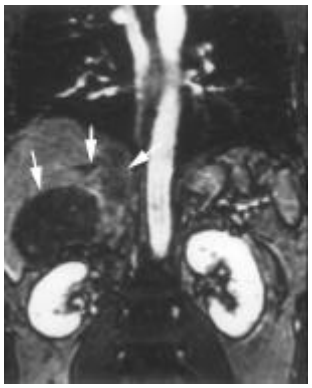

Figure 1 Source image of three-dimensional contrast-enhanced magnetic resonance angiography shows tumor thrombosis of the right hepatic vein (short arrow) and inferior vena cava (long arrow). A hypointense hepatocellular carcinoma (arrowhead) is shown simultaneously.

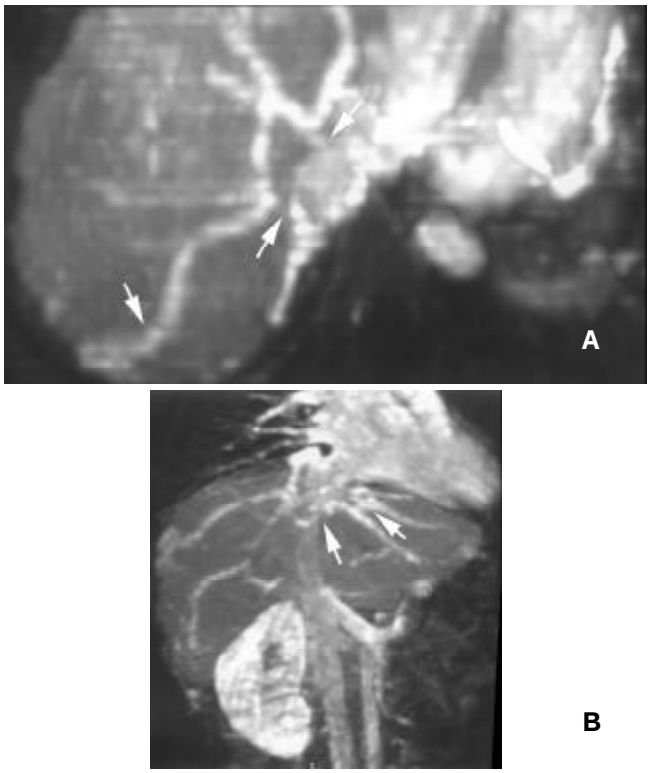

Figure 2 A: Axial reconstruction of three-dimensional contrast-enhanced magnetic resonance angiography demonstrates focal stenosis of right and middle hepatic veins (arrow heads). Intrahepatic collateral between right hepatic vein and subcapsular vein is also demonstrated (arrow). B: Coronal reconstruction reveals fine collaterals between hepatic veins (arrows), resembling a "spider web".

Intra-and extrahepatic collaterals 3D CE MRA revealed fine venous collaterals between the right hepatic veins and subcapsular veins, and between the right, middle and left hepatic veins in 2 patients with focal hepatic vein stenosis, appearing as the typical "spider web" sign (Figure 2B). Large and tortuous veins between enlarged right inferior accessory hepatic veins and right main hepatic veins were identified in 3

patients with IVC occlusion (Figure 3B). Various extrahepatic collaterals were found in the abdominal wall, peritoneal and retroperitoneal areas. Prominent azygos and hemiazygos veins were demonstrated in 13 patients. The left renal-inferior phrenic-pericardiophrenic collaterals were displayed in 2 patients (Figure 5).

Portal veins and porto-systemic varices The portal veins were found patent in all observed patients except 2 whose left intrahepatic portal veins were occluded (Figure 6). Gastroesophageal/esophageal varices and spontaneous splenorenal shunts were identified in 8 and 2 patients respectively.

Liver parenchyma An enlarged caudate lobe was found in 7 patients. Heterogenous liver enhancement was observed in 18 cases (Figure 6). HCC, which showed hyperintensity in arterial phase and hypointensity in portal venous phase, was found in 13 patients (Figure 1). In 2 of them, the tumor was developed after the primary BCS formation, because these two patients underwent long-term follow-up studies and the initial imaging findings indicated no intrahepatic tumors.

Figure 3 A: Source image depicts occlusion of the inferior vena cava(arrowhead). B: Maximum intensity projection of three-dimensional contrast-enhanced magnetic resonance angiography depicts tortuous intrahepatic collaterals (arrows) between right inferior accessory hepatic vein and right main hepatic vein. C: Inferior vena cavography confirms the occlusion of the inferior vena cava (arrowhead) and the intrahepatic collaterals (arrow).

Figure 4 Three-dimensional contrast-enhanced magnetic resonance angiography identifies a septum (arrowheads) in the inferior vena cava.

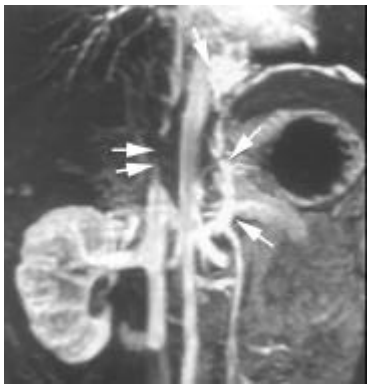

Figure 5 Three-dimensional contrast-enhanced magnetic resonance angiography detects occlusion of the inferior vena cava(white arrowheads), prominent left renal-inferior phrenic-pericardiophrenic collaterals (arrows) and esophageal varix (black arrowhead).

Figure 6 Three-dimensional contrast-enhanced magnetic resonance angiography demonstrates occlusion of the left portal vein (arrowhead) and heterogeneous enhancement pattern of the liver (arrows).

DISCUSSION

BCS is difficult to be diagnosed clinically. However, accurate and early diagnosis is important for its treatment. Radiologic assessment is an important step for its diagnosis. Diagnosis by US was noninvasive, relatively inexpensive and readily available, but its accuracy was limited by operator' s experience, poor acoustic window, inaccessible anatomic structure and body forms[1,3,7]. Contrast-enhanced CT was readily available too, but it used ionizing radiation and required intravenous administration of a large amount of iodinated contrast material with the risk of

nephrotoxicity and possible allergic reactions[1,5,6]. X-ray angiography was the reference criteria for the evaluation of BCS, due to its superb spatial resolution[1,3], but it was invasive and uncomfortable. Like CT, it also involved radiation and use of iodinated contrast material. Disadvantages also included high cost, requirement of operator' s expertise (especially for hepatic venography), and associated complications such as hemorrhage. MRI and non-enhanced magnetic resonance angiography (MRA) with time-of-flight (TOF) and phase-contrast (PC) techniques were other non-invasive means for demonstrating the hepatic venous system, but were limited by long acquisition time, motion and flow artifacts, and saturation effects[2,4,18-21].

3D CE MRA is a recently developed, non-invasive, fast and easy to be performed technique, which is capable of depicting vascular anatomy in multiple projections. It involves no radiation. With this technique, the imaging of the hepatic veins, IVC and portal veins is accomplished with only one injection of contrast material and short breath holding. It requires only a peripheral venous injection of a small amount of gadolinium, which is much safer than iodine-based contrast material. By using gadolinium to shorten the T1 value of the blood, it overcomes flow artifacts and saturation effects in TOF and PC. Moreover, it permits assessment of liver parenchyma and extravascular abnormalities during investigation of the vascular system[12,15,17]. So 3D CE MRA has many advantages over the currently more conventional methods for imaging the BCS.

According to our study, 3D CE MRA was able to demonstrate the patency of the hepatic veins, IVC and portal veins. It could show intra- and extrahepatic collaterals as well as porto-systemic varices caused by cirrhosis. 3D CE MRA could distinguish extravascular compression from intravascular thrombosis, detect liver abnormalities and evaluate the extent of the disease. By means of only one examination, 3D CE MRA provided all these crucial information for accurate diagnosis of BCS and for possible surgical or interventional managements, such as porto-caval shunt, liver transplantation, transjugular intrahepatic porto-systemic shunt (TIPSS), percutaneous transluminal angioplasty (PTA) and stent placement[22-27].

Among 13 patients of secondary BCS, tumor thrombosis, external compression and direct invasion of hepatic veins and/or IVC by tumors were the main causes of this disease. Through demonstration of intra- and extrahepatic disorders and the involved blood vessels, 3D CE MRA could disclose the etiology of BCS. For patients with primary BCS, nonvisualization, focal stenosis of the hepatic veins, occlusion or a septum formed in IVC were the most common findings on 3D CE MRA, as have been reported by Miller *et al*[5] with CT and MRI techniques. Compared with vena cavography, 3D CE MRA was 100 % accurate in diagnosis of IVC obstruction. On the basis of this study and Erden' s report[17], 3D CE MRA could replace inferior vena cavography for diagnosing IVC obstruction.

3D CE MRA could evaluate the intra- and extrahepatic collateral pathways. Identification of intrahepatic collateral veins is highly suggestive of BCS[6,17,28]. The intrahepatic collateral veins divert blood away from the stenotic or occluded hepatic vein and into a patent hepatic vein or a systemic vein. According to Cho' s report[6], intrahepatic collaterals were poorly defined on contrast-enhanced CT. In this study, 3D CE MRA found these collateral veins in 2 patients with stenosis of the hepatic veins. On 3D CE MRA, they were identified either by typical "spider web" sign or by large connecting veins between accessory and main hepatic veins. The dilated azygos and hemiazygos veins were the most commonly collateralized extrahepatic routes shown in this study. The infrequent left renal-inferior phrenic-pericardiophrenic collaterals were also seen on 3D CE MRA.

Our study indicated that a strong point of 3D CE MRA was to display the portal venous system simultaneously with hepatic veins and IVC. Obstruction or increased pressure in hepatic veins resulted in portal hypertension and portal flow stasis, which might further cause porto-systemic varices and portal vein thrombosis. Complications of portal hypertension were fatal in more than 50 % of BCS patients[27]. Thus the accurate delineation of the abnormalities of the portal vein, and the anatomic relationship between portal vein, hepatic veins and IVC were very important, particularly when preparing the treatment with porto-caval shunt or TIPSS[22-24,27]. In this study, 3D CE MRA showed the ability to provide all these relevant information.

Hypertrophy of the caudate lobe was found on 3D CE MRA. This was related to independent blood supply and drainage of this lobe. Heterogeneous enhancement pattern observed by 3D CE MRA has been already known from studies on contrast-enhanced CT[1]. It reflected the hemodynamic disturbance in the liver with BCS. 3D CE MRA found 2 patients with primary BCS developed HCC during a long-term follow-up period. The development of HCC in patients with chronic BCS has been reported in the literature[29]. According to that report, many factors, such as chronic viral infection or cirrhosis might play a role in the development of this malignancy.

Our study had two limitations. Firstly, a detailed comparison between 3D CE MRA and X-ray angiography was not performed, because none of our patients underwent hepatic venography and only some had inferior vena cavography. But 3D CE MRA could demonstrate various findings of BCS, which might provide clues to the correct diagnosis. Secondly, the opacification of IVC, after injection of contrast material into an arm vein, was inadequate in 2 patients with severe cirrhosis, portal hypertension and edema. We speculated this was due to the dilution of the contrast material in the porto-systemic collaterals, enlarged spleens and increased extracellular fluid. In these circumstances, the IVC could be enhanced properly by injecting contrast material into a pedal vein.

In conclusion, 3D CE MRA can display various features of BCS and provide an accurate diagnosis.

Abstract

AIM: The healthy ranges for serum alanine aminotransferase (ALT) levels are less well studied. The aim of this study was to define the upper limit of normal (ULN) for serum ALT levels, and to assess factors associated with serum ALT activity in apparently healthy blood donors.

METHODS: A total of 1 939 blood donors were included. ALT measurements were performed for all cases using the same laboratory method. Healthy ranges for ALT levels were computed from the population at the lowest risk for liver disease. Univariate and multivariate analyses were performed to evaluate associations between clinical factors and ALT levels.

RESULTS: Serum ALT activity was independently associated with body mass index (BMI) and male gender, but not associated with age. Association of ALT with BMI was more prominent in males than in females. Upper limit of normal for non-overweight women (BMI of less than 25) was 34 U/L, and for non-overweight men was 40 U/L.

CONCLUSION: Serum ALT is strongly associated with sex and BMI. The normal range of ALT should be defined for male and female separately.

INTRODUCTION

Elevation of aminotransferase level is an important and common finding in different types of parenchymal liver disease. Measurement of serum ALT is one of the most important tests for detection of patients with viral hepatitis or non-alcoholic steatohepatitis (NASH), and the exact definition of upper normal levels of serum ALT activity is an initial and critical step in different screening and follow up studies for chronic liver diseases. Current upper limits of normal for ALT level are set on average, at 40 U/L. This normal range was set in the 1950s and has changed a little since then[1]. Several studies have recently questioned whether previously established values to define normal ALT range are accurate and have suggested that the upper limit of normal should be assessed more accurately and revised accordingly[2,3].

There is no study regarding normal level of ALT in Iranian healthy adults at low risk for chronic liver diseases. This information, in addition to daily clinical practice, is specially important and necessary for different research studies of chronic liver diseases in Iran. The aim of this study was to assess the normal value of ALT in a population at low risk for subclinical chronic liver diseases in the capital city of Tehran and to investigate factors associated with abnormal ALT in this population.

MATERIALS AND METHODS

Study population

From March 2001 through April 2002, 1 959 apparently healthy blood donors at Tehran Blood Donation Center were randomly recruited into the study. The participants were part of a study for identifying the causes of elevated serum ALT level. After explanation about the objectives of the study and possible necessity for further blood test and follow up, a written informed consent was obtained, and a clinical questionnaire with emphasis on psychosocial and medical history to exclude subjects who were considered the high risk group for blood born infections was completed by a physician interviewer, and serum samples were collected from all consenting subjects. Our study was in accordance with the ethical standards for human experimentation and approved by the Ethical Committee of the Digestive Disease Research Center, Tehran University of Medical Sciences. Body weight and height of all subjects were measured and history of alcohol and drug use was taken.

Laboratory methods

Blood samples were centrifuged within 30 minutes of collection. The biochemistry and virologic tests including hepatitis B s antigen (HBsAg), and hepatitis C virus antibody (HCV Ab), and rapid plasma regain test, and HIV Ab were measured. All tests were performed at Digestive Disease Research Center, Tehran University of Medical Sciences, Tehran, Iran. Analyses of serum ALT levels were performed by using the Hitachi 704 autoanalyser, Tokyo, Japan. The upper limit of normal introduced by manufacturer was 40 U/L for both men and women. Body mass index (BMI) was calculated by dividing the weight (in kg) and the squared height (in meter). We considered a BMI of 24.9 kg/m^2 as the upper limit for healthy weight[5].

Definitions of ULN ALT value

Seven methods were used to compare their impact. Method 1: 95th percentile of ALT distribution regardless of the sex. Method 2: 95 th percentile of ALT distribution after separating males and

females. Method 3: a common threshold of 40 IU/L for both males and females proposed by the manufacturer. Method 4: 95th percentile after separating subjects with body mass index (BMI) under the median which was 27.12. Method 5: 95th percentile after separating subjects with body mass index (BMI) under 25 -a threshold proposed for separating abnormal and normal weight-[5]. Method 6: 95th percentile of ALT distribution stratified according to BMI (<25) and sex. Method 7: 95th percentile of ALT distribution in each age decade after separating males and females.

Statistical analysis

Statistical analyses were performed by using the SPSS, version 10.1, software package (SPSS, Inc., Chicago, IL). The 50th (median), and 95th percentiles for ALT level were calculated on the basis of the empirical distribution of the data. We set the upper limit for healthy ALT level to the 95 th percentile, as is commonly done for distribution of a continuous variable in the normal population. The univariate associations between factors and ALT expressed in decimal logarithm were assessed by Pearson's correlation coefficient for quantitative factors and by the Student's *t* test for qualitative factors. Multivariate analyses were used to identify factors independently associated with ALT: linear regression, and logistic regression. *P* values less than 0.05 were considered statistically significant.

RESULTS

Twenty persons were excluded because of positive HBsAg (10 persons), positive HCV Ab (9 persons), or use of alcohol more than 20 grams daily (1 person). Four persons also consumed less than 20 grams per day of alcohol who were included into the study. Thus a total of 1 939 persons (1 451 males, and 488 females) were included. The characteristics of tested individuals are given in Table 1. Except one subject who took drugs containing female sex hormones, no body had a history of regular drug usage.

Table 1 Characteristics of 1 939 Blood Donors

Factor	Mean	SE
Age (yr)	37.4	0.26
Weight (kg)	79	0.3
Height (cm)	169.96	0.19
BMI (kg/cm^2)	27.35	0.09
ALT (U/L)	19.87	0.27

						Female: 34 for BMI<25
						34 for BMI⩾25

Correlation between factors and ALT

ALT was significantly correlated with BMI, weight, and height, but was not correlated with age (Table 2).

For qualitative factors (Table 3), ALT was higher in males than in females, and ⩾25 than BMI<25 in persons with BMI. Association of ALT with BMI was more prominent in men (P<0.001) than in women (P=0.025).

Linear regression analysis showed that ALT was independently associated with male sex (Regression coefficient: 4.633, 95 % CI: 3.459-5.808, P<0.0001), and BMI (Regression coefficient: 0.362, 95 % CI: 0.237-0.487, P<0.0001), but not with height, weight, and age.

Also, logistic regression analysis showed that men were 4.57 times more likely to have elevated ALT (ALT>40) than women (95 % CI, 2.1-9.96, P=0.0001). BMI was also independently associated with elevated ALT (OR: 1.07, 95 % CI: 1.03-1.13, P=0.004). Age, height, and weight were not found to be related to elevated ALT.

Different definitions of abnormal ALT

The thresholds corresponding to the first six methods to the definition of abnormal ALT are given in Table 4. The threshold to the definition of abnormal ALT according to method 7 is demonstrated in Figure 1.

The threshold for ULN ALT varied from 34 U/L (methods 2 and 6 for females) to 46 U/L (method 6 for males with BMI>25).

The overall median ALT level for the entire study sample was 17 U/L, and the level across the 95th percentile was 40 U/L. In the 1 451 male participants, the median serum ALT level was 18 U/L, and the ALT levels across the 95 th percentile was 45 U/L. The median and 95th percentiles of ALT level in women were 14 U/L and 34 U/L, respectively. When we considered the population at the lowest risk for liver diseases (persons with negative viral markers, use of alcohol less than 20 g/d, normal BMI, and absence of concurrent medication use), the threshold for abnormal ALT was 40 U/L for men, and 34 U/L for women.

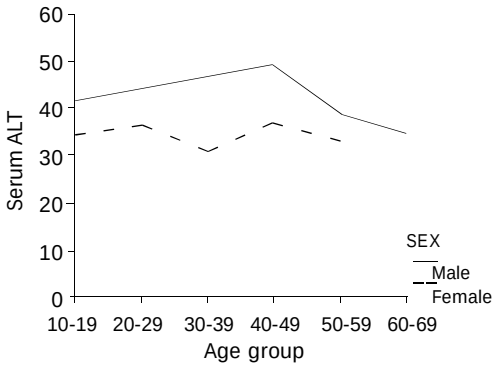

Figure 1 95th percentile of ALT distribution in each age decade after separating males and females. Note that males over age 70 (41 subjects), and females over age 60 (8 subjects) were omitted from the chart, because of a small number of them.

DISCUSSION

This study has identified the factors associated with ALT variability, and determined the thresholds for ALT according to different definitions of ULN ALT. This study further emphasized the findings of previous studies regarding the strong correlation of ALT with sex and BMI[2,3]. This has probably reflected the association between liver steatosis and obesity. The correlation between abnormal ALT and BMI was stronger in men than in women. Additionally, the 95th percentile of ALT in females with BMI <25 was equal to females with BMI ⩾25. This may be due to the fact that the waist to hip ratio (WHR) is higher in men than in women, and non-alcoholic fatty liver disease (NAFLD) is associated with central obesity and higher WHR[5]. WHR was correlated with visceral adipose tissue, which provided a greater supply of potentially hepatotoxic fatty acids to the liver[6].

Our study had some limitations. The study population were apparently healthy blood donors. They could have other unknown factors associated with ALT and they might not exactly reflect the normal general population. Second, the estimation of alcohol consumption was based only on the interview data and might be inaccurate. Third, we could not measure some paraclinical factors associated with ALT such as serum glucose, triglyceride and cholesterol[2,5].

The ULN ALT may differ from different nations and populations and may be influenced by mean BMI and alcohol usage in different societies.

The 95th percentile of ALT in overweight and obese persons may be too high to be defined as the threshold for healthy ranges of ALT. We suggest that even in overweight and obese persons healthy ranges of ALT should be defined as in non-overweight persons (40 U/L and 34 U/L in men and in women respectively). Since higher values may be due to liver steatosis which occurs more frequently in obese persons, and thus may be abnormal. Adjustment of ALT for sex but not for BMI has also been proposed previously[1]. It seems necessary to repeat this type of investigations in a population based sample and in different ethnic and nationals in order to check whether the impact of sex and BMI remain consistent and if it is proved to be so, then the laboratories should set different ranges of ALT for male and female independently.

In conclusion, this study has demonstrated a strong impact of sex and BMI on serum ALT level. Furthermore, if these findings are proved by other studies, then the normal range of ALT according to sex should be defined. This is particularly helpful in follow up and therapy of patients with chronic hepatitis and designing research protocols.

Abstract

AIM: Adrenomedullin (ADM) is a potent vasodilator peptide. ADM and nitric oxide (NO) are produced in vascular endothelial cells. Increased ADM level has been linked to hyperdynamic circulation and arterial vasodilatation in cirrhotic portal hypertension (CPH). The role of ADM in non-cirrhotic portal hypertension (NCPH) is unknown. plasma ADM levels were studied in patients with NCPH, compensated and decompensated cirrhosis in order to determine its contribution to portal hypertension (PH) in these groups.

METHODS: There were 4 groups of subjects. Group 1 consisted of 27 patients (F/M: 12/15) with NCPH due to portal and/or splenic vein thrombosis (mean age: 41±12 years), group 2 consisted of 14 patients (F/M: 6/8) with compensated (Child-Pugh A) cirrhosis (mean age: 46±4), group 3 consisted of 16 patients (F/M: 6/10) with decompensated (Child-Pugh C) cirrhosis (mean age: 47±12). Fourteen healthy subjects (F/M: 6/8) (mean age: 44±8) were used as controls in Group 4. ADM level was measured by ELISA. NO was determined as nitrite/nitrate level by chemoluminescence.

RESULTS: ADM level in Group 1 (236±61.4 pg/mL) was significantly higher than that in group 2 (108.4±28.3 pg/mL) and group 4 (84.1±31.5 pg/mL) (both $P<0.0001$) but was lower than that in Group3 (324±93.7 pg/mL) ($P=0.002$). NO level in group 1 (27±1.4 μmol/L) was significantly higher than that in group 2 (19.8±2.8 μmol/L) and group 4 (16.9±1.6 μmol/L) but was lower than that in Group 3 (39±3.6 μmol/L) (for all three $P<0.0001$). A strong correlation was observed between ADM and NO levels ($r=0.827$, $P<0.0001$).

CONCLUSION: Adrenomedullin and NO levels were high in both non-cirrhotic and cirrhotic portal hypertension and were closely correlated, Adrenomedullin and NO levels increased proportionally with the severity of cirrhosis, and were significantly higher than those in patients with NCPH. Portal hypertension plays an important role in the increase of ADM and NO. Parenchymal damage in cirrhosis may contribute to the increase in these parameters.

INTRODUCTION

Portal hypertension (PH) is a clinical condition characterized by specific hemodynamic abnormalities such as low arterial pressure, high cardiac output, over activity of vasoconstrictor systems and marked decrease in total systemic vascular resistance. Arterial vasodilatation and activation of several vasoactive and neurohumoral systems may play a key role in pathogenesis of sodium and water retention and ascites formation in cirrhosis[1,2]. These changes have been attributed to increased production of vasodilator substances[2,3]. Adrenomedullin (ADM) and nitric oxide (NO) are considered as essential mediators of hyperdynamic state. NO, a potent vasodilator substance synthesized from L-arginin by NO synthase, is increased in cirrhotic patients and experimental models of cirrhosis[3,4]. Specific NO inhibitors have been shown to counteract vasodilatation and hyperdynamic circulation in these groups[4,5]. In addition, circulating levels of potent vasodilating peptides (substance P, CGRP), pulsatile blood flow, and shear stress could contribute to the up regulation of endothelial NO-synthase (e-NOS)[3,6].

ADM is a potent endogenous vasorelaxing factor that was originally isolated from the extracts of human pheochromocytoma[7]. ADM is expressed in adrenal gland, lungs, kidneys, smooth muscle vascular endothelial cells, and splanchnic organs[3,8]. ADM level is increased after stimulation with bacterial endotoxin and cytokines[9]. The renal effects of ADM and part of its cardiovascular effects seem to be mediated by NO[10,11]. Previous studies reported that increased ADM level in cirrhotic patients occurred via increased production or decreased clearance of this substance, the elevation was more prominent in decompensated cirrhotic patients with marked PH[2,4,12,13]. Although ADM level is known to be increased in cirrhotic PH (CPH), there are no data concerning its level in non-cirrhotic PH (NCPH).

To our knowledge this is the first study determining plasma ADM concentrations in NCPH patients. We also aimed to compare the results within the group of compensated and decompensated cirrhotic patients (Child-Pugh A & C) and healthy subjects in order to estimate the contribution of cirrhosis and PH either separately or concomitantly to the elevation of ADM and NO level.

We compared ADM levels in the patients with compensated or decompensated cirrhosis and also in healthy subjects in order to determine whether portal hypertension or cirrhosis led to elevation in ADM and NO levels.

MATERIALS AND METHODS

Patients

Our study included patients with NCPH, cirrhosis and healthy subjects as control. Cirrhosis was due to hepatitis C infection in all-cirrhotic cases, while in all cases of NCPH the origin was extrahepatic portal venous thrombosis. group 1 included 27 patients (F/M: 12/15 with NCPH due to portal and/or splenic vein thrombosis (mean age: 41±12 years), Group 2 consisted of 14(F/M: 6/8) compensated (Child-Pugh A) cirrhotic patients (mean age: 46±4), group 3 included 16 (F/M: 6/10) decompensated cirrhotic (Child-Pugh C) patients (mean age: 47±12), and group 4 consisted of 14 (F/M: 6/8) healthy subjects (mean age: 44±8) taken as controls.

The diagnosis of PH and cirrhosis was established on the basis of clinical, biochemical and ultrasonographic findings and/or liver biopsy. Patients with active or recent gastrointestinal bleeding, bacterial infection, severe hepatic encephalopathy, cardiopulmonary disease and portal vein thrombosis within the previous ten days were excluded.

Study protocol

All patients and controls received restricted sodium diet (70 mmol/day) for at least 5 days before the study. Diuretics, beta-blockers and other cardioactive drugs were withheld during the 10-day period before the study. At 8.00 a.m. on the day of study, blood samples were drawn after the patients were fasted overnight and then waited for 45 min in supine position. This study was performed in accordance with the Declaration of Helsinki. A written informed consent was obtained from each patient and control subject participating in the study.

Biochemical analysis

Nitric oxide heparinized whole blood was obtained by venipuncture, centrifuged (3 000 rpm, 10 minutes, 0-40 C). Plasma concentration of NO was studied by chemoluminescence method using commercially available colorimetric assay (Roche, Cat No 1746081)[14].

Adrenomedullin

Blood samples for ADM were collected into the vacutainer tubes, which contained EDTA. Blood was transferred from the vacutainer tubes to centrifuge tubes containing aprotinin (0.6 TIU/ml of blood) and gently rocked for several times to inhibit the activity of proteinases. Blood was centrifuged at 1 600 G for 15 min at 4 ℃. Plasma ADM concentration was measured by enzyme immunoassay (Phoenix Pharmaceuticals Inc. Harbor Boulevard, Belmont, California 94002) after extraction through the Sep-pak C-18 column supplied by the manufacturer[15,16].

Plasma in both parameters was immediately frozen and stored at -80 ℃ until assayed.

Statistical analysis

All results were expressed as mean ± standard deviation. Comparisons between the groups were performed by Kruskal-Wallis variance analysis and a *P*- value <0.05 was accepted as statistically significant.

RESULTS

ADM level in Group 1 (236±61.4 pg/mL) was significantly higher than that in Group 2 (108.4±28.3 pg/mL) and Group 4 (84.1±31.5 pg/mL) (both $P<0.0001$) but was lower than that in Group 3 (324±93.7 pg/mL)($P=0.002$) (Figure 1).

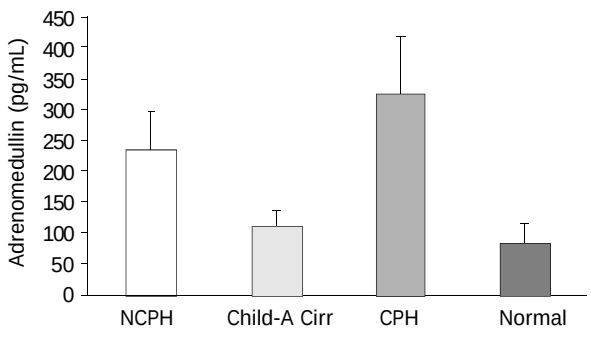

Figure 1 Adrenomedullin levels in various groups. NCPH: Non-cirrhotic portal hypertension, Cirr: Cirrhosis, CPH: Cirrhotic portal hypertension, Normal: Healthy subjects. NCPH *vs* Child-Pugh A Cirr: $P<0.0001$, NCPH *vs* Healthy Subjets: $P<0.0001$, NCPH *vs* Child-Pugh C CPH: $P=0.002$.

Nitrite/nitrate level in Group 1 (27±1.4 μmol/L) was significantly higher than that in Group 2 (19.8±2.8 μmol/L) and Group 4 (16.9±1.6 μmol/L) but was lower than that in Group 3 (39±3.6 μmol/L) ($P<0.0001$ for all three) (Figure 2). A significant correlation was observed between ADM and NO levels ($r=0.827$, $P<0.0001$) (Figure 3).

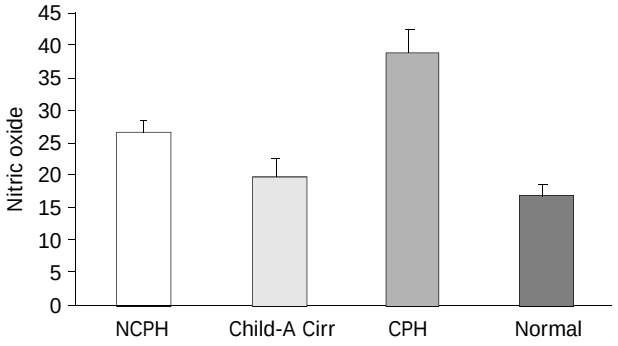

Figure 2 Nitric oxide levels in various groups. NCPH: Non-cirrhotic portal hypertension, Cirr: Cirrhosis, CPH: Cirrhotic portal hypertension, Normal: Healthy subjects. NCPH *vs* Child-Pugh A Cirr: $P<0.0001$, NCPH *vs* Healthy Subjets: $P<0.0001$, NCPH *vs* Child-Pugh CCPH: $P<0.0001$.

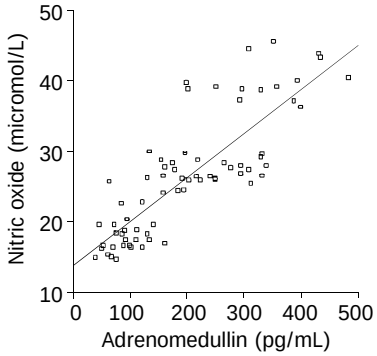

Figure 3 Correlation between nitric oxide and adrenomedullin A significant correlation was observed between two vasoactive agents ($r=0.827$, $P<0.0001$).

DISCUSSION

Our study demonstrated increased plasma ADM and NO concentrations in both CPH and NCPH patients, the level of ADM was the highest in the CPH group. Increased ADM level was strongly associated with PH and plasma volume expansion[10,11]. In our series, ADM level was not different between compensated cirrhotic patients and controls but higher in both groups of patients with CPH and NCPH, evidencing the role of PH in the increase of ADM.

Cirrhotic patients showed hemodynamic abnormalities such as arterial hypotension, increased cardiac output and reduced systemic vascular resistance. These changes have been attributed to peripheral vasodilatation. The reduction in the effective blood volume, and the subsequent activation of renin-angiotensin-aldosterone system (RAAS) and sympathetic nervous system initiated renal sodium and water retention and ultimately led to ascites formation[11]. Furthermore, excessive production of endogenous vasodilatators played an important role in peripheral vasodilatation. ADM and NO are well known mediators in the pathophysiology of PH. ADM is a potent vasodilatator and natriuretic peptide[4]. ADM concentration was positively correlated with plasma renin activity and aldosterone, which are indicators of RAAS activity[1]. ADM had an indirect effect on hyperdynamic circulation. It might play a role in the

mechanism of initiation of peripheral vasodilatation counterbalanced by the activation of RAAS and sympathetic nervous system and followed by renin and aldosterone increase. Previous studies reported that concentrations of ADM similar to those found in patients with ascites had vasodilatatory effect in the rat mesenteric circulation[2,12]. In addition, administration of ADM to anesthetized rat caused arterial hypotension, increased cardiac output and reduced systemic vascular resistance similar to the circulatory changes observed in cirrhosis[13]. All these changes may account for increased ADM level in patients with ascites and may also be seen in non-cirrhotic PH.

Cytokines were incriminated as to contribute to increased ADM levels via increased levels of TNF-α, interleukin-6 and bacterial endotoxin in advanced liver cirrhosis[18,19]. These factors are the result of parenchymal damage, which is known to stimulate the production of ADM by vascular smooth muscle and endothelial cells. However, a previous study reported that TNF-α and interleukin-6 levels showed very weak correlations with ADM levels[4]. In our study ADM level in CPH patients was significantly higher than that in NCPH patients. We conclude that cytokines are not completely responsible for the significant increase of ADM level in liver cirrhosis but they may contribute to this change.

Increased hepatic outflow resistance is the initial cause of CPH. It stimulates endothelial shear stress. Previous studies reported that ADM mRNA expression in endothelial cells was markedly increased by shear stress[20]. Thus ADM could be increased by the shear stress secondary to hyperdynamic circulation. ADM may also be produced in excess as an outcome of the volume expansion. Increased ADM level was found in cirrhotic chronic renal failure patients[2]. An increased ADM production to balance plasma volume overload might be an additional mechanism accounting for elevated ADM plasma concentration in patients with chronic renal disease.

NO is an important mediator of the hemodynamic alterations of liver cirrhosis. In our study ADM levels correlated with serum nitrite and nitrate levels. It was probably due to the fact that elevated NO levels in patients with advanced liver cirrhosis might further stimulate the production of NO and aggravate the vasodilatation in a vicious cycle[9,10].

In our study, ADM and NO levels in NCPH and advanced cirrhosis were higher than those in healthy controls and compensated cirrhotics. Likewise ADM and NO levels in CPH were higher than those in NCPH. Increased ADM level was closely correlated with NO level.

In conclusion, the results of our study suggest that portal hypertension *per se* is an independent factor for the elevation of ADM and NO in both cirrhotic and non-cirrhotic portal hypertension. Parenchymal destruction at various stages in cirrhosis may further contribute to the effects of these potent vasodilators and lead to a vicious cycle.

Abstract

AIM: *Candida* esophagitis is a frequent infection in immunocompromised patients. This study was designed to determine its characteristics in non- human immune deficiency virus (HIV) infected patients attending a teaching hospital.

METHODS: Clinical records of all patients coded by international classification of diseases 9th revision with clinical modifications' (ICD-9-CM), with *candida* esophagitis diagnosed by esophagogastroduodenoscopy (EGD) and histopathology over a period of 5 years were studied.

RESULTS: Fifty-one patients (27 males, 24 females, range 21-77 years old and mean age 52.9 years) fulfilled the criteria (0.34 % of the EGD). The common predisposing factors were carcinoma (OR 3.87, CI 1.00-14.99) and diabetes mellitus (OR 4.39, CI 1.34-14.42). The frequent clinical symptoms were retrosternal discomfort, dysphagia and epigastric abdominal pain with endoscopic appearance of scattered mucosal plaques. Another endoscopic lesion was associated with *candida* esophagitis in 15 % patients.

CONCLUSION: Carcinomas, diabetes mellitus, corticosteroid and antibiotic therapy are major risk factors for *candida* esophagitis in Pakistan. It is an easily managed complication that responds to treatment with nystatin.

INTRODUCTION

Infective esophagitis is a rare disease, affecting mostly immunocompromised patients. *Candida* esophagitis is one of the most common opportunistic infections in patients with impaired immunity and the most common cause of esophageal disease in patients with acquired immune deficiency syndrome (AIDS)[1]. It also occurs in debilitated patients who have received broad-spectrum antibiotics, steroids and immunosuppressants. With the advent of transplantation and AIDS, esophageal infection is now a common medical problem[2]. The common infections involving immunocompromised non-human immunodeficiency virus (HIV) infected patients include *candida* and viral diseases such as *cytomegalovirus* (*CMV*) and *herpes simplex virus* (*HSV*)[2]. Immunocompromised patients who develop esophageal symptoms need to undergo endoscopy to rule out *candida* esophagitis. It is well recognized that *candida* esophagitis may coexist with other esophageal disorders in these patients[3]. The occurrence of multiple simultaneous processes makes definitive endoscopic examination important[4]. Several studies have been carried out in the west for *candida* esophagitis but it has not been studied before in Pakistan. Incidence of AIDS and HIV prevalence are still very low in Pakistan[5]. The purpose of our study was to assess the risk factors associated with *candida* esophagitis in our patients who came from an area with a low incidence of AIDS.

MATERIALS AND METHODS

Patients

The study was conducted at Agha Khan University Hospital (AKUH) in Karachi, a private Academic Medical Center that offers state of the art medical facilities and is used as a referral center for patients from all over the country for expert opinion and treatment. Karachi is a southern port and the largest metropolitan city in Pakistan with a population of over 11 million. In August 2002 we carried out a retrospective analysis of medical records of all the patients who attended endoscopy unit of gastrointestinal section at the AKUH from January 1997-December 2001 and were diagnosed as *candida* esophagitis. These patients had undergone endoscopy for symptoms arising from the upper gastrointestinal tract over this period and were diagnosed on the basis of endoscopy and histopathology as *candida* esophagitis. Clinical symptoms at the time of presentation, diagnosis, drug treatment dosage and duration preceding the symptoms such as nystatin suspension or fluconazole, past history of oral candidiasis, candida esophagitis, neutrophil and lymphocyte counts from complete blood picture, random blood glucose, hepatitis B, C and HIV serology were noted. A lymphocyte count was described as low when it was less than 1.5×10^9 per liter[6]. All endoscopic examinations were performed by staff-members of our hospital's gastroenterology section, using an Olympus videoscope GIF x Q 140. *Candida* esophagitis was diagnosed when characteristic *candidal* plaques were endoscopically identified and pathological confirmation of yeast forms typical for *candida* was found in association with an active esophagitis. Case patients were labeled as group A and the control group as group B which consisted of those patients without a diagnosis of *candida* esophagitis and in whom an endoscopic examination was performed immediately before and after every case patient was examined endoscopically (2 controls per case). Therefore, *candida* esophagitis cases and controls were evaluated by the same medical team using the same diagnostic criteria.

Endoscopy

To describe the severity of *candida* esophagitis both in AIDS[7,8] and in non-AIDS populations, a grading scale was described by Kodsi *et al*[9] or a modification thereof has been

used[10]. *Candida* esophagitis was graded as the following: Grade 1 as scattered mucosal plaques involving less than 50 % of the esophageal mucosa, grade 2 as mucosal plaques involving more than 50 % esophageal mucosa, grade 3 as confluent plaque material circumferentially coating at least 50 % of the esophageal mucosa but without luminal impingement, grade 4 as circumferential plaque mat coating at least 50 % of the esophageal mucosa with luminal impingement despite air insufflations. In most cases, an ulcer could be readily distinguished endoscopically by the marked hyperemia and granularity of the ulcer base from the surrounding *candida* esophagitis.

Histopathology

At the time of endoscopy, routine biopsies were performed on all endoscopic abnormalities. At least 2 biopsies were performed on each esophageal lesion with standard biopsy forceps. All tissue specimens were submitted for routine histopathology, and stained with hematoxylin-eosin (H-E) and periodic acid-Schiff stains (PAS). In the presence of ulcer tissue, immuno-histochemical staining for *CMV* and *HSV* was performed using previously described technique to confirm infection[3]. An ulcer was considered secondary to *candida* esophagitis alone when it was found endoscopically and histopathologically. Fungal organisms compatible with *candida* were seen in the superficial epithelium, there was an absence of viral cytopathic effect histopathologically, no clinical or endoscopic evidence of gastroesophageal reflex disease or drug-induced esophagitis existed.

Statistical analysis

Results were expressed as mean ± standard deviation, median range for all continuous variables (e.g., age) and number (percentage) for categorical data (e.g., gender, diabetes mellitus, steroids, etc) were provided. Univariate analysis was performed using the independent sample *t*-test, Pearson Chi-square test and Fisher exact test when ever appropriate. A *P* value <0.05 was considered as statistically significant. All *P* values were two sided. Statistical interpretation of data was performed using the computerized software programme SPSS version 10.0.

RESULTS

Patients

During the study period, 15 000 upper endoscopies were performed in our endoscopy unit. Fifty-one patients were diagnosed with *candida* esophagitis on the basis of endoscopic and histopathologic criteria. The age, sex and percentage of inpatients are given in Table 1.

Risk factors

The common risk factors for candida esophagitis were carcinoma (OR 8.05, 95 % CI 1.91-47.1 and *P*=0.001), uncontrolled diabetes mellitus (OR 7.34, 95 % CI 2.26-27.5 and *P*=0.001), corticosteroid therapy (OR 6.67, 95 % CI 2.20-22.3 and *P*=0.001) and antibiotics (OR 4.56, 95 % CI 1.14-21.5 and *P*=0.02) (Table 2).

Clinical feature

The clinical details are given in Table 1. The clinical symptoms in group A were retrosternal discomfort in 39.2 % (20/51) patients, of these 6/20 were associated with dysphagia and 3/20 with epigastric pain. Dysphagia was present in 25.4 % (13/51) and epigastric symptoms in 35.2 % (18/51) with only 9/18 describing it as an epigastric pain (Table 1). In control group B, retrosternal discomfort was described in 30.3 % (31/102), dysphagia in 19.6 % (20/102) and epigastric symptoms in 50 % (51/102). These patients responded well to treatment with nystatin or fluconazole, 84.3 % (43/51) and 15.7 % (8/51), respectively (Table 1).

Table 1 Details of patients presenting with *candida* esophagitis and controls

	Cases *n*=51	Control *n*=102
Sex		
Male	27 (53)	58 (57)
Female	24 (47)	44 (43)
Age in years (yrs)		
Range:	21-77	19-74
Mean ±SD	52.9±14.6	50.08±12.64
No: % of In-patients	34 (64)	58 (54)
Risk factors for *candida* esophagitis		
Steroid therapy	15 (29.4 %)	6 (5.8 %)
Diabetes mellitus type 1 and 2	14 (27.4 %)	5 (4.9 %)
Carcinoma (e.g. breast, gastric, esophagus)	10 (19.6 %)	3 (2.9 %)
Broad spectrum antibiotics	8 (15.6 %)	4 (3.9 %)
Chronic liver disease	2 (3.9 %)	6 (5.8 %)
Tuberculosis	2 (3.9 %)	1 (0.9 %)
Ischemic heart disease	-	26 (25.4 %)
Peptic ulcer disease	-	26 (25.4 %)
Hypertension	-	20 (19.6 %)

Osteoporosis	-	1 (0.9 %)
Clinical symptoms		
Retrosternal discomfort	20 (39.3 %)	31 (30.3 %)
Dysphagia	13 (25.4 %)	20 (19.7 %)
Epigastric symptoms	18 (35.3 %)	51 (50 %)
Endoscopic grading		
Grade 1	9	
Grade 2	19	
Grade 3	10	
Grade 4	13	
Treatment		
Nystatin	84.3 % (43/51)	
Fluconazole	15.7 % (8/51)	

Results were expressed as number and percentage, mean ± standard deviation (SD).

Polymorphonuclear leucocyte and lymphocyte counts

All of our patients had polymorphonuclear leucocyte count within the normal range, while 33.3 % (17/51) had lymphocyte count below the normal range. These patients were mostly those who were on steroid or antibiotics therapy (Table 3).

Endoscopy finding

The endoscopic appearance of plaques varied in color from yellow to white. With increasing severity, scattered mucosal plaques coalesced circumferentially coating the mucosal surface and impinged into the esophageal lumen. In group A, 9 patients had localized disease, 5 patients had disease more prominent in the distal esophagus than in proximal esophagus, while it involved middle esophagus and middle to distal esophagus equally in 4 patients (Table 1). Esophageal ulceration was noted endoscopically and histopathologically in 3.9 % (2/51). In these patients, ulcer was believed to be secondary to *candida* esophagitis alone, as other etiologies of esophageal ulceration were excluded by testing for *CMV*, *HSV* and *HIV* by serology and immuno-histochemistry. In 15.6 % (8/51) of group ‘ A’ patients, associated endoscopic findings included 7.8 % (4/51) with antral gastritis, 1.9 % (1/51) with gastric ulcer, 5.8 % (3/51) with duodenitis. In control group B

esophageal disease was found in 35.3 % (36/102) cases, gastric disease in 38.3 % (39/102) cases, and duodenal pathology was seen in 26.4 % (27/102) cases.

Correlation of clinical symptoms and endoscopic feature

There was no correlation between clinical symptoms and endoscopic findings.

Hepatitis B, C and HIV serology

HIV serology was negative for hepatitis B, and 9.8 % (5/51) were positive for hepatitis C virus.

Histopathology

Histopathology revealed varying degrees of hyperplastic squamous mucosa with moderate-severe degree of acute-chronic inflammation in the surface epithelium. Mucosal surface was covered with desquamated epithelium and inflammatory necrotic slough. Superficial colonies of *candida* organism showed non-branching hyphae. In cases of ulcerative esophagitis, intact and focally ulcerated mucosa revealed moderate-severe inflammation, basal cell hyperplasia with non-septate fungal hyphae.

Table 2 Results of univariate analysis of potential risk factors for acquisition of *candida* esophagitis

Variable	No. of cases (%)	No. of control (%)	Odd ratio (95% CI)	*P* value
Carcinoma	10 (19.6 %)	3 (2.9 %)	8.05 (1.91-47.1)	0.001
Diabetes mellitus	14 (27.4 %)	5 (4.9 %)	7.34 (2.26-27.5)	0.001
Prior use of steroid	15 (29.4 %)	6 (5.8 %)	6.67 (2.20-22.3)	0.001
Prior use of antibiotics	8 (15.6 %)	4 (3.9%)	4.55 (1.14-21.5)	0.02

Table 3 Distribution of low lymphocyte counts in patients presenting with *candida* esophagitis

Association	Cases (*n*=17)
Steroids	6
Antibiotics	6
Malignancy	3
Diabetes mellitus	1
Chronic liver disease	1

DISCUSSION

Our study is the first attempt to evaluate the risk factors and endoscopic manifestations of *candida* esophagitis in Pakistan, an area where AIDS is not endemic. All of our patients diagnosed with *candida* esophagitis did not have oral thrush. This was similar to a study by Bonacini *et al* in which 110 HIV positive patients with esophageal symptoms, 38 % of those without oral thrush had *candida* esophagitis[11]. In this study, the patients had oral, intravenous and nebulizer steroid treatment in varying durations and doses of therapy. Steroid levels were not measured on admission. However, steroid therapy was associated with lymphopenia and 33.3 % of our patients presented with a low lymphocyte count[12]. Diabetic patients complicated with *candida* esophagitis had uncontrolled diabetes at the time of presentation, irrespective of its type. Malignancies beside other mechanisms were also associated with esophageal stasis due to mechanical obstruction that predisposes to *candida* esophagitis[13]. However, esophageal obstruction was not a feature in our cases of *candida* esophagitis associated with malignancies. A high frequency of bacterial or mycotic infections has been reported in HCV-associated membranoproliferative glomerulonephritis and diabetes mellitus due to acquired defects of polymorphonuclear leukocyte (PMN) functions[14,15]. In HIV seropositive cases, coexistent *candida* esophagitis and tuberculosis have been frequently described [16], but in non-HIV immunosuppressed patients, there were few reports of active pulmonary or intestinal tuberculosis associated with *candida* esophagitis[17].

Epigastric pain has been known to be associated with *candida* infection[18]. In our study, no correlation was found between the symptoms and the endoscopy grade score similar to another study[19]. At endoscopy, the presence of classic whitish exudates or plaques should predict candidiasis in at least 90 % of cases, although viral infection occasionally might cause a similar appearance[11]. We found that *candida* esophagitis resulted in typical endoscopic appearances and both characteristic and uniform histopathologic findings. These *candida* esophagitis patients were treated with either nystatin 5 ml QDS/fluconazole 100 mg a day by mouth for 5 days. None of these candida esophagitis patients was found to be resistant to this treatment. As treatment with fluconazole was expensive, fewer patients were prescribed this medication. Culture for identifying *candida* species was not carried out, as it would have added cost to the management of disease. The limitation of our study included a small number of patients and a retrospective design. There were few patients with risk factors in the control group B as their stable disease did not predispose them to *candida* esophagitis (Table 1).

The implications of our study are that in Pakistan *candida* esophagitis is associated with chronic diseases and those on treatment with corticosteroids and antibiotics are predisposed to it. Patients on these medications need to be monitored and reviewed frequently. *Candida* esophagitis should be considered early in patients who have been on steroids and antibiotic treatment and presented with upper gastro-intestinal symptoms. Oral candidiasis does not accompany candida esophagitis. Our study showed that *candida* esophagitis by itself was an easily managed complication. In conclusion, *candida* esophagitis in Pakistan is more common due to chronic diseases, corticosteroid and antibiotic therapy which impaires the immune system rather than as an AIDS-defining disease. It occurs in the absence of local obstructive lesions and responds to treatment with nystatin and fluconazole.

Abstract

AIM: The aim of the study was to investigate the changes of serum malondialdehyde level, i.e; the oxidative stress hypothesis in patients infected with *Ascaris lumbricoides*.

METHODS: Serum malondialdehyde activity was measured in 43 patients who were positive for intestinal parasite of *Ascaris lumbricoides*. Scores were obtained for the positives and their age-and sex-matched 60 *Ascaris lumbricoides* negative healthy controls.

RESULTS: The difference between malondialdehyde levels of patients infected with *Ascaris lumbricoides* and control group was statistically significant both for females ($P<0.05$) and for males ($P<0.05$). In the patient and control groups, no correlation was found between age and malondialdehyde levels ($P>0.05$) both in females and in males. In addition, no significant correlation could be found between malondialdehyde levels of both females and males for patients and control groups ($P>0.05$).

CONCLUSION: Malondialdehyde levels clearly increase in patients infected with *Ascaris lumbricoides*.

INTRODUCTION

Ascaris lumbricoides (A. lumbricoides) is one of the largest nematode (roundworm) parasitizing the human intestine[1-5]. It is estimated that 25 % of the world' s population was infected with this nematode[4]. The adult worms live in the small intestine and eggs are passed in the feces. A single female can produce up to 200 000 eggs each day. About two weeks after passage in the feces the eggs contain an infective larval or juvenile stage, and humans are infected when they ingest such infective eggs. The eggs hatch in the small intestine, the juvenile penetrates the small intestine and enters the circulatory system, and eventually the juvenile worm enters the lungs. In the lungs the juvenile worm leaves the circulatory system and enters the air passages of the lungs. The juvenile worm then migrates up the air passages into the pharynx where it is swallowed, and once in the small intestine the juvenile grows into an adult worm.Why *Ascaris lumbricoides* undergoes such a migration through the body to only end up where it started is unknown.Such a migration is not unique to *Ascaris lumbricoides*, as its close relatives undergo a similar migration in the bodies of their hosts[1-3,5].

Ascaris lumbricoides infections in humans can cause significant pathology.Infection with ascarids is called ascariasis. The migration of the larvae through the lungs causes the blood vessels of the lungs to hemorrhage, and there is an inflammatory response accompanied by edema. The resulting accumulation of fluids in the lungs results in "ascaris pneumonia", and this can be fatal[1,3,5,6]. The large size of the adult worms also presents problems, especially if the worms physically block the gastrointestinal tract. *Ascaris lumbricoides* is notorious for its reputation to migrate within the small intestine, and when a large worm begins to migrate there is not much that can stop it. Instances have been reported in which *Ascaris lumbricoides* has migrated into and blocked the bile or pancreatic duct or in which the worms have penetrated the small intestine resulting in acute (and fatal) peritonitis. *Ascaris lumbricoides* seems to be especially sensitive to anesthetics, and numerous cases have been documented where patients in surgical recovery rooms have had worms migrating from the small intestine, through the stomach, and out the patient' s nose or mouth[1-3,5].

Infections are diagnosed by finding the typical eggs in the patient' s feces, on occasion the larval or adult worms are found in the feces, or especially for *Ascaris lumbricoides*, in the throat, mouth, or nose[1]. This infection may self-cure after the larvae have matured into adults or may require anthelmintic treatment. In severe cases, surgical removal may be necessary. Allergic symptoms (especially but not exclusively of the asthmatic sort) are common in long-lasting infections or upon reinfection in ascariasis[1,3,7]. Eggs of *Ascaris lumbricoides*. have been detected on fresh vegetables[2,3,5]. This infection is cosmopolitan, but ascariasis is more common in North America and in Europe. Relative infection rates on other continents are not available[3,4].

Lipid peroxidation is a well-established mechanism of cellular injury in human, and is used as an indicator of oxidative stress in cells and tissues. Lipid peroxides derived from polyunsaturated fatty acids, are unstable and can decompose to form a complex series of compounds. These include reactive carbonyl compound, which is the most abundant malondialdehyde (MDA). Therefore, measurement of malondialdehyde is widely used as an indicator of lipid peroxidation. Increased levels of lipid peroxidation products have been associated with a variety of chronic diseases in both humans and model systems[8-10]. The aim of this study was to test the hypothesis of decreased activity of defense system protecting tissues from free radical damage in patients with *A. lumbricoides* by measuring the level of MDA (an end-product of lipid peroxidation) in serum samples.

MATERIALS AND METHODS

Patients

We assayed MDA activities of 103 subjects aged between 12-44 years (48 males and 55 females). None of them was smoker,

and had any known pathologies and taking steroids or medications such as iron for anemia at the time of sampling. Serum samples for control group were obtained from healthy people who came to the different departments of Medical Faculty Erciyes University, for regular check-up and students or employees of the University. All subjects weer fasted after midnight before blood collection the next morning. 43 patients and 60 controls were examined in this study. The mean age of the patient group, which consisted of 21 men and 22 women were 25±13 years and 27±13 years, respectively. The mean age of the control group, which included 27 men and 33 women were 30±14 years and 29±12 years respectively. Wet mount preparations in 0.9 % NaCl, diluted Lugol's iodine and flotation technique in saturated saline solution were used for the detection of intestinal parasites.

Assay

All venous blood samples taken between 8 and 9 a.m. after 8 h of fasting were collected in polystyrene tubes and vacutainers containing heparin. The tubes were centrifuged at 500×g for 15 min. Sera were then removed and stored at -20 ℃ until analysis. Serum MDA levels were measured by the double heating method[11,12]. The principle of the method was based on the spectrophotometric measurement of the color occurred during the reaction to thiobarbituric acid with MDA. Concentration of thiobarbituric acid reactive substances (TBARS) was calculated by the absorbance coefficient of malondialdehyde-thiobarbituric acid complex and expressed in nmol/ml.

Statistical analysis

Statistical analysis was performed with SPSS software package (Version 11.0 for Windows). The data were expressed as mean ± standard deviation (SD). For comparison of two groups of continuous variables, independent sample *t*-test was used. A probability value of $P<0.05$ indicated a statistically significant difference.

RESULTS

Malondialdehyde scores are given in Table 1.

Table 1 MDA levels of patients infected with *A. lumbricoides* and control group

Patients	Age(year)	MDA levels (nmol/ml)
Female (22)	27±13	0.67±0.16
Male (21)	25±13	0.62±0.11
Controls	Age(year)	MDA levels (nmol/ml)
Female (33)	29±12	0.21±0.15
Male (27)	30±14	0.22±0.14

The difference between MDA levels of patients and control group was statistically significant both for females ($P<0.05$) and males ($P<0.05$), (Table 1). In the patient and control groups, no correlation was found between age and MDA levels ($P>0.05$) both in females and in males. In addition, no significant correlation could be found between MDA levels of both females and males for patients and control group ($P>0.05$).

DISCUSSION

This present study was aimed to evaluate and characterize the relationship between intestinal parasite infection of *ascariasis*, which can cause pathology and oxidative stress mechanism as a mediator of tissue damage concurrent with ascariasis infection.

Ascariasis is the most common human worm infection. Human can become infected after touching mouth with hands contaminated with eggs from soil or other contaminated surfaces. Infection has occurred worldwide and has been most common in tropical and subtropical areas where sanitation and hygiene were poor[1-3,5]. Children are infected more often than adults. Estimates suggest that 1 in 4 of the world's population, or more than 1 billion people, are infected with the intestinal roundworm *A. lumbricoides*. In Europe, infection was common, but the most common in rural areas of the southeast[3-5].

Although *Ascaris lumbricoides* has only a single host and it is found in the small intestine, its life cycle is far from simple. It has been suggested that from an evolutionary perspective that *Ascaris lumbricoides* originally had two hosts and has secondarily lost its intermediate host[1-3,5-7]. Although most people have no symptoms, symptoms can be broken down into 2 categories: early (larval migration, 4-16 days after egg ingestion) fever, cough and wheezing and late (mechanical effects, 6-8 weeks after ingestion). All symptoms resulted from mechanical irritation include; vague abdominal complaints (i.e, cramping, nausea, vomiting), small bowel obstruction (mostly in children), pancreatitis (secondary to worm migration), cholecystitis (secondary to worm migration), appendicitis (less common, secondary to worm migration). Secondary complications could arise with *Ascaris lumbricoides* infections because sometimes when the worms were undergoing this migration they appeared to get lost and started wandering through other organs such as the brain, bile duct, pancreas or appendix[1-3,5,7].

Ascaris lumbricoides proteins are very immunogenic and people can become very sensitive to the worm and have strong allergic reactions. The parasite could be treated very easily with drugs such as mebendazole or pyrantel pamoate[1,3,5,13,14]. However, reinfections frequently occur if other control measures are not taken. This is a particular problem where night soil is used as a fertilizer.

Oxidative stress as a mediator of tissue damage concurrent with *A. lumbricoides* infection was investigated. This was the first study to characterize the relationship between *A. lumbricoides*, (may cause no symptoms however, some complains of cramping, nausea, vomiting, small bowel obstruction, pancreatitis, cholecystitis, appendicitis can be seen) and MDA (lipid peroxidation), which is a well-established mechanism of cellular injury in human, and is used as an indicator of oxidative stress in cells and tissues.

Levels of MDA were significantly increased in patients infected with *A. lumbricoides*. The results of our study strongly suggested that one of the main reasons for high MDA levels in patients infected with *A.lumbricoides* could be decreased activity of defense system protecting tissues from free radical damage. However, in the patients and control groups, no correlation was found between age and MDA levels both in females and in males. In addition, no significant correlation could be found between MDA levels of both females and males for *A. lumbricoides* infected and control groups. These results for patients infected with *A. lumbricoides* could possibly be explained as that with high MDA activity in all ages.

As it is known that lipid peroxidation is a free radical-related process that in biologic systems may occur under enzymatic control, e.g., for the generation of lipid-derived inflammatory mediators, or nonenzymatically. This latter form was associated mostly with cellular damage as a result of oxidative stress, which also involved cellular antioxidants in this process[10]. The high infection/control ratio of MDA concentration and the significant correlation strongly indicate the occurrence of oxidative stress and lipid peroxidation as a mechanism of tissue damage in cases of *A.lumbricoides* infection.

Abstract

AIM: To explore the problems in the screening of colorectal carcinoma in the elderly.

METHODS: Three models of colorectal cancer prevention were examined: standard screening, active check-up of suspected cases and summons to have endoscopic check-up for previously diagnosed colorectal polyps. The study was performed among three groups of elderly individuals: Group 1 (167 cases), hospitalized asymptomatic individuals without symptoms in large intestines. Group 2 (612 cases): old individuals at home for the aged, out of which 32 showed symptoms of colon disorders; Group 3 (44 cases): elderly people with diagnosed polyps. As a result of 1788 rectosigmoidoscopies, we identified 61 individuals with polyps, out of which 44 patients were over 65 years old. However, only 9 of these 44 individuals agreed to have the endoscopy performed again.

RESULTS: One cancer and 13 polyps were detected in Group 1, and two polyps in Group 2. However, it should be noted that only eleven individuals from Group 2 agreed to have the endoscopy. In Group 3, there were no relapses of the polyps among the nine individuals who came back for the endoscopy.

CONCLUSION: Poor understanding of the screening procedures is one of the greatest problems in early detection of the cancer in the aged. Paradoxically, the cooperation is better with hospitalized patients, than with "successfully old" persons.

INTRODUCTION

Incidence of colorectal cancer in the world has increased over the past few decades, which is in turn, the cause for the increased importance of the screening for colorectal *carcinoma* (CRC). The incidence of colorectal cancer increases with age and doubles every ten years after the age of 40. In USA, the incidence of CRC is 35/100 000 population, thus one from 20 people will suffer from CRC during their life. High incidence of CRC has been recorded in Western European countries, which stands opposed to the numbers from the Far-East countries and Africa where the incidence is low, i.e. Nigeria has the incidence of 3.4/100 000. The average colorectal cancer age-adjusted death rates in Serbia from 1971 to1996 were 11.2/100 000 for men, and 8.3/100 000 for women[1].

Colorectal cancer screening includes fecal occult blood tests (FOBT), sigmoidoscopy, air-contrast *barium enema* examination and colonoscopy. These methods are recommended for persons in moderate risk, but its merits and limitations are still under investigation. Persons at high risk, i.e. family history of hereditary non-polyposis CRC, patients with ulcerous colitis, should be screened by colonoscopy. Screening method can surely have a positive effect on the survival rate of CRC. Since survival rate of CRC correlates to the anatomical spread of tumor, as well as to the surgical treatment at the right time, rectosigmoidoscopy can prevent and disclose the earliest stages of distal colon *carcinoma*.

Colonoscopy is certainly the "gold standard" for colorectal examination, but it is not most commonly accepted due to costs, bowel preparation, sedation and perforation risks (1/2 000 examinations). It is the most efficient method for detecting adenomas and probably has greater significance in the detection of the advanced tumor than other screening methods.

In carrying out our project on screening rectosigmoidoscopy, we found two kinds of problems. Like in all screening projects, one was the motivation of the participants (both the researchers and especially the subjects). The other problem was related to, what was in the developed countries called the cost/benefit issue, and in the under-developed countries was simply the issue of cost, which was extra high.

In the recent "American Cancer Society Guidelines for the Early Detection of Cancer"[2], the prevalence of screening procedure in American adult population was 19.0 % for FOBT, and 32.3 % for colonoscopy or sigmoidoscopy. Chinese author Wan J[3] claimed that multimorbidity was noted in 87 % of the investigated elder cases and the incidence of complication was only 0.05 %.

MATERIALS AND METHODS

Patients

The study was performed among three groups of elderly (from 65 to 80 yr, mean age 74.37) individuals: Group 1 had 167 hospitalized asymptomatic individuals without any symptoms in the large intestine, Group 2 consisted of 612 old individuals at home for the aged, out of which 32 had symptoms of colon disorders and Group 3 consisted of 44 individuals with polyps. Group 3 resulted from 1788 rectosigmoidoscopies, among which 61 individuals with polyps were found. 44 of these individuals were over the age of 65, and only 9 agreed to come back for a check-up of endoscopy.

Endoscopy

In our study, screening rectosigmoidoscopy was used with the purpose of assessing the importance of the rectoscopic examination for the early diagnosis and prevention of colorectal cancer. Rectosigmoidoscopy was performed with OLYMPUS endoscope after colon cleaning which was usually with SENNA.

Grouping

We selected three groups of elderly persons. The first one was the group of asymptomatic individuals (regarding digestive

tract) hospitalized at our institute. The answer to the screening was optimal, however it was difficult to obtain such results in the majority of the old population. The second trial was more selective. We included in our endoscopy proposition only the persons with digestive disorders. This selection was based on and followed the assessment procedure in home for the aged. There was a very low percentage of agreement to the endoscopy. Finally, Group 3 was reselected from the elderly persons with previously diagnosed colon polyps, and invited for a control endoscopy. Only 25 % of the group was available for the control rectosigmoidoscopy.

RESULTS

Three models of colorectal cancer prevention were examined: standard screening, active check-up of suspected cases and summons to endoscopic check-up for previously diagnosed colorectal polyps.

Group 1 consisted of hospitalized asymptomatic persons (without symptoms in large intestines).

The second trial (Group 2)was more selective. We included only the persons with digestive disorders in our endoscopy proposition, after the assessment procedure in home for the aged.

Group 3 consisted of the patients who already had polyps of the *rectum* removed and had never reported for endoscopic follow up although advised to do so. All the subjects were summoned by phone and letter.

Table 1 Data of three groups

Number of investigated cases	Selection criteria	Results
167	Hospitalized asymptomatic	1 cancer and 13 polyps
612 (32 with symptoms of colon disorders), 11 agreed to have the endoscopy	Home for the aged	2 polyps
1788 rectosigmoidoscopies (61 polyps) 44 older than 65 y 9 agreed on the endoscopy	With previous diagnosis of colon polyp	0 relapses of polyps

DISCUSSION

As colorectal tumor represents a considerable medical problem in the elderly, early detection of adenomatous polyps, as the precursors of intestinal *carcinomas*, is increasingly important and relevant to geriatricians.

The incidence of colorectal cancer increases with age, and approximately half of patients who develop it die from it. The possibility of developing cancer during the lifetime is approximately 5-6 %. Those that belong to the risk groups are more in a position to get this disease. In all cases, however, early diagnosis is decisive.

Sigmoidoscopy studies showed that regarding the possibility of CRC development, people older than 65 years were equaled in the incidence with patients having an *adenoma* of distal colon for more than 90 % CRC cases were diagnosed after the age of 55 and the peak of incidence of sigmoidoscopically discovered *adenomas* was before 70 years old.

The reason for lack of improvement in survival is that in most cases of CRC the disease has already been at an advanced stage by the time of diagnosis. Therefore, the main goal of screening is to discover CRC at the early stage when successful radical treatment is possible. Screening is an examination in asymptomatic individuals for CRC.

The American Cancer Society' s (ACS) Colorectal Cancer Advisory Group recommends FOBT once a year for people older than 50, rectosigmoidoscopy every 5 years, *barium enema* every 5 years and colonoscopy every 10 year[4].

According to WHO, screening tests must be sensitive, specific, applicable in the asymptomatic population and it must aim at lowering morbidity and mortality rate. Although rectosigmoidoscopy has certain disadvantages (such as being invasive, unpleasant and expensive compared to FOBT), it is more reliable than other screening tests in that it is highly sensitive (no false negative results even for lesions less than 5 mm in diameter) and the lesion can be removed during the screening examination.

In almost all patients with CRC, preceding lesions were asymptomatic *adenoma*. Therefore, it is of great importance to locate and remove *adenoma* before the development of *dysplasia* and the following malignant alterations, which, at the same time, represents secondary prevention of colorectal cancer. This is also obvious in British National Polyp Study from 1993, which showed 90 % decline of CC incidence in a group of 1500 patients who underwent polypectomy and were followed up for 6-8 years[5].

There are different problems regarding colorectal screening in old age: (1) The problem of performing screening or not seems that consensus was reached that different panel group and association have agreed that the answer was YES[7-15,17]; (2) Recently there were more references that supported colonoscopy as a choice[11,12,16,17]; (3) Are there any age limits for the colorectal screening procedure? There were two opposed opinions: No limits, or regarding biological age, and individual limit as consequence of the personal expected survival, on average, 75 to 80 y[19]; (4) What about national programs, accepted by the national authority supported by health funds? There were no such data[11]; (5) Regarding cost/ benefits ratio, it is rational to invest in screening procedure. Developing countries are between high standards and low economies. With minute financial support, the choice is to modify screening method, to reduce the number of investigated persons, or to quit the program of prevention; (6) It seemed very important to have influence on public opinions regarding screening procedure[15,16 ,19].

The authors do not have any doubts about the justification of the screening procedure, so an attempt should be made to find a solution for active prevention. However, in developing countries which have fewer technological and financial options, better choice, and the only choice for prevention must be a less costly one. The relation of cost and benefit is principally dependent on the economic possibilities of a country' s health service, within which the priorities of a health system play an especially meaningful role.

Further, the selection of hospitalized patients with other diagnosis is not statistically proper for screening of rectosigmoidoscopy. Hypothetically, optimal way to find patients for screening is to start from the homes for the aged or with the patients with colon symptoms that are treated at their homes. This is the best way to find patients when it is not possible to perform massive screening. Periodical checkup of the patients with polyipectomy is necessary.

Judging by the commentary[6], the idea on a prior questionnaire in active search for persons with high risk of contracting (developing) colon malignome is not recommended. In the same article, the recommendation of USA on compulsory screening of persons over 50 is adjusted to the needs of UK service. If the choice is either screening an insignificantly small population or absolute impossibility of screening or just screening of the high-risk group, including those actively detected after the questionnaire, it is highly probable that the latter solution is the one that should be chosen.

Results of our investigation showed that the main problem in the prevention of cancer was the extent of acceptance of

this method by the elderly patients. Screening methods for hospitalized patients (Group 1) were necessary, since they were already motivated for medical treatment. However, the screening method had the lowest acceptance among the old persons from the homes for the aged. A very small number of patients were going for endoscopic checkups. Those patients usually conducted controls on repeated doctor' s invitations.

Abstract

AIM: To evaluate the main factors associated with mortality in patients undergoing surgery for perforated peptic ulcer referred to an academic department of general surgery in a large southern Italian city.

METHODS: One hundred and forty-nine consecutive patients (M:F ratio=110:39, mean age 52 yrs, range 16-95) with peptic ulcer disease were investigated for clinical history (including age, sex, previous history of peptic ulcer, associated diseases, delayed abdominal surgery, ulcer site, operation type, shock on admission, postoperative general complications, and intra-abdominal and/or wound infections), serum analyses and radiological findings.

RESULTS: The overall mortality rate was 4.0 %. Among all factors, an age above 65 years, one or more associated diseases, delayed abdominal surgery, shock on admission, postoperative abdominal complications and/or wound infections, were significantly associated (χ^2) with increased mortality in patients undergoing surgery ($0.0001<P<0.03$).

CONCLUSION: Factors such as concomitant diseases, shock on admission, delayed surgery, and postoperative abdominal and wound infections are significantly associated with fatal outcomes and need careful evaluation within the general workup of patients admitted for perforated peptic ulcer.

INTRODUCTION

There has been a marked decrease in elective surgery for peptic ulcer disease (PUD) following introduction of medical therapies including H_2-receptor antagonists, and more recently proton pump inhibitors with or without antibiotics for *H pylori* eradication. By contrast, the number of acute complications *e.g.* ulcer perforation and bleeding requiring emergency surgery, have remained quantitatively constant[1,2]. Peptic ulcer perforation is a serious complication which affects almost 10 % of PUD patients. Overall, PUD accounts for more than 70 % of mortality associated with the disease[3,4]. Several potential predicting factors for perforation have been evaluated in the literature, including use of ulcerogenic drugs (*e.g.* steroids, NSAIDs, immunosuppressive agents, *etc*.), and the development of an acute, rather than chronic peptic ulcer[5-8].

In this paper, we studied the main factors associated with mortality in a large number of patients undergoing surgery for perforated peptic ulcers (PPU) in a large referral academic hospital in southern Italy.

MATERIALS AND METHODS

Patients

The study population comprised 149 consecutive patients with an established intra-operative final diagnosis of PUD referred for emergency surgery to the 1st Department of General Surgery of the University of Bari. Bari is the main city of a province of about 1 500 000 inhabitants in the south-eastern coast of Italy. During a time spanning from 1988 to 1997 all patients were treated exclusively by open surgical approach, as agreed by all staff members. Since then, additional patients have been treated also by laparoscopy for PPU, but due to the scant number of cases, they were not included in the present analysis. Overall, there were 39 females and 110 males (mean age 52 years, range 16-95). The diagnosis of gastrointestinal ulcers was based on clinical features, blood tests, routine laboratory tests, and radiological findings (*i.e.* plain abdominal X-ray in all cases and abdominal CT scan in 87 % of patients). Invariably, the definitive diagnosis of PPU was obtained at surgery. The time between presumed perforation and surgery was considered delayed if longer than 12 h. The following factors were analysed: age >65 years, sex, previous ulcer history, associated medical diseases, delayed operation, site of ulcer, type of operation, shock on admission, postoperative general complications, postoperative intra-abdominal and/or wound infections.

Surgical procedure

An open surgical approach was performed leading to a non definitive operation (*i.e.* ulcer excision and suture with or without pyloroplasty) in 120 patients (80.5 %) and to definitive operations (*i.e.* Billroth II resection) in 29 patients (19.5 %). The decision to perform one or the other type of surgery depended on several known factors including location and extent of lesions, feasibility of a safe non-definitive surgery, presence or absence of anaesthesiological risk factors, and surgeon' s attitude. No truncal or selective vagotomies were performed. All operations were performed by the same surgical staff whose colleagues were well trained in gastrointestinal surgery.

Statistical analysis

All calculations were performed with the *NCSS 2001* statistical software (Kaysville, UT, USA). The chi-square test was used to compare proportions. A two-tailed probability (*P*) value of less than 0.05 was considered statistically significant[9,10].

RESULTS

The time between perforation and surgery was delayed in 51 patients (34.2 %), 79 patients (53.0 %) had associated diseases which are listed in Table 1. Cardiovascular, chronic obstructive pulmonary diseases and diabetes mellitus were the most frequently (over 65 %) associated conditions. A previous history of PUD was found in 53 (35.6 %) patients and 9 (6.0 %) were shocked on admission. Gastric and duodenal ulcers were perforated in 23 (15.4 %) and 126 (84.6 %) patients, respectively.

Table 1 Associated diseases in study group

Cardiovascular disease	27
Diabetes mellitus	20
Chronic obstructive pulmonary disease	19
Impaired liver function	8
Renal failure	7
Coagulation disorders	6
Cerebrovascular disease	4
Neurological disease (others)	3
Malignancy	2
Thyroid disease	1
Gallstones	1
Acute pancreatitis	1
Total	99

Types of postoperative complications are reported in Table 2. The most frequent events were due to general, rather than abdominal complications or wound infections.

Table 2 Postoperative complications

General	
Cardiac	7
Respiratory	7
Sepsis	7
Renal	5
Mental disorders	2
Ictus	1
Deep venous thrombosis	1
Total	30
Abdominal	
Abscess	6
Bleeding	2
Stenosis	2
Total	10
Wound infections	8
Total	48

The analysis of factors associated with mortality is depicted in Table 3. Of the 149 patients, 6 died yielding an overall mortality rate of 4.0 %. The presence of one or more associated diseases, delay in surgical approach, shock on admission, postoperative abdominal complications (6 dehiscence/abscess, 2 bleedings, 2 stenosis) and the postoperative wound infections were all significantly ($0.0001<P<0.04$) associated with increased mortality in patients undergoing surgery for PPU. By contrast, age, sex, previous history and site of peptic ulcer, type of surgical treatment and the development of postoperative general complications were not associated with increased mortality.

Table 3 Analysis of factors associated with mortality in 149 patients undergoing surgery for perforated peptic ulcer

	n	Mortality (%)	*P* value
Male:Female	110:39	3.6 *vs.* 5.1	NS
Age (<65: >65 years)	63:86	1.6 *vs.* 5.8	NS
Previous ulcer history (yes:no)	53:96	5.7 *vs.* 3.1	NS
Associated disease (yes:no)	79:70	7.6 *vs.* 0.0	0.02
Delayed operations (yes:no)	41:108	9.8 *vs.* 1.9	0.04
Site (duodenal:gastric)	126:23	3.1 *vs.* 8.7	NS
Operation type (non definitive:definitive)	120:29	2.5 *vs.* 10.3	NS
Shock on admission (yes : no)*	9:140	55.6 *vs.* 0.7	0.0001
Postop. general complications (yes:no)	30:119	6.7 *vs.* 3.4	NS
Postop. abdominal complications (yes:no)*	10:139	50.0 *vs.* 0.7	0.0001
Postoperative wound infections (yes:no)*	8:141	37.5 *vs.* 2.1	0.0001

Data analyzed by χ^2 test and *Fisher's exact test.

DISCUSSION

Several factors might contribute to increased postoperative mortality in patients with PPU. Perforation has been found to be a major complication of PUD with a mortality rate ranging from 6 % to 31 %[6-8, 11-20].

Age of patients with PPU has been gradually increasing over the last years[21-23]. In this series, an age >65 years tended to be associated with increased mortality. This finding is in line with other studies in which older patients frequently had associated diseases, or they were more on NSAIDs treatment[8,16,22]. It should be also noted that the mean age of patients from this series was considerably lower than that from patients included in different studies. Thus, such differences might account for the markedly lower overall mortality rate (4.0 %), as compared to other series[6-8, 11-20].

In accord with others[19, 23], we could not find that male sex was associated with a greater mortality rate. Also, there was no significant difference in mortality rate between gastric or duodenal ulcer and in patients with or without previous ulcer history. Apparently, these findings were at variance with those from two other studies[13, 24] reporting a higher mortality rate in gastric peptic ulcer than in duodenal peptic ulcer and in acute peptic ulcer than in chronic peptic ulcer. Such apparent discrepancies might be explained by the characteristics of patients included in the study, and/or by different age or different surgical procedures[16,18].

This study confirmed the previous observations[5,8,15,25-28] that shock on admission and delayed operation were both associated with a greater mortality rate.

Despite the fact that surgery remains the choice of treatment for PPU, the type of procedure in emergency is still debated. In some series definitive surgery had lower rates of recurrence and mortality than non definitive surgery[16,18,19,29,30]. Otherwise, non-definitive surgery was more frequently performed in patients admitted with more risk factors than definitive surgery, and this might explain the higher mortality rate of such studies. Moreover, diffusion of the laparoscopic approach to PPU with less surgical trauma and less metabolic and physiological disturbances, has determined an increase of non definitive surgical procedures performed by simple closures[3,20,22,31]. In the present study, there was no difference in mortality rate between definitive (*i.e.* Billroth II resection) or non-definitive (*i.e.* ulcer excision and suture with or without pyloroplasty)

surgical procedure.

It has been reported that mortality rate increased progressively with increasing numbers of risk factors[6,8]. Indeed, the mortality rate was 0 % and 7.6 % in the group of patients without and with associated diseases, respectively. In the present study cardiovascular, chronic obstructive pulmonary diseases and diabetes mellitus were the most frequent concomitant diseases. Besides, 6 patients developing a postoperative abscess had a previous history of chronic obstructive pulmonary disease. A possible explanation for such an outcome could be the reduced tissue oxygenation resulting in damage of post-surgical wound healing process. This possibility was supported by recent studies from our group at the intestinal level in both experimental and clinical conditions[32-36].

We also observed that in patients developing postoperative abdominal complications (*i.e.* 6 abscesses, 2 bleedings, and 2 stenosis) and wound infections, the mortality rate was significantly higher (P=0.0001) than those without abdominal complications. We would like to explain that such a striking difference was due to the development of a generalized sepsis in the group of patients with intra-abdominal abscess. Indeed, 83.3 % (*i.e.* 5/6) of patients with dehiscence and abdominal abscess, died in the postoperative period, otherwise, in this group with postoperative complications, the appearance of stenosis or bleeding was not associated with a higher mortality rate. In our experience the presence of wound infection appeared to be a predictive factor for mortality. A careful analysis of the 3 patients who died of wound infection, however, revealed that the cause of exitus was septicaemia complicating an abdominal abscess. By contrast, postoperative general complications did not influence the prognosis of patients with PPU.

In conclusion, concomitant diseases, shock on admission, delayed surgery, and postoperative abdominal and wound infections are factors significantly associated with fatal outcomes in patients undergoing emergency surgery for perforated peptic ulcer. Older age tends to fulfill a similar trend. Thus, such factors need to be carefully taken into account during the general workup of patients admitted for PPU.

Abstract

AIM: To study the antitumour activity of resveratrol and its effect on the expression of cell cycle proteins including cyclin D1, cyclin B1 and p34cdc2 in transplanted liver cancer of murine.

METHODS: Murine transplanted hepatoma H22 model was used to evaluate the *in vivo* antitumor activity of resveratrol. Following abdominal administration of resveratrol, the change in tumour size was recorded and the protein expression of cyclin D1, cyclin B1 and p34cdc2 in the tumor and adjacent noncancerous liver tissues were measured by immunohistochemistry.

RESULTS: Following treatment of H22 tumour bearing mice with resveratrol at 10 or 15 mg/kg bodyweight for 10 days, the growth of murine transplantable liver cancer was inhibited by 36.3 % or 49.3 %, respectively. The inhibitory effect was significant compared to that in control group ($P<0.05$). The level of expression of cyclin B1 and p34cdc2 protein was decreased in the transplantable murine hepatoma 22 treated with resveratrol whereas the expression of cyclin D1 protein did not change.

CONCLUSION: Resveratrol exhibits anti-tumour activities on murine hepatoma H22. The underlying anti-tumour mechanism of resveratrol might involve the inhibition of the cell cycle progression by decreasing the expression of cyclinB1 and p34cdc2 protein.

INTRODUCTION

Resveratrol (3,4,5-trihydroxy-trans-stilbene) is a kind of phytoalexin found in root extract of the weed polygonum cuaspidatum and in grape skins as well as red wine. Studies have demonstrated that resveratrol can alter the synthesis and secretion of lipids and lipoproteins by liver cells, block human platelet aggregation and inhibit the synthesis of pro-aggregatory and proinflammtory eicosanoids by platelets and neutrophils[1-5]. Moreover, some reports have shown that resveratrol is a potential chemopreventive agent of cancer and it can prevent tumor growth and metastasis in human lung carcinoma, pancreatic cancer, prostate cancer, bronchial epithelioma cancer and breast cancer models[6-10]. The present investigation evaluated the potency of resveratrol on tumour cell growth and proliferation and on expression of cell cycle proteins in a transplantable murine hepatoma 22 model.

MATERIALS AND METHODS

Materials

Resveratrol was purchased from Sigma Co (USA). The resveratrol was dissolved and sterilized in dimethyl sulfoxide (DMSO) first and then diluted to the required working concentration in RPMI-1640 (Gibco, USA) containing 10 % calf serum (SiJiQing Co, Hangzhou, China). MS-110cdk1/p34cdc2 Ab-1 0.1 ml, MS-210 cyclin D1/bcl-1 Ab-1 0.1 ml, MS-338 cyclin B1 Ab-1 0.1 ml were purchased from Santa Cruz Co (USA). S-P ultra sensitive immunostaining kit was purchased from Maixin Biotechnology Developing Co (Fuzhou, China). Mouse hepatocellular carcinoma cell line H22 was kindly supplied by Cheng Wei (Center of Molecular Biology, First Affiliated Hospital, Xi' an Jiaotong University). Balb/c mice were purchased from the Animal Center of Xi' an Jiaotong University.

Methods

Suppressive effect of resveratrol on transplanted liver cancer of mouse H22 cells were first subcultured in RPMI 1640 containing 10 % fetal bovine serum. Then the cells were washed twice and resuspended in RPMI 1640 culture medium (1×10^8/ml). About 0.2 ml cell solution (including 2×10^7 cells) was taken and injected into the right groin of 5 Balb/c mice. After 14 days, when tumors of 3-5 mm in diameter formed in the right groin of these mice, they were taken out and sheared into small pieces of 1 mm^3 under sterile condition. Forty Balb/c mice were anesthetized by using coelio-injection of pentobarbitone (70 mg/Kg) and laparotomy was performed. Under sterile condition their middle lobes of liver were punctured to form a 3 mm-long sinus tract and a small piece of tumor tissue was put into each sinus tract. Then these mice were divided into 4 groups randomly: one control group and 3 experimental groups. The experimental groups were designed to be injected with resveratrol (dissolved in DMSO and diluted to the working concentration of 25 mM in RPMI-1640 containing 10 % calf serum) at 5, 10 or 15 mg/kg body weight while the control group was designed to be given the same volume of the solution as for experimental group but absent of resveratrol. Twenty-four hours following liver tumour transplantation, each mouse was injected corresponding dosage of resveratrol into its abdominal cavity once a day for 10 days. These mice were then sacrificed on the following day after the last injection. After the maximum diameter and transverse length of tumour were measured, the hepatocellular carcinoma tissues and adjacent noncancerous liver tissues were sampled and fixed in 10 % formalin.

Measurement of tumour volume The tumour volume was

calculated using formula V=1/2 (maximum diameter x transverse length^2). The suppressive rate of tumour growth was calculated as [(mean V of tumour in control group - mean V of tumour in experimental group)/mean V of tumour in control group]×100 %.

Determination of protein expression of cyclin D1, cyclin B1 and p34cdc2 in murine transplantable liver cancer tissue

The tumour tissues and adjacent noncancerous liver tissues taken from therapeutic group (resveratrol in 10 mg/kg) and control group were 10 % formalin-fixed, paraffin-embedded and cut into 4 μm thick sections for staining. PBS of 0.01 mol· L^{-1} was used to substitute for primary antibody for negative control while a breast cancerous tissue expressing cyclin D1 and a tonsil tissue expressing cyclin B1 and cdk1/p34cdc2 were used for positive controls. The working concentration of each antibody was cyclin B1 (1:100), cyclin D1 (1:40) and cdk1/p34cdc2 (1:70), respectively. The staining procedures used were as described in S-P immunostaining kit. The sections were examined twice on different days by the same pathologist and the distribution of positively stained cells for each protein was evaluated semi-quantitatively by calculating the percentage of positive cells in nonoverlaping microscopic fields. The protein expression was then scored arbitrarily as "-" <5 % positive cells, "+" 5-50 % positive cells, "++" >50 % positive cells. χ^2 test was used to evaluate the statistical significance of the difference between experimental and control groups.

RESULTS

Suppressive effect of resveratrol on murine transplantable liver cancer

Except 2 Balb/c mice (one in control group and one in 15 mg/kg resveratrol therapeutic group), all the mice inoculated with hepatocarcinoma cell line H22 were successively transplanted with liver cancer. After treatment of the tumour bearing mice with 5, 10 or 15 mg/kg resveratrol for 10 days, the tumour size was reduced from 134 mm^3±40 mm^3 in control group to 105 mm^3±14mm^3, 85 mm^3±22mm^3 and 68 mm^3±17mm^3 in experimental groups, resulting in an inhibition rate of tumour growth of 21.6 %, 36.3 % and 49.3 %, respectively. The inhibition effect in the latter 2 therapeutic groups was significant compared with that in control group (all P<0.05) (Table 1).

Table 1 The suppressing effect of resveratrol on murine transplanted liver tissue

	Dose (mg/kg)	No. of mice (begin/end)	Tumour size (mm^3, $\bar{x}$±s)	GIR (%)
Control group	0	10/9	134±40	
Resveratrol	5.0	10/10	105±14[a]	21.6
	10.0	10/10	85±22[b]	36.3
	15.0	10/9	68±17[b]	49.3

Effect of resveratrol on expression of cyclin D1, cyclin B1 and p34cdc2 in murine liver cancer tissue

Cyclin D1 immunoreactivity was observed in the nucleolus of tumour cell, cyclin B1 immunoreactivity and p34cdc2 immunoreactivity were observed in the cytoplasm of tumour cell. The expression level of cyclin D1, cyclin B1 and p34cdc2 in transplanted liver cancer tissue was significantly higher than that of adjacent noncancerous liver tissues in control group (All P<0.05) (Tables 2-4). Following treatment with resveratrol, a depressed expression of cyclin B (77.8 % *vs* 30.0 %, P<0.05) and p34cdc2 protein (88.9 % *vs* 40.0 %, P<0.05) was observed, but the expression of cyclin D1 protein (66.7 % *vs* 60.0 %, P>0.05) did not change.

Table 2 Effect of resveratrol on the expression of cyclin D1 in murine liver tumor and adjacent noncancerous liver tissues

	No. of mice	Cyclin D1			Positive rate (%) (+, ++)

DISCUSSION

In 1997 Park *et al*, showed that resveratrol inhibited tumorigenesis in a mouse skin cancer model[11]. Since then, many studies have shown that resveratrol has suppressive effects on tumour cells in human lung carcinoma, prostate cancer, bronchial epithelioma and breast cancer models[12-14]. The ability of resveratrol to inhibit cellular events associated with tumour initiation, promotion, and progression might be attributed to its anticyclooxygenase activity (COX-1), inducing apoptosis of tumour cells, antagonizing mutation, antioxidation and anti-free radicals activity and its effect on cell cycle[15,16].

Recent studies have shown that many drugs exhibited their anti-tumour activity by interfering cell cycles. The cell cycle regulators have thus become a new target in drug discovery research. Of the 3 cell cycle regulators of cyclins, CDKs, and CKIs which have been found, CDKs is the core of the modulation network, which is positively regulated by cyclins and negatively by CKIs. Cyclin D1, a member of cyclins family, modulates mainly G1/S stage transition. Under normal conditions, the amount of cyclin D1 is invariable in G1 stage and its overexpression will lead to cells passing through G1/S without control, which is considered to be associated with carcinogenesis. Cyclin B1 is related mainly to the completion of M stage. CDC2 (CDK1) gene, a modulating core of G2/M inspect point, codes for p34cdc2 protein. The p34cdc2 combines with cyclin B1 to form MPF which plays an important role in the process from G2 stage to M stage. Studies have shown that cyclin B1-CDC2 was in activated state in many tumour cell lines no matter what the state of DNA was. Even

though cells had DNA damage, they could still enter the cleavage stage. Therefore, p34cdc2 and cyclinB1 were also associated with carcinogenesis[17].

In the present investigation, resveratrol was administered into murine abdomen and its potency on growth and proliferation of H22-innoculated tumour was evaluated by measuring the size of hepatoma and examining the expression of cell cycle proteins. The tumour size was found to be reduced by each dosage of 5, 10 or 15 mg/kg of resveratrol for 10 days. When the higher dosage of resveratrol was applied, the tumour size was significantly reduced, the inhibition rate of tumour growth by 10 or 15 mg/kg reached to 36.3 % and 49.3 %, respectively (P<0.01). We also found the protein expression of cyclin D1, cyclin B1 and p34cdc2 in murine transplanted liver cancer tissue was significantly higher than that in adjacent noncancerous liver tissues, suggesting that the overexpression of these cell cycle proteins may play a role in the onset and development of carcinoma. Compared with control group, a depressed expression of cyclin B1 and p34cdc2 protein was observed in the transplantable murine hepatoma following treatment with resveratrol, suggesting that the anti-tumor mechanism of resveratrol may be to prevent mitosis of tumor cells by suppressing the protein expression of cyclin B1and p34cdc2, and thus, interfering with the process of tumor cells from S stage to G2/M stage.

In short, the data presented in this paper suggest that resveratrol has an apparent antitumour activity, and blocking of S stage of tumour cells may be the underlying mechanism. The demonstration of modulating effect of resveratrol on cell cycle should provide certain theoretical basis for further study of resveratrol and other cell cycle interfering agents.

Abstract

AIM: To develop a simple and rapid detection of HBV gene variants and prediction of lamivudine-resistance in patients.

METHODS: Initially, plasmids harboring the wild-type or mutant HBV DNA fragments were used in a model system. The technique was then applied to clinical samples for an analysis of YMDD mutations. The sera were extracted from chronic hepatitis patients who had received lamivudine treatment for more than one year. P region gene of HBV was amplified by polymerase chain reaction. The excess primers and dNTPs in PCR products were removed by cleaning-up reagents. Template-directed dye-terminator incorporation reaction was performed and R110 or TAMRA labeled acyclo-terminator was added on the 3' end of TDI-primer specifically. Fluorescence polarization value was measured with Victor 2 multilabel counter and the genotypes of HBV were analyzed.

RESULTS: The YMDD genotypes in recombined positive plasmid and 56 serum samples of HBV infected patients were analyzed by using our TDI-FP method and the specificity and sensitivity were confirmed by DNA sequencing. Five of 56 serum samples showed YVDD phenotype (9 %), including 1 YMDD and YVDD mixed infection. Four of 56 showed YIDD phenotype (7.1 %).

CONCLUSION: This is a simple, rapid, low cost and high throughput assay to detect HBV polymerase gene variants and suitable for large-scale screening and prediction of the lamivudine-resistance in clinical samples.

INTRODUCTION

Hepatitis virus B (HBV) is the causative agent of acute and chronic hepatitis. Approximately 400 million people worldwide are chronically infected with HBV. There are 170 million people infected in China[1,2]. HBV infection can lead to cirrhosis and primary hepatocellular carcinoma[3-5]. To date, interferon alfa and lamivudine are the only two agents approved for chronic hepatitis[6-10]. Because interferon alfa shows significant dose-dependent side effects, lamivudine has emerged as the first therapeutic agent[11-13]. Chinese patients are immunotolerant to interferon alfa because of acquisition of the disease during early childhood. The efficacy of interferon alfa in Chinese is lower than in white patients[14]. However, the efficacy of lamivudine is equal in Chinese and white patients.

Lamivudine is an antiviral nucleoside analogue. It can inhibit HBV reverse transcriptase activity and also act as a viral DNA chain terminator[15]. It is an inactive form before activated in hepatocytes by addition of phosphate group[2]. Lamivudine has two pathways of viral suppression. First, the active triphosphate metabolite is incorporated into newly synthesized HBV DNA to stop the chain extension. Second, it inhibits HBV reverse transcriptase. Its clinical use has resulted in HBeAg seroconversion and undetectable HBV DNA[16]. Unlike some nucleoside analogues, lamivudine is well tolerated and has an excellent safety profile. It has little or no effect on bone marrow, hepatocytes, kidney, or muscle tissues. However, long-term lamivudine treatment has led to emergence of HBV variants resistant to lamivudine therapy in some patients. The major sites of mutation are situated in the highly conserved motif, tyrosine (Y), methionine (M), aspartate (D), aspartate (D) (YMDD), of the catalytic (C) domain of the reverse transcriptase. Mutations consist of an amino acid substitution from M to either valine (A739G, $Met_{552} \rightarrow Val_{552}$) or isoleucine (G741T, $Met_{552} \rightarrow Ile_{552}$). Those mutations at the YMDD motif could render HBV resistant to lamivudine[17].

Fluorescence polarization assay (FPA) is a well established method used to analyze associations and dissociations between molecules in solution. This technique relates the change in the molecular size of a fluorophore to a change in the fluorescence polarization value (mp unit). The value changes indicate molecular associations or dissociations, so that FPA have been used to examine the interactions between molecules, such as protein-protein interactions, DNA-protein interaction and DNA-DNA hybridization.

Based on the FP detection method and the combined template-directed dye-terminator incorporation technique, a novel SNP (single nucleotide polymorphism) detection system (TDI-FP) has been developed[18]. It relies on the ability of AcycloPol™, a novel mutant thermostable polymerase from the Archeon family, to extend accurately an annealed probe by a single dye-terminator that is complementary to the opposite strand. It performs an assay to determine the base at a SNP site with many advantages over the other methods, such as homogeneity, low cost, high accuracy, high throughput and ready adaptation to automation. This method has been used to genotyping and SNP detections but has not, to our knowledge, been used to microbial mutant analysis yet.

Routine detection of HBV YMDD mutation after lamivudine treatment will be required to increase the efficacy. In this study, we undertook such a study using TDI-FP to detect the YMDD variants using mutagenesis plasmids and serum samples of 56 patients. This new method is a rapid, accurate and high throughout method to analyses the YMDD mutations**.** It will be a very useful tool for the clinical diagnosis and monitor of the lamivudine resistance.

MATERIALS AND METHODS

Instrumentation

Fluorescence polarization values were determined with the VICTOR2 multilabel counter (Perkin-Elmer, USA). The excitation and emission wavelengths were 544 nm and 595 nm for R110 and 485 nm and 535 nm for TAMRA, respectively. The samples were measured in 384 well PCR plates (MSP-3862 MJ Research, USA).

Reagents

Taq DNA polymerase, DNA extractor kit were obtained from Hua-mei Bio-tech Co., LTD. AcycloPrime™-FP detection kit (including AcycloPol™, AcycloTeminators™ labeled with R110 and TAMRA, shrimp alkaline phosphatase, exonuclease I) was product of Perkin-Elmer Co., Ltd.

Oligonucleotides

A set of PCR primers was designed to amplify the P region of HBV gene including the YMDD motif encoding sequences. 2 TDI-primers were also designed to encompass 17-21 bp 5' (A739Gtdi, sense) or 3' (G741T, antisense) to the nucleotide adjacent to the mutation sites using DNAStar software. 3 sets of primers for the site-directed mutagenesis were also designed using DNAStar software. All the primers, whose sequences are shown in Table 1, were synthesized using 391 DNA synthesizer (Perkin-Elmer, USA) by Bao Tai Ke Biotech Co.

Site-directed mutagenesis

The site-directed HBV YMDD mutants were made using Takara MutanBEST Kit by TaKaRa Biotechnology Co., Ltd. The A719G mutation was created using primers A739G*for* and A739G*rev*. The G741T mutation was created using primers G741T*for* and G741T*rev*. The A739G/G741T double mutants were made using primers diMut*for* and diMut*rev* with the plasmid pMD/HBV as a template respectively. (All the sequences of primers are shown in Table 1). The mutagenesis was detected according to the manufacture' s manual and verified by DNA sequencing.

Table 1 Primer sequences

Primer	Sequence

diMut*for*	5'-CTTTCAGTTATGTTGATGATGTGGTA 3'
diMut*rev*	5' -CCAGACAGTGGGGGAAAGC 3'

DNA samples

Venous blood (1 ml) was obtained from 56 patients with HBV chronic hepatitis B in Tangdu Hospital and Second Hospital of Jiaotong University, Xi' an.

Amplification of P region of HBV gene

PCR amplification was performed in a total volume of 50 μL, containing 1.5U Taq polymerase, PCR buffer, 0.1 mmol/L dNTPs, 1 μL of DNA sample (10 ng plasmid DNA or 100 ng genome DNA), 100 nmol/L PCR*for* and PCR*rev* primer each. The amplification procedure consisted of an initial denaturation and enzyme activation step at 94 ℃ for 5 min, followed by 40 cycles containing denaturation at 94 ℃ for 30 s, annealing at 56 ℃ for 30 s and extension at 72 ℃ for 1 min. After a final extension step at 72 ℃ for 10 minutes, the reactions were cooled to 4 ℃ until further use. The PCR reaction was carried out in a Touchgene gradient termal cycler (TECHNE Co. USA). In order to evaluate the amplification, each 5 μL of PCR products was separated on a 20 g/L agarose gel in 0.5× TBE buffer. The products were visualized and photographed under ultraviolet (UV) light.

Fluorescence polarization detection

Following PCR amplification, 2 μL clean-up reagent (including shrimp alkaline phosphatase and exonuclease I and reaction buffer) was added into 5 μL of PCR product and incubated at 37 ℃ for 60 min to remove unincorporated dNTPs and free primers. The enzymes were then heat-inactivated at 80 ℃ for 30 min.

TDI-FP was performed according to the protocol supplied by the manufacturer (Perkin-Elmer Life Sciences, Inc, USA). The reaction system consisted of 13 μL of AcycloPrime-FP mixture (containing 0.05 μL of AcycloPol™ polymerase, 2 μL of 10× reaction buffer, 1 μL of Acyclo-Terminator Mix, 0.5 μL mutant detection primer and 9.45 μL of water) and 7 μL of amplified and processed target DNA. After an initial denaturation at 95 ℃ for 2 min, 25 cycles at 95 ℃ for 15 sec and at 55 ℃ for 30 s were performed on a black 384-well PCR plate (MSP-3862, MJ Research). The fluorescence polarization values were measured on the 384-well plate using Victor2 multilabel counter directly.

RESULTS

PCR amplification

The PCR products were analyzed by agarose gel electrophoresis (Figure 1). A single band corresponding to a molecular size of 200 bp was detected, which was in concordance with expectation.

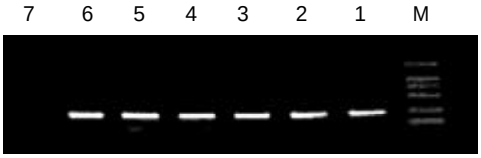

Figure 1 Electrophoretic analysis of PCR products. 1: plasmid pMD / HBV-A739G as PCR template, 2-6: serum samples as PCR template, 7: water as template (negative control), M: DNA molecular weight marker.

TDI-FP assay

Following PCR amplification, excess primers and dNTPs were removed. In the TDI extension reaction, 729*tdi* primer and dye-terminators mix (R110-acyGTP/ TAMRA-acyATP) were used to detect the A739G mutation (Figure 2). 741*tdi* primer and R110-acyCTP/TAMRA- acyATP) were used to detect the G741T mutation. The dye-terminator was incorporated and the TDI-primer was extended by one base complementary to the specific mutation site. The fluorescence intensity was measured using Victor 2 multilabel counter and the FP value was calculated by the instrument software automatically. The graph was created from an Excel workbook and the cluster of AcycloPrime-FP data was obtained by plotting the TAMRA polarization *vs* the R110 polarization. The FP reading of the samples was clustered into four distinct groups (Figure 3). As expected, for HBV YVDD samples, the values for R110-acyGTP were high and the values for TAMRA-acyATP were low, reflecting incorporation of the R110-acyGTP but not

TAMRA-acyATP. The genotypes were represented by the cluster in the lower left. Conversely, the YMDD genotypes appeared in the upper right. YMDD and YVDD double mutations or mixed infection samples appeared in the upper right. Negative controls were in the lower left cluster (Figure 3). For the G741T detection, the YIDD samples appeared in the upper left, YMDD samples in the lower right and the negative control in the lower left.

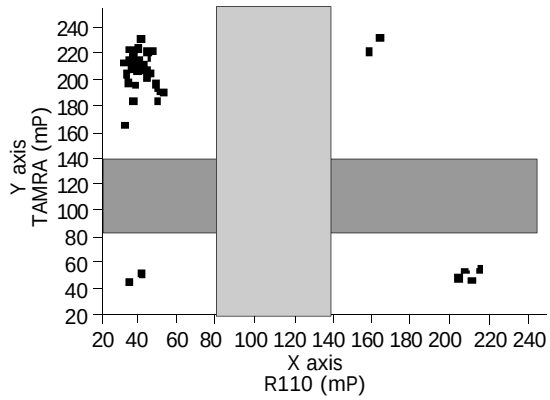

Figure 3 TDI-FP analysis data of YMDD mutation.

Detection of YMDD mutation in clinical samples

To evaluate the utility and accuracy of the TDI-FP in clinical samples, 56 serum samples from patients with chronic hepatitis B were analyzed. Among the sera analyzed, the wild-type YMDD variant was detected in 46 (82 %), the YVDD variant in 5 (8.9 %) and the YIDD in 4 (7.1 %). In one patient (1.8 %), both YMDD and YVDD variants were detected, which might reflect a mixed infection.

DISCUSSION

As reported before, the major drawback to the therapy of lamivudine is the emergence of drug-resistance due to the HBV DNA mutations. The patients who have lamivudine resistant HBV variants infection are more likely to develop more severe liver damage than those who do not have drug-resistant mutants. The mutation at YMDD (YMDD→YVDD or YMDD →YIDD) is considered to be the major lamivudine-resistance related variants. DNA sequencing is considered as the ideal method for characterizing DNA mutants, but it can not be afforded by most laboratories, especially clinical laboratories due to the cost and equipment requirement. Type-specific PCR, PCR-RLFP and PCR-SSCP have been used to detect HBV YMDD mutants. However, all the methods have drawbacks, e.g. lack of accuracy, difficulty in determining the mutation sites exactly or detecting mixed infection[19].

We reported here, for the first time, the successful application of the TDI-FP to detect the HBV YMDD mutation in hepatitis B patients. As a homogenous assay, the FP value reflected the total sum of free and incorporated dye-terminators. Two major factors affecting the result were faced: (1) The concentration of the first PCR product in TDI extension was too high or too low, which would create misincorporation or lower incorporation of dye-terminators, (2) the excess primers

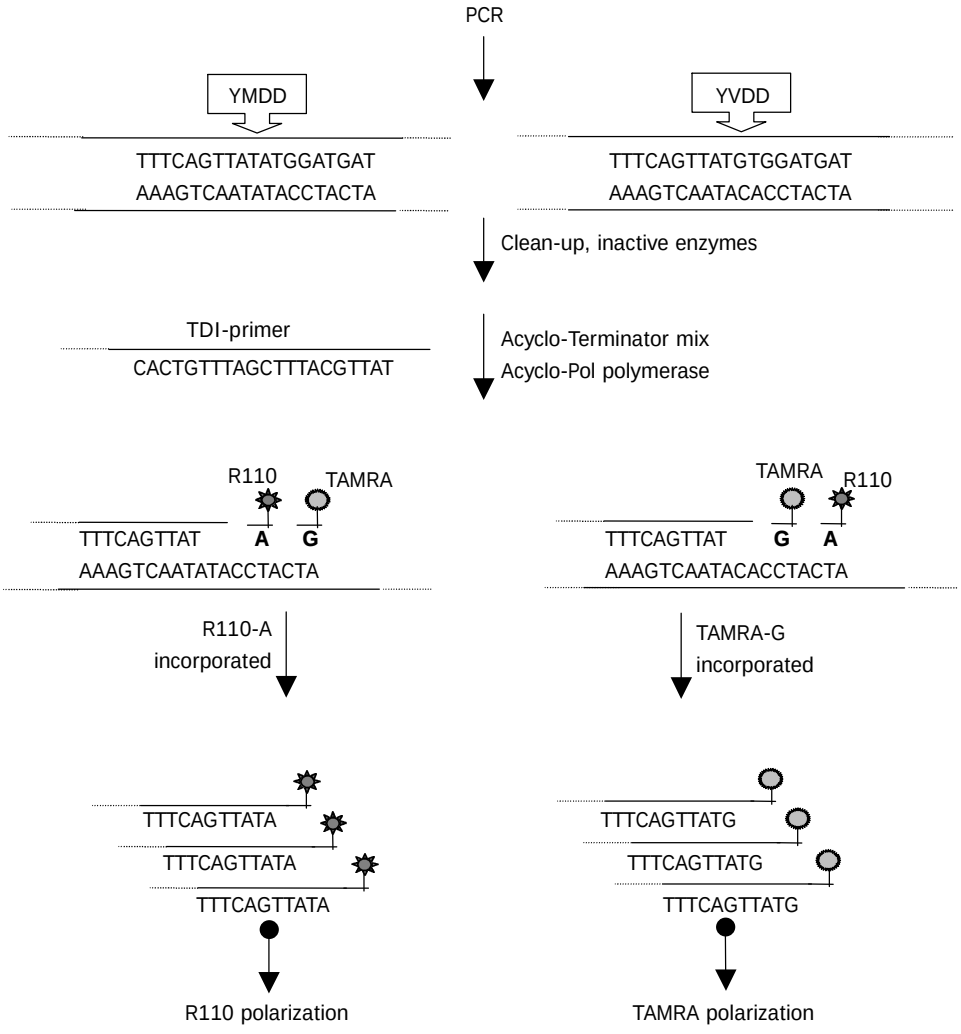

Figure 2 The scheme of TDI assay of YMDD.

in the first PCR product might lead to misincorporation, while excess dNTPs would interfere the dye-terminator incorporation competitively. We increased the number of thermal cycles to 40-45 to ensure that all PCR components were exhausted and adjusted to the concentration of dNTPs and primer in PCR reaction, which were lower than standard PCR protocol. We also prolonged the digestion time from 30 min to 60 min to completely remove the dNTPs and primers. At the same time, to get best TDI-FP performance, forward and reverse TDI primers were used and compared in our study (data not shown). The predicted reaction conditions (annealing temperature and $MgCl_2$) were tested on several nonessential DNA samples to optimize the system.

DNA diagnostic tests will no doubt be applied more and more in clinical rather than in research laboratories. The main advantages of our technique over the other methods for scoring DNA variation, are high accuracy, high throughput and easy to adaptation automatic. It will improve the analysis and prediction of drug-resistance in clinic.

Abstract

AIM: To evaluate the value of ultrasonography in predicting and screening liver cirrhosis in children.

METHODS: Twenty-eight children with liver cirrhosis of various etiologies were examined by routine ultrasonography. A percutaneous liver biopsy guided by ultrasound was also performed on each patient, and the results of liver biopsy and ultrasonography were compared.

RESULTS: When compared with the biopsy results, ultrasonography in combination of clinical and laboratory findings gave accurate diagnoses of children liver cirrhosis. Although ultrasound imaging of children with liver cirrhosis revealed abnormal characteristics, these images were not specific to this disease, thus reinforcing the necessity of ultrasound-guided liver biopsy in the diagnosis of children liver cirrhosis.

CONCLUSION: Ultrasonography is reliable in the diagnosis of children liver cirrhosis, and its usefulness should be stressed in the screening and follow-up of high-risk pediatric patients.

INTRODUCTION

Cirrhosis of the liver is a morphological entity, and it has been assumed to be an end-stage condition of all chronic active liver diseases. There are many types of liver cirrhosis, including posthepatitic, alcoholic and mixed types of cirrhosis, and congestive, biliary and parasitic cirrhosis, etc. The etiological factors underlying this disease, as well as its morbidity, have been shown to be different in different geographical regions[1-8]. It should be mentioned that morphological changes are different in liver cirrhosis, which include the structural changes not only in the parenchymal disorganizations, but also in the stromal vascular changes in the cirrhotic process[9,10]. It has been widely accepted that ultrasonography is a useful diagnostic procedure for advanced liver cirrhosis. However, liver cirrhosis of children and its applicable techniques are usually different from those of adults. Several types of the cirrhosis resulted from metabolic diseases including glycogen storage disease and hepatolenticular degeneration are rare in adults. In children, the onset of cirrhosis is often occult. Children cirrhosis lacks the early typical clinical symptoms as seen in adult patients, thus contributing to its frequent misdiagnosis[11]. Unfortunately, reports on children cirrhosis are few. To determine if ultrasonography could be of clinical value in predicting the etiology of children cirrhosis, we performed this test in 28 children whose cirrhosis was confirmed by histopathology.

MATERIALS AND METHODS

Patients

We studied 45 children with clinically and ultrasonically suspected cirrhosis of the liver. Only 28 children (23 males and 5 females) aged from 11 months to 12 years (mean 7.9 years) who had a definite biopsy were included in this study. The other 17 children who had no biopsy were excluded.

All the patients were regularly evaluated by clinical assessment, biochemical tests, ultrasound study, and liver biopsy when clinically indicated. Among them, six had chronic hepatitis, and two lived in areas with a high prevalence of *Schistosoma mansoni* while the other 20 had no known etiology. In eight cases, their mothers were positive for HbsAg, among these cases three had hepatitisB. In three cases, their fathers were positive for HbsAg, among these cases one had hepatitisB. In two cases, both parents were positive for HbsAg. Seventeen patients came to hospital because of indigestion or abdominal bloating, four because of diarrhoea, and one each because of dyspneic respiration, bellyache, or jaundice. One patient was identified during routine physical examination.

Sonography

Ultrasonography was performed by conventional techniques with a high-resolution, real-time scanner (Sonoline AC) equipped with 5 MHz and 7 MHz rectilinear array or convex scan probes combined with a puncture guider. Liver size was assessed according to routine methods (transverse and longitudinal sections, relationship between the hepatic border and the right kidney). The contour of the liver (smooth and nodular) was observed. The ultrasound patterns of the liver (nonspecific hepatomegaly, homogeneously increased echogenicity, heterogeneously increased echogenicity, and nodular liver) were observed. The presence of ascites, signs of portal hypertension, and splenomegaly were also recorded.

Ultrasound guided biopsy was performed on all the patients, each biopsy was subsequently examined immunohistochemically.

RESULTS

The diagnosis of children cirrhosis was confirmed in the 28 cases by histopathology, and liver cirrhosis was classified into six groups: post-hepatitis B, biliary disease, congestive disease, schistosomiasis, glycogen storage disease and hepatolenticular degeneration cirrhosis according to the results from biopsy (Table 1).

Among the patients, most were post hepatitis B, accounting for 67.9 % (Table 1). The ultrasound patterns of post-hepatitis B cirrhosis were similar in appearance to the adult disease, with increased parenchymal echo, coarsened echo texture,

irregularities on the liver surface, abnormalities of the intrahepatic biliary tree and splenomegaly. Because the etiology of liver cirrhosis was multifactorial, each particular patient might have a different pathogenesis and different hepatic ultrasound changes. Sonography revealed intrahepatic cholangiectasis in three children with cholestasic cirrhosis. One case of congestive cirrhosis showed an enlargement of the venae hepaticae and inferior vena cava, and almost no change in the inner diameter of the vessels during respiratory movement. In two cases of schistosomiasis cirrhosis, who lived in an epidemic region for *Schistosoma mansoni*, a grid pattern was observed. By sonography, two patients with glycogen storage disease and one hepatolenticular degeneration showed relatively characteristic ultrasound patterns. The echo patterns of liver parenchyma of glycogen storage disease were found to have coarsened echo texture, but the surface of their livers appeared smooth. The pattern of hepatolenticular degeneration showed a coarsened parenchymal echo, with a normal distribution, and the route of the intrahepatic biliary duct was not altered.

Table 1 Diagnosis of children with cirrhosis

Classification	<2 years	2-7 years	8-12 years	Total	%
Post hepatitis B cirrhosis	1	2	16	19	67.9
Biliary cirrhosis		1	2	3	10.7
Congestive cirrhosis			1	1	3.6
Schistosomiasis cirrhosis			2	2	7.1
Glycogen storage disease		1	1	2	7.1
Hepatolenticular degeneration			1	1	3.6
Total	1	4	23	28	100

DISCUSSION

The value of ultrasonography in diagnosing cirrhosis of the liver has been recognized clinically[12-14]. By observing the press extents of the surface of the left hepatic septum in front of the inferior vena cava, real time ultrasound could directly determine the degree of cirrhosis. Estimating the condition of esophageal varices by detecting portal hypertension was important in differentiating the source of gastrointestinal hemorrhage[14]. Because the child liver was smaller in size, we obtained high-resolution ultrasound images by using high frequency probes (5 MHz and 7 MHz).

Our results showed that the echo pattern revealed by ultrasound in combination of the patient' s medical history, could be useful in the diagnosis of children liver cirrhosis and prediction of its the etiology. Then, physicians could select appropriate subsequent diagnostic methods to confirm the diagnosis. Since ultrasound does not allow for the specificity of imaging, we suggest that percutaneous liver biopsy guided by ultrasound should be performed when possible, in order to provide the most accurate method for clinical diagnosis. Ultrasonic scans could localize areas for biopsy away from major vessels and the gall bladder.

Most children with chronic hepatitis have no history of acute hepatitis. Chronic hepatitis has few clinical symptoms and most children patients cannot be diagnosed early in the course of their disease. Thus, by the time they do present the symptoms, the disease is well advanced, and their prognosis is poor. Of the 28 children described here, only six had a previous history of hepatitis. More than half of them came to hospital because of indigestion and abdominal bloating. One patient was misdiagnosed as having biliary ascarid, and was not diagnosed as cirrhosis until bleeding of the digestive tract was observed following ineffective antihelminthic treatment. One child with chronic diarrhoea was found to have complications of ascites. Children cirrhosis was thus easily misdiagnosed. For this reason, if a child manifests symptoms associated with cirrhosis, such as hypodynamia, poor appetite, nausea, vomiting, diarrhea, and intense stomach pains, an ultrasound examination and correlated clinical examination should be performed.

Of the 28 children in this study, 19 (67.9 %) had post-hepatitis B cirrhosis. China is a country with a high prevalence of hepatitis B infection. Perinatal infection is recognized as the predominant mode of transmission of the virus, resulting in many carriers of HbsAg. Infection occurred predominantly at or after birth by maternal-infant transmission, and might even occur as early as the oosperm stage[15]. Embryos infected in the uterus have been reported to develop cirrhosis. Thus the children' s parents who are positive for HbsAg or have a history of hepatitis B infection should be examined by ultrasound and correlated clinical tests at regular intervals. This may lead to an early detection of children liver cirrhosis.

In conclusion, ultrasonography can accurately reveal morphological characteristics and predict the etiologic factors underlying children liver cirrhosis. This technique can be used to screen high-risk groups and allows for early treatment.

Abstract

AIM: To explore a safe, efficient, and cost-effective technique for local thermo-ablation of hepatic tumors.

METHODS: The livers of 16 healthy rabbits were thermocoagulated by diode-laser with a hand-made scanner fiber tip, 6 w for 10 min. At the same time, the temperature was measured at 5 and 10 mm from the laser tip. Liver function 7 days post-thermocoagulation was compared to pre-thermocoagulation. Pathological changes were also studied 1 month after laser thermocoagulation.

RESULTS: All the rabbits lived and the temperature of hepatic tissues at 0 mm, 5 mm, 10 mm from laser tip reached 96.39±3.97 ℃, 60.79±6.21 ℃, 46.10±4.58 ℃, respectively after 10 min thermocoagulation. There was no significant change in liver function. The hepatic thermocoagulated necrosis and the surrounding fibrosis was 26.0 mm in diameter. Light microscopy observation revealed no surviving cells in the coagulated area.

CONCLUSION: Hepatic tissue can be locally ablated safely and effectively by diode-laser with scanner fiber tip, and this technique may be a new method to treat hepatic tumors.

INTRODUCTION

In recent years, thermo-ablation of liver cancer has received increasing attention. Generally this can be achieved by radio-frequency (RF) or Nd: YAG laser. Several factors have prevented these techniques from gaining widespread use including availability and cost, in addition to some uncertainty about their therapeutic effectiveness. With these concerns in mind, it is appropriate to consider a new technique for thermo-ablation that we believe is safe, stable, convenient and cost effective. Semiconductor taper-scattered light for thermo-ablation of liver tissue in an experimental model is advanced as such a technique with details presented as follows.

MATERIALS AND METHODS

Material and apparatus

Hand-made semiconductor taper-scattered laser therapeutic system (HTLTS) has a wavelength of 810±10 nm. The working tip is 10 mm long and 1 mm in diameter. Power utilization was 6 w and after dispersion output power was at 2.1 w with an exposure time of 10 min. Sixteen adult rabbits were obtained from the Animal Laboratory of Zhejiang University, weighing 2 to 3 kg.

Methods

Intravenous anesthesia was administered via ear vein using 2 % sodium pentothal. The abdomen was entered with a midline incision and right or left lobes of the liver were exposed. A 18G PTC needle was introduced into the liver and through it, the laser tip was advanced into the liver tissue before turning on the power for the laser. Care was taken to advance the laser tip fully into the liver tissue. Power input was 6 w and 2.1w after dispersion.

For temperature measurement during laser application, a nickel-chrome-nickel thermocouple 300 μm in diameter was placed intrahepatically at 5 and 10 mm from the laser tip. Temperature was continuously measured during application. After thermocoagulation the abdomen was closed with silk suture. Liver function was measured before surgery and 7 days afterwards. One month after irradiation the rabbits were sacrificed and the liver specimen was fixed in formaldehyde. Multiple sections were taken from the ablative and surrounding area in the verticle plane of the optical fiber. After H&E staining the sections were examined grossly and microscopically with particular attention to the diameter of the coagulated area. Liver function data were analyzed using the *t*- test with the "SAS" software.

RESULTS

The temperature variation is shown in Table 1. Note that two of the rabbits were irradiated for only six minutes because of carbonization of tissue at the center of the optical fiber.

Table 1 The temperature variation

Time (Seconds)	Temperature (℃)		
	0 mm	5 mm	10 mm
0	34.00±0.00	34.00±0.00	34.00±0.00
120		55.70±4.81	40.50±1.47
240		58.75±5.65	43.30±2.54
360		60.26±5.52	45.00±2.67
480		59.89±6.65	46.10±3.87
600	96.39±3.97	60.79±6.21	46.10±4.58

Liver function changes are shown in Table 2.

Table 2 Liver function changes

	Pre-coagulation	7 days after coagulation	*P*
ALT(IU / L)	67.78±24.98	77.11±49.79	>0.05
AST(IU / L)	87.22±58.82	66.55±44.75	>0.05
TBIL(mg / dl)	1.84±1.79	1.21±0.51	>0.05
ALB(g / L)	17.90±3.98	14.77±2.79	>0.05
TP (g / L)	66.54±13.95	59.40±9.55	>0.05

All rabbits were alive after the procedure. When the animals were sacrificed after one month the livers were cut in the vertical plane of the optical fiber and the gray coagulated necrotic tissue was measured. Gross evaluation demonstrated a diameter of 23 mm with a perimeter zone of 3 mm (Figure 1). Under light microscopy the central zone of coagulation necrosis was followed by a layer showing inflammatory cell infiltration and finally the layer of fibrosis, the last two were 0.5 mm and 2.4 mm, respectively.

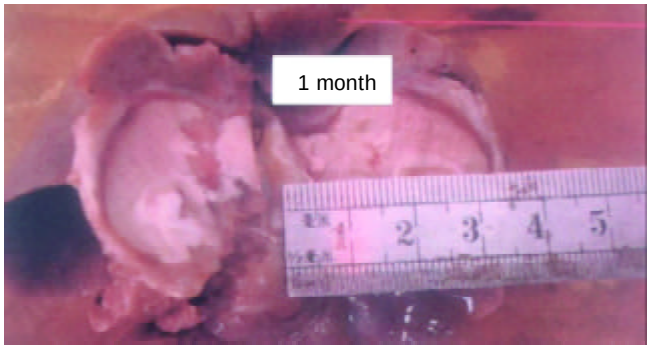

Figure 1 The necrotic center with surrounding fibrosis (HE).

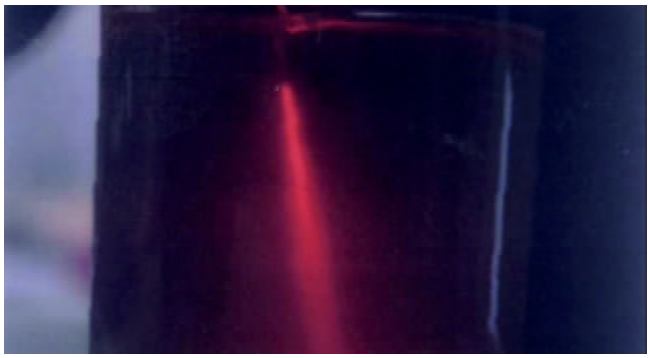

Figure 2 High density linear laser energy from fiber.

Figure 3 Low density up-tip taper scattered laser energy after conversion.

DISCUSSION

Currently the optimal treatment for liver cancer is surgical excision with curative intent. However, because of the frequency of coexistent cirrhosis and the difficulty of early detection, only 25 to 30 percent of newly diagnosed patients with primary or metastatic liver cancer undergo potential curative resection and the recurrence rate is at least 50 %[1-2]. This means many patients are not even candidates for a surgical procedure and have little chance even for palliation, which has led to increasing interest in alternatives such as thermo-ablative procedures including radio-frequency, Nd:YAG laser and microwave. However, limited benefit, high cost and difficulties in technical application have limited the usefulness of these modalities as well[3-6].

The basis for laser thermo-ablation is that light energy can be absorbed by tissues after its conversion into heat, resulting in deep penetration with therapeutic destruction of tumor tissues. The temperature and therefore the extent of destruction are controlled by the intensity and duration of the energy transmitted. This has already been shown effective using Nd: YAG laser as the energy source. However high cost and difficulties in use have restricted its application in this setting[6-9]. More recently, semi-conductor focused laser energy has come to the forefront due to decreased cost, stable-performance, durability and ease of use. In addition it does not require water cooling equipment[7,8]. In this report, we have examined a similar process using semiconductor taper-scattered light. We have shown 1064 nm Nd:YAG and 800-900 nm semiconductor laser light both exhibit deep penetration in tissue. Dong[10] has shown normal liver cells necrotize in one minute with a temperature of 54 ℃ and immediately with a temperature of 60 ℃. In addition he has shown liver carcinoma cells are more sensitive than normal cells if the temperature is less than 130 ℃. We also know penetration of laser energy is significantly reduced by vaporization and carbonization of tissues. Obviously, to enlarge the treatment area and avoid injury to adjacent areas it is necessary to elevate the temperature of the treatment area but not so high as to cause vaporization and carbonization. It is our opinion that semiconductor taper-scattered laser light may be superior to other systems in this regard. HTLTS can convert high density linear laser energy into up-tip taper scattered laser light which is lower in energy and density as shown in Figure 2 and Figure 3. In effect it can increase the power of laser light equipment, enlarge the treatment area, shorten the duration of application and avoid injury to important areas adjacent to the treatment area such as major hepatic vessels. Specifically, the power is only 6 watts and after scatter only 2.1 W. Ten minutes after thermocoagulation the temperature at the center of the optical fiber is 96.39±3.97 ℃ and 10 mm from the center the temperature is 46.1±4.58 ℃. One month after the procedure the diameter of necrosis was 26 mm and there was no viable tissue in this area. HTLTS is more efficient than Nd:YAG or semiconductor focused laser light. In the study by Ping Liang[5] Nd:YAG provided only 15 mm necrosis using 2 to 6 W energy after 15 to 40 min application. Fan[7] demonstrated only 7-13 mm necrosis with semiconductor focused laser energy from a British laser using 2 W and 2800-8400 J respectively. Injury beyond the intended area is less likely since it is not necessary to place the tip of the instrument exactly in the center of the lesion and this makes the procedure also applicable for more superficial lesions. The optical fiber can be separated from the tissue with the catheter thus avoiding contamination from the blood and the length of the fiber tip can be altered to fit the diameter of the tumor. Furthermore, the optical fiber can be sterilized and reused, the fiber is flexible, allowing access to areas one side or the other of the primary objective. Overall,

HTLTS is more convenient, economical and effective than the currently available ablative procedures.

In regards to the effect of HTLTS on hepatic carcinoma or metastatic lesions, we have shown greater penetration than in normal tissue. For example, the penetration of YAG (wavelength 670 nm) in normal liver tissue, liver sclerosis, HCC, and metastatic lesions is 0.75 mm, 0.97 mm, 1.43 mm and 2.78 mm, respectively[11]. HCC is also more sensitive to thermal ablation than normal tissue. Again HTLTS is more effective and efficient than the other methods. HTLTS can also be applied to the clinical area easily. The fiber is passed into the intended tissue through a 18G paracentesis needle guided by B-ultrasound. The length of the fiber tip can be adjusted according to the size of the target tissue. Special techniques are also available to utilize more than one fiber at a time to improve the resulting effect according to the exact size and location of the target tissue.

In conclusion, we believe that the foregoing report indicates HTLTS may be the best technique yet devised for thermo-ablation of hepatic lesions.

Abstract

AIM: To determine whether or not a low dose of HB vaccine can be effectively used in the rapid vaccination.

METHODS: Rapid vaccination (0, 1, 2 months) with low dose (5 μg) or routine dose (10 μg) HB vaccine was studied in 250 subjects (130 school children and 120 university students). Serum from all the participants was tested for HBsAg, anti-HBs and anti-HBc at 1, 3 and 7 months after the first dose of vaccination and all subjects were serum HBV marks negative before the vaccination. Non-responders to a complete initial vaccination from university students were given an additional vaccination with 10 μg of HB vaccine and their serum anti-HBs was tested again one month later.

RESULTS: One month after the third dose of vaccination (third month) sero-conversion rates and geometric mean titer (GMTs) were significantly ($P<0.01$) higher in the routine dose (resp. 89 % and 106.8) than in the low dose group (resp. 72 % and 59.5). Sero-conversion rates and GMTs were maintained stable for another 4 months in both groups. After an additional vaccination to non-responders with 10 μg HB vaccine, 17/23 subjects (13/15 from those vaccinated with 5 μg vaccine and 4/8 from those vaccinated with 10 μg vaccine) became anti-HBs positive, yielding similar sero-conversion rates for both dose groups.

CONCLUSION: Higher sero-conversion rates and GMTs were reached in those vaccinated with 10 μg HB vaccine than in those vaccinated with 5 μg HB vaccine after a complete vaccination with a 0, 1, 2 month scheme. But the subjects vaccinated with 5 μg vaccine can also reach the similar sero-conversion rate after an additional vaccination.

INTRODUCTION

Although hepatitis B vaccine has been available for 20 years, hepatitis B nowadays remains prevalent in the world, especially in a majority of the developing countries. In China, 5 μg of vaccine (Merck) has been used in the HB vaccination for several years and acquired acceptable results. The long-term effectiveness of low-dose HB vaccine immunization in the infancy has been observed, but that in school children or adults remains to be determined. It is known that protective anti- HBs antibody titers can generally be reached in 80-90 % of individuals vaccinated with 10 μg vaccine according to a 0,1, 6 month vaccination scheme. Considering of the relative length of the current HB vaccination scheme and the availability of low dose HB vaccine in the market, it seemed, therefore, worthwhile to test a routine dose (10 μg) vaccination in a rapid scheme (0, 1, 2 months) compared to a low dose (5 μg) vaccination. We here report that significantly higher sero-conversion rates and GMTs are reached in those vaccinated with a 10 μg dose vaccination than those vaccinated with 5 μg dose vaccination after 3 months from the initial dose. School children and university students showed no significant differences apart from a more rapid response in school children.

MATERIALS AND METHODS

Two hundred and fifty subjects (130 school children aged 8-10 years old and 120 university students aged 18-20 years old) with negative HB marks (HBsAg, anti-HBs, anti- HBc) were included in the study. One hundred and thirty subjects (72 school children and 58 university students) nominated as low dose group and were vaccinated with 5 μg HB vaccine, 120 subjects (55 school children and 65 university students) named as routine dose group received 10 μg HB vaccine (5 μg dose x 2) respectively according to a 0, 1, 2 month vaccination scheme. All non-responding university students after a complete initial vaccination series were given a fourth dose with 10 μg HB vaccine at the 8th month. All injections were given intramuscularly at the site of deltoid muscle. The HB vaccine used in this study is 5 μg yeast recombinant HB vaccine (Lot no: 2990104-1, from Merck), provided by Kangtai Biological Pharmaceutical Company, China.

Blood samples that were collected from all vaccinees for three times performed were used to detect serum anti-HBs (Ausab EIA, No 642841 M401) at month 1, 3 and 7 after the first dose of vaccination respectively. The third month serum specimen from all non responders after the initial vaccination was tested for HBsAg and anti-HBc by ELISA (Lizon Kit, China) in order to make sure that they are real no-responders to HB vaccine and not HBV carriers. Those with negative tests

received a fourth dose of vaccine at 8th month after vaccination and were again tested for serum anti- HBs one month later.

RESULTS

128/130 subjects in low dose group were tested for serum anti-HBs levels one month after the first dose of vaccination and only 114 subjects were available for the test one month after the third vaccination. The anti-HBs sero-conversion rate and GMT in this group was 71.9 % and 9.5 respectively (Table 1). 116/120 subjects in the routine group were tested for anti-HBs levels one month after the first dose of vaccination and only 110 subjects were available for the test one month after the third dose of vaccination. A significantly higher anti-HBs sero-conversion rate (89.1 %, $P<0.01$) and GMT (106.8, $P<0.01$) in routine dose group were observed after the third dose of vaccination compared with that in low dose group. At the seventh month the sero-conversion rate and GMT persisted at similar level to that after the second dose of vaccination.

Table 1 Serum conversion rate and GMT induced by low and routine dose of vaccines

Dose of vaccine	Time after first injection	*n*	Sero- conversion rate (%)	GMT
5 μg	1st time	128	12.5	
	2nd time	114	71.9	59.5
	3rd time	113	69.9	58.5
10 μg	1st time	116	19 .0	
	2nd time	110	89.1[b]	106.8
	3rd time	98	91.8[b]	94.6

[b]$P<0.01$ *vs.* 5 μg group.

Twenty three non-responding university students (15 vaccinated with 5 μg vaccine and 8 with 10 μg vaccine) were given a fourth dose of 10 μg HB vaccine after completion of the initial vaccination. Of these individuals, 13/15 non-responders in the low dose group and 4/8 non-responders in the routine dose group responded with anti-HBs one month after the additional dose. As a result of this additional vaccination, serum conversion rate in the low dose group was nearly similar to that in the routine dose group (95.2 % *vs* 92.9 %, Figure 1).

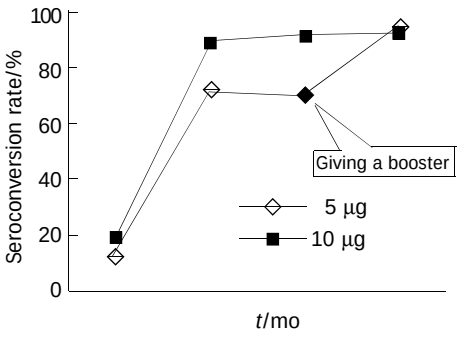

Figure 1 Seroconversion rate before and after a booster.

DISCUSSION

Since the introduction of hepatitis B vaccination in the early 1980s, the safety and immunogenicity of the plasma-derived and yeast-derived hepatitis B vaccines have been well demonstrated[1-12]. However, the disease remains a global problem. The failure of obtaining a complete 3 doses HB vaccination due to the length of the scheme probably contributes to the current prevalence of hepatitis B in the developing countries. Clearly, the protection against hepatitis B could be improved if a shorter vaccination regimen of achieving protective anti-HBs levels in >90 % of vaccinees was available. Our results clearly showed that with a rapid vaccination scheme (0, 1, 2 months) using 10 μg HB vaccine, serum anti-HBs levels can be induced, while it can not be reached by using 5 μg of HB vaccine. The similar results were also reported previously by Carlsson *et al*[13] who vaccinated some medical staff and compared the effects of intramuscular (I m, 20 μg.) vaccination with the low-dose intradermal (i d, 2 μg) vaccination on their early sero-conversion rates according to a 0, 4, 8 week scheme or to an accelerated 0, 2, 6 week scheme. He concluded that when a rapid protection against hepatitis B virus (HBV) infection was needed, such as the post-exposure prophylaxis, low-dose i.d. vaccination schedule could not be used.

A study on evaluating the potential for developing rapid seroprotection was performed by Young *et al*[14], beneficial results of a one month/two dose regimen with a novel triple antigen vaccine (Hepacare) have been achieved[14]. These results confirmed that an accelerated vaccination could be achieved with appropriate vaccinating protocols.

Low-dose vaccination has been proposed as a cost-saving strategy to implement mass vaccination of neonates with HB vaccine world-wide, particularly in developing countries. In a previous study, Shokri F compared the effectiveness of three doses of recombinant HB vaccine (Heberbiovac) in three different doses, among three groups of healthy Iranian neonates. His results showed that there were no significant differences in sero-protection rate and GMTs between the 10 and 5 μg dose recipients. Both parameters, however, were significantly lower in neonates vaccinated with a 2.5 μg vaccine dose[12]. Leroux-Roels G observed the immunogenicity and reactogenicity profiles of different doses of Engerix-B(R) (10 microg hepatitis B surface antigen) and Recombivax (R) (5 microg hepatitis B surface antigen), on a 0, 1, 6 month schedule in healthy adolescents. One month following the third dose of vaccination, seroprotection rates of Engerix-B and Recombivax vaccination were similar but the geometric mean titer was significantly higher in those vaccinated with Engerix-B than that with Recombivax[15]. Similar results were also reported that higher immunogenicity is usually related with higher vaccine dosages, especially in older adult population[13-18]. Our results showed that a higher dose (10 μg) of vaccine can induce much higher sero- conversion rate and higher GMTs compared with the reduced dose (5 μg) vaccination whereas the GMTs can be sustained for at least 5 months in both groups after the primary vaccination.

In most studies on immunocompetent subjects, 5 % to 10 % vaccinees failed to respond to HB vaccination. The possible reasons for lack of adequate antibody response have been well reported[16-22]. In order to confirm if the reduced dose of HB vaccination could cause a higher rate of non- or hypo-response to HB vaccine, we gave all non-responders an additional dose after the initial HB vaccination scheme and one month later, the majority of them converted into anti-HBs positive. The final sero-conversion rates of non-responders in low dose group and routine dose group were 95.2 % and 92.9 % respectively, showing that it is rather a hyporesponse to a lower dose of HB vaccine than a non-response as found earlier [23-31]. Based on the results, we conclude that it is better for adults to choose 10 μg HB vaccine, especially when a rapid vaccination program is needed.

Abstract

AIM: To study and compare the difference of activation-induced cell death (AICD) in peripheral blood T-lymphocytes (PBL-Ts) from patients with chronic hepatitis B (CHB) and the normal people *in vitro*, and to explore the role of AICD in chronic hepatitis B virus (HBV) infection and the pathogenesis of CHB.

METHODS: Twenty-five patients and fourteen healthy people were selected for isolation of PBL-Ts. During cultivation, anti-CD3 mAb, PMA and ionomycin were used for AICD of PBL-Ts. AICD ratio of PBL-Ts was detected with TdT-mediated dUTP nick end labeling and assessed by flow cytometry.

RESULTS: When induced with anti-CD3, PMA and ionomycin *in vitro*, AICD ratio of PBL-Ts from CHB patients was significantly higher than that from healthy control (17.24±1.21 *vs*. 6.63±1.00, $P<0.01$) and that from CHB patients without induction (17.24±1.21 *vs*. 9.88±1.36, $P<0.01$). There was a similar AICD ratio of PBL-Ts between induction group and without induction group, but no difference was found before and after induction in healthy control. The density of INF-γ in culture media of induction groups of CHB was lower than that of other groups ($P<0.01$). There was no difference between these groups in density of IL-10 ($P>0.05$).

CONCLUSION: When induced during cultivation *in vitro*, PBL-Ts from CHB have AICD very commonly. This phenomenon has a potentially important relation with pathogenesis of CHB and chronicity of HBV infection.

INTRODUCTION

Currently, the exact pathogenesis of chronic hepatitis B (CHB) and the reason of chronic hepatitis B virus (HBV) infection are still not completely understood. Activation-induced cell death (AICD) is related with lymphocytes decrease and functional defect. This phenomenon can cause decrease of immune clearance. Alloreactive T cells can effectively be depleted from allogeneic T cells by induction of AICD to prevent graft-versus-host disease[1]. AICD is essential for the function, growth and differentiation of T-lymphocytes[2]. This may be an important reason of persistent infection of HBV. AICD in peripheral blood T-lymphocytes (PBL-Ts) of CHB *in vivo* has been approved by some reports, but does AICD occur more easily in PBL-Ts of CHB than in those of healthy control? In order to explore the role of AICD in chronic HBV infection, we studied and contrasted the difference of AICD in PBL-Ts from patients with CHB and from normal people *in vitro*.

MATERIALS AND METHODS

Patients

Twenty-five patients (17 men, 8 women, aged 19-49, mean age 35.6 years) with CHB between March 2000 and April 2001 were selected from the Second Affiliated Hospital of Harbin Medical University. The diagnoses of all the patients were in accord with the Fifth National Conference on the Diagnostic Criteria of Virus Hepatitis (Beijing, 1995). And 14 healthy persons were selected as control.

PBL-Ts isolation

10 mL peripheral blood was taken and heparin was added for anticoagulation. After equivalent Ficoll-Paque (from Amersham-Pharmacia, USA) was gently added, peripheral blood monocytes (PBMCs) were isolated by density gradient centrifugation (600 g, 20 min). Then PBL-Ts were purified with negative selection technique using immune-magnetic beads as follow. After PBMC was washed, mouse-anti-human anti-CD_{14}, anti-CD_{16}, anti-CD_{19} (2 μg· mL^{-1}, DAKO Company, Denmark) were added and incubated for 30 min at 0 ℃, centrifuged for removing the uncombined antibody. Then goat-anti-mouse CD3 mAb coating with magnetic beads (1 cell *vs.* 30 beads, Promega Company, USA) was added and incubated for 30 min at 0 ℃. B cells, NK cells and monocytes were all linked with immune-magnetic beads and absorbed by magnetic stock (DAKO Company, Denmark). After the liquor was gently extracted by centrifugation, PBL-Ts were purified. The viability (95 %) of the cells was confirmed by trypan blue staining. When detected by flow cytometry, the purity of PBL-Ts was over 97 %.

Cultivation and AICD induction of PBL-Ts in vitro

After washed 3 times with PBS, 2×10^6· mL^{-1} PBL-Ts were added to a 24 well plate (NENC Company, USA) for cultivation. The samples were divided into treatment group and control group. The culture medium was RPMI1640 (GIBCO Company, USA) containing 10 % calf blood serum (BANDIN TECH Company, China), penicillin (100 U· mL^{-1}, BANDIN TECH Company, China) and streptomycin (100 U· mL^{-1}, BANDIN TECH Company, China). The wells of treatment group were pre-coated with anti-CD_3 mAb (5 μg· mL^{-1}, DAKO

Company, Denmark). Phorbol 12-myrisate 13-acetate (PMA) (50 ng· mL^{-1}, Sigma Company, USA) and ionomycin (50 ng· mL^{-1}, Sigma Company, USA) were added to the culture medium[3]. The culture medium of control group did not contain CD_3, PMA and ionomycin. The liquid of culture medium was adjusted to 1 mL. After cultured for 14 h (37 ℃, 5 % CO_2), PBL-Ts were harvested for AICD detection.

Observation by fluorescence microscope

Some PBL-Ts were put on the carry sheet glass, dried naturally and fixed by 4 % formaldehydum polymerisatum. Then, all the cells were stained with TdT-mediated dUTP nick end labeling (TUNEL, procedure according to clarification of the kit) (Promega Company, USA). The positive cells of TUNEL staining were detected by fluorescence microscope (BG-12, Olympass, Japan).

Flow cytometry detection

1×10^6 PBL-Ts were washed, fixed by1 % formaldehydum polymerisatum, stayed overnight in 70 % ethanol (-20 ℃) and stained with TUNEL for apoptosis detection (procedure according to clarification of the kit). The apoptotic ratio of PBL-Ts was detected by a flow cytometer (Fort, B-D Company, USA).

Cytokine detection

100 μl supernatant of medium was collected respectively from each group after cultured for 14 h and frozen in -20 ℃ refrigerator for detection. The contents of IFN-γ and IL-10 were detected by using an ELISA kit. The parallel sample was set up for each sample. The OD450 value of each sample was measured with an enzyme label meter (550 model, Bio-RAD Program, USA), and then the content of each sample was converted according to the standard curve.

Statistical analysis

The data were presented as $\bar{x}\pm s$. ANOVA was used to compare the means.

RESULTS

Observation by fluorescence microscope

The apoptotic PBL-Ts presented DNA breakage. The breakage DNA could be linked by fluorescence labeling dUTP when TUNEL staining was adopted. The apoptotic cells took on kelly fluorescence under fluorescence microscope (Figure 1). This was named positive TUNEL staining. The plasm of PBL-Ts with AICD took on red fluorescence and the nuclei took on kelly fluorescence when TUNEL and PI double staining were adopted. But the cells without AICD only took on red fluorescence (Figure 2). The positive cells of TUNEL staining in PBL-Ts of CHB (with and without anti-CD3mAb, PMA and ionomycin) were more excessive than that of healthy control.

Results of flow cytometry detection

After cultivated for 14 h with induction, the PBL-Ts of CHB patients displayed distinct apoptosis. Apoptosis was also found in groups without anti-CD3 and other inductions, but their apoptotic ratio was lower. There was a similar AICD ratio of PBL-Ts between induction group and healthy control without induction. AICD ratio of PBL-Ts from CHB patients (with or without induction) was significantly higher than that from healthy control (Table 1).

Results of cytokine detection

Activated T lymphocytes may produce plentiful endogenous cytokine. Th_1 mainly produces IFN-γ, IL-2 and TNF-α. But Th_2 mainly produces IL-4, IL-5, IL-6, IL-10, etc. Cytokine IFN-γ, IL-10 were detected in this test. In all groups, the density of INF-γ in culture media of healthy control with induction group was the highest, and the patient in groups with induction was the lowest. But there was no difference among these groups in density of IL-10 (Table 2).

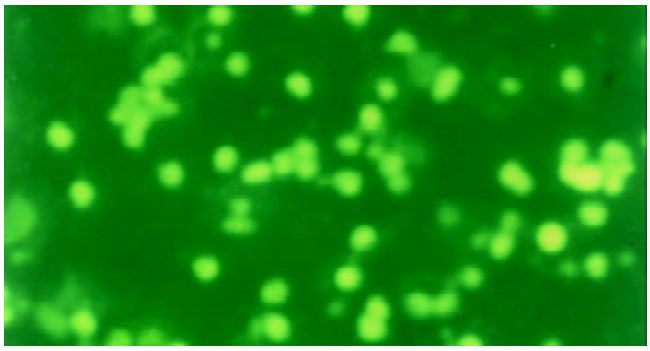

Figure 1 PBL-T with AICD took on kelly fluorescence and the cell without AICD did not take on any fluorescence (TUNEL staining, 200×, fluorescence microscope).

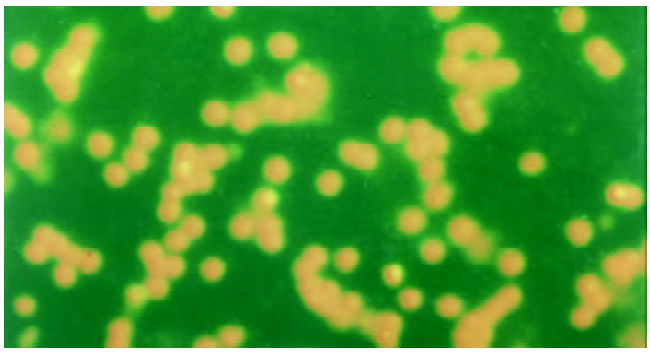

Figure 2 The plasm of PBL-T with AICD took on red fluorescence and the nucleus took on kelly fluorescence. But the cell without AICD only took on red fluorescence (TUNEL and PI double staining, fluorescence microscope, 200×).

Table 1 AICD ratio of each group ($\bar{x}\pm s$)

Group	*n*	AICD Ratio (%)
Patient with induction	26	$17.24\pm1.21^{a,b,c}$
Patient without induction	26	9.88 ± 1.36^{b}
Healthy control with induction	15	6.63 ± 1.00^{c}
Healthy control without induction	15	6.44±1.01

$^aP<0.01$ (F=164.34) *vs*. other groups; $^bP<0.01$ (F=660.45) *vs*. healthy control groups; $^cP<0.01$ (F=326.37) *vs*. without induction groups.

Table 2 The density of IFN-γ and IL-10 from medium of each group ($x\pm s$, pg·mL^{-1})

Group	*n*	IFN-γ	IL-10
Patient with induction	26	$728.32\pm149.59^{a,b,c}$	175.75 ± 34.65^{d}
Patient without induction	26	$1\,313.35\pm403.98^{b}$	74.48±37.21
Healthy control with induction	15	$2\,255.18\pm465.56^{c}$	188.86±66.26

DISCUSSION

Chronic HBV infection is mainly related to the immune function of patients. In a large degree, immune tolerance, especially neonatal immune tolerance, results in persistence of chronic HBV infection. Because naive T cells are sensitive to Fas-mediated AICD and more easily deleted by Ag restimulation than primed T cells[4]. AICD of PBL-Ts plays a key role in central and peripheral immune tolerance[5,6]. AICD is one kind of apoptosis of reactivated lymphocytes when these lymphocytes are induced by activation signals (especially by complex of TCR/CD_3). Ashwell and his colleagues first detected the AICD phenomenon in 1987 when they studied T lymphocyte hybrid tumors. AICD plays an important role in the negative selection of T lymphocytes in thymus, peripheral elimination and clearance of T lymphocytes that have already cleaned the foreign antigens. Therefore, AICD is an important mechanism in maintaining immunoregulation and achieving immune system homeostasis[6,7]. If one' s AICD mechanism is disordered (up-regulation or down-regulation), immune tolerance or autoimmune disease would occur.

In this experiment, AICD of PBL-Ts was successfully induced using anti-CD3 mAb, PMA and ionomycin. The responses of PBL-Ts from CHB and healthy control were different. The results indicated that when induced with anti-CD3, PMA and ionomycin *in vitro*, AICD ratio of PBL-Ts from CHB patients was significantly higher than that from healthy control and that from CHB patients without induction. But there was a similar AICD ratio of PBL-Ts between induction group and healthy control without induction. The results imply that AICD exists in PBL-Ts of CHB and causes decrease of T lymphocytes especially Th_1 cells and functional defect. Specific immune response aiming directly at HBV should not occur. Finally, immunology tolerance to HBV would occur. Ji *et al* using staphylococcus aureus enterotoxin B and rHBcAg proved that AICD of PBMCs in patients would lead to persistent infection of HBV[8].

Reduction of deferent cytokines in culture medium implies apoptosis of deferent subtype T lymphocytes, because the types of cytokine secreted by Th1 and Th2 are different. The detection results revealed that the density of INF-γ in culture media of induction groups from CHB was lower than that of other groups ($P<0.01$). There was no difference between these groups in density of IL-10 ($P>0.05$). These results imply AICD cells are mainly Th1 cells.

After infection of HBV, the virus elimination depends on specific cell immunity of the body. Mostly, specific cell immunity responses are induced by Th1 lymphocytes, but humoral immunity responses are induced by Th2 type lymphocytes. The sensitivity of the two types of T lymphocytes is not equal. The occurrence of AICD is easily induced by Th1 but not Th2 when induced by Anti-CD3 and corresponding antigen[9-11]. Fan *et al* have proved that enhanced Th2 responses are present in chronic HCV infection, and this should be responsible for the persistent HCV infection[12-14]. So, if specific PBL-Ts of CHB are reactivated by HBV antigens, AICD would occur mostly in Th1 type lymphocytes. Thus, specific cell immunity response aiming directly at HBV would be defective, and HBV permanent infection would occur. However, it would be a possible method to surmount immune tolerance and to clean HBV of CHB patients that we have managed to block the apoptosis of activated T lymphocytes[6,15] and raise the amount of specific T lymphocytes.

Abstract

AIM: To study the therapeutic efficacy of temporary partially-covered metal stent insertion on benign esophageal stricture.

METHODS: Temporary partially-covered metal stent was inserted in 83 patients with benign esophageal stricture. All the patients had various dysphagia scores.

RESULTS: Insertion of 85 temporary partially-covered metal stents was performed successfully in 83 patients with benign esophageal stricture and dysphagia was effectively remitted in all the 83 cases. The dysphagia score was 3.20±0.63 (mean±SD) and 0.68±0.31 before and after stent insertion, and 0.86±0.48 after stent removal. The mean diameter of the strictured esophageal lumen was 3.37±1.23 mm and 25.77±3.89 mm before and after stent insertion, and 16.15±2.96 mm after stent removal. Follow-up time was from 1 week to 96 months (mean 54.26±12.75 months). The complications were chest pain (n=37) after stent insertion, and bleeding (n=12) and reflux (n=13) after stent removal.

CONCLUSION: Temporary partially-covered metal stent insertion is one of the best methods for treatment of benign esophageal stricture.

INTRODUCTION

Benign esophageal stricture is a common complication in esophageal diseases. Balloon catheter dilation under X-ray was previously the most common treatment for benign esophageal stricture. Its short-term curative efficacy is good, but it does not last long. The development in stenting techniques has led to the increased application of stents in benign esophageal stricture. However, because of the relatively high incidence of complications and the difficulty of handling those complications, it is preferable to use stents with discretion. Here we report our experiences in using temporary partially-covered metal stent insertion in 83 patients with benign esophageal stricture.

MATERIALS AND METHODS

Materials

Eighty-three patients (48 males, 35 females, age 18-82 years) came to our clinic due to dysphagia. A dysphagia score was assessed by the quality of swallowing[1,2]. Grade 0 is for normal swallowing, grade 1 for swallowing most solid food, grade 2 for swallowing semisolids, grade 3 for swallowing liquid food only, and grade 4 for complete dysphagia. The dysphagia score of the 83 patients was 3.20±0.63 (mean±SD), and the causes of stricture were achalasia of cardia (n=70), anastomotic stenosis (n=5), sclerotic stricture due to ingestion of corrosive agents (n=3) and simple sclerosis stricture after radiation therapy for esophageal carcinoma (n=5). The diagnoses were made by an upper gastrointestinal contrast examination using barium-meal radiography and gastroscopic assessment. The mean diameter of the strictured esophageal lumen was 3.37±1.23 mm in the 83 patients with partially-covered metal stent insertion.

Methods

The preparation before stent insertion involved ensuring an empty stomach for at least 4 hours, testing of the bleeding and clotting times, and intramuscular injection of ataractics before interventional procedure. The stent made from nitinol (a nonmagnetic Ni-Ti alloy) by Chinese manufacturers (Zhiye Medical Instruments Corporation, Changzhou, China, and Youyan Yijin Advanced Materials Co.Ltd, Beijing, China) has a length of 4-12 cm and a diameter of 16-30 cm. Its surface is covered with silica gel. The savary conical silica-gel dilator has a diameter of 0.5-2 cm, and contrast medium.

The patients were placed in a sitting position or lying on the side during the stent-placement operation, and false teeth were removed and dental pads were placed. A 260-cm-long exchange guidewire was inserted into the stomach. Along with the guidewire, the nitinol stent was installed in the propeller. After the propeller was pushed to the stricture segment, the mantle annular tube was retracted, after which the stent would automatically expand. After stent expansion, barium-meal radiography was routinely used to examine the stent position and the dilated stricture. Three to seven days after stent deployment, 500-1 000 ml of ice-cold water was poured into the side hole of a gastroscope. A protractor was then used to loosen the stent from its surroundings and was then connected to the stent orifice. The stent orifice shrank when we contracted the protractor, and then the stent was removed along with the gastroscope. After that, a gastroscope was again inserted to examine bleeding and mucosa tearing membranes. The patients were allowed to consume cold food for the first 2 days after interventional procedure, and resumed a normal diet afterwards. Within 1 week, barium-meal examination was used to observe the intraluminal patency and swallowing function.

one-month, 6-months, and 1-year follow-ups were recommended.

RESULTS

We inserted 85 temporary partially-covered metal stents in 83 patients with esophageal stricture, which were removed 3-7 days later. The placement and removal of stents were successful in 100 % of cases. Immediately after placing the stent, we performed an esophageal contrast examination, which confirmed good stricture patency. The mean diameter of the esophageal lumen was 25.77±3.89 mm after stent insertion, and 16.15±2.96 mm after stent removal. The dysphagia score was 0.68±0.31 after stent insertion, and 0.86±0.48 after stent removal. The mean follow-up time was 54.26±12.75 months (range 1 week-96 months). The complications immediately after stent insertion were chest pain (37 cases). After stent removal, 12 cases had a small amount of bleeding and 13 had reflux. All these complications were managed effectively. Temporary partially-covered metal stent insertion and removal were obviously effective on the esophageal stricture and dysphagia.

DISCUSSION

The short-term effect of balloon dilation on esophageal benign stricture was good, but its mid-term and long-term curative effect was not ideal. In 1990 Domschke *et al*[1] first reported an expandable stent used in malignant esophageal strictures. Since then different types of stent have been developed and applied to the gastrointestinal system[2]. In 1993 Cwikiel *et al*[3] reported the application of silica-gel-covered stent in benign esophageal strictures. The covering of the stent was found to be effective against recurrence of esophageal stricture[4-39]. Because covered stents would migrate, they have not been widely used for some time. However, patients with uncovered stents exhibited more complications such as reflux, stricture recurrence (hyperplasia of granulation tissue), and pain. There is no effective way to manage these complications, which impacts on the long-term curative effect. The worse thing for cases was that another surgical operation was sometimes required to resect the stricture section and the stent placed previously. In order to solve these problems, we used temporary partially-covered metal stent insertion in benign esophageal stricture[40]. The follow-up time was approximately 8 years. The curative effect was long-lasting, dysphagia was clearly palliated, and complications were reduced and easy to manage. Temporary partially-covered metal stent insertion was effective on benign esophageal stricture. Our follow-up investigations revealed that the mid-term and long-term curative effect of temporary stent insertion was better than that of balloon dilation and permanently uncovered or antireflux covered or partially-covered metal stent[41-48]. Our results demonstrated that it was unnecessary to perform graded diameter increment in such stents, unlike when dilating the balloon catheter. Its necessity could be decided based on the follow-up data. After stent insertion, the complications of pain and reflux due to dilating the esophageal stricture by the stent were mainly caused by the chronic tissue tearing of the layer of esophageal muscle and the damage to the original anatomy of the stomach cardia. The stent continued to expand until it reached to body temperature. Since this took 16-24 hours, the tearing of the esophageal muscle tissue was relatively regular and comparatively less scar tissue was formed. Therefore, the recurrence of stricture was low, unlike in balloon dilation which caused acute and irregular tearing on the layer of esophageal muscle, and a corresponding high recurrence of stricture. This is one reason why the method of temporary partially-covered metal stent insertion in benign esophageal stricture is better than that of balloon dilation. We used uncovered stents in patients with benign esophageal strictures in order to reduce the occurrence rate of stent migration. After stent placement, dilation was excellent and dysphagia disappeared, thus achieving the goal of treatment. However, it was accompanied by new problems such as gastroesophageal reflux and recurrence of stricture (hyperplasia of granulation tissue). The reflux could be treated with drugs, but this took a long time. Recurrence of stricture could be reduced by heat cauterization under gastroscope, but it could easily reccur. When we used antireflux covered stent, compications of gastroesophageal reflux and hyperplasia of granulation tissue were not found, but many unexpected results occurred. Comparative studies and experimental research are recommended to further explore the recurrence mechanisms. Further research and development of new stents that are biodegraded by esophageal organism within 2 months after insertion would improve their curative effect, and provide a new therapeutic method for benign esophageal stricture[49]. With further developments in molecular biology, application of gene therapy in the treatment of benign esophageal stricture is expected.

Abstract

AIM: To investigate the antiproliferative effect of octreotide, a long-acting analogue of somatostatin, on gastric cancer cell line SGC7901 and its possible molecular mechanisms.

METHODS: Gastric cancer cell line SGC7901 employed in the study was treated with 0.008, 0.04, 0.2, 1, 5 and 25 $\mu g \cdot ml^{-1}$ of octreotide respectively for 24 h to evaluate the antiproliferative effect of somatostatin analog on the tumor cells by MTT assay method. To elucidate the underlying mechanism, the cells were exposed to 1 $\mu g \cdot ml^{-1}$ of octreotide for 0, 12, 24 and 48 h, when their Akt/PKB and telomerase activities were respectively determined using PCR-ELSIA and nonradioactive protein kinase assay protocols. The same experimental procedures were also performed in the control cells that were treated with corresponding vehicles instead of somatostatin analog.

RESULTS: After exposed to octreotide for 24 h at the concentrations of more than 1 $\mu g \cdot ml^{-1}$, SGC7901 cells exhibited a dose-dependent inhibition of growth with the inhibiting rate to be as high as 34.66 % when 25 $\mu g \cdot ml^{-1}$ of octreotide was applied. The Akt/PKB and telomerase activity of SGC7901 cells was significantly inhibited when the cells were exposed to 1 $\mu g \cdot ml^{-1}$ of octreotide for 12, 24 and 48 h compared with that of their control counterparts ($P<0.01$), both of which exhibited in a time-dependent manner.

CONCLUSION: The antiproliferative effect of octreotide on SGC7901 cells might be mediated by the inhibition of Akt/PKB and telomerase.

INTRODUCTION

Gastric cancer continues to be one of the most common malignancies in human worldwide[1-4]. In China, its average rate of annual mortality is estimated to be as high as 16 per 100 000 population that accounts for the leading cause of death among malignant tumors[5-7]. Due to the limited efficacy and considerable toxicity of conventional chemotherapy, some novel cytotoxic and noncytotoxic agents such as certain dietary substances, natural hormones and synthetic compounds have been proposed to stop or reverse the process of carcinogenesis[8], in which increasing attention has been paid to somatostatin and its analogs that have been reported to exert antineoplastic effects in a wide range of tumor types such as carcinoid, osteosarcoma, leukemia, and cancers of thyroid, breast, lung, liver, pancreas, colon, as well as gastric carcinomas[9-19]. However, detailed mechanisms underlying the antineoplastic actions of somatostatin and its analogs that remain to be clarified have limited the therapeutic efficacy of these agents in the treatment of clinical malignancies[20, 21].

Recent advances in molecular biological science have revealed that some molecules such as telomerase and protein kinase B or Akt (PKB/Akt) are involved in the process of carcinogenesis. Telomerase is an enzyme that replaces repetitive (TTAGGG)n sequences on the ends of chromosomes that would otherwise be lost during successive cell divisions. Its activation is closely linked to the attainment of cellular immortality and considered to be an important step in tumorigenesis[22-26]. Another molecule PKB/Akt, a serine/threonine kinase, has also recently been a focus of intense research. It appears that Akt/PKB lies in the crossroads of multiple cellular signaling pathways and acts as a transducer of many functions initiated by growth factor receptors. It is particularly important that Akt/PKB can mediate cell survival and serve as a critical factor in the genesis of malignancies[27-30]. Thus, an investigation to clarify how the antiproliferative effects on these couple of molecules might be helpful in elucidating antineoplastic mechanisms of somatostatin analogs, which is no doubt of both theoretical and practical importance.

MATERIALS AND METHODS

Materials

Human gastric cancer cell line SGC7901 was obtained from Shanghai Institute of Cell Biology, Chinese Academy of Sciences. Somatostatin analogue octreotide was provided by Sandoz Corp, RPMI1640 and fetal bovine serum (FBS) were from Gibco. 3-(4,5-dimethyl thiazol-2- yl)-2, 5-diphenyl tetrazolium bromide (MTT), telomerase TRAP PCR-ELISIA kit and Akt/PKB kinase assay kit were purchased from Sigma, Roche Molecular Biochemicals and CST respectively. Microtiter plate reader was made by Digiscan, Austria ASYS Hitech.

Cell culture

SGC7901 cells were maintained in flasks with RPMI-1640 supplemented with 10 % heat- inactivated FBS, 100 $U \cdot ml^{-1}$ penicillin, 100 $U \cdot ml^{-1}$ streptomycin and 20 mM sodium bicarbonate at 37 ℃ in a humidified atmosphere containing 5 % of CO_2. The culture medium change was performed every 3 days.

MTT assay

A MTT assay was conducted to determine the cell proliferation. In brief, SGC-7901 cells were seeded at $5\times10^3 \cdot$ $wells^{-1}$ in a 96-

well plate and incubated in 200 μl of culture medium overnight. Then the cells were made quiescent by serum deprivation and treated with 0.008, 0.04, 0.2, 1, 5, 25 $\mu g \cdot ml^{-1}$ of octreotide respectively as the different observatory groups. The cells treated with equal amount of normal saline instead of octreotide served as the control. After cultivated for 24 h, 20 μl of stock MTT solution (2.5 $mg \cdot ml^{-1}$) was added to cells for each well which were further incubated at 37 ℃ for 4 hours. The culture medium was carefully removed followed by adding of 150 μl of DMSO to each well and vibrating culture well for 10 min. The absorbance of samples was measured at a wavelength of 490 nm with a microtiter plate reader. The negative control was conducted using only cell-free culture medium and each assay was performed in triplicate. The inhibiting rate of cell growth was expressed as (A-B)/A×100 %, where A is the absorbance value from the controls and B is that from the experimental cells.

Immunoprecipitation kinase assay

Akt/PKB activity was examined by the immunoprecipitation kinase assay. Briefly, 5×10^5 of SGC7901 cells were seeded in a 25-cm^2 flask and cultured for 3 days. When being confluent at 70 %, cells nominated as group A were incubated in serum-free RPMI-1640 for 24 h and then treated with 1 $\mu g \cdot ml^{-1}$ octreotide for further cultivation of 0-, 12-, 24- and 48-h respectively. Same procedures were also performed in group B cells that served as the control except being treated with equal volume of normal saline instead of octreotide. Confluent cells were washed three times in cold PBS, then lysed in buffer containing 20 $mmol \cdot L^{-1}$ Tris-HCl (pH 7.5), l50 $mmol \cdot L^{-1}$ NaCl, 1 % Triton X-l00, 1 $mmol \cdot L^{-1}$ EDTA, 1 $mmol \cdot L^{-1}$ EGTA, 2.5 $mmol \cdot L^{-1}$ sodium pyrophosphate, 1 $mmol \cdot L^{-1}$ β-glycerophosphate, 1 $mmol \cdot L^{-1}$ Na_3VO_4, 1 $\mu g \cdot ml^{-1}$ leupeptin and 1 $mmol \cdot L^{-1}$ phenyl-methyl-sulfonyl fluoride (PMSF) for 10 min at 4 ℃. Samples were microcentrifuged for 10 min and 200 μl of the cell lysate was incubated with 20 μl of resuspended immobilized Akt antibody slurry at 4 ℃ for 2 h to immunoprecipitate Akt/PKB, the latter was next used to phosphorylate a specific substrate, GSK-3 fusion protein (Ser21/9). That is, 1 μg of GSK-3 fusion protein was incubated with immunoprecipitated Akt/PKB in the presence of ATP for 30 min at 30 ℃ followed by adding 20 μl of 3×SDS sample buffer to terminate the reaction. Samples were then boiled for 5 min, separated by 12 % SDS-PAGE and transferred onto nitrocellulose membrane. Nonspecific reactivity was blocked by 5 % fat-free milk in TBST (10 mM Tris-HCl, pH7.5, l50 mM NaCl, 0.05 % Tween 20) for 1 h. The membrane was incubated with a 1:1 000 dilution of phospho-GSK-3 α/β antibody for 2 h, then with HRP-conjugated anti-rabbit (1:2 000) and anti-biotin antibody (1:1 000) for 1 h at room temperature. Finally, reactive protein was revealed by incubating with 10 ml of LumiGLO for 1 min and exposed to x-ray film for 1-2 min at room temperature.

Determination of telomerase activity

The telomerase activity was determined by using TRAP-ELSIA. 5×10^5 of SGC7901 cells were seeded in a 25-cm^2 flask and cultured for 3 days. When being confluent at 70 %, cells nominated as group A were incubated in serum-free RPMI-1640 for 24 h and then treated with 1 $\mu g \cdot ml^{-1}$ octreotide for further cultivation of 0-, 12-, 24- and 48-h respectively. Same procedures were also performed in group B cells that served as the control except being treated with equal volume of DMSO instead of octreotide. Confluent cells were harvested and centrifuged at 3 000 g for 10 min at 4 ℃. After resuspended, 5×10^3 cells were lysed in an Eppendorf tube, whose extract was next used to amplify telomeric repeat. The telomerase activity was determined with PCR-ELISA according to the manufacturer' s protocol. Sample absorbance was measured with a microtiter plate reader at the wavelength of 450/690 nm within 30 min after addition of the stop reagent.

Statistical analysis

Experimental data were analyzed by ANOVA and Student' s *t* test for multiple comparisons between groups. The data were finally expressed as mean ± standard error of the mean. *P* value less than 0.05 was considered statistically significant.

RESULTS

Antiproliferative effect of octreotide on SGC7901 cells

When exposed to octreotide for 24 h at the concentration of more than 1 $\mu g \cdot ml^{-1}$, SGC7901 cells exhibited a dose-dependent inhibition of growth with the inhibiting rate to be as high as 34.66 % when 25 $\mu g \cdot ml^{-1}$ of octreotide was applied (Table 1).

Table 1 Antiproliferative effect of octreotide on SGC7901 cells

Octreotide (μg / ml)	OD_{490}	IR (%)
Control	0.528±0.032	/
25	0.345±0.041	34.66[b]
5	0.436±0.022	21.21[b]
1	0.465±0.019	11.93[a]
0.2	0.493±0.008	6.63
0.04	0.510±0.031	3.41
0.008	0.504±0.065	0.76

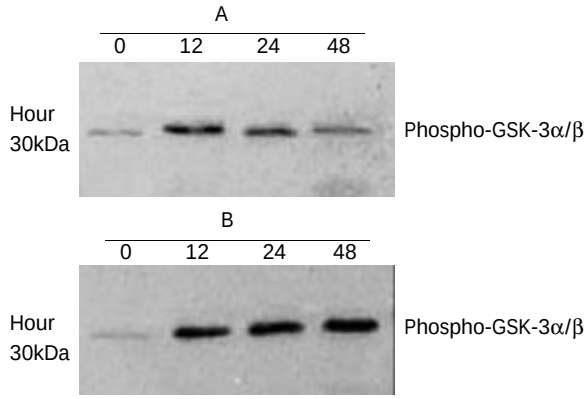

Figure 1 Inhibitory effects of octreotide on Akt / PkB activity in SGC7901 cells. The Akt / PKB activity in group A SGC7901 cells was significantly inhibited after the cells were exposed to 1 $\mu g \cdot ml^{-1}$ of octreotide for 12, 24 and 48 h compared with that of their control counterparts (Figure 1B), which manifested in a time-dependent manner as shown in Figure 1A.

Inhibition of Akt/PKB activity

The Akt/PKB activity in group A SGC7901 cells was significantly inhibited after the cells were exposed to 1 $\mu g \cdot ml^{-1}$ of octreotide for 12, 24 and 48 h compared with that of their control counterparts (Figure 1B), which exhibited in a time-dependent manner as shown in Figure 1A.

Inhibition of telomerase activity

Just like that of the Akt/PKB, the telomerase activity in group A SGC7901 cells was also significantly inhibited after the cells were exposed to 1 $\mu g \cdot ml^{-1}$ of octreotide for 12, 24 and 48 h compared with that of their control counterparts (*P*<0.01), which exhibited in a time- dependent manner as shown in Figure 2A.

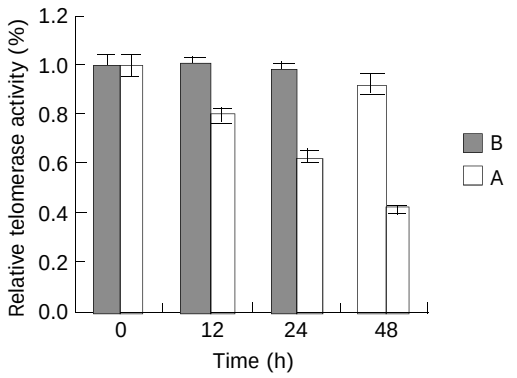

Figure 2 Inhibitory effects of octreotide on telomerase activity in SGC7901 cells. The telomerase activity in group A SGC7901 cells was significantly inhibited after the cells were exposed to 1 μg· ml^{-1} of octreotide for 12, 24 and 48 h compared with that of their control counterparts (P<0.01), which exhibited in a time-dependent manner as shown in Figure 2A.

DISCUSSION

Over the past decade, impressive antineoplastic effects of somatostatin and its analogs have been reported in plenty of tumor models and cancer cell types[9-19]. A more recent research has further provided considerable information regarding the mechanisms underlying the antiproliferative and apoptosis-inducing actions of these compounds. These included both "direct" mechanisms that were the sequellae of binding of somatostatin analogs to their corresponding receptors present on neoplastic cells and "indirect" mechanisms that might be the result of reduced or inhibited secretion of growth-promoting hormones and growth factors that stimulated the growth of various types of malignancies[21,31-33]. Apart from these discoveries, some biological actions such as the inhibition of angiogenesis and the negative influence on the immune system were also considered to be the important factors contributing to the antineoplastic effects of somatostatin analogs[21, 34], which therefore suggested that the latter might be involved in an even wider mechanism.

In the present study, we observed the inhibitory effects of octreotide on gastric cancer SGC7901cells, as well as on the activities of Akt/PKB and telomerase. As to our knowledge, it is one of the fewer reports in recent years that concerned about this subject. It revealed that after exposed to octreotide for 24 h at the concentration of more than 1 μg· ml^{-1}, SGC7901 cells exhibited a dose-dependent inhibition of growth with the inhibiting rate to be as high as 34.66 % when 25 μg· ml^{-1} of octreotide was applied. Furthermore, in a previous study, we also noted that this inhibitory action could not be abrogated by supplementing 10 % FBS to the cultured cells, which only prolonged the time course of cell death (data to be published). It indicated the mitogenic action provided by serum growth factors in the culture medium could be overcome by octreotide. Akt/PKB and telomerase are the enzymes that have recently been considered to be closely related to carcinogenesis[22-30]. Whether the activation of Akt/PKB was one of the critical factors in cell to determine either a survival or an apoptotic message was conducted on the signal passway[35]. Amplification of genes encoding Akt/PKB isoforms has been found in several types of human cancers[36]. In addition, Akt/PKB has been reported to promote tumor progression and invasiveness by enhancing angiogenesis[28]. So far as the telomerase is concerned, its activity has been detected in over 90 % of human cancers[37-41], In gastric cancer, telomerase was activated very early in the process of this disease[42], which suggested the activation of telomerase might be also a determining factor contributing to the tumorigenesis. The relationship between Akt/PKB and telomerase has also been noted by Kang and his coworkers[43] with the founding that Akt kinase enhanced human telomerase activity through phosphorylation of hTERT subunit as one of its substrate proteins in SK-MEL28 cells. In the present study, we found that both activities of Akt/PKB and telomerase in SGC7901 cells were significantly inhibited after the cells were exposed to 1 μg· ml^{-1} of octreotide for 12, 24 and 48 h compared with that of their control counterparts. Based on these findings, it can be concluded that the antiproliferative effects of somatostatin analogs on SGC7901 cells might be mediated at least in part via a mechanism of inhibition of Akt/PKB and then telomerase. Our further study should aim at elucidating the components on the signal conduction passway in up and downstreams of these events.

Abstract

AIM: To study the molecule action mechanisms of NM-3 on the growth of human gastric cancer SGC-7901 cells *in vivo* or *in vitro*.

METHODS: SGC-7901 from human non-differentiated gastric cancer cell line was cultured with NM-3 at 100 mg/ml for 24 h. We observed its inhibitory rate and the density of micro-vascular growth in grafted mice with human gastric cancer SGC-7901. The apoptosis of human gastric cancer SGC-7901 was revealed in NM-3 treatment group by using terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate-fluorescene nick end labeling (TUNEL) method and flow cytometry analysis.

RESULTS: The growth of SGC-7901 cells was markedly inhibited compared with control growp, which was smaller than that in normal saline control group (4.17 g±0.22 g *vs* 9.45 g±1.38 g, $P<0.01$). The level of apoptosis of human gastric cell line SGC-7901 was obviously increased in NM-3 treatment group at 1 mg.L^{-1} for 24 h. NM-3 inducing apoptotic index in NM-3 plus carboplatin group was 3.5 times that of carboplatin control group (TUNEL: 27.98±6.12 % *vs* 12.94±2.12 %, FACScan: 26.86±5.69 % *vs* 11.86±1.09 %, $P<0.01$). Western blot analysis showed that the apoptotic index of human gastric cancer was elevated for 12, 24 and 36 h with an evident time-effect relationship in groups at 100 mg.L^{-1}. NM-3 enhanced the inhibitive effects and sensitivity of chemotherapy for human gastric cancer in nude mice. These results suggested that NM-3 played a key inhibitive role in the growth of grafted human gastric cancer in nude mice.

CONCLUSION: NM-3 can inhibit the growth of human gastric cancer cell line SGC-7901, and enhance the sensitivity of carboplatin on SGC-7901 and induced its apoptosis.

INTRODUCTION

Apoptosis plays a key role in the proliferation and turnover of malignant tumor cells. It has been known that its extent is often enhanced in gastric cancer by some anti-cancer drugs, such as chemotherapeutic drugs, hormones or immune agents, micro-vascular growth inhibitors have been proved to have some inhibitory effects on maligant tumors,especially on gastric tumors. But it has not been clear whether NM-3 is a micro-vascular inhibitive agent for solid tumor growth[1-3], it might suppress gastric cancer cell proliferation and cause tumor cell loss and nuclear condensation *in vitro*. Up to date, NM-3 is considered as the newest micro-vasular inhabitor[1-4]. Combined with carboplatin, it can soften hard lumps and dissolve phlegm, enhance apoptosis of human gastric cancer xenografts in nude mice. On the other hand, NM-3 can enhance the sensitivity of chemotherapeutic drugs on human gastric cancer. Based on previous studies, NM-3 exerts its effects on solid tumor growth by promoting apoptosis of human gastric cancer cell SGC-7901 and increasing the suppressive effects of carboplatin.

MATERIALS AND METHODS

Materials

A human gastric cancer cell line SGC-7901 grafted onto nude mice was used as the animal model, the age of these 60 mice was 6-7 weeks old female balb/c-nu/nu mice (weight 18-22 g) and a human gastric cancer cell line SGC-7901 was obtained from Shanghai Tumor Institute (No: 01842). The animals were subcutaneously xerografted under abdominal skin with the SGC-7901 cell line. The tumor transplantation procedure was described previously. The animal model and SGC-7901 cell line were obtained from Shanghai Experimental Animal Centre, Chinese Academy of Sciences.

NM-3 was composed of 2-c8-hydroxy-6-methoxy-1-oxo-1 h-2-benzopyran-3-yd, concentrantion of NM-3 was 100 mg· L^{-1}, the concentration of carboplatin was 100 mg· L^{-1}.

Methods

Experimental schedule: After grafting, these nude mice were randomly divided into 3 groups: control group and two experimental groups assigned to receive NM-3 or carboplatin respectly. Each experimental mouse in two experimental groups was given a 0.5 ml dose of NM-3 drug via intra-abdominal injection or gastric perfusion (empty control group) once every three days over a 40-day period beginning at 1st day after being xerografted. The control animals received normal saline according to the same schedule by gastric perfusion. The animals were killed 41 days after being xerografted.

In our study, NM-3 induced gastric cancer cell apoptosis, and enhanced the chemotherapeutic sensitivity of human gastric cancer cell line SGC-7901 on carboplatin *in vitro*. Apoptosis induced by NM-3 needed further investigation.

Therapeutic effects on human gastric cancer cell growth were assessed. Tumor size was measured twice a week by multiplying two perpendicular diameter and tumor weight was determined immediately by electron balance after the animals were killed. Apoptotic cells and apoptotic index were

determined by the terminal deoxynucleotidyl transferase-mediated deoxy-uridine triphosphate-fluorescene nick end labeling (TUNEL) method and flow cytometry analysis. Morphological atterations were observed with electron microscope.

Flow cytometry analysis: Propidium iodide (PI) staining was used for flow cytometric detection of apoptosis. 1×10^6 cells from each of the samples were treated with RNase and stained with PI.The apoptotic cells labled by DNA strand were measured with a flow cytometer (FACS Calibur,Becton Dickinson,U.S.A).The data from 1×10^6 cells/sample were collected,stored,and analyzed using CELLQUES' T and MODFITLT for macV1.01 software[4-12].

Statistical analysis

The results were expressed as $\bar{x}\pm s$, Student' s *t* test was used. *P* value <0.05 was concidered significantly.

RESULTS

NM-3 inhibited growth of micro-vascular of tumor in nude mice with human gastric cancer SGC-7901

NM-3 group decreased signicantly the neo-microvascular density (1.17±0.05 mm^3) of gastric cancer tumor implanted onto nude mice was significantly decreased in NM-3 group compared with that in saline group (5.37±1.12 mm^3) and carboplatin group (4.72±1.18 mm^3, $P>0.05$). The micro-vascular density in NM-3 combinated with carboplatin group (1.18±0.05 mm^3) was not significantly different from that in NM-3 group ($P>0.05$, Table 1).

Table 1 Growth of neo-microvascular around gastric tumor supressed by NM-3 ($\bar{x}\pm s$)

Treatment	*n*	Density (mm^3)
Carboplatin	10	4.72±1.18[a]
NM-3 plus carboplatin	10	1.18±0.05[b]
Saline	10	5.37±1.72

[a]$P>0.05$, [b]$P<0.01$ *vs t* test in saline control group.

NM-3 enhanced sensitivity of carboplatin on human gastric cancer induced by apoptosis of human gastric cancer cell in vitro or in vivo

The apoptotic indix (AI) of SGC-7901 induced by carboplatin was enhanced in NM-3 group. The apoptotic indix (TUNEL: 27.98±6.12 %, FACScan: 26.86±5.69 %) was markedly increasd in that of carboplatin group by using either TUNEL method or flow cytometry analysis compared with the carboplatin group (TUNEL: 12.94±2.12 %, $P<0.01$; FACScan: 11.86±1.09 %, $P<0.01$). The apoptotic indix in NM-3 group (TUNEL: 16.47±4.13 % FACScan: 15.97±1.49 %) was higher than that in normal saline group (TUNEL 1.83±0.12 %, $P<0.01$; FACScan: 1.06±0.09 %, $P<0.01$, Table 2).

Table 2 Apoptotic indix (AI) of human gastric cancer line SGC-7901 enhanced by NM-3 *in vitro* ($\bar{x}\pm s$)

Treatment	*n*	AI (TUNEL)%	AI (FACScan) %
NM-3	10	16.47±4.13[b]	15.97±2.49[b]
Carboplatin	10	12.94±2.12[b]	11.86±1.09[b]
NM-3 plus carboplatin	10	27.98±6.12[b]	26.86±5.69[b]
Saline	10	1.83±0.12	1.06±0.09

[a]$P>0.05$, [b]$P<0.01$ *vs t* test, in saline control group.

NM-3 effected on growth of xerografted human gastric cancer cell line SGC-7901 in nude mice

The tumor weight of nude mice in NM-3 group (4.17±0.22 g) was obviously lower than that in normal saline controls (9.45±0.38 g), the tumor size of the prior group (0.68 g±0.07cm^3, $P<0.05$) was smaller than that in normal saline control group (8.94±1.46 cm^3). The tumor weight and size of nude mice in NM-3 combinated with carboplatin group were 2.78±0.18 g and 0.34±0.02 cm^3 respectively. However, those in NM-3 group were not significantly different compared with carboplatin group (4.46±0.23 g, 0.71±0.08 cm^3) 7 weeks later. Tumor growth was (size and weight) markedly inhibited by treatment with NM-3 ($P<0.01$). The tumor inhibitory rate of single NM-3 on tumors was 67.7 %, that in NM-3 combinated with carboplatin group was up to 98.7 % (Table3).

Table 3 Growth of xerografted human gastric tumor affected by NM-3 in nude mice ($\bar{x}\pm s$)

Treatment	*n*	Weight (g)	Size (cm^3)
NM-3	10	4.17±0.22[a]	0.68±0.07[a]
Carboplatin	10	4.46±0.23[a]	0.71±0.08[a]
NM-3 plus carboplatin	10	2.78±0.18[b]	0.34±0.02[b]
Saline	10	9.45±1.38	8.94±1.46

[a]$P<0.05$, [b]$P<0.01$ *vs t* test, in saline control group.

DISCUSSION

Gastric cancer remains one of the most common causes of cancer-related death in the world. At present, gastric cancer is still diagnosed at its advanced stage in most patients throughout the world. Even with curative resection, they remain at a high risk of relapse[13-32]. Thus, there is a great need for effective adjuvant therapy for patients with gastric cancer. Our previous clinic paired comparative studies suggested that NM-3 had therapeutic effects on advanced gastric cancer. It could increase the surviving period of the patients, improve the life quality and increase the metastasis and recurrence after operation because of its lower toxic side-effect compared with intravenous chemical therapy[33-47]. Up to date, the effect of NM-3 on human gastric cancer has not been reported in the world. So we thought it is worth to make a further research on its anti-cancer mechanisms.

Gastric cancer is not only a disease with abnormal cell proliferation and differentiation, but also a disease with abnormal apoptosis. Enhanced apoptosis in human gastric cancer cells could be observed after treatmemt with 5-fluorouracil, cisplatin, arsenous oxide, *etc*. These data suggest that it is a therapeutic method for patients with gastric cancer to induce apoptosis of cancer cells[64]. The present study indicated that tumor growth was significantly inhibited by treatment with carboplatin or NM-3. The results obtained by TUNEL method and cytometry analysis suggested that gastric cancer cells were suppressed *in vivo*, NM-3 was related to the induction of apoptosis of human gastric cancer cell line SGC-7901. These data suggest that NM-3 can inhibit gastric cell proliferation. So inhibition of gastric cancer induced by NM-3 is also related to the suppression of its proliferation.

Apoptosis is a complex and active cellular process, whereby individual cells are triggered to undergo self-destruction in a manner that would neither injures neghiboring cells nor elicites any inflammatory reation. Various triggering factors initiate corresponding proteo-lysis cascade reaction depending on mitochondrion or APO 1\FAS\CD95 receptors mediate apoptotic pathways. There are oncogenes and tumor suppressor gene products in the regulation and execution of apoptosis.

It has been proved[14-22] that p53, Rb, myc, ras, raf, play important roles in apoptosis and are thus named the guardians of genomes[23-44]. They monitor the state of DNA and cell cycle is blocked in case of DNA damage. This takes place through the induction of CIP/Swaf/p21. In the absence of phosphorylated active cyclin-dependent kinases, the cell cycle remains inactive (unphosphorylated).

This leads to activation of DNA repair machinery. If DNA repair fails, p53 will take over again and trigger apoptosis in a process that involves upregulation of the apoptosis-inducing bax and down-regulation of the apoptotic bal-2[45-60]. We also detected apoptosis-inhibiting member of the bcl-2 family[61-64]: bcl-2 mRNA. The interaction between NM-3 and gastric cancer cell SGC-7901 induced its apoptosis of gastric cancer cells, but further *in vivo or in vitro* studies are needed.

Abstract

AIM: To determine the best method out of the three types of interventional procedure for achalasia based on a long-term follow-up.

METHODS: The study cohort was comprised of 133 patients of achalasia. Among them, 60 patients were treated under fluoroscopy with pneumatic dilation (group A), 8 patients with permanent uncovered or antireflux covered metal stent dilation (group B), and 65 patients with temporary partially covered metal stent dilation (group C).

RESULTS: One hundred and thirty dilations were performed on the 60 patients of group A (mean 2.2 times per case). The mean diameter of the strictured cardia was 3.3±2.1 mm before dilation and 10.6±3.8 mm after dilation. The mean dysphagia score was 2.7±1.4 before dilation and 0.9±0.3 after dilation. Complications in group A were chest pain (n=30), reflux (n=16), and bleeding (n=6). Thirty-six patients (60 %) in group A exhibited dysphagia relapse during a 12-month follow-up, and 45 patients (90 %) out of 50 exhibited dysphagia relapse during a 36-month follow-up. Five uncovered and 3 antireflux covered expandable metal stents were permanently placed in the 8 patients of group B. The mean diameter of the strictured cardia was 3.4±1.9 mm before dilation and 19.5±1.1 mm after dilation. The mean dysphagia score was 2.6±1.3 before dilation and 0.4±0.1 after dilation. Complications in group B were chest pain (n=6), reflux (n=5), bleeding (n=3), and hyperplasia of granulation tissue (n=3). Four patients (50 %) in group B exhibited dysphagia relapse during a 12-month follow-up, and 2 case (66.7 %) out of 3 patients exhibited dysphagia relapse during a 36-month follow-up. Sixty-five partially covered expandable metal stents were temporarily placed in the 65 patients of group C and withdrawn after 3-7 days via gastroscopy. The mean diameter of the strictured cardia was 3.3±2.3 mm before dilation and 18.9±3.5 mm after dilation. The mean dysphagia score was 2.4±1.3 before dilation and 0.5±0.2 after dilation. Complications in group C were chest pain (n=26), reflux (n=13), and bleeding (n=8). 6 patients (9.2 %) out of 65 exhibited dysphagia relapse during a 12-month follow-up, and 8 patients (14.5 %) out of 55 exhibited dysphagia relapse during a 36-month follow-up. All the stents were inserted and withdrawn successfully. The follow-up in groups A-C lasted 12-96 months.

CONCLUSION: Temporary partially covered metal stent dilation is one of the best methods with interventional procedure for achalasia in terms of long-term follow-up.

INTRODUCTION

Achalasia is the most common primary motility disorder of the esophagus. Three interventional procedures are used clinically for achalasia, namely pneumatic dilation, permanent metal stent dilation, and temporary metal stent dilation. These methods provide excellent immediate therapeutic efficacy, but their long-term results are unknow[1,2]. Therefore, we formulated several treatment plans for patients with achalasia from July 1994 to May 2002 and evaluated them in terms of long-term follow-up.

MATERIALS AND METHODS

Materials

The subjects were 133 patients (77 males, 56 females; aged 12-84 years, mean 48.3 years) with symptoms of dysphagia. A dysphagia score was assessed by the quality of swallowing[1,2]: grade 0 for normal swallowing, grade 1 for swallowing most solid food, grade 2 for swallowing semisolids, grade 3 for swallowing liquid food, and grade 4 for complete dysphagia. Based on different methods of interventional procedure, the patients were divided into three groups as follows. In 60 patients with pneumatic dilation (group A), the mean dysphagia score was 2.7±1.4, and the mean diameter of the narrowest region of the cardia was 3.3±2.1 mm. In 8 patients with permanent uncovered or antireflux covered metal stent dilation (group B), the mean dysphagia score was 2.6±1.3, and the mean diameter of the narrowest region of the cardia was 3.4±1.9 mm. In 65 patients with temporary partially covered metal internal stent dilation (group C), the mean dysphagia score was 2.4±1.3, and the mean diameter of the narrowest region of the cardia was 3.1±2.3 mm. The course of disease in all the patients was 1-10 years (mean 5.4±4.4 years). All the patients were examined by barium-meal radiography of the upper digestive tract and gastroscope or esophageal intracavity manometric method.

Methods

Preoperative preparation involved an empty stomach for at least 4 hours and examination of the bleeding and clotting times. The device used was an SY dumbbell-like catheter (manufactured in Jinan, Shandong, China). The metal stent

for achalasia was a nitinol stent (developed by Zhiye Medical Equipment Research Institute, Changzhou, China, and Youyan Yijin Advanced Materials Co.Ltd, Beijing, China). Uncovered and antireflux covered metal stents were used in group B, partially covered metal stents were used in group C. The body of partially covered stents was covered with intracavity silica gel. The areas within 2 cm of both ends of partially covered stents were not covered. Stents were 6-10 cm in length and 16-30 mm in diameter.

The patients in which pneumatic dilation was used were placed in lying on the side or sitting position. Topical anesthesia of the pharynx was administered before the procedure. A guidewire was inserted through the mouth and passed through the stricture section under fluoroscopy. A catheter with a diameter of 28 mm was passed through the region of achalasia of the esophagus via the guidewire, which aligned the center of saccule with the most strictured point. The saccule was injected using an injector with dilated contrast medium or gas. Under fluoroscopy, and according to the pain reaction of the patient, pressurization was applied to gradually dilation of the saccule. The back of saccule was dumbbell-shaped. When further pressurization flattened the surface of saccule or when the pressure did not change as pressurization was applied, pressurization was suspended and the piston was closed off. The pressure of saccule was maintained for 5-30 min, after which the piston was released. After the pressure of saccule had been reduced for 5 min, pressurization was again applied. Typically each treatment involved 3-5 dilations, after which the catheter was withdrawn. The second and third treatments with graded pneumatic dilation were carried out using dilators with diameters of 30 mm and 32 mm, respectively, in some of the patients every 2 weeks until clinical symptoms disappeared and the patients returned to a nomal diet.

When stents were placed in groups B and C, the sites of thoracic vertebra and spine were determined by barium-meal radiography to facilitate the stent placement. Patients were placed in a sitting position or lying on the side, and false teeth were removed and a teeth bracket was mounted. A 260-cm-long exchange guidewire was firstly led into the stomach. The stent was installed on the propeller whose front end was covered with sterilized liquid paraffin. Guided by the guidewire, the propeller on which the stent was mounted was moved through the segment with lesions. Under fluoroscopic control, the outer sheath was slowly withdrawn and the stent expanded under its own tension. After a stent was placed, esophageal radiography was performed to observe the patency of the esophagus. In group C, 500-1 000 ml of ice-cold water was injected 3-7 days after stent placement via a bioptic hole under gastroscope, which caused the stent to retract and reduce its diameter. Bioptic pliers were then used to withdraw the stent with the help of a gastroscope. Gastroscopy was performed again to detect complications, such as bleeding, mucosa tearing, and esophageal perforation. The patients returned to the ward and consumed cold drinks and snacks for 2 days before returning to a normal diet. It was preferable for patients to eat solid food since the natural expansion of food reduced retraction of the esophagus.

The criteria for therapeutic efficacy were as follows: the diameter of the narrowest region of the esophagus before and after dilation, and the dysphagia score before and after dilation. Postoperative treatment of pneumatic dilation, barium-meal radiography of the esophagus was performed immediately after interventional procedure to check the esophagus patency and perforation and submucous hematomas. Patients drank fluids for 2 h after interventional procedure and were treated with antibiotics, antacid drugs, and analgesics. In groups B and C, after stent placement, barium-meal radiography was used to observe the patency of the esophagus. Patients ate semisolid food on the day after interventional procedure and were treated with antibiotics and antacid drugs. In group C, esophageal radiography was performed within 1 week after stent removal to observe the patency of the esophagus. The follow-up time was 1 month, 6 months, 1 year and 3 years by telephone or clinic visit.

All the data were expressed as the mean±SD, and the paired *t*-test was used for statistical comparisons before and after interventional procedure within a group.

RESULTS

The 60 patients in group A involved 130 dilations (mean 2.2 times per case), of which 29 patients had three graded dilations of increasing diameter, 12 patients had two graded dilations of increasing diameter, and 19 patients had one dilation. In 8 patients of group B, 5 uncovered and 3 antireflux covered stents were successfully placed. In group C, 65 partially covered stents were placed and removed under gastroscope guidance 3-7 days after intervertional procedure. The success rate of stent placement and removal was 100 %. The differences in the cardia diameter before and after the three methods of interventional procedure and the dysphagia scores (Table 1) were statistically significant ($P<0.01$). The incidence of complications in the three interventional procedures is presented in Table 2 and the rate of dysphagia recurrence during follow-up is shown in Table 3. The follow-up period for the three interventional procedures was 12-96 months.

Table 1 Diameter of the narrowest cardia region before and after treatment with three interventional procedures, and dysphagia score

Group	Diameter of cardia before and after treatment (mm)		Dysphagia score before and after treatment (grade)	
A	3.2±2.1	10.6±3.8[b]	2.7±1.4	0.9±0.3[b]
B	3.4±1.9	19.5±1.1[b]	2.6±1.3	0.4±0.1[b]
C	3.1±2.3	18.9±3.5[b]	2.4±1.3	0.5±0.2[b]

[b]$P<0.01$ *vs* before and after treatment.

Table 2 Incidence of complications following treatment with three interventional procedures (%)

Group	Pain (*n*)	Reflux (*n*)	Bleeding (*n*)	Hyperplasia of granulation tissue (*n*)
A	50.0 %(30/60)	26.7 %(16/60)	10.0 %(6/60)	-
B	62.5 %(5/8)	62.5 %(5/8)	37.5 %(3/8)	37.5 %(3/8)
C	40.0 %(26/65)	20.0 %(13/65)	12.3 %(8/65)	-

C	65	6	9.2%	55	8	14.5 %

DISCUSSION

Techniques of interventional procedures

The techniques used to treat achalasia, such as surgery, bougienage, pneumatic dilation, botulinum toxin injection, permanently uncovered or antireflux covered metal stent dilation and temporary partially covered metal stent dilation, had advantages and drawbacks[1-5]. Bougienage is now uncommon since it has poor therapeutic efficacy and many complications. The use of surgery is declining due to the associated large lesion, a high risk, and high recurrence rate. Pneumatic dilation was first introduced in the plasty of hematostenosis, as its reliable therapeutic efficacy led to its gradual application to other plasty operations. Remarkable results were achieved when it was used in benign gastrointestinal strictures, and later it was widely used in the nonsurgical treatment of achalasia, exhibiting remarkable therapeutic efficacy. Many authors[6-15] have reported that graded dilation is better than single dilation in therapeutic efficacy, and our experience has confirmed this. Botulinum toxin injection in achalasia had a short term therapentic efficacy, dysphagia was relapsed witnin 6 months.

Permanent metal stent dilation is primarily used in the treatment of malignant gastrointestinal stricture and obstruction, and exhibits remarkable palliative therapeutic efficacy. Cwikiel *et al*[1] reported an experimental and clinical study of the treatment of benign esophageal stricture with expandable metal stents. We used uncovered stents in five patients with achalasia in order to reduce the occurrence rate of stent migration. After stent placement, dilation was excellent and dysphagia disappeared, thus achieving the goal of treatment. However, it was accompanied by new problems such as gastroesophageal reflux, recurrence of stricture (hyperplasia of granulation tissue). The reflux could be treated with drugs, but this took a long time. Recurrence of stricture could be reduced by heat cauterization under gastroscope, but it could easily reccur. So we used antireflux covered stent, compication of gastroesophageal reflux and hyperplasia of granulation tissue were not found, but many unexpected results occurred. These difficulties led to the use of a temporary partially covered metal stent dilation. Clinicians and patients have gradually accepted and now prefer to use temporary partially covered metal stent dilation due to its fewer complications and excellent therapeutic efficacy[16-22].

Long-term follow-up

Dysphagia recurred in 60 % of the patients at a 12-month follow-up, and in 90 % of the patients at a 36-months follow-up, demonstrating that pneumatic dilation of achalasia has excellent immediate therapeutic efficacy but its long-term therapeutic efficacy is poor[23-44]. Firstly, this was associated with the diameter of the saccule. Kadakia *et al*[10] suggested that the saccule diameter in pneumatic dilation should be 35-45 mm, but the incidence of complications was very high (e.g., 15 % had esophageal perforation). We used saccules with diameters of 28-32 mm in order to reduce the incidence of serious complications, but their long-term therapeutic efficacy was not satisfactory. Secondly, the therapeutic efficacy was associated with the frequency of dilation. One dilation did not produce excellent therapeutic efficacy, since it was affected by various factors. For example, whether the saccule was correctly located, whether pressure applied to the saccule reached the stipulated index, and variations in the anatomy of the cardia. It was suggested that three graded dilations should be used to achieve the treatment goal. Thirdly, the therapeutic efficacy was associated with the course of the disease. If this was very short, the cardiac muscularis was not fleshy and elastic. If this was very long, the cardiac muscularis was fleshy and not elastic. We used permanently uncovered stent dilation in five patients with achalasia and achieved excellent immediate therapeutic efficacy, but its long-term therapeutic efficacy was poor. This was mainly due to the frequent occurrence of serious gastroesophageal reflux and hyperplasia of granulation tissue. After a 12-month follow-up the stent could not be removed in three patients, and hence we had to resect and reconstruct the esophageal cardia. Therefore, permanently uncovered metal stent dilation was unsuitable for patients with achalasia[45-48]. Temporary partially covered metal stent dilation had excellent immediate and long-term therapeutic efficacy. First, the design of the stent coincided with the specific physiological structure of the cardia and the specific pathological manifestations of achalasia. The epicardia is a part of the expanded esophagus and the lower cardiac part is a very large gastric cavity. If a stent is not well designed, it will lose its therapeutic efficacy, and moreover, the rate of stent migrations will increase. To avoid these problems, we designed a special stent for achalasia. The stent was partially covered with a membrane covering the inner wall of the stent but not covering the area within 2 cm of the stent outlet. The upper outlet of the stent was a large horn, which increased the stability of the stent but made it difficult to extract. Second, the diameter of the stents used in this group was 20-30 mm. By expanding the stent, the cardia could be returned nearly to the maximum diameter of the normally dilated esophageal lumen. The most appropriate stent diameter was that which could expand the cardia stricture while not cause gastroesophageal reflux. This needs to be investigated further. Thirdly, the internal metal stent expansion procedure took a long time, and the stent was placed for 3-7 days. Why the therapeutic efficacy of temporary partially covered stent dilation was better than that of pneumatic dilation? We considered that this was mainly due to the stent expansion which caused chronic tearing of the cardia muscularis. The stent gradually expanded with body temperature, taking 12-24 h to reach 36 ℃, for it to reach the expected diameter. Therefore, the cardia muscularis was torn regularly with relatively few scars formed and a very low incidence of restenosis when it was repaired. In pneumatic dilation the tearing of cardia muscularis was acute and irregular with many scars formed when it was repaired. Therefore, restenosis was common and the long-term therapeutic efficacy was poor. This might explain why the therapeutic efficacy of temporary partially covered metal stent dilation was better in the treatment of achalasia than that of pneumatic dilation.

Developments in biologically degradable stents for the esophagus which are degraded within 2 months, would provide the advantages of a long retention time without the need for stent removal. This would provide another interventional procedure for patients with achalasia. We compared three methods of interventional procedure for patients with achalasia and took the following factors into consideration such as extent of lesion, incidence of complications, therapeutic efficacy, and degree of patient acceptance. We found that in the treatment of benign gastrointestinal stricture, the use of temporary partially covered metal internal stent dilation was preferred due to its superior long-term therapeutic efficacy.

Abstract

AIM: To evaluate the effect of glycine on plasma and liver tissue changes of tumor necrosis factor-α (TNF-α), endothelin-1 (ET-1) and nitric oxide (NO) contents in rats with obstructive jaundice.

METHODS: Ninety healthy Wistar rats of both sexes weighing 275±25 g were randomly divided into sham-operated, bile duct-ligated, and bile duct-ligated plus glycine-treated groups, the latter was performed with 5 % glycine solution substituting for tap water drunk *ad libium* for 5 days before and 6 days after operation. Blood and liver tissue were sampled at the time of sacrifice on the 8th day post operation. Plasma total bilirubin, endotoxin, levels, as well as TNF-α, ET-1 and NO contents in liver tissue were determined.

RESULTS: Plasma endotoxin and total bilirubin levels were significantly higher in both bile duct-ligated and bile duct-ligated plus glycine-treated rats than in sham-operated animals (P=0.000613, 0.00921 and 0.00737, 0.00841 respectively), whereas they did not display any statistically significant difference between the former groups (P=0.417 and 0.374 respectively). Likewise, TNF-α, ET-1 and NO contents in both plasma and liver tissue were significantly increased in both bile duct-ligated and bile duct-ligated plus glycine-treated rats compared with sham-operated animals (P=0.00813, 0.00793, 0.00671, 0.00804, 0.00872, and 0.00947 in plasma and 0.00531, 0.00785, 0.00912, 0.00981 and 0.00635 in liver tissue respectively). However, these inflammatory mediators in both plasma and liver tissue were significantly reduced in bile duct-ligated rats fed on 5 % glycine solution compared with that without (P=0.00953, 0.00891, 0.0795, 0.00867, 0.0697 and 0.00907 in plasma and liver tissue respectively).

CONCLUSION: Reduction of TNF-α, ET-1 and NO contents in plasma and liver tissue of rats fed on glycine may be helpful to alleviate pathological lesions in obstructive jaundice.

INTRODUCTION

Endotoxemia is one of the major causes that can lead to complicated pathophysiologic alterations in the process of obstructive jaundice. Current research has demonstrated that severe endotoxemia in obstructive jaundice could activate immunocompetent cells such as monocytes, macrophages and endothelial cells to produce a variety of cytokines that could contribute to an uncontrollable inflammatory cascade causing multiple organ dysfunction (MODS) or even death[1-3]. Among these cytokines, TNF-α, ET-1 and NO have been considered to be the main effectors in endotoxemia[4-10]. It is also worthy to note that glycine could provide an effective protection against endotoxemia that has been recently published in several repots[11-15]. The present study, therefore, was conducted with the aim to evaluate the effect of glycine on the plasma and liver tissue changes of TNF-α, ET-1 and nitric oxide contents in rats with obstructive jaundice.

MATERIALS AND METHODS

Animal model and experimental protocol

Ninety healthy Wistar rats of both sexes weighing 275±25 g were employed in the study. According to the experimental protocol, the animals were randomly divided into Group A in which the rats were performed a sham operation, Group B in which the rats were operated merely to ligate the common bile duct and Group C in which the rats were treated with both the ligation of common bile duct and a glycine regimen. Before operation, all animals were allowed access to standard rat chow and water *ad libium* for 5 days except that the rats in Group C drank 5 % glycine solution (provided by Shanghai Institute of Biological Products Research) instead of water[2]. After a 12-h fasting period, the animals were weighed and anesthetized with 1 % pentobarbitale sodium (30 mg/kg, ip) and their common bile duct was exposed and ligated to form a complete obstruction of the extrahepatic bile duct except that the common bile duct in rats of Group A was only exposed following laparotomy. When recovered for a period of 24 h, the rats were fed on their corresponding regimens for another 6 days. Rat venous blood was sampled and liver was removed surgically at the time of sacrifice on the 8th day post operation under anesthesia. Blood samples were prepared respectively according to the procedures for determinating different variables and the resulting plasma was stored at -70 ℃ until use. The liver was perfused via a cannula inserted into the portal vein with sterile normal saline to remove residual blood, and then prepared into 10 % tissue homogenate with 1.0 mol· L^{-1} acetic acid and centrifuged at 3 000×g for 40 min. The supernatant was stored at -70 ℃ until analysis.

Measurements

For determination of plasma endotoxin level, 1 ml of blood sample was collected in a pyrogen-free heparinized tube and centrifuged at 500×g for 5 min. The resulting plasma was analyzed with the limulus-amoebocyte-lysate test (LAL) kit according to the protocol of its manufacturer (Shanghai Yihua Medical Science & Technology Ltd.). The endotoxin

concentration was finally expressed as Eu/ml.

Measurement of ET-1 level was performed using 1 ml of blood samples that was collected in a test tube containing 15 μl of 10 % disodium edentate and 20 μl of aprotinin, and centrifuged at 3 000×g for 10 min at 4 ℃. The resulting plasma and liver homogenate were determined with ET-1 radioimmunoassay kit following the protocol of Research Institute of Radioimmunotechnology, General Hospital of PLA. Heparinised blood samples were collected in a separator tube and spun at 4 000 g for 10 min for detection of plasma bilirubin and TNF-α. To measure TNF-α, the resulting plasma and liver homogenate were analysed with a radioimmunoassay kit according to the instructions supplied by Research Institute of Radioimmunotechnology, General Hospital of PLA. Plasma bilirubin was determined with an automatic multifunction-biochemical analyzer.

Measurement of NO_2^-/NO_3^- content two ml of heparinised blood samples was incubated at 37 ℃ for 1 h and then centrifuged at 2 000×g for 5 min. The resulting plasma and liver homogenate were determined with a NO_2^-/NO_3^- assay kit following the procedures of Research Institute of Radioimmunotechnology, General Hospital of PLA.

Statistical analysis

Experimental data were processed by analysis of variance and *t*-tests for comparison between groups. Results were expressed as mean ± SE. $P<0.05$ was selected as the level of significance.

RESULTS

Poor appetite and jaundice were observed in rats of Groups B and C on the 2nd day after operation, the jaundice was more apparent on the ear and tail end skin. The dilation of proximal bile duct at the site of ligation, deep-brown-coloured liver and significantly elevated plasma total bilirubin (P=0.00921 and 0.00841 in Groups B and C respectively as compared to Group A) were also noted in these animals at the time of sacrifice on the 8nd day post operation. Animals in Group A did not exhibit obvious abnormalities. But there was no significant difference of plasma total bilirubin between rats in Groups B and C (P=0.374).

Plasma endotoxin levels in rats of Groups B and C were significantly increased compared with that in rats of Group A (P=0.000613 and 0.00737 respectively). However, It did not exhibit significant difference between rats in Groups B and C (P=0.417).

Plasma levels of TNF-α, ET-1 and NO in Group B rats were significantly elevated compared with that in Group A rats (P=0.00813, 0.00793 and 0.00671 respectively), which were significantly improved when the rats were fed on 5 % glycine solution as shown in Table 1 (P=0.00953, 0.00891 and 0.0795). The data for TNF-α, ET-1 and NO levels in liver tissue are shown in Table 2. In accordance with their plasma counterparts, significant reduction of these variables was found in bile duct-ligated rats fed on 5 % glycine solution (0.00867, 0.0697 and 0.00907).

DISCUSSION

Obstructive jaundice is associated with an increased incidence of postoperative complications such as infection, systemic inflammatory response, and even multiple organ failure due to metabolic and hemodynamic disorders, as well as depressed immune function. Current studies have revealed that endotoxemia was one of the major causes leading to high morbidity and mortality in patients with obstructive jaundice[1-3]. Therefore, the therapeutic strategy aimed at reducing plasma endotoxin level and interrupting its biological activities has become a focus of great concern[4].

It has been found that endotoxin could stimulate monocytes and macrophages to produce a variety of cytokines, because the elevated intracellular Ca^{2+} concentration in these cells was resulted from the activation of Ca^{2+} channel by endotoxin[11,12]. It has also been noted that glycine, a nonessential amino acid, could exert protective effects on animals in multiple morbid conditions by minimizing oxidative stress, as well as toxic eicosanoid cytokine production[11,13] Ding *et al*[14,15] demonstrated that the biological effects of endotoxin could be significantly inhibited by glycine via a mechanism of blocking TNF-α production in immunocompetent cells, the latter could play a critical role in the pathogenesis of endotoxin lesions[4-7]. ET and NO, although as the intense vasoconstrictor and vasodilator respectively, were also pleiotropic factors involveded in endotoxin-mediated pathological processes with endotoxin and TNF-α as their potent releasing irritants[3,8-10]. The present study demonstrated that severe endotoxemia could be observed in obstructive jaundice, and the TNF-α, ET and NO contents in plasma and liver tissue were all significantly increased in bile duct-ligated rats.

Persistent severe endotoxemia in obstructive jaundice could stimulate not only Kupffer cells to release TNF-α to insult directly parenchymal cells of the kidney and liver[3,16-18], but also other immunocompetent cells to produce excessive amount of ET-1 and NO[8] to aggravate the disturbance of splanchnic circulation leading to decreased oxygen delivery, and ultimately multiple organ dysfunction syndrome (MODS).

Table 1 Plasma levels of bilirubin, endotoxin, TNF-α, ET-1 and NO_2^-/NO_3^- in different groups of rats ($\bar{x}\pm s$, n=30)

Group	Bilirubin (μmol/L)	Endotoxin (Eu/ml)	TNF-α (pg/ml)	ET-1 (pg/ml)	NO_2^-/NO_3^- (μmol/L)
A	5.80±1.65	5.98±1.00	61.37±3.08	88.79±7.56	5.51±0.44
B	45.45±6.69[a]	11.65±1.57[a]	352.52±20.65[a]	183.24±34.01[a]	12.06±0.62[a]

Group	Samples	TNF-α (pg/ml)	ET-1 (pg/ml)	NO_2^-/NO_3^- (μmol/L)
A	10	43.51±2.58	43.18±4.47	2.15±0.18
B	10	298.46±18.74[a]	124.56±11.67[a]	10.53±0.87[a]
C	10	113.45±6.67[ab]	81.49±7.39[ab]	7.23±0.34[ab]

[a]$P<0.01$ *vs* group A, [b]$P<0.01$ *vs* group B.

Besides, NO itself is also a highly active free radical and can convert further into NO_2^- and peroxynitrite. The more vigorous oxidants could result in cell injury[9]. Although glycine could reduce the plasma and liver tissue endotoxin level in our study, it did prevent TNF-α, ET-1 and NO from excessive production, which might be beneficial to alleviate the organ injury in obstructive jaundice. However, TNF-α, ET-1 and NO levels in both plasma and liver tissue remained elevated to some extent in rats fed on glycine as rats compared with sham-operated rats. To elucidate the mechanism underlying this phenomenon is thus the purpose of our further studies.

Abstract

AIM: To highlight the fatal complication caused by expanding biliary stents and the importance of avoiding use of expanding stent in potentially curable diseases.

METHODS: Arteriobiliary fistula is an uncommon cause of haemobilia. We describe a case of right hepatic artery pseudoaneurysm causing arteriobiliary fistula and presenting as severe malena and cholangitis, in a patient with a mesh metal biliary stent. The patient had lymphoma causing bile duct obstruction.

RESULTS: Gastroduodenoscopy failed to establish the exact source of bleeding and hepatic artery angiography and selective embolisation of the pseudo aneurysm successfully controlled the bleeding.

CONCLUSION: Bleeding from the pseudo aneurysm of the hepatic artery can be fatal. Mesh metal stents in biliary tree can cause this complication as demonstrated in this case. So mesh metal stent insertion should be avoided in potentially benign or in curable conditions. Difficulty in diagnosis and management is discussed along with the review of the literature.

Rai R, Rose J, Manas D. Potentially fatal haemobilia due to inappropriate use of an expanding biliary stent. *World J Gastroenterol* 2003; 9(10):2377-2378
http://www.wjgnet.com/1007-9327/9/2377.asp

INTRODUCTION

With increasing surgical and radiological intervention in the liver and biliary tree, incidence of haemobilia is on the rise. The mesh metal stent insertion can cause haemobilia as described. Thus inappropriate use of mesh metal stents in potentially curable diseases should be avoided.

The diagnosis of haemobilia may be difficult to establish and the bleeding may be fatal. Pseudoaneurysm of the right hepatic artery is an uncommon cause of haemobilia. A proper facility for radiological and surgical intervention is important to achieve success in control of bleeding.

The presentation and management of a case of haemobilia in a patient with mesh metal stent is described.

CASE REPORT

A 47-year-old lady was referred as an emergency from another hospital with recurrent cholangitis and severe malena.

Two years previously she had presented in the referring hospital with an abdominal mass, vomiting and obstructive jaundice. Further investigation including computed tomography (CT) scan of the abdomen was inconclusive. A laparotomy was carried out which revealed a large nodular mass in the abdomen causing gastric outlet obstruction and compression at the porta hepatis. It was not possible to resect this mass and because there were extensive small bowel adhesions, an enteric or biliary surgical bypass was not considered a safe option. A sample from the lesion was taken for histology.

Postoperatively the patient underwent percutaneous placement of a self expanding mesh metal stent in her bile duct to relieve the jaundice. Histology suggested the presence of a non-Hodgkin' s lymphoma. Radiotherapy and chemotherapy were commenced, which produced a very good response. The patient was asymptomatic for 6 months and during that time a repeated CT scan showed no evidence of intra-abdominal diseases. Six months later the patient presented with obstructive jaundice and ultrasound examination suggested occlusion of the metal stent. On endoscopy the metal stent was protruding into the duodenum, which was associated with duodenal ulceration. A plastic stent was inserted through the metal stent at ERCP.

After a few months the patient developed further cholangitis and had severe malena leading to referral to our unit.

On arrival the patient had symptoms and signs suggestive of cholangitis. The patient was pale and required blood transfusion and was started on antibiotics for cholangitis. After resuscitation, endoscopy examination showed ulcerations in the 2nd part of duodenum adjacent to the metal stent but no active bleeding. On the 2nd day the patient developed more severe malena and it necessitated laparotomy to control the bleeding. At laparotomy there was an inflammatory mass around the porta, and the common bile duct was adherent to the hepatic artery and portal vein. During dissection the common bile duct was entered inadvertently and the blocked plastic stent was therefore removed. As soon as the plastic stent came out, profuse bleeding occurred inside the common bile duct. The source of this bleeding was unclear. As it was impossible to control the bleeding coming from the bile duct urgent on table, hepatic angiography was performed via the right femoral artery. It showed a pseudo-aneurysm of the right hepatic artery which had ruptured into the common bile duct. A successful embolisation of the right hepatic artery aneurysm was carried out. A t-tube was placed in the common bile duct. Within 24 hours of surgery, percutaneous drainage of the obstructed biliary tree was achieved with an external-internal drain. The patient recovered from surgery with no further malena. The biliary drain was internalised using a plastic stent, T- tube was removed prior to discharge.

Over the fourteen months since laparotomy and embolisation of the right hepatic artery pseudo-aneurysm, the patient has been asymptomatic, the biliary drain has remained patent and a recent CT scan showed no evidence of residual lymphoma.

DISCUSSION

Haemobilia is an uncommon cause of gastrointestinal bleeding

and currently the most common cause of haemobilia in the Western world is as a consequence of percutaneous liver procedures. In a recent review of 222 cases of haemobilia, 147 were iatrogenic in aetiology following hepatobiliary intervention[1]. The origins of haemobilia might be diverse and included the cystic artery, anomalous hepatic artery, and hepatic artery to portal vein fistulas[2,3]. One of the reported causes of haemobilia was pseudoaneurysm of the hepatic artery, and the most common causes of this include laparoscopic cholecystectomy, exploration of the bile duct and other surgical biliary procedures.

Aneurismal disease of the hepatic artery from any cause is rare. Different authors have identified 21 % to 44 % of all splanchnic artery aneurysms as occurring in the hepatic artery[4,5]. Causes included arteriosclerosis (30-50 %), medial degeneration (25 %), trauma (20 %), mycotic infection (10 %), and congenital disorders (15 %)[3]. Eighty percent of hepatic artery aneurysms are extra hepatic and 20 % are intrahepatic. Extra hepatic aneurysms are distributed in the common hepatic artery (60 %), the right hepatic artery (30 %), the left hepatic artery (5 %), and rarely, in both (4 %).

In the present case, the severe bleeding on table was precipitated by removal of the plastic stent from the bile duct. The inflammation surrounding the bile duct and the presence of adhesions between the metal stent and the hepatic artery may have contributed to the formation of the pseudo-aneurysm of the right hepatic artery which was adherent to the metal stent. The previous episodes of malena probably indicated intermittent bleeding from the pseudoaneurysm, which was partially occluded by the plastic stent.

Thus mesh metal stent insertion can lead to this fatal complication. The most important aspect of this case is that the mesh metal stent was inserted before the response to radiotherapy and chemotherapy. The patient had no evidence of residual lymph node after therapy. Thus a long term mesh metal stent was unnecessary and could have been avoided.

The best treatment option for an occluded metal stent is not clear. The options are placement of a new coaxial metal stent, mechanical cleaning of the blocked stent or coaxial insertion of a plastic stent[6]. In a multicentric study of treatment of an occluded mesh metal stent due to tumour overgrowth, all the three methods were found to be equally effective but insertion of a plastic stent within a mesh metal stent appeared to be the most cost effective method[6].

Diagnosing haemobilia can be difficult. Haemobilia can present as upper or lower GI bleeding and the first investigation should be upper gastrointestinal tract endoscopy. If blood is seen coming from the ampulla of Vater, haemobilia is the likely cause of bleeding. But as few as 12 percent of these endoscopies might be diagnostic[7]. Due to intermittent bleeding from the biliary tree the source of bleeding may not be apparent. In a series of 29 patients with haemobilia, 22 patients had a normal endoscopy[8]. In our case as well the bleeding was not seen coming from the ampulla of Vater at the time of endoscopy and in the presence of duodenal ulceration due to the protruding metal stent, the cause of gastrointestinal bleeding was presumed to be duodenal ulcerations.

The choice of further investigation has varied over the years. Goodnight and Blaisdell[9] in 1981 recommended computed tomography (CT) and then angiography. But now angiography is recognised as the investigation of choice after gastrointestinal endoscopy, as it can be diagnostic as well as therapeutic.

Angiography could be expected to detect a vascular abnormality in over 90 % of cases of significant haemobilia[1]. Angiography can not only demonstrate pseudo-aneurysm of the arteries but also demonstrate arterio-biliary and arterio-portal fistulas.

Once the diagnosis of haemobilia is established, the aim is to stop the bleeding. It is important to correct any coagulopathy if present. The bleeding might stop on conservative treatment depending on the cause of bleeding. In a recent review of 171 cases of haemobilia, 73 (43 %) patients required only conservative treatment[1]. In case of continued bleeding, transarterial embolisation has been shown to be successful in 80 % to 100 % of cases[10-14]. Since the reported morbidity and mortality rates of transhepatic arterial embolisation (TAE) were lower than surgery[14], angiographic embolisation should be attempted first. The relative contraindication of arterial embolisation is hepatic sepsis, and in case of portal vein obstruction, arterial embolisation can cause hepatic necrosis.

Surgery is indicated if embolisation has failed or in case of hepatic sepsis. Adequate drainage of the biliary tree by endoscopic, percutaneous route or by surgery is important.

In conclusion, mesh metal stent insertion in the biliary tree can lead to fatal haemobilia. The diagnosis and management of haemobilia can be difficult and need an experienced multi-disciplinary team - mainly hepatobiliary surgeons, endoscopists and interventional radiologists. To avoid this complication unnecessary use of a mesh metal biliary stent in potentially curable diseases should be avoided.

Abstract

A 57-year-old woman was referred to our hospital because of a liver mass detected by computed tomography. She had taken oral contraceptives for only one month at the age of thirty. Physical examination revealed no abnormalities, and laboratory data, including hepatic function tests, were within the normal range, with the exception of elevated levels of those serum proteins induced by the absence of vitamin K or by raised levels of the antagonist (PIVKA)-II (3 502 AU/ml). Abdominal ultrasonography revealed a hyperechoic mass measuring 10×10 cm in the left posterior segment of the liver. Because hepatocellular carcinoma could not be completely excluded, this mass was resected. The tumor consisted of sheets of uniform cells with clear cytoplasm, perinuclear eosinophilic granules and round nuclei. These histological findings were consistent with liver cell adenoma. Background hepatic tissue appeared normal. After resection of the tumor, serum PIVKA-II fell to within the normal range. An area of hepatocellular carcinoma (HCC) with a mid-trabecular pattern was immunohistochemically found, which was positive for PIVKA-II. Sinusoidal endothelial cells were CD34-positive, containing scattered PIVKA-II positive cells. This tumor was therefore finally diagnosed as liver cell adenoma with focal malignant transformation to HCC.

INTRODUCTION

Liver cell adenoma (LCA) is a benign neoplasm composed of cells that closely resemble normal hepatocytes. The lesion arises in normal liver. LCA typically develops in the setting of a hormonal or metabolic abnormality which stimulates hepatocyte proliferation. Exogenous steroid hormone ingestion is undoubtedly the most common such stimulus. Hence, oral contraceptive steroids are the cause of most LCAs[1] although some cases are related to glycogen storage diseases. LCA is still uncommon in countries where oral contraceptives are not used[2-4]. Although the incidence is very low, LCA has been reported in men, children, and women not taking oral contraceptives.

We report here a case of LCA with transformation to hepatocellular carcinoma (HCC) in a woman who had received oral contraceptives for only one month 30 years before.

CASE REPORT

A 57-year-old woman attended hospital because of slight abdominal fullness. She was referred to our hospital because of a liver mass detected by abdominal CT in June 2001. Computed tomography revealed a single mass at the left hepatic lobe measuring 10×10×8 cm. Her past history was unremarkable and she had no history of drug or alcohol abuse. At the age of thirty she had taken oral contraceptives for one month. Physical examination revealed no hepatomegaly or other abnormalities. The results of urinalysis and peripheral blood analysis were normal. Biochemical findings for blood, i.e. AST, ALT, LDH, γ-GTP, cholinesterase, total bilirubin, and total protein, were also normal. Hepatitis B surface (HBs) antigen, anti-HBs antibody, and anti-hepatitis C virus antibody were negative. Although serum protein induced by the absence of vitamin K, or by increased antagonist-II (PIVKA-II) levels, was elevated, serum alpha fetoprotein levels were normal (18 ng/ml). On June 11, PIVKA-II was 234 μAU/ml and increased rapidly to 3 503 μAU/ml on July 19. Levels of other tumor markers, i.e., CEA and CA 19-9 were all within normal limits.

Abdominal ultrasonography revealed a highly echoic lesion, measuring 10×9 cm in the left posterior segment of the liver. Computed tomography of the abdomen confirmed a large low-density mass, measuring 10.5×8.5 cm in size. Celiac angiography demonstrated a large hypervascular mass (Figure 1). On CT angiography, the mass lesion was enhanced heterogeneously during the early phase, and a sharply demarcated tumor stain was noted during the late phase. This abnormal lesion of the liver was also detected as iso-intensity on T1-weighted and hyper- and hypo-intensity on T2-weighted magnetic resonance imaging (MRI). Therefore, a left lobectomy of the liver was performed under the clinical diagnosis of HCC, in August 2001. After resection of the tumor, serum PIVKA-II fell to the normal level.

The surrounding liver tissue revealed no fibrosis or cirrhosis. The tumor was solitary and spherical, and measured 10×10×8 cm (Figure 2A). On the cut surface, the tumor was firm and well encapsulated. The color varied from yellow-white to reddish brown. There were irregular scars and a variegated appearance with hemorrhage. Microscopically, tumor cells were of uniform size but larger and paler than non-tumor hepatocytes in the surrounding tissue, and arranged in small sheets and cords with an occasional acinar pattern (Figure 2B). Background hepatic tissue looked to be normal. Tumor cell cytoplasm was clear and hydropic with eosinophilic granules around the nucleus in each cell. PAS staining revealed abundant accumulation of glycogen in the cytoplasm. The nuclei of tumor cells were uniform and regular, and mitosis was not seen. Thin-walled vascular channels were scattered throughout the tumor. Peliosis hepatic-like sinusoidal dilatation and hemorrhage were present especially in the central part of the tumor (Figure 2C). Portal tracts were absent throughout the tumor. These histological findings indicated LCA, but not simple LCA because of the following

features. Distinct areas with a mid-trabecular pattern were evident (Figure 2D). Reticulin fibers were well represented in each sheet, and most cell plates were of two-cell thickness. However, three or more cell plates were present in some hypercellular areas. Pseudoglandular structures were not encountered. Immunohistochemistry revealed that PIVKA-II (18B7, Eisai Co. Ltd.; Tokyo) was positive both in the adenoma cells and in mid-trabecular areas (Figure 3A). CD34 (Nichirei, Tokyo, Japan) was positive throughout the endothelial cells of the tumor (Figure 3B). Ki-67 (Dako) was positive sporadically in mid-trabecular area and tumor cells with enlarged nuclei. AFP (Dako, Demark), P53 (DO-7, Dako), estrogen receptor (Novocastra, Newcastle, UK), and progesterone receptor (Novocastra) were all negative throughout.

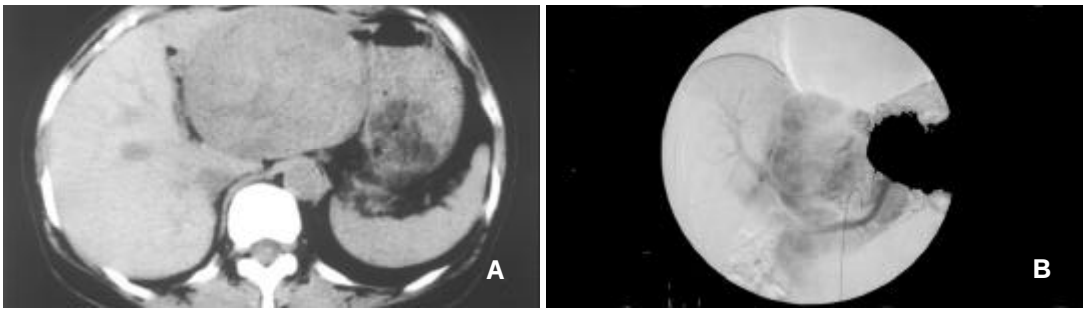

Figure 1 A: Computed tomography revealing a large tumor in the left lobe. B: Celiac angiography during the arterial phase, showing a large hypervascular lesion.

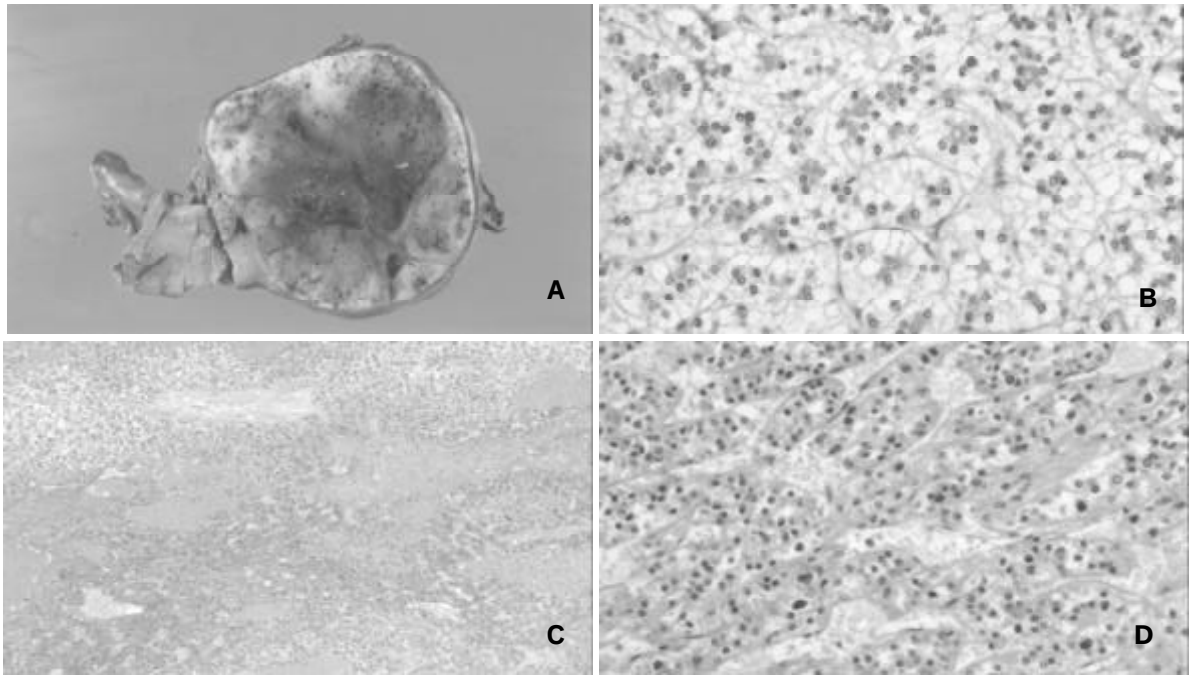

Figure 2 A: Macroscopic appearance of resected tumor. The tumor was incompletely encapsulated by thin fibrous tissues, and its cut surface was tan-yellowish. Hemorrhage was observed inside part of the tumor. B: Microscopic appearance of tumor. Tumor cells were relatively uniform and had clear eosinophilic cytoplasm with small round nuclei. C: Trabecular structures were sporadically encountered in association with hemorrhage. D: The tumor cells were arranged predominantly in a thin trabecular pattern with moderate nuclear atypia.

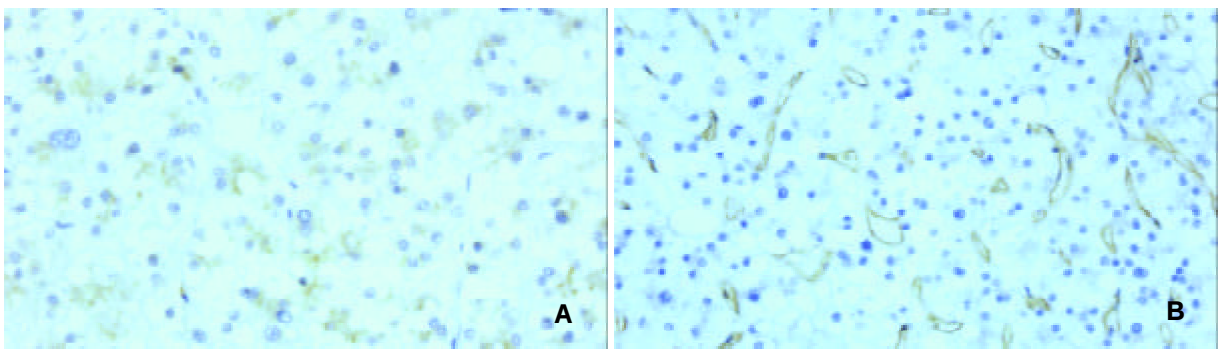

Figure 3 Immunohistochemistry. A: PIVKA-II. B: CD34. PIVKA-II was positive in the tumor cells with or without nuclear atypism and trabecular structure (A). CD34 was expressed diffusely in the sinusoidal endothelial cells (B).

DISCUSSION

Oral contraceptive steroids are the cause of most LCAs, as demonstrated by epidemiological case-control studies conducted in the 1970's[5]. The tumor is nearly always found in women aged 15 to 45, with an incidence estimated to be 3 to 4 per 100 000 long-term contraceptive steroid users per year. An incidence of only 1 per million occurs in non-users or women with less than 2 years' exposure to contraceptive steroids. The risk increases with the duration of contraceptive steroid use and with the potency of the preparation. The present case was not related to oral contraceptives although she had a very short period of oral contraceptive use about 30 years before.

Malignant transformation of LCAs is rare, because most are resected on discovery. However, there were a few well documented cases of hepatocellular carcinoma arising in unresected solitary and multiple adenomas[6-8]. This might represent an adenoma-carcinoma progression sequence in hepatocellular neoplasia, similar to that seen in colon cancer[9]. Intratumoral hemorrhage and intraperitoneal tumoral rupture occasionally occurred in LCA, so that surgical excision has been usually advised for LCA to prevent the risk of rupture and hemorrhage, and malignant transformation[10].

Distinguishing LCA from well-differentiated HCC by histopathology is a difficult task in small biopsies and occasionally even in resected tumor specimens. LCA can be differentiated clinically from HCC on the basis of tumor marker abnormalities, such as AFP and PIVKA-II. Gene analysis is one of the useful methods distinguishing these tumors, although it is not practical in ordinary diagnostic procedure. Multiple chromosomal aberrations detected by CGH, including gains or losses in one or more of six chromosomes (*1q, 4q, 8p, 8q, 16p*, and *17p*) have been reported in hepatocellular carcinomas, but not in LCAs[11]. The detection of frequent aberrations supported a diagnosis of carcinoma and made LCA unlikely, as consistently reported by several investigators[12,13].

LCA has a small but not negligible risk of malignant transformation into HCC. LCAs are rare tumors which may be difficult to differentiate from well differentiated HCCs. In the present case the key finding of malignant transformation into HCC was the presence of an irregular mid-trabecular growth pattern as determined histologically. p53 and Ki-67 are useful markers for differentiation of LCA from HCC. p53 protein was detected in the nuclei of tumor cells of 8.5 % to 44 % of HCC. In contrast, immunostaining of p53 was seen in none of the focal nodular hyperplasias examined, and also in none of the LCAs. In addition, mutant p53 expression in HCC was positively correlated with tumor grade[14,15]. Ki-67, assessed using the monoclonal antibody MIB-1, is expressed in the nuclei of cells of HCC, but not in adenoma cells. The nuclei of LCAs are typically uniform and regular, the nuclear/cytoplasmic ratio is normal, and mitosis is not seen. In the present case, p53 was negative throughout the tumor, even in the areas with a trabecular growth pattern that was the key finding of malignant transformation. Ki-67 was sporadically positive in mid-trabecular area and relatively large nuclei, but not many as conventional HCC.

In contrast to the results of Ki-67 and p53 staining, those of CD34 and PIVKA-II supported malignant transformation. CD34 was reported to show diffuse staining of a large number of sinusoids in HCC in contrast to LCA where the staining was focal or identified only marginal sinusoids[16]. However, consideration should be given to the possibility of LCA and focal nodular hyperplasia, which could also exhibit significantly diffuse CD34 reactivity[17]. PIVKA-II levels were elevated in most patients with HCC. Although LCAs with elevated serum levels of PIVKA-II have been sporadically reported, these were relatively low. Diffuse positive reactions of CD34 on sinusoid endothelial cells in the area of suspicious HCC and marked increase of PIVKA-II (3 503 mAU/ml), as seen in the present case, might indicate malignant transformation. The evaluation of a hepatic nodule is a very common clinical problem. Identification of malignant features remains, at times, inconsistent and controversial, and the distinction of HCC from dysplastic nodule can be difficult. Establishment of diagnostic standards for malignant features should be expected. Finally, this case was reviewed by four Western experts, and was diagnosed as LCA with malignant transformation to HCC (personal communication).

Abstract

Although the lung is the major site for *Mycobacterium tuberculosis* infection, gastrointestinal involvement can be present as part of multiorgan disease process or, less commenly, can be seen as primary gastrointestinal tuberculosis. In the cases where the culture is negative, it can be difficult to differantiate tuberculosis from Crohn's disease based on both the clinical and histological features. When side effects of classic antimycobacteria are encountered, we can initially add ciprofloxacin to the treatment of tuberculosis. We reported a case of 19-yr-old patient, who was treated as Crohn's disease and worsen. We began to tuberculosis treatment, and the patient improved clinically and histologically. The main point in this case is that widespread involvement of gastrointestinal tract can be brought about by non resistant strains of *Mycobacterium tuberculosis* even in immunocompetent patients.

Settbas Y, Alper M, Akcan Y, Gurbuz Y, Oksuz S. Massive gastrointestinal tubercolsis in a young patient without immunosupression. *World J Gastroenterol* 2003; 9(10):2382-2384

INTRODUCTION

Mycobacterium tuberculosis is the primary cause of tuberculosis, infects one third of world' s population and causes the most deaths per year of any infectious agents. It is found primarily in devoloping countries, where poor sanitation contributes to its spread. Although pulmonary manifestations predominate in most tuberculosis cases, gastrointestinal involvement may be present as a part of multiorgan disease process or, less commonly as primary gastrointestinal tuberculosis. Gastrointestinal tuberculosis is usually caused by *Mycobacterium tuberculosis* but may also be caused by *Mycobacterium bovis*. Prior to AIDS epidemic, it was seen most commonly in immune competent persons with untreated advanced pulmonary disease[1]. Today, it is most commonly observed in association with immunosupression and, in one series, more than 40 % of patients with gastrointestinal tuberculosis had AIDS[2]. Other groups at highest risk include those who abuse alcohol, injection drug users, those who take chronic steroids, elderly persons. Here, we described a case of gastrointestinal tuberculosis with diffuse involvement of esophagus, stomach, ileum and colon, who did not possess any known immunosuppressive state in his history (Diabetes mellitus, alcohol abuse, protein calori malabsorbtion, AIDS).

CASE REPORT

A 19 year old male patient presented to the outpatient department with complaints of dispepsia and nausea for two years. Recently, vomiting after meals made the patient fear of eating. He first recieved anti ulcer medication with the diagnosis of peptic ulcer in another center. Since his complaints continued, endoscopic and colonoscopic examinations were performed and several biopsies were obtained. A diagnosis of Crohn' s disease was made at the same center. Lansaprazol 30 mg, mesalazine (500 mg *p.o. t.i.d*), hydrocortisone 10 mg/kg/day were begun. Despite the treatment regimen, no response to mesalazine and hydrocortizone was seen and since his complaints increased, he was admitted to our center with abdominal pain, anorexia, nausea, fatigue, weigth loss (15 kg/6 month). There were no pathologic findings on his chest x-ray. Ultrasound examination of the abdomen revealed unremarkable findings, except some degree of cahexia and apathetic appereance. Laboratory data included hemoglobin 11.5 g/dL, erythrocyte sedimentation rate 10 mm/hr, alanin aminotransferase 30 U/L, aspartat aminotransferase 40 U/L, total protein 4.1 g/dL, albumin 2 g/dL white blood cell count 6 600, platelet count 314 000, HBsAg (-), AntiHBsAg(-), Anti-HCVAg(-), HIV(-) and PPD levels 7 mm. Physical examination did not find any abnormal findings. He had no history of any disease which practically can cause diabetes mellitus, alcoholism and renal insufficiency, which are associated with immunodefficiency.

Endoscopy and colonoscopy were performed due to these complaints in our institution. Endoscopy revealed hyperemia with granulomatous lesions at the lower third of the esophagus. A granular appereance was seen along small curvature of the corpus. Antrum had extensive hyperdmia. Additionally granulomas were seen at bulbar and the second part of duodenum. Subsequently biopsies were obtained from all described areas. A histopathological examination revealed existance of granuloma in the esophagus, stomach and small intestine with caseous necrosis in the stomach (Figures 1-3). Although ileal biopsy revealed edematous *lamina propria* with increase of inflammatory cells, there was a granulation at the ileal biopsy which was done 3 months before the treatment of Crohn' s disease started at another center (Figure 4).

Under the light microscopy of these findings, gastrointestinal tuberculosis was concluded and treated with anti tuberculosis treatment of isoniazid 200 mg/day, rifampicin 450 mg/day, morfazinamid 1 g/day and ethambutol 500 mg/day. During the follow up of the first and second month, retrobulber neuritis and peripheral neuritis were seen as the side effects of ethambutol and isoniazid respectively. At the second month of the treatment, morfazinamid was also stopped. Ciproxin 500 mg two times a day with the combination of rifampicin 450 mg/day was given. A significant improvement in clinical

situation of the patient was observed. He gained 25 kg during the theraphy and got 60 kg. The patient recieved anti tuberculosis treatment for 12 months. Check up endoscopy at the end of treatment revealed normal findings with no granulation and caseous necrosis.

DISCUSSION

The diagnosis of gastrointestinal tuberrculosis is always difficult. We must keep in mind the possibility of patients with abdominal pain, even without concomitent lung involvement[2,3]. Tuberculosis may affect any part of gastrointestinal tract, but it most commonly involves the terminal ileum and ileocaecal region, as Crohn' s disease did[4]. However it is rare to see the involvement of all parts of the gastrointestinal tract. Therefore, our case is intresting as almost the whole gastrointestinal tract has been affected.

The symptoms of gastrointestinal tuberculosis are nonspecific, and in the absence of pulmonary tuberculosis the diagnosis may be difficult. The most common symptom associated with gastrointestinal tuberculosis is abdominal pain. Other symptoms included diarrhea, fever, anorexia, weight loss, constipation, and hemorrhage[5].

A presumptive diagnosis can be made in the presence of known active pulmonary tuberculosis and based on the clinical and radiological findings in the bowel. Definitive diagnosis is essentially made by histology, with Ziehl-Neelsen staining for acid fast *bacilli* and culture. Colonoscopy and endoscopy of gastrointestinal system are the most useful nonoperative diagnostic tools. A combination of histology and culture can establish the diagnosis up to 80 % of the patients. Altough more expensive PCR of biopsy specimens may facilitate diagnosis since it has higher sensitivity and specifity than routine culture, and results could be obtained in 48 hours instead of weeks[6]. The detection of anti-cord antibodies has recently been shown to facilitate the diagnosis of intestinal tuberculosis from Crohn' s disease[7]. However, the cases, which have negative results of culture and PCR can be seen and the diagnosis is achieved throuh histological assesment and response to antituberculosis treatment. Sometimes we could see the cases that had culture and PCR negative results were diagnosed histologically and recovered by tuberculosis tretment[8]. In our case, we established the diagnosis of tuberculosis by the presence of caseation and granulomatous lesions suggestive of tuberculosis, and essentially by the occurence of dramatic clinical improvement.

The lesions of gastrointestinal tuberculosis have clinically been divided into an acute ulcerative stage and chronic hypertrophic stage of the disease that is characterized by granulomas and extensive fibrosis. Ulcers are typically irregular with a necrotic base, which may extend to perforation. *Fistulae* and anorectal lesions may occur. These features are non-specific, and can also be seen in Crohn' s disease. In contrast, distinguishing histological features of granulomas in intestinal tuberculosis from Crohn' s disease have been described. Caseation, if present, strongly suggests tuberculosis. However central acute necrosis of granulomas may also be seen occasionally in Crohn' s disease.

Tuberculosis should always be considered in the differential diagnosis of patients with obscure abdominal symptoms. Other entities, which are commonly misdiagnosed are Crohn' s disease, lymhoma, carcinoma, diverticular diseases, appendicities and other infections of gastrointestinal tract. Ulcers were more typically linear, and granulomas, when they were found had no caseation necrosis or organisms[9,10].

The prognosis of gastrointestinal tuberculosis depends primarily on the imuune status of the apropriate theraphy in a timely manner. In untreated HIV-infected patients, the disease progresses rapidly and is almost always fatal. If there is suspicious tuberculosis as histologically, treatment should beginn without waiting the result of the culture. The regimen of choice in most of the cases is isoniazid 3 to 5 mg/kg, rifampin 10 mg/kg, pyraazinamid 20-25 mg/kg and ethambutol 15 mg/kg all given once daily. In resistant cases ciprofloxacin can be used. However in our case because of the side affects of

ethambutol and isoniazid, ciprofloxacin was given[11]. After a while of treatment histologic and clinical response was seen. It could be thought that ciprofloxacin could also be used in the treatment of Crohn' s disease[12]. Since the disease was worsen with the use of steroids, it should be thought that the effect of ciprofloxacin was against the tuberculosis.

This case report illustrates that the diagnosis of colonic tuberculosis requires a high index of suspicion. In cases where there is any doubt about the the diagnosis of Crohn' s disease, and even if the histology of colonic biopsies suggests Crohn' s disease, corticosteroids should be withheld due to disastrous results such as dissemination of tuberculosis. On the other hand, if the information not available to differentiate Crohn' s disease from tuberculosis, therapeutic trial of tuberculosis is justified because it whould not aggravate Crohn' s disease. In the cases of side affects of the drugs in tuberculosis, ciprofloxacin can be preferred in the combination with anti-mycobacterials which have no side affects. Tuberculosis of gastrointestinal tract can mostly be seen in immune compromised individuals such as HIV (+) individuals, alcoholic and chronic steroids users,but can also be seen in immunocompatible peoples. Although it' s mostly seen in the ileocecal region of gastrointestinal tract,it must be kept in mind that it can be widespreadly disseminated as in our case.

Abstract

The intestinal barrier function of GI tract is very important in the body except for the function of digestion and absorption. The functional status of gut barrier basically reflects the stress severity when body suffers from trauma and various stimulations. Many harmful factors such as drugs, illnesses, trauma and burns can damage the gut barrier, which can lead to the barrier dysfunction and bacterial/endotoxin translocation. The paper discusses and reviews the concepts, anatomy, pathophysiology of gut barrier and its clinical relations.

INTRODUCTION

The gut has long been thought to be quiescent or inactive during illnesses. It has not been paid much attention and not protected just like other organs such as the heart, lung, and kidney in ICU patients. It is generally considered that biochemical metabolism of the body takes place mainly in the liver. Developments in studying technology and advances in surgical skills have led to a better understanding of nutrients metabolism, anatomic architecture and physiological functions of the gut. Gastrointestinal (GI) tract has functions not only to digest and absorb nutrients, but also to modulate systemic immunity and to prevent enteric bacterial/endotoxin' s invasion, so-called gut barrier function. Functional status of the gut sometimes determines the patients' prognosis and recovery from diseases. Some traditional managements are not beneficial or completely harmful to intestinal barrier capability, and aggravate the primary diseases the body suffers. There is a practical significance to further study the physiological functions of GI tract. An overall understanding of the mechanisms of pathophysiological changes of the gut in illness would make us take measurable treatments to patients clinically. This review deals with a series of new concepts and advances in research of intestinal barrier that might be helpful to clinicians.

INTESTINAL BARRIER AND RELATED CONCEPTS

Intestinal barrier function

The definition of intestinal barrier function means that the gut can prevent the harmful materials in intestinal lumen such as bacteria and endotoxin from entering other aseptic organs, tissues and blood circulation through intestinal mucous membrane. The gut barrier is chiefly composed of three components: mucous epithelia, intestinal flora, and secreting immunoglobulin and gut associated lymphatic tissues (GALT)[1], namely the ecological barrier (normal inhabitant flora within intestine), mechanical barrier (mucous epithelia) and immune barrier (or secreting IgA, miscellaneous immune cells including intraepithelial lymphocytes and macrophages, neutrophils, natural killer cells underlying the mucous membrane, Payer' s nodes and mesenteric lymph node). Among them mucous epithelium is the most important one that establishes a mechanical barrier between the lumen and blood circulation. The gut barrier in general term means this structural epithelia[2-5].

Architecture of intestinal barrier

There are two pathways for materials in the lumen when entering into the blood circulation through mucous membrane. One is the transcellular route, the other is the paracellular route, which occupies 5 % of the total intestinal surface area. These two configurations are the main constituents of epithelial barrier[3,6]. It is considered that there are dispersively nonpolarized holes which are full of water and have a radius of 0.3-0.8 nm on the top of villous cells and a tight-junction of 0.95 nm in radius between villous cells. Substances with different sizes of radius get across intestinal epithelia through transcellular or paracellular way when entering into the body. Molecules smaller than 0.3-0.8 nm in radius could enter into the mucous membrane through these holes. Molecules bigger than those such as disaccharides (lactulose and cellobiose etc) and ^{51}Cr-EDTA seem to enter into epithelia through paracellular tight-junctions. Based on this mechanism the intestinal permeability is measured by combining the smaller (such as monosaccharide) and bigger molecules (such as disaccharide) clinically and experimentally[3,6,7]. The two accesses are influenced by alterations of absorbing intestinal area. Substanecs absorbed by the intestine would reduce after atrophy of villi or bowel resection[3, 5-7].

Bacterial translocation

Bacteria come into aseptic tissues from the bowel lumen through mucosal barrier and colonize in tissues such as mesenteric lymph node, liver, spleen and blood. This process is called bacterial translocation (BT). Studies in experimental rodents showed that translocated bacteria seen most oftenly within intact epithelial cells were *Candida*, *E. coli*, *Proteus mirabilis*, *Enterococcus faecalis* and so on, whereas *E. coli* was common and anaerobes and fungi were rare in human beings[1,8]. Endotoxin could pass through bowel wall into the body easier than bacteria in the lumen[9].

Mechanisms of intestinal barrier damage

Hunger, malnutrition and longer parenteral nutrition could cause intestinal mucosa atrophy and impair the mechanical bowel barrier[1,3,10,11]. Shock, ischemia/reperfusion damage, endotoxin of bacteria are the factors that lead to deterioration of intestinal barrier[4,12]. It was found that changes in

prostaglandin and related enzymes-Ca^{++} and cAMP system within cells affected significantly the structure of gut barrier. Non-steroid anti-inflammatory drugs (NSAIDs) could destroy the system and increase the intestinal permeability. Thus it caused bacteria/endotoxin translocating from intestinal lumen into blood circulation and other aseptic tissues, and sepsis would ensue[2,6]. Because of the increments of intestinal permeability, a series of alterations occurred, such as edema of tissues underlaid mucous membrane, microvasculature compression, stasis of blood circulation and thrombosis in microvasculature system. These patho-physiological changes impaired the microvasculature underlaid mucosa and aggravated further the damage of mucosal barrier[2]. Animal experiments showed that treatment with non-steroid anti-inflammatory drugs in aseptic rats did not cause impairment of intestinal mucous membrane. The clinical symptoms were remitted evidently by treatment with metronidazol to human bowel lesions caused by NSAIDs[13]. Managements with antibiotics in rats (it decreased the bacteria load within the intestine) also prevented NSAIDs from inducing intestine inflammation. In addition, the method of fasting for reducing bacterial antigen in alimentary tract could counteract inflammatory intestinal lesions that caused by NSAIDs either[2,14]. Studies showed that factors causing alterations in hormones secreted by mucous enterocytes and changes of related enzymatic system caused damage of intestinal barrier, and the enteric bacteria and endotoxin reinforced the damage. Prabhu *et al*[15] concluded from researches in rats that surgical stress in the small intestine caused structural and functional alterations in the brush border membrane (BBM) through oxidative stress which could affect gut barrier integrity and the generation of arachidonic acid, might mediate distal organ dysfunction. Activation of phospholipase A2 during the process was considered as a pivotal step. Other investigations discovered that the increment of intestinal permeability was mainly due to the relaxation of the tight-junction between intestinal epithelial cells, indicating that there are close connections between changes in tight-junction and cytoskeleton. Any drugs or chemical materials that could impact on cytoskeleton such as lipopolysaccharide, growth factors, cytokines, and hormones, would affect the intestinal permeability[16].

Nitric oxide and intestinal barrier

Nadler *et al*[12] considered that various insults working on human body could cause overexpression of inducible nitric oxide synthase (iNOS) and hence a redundant production of nitrix oxide (NO) occurred. This higher concentration of NO could lead to deposition of protein salts of nitrite-peroxide (and nitric-peroxide) on mitochondrial membrane, impair mitochondrial membrane potential (or permeability) or decrease ATP production. It would destroy the cellular respiratory function and aggravate cellular apoptosis, thus resulting in a breakage in mucous epithelial continuity and "bare area". Bacteria entering through the "bare area", so-called bacterial translocation takes place. A number of researches have shown that endotoxin increases NO over-production with intestinal barrier damages[17-20]. Our animal experiments confirmed this finding (data not published).

Gut is a central organ for surgical stress

The gut has long been thought to be quiescent or inactive during illnesses[29]. A large number of animal experiments and clinical investigations have suggested that functional changes in gastrointestinal mucous mumbrane occur during illness. Bacteria and endotoxin within the lumen enter into the other aseptic tissues and blood circulation through disordered functional and/or disorganized structural mucous epithelia, which influence greatly on occurrence, progress and transformation of illnesses[1-4,6,10-12,21-30]. In recent decades based on large amounts of animal experiments and clinical investigations, a series of new functions concerning gut metabolism and nutrition, intestinal barrier and immunity function, have been recognized. Following the elucidation on mechanisms of systemic inflammatory response syndrome (SIRS) and multiple-organ dysfunction syndrome (MODS)[4,11,29,31-37], the action of the gut as a central organ for surgical stress has also been put forward[29,30,32,35]. It is now known that the gastrointestinal tract contains about 50 % of reticular endothelia and other immune cells, and occupies about 80 % of the total humoral immunity of a human body. It is therefore the largest immune organ of the body[32-35]. Various insults such as trauma, burn, infection, shock, ischemia/reperfusion, irradiation therapy, chemical therapeutical medicines, and SIRS, could directly or indirectly cause an overgrowth of bacteria in bowel and lead to deterioration of intestinal barrier. Hence translocation of enteric bacteria and/or endotoxin, SIRS, sepsis and even MODS ensue[8,38-40], suggesting that the function of the gut in illness determines the patient' s prognosis[38, 41]. Based on this theory and clinical practice above, Wilmore *et al* put forward that gut was a reservoir of pathogens in illness and a central organ for surgical stress[29, 41]. This has been accepted by most scholars[8,38].

EVALUATION OF GUT BARRIER

There are many ways for measuring intestinal barrier function, but no one is perfect. Three regular approaches are often used to measure the function of gut barrier. The first is to examine the morphologies of mucous membrane such as thickness of mucosa, depth of crypts, architecture of villi, proliferating cellular nuclear antigen (PCNA) and intraepithelial lymphocytes (IELs). The second is to test translocation of bacteria/endotoxin, or bacteria growth and endotoxin concentration in mesenteric lymph node (MLN), liver, spleen, portal vein and/or systemic circulation. The third is to measure intestinal permeability[5,6], which is often carried out by using some labeling substances in experimental and clinical researches. Such substances could be water-soluble, nontoxic, and freely permeated through numerous small ' water pores' in the cell membranes of mucosal enterocytes. There is few or no such substances in body tissues that could not be metabolized. They should be excreted rapidly in an easily measured form. The substances matching with conditions mentioned above are lactulose, mannitol, ^{51}Cr-EDTA, PEG400 and inulin[2,6,42]. The approches that are most frequently used to examine intestinal permeability are the two-sugar test, or lactulose/mannitol test. There are two pathways for the subtances to get across the bowel mucous membrane, transcellular (through plasma membrane of enterocyte in the tip) and paracellular (the tight-junction between cells) routes. Smaller molecular substances (such as monosaccharide) pass through enterocytes by transcellular route, whereas bigger molecules (such as disaccharide) get across enterocytes by paracellular pathway. Thus, the increase of small intestinal permeability reflects the "leakeage degree" of mucous enterocytes [2,5-7].

DISEASES AND FACTORS CAUSING GUT BARRIER DYSFUNCTION

Any insults that lead to an overgrowth of enteric bacteria, an impairment of immune defence function and a damage to mechanical barrier of the gut would result in disorders of the intestinal barrier, and bacteria/endotoxin translocation would ensue[1,4,6,10,11,27]. Followings are the causes that lead to an increase of intestinal permeability.

Infection
This includes intestinal and intraperitoneal infections[38] and infections out of the intestinal tract (such as pneumonia)[43].

Parenteral nutrition
The issue has been confirmed by many animal experiments and clinical researches[10,11,21,25,44,45]. The reason is that 70 % of nutrients are absorbed directly from gut lumen, whereas only 30 % is provided by arterial blood supply[1]. Thus parenteral nutrition makes intestinal mucous membrane in a hunger state and leads to gut mucosa atrophy.

Mulnutrition
Mulnutrition could cause atrophy of intestinal mucosa, an insufficiency of protein synthesis and deficiency of body immunity. These would impair the gut barrier[3-27,28,32,34].

Overgrowth of enteric bacteria
Drugs or infection caused by some pathogens could lead to the overgrowth of intestinal bacteria and hence injures the gut barrier[8,27,39,45, 46].

Endotoxin
Endotoxin could increase NO production in the body and lead to impairment of intestinal barrier function[27,46,47]. Our animal experiments were in accordance with this (not shown).

Surgical stress
Various injuries such as burn/scald[10], organ transplantation (reperfusion injury), surgery and trauma[48-50], haemorrhagic shock and many other insults that lead to SIRS, would bring about an increment of intestinal permeability and damage of gut barrier[4,21].

Drugs
Oral administration of castor oil would cause a physical damage of intestinal mucous membrane in mice. Diabetes mellitus induced by streptozotocin in mice caused an overgrowth of enteric bacteria and an immunity injury of the body. Cyclo-oxygenase inhibitors of prostglandin such as mezolin can block production of prostacyclin in bowel mucous membrane, which increases the permeability of mucous epithelium and bacterial translocation[2,14]. It can also bring about intestinal pathological changes[13,51]. Immunosupressive agents such as chemotherapy drugs, anti-transplant rejection drugs[4,52], and antiacids can destroy gut mucosal barrier[53].

Multiple illnesses
Various abdominal diseases could cause an increase of intestinal permeability. One of these is inflammatory bowel disease (IBD)[2,9,42]. Others are intestinal obstruction, biliary block[4,9], leukemia, endotoxemia, parenteral and enteral nutrition[1, 4,10,11].

Physical injury
It includes radioactive intestinal damage[54].

AGENTS DECREASING INTESTINAL PERMEABILITY
Enteral nutrition could alleviate intestinal atrophy of mucous membrane during stress and could lower gut permeability, improve mucosal immunity. These have been confirmed by experiments and clinical practices[11,37]. Treatments with some special nutrients or immune-modulating drugs for patients with parenteral nutrition could also ameliorate intestinal barrier function[2,3,21].

Glutamine
Except for nutrient digestion and absorption, one of the functions of intestinal mucosa is to prevent enteric bacteria and endotoxin from entering into other parts and blood circulation of the body. It is now considered that gut barrier dysfunction is an important cause for infectious complications when patients suffer from hyper-metabolism after surgery and trauma[1,4,10,27,29,31]. It is still unclear what pathological mechanisms lead to gut barrier failure. It is taken for granted that two important factors causing intestinal barrier failure are the damage of intestinal blood supply and the lack of nutrient support[21]. It has been discovered from animal models and septic patients that the state is associated with insufficiency of perfusion (including disorders of microcirculation) and lack of essential nutrients (including glutamine) in their mucosa[2, 21]. Except for antimicrobial therapy of selective decontamination aiming at getting rid of enteric pathogens, it has been carried out to protect gut barrier function from being injured or have been injured in patients threatened by enterogenous infection. A promising approach is to use glutamine parenterally, which is an essential nutrient for the gut in stress and decreases sharply in illness. A series of experiments and clinical researches showed that nutritional support supplemented with glutamine could improve gut barrier function and enhence the body immunity[8,10,21,32,34,42,44,55-58].

Glutamine exerts its effects on the body in many ways. It supplies fuels for mucous enterocytes and strengthens the barrier structure of the gut on the one hand, and increases secretion of IgA by regulating IL-4 and IL-10 on the other hand, thus preventing enteric bacteria from adhesion to intestinal mucosa and subsequent bacterial translocation[59].

Arginine
Arginine influences the body immune system extensively. First, it is the precursor of polyamines and nucleic acids, which are essential for cell hyperplasia and differentiation. Second, it can produce hydroxyproline through metabolism to promote collagenation. Third, it can stimulate different human cells to secrete hormones such as growth hormone, glycagon, insulin-like growth factor 1 and insulin etc., which have various effects on the immune reactions of the body. In addition, arginine is also a precursor of nitric oxide, an important immune molecule[32,44], and has functions to kill bacteria, protect or impair intestinal barrier[32,44,60,61]. Some scholars reported that arginine could alleviate the secondary damage of gut barrier[62,63], whereas others held a completely different opinion, which had also confirmative evidences[50, 64]. Further investigations on the effects and mechanisms of arginine on the body are needed.

Recombinant human growth hormone (rhGH)
Growth hormone has many biological functions[22,44,64-66]. It could decrease intestinal permeability and improve gut barrier function in illness[39,58,69-71]. Possible mechanism of this may be that it promotes hyperplasia of intestinal epithelia[72], or enhances the mechanical barrier of mucous membrane.

Insulin-like growth factor-(IGF-I)
The main effects of IGF-I on the body are basically the same as rhGH[73, 74]. It promotes hyperplasia of mucous membrane of the intestine, and increase the uptake and utilization of glutamine by the bowel when in sepsis[70].

Nucleic acid
Kishibuchi *et al*[75] observed the alterations of cellular ultrastructure under electronic microscope, variations of intestinal permeability and changes of protease in bowel

mucous membrane, which showed that intestinal barrier function was significantly improved.

Others

Epidermal growth factors (EGF) have positive effects on the proliferation of mucous epithelia[76].

Abstract

Gastric cancer is common in China, and its early diagnosis and treatment are difficult. In recent years great progress has been achieved in gene therapy, and a wide array of gene therapy systems for gastric cancer has been investigated. The present article deals with the general principles of gene therapy and then focuses on how these principles may be applied to gastric cancer.

INTRODUCTION

Enormous progress has been seen in molecular genetics over the past few decades. It has given us insights at the molecular level, into vital progresses in living organisms, such as embryonic development, growth regulation, differentiation, pathogenesis and carcinogenesis. Insights into the mechanism of pathologic progresses such as developmental disorders and carcinogenesis, have stimulated efforts to develop therapeutic approaches to prevent or correct these processes. Techniques to directly change the genetic information of a cell have greatly improved expectations of the therapeutic potential of genetic manipulation. These developments have raised hopes that diseases appearing to be incurable can soon be cured. Especially for cancer such as gastric cancer, which is common in China. It is well established that most cancers result from a series of accumulated, acquired genetic lesions in somatic cells that are faithfully reproduced until a malignant clone is created, which is ultimately able to destroy the host. Gene therapy has emerged as a new method of therapeutic and possibly preventive intervention against cancer at the level of cellular gene expression[1-14]. Generally speaking, gene therapy can be defined as the introduction and expression of an exogenous gene into human cells for therapeutic benefit, and is conventionally restricted to human diseases associated with single gene defects[15].

In oncology, it can be defined as the introduction of DNA into cells (either neoplastic or normal) in order to shrink or eliminate a malignant tumor. This may be achieved by means of directly inducing malignant cell death, modulating immune response to tumors or reversing the malignant process by correcting genetic abnormalities. It may also be possible to enhance a tumor's responsiveness to conventional treatments such as chemotherapy and radiotherapy, and to protect normal tissue by introduction of genetic materials that confers resistance to the toxic effects of such treatment[16, 17]. A number of strategies have been developed to accomplish cancer gene therapy. These approaches included cytotoxic gene therapy, antisense therapy, and immunotherapy[18-22]. However, despite progress in the field, wide clinical applications and success have not been achieved[23,24]. As with all forms of gene therapy in cancer, the main problems to overcome will be optimizing delivery in order to maximize the proportion of successfully transduced cancer cells, In treatment of human malignant tumours, several obstacles explain the limitations of currently available treatments for achieving definitive cures in most cases of advanced disease. There are some problems in gene therapy. A combination of new chemotherapy drugs, higher doses of drugs, novel cytokines, improved regimens of radiotherapy, and more sophisticated surgery can achieve incremental improvements in cancer treatment. But these therapies do not address critical biological obstacles, and thus, probably will not bring about the much-needed radical advances in the implementation and results of cancer treatment. In contrast, gene therapy offers the potential for overcoming some of these fundamental barriers.

APPROACHES TO GENE THERAPY

Vector

One of the major problems in gene therapy is difficulty in delivering appropriate nucleic acid sequences to target cells. Various strategies have been evolved, which can be essentially divided into two types. One use viral vectors while the other uses non-viral vectors.

Viruses vector The main viruses which have been studied as potential vectors for transducing genes into cancer cells are retrovirus and adenovirus. Retroviruses are single-stranded RNA viruses, and after deletion of one or more structural genes, a foreign gene can be incorporated forming a "recombinant" retrovirus. This could then be used to infect a cell so that it integrates into the host cell's genome which then expresses viral genes as well as the "therapeutic" gene[25,26]. Adenoviruses consist of a core containing double-stranded DNA surrounded by a protein capsid. When an adenovirus vector is created, E1 genes are deleted in order to render the virus incapable of replication, thereby obviating the risk of transforming healthy host cells[27]. Adenoviruses have a greater potential than retroviruses in that they have a higher efficiency of infection and it is possible to incorporate larger segments of DNA. Weber *et al*[28] thought that oncoretrovirus-based vector was a safe and reliable vector system that could achieve permanent integration of delivered transgenes. Successful application of these vectors for gene therapy has proven difficult due to their relatively low transduction efficiency. However, cumulative improvements in methodology have recently yielded promising clinical results. Furthermore, significant improvements in basic retrovirus vector technology now can revitalize the field. But they do induce antiviral immune responses that may compromise the ability to treat an immunocompetent host on more than one occasions. Other viruses which have been used in this context include herpes virus, vaccinia virus and adenovirus-associated virus. Pieroni *et al*[29] found the use of baculovirus vectors for gene expression in mammalian cells was in continuous expansion. These vectors do not replicate in mammalian cells, do not cause a cytopathic effect upon

infection and are able to carry large DNA inserts. Baculovirus vectors have been shown to transduce various cell types *in vitro* and *in vivo* with significant efficiency leading to stable gene expression. This review focuses on recent the developments in baculovirus vector that highlight its potential use for new gene therapy strategies. Okada *et al*[30]. have done something about adeno-associated viral vector-mediated gene therapy for ischemia-induced neuronal death.

Non-viral vector The most widely studied non-viral vector is liposome. Liposome is a positively charged lipid membrane which can be complexed with DNA, and fusion of liposome-DNA complex with a negatively charged membrane leads to transfer of DNA into cells. Lasic *et al*[31] reviewed stabilized liposomes in cancer therapy and gene delivery. Unfortunately, the efficiency of gene transduction using liposomes was currently much lower than that achieved by viral vectors[32].

Other approach

Another approach is to use direct injection of plasmid DNA, but this technique can only transfect cells immediately adjacent to the injection site so that only a small number of cells can be treated[33].Vanden *et al*[34] found that oncoretroviral vectors and lentiviral vectors offered the potential for long-term gene expression by virtue of their stable chromosomal integration and lack of viral gene expression. Gomez *et al*[35]analyzed conditionally replicative adenoviral vectors. Liu *et al*[19] described that the successful transformation of C. sporogenes, a clostridial strain with the highest reported tumor colonization efficiency, with *E. coli* cytosine deaminase (CD) gene and showed that systemically injected spores of these bacteria expressed CD only in the tumor.

It is hoped, however, that by complexing adenovirus and plasmid DNA with protein ligands which bind to specific receptors, enhanced gene transfer into specific cellular targets might be achieved[36]. An example of this is the argenine-glycine-aspartic acid motif that targets integrin receptors[37]. Aside from different approaches to introducing genetic material into cells, gene therapy can be classified according to the different end results. The main aims in this respect are gene replacement, antisense therapy, cytotoxic gene therapy, immunotherapy and drug resistance transfer.

Cytotoxic gene therapy

One of the most promising strategies for gene therapy against various types of cancer is the introduction of a suicide gene, which is transduction of a gene that transforms a non- toxic "pro-drug" into a toxic substance. One approach to this general concept is the transfer of the gene for HSV thymidine kinase (HSV-tk), as this phosphorylates nucleoside analogues such as acyclovir and ganciclovir which are then incorporated into DNA as it replicates[38]. Floeth *et al*[39] analyzed the mechanisms of the "bystander effect" in VPC-mediated HSV-Tk/GCV gene therapy. Thus, these compounds are only toxic to cells expressing HSV-tk, although the bystander effect has also been noted in this type of gene therapy[40]. This is presumably due to release of toxic metabolites produced by the prodrug-activating enzymes which then kill surrounding non-transduced cells. A similar type of cytotoxic gene therapy involves an adenovirus carrying cDNA for cytosine deaminase enzyme of *E.coli* and prodrug 5-fluorocytosine. The prodrug is given orally and converted to 5-fluorouracil in the cells containing cytosine deaminase[41,42].

Antisense therapy

When oligonucleotides bind to their complementary RNA or DNA, they prevent translation or transcription, respectively. This process, known as "anti-sense", is a theoretically attractive method for inactivating oncogenes which are overexpressed in tumors[43,44]. Tang *et al*[45] amplified the 200 VEGF cDNA fragment and inserted it into human U6 gene cassette in the reverse orientation transcribing small antisense RNA which could specifically interact with VEGF165 and VEGF121 mRNA. Their conclusion was expression of antisense VEGF RNA in SMMC-7721 cells could decrease tumorigenicity and antisense-VEGF gene therapy might be an adjuvant treatment for hepatoma. Like gene replacement therapy, however, it would seem that all cells in tumors would have to be transduced, and oligonucleotides would have to last long enough to down-regulate the appropriate genes. Nonetheless, this approach did seem to be effective in certain animal models[46-48]. Kumai *et al*[49] investigated the effect of antisense oligodeoxynucleotides (AS ODN) against tyrosine hydroxylase (TH) on hypertension and sympathetic nervous system activity in spontaneously hypertensive rats (SHR). Systolic blood pressure (SBP) in SHR treated with TH AS ODN (50, 200 mg/rat, i.v.) was significantly lower than that in control SHR. Epinephrine and norepinephrine levels, TH activity, and TH protein levels in adrenal medulla of SHR were reduced concomitantly with TH AS ODN treatment-induced changes in SBP. In contrast, TH AS ODN (200 mg/rat) had no effect on SBP in Wistar-Kyoto rats (WKY), though catecholamine levels, TH activity, and TH protein levels were significantly decreased. These findings suggest that peripheral systemic injection of TH AS ODN may be effective as hypotensive therapy in SHR. Marchand *et al*[50] found the use of miniosmotic pumps, phosphate-buffered saline, VEGF, or VEGF combined with AS-Flk-1, AS-Flt-1, or AS-scrambled oligonucleotides were released in mouse testis for 14 days. VEGF (1, 2.5, and 5 mg) increased the formation of new capillary blood vessels by 236 %, 246 %, and 287 %, respectively. The combination of AS-Flk-1 or AS-Flt-1 (200 mg) to VEGF (2.5 mg) reduced by 87 % and 85 % of new blood vessel formation, respectively, and the expression of their corresponding proteins. These data demonstrate the therapeutical potential of AS-Flk-1 or AS-Flt-1 to prevent VEGF-mediated angiogenesis *in vivo*.

Immunotherapy

The main principle of genetic immunotherapy is to improve the host' s immune response to a particular tumor. One approach is to employ intramuscular injection of DNA which encodes a tumor-associated antigen such as CEA either directly or in form of a viral vaccine[51]. Cheng *et al*[52] have developed a new strategy to enhance nucleic acid vaccine potency by linking VP22, a herpes simplex virus type 1 (HSV-1) tegument protein, to a model antigen. This strategy facilitated the spread of linked E7 antigen to neighboring cells. In their study, they created a recombinant Sindbis virus (SIN)-based replicon particle encoding VP22 linked to a model tumor antigen, human papillomavirus type 16 (HPV-16) E7, using a stable SIN PCL. The linkage of VP22 to E7 in these SIN replicon particles resulted in a significant increase in the number of E7-specific CD8(+) T cell precursors and a strong antitumor effect against E7-expressing tumors in vaccinated C57BL/6 mice relative to wild-type E7 SIN replicon particles. Furthermore, a head-to-head comparison of VP22-E7-containing naked DNA, naked RNA replicons, or RNA replicon particle vaccines indicated that SINrep5-VP22/E7 replicon particles generated the most potent therapeutic antitumor effect. By leading to an active immune response, this was thought to be more effective than passive immunisation using specific antibodies against the antigen in question. Another way was to enhance immunity by using genes for cytokines such as interleukins (IL) which could recruit and stimulate appropriate effector cells[53,54]. Nishioka *et al*[55] have done something about genetic modification of dendritic cells and its application to cancer

immunotherapy. Although the results in the experimental systems were promising, the clinical application of gene-modified DCs had several problems such as the standardization of methods of manipulation and gene-transduction of DCs. Approaches to solve them require further studies. Takemura *et al*[56] have previously produced an anti-MUC1 x anti-CD3 diabody (Mx3 diabody) in an Escherichia coli (*E. coli*) expression system, other approaches have been found, for instance, Vonderheide *et al*[57] applied telomerase as a universal tumor-associated antigen. Schadendorf *et al*[58] reviewed the use of histamine in cancer immunotherapy.

APPLICATION OF GNEE THERAPY FOR GASTRIC CANCER

p53 gene

About 60 % of human gastric cancers carry point mutations of p53 gene, and because of its central role,this nuclear protein is believed to play a role in the regulation of cellular response to DNA damage. Wild-type p53 replacement therapy is an attractive concept in this disease. The responses of human gastric cancer cell lines to recombinant adenovirus encoding wild-type p53 gene have been analysed *in vitro* and *in vivo*[59]. In that study, growth inhibition was observed in cell lines expressing p53 mutations, but not in lines with wild-type p53. Furthermore, the mechanism of cell killing was found to be apoptosis. Thus, it seems that p53 replacement therapy has potential as a therapeutic strategy for human gastric cancer.

Antisense therapy

Antisense therapy has also been used in gastric cancer cell line. Proliferating cell nuclear antigen (PCNA) has been shown to stimulate DNA synthesis by DNA polymerase delta, and to be strongly expressed by gastric cancer cells with a high proliferative activity. Antisense oligonucleotides specific for PCNA mRNA have been shown to inhibit the growth of all gastric cancer cell lines tested, whereas random sequence oligonucleotides had no effect.

Cytotoxic gene therapy

Gastrointestinal cancer is the most important clinical target of gene therapy. Suicide gene therapy with herpes simplex virus type 1 thymidine kinase (HSV-TK) gene, has been shown to exert antitumor efficacy in various cancer models *in vitro*. A modificiation of this approach has been madee to insert carcinoembryonic antigen (CEA) promoter into the viral vector to increase the efficiency of transfection of HSV-tk into cells expressing CEA. When compared with transduction of HSV-tk with a ubiquitous promoter, the use of CEA promoter enhanced the killing effect of ganciclovir in CEA producing cells. While in colorectal cancer, about 40 % of gastric cancer expressed CEA, and CEA producing gastric cancer cell lines were susceptible to this treatment. Okino *et al*[60] described the sequential histopathological changes after suicide gene therapy of N-methyl-N' -nitro-N-nitrosoguanidine (MNNG)-induced gastric cancer in rats. Gastric tumors were induced by MNNG in 38/73 (52 %) of Wistar strain rats. The suicide gene therapy group (14 rats) was subjected to *in situ* gene transfer with a recombinant adenovirus vector carrying the HSV-TK gene driven by CAG promoter (Ad.CAGHSV-TK) in gastric tumor, followed by the antiviral drug ganciclovir (GCV). They observed the histopathological changes at various times after HSV-TK/GCV gene therapy, groups of animals were sacrificed at 3, 8, and 30 days after gene transfer. Apoptosis in gastric tumors was detected by the TUNEL method to assess the efficacy of HSV-TK/GCV gene therapy, and it was markable in the 8- and 30-day treatment groups compared to the sham operation controls (P<0.001). Various histopathological changes, degeneration of cancer tissue and fibrosis after necrosis and apoptosis were significantly greater in the 30-day treatment group. The HSV-TK gene was detectable in peripheral blood by PCR until 30 days after gene transfer. These results might be useful in devising a method of suicide gene therapy for humans.

Other forms of cytotoxic gene therapy which have been used with success in gastric cancer cell lines include transfection of E.coli phosphoribosyltransferase (UPRT) which could catalyse the synthesis of UMP from uracil and 5-phosphoribosyl-alpha-1-diphosphate, thereby sensitising the cell to 5-fluorouracil (5-FU). This has been shown to enhance the cell killing effect of 5-FU in gastric cell lines both *in vitro* and *in vivo*. Shimizu *et al*[61] have generated a recombinant adenovirus encoding the UP gene (AxCA.UP) which has been applied in gastric cancer gene therapy to sensitize cancer cells to lower concentrations of 5-FU.

Immunotherapy

Genetic immunotherapy is another area of active research, and work with severe combined immunodeficiency (SCID) mice given human peripheral lymphocytes and autologous human tumour cells from patients with gastric cancer has yielded interesting results. In one study, administration of an adenovirus vector expressing IL-6 cDNA-induced CD8+cytotoxic T-lymphocytes specific for tumour cells from the precursor human T-lymphocytes *in vivo*, inhibited growth and metastasis of autologous human tumours. In another study, SCID mice reconstituted with peripheral blood cells containing CD34+cells were inoculated with human gastric cancer cell lines transduced with cytokine genes including IL-2 and IL-6. It was found that the tumourigenicity of IL-2 producing tumour cells was significantly reduced in the CD34+ reconstituted but not in the non-reconstituted mice, whereas transduction of IL-6 did not affect tumourigenicity, irrespective of the reconstitution status of the mice. This system could provide a model for investigating the utility of transfecting tumours with individual cytokines. Yu *et al*[62] described the bioactivity of MG7 scFv for its application as a targeting mediator in gene therapy of gastric cancer. Two positive recombinant phage clones have been found to contain the exogenous scFv gene. ELISA showed that MG7 scFv had a strong antigen-binding affinity. Immunodotting assay showed that transfected E.coli HB2151 could successfully produce soluble MG7scFv with a high yield via induction by IPTG. The molecular mass of MG7 scFv was 30 kDa by Western blot. DNA sequencing demonstrated that VH and VL genes of MG7 scFv were 363 bp and 321 bp, respectively.

PROSPECT

With development of the genomic research, more and more individual patients have benefited from the revolution so far. Thus, despite a paucity of clinical information, gene therapy for gastric cancer is on the horizon. As with all forms of gene therapy in cancer, the main problems are to optimize delivery in order to maximize the proportion of successfully transduced cancer cells, and to choose the most appropriate targets for an individual tumor. There is no doubt that human cancers are heterogeneous in terms of genetic abnormality, and a better understanding of the mutational spectrum associated with a cancer type along with the ability to obtain mutation profiles for individual tumors is an important step to successful gene replacement and antisense therapy[63-68].

One factor critical to successful human gene therapy is the development of efficient gene delivery systems. Although numerous vector systems for gene transfer have been developed, a perfect vector system has not yet been constructed. Difficulties of *in vivo* gene transfer appear to be due to

resistance of living cells to invasion by foreign materials and interference of cellular functions. We should analyze what barriers in tissues affect *in vivo* gene transfection and focus on how to solve these problems for gene therapy[68-71].

Abstract

AIM: To investigate telomerase activity and hTERT, TP-1 expression and their relationships in esophageal squamous cell carcinoma (ESCC).

METHODS: Telomerase activity was measured in 60 ESCC tissues using telomeric repeat amplification protocol (TRAP) assay by silver staining. *In situ* hybridization was used for detecting hTERT and TP-1mRNA.

RESULTS: The telomerase activity was detected in 83.3 % of ESCC tissues. The difference of telomerase activity was significant between well and poorly cancer differentiated lesions ($P<0.05$). The positive rate of telomerase activity was higher in patients with lymphatic metastasis than in patients without lymphatic metastasis. In cancer tissues hTERT mRNA expression was 75 % and TP-1 mRNA expression was 71.7 %. The expression of hTERT, TP-1 mRNA in well and poorly differentiated carcinoma was not significant. The expression of hTERT mRNA was correlated with telomerase activity, but TP-1 mRNA expression was not correlated with it.

CONCLUSION: Telomerase activity and hTERT, TP-1 mRNA expression are up-regulated in ESCC. Telomerase activity in ESCC is correlated with lymphatic metastasis and cancer differentiation. Telomerase activity may be used as a prognostic marker in ESCC. hTERT mRNA expression is correlated with telomerase activity. Enhanced hTERT mRNA expression may initially comprehend the telomerase activity level, but it is less sensitive than TRAP assay.

INTRODUCTION

Repetitive telomere sequences are present at the ends of eukaryotic chromosomes that protect the ends from damage and rearrangement. Progressive shortening of telomeric sequences is associated with cell division owing to the end replication involved in DNA replication. Telomerase is a special type of reverse transcriptase that stabilizes the telomeric ends of chomosome by adding TTAGGG repeats onto the chromosome ends. In humans, telomerase is composed of at least two components. hTR containing the template for reverse transcription[1], and telomerase associated proteins. Telomerase associated protein consists of hTP-1[2,3] and human telomerase reverse transcriptase (hTERT). hTERT is thought to be a enzyme' s catalytic subunit. In human, telomerase was active during embryonic development, and it was active in adult germ-line tissues, immortal cell[4,5] and most malignant tumors[6,7]. We have reported that telomerase activities were high both in esophageal squamous cell carcinoma (ESCC) and in their preneoplasia lesions[8]. This study was to examine telomerase activity, expression of hTERT mRNA, and hTP-1 mRNA in ESCC tissues and to analyze the relationship between teolmerase activity and its associated proteins.

MATERIALS AND METHODS

Materials

Esophageal squamous cell carcinoma tissues from 60 patients (40 men and 20 female, aged from 34 to 70 years) undergone surgical resection in Tumor Hospital of Medical College Shantou University from 1999 to 2001 were analyzed. All fresh tissues were taken immediately after operation and stored at -70 ℃.

TRAP-silver staining for telomerase activity

We used $TRAP_{EZE}$ telomerase detection kit (Intergen Company). After addition of 10-20 μl telomerase assay lysis buffer (1×CHAPS), the cells were lysed on ice. The lysate was incubated on ice for 30 min and then centrifuged at 12 000 r/min for 20 min at 4 ℃. The supernatant was collected and the protein concentration was determined by standard procedures (BCA protein assay). A volume of 0.6 μg protein equivalent was added to 48 μl reaction solution containing TRAP buffer, dNTP Mix, TS primer, RP primer, K_1 primer and 2 units Taq polymerase. PCR condition was 33 cycles at 94 ℃ for 30 s, at 59 ℃ for 30 s. PCR products were loaded and run on 12.5 % non-denaturing polyacrylamide gel. After electrophoresis, the gel was stained with silver.

In situ hybridization for hTERT and TP-1 mRNA expression

Samples were frozen and serially cut into 5 μm thick sections. One section was stained by hematoxylin and eosin (HE) for microscopic examination. Another was detected for hTERT and TP-1 mRNA expression. Expression of hTERT mRNA and hTP-1 mRNA was detected by digoxigenin-labeked gene probe which form a commercial kit (Boster Company, China) according to the manufacturer' s instructions. The hTERT oligonucleotides probes were 5' -AGTCA GGCTG GGCCT CAGAGAGCTG AGTAG GAAGG-3' , 5' -GCATG TACGG CTGGA GGTCT GTCAA GGTAG AGACG-3' , and 5' -AGCCA AGGTT CCAGG CAGCT CACTG ACCCT-3' . The hTP-1 oligonucleotides probes were 5' -ATATC TGAGT

GGGTA GATAC ATGCT GATGT-3', 5'-GTCAG ATAGA CCAAG ACAGT GCGGC CTGGC CTGGC-3', and 5'-AGCCA AGGTT CCAGG CAGCT CACTG ACCCT-3'. The positive expression showed brown staining signals in cytoplasm. The positive cancer cells constituted more than 75 % of all cancer cells on the section were defined as a score of 3+ (strong), about 25-75 % of positive cells had a score of 2+ (moderate), and less than 25 % had a score of 1+ (weak). The score of - (negative) had no positive cancer cell.

Controls

TRAP telomerase activity analysis: Esophageal cancer cell line EC109 was used as positive telomerase control, which was identified to be telomerase positive by our laboratory. Negative control was to perform a $TRAP_{EZE}$ kit assay with 1×CHAPS lysis buffer substituted for the cell extract. Heat-treatment of each sample by incubating at 85 ℃ for 20 minutes prior to $TRAP_{EZE}$ kit assay to inactivate telomerase served as a heat inactivation control. The $TRAP_{EZE}$ primer Mix contains internal control, which produce a 36 bp band (S-IC) in every lane to monitor PCR inhibition. If the extract with telomerase activity, a ladder of products with 6 bp increment starting at 50 bp nucleotide and a 36 bp internal control band could be seen. If the extract was telomerase negative, there was only a 36 bp internal control band (S-IC) (Figure1).

In situ hybridization: Positive control section was provided with the kit. Negative control included using incubation solution instead of the probe or the sections digested with ribonucleases (RNase) (10 mg· L^{-1}) before hTERT or hTP-1 detection.

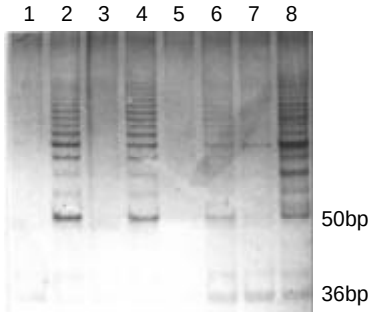

Figure 1 Carcinoma telomerase activity detected by TRAP-silver assay and separated on a 12.5 % polyacrylamide gel. Lane 1: primer-dimer/PCR contamination control, Lane 2: telomerase positive control, Lanes 4, 6 and 8: telomerase positive samples, Lanes 3, 5 and 7: heat-treated controls.

Statistical analysis

Statistical significance was tested using rectified chi-square test and exact method.

RESULTS

Relationship between telomerase activity and cancer differentiation

Histopathologically, the study population (n=60) was divided into 3 categories according to cancer differentiation as follows: grade I (n=15), grade II (n=33), and grade III (n=12). In 60 cases of esophageal SCC, telomerase activity was detected in 50 cases. The positive rate was 83.3 %. As showed in Table 1, the positive rates of telomerase activity were low in grade I and progressively increased from grade I to grade III. The significant difference of telomerase activity rate was found between grade I and grade II (χ^2=4.597, P<0.05), while, there was no significant differences between grade II and grade III (χ^2=0.263, P>0.05).

Table 1 Relationship between differentiation degree and telomerase activity in 60 cases of ESCC

Tumor stage	Sample (n)	Positive (n)	Prositive rate (%)	P value
I	15	9	60	
II	33	30	90.9	P<0.05
III	12	11	91.6	

Relationship between telomerase activity and lymphatic metastasis

There were 41 patients with lymph node metastasis out of the 60 patients. Telomerase activity rates were higher in patients with lymphatic metastasis (90.2 %) than in those without (63.2 %) (Table 2), and this difference was significant (χ^2=4.68, P<0.05).

Table 2 Relationship between telomerase activity and lymphatic metastasis

Sample (n)	Lymphatic metastasis	Telomerase activity		P value
		+	-	
41	+	37	4	P<0.05
19	-	12	7	

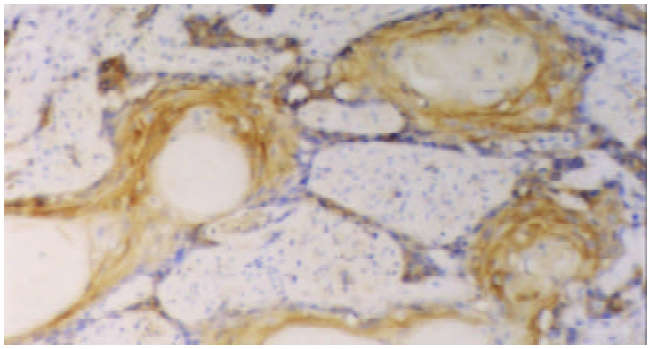

Figure 2 Esophageal squamous cell carcinoma (grade I). expression of hTERT mRNA was limited to the basaloid cell nests (40×).

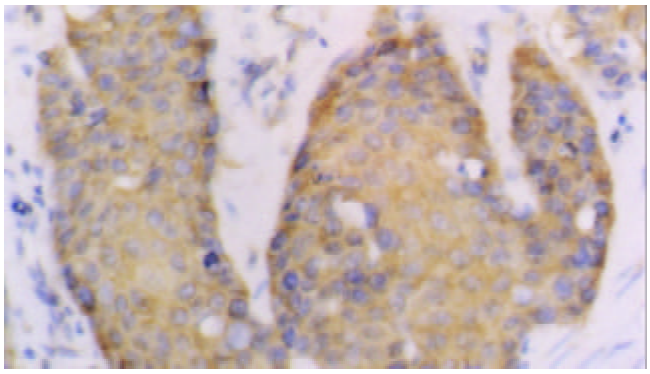

Figure 3 Poorly-differentiated esophageal squamous cell carcinoma. The expression of TP-1 mRNA was diffuse in cancer cells (40×).

Expression of hTERT and hTP-1 mRNA in esophageal squamous cell cacinoma

The positive rates of hTERT and hTP-1 mRNA expression were 75 % and 71.7 % respectively. The expression of hTERT and hTP-1 in well-differentiated carcinoma was limited to the basaloid cell nests (Figure 2). In the poorly-differentiated carcinoma, most tumor cells showed diffuse or occasionally

Table 3 Intensity of hTERT and hTP-1 mRNA expression in esophageal carcinoma tissues

Tumor stage	hTERT						*P* value	hTP-1					*P* value
	n	-	+	++	+++	Positive rate (%)		-	+	++	+++	Positive rate (%)	
I	15	7	4	3	1	53.3		7	5	3	0	53.3	
II	33	6	7	11	9	81.8	*P*>0.05	8	6	12	7	75.8	*P*>0.05
III	12	2	2	4	4	83.3		2	2	5	3	83.3	

Table 4 Relationship between hTERT, hTP-1 expression and telomerase activity

Telomerase activity	hTERT		*P* value	TP-1		*P* value
	+	-		+	-	
+	41	9	*P*<0.05	38	12	*P*>0.05
-	4	6		5	5	

focal expression (Figure 3). As showed in Table 3, the positive intensity and the positive rate of hTERT and hTP-1 expression progressively increased from grade I to grade III, but no significant differences existed between them (hTERT: χ^2=4.95, *P*>0.05; TP-1: χ^2=3.49, *P*>0.05).

Relationship between hTERT, hTP-1 expression and telomerase activity

Relationship between hTERT and hTP-1 expression and telomerase activity are summarized in Table 4. By statistical analyses, the expression of hTERT mRNA was correlated with telomerase activity (χ^2=5.76, *P*<0.05), but the expression of hTP-1 mRNA was no correlated with telomerase activity (χ^2=1.64, *P*>0.05).

DISCUSSION

Telomerase is a ribonucleoprotein reverse transcriptase that utilizes its own RNA template for the addition of telomeric sequences to chromosomal ends in order to maintain telomeric length. *In vivo* and *in vitro* studies suggested that telomerase was associated with cellular immortality and malignance, indicating that activation of telomerase might play an important role in tumorigenesis and immortalization. Telomerase activation has been demonstrated in many types of human tumors, including tumors in breast[9], nasopharynx[10,11], stomach[12-14], prostate[15], urinary bladder[16], skin[17], cervix[18], lung[19,20] and brain[21]. Some scientists suggested that telomerase activity was a diagnostic and prognostic marker for malignant tumors[22,23]. Previous research suggested that the positive rate of telomerase activity in esophageal carcinoma was 79-87 %, but there were different conclusions regarding the relationship between telomerase activity and cancer differentiation in esophageal cacinoma. Asai *et al*[24] reported that well-differentiated cancer had higher detectable telomerase activity, but Ikeguchi *et al*[25] found the opposite result. Zhao *et al*[26] concluded that telomerase activity had no correlation with cancer differentiation. Our present study results suggested that the detectable rate of telomerase activity was gradually increased from well-differentiated carcinoma to poorly-differentiated one. The difference between grade I and grade II was significant, while the difference between grade II and grade III was not significant. This result gave more evidences that telomerase activity was correlated with differentiation in esophageal SCC. The presence of telomerase activity in esophageal SCC with lymphatic metastasis suggested that the telomerase activity in patients with lymphatic metastasis was higher than that in patients without lymphatic metastasis.

Collins *et al*[27,28] first purified tetrahymena telomease protein p80. The p80 components could be specifically cross-linked to telomerase RNA. Then, the mammalian (mouse and human) homology of p80 was found, and termed telomerase-associated protein 1 (TP-1)[29]. The sequence of TP-1 showed most homology to tetrahymena p80. *In vitro* experiments suggested that TP-1 interacted specifically with telomerase RNA and that TP-1 was associated with telomerase activity. However, expression of TP-1 did not reflect the level of telomerase activity[30-32]. In the present study, we found that TP-1 expression was high in esophageal squamous cell carcinoma, but it was not correlated with telomerase activity. The specific mechanism by which the protein participated in telomerase function has not been defined.

Two related proteins, Est2p from the yeast *Saccharomyces cerevisiae* and p123 from the ciliate Euplotes aediculatus, have been identified as the catalytic subunits of telomerase in their respective species[33-36]. Est2 was first identified as a gene required for telomere maintenance in yeast[37] and was essential for telomerase activity. Then, a human gene, hEST2/hTERT (human telomerase reverse transcriptase), sharing significant sequence similarity with telomerase catalytic subunit genes of lower eukaryotes was cloned and the protein was identified[38]. Studies suggested that hTERT expression was correlated with telomerase activity. The expression of hTERT was up-regulated concomitantly with the activation of telomerase during the immortalization of cultured cells and down-regulated during *in vivo* cellular differentiation[39]. *In vitro*, changes in the sequence of hTERT amino acid might reduce telomerase activity, and transfer of hTERT into normal human cell might resurrect telomease[40]. Designing a ribozyme targeting hTERT also reduced telomerase activity[41]. However, some studies revealed that the levels of hTERT expression and detectable telomerase activity were not concomitant[42-48]. The present experiment suggested that hTERT mRNA expression was correlated with telomeras activity in esophageal SCC. But we found that the positive rate of hTERT mRNA expression was lower than detectable telomerase activity. The positive intensity and the positive rate of hTERT expression were progressively increased from grade I to grade III, but the differences between them was not significant. In 50 detectable telomerase activity cases, just 41 cases expressed hTERT mRNA, 9 cases had negatively expression of hTERT mRNA. There were 4 hTERT positive cases without detectable telomerase activity. It indicated that hTERT gene expression was an important factor to resurrect telomease, but not the only one. There was a possibility that other mechanisms were intervened to modulate telomerase activity. The reasons why the tissue had expression of hTERT mRNA without detectable telomerase activity are not clear. Following might be the explanations. Posttranscriptional modification of telomerase subunits would modulate telomerase activity, and there were some inhibitors in telomerase extract solution to reduce its activity. Using *in situ* hybiridization assay detected hTERT

expression might initially comprehend telomerase activity level. However, the result of hTERT expression and detectable telomerase activity were not identical. It was less sensitive than TRAP assay.

In summary, detectable telomerase activity and telomerase subunit expression are high in esophageal squamous cell carcinoma. Telomerase activity is related to tumor differentiation and lymphatic metastasis, which may provide a new marker for evaluating the prognosis of patients with esophageal SCC. Expression of hTERT mRNA is correlated with telomerase activity, but the expression of TP-1 mRNA is not correlated with telomerase activity.

Abstract

AIM: To estimate the mortality rates of gastroenterologic cancers for the period between 1974 and 1999, in Henan Province, China and its epidemiologic features.

METHODS: Information on death of patients with cancer was provided by the county-city registries. Population data were provided by the local police bureau. All the deaths of cancer registered were classified according to the three-digit rubric of the ICD-9. Cancer mortality rates reported herein were age-adjusted, using the world population as standard and weighted piecewise linear regression analysis.

RESULTS: Total cancer age-adjusted mortality rates were 195.91 per 100 000 for males and 124.36 per 100 000 for females between 1996 and 1998. During the period of 1974-1999, a remarkable decrease took place in esophageal carcinoma, stomach cancer remained essentially stable and liver cancer, a moderate increase. Colorectal cancer was slightly increased over the last two decades.

CONCLUSION: The population-based cancer registry can give an accurate picture of cancer in Henan Province, by providing a set of analyses of selected cancer mortality data as a source of reference for researchers in cancer, public health and health care services.

INTRODUCTION

China is one of the countries with the highest esophageal cancer and gastric cancer risk over the past century which is still the leading cause of deaths worldwide[1-9]. The aim of this study was to estimate the mortality of digestive tract cancers in Henan Province.

Promotion of cancer control programs requires accurate data on cancer incidence and mortality from population-based registries. In 1977, we reviewed all causes of death between 1974 and 1976 retrospectly and enlisted the participation in this survey of the 15 cancer registries from 1983 to 1999 in Henan Province which was inhabited with about 9 million people, one-tenth of the province's total population. The geographical locations of these units are shown in Figure 1.

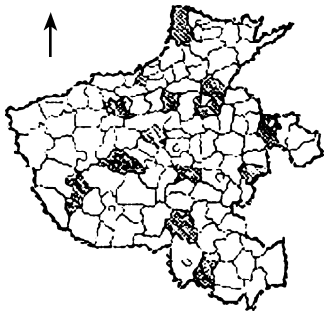

Figure 1 Geographical locations of the participating county and city registries of Henan Province, China.

MATERIALS AND METHODS

Information on death of patients with cancer was provided by the county-city registries, that consisted of the rural doctors and the local hospital doctors. Information was requested on demographic factors such as place of residence, age, sex, date of birth, and primary site of cancer as well as different diagnostic methods used such as radiology, cytology, and histology. Population data were provided by the local police bureau, consisting of the total population and the age-sex structure at the end of each year in each site studied.

All cancer deaths registered were classified according to the three-digit rubric of the ICD-9[10]. To facilitate comparison on an international basis, cancer mortality rates reported herein were age-adjusted, using the world population as standard. The direct standardization method was used to calculate various age groups from 5-years to 80 years and older. Cancer mortality trends from 1974 to 1999 were determined for more than 4 anatomic sites in males and females using weighted piecewise linear regression analysis.

RESULTS

The total cancer age-adjusted mortality rates were 193.68 per 100 000 for males and 133.29 per 100 000 for females in 1974-1976, and 218.29 per 100 000 and 125.52 per 100 000 in 1986-1988, and 195.91 per 100 000 and 124.36 per 100 000 in 1996-1998, respectively, accounting for 13.12 % for males and 10.71 % for females in 1974-1976, and 19.78 % and 15.82 % in 1986-1988, and 22.37 % and 17.25 % in 1996-1998, respectively of all cancer deaths. The major cancers diagnosed in Henan Province among males and femals are presented in Table 1. The main cancers in men included esophagus, stomach, liver and lung cancers, and the main cancers in women included esophagus, stomach, liver, lung, cervical and breast cancers. In general in Henan Province, men had higher mortality rates than women.

Table 1 Estimated cancer mortality rates[1] for males and females in Henan Province based on 15 selected registries

Site[2]	Years	Male		Female	
		ADM[1]	%	ADM[1]	%
All sites	1974-76	193.68	100.00	133.29	100.00
(140-208)	1986-88	218.29	100.00	125.52	100.00
	1996-98	195.91	100.00	124.36	100.00
Esophagus	1974-76	70.06	45.62	36.34	36.65
(150)	1986-88	67.78	31.04	35.99	32.14

	1996-98	32.02	16.37	16.16	14.58

1: Age-adjusted mortality, standardized using world standard population. 2: Numbers in parentheses are ICD-9.

Table 2 illustrates urban-rural comparisons for selected cancer deaths from 1983 -1985 and 1997 in Henan Province, which included 12 counties and three cities. In Henan Province, rural areas had higher cancer mortality rates than urban areas, except for liver cancer in males.

Table 2 Urban and rural differences in mortality rates[1] of cancer from selected sites in Henan Province, China (1980's and 1990's)

Site[2]	Sex	Urban area		Rural area	
		1983-85	1997	1983-85	1997
All sites	M	170.09	149.52	208.80	190.34
(140-208)	F	99.89	52.83	126.99	103.07
Esophagus	M	78.74	12.10	87.63	50.03
(150)	F	45.62	5.48	57.29	25.58
Stomach	M	35.13	21.01	54.06	49.66
(151)	F	17.35	4.05	31.86	23.52
Colon / Rectum	M	8.10	8.92	6.38	9.17
(153-154)	F	5.48	2.36	4.36	4.81
Liver (155)	M	30.47	38.48	23.40	36.10
	F	11.11	9.43	11.28	17.06

1: Age-adjusted mortality, standardized using world standard population. 2: Numbers in parentheses are ICD- 9.

Cancer mortality rates at all sites did not change over the past two decades (Figure 2). During the period of 1974 -1999, marked changes took place in Henan Province in cancer mortality rates at certain sites. Esophageal carcinoma markedly declined, esophageal cancer mortality rates decreased over the period studied for males from approximately 70 per 100 000 in 1974-1976 to 43 per 100 000 in 1996-1998, and for females from approximately 36 per 100 000 to 25 per 100 000, respectively (Figure 3). Stomach cancer remained essentially stable (Figure 4), liver cancer have markedly increased (Figure 5). Colorectal cancer was the fifth most frequently diagnosed cancer in Henan Province. Men were diagnosed with this cancer slightly more frequently than women. Mortality rates for colorectal cancer have slightly increased over the last two decades (Table 1).

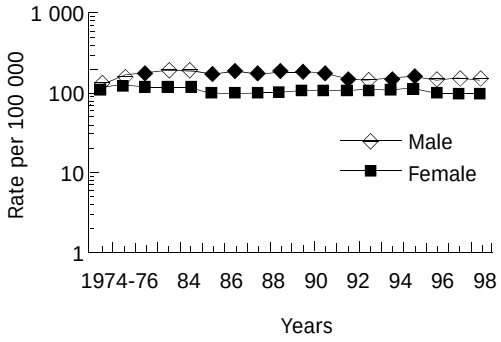

Figure 2 Total cancer mortality in Henan Province, China,1974-1999.

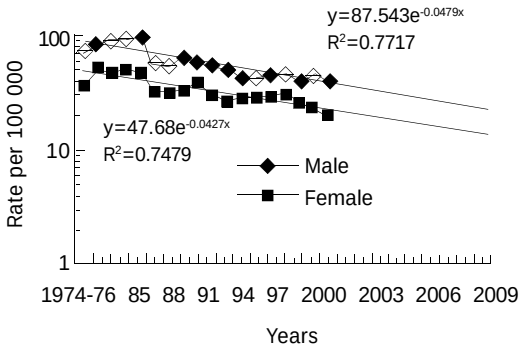

Figure 3 Age-adjusted mortality of esophageal cancer in Henan Province, China, 1974-1999.

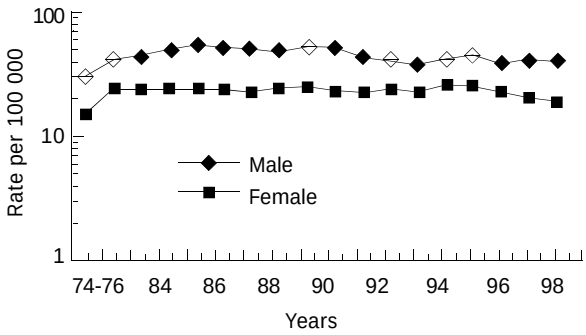

Figure 4 Age-adjusted mortality of stomach cancer in Henan Province, China, 1974-1999.

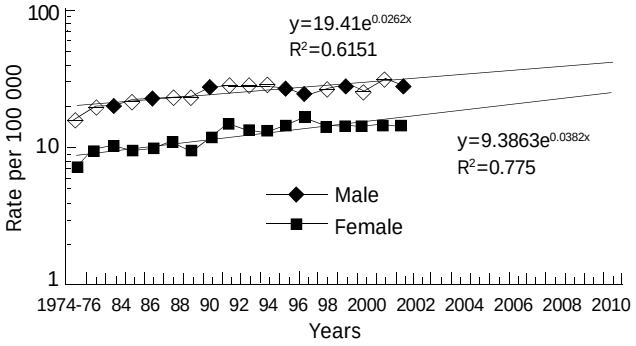

Figure 5 Age-adjusted mortality of liver cancer in Henan Province, China, 1974-1999.

DISCUSSION

Generally, genetic factors, per se, do not produce marked mortality changes over a short period of time, unless a specific

genetic factor present in the population interacts with a newly introduced agent in the environment. Thus marked changes in mortality rates, either increased or decreased, usually indicate that a new environmental agent has been introduced into or removed from the population in question. Compared with many other countries[11-18], all cancer mortality in Henan Province varied slightly over the past 25 years. Although mortality rates varied widely in specific cancers, cancers of the esophagus, stomach, liver and lung accounted for over 86 % of all cancer deaths in Henan Province. Cervical cancer and breast cancer made up 81 % of deaths in women. In general in Henan Province, men had higher mortality rates than women, and rural areas had higher mortality rates than urban areas, except for lung cancer.

Cancer mortality rates at all sites have been associated with many factors, including diet and nutrition[19-23], occupational exposure to toxic chemicals, tobacco and alcohol use, and certain viruses[24-31]. We found that lower socio-economic status, environmental pollution around the residential areas, lampblack in rooms, lower body mass index (BMI), more pickled food intake, cigarette smoking, alcohol drinking, mental-trauma and depression were risk factors of esophageal cancer. It also showed that the subjects having histories of upper digestive tract operation, dysplasia of esophagus and family histories of carcinoma had markedly increased risks for developing esophageal cancer[32]. Over the last 20 years, the dietary change occurred in Linzhou which was associated with the incidence and mortality decrease of esophageal cancer in the past ten years[33,34]. Cancer mortality rates at all sites remained essentially stable for males during the period studied, from approximately 193 per 100 000 in 1974-1976 to 195 per 100 000 in 1996-1998. Cancer mortality rates of females decreased over the last two decades from 133.29 per 100 000 in 1974-1976 to 124.36 per 100 000 in 1996-1998.

At the time of this study, esophageal cancer mortality rates decreased over the period studied for males, from approximately 70 per 100 000 in 1974-1976 to 43 per 100 000 in 1996-1998, and for females, from 36 per 100 000 in 1974-1976 to 24 per 100 000 in 1996-1998. Stomach cancer mortality rates did not change substantially during the period studied. Inversely, gastric cancer incidence and mortality rates showed a consistent decline in recent decades world-wide[12-15,21,22,35]. Liver cancer mortality rates for males markedly increased over the last two decades, from 17 per 100 000 in 1974-1976 to 32 per 100 000 in 1996-1998, for females from 8 per 100 000 in 1974-1976 to 16 per 100 000 in 1996-1998. Primary liver carcinoma (PLC) incidence and death rates in Australia increased in the past two decades[36]. Based on selected cancer registries around the world, developing countries have experienced PLC increases in incidence wherease developed countries have experienced declines[37].

The data analyzed in this report were age-adjusted using world standard population and stratified for sex and places. In temporary variation, the patterns presented were descriptive in nature. Secular trend in esophageal cancer and live cancer for both sexes in 1974-2010 with regression was used for spatial analysis.

At the end of the 20th century, cancer was the second leading cause of death in Henan Province. In the new century cancer will be the number one killer in Chinese.

Future cancer control research must aim to reduce cancer risk, incidence and mortality, and improve the quality of life[38].

CONCLUSIONS

The role of population-based cancer registry is to collect the data which give an accurate picture of cancer in a population, in order to understand and control the impact of cancer on that population. The cancer registry data can also be used to plan medical facilities and requirements needed for cancer control.

ACKNOWLEDGEMENTS

We thank the doctors from the 15 counties and cities for their assistance in data collection.

Abstract

AIM: To investigate the inhibition of p27kip1 gene on the growth of esophageal carcinoma cell strain (EC9706).

METHODS: Recombinant adenovirus Ad-p27kip1 was constructed and transfected into esophageal carcinoma cell EC-9706, and its effect on p27kip1 expression, the growth of esophageal carcinoma cell, DNA replication, protein synthesis, cell multiplication and apoptosis were explored by means of cell growth count, ^{3}H-TdR, ^{3}H-Leucine incorporation, flow cytometry, DNA fragment analysis and TUNEL.

RESULTS: Recombinant adenovirus Ad-p27kip1 was successfully constructed with a virus titer of 1.24×10^{12} pfu/ml. p27kip protein expression increased markedly after EC-9706 transfection, while incorporation quantity of ^{3}H-TdR and ^{3}H-Leucine decreased significantly. The growth of esophageal carcinoma cell was inhibited obviously. Testing of flow cytometry displayed a typical apoptosis peak, and DNA gel electrophoresis showed a typical apoptosis ladder. TUNEL showed the apoptosis rate of Ad-p27kip1 group and control group to be 37.3 % and 1.26 % ($P<0.001$) respectively.

CONCLUSION: Ad-p27kip1 can inhibit the growth and multiplication of esophageal carcinoma cells and induce apoptosis. Therefore, enhanced p27kip1 expression may be a new way to treat esophageal carcinoma.

INTRODUCTION

As a kind of thermostable cell cycle inhibitive protein, p27 (mol. wt=27 KD) can inhibit CDK activity and consequently regulate cell cycle negatively when combined with CyclinE-CDK2 or CyclinE-CDK4[1]. The expression level and activity of p27 protein are associated with the formation of tumor. p27 protein quantity in tumor is markedly lower than that in normal cells level and its content is also closely related to the degree of differentiation, action of molecular biology and prognosis of tumor[2-7]. In the present study, we aim to give a tentative answer to whether enhanced expression of p27 protein inhibit the growth of cancer cell?

MATERIALS AND METHODS

Materials

Reagent p27kip1SP reagent was obtained from Beijing Zhongshan Biology Company. Endoenzyme, KpnI, BamHI and T4 DNA ligase were purchased from Huamei Biological Engineering Company. DMEM, RPMI1640, Lipofectamine were purchased from GIBCO/BRL Company. Low melting-temperature agarose and X-gal were obtained from Promega Company. CsCl was from Sigma Company. And high-grade neogenetic bovine serum from Hangzhou Sijiqing Biological Engineering Material Co. Ltd. p27kiplcDNA and adenovirus PCR primer were designed and synthesized by Saibaisheng Biological Company. And tryPsase from Shanghai Biological Products Company. ^{3}H-TDR and ^{3}H-Leucine were provided by Beijing Atomic Power Research Institute. DNA-PREPTMLPR and DNA-PREPTMstain were obtained from America Beckman Coulter Company.

Plasmid, strain, adenovirus and cell line PCMV5p27kip1 was presented by Dr. Wang Gang, Urinary Surgery Research Institute of the First Hospital of Beijing Medical University. PAACCMVPLPA and PJM17 were presented by academician Wu Zhuze, No. 2 Research Institute of Military Academy of Medical Science. DH 5a was presented by Dr. Peng Xu, Endocardial Department of the First Hospital of Beijing Medical University. Recombinant adenovirus was constructed by Molecular Biology Laboratory of Taihe Hospital. 293 cell was Hek cell line transferred from the gene of adenovirus E1 region, esophageal carcinoma cell strain EC9706 was presented by professor Wang Mingrong, China Academy of Medical Sciences.

Methods

Construction of adenovirus shuttle plasmid carrying p27kip1 Double enzyme cut was performed on pCMV5 p27kip1 and pACCMVPLPA with KpnI and BamHI respectively, and the fragments were separated at low melting-temperature agarose gel electrophoresis. The recovered p27kiplcDNA and adenovirus fragments were connected overnight with T_4DNA ligase at 4 ℃ by directional clone, and then transferred into receptive colibacillus DH_{5a}. From the selection of colonial amplification, a small quantity of plasmid was extracted and double cut with KpnI and BamHI. The presence of 690 bp and 8 800 bp in agarose gel after electrophoresis indicated that p27kip1cDNA had been inserted into adenovirus shuttle vector, hence successful construction of adenovirus shuttle plasmid pAd-p27kip1 carrying p27kip1.

Transfection of 293 cell by Lipofectamine-mediated pAd-p27kip1 and pJM17, and preparation of adenovirus recombinant Ad-p27kip1 (1) 293 cell was inoculated in a 9 cm plat, cultured in an incubator at 37 ℃ and 5 % CO_2, and transfected at 80 % fusion. (2) DNA-lipofectamine compound was dripped in an Eppendorf tube. Plasmid pAd-p27kip1 and pJM17 were diluted in 1 ml DMEM culture fluid, and revolved

for 1 s, then lipofectamine suspension was added uniformly. It was kept at room temperature for 30 minutes. (3) DNA-lipofectamine compound was dripped in culture flasks, and cultured in an incubator at 37 ℃ and 5 % CO_2. 0.5 % agarose was added for covering (0.5 % agarose contains 1×DMEM, 10 % Fcs), and cultured in an incubator with 37 ℃ and 5 % CO_2 after its coagulation, then pathological changes of 293 cell were observed.

PCR appraisal of recombinant adenovirus Ad-p27kip1[8] From 293 cell undergone pathologic changes after common transfection, culture supernate 100 μl was drawn, form which cell chip was removed centrifugally, and DNA was extracted and precipitated, then PCR amplification was performed on this DNA model. Primers 1 and 2 were used for amplifying p27kip1 gene, primer 3 and primer 4 for amplifying adenovirus skeleton gene fragments. The product of PCR amplification was appraised with 0.8 % agarose through electrophoresis, and held to be recombinant adenovirus Ad-p27kip1 containing human p27kip1 if gene fragments of 275 bp and 860 bp were both amplified. The sequence of primers was as follows.

Primer 1: 5' CCTAGAGGGCAAAGTACGAGTA 3'
Primer 2: 5' GAAGAATCGTCGGTTGCAGGTCGCT 3'
Primer 3: 5' TCGTTTCTCAGCAAGCTGTTG 3'
Primer 4: 5' CAATCTGAACTCAAAGCGTGG 3'

Amplification, purification and titer of recombinant adenovirus Ad-p27kip1 Recombinant adenovirus supernate 500 ul was added to 293 cell with 80 % fusion, and cultured in an incubator at 37 ℃ and 5 % CO_2. Ultracentrifugation in CsCl gradient and purification were performed on the adenovirus supernate by Graham method[8]. Then purified virus fluid 100 ul, 10 % SDS 20 ul, PBS 880 ul were taken to test light absorption value of OD_{260}nm and OD_{280} nm of the DNA of virus gene group, and accordingly to calculate the grannule quantity and purity of the virus. $1OD_{260}=10^{12}$pfu/ml, $OD_{260}/OD_{280}>1.3$ showed the purity was fairly high, virus titer pfu/ml=A260 ×dilution×10^{12}.

Transduction efficiency test of adenovirus Recombinant adenovirus Ad-LacZ was used to infect cells of esophageal carcinoma EC-9706 respectively by MOI 25, 50, 100 and 200. When X-gal was dyed, the cells dyed blue under microscope were positive cells expressed by LacZ gene, then the percentage of the cells dyed blue was calculated.

Influence of Ad-p27kip1 on growth curve of esophageal carcinoma cell $1×10^4$/ml cell suspension was made of the cultured esophageal carcinoma cells (5 % FcsRPMI1640) after digestion and collection. The cells of esophageal carcinoma were inoculated in 4 pieces of culture boards with 24 holes/piece according to the quantity of 1 ml/hole, cultured for 24 h. When in 40-50 % fusion, cells were rinsed with RPMI1640, and went on culture for 24 h for synchronization. The test was divided into three groups: experimental group: Ad-p27kip1, negative control groups: Ad-LacZ ,blank group: free-virus.The test groups were infected with the cells of esophageal carcinoma (RPMI1640) for 2 h with 100 MOI, during which the culture fluid was shaken every 15 min, and two hours later exchanged with 5 % Fcs RPMI1640 for culture. Prior to the transfection of esophageal carcinoma cells by virus, three holes were taken as cell count to obtain the average value, afterwards daily cell count was collected for 4 days, and the changes of growth curve of esophageal carcinoma cell were recorded.

Incorporation test of ^{3}H-TdR and ^{3}H-leucine As described above, the experimental group and control group were cultured for 3 h with 5 % Fcs RPMI1640, and then for 12 h with free-Fcs RPMI1640. Each group was added 1 μ Ci ^{3}H-TdR or ^{3}H-leucine, which was rinsed with PBS at the 24th, 48th and 72th hour and fixed with methyl alcohol for 10 min and absolute ethyl alcohol for 10 min. Finally, 0.1M NaOH 200 μl was added. 200 μl of each was taken after blowing, and mixed in 5 ml scintillation liquid for overnight. On the following day, the CPM of ^{3}H was tested, three times for each group with three wells.

Change of p27 protein expression of cell of esophageal carcinoma p27 protein expression of the three groups was detected by immunohistochemical SP method.

FCM detection after occurrence Ad-p27kip1 effect on esophageal carcinoma cell After 48 h effect, cells from the three groups were collected, centrifugated under digestion (1 000 rpm, 5 min). PBS was added for regulating the cell density to 10^6/ml with supernates removed. 100 ul cell suspension was put in a preparatory tube, and mixed with DNA-PREPTMLPR 200 ul. Half a minute later DNA-PREPTM stain reagent (PI staining) 2 ml was added for mixing. After staying static for half an hour, cell cycle and apoptosis were detected with FCM, and processed by SYSTEM II TM software from Coulter Company.

Apoptosis detected with DNA fragment analysis and TUENL method From the experimental group after the above-mentioned effect, genome DNA was extracted regularly. DNA fragment was analyzed by agarose gel electrophoresis. At the same time, apoptosis was detected by TUNEL method, and contrasted with that in the blank group.

RESULTS

Construction of pAd-p27kip1 shuttle plasmid

Double enzyme cutting was performed on pCMV5p27kip1 and pACCMVpLpA with KpnI and BamHI, then 690 bp fragment and 8 800 bp fragment were collected respectively at low melting-temprature agarose gel electrophoresis, for the production of plasmid pAd-p27kip1 with coupled reaction. Through transformation, amplification and extraction of colibacillus, enzyme cutting appraisal were conducted to approve that pAd-p27kip1 contained p27kip1 and adenovirus carrier skeleton (Figure 1).

Figure 1 pAd-p27kip1 appraisal 1 200 bp ladder Marker: 200, 400, 600, 800, 1 000, 1 200, 1 400, 1 600, 1 800, 2 000 bp. 2, pCMV5p27kip1 (kpnI+BamHI): 690 bp segment. 3, pAd-p27kip1(kpnI+BamHI): 690 bp and 8 800 bp segment. 4, pACCMVPLPA (kpnI+BamHI): 8 800 bp segment. 5, Hind III marker: 2 027, 2 322, 4 361, 6 557, 9 416, 23 130 bp.

Construction, amplification, purification, titer test of Ad-p27kip1 and PCR appraisal

When contransfected with the above synthesized pAd-p27kip1 and pJM17, 293 cells underwent pathologic changes and floated as in grape clusters, which suggested that Ad-p27kip1 was produced through homologous recombinant, ultracentrifugation in CsCl gradient and purification. Spectrophotometer detection showed that the virus titer was $1.24×10^{12}$ pfu/ml, $OD_{260}/OD_{280}>1.3$, which suggested that both the virus titer and the purity were fairly high. The extracted Ad-p27kip1 adenovirus DNA underwent PCR amplification for a contrast between PCMV5p27kip1 and pACCMVpLpA, with 275 bp and 860 bp as the amplification products (Figure 2).

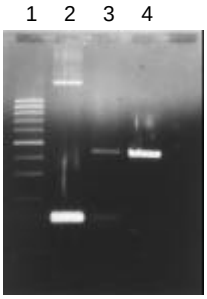

Figure 2 Ad-p27kip1 PCR appraisal 1 200 bp ladder Marker: 200, 400, 600, 800, 1 000, 1 200, 1 400, 1 600, 1 800, 2 000 bp, 2, pCMV5p27kip1model, 275 bp gene segament, 3, Ad-p27kip1 model: 275 bp and 860 bp gene segament, 4, PAVVMVPLPA model, 860 bp gene segament.

Transfection efficiency of recombinant adenovirus

Cells of esophageal carcinoma were infected with Ad-LacZ by MOI 25, 50, 100, 200 respectively, then stained with X-gal 48 h later. The transfection efficiency (%) was found to be 90, 100, 100, 100 respectively. It was concluded that 100 % transduction efficiency could be achieved with MOI $\geqslant$50, hence MOI 100 should be adopted for EC-9706 in the fellowing experiments.

Growth curve of esophageal carcinoma cell

Cell growth curve showed that the count of cancer cell in the experimental group declined over time, reached the bottom on the fourth day, but in Ad-Lacz group and blank group, it was just the opposite (Figure 3).

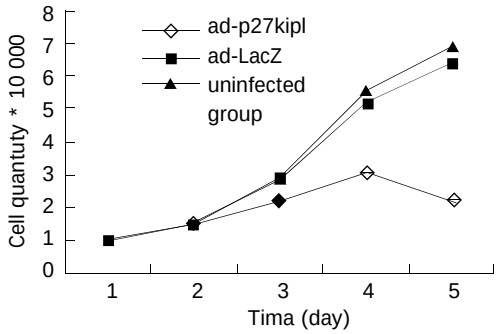

Figure 3 Growth curve of cell of esophageal carcinoma.

Table 1 ^{3}H-TdR incorporation quantity ($\bar{x}\pm s$ CPM / Well)

Group	2nd day	3rd day	4th day
Ad-p27kip1	2 013.42±84.38[a]	1 546.54±104.14[a]	244.22±39.62[a]

Blank	3 564.34±72.82	3 685.72±122.23	4 468.65±237.36

[a]P<0.001 *vs* Blank group, [b]P>0.05 Ad-LacZ group *vs* Blank group.

Table 2 Incorporation quantity of ^{3}H-Leucine ($\bar{x}\pm s$ CPM / Well)

Group	2nd day	3rd day	4th day
Ad-p27kip1	595.16±57.06[a]	422.82±45.81[a]	267.58±37.56[a]
Ad-LacZ	886.47±48.47[b]	915.44±93.58[b]	1 139.46±89.24[b]
Blank	895.21±967.52	967.52±78.35	1 243.95±06.72

[a]P<0.001 *vs* Blank group, [b]P>0.05 Ad-LacZ group *vs* Blank group.

Effect of Ad-p27kip1 on incorporation quantity of esophageal carcinoma cells ^{3}H-TdR and ^{3}H-leuine

The incorporation quantity of experimental group was markedly lower than that of the control group (P<0.001), declined over time as against the rise in Ad-LacZ group and blank group. There was no statistical difference (Table 1 and Table 2) between them.

Influence of Ad-p27kip1 on p27 expression of esophageal carcinoma cell

Immunocytochemical staining after virus transfection of esophageal carcinoma cells for 24 h showed that p27 expression increased clearly in experimental group, whereas there was not any change in control group (Figure 4 and 5).

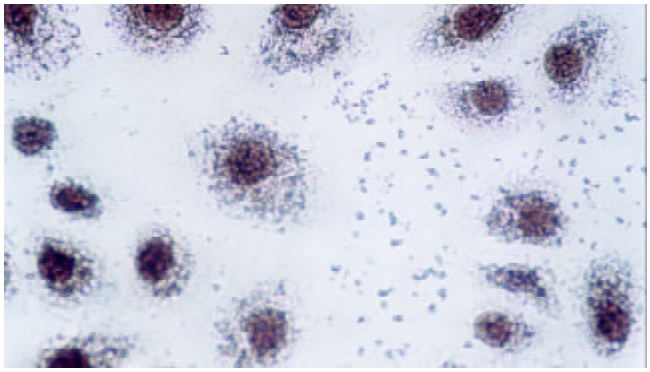

Figure 4 p27kip1 overexpression in transfection group ×200.

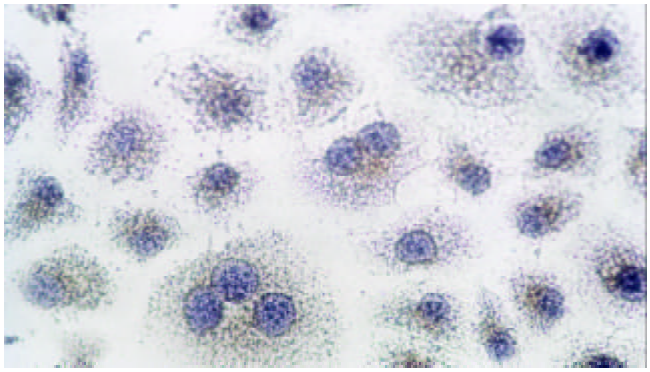

Figure 5 p27 negative expression in control group ×200.

Induction and quantitative detection of apoptosis esophageal carcinoma cells by Ad-p27kip1

Forty-eight hours after Ad-p27kip1, Ad-Lacz and blank management for EC-9706 cell, FCM determination showed that apoptotic cells took on an obvious apoptosis peak prior to G0/G1 peak. The apoptosis value of Ad-p27kip1, Ad-LacZ and blank group was 32.7 %, 5.72 % and 0.05 % respectively. Ad-p27kip1 group had the highest rate of apoptosis whereas blank group had the lowest rate.

Influence of Ad-p27kip on cell cycle of esophageal carcinoma

Cell cycle from FCM is listed in Table 3. In Ad-LacZ and blank control group, G1/G0 stage ratio decreased gradually whereas S stage increased, which indicated a rapidly changing G1/G0→S procedure and active cell multiplication. However, in the experimental group, G1/G0 stage ratio was fairly high and S stage decreased. There was a significant difference from control group (P<0.05). Cell cycle arrested G1 and inhibited cell multiplication.

Table 3 Effect of Ad-p27 on EC9706 cell cycle through fluid cell meter

Group	Distribution of cell cycle (%)		
	G0/G1	S	G2/M
Blank	40.39±3.86	49.61±4.27	13.10±1.03
Ad-LacZ	44.17±2.63	39.56±3.39	16.27±2.85
Ad-p27kip1	66.52±5.48[a,b]	21.15±3.26[a,b]	12.33±2.72

[a]P<0.05 *vs* Blank group, [b]P<0.05 *vs* Ad-LacZ group.

Analysis of DNA fragment

After cell EC-9706 was processed by Ad-p27kip1, gel electrophoresis of genome DNA displayed a clear ladder band, but no ladder band was found in contrasting group (Figure 6).

Figure 6 DNA fragment analysis 1 200 bp ladder marker: 200, 400, 600, 800, 1 000, 1 200, 1 400, 1 600, 1 800, 2 000 bp. 2, Ad-p27kip1group: 2 μg. 3, Ad-p27kip1group: 1 μg. 4. Blank group.

Detection of cell apoptosis by TUNEL Method

If brownish yellow color of karyon was found with TUNEL, it showed positive apoptosis, and no color was negative. The apoptosis rate of Ad-p27kip1 group and control group was 37.3 % and 1.26 % respectively, and there was obvious difference X^2 testing (P<0.01).

DISCUSSION

Advances in cellular biology of tumor and molecular biology have found that the occurrence of esophageal carcinoma is a comprehensive pathologic process with multifunction, multistage and multigene variations. Activation of various oncogenes and inactivation of anti-oncogene may be the major factors for normal epithelial canceration. Genetic treatment aimed to import objective genes into gene mutation or lost cells with the use of gene engineering technology, and to have functional expression replacing the original genes in order to recover the functions and effects of original genes and correct genetic distortion or genetic loss resulted from cellular developmental disturbance and realize the treatment[9]. p53, p21, Egr-1, FHIT, VEGF, E2F-1and hIFN-beta have been used as target genes in the treatment of esophagus carcinoma both *in vivo* and *in vitro*, and certain efficacy has been obtained[10-18]. Currently the analysis on esophagus carcinoma treatment through gene recombinant adenovirus p53 has entered the clinical stage[19], which will provide a bright future for tumor treatment.

P27 as candidate objective gene for tumor genetic treatment.

The key to genetic treatment is the correct selection of exogenous objective genes, its import into target cells and steady expression. Koguchi[20] used adenovirus carrier to pack p27 gene to transfect astrocytes, and found its overexpression inhibited multiplication activity of astrocytes. Katner[21] used adenovirus carrier containing p27kiplcDNA to transfect human 786-0 renal carcinoma cells, and found that the cell with p27kip1 overexpression lost the growth features of tumor cells, and that CDK activity of transfected cells was inhibited obviously, and that the multiplication time was extended. Patel[22] used p27kip gene to transfect human tumor cell line AV-W9 to induce cell death.The study of p27 gene in human breast cancer cells[23], neuroblastoma cells[24], prostate carcinoma cells[25]and lymphoma[26] showed the similar results, suggesting that p27 gene could be used as an objective gene for genetic treatment of tumor.

Construction of recombinant adenovirus carrier Ad-p27kip1 and its influence on p27 expression

Adenovirus carrier is of small pathogenicity and low genetic toxicity. With its wide host range, adenovirus can infect not only duplicated cells or cleavage cells, but also resting cells. Its huge package volume allows the insertion of 7.5kb exogenic gene fragment without any active carcinogene or insertion mutation within non-integral host chromosome. The virus can reach a high titer and 100 % infection rate through reproduction and purification. With its stable properties and safety for the human, it was considered as a gene conversion carrier of highly efficient expression[27] and most promising for genetic treatment[28].

Ad-p27kip1 constructed in the present study is a kind of replication of E1-deleted adenovirus vector. pJM17, the adenovirus skeleton with E1 region removed, can produce homologous recombinant with shuttle plasmids for producing infective adenovirus. Gene in E1 region is needed for adenovirus duplication, which requires that the duplication of intact adenovirus should be carried out in cell transfected by gene of E1 region. But since 293 cell is the right packaging cell for the transfection, replication of defective adenovirus has only one opportunity for infection in target cell without any duplication ability to fulfil the functions of adenovirus carrier, avoid damage of adenovirus itself to target cells and reach gene conversion.

Ad-p27kip1 containing human p27kip1 can positively connect p27kip1cDNA to CMV promoter of adenovirus. And as appraised by PCR amplification, p27 expression increased markedly after transfection of esophageal carcinoma cell. Contrasting adenovirus Ad-LacZ used in our study achieved 100 % induction efficiency with MOI=50. Ad-p27kip1 virus titer was 1.24×10^{12} pfu/ml, OD_{260}/OD_{280}>1.3, virus titer and purity were fairly high. This suggests that high expression of p27 after transfection is related to high induction efficiency and high purity, it can meet the demands of genetic treatment.

Inhibition of Ad-p27kip1 on growth of esophageal carcinoma

Studies demonstrated that declination of p27kip1 expression was an early event of esophageal carcinoma genesis, and also an independent prognostic factor of esophageal carcinoma[29-32]. We imported human p27kip1 gene into esophageal carcinoma cell EC9706 and analyzed its biological properties through cell growth curve, ^{3}H-TdR and ^{3}H-Leucine incorporation experiment, FCM and DNA fragment analysis. We found that esophageal carcinoma cell displayed G1 stage block after import of the gene, and that p27 inhibited cell multiplication of esophageal carcinoma obviously, and that from G1 stage to S stage, the self-multiplication ability of the control cell decreased, and the apoptosis rate increased to 32.7 %, a significant difference (P<0.01) compared with that of control group and Ad-LacZ group. It may be concluded p27kip1 gene is an important gene for occurrence of esophageal carcinoma, decreased p27 expression may be a major factor to cell differentiation and death disturbance, while increased of p27 expression can promote

cell death of esophageal carcinoma, which offers a new perspective on treating esophageal carcinoma.

Abstract

AIM: To investigate the alteration of molecular events and the early carcinogenesis mechanism of esophageal epithelial cells in the high incidence area of esophageal cancer.

METHODS: Esophageal epithelial cells of esophageal cancer patients were collected from the high incidence area in China. Content of DNA and telomerase as well as multi-gene expressions such as p^{53}, p^{21} and cyclin D_1 in esophageal precancer cells were quantitatively analysed by flow cytometry (FCM) with indirect immunofluorescence technique and DNA propidium iodide fluorescence staining.

RESULTS: FCM analysis results showed the DNA content increased significantly and the heteroploid rate was 87.9 % in occurred carcinogenesis. P^{53} protein accumulation and ras p^{21} increase were seen in the early carcinogenesis of the esophagus. The positive rate of p^{53} and ras p^{21} was 100 % (5/5, 4/4 respectively) in the cancer group. Telomerase and oncogene cyclin D_1 were over- expressed in all of the cancer patients.

CONCLUSION: Increased DNA content and heteroploid rate, accumulation of p53 protein, and over-expression of p21, telomerase and cyclin D_1 proteins were early molecular events during the development of esophageal cancer.

INTRODUCTION

Esophageal cancer is one of the most common malignant tumors, and many studies have been made on it[1-3]. Former studies focused primarily on precancerous lesions and carcinogenesis of esophagus. But early carcinogenesis of esophageal cancer is unclear. In the present study, we investigated the DNA, telomerase content and P^{53}, ras P^{21} and cyclin D_1 multi-gene product of exfoliated cell samples from Cixian County, a high incidence area of esophageal cancer in Hebei Province of China with flow cytometry. It may provide a theoretic basis for under standing the carcinogenesis of esophageal epithelial cells and early diagnosis of esophageal cancer.

MATERIALS AND METHODS

Specimen collection

All samples were collected from Cixian County, a high incidence area of esophageal cancer, Hebei Province, China. One thousand nine hundred and sixteen cases of exfoliated cell specimens of esophagus were obtained with a mesh saccule. The exfoliated cell sample in each case was divided into two parts. One part was used for smear preparation on slides with papanicolaou stain for cytologic diagnosis, another part was used for preparation of a single cell suspension for flow cytometry analysis.

Specimen preparation for FCM DNA analysis

Exfoliated cells from 1916 cases for DNA analysis were obtained as follows. The exfoliated cells were washed out from the saccule with 0.9 % NaCl solution, centrifuged and fixed in 70 % ethanol. Before DNA analysis the cell samples were washed off 70 % ethanol in 0.9 % NaCl solution. Cell suspension (1×10^6 cells/ml) was centrifuged (5 min, 1 000 r/min) and washed twice with 0.9 % NaCl solution. After centrifugation the cells were stained in one million of propidium iodid (PI) solution (PI 50 μg/ml with triton-x-100 and RNase) for 30 minutes and filtered through a 47 μm nylon mesh to remove cellular fragments and clusters. Chicken red blood cells were added to the sample before stained as an internal standard for calibration of the FCM instrument.

The antibodies for immunofluorescence detection of telomerase, P^{53}, P^{21} and cyclin D1 protein were described as below: (1) Monoclonal antibody (MoAb) P^{53} was a mouse antibody against human P^{53} protein (Clone PAB1801, Oncogene Science, Inc. U S. working concentration 1:100). (2) MoAb P^{21} was a mouse antibody against human pan-ras P^{21} protein (Clone F-132, Santa Cruz, US, working concentration 1:100). (3) MoAb cyclin D1 was a mouse antibody against human cyclin D1 protein (Clone DCS-6, Santa Cruz, US, working concentration 1:100). (4) Telomerase was rabbit antibody against human telomerase associated protein (TP1) polyclonal antibody (Clone C-20, Stanta Cruz, US, working concentration 1:50). (5) The second antibody was used with FITC-conjugated goat anti-mouse/anti-rabbit IgG (Tackson Immunoresearch Laboratories Inc, code number 115-095-003/115095, working concentration 1:100).

Labeling method

The sample fluorescence staining was performed using indirect immunofluorescence labeling method. Samples from 100 cases were randomly selected for each antibody labeling. Each sample (10^6 cells/ml) was washed twice with PBS and incubated in water-bath for 30-min at 37 ℃ with 100 μl antibody (p53, p21, cyclin D1, telomerase). The samples were then washed twice with PBS and incubated in water-bath for 30 min at 37 ℃ with 100 μl of the second antibody of FITC-conjugated goat anti-mouse/rabbit IgG. The cell suspension

was washed, and resuspended in l.0 ml PBS, filtered through a 47 μm nylon mesh, analyzed by flow cytometry, before the samples were analyzed.

Three control samples were used. One sample was used as negative control with PBS replacing the first/second antibody. Another sample was used as positive isotype control with only the first antibody incubated. The remaining sample was incubated only with the second fluorescence antibody as positive isotype control.

Flow cytometry measurement of DNA and immunofluoresence

The stained samples were analyzed in a FACS 420 flow cytometer (FACS 420 Fluorescence Activated Cell Sorting, Becton. Dickinson, Sunnyvale. California, U S A). The light source was a 2w argon ion laser using a wave-length of 488 nm. The working power was 300 mw. Single parameter was measured respectively in DNA (with a liner mode) and each protein (with a Log mode). Usually, 10 000 cells for each sample were analyzed. The analytic data were processed with a HP-300 consort 300 computer. The coefficient of variation (CV)of the instrument was adjusted within 5 % using PI staining chicken red blood cells.

Measured data analysis

DNA ploid analysis DNA content was presented as the DNA index (DI), DI=G0/1 peak average channel value in experimental sample DNA histogram / G0/1 peak average channel value in normal cell sample DNA histogram. DNA ploids were judged according to DI value. The normal epithelial cells in each sample were used as internal standard reference cell for diploid DNA value, DI in diploid cell was 1.0. A diploid DNA histogram was defined as DI=1.0±2 cv. An aneuploid DNA histogram was defined as DI≠1.0±2 cv.

Cell cycle analysis DNA cell cycle was analyzed using a software of DNA histogram distribution (sum of broadened retangled model). The phases in G0/1.S.G2M were calculated according to DNA content distribution histogram. The proliferation index (PI) was used to present cell proliferation activity PI(%)=S+G2M/G0/1+S+G2M.

Quantitative analysis of P^{53}, rasP^{21}, cyclin D1 and telomerase expression Fluorescence index (FI) was used to describe P^{53}, P^{21}, cyclin D1 and telomerase expression. Following FI calculated formulation: FI=average fluorescence intensity of sample protein expression - average fluorescence intensity of isotype control/average fluorescence intensity of normal control. The sample was considered positive when FI was above 1.0.

Statistical analyses

Chi- square test and *t* test were used for statistical analysis of the results. The study was double blind with a group of cytologists making cytologic diagnosis, while another group performed DNA analysis.

RESULTS

Cytologic diagnosis

The cytologic observation showed that among the 1 916 cases of exfoliated cell smears, 217 were normal, 306 were mild dysplasia, 952 were moderate dysplasia, 349 were severe dysplasia and 92 were esophageal cancer.

Relationship between DI and cytologic diagnosis

The FCM DI value and corresponding cytologic diagnosis of 1916 samples are presented in Table 1. Table 1 shows that cellular DNA content was closely related to epithelial changes in esophagus. DI increased as the grade of dysplasia increased. Significant differences in DI were found in the mild, moderate and severe dysplasia groups. There was no significant difference in DI between the normal and mild dysplasia groups.

Table 1 Relationship between cellular DNA content and cytologic diagnosis

Cellular diagnosis	No.of cases	DI value ($\bar{x}$±s)	*P* value (*t* test)
Normal	217	1.01±0.06	>0.2
Mild dysplasia	306	1.03±0.10	<0.01
Moderte dysplasia	952	1.06±0.27	<0.01
Severe dysplasia	349	1.09±0.14	<0.01
Cancer	92	1.24±0.18	<0.01

Relationship between DNA ploid and cytologic diagnosis

The results of DNA ploid status in different cytologic groups of exfoliated esophageal cells are shown in Table 2, which shows that 21 cases in normal group were DNA heteroploid, but none became cancerous in follow-up. Thus, DNA heteroploidy in normal group was defined as false heteroploid. The rate of DNA heteroploid in dysplasia increased as the dysplasia lesion progressed. The difference in DNA heteroploid among three dysplasia groups was statistically significant (P<0.01).

Relationship between PI value and cytologic diagnosis

The results of cell cycle analysis showed that cell proliferation activity was closely related to epithelial changes in esophagus, PI value was 13.8±4.3 % in normal group, 16.4±2.5 % in mild dysplasia group, 17.9±4.1 % in moderate dysplasia group, 19.8±2.9 % in severe dysplasia group, 24.6±4.2 % in cancer group, respectively. PI value increased as dysplasia lesion progressed. The difference in PI value between normal group and the three dysplasia groups had a statistical significance (P<0.05).

Table 2 Relationship between DNA ploid and cytologic diagnosis

Cellular diagnosis	No.of cases	DNA ploidy pattern		Rate of heteroploid (%)	*P* value x^2 test
		diploid	heteroploid		
Normal	217	196	21	9.7	>0.05
Mild dysplasia	306	280	26	8.5	>0.01
Moderate dysplasia	952	791	161	16.9	<0.01
Severe dysplasia	349	229	120	34.4	<0.01
Cancer	92	20	72	78.3	<0.01

Relationship between P^{53}, P^{21} protein expression and cytologic grade

The results of P^{53}, P^{21} protein expression are shown in Table 3.

Table 3 Expression of P^{53}, P^{21} in various lesions of esophageal epithelial cells

Cytological group	No.of cases	P^{53} FI ($\bar{x}$±s)	P^{53+}cases (%)	P^{21} FI ($\bar{x}$±s)	P^{21+} cases (%)
Normal	10	1.00±0.11	0	1.00±0.19	0
Mild dysplasia	24	1.10±0.15	5 (20.8 %)	1.09±0.21	6 (25.0 %)
Severe dysplasia	61	1.36±0.32	34 (54.8 %)	1.34±0.35	35 (57.4 %)
Cancer	5	2.28±0.20	5 (100 %)	1.82±0.24	5 (100 %)

Expression of P^{53} and ras P^{21} in Table 3 showed that FI value increased as the grade of cytologic diagnosis of the esophageal epithelia increased. The differences in FI values among the normal, mild and severe dysplasia and cancer groups were statistically significant (P<0.01). The positive

rate of P^{53} and ras P^{21} expression among the four groups of esophageal epithelial lesion was also statistically significant ($P<0.01$).

Correlation of cyclin D1 and telomerase associated protein (TP1) expression with cytologic diagnosis grading

Table 4 Results of cyclin D1 and TP1 expression in various lesions of esophageal epithelia

Cytologic diagnosis	No.of cases	Cyclin D1, FI ($\bar{x}\pm s$)	Cyclin D_1^+ cases	TP FI ($\bar{x}\pm s$)	TP_1^+ cases
Normal	7	1.00±0.07	0	0.99±0.07	0
Mild dysplasia	11	0.97±0.12	1 (9.1 %)	1.22±0.15	7 (63.6 %)
Severe dysplasia	76	1.21±0.22	45 (59.2 %)	1.33±0.27	64 (84.2 %)
Cancer	6	1.84±0.18	6 (100 %)	1.70±0.15	6 (100 %)

Table 4 contains the cyclin D1 and TP1 expression data from 100 cases of esophageal epithelial lesion. The results showed that the cyclin D1 and TP1 protein expression level was correlated with cytologic diagnosis grading. FI values of cyclin D1 in normal group were not significantly different from that in mild esophageal dysplasia group. But FI values of TP1 between normal group and mild dysplasia group were significantly different ($P<0.05$).

The difference in FI value of cyclin D1 and TP1 among the mild, severe dysplasia and cancer groups was markedly significant ($P<0.01$), and the positive rate of cyclin D1 and TP1 protein expression among the four groups was also significantly different ($P<0.01$).

DISCUSSION

The results of this study showed that alteration of multiple molecular events occurred during esophageal epithelial carcinogenesis.

In this study, we found that the increased DI value was correlated with the precancerous lesion progression. Cellular DNA content and DNA ploid status were closely related to the severity of epithelial dysplasia. The rate of FCM DNA heteroploid increased significantly in the transition of dysplasia from mild to severe. Thus it is clear that cellular DNA content could reflect the pathologic changes in the epithelium of esophagus[4]. DNA content increase and DNA heteroploidy were the very important early signals of carcinogenesis[3,4].

Detection of FCM DNA heteroploidy might provide early cancerous information, before the morphologic evidence of cancer occurred[3,4]. It has been proved in previous studies that proliferation index (PI) is an indicator to reflect cell proliferation activity. In our study, the cell proliferation activity was closely related to the dysplasia degree of esophagus. PI was 16.4 % in mild dysplasia group, 17.9 % in moderate dysplasia group, 19.8 % in severe dysplasia group. The results proved that the rate and speed in cell proliferation were obviously increased during esophageal epithelial carcinogenesis.

In carcinogenesis, the precancerous cell lesion resulted in not only abnormal DNA change but also abnormal change in multiple genes and its product expression[3-14]. Previous studies demonstrated that lots of genetic alteration existed in esophageal precancer cells. P^{53} mutation in tumor-suppressor gene and ras P^{21} activated in tumor gene were revealed to be early molecular events during esophageal carcinogenesis[5,9,10,16]. In our studies, expression of P^{53} and P^{21} protein varied with dysplasia degree, FI value increased significantly from mild to severe dysplasia. Overexpression of P^{53} and P^{21} was closely related to early stages of esophageal carcinogenesis. The studies by Yasuda' s group also revealed that P^{53} mutation was a key molecular event in esophageal carcinogenesis[6]. The expression of P^{53} protein in our study accumulated at early stages of esophageal carcinogenesis.

The ras gene in normal cells possesses an important effect on cell growth and proliferation. The ras gene activation can speed up cell proliferation and malignant transformation. Overexpression of ras gene (P^{21}) occurred frequently in precancerous lesion of esophagus[15]. In our studies, expression of ras P^{21} varied with dysplasia degree. FI of ras P^{21} expression was significant among the normal, mild, severe dysplasia and cancer groups ($P<0.01$). It is suggested that ras P^{21} overexpression may be an important factor during esophageal epithelial carcinogenesis, and ras P^{21} may be a valuable marker at the early stages of carcinogenesis.

Recent studies have indicated that cyclin D1 is an oncogene which is related to the regulation of cell cycle[17-21]. The cyclin D1 gene product is a key protein which makes cells enter into proliferation condition, and cyclin D1 and CDK4 are composed of a complex which could functionally inhibit tumor suppressor gene P^{16} and Rb activity[23], thus promoting the cell proliferation ability. Many cells could enter into proliferation stage from G1 to S,G2M phase, so that excessive cell proliferation could cause carcinogenesis[19,23]. In this study, the expression of cyclin D1 protein increased in severe degree of esophageal epithelial dysplasia. The results indicate that overexpression of cyclin D1 plays an important role during esophageal carcinogenesis. An increase in cyclin D1 might result in an oncogene[22-25].

Recently, it has become a new research target of telomerase activity and its relation to carcinogenesis. It has been demonstrated that telomerase activity is increased in esophageal carcinoma. Telomerase activity could be used as an early stage marker of esophageal epithelial carcinogenesis[25-27]. Telomerase quantitative analysis of esophageal precancerous lesion has not been reported. In this study, telomerase content in esophageal epithelial dysplasia cells was quantitatively analyzed by flow cytometry. The results showed that telomerase content obviously increased in severe dysplasia group and cancer group. The positive rate of telomerase expression was 83.1 % in severe dysplasia group and 100 % in cancer group. Overexpression of telomerase might be an important factor and early molecular event to monitor the patients with high-risk of precancerous lesion during esophageal epithelial carcinogenesis[28-31]. Therefore, quantitative detection of telomerase content might be an early diagnostic method for esophageal cancer[27]. It is suggested that inhibition of telomerase activity might be a new therapy for cancer[29-31].

In summary, the DNA content, P^{53}, ras P^{21}, cyclin D1 and telomerase content showed significant changes during esophageal epithelial carcinogenesis, they could also become biomarkers to identify precancerous lesions in high-risk population at high incidence areas of esophageal cancer. These results indicate that combined analysis of multiple parameters can greatly increase the accuracy of early identification of esophageal cancer in the high risk population.
