development, progression and metastasis of CRC. It is reasonable to predict that the NGX6 gene plays an important role in suppressing CRC tumorigenesis; losses of its function may contribute to the development of CRC. Deletion of this gene may occur as a later event associated with tumor progress, and may contribute to the metastatic potential of CRC. So, it is speculated that NGX6 gene located on chromosomes 9p21-22 may be a candidate tumor suppressor gene and a putative metastasis suppressor gene associated with CRC. The possible mechanism of this gene suppressing CRC tumorigenesis remains unclear. We speculated that the possible mechanism might be as follows. Firstly, NGX6 gene may be involved in cell cycle regulation and play an important role in tumor growth suppression. Our previous studies showed that significant accumulation of cells in the G0-G1 fraction was observed in HNE_1 cell transfected with NGX6 gene by using flow cytometric analysis, and several genes related to cell cycle and transcription regulation were differentially expressed in NGX6 overexpressed nasopharyngeal carcinoma cells by cDNA array assay[34,35,40]. Combined with our data presented here, it is reasonable to speculate that deletion or down-regulation of NGX6 gene in colorectal cancer may contribute to tumor cell proliferation and tumor metastasis. Secondly, NGX6 gene encodes a putative transmembrance protein including an important structural feature-EGF-like domain signature. In our study, NGX6 gene was significantly down-regulated in CRC, indicating that NGX6 protein might function as an inhibited membrane receptor or a negative growth factor in the initiation and progression of CRC. However, many previous studies showed that the proteins with EGF-like domains such as EGF, TGF-a were overexpressed in tumor tissues and might play a role in promoting tumor growth and metastasis[41-43]. Recently, Williams *et al*[44] identified two novel mucin genes, which encoded two putative transmembrane mucins with EGF-like domains and were commonly downregulated in colorectal carcinoma. This detection further confirmed that the transmembrance protein with EGF-like domain could act as a suppressive membrane receptor or a negative growth factor. Finally, NGX6 gene may exert functions by up-regulating and down-regulating some proteins. Recently, Li *et al*[45] found that seven proteins were up-regulated and seven proteins were down-regulated in NGX6 transfected cells using high-resolution two-dimensional electrophoresis. These proteins included Fas, zinc-finger protein (ZNF), RAB, and Ah receptor-interacting protein (AIP), which may affect the signaling pathway, alter the cell metabolism, and inhibit cell proliferation, induce cell apoptosis and prevent tumor invasion. Therefore, all these protein roles on cells indicate that NGX6 gene has the capacity to suppress both NPC and CRC tumorigenesis.

In this study, we did not find the existence of up- or down-regulated NGX6 in 34 gastric carcinoma specimens and their corresponding normal tissues by RT-PCR. The expression of NAG-7 and BRD7 genes did not display any significant difference between gastric and colorectal carcinomas and their corresponding normal tissues. The results of RT-PCR were also confirmed by Northern blot analysis and dot hybridization. This seems to suggest that NAG-7 and BRD7 genes play no roles in the pathogenesis of gastric and colorectal carcinomas, and NGX6 gene may not contribute to the occurrence and development of gastric carcinoma.

In summary, the results of this study have shown that NGX6 is down-regulated in colorectal carcinoma, and the down-regulation of this gene has a close correlation with lymph node or distant metastasis of CRC, suggesting that NGX6 plays an important role in tumor suppression. However the mechanism of this gene is still unclear. Further studies are needed to better understand the function of this novel gene and its role in CRC tumorigenesis *in vivo*.

Abstract

AIM: To explore the transcriptional gene expression profiles of HGF/SF-met signaling pathway in colorectal carcinoma to understand mechanisms of the signaling pathway at so gene level.

METHODS: Total RNA was isolated from human colorectal carcinoma cell line LoVo treated with HGF/SF (80 ng/L) for 48 h. Fluorescent probes were prepared from RNA labeled with cy3-dUTP for the control groups and with cy5-dUTP for the HGF/SF-treated groups through reverse-transcription. The probes were mixed and hybridized on the microarray at 60 ℃ for 15-20 h, then the microarray was scanned by laser scanner (GenePix 4000B). The intensity of each spot and ratios of Cy5/Cy3 were analyzed and finally the differentially expressed genes were selected by GenePix Pro 3.0 software. 6 differential expression genes (3 up-regulated genes and 3 down-regulated genes) were selected randomly and analyzed by β-actin semi-quantitative RT-PCR.

RESULTS: The fluorescent intensities of built-in negative control spots were less than 200, and the fluorescent intensities of positive control spots were more than 5000. Of the 4004 human genes analyzed by microarray, 129 genes (holding 3.22 % of the investigated genes) revealed differential expression in HGF/SF-treated groups compared with the control groups, of which 61 genes were up-regulated (holding 1.52 % of the investigated genes) and 68 genes were down-regulated (holding 1.70 % of the investigated genes), which supplied abundant information about target genes of HGF/SF-met signaling.

CONCLUSION: HGF/SF-met signaling may up-regulate oncogenes, signal transduction genes, apoptosis-related genes, metastasis related genes, and down-regulate a number of genes. The complexity of HGF/SF-met signaling to control the gene expression is revealed as a whole by the gene chip technology.

INTRODUCTION

HGF/SF-met signaling is a pathway by stimulation of c-met via its ligand hepatocyte growth factor /scatter factor (HGF/SF), leading to a considerable variety of biological and biochemical effects on the cells[1-3]. HGF/SF, a multifunctional cell growth factor, is yielded by interstitial cells such as fibroblast, neuroglial cell, glial cell, fat-storing cell and macrophage[3,4]. It binds to the c-met receptor specifically, inducing a series of conformational changes of signaling proteins by activating JAK[5], phosphatidylinositol 3-kinase (PI-3 K)[6], phospholipase C-γ[7], Raf-1 kinase[8] etc, by which it transmits the signal to the nuclear transcription machines to control certain gene transcription and expressions. Finally it affects the cell proliferation, differentiation, locomotion and other cell functions[9-12]. HGF/SF has been proved to have mitogen, motogen, morphogen activity for almost all epithelial cells, and to promote adhesiveness, invasiveness, motion and metastasis and stimulation for blood vessel growth of cancer cells[8-13]. It was revealed to have anti-cytotoxin and anti-apoptosis for cancer cells in the recent investigation[11,12]. It is evidenced that abnormal activation of HGF/SF-met signaling plays an important or critical causal role in tumor progression and invasion and metastasis. However, little is known about the target genes and gene expression profiles by which HGF/SF exerts biological functions through start-up of transcriptional gene expression.

In the present study, we aimed to explore the transcriptional gene expression profiles by activating HGF/SF-met signaling in colorectal carcinoma cells using the microarray technology by which thousands of genes could be detected at the same time.

MATERIALS AND METHODS

Reagents

Hepatocyte growth factor/scatter factor (HGF/SF), ethidium bromide(EB), and SDS were purchased from Sigma. AMV reverse transcriptase, oligo(dT), dNTP, Taq, and agarose were Promega products. Trypsin, Cy3-dUTP, and Cy5-dUTP were purchased from Amersham Phamacia, and Oligotex mRNA midi kit from Qiagen, and other reagents from Shanghai Biostar Co.

Cells and cell culture

Human colorectal carcinoma cell line LoVo was routinely cultured in RPMI-1640 medium with 10 % FCS, incubated at 37 ℃ with 5 % CO_2. The well-grown cells at the logarithmic growth phase were treated with HGF/SF (80 ng/L) for 24-48 h in the same medium containing 2.5 % FCS. The blank control groups were treated with D-Hanks solution in the same culture condition as HGF/SF-treated groups. Triduplication of the experiments was for the microarray assay.

Construction of microarrays

The genes for HGEC-40S microarray containing 4096 cDNA spots (including 92 negative and positive control spots) were provided by Shanghai Biostar Co. These genes were amplified by PCR with universal primers and then purified by the routine method[13-15]. The purity of PCR products was supervised by agarose electrophoresis and then the PCR products were

dissolved in 3 X SSC solution. The target genes were spotted on siliconlated slides (TeleChem Inc) by using Cartesian 7500 spotting robotics (Cartesian Inc), then hydrated for 2 h, dried for 0.5 h, UV cross-linked by UVP CL-1000 at 65 mJ/cm, and then treated with 0.2 % SDS(10min), H_2O (10 min) and 0.2 % $NaBH_4$ (10 min). Finally the slides were dried again and ready for use.

Probe preparation

Total RNA was isolated from human colorectal carcinoma cell line LoVo by the routine method[13-15]. And then they were tested by hot-stabilization experiments and RNA electrophoresis. cDNA probes were prepared through reverse transcription in 50 μl reaction system in reference to Schena *et al*[15]. The fluorescent probes derived from cDNA reverse-transcripted from RNA were labeled with cy3-dUTP for the control groups and with cy5-dUTP for the HGF/SF-treated groups. The two kinds of probes were mixed equally after ethanol precipitation, then inspissated by vacuum to 50 μl, purified by using S-200 columns, and finally dissolved in hybridizing solution (20 μl 5×SSC+0.2 % SDS).

Microarray hybridization[16-19]

After denatured at 95 ℃ water bath, the microarray was prehybridized with 6 μl hybridization solutions 1 and 2 (Biostar) at 42 ℃ for 6 h. The probe mixtures were added on the prehybridized microarray, denatured at 95 ℃ for 5 min, then inoculated in hybridization cabin at 60 ℃ for 15-20 h. After the glass cover was removed, the microarray was washed in solutions 1 (2×SSC+0.2 % SDS), and 2 (0.1×SSC+0.2 % SDS) and 3 (0.1×SSC) for 10 min each, then dried at room temperature.

Detection and analysis

GenePix 4000B laser scanner (Axon) was used to scan microarray, with laser power 3.72 and photomultiplier tube volts 750. GenePix Pro 3.0 software was used for analysis of intensity of each spot and ratio of Cy5/Cy3 from the acquired images. The intensities of Cy3 and Cy5 were normalized by a coefficient according to the ratio of the located 40 housekeeping genes. The standards for differentially expressed genes were as follows: the ratio of Cy5/Cy3 was more than 4 or less than 0.25, and the intensity value of Cy3 and Cy5 was more than 200.

Verification by RT-PCR[20,21]

RT-PCR primers were designed by Omiga 2.0 software with basic reaction parameters as follows: primer length 18-22 bp, primer % GC 40-60 %, primer Tm 55 ℃; PCR products length 100-600 bp, PCR products % GC 40-60 %, and PCR products Tm 82.5 ℃. The primer sequences were as follows:

CAMK4 (321 bp): 5' GAGACCCTTCTCCAATCC3'
5' GAACTTCAAAACCCACAGC 3'
SHPG (555 bp): 5' ACATCTCCCCTTTGCTAACG 3'
5' GCCACAGTACCCTCATAACTCC 3'
Heregulin (424 bp): 5' TGCTCAACAGCAACATCC 3'
5' TCATACATCTGCCCCTCC 3'
p130 (523 bp): 5' GCACTTCAGTGTTCTAATCG 3'
5' GGCTATTCTCCTTAATGTACC 3'
DAP-1 (322 bp): 5' ACATGAGACACCACATTCC 3'
5' ACGACACAGTTGCTGACC 3'
TRAMP (381 bp): 5' ATTCGCAAGAAAAGCACC 3'
5' GTAGAACGCACTAAGCTGACC 3'
β-actin (206 bp): 5' GGCGGCACCACCATGTACCCT 3'
5' AGGGGCCGGACTCGTCATCATACT 3'

Components of the reverse transcription reaction system were as follows: oligo (dT) 0.5 μl, AMV5x buffer 4 μl, dNTP (10 mM) 1 μl RNasin (20u/ μl) 1 μl, AMV (10u/ μl) 0.5 μl, and DEPC-treated water 12 μl. Components of PCR reaction system were as follows: 10X PCR buffer 2 μl, cDNA 5 μl, dNTP (10 mM) 1 μl, forward primer 1 μl (1 μM), reverse primer 1 μl (1 μM), β-actin forward primer 0.5 μl (0.2 μM), β-actin reverse primer 0.5 μl (0.2 μM), Taq DNA polymerase (2U/ μl) 1 μl, and DEPC-treated water 8 μl, PCR amplification consisted of 35 cycles of denaturation for 60-90 s at 94 ℃, annealing for 60-90 s at 56 ℃, and extension for 90-120 s at 72 ℃. After 35 turns of the cycle, it ended after extension at 72 ℃ for 7 min. DEPC-treated water was replaced with DNA template for the negative control. 1.5 % agarose gel electrophoresis with ethidium bromide was used for the analysis of PCR products. Bandleader 3.0 software was applied to detect the density of bands of PCR products. The value of gene expression was calculated from percent of the ratio of band density of PCR product and the band density of β-actin.

Statistical methods

Data for gene expression were analyzed by two sided Student' s *t* test using SPSS 10.0 software and the significant value was $P<0.05$.

RESULTS

Total RNA electrophoresis and hot-stabilization test

The values of D_{260}/D_{280} for control and HGF/SF-treated groups were 2.022, 2.103 respectively. After hot stabilization test the 18S and 28S bands of total RNA extracts were as clear as before the test (Figure 1).

Microarray quality control

The fluorescent intensities of built-in negative control including rice U2 RNA gene, HCV coat protein gene, spotting solution (without DNA) as blank spots were lower than 200, while the intensities of built-in 40 house-keeping genes as positive control spots were larger than 5000. Normalization coefficient was 1.028. The odds of spot average intensities with background for HGF/SF-treated groups and the control groups were 10.254, 12.856 respectively. The ratio of Cy5/Cy3 by self-check test was 0-1.7, with the average 1.0112.

Scanning results of microarray

The scanning images for HGF/SF-treated groups labeled with Cy5 and images for control groups labeled with Cy3 showed lower noise background and appropriate spot intensity of signal with clear circle appearance. The overlaying image for bicolor fluorescence label is shown in Figure 2.

Filter of the differential expression genes

Of the 4 004 human genes analyzed by microarray, 129 differential expression genes were identified by the filter standard mentioned above. Among the 129 differential expression genes, 61 genes were up-regulated and 68 genes were down-regulated. The up-regulated genes by HGF/SF-met signaling consisted of cell growth factor genes, cell surface receptor genes, angiogenesis genes, cell cycle positive-regulation genes, calcium-, MAPK signaling-related genes and nuclei-receptor genes, etc. The down-regulated genes by HGF/SF-c-met signaling were cell death correlation receptor genes, transmembrane-4 superfamily, cell cycle negative- regulation genes, calcium-, MAPK signaling-related negative genes, cytoskeleton rearrangement inhibitor, anti-oncogene and protease inhibitor, etc.

Results of RT-PCR

To validate the reliability of microarray results, 6 differential expression genes (3 up-regulated genes and 3 down-regulated genes) were selected randomly and analyzed by β-actin semi-quantitative RT-PCR. Expressions of the 6 differential genes by RT-PCR were confirmed to be consistent with the results of microarray (shown in Figure 3 and Figure 4). The average

relative densities of bands detected by Bandlead 3.0 computer program showed significant differences (P<0.05) between HGF/SF-treated groups and control groups except SHPG, heregulin, and DAP-1 groups.

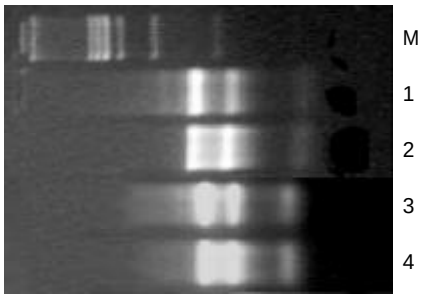

Figure 1 Result of total RNA electrophoresis and hot-stabilization test. M: PCR marker; 1: RNA of HGF/SF-treated group; 2: RNA of control group; 3: RNA of HGF/SF-treated group after hot-treatment; 4: RNA of control group after hot-treatment.

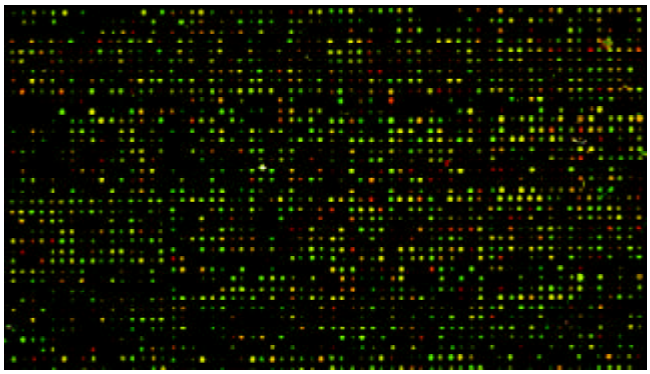

Figure 2 The overlaying image for bicolor fluorescence label on gene chip. red: high expression; green: low expression; yellow: no change in expression.

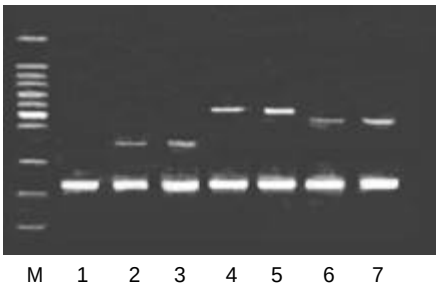

Figure 3 Result of RT-PCR for up-regulated genes. M: 100 bp DNA ladder marker; 1: negative control; 2: CAMK4 blank control; 3: CAMK4 HGF 80 ng/ml; 4: SHPG blank control; 5: SHPG HGF 80 ng/ml; 6: Heregulin blank control; 7: Heregulin HGF 80 ng/ml.

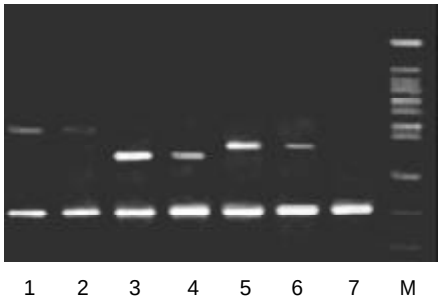

Figure 4 Result of RT-PCR for down-regulated genes. 1: p130 blank control; 2: p130 HGF 80 ng/ml; 3: DAP-1 blank control; 4: DAP-1 HGF 80 ng/ml; 5: TRAMP blank control; 6: TRAMP HGF 80 ng/ml; 7: negative control; M: 100 bp DNA ladder marker.

DISCUSSION

Reliability of the microarray assay

Gene chip, or DNA chip, including oligonucleotide chip synthesized *in situ* and cDNA microarray by direct-spot or cDNA array[22-24], is a key technique platform[25-27] in post-genome times for its striking superiority of high-throughput, high-parallelity, high-sensitivity, micromation and automatization. cDNA microarray is a mature and widespread technique. Its stability, reliability and reproducibility have been confirmed by many investigators[28-31]. The microarray experiment in this research was successful and under strict quality control, with mRNA in good quality and no degradation tested by the test of hot-stabilization. In our experiment the built-in positive and negative control showed the qualified results, the scanning images showed lower noise background, and the positive spots indicated high intensity of signal with clear circle appearance. All the parameters such as odds of spot average intensity with background for the HGF/SF-treated group and for the control, normalization coefficient, and ratio of Cy5/Cy3 by self-check test were in accord with theoretic values of successful experiment. The expressions of the 6 differential expression genes randomly selected by RT-PCR were confirmed to be consistent with the results of microarray. These results indicate satisfactory reliability of the microarray experiment.

Superiority of microarray for study of target genes related to the HGF/SF-met signaling

It has been evidenced that HGF/SF-met signaling plays an important, even a critical role in tumor progression, invasion and metastasis. Hamasuna *et al*[32] showed that HGF/SF activated membrane type metalloproteinases (MT1-MMP) in dosage-related manner and decreased wild-type metalloproteinases inhibitor TIMP-2 mRNA. They indicated that glioblastoma cells U251 excreted more MMP-2 protein and MMP-2 mRNA expression increased by 2.5 fold by HGF/SF stimulation. Abouader *et al*[33] argued that HGF/SF-met signaling was a key molecule path for control of glioblastoma cells growth, progression, invasion and metastasis. Recently Webb *et al*[34] have confirmed that HGF/SF-met-uPA -plasmin pathway exists in some tumor cell lines and is related to invasion, metastasis and other malignant behaviors. Only a few genes can be investigated by the traditional technology of molecular biology and the whole transcriptional gene expression profiles of HGF/SF-met signaling pathway can hardly be explored. In this paper the transcriptional gene expression profiles of HGF/SF-met signaling pathway in colorectal carcinoma cells were discussed for the first time so as to explore the target genes related to the signaling pathway. The results indicated that HGF/SF-met signaling might activate oncogenes, signal transduction genes, apoptosis-related genes, metastasis related genes and many other genes with up-regulation effects, and meanwhile it might down-regulate a number of genes. It is suggested that a complex signaling-adjusting-gene-expression network may be in existence, and contribute to extensive gene transcription effects and comprehensive biological roles. The complexity of HGF/SF-met signaling to control the gene expression was revealed as a whole by the gene chip technology, by which it manifested incomparable superiority.

Transcriptional gene expression profiles of HGF/SF-met signaling

Of the 4 004 human genes analyzed by microarray (totally 4 096 spots, subtracted 92 built-in positive and negative control

spots), 129 genes (holding 3.22 % of the investigated genes) revealed differential expression in the HGF/SF-treated groups compared with the control groups, which supplied abundant information about target genes of HGF/SF-met signaling. Among the 129 differential expression genes, 61 genes were up-regulated (holding 1.52 % of the investigated genes), and 68 genes were down-regulated (holding 1.70 % of the investigated genes). The expressions of some differential genes analyzed by microarray, for instance, collagenase IV[35], catenin[36], were consistent with the results reported in literatures that they were uncovered by traditional technology. Still a number of genes with differential expression not reported previously were found in our investigation. Some of them are genes with unknown function. Some genes with elevated expression by HGF/SF stimulation not reported previously are listed as following: Syndeans-2, calmodulin-dependent protein kinase IV(CaMK4), cadherein 8, protocadherin, calcium-dependent serine protein kinase (CASK), human keractnocyte growth factor(KGF), Heregulin, angiogenin, *etc*. In a word, the up-regulated genes by HGF/SF stimulation usually belong to cell growth factor genes, cell surface receptor genes, angiogenesis genes, cell cycle positive-regulation genes, calcium-, MAPK signaling-related genes, transcription factor, cytoskeleton regulation genes, and nuclei-receptor genes. These up-regulation genes stimulating cell growth, promoting cell transformation, resisting apoptosis, facilitating cell locomotion, accelerating signal conduction, and promoting vascularization and extracellular matrix lysis[37-44], may provide a foundation for mitogen, motogen, and morphogen activity in HGF/SF-met signaling pathway further.

Versatile effects on down-regulated gene expression by HGF/SF-met signaling have been found in this microarray assay. The genes of reduced expression by HGF/SF stimulation not reported previously include dual-specificity phosphatase 6 (DUSP6), SPINT2 (serine protease inhibitor, Kunitz-type 2, hepatocyte growth factor activator inhibitor type 2), TIMP1(tissue inhibitor of metalloproteinases 1), elastase inhibitive factor, TAPA1(Target of antiproliferative antibody 1, CD81), MRP-1 (motility-related protein 1, CD9), PRB2/p130, pRB2/p107, TRAMP (TNF receptor-related apoptosis mediating protein, DR3), WD40, DAP-1, etc. On the whole, the adjustability of multi-aspects and multi-targets in down-regulation of gene expression in colorectal carcinoma cells by HGF/SF-met signaling was revealed by microarray assay. The down-regulated genes by HGF/SF stimulation usually belong to cell death correlated receptor genes, transmembrane-4 superfamily, cell cycle negative-regulation genes, calcium and MAPK signaling-related negative genes, cytoskeleton rearrangement inhibitors, anti-oncogene and protease inhibitors. These genes are responsible for the negative control of cell function, which makes reinforcement and maintenance in stimulation of cell growth, promotion of cell transformation, resistance to apoptosis, facilitation for cell locomotion, acceleration of signal transduction, promotion of vascularization and lysis of extracellular matrix[45-56]. These are another annotation for mitogen, motogen, and morphogen activity of HGF/SF-met signaling pathway in tumor progression, also the first confirmation of pluripotency and versatility in regulation of gene expression by HGF/SF-met signaling.

The transcriptional gene expression profiles induced by HGF/SF-met signaling pathway in the colorectal carcinoma cells were described by cDNA microarray technology, and meanwhile the complexity and pluripotency of regulation in gene expression were also revealed for the first time. A majority of the genes with differential expression can be explained by the existing scientific theories, although some of them have unknown-function and a few of them cannot be explained reasonably for the time being, which deserve further investigation.

Abstract

AIM: To determine the pathogenicity of GB virus C (GBV-C) on liver and the effects of its co-infection on the clinical features and prognosis of patients with hepatitis B and C.

METHODS: Cross-sectional study was carried out in 413 patients with acute, chronic hepatitis B or liver cirrhosis, and in 67 hemodialysis patients. A 20-month prospective cohort study was carried out in 95 hepatitis B and 80 hepatitis C patients. A reverse transcriptase nested polymerase chain reaction (RT-nPCR) of the 5'-noncoding region was used to detect circulating GBV-C RNA. Liver function was determined by an automated analyzer for all patients.

RESULTS: The prevalence of GBV-C in the high-risk populations with the virus transmitted via blood was high, ranging from 16.2 to 28.8 %. Co-infection with GBV-C in hepatitis B patients did not affect the clinical features of the disease or liver function. The dialysis patients infected with GBV-C alone did not develop functional changes to the liver. Prospective cohort study showed that GBV-C co-infection did not affect the clinical features, prognosis or negative serum conversion rate of chronic hepatitis B and C.

CONCLUSION: The results suggest that GBV-C has no marked pathogenicity on liver, so it may not be a hepatitis virus.

INTRODUCTION

Hepatitis B and C viruses (HBV, HCV) jointly contribute to 90 % of cases of post-transfusion non-A, non-B hepatitis (HNANB). The remaining 10 % of cases could not be attributed to any of the other known hepatitis viruses or other factors such as alcohol, drug, or any disease related causes[1,2]. These cases are named non-A-E hepatitis (HNA-E) and may be caused by an unknown viral agent. In 1995 and 1996, GB virus-C (GBV-C) and hepatitis G virus (HGV) were cloned by Simons *et al.* and Linnen *et al.*, respectively, in the United States[3,4]. Sequence analysis revealed that these two viruses had 85 % and 95 % identical nucleotide and amino acid sequences, respectively. And now these two viruses are named as GBV-C. Initially, GBV-C was isolated from the serum of patients with HNA-E[3,4]. However, there are still a lot of arguments up to now on the pathogenicity of GBV-C on liver and on whether GBV-C is an aetiological agent of HNA-E[5,6]. The prevalence of GBV-C in patients with chronic hepatitis B or chronic hepatitis C is very common, because of the similar transmission routes[7-12]. In the present study, we investigated the prevalence of GBV-C and evaluated its pathogenicity on liver with a cross-sectional study in 413 patients with acute, chronic hepatitis B, or liver cirrhosis, and in 67 hemodialysis patients. We also carried out a 20-month prospective cohort study in 95 patients with chronic hepatitis B and 80 patients with chronic hepatitis C. The results suggest that GBV-C has no marked pathogenicity on liver, so it may not be a new hepatitis virus.

MATERIALS AND METHODS

Patients

A total of 413 inpatients with confirmed diagnoses of acute, chronic hepatitis B or liver cirrhosis in two hospitals for infectious diseases in Beijing from January to December 2000 were enrolled in this study. Anti-HAV IgM, anti-HCV, anti-HDV and anti-HEV antibodies were all negative in these patients. Serum samples of the inpatients were collected and tested to assess liver biochemical characteristics on the day of admission. The rest serum was tested and stored at -80 ℃ for pathogen analysis.

Serum samples of hemodialysis patients with renal failure were collected from 67 patients in 3 general hospitals from December 2001 to March 2002 in Beijing. All samples were stored at -30 ℃ before analysis.

A cohort of 95 patients with chronic hepatitis B and 80 patients with chronic hepatitis C was enrolled from villages of a county in Zhoukou area, Henan Province. All patients were infected with HBV or HCV from 1991 to 1992 as a consequence of blood donation. All the patients had persistently elevated serum alanine aminotransferase (ALT) (at least 1.5 times the upper limit of the normal level) and were positive for serum HBV DNA or HCV RNA as detected by PCR or RT-PCR, respectively. All the patients were negative for serum anti-HAV IgM and anti-HEV. The average disease course of these patients was 3 years when investigation and confirming diagnosis were carried out in April 1994. All the patients of the cohort showed no evidence of liver cirrhosis or hepatocellular carcinoma in regular ultrasonic graphic examinations. All the patients were followed up twice, i.e., 6 and 20 months after the first investigation.

Laboratory examination

For GBV-C RNA detection, RNA was first extracted from 50 μl of serum using a commercial RNA extraction kit (Promega, Z5110). Reverse transcriptase and nested polymerase chain reactions (RT-nPCR), 35 cycles for two round, were performed using a PCR machine (SABC Thinker Series II, Sino-American Biotechnology Company, China). The primers used were from

the 5' -noncoding region of the GBV-C genome, outer primers (sense, 5' -TCTTGGTAGCCACTATAGGTG-3' , and antisense, 5' -GGCAAAGCCTATTGGTCAAG-3'), and inner primers (sense, 5' -AGAAAGAGCACGGTCCACAG-3' , and antisense, 5' -CCACTGGTCCTTGTCAACTC-3'). The amplified product (158 base pairs) was visualized under ultraviolet light after gel electrophoresis and stained with ethidium bromide. GBV-C RNA was assessed in duplicate sera and scored as positive only when consistent results were obtained. Liver biochemistry tests including alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin (TBil), direct bilirubin (DBil), total protein (Tp), and serum albumin/globulin ratio (A/G) were measured with an automated analyzer.

Statistical analysis

Data in the text and tables were expressed as $\bar{x}\pm s$. Student' s *t*-test and one-way analysis of variance were used for statistical analysis according to the data obtained. For all tests, *P* values less than 0.05 were considered to be statistically significant, and *P* values less than 0.01 were considered to be greatly statistically significant.

RESULTS

Of the serum samples from 413 patients infected with HBV, 67 were co-infected with GBV-C (16.22 %). 169 cases had integrated clinical data. The patients suffering from acute, chronic hepatitis B or liver cirrhosis were grouped on the basis of the presence or absence of GBV-C co-infection, and the levels of ALT, AST, TBil, DBil, Tp of the different groups were compared (Table 1).

Results shown in Table 1 indicated that there was no significant difference in the serum biochemistry characteristics of 3 types of patients (acute, chronic hepatitis B and liver cirrhosis) between GBV-C RNA infected group and non-infected group ($P>0.05$).

11 of the 67 dialysis patients were GBV-C RNA positive (16.42 %) and the positive rate of GBV-C RNA increased with the number of times of dialysis. The comparison of serum ALT and AST levels in 67 patients infected with different viruses is shown in Table 2.

Table 2 Comparison of serum ALT and AST in dialysis patients with different virus infection

Group	*n*	Average dialysis times	ALT/IU·L^{-1}	AST/IU·L^{-1}
(1) HBV DNA(+) HCV RNA(-) GBV-C RNA(-)	11	243.75±224.53	31.63±22.32	35.12±18.06
(2) HBV DNA(-) HCV RNA(+) GBV-C RNA(-)	6	306.67±296.41	30.67±9.45	25.00±12.28

GBV-C RNA(-)	102	578.63±807.04	314.98±345.05	5.85±7.85	3.87±4.80	67.21±10.92

No significant difference ($P>0.05$) was found in all the biochemistry characteristics between hepatitis B patients with or without GBV-C infection.

Table 3 Comparison of biochemistry characteristics between chronic hepatitis B patients with or without GBV-C infection

GBV-C RNA	*n*	A/G	ALT/IU·L^{-1}	AST/IU·L^{-1}	TBil/μmol·L^{-1}
(1) Positive group	24	1.65±0.26	90.84±48.43	43.21±31.56	5.91±1.86
(2) Negative group	71	1.63±0.21	95.36±51.96	44.45±38.07	7.66±1.95

No significant difference ($P>0.05$) was found in all the biochemistry characteristics between the two groups.

Table 4 Comparison of biochemistry characteristics between chronic hepatitis C patients with or without GBV-C infection

GBV-C RNA	*n*	A/G	ALT/IU·L^{-1}	AST/IU·L^{-1}	TBil/μmol·L^{-1}
(1) Positive group	23	1.82±0.30	110.23±59.61	45.96±40.11	4.53±1.55
(2) Negative group	57	1.65±0.25	97.65±56.74	52.94±48.00	5.77±1.73

No significant difference ($P>0.05$) was found in all the biochemistry characteristics between the two groups.

On statistic analysis, ALT levels were significantly different between groups 1 and 4 ($P<0.01$) and groups 2 and 4 ($P<0.05$). AST levels were also significantly different between groups 1 and 4 ($P<0.01$). The results showed a significant elevation in the levels of ALT and AST in hemodialysis patients infected with HBV or HCV compared with that in those not infected with the two viruses. Significant difference ($P<0.05$) was found in dialysis times between groups 2 and 4, and groups 3 and 4. Three patients had abnormal liver function (ALT>40 IU/L, AST>40 IU/L), among them one was infected with HCV, the other two were infected with HBV. Serum ALT and AST levels were normal in patients with GBV-C infection alone.

A cohort study was carried out in 95 patients with chronic hepatitis B and 80 patients with chronic hepatitis C enrolled from villages in Henan Province. Serum GBV-C was positive in 24 (25.26 %) chronic hepatitis B patients and 23 (28.75 %) chronic hepatitis C patients (Tables 3 and 4).

When following up the patients 6 months later, we found that 23 of the 95 chronic hepatitis B patients (24.21 %) became HBV DNA negative and 21 of the 80 (26.25 %) chronic hepatitis C patients became HCV RNA negative. GBV-C RNA could not be detected in 12.50 % (3/95) chronic hepatitis B patients and in 17.39 % (4/80) chronic hepatitis C patients. Table 5 and Table 6 show the biochemistry characteristics of chronic hepatitis B and C patients.

Table 5 Comparison of biochemistry characteristics between chronic hepatitis B patients with or without GBV-C infection at the 6-month follow-up

Group	*n*	A/G	ALT/IU·L^{-1}	AST/IU·L^{-1}	TBil/μmol·L^{-1}
(1) HBV DNA(+) GBV-C RNA(+)	14	1.74±0.19	93.29±60.67	29.14±13.87	7.64±5.47
(2) HBV DNA (+) GBV-C RNA (-)	58	1.73±0.18	62.33±41.67	27.68±11.99	6.10±2.09
(3) HBV DNA (-) GBV-C RNA (+)	7	1.61±0.11	30.00±7.80	21.57±8.18	7.57±3.41
(4) HBV DNA (-) GBV-C RNA (-)	16	1.64±0.14	32.65±17.01	26.65±11.96	7.71±2.76

Significant difference ($P<0.05$) was found only in ALT between group 1 and group 3, group 2 and group 4. No significant difference ($P>0.05$) was found in other biochemistry characteristics among the 4 groups.

Table 6 Comparison of biochemistry characteristics between chronic hepatitis C patients with or without GBV-C infection at the 6-month follow-up

Group	*n*	A/G	ALT/IU·L^{-1}	AST/IU·L^{-1}	TBil/μmol·L^{-1}
(1) HCV RNA(+) GBV-C RNA(+)	11	1.76±0.17	127.11±82.12	41.13±19.07	7.49±5.82
(2) HCV RNA(+) GBV-C RNA (-)	48	1.82±0.20	71.62±47.74	26.05±12.49	7.97±3.91
(3) HCV RNA (-) GBV-C RNA(+)	8	1.60±0.13	33.11±8.08	22.97±9.78	7.26±4.25
(4) HCV RNA (-) GBV-C RNA (-)	13	1.60±0.14	30.74±20.01	24.65±11.84	7.65±3.23

Significant difference ($P<0.05$) was found both in ALT between group 1 and group 3, group 2 and group 4, and in AST between group 1 and group 4. No significant difference ($P>0.05$) was found in other biochemistry characteristics among the 4 groups.

At the 20-month follow up, the biochemistry characteristics of chronic hepatitis B and C patients were compared between two groups: one with and the other without GBV-C co-infection (Tables 7 and 8). At this time point, 26.0 % (25/95) chronic hepatitis B patients and 20.0 % (16/80) chronic hepatitis C patients were lost in the follow up.

Table 7 Comparison of biochemistry characteristics between chronic hepatitis B patients with or without GBV-C infection after 20 months

Group	*n*	ALT/IU·L^{-1}	AST/IU·L^{-1}
(1) HBV DNA(+) GBV-C RNA(+)	8	52.13±44.90	44.25±28.42
(2) HBV DNA (+) GBV-C RNA (-)	30	44.40±37.26	34.67±24.23
(3) HBV DNA (-) GBV-C RNA (+)	8	28.14±15.36	25.29±17.21
(4) HBV DNA (-) GBV-C RNA (-)	24	25.15±11.59	25.73±13.16

Significant difference ($P<0.05$) was found only in ALT and AST between group 1 and group 3, and group 2 and group 4.

Table 8 Comparison of biochemistry characteristics between chronic hepatitis C patients with or without GBV-C infection after 20 months

Group	*n*	ALT/IU·L^{-1}	AST/IU·L^{-1}
(1) HCV RNA(+) GBV-C RNA(+)	6	72.24±73.87	49.29±48.49
(2) HCV RNA(+) GBV-C RNA (-)	22	42.43±39.10	32.91±30.57
(3) HCV RNA (-) GBV-C RNA(+)	7	26.98±24.47	25.11±19.07
(4) HCV RNA (-) GBV-C RNA (-)	29	25.39±13.16	26.74±16.99

Significant difference ($P<0.05$) was found only in ALT and AST between group 1 and group 3, and group 2 and group 4.

After 20-month follow up, correlation was seen between the abnormal levels of the liver biochemistry characteristics and HBV DNA in chronic hepatitis B patients. However, no correlation was found between the abnormal levels of the liver function and co-infection with GBV-C. The same result was found in chronic hepatitis C patients. During the period of follow up for 20 months, 50.00 % (8/16) hepatitis B patients with GBV-C infection and 44.44 % (24/54) hepatitis B patients without GBV-C infection became HBV DNA undetectable. 53.85 % (7/13) hepatitis C patients with GBV-C infection and 56.86 % (29/51) hepatitis C patients without GBV-C infection became HCV RNA undetectable. The rates of negative serum conversion of HBV DNA and HCV RNA were not significantly different between the two groups.

DISCUSSION

Since GBV-C was cloned, there have been a lot of arguments on the pathogenicity of GBV-C. Although a number of reports have indicated that GBV-C can induce acute, chronic, and even fulminant hepatitis[13-16], most of the clinical observations have demonstrated that GBV-C infection alone has little significance in causing liver damage in human[17-20]. There were 363 research publications on GBV-C/HGV in MEDLINE database from 1999 to February 2001, among which only 8 supported GBV-C pathogenicity on the liver. Most researches implicated that no correlation existed between GBV-C and liver diseases. Patients with HBV or HCV co-infected with GBV-C did not have different clinical manifestations and outcomes when compared with patients with HBV or HCV infection alone[21-23].

GBV-C, HBV and HCV have a similar route of transmission. Many of the reports limited their research on the prevalence of GBV-C in hepatitis B and hepatitis C patients and had relatively small numbers of cases. Therefore, it was difficult for them to draw a definite conclusion on GBV-C pathogenicity on the liver. The subjects of this study were a large sample in the high-risk population with GBV-C infection (hepatitis B, hepatitis C and hemodialysis patients). This work combined the cross-sectional and prospective cohort studies and applied the methods of cross-experimental design and analysis. Therefore, it could analyze more reasonably the pure effects of GBV- C infection on liver.

All data in this study were pooled from experiments carried out by many graduate students and repeated many times. Hepatitis B, hepatitis C and hemodialysis patients belonged to the high-risk population transmitted via blood. Previous investigations have shown that there was no significant difference between the prevalence rates of GBV-C in patients with HNA-E and of the aforementioned high-risk population (P>0.05)[23-25]. So these findings do not support the argument that GBV-C was the etiological factor of HNA-E. No significant difference was seen in the abnormal level of liver biochemistry characteristics between positive and negative serum GBV-C RNA in acute, chronic hepatitis B or liver cirrhosis patients (P>0.05). But the abnormal level of liver biochemistry characteristics correlated well with HBV DNA. Therefore, these results demonstrated that co-infection with GBV-C did not affect the liver biochemistry characteristics and illness. Infection with HBV or HCV could elevate the level of liver enzymes (ALT and AST) in hemodialysis patients, but infection with GBV-C did not demonstrate such effects. So these results showed that the hemodialysis patients had no abnormal liver biochemistry characteristics when infected with GBV-C alone without the known hepatitis virus co-infection. The dynamic observation in 3 follow-ups of the cohort of chronic hepatitis B and C patients during a period of 20 months indicated that co-infection with GBV-C did not significantly affect the illness, outcome or rate of negative serum conversion. In summary, this work demonstrates that, though GBV-C is highly prevalent in high-risk populations with virus infection via blood, it seems to have no pathogenicity on the liver and therefore may not be a hepatitis virus.

Abstract

AIM: Point mutation, one of the commonest gene mutations, is the most important molecular pathogenesis of cancer and chronic infection. The commonest methods for detection of point mutation are based on polymerase chain reaction (PCR). These techniques, however, cannot be used in large scale screening since they are neither accurate nor simple. For this reason, this study established a novel method of competitively differentiated PCR (CD-PCR) for screening point mutation in clinical practice.

METHODS: Two competitively differentiated primers for mutant-type and wild-type templates respectively with an identically complemented region in 3' end except for last 2 base pairs and a different non-complemented region in 5' end were designed. Thus, competitive amplification might be carried out at a lower annealing temperature at first, and then differentiated amplification at a higher annealing temperature when primers could not combine with initial templates. The amplification was performed in one-tube. The products of CD-PCR were detected using microplate hybridization assay. CD-PCR was evaluated by detecting G1896A variant of hepatitis B virus (HBV) in form of recombinant plasmids and in sera from patients with hepatitis B, and compared with allele-specific PCR (AS-PCR) and competitive AS-PCR.

RESULTS: CD-PCR was successfully established. It could clearly distinguish wild-type and mutant-type plasmid DNA of G1896A variant when the amount of plasmid DNA was between 10^2-10^8copies/reaction, while for AS-PCR and competitive AS-PCR, the DNA amount was between 10^2-10^4copies/reaction. CD-PCR could detect one copy of G1896A variant among 10-100 copies of wild-type plasmid DNA. The specificity of CD-PCR was higher than those of AS-PCR and competitive AS-PCR in the detection of HBV G1896A variant in sera from patients with hepatitis B. CD-PCR was independent of the amount of HBV DNA in serum. HBV G1896A variant was more often found in HBeAg (-) patients with a lower level of detectable viremia than that with a higher level of detectable viremia (P=0.0192).

CONCLUSION: CD-PCR is more specific since it is less influenced by the amount of initial templates and the cross amplification between mutant- and wild-type amplified products. It is also simple and time-saving. Thus, CD-PCR might be useful in routine gene typing and point mutation screening. HBV G1896A or other more important mutations have to be routinely detected in patients with a detectable level of viremia after HBeAg/antibody conversion in clinical practice.

INTRODUCTION

Point mutation is one of the commonest gene mutations not only in human genome but also in genome of pathogens. It is the most important molecular pathogenesis of cancer and chronic infection[1-3]. The commonest method for detecting point mutation is based on polymerase chain reaction (PCR), which can be divided into two types. One type is to analyze the PCR products using direct sequencing, restriction fragment length polymorphism and single strand conformation polymorphism[4-7]. This type of technique is usually accurate, but cannot be used in routine clinical examination since it needs additional manipulation. The other type is allele specific-PCR (AS-PCR), sequence specific-PCR or amplification refractory mutation system[8-13]. This type of techniques is usually simple, but its specificity is influenced by the amount of initial templates of PCR. This deficiency was not so obvious when this type of methods was used to detect point mutation or gene typing of human gene in the past since the initial templates in these samples could be controlled[8,12,13]. Some investigators, however, have made efforts to improve AS-PCR by introducing competitive mechanism, and established the so-called bidirectional AS-PCR and competitive PCR in order to decrease the influence of the amount of initial templates on its specificity[14-19]. AS-PCR has been used to detect point mutation of pathogens recently[10, 20-22]. However, the specificity of AS-PCR in detection of pathogen mutations was challenged by uncontrollable amount of initial templates and the requisition of high sensitivity. For these reasons, a novel method of competitively differentiated polymerase chain reaction (CD-PCR) was established in this study and compared with AS-PCR and competitive AS-PCR in the detection of G1896A variant of HBV.

MATERIALS AND METHODS

Materials

One hundred serum samples with (hepatitis B surface antigen) HBsAg(+), anti-(hepatitis B e antigen) HBe(+) and anti-(hepatitis B core antigen) HBc(+), 60 serum samples with HBsAg(+), HBeAg(+) and anti-HBc(+) and 40 serum samples without HBV serum markers were collected. The serum markers were demonstrated by enzyme-linked immunoabsorbent assay. Recombinant plasmid pG1896A was constructed as described

before[23]. TZ19U-HBV that contained double copies of HBV DNA (adw) was a gift from Professor Huang Zhimin (Zhongshan University, Guangzhou, China) and was used as wild-type DNA control. T4 DNA ligase and pfu DNA polymerase were purchased from Promega (USA). DNA gel extraction kits and plasmid isolation kits were purchased from Qiagen (Germang). Anti-digoxigenin and anti-fluorescein labeled with horseradish peroxidase were purchased from Roche (USA). Primers shown in Table 1 were designed with the Omega 2 software and synthesized in Bioasia Biological Engineering Company (Shanghai, China).

BIO: the abbreviation of biotin; DIG: the abbreviation of digoxigenin; FLU: the abbreviation of fluorescein.

Methods

Principles of CD-PCR Two competitively differentiated primers (CDP) with different labels in 5' end were designed. CDP had a complemented region of 17-20 bp long with penultimate mismatch and a 3' terminus matching the mutant or the normal bases of the templates. The annealing temperature of this part was about 52-54 ℃. There was also a non-complemented region of 14 bp long, which was different from each other in 5' end. The total annealing temperature of CDP was about 75-80 ℃. PCR was performed in one tube. Competitive amplification was performed first when CDP competed for templates under lower annealing temperature. After certain amounts of products of each primer were obtained, differentiated amplification was then performed under higher annealing temperature when CDP could only use its own products as templates. This amplification model would keep the products ratio of mutant and wild templates and allow the templates to be fully amplified.

G1896A variant detected by CD-PCR Wild-type and G1896A mutant-type plasmids were used for the optimization of CD-PCR. A total volume of 30 μl was used in the final conditions of PCR reaction. The reaction mixture consisted of 10 mmol/L Tris-HCl, pH 8.5,50 mmol/L KCl, 1.5 mmol/L $MgCl_2$, 0.2 mmol/L dNTPs, 2U pfu DNA polymerase, 20 pmol FLU-PCWd, 20 pmol DIG-PCMd, 20 pmol PCA and 5 μl plasmid or extracted DNA. The cycling conditions were as follows: 3 cycles (first set) at 94 ℃ for 40 s, at 52 ℃ for 40 s and at 72 ℃ for 90 s followed by 35 cycles (second set) at 94 ℃ for 40 s, and at 72 ℃ for 90 s. The PCR products were then hybridized with solidified biotin-labeled probe PCP in two wells of microplate. The color reaction was obtained after captured PCR products reacted with anti-DIG or anti-FLU respectively, which were conjugated with horseradish peroxidase.

G1896A variant detected by competitive AS-PCR Except for the replacement of primer FLU-PCWd and DIG-PCMd with primer FLU-PCWc and DIG-PCMc, the components of competitive AS-PCR were similar to CD-PCR. The cycling conditions were as follows: 25 cycles (first set) at 94 ℃ for 40 s, at 60 ℃ for 40 s, and at 72 ℃ for 90 s followed by 10 cycles (second set) at 94 ℃ for 40 s, at 52 ℃ for 40 s, and at 72 ℃ for 90 s. The PCR products were then detected similar to CD-PCR.

G1896A variant detected by AS-PCR Except for the absence of FLU-PCWc, the components and the cycling conditions were similar to competitive CD-PCR. The PCR products were visualized under an ultraviolet transilluminator.

Quantification of serum HBV DNA by fluorescent quantitive PCR The HBV DNA level of 200 sera was detected using fluorescent quantitive PCR following the instruction (Taqmen, Roche).

DNA sequencing A fragment of HBV precore in positive or negative sera by all three methods and in sera that were positive for AS-PCR and competitive AS-PCR, and negative for CD-PCR was analyzed using DNA sequencing after it was amplified using primers PCSc and PCAc and cloned into plasmid pUC19.

RESULTS

Detection of HBV G1896A variant in recombinant plasmid DNA

The typical results of HBV G1896A variant detected by means of AS-PCR, competitive AS-PCR and CD-PCR are shown in Figure 1. To detect G1896A variant, the sensitivity of AS-PCR was 10^3 copies/reaction, and there was non-specific amplification when the amount of wild-type initial templates was higher than 10^4 copies/reaction. For competitive AS-PCR, the wild-type and mutant-type plasmid DNA could be clearly distinguished when the initial templates were 10^2-10^4 copies/reaction. CD-PCR could clearly distinguish them in the range of 10^2-10^8 copies/reaction. There was some degree of non-specific reaction when the amount of initial templates was higher than 10^4 copies/reaction, but the difference of color intensities between wild-type and mutant-type product wells was obvious. CD-PCR could detect one variant G1896A copy among 100 wild-type copies of DNA when the initial templates were 10^2-10^5 copies/reaction, but one out of 10 copies when the initial templates were 10^5-10^8 copies/reaction.

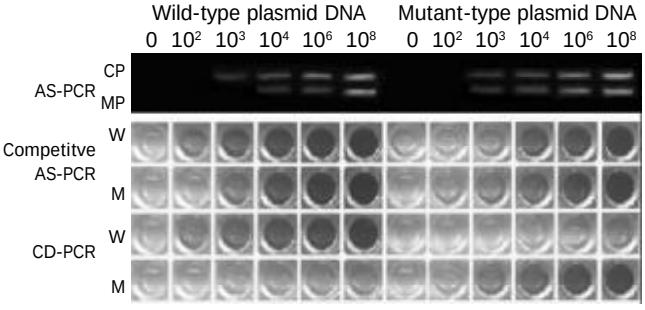

Figure 1 HBV G1896A variant detected by AS-PCR, competitive AS-PCR and CD-PCR using its wild-type or mutant-type recombinant plasmid DNA as objects. CP: common product band; MP: mutant product band; W: wild-type products; M: mutant-type products.

Detection of HBV G1896A variant in sera

Among 200 sera, HBV DNA was positive in 104 cases using AS-PCR, in 119 cases using competitive AS-PCR and in 122 cases using CD-PCR. The sensitivity for HBV DNA detection by CD-PCR was similar to that of competitive AS-PCR, but higher than that of AS-PCR (χ^2=5.47, P=0.0193). The results of G1896A variant in sera are shown in Table 2. Among the 104 cases with positive HBV DNA detected by all the three methods, there were 33 positive cases, and 31 negative cases

of G1896A variant detected by both CD-PCR and AS-PCR, and 40 cases that were positive by AS-PCR but not by CD-PCR.

Table 2 HBV G1896A variant and its relationship with HBV serum markers

	Cases	CD-PCR(%)		CAS-PCR(%)		AS-PCR(%)	
		HBV DNA(+)	G1896A variant	HBV DNA(+)	G1896A variant	HBV DNA(+)	G1896A variant
HBsAg(+)/ HBeAg(+)	60	100.0	6.7	100.0	63.3[b]	93.3	55.0[b]
HBsAg(+)/ HBeAg(-)	100	62.0[c]	38.0	59.0	46.0	48.0	40.0
HBsAg(-)/ HBeAg(-)	40	0	0	0	0	0	0

[b]$P<0.01$, compared with group of CD-PCR, χ^2 test, [c]$P<0.05$, compared with group of AS-PCR, χ^2 test.

The results of DNA sequencing

HBV G1896A mutation was confirmed by DNA sequencing in 3 positive sera by all the three methods, and excluded in 3 negative sera by all the three methods and in 4 sera that were positive by AS-PCR and competitive AS-PCR, but negative by CD-PCR.

The relationship between G1896A variant and HBV DNA level

The relationship between G1896A variant detected by AS-PCR, competitive AS-PCR and CD-PCR and HBV DNA level in the sera is shown in Table 3. More G1896A variants were found in patients with positive HBeAg by AS-PCR and competitive AS-CR. These could be false positives. These false-positive findings occurred more often in patients with a higher level of HBV DNA in serum. CD-PCR seemed more specific since only 4 patients were found to be infected with both wild-type HBV and G1896A variants in HBeAg positive cases. By CD-PCR, HBV G1896A variant was more often found in HBeAg (-) patients with a lower level of viremia (P=0.0192).

Table 3 Relationship between G1896A variant and HBV DNA level in serum

	HBeAg(+)(n=56)		HBeAg(-) (n=48)	
	$\leqslant 10^6$copies / ml (n=14)	$>10^6$ copies / ml(n=42)	$\leqslant 10^6$ copies / ml(n=28)	$>10^6$ copies / ml(n=20)
AS-PCR	2	31	21	19
Competitive AS-PCR	2	35	23	20
CD-PCR	2	2	21[a]	8

[a]Compared with HBeAg(-) group with a level higher than 10^6 copies / ml of HBV DNA in serum, Fisher's exact possibility test, P=0.0192.

DISCUSSION

AS-PCR has been considered as a simplest and quickest method for the detection of known point mutations[5,10-19]. False positive results, however, seem inevitable since the amplification of wild-type templates by allele-specific or sequence-specific primers for mutant-type templates can not be completely prevented. Once non-specific products occur, they will be amplified subsequently. Thus the ratio of specific and non-specific products will decrease, and become even smaller as the plateau of PCR reaches at the late stage. It is understandable that false band will occur when a large amount of initial templates or too many cycles are used in AS-PCR. To improve the specificity of AS-PCR, the specificity of primers was designed by introducing penultimate mismatch[24], and the cycles of specific amplification were reduced by introducing basic amplification[6,25]. The application of competitive mechanism is another important step to improve AS-PCR.

Competitive AS-PCR and bidirectional or tetra-primer AS-PCR are common assays that have a competitive mechanism[6,14-19,25]. Bidirectional or tetra-primer AS-PCR is in fact a competition for PCR system, while competitive AS-PCR is the competition for both templates and PCR system. However, these PCRs can not exclude the non-specific amplification from initial templates in each cycle. For competitive AS-PCR, it is possible to reduce the influence of initial templates, but a new problem will occur, which is that the initial products will become the templates for non-specific amplification in subsequent cycles. This might be the underlying mechanism that the competitive AS-PCR seemed worse than AS-PCR in this study. Therefore, to reduce the influence of the initial templates and products would be a very important measure to improve AS-PCR assay on specificity of amplification

For CD-PCR, competitive amplification was performed first, and followed by differentiated amplification, which was different from competitive AS-PCR. This protocol would allow allele- or sequence-specific amplification to begin at a low level of templates. Thus, the influence of initial templates could be controlled to a minimal level. After a few cycles, differentiated amplification was carried out under higher annealing temperature at which primers could not combine with initiated templates and the initial products could not be used as templates for non-specific amplification in subsequent cycles under higher annealing temperature either. These might be the mechanisms that CD-PCR had much better performance than that of AS-PCR and competitive AS-PCR in this study. The molecular weights of wild-type and mutant-type products were the same, therefore, products of CD-PCR could not be distinguished by electrophoresis. It was convenient and time-saving when microplate hybridization assay was used to demonstrate the products in this study. Automatic detection was possible too when CD-PCR was adapted to real-time fluorescent PCR assay as used in AS-PCR or competitive AS-CR[26,27]. CD-PCR could also be used by combining with other high resolution techniques[28,29]. It could be used in gene typing for organ transplantation or gene polymorphism in addition to the detection of gene point mutations as AS-PCR[30,31].

Detectable viremia was found in sera of some patients with hepatitis B after HBeAg/antibody conversion[32-34]. This type of viremia resulted in G1896A mutation in 60.4 % out of such patients, especially in patients with a much lower level of HBV DNA. This result is conformable to the fact that the replication ability of G1896A variant has decreased[35], and suggests that G1896A or other more important mutations have to be detected in patients with a detectable level of viremia after HBeAg/ antibody conversion in clinical practice.

Abstract

AIM: The genomes of *Helicobacter pylori* (*H. pylori*) from different individuals are different. This project was to identify the strain specific DNA sequences between two clinical *H. pyl*ori isolates by suppression subtractive hybridization (SSH).

METHODS: Two clinical *H. pylori* isolates, one from gastric ulcer (GU, tester) and the other from non-ulcer dyspepsia (NUD, driver), were cultured and the genomic DNA was prepared and submitted to *Alu* I digestion. Then two different adaptors were ligated respectively to the 5'-end of two aliquots of the tester DNA fragments and SSH was made between the tester and driver DNA. The un-hybridized tester DNA sequences were amplified by two sequential PCR and cloned into pGEM-T-Easy Vector. The tester strain specific inserts were screened and disease related DNA sequences were identified by dot blotting.

RESULTS: Among the 240 colonies randomly chosen, 50 contained the tester strain specific DNA sequences. Twenty three inserts were sequenced and the sizes ranged from 261 bp to 1 036 bp. Fifteen inserts belonged to the *H.pylori* plasmid pHPO100 that is about 3.5 kb and codes a replication protein A. Other inserts had patches of homologous to the genes of *H.pylori* in GenBank. Various patterns of dot blots were given and no GU strain unique DNA sequences were found when 4 inserts were used as probes to screen the genomic DNA from 27 clinical isolates, 8 from GU, 12 from duodenum ulcer (DU), 4 from GU-DU, 2 from NUD and 1 from gastric cancer (GC). But a 670 bp DNA fragment (GU198) that was a bit homologous to the 3'-end of the gene of thymidylate kinase was positive in 7 GU strains (7/8), 3 GU-DU strains (3/4) and 3 DU strains (3/12). A 384 bp fragment (GU79) of the replication gene A (repA) was positive only in 4 *H.pylori* isolates, 2 from GU and 2 from GU-DU.

CONCLUSION: Differences exist in the genes of different *H.pylori* isolates. SSH is very effective to screen *H.pylori* strain specific DNA sequences between two clinical isolates, and some of these sequences may have clinical significance.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a microaerophilic Gram-negative bacterium that colonizes the stomach in more than half of the world population. It is the causative agent of chronic gastritis and contributes to peptic ulcer[1, 2] and also plays an important role in the pathogenesis of gastric cancer[3-16]. When one is infected by this bacterium, the clinical outcome depends on the interaction of virulent effects of the bacterium, the host response, and the environment[18]. The genomes of *H.pylori* from different individuals are quite different and each one contains about 1 600 genes, among which almost 320 genes are dispensable and 100 genes are strain unique[17-19]. Genes that are present in one strain and absent or substantially different in the others can be of great biological interest[20].

H. pylori strains with the cag pathogenicity island (PAI) can induce more severe inflammation, proliferation and apoptosis in the gerbil mucosa than do the strains partial or complete lack of the cag PAI[21]. In contrast to the $CagA^-$ *H. pylori* infection, $CagA^+$ *H. pylori* infection is associated with a higher prevalence of p53 mutation in gastric adenocarcinoma[22]. In addition to the *cag* island, other polymorphic loci that appear clinically relevant have to be identified.

We screened the strain specific DNA sequences between two clinical isolates and tried further to identify the disease related sequences. Different methods, such as microarray[19,21], and subtractive hybridization[18, 23,24] could be used for bacterial strain specific DNA screening. Suppression subtractive hybridization (SSH), in which the genomic DNA sample containing the sequences of interest is called "tester", and the reference sample is called "driver", is a powerful approach for assessing the DNA sequence differences among the closely related bacterial strains.

MATERIALS AND METHODS

H.pylori growth and genomic DNA extraction

H. pylori clinical isolates preserved in the brain heart infusion broth (BHI, Gibco) supplemented with 100 mL/L horse serum (Gibco) and 200 mL/L glycerol (BDH) were inoculated on the *H.pylori* selective chocolate blood agar containing 40 g/L blood agar base No.2 (Oxoid) and 50 mL/L horse blood (Gibco). Antibiotics were also used at the following concentrations: vancomycin (Sigma) 3 mg/L, trimethoprim (Sigma) 5 mg/L, nalidixic acid (Sigma) 10 mg/L and amphotericin B (Sigma) 2 mg/L. The plates were incubated in microaerobic atmosphere (50 mL/L CO_2) in a CO_2 incubator (Forma Scientific) at 37 ℃ for up to 5 days. *H.pylori* genomic DNA was extracted following Bow's method[25].

Driver and tester DNA preparations

The subtractive DNA library was made by using the PCR-select bacterial genome subtraction kit (Clontech) with Akopyants NS's method (*Proc Natl Acad Sci U S A.* 1998;95: 13108) as reference, but with some change at certain procedures. Genomic DNA of an *H.pylori* strain from gastric ulcer (GU) was used as the tester, and DNA of a strain from non-ulcer dyspepsia (NUD) was used as the driver. The

sequences of the adaptors and primers were listed as followings: adaptor 1, 5'-CTAATACGACTCACTATAGGGCTCGAGCGGCCGCCCGGGCAGGT-3',5'-ACCTGCCCGG-3',adaptor 2R, 5'-CTAATACGACTCACTATAGGGCAGCGTGGTCGCGGCCGAGGT-3',5'-ACCTCGGCCG-3',P1,5'-CTAATACGACTCACTATAGGGC-3', NP1, 5'-TCGAGCGGCCGCCCGGGCAGGT-3', NP2, 5'-AGCGTGGTCGCGGCCGAGGT-3'. In brief, 4 μg of the tester or driver genomic DNA was digested with 40 units of *Alu*I (New England Biolabs) in 400 μL reaction volume at 37 ℃ for 16 hours. The DNA fragments were then extracted with phenol and precipitated with ethanol, and resuspended in sterile distilled water at a final concentration of 300 mg/L. Two aliquots of tester DNA (120 ng each) were ligated separately to the two adaptors (2 μmol/L final concentration) at 16 ℃ for 16 hours, each in a total volume of 10 μL, with 1 μL (New Engl and Biolabs, 400 units) of T4 DNA ligase in the buffer supplied by the manufacturer. After ligation, 1 μL of 0.2 mol/L EDTA was added, and the sample was heated at 70 ℃ for 5 minutes to inactivate the ligase and then stored at -20 ℃.

Suppression subtractive hybridization

Two microliters of the driver DNA fragments (600 ng) were added to 1 μL (12 ng) of each adaptor-ligated tester DNA (50:1 ratio). One microliter of 4×hybridization buffer (2 mol/L NaCl, 200 mmol/L Hepes, pH 8.0, 0.8 mmol/L EDTA) was added to each tube, and the solution was overlaid with a drop of mineral oil. The DNA fragments were then denatured at 98 ℃ for 2 minutes, and allowed to anneal at 65 ℃ for 1.5 hours. After the first hybridization, the two samples (one with adaptor 1, the other with adaptor 2R) were combined and 300 ng more heat-denatured driver DNA dissolved in 2 μL of 1× hybridization buffer was added. The 10 μL mixture was allowed to hybridize at 65 ℃ for an additional 14 hours. After being diluted to 200 μL with dilution buffer (50 mmol/L, NaCl, 20 mmol/L Hepes, pH8.3, 0.2 mmol/L EDTA), the sample was heated at 65 ℃ for 10 minutes, and stored at -20 ℃.

The first and second PCRs

The first PCR mixture (25 μL) containing 1 μL of the above diluted DNA, 1 μL of 10 μmol/L PCR primer P1, 2 μL of 2.5 mmol/L dNTPs, 2.5 μL of 10×PCR reaction buffer, and 5 μL of the Advantage 2 Polymerase Mix (Clontech) was incubated in a thermal cycler (Perkin-Elmer 2400) at 72 ℃ for 2 minutes and subjected to 25 cycles at 94 ℃ for 30 s, at 66 ℃ for 30 s, and at 72 ℃ for 1.5 minutes. Seven microliters of the PCR products were analyzed by 15 g/L agarose gel electrophoresis. The products were then diluted 40-fold in 10 mmol/L Tris· HCl (pH 7.5). The second PCR mixture (25 μL) contained 1 μL of the diluted first PCR products, 1 μL of the nest PCR primers (NP1 and NP2, 10 μmol/L each), 2 μL of 2.5 mmol/L dNTPs, 2.5 μL of 10×PCR reaction buffer, and 5 μL of the Advantage 2 Polymerase Mix. The cycling program was 12 cycles at 94 ℃ for 30 s, at 68 ℃ for 30 s, and at 72 ℃ for 1.5 minutes, followed by further extension at 72 ℃ for 5 minutes. The PCR products were analyzed by 15 g/L agarose gel electrophoresis, purified by using the Quaquick Spin PCR Purification Kit (Qiagen) and cloned into the pGEM- T Easy Vector (Promega) following the protocols. The recombinant plasmids were transformed into *E. coli Top*[10], which was then cultured overnight on the selective agar plates containing 20 μL of 50 g/L ampicillin, 35 μL of 100 mmol/L IPTG and 40 μL of 20 g/L X-gal. White colonies were randomly picked and suspended in 100 μL of Luria-Bertani medium containing ampicillin in an eppendorf tube and cultured at 37 ℃ for 2 hours. One microliter of the cell suspension, after being frozen and thawed three times, was used as templates and the inserts were amplified under condition as in the second PCR except for 25 cycles. The sizes of the inserts were identified by agarose gel electrophoresis.

Strain specific insert screening and disease related DNA sequence identification

One microliter of each PCR product (10 ng) was dotted on the Hybond N+ membrane (Amersham) in duplicating forms and DNA fixation was carried out by irradiation under a UV transilluminator (Vilber Lourmat) for 5 minutes. The *Alu*I-digested DNA fragments of the tester and driver *H.pylori* were used as probes and dot blotting was preformed using the ECL direct nucleic acid labeling and detection system (Amersham Phamacia Biotech). The pre-hybridization and hybridization were carried out in the hybridization oven (Amersham) at 42 ℃ for 1 hour and 12 hours respectively. After stringently washing the Hybond N+ membrane (twice for 20 minutes in 6 mol/L Urea, 4 g/L SDS and 0.1×SSC, and twice for 5 minutes in 2× SSC), the chemiluminenscence signals were detected by exposure of the Hyperfilm to the membrane for 5 to 30 minutes. The inserts that gave positive results to the tester probes and negative to the driver probes were sequenced using a Big Dye Terminator DNA sequencing kit (Perkin-Elmer) and ABI automated sequencer. The sequences were then submitted to gene and protein homologous analysis. In the same way, by dotting 100 ng of each genomic DNA from different *H.pylori* isolates on the membrane and using the inserts interested as probes, the disease related DNA sequences were identified. In the above cases, 1 ng of each probe DNA was dotted on the membrane to be used as positive control.

RESULTS

Tester strain specific DNA sequencing and homologous analysis

After SSH between the tester and driver DNA fragments, about 900 colonies grew on the ampicillin plates and two thirds of them were white in color. Two hundred and forty white colonies

Table 1 Homologous analysis of some strain specific DNA sequences

Inserts	GenBank accesion No.	Homolog/genes or proteins	DNA matches
GU79	AF056496	*H.pylori* plasmid pHPO100/ RepA, $2e^{-53}$	1882-2265
GU150	AE000629	Carbamoyl-phosphate synthetase, $3e^{-29}$	1029-1229
GU185	AE000595	Putative outer membrane p1, $7e^{-24}$	2993-3177
GU198	AE001560	Thymidylate kinase, $2e^{-10}$	640-717
GU210	AE000590	Hypothetical protein , $3e^{-33}$	789-396
GU212	AE000531	Type II restriction enzyme R protein, $4e^{-26}$	1-597
GU223	AE000647	Hypothetical protein, $4e^{-16}$	7724-8193
GU234	AE000650	Site specific DNA-methyltransferase, $3e^{-54}$	9070-8752
GU235	AE000547	Toxin-like outer membrane protein, $2e^{-64}$	13943-14494

were randomly chosen and the inserts were amplified using the primers as in the nest PCR. By dotting and fixing the equal amount of each PCR product in replica form on the membrane, dot blotting was carried out using the *Alu*I digested DNA fragments as probes (Figure 1). Fifty tester strain specific DNA sequences were screened and 23 of them were sequenced. The sizes of the inserts ranged from 261 to 1 036 bp. Blast analysis showed that, of the 23 inserts sequenced, 15 belonged to parts of the *H.pylori* plasmid pHPO100 (Table1 only shows GU79) and 2 of them contained the same fragment. The size of this plasmid is 3 520 bp, which codes a replication protein A (RepA, 1 842-2 765) and an unknown protein (2 762-3 520). The other 8 inserts were homologous to genes of *H.pylori* in GenBank to different extent (Table1).

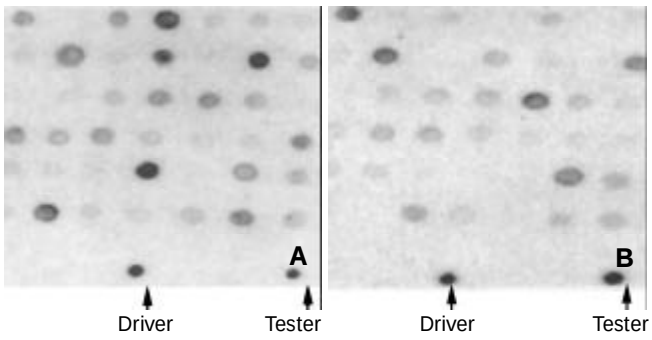

Figure 1 Dot blotting to screen the tester strain specific inserts by using the *Alu* I digested tester DNA (A) and driver DNA (B) as probes. The arrowheads indicate the spots of positive controls.

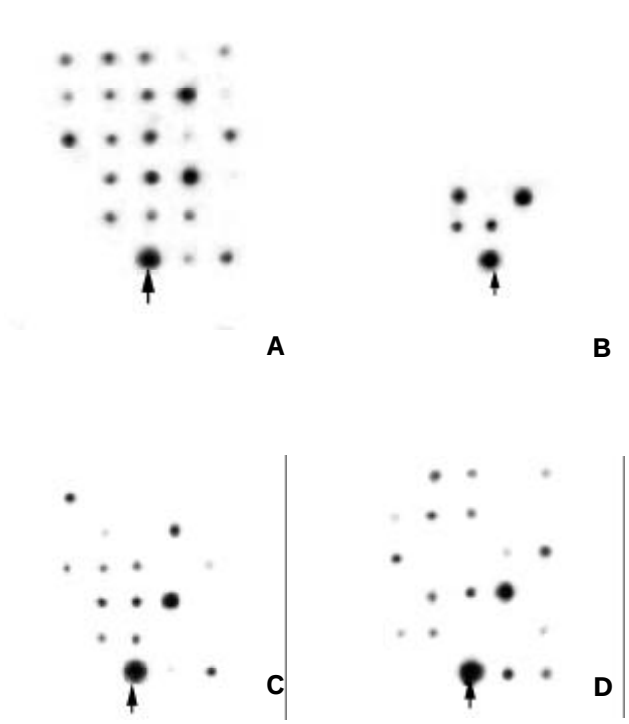

Figure 2 Dot blotting for identification the disease related DNA sequences in 27 different clinical isolates by using GU210 (A), GU79 (B), GU198 (C) and GU235 (D) as probes. The arrowheads indicate the spots of positive controls.

Disease related DNA sequence screening

We next chose 4 tester strain specific DNA sequences as probes to screen the genomic DNA of *H.pylori* with different clinical background, 8 from GU, 12 from duodenum ulcer (DU), 4 from GU-DU, 2 from NUD and 1 from gastric cancer (GC), to know if some of them were specific for the GU isolates. We found that the 4 different inserts gave 4 different dot blotting profiles (Figure 2) and there were no GU strain unique sequences. But a DNA fragment GU198 (670 bp) that was a bit (78 bp) homologous to the 3' -end of the gene of hymidylate kinase was positive in 7 of the 8 GU strains, 3 of the 4 GU-DU strains, and 3 of the 12 DU strains. It was also positive in one of the 2 NUD strains and the GC strain. The replication gene A fragment GU79 (384 bp) was positive in 4 *H.pylori* isolates, 2 from GU and 2 from GU-DU.

DISCUSSION

A remarkable feature of *H.pylori* is the high diversity of its genomic DNA[26-29]. Clinical isolates of *H.pylor*i from different individuals show enormous variations in their genomes or genes[30-33]. The genetic diversity is represented in many forms, including point mutations and inserted sequences[34]. Such variation has given rise to the notion that *H. pylori* has a very plastic genome, and that such plasticity confers a selective advantage on a bacterium that must co-evolve with its host over the course of decades[17]. Based on this, it is conceivable that there are different DNA sequences between two genomes of *H.pylori* with different clinical background.

SSH is a powerful technique that has been applied to research in many different fields. In studies of eukaryotic systems, application of subtraction techniques typically focuses on differential gene expression between two cDNA populations rather than differences between genomes (Diatchenko L. *Proc Natl Acad Sci U S A* 1996; 93: 6025). This is because eukaryotic genomes are too complex for existing subtraction technologies. In contrast, bacterial genomes are considerably smaller, and are even less complex than many eukaryotic cDNA populations. Thus, subtraction methods can be used to identify sequences that are present in one bacterial genome, but absent in another. It requires only about several micrograms of genomic DNA, takes only several days, and does not involve the physical separation of single strain and double strain molecules. Furthermore, the suppression PCR prevents undesirable amplification while enrichment of target molecules proceeds. Even so, the conditions of the SSH were carefully optimized in this experiment. By comparing the genomic DNA digestion efficiency of *Hae* III, *Rsa* I and *Alu* I, *Alu* I was finally selected. The time of the adaptor ligation should be within 16 hours to avoid ligation between the DNA fragments. The ratio of tester and driver DNA was 1:50 in the first hybridization. In this way, we established a GU strain specific DNA sequence library.

When we used the tester and driver DNA fragments as probes to hybridize separately with different PCR products of the subtracted inserts, the tester specific DNA sequences were screened. Of the 23 sequenced DNA fragments, 15 were homologous to the *H.pylori* plasmid pHPO100. The size of this plasmid is about 3.5 kb and codes a replication protein A, which appears to be the predominant plasmid replication protein of *H. pylori* and has the highly conserved (76-96 %) amino acid sequence and may play an important role in the DNA sequence exchange between plasmid and the chromosome[35]. Thus the protein may increase the gene diversity and have the pathogenic significance. Other inserts had patches of homologous to the genes of different *H.pylori* proteins in GenBank. The results indicate that SSH can be used to screen the strain specific DNA sequences between clinical isolates even though the dominant subtracted fragments come from the plasmid of the tester strain.

When we tried to find out if some of the tester strain specific DNA sequences were unique to GU strains, no such DNA sequences were identified. Whereas a DNA fragment GU198

that is partly homologous to the gene of thymidylate kinase was positive in 7 of the 8 GU strains, 3 of the 4 GU-DU strains, and only 3 of the 12 DU strains. This is also of clinical significance. Study on identification of this DNA fragment is still going on.

Several aspects regarding the identification of disease related DNA sequences need to be discussed. First, the tester strain specific DNA sequences mean that, comparing with the driver strain, these sequences are unique to the tester strain, other strains from GU patients may share or may not share these sequences. Second, since the strain specific genes account for about 6 % of the whole genes of a given *H.pylori* strain[19], more colonies should be screened and more DNA fragments be used to identify the disease specific DNA sequences. Third, dot blotting can be used as a primary screening method, and, if possible, Southern blotting be employed for further identification. Fourth, it is better to choose the plasmid free *H. pylori* for the strain specific DNA sequence screening. Since the copies of a plasmid in the bacterium are often more than that of a gene in its genome, amplification of the subtracted gene sequences coming from the genome would be suppressed in the PCR and, as a result, the dominant strain specific DNA sequences would belong to the plasmid. Although about 50 % of *H. pylori* strains carry cryptic plasmids ranging in size from 2 to about 100 kb[35,36], the role of these plasmids is not well understood. In this investigation, the repA gene was positive in 4 *H.pylori* strains, 2 from GU (2/8), and 2 from GU-DU (2/4). This may be due to the homologous of the genomic DNA to the repA or the insertion of the repA fragment into the genome (De Ungria MC. *Plasmid* 1999; 41: 97) or the plasmid DNA being not eliminated during genomic DNA preparation. Study on the relationship between repA gene and the disease state of the patients is also necessary.

Anyway, we have successfully screened some tester strain specific DNA sequences by SSH, and this study is one of the few attempts trying to identify the disease specific genes using *H.pylori* clinical isolates[23]. Though we failed to get the disease specific DNA sequences, we believe that, at least, some tester strain specific sequences may have significantly high positive rates in strains with similar background to the tester strain. This may aid in the effective diagnosis and treatment of *H. pylori* infection and have the potential value for pathogenic investigation of this bacterium.

ACKNOWLEDGEMENT

Mr. Mun-Fai Loke, from Department of Microbiology, National University of Singapore, prepared some of the *H. pylori* clinical isolates.

Abstract

AIM: To explore the seropositive rate of antibodies against *H. pylori* (anti-HP) in Taipei City and to compare the relationship of ABO blood groups and *H. pylori* infection.

METHODS: In 1993, high school students in Shih-Lin District were randomly selected for blood samplings by their registration number at school. In addition, similar procedures were performed on the well-children clinics of Taipei Veterans General Hospital. Besides, randomly selected sera from the adults who took the physical examination were recruited for evaluation. Informed consents were obtained from all the subjects before blood samplings and parents were simultaneously informed for those who were younger than 18-year-old. Blood tests for anti-HP and ABO blood groupings were performed by enzyme-linked immunosorbent assay. Chi square tests were used for the comparisons between seroprevalence of *H. pylori* and ABO blood groups.

RESULTS: Totally, 685 subjects were recruited (260 children aged 1-14 years, 425 high school students aged 15-18 years) were evaluated, and another 88 adult healthy volunteers were studied as well for comparison. The age-specific seropositive rate of anti-HP was 1.3 % at age 1-5 years, 7.7 % at age 6-10 years, and 11.5 % at age 11-14 years. The seroprevalence of *H. pylori* infection was abruptly increased in young adolescence: 18.6 % at age 15 years, 28.1 % at age 16 years, 32.4 % at age 17 years and 41.0 % at age 18 years, respectively. In the 425 high school students, ABO blood groupings were performed, which disclosed 48.5 % (206/425) of blood group O, 24 % (102/425) of blood group A, 21.8 % (93/425) of blood group B and 5.6 % (24/425) of blood group AB. In comparison of the subjects with blood group O and the other blood groups, no statistical significance could be identified in the seroprevalence of *H. pylori* (P=0.99).

CONCLUSION: The seroprevalence of *H. pylori* infection in Taipei City in adults is similar to the developed countries, and the abrupt increase of *H. pylori* during high school may be resulted from marked increase of interpersonal social activities. Although blood group O was reported to be related to *H. pylori* infection in previous literature, we found no association between *H. pylori* infection and ABO blood groups.

INTRODUCTION

Helicobacter pylori (*H. pylori*) infection is the most common chronic bacterial infection in the world. Previous seroepidemiologic studies indicated that about 50 % of adults in the developed countries and nearly 90 % of adults in the developing countries were positive of serum antibodies against *H. pylori*[1]. Chronic *H. pylori* infection may be related to several conditions, including chronic gastritis[2,3], peptic ulcer disease[4,5], primary gastric lymphoma (mostly mucosa-associated lymphoid tissue, MALToma)[6,7], and gastric adenocarcinoma[8,9].

The seroprevalence of *H. pylori* infection of adults in Taiwan varied from 54.4 % to 59 % in previous reports, which was similar to developed countries[10-12]. However, the seroprevalence of *H. pylori* infection was low in the preschool children in Taiwan. The seropositive rate of antibodies against *H. pylori* was 8.1 % in 2 551 healthy preschool children aged 3-6 years[13], and it was significantly increased to 21.1 % in young adolescence[14]. Therefore, marked increase of interpersonal social activities during the school age was proposed to be the most likely source of *H. pylori* infection.

People with blood group O have been noted to be more susceptible to peptic ulcer disease for decades without appropriate explanations[15,16]. In 1993, Boren *et al*[17] reported that people with blood group O had more *H. pylori* receptors, and Lewis^b antigens mediated the attachment of *H. pylori* to the gastric mucosa. Furthermore, higher density of colonization of *H. pylori* was noted in the gastric mucosa of people with blood group O[18]. However, absence of correlation between *H. pylori* infection and ABO blood groups was reported in some following studies[19,20].

In Taiwan, blood group O was reported to correlate with the prevalence of *H. pylori* infection in patients with gastroduodenal diseases[21], but it remained unknown for those asymptomatic individuals who were infected by *H. pylori*. Therefore, we conducted a study to evaluate the relationship between *H. pylori* and ABO blood groups in those healthy volunteers in Taipei City to clarify the possible association.

MATERIALS AND METHODS

We conducted a cross-sectional survey among senior high schools in the Shih-Lin District, Taipei City in 1993. All the recruited subjects were randomly selected in each age group (from 15 to 18) according to the registration number in schools. Blood samplings were performed after the informed consents were signed by themselves or their parents (if the subjects were younger than 18-year-old). In addition, children at age 1 to 14 years from the well-children clinics of Taipei Veterans General Hospital were recruited if their parents agreed with the study

and signed the informed consents. Moreover, we randomly collected the sera of adults who underwent physical examinations from the Department of Physical Examination to evaluate the seroprevalence of *H. pylori*. This study was evaluated and approved by the Ethical Committee of Taipei Veterans General Hospital.

The blood samples were centrifuged and the sera were stored in aliquot at -80 ℃ until analysis. The serum antibodies against *H. pylori* were tested by the commercial enzyme-linked immunosorbent assay (ELISA) kit (HEL-P test, AMRAD, Sydney, Australia). In addition, ABO blood groupings were also done by the ELISA test (Gamma Biologicals, Houston, TX, USA). ABO blood groupings were not performed in children from the well-children clinics because we reserved the sera from the blood samplings in the beginning, which were not possible for ABO blood groupings by the commercial kit.

Data of the recruited individuals were expressed in categories. The comparisons of seroprevalence of *H. pylori* between each ABO blood group were evaluated by chi-square test or Fisher' s exact test if appropriate. A *P* value of less than 0.05 would be considered statistically significant. All the available data were analyzed by a computer program (SPSS, Chicago, IL, USA).

RESULTS

Totally, 685 subjects were recruited, including 260 children aged 1-14 years from the Well-children Clinic, and 425 young adolescents aged 15-18 years from high school students in Shih-Lin District, Taipei City. In addition, sera of 88 randomly selected subjects from the Department of Physical Examination were evaluated for the referential seroprevalence of *H. pylori* in adults (Table 1).

Table 1 Age and sex distribution of seroprevalence of antibodies against *Helicobacter pylori* (anti-HP), and comparisons between sex and age groups

Age	Male		Female		*P*
	Anti-HP (+)/*n*	(%)	Anti-HP (+)/*n*	(%)	
1-5	0/26	0	1/42	2.4	0.32
6-10	4/39	10.3	2/39	5.1	0.40
11-14	9/53	17.0	3/51	5.9	0.08
Subtotal	13/118	11.0	6/132	4.5	0.06
15	7/34	20.6	11/63	17.5	0.72
16	9/38	23.7	27/90	30	0.46
17	21/65	32.3	24/74	32.4	0.99
18	14/41	34.1	11/20	55.0	0.14
Subtotal	51/179	28.5	73/246	29.7	0.79
Adults	27/49	55.1	19/39	48.7	0.56
Total	91/346	26.3	98/417	23.5	0.37

The age-specific seropositive rate of antibodies against *H. pylori* was 1.3 % at age 1-5 years, 7.7 % at age 6-10 years, and 11.5 % at age 11-14 years. The seroprevalence of *H. pylori* infection abruptly increased in young adolescence: 18.6 % at age 15 years, 28.1 % at age 16 years, 32.4 % at age 17 years and 41.0 % at age 18 years, respectively. In randomly selected adults, the seropositive rate of anti-HP reached 52.3% (Figure 1).

In the 425 randomly selected high school students, ABO blood groupings were performed, which disclosed 48.5 % (206/425) blood group O, 24 % (102/425) blood group A, 21.8 % (93/425) blood group B and 5.6 % (24/425) blood group AB. Further analysis on the ABO blood groupings and seroprevalence of *H. pylori* demonstrated that seropositive rate of anti-HP was 27.7 % (57/206) in blood group O, 31.4 % (32/102) in blood group A, 30.1 % (28/93) in blood group B, and 29.2 % (7/24) in blood group AB (Table 2). In comparison of the subjects with blood group O with the other blood groups, no statistical difference could be identified in the seroprevalence of *H. pylori* (*P*=0.98). Neither was the difference significant among the groups as for being vulnerable to *H. pylori* infection.

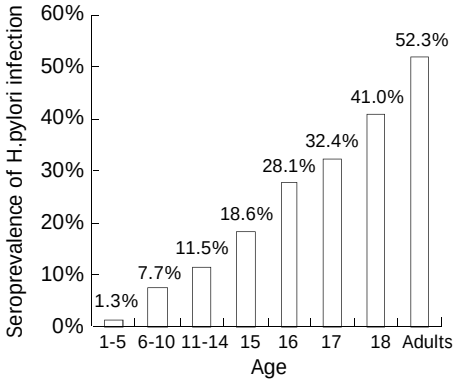

Figure 1 Age-specific seroprevalence of *H. pylori* infection in 773 healthy subjects in Taipei.

Table 2 Relationship of ABO blood groups and seropositivity of antibodies against *Helicobacter pylori* (anti-HP) infection

Blood group	Serum anti-HP (+)	Serum anti-HP (-)	*P*
O	57 (27.7%)	149 (72.3%)	-
A	32 (31.4%)	70 (68.6%)	0.99
B	28 (30.1%)	65 (69.9%)	0.99
AB	7 (29.2%)	17 (60.8%)	0.99
Total	124 (100%)	301 (100%)	

DISCUSSION

H. pylori infection is the most prevalent chronic bacterial infection in the world. Despite of the worldwide infection, the transmission pattern remains uncertain. *H. pylori* infection is rare before first two decades of life in developed countries, ranging from 6 % to 16 %[22-24]. However, children in Gambia and Nigeria are almost all infected by *H. pylori* at age of 5 years[25,26]. According to the previous reports, the seroprevalence of *H. pylori* infection in Taiwanese preschool children (3-6 years old) was 8.1 %, with the age-dependent progression (4.5 % in 3-year-old children, 4.4 % in 4-year-old children, 9.4 % in 5-year-old children, and 11.7 % in 6-year-old children)[13]. Furthermore, the seropositivity of antibodies against *H. pylori* was reported to be 21.1 % in adolescents[14], and 54.4 % in adults over 30-year-old in Taiwan[10]. Moreover, age-specific prevalence of *H. pylori* infection in patients with gastroduodenal diseases was 11.1 % in those aged 1 to 20, 73.1 % at age 21-30, and 79.8 % at age 51-60 in Central Taiwan[27]. In this seroepidemiological study, we also found a similar pattern of age-dependent progression. However, the seroprevalence of *H. pylori* in this study (1.3 % at age 1-5 years, 7.7 % at age 6-10 years, and 11.5 % at age 11-14 years) was significantly lower than that in the Taiwan islandwide survey. The better socioeconomic status in Taipei City may account for the differences of seroprevalence of *H. pylori* infection. However, the seroprevalence of *H. pylori* infection among adults in Taipei City was about the average of the Taiwan islandwide survey.

The transmission pattern of *H. pylori* currently remains uncertain, but the role of fecal-oral route seems to be minor[28,29]. The genotypic study did not support oral-oral transmission

pattern of *H. pylori* infection, either[30]. Intrafamilial and person-to-person transmission has been shown being more important in *H. pylori* infection[31,32]. Risk factors analysis of *H. pylori* infection has been extensively performed including gender, race, family income, type of housing, location of housing, water supply, health status, and keeping pets, but only the socioeconomic status was better confirmed[33-36]. Broutet *et al* [37] proposed that male gender deserve more attention in epidemiological studies of *H. pylori* infection. In this study, the male predominance of *H. pylori* infection was observed. However, similar findings were not supported in previous epidemiological reports despite of different areas, ethnicity, and age[38-41]. The sex difference of *H. pylori* infection at age 11-14 years was unclear, which deserves further investigations.

The seropositive rate of anti-HP increased abruptly in subjects at age 15 years to 18 years (18.6 % to 41.0 %) in this study. The estimated annual incidence was 7.5 % in this cross-sectional survey, which might be resulted from the extensive social activities at this stage. On the other hand, smoking is an important factor in *H. pylori* infection, particularly in young adults[42,43]. Most smokers start smoking at their young adolescence. Therefore, smoking may be another explanation of such an abrupt increase of *H. pylori* infection among people aged 15 to 18.

People with blood group O were found more susceptible to peptic ulcer disease for decades without known cause until the relationship between Lewis^b antigens and the attachment of *H. pylori* to gastric mucosa was observed[15-18]. However, the correlation between *H. pylori* infection and ABO blood types was not supported in some reports[19,20]. Nevertheless, Lin *et al*[21] demonstrated the close relationship between *H. pylori* infection and blood group O patients with gastroduodenal diseases in Central Taiwan. In our study, healthy individuals rather than symptomatic patients with blood group O were not particularly vulnerable to *H. pylori* infection.

In conclusion, the abrupt increase of *H. pylori* infection in high school students was noted with the estimated yearly incidence to be 7.5 %. Subjects with blood group O do not increase clinical susceptibility to *H. pylori* infection than those with other blood groups.

Abstract

AIM: To construct a recombinant vector which can express outer membrane protein (OMP) with M_r18 000 and heat shock protein A (HspA) from *Helicobacter pylori* (*H. pylori*) in *E. coli* BL21, and to exploit the possibility for obtaining the vaccine conferring protection from *H. pylori* infection.

METHODS: The target gene of HspA was amplified from *H. pylori* chromosome by PCR, and then inserted into the prokaryotic expression vector pET32a (+) by restrictive endonuclease enzyme *kpn* I, *Bam*H I simultaneously. The recombinant vector was used to sequence, and then together with pET32a (+)/Omp_{18}, digested by restrictive endonuclease enzyme *Hind* III and *Bam*H I simultaneously. pET32a(+)/HspA and Omp_{18} were recovered from 1 % agarose gel by gel kit, and ligated with T_4 ligase by *Bam*H I digested viscidity end. The recombinant plasmid of pET32a(+)/HspA/Omp_{18} was transformed and expressed in *E. coli* BL21 (DE3) under induction of IPTG. After purification, its antigenicity of the fusion protein was detected by Western blot.

RESULTS: Enzyme digestion analysis and sequencing showed that the target genes were inserted into the recombinant vector, composed of 891 base pairs, encoded objective polypeptides of 297 amino acid residues. Compared with GenBank reported by Tomb *et al,* there were 1.3 % and 1.4 % differences in obtained *H. pylori* nucleotide sequence and amino acid residues, respectively. SDS-PAGE analysis showed that relative molecule mass (M_r) of the expressed product was M_r 51 000, M_r of protein expressed by pET32a (+) was about M_r 20 000, and soluble expression product accounted for 18.96 % of total bacterial protein. After purification with Ni^{+2}-NTA agarose resins, the purification of recombinant fusion protein was about 95 %. Western blot showed that recombinant fusion protein could be recognized by the patients' serum infected with *H. pylori* and anti-Omp_{18} monoclone, suggesting that this protein had good antigenicity.

CONCLUSION: The gene coding for *H. pylori* M_r18 000 OMP and HspA was cloned and expressed successfully. The results obtained lay the foundation for development of *H. pylori* protein vaccine and a quick diagnostic kit.

INTRODUCTION

Helicobacter pylori (*H.pylori*) is a microaerophilic, spiral and gram-negative bacillus first isolated from human gastric antral epithelium in 1982. It has been recognized as a human-specific gastric pathogen that colonizes the stomaches of at least half the world's population[1], and there are approximately thousands of newly infected people annually. Most infected individuals are asymptomatic. However, in some individuals, their infections are associated with the development of peptic ulcer, gastric adenocarcinoma, mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma[2-20], moreover with extradigestive diseases[21-37]. This organism was recently categorized as a class I carcinogenetic factor by the World Health Organization, and direct evidence of carcinogenesis was recently demonstrated in an animal model[38,39]. Although there are many methods for eradication of *H. pylori* infection, such as bi-, tri- drug therapy, the definitive curative effects were acquired by using a serial of antibiotics, which has led to resistant *H. pylori*. Meantime medical side effects, patients' endurance and compliance were challenged. This has drawn increasing interests of scientists in developing *H. pylori* vaccine so as to reduce and prevent *H. pylori* infection, extinct diseases associated with *H. pylori* infection. Immunization against this bacterium represents a cost-effective strategy to reduce global *H. pylori*-gastric cancer and peptic ulcer rates[40]. To date, *H. pylori* vaccine candidate antigens identified include urease enzyme, VacA, and so on[41-50]. M_r18 000 and HspA are outer membrane proteins of *H. pylori*, and the vaccines prepared with M_r18 000 OMP and HspA respectively were used to inoculate Balb/c mice, 70-80 % of experimental mice were protected. In order to acquire a better immunocompetent effect, some investigators suggested that bi-valent antigen vaccine was possibly superior to single antigen. So in this study, the recombinant plasmid encoding *H. pylori* M_r18 000 OMP and HspA genes was constructed and expressed in BL21 to explore the possibility for obtaining a vaccine conferring protection from *H. pylori* infection.

MATERIALS AND METHODS

Material

A well-characterized strain of *H. pylori* was afforded by the Department of Microbiology, Chongqing University of Medical Sciences. Top10, BL21 *E.coli* strains and pET32a (+), pET32a(+)/Omp_{18} plasmid, anti-Omp_{18} antibody were provided by the Institute of Viral Hepatitis of Chongqing University of Medical Sciences. Restriction endonuclease enzymes (*Kpn* I, *Hind* III, *Bam*HI) and T_4DNA ligase were purchased from Promega, *Tag*DNA polymerase was produced by the Immunology Department of Beijing University of Medical Sciences. Isopropyl-β-D-thiogalactopyranoside (IPTG), dNTP and oligonucleotide primers were obtained from Sigma.

Cloning of H.pylori HspA gene

Oligonucleotide primers were designed to amplify *H. pylori* open reading frame (ORFs) of HspA based on GenBank. The primers had a *KpnI* site incorporated into the 5' end and a *Bam*HI site at the 3' end and their sequences were as follows (5'-3'): CCGGTACCATGAAGTTTCAACCATTAGG (forward) and CCGGATCCGTGTTTTTTGTGATCATGAC (reverse). The reverse 5' end stop codon TAA was banned. Genomic DNA prepared from Chinese *H. pylori* strains was used as the template in PCR. The PCR consisted of 30 cycles of denaturation at 94 ℃ for 60 s, annealing at 52 ℃ for 50 s, and an extension step at 72 ℃ for 50 s. The products were visualized on 10 g· L^{-1} agarose gel and purified using a PCR purification kit. After digestion with the restriction endonuclease enzymes *Bam*HI and *KpnI* simultaneously, the purified products were cloned into the compatible sites of the expression vector pET32a (+) by using T_4 DNA ligase at a molar ratio of 4:1 at 4 ℃ overnight.

Construction of recombinant plamids

After the above connected products were transfected into Top10, pET32a(+)/HspA was selected and identified by the methods reported by Jiang *et al*[51]. After pET32a(+)/HspA and pET32a(+)/Omp_{18} were digested by restrictive endonuclease enzymes *Bam*HI and *Hind* III simultaneously, the segments of Omp_{18} and pET32a(+)/HspA were recycled by gel extract kit, and ligated by using T_4 DNA ligase at a molar ratio of 4:1 at 4 ℃ overnight. pET32a(+)/HspA /Omp_{18} was selected, appraised by PCR or enzyme digestion (Figure 1).

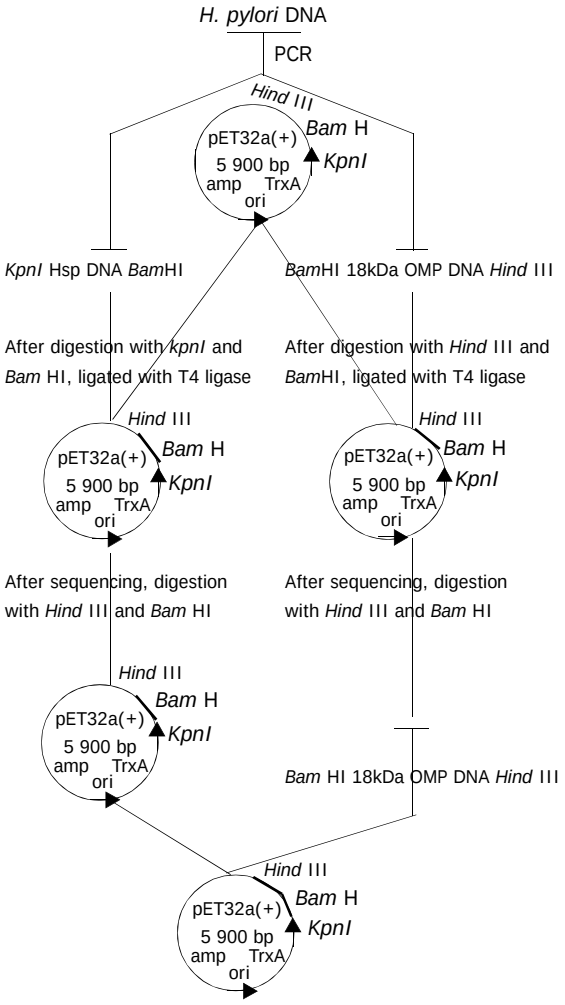

Figure 1 Schematic construction of plasmid pET32a(+)/HspA-Omp_{18}.

Extraction and expression of recombinant plasmid

The single bacterial colony (Top10/pET32a (+)/HspA/Omp_{18}) was picked, and cultivated in 2 ml LB broth containing 100 mg· L^{-1} of ampicillin, at 300 r· min^{-1} at 37 ℃ overnight, then recombinant plasmids were extracted according to the manufacturer's instructions, in the meantime, identified by PCR and restriction endonuclease enzyme digestion. The recombinant plasmid was transfected into competent BL21 (DE3) *E.coli* strains by using standard procedures reported by Jiang *et al*. BL21 *E.coli* strains containing recombinant plasmid were grown until mid-log phase (optical density at 600 nm=0.5 to 1.0), and then induced to express recombinant fusion protein by adding 1 mmol· L^{-1} IPTG for 4 h. Following induction, bacteria were harvested by centrifugation at 12 000 r· min^{-1} for 2 min, resuspended in protein-buffer and seethed for 5 min. Total proteins were electrophoresed on 150 g· L^{-1} SDS-PAGE gel and stained with Coomassie. The rate of recombinant fusion protein to total protein was deduced by Image Master Totallab v1.11 software.

Immunoblotting analysis of the recombinant fusion protein

Due to C end of recombinant fusion antigen with six histidines, the recombinant fusion antigen was purified by using Ni^{2+}-NTA agarose resin. Briefly, 500 ml of bacteria cultivated suspension was prepared, centrifugated, resuspended with the buffer liquid (50 mmol· L^{-1} phosphate, 300 mmol· L^{-1} NaCl, pH 7.0), and sonicated by ultrasonic wave with the energy of 600W×35 % for 40 min, and ultracentrifugated for 15 min at 10 000 r· min^{-1} at 4 ℃. The sonicated recombinant fusion antigen was purified by using Ni^{2+}-NTA agarose resin with abluent (50 mmol· L^{-1} phosphate, 300 mmol· L^{-1} NaCl, 20 mmol· L^{-1} imidazole, pH 7.80) and lavation (50 mmol· L^{-1} phosphate, 300 mmol· L^{-1} NaCl, 250 mmol· L^{-1} imidazole, pH 7.80) respectively, and quantified. The antigenicity of expressed recombinant fusion protein was determined by immunoblotting. Following electrophoretic transfer of SDS-PAGE-separated (150 g· L^{-1} acrylamide) recombinant fusion protein to 0.45 μm pore size PVDF membrane, and after a 30-min wash in tris-saline blotting buffer, antigen-impregated PVDF strips were incubated with the sera of patients infected with *H. pylori* and anti-Omp_{18} antibody for 2 h at RT. After a washing, the protein was detected by incubating the strips in alkaline phosphatase-conjugated goat anti-man IgG antibody for 1 h at RT.

RESULTS

PCR amplification of H.pylori HspA gene

According to literature[55], *H. pylori* HspA ORF was amplified by PCR with Chinese *H. pylori* strain's chromosomal DNA as the templates. The cloning products were electrophoresed and visualized by10 g· L^{-1} agarose gel (Figure 2). It revealed that the size of HspA DNA fragment amplified by PCR was between 250-500 base pairs, and contained a gene of approximately 357 nucleotides, and was compatible with the previous reports[55].

Identification of recombinant vector by PCR or restriction enzyme digestion

pET32a(+)/HspA identification by PCR After the single colony of Top10 *E. coli* /recombinant pET32a(+)/HspA was picked and incubated in 2 ml LB broth containing 100 mg· L^{-1} of ampicillin at 300 r· min^{-1} at 37 ℃ overnight, then 50 μl was incubated and seethed for 10 min, with the genomes of supernate and recombinant vector as templates respectively, products were amplified by PCR under the condition as mentioned above. The PCR products were visualized by 10

g· L^{-1} agarose gel electrophoresis (Figure 3). It indicated that recombinant plasmid contained the objective gene. At the same time, it was successful in transfecting recombinant plasmid into Top10 *E. coli*.

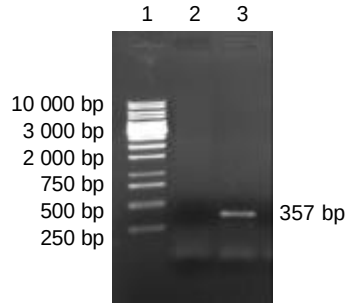

Figure 2 10 g·L^{-1} agarose gel electrophoresis of HspA DNA fragment amplified by PCR from Helicobacter pylori. Lane 1. PCR marker, Lane 2. Negative control, Lane 3. PCR products.

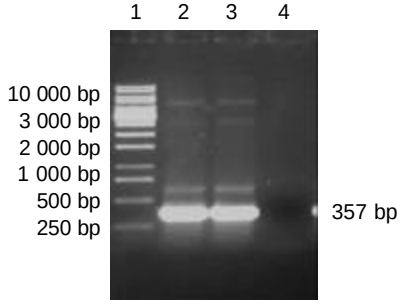

Figure 3 The identification of recombinant vector by PCR. Lane 1. DNA Marker, Lane 2, 3. PCR products with the template of Top10/recombinant vector, and recombinant vector respectively, Lane 4. Negative control.

pET32a(+)/HspA-Omp$_{18}$ identification by restriction enzyme digestion Recombinant plasmids pET32a(+)/HspA-Omp$_{18}$ were digested by single, bi-, tri-enzyme digestion with *Hind*III, *KpnI* and *Bam*HI, respectively, then digestive products were visualized on 10 g· L^{-1} agarose gel (Figure 4). It demonstrated that recombinant plasmids were digested to 357 bp, 528 bp DNA fragment, and contained the objective gene.

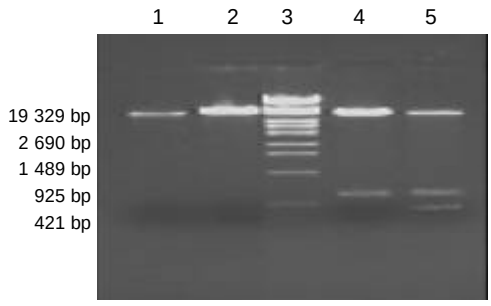

Figure 4 Identification of recombinant plasmid by restriction enzyme digestion. Lane 1. pET32a(+)/HspA digested by *Bam*HI, Lane 2. pET32a(+)/HspA-Omp$_{18}$ digested by *Bam*HI, Lane 3. DNA marker, Lane 4. pET32a(+)/HspA-Omp$_{18}$ digested by *Bam*HI and *Hind* III simultaneously, Lane 5. pET32a(+)/HspA-Omp$_{18}$ digested by kpnI, *Bam*HI and *Hind* III simultaneously.

Sequence analysis of cloned HspA, M_r18 000 OMP nucleotide

The nucleotide sequence of the cloned genes M_r18 000 OMP and HspA inserted into pET32a (+) was analyzed by automated sequencing across the cloning junction, using the universal primer T_7. The results showed that the cloned genes M_r18 000 OMP and HspA were connected by *Bam*H I enzyme digestion adhesion end. The cloned HspA genes contained 357 nucleotides with a promoter codon coding a putative protein of 119 amino acid residues with a calculated molecular mass of M_r13 000, and provided a putative signal peptide. Compared with previous reports, 5 base pairs of the cloned gene and 2 amino acid residues (G→D, A→S) encoded were changed. The cloned gene M_r18 000 OMP and its encoding protein sequences were published in GenBank (AF374387).

Analysis of the recombinant fusion protein

After pET32a(+)/HspA-Omp$_{18}$ was transfected into BL21 *E. coli* strains, the strains with high expressions of fusion proteins were selected. BL21 (DE3) *E.coli* strains containing recombinant plasmid were grown until mid-log phase (optical density at 600 nm=0.4 to 0.6), and then induced to express recombinant fusion protein by adding of 1 mmol· L^{-1} IPTG for 4 h. Following induction, bacteria were harvested by centrifugation at 12 000 r· min^{-1} for 5 min, resuspended in protein-buffer and seethed for 5 min. Total protein was electrophoresed on 150 g· L^{-1} SDS-PAGE gel and stained with Coomassie. Its molecular mass was M_r 51 000 by 150 g· L^{-1} SDS-PAGE gel analysis. After the recombinant bacteria were sonicated by ultrasonic wave and ultracentrifuged (10 000 r· min^{-1}, 15 min, 4 ℃), the level of soluble fusion protein in the supernate was about 18.96 % of total cellular protein. After purification by Ni^{2+}-NTA agarose resin columniation, the purity of recombinant fusion protein was about 95 % (Figure 5).

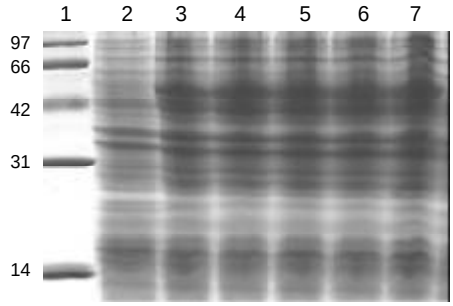

Figure 5 150 g·L^{-1} SDS-PAGE of total protein in recombinant vector expressed in BL21 *E.coli*. Lane 1. Standard protein marker (M_r 14; 31; 42; 66; 97×10^3), Lane 2. Bacterial protein expressed in BL21 after induction for 4 hours with IPTG, Lane 3-7. Expression of recombinant vector in BL21 after induction for 4 h with IPTG.

Antigenicity of recombinant fusion protein

After bacteria BL21/pET32a(+)/HspA-Omp$_{18}$, BL21/pET32a (+), BL21/pET32a(+)/HspA were induced to cultivate by adding of 1 mmol· L^{-1} IPTG for 4 h respectively, 1 ml of cultivated medium was respectively ultracentrifuged, resuspended in protein-buffer and seethed for 5 min. Total protein was electrophoresed on 150 g· L^{-1} SDS-PAGE gel, and then the proteins of SDS-PAGE-separated (150 g· L^{-1} acrylamide) were transferred to 0.45 μm pore size PVDF membrane at 14V, at 4 ℃ overnight. Following a 30-min wash in tris-saline blotting buffer, antigen-impregated PVDF strips were incubated with the sera of patients infected with *H. pylori* and anti-Omp$_{18}$ antibody for 2 h at RT. After a washing, the proteins were detected by incubating the strips in alkaline phosphatase-conjugated goat anti-man IgG antibody for 1 h at RT. In this study, antigen-impregated PVDF strips of BL21/pET32a(+)/HspA-Omp$_{18}$ were recognized by anti-Omp$_{18}$ antibody, showing brown strip corresponding to the site of the

recombinant fusion protein. Antigen-impregated PVDF strips of BL21/pET32a(+)/HspA were recognized by patient' s sera infected with *H. pylori*, also showing brown strip corresponding to the site of the fusion protein, while antigen-impregated PVDF strips of BL21/pET32a(+) were not recognized by patient' s sera infected with *H. pylori* (Figure 6).

DISCUSSION

Heat shock phenomena were found by a geneticist Ritossa in studying on change of drosophila cell chromosome stimulated by heat in 1962. Heat shock protein, found by Tissiers *et al* in 1974, indwells in man, microbe, foliage, and animal. It belongs to secretory protein, and accounts for 5 % of total cellular proteins. When cells are stimulated by environment, Hsps are induced to synthesize. A series of heat shock proteins, such as HspA, HspB, Hsp60, and Hsp70, synthesized by *H. pylori*, play a significant role in *H. pylori* pathogenesis, for example, taking part in regulation of cell immunization, initiating auto-immunoreaction of gastric epithelial cell, serving as a promotor in development of chronic gastric pathological changes, and mediating recognition and adhesion of pathogens with host. HspA and HspB genes encode 118, 545 amino acid residues respectively, corresponding to calculated molecular mass of M_r 13 000, 58 200. HspA is consisted of two domains: N domain is conservative sequence, associated with immune appearance; C domain is composed of 27 amino acid residues, including 8 histidines, and 4 cysteines. So the frame is a nickel combinative region, and plays a role in nickel ion translation and presentation. The experiments suggested that HspA, B were important factors in *H. pylori* conglutination and *H. pylori* active proteins stabilization under the extremely unfavorable conditions, meantime they increase urease activity. Others suggested that Hsp60 and HopZ (*H. pylori* outer membrane protein Z) of *H. pylori* were associated with *H. pylori* adhesion. HspA and HspB were homologous with *E. coli* GroEs and GroEI, associated with auto-immunoreaction, which might lead to the production of damaging auto-antibody. Animal experiments demonstrated that mice fed with HspA, B resulted in coronary artery sclerosis[52].

The outer membrane is a continuous structure on the surface of gram-negative bacteria and an asymmetric bilayer with phospholipids in the inner monolayer and the bulky glycolipid lipopolysaccharide (LPS). In the outer monolayer, *H. pylori* as bacterial pathogens, has particular significance as a potential target for inducing host protective immunity and escaping from the host' s immune system. Outer membrane vaccines have been used with considerable success to induce protection against a number of organisms, including the heat shock protein in *H. pylori*, urease A, and B. M_r18 000 OMP is a lipoprotein (Lpp20) belonging to other outer membrane protein[53]. In an earlier study, immunoreactive species-specific M_r19 500 *H. pylori* OMP actually was Lpp20-M_r18 000 OMP. The Lpp20 antigen appears to be commonly expressed in all *H. pylori* strains examined so far. Furthermore, no cross-reaction was shown when antibodies (polyclonal and monoclonal) to *H. pylori* Lpp20 were used to immunoscreen closely related species of helicobacter, campylobacter, or a diverse range of other bacteria. It shows that the Lpp20 gene to be unique to *H. pylori*[54]. Keenan *et al* demonstrated the protein was expressed on the surface of the bacteria by immunolabeling of *H. pylori* with gold-labeled anti-Lpp20 antibodies. Bacterial lipoproteins have been well described, not only as vaccine target candidates, but also as immunostimulatory molecules.

In order to overcome the weak antigenicity of a single antigen, *H. pylori* M_r18 000 OMP and HspA gene were amplified by PCR, and inserted into pET32a(+) vector simultaneously in our study. The pET32a(+) vector was designed for cloning and high-level expression of peptide sequences with the 109aa Trx.· Tag™ thioredoxin protein. Cloning sites were available to produce objective proteins also containing cleavable His· Tag and s· Tag™ sequences for detection and purification. The expressed protein of pET32a(+) vector had a putative molecular mass of M_r 20 000, so the expression of recombinant vector was a fusion protein with a calculated molecular mass of M_r 51 000, consistent with our results. Compared with the reports, 1.8 % of the cloned genes was mutated, and 1.7 % of amino acid residues was changed. The reasons for the discrepancy might be as follows: (1) *H. pylori* chromosomal DNA as templates was different, (2) there were heterogeneity among *H. pylori* strains, and (3) *H. pylori* was provided with the ability of transformation, which could lead to *H. pylori* variation and genome reset[54]. But there was much homogeneity between them.

Todoroki *et al*[55] investigated the effect of DNA vaccines encoding *H. pylori*-heat shock proteins A and B (pcDNA3.1-hspA and -hspB) on inducing immune responses against *H. pylori* in mice. C57BL/six mice aged 5 weeks were immunized by a single injection of 10microg of pcDNA3.1-hspA and pcDNA3.1-hspB into intracutaneous tissue. Plasmid DNA lacking the inserted Hsp was injected as a control. The results demonstrated that DNA vaccines encoding *H. pylori*-Hsp induced significant immune response against *H. pylori*, decreased gastric mucosal inflammation, indicating that a pcDNA3.1-hspA or -hspB DNA vaccine can be a new approach against *H. pylori* in human. Jiang *et al*[51] reported that recombinant fusion OMP$_{18}$ protein also had good antigenicity. While being an immunogenic marker, the patient sera infected with *H. pylori* M_r 18 000 Omp antigen showed high sensitivity and specificity[56]. Moreover, a significant association was found between the serologic response to M_r 18 000 Omp antigen and malignant outcome of *H. pylori* infection[57]. So the serum test for detecting antibody with lower-molecular-weight proteins of *H. pylori* could be used to identify *H. pylori*-infected patients at risk of peptic ulcer or malignancy. A recently published study also identified M_r 18 000 Omp as a candidate following the successful immunization of mice with purified recombinant antigen. In our study, the purified M_r 51 000 recombinant fusion HspA-Omp$_{18}$ protein could be recognized by patients' sera infected with *H. pylori* and anti-Omp$_{18}$ monoclonal antibody, and the purified M_r 33 000 recombinant fusion HspA protein could also be recognized by patients' sera. The results demonstrated that recombinant fusion protein had good antigenicity. These showed that M_r 51 000 recombinant fusion HspA-Omp$_{18}$ protein would not only provide HspA characteristics, but possess M_r 18 000 Omp specialty. Meantime, M_r 51 000 recombinant fusion HspA-Omp$_{18}$ protein was suggested to be a true vaccine candidate and not merely an immunogenic marker for *H. pylori* infection.

In addition to construction of the recombinant vector, looking for living carriers would be a key step. Immunization via the mucosal or intracutaneous-inoculated route offers the advantage that has the potential to stimulate both mucosal and systemic immunity. It is simple, safe and can be used for the

immunization of a large population. Bacillus Calmette-Guerin (BCG), the attenuated strain of mycobacterium bovid and the current vaccine against tuberculosis, has been widely used as a living, innately immunogenic vehicle for multiple protective recombinant antigens for vaccines against pathogenic microorganisms. With the aim of developing a recombinant vaccine, vaccines against human immunodeficiency virus, diphtheria, pertussis, tetanus (DPT), and parasite[58-68] have been investigated. We are developing a living carrier-BCG to provide a mucosal or intracutaneous-inoculated vaccine vector to deliver M_r 51 000 recombinant fusion HspA-Omp_{18} protein to antigen-presenting cells on mucosal surface. We believe that before long, *H. pylori* vaccine could be constructed successfully for eradicating *H. pylori* infection and *H. pylori* associated diseases.

Abstract

AIM: To establish stock of clinical *Helicobacter pylori* (*H. pylori*) isolates, to perform cagA and vacA typing of these isolates, to evaluate the relationship between genotypes of cagA and vacA and upper gastrointestinal diseases and to assess the association of vacA genotypes with presence of the pathogenicity marker-cagA.

METHODS: Clinical *H.pylori* strains were isolated from the antrum of 259 patients in Clumbia agar. The isolated *H. pylori* strains were identified by histology, and16SrRNA PCR. CagA genotypes were detected by colony hybridization, the probe was derived from the cloned plasmid PcagA, and digested by *Eco*RI-*Hin*dIII and the isolated PcagA DNA fragment was radioactively labelled by the random priming method. vacA genes types (s,m)and subtypes (s1a, s1b, s2) were typed by PCR. Vacuolating toxin was detected with neutral red absorb test. The results were treated statistically by χ^2 test, *t* test, and rank sum test.

RESULTS: A total of 192 clinical *H.pylori* strains were isolated and the stock of *Helicobacter pylori* was established. The total positive rate of cagA was 87 % in all gastric diseases, and 95 % in gastric cancer group. There was a difference between gastric cancer group and the other groups ($P<0.05$) except duodenal ulcer group. The expression of type s1 of vacA was more than type s2 ($P<0.05$), and, the expression of type m1 was equal to type m2. In gastric cancer group, there was a difference between s1a and s1b ($P<0.05$), and s1a was more than s1b. Vacuolating toxins were more in Xi'an area isolates.

CONCLUSION: The cagA$^+$ vacA type s1 clinical isolates are more in Xi'an area, but this can not serve as an index to predict gastric cancer.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is an important human pathogen that causes chronic gastritis and is associated with development of peptic ulcer diseases, and gastric malignancies[1]. Epidemiological studies have shown that *H. pylori* is a class 1 carcinogen for gastric adenocarcinoma, which is one of the most common cancers worldwide, and the odds ratio for developing gastric cancer is 3.8 to 8.7 in *H.pylori* infected subjects[2-6]. The pathophysiological mechanism by which *H.pylori* leads to gastric cancer has not yet been defined, although many hypotheses have been put forward.

The genetic variability among *H.pylori* strains is relatively high[7]. Approximately 50-60 % of *H. pylori* strains contain cytotoxin-associated (cagA) gene and consequently produce 128 ku CagA protein[8,9]. The presence of cagA is associated with gastric cancer, gastric mucosal atrophy, and duodenal ulcer. CagA is a part of a large genomic entity, designating the pathogenicity (cag) island[10,11], which contains multiple genes that are related to the virulence and pathogenicity of *H. pylori* strains. Therefore, the presence of cagA can be considered as a marker for this genomic pathogenicity island and is associated with more virulent *H.pylori* strains.

Another important virulence factor, produced by approximately 50 % of *H. pylori* strains, is a cytotoxin that induces formation of vacuolates in mammalian cells *in vitro* and leads to cell death[12]. The toxin is encoded by vacA gene, which is virtually present in all *H.pylori* strains[13]. The existence of different allelic variants in two parts of this gene has been described[14-17]. The N-terminal signal (s) region occurs as either a s1a, s1b or s2 allele. The middle (m) region is present as a m1 or m2 allele. The mosaic structure of vacA gene accounts for differences in cytotoxin production between strains[18-20].

The aim of this study was to detect and type the virulence-associated cagA and vacA genes of clinical *H.pylori* isolates in Xi'an area of China. Finally, the clinical relevance of vacA and cagA genotyping was investigated with gastric cancer and precancerous conditions.

MATERIALS AND METHODS

Bacterial isolation and culture

A total of 192 *H.pylori* isolates were obtained from patients undergoing upper gastrointestinal examination. The diagnosis obtained by endoscopy and histology was recorded for all the patients from whom the strains were isolated. Following primary isolation, *H.pylori* strains were grown on Columbia agar with 50 mL/L frozen-melting sheep blood, 100 mL/L fetal bovine serum, and Skirrow's antibiotic supplement in a microaerophilic atmosphere for 5 days at 37 ℃, then frozen at -70 ℃. Most of the strains were frozen four to six passages after primary isolation. Subsequent analyses were performed on strains derived from the frozen stocks. The isolated *H.pylori* strains were identified by histology, and16SrRNA PCR.

Plasmid DNA preparation

A signal bacteria clone was incubated at 37 ℃ overnight, harvested, and suspended in 0.5 mol/L EDTA-1M Tris-HCl

(pH 8.0), 10 mol/L NaOH and 100 g/L SDS was added, mixed, then 5 mol/L KAc and ice HAc were added. The mixture was centrifuged at 12 000 r/min for 10 min. The supernatant was extracted with phenol-chloroform followed by with chloroform. After extraction, the DNA solution was mixed with absolute ethanol and 3 mol/L NaAc at -20 ℃ for 20 min, washed with 700 mL/L ethanol, and dried. The DNA pellet was suspended in TE (10 mmol/L Tris-HCl, 1 mmol/L pH8.0 EDTA), and stored at -20 ℃.

DNA probes

The probe was derived from the cloned plasmid PcagA, and digested by *Eco*RI-*Hin*dIII. The enzyme digestion segment of PcagA was retrieved by DNA purification reagent kit (Baotaike Biotechnology Company). The isolated PcagA DNA fragment was radioactively labelled by the random priming method.

Colony hybridization

SDS of 100 g/L was added in fresh *H.pylori* liquid for 10 min, 2×SSC (1×SSC is 0.15 mol/L NaCl plus 0.015 mol/L sodium citrate) for 5 min, then *H.pylori* degeneration liquids were dotted on NC membranes which had been treated by 2×SSC, heated at 80 ℃ for 2 h. The membranes were put into pre-hybridization liquid (1×Denhardt, 1 g/L SDS, 5×SSC, 500 g/L deionised fomamide) at 42 ℃ for 3 h, then α-^{32}P labeled probes were added at 43.5 ℃ overnight. The membrane filters were subsequently washed once in 2×SSC-5 g/L SDS and three times in 0.1×SSC-1 g/L SDS, then exposed to X-ray film and their radioactivity was self-developing at -20 ℃ for 48 h. The film was developed and then fixed.

H.pylori chromosomal DNA extracts

Fresh *H. pylori* strains were harvested, suspended in 0.1 mol/L NaCl-10 mmol/L Tris-HCl-1 mmol/L EDTA (pH 8.0), and incubated at 37 ℃ for 15 min. NH_4Ac was added and the mixture was placed on ice for 5 min and extracted once with chloroform, mixed with isopropanol and placed on ice for 10 min. After extraction, the DNA solution was mixed with absolute ethanol at -20 ℃ for 1 h, washed with 700 mL/L ethanol, and dried. The DNA pellet was suspended in distilled water and stored at -20 ℃.

VacA genotyping

The vacA was typed by PCR. Table 1 shows the primer sequence of vacA. And Table 2 shows the system of PCR. The reaction condition was at 94 ℃ for 1 min, at 52 ℃ for 1 min, and at 72 ℃ for 1 min for 35 cycles and extension at 72 ℃ for 6 min. The PCR product was analyzed by 20 g/L agarose gel. The reference *H.pylori* strains were 60 190 (s1a/m1), 84 183 (s1b/m1) and 86 313 (s2/m2).

Cytotoxicity test on hela cells

Hela cells were cultured in plastic flasks in Dulbecco' s modified Eagle' s medium (DMEM) containing 25 mmol/L HEPES buffer (N-2-hydroxyethylpiperazine-N' -2-ethanesulfonic acid, pH7.2) and 100 g/L fetal bovine serum. Cells were maintained at 37 ℃ in a 50 mL/L CO_2 atmosphere. After cultured for 24 h, the cells were suspended with trypsin-EDTA and seeded in 96-well titration plates to make the density of cells of 10^4 per well. The supernatant prepared by water extracts from different strains was diluted two-fold from 1:2 to 1:32 and incubated with Hela cells for 12 h, then added 0.5 g/L neutral red- normal saline for 5 min, washed 3 times with 2 g/L BAS-normal saline and added HCl-ethanol. The absorbance was detected at 540 nm. When the detected value was more than 3 times of the negative control, it was defined as a positive result.

Table 2 The system of PCR

Constituents	Volume / per tube (μL)	Final concentration
Water	36	
10×PCR buffer	5	1×
4dNTP, 2.5mmol/L /each	4	0.2mmol/L each
primer 1.25 μmol/L	1	0.5 μmol/L
primer 2.25 μmol/L	1	0.5 μmol/L
$MgCl_2$, 50 mmol/L	1.5	1.5 mmol/L
Taq DNA polymerase, 5MU/L	0.5	0.1 MU/L
Template DNA	1	

Statistical analysis

χ^2 test, *t* test, and rank sum test were used for statistical analysis.

RESULTS

Presence of cagA gene

The presence of cagA gene was investigated in all clinical isolates by colony hybridization. *Eco*RI-*Hin*dIII-digested chromosomal DNA (Figure 1) was probed with an α ^{32}P-labelled DNA fragement internal to cagA. Typical examples of the results obtained with colony hybridization are reported in Figure 2. Of the 192 clinical isolates, 165 strains (86 %) had a positive hybridization dot, while 27 strains (14 %) did not show hybridization dot. In the 192 strains, the positive rate of gastric cancer group was 95 %, chronic superficial gastritis (CSG) 77 %, chronic atrophic gastritis (CAG) 86 %, gastric ulcer (GC) 69 %, and duodenal ulcer (DU) 95 %. There were differences between CAG and GU (P<0.05), and between GU and DU (P<0.05), but there were no statistical differences between CSG and CAG (P>0.05), and between CSG and GU (P>0.05).

Presence of signal sequence typing of vacuolating toxin gene

The signal sequence gene was typed by PCR in all *H. pylori* clinical isolates. The products of s1 and s2 were 259 bp and 286 bp, respectively. In the 192 strains, 174 strains (90.6 %) were s1 type, and 18 strains (9.4 %) were s2. The subtypes of s1 were typed by two pairs of primers (SS1-F/VA1-R and SS3-

Table 1 Oligonucleotide primers used for vacA typing

Presence of middle region typing of vacuolating toxin gene

The middle region gene was also typed by PCR in all *H. pylori* clinical isolates. The products of m1 and m2 were 567 bp and 642 bp, respectively. In the 192 strains, 99 strains (51.6 %) were m1 type, and 93 strains(48.4%) were m2, (Table 4 and Figure 6).

s type	GC	CSG	CAG	GU	DU	Total(%)
s1a	43a	14	37	5	12	111(57.8)
s1b	10	13	25	8	7	63(32.8)
s2	3	4	7	3	1	18(9.4)
Total	56	31	69	16	20	192(100.0)

[a]$P<0.05$ *vs* GU, CSG, CAG.

Table 4 *H.pylori* signal sequence typing and gastric diseases

m type	GC	CSG	CAG	GU	DU	Total(%)
m1	31	13	36	7	12	99(51.6)
m2	25	18	33	9	8	93(48.4)
Total	56	31	69	16	20	192(100.0)

No difference at all.

Presence of middle region typing and signal sequence of vacuolating toxin gene

In the 192 strains, 65 strains (33.9 %) were sla/m1, 34 strains (17.7 %) s1b/m1, 46 strains (24.0 %) s1a/m2, 29 strains (15.1 %) s1b/m2, and 18 strains (9.4 %) s2/m2.

Relationship between vacA typing and detecting of vacuolating cytotoxin activity in vitro

The maximum diluting times of positive result were the value of vacuolating toxin. Based on the maxium diluting unit, the strains were divided into three types: high toxin ($\geqslant$8), low toxin (1-8) and none toxin (less than 1). In the 192 strains, high toxin was 90 strains (46.9 %), low toxin 62 (32.3 %) and none toxin 40 (20.8 %, Table 5).

Relationship between cagA and vacA subtype

In the 165 cagA gene positive strains, 165 strains (100 %)

were vacA s1 type; 97 strains (58.8 %) vacA m1 type, and 78 strains (46.2 %, Table 6) vacA m2 type.

Table 5 Relationship between vacA typing and grade of vacuolating cytotoxin activity

vacA type	Grade of vacuolating cytotoxin activity		
	None	Low	High
s1a	5	38	68
s1b	17	24	22

m1	31	12	36	6	12	97(58.8)
m2	22	12	23	4	7	78(46.2)

DISCUSSION

H. pylori is the major causative agent of chronic superficial gastritis and plays a central role in the etiology of peptic ulcer disease. Evidence suggests that *H. pylori* infection pre-exists in gastric carcinoma and precancerous lesions, and is a risk for development of gastric carcinoma. Cittelly showed that lower frequencies of cytotoxic genotypes such as cagA and vacA s1m1 were observed in patients with NAG (non atrophic gastritis), when compared to patients with GC (gastric cancer) or PU (peptic ulcer). He suggested that vacA and cagA could be used as markers for increased virulence. In 1994, *H. pylori* was designated as a class I carcinogen by the World Health Organization[21,22]. *H. pylori* infection is high among Chinese people (the infected rate is 40-70 %), and also high in gastric cancer. The mortality of gastric cancer ranks the first among malignancies. The results of epidemiologic surveys on the relationship between *H. pylori* and gastric cancer show that infection of *H.pylori* in Lanzhou, an area with a high occurrence of gastric cancer, is higher than that in Guangzhou, an area with a low occurrence of gastric cancer[23, 24].

Recent researches suggested that the positive cytotoxin-associated gene A of *H.pylori* was about 60 %. This toxin can induce severe inflammation of gastric mucosa and is related with peptic ulcer and gastric cancer[25]. We detected the cagA gene in 192 clinical strains by colony hybridization, with a total positive rate of 86 %. In gastric cancer and duodenal ulcer, *H.pylori* infection rate (91 %) was the highest in all gastric diseases. In gastric ulcer group it was the lowest, only 69 %. Our results suggest that positive cagA of *H.pylori* isolated strains is related with gastric diseases in Xi' an area, Because the expression of cagA positive strains in gastric cancer group was higher than that in chronic gastritis group and the difference was apparent ($P<0.05$). CagA can increase the serious consequences of carcinogenesis from chronic inflammation. The detectable rate of CagA antibody in human group in high occurrence region of gastric cancer was obviously higher than that in low occurrence area. Some researches have also proved that cagA positive strains are easy to cause inflammation of gastric mucosa and can stimulate hyperplasia of gastric mucosal cells. Many studies have shown that there is a relationship between cagA positive antibody and peptic ulcer and gastric cancer. One research suggested that development of more prominent gastritis and severe atrophy in cagA (+) patients was an indicator for the importance of cagA rather than *H. pylori* load. Our research was consistent with theirs[26, 27].

All strains have the gene encoding toxin vacA, but its structure varies, especially in the mid-region which may be type m1 or m2 and the region encoding the signal sequence (type s1a, s1b or s2). The final structure is a mosaic, and all combinations of signal sequence and mid-region types are found except s2/m1. A strain' s vacA structure determines its *in vitro* cytotoxin activity, with type m1 vacA being more active than type m2, type s1a being more active than type s1b, and type s2 vacA not producing detectable activity. Our results showed that the main genotype was s1a in gastric cancer group, and there was an apparent difference between s1a and s1b ($P<0.05$), and the s2 genotype was seldom found. In the meantime, there was no apparent difference between m1 and m2 ($P>0.05$). The expression of s1a type was different among gastric cancer, gastric ulcer, and chronic gastritis. In gastritis group, there was no difference between s1a type and s1b type. Andreson' s research showed that the presence of the cagA gene was correlated with that of vacA signal sequence type s1a. However, no clear differences were found in the distribution of cagA and vacA genotypes among patients with peptic ulcer or chronic gastritis in Estonia. The reason why the different regional distribution can cause different genotype of *H.pylori* is not clear[28].

Our results showed that the infected *H.pylori* in Xi' an area was mainly toxin strains. In the meantime, the expression of s1a and s1b in the toxin strains was obviously different ($P<0.05$), and there was no significant difference between m1 and m2 ($P>0.05$). This suggests that s2 type can not produce detectable vacuolating toxin, and s1 type can produce the toxin. The middle-region is not obviously related to toxin production. The toxin produced by s2 type may not effectively pass through cellular membrane[29].

In cagA positive strains, the main vacA subtype was s1a, about 67 %, and s1b was only 33 %, and there was an apparent difference between these two subtypes ($P<0.05$). But there was no difference between m1 and m2 ($P>0.05$). We found that s1 type was related with gastric cancer[30].

Inactivation of multiple antioncogenes and *H.pylori* infection may be involved in the development and progress of gastric carcinoma, and *H.pylori* infection may be associated with the inactivation of some oncogenes[31]. The genotype expression of *H.pylori* in gastric cancer was mainly $cagA^+$/s1a strains in Xi' an area, but this can not serve as an index to predict gastric cancer. The main genotype of vacA in chronic gastritis, gastric ulcer and duodenal ulcer is s1, but there is no difference between s1a, s1b, m1 and m2.

Abstract

AIM: To explore the roles of nitric oxide synthase (NOS), heme oxygenase (HO) and cyclooxygenase (COX) in gastric ulceration and to investigate the relationships of the expression and activities of these enzymes at different stages of gastric ulceration.

METHODS: Gastric ulcers (kissing ulcers) were induced by luminal application of acetic acid. Gastric tissue samples were obtained from the ulcer base, ulcer margin, and non-ulcerated area around the ulcer margin at different time intervals after ulcer induction. The mRNA expression and protein levels of inducible and constitutive isoforms of NOS, HO and COX were analyzed with RT-PCR and Western blotting methods. The activities of the total NOS, inducible NOS (iNOS), HO, and COX were also determined.

RESULTS: Differential expression of inducible iNOS, HO-1 and COX-2 and enzyme activities of NOS, HO and COX were found in the gastric ulcer base. High iNOS expression and activity were observed on day 1 to day 3 in severely inflamed ulcer tissues. Maximum expressions of HO-1 and COX-2 and enzyme activities of HO and COX lagged behind that of iNOS, and remained at high levels during the healing phase.

CONCLUSION: The expression and activities of inducible NOS, HO-1 and COX-2 are found to be correlated to different stages of gastric ulceration. Inducible NOS may contribute to ulcer formation while HO-1 and COX-2 may promote ulcer healing.

INTRODUCTION

Nitric oxide synthase (NOS), heme oxygenase (HO) and cyclooxygenase (COX) are three important enzymes with constitutive and inducible isoforms. NOS catabolizes L-arginine to L-citrulline and nitric oxide (NO)[1,2], COX converts arachidonic acid to bioactive prostanoids[3,4], while HO metabolizes heme to biliverdin, carbon monoxide, and iron[5,6]. All these products play important roles in physiological and pathological conditions. The constitutive forms, namely eNOS, HO-2 and COX-1, are normally expressed in cells and tissues. Their expressions and activities are unaffected or only marginally modified during the process of inflammation. On the contrary, the inducible isoforms, namely iNOS, HO-1 and COX-2, are highly inducible in acute and chronic inflammation[7-9]. These induced enzymes may directly mediate the inflammatory reaction or contribute to the resolution of inflammation. Although the inducible property of these enzymes in inflammation has been proven and widely studied, their expression and activities at different stages of gastric ulceration have not been well defined. In this study, the temporal changes in the expressions and activities of these enzymes in rat stomaches during inflammation and ulcer healing were examined.

MATERIALS AND METHODS

Animals

The protocol of the study was approved by the Committee on the Use of Live Animals for Teaching and Research of University of Hong Kong. Male SD rats (weighing between 150-170 g) were fed on a standard laboratory diet (Ralston Purina Co., Chicago, IL) and kept inside a room with well-regulated temperature (22±1 ℃), humidity (65-70 %), and day/night cycle (12 h/12 h). The rats were starved for 24 h and water withdrawn 1 hour before the operation of the induction of gastric ulcer.

Preparation of gastric kissing ulcers

Gastric kissing ulcers were induced by luminal application of an acetic acid solution as previously described[10,11]. Briefly, the abdomen was opened under ether anesthesia, and the stomach was exposed. The anterior and posterior walls of the stomach were clamped together by a clip with metal rings of 11 mm internal diameter attached to both ends. Acetic acid solution (60 %, v/v) of 0.12 mL was injected with a syringe through the forestomach into the gastric lumen between the two rings. The acid solution was withdrawn 45 s later into the same syringe, and the operating site was disinfected with 70 % ethanol. Thereafter the animals were allowed to feed on standard diet and tap water *ad libitum* until collection of gastric tissue samples.

Sample collection

The rats were killed by ether anesthetization at 2 h, 6 h, 12 h, 1 d, 2 d, 3 d, 5 d, 8 d, and 15 d after ulcer induction and their stomachs were excised. The stomach was opened along the greater curvature and rinsed with cold normal saline, then blotted dry. The ulcer area (mm^2) was traced onto a transparency and then copied to a grid paper with 1 mm^2 square. The ulcer area was determined by counting the numbers of square it covered. Gastric tissues from the ulcer base, ulcer margin (1-2 mm adjacent to the ulcer base) and intact tissues around the ulcer margin were obtained and immediately frozen

in liquid nitrogen before storage at -70 ℃ until used for reverse transcription polymerase chain reaction (RT-PCR), Western blot and enzyme activities analysis. Gastric samples obtained from each time point were also fixed in 10 % buffered formalin for histological examinations. Gastric tissues from the rats without kissing ulcers were used as the control.

Histology

Paraffin embedded sections were prepared and hematoxylin and erosin staining (H&E) was used for morphological examinations of histological changes during tissue inflammation and ulcer healing.

RT-PCR analysis of mRNA expression

Total RNA was isolated from gastric tissues using Trizol reagent (Gibico BRL, Gathersburg, MD, USA). First strand complementary DNA (cDNA) was synthesized from 5 μg RNA by using oligo $(dT)_{20}$ primer with the thermoscript RT-PCR system (Gibico BRL). PCR cycles were performed for amplification of iNOS, eNOS, COX-1, COX-2, HO-1, HO-2 and β-actin cDNA using a PCR thermal cycler (Gene Amp PCR System 9700; Perkin-Elmer Corp., Norwalk, CT, USA) and oligonucleotides (Gibico BRL) of sequences are listed in Table 1. The number of PCR cycles was adjusted carefully to avoid saturation of the amplification system. PCR products were visualized by UV illumination (Bio-Rad, Hercules, CA, USA) after electrophoresis through 1 % agarose gel containing 0.5 μg/mL ethidium bromide. The gel photographs were scanned with a computerized densitometer (Multi-Analyst, Bio-Rad, Hercules, CA).

Table 1 Primer sequences of iNOS, eNOS, COX-1, COX-2, HO-1, HO-2 and β-actin

Western blot analysis of NOS, HO and COX proteins

Gastric tissues for the analysis of protein expressions of iNOS, eNOS, HO-1, HO-2, COX-1 and COX-2 were homogenized in a proteinase inhibitor buffer (50 mmol/L Tris HCl, pH 7.5, 150 mmol/L NaCl, 0.5 % α-cholate sodium, 0.1 % SDS, 2 mmol/L EDTA, 1 % Triton X-100, 10 % glycerol, 1 mmol/L PMSF and aprotinin) and then centrifuged at 10 000 rpm for 15 min at 4 ℃. The supernatant was collected and the protein content was determined with dye-binding (Bio-Rad) method. 30 μg of total protein was loaded onto SDS-polyacrylamide gel and blotted onto hybrid C membranes (Amersham Life Science, Little Chalfont, Buckinghamshire, England) by electrophoresis. Pre-stained rainbrow recombinant protein molecular weight markers (Amersham International plc, Little Chalfont, Buckinghamshire, England) were used for molecular weight determinations. Membranes were blocked with blocking buffer containing 5 % fat free milk powder, 10 mmol/L Tris-HCl (pH 7.5), 100 mmol/L NaCl and 0.1 % Tween 20 for 1 h at room temperature. The blots were incubated overnight at 4 ℃ with 1:500 dilution of polycolonal antibodies against HO-1 and HO-2 (Stress-Gen, Victoria, Canada), monoclonal antibodies against iNOS and eNOS (Transduction Lab, Lexington, Kentucky, USA), polyclonal antibodies against COX-1 and COX-2 (Santa Cruz Biotechnology INC, Santa Cruz, California, USA). After washed in washing buffer for 30 min, the membranes were treated with HRP conjugated secondary antibody (1:5 000) (Bio-Rad) for 1 h at room temperature followed by another 30 min of washing. The ECL Western blotting system (Amersham Life Sciences) was used in accordance to the manufacturer's instructions for chemiluminescence of proteins, and the blots were then exposed to photographic films (Fuji Photo Film Co., Tokyo, Japan).

Determination of NOS activity

NOS activity in the gastric tissue was measured as the ability of tissue homogenates to convert L-[^{3}H]-arginine to L-[^{3}H]-citrulline[12]. Gastric samples were homogenized at 4 ℃ in a buffer containing 10 mmol/L HEPES (pH 7.2), 320 mmol/L surcose, 0.1 mmol/L EDTA, 1 mmol/L dithiothreitol, 10 μg/mL leupeptin, 2 μg/mL aprotinin (Sigma, St. Louis, MO, USA) and 1 mmol/L PMSF (Sigma), then centrifuged at 12 000 rpm for 30 min at 4 ℃. The supernatant was collected and the protein contents were measured. 100 μL of supernatant was then mixed with a buffered solution consisting of 0.7 mmol/L NADPH, 150 μmol/L $CaCl_2$, 7 mmol/L L-valine, 10 mmol/L HEPES (pH 7.2) and 1μ Ci [^{3}H]-L-arginine (Gibico BRL) and incubated at 37 ℃ for 30 min to determine the total NOS activity. For determination of the iNOS activity, 1 mmol/L EGTA was used to inhibit the activity of calcium-dependent constitutive eNOS. The reaction was stopped by adding 50 μL 20 % perchloric acid, 160 mL 1 mmol/L NaOH and 540 mL dilution solution containing 1 mmol/L each of L-arginine and DL-citrulline. The newly formed L-[^{3}H]-citrulline was separated from L-[^{3}H]-arginine by passing the reaction mixture over 1 mL AG50W-X8 resin columns (Bio-Rad), and the eluted labelled material was measured using a Beckman scintillation counter (LS-6500, Beckman Instrument, USA). The final result was expressed as pmol of L-[^{3}H]-citrulline formed per milligram of protein per 30 min.

Determination of HO activity

Heme oxygenase activity was measured as the ability of tissue homogenates to metabolize heme to bilirubin[13]. In brief, gastric tissues were homogenized in 0.1 mol/L potassium phosphate-buffered saline (pH 7.4) and centrifuged at 12 000 rpm for 30 min. Then 500 μL supernatant (about 4 mg total protein) was added to an equal volume of reaction mixture (2 mmol/L $MgCl_2$, 30 μmol/L hemin, 30 mg rat liver cytosol, 0.2 U glucose-6-phosphate dehydrogenase, 2 mmol/L glucose-6-phosphate, and 0.8 mmol/L NADPH), and incubated at 37 ℃ in the dark for 1 h. The formed bilirubin was extracted with benzene and the absorbance of bilirubin at 462 nm was measured against a baseline absorbance at 530 nm. Heme oxygenase activity was expressed as μg of bilirubin formed/mg protein per hour. The protein content in the supernatant was determined by dye-binding method with BSA as a standard.

Assessment of COX activity

Cyclooxygenase activity was measured as the ability of tissue homogenates to metabolize arachidonic acid to PGE_2 according to the method described by Tomlinson and Vane[7, 8]. Gastric tissues were homogenized at 4 ℃ in proteinase inhibitory

buffer containing 50 mmol/L Tris-Cl (pH 7.4), 3.15 % trisodium citrate, 1 mmol/L PMSF, 0.2 mmol/L leupeptin. The protein concentration in the homogenates was measured. Homogenates were incubated at 37 ℃ for 30 min in the presence of excess arachidonic acid (30 mmol/L). The samples were then boiled and centrifuged at 12 000 rpm for 30 min. The concentration of PGE_2 in the supernatant was measured by immunoassay, using R&D PGE_2 kits (R&D Systems, Inc. Minneapolis, MN, USA). Results were expressed as ng PGE_2 produced per mg protein in 30 min.

Statistical analysis

All the data were expressed as mean ± S.E.M. Statistical analysis was performed using Student' s *t*-test. Values of $P<0.05$ were considered statistically significant.

RESULTS

Morphology and histology

Two symmetrical ulcers were induced in the anterior and posterior walls of the stomach by acetic acid injection. The ulcer base was denuded of mucosal layers because of the necrotic changes and it reepithelized gradually during ulcer healing. Histological accumulation of neutrophils was found at 6 h and prominent inflammatory infiltration was observed at the ulcer base on day 1 to day 3 after ulcer induction. This period was defined as the inflammatory stage of gastric ulceration. After 3 days, the ulcer healed rapidly and was characterized by a reduction in ulcer area (Figure 1). There was intensive proliferation of epithelial cells at the ulcer margin, accompanied by the development of granulation tissues with angiogenesis. The period from day 3 onwards was considered to be the healing phase of gastric ulceration. Complete reepithelization of the ulcer craters was found in some stomaches on day 15 after ulcer induction.

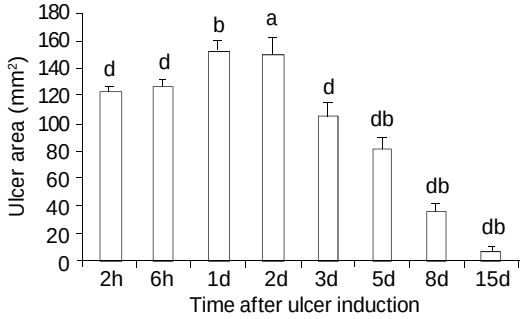

Figure 1 Sequential change of ulcer areas at different time points after ulcer induction. Significant decrease of ulcer area was found on day 3 after ulcer induction. The data were represented as mean ± S. E. M of 20 rats in each group, $^aP<0.05$ *vs* the 2 h group; $^bP<0.001$ *vs* the 2 h group; $^dP<0.001$ *vs* the day 1 group.

Expression of HO, NOS and COX mRNA

Basal levels of COX-2 and HO-1 mRNA expression were detected in normal and non-ulcerated gastric tissues around the ulcers, while expression of iNOS mRNA could only be detected in the ulcer tissue 6 h after ulcer induction. Dramatic increase in mRNA expression of HO-1, iNOS and COX-2 was found from 6 h onwards. High level of iNOS expression persisted for only 3 days then declined rapidly over the healing phase. The expression of HO-1 and COX-2 mRNA remained at high levels during the healing stage from day 3 to day 8. Unlike their inducible isoforms, mRNA expression of HO-2, eNOS and COX-1 was relatively stable. The HO-2 mRNA appeared to be slightly increased in the ulcer base at 12 h after ulcer induction (Figure 2).

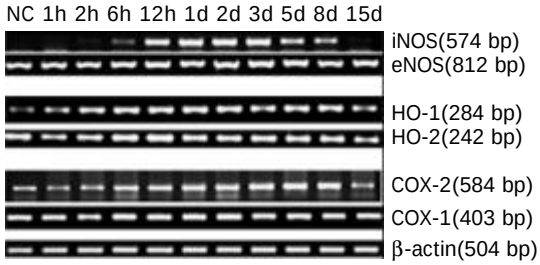

Figure 2 Time course of mRNA expression of inducible and constitutive isoforms of NOS, HO and COX in the ulcer bases. NC=normal control group.

Western blot analysis of HO, NOS and COX

A basal level of HO-1 protein was found in normal gastric tissues, while the iNOS and COX-2 proteins were undetectable. Acetic acid-induced ulceration resulted in a transient loss of HO-1 protein at 2 h, but re-appeared at 6 h and then increased persistently until its peak expression on day 3 to day 5. Its level decreased but still remained higher than normal during day 5 to day 15, at which the ulcer decreased in size and reepithelized.

Expression of COX-2 protein was found to be induced 6 h after ulcer induction and peaked on day 5. Afterwards it remained at a high level during the healing stage. Unlike HO-1 and COX-2, high level of iNOS protein was only detected at the inflammatory stage from day 1 to day 3. The protein expressions of HO-2, eNOS and COX-1 were relatively stable. Transient losses of eNOS and COX-1 proteins were observed at 2 h after acetic acid injection, and then gradually returned to normal levels during the healing process. The level of HO-2 protein was slightly increased after ulcer induction and peaked on day 1, then returned to normal level during ulcer healing (Figure 3).

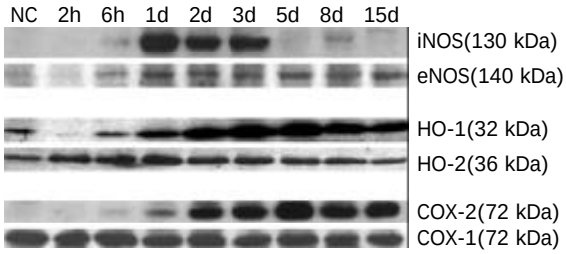

Figure 3 Western blot analysis of the protein levels of inducible and constitutive isoforms of NOS, HO and COX in the ulcer bases at different time after ulcer induction. NC= normal control group.

Expressions of iNOS and COX-2 in the ulcer margin were lower than those in ulcer base during the inflammatory phase. HO-1 expression in the ulcer margin was higher than that in non-ulcerated tissue but lower than that in the ulcer base both in the inflammatory and healing stages.

Enzyme activities of HO, NOS and COX

Marked increase of HO, NOS and COX activities at the ulcer base was found 6 h after ulcer induction. High level of iNOS activity was detected in ulcer base on day 1 to day 3, which was in consistent with the Western blot findings of iNOS protein expression. Similar trend was found in the margins but to a lesser extent (Figure 4). The activity of HO increased in 6 h and peaked on day 2, then remained at an elevated level on day 3 to day 8 (Figure 5). COX activity was persistently increased during the healing stage and was markedly elevated on day 15. Similar trend was found in the margin tissues but to a lesser extent (Figure 6). The trends for HO, NOS and COX activities in the ulcer margin were similar to those found in the ulcer base but with a lower value.

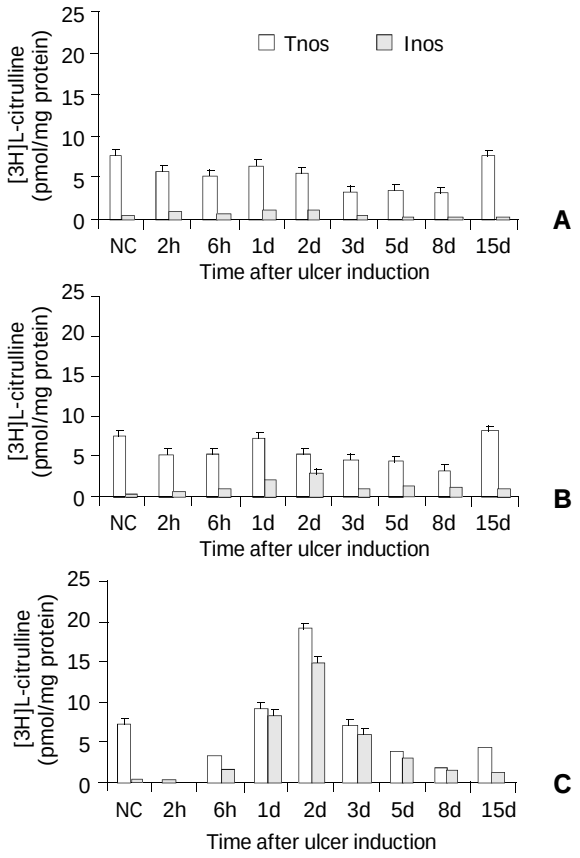

Figure 4 Total NOS (tnos) and iNOS (inos) activities at the non-ulcerated tissues (A), margins (B), and ulcer base (C) of acetic acid induced gastric ulcer. Each bar represents the mean ± S.E.M of 8 rats in each group. NC=normal control group.

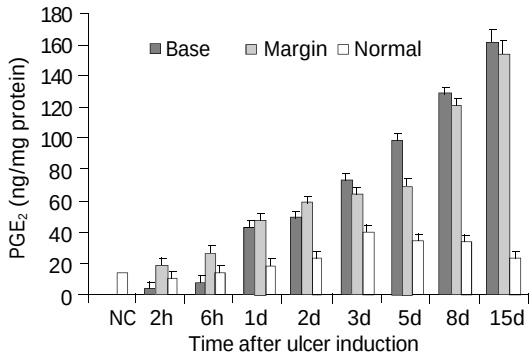

Figure 6 COX activities in the gastric tissues of normal control rats (NC) and the non-ulcerated tissues, ulcer margins and ulcer bases of acetic acid induced gastric ulcer. Each bar represents the mean ± S.E.M of 8 rats in each group.

DISCUSSION

In this study, the expression and activity patterns of NOS, HO and COX were investigated in rats with acetic acid-induced kissing ulcers. The results showed that the inducible isoforms of HO-1, iNOS and COX-2 were all up-regulated during the inflammatory phase. High expression and activity of iNOS were found to coincide with severe inflammation in the ulcer tissue, suggesting that it could be contributed by inflammatory cells that were involved in the inflammatory process. Maximum expressions and activities of HO-1 and COX-2 were found during the ulcer healing phase and thus they might play a role in ulcer healing.

It has been found that NO released from endothelial cells and neuronal cells by the constitutive isoform of NO synthase has regulatory roles in blood flow, motility and secretion. It also protects the gastrointestinal tract against injurious substances. NO produced from inflammatory cells by the inducible isoform of NOS has antimicrobial, antitumor and cytotoxic effects, but excessive amount may lead to peroxynitrite formation, protein tyrosine nitration, hydroxyl radical production and tissue damage[14, 15]. The present study also demonstrated that overexpression of iNOS on day 1 and day 2 after ulcer induction was accompanied by enlargement of ulcer crater. The expression of iNOS protein and activity were observed to be declined when the ulcer began to heal. NO generated from iNOS may also play a beneficial role during ulcer healing by inducing apoptosis in inflammatory cells[16].

The roles of HO-1 and COX-2 in gastric ulcer healing have not been clearly defined. HO-1 has been shown to possess cyto-protective and anti-inflammatory actions. Its expression is associated with the resolution of non-immune as well as immune-driven inflammation[9]. The role of HO-1 as an inflammatory defensive factor may be due to its conversion of oxidant heme to antioxidants biliverdin and bilirubin. It also elevates intracellular free iron levels to facilitate ferritin up-regulation, and regulation of vascular tension through CO generation. Moreover, a recent study has found that CO is able to inhibit the expression of lipopolysaccharide-induced pro-inflammatory cytokines and increase the anti-inflammatory cytokine through a pathway involving the mitogen-activated protein kinases (MAPK)[17]. Besides a role in resolution of inflammation, evidence has also been found that HO-1 may participate in the regulation of endothelial cells activation, proliferation and angiogenesis[18,19], which is essential for wound healing. In this study, the expression and activity of HO-1 were significantly elevated during early ulcer healing and this could be due to the contributory actions of HO-1 in inflammatory resolution and angiogenesis in tissue regeneration.

High expression of COX-2 protein and enzymatic activity of COX at the late ulcer healing stage were observed in this study. The expression of COX-1 protein was relatively stable, thus the change of COX activity might mainly be due to the change of protein level and activity of COX-2. Since tissue remodeling which includes reepithelization of gastric mucosa, maturation of granulation tissue, and reconstruction of extracellular matrix (ECM) mainly occurs at the late ulcer healing stage, the results of this study suggest that COX-2 may play an essential role in these remodeling processes. This is supported by the fact that non-selective as well as selective COX-2 inhibitors delay ulcer healing and prevent regeneration of the mucosa, maturation and angiogenesis in the ulcer base[20-26].

There may be interactions among NOS, HO and COX. HO may modulate NOS and COX systems since they are all heme-containing enzymes. NO and NO donors have been found to stimulate HO-1 expression in different cell lines[27-31] and NO was found to be able to stabilize HO-1 mRNA[32]. On the other hand, HO-1 may have a negative feedback regulation on NO production. Induction of HO-1 by cadmium, bismuth salts,

heme, and nitric oxide (NO) donors have been shown to inhibit the expression of iNOS[33, 34], while inhibition of HO-1 by its inhibitor enhanced iNOS expression. In the present study, a dramatic decrease of iNOS expression and activity was accompanied by an increase in expression and activity of HO-1 on day 5 after ulcer induction. This inverse relationship between iNOS and HO-1 expression and activities supports the existence of close interaction among these enzymes.

In summary, differential expression and activity patterns of inducible enzymes of iNOS, HO-1 and COX-2 during gastric ulceration and healing were found in the present study. The results indicate that iNOS may contribute to tissue inflammation during ulcer formation, while HO-1 and COX-2 may promote ulcer healing, since their expression and activities correlate with the resolving of inflammation and remodeling of ulcer tissues. Close interaction between iNOS and HO-1 may exist because the decrease of iNOS expression and activity coincide with the increase in expression and activity of HO-1. However, further experiments that enroll the use of selective blockers of these inducible enzymes should be conducted to substantiate these conclusions.

Abstract

AIM: To determine the changes of pS2 and ITF of TFF expression in gastric mucosa and the effect on ulcer healing of pS2, ITF to Water-immersion and restraint stress (WRS) in rats.

METHODS: Wistar rats were exposed to single or repeated WRS for 4 h every other day for up to 6 days.Gastric mucosal blood flow (GMBF) was measured by LDF-3 flowmeter and the extent of gastric mucosal lesions were evaluated grossly and histologically. Expression of pS2 and ITF mRNA was determined by RT-PCR. Immunohistochemistry was used to further detect the expression of pS2 and ITF.

RESULTS: WRS applied once produced numerous gastric mucosal erosions, but the number of these lesions gradually declined and GMBF restored at 2, 4, 8 h after stress. The area of gastric mucosal lesion was reduced by 64.9 % and GMBF was increased by 89.8 % at 8 h. The healing of stress-induced ulcerations was accompanied by increased expression of pS2 (0.51±0.14 *vs* 0.77±0.11, $P<0.01$) and ITF (0.022±0.001*vs* 0.177±0.010, $P<0.01$). The results were demonstrated further by immunohistochemistry of pS2 (0.95±0.11 *vs* 1.41±0.04, $P<0.01$) and ITF (0.134±0.001*vs* 0.253±0.01,$P<0.01$). With repeated WRS, adaptation to this WRS developed, the area of gastric mucosal lesions was reduced by 22.0 % after four consecutive WRS. This adaptation to WRS was accompanied by increased GMBF (being increased by 94.2 %), active cell proliferation in the neck region of gastric glands, and increased expression of pS2 (0.37±0.02 *vs* 0.77±0.01, $P<0.01$) and ITF (0.040± 0.001*vs* 0.372±0.010, $P<0.01$). The result was demonstrated further by immunohistochemistry of pS2 (0.55±0.04 *vs* 2.46±0.08, $P<0.01$) and ITF (0.134±0.001*vs* 0.354±0.070, $P<0.01$).

CONCLUSION: TFF may not only participate in the early phase of epithelial repair known as restitution(maked by increased cell migration),but also play an important role in the subsequent,protracted phase of glandular renewal(made by cell proliferation).

INTRODUCTION

Stress ulcer is a highly prevalent clinical complication. Fully understanding the mechanism of healing of stress-induced gastric lesions not only deepens our insights into stress ulcer, but also provides new ways for its prevention and treatment in clinical practice. The mechanism of the recovery of gastric mucosa after stress exposure has not been fully explained, the healing of stress ulcerations is a complex process which is affected by different factors. Current research has found that a variety of peptides are considered to play a crucial role in the control of mucosal integrity and repair. Among them, an important role was attributed to epidermal growth factor and transforming growth factor alpha[1-3].

Recently, a group of new peptides has been discovered, called TFF (trefoil factor family or trefoil peptides) because of their uniquely distinctive cysteine-rich "three-leaf" secondary structure, which probably protects these peptides from degradation by luminal acid and proteases within gastrointestinal tract. pS2 and intestinal trefoil factor (ITF) belong to the growing family of trefoil peptides[4,5].

The physiological role of TFF is poorly understood so far. The aim of the present study was to investigate the expression of pS2 and ITF in gastric mucosa of rats undergone WRS, and to probe the role of TFF in the early phase of epithelial repair of stress-induced gastric lesion.

MATERIALS AND METHODS

Induction of gastric adaptation to WRS: Thirty male Wistar rats, weighing 210-250 g (purchased from Xipuer-Bikai Experimental Animal Co. LTD, Shanghai) which had been fasted for 24 h with free access to water, were used. The animals were deprived of water 1 h before the experiment and divided into normal control group (n=6) and experimental control group (n=24). After being fasted for 24 h, the rats of normal control group were lightly anesthetized with ether and tied up on the rat board, the abdomen was opened, the stomach was exposed and GMBF was measured in the oxyntic gland area, gastric mucosa was sampled. The rats of experimental control group were divided into four subgroups (6 in each group) and exposed to WRS[6] for 4 h. They were killed either immediately (0 time: namely 0 h) or after 2 h, 4 h, 8 h. GMBF was measured and gastric mucosa was sampled as described below.

The rats of experimental control group were divided into four subgroups (6 each group) and exposed to repeated WRS[7]: The rats of group I were lightly anesthetized with ether, tied up on the rat board and exposed to WRS for 4 h by placing in water at 20-23 ℃ to the rat's xyphoid level at 10:00 AM on day 1. Then the rats were anesthetized with pentobarbital (30 mg· kg^{-1} i.p.), GMBF was measured and gastric mucosa was sampled. the rats of group II were treated similarly except that after WRS, they were removed from water and placed at

room temprature, and refed with food and water until 10:00 AM the next day, and starved again for 24 h, WRS was repeated. the rats of group III and IV were exposed to the 3rd or 4th WRS as described above.

Measurement of GMBF: GMBF was measured by using laser Doppler flowmetry (LDF-3 flowmeter, Nankai University, Tianjin, China). In brief, the rats were anesthetized with pentobarbital (30 mg· kg^{-1} i.p.), the abdomen was opened, the stomach was exposed and transected, the gastric contents were gently evacuated to the exterior through the cut made in the forestomach.Then, an optical probe was placed gently 0.5 mm above perpendicular to the mucosal surface in the oxyntic gland area to monitor GMBF displayed in mV (value of Doppler signal voltage) on the digital panel of the flowmeter. When GMBF became stable, four points were selected for measurement (one point for 1 minute) and the average value was calculated and expressed as *U/mV*.

Appreciation of UI: Mucosal lesions were evaluated by the score systems reported by Nie S[7]. Briefly, after the measurement of GMBF, the stomach was dissected out and opened along the greater curvature. The stomach was then examined with a 10×magnifier for the presence of erosions and scored as follows: 1 point for small round hemorrhagic erosion, 2 points when the length of hemorrhagic erosion was less than 1 mm, 3 points when the length was 1-2 mm, 4 points when the length was 2-3 mm, 5 points when the length was longer than 4 mm. The score value multiplied 2 when the width of erosion was larger than 1 mm.

Reverse-transcriptase-polymerase chain reaction (RT-PCR) for detection of messenger RNA (mRNA) for pS2 and ITF: The stomachs were removed from rats with intact gastric mucosa and from those exposed to single or repeated stress. Mucosal specimens (about 100 mg) were scraped off using a slide glass and immediately snap frozen in liquid nitrogen and stored at -80 ℃ until analysis. Total RNA was isolated from mucosal samples using a guanidium isothiocyanate/phenol chloroform single step extraction kit from Stratagene (Gibco BRL,USA). Following precipitation, the RNA was resuspended in RNAse-free TE buffer and the concentration was estimated by absorbance at 260 nm wavelength. Furthermore, the quality of each RNA sample was determined by running the agarosefomaldehyde electrophoresis. RNA samples were stored at -80 ℃ until analysis.

Single-strand cDNA was generated from 5 μg of total cellular RNA using StrataScript™ reverse transcriptase (Gibco BRL,USA) and oligo (dT) primers (Gibco BRL,USA). Briefly, 5 μg of total RNA was used as the template to synthesize complementary DNA with 2.5 U of Maloney murine leukemia virus reverse transcriptase in 5 μl of buffer containing 10 mM Tris-HCl, pH 8.3; 50 mM KCl, 5 mM $MgCl_2$; 1 mM of each deoxyribonucleoside triphosphate; 2.5 mM of oligo (dt) primers and 1.4 U μl^{-1} RNAse blocker. Reverse-transcription was performed at room temperature for 20 min, then at 37 ℃ for 15 min, at 90 ℃ for 5 min and at 5 ℃ for 10 min. The resulting complementary DNA was used as a template for subsequent polymerase chain reaction (PCR).

A 124-base pair (bp) fragment of pS_2 was amplified from single-stranded DNA by polymerase chain reaction (PCR) using two oligonucleotide primers for pS_2 sequence: Sense primer, 5' -CCATGGAGCACAAGGTGACCTG-3' and antisense primer, 5' -GGGAAGCCACAATTTATTCT-3' . A 221-base pair (bp) fragment of ITF was amplified from single-stranded DNA by polymerase chain reaction (PCR) using two oligonucleotide primers to ITF sequence: Sense primer, 5' -ATGGAGACCAGAGCCTTCTGGAC-3' and antisense primer, 5' -AGAGGTTTGAAGCACCAGGGC-3' . Concomitantly, amplification of the 521 bp fragment of rat β-actin was performed on the same RNA samples to assess RNA integrity, two oligonucleotide primers to β-actin sequence: Sense primer, 5' -TGGGACGATATGGAGAAGAT-3' and antisense primer, 5' -ATTGCCGATAGTGATGACCT-3' . The nucleotide sequences of the primers for pS_2 were based on the pulished cDNA sequences encoding pS2[8] and the nucleotide sequences of the primers for ITF were based on the published cDNA sequences encoding ITF[9]. The primers were synthesized by Bo-Ya Biotechnical Co. LTD, Shanghai, China.

Reaction mixture for PCR contained cDNA template (2 μl), 50 pmol of each primer, and 2.5 U of Termus aquaticus DNA (Promega) in 10 mM Tris-HCl (pH 8.8), 50 mM KCl, 1.5 mM $MgCl_2$, 0.5 mM dNTPs in a volume of 50 μl. RT blanks (no RNA included) were incubated in each analysis. The mixture was overlaid with 25 μl of mineral oil to prevent evaporation. Amplification was performed using a DNA thermal cycler for 35 cycles, each of which consisted of 2 min at 94 ℃ for denaturation, 45 s at 52 ℃ (pS_2) and at 50 ℃ (ITF) for annealing, and 1 min at 72 ℃ for extension. The final cycle included extension for 5 min at 72 ℃ to ensure full extension of the product. The number of amplification cycles was previously determined to keep amplification in linear to avoid the "plateau effect" associated with increased numbers of PCR cycles. 8 μl of each PCR -product was electrophoresed on 1.6 % agarose gel stained with ethidium bromide, and then visualized under UV light. Location of predicted PCR-product was confirmed by using DNA digest phix 174/Hae III as a stained size marker. The gel was then photographed under UV transillumination. In addition to size analysis by agarose gel electrophoresis,specificity of the primer pair for pS_2 and ITF was assessed by sequencing PCR products. For quantification,we determined the intensity of polymerase chain reaction products on the negative film of gel photographs according to Konturek PC *et al*[10]. Expression of the products was quantified using video image analysis system (TanonGIS-1000, Tanon Technical Co, LTD, Shanghai, China). An index of messenger RNA expression was determined in each sample using the following equation according to Konturek PC *et al*[11].

Immunocytochemistry: For histological assessment, the other half of the stomach was fixed in 10 % formalin, embedded in paraffin, and stained with hematoxylin and eosin. For immunohistochemistry, serial sections obtained from these paraffin blocks were dewaxed and rehydrated. Endogenous peroxidase was blocked with 3 % hydrogen peroxide for 15 min. Sections were then incubated for 35 min with a specific monoclonal antibody against pS_2 and ITF (Asgiraud, Italy), washed and incubated with biotinylated rabbit anti-mouse antibody. After 35 min incubation in avidin-biotin complex, the sections were incubated for 2 min in peroxidase substrate (diaminobenzidine, PBS, in addition to 0.3 percent of hydrogen peroxide) and counterstained with haematoxylin.

The intensity of pS_2 and ITF staining (Mean score) for each cell was graded according to the criteria described by Nie *et al*[6]. as follows: 0=no staining, I=weakly positive, II=moderately positive (cytoplasm positive but other cytoplasmic details also visible), or III=densely stained. The staining intensity was calculated in 300 consecutive cells in three regions of the gastric mucosa: Surface epithelium (top), neck region (neck) and basal portions of the gastric glands (base). The mean intensity per section and region was calculated. Negative control sections were processed immunohistochemically after replacing the primary antibody with an irrelevant monoclonal antibody or phosphate-buffered-saline (PBS).

Statistical analysis: Results were presented as *means±SD*. Statistical comparisons were made by Student' s *t* test.The linearly relevant analysis was applied to analyse the relationship between two variants, *P* values less than 0.05 were considered statistically significant.

RESULTS

Gastric lesion induced by single or repeated WRS: WRS applied once produced numerous gastric mucosal erosions in oxyntic mucosa with the mean lesion number of 45.32±1.41 per rat. No microscopic evidence of damage occurred in the forestomach. Microscopical examination of the mucosa after 4 h stress revealed widespread damage of the surface epithelium with many cells sloughed off into the gastric lumen and focal area of deep haemorrhagic necrosis (Figure 1). The number of stress lesions was gradually declined at 2, 4, 8 h after the end of stress. UI was reduced to about 20.8 % of the initial number at 8 h after the end of stress (Table 1). With repeated WRS, adaptative cytoprotection against stress was developed, UI in II, III, IV groups markedly reduced as compared with group I (P<0.01). UI after four consecutive WRS was 22 % of UI after one WRS. Cell proliferation in the neck regions of gastric glands was activated (Figure 2, Table 2).

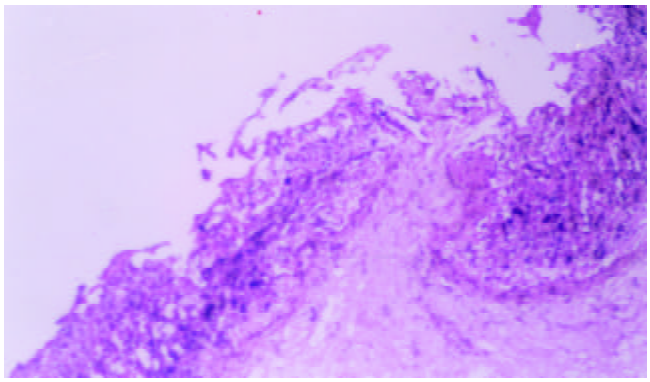

Figure 1 Necrosis appeared as craters in rats after exposed to single WRS for 4 h (HE×200).

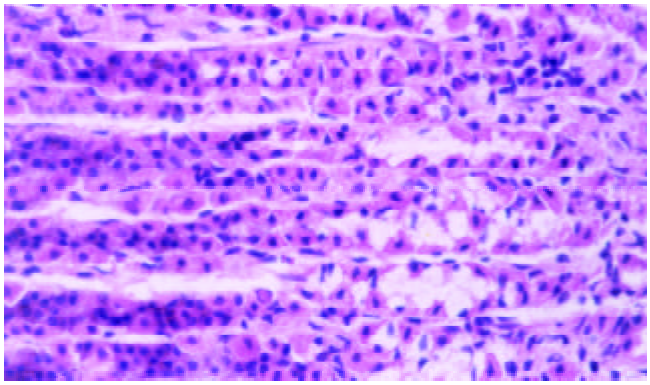

Figure 2 Foveolae and neck region elongated and the mucosa appeared thicker after rats exposed to 4th WRS for 4 h(HE×400).

Change of GMBF after single or repeated WRS: GMBF of normal rats was 424.70±7.72*U/mV*. GMBF significantly decreased after single exposure to WRS and restored at 2, 4, 8 h after the end of stress. It increased up to 94.5 % of normal value at 8 h after the end of stress (Table 1). GMBF of normal rats was 484.01±10.97*U/mV*. GMBF significantly decreased after single exposure to WRS.With repetitive challenge with WRS, there was an adaptive increase of it in experimental group, and GMBF of groups II, III, IV markedly increased as compared with that of group I (P<0.01). After the 4th time of WRS, the value of GMBF was almost restored to normal level (94.2 % of normal value). There was a significantly negative relevance between GMBF and UI (r=-0.953, P<0.01) (Table 2).

Expressions of pS_2 and ITF mRNA and immunohistochemical staining for expression of pS_2 and ITF proteins during recovery from stress damage: The expressions of pS_2 and ITF could be detected in normal gastric mucosa. They were expressed mainly in the regenerative zone of cytoplasm and weaker expressions were found at the basal portions of the gastric glands. The expressions of pS_2 and ITF in single WRS significantly decreased and was absent in the necrotic region, whereas repeated WRS significantly increased expression of pS_2 and ITF. In addition to the regenerative zone,other areas including the lumen of gastric glands also expressed pS_2 and ITF.

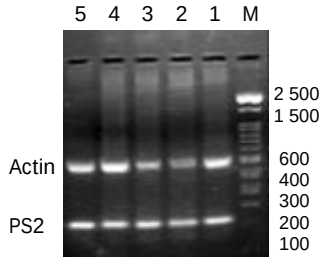

Figure 3 Messenger RNA expression of pS_2 mRNA and β-actin in gastric mucosa of rats after single exposure to WRS and in control intact rats (M=PCR size marker, 1=control group, 2=group 1, 3=group 2, 4=group 3, 5=group 4).

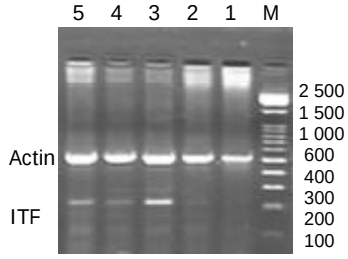

Figure 4 Messenger RNA expression of ITF mRNA and β-actin in gastric mucosa of rats after single exposure to WRS and in control intact rats (M=PCR size marker, 1=control group, 2=group 1, 3=group 2, 4=group 3, 5=group 4).

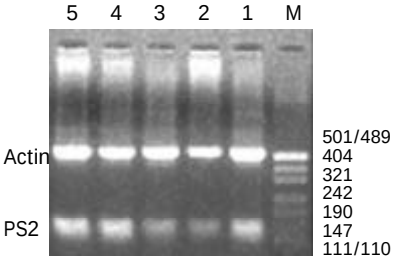

Figure 5 Messenger RNA expression of pS_2 mRNA and β-actin in gastric mucosa of rats after repeated exposure to WRS and in control intact rats (M=PCR size marker, 1=control group, 2=group I, 3=group II, 4=group III, 5=group IV).

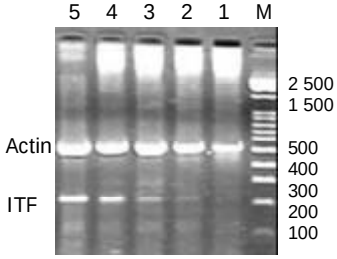

Figure 6 Messenger RNA expression of ITF mRNA and β-actin in gastric mucosa of rats after repeated exposure to WRS and in control intact rats (M=PCR size marker, 1=control group, 2=group I, 3=group II, 4=group III, 5=group IV).

The expressions of pS2 and ITF mRNA were increased during the healing after single WRS (pS2: 0.51±0.14 *vs* 0.77±0.11, *P*<0.01; ITF: 0.022±0.001*vs* 0.177±0.010, *P*<0.01) (Figure 3, 4). The same results were observed by immunohistochemistry (pS2: 0.95±0.11 *vs* 1.41±0.04, *P*<0.01; ITF: 0.134±0.001*vs* 0.253±0.01, *P*<0.01). With repeated WRS, adaptative cytoprotection against stress was developed.The expression of pS2 and ITF mRNA was increased by using RT-PCR (pS2: 0.37±0.02 *vs* 0.77±0.01, *P*<0.01; ITF: 0.040±0.001*vs*0.372±0.010, *P*<0.01) (Figure 5,6) and immunohistochemistry (pS2: 0.55±0.04 *vs* 2.46±0.08, *P*<0.01; ITF: 0.134±0.001*vs* 0.354±0.070, *P*<0.01). There was a significantly negative relevance between expressions of pS_2 or ITF and UI (*r*=-0.921, *P*<0.01; *r*=-0.965, *P*<0.01), and positive relevance was found between expressions of pS_2 or ITF and GMBF (*r*=0.826, *P* <0.05; *r*=0.854, *P*<0.05) (Table 2).

DISCUSSION

The cytoprotective functions in protecting gastrointestinal tract against ongoing damage may be accomplished in several ways, and evidences for participation in both the early phase of epithelial repair known as restitution (marked by increased cell migration but no proliferation), and in the subsequent, protracted phase of glandular renewal (marked by proliferation, differentiation and migration) have been published[12-14].

This study assessed for the first time immunohistochemical and RT-PCR analyses of pS2, ITF expression in rat gastric mucosa after exposure to water immersion and restrained stress. Our observation showed that expression of pS2 and ITF in gastric mucosa was enhanced shortly after the stress, leading us to hypothesize that this process might be mediated by pS2 and ITF.

The importance of trefoil peptides in the process of response to the damage action of strong irritants has not yet been evaluated.The members of the trefoil peptide family, including pS2 and ITF, share a common structural feature, which is a motif of six cysteine residues termed a trefoil or a P domain. There are increasing evidences that pS2 and ITF are important in maintaining the integrity of gastric mucosa and involved in the repair of ulcerated areas in gastrointestinal tract[15-19]. This is supported by an observation that increased expressions of pS2 and ITF were found in the ulcer-associated cell lineage (UACL), which is a glandular structure that develops in the area of gastrointestinal tract adjacent to ulcerated mucosa[20]. This is supported by the findings obtained from *in vitro* study which showed that pS2 and ITF exhibited a mitogenic effect on different cell lines[21,22]. Moreover, exogenously recombinant TFF has been shown to significantly attenuate the extent of acute mucosal injury induced by a variety of ulcerogens such as 96 % ethanol, indomethacin or stress[23], indicating that this peptide does exhibit gastroprotective activity.

The present study showed that, WRS applied once produced numerous gastric mucosal erosions. UI gradually declined at 2, 4, 8 h after the end of stress, the expression of pS2 and ITF was increased during the healing of stress-induced ulceration, there was not a correlation between the expression of pS2 or ITF and UI.

The facts that pS2 or ITF is over-expressed in gastric mucosa immediately after stress injury and that this peptide stimulates cell migration, strongly suggest that it might mediate the early phase healing of acute gastric lesion called restitution[24-28].

It has also been proposed that trefoil peptide family contribute to gastric mucosal defence and repair by affecting cell proliferation[29,30].

In the present study, we found this adaptation was accompanied by an increased mucosal cell proliferation and enhanced expressions of mRNA for pS2 and ITF, suggesting the involvement of pS2 and ITF in the adaptation process.

The major finding of this report was the demonstration for the first time that gastric adaptation to WRS involved overexpressions of mRNA for pS2 and ITF and an increased rate of cell proliferation in gastric mucosa, and enhanced cell proliferation was preceded by overexpressions of pS_2 and ITF mRNA, although the expressions of mRNA for pS_2 and ITF decreased in initial phase after exposure of gastric mucosa to WRS, suggesting that this trefoil peptide contributes to cell proliferation.

The present study also showed that with repeated WRS, adaptative cytoprotection against stress was developed, the mucosal lesions reduced markedly after 2nd, 3rd and 4th WRS. The expression of pS2 and ITF was increased. There was a significantly negative relevance between expressions of pS2 or ITF and UI.

After the 4th WRS, GMBF was almost restored to normal level. Therefore, during the process of tolerant cytoprotection, GMBF, UI and expression of pS2 and ITF showed regular

changes and there was a good relationship beween them.

Indeed, we have confirmed that WRS-adapted mucosa exhibits an augment GMBF, but it is not clear whether this factor could directly or indirectly account for the mucosal adaptation, or what could be the mechanism of this mucosal hyperemia in the stomach. TGFα has been shown to increase GMBF[2,31], while TFF can promote synthesis of TGFα. So hyperemia observed during the development of adaptation can be mediated, at least in part by the release of this peptide.

Abstract

AIM: To clone human 15ku selenoprotein gene.

METHODS: H9 human T cells were cultured in RPMI1640 medium supplemented with 100 mL /L fetal calf serum. mRNA was isolated from the cells. cDNA library was constructed by RT-PCR. The human 15ku selenoprotein gene was obtained by PCR and cloned into T vector and sequenced.

RESULTS: A unique cDNA fragment about 1 244 bp was obtained. Sequence analysis identified an open reading frame within the cDNA. The gene had an in-frame TGA, which encoded selenocysteine (Sec), and a 3'-UTR SECIS element, which was required for synthesis of selenoprotein. The predicted protein molecular mass was about 15ku (162 residues). The result was identical with human liver 15ku selenoprotein gene published in Genbank.

CONCLUSION: Human 15ku selenoprotein gene can be successfully obtained from T cell line.

INTRODUCTION

The trace element selenium (Se) is an essential human nutrient[1]. It has been shown to prevent cancers, especially liver and stomach cancers[2] in both epidemiological studies and clinical supplementation trials[3]. However, the mechanism by which Se suppresses tumor development remains unknown. Se is present in known human selenoproteins as amino acid selenocysteine (Sec)[4]. Sec is the active form of Se in selenoproteins and has important biological functions. Recently, a human 15ku selenoprotein (Sep15) containing Se in the form of Sec was identified. It was an acid protein with a PI value of 4.5. It was recently identified in human T cells[5, 6] and was present in various human tissues, such as liver, kidney, testis and brain, but it was highly expressed in epithelial cells of the prostate gland[6] and thyroid[5]. The level of this selenoprotein was reduced substantially in hepatocellular carcinoma[7] and in a malignant prostate cell line[8]. Furthermore, epidemiological data have indicated a statistically significant inverse correlation between Se in the diet and occurrence of liver cancer. These facts have provoked our interest to study Sep15. The recent finding that the gene of Sep15 was located on human chromosome 1p31, often affected in human cancer[9], also supports the hypothesis that this protein might play a role in the development of cancers[5]. To get a better understanding of the relationship between Sep15 and tumor, and the mechanism by which it suppresses the tumor, we firstly cloned the gene of this selenoprotein.

MATERIALS AND METHODS

Materials

H9 T cell line was purchased from ATCC. RPMI1640 was purchased from Gibco. Fetal bovine serum was from Hangzhou Sijiqing Company. Main biochemical reagents of T vector, T4 DNA ligase, *Taq* DNA polymerase and Trizol reagent were from Promega. Small amount plasmid extraction kit and PCR products purification kit were from Huashun Shengwu Engineering Company. Bacteria species JM109 was from the Department of Biochemistry of the Fourth Military Medical University. Agarose was from Huamei Shengwu Engineering Company. The restriction endonuclease *Not* I was from Takara. RNA extraction kit was from Promega. RT-PCR kit was from American Bior' s Company. The primers were synthesized by Georgia University of America. The forward primer was 5'-AGCGATGGCGGCTGGGCCGAG-3'. The backward primer was 5'-GATTTTTGAAACTTTTTATTTATA-3'.

Methods

mRNA extraction of H9 T cells H9 T cells were cultured in the RPMI1640 containing new born bovine serum under the condition of 50 mL/L CO_2 at 37 ℃ in a CO_2 incubator. About 10^7 H9 T cells were absolutely split with trizol reagent. Total RNA was extracted with chloroform, deposited with isopropanol, then dried at 37 ℃. mRNA was isolated with a mRNA purification kit from Promega[10]. The procedure in details was performed according to the instructions of the kit.
RT-PCR[11] By using the reverse transcription system from Promega[12], cDNA synthesis was performed according to the following instructions. mRNA previously extracted and random hexamers were used to synthesize first strand of cDNA[13], which was used to synthesize the double-strand DNA in the latter PCR[14]. PCR was performed as follows[15, 16]. The total volume of the PCR amplification system was 100 μL. First, 10 μL reverse transcription reaction liquid, 4 μL 20 pmol/L primers (each 2 μL), 8 μL 10 mmol/L dNTP, 10 μL 10×PCR reaction liquid, and 10U *Taq*DNA were added consecutively, then water was added to a total volume of 100 μL. The PCR was performed by incubating at 94 ℃ for 2 min, at 94 ℃ for 1 min, at 55 ℃ for 1 min, at 72 ℃ for 1 min, totally 35 cycles. The reaction mixture was incubated at 72 ℃ for 7 min. Finally all the PCR products were used for 10 g/L agarose gel electrophoresis to purify the products. Purification was performed according to the instructions of the gel extraction kit from Huashun Company.
Linkage and conversion 5 μL T vector, 1 μL T_4DNA ligase,

1 μL 10×buffer were added into previously purified PCR products, incubated at 16 ℃ overnight. 5 μL linkage products was picked up to infect competence bacteria of JM109. The conversion products were spread on a LB agarose plate containing ampicillin at 37 ℃ overnight.

Restriction endonuclease digestion and evaluation First, 3 monoclonal colonies were randomly chosen, and put into 10 g/L LB containing ampicillin, the culture was shaken at 37 ℃ overnight in air bath, then the plasmid of $P^{GEM\text{-}T\text{-}15ku\text{-}selenoprotein}$ was extracted. The procedure was performed according to the instructions of the low-dose plasmid extraction kit from Huashun Company. 5 μL previously extracted plasmid was digested with *Not* I. The reaction system containing 5 μL plasmid, 1 μL *Not* I, 2 μL 10×BSA buffer, 2 μL 10×H buffer, 2 μL 10×TritonX-100, and 8 μL sterilized water was performed at 37 ℃ for 3 hours. Finally 5 μL reaction mixture was used for 10 g/L agarose gel electrophoresis for 45 minutes. At the same time, the plasmid DNA was sent to the laboratory of Georgia University in America to sequence the DNA.

RESULTS

Sep15 gene amplification

After 35 cycles of RT-PCR, 5 μL PCR products were used for 10 g/L agarose gel electrophoresis. When compared with the DNA marker, cDNA fragment was between 1 000 bp and 2 000 bp. It was coincident with the length of purposed gene (Figure 1).

Figure 1 Agarose gel electrophoresis of RT-PCR amplified Sep15 gene fragment.

Sep15 gene cloning and its digestion and evaluation

After 3 monoclonal colonies were randomly chosen, the plasmid was extracted and digested with *Not* I. Then, 5 μL was used for 10 g/L agarose gel electrophoresis, the straps were found to be coincident with the length of purposed gene (Figure 2).

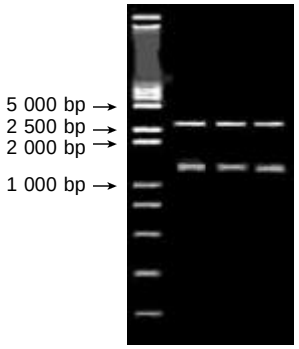

Figure 2 *Not* I cut plasmid of $P^{GEM\text{-}T\text{-}15ku\text{-}selenoprotein}$.

DNA sequencing

The sequencing of $P^{GEM\text{-}T\text{-}15ku\text{-}selenoprotein}$ showed that the Sep15 gene we cloned was completely coincident with the sequence in GenBank. It was 100 % homology with the human Sep15 gene. The sequences were as follows.

DISCUSSION

Se was recognized as an essential trace element in human and animal' s life by WHO in 1978. The relationship between Se and many kinds of disease including cancer is a hot point of medical research[17, 18]. Usually, Se is incorporated into proteins in the forms of selenocysteine (Sec) and selenomethionine (SeMet). The term "selenoprotein" is restricted to the proteins which contain Se in the form of selenocysteine[19]. Selenoproteins are distinguished from proteins which nonspecifically incorporate selenomethionine not contributing to the biological function of the Se. About 21 specific selenoproteins have been identified in mammals and bacteria, and 18 of them could have biological functions attributed to them. Mammalian Se-containing proteins can be divided into three groups: proteins containing nonspecifically incorporated Se, specific Se-binding proteins, and specific selenocysteine-containing selenoproteins[5]. Selenoproteins with a known function identified so far include five glutathione peroxidases, two deiodinases, several thioredoxin reductases, and selenophosphate synthetase 2. Sep15, selenoprotein P, selenoprotein W, an 18-ku selenoprotein and several selenoproteins identified in silico from nucleotide sequence databases have been found to contain selenocysteine, but their functions are not known. Gel electrophoretic separation of tissue samples from rats labeled with ^{75}Se showed the existence of further Se-containing proteins[5].

It has been shown that Se could prevent cancer in a variety of animal model systems[20, 21]. Both epidemiological studies and supplementation trial supported its efficacy in humans[22]. However, the mechanism by which Se suppresses tumor development remains unknown[23]. Se is present in known human selenoproteins as selenocysteine. Selenocysteine represents the 21st amino acid and is encoded by UGA triplet in selenoprotein mRNA[24, 25]. Although UGA most often functions as a stop codon, UGA-encoded incorporation of selenocysteine into the growing polypeptide is determined by the presence of a specific stem-loop secondary structure within the 3' -untranslated region of the selenoprotein mRNA[26]. Sep15 was firstly found in human T cells, and it contains a selenocysteine residue encoded by TGA. Its coding sequence has no homology to known protein-encoding genes. Computer analysis of transcript map databases indicated that this gene included five exons and four introns[27]. Recent findings indicate that the chromosome, in which the gene of Sep15 is located, is a genetic locus commonly mutated or deleted in human

cancers. One in-frame TGA codon and two stem loop structures resembling selenocysteine insertion sequence (SECIS) elements were identified in the 3' -untranslated region of the gene, and only one of them was functional[9]. Examination of the available cDNA sequence of this protein revealed that two polymorphisms were located at position 811(C/T) and 1 125 (G/A)[28] within the 3' -untranslated region. They were organized into two alleles, C^{811}/G^{1125} and T^{811}/A^{1125} in the 68 %/32 % frequency distribution. These 3' -untranslated region polymorphisms resulted in changes in selenocysteine incorporation into protein and different response. To Se supplementation[9]. Human epidemiological studies have revealed that Se has a negative correlation with the occurrence of prostate cancer[29, 30] and lung cancer[31]. Moreover, recent investigations have shown that Se supplementation may be effective on the reduction of common human cancers, including prostate cancer[9], colon[32] cancer and lung cancer. Northern blot analysis of the human Sep15 mRNA demonstrated that the expression of Sep15 was significantly decreased in malignant prostate cancer cell line and in hepatocellular carcinoma cell line. The Sep15 protein levels in liver tumors, adjacent tissues, and normal hepatic tissue were significantly different. The Sep15 level was significantly decreased in tumors compared with that in the normal control. It was consistent with the observation that Sep15 protein was not detectable in mouse prostate adenocarcinoma cells, while normal mouse prostate showed a strong signal with Sep15 protein-specific antibodies.

Different expression patterns of the Sep15 protein in normal and malignant tissues, the occurrence of polymorphism associated with protein expression, the role of Se in differential regulation of polymorphisms, and loss of heterozygosity at the Sep15 locus in certain human tumor types make us suggest that Sep15 may be involved in cancer development[28]. We have cloned the gene of Sep15 in our country for the first time in order to study the expression of Sep15 protein in different tissue, its structure, function and the relationship with cancer due to the worldwide cancer[33-37] , and digestive in china[38-40].

Abstract

AIM: To explore molecular mechanism of nicotinamide adenine dinucleotide (NADH) antagonization against X-ray induced L02 cells damage.

METHODS: L02 liver cells were cultured in RPMI 1640, exposed to X-ray irradiation and continued to culture in the presence or absence of NADH. Cellular viability was analyzed by routine MTT methods. The percent age of apoptotic cells and positive expressions of p53, bax and bcl-2, fas, fasL proteins were determined by FCM. Level of intracellular ROS was determined by confocal microscope scanning. Morphological change was detected by scanning electron micrograph.

RESULTS: The viability of L02 cells was decreased with increasing dose of X-ray irradiation. NADH could not only eliminate the apoptosis induced by X-ray irradiation, but also up-regulate expression of bcl-2 protein and down-regulate expression of p53, bax, fas and fasL proteins ($P<0.05$). At the same time, NADH could reduce level of intracellular ROS in radiated L02 cells.

CONCLUSION: NADH has marked anti-radiation effect, its mechanism may be associated with up-regulation of bcl-2 expression and down-regulation of p53, bax fas and fasL expression, as well as decline of intracellular ROS. However, further investigation of its mechanism is worthwhile.

INTRODUCTION

Recent radiobiological studies have demonstrated that ionizing radiation can induce cell death. Exposure of cell to ionizing radiation over a wide dose range results in activation of cellular response pathways, including p53-dependent and p53-independent ways[1,2]. At the same time, apoptosis resulted from a coordinate sequence of biochemical events eventually leads to cell death. Among these,the generation of ROS with perturbation of prooxidant/antioxidant ratio, alterations in mitochondria structure and $\triangle \Psi m$, and diminutions of plasma membrane potential have been investigated[3,4]. The stabilized electrochemical gradient relies on a functional ion exchange via the electrogenic transporter Na+/K+-ATPase. Na+/K+-ATPase is an energy hungry process which consumes a major of cellular ATP production. Therefore, there may be a decrease of ATP level when apoptosis starts within a few minutes after ionizing irradiation. NADH, an important coenzyme, participates in three carboxyl cycles and ultimately produces ATP molecules. We added NADH to L02 cells undergoing X-ray irradiation *in vitro*, and observed change of survivals and apoptosis as well as radiation associated proteins which take part in signal transduction of apoptosis.

MATERIALS AND METHODS

Reagents

NADH (purity: 97 %) was gifted by Professor Birkmay from Chemical Department of Graz University. Monoclonal mouse anti-p53, bcl-2, bax antibodies and rat anti-Fas, FasL antibodies were from Beijing Zhongshan Biotechnology Company. PI/Annexin V kits were purchased from Immunotech (France). High FITC-labeled goat anti-mouse antibodies were from Zhongshan Company. H_2DCF probe was purchased from America Molecular Probe Company.

Cell lines and culture

Normal human liver cell line L02 was purchased from Shanghai Institute of Cell Biology, Chinese Academy of Sciences. The cells were cultured in RPMI 1640 supplemented with streptomycin (50 U/ml), glutamate (2 mM) and 10 % fetal bovine serum.

Induction of apoptosis

The L02 cells were seeded in 6-well tissue cultured plates, the supernatant was discarded and 0.01 M PBS (pH 7.4) was added. The L02 cells were X-ray-irradiated with 2.5, 5.0 and 7.5 Gy. The cells were then cultured in a complete medium in the presence or absence of NADH at a concentration of 400 ug/ml, respectively. Non-irradiated culture served as control.

MTT cell viability assay

The cells were seeded into 96-well dishes (5×10^3 cells/well), incubated for 24 h to allow attachment, treated with X-ray at 5.0 Gy, and continued to culture for 12, 24, 36, 48 h in the presence or absence of NADH. Absorbance was read at 570 nm by using DG3022 ELISA according to the routine MTT methods. The cellular viability was calculated as the amount of MTT uptake[5].

Assessment of apoptotic cells

The L02 cells were seeded at 5×10^4-5×10^5/ml in 6 well tissue cultured plates and cultured for 48 hours in RPMI-1640 medium containing 10 % FBS. Apoptosis was induced by X-ray irradiation, the LO2 cells were continued to culture for 24 h. A total of 5×10^5-5×10^6/ml cells were collected by centrifugation at 200 g (×5 min) and washed twice with ice-cold PBS (pH 7.4). Percent age of apoptosis was detected by flow cytometry according to PI/Annexin V kits.

Scanning electron microscope

24 hours following exposure to 2.5 Gy X-ray radiation, the L02 cells were fixed for 1 hour at room temperature using 4 % glutaraldehyde in PBS and proceeded for scanning electron microscopy as routine methods.

Protein expression of bcl-2, bax, fas, FasL and p53

The L02 cells were collected and then washed twice with ice-cold PBS, followed by fixation in 0.5 % paraformaldehyde at 4 ℃ for 30 min. The fixated cells were treated with PBS containing 0.1 % Triton-100 and washed twice. The treated cells of every tube were divided into five tubes and washed. The supernatant was aspirated. The antibodies against bcl-2, bax, p53, fas, FasL were added into each tube, mixed and incubated for 1 h at 37 ℃. The cells were washed twice and the FITC-labeled second antibodies were added for 30 min at 37 ℃. Then, the cells were washed twice with ice-cold PBS and resuspended with 500 μl PBS. 10 000 events were analyzed and the positive rate of protein expression was detected by FCM.

Determination of intracellular ROS concentration

The cell suspension was dispensed into special culture plates at a density of 2×10^4 cells per ml and incubated at 37 ℃, 5 % CO_2 for 48 h. The supernatant was removed and replaced with Hank' s solution , then exposed to 2.5 Gy X-ray radiation. The supernatant was discarded at once, and replaced with RPMI-1640 medium with or without NADH at a concentration of 400 ug/ml for 4 h, respectively. Non-irradiated culture served as control, followed by washing three times with Hank' s solution. Measurement of intracellular ROS concentration was described in literature. Briefly, the cells were loaded with 0.5 ml H_2DCF in DMSO solution at 5 μg/ml and incubated at 37 ℃ for 30 min. After washed three times with PBS, 0.5 ml PBS was loaded and the change of intracellular ROS was detected by scanning fluorescence intensity under confocal microscope.

RESULTS

X-ray treatment inhibited growth of L02 cells

The L02 cells were treated with different doses of X-ray irradiation. Cell survival was determined after 12, 24, 36, 46 h. Inhibition of growth in X-ray treated cells occurred in a dose-dependent manner (Figure 1). Survival of L02 cells decreased as the dose of X-ray increased. It was most obvious at 24 h post-irradiation.

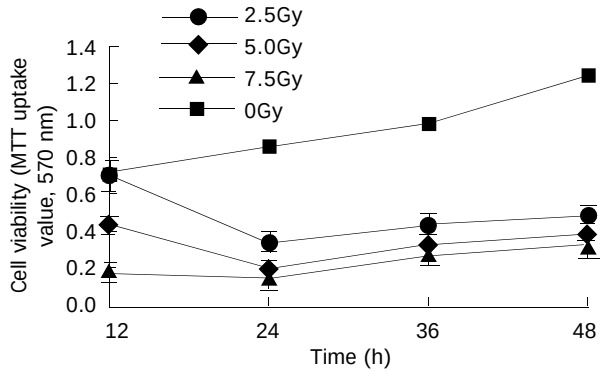

Figure 1 X-ray induced inhibition of growth of L02 cells.

NADH antagonized apoptosis of X-ray treated L02 cells

The L02 cells were treated with 2.5, 5.0, 7.5 Gy X-ray irradiation, then post-incubated in fresh complete RPMI 1640 medium containing NADH or NADH free drug for 24 h. Percent age of apoptosis was determined by FCM using PI/ Annexin V stain method. The results showed that NADH diminished apoptosis of L02 cells exposed to X rays. The percent age of apoptosis was (7.08±2.34) %, (28.16±2.46) %, (47.30±3.43) % in the absence of NADH. However, it was (6.04±0.86) %, (8. 25±1.64) %, (15.30±1.98) % in the presence of NADH. The difference was significant between L02 cells treated with 5.0 Gy,7.5 Gy X rays and cultured for 24 h in the presence of NADH and L02 cells cultured in the absence of NADH ($P<0.05$). These findings suggested that NADH was involved in cytoprotection by blocking the induction of apoptosis.

NADH rescued L02 cells damage from X-ray radiation

X-ray radiation could induce L02 cells damage. As shown in Figure 2, Part(b) and part(c) represented different morphologic changes of 2.5 Gy X-ray radiated L02 cells in the absence or presence of NADH. Part(a) represented the shamly irradiated L02 cells, which had normal liver cell surface structure with normal protuberance and volume. But, Part(b) had decreased protuberance and atrophy. However, degree of damage in L02 cells of part(c) group was becoming less than that of part(b). These suggested that NADH could rescue L02 cells damage from X-ray irradiation.

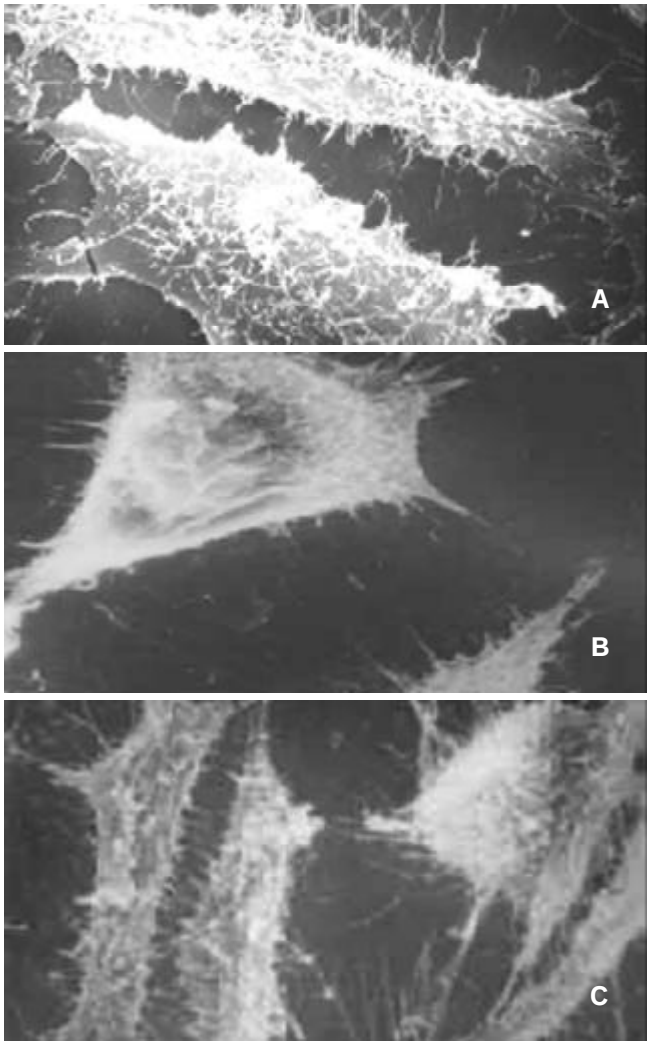

Figure 2 The result of scan electron microscopy. (a) Normal liver cell surface structure. (b) Irradiated hepatocytes with atrophy and decreased protuberance. (c) Morphological changes of hepatocytes irradiated and incubated in the presence of NADH.

Expression of p53, bax, bcl-2, Fas and Fas-L in L02 cells

The results of FCM analysis for p53, bax, bcl-2, Fas and FasL protein expression in X-ray irradiated and mockly irradiated

L02 cells are summarized in Table 1. Significantly high levels of p53, bax, Fas and Fas-L protein expression were detected in cells irradiated and cultured in the absence of NADH than in those cells cultured in the presence of NADH and mockly irradiated, but expression of bcl-2 protein tended to be low in L02 cells. Our results showed that NADH up-regulated expression of bcl-2 protein and down-regulated expression of p53, bax, bcl-2, Fas and FasL protein in L02 cells undergoing X ray irradiation. It might be one of the mechanisms that NADH rescues L02 cells injury from ionizing irradiation.

Table 1 Effect of NADH on regulation of apoptosis associated proteins in L02 cells treated with X-ray (n=3, $\bar{x}\pm s$)

Group	p53	Fas	FasL	bcl-2	bax
Mock IR	22.40±0.91	7.01±0.21	66.66±1.60	5.27±0.12	74.71±1.81
IR	37.4±1.11[a]	13.40±0.78[a]	74.40±1.09[a]	2.22±0.18[a]	86.76±2.14[a]
IR+NADH	26.93±6.73	11.29±1.40	68.93±1.88	3.62±1.34	71.60±2.92

Based on *t* test, "Mock IR" represented L02 cells of non-irradiated group. "IR+NADH" represented L02 cells irradiated and continued to culture in the presence of NADH. [a]P<0.05 *vs* Mock IR group and IR+NADH group.

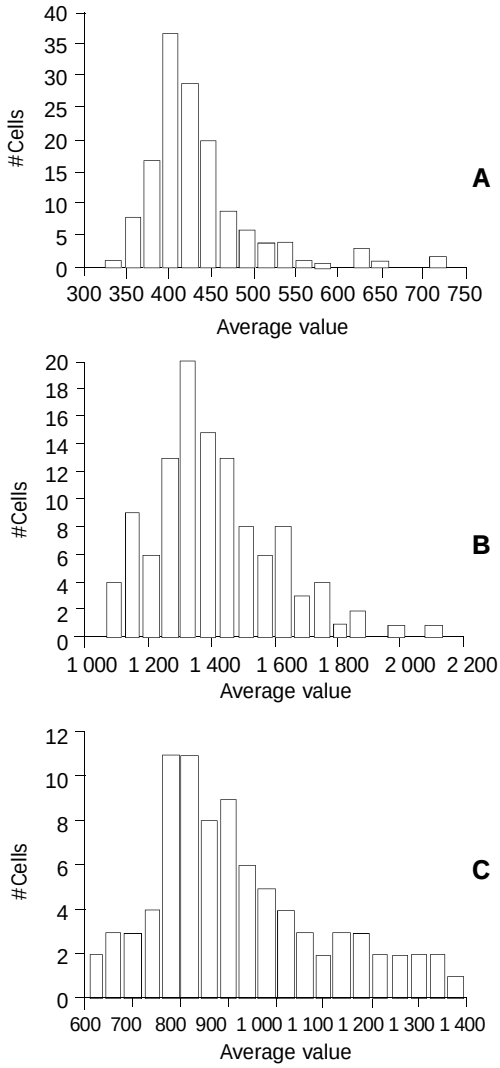

Figure 3A The change of intracellular H_2O_2 production in L02 cells cultured with or without NADH for 4 h after X-ray irradiation. (a) Sham irradiation group. (b and c) X-ray treated (2.5 Gy) L02 cells were respectively cultured in the absence or presence of NADH. Mean value of fluorescence was calculated according to the number of L02 cells. [a]P<0.05 compared with sham irradiation (a) and test group (c).

Determination of intracellular ROS

Figure 3A and Figure 3B show that 2.5 Gy X-ray irradiation increased the level of intracellular ROS after 4 h irradiation in L02 cells compared with that in L02 cells of sham irradiation group. However, NADH could reverse the effect of X-ray irradiation.

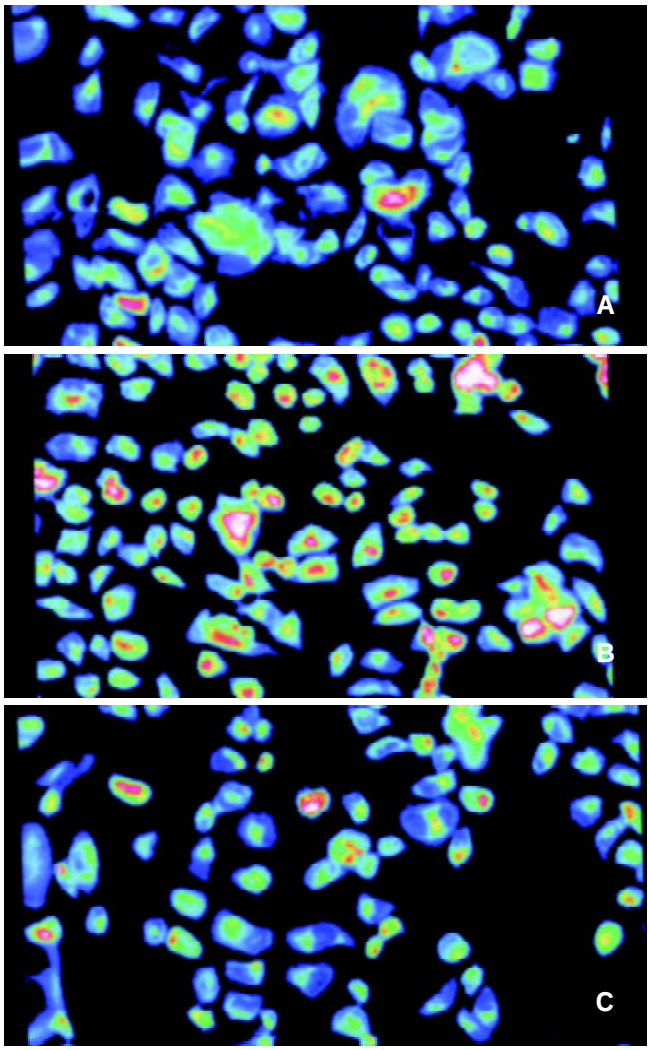

Figure 3B The graph showed the cell fluorescence change of intracellular ROS by confocal microscope scanning in L02 cells of different treatment.

DISCUSSION

When a cell exposed to ionizing irradiation, at least two signal-generating targets are activated, one at the membrane and the other at the DNA. Signal may also originate in cytoplasm[6,7]. These signal targets ultimately result in cell death or non-death stress response. Apoptosis, also called programmed cell death (PCD),is a peculiar form of cell death characterized by several morphological and biochemical aspects which are different from necrosis, an other form of death. X-ray irradiation is one of the ionizing radiations, which can cause both membrane and DNA damage to cells and result in cell apoptosis. How ionizing radiation triggers apoptosis is not known. It was reported that apoptosis mediated by DNA damage occurred via p53-dependent and p53-independent pathways[1,2]. However, several pathways of apoptosis have been reported. One of these is the Fas/FasL pathway, which involves binding of a death receptor to a death domain, initiating a cascade of proteases that leads to cell apoptosis[8]. In the present study, we tested whether apoptosis induced by X-ray irradiation

occurred via DNA damage or Fas/FasL pathway. Our results demonstrated that X-ray irradiation led to cell apoptosis by increasing positive rate of L02 cells expressing p53 and bax proteins, and decreasing positive rate of bcl-2 protein. At the same time, Fas and FasL expression in L02 cells exposed to irradiation was up-regulated as compared with that in mockly irradiated-cells.

Cellular sensitivity to radiation reflects a culmination of distinct molecular pathway including DNA repair, cell cycle checkpoint fidelity, and particularly apoptosis. Several oncogenes and tumor suppressor genes play a pivotal role in modulating the response of cells to radiation. An important molecule, p53, initiates responses to DNA damage, and affects the sensitivity of cells to apoptosis. Functional inactivation of p53 is associated with resistance to radiotherapy. Overexpression of wtp53 gene was found to be associated with increased cellular sensitivity to apoptosis induced by ionizing irradiation[9,10]. Bcl-2, an important regulator of apoptosis, was found to be associated with anti-apoptosis response. Over expression of bcl-2 by transferring bcl-2 gene into deficient cells has been associated with increased cellular resistance to induction of apoptosis by a variety of DNA-damaging agents including ionizing irradiation, drugs. However, bax, another member of bcl-2 family, as an inhibitor of apoptosis, can bind bcl-2 to form homo- and heterodimers. Rate of bcl-2 to bax may determine the extent to which apoptosis is induced or suppressed[11,12]. At the same time, high expression of wild - type p53 protein induced by ionizing irradiation appears to regulate expression of bcl-2, bax, p21 and p16 genes[13]. Our results showed that X-ray radiation induced DNA damage resulted in an increase of positivity of p53 and bax protein expression, and decrease of bcl-2 protein expression in L02 cells. But it is necessary to further confirm whether p53 may regulate expression of bcl-2 and bax genes.

Recently, it has been suggested that Fas/FasL system plays a key role in the regulation of apoptosis. Fas is located on the plasma membrane of hepatocytes abundantly, and FasL, a glycoprotein of 40 kd is located on the plasma membrane of the lymphocytes. The interaction of the Fas ligand and Fas receptor initiates a chemical process in the cells that leads to apoptosis. Fas, named CD95, expresses in alcoholic liver disease, viral hepatitis, hepatocarcinomas, and hepatocirrhosis[14-16]. Fas-FasL interaction may contribute to hepatocyte apoptosis in these patients. It was rarely reported that apoptosis induced by ionizing irradiation occurred via Fas-FasL interaction pathway, particularly apoptosis induced by Fas-FasL interaction itself in hepatocytes. It was recently reported that the Fas/Fas ligand system was involved in modulating keratocyte apoptosis induced by UV irradiation[17]. Newton reported that apoptosis induced by ionizing radiation required p53 and was regulated by the Bcl-2 protein family but did not require signals transduced by Fas and FADD/MORT1[18]. Our experiment indicated that X-ray irradiation enhanced the positive rate of L02 cells expressing Fas and FasL protein as compared with shamly irradiated cells. It is suggested that FasL-Fas interaction play an important role in liver cell apoptosis induced by X-ray irradiation. It is different from the model in which ionizing irradiation triggers apoptosis via p53-dependent activation of caspase-9.

Several biochemical alterations, including excessive generation of reactive oxygen species (ROS), calcium flux, Caspase activation, have been shown to be essential in cell apoptosis[19-21]. ROS plays a pivotal role in ionizing irradiation -induced cell apoptosis[22-24]. ROS, as a signal molecule, could regulate gene expression and mitochondria membrane potential[25,26]. Free radicals are an integral part of metabolism and formed continuously in the body. Many sources of stress heat, irradiation, hyperoxia, inflammation and any increases in metabolism including exercise, injury, and even repair processes lead to increased production of free radicals and associated reactive oxygen or nitrogen species (ROS/RNS)[27-29]. Evidences have shown that free radicals have important functions in the signal network of cells, including induction of growth and apoptosis and as killing tools of immunocompetent cells[30,31]. Massive intervention into the redox state by pharmaceutical doses of exogenous antioxidants should be considered with caution due to the ambiguous role of free radicals in regulation of growth, apoptosis, and cytotoxicity of immunocompetent cells. Our results showed that X-ray irradiation could give rise to increases of ROS generation after 4 h irradiation, but NADH could reverse the effect of X-ray irradiation, lower the level of intracellular ROS. These results indicated that NADH rescued L02 cells damage from X-ray irradiation by regulation of ROS generation.

NADH, a kind of important coenzyme, takes part in triggering biological anti-oxidation and regulating the expression of membrane glycoprotein receptors[32]. But it was seldom reported that NADH played a role in antagonizing ionizing irradiation induced apoptosis and regulating expression of membrane receptors. Recently, it was reported that the content of intracellular NADH changed after UV or ionizing irradiation[33,34]. Most of the results indicated that the content of intracellular NADH declined after ionizing irradiation or PDT treatment by confocal microscope scanning analysis. Pogue reported that the endogenous fluorescence signal attributable to reduced nicotinamide adenine dinucleotide (NADH) was measured in response to photodynamic therapy (PDT)-induced damage. Measurements on cells *in vitro* have showed that NADH fluorescence decreased relatively to that of controls after treatment with a toxic dose of PDT, as measured within 30 min after treatment. Similarly, assays of cell viability indicated that mitochondria function was reduced immediately after treatment in proportion to the dose delivered[35]. It was seldom reported that signal transduction molecules changed after ionizing irradiation by extraneously added NADH. Recent studies of repairing ionizing irradiation injury focused on antioxidant drugs. Bush reported that NAC could protect immune function and regulate expression of oncogenes in bone marrow cells exposed to ionizing irradiation[36]. Zhou found that bilobalide might block PC12 cells from reactive oxygen species-induced apoptosis in the early stage and then attenuate the elevation of c-Myc, p53, and Bax and activation of Caspase-3[37]. Our results indicated that expression of p53, bax, Fas and FasL proteins was up-regulated and expression of bcl-2 protein was down-regulated in L02 cells undergoing X-ray irradiation. However, when L02 cells undergoing X-ray irradiation continued to culture in the presence of NADH, expression of p53, bax, Fas and FasL proteins were down-regulated and expression of bcl-2 protein was up-regulated. At the same time, level of intracellular ROS declined, survival of cell increased. Our observations provide evidence that NADH is a new kind of radiation protector.

Abstract

AIM: To investigate the effect of gastrin on differentiation of IEC-6 cell line *in vitro*.

METHODS: IEC-6 cells were incubated with gastrin. On day 7 after treatment, cell morphology was examined by light microscope, and on day 20, the cellular ultrastructures were examined by electron microscope. After exposure to gastrin for 6 hours, villin mRNA was analyzed by reverse transcription-polymerase chain reaction, and on day 7, the expression of villin was examined by immunocytochemical analysis with laser confocal microscope.

RESULTS: After exposure to gastrin, IEC-6 cells showed differentiated phenotypes as villas enterocytes and contained an abundance of plasma, small nuclei with nucleoli, and were arranged regularly. There were numerous microvilli around edge of the cells, and several cells showed columnar structures. Villin mRNA expression in cytoplasm was increased in comparison with control.

CONCLUSION: Differentiated characteristics of villus enterocytes and phenotypic changes of rat intestinal epithelial cells (IEC-6) are induced by gastrin, and the effects of gastrin are correlated to increased villin expression.

INTRODUCTION

Gastrin stimulates cell proliferation in gastric mucosa under physiological conditions[1]. Studies have demonstrated that gastrin many increase ornithine decarboxylase activity of IEC-6 cells, cause intracellular polyamine synthesis, and therefore promote cell proliferation[2,3] and migration[4]. Polyamine has been demonstrated to be closely correlated to cytoskeleton reconstitution, an important process of cellular differentiation[5-9], but it is not clear yet whether gastrin plays roles in differentiation of IEC-6 cells. This study was to investigate gastrin-induced morphological changes of intestinal epithelial cell (IEC-6) and the intracellular expression of villin.

MATERIALS AND METHODS

Cell culture

IEC-6 cells (ATCC, Rockville, MD) were grown at 37 ℃ in a 900 mL· L^{-1} air-100 mL· L^{-1} CO_2 atmosphere in Dulbecco' s modified Eagle' s medium (pH7.2) containing 50 g· L^{-1} dFBS, 10 mg· L^{-1} insulin, 50 mg· L^{-1} gentamycin sulfate, and subcultured once a week. When cultured cells became confluence, they were dissociated with 0.5 g· L^{-1} trypsin and 0.2 g· L^{-1} EDTA, and seeded into 6-well cell culture plates. Pentagastrin (Sigma. Louis, MO) was dissolved in two or three drops of 300 g· L^{-1} ammonium hydroxide (sterile), the solution was adjusted to pH 7.5, and then diluted with medium to 62.5 mg· L^{-1} before use.

Morphology

Light microscopy Monolayer of IEC-6 cells was prepared on glass coverslips, which were placed in 6-well cell culture plates (Corning Glass Works). The cells were seeded at a concentration of 1.0×10^5 per well, and incubated at 37 ℃ in a 900 mL· L^{-1} air-100 mL· L^{-1} CO_2 atmosphere for 24 h. The media containing cDMEM 2 000 μL, PBS 490 μL and 10 μL pentagastrin solution were replaced to make a final concentration of pentagastrin 250 μg· L^{-1} in culture. The medium in control group was the same as that in the treatment group except gastrin. Cells were harvested on day 7 from the initial treatment. The coverslips were removed and fixed for 15 min at room temperature in 3.5 % paraformaldehyde in PBS, washed with distilled water, followed by HE staining and examined under light microscope.

Electron microscopy The cells were seeded in 6-well cell culture plates with a concentration of 1.0×10^5 per well under the same culture condition as above. Cultured cells were harvested on day 20 from the initial treatment of gastrin, washed with PBS, fixed in 2 % glutaraldehyde, postfixed in 1 % osmium tetroxide, dehydrated, and embedded in Epon, and examined under electron microscope.

Villin expression

mRNA level analysis After incubated with gastrin for 6 hours, cultured cells were harvested for extraction of total RNA with RNA TRIzol reagent (Gibco, Gaithersburg, MD). Isolation was performed according to the manufacturer' s protocols. The concentration of extracted RNA was determined. RT-PCR kit (Gibco, Gaithersburg, MD) was used for RT-PCR reaction following the attached protocol of the product. The primers (Seagon, Shanghai, China) were synthesized according to sequences of rat villin gene (GenBank™ accession number M98454) as follows: coding strand primer: 5' -ATG CCC AAG TCA AAG GCT CTC TCA ACA TCA C-3' , noncoding strand primer: 5' -TGC AAC AGT CGC TGG ACA TCA CAG G-3' [10]. The reference primers (Seagon, Shanghai, China) were according to sequences of rat β-actin gene (GenBank™ accession number AB028846) as follows: coding strand primer: 5' -TTC CAG CCT TCC TTC CTG G-3' , noncoding strand primer: 5' -TTG CGC TCA GGA GGA GCA AT-3' . 2 μL of

RT products was added to the PCR master mix. After incubation at 94 ℃ for 2 min, reaction was done for 35 cycles at 94 ℃ for 60 s, at 55 ℃ for 60 s, and at 72 ℃ for 30 s. The expected cDNA amplification products were 408 bp for villin and 238 bp for β-actin. After electrophoresis on agarose gel and staining with ethidium bromide, DNA bands were visualized with an ultraviolet transilluminator.

Protein level analysis On day 7 from the initial treatment, cultured cells were fixed for 15 min at room temperature in 3.5 % paraformaldehyde in PBS, and washed three times. For study of villin expression, the cells were permeabilized by incubation with 0.2 % Triton X-100 in PBS for 4 min, washed three times with PBS, and then treated with goat serum for 10 min. The permeabilized cells were incubated with goat anti-rat antibody with dilution of 1:100 in PBS (Santa Cruz) for 2 hours at room temperature, washed, and then incubated with FITC-conjugated rabbit anti-goat IgG with dilution of 1:50 in PBS (Sigma. Louis, MO). The treated cells were visualized under TCS SP confocal laser scanning microscope (Leica, Heidelberg, Germany).

RESULTS

Effect of gastrin on morphology of IEC-6 cells

Light microscopy Seven-days after treatment with gastrin, cells were arranged regularly with an abundance of plasma, and small nuclei with nucleoli. Typically differentiated cells showed a tendency to form microvilli on the edge, and remarkable cytoskeleton-like structure, which was similar to cytoskeleton distribution in well-differentiated enterocytes. Cells in control group contained sparse plasma, large nuclei without nucleoli, and were arranged irregularly (Figure1).

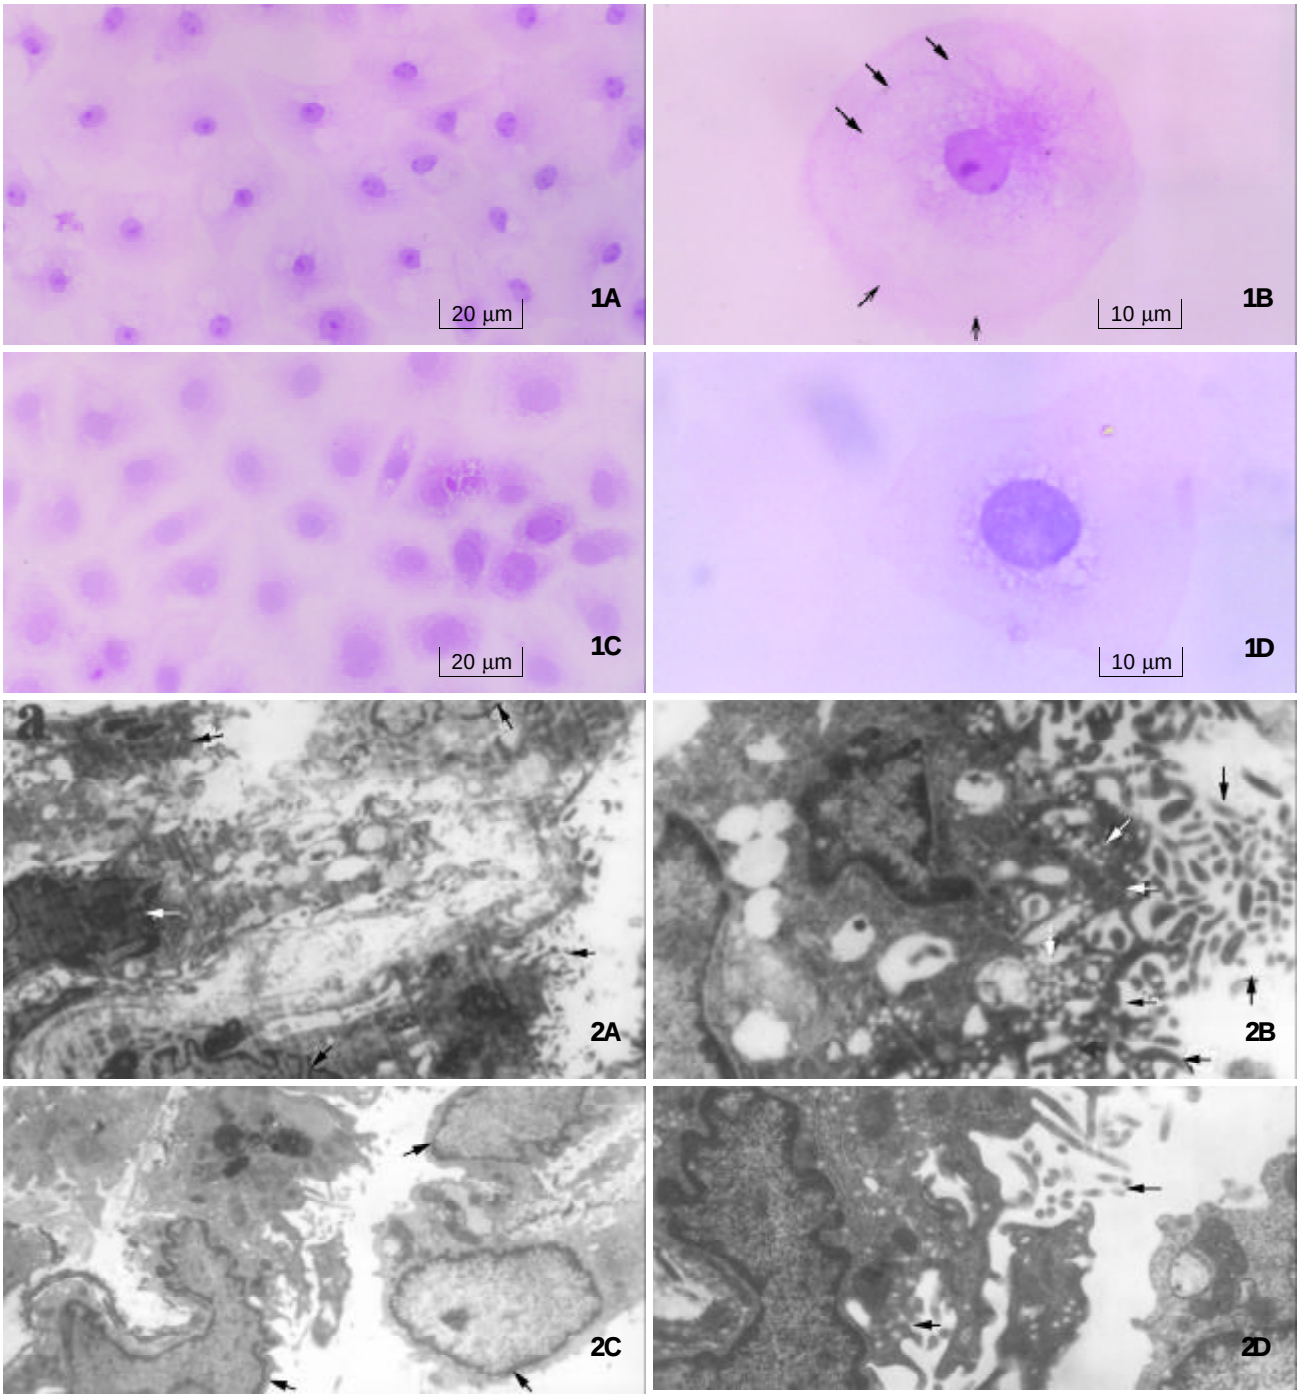

Figure 1 Morphology of IEC-6 cells. a: Gastrin-treated cells(250×) contained an abundance of plasma, small nuclei with nucleoli, and were arranged regularly. b: One of gastrin-treated cells (400×) showed the tendency to form microvilli on the edge(open

arrows), and cytoskeleton-like staining in plasma (solid arrows). c: Control cells (250×) contained sparse plasma, large nuclei without nucleoli, and were in irregular arrangement and immature shape. d: One of control cells (400×) showed no tendency to form microvilli on the edge, and nucleus was relatively larger and had no nucleolus.

Figure 2 Ultrastructural changes of IEC-6 cells. a: Gastrin-treated cells (5 000×, bar=1 μm) showed columnar structures(the nuclei were shown by open arrows) with numerous microvilli on the edge (solid arrows). b: Gastrin-treated cells (12 000×, bar=500 nm)developed numerous microvilli (open arrows) and lots of endocytic vesicles appeared under the apical membrane (solid arrows). c: Control cells (5 000×, bar=1 μm) were thin and flat. Relatively large nuclei (open arrows) and scanty plasma were observed. d: Only sparse microvilli (open arrow) and endocytic vesicles (solid arrow) were seen in control cells (12 000×, bar=500 nm).

Electron microscopy Twenty days after 20-day treatment with gastrin, numerous microvilli appeared on the edge of IEC-6 cells, many endocytic vesicles occurred under the apical membrane, and columnar structures were seen in some cells. Control cells were thin and flat, the nuclei were relatively large with scanty of cytoplasm. Only sparse microvilli were observed on the edge of control cells, and few endocytic vesicles were noticed (Figure 2).

Effect of gastrin on villin expression in IEC-6 cells

mRNA level After exposure to gastrin for 6 hours, villin mRNA expression in gastrin-treated cells was stronger than that in control cells (Figure 3).

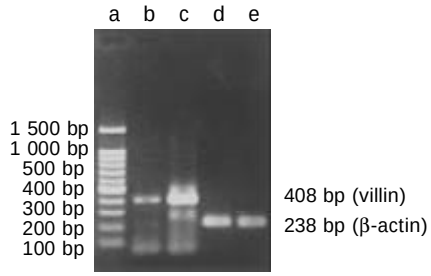

Figure 3 RT-PCR products from IEC-6 cells on agarose electrophoresis. a: Marker (brighter band: 500 bp), b: Control, c: Gastrin treated cells, d: β-actin(Control), e: β-actin (Gastrin).

Protein level On day 7 after treatment, plenty of cytoplasmic villins were observed obviously in gastrin-treated cells and few in control cells (Figure 4).

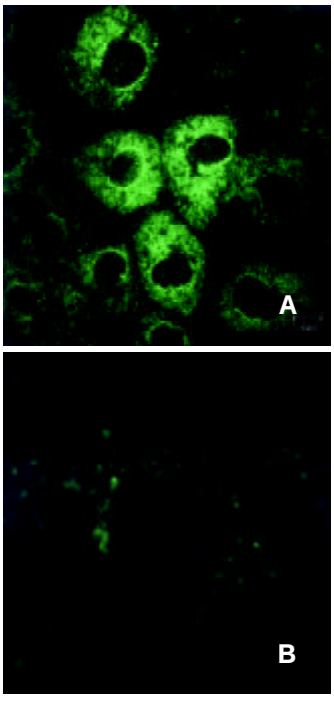

Figure 4 Villin expression in IEC-6 cells. a: Gastrin-treated cells (800×), b: Control cells (800×).

DISCUSSION

The barrier function of intestine is based on the physiological renewal or pathological repair of intestinal epithelia. The process includes proliferation, migration and terminal differentiation of the crypt cells. Development and differentiation of intestinal epithelia proceed in at least two distinct steps: the conversion of a nonepithelial cell to a protoepithelium, followed by a process of terminal differentiation. Terminal differentiation continues to occur in adult animals in the intestine[11], and is the last process. It not only indicates the completion of renewal or repair and the degree of differentiation, but also determines whether the new epithelia have physiological functions. There are two morphological characteristics in differentiated intestinal epithelia. One is the columnar shape cells with microvilli at the apical membrane, the other is organization of intestinal epithelial cells on a basement membrane into multicellular structures.

Intestinal epithelial cells (IEC-6) have features of undifferentiated small intestinal crypt cells[12], and are often used as a model of intestinal mucosal repair and cell differentiation[13,14]. The differentiation of intestinal crypt cell is a complex process, which is controlled by multiple factors. It has been known that several genes, such as p38 mitogen-activated protein kinases (p38MAPK)[15], Cdx gene family[16-20], pancreatic-duodenal homeobox (Pdxs) gene[21-23], sucrase-isomaltase (SI) gene[18,24,25], villin[26], activin[27], provoke cells towards the phenotype of differentiated villus enterocytes. Some cytokines such as epidermal growth factor (EGF)[6,7], insulin, insulin-like growth factor (IGF)-I and II[28,29], transforming growth factor (TGF)-β1[29], glucagon-like peptide-2 (GLP-2)[30] also have effects on the process. Astragalus injection could promote IEC-6 cell differentiation by inducing ODC activity and polyamine biosynthesis[31].

Moreover, the interaction between cells or between cells and extracellular matrix (ECM) also plays an important role in differentiation of IEC-6 cells[32]. Both humoral and matrix factors from intestinal mesenchyme are involved in intestinal epithelial differentiation and these factors appear to be organ specific[33,34]. And in conjunction with cell-cell contact and/or ECM, many regulatory cytokines such as enteroglucagon, interleukin-2 (IL-2), fibroblast growth factor (FGF), and EGF family members lead to specific differentiation signals[35]. Cdx2 gene provokes pleiotropic effects triggering cells towards the phenotype of differentiated villus enterocytes, but its expression is also modulated by basement membrane components[18].

Previous studies on differentiation of IEC-6 cells have found that laminin can lead the organization of IEC-6 cells on a basement membrane into multicellular structures[36], and the down-regulation of c-jun expression mediated by laminin might result in the event[37]. IEC-6 cell culture on Englebreth-Holm-Swarm (EHS) extracellular matrix proteins also displays morphological changes, correlated with loss of nuclear localization of c-myc protein and development of cell surface alkaline phosphatase (ALP) enzymatic activity[14]. And it has been documented that striking morphological and functional alterations can be induced by glucocorticoid in IEC-6 cells. These effects are consistent with the activation or modulation of multiple genes important in physiological functions of

absorptive villous cells[38]. Other data showed differentiation of IEC-6 cells was associated with upregulation of 11β-hydroxysteroid dehydrogenase (11β-HSD2) activity[39]. Members of the Cdx gene family play a fundamental role in both the establishment of the intestinal phenotype during development and maintenance of this phenotype via transcriptional activation of differentiated intestinal genes[40-43].

Our results showed that significantly morphological changes were observed in IEC-6 cells treated with gastrin in comparison with control group. The cells were in regular arrangement. Typically differentiated cell had an abundance of cytoplasm and a small nucleus containing nucleolus. There was a tendency to form microvilli and cytoskeleton-like structures were observed in the cytoplasm. Twenty-days after treatment of gastrin, a great number of microvilli appeared on the edges of the cells, and several cells displayed a simple columnar structure, and were fundamentally different from adenocarcinoma-like differentiation induced by Cdx1 transfection, which exhibited stratified columnar structure[16]. The absence of a multilayer structure indicated that these cells did not lose their contact inhibition characteristics, and they were not tumor cells. The existence of lots of endocytic vesicles as found under the apical membrane was also a typical feature of terminally differentiated enterocytes[11,44]. These results indicated that the cells might have the function of endocytosis as well as enterocytes. In control cells, only few microvilli were observed on the edge of cells with few endocytic vesicles.

Villin is one of the actin-binding proteins which have been reported to play a major role in the formation of the microvillus core bundle[45]. These proteins are known to modulate the dynamics of the actin cytoskeleton by mediating the state of actin polymerization and the spatial arrangement of actin protofilaments[46-49]. Villin may also respond to the apical calcium gradient, fragmenting actin microfilaments (MFs), and thus locally facilitate actin remodeling[50], and has a very important role in the alteration of cell morphology. The villin mRNA was expressed at high levels in the small intestine, to a lesser degree in the colon, and was not detected in the brain or liver[51]. The results indicate that villin is a kind of intestine-specific structure protein. In HT-29 cells, increase of villin mRNA levels was consistent with the process of enterocyte differentiation. Similarly, villin gene expression was induced in Caco-2 cells during postconfluence differentiation[51]. Immunolocalization studies on the distribution of the brush border-specific microvillar protein, villin, in human colonic mucosa indicated that localization of this protein was disrupted in certain dysplastic and neoplastic states. Thus, the expression and/or distribution of brush border-specific proteins such as villin may be useful markers for defects in the differentiation state of enterocytes[52].

Changes of cellular morphology and expression of mRNA and protein of villin in IEC-6 were investigated in order to observe the effects of gastrin on the differentiation of IEC-6 cells. The results showed that gastrin could obviously up-regulate villin expression at both mRNA and protein levels. These results were in consistent with the morphological alterations of these cells, and indicated that there was causality between the two events, i.e., gastrin induced characteristic features of differentiated enterocytes may account for its up-regulation to villin expression in IEC-6 cells. All these results indicate that gastrin can promote differentiation of IEC-6 cells, which is correlated to the up-regulation of villin expression.

ACKNOWLEDGEMENTS

We are grateful to Professor Peixun Wang, Associate Professors Weiwei Lei and Qin Xu, and Dr. Haibin Wang for their technical advice and excellent assistance.

Abstract

AIM: To explore the role of bile liquid crystal in the process of gallbladder stone formation and to provide bases for preventing and treating cholelithiasis.

METHODS: 46 guinea pigs, half males and half females, were randomly divided into control group and stone-causing group. Normal feed and stoneleading feed were used respectively to raise guinea pigs in the control group and stone-causing group. The guinea pigs were killed in three batches during the raising period. Under polarizing microscope, the pattern changes of bile liquid crystal in the gallbladder biles of the guinea pigs in the control group and stone-causing group were dynamicly observed respectively in single-blind trial.

RESULTS: It was found that there were few crystals in the guinea pigs' biles of the control group, and their Malta cross was small and scattered, and existed in single form. With the increase of the feeding days, bile liquid crystals grew and Malta cross became bigger with their distribution densified, denser somewhere, but always existed in single form. While those of the stone-causing group had more bile liquid crystals, Malta cross was big and merged in strings. With the increase of the feeding days, bile liquid crystals grew in amount and strings of Malta cross increased and became bigger. The crosses in strings were arranged more and more regularly and they gradually changed into stone crystals.

CONCLUSION: Formation of gallbladder stone is a process of nucleation from different substances, and the causing-stone gallbladder bile is a constantly supersaturated solution, and bile liquid crystal is a nucleation factor in the formation of gallbladder stones. The process of nucleation includes gathering, merging and phase-changing of bile liquid crystals. The process of gathering, merging of bile liquid crystal is the key to nucleation.

INTRODUCTION

Bile liquid crystal is a type of liquid crystal in the living beings' bile. Since American scholar Olszewski *et al*[1] found the substance of liquid crystal in the bile liquid of human body in 1973, some scholars at home and abroad have explored the matter of liquid crystal in the living beings' bile[2-4], but the relation between bile liquid crystal and formation of gallbladder stone has not been clarified so far. In order to explore the role of bile crystal in the process of gallbladder-stone formation and to provide certain bases for the prevention and treatment of gallbladder stone, we made dynamic observations and studied on the nucleation of bile liquid crystal in gallbladder stone through animal tests in guinea pigs.

MATERIALS AND METHODS

Materials

46 guinea pigs (provided by the animal branch of the Scientific Research Department in Kunming Medical College, with qualified animal testing certificate issued by Yunnan Province), each weighing about 300 grams, half males and half females, were randomly divided into control group (n=23) and stone-causing group (n=23).

Methods

Animal raising The control group was given normal feed which was provided by the animal branch of the Scientific Research Department in Kunming Medical College, while the stone-causing group was given stoneleading feed. The two groups were separately raised in flocks, with free access to water containing 1 % vitamin C.

Stone-causing feed The components of the stone-causing feed were as follows: starch 25 %, bran 25 %, glucose 12 %, lard 1.5 %, cholesterol 1.5 %, normal feed 35 %[5]. They were mixed evenly and made granule with feed machine.

Sample preparation Guinea pigs were killed in three batches. The first batch was killed after raised for 10 days, with 5 pigs in each group, totally 10 pigs in the 2 groups. The 2nd batch was killed after raised for 25 days, with 5 pigs in each group, totally 10 pigs in the 2 groups. The 3rd batch was killed after raised for 60 days, with 13 pigs in each group, totally 26 pigs in the 2 groups. The pigs were whacked at head to stupor with a blood vessel forceps, immediately cut open belly and their cystic duct was blocked with a blood vessel forceps to take out gallbladder and all bile. The bile was centrifugalized for 30 minutes with a China-made TGL-16B bench centrifuge, 4 000 r/min, and observed under polarizing microscope.

Polarizing microscope observation A China-made W-104 micro-sample advancer (precision of 0.2 μL) was used to stratify the centrifuged bile and drip 6.0 μL of it on a carrier flake, then it was covered with the cover-glass and the bile naturally spread out to form slices. Under an advanced polarizing microscope (BHSP model of Olympus, Japan), the pattern changes of the bile liquid crystal in the process of gallbladder stone formation were observed.

RESULTS

Patterns change of bile liquid crystals in control group

Under the perpendicular polarized microscope, the

morphological changes of bile liquid crystal in the gallbladder bile of guinea pigs in the control group were observed, and it was found that there were few matters of liquid crystal in gallbladder bile, and that the interference pattern, named Malta cross, was small and scattered, in single form. With the increase of the feeding days, bile liquid crystals grew larger and Malta cross became bigger with their distribution densified unevenly, but always existed in single form, as shown in Figure 1 (a), (b), (c) and (d). No regularly shaped stone crystal was found in the biles.

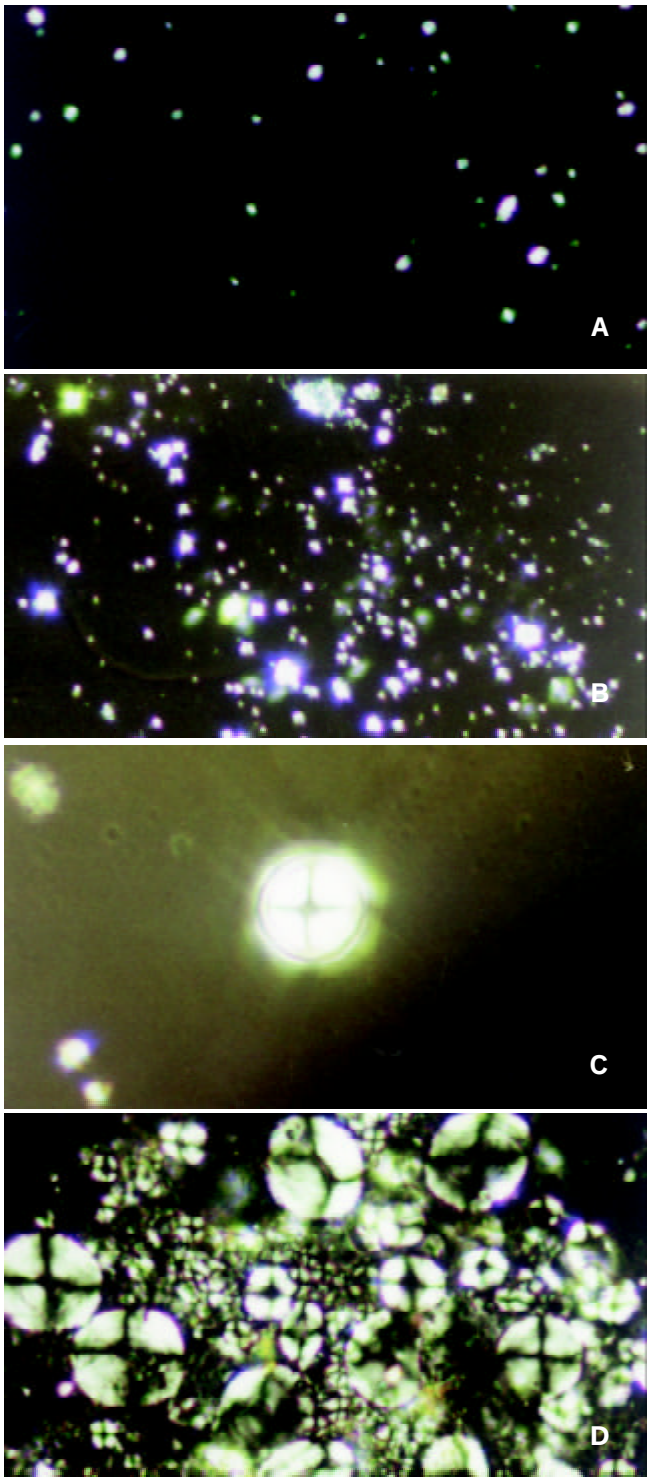

Figure 1 Malta cross showed in bile liquid crystals in gallbladders of guinea pigs in the control group: (a) Small and scattered crosses (10 days, ×400). (b) The crosses gradually grew in size and number (25 days, ×400). (c) Single big crosses (25 days, ×400). (d) Densely distributed crosses (60 days, ×400).

The pattern changes of bile liquid crystals in the stone-causing group

Under the polarizing microscope, the morphological changes of bile liquid crystal in guinea pigs' gallbladders in stone-causing group were observed, and it was found that there were more matters of liquid crystal in gallbladder biles, and that the interference pattern, Malta cross was big and merged into strings. With the increase of the feeding days, bile liquid crystals grew in number and strings of Malta crosses increased and became bigger. The crosses in strings were arranged more regularly so that they gradually phase-changed into stone crystals, as shown in Figure 2 (a), (b), (c) and (d). It exhibited variously shaped stone crystals in the biles, as shown in Figure 3 (a), (b), (c) and (d).

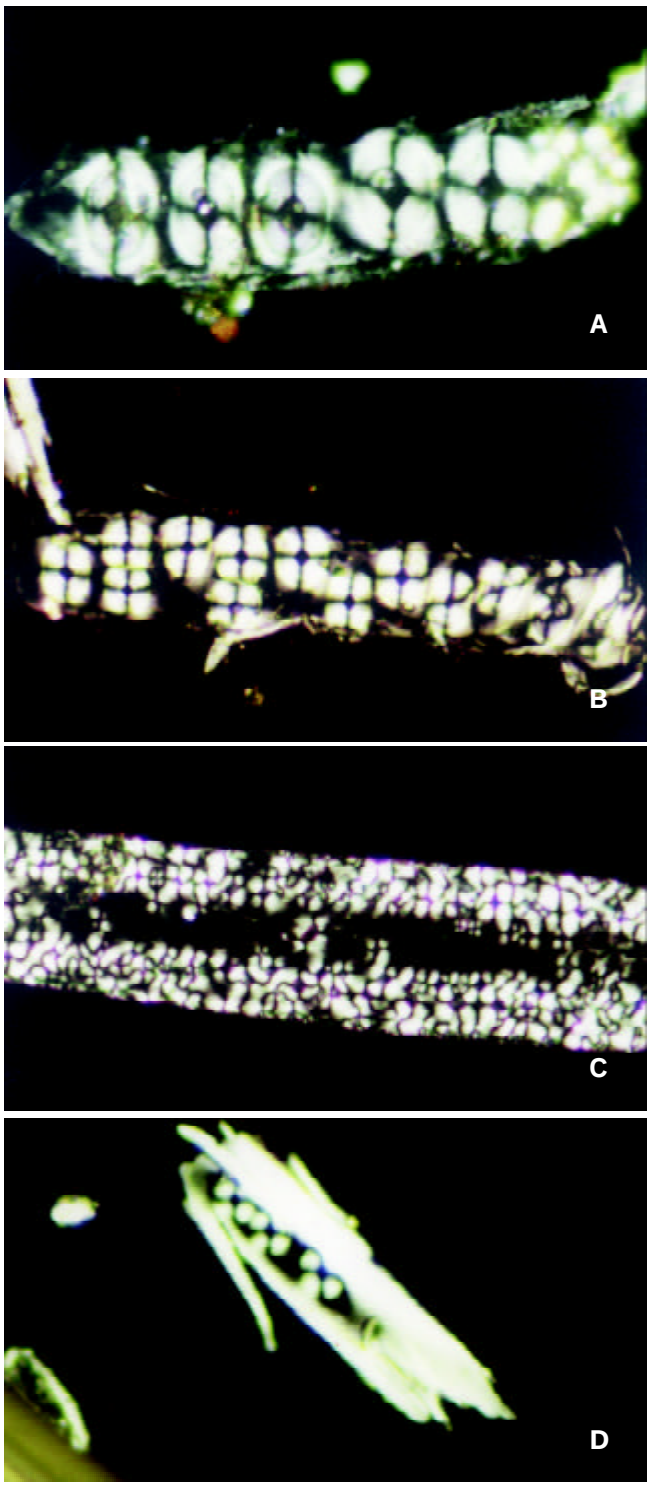

Figure 2 Malta cross shown in bile liquid crystals in gallblad-

ders of guinea pigs in the stone-causing group: (a) The cross merged into strings (10 days, ×400). (b) Gradually growing strings of the cross (25 days, ×200). (c) Strings of the cross in phase-changing (60 days, ×400). (d) Stone crystals nucleated by strings of the cross (60 days, ×200).

DISCUSSION

The cause of gallbladder stone is very complicated, various factors are involved[5-9]. The basic factor is now considered to be the change of compositions and physical-chemistry characteristics of biles, which results in cholesterol in the state of super-saturation in the bile. And it is very likely to form crystals, which is then deposited to form gallbladder stones. It also causes imbalance between nucleation-leading factors and antinucleation factors and abnormal function of the gallbladder and so on[10-19]. From the viewpoint of crystallogeny, in a system of solution, the precondition for solute to be separated out and to form crystal is that the solute in the system must be in the state of super-saturation, which is an unstable state in thermodynamics. Only in this state, can the solute be crystallized and separated out. The formation of crystals has two steps of nucleation and crystallization, it firstly forms a crystalline nucleus containing hundreds of molecules, then crystals grow. In a system of solution, spontaneous nucleation of solute often requires a very high degree of saturation, the supersaturated solution in this state is called unstably supersaturated solution. When a certain type of special nucleating factors is added, supersaturated solution of a relatively low degree also can produce nucleation, which is called heterogeneous nucleation, and the supersaturated solution in this state is called substably supersaturated solution[20,21]. Homogeneous nucleation of bile cholesterol requires a very high degree of saturation (estimated at about 300 %), which is not possible to occur in human body, and even less possible in guinea pigs' body. So the formation of gallbladder-stone should be a process of heterogeneous nucleation, stone-causing gallbladder bile should be a substably supersaturated solution, and bile liquid crystal should be a type of nucleating factors for gallbladder stones.

As we observed under the polarizing microscope, there were many substances of liquid crystal in the gallbladder bile of the guinea pigs in the stone-causing group, which were big and string of Malta crosses. With the increase of the feeding days, bile liquid crystals grew in number, more and more strings of Malta cross appeared and steadily became bigger and bigger, and their arrangement became more and more regular, and gradually phase-changed into stone crystals. These have proved that the formation of gallbladder stone is indeed a process of heterogeneous nucleation, and stone-causing gallbladder bile is a type of substably supersaturated solution, and that bile liquid crystal is a type of nucleating factors in gallbladder-stone. Its process of nucleation is such that bile liquid crystals get together, merge and phase change. In another word, single Malta crosses assemble into strings, then merge as slices, and finally phase-change into crystals. The assemblage and merger of bile liquid crystals are the key for nucleation. Although there were also substances of liquid crystal existing in gallbladder biles in the control group and bile crystals also increased with feeding time, they neither assembled nor merged, and Malta crosses always existed in single forms which were unable to nucleate to form stone. If some way can be found to prevent or retard the assemblage and merger of bile liquid crystals, i. e., formation of the nucleus, it will be of a great significance in theory and practice for prevention and treatment of cholelithiasis.

Cholesterol can not dissolve in water, but it can dissolve in bile. The concentration of cholesterol in bile is about 10-20 mmol/L, this concentration is about 10^6 times[22] denser than that of the solubility of cholesterol in water. Studies concerned pointed out that cholesterol in bile maintained its state of dissolution in forms of micelle and vesicle. Micelle is the polymer of cholesterol, phosphatide and cholate, while vesicle is the compound of cholesterol and phosphatide[23-31]. These two form a system of thermodynamic balance in bile so that they are interlinked and interconverted, and play the role of modulation for dissolution and separation of cholesterol. Under the effect of nucleation-leading factors and antinucleation factors in bile, vesicles in bile assemble, merge and separate out crystalline nuclei of cholesterol which then gradually grow up to form stones[32]. As we observed under the polarizing microscope, single Malta cross in bile liquid crystal of guinea pigs in stone-causing group, gradually assembled into strings,

then merged into slices, and finally phase-changed into stone crystals. The present study supports the above viewpoints from the studies of morphology. Whether bile crystal is such a kind of vesicles or vesicles aggregate and what factors cause or stop bile liquid crystal assembling and merging, still need to be further studied.

Abstract

AIM: To investigate the toxicities, biodistribution and anticancer effect of 5-fluorouracil controlled release implant (5-FUCI) on Walker 256 carcinosarcoma cells in Wistar rats.

METHODS: Experiment 1: Wistar rats were randomly divided into three groups (27 rats per group). Blank implant was implanted in left lobe of the liver, and rats were treated with saline solution (in group A) or 5-fluorouracil (subcutaneous injection, group B). 5-FUCI was inserted in left lobe of the liver (group C). The gastrointestinal and hematological toxicities were observed and contents of element F in group C were assayed. Experiment 2: on day 6 after Walker-256 carcinosarcoma transplantation in left lobe of the liver, 5-FUCI was implanted in right lobe of the liver (group E) or left lobe (group F), and rats in control group (group D) were inserted blank implant. Tumor inhibition rate and survival time were investigated.

RESULTS: 5-FUCI showed no obvious toxic effect, extraction of Evan's blue from gastrointestinal tissue was normal, the peripheral white blood cells and bone marrow nucleated cells were not reduced, compared with control group ($P>0.05$). Histological examination revealed that there were no visible changes in small intestinal mucosa, The concentration of 5-fluorouracil in left lobe of the liver was 9.84, 28, 34 times as much as those of right lobe of the liver, heart and kidney respectively after the implantation in group C. They kept a high level of fluorouracil in left lobe of the liver, ranging from (4.414±0.482) % to (7.800±0.804) %, for eight weeks. Survival days were 28.0±2.2, 30.0±3.2 and 38.7±6.7 d in group D, E and F, respectively.

CONCLUSION: 5-FUCI shows no obvious toxicities to gastrointestinal tract and myelotoxicity. After implantation, it kept a high level of 5- fluorouracil in surrounding tissues of the implant for eight weeks. Its antitumor effect on Walker-256 carcinosarcoma is demonstrated.

INTRODUCTION

5-Fluorouracil (5-FU) is one of the most widely used chemotherapeutic drugs in the treatment of malignant gastrointestinal cancers[1-7], but its use has been limited by is systemic toxicities, i.e. severe gastrointestinal toxicities, hematological side effects, and severe disturbance in bone marrow[8,9]. Moreover, 5-FU has a serum half-life of only 10 minutes[10-13], further limiting its usefulness. To maximize the therapeutic effect of 5-FU and minimize any adverse effect, we developed silicone as a polymer matrix, and 5-FU as a model drug to prepare a controlled-release implant of 5-fluorouracil (5-FUCI, Figure 1) for delivering agents directly to the site of the tumor. Tube-type pellets made of silastic elastomer were of 2 mm in outer diameter, 0.5 mm in wall thickness and 25 mm in length. Per pellet contained 13.2 mg of 5-FU. The daily delivery dose of 5-FU was approximately 30 $\mu g \cdot d^{-1}$, zero-order release profiles lasted for 24 weeks *in vitro* (unpublished data). This study investigated its toxicities as compared with standard systemic therapy, the biodistribution of 5-FU after 5-FUCI was implanted in the liver of rats, and therapeutic effect on the Walker-256 carcinosarcoma in the liver of Wistar rats. Two experiments were performed.

MATERIALS AND METHODS

Experiment 1: Toxicity evaluation and biodistribution of 5-FUCI

5-FUCI and blank implant 5-FUCI and blank implants were prepared and kindly provided by Prof. Huaiying Wu (from Shanghai Medical University, China). 5-Fu was purchased from Shanghai Haipu Pharmaceutical Company.

Animals Adult male Wistar rats, weighing 300-320 g, were obtained from the Experimental Animal Center of Wuhan University, China. They were housed in stock cages (3 rats per cage) and given free access to water and the commercial laboratory rodent diet. Twelve hours prior to experiment, the rats were fasted, but allowed free access to water.

Implantation and treatment The rats were anesthetized with i.p. of sodium pentobarbital (40 $mg \cdot kg^{-1}$). All procedures were carried out aseptically. Then, they were randomly divided into three groups (27 rats per group) and received implantations.

Group A: A blank implant was implanted in left lobe of the liver. Subcutaneous injection of 1 ml saline solution was administered (daily×7, weekly×7).

Group B: A blank implant was implanted in left lobe of the liver. 5-FU (10 $mg \cdot kg^{-1}$) was subcutaneously injected (daily×7, weekly ×7).

Group C: 5-FUCI was implanted in left lobe of the liver. 1 ml saline solution was subcutaneously injected (daily×7, weekly ×7).

Counts of WBC and bone marrow nucleated cells Three rats per group were respectively anesthetized weekly, counts of the peripheral white blood cells and bone marrow nucleated cells were assessed. The jugular vein was isolated and received injection of 1 % Evan' s blue solution (1.0 $mg \cdot kg^{-1}$). The rats were killed by cervical dislocation at 45 min postinjection.

Toxicity evaluation of small intestine Two cm sections of the proximal jejunum were cut and weighed, and treated with 40 % trichloroacetic acid solution (1:8, w/v), then left at 25 ℃ overnight and centrifuged at 1 500 g for 10 min. The upper aqueous phase was collected and extraction of Evan' s blue

was measured by spectrophotometer.

Morphological changes of small intestinal mucosa The small intestine segments were collected, and haematoxylin and eosin stained slides were used. The area of small intestinal mucosal cells and integrated optical density (IOD) of inner mucosal surface of the small intestine were measured by using image analysis system (IBAS, Kontron Co. Ltd., Germany).

Assay of element F in group C To evaluate the biodistribution of 5-FU postimplantation, major organs (left/right lobe of the liver, heart, kidney) in group C were resected, adherent blood was removed and weighed. The contents of F were measured by an electron probe analyzer (JCXA-733, JEDL Co. Ltd., Japan).

Experiment 2: Antitumor activities of 5-FUCI

Preparation of TB rats Walker-256 carcinosarcoma cells were obtained from Chinese Center of Culture Preservation. On day 0 following laparotomy, 10^7 tumor cells of approximately 0.1 ml of cell suspension were transplanted in left lobe of the liver under slight ketamine anesthesia.

5-FUCI transplantation and treatment On day 6 after tumor transplantation, the tumor-bearing (TB) rats were randomly assigned to three groups (12 rats per group) for treatment and reoperated for insertion of 5-FUCI or blank implant.

Group D: The TB rats were treated by intratumoral implantation of a blank implant in left lobe of the liver.

Group E: 5-FUCI was implanted in right lobe of the liver.

Group F: The TB rats were treated by intratumoral implantation of 5-FUCI in left lobe of the liver.

Tumor volume and survival days On day 21, six rats per group were sacrificed, solid tumors were excised, weighed and the rate of tumor inhibition was calculated by the formula: (the tumor volume of control group- tumor volume of experimental group)/(the tumor volume of control group)×100 %. The life span of rest rats was investigated.

Pathological examination The tumor tissues taken from control group and experimental group were embedded in paraffin, and 5 μm sections were taken, stained with hematoxylin-eosin, and observed under light microscope to examine the therapeutic effect of 5-FUCI.

Statistical analysis

The differences between the mean values were analyzed for significance using the Student' s *t* test for independent samples. Survival time was examined with time sequence examination. $P \leqslant 0.05$ was considered to be statistically significant.

RESULTS

Changes of counts of WBC and bone marrow nucleated cells before and after treatment

Counts of the peripheral white blood cells in group B decreased from 11.5 g· L^{-1} before chemotherapy to 2.0 g· L^{-1} 3 weeks after treatment, but the data were not significantly different in group C compared with control group (group A, $P>0.05$). Counts of the bone marrow nucleated cells after subcutaneous injection of 5-FU decreased from 41.4×10^9· L^{-1} to 24.0×10^9· L^{-1}, and the data were normal in groups A and C ($P>0.05$).

Small intestinal mucosal image analysis

Morphological changes of small intestinal mucosa are listed in Tables 1 and 2.

Gastrointestinal toxicity

Gastrointestinal toxicity was positive by correlated with extraction of Evan' s blue from gastrointestinal tract. The results of extraction of Evan' s blue from small intestine are shown in Table 3.

Biodistribution of 5-FU after implantation

After 5-FUCI implantation, the local high accumulation of 5-FU was demonstrated in the adjacent tissue surrounding 5-FUCI implant (in left lobe of the liver). On the other hand, the concentration of 5-FU was lower in right lobe of the liver, heart and kidney (Table 4).

Table 4 Contents of element F in group C in major organs (%)

Observations of the anticancer effect

Changes of tumor volume and survival time in cancer-bearing rats are listed in Table 5. One animal in group F survived to the end of the experiment (50 days) and no viable tumor was found.

Table 5 Changes of tumor volume and survival days in tumor-bearing rats

Results of pathologic examination

5-FUCI implantation had no apparent pathological changes in the heart, liver, kidney and small intestine in group C. Some local effects of 5-FUCI were observed. The tumor cell proliferation in group D was very active (Figure 2). A number of focal necrosis were observed in group E (Figure 3) Most necrotic tissues were found at a distance of up to 1 cm from the implant in group F(Figure 4).

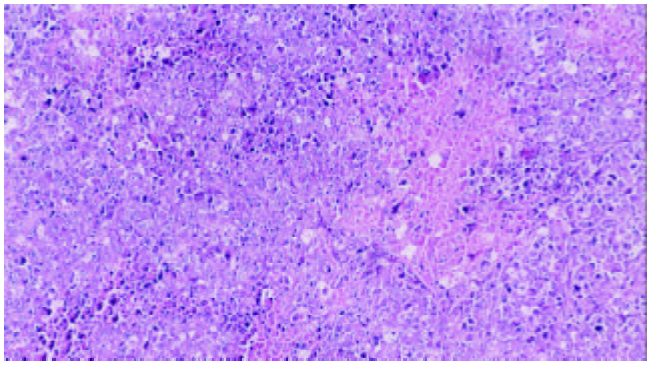

Figure 3 Tumor section (HE×100): a number of focal necrosis observed in group E.

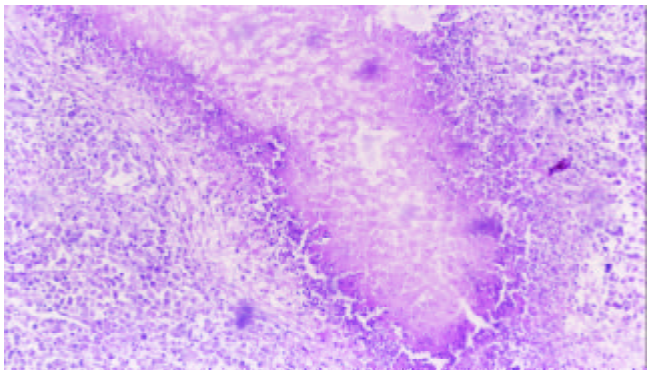

Figure 4 Tumor section (HE×100): the island of necrosis and lymphocytes infiltrated around the necrotic tissue found in group F.

DISCUSSION

Controlled release implant is a newly developed agent[14-17]. Different from other kinds of common or slow-released agents, it is capable of being administered through implantation to target organ, and can result in a therapeutically suitable plasma concentration of agents for an extended period of time[18-22], and exert a full antitumor action, despite the short half-life of drugs[23,24].

This study illustrated that the concentration of 5-FU in left lobe of the liver was 9.84, 28 and 34 times as much as that in right lobe of the liver, heart and kidney respectively after the implantation. It kept a high level of 5-FU in surrounding tissues of the implant, ranging from (4.414±0.482) % to (7.800±0.804) %, for eight weeks. 5-FUCI not only provided higher drug and /or drug metabolite concentrations in the tumor than the drug administered as an aqueous solution s.c. or systemically, but also resulted in a prolonged exposure of the tumor tissue to the drug and /or its metabolites. Consequently, 5-FUCI would be expected to improve effectiveness and to minimize the systemic toxicity associated with current systemic therapy of 5-FU[25-28].

New insights indicate that the toxicity of 5-FU is dose dependent, frequent low-dose infusions are less toxic to host than less frequent higher doses. No sign of systemic toxicities of 5-FUCI was detected because the daily delivery dose of 5-FUCI was only approximately 30 $\mu g \cdot d^{-1}$.

In previous studies, Smith *et al* demonstrated the sensitivity of tumor cells to 5-FU and dependence on drug concentration and exposure time[25,29]. If the exposure time was increased, the required drug concentration could be reduced. For example, the concentration of 5-FU that inhibited growth of 50-90 % (IC_{50}, IC_{90}) of BxPC-3 pancreatic cancer cells was eight to ten times less with a 72-h drug exposure than with a 24-h exposure[29]. We have shown that delivery of drugs administrated in 5-FUCI resulted in growth inhibition of Walker-256 carcinosarcoma cells that could hardly be accomplished with s.c. 5-FU solution.

Controlled release implant may enhance the pharmacological alternatives for the treatment of malignant tumors. Some researches have proved that tumor cell growth could be inhibited at a distance of 0.5-5 cm from the implant[30-32]. Therefore an implant needs to be inserted in many sites for multicenter or >5 cm neoplasms in outer diameter.

The data indicated that silicone pellets were transparent, and without fracture or apparent degradation after 8 weeks of implantation. In addition, a fibrous capsule was not detected around the pellets. Release of 5-FU from these pellets allows the drug to remain in the plasma for 1 to 8 weeks, in spite of its short plasma half-life (10 min)[10-13]. This was an

improvement compared with the injection of drugs. Administration of 5-FU by implantation of silastic elastomer seems to be a good candidate for 5-FU therapy. It suggests that 5-FUCI is a novel clinical approach and can offer an effective local chemotherapy.

Abstract

AIM: Heme oxygenase (HO)-1 catalyzes the conversion of heme to biliverdin, iron and carbon monoxide. HO-1 is induced by many stimuli including heme, Hb, heat stress, lipopolysaccharide (LPS) and cytokines. Previous studies demonstrated that LPS induced HO-1 gene activation and HO-1 expression in liver. However, the mechanisms of LPS-induced HO-1 expression in liver remain unknown. The effect of toll-like receptor-4 (TLR4) on LPS-induced liver HO-1 expression and the role of TNF-α and IL-1β in this condition were determined.

METHODS: HO-1 expression was determined by immunofluorescent staining and immunoblotting. Double immunofluorescent staining was performed to determine the cell type of HO-1 expression in liver.

RESULTS: A low dose of LPS significantly increased HO-1 expression in the liver which was localized in Kupffer cells only. Furthermore, HO-1 expression was enhanced by three doses of LPS. HO-1 expression was significantly inhibited in the liver of TLR4 mutant mice. While the liver HO-1 expression in TNF KO mice was much lower than that in C57 mice following the same LPS treatment, IL-1β KO had a slight influence on liver HO-1 expression following LPS treatment.

CONCLUSION: The present results confirm that macrophages are the major source of HO-1 in the liver induced by LPS. This study demonstrates that TLR4 plays a dominant role in mediating HO-1 expression following LPS. LPS-induced HO-1 expression is mainly mediated by endogenous TNF-α, but only partially by endogenous IL-1β.

INTRODUCTION

Heme oxygenase (HO) catalyzes the degradation of heme into biliverdin, iron and carbon monoxide[1-3]. Heme oxygenase has three known isoforms that consist of the inducible isoform heme oxygenase-1 (HO-1), the constitutive isoform heme oxygenase-2 and heme oxygenase-3. HO-1 is induced not only by its substrate, hemin, but also by oxidative stress, heat stress, UV irradiation, heavy metals, lipopolysaccharide (LPS) and cytokines[4-8]. This diversity of HO-1 inducers has provided further support for the speculation that HO-1 may play a vital function in maintaining cellular homeostasis, and some studies suggest that HO-1 can serve as a key biological molecule in the adaptation and/or defense against oxidative stress.

LPS is generally regarded as a key initiating factor in the pathogenesis of septic shock, and it stimulates inflammatory cells to produce cytokines, and other inflammatory mediators. HO-1 is induced by LPS in some cultured cell models *in vitro*[4,9], and also in lungs[10], kidneys and spleen[11,12] *in vivo*. It has been reported that HO-1 is induced in the liver after administration of LPS[11,13,14], but little is known about the mechanism of LPS-induced HO-1 expression in liver.

Studies have demonstrated that LPS induces cellular response by the signaling molecules belonging to the Toll-like receptor (TLR) family[15]. So far, six members (TLR1-6) have been reported and two of these, TLR2 and TLR4, have been shown to be essential for the recognition of distinct bacterial cell wall components[15,16]. TLR4 recognizes LPS, lipoteichoic acid and Taxol[17-19]. Recently, it was demonstrated that TLR4 mediated heat shock protein 60 signaling[20]. Although TLR4 is clearly critical to LPS signaling, the role of TLR4 in LPS-induced HO-1 expression has remained unclear. TLR4 mutation attenuates LPS-induced NF-κB activation and the production of cytokines[21,22]. Previous studies showed that cytokines, TNF-α, IL-α, or IL-1β induced HO-1 expression *in vitro*[8,23,24]. Do endogenous cytokines, TNF-α and IL-1β play a role in LPS-induced HO-1 expression?

The purposes of this study were to examine: the time course and localization of HO-1 expression in the liver by LPS stimulation, the role of TLR4 in LPS-induced liver HO-1 expression, whether LPS-induced HO-1 expression is dependent on TNF-α, and whether IL-1β plays a role in LPS-induced HO-1 expression.

MATERIALS AND METHODS

Animals

Male mice of the C57 BL/6, BALB/cJ and C.C3H-Tlr4Lps-d (TLR4 mutant) aged 8-10 weeks were obtained from Jackson Laboratory (Bar Harbor, ME). TNF-α knockout (TNF KO) mice of the same age range were generous gifts from Dr. David Riches of National Jewish Medical and Research Center (Denver, CO). IL-1β knockout (IL-1KO) mice were obtained from National Jewish Medical and Research Center (Denver, CO). The mice were kept on a 12-h light/dark cycle with free access to food and water. All animal experiments were approved by the University of Colorado Health Science Center Animal Care and Research Committee. During experiments, all the animals received humane care in compliance with the "Guide for the Care and Use of Laboratory Animals" [DHEW Publication No. (NIH) 85-23, revised in 1985, Office of Science and Health Reports, DRR/NIH, Bethesda, MD 20205].

Chemicals and reagents

Rabbit polyclonal antibody to HO-1 and the recombinant rat HO-1 were purchased from StressGen Biotechnologies Corp (Victoria, BC, Canada). Rat monoclonal antibody to mouse CD 68 was purchased from Serotec (Oxford, UK). Rat IgG and Cy3-conjugated goat anti-rabbit IgG were purchased from Jackson ImmunoResearch Laboratories (West Grove, PA). Fluorescein-conjugated wheat germ agglutinin was obtained from Molecular Probes (Eugene, OR). LPS (Escherichia coli, O55:B5) and all other chemicals were obtained from Sigma (St Louis, MO).

Experimental protocols

To determine HO-1 expression in the liver, the mice received either LPS (0.5 mg/kg) or normal saline by tail vein injection. To determine a time course of HO-1 expression, a single dose, two or three doses of LPS were used in each every 24 hours. After anesthesia and heparinization (40 mg/kg of pentobarbital sodium, ip), the liver tissue samples were prepared for the assessment of HO-1 expression. A portion of the liver tissue was embedded in a tissue-freezing medium and frozen in dry-ice-chilled isopentane. The remaining liver tissue was frozen in liquid nitrogen. All the samples were stored at -70 ℃ prior to use.

Immunofluorescent detection of HO-1 expression

Liver HO-1 expression was determined by immunofluorescent staining as previously described[25]. Tissue cryosections (5 μm thick) were prepared with a cryostat (IEC Minotome plus, Needham Heights, MA) and collected on poly-l-lysine-coated slides. All incubations were performed at room temperature. Sections were treated with a mixture of 70 % acetone and 30 % methanol for 5 min, and then fixed with 3 % paraformaldehyde for 20 min. Sections were washed with PBS, blocked with 10 % normal goat serum for 30 min, and incubated for 1 h with a polyclonal rabbit anti-HO-1 antibody (1:300 in PBS containing 1 % bovine serum albumin). Control sections were incubated with nonimmune rat IgG (5 mg/ml). After washed with PBS, sections were incubated with Cy3-conjugated goat anti-rabbit IgG (1:300 dilution with PBS containing 1 % bovine serum albumin). The cell surface was counterstained with fluorescein-conjugated wheat germ agglutinin, and the nucleus with *bis*-benzimide. The sections were mounted with aqueous media. Microscopic analysis was performed with a Leica DMRXA digital microscope (Germany) equipped with Slidebook software (I. I. I. Inc., Denver, CO).

Double immunofluorescent staining of HO-1 and macrophage

Double immunofluorescent staining was performed to determine the cell type stained positively of HO-1. CD68 (macrophages)-positive cells were studied. Tissue cryosections (5-μm thick) were prepared, fixed as described for staining of HO-1. Sections were blocked with 5 % normal goat serum + 5 % normal donkey serum for 30 min. Then slides were incubated for 1 h with a rat monoclonal antibody to mouse macrophages (CD68, 1:200) and rabbit polyclonal antibody to HO-1 (1:300). Control sections were incubated with non-immune rat IgG and rabbit IgG. After washed with PBS, the sections were incubated with Cy3-conjugated donkey anti-rat IgG (CD68) and FITC-conjugated goat anti-rabbit IgG (HO-1). The nucleus was counterstained with *bis*-benzimiade. The sections were washed with PBS, and then mounted on aqueous mounting media. Microscopic observation and photography were performed as described above.

Immunoblotting of HO-1

Liver tissue was homogenized with 4 volumes of homogenate buffer (PBS containing the protease inhibitor cocktail and 1 % Triton X100, pH 7.4), and centrifuged at 10 000×g for 20 min at 4 ℃. The resulting supernatant was collected and stored at -70 ℃ for immunoblotting of HO-1. Aliquots of protein (60 μg/lane) in the liver tissue homogenate were separated on a 4-20 % SDS-polyacrylamide gel (Bio-Rad, Hercules, CA). Separated proteins were blotted onto a nitrocellulose membrane (Bio-Rad, Hercules, CA), and equal loading was confirmed by densitometric assessment of protein band staining with Ponceau S solution. The membrane was rinsed in PBS and blocked for 1 h at room temperature with 5 % dry milk in PBS. The membrane was then incubated with a polyclonal rabbit anti-HO-1 antibody (1:1 000 dilution with 5 % dry milk in PBST) at room temperature for 1 h. Following an incubation with HRP-conjugated goat anti-rabbit IgG (1:10 000 dilution with 5 % dry milk in PBST), HO-1 bands were developed using ECL and visualized by exposure to Kodak X-Omat film (Eastman Kodak, Rochester, NY).

Statistical analysis

Data were expressed as mean ± standard error of the mean (SE). An analysis of variance (ANOVA) was performed with Statview 4.0 statistical analysis software (SAS Institute, Cary, NC), and a difference was accepted as significant if the P value was smaller than 0.05 as verified by the Bonferroni/ Dunn post hoc test.

RESULTS

Time course of liver HO-1 expression following LPS administration

Liver HO-1 expression in C57 mice after LPS administration was assessed by immunofluorescent staining and immunoblotting. HO-1 had low basal level expression in control liver by immunofluorescent staining (Figure 1A), but was barely detectable by immunoblotting (Figure 1B). A low dose (0.5 mg/kg) of LPS significantly increased HO-1 expression in the liver at 24 h after LPS administration. Furthermore, HO-1 expression was enhanced by three doses of LPS (Figure 1A and Figure 1B). The integrated intensity of HO-1 expression was significantly increased in liver of LPS-treated mice as compared with sham treatment mice (Figure 1C, $P<0.05$). However, cellular HO-1 level went down if animals were allowed to recover for 48 h following the last LPS injection, then gradually declined to control level at 72 h (data not shown).

Cell type involved in liver HO-1 expression

HO-1 protein was barely detectable in parenchymal liver cells following LPS stimulation, whereas high amounts of HO-1 were detectable in interstitial cells. To further characterize the cell types expressing HO-1, we attempted to localize the cell type(s) responsible for LPS-induced HO-1 expression in liver by double immunofluorescent staining. Rat anti-mouse CD68 monoclonal antibody and rabbit anti-HO-1 polyclonal antibody were used. We found that lower percentages of Kupffer cells exhibited positive staining for HO-1 in sham treatment. After three doses of LPS treatment, the majority of CD68 positive cells (>90 %) were HO-1 positive (Figure 2).

Effect of TLR4 on liver HO-1 expression

To examine the mechanism of regulation of liver HO-1 expression in response to LPS, we used C.C3H-Tlr4Lps-d mice, mice of TLR4 mutation. In BALB/cJ (wild type) mice, LPS-induced HO-1 expression in liver was comparable to C57 mice. In contrast, liver HO-1 expression in TLR4 mutant mice was significantly inhibited following the same treatment with LPS (Figure 3). These results suggested that mutation of

TLR4 exerted a dominant effect on liver HO-1 expression after LPS treatment.

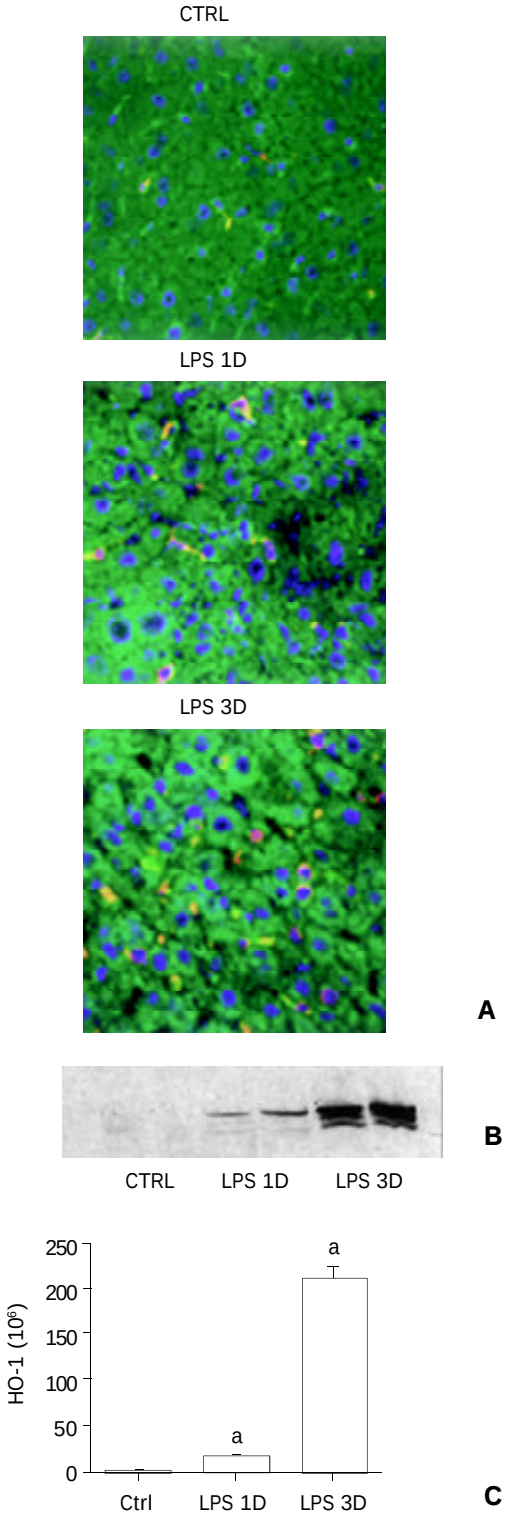

Figure 1 Liver HO-1 expression in wild type mice. A: Immunofluorescent detection of HO-1 in liver. After different doses of LPS or sham treatment, liver HO-1 expression of wild type (C57) mice were visualized by immunofluorescent staining with a specific rabbit polyclonal antibody against HO-1 followed by indocarbocyanine (Cy3)-conjugated anti-rabbit IgG (red). The cell surface was counterstained with fluorescein-conjugated wheat germ agglutinin (green), and the nucleus was counterstained with *bis*-benzimide (blue). HO-1 was present in liver of sham-treated animals (Ctrl). A single dose of LPS treatment increased liver HO-1 expression (LPS 1D). Furthermore, HO-1 expression was enhanced by three doses of LPS treatment (LPS 3D, magnification ×400). B: Immunoblotting detection of HO-1 in liver. C57 mice were treated with vehicle (Ctrl), single dose of LPS (LPS 1D) and three doses of LPS (LPS 3D). Liver tissue was homogenized, and immunoblotting analysis was performed. HO-1 protein was detected by immunoblotting with polyclonal rabbit antibody against HO-1. Data were representative of at least 2 experiments. C: Immunofluorescent staining to quantitate HO-1 expression. Liver HO-1 expression was determined by immunofluorescent staining. Integrated intensity of HO-1 positive signal was masked and quantified by using Slidebook software (I. I. I. Inc., Denver, CO). $^aP<0.05$ *vs.* sham.

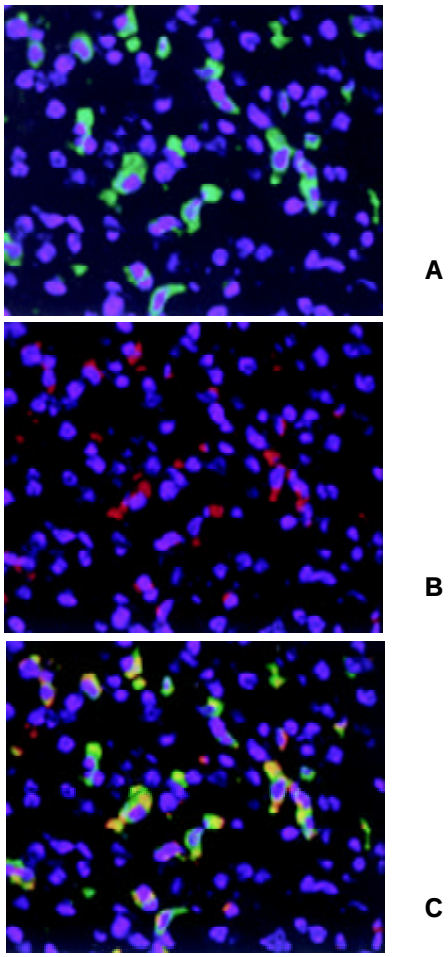

Figure 2 Double immunofluorescent staining of HO-1 localization in liver. After three doses of LPS treatment, HO-1 and CD68 in liver tissue were detected by double immunofluorescent staining with polyclonal rabbit antibody against HO-1 followed by FITC-conjugated anti-rabbit IgG (green) and monoclonal rat antibody against mouse CD68 followed by Cy3-conjugated anti-rat IgG (red). Cell nuclei were counterstained with *bis*-benzimide (blue). A: HO-1; B: Macrophages (Kupffer cells); C: HO-1 + Macrophages. magnification ×400.

Effect of TNF knockout on HO-1 expression

LPS is a potent inducer of TNF-α. Recent evidence suggests that LPS-induced TNF-α production is mediated through TLR4. Previous study demonstrated that TNF-α induced HO-1 expression in endothelial cells. Does TNF-α play an important role in LPS-induced HO-1 expression in liver? To examine the mechanism of regulation of liver HO-1 expression in response to LPS, we used C.C3H-Tlr4Lps-d mice, mice of TLR4 mutation. In BALB/cJ (wild type) mice, LPS-induced HO-1 expression in liver was comparable to C57 mice. In contrast, liver HO-1 expression in TLR4 mutant mice was significantly inhibited following same treatment as wild type mice (Figure 3). These results suggested that TLR4 exerted a dominant effect on liver HO-1 expression following LPS treatment.

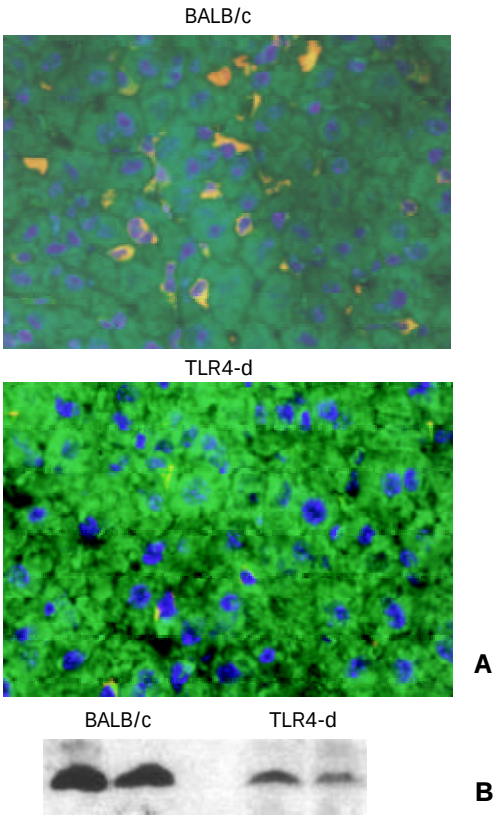

Figure 3 Effect of TLR4 mutation on liver HO-1 expression. A: Immunofluorescent detection of HO-1 in liver. After three doses of LPS treatment, liver HO-1 expression was visualized by immunofluorescent staining with a specific rabbit polyclonal antibody against HO-1, followed by indocarbocyanine (Cy3)-conjugated anti-rabbit IgG (red). The cell surface was counterstained with fluorescein-conjugated wheat germ agglutinin (green), and the nucleus was counterstained with *bis*-benzimide (blue). Liver HO-1 expression was abrogated in TLR4 mutated mice following LPS, but neither was influenced in BALB/c (control) mice (magnification ×400). B: Immunoblotting detection of HO-1 in liver. BALB/c and TLR4 mutated mice were treated with three doses of LPS. Liver tissue was homogenized, and immunoblotting analysis was performed. HO-1 protein was detected by immunoblotting with polyclonal rabbit antibody against HO-1. Data were representative of at least 2 experiments.

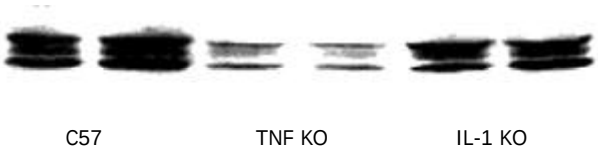

Figure 4 Effect of TNF KO and IL-1 KO on liver HO-1 expression. Immunoblotting detection of HO-1 in liver. C57, TNF KO and IL-1 KO mice were treated with three doses of LPS. Liver tissue was homogenized, and immunoblotting analysis was performed. HO-1 protein was detected by immunoblotting with polyclonal rabbit antibody against HO-1. Data were representative of at least 2 experiments.

Effect of IL-1b knockout on HO-1 expression

IL-1β is characteristically present in many inflammatory disorders. Although previous studies showed that IL-1β induced HO-1 expression *in vitro*, little is known about the role of endogenous IL-1β in LPS-induced HO-1 expression. We determined liver HO-1 expression in IL-1β KO mice. Mice were treated with LPS same as C57 mice. Compared with C57 mice, mice of IL-1β KO showed only a slight difference in liver HO-1 expression following LPS treatment (Figure 4), indicating that the expression of HO-1 following LPS was partially mediated by endogenous IL-1β.

DISCUSSION

In this study, we found that a low dose of LPS significantly increased HO-1 expression only in macrophages of wild type mice. This effect was further enhanced by the same dose of LPS for 3 consecutive days. However, HO-1 expression was significantly inhibited in TLR4 mutant mice. While liver HO-1 expression in TNF KO mice was much lower than that in C57 mice following the same LPS treatment, IL-1 KO had a slight influence on liver HO-1 expression following LPS treatment. The present results confirmed that macrophages were the major source of HO-1 in the lungs and liver as induced by LPS. This study demonstrated that TLR4 played a dominant role in mediating HO-1 expression following LPS. LPS-induced HO-1 expression was mainly mediated by endogenous TNF, but only partially by endogenous IL-1.

HO-1 is the rate-limiting enzyme in heme catabolism, and is also known as heat shock protein 32. Previous studies demonstrated that HO-1, besides its role in heme degradation, may also play a vital function in maintaining cellular homeostasis[26]. HO-1 is induced not only by its substrate, hemin, but also by oxidative stress, heat stress, UV irradiation, heavy metals, LPS and cytokines[4-8]. It has also been reported that HO-1 is induced in liver after LPS administration[11,13,14]. But most of studies just determined the changes of HO-1 mRNA in liver. Little is known about the time course and localization of HO-1 protein expression in liver. We examined liver HO-1 expression following LPS. We found that HO-1 had a low basal level expression in normal mouse liver by immunofluorescent staining. A low dose of LPS significantly increased HO-1 expression in the liver at 24 h after LPS administration. HO-1 expression was enhanced by three doses of LPS. Induction of HO-1, however, went down when animals were allowed to recover 48 h following the last LPS injection, then gradually declined to the control level by 72 h (data not shown). These results indicate that LPS-induced HO-1 expression in liver is in a dose-dependent fashion. Furthermore, we detected and localized HO-1 using immunofluorescent double staining. Hepatocytes were involved in the removal of plasma hemoglobin and some studies suggested that LPS mediated HO-1 mRNA accumulation in hepatocytes[7,13]. Interestingly, in the present study, most of HO-1 positive signals were co-localized in Kupffer cells. This finding formed a contrast to those from other animal models by hemin and LPS treatment. It is possible that the differences of experimental design, i.e, different stimuli, doses, and animals may lead to different results. In addition, the method of HO-1 staining by others was different from ours, it could be a reason for different expression of HO-1 in liver. Kupffer cells are the first line defense and effector cells in liver inflammatory response. The present results confirm that Kupffer cells are the major source of HO-1 in liver induced by LPS. HO-1 expression in Kupffer cells may play a protective role by inducing an adaptive hepatocellular stress response after LPS stimulation.

Studies demonstrated that LPS induced a cellular response by the signaling molecules belonging to the Toll-like receptor family[15]. TLR4 has been shown to be essential for the recognition of LPS, lipoteichoic acid (LTA) and Taxol[17-19]. Recently, it was demonstrated that TLR4 mediated heat shock protein 60 signaling[20]. Although TLR4 is clearly critical to LPS signaling, the role of TLR4 in LPS-induced HO-1 expression has remained unclear. To examine the mechanism of regulation of liver HO-1 expression in response to LPS, we determined liver HO-1 expression in TLR4 mutant mice. Liver

HO-1 expression in TLR4 mutant mice was significantly inhibited following the same treatment as wild type mice. This result suggests that TLR4 exerts a dominant effect on liver HO-1 expression after LPS treatment.

TNF-α is a pleiotropic early response cytokine and is rapidly produced by LPS stimulation. To determine the role of TNF-α in HO-1 expression following LPS *in vivo*, we subjected TNF KO mice to the same treatment as C57 mice. This treatment could also result in liver HO-1 expression comparable to that in the liver of C57 mice. We found that liver HO-1 expression in TNF KO mice was much lower than that in C57 mice following the same LPS treatment. This result suggests that LPS induces HO-1 expression mainly through endogenous TNF.

As an important inflammatory cytokine, IL-1 (IL-1α and IL-1β) induces HO-1 expression in endothelial cells and pancreatic islets[23-28]. Toll-like receptors belong to the IL-1 receptor family containing repeated leucine-rich motifs in their extracellular portion and are linked to a signaling pathway that involves the IL-1-receptor-associated kinase and NF-κB. It is likely that IL-1-induced HO-1 expression is mediated by TLR4. But it is unclear about the role of endogenous IL-1 in LPS-induced liver HO-1 expression. So, in the present study, IL-1 KO mice were used to determine liver HO-1 expression following LPS induction. Mice were treated with LPS the same as C57 mice. Compared with C57 mice, IL-1β KO has a slight influence on liver HO-1 expression following LPS treatment of IL-1β KO mice, indicating that the expression of HO-1 following LPS is partially mediated by endogenous IL-1β.

Taken together, the current study *in vivo* showed that TLR4 mutation attenuated LPS-induced HO-1 production in tissues. This provides a strong support to the hypothesis that TLR4 plays an important role in HO-1 signals. However, some aspects of its action remain unknown. What are the down stream signals of TLR4? In this context, future investigations are necessary to determine the signal transduction pathway of HO-1 expression induced by LPS.

Abstract

AIM: To investigate whether emodin has any effects on circular smooth muscle cells of rat colon and to examine the mechanism underlying its effect.

METHODS: Smooth muscle cells were isolated from the circular muscle layer of Wistar rat colon and the cell length was measured by computerized image micrometry. Intracellular Ca^{2+} ($[Ca^{2+}]i$) signalling was studied in smooth muscle cells using Ca^{2+} indicator Fluo-3 AM on a laser-scanning confocal microscope.

RESULTS: Emodin dose-dependently induced smooth muscle cells contraction. The contractile responses induced by emodin were inhibited by preincubation of the cells with ML-7 (an inhibitor of MLCK). Emodin caused a large, transient increase in $[Ca^{2+}]i$ followed by a sustained elevation in $[Ca^{2+}]i$. The emodin –induced increase in $[Ca^{2+}]i$ was unaffected by nifedipine, a voltage-gated Ca^{2+}-channel antagonist, and the sustained phase of the rising of $[Ca^{2+}]i$ was attenuated by extracellular Ca^{2+} removal with EGTA solution. Inhibiting Ca^{2+} release from ryanodine-sensitive intracellular stores by ryanodine reduced the peak increase in $[Ca^{2+}]i$. Using heparin, an antagonist of IP_3R, almost abolished the peak increase in $[Ca^{2+}]i$.

CONCLUSION: Emodin has a direct excitatory effect on circular smooth muscle cells in rat colon mediated via Ca^{2+}/CaM dependent pathways. Furthermore, emodin-induced peak $[Ca^{2+}]i$ increase may be attributable to the Ca^{2+} release from IP_3 sensitive stores, which further promote Ca^{2+} release from ryanodine-sensitive stores through CICR mechanism. Additionally, Ca^{2+} influx from extracellular medium contributes to the sustained increase in $[Ca^{2+}]i$.

INTRODUCTION

Emodin (1, 3, 8-trihydroxy-6-methylanthraquinone) is an anthraquinone derivative isolated from *Rheum palmatum*[1]. Pharmaceutical preparations based on *Rheum palmatum* have been widely used in China for hundreds of years to treat gastrointestinal disorders[2-4]. The reported biological effects of emodin include antitumor, antibacterial and anti-inflammatory actions[5-7]. Emodin also possesses prokinetic effect on gastrointestinal smooth muscle. Stimulatory actions of emodin on gastrointestinal smooth muscle have been described in several studies, and emodin-induced contractions have been related to calcium ions[8-10]. However, the effects of emodin on the contractility of smooth muscle cells have not yet been explored. Thus, the present study was designed to determine whether emodin had any effects on circular smooth muscle cells of rat colon and to examine the mechanism underlying its effects.

MATERIALS AND METHODS

Materials

Fluo-3 AM (Molecular Probes,USA) was dissolved in DMSO (Sigma) and stored at -20 ℃. Pluronic F-127, collagenase type II, emodin, nifedipine, ryanodine, heparine, Egtazic acid (EGTA), trypsin inhibitor and HEPES were all purchased from Sigma Co. Ltd, USA. DMEM was purchased from GIBCO Co, USA, other chemicals were from LianXing BIO Co. Ltd (Beijing). Nifedipine, ryanodine and heparin were all dissolved in standard buffer and kept at 4 ℃.

Methods

Preparation of dispersed smooth muscle cells Smooth muscle cells were isolated from the circular muscle layer of Wistar rat colon as previously described with slight modifications[11]. Briefly, muscle strips were digested for 30 min at 31 ℃ in HEPES medium containing 0.1 % type II collagenase and 0.01 % trypsin inhibitor. The partly digested strips were washed with PBS, and muscle cells were allowed to disperse spontaneously for 30 min. The cells were harvested by filtration through 500 μm Nitex filter and centrifuged at 350 g for 10 min, and the filtrate (cell suspension) was equilibrated for 20 min before the experiment. For some experiments, cells were permeabilized with a brief exposure to saponin (75 μg/ml for 4 min) and equilibrated in a cytosolic buffer.

Measurement of muscle cell contraction Contraction was measured in smooth muscle cells by computerized image micrometry as described previously[12]. An aliquot consisting of 1×10^4 cells in 0.25 ml of medium was added to 0.1 ml of a solution containing the test agents. The reaction was interrupted at 1 min by adding 0.1 ml of acrolein at a final concentration of 0.1 %. Individual cell length was measured by computerized image micrometry. The average length of cells in the control state or after adding test agents was obtained from 50 cells randomly. The contractile response was defined as the decrease in the average length of the 50 cells and expressed in percentage as compared with control length.

Measurements of $[Ca^{2+}]i$ in smooth muscle cells Changes in $[Ca^{2+}]i$ were estimated by fluorescence measurement using

Ca^{2+} indicator Fluo-3 AM as described elsewhere[13], using a laser scanning confocal microscope(Radiance 2000; Bio-rad, Hertfordshire, UK).

Freshly dissociated smooth muscle cells were seeded onto glass coverslips and incubated with Fluo-3 working solution (Fluo-3 AM 5 μmol and Pluronic F-127 0.03 % dissolved in standard buffer) at 37 ℃ under an atmosphere of 5 % CO_2. After a loading period of 30 min, the cells were washed with PBS to remove extracellular Fluo-3 AM and incubated for an additional 20 min to allow complete desterilization of the cytosolic Fluo-3 AM.

Coverslips mounted on the chamber slide (Molecular Probe) were placed on the stage of the microscope. The fluorescence in the cell was excited at 488 nm by an argon-ion laser, emission at wavelength between 515-545 nm was detected by a photomultiplier. Changes in the Fluo-3 fluorescence intensity indicating fluctuations in cytosolic Ca^{2+} were recorded using T-series acquisition. After stable baseline fluorescence intensity was measured, 10 μl of an agent was added to extracellular medium to yield a 1/100 concentration, and the fluorescence intensity was recorded. The ratio representing the intracellular calcium variations related to the basal level was calculated. Baseline and sustained phases of agonist induced [Ca^{2+}]i were determined from the average of 5 data points. Peak [Ca^{2+}]i was determined from the average of 3 data points including the absolute maximum of the response.

Statistical analysis

Data represented means ± standard error of the mean. Values of *n* were the numbers of cells. Student' s *t*-test was performed and a *P*-value of less than 0.05 was considered statistically significant.

RESULTS

Effect of emodin on smooth muscle cell length

In resting state, the average length of isolated smooth muscle cells was 81.27±6.29 μm. The application of emodin to freshly isolated smooth muscle cells induced a reduction in cell length. This reduction in cell length reflected contraction of the smooth muscle cells. Emodin at concentrations of 5 to 100 μmol/L induced a concentration-dependent contraction (Figure 1). Maximal contraction of 17.26±3.51 % was observed with 50 μmol/L of emodin. In order to determine the signal mechanism underlying emodin-induced contraction, the effect of ML-7, an inhibitor of MLCK, on the cell contraction induced by emodin was examined. 36.61±4.69 % of the contractile response induced by 50 μmol/L emodin was inhibited by preincubation of the cells with ML-7(Figure 2).

Role of calcium in emodin-induced responses

The exposure of freshly isolated smooth muscle cells to emodin (50 μmol/L) induced an increase in [Ca^{2+}]i. The emodin-induced increase in [Ca^{2+}]i was a biphasic rise, consisting of a transient peak followed by a decline to steady-state level that remained significantly above baseline during scanning (Figures 3 and 4).

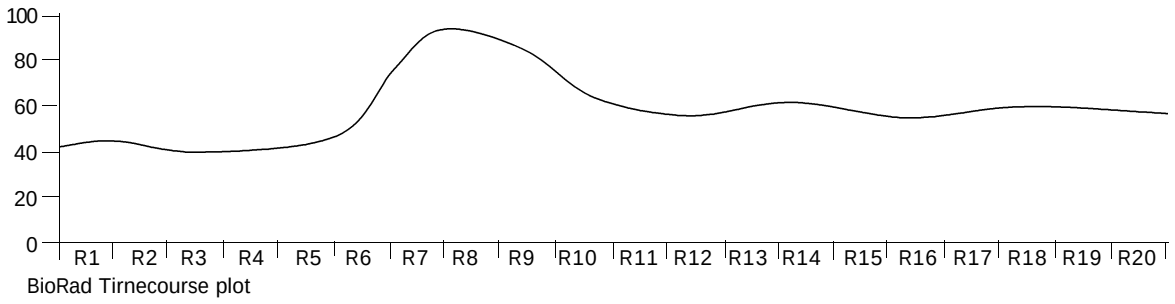

Figure 3 Timecourse changes of [Ca^{2+}]i induced by emodin in a circular colonic smooth muscle cells (analysed by BioRad Laserpix software).

To determine whether the emodin-induced increase in $[Ca^{2+}]i$ required calcium influx from extracellular medium, the effect of nifedipine, an antagonist of voltage-gated Ca^{2+} channel in response to emodin was investigated. Emodin was applied after 15 min-exposure to nifedipine. Exposing smooth muscle cells to nifedipine had no effect on the increase in $[Ca^{2+}]i$ induced by emodin ($P>0.05$). To further evaluate the role of extracellular Ca^{2+} influx to the emodin-induced rise in $[Ca^{2+}]i$, emodin was applied to cells incubation with Ca^{2+}-free extracellular solution. Removal of extracellular Ca^{2+} by EGTA solution significantly reduced the sustained changes in $[Ca^{2+}]i$ (Figure 4, $P<0.05$) compared with the sustained increase in $[Ca^{2+}]i$ induced by emodin, and had no effect on peak changes in $[Ca^{2+}]i$ (Figure 4, $P>0.05$).

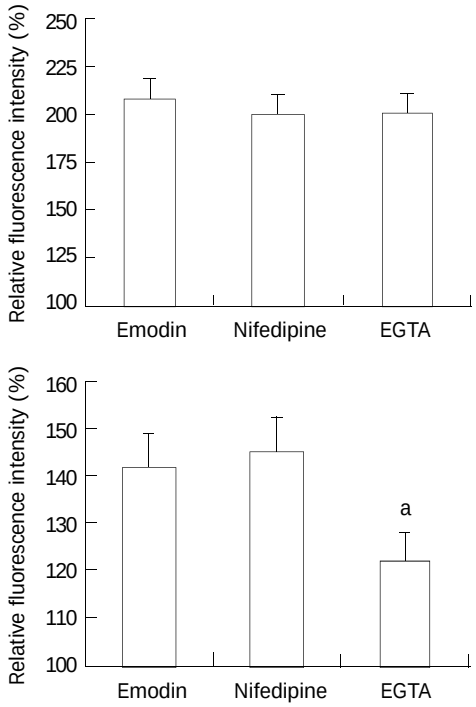

Figure 5 Average peak (top) and sustained (bottom) changes in $[Ca^{2+}]i$ in response to emodin under control conditions, in the presence of nifedipine, and EGTA solution. $n=15$. $^aP<0.05$ *vs* emodin group.

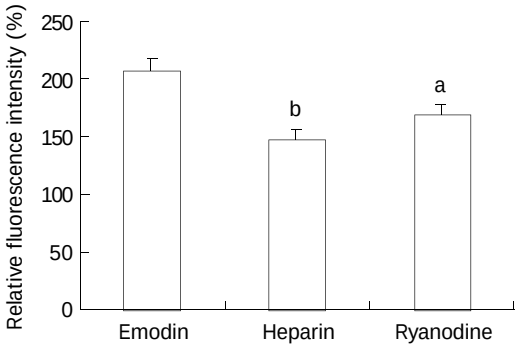

Figure 6 Effect of ryanodine and heparin on the change in $[Ca^{2+}]i$ induced by emodin. $n=15$ $^aP<0.05$ *vs* emodin group $^bP<0.01$ *vs* emodin group.

Because emodin-induced peak increase in $[Ca^{2+}]i$ was not affected by pretreatment with EGTA and nifedipine, the contribution of calcium release from the intracellular stores to the changes in $[Ca^{2+}]i$ in response to emodin was examined. Smooth muscle cells were pretreated for 10 min with ryanodine (10^{-5}M) to inhibit Ca^{2+} release from ryanodine-sensitive intracellular stores. Ryanodine markedly attenuated the peak increase in $[Ca^{2+}]i$ in response to emodin (Figure 5, $P<0.05$). In order to examine the role of IP_3 in emodin-induced increases in $[Ca^{2+}]i$, the effect of low molecular weight heparin, a specific IP_3 receptor antagonist was tested. Heparin did not diffuse across the plasma membrane, therefore, it was used in permeablized smooth muscle cells. In permeablized smooth muscle cells, the peak rise in $[Ca^{2+}]i$ induced by emodin was almost abolished by incubation with 10 μg/ml heparin (Figure 5).

DISCUSSION

The contractile effects of emodin on gastrointestinal smooth muscle have been described in several reports[8-10]. In this study, we have attempted to investigate the effects of emodin on circular smooth muscle cells of rat colon and to examine the mechanisms underlying its effects.

The result of this study showed that emodin had a direct contractile effect on smooth muscle cells freshly isolated from rat colon, as application of emodin resulted in a decrease in cell length. It was also found that exposure of smooth muscle cells to emodin induced an increase in $[Ca^{2+}]i$, and the rising in $[Ca^{2+}]i$ induced by emodin was a biphasic rise in $[Ca^{2+}]i$ consisting of a rapid, transient peak followed by a decline to sustained level that remained elevated than baseline. The involvement of calcium in emodin-induced contraction was in agreement with previous studies[9,10], reporting that emodin-induced contractions were related to calcium ion.

Calcium is believed to be the crucial signal for tension generation or shortening of smooth muscle cells[11-16]. The increase in $[Ca^{2+}]i$ induced by contractile agonists in smooth muscle cells is accompanied by Ca^{2+}/CaM-dependent activation of myosin light chain (MLC) kinase, leading to activation of myosin ATPase and cell contraction[14,17-19]. In these experiments, suppression of Ca^{2+}/CaM-dependent MLCK activity with ML-7 while maintaining Ca^{2+} mobilization partly inhibited emodin-induced cell contraction. This implies that Ca^{2+}/CaM-dependent MLCK signal pathway is involved in emodin-induced cell contraction.

Regulation of intracellular Ca^{2+} concentration ($[Ca^{2+}]i$) in smooth muscle cells involves multiple mechanisms[14,15,20]. Increases in $[Ca^{2+}]i$ can be resulted from either the transplasma membrane flux through plasma membrane Ca^{2+} channels or release of Ca^{2+} from intracellular stores, with a relative contribution from these two Ca^{2+} pools varying in different smooth muscle cells and in response to different stimuli[21-23]. The present study demonstrated that both Ca^{2+} influx and release of Ca^{2+} from intracellular sources contributed to the emodin-induced increase in $[Ca^{2+}]i$ in smooth muscle cells.

Removal of extracellular Ca^{2+} by EGTA solution caused a reduction of sustain phase of $[Ca^{2+}]i$ in response to emodin indicated extracellular Ca^{2+} contributed to the sustained elevation in $[Ca^{2+}]i$. Furthermore, compared with EGTA, blockade of L-type Ca^{2+} channel with nifedipine had no effect on the increase in $[Ca^{2+}]i$ induced by emodin. These results suggest that extracellular Ca^{2+} is essential for the sustain phase of $[Ca^{2+}]i$ and extracellular Ca^{2+} influx did not occur through L-type Ca^{2+} channel. These results also indicate that Ca^{2+} release from intracellular sources may be the main resources for the peak increases in $[Ca^{2+}]i$ induced by emodin.

Because pretreatment with EGTA and nifedipine had no effect on emodin-induced peak increase in $[Ca^{2+}]i$, it seemed likely that the portion of peak emodin-induced Ca^{2+} transient mainly depended on the calcium release from intracellular stores. The sarcoplasmic reticulum (SR) is the physiological intracellular source and sink of activator Ca^{2+} in smooth muscle cells[15,24]. The SR of smooth muscle is endowed with two different types of Ca^{2+} release channels, i.e. inositol 1, 4, 5-triphosphate receptors (IP_3Rs) and ryanodine receptors

(RyRs)[14,15,24-26]. Pretreating cells with ryanodine, a RyRs antagonist, attenuated but did not abolish the peak in $[Ca^{2+}]i$. In contrast, heparin, which inhibits the IP_3 binding to its receptor, almost abolished the peak component of the Ca^{2+} transient. These observations suggest that the residual Ca^{2+} peak observed in the presence of ryanodine is due to release of Ca^{2+} from IP_3-sensitive stores, and Ca^{2+} release through RyR receptors is possibly linked with the Ca^{2+}-induced Ca^{2+}-release (CICR). CICR means a process that a rise in $[Ca^{2+}]i$ resulted from extracellular Ca^{2+} influx or Ca^{2+} release from IP_3-sensitive store triggers further calcium release from RYR in the SR[14, 26-29]. Ryanodine receptors contain Ca^{2+} binding sites, allowing increased $[Ca^{2+}]i$ to initiate release from intracellular calcium stores[30,31]. CICR has been demonstrated to occur in a number of studies. On the basis of our findings, it appears to be operative in emodin-induced increase of $[Ca^{2+}]i$ in rat colonic smooth muscle cells.

Taken together, the results of this study indicate that emodin has a direct excitatory effect on circular smooth muscle cells from rat colon and its effect is mediated via Ca^{2+}/CaM-dependent MLCK signal pathway. The data suggest that the emodin-induced peak increases in $[Ca^{2+}]i$ primarily depend on Ca^{2+} release from IP_3 sensitive stores, which trigger Ca^{2+} release from ryanodine-sensitive stores through CICR mechanism. Additionally, Ca^{2+} influx from extracellular medium contributes to the sustained increase in $[Ca^{2+}]i$ observed in response to emodin.

Abstract

AIM: To directly investigate the relationship between telomerase activity and its subunit expression and the inhibitory effect of antisense hTR on pancreatic carcinogenesis.

METHODS: We examined the telomerase activity and its subunit expression by cell culture, polymerase chain reaction (PCR), PCR-silver staining, PCR-ELISA, DNA sequencing, MTT and flow cytometry methods.

RESULTS: PCR-silver staining and PCR-ELISA methods had the same specificity and sensitivity as the TRAP method. Telomerase activity was detected in the extract of the 10^{th}, $20^{th}$and 30^{th} passages of P3 cells,while it was absent in fibroblasts. Furthermore, after the 30th generation, the proliferation period of fibroblast cells was significantly prolonged. Telomerase activity and hTERTmRNA were detected in two pancreatic carcinoma cell lines, but were found to be negative in human fibroblast cells. Telomerase activity and hTERTmRNA were tested in pancreatic carcinoma specimens of 24 cases. The telomerase activity was positive in 21 of the 24 cases (87.5 %), and the hTERTmRNA in 20 cases (83.3 %). In adjacent normal tissues positive rates were both 12.5 %. There was a significant difference between the two groups. This indicated a significant correlation between the expression level of telomerase activity and histologic differentiation, metastasis and advanced clinical stage of pancreatic carcinoma. Our findings showed that the expressions of hTR and TP1mRNA were not correlated with the activity of telomerase but the expression of hTERTmRNA was. After treatment with PS-ODNs, telomerase activity in P_3 cells weakened and the inhibiting effect became stronger with an increase in PS-ODNs concentration. There was a significant difference between different PS-ODN groups ($P<0.05$). Inhibition of telomerase activity occurred most significant with PS-ODN1.The results of the FCM test of pancreatic cancer P_3 cells showed an increase in the apoptotic rate with increasing PS-ODN1 and PS-ODN2 concentrations.

CONCLUSION: The expression of telomerase activity has a significant relationship to carcinogenesis. A strong correlation exists between telomerase activity and hTERTmRNA expression. The up-regulation of hTERTmRNA expression may play a critical role in human carcinogenesis. The expression of telomerase activity and its subunit level in pancreatic carcinoma significantly correlate with the clinical stage of pancreatic carcinoma and hence, may be helpful in its diagnosis and prognosis. The anti-hTR complementary to the template region of hTR is sufficient to inhibit P3 cell telomerase activity and cell proliferation *in vitro*, and can lead to a profound induction of programmed cell death.

INTRODUCTION

Telomerase is a DNA-dependent RNA polymerase[1] carrying template features. It is different from reverse transcriptase, DNA polymerase of commonly pure proteins. The activated telomerase takes the 3' distal end of telomeres as the primer and its RNA component acts as the template. The protein component of telomerase regulates the catalytic activity in the synthesis of telomere repetitive sequence to maintain the telomere length. Human telomerase mainly consists of three subunits-human telomerase RNA (hTR), human telomerase-associated protein 1(TP_1) and human telomerase reverse transcriptase (hTERT). Telomerase activity has been found in most human tumor cells[2], while there is no evident expression in normal human tissues other than in germ cells, hemopoietic stem cells and cuticle basal cells[3,4]. This suggests that telomerase is a broad spectrum tumor marker[5-9]. It is recognized that activation of telomerase and stability of telomere length are necessary for tumor immortalization. However, it has been found that expression of hTERTmRNA is obviously related to telomerase activity. It is suggested that up-regulation of the expression level of hTERTmRNA is a key factor in the formation of tumor cells.

Human pancreatic cancer is one of the most frequent tumors. The present clinical treatment however has a low curative effect. The mortality rate of human pancreatic cancer is very high. Post-operative metastases are common and less than 3 % of patients have a survival rate of 5-years. In recent years, a close relationship has been found between telomerase and pancreatic cancer. By cell culture, PCR-silver staining, PCR-ELISA, RT-PCR, DNA sequencing technology, MTT and Flow cytometry methods, we have investigated the expression of telomerase activity and its subunits in pancreatic cancer cell line, fibroblasts, and in pancreatic cancer samples of 24 cases and their adjacent normal tissues. The purpose of this research was to explore the relationship between the biological behavior and clinico-pathological characteristics of human pancreatic cancer, as well as the inhibitory effects of hTR antisense oligonucleotide on pancreatic cancer cells.

MATERIALS AND METHODS

Cell lines and tissuse samples

In this study, the pancreatic cancer P_3 cells were provided by Peking Union Medical College Hospital, PaTu-8801 cells were provided by Shanghai Changhai Hospital, and the human skin fibroblasts were developed in the Zhongda Hospital. Cancer tissues and adjacent normal tissues from 24 patients with pancreatic cancer were provided and assayed by the Surgical Department of Zhongda Hospital Affiliated to Southeast University and Jiangsu Provincial People·s Hospital. These samples were frozen at -80 ℃ within 15 min after surgical removal and stored until use. Of the 24 patients, 13 were male and 12 female.Their age ranged between 55-74 years with an average of 63 years.

Cell culture

Culture of the pancreatic cancer P_3 cells and PaTu-8801 cells: P_3 cells and human skin fibroblasts were cultured in 1640 culture medium and PaTu-8801 cells in DMEM culture medium (high glucose content) with 10 % inactivated calf serum and all were put in 5 % CO_2 at 37 ℃ for generational culture at 100 % RH.

Telomerase assay

Telomerase extracts and assays of activity were done as TRAP method. Briefly frozen pancreatic tissue samples of approximately 200 mg were homogenized in 200 μl of lysis reagent containing 5 % CHPAS (3-(3-cholamidopropyl dimethyammonio)-1-propanesulfonate lysis buffer, Roche Co.). The cells obtained by cell culture were also treated with lysis reagent containing 5 % CHPAS (Roche Co.). After 30 min of incubation on ice,the lysates were centrifuged at 16 000×g (tissue) or 34 000×g (cell) for 20 min at 4 ℃, and the supernatants were rapidly frozen in liquid nitrogen and stored at -80 ℃ until use. In the extracts from frozen tissues, the concentration of protein was measured using the Coomassie brilliant blue method. BCA. Extracts of 293 cell line with telomerase activity were used as the standard, while extracts obtained by inactivation for 10 min at 94 ℃ or treated with RNase for 10 min at 37 ℃ were used as the negative control. For cell samples, aliquots corresponding to extracts derived from approximately 10^2, 10^3, 10^4, 10^5 cells were used for TRAP assay. Extracts of tissues containing 0.06, 0.6 and 6 μg of protein were used for TRAP assay. Each extract specimen was assayed in 25 μl reaction mixture (Roche Co assay kit containing dNTP, Taq enzyme, biotin tagged TS primer and CX primer) which was diluted to 50 μl with DEPC water solution. After 30 min incubation at 25 ℃ for telomerase-mediated extension of the TS primer, the reaction mixture was heated at 94 ℃ for 5 min and then subjected to 30 PCR cycles at 94 ℃ for 30 s, at 50 ℃ for 30 s and at 72 ℃ for 50 s and then extended for 10 min at 72 ℃. Firstly, the PCR product went through enzyme-linked immunosorbent assay (PCR-ELISA) containing DIG-labeled probes (Roche Co assay kit). After spectrophotometric determination, the absorbance value A(=A_{450}-A_{690}) was calculated. The result was positive if A >0.2. Secondly, the PCR product was electrophoresed on a 10 % polyacrylamide gel. The telomerase activity was positive if the specific band appeared. For each sample of pancreatic carcinoma tissue, the intensity of telomerase was graded according to the different contents of protein in the extract specimen. A sample intensity of telomerase was represented as (-) if the specimen containing 6 μg extracted protein was tested to be negative, or (+) if the specimen containing 6 μg extracted protein was tested positive. If both sample specimens containing 6 μg and 0.6 μg extracted protein were tested positive, while the specimen containing 0.06 μg extracted protein was tested to be negative, it was represented by (++), and (+++) if all three specimens containing 6 μg, 0.6 μg, and 0.06 μg extracted protein were tested positive[10].

Expression of the subunit of telomerase

Analysis of the expression of each telomerase subunit was performed by RT-PCR amplification[11-13]. hTERT mRAN was amplified by using the primer pair (145 bp): LT5 5' -CGGA AGAGTATCTGGAGCAA-3' , LT6 5' -GGATGAAGCGGA GTCTGGA-3' . TP1 mRAN was amplified by using the primer pair (340 bp), TP1.1 5' -TCAAGCCAAACCTGAATCTGAG-3' , TP1.2 5' -CCCCGAGTGAATCTTTCTACGC-3' . hTR was amplified by using the primer pair (134 bp): F3b 5' -TCTAACCCTAACTGAGAAGGGCGTAG-3' , R3c 5' -GTTTGCTCTAGAATGAACGGTGGAAG-3' . The efficiency of cDNA synthesis from each sample was estimated by PCR with glyceraldehyde-3-phosphate-dehydrogenase (GAPDH)-specific primers of (450 bp): K136 5' -CTCAGACACCATG GGGAAGGTGA-3' ,K137 5' -ATGATCTTGAGGCTG TTGTCATA-3' . cDNA was synthesized in 20 μl of reaction mixture containing 5×RT Buffer 4 μl, RNasin 0.5 μl, total RNA 1 μl, and MLV 0.8 μl with 1 μl random primers. The reaction mixture was incubated at 94 ℃ for 5 min before it was heated at 95 ℃ for 5 min to inactivate MLV. To amplify the cDNA 2 μl aliquots of the reversely-transcribed cDNA was subjected to 35 cycles of PCR in 50 μl containing 10×buffer (10 mM Tris-HCl (pH8.3), 25 mM $MgCl_2$, 500 mM KCl) 10 mM dNTP 1 μl, 25 mM $MgCl_2$ 2-3 μl, Taq enzyme 4 unit and 10 pM of specific primers 22 μ1. After heated at 94 ℃ for 5 min, each cycle consisted of de-naturation at 94 ℃ for 45 s, annealing at 56 ℃ for 45 s (hTERT) or at 61 ℃ for 45 s (hTR) or at 60 ℃ for 45 s (TP_1) and extension at 72 ℃ for 90 s and then extended at 72 ℃ for 10 min. PCR products were electrophoresed on 3 % agarose gel with ladder marker to determine the concentrations and purity of PCR amplified products. hTERTmRNA PCR products were sequenced (sent to Shanghai Biolottering Co, Ltd.).

Inhibitory effects of antisense hTR

Four nucleotides were synthesized as hTR template sequence (5' -CUAACCCUAAC-3') and modified by thiophosphoric acid. They were PS-ODN1: 5' -GTTAGG-3' (antisense), PS-ODN2: 5' -GTTAGGGTTAG-3' (antisense), PS-ODN3: 5' -CCTAAC-3' (pro-sense), and a PS-ODN4 with random sequence: 5' -AACTCGTAGTC-3' . After 5×10 P_3 cells and human fibroblasts were inoculated into culture bottles and replaced the old culture medium with a fresh one after 24-h-lasting cultivation, the cells stuck to the wall of bottle. The test group was arranged PS-ODN1, PS-ODN2, PS-ODN3, PS-ODN4 so that each had four concentrations, 3.16 μmol/L, 10 μmol/L, 31.6 μmol/L, and 100 μmo1/L. They were added into the culture bottles, respectively. Additional sets were the control groups which had no PS-ODN. The following tests were conducted when obvious change in cytomorphology was observed under the optical microscope. Firstly, P_3 and human fiber forming monolayer anchorage-dependent cells were digested. The suspended cells were cultured in RPMI 1640. After the suspended cell liquor was inoculated into a 96-cave culture board (100 μ1 per cave), 20 μ1 of freshly prepared 5 mg/ml MTT solution was added into each cave. This was incubated for 4 h at 37 ℃, the culture medium in the caves was discarded, and then dimethyl sulfoxide (DMSO) 150 μ1 was added into each cave to be shaken for 10 min to solve the crystal. The activity of succinic dehydrogenase (SDH) was determined according to the optical absorbance of the content in each cave at 540 μm in an enzyme-linked immunoassay analyzer. Secondly, after 2×10^6 P_3 cells were treated with each

of the different PS-ODNs, the activity of telomerase extracts was assayed according to the TRAP, PCR-ELISA and polyacrylamidedel gel (10 %) electrophoresis (PAGE). The telomerase extract of 293 cell line was taken as the positive control. The extract that was subjected to inactivation for 10 min at 94 ℃ or RNase treatment for 10 min at 37 ℃ was taken as the negative control. Finally, the single cell suspension was prepared by digesting anchorage-dependent cells after treatment with PS-ODN1 and PS-ODN2, respectively. It was cool-washed three times, and then centrifuged for 10 min at 2 000 rpm. After the supernatant was discarded and dried, precooled 95 % alcohol was added and the sample was placed into a refrigerator at 4 ℃ for 1 h, and then incubated with 10 μg/ml RNase at 4 ℃ for 3 h. The apoptotic rate and the cell cycle distribution of pancreatic cancer cells were analyzed by a flow cytometer (DB Corp. United States) after 1 ml propidium iodide comprehensive staining solution was added in an ice-bath for 15 min. Data were collected by Cellquest software and analyzed by Mmodift Lt software.

Statistic analysis

The data were processed by *t*-test and variance analysis. The *P* value was determined according to the *t* value, *F* value and FI value.

RESULTS

Cell culture

There were morphological changes in the fibroblasts (HE stain) of the 32nd generation, such as karyopyknosis, cytoplasmic concentration, and cell body shrinkage. No changes were found in P_3 cells. P_3 cells, and fibroblasts of the 10th, 20th, and 30th generations were used to detect the activity of telomerase in this test. All results were positive for P_3 cells, and negative for fibroblasts (Figure 1).

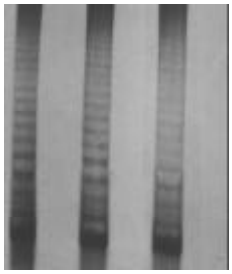

Figure 1 Telomerase activity of fibroblasts and P_3 cells of different generations (1, 3 and 5 were P_3 cells of the 10th, 20th, and 30th generations; 2, 4, and 6 were fibroblasts of the 10th, 20th, and 30th generations).

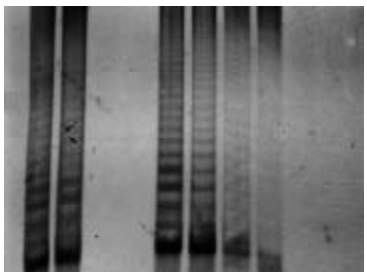

Figure 2 Specificity and sensitivity of telomerase activities in P3 cells (1, 293 cells as the positive control; 2,104 P_3 cells; 3, treated with RNase; 4, heat treated; 5, 6, 7, and 8 were 103, 102, 101, and 100 P_3 cells, respectively; 9, the lytic liquid).

Telomerase assay

The protein content was calculated from the sample extract, and standard curves were prepared by using the data. The protein contents in the sample extracts were determined by Coomassie brilliant blue method. PCR-silver staining method was used to detect the activities of telomerase in 10 cells or 1 μg protein extracted from a sample. PCR-ELISA method had a same sensitivity as PCR-silver staining (Figure 2).

The results were positive for the activity of telomerase in pancreatic cancer cells, and negative for fibroblasts. There were 21 cases whose telomerase activity was detected in the 24 pancreatic cancer tissues by PCR-ELISA or PCR silver staining. Four cases of them were (+++), 11 cases (++), and 6 cases (+). The rate of positive findings was 87.5 %. However, there were only 3 cases with telomerase activity (+) was found in adjacent normal tissues, with a positive rate of 12.5 % (Figure 3).

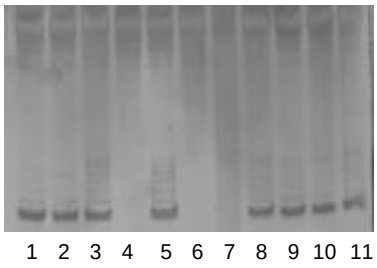

Figure 3b Semiquantitative telomerase activity of tumor and normal pancreas (1 2 3; 5 4 6; 9 10 11: T_{10}, T_{15} T_{18} 6 μg 0.6 μg 0.06 μg; 7: negative control, 8: positive control; T: tumor).

Detection of telomerase subunit

Pancreatic cancer cell P_3, and PaTu-8801 were taken as the positive control, while the fibroblast was taken as the negative control. There were 20 cases which expressed hTERTmRNA in cancer tissues of 24 cases, and 3 cases expressed hTERTmRNA in the adjacent normal tissues. 4 of 24 cases of cancer tissue did not express hTR and 3 cases of the adjacent normal tissues did not express hTR. Two cases tested were negative for TP_1 (Figure 4).

The cDNA sequencing of hTERTmRNA PCR products showed that there were 143 base groups that were significant sequences between the 51st and the 193rd base groups.The homology with hTERTcDNA reached 98.6 %, proving that the amplification products were the hTERTcDNA sequence amplified from hTERT.

Relationship between the expression of telomerase activities and its subunit with human pancreatic cancer, its biological behavior and clinico-pathological characteristics

[a]P<0.01 (F=26.06); [b]P<0.01 (t=3.22); [c]P<0.01 (F=9.31).

A correlation existed between the expression level of telomerase activity in pancreatic cancer tissues with histologic differentiation, presence of lymph node metastasis, and clinical TNM stage of the tumor (no significant difference between stages III and IV). However, in pancreatic cancer patients no correlation was found between the expression level of telomerase activities and age or sex of patients, pathologic category or tumor infiltration.

Table 3 shows the relationship between telomerase activity and telomerase subunit.

There was also an obvious correlation between expression of hTERT and telomerase activities in pancreatic cancer tissues, but no correlation was found between expressions of hTR and TPlmRNA and telomerase activities.

In 24 pancreatic cancer tissues and adjacent normal tissues, their hTR/GAPDH ratios were 0.592±0.056 and 0.510±0.059, respectively. No difference was found in the expression level of hTR.

Inhibitory effects of antisense hTR

In the control groups, pancreatic cancer cells extended in polygon, showed large differences in their size and shape. The cells were more transparent, strong refractive, overlapped to grow after fully covering the bottom of the bottle and mitotic figures increased. After treatment with PS-ODN1 and PS-ODN2, morphologic changes of cells were obvious-refractiv, intercellular space became larger and the cells gradually became round, crenated, and fell off[14]. Occasionally, ballooning could be seen. When P_3 cells and human fibroblasts were treated with four PS-ODNs for reflecting the survival rate of cells, the results of SDH activity are shown in Table 4 and Table 5. There was a significant difference in the effects between the different PS-ODN groups (P<0.05). Along with an increase in concentrations of PS-ODN1 and PS-ODN2, the survival rate of cells significantly decreased. There was a significant difference between different concentrations in the same groups (P<0.05). No significant difference was found between PS-ODN1 and PS-ODN2. It was found that PS-ODN3 also might cause a decrease in SDH activity,but the decrease was less obvious than that of the former two. Inhibition of SDH activity occurred earliest with PS-ODN1. Comparison between different PS-ODNs and different concentrations of any PS-ODN (P<0.05) showed that the four PS-ODNs of any concentration had no significant effect on the survival rate of normal human fibroblasts.

After P_3 cells were treated by four PS-ODNs, their telomerase activity was detected using the PCR-ELISA method. The results showed that there was a significant difference between different PS-ODN groups ($P<0.05$). PS-ODN1 and PS-ODN2 showed similar results when different concentration groups were compared ($P<0.05$), suggesting that telomerase activity in P_3 cells weakened and the inhibiting effect became stronger with increasing concentration. There was no significant difference of telomerase activity between the different concentration groups of PS-ODN3 and PS-ODN4 ($P>0.05$) (Table 6). The results of quantitative tests of telomerase activity in PS-ODNs-treated P_3 cells by TRAP-PAGE silver staining method are shown in Figure 5. After treatment by PS-ODN1 and PS-ODN2, the telomerase activity in P_3 cells was positive. The brightness of the bands darkened with increasing PS-ODN1 and PS-ODN2 concentrations, and expression of the telomerase activity had a tendency to be depressed.

The FCM results of pancreatic cancer P_3 cells showed the apoptotic rate of cells increased along with increasing PS-ODN1 and PS-ODN2 concentrations. Fifty days or so after continuous treatment of the cells at 100 μM concentration of PS-ODN1 and PS-ODN2, the apoptotic rate of cells was 81.03 % and 70.75 %, respectively. The cycle distribution increased from 86.51 % and 83.89 % to 94.53 % and 95.39 % for cells in stage G_o/G_1, and reduced from 13.49 % and 16.11 % to 5.47 % and 2.11 % for cells in stage S, respectively (Figure 6).

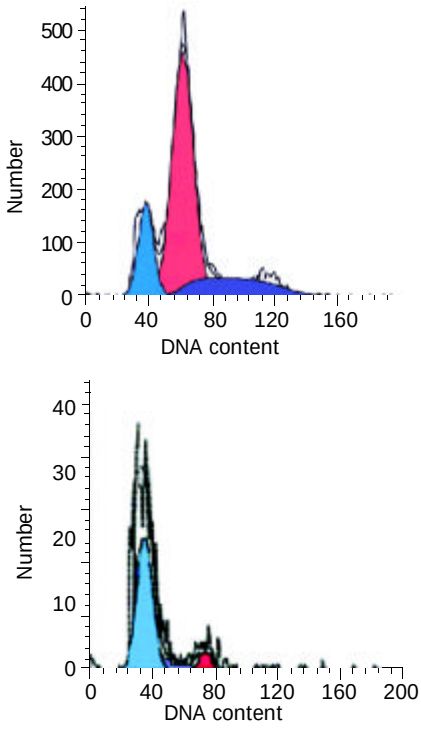

Figure 6 The apoptotic rate of P3 cells by the FCM test after treatment in P_3 cells with PS-ODN. A: PS-ODN1 10 μmol/L group; B: PS-ODN1 100 μmol/L group.

DISCUSSION

The activation of telomerase and maintenance of telomere length are essential for tumor cell immortalization. The positive rate of telomerase activity was 85-95 % in patients with pancreatic cancer, much higher than that in patients with benign pancreatic diseases[15-18]. Therefore, it can be deduced that there is a close link between telomerase activity and metastatic potential of pancreatic cancer cells[19].

The 10th, 20th, and 30th generations of cultured tumor cells and fibroblasts showed a significant difference in their telomerase activities. The results showed a positive telomerase activity for tumor cells, whereas it was absent in all generations of fibroblasts. After the 30th generation, the fibroblast cell proliferation period was obviously elongated, and part of the cells were found to have morphologic changes such as karyopyknosis, cytoplasmic concentration and cell-body shrinkage on HE stain. These findings indicate that telomerase is involved in immortalization of pancreatic cancer cells.

Hiyama *et al*[15]. reported positive telomerase activity was found in 43 cases. Among them, five cases were found to have a low level of telomerase activity expression in the adjacent normal tissues. In 24 pancreatic cancer samples, the positive rate of telomerase activity was 87.5 %, while there were 3 cases whose telomerase activity appeared in the adjacent normal tissue, a positive rate of 12.5 %. Of the three cases, one was proven to be infiltrated by tumor cells. The positive rate of hTERTmRNA in pancreatic cancer samples was 83.3 %, and 12.5 % in the adjacent normal tissue.

The results of this study support the theory that telomerase is involved in the formation of pancreatic cancer. It is a consensus that the prognosis is poor in patients with low differentiation and wide infiltration of human pancreatic cancer, i.e., those falling into the TNM stages III-IV of the

pancreatic cancer[20-22]. By statistic analysis, our data showed that there was a definite correlation between the expression level of telomerase activity in pancreatic cancer and histologic differentiation, presence of lymph node metastasis and TNM staging of the tumor. However, no significant correlation was found between it and age, sex of the subjects, pathologic category and degree of infiltration. Along with increasing expression level of telomerase, the tumor showed a higher lymph node metastasis. Therefore, the prognosis became much worse. We did not perform any post-operative follow-up studies.Tang *et al*[22] reported that patients with pancreatic endocrine neoplasm who were positive in telomerase expression usually had a shorter life expectancy than those who were negative in telomearse expression.

In the tumor cell line with positive telomerase expression, hTERTmRNA was found to have a higher expression level, whereas it was absent in normal tissues. In 21 cases of pancreatic cancer tissues with positive telomerase activity, hTERTmRNA was detected in 18 cases and only one case was found to be positive in the adjacent normal tissue which showed no telomerase activity.

Statistic analysis showed a significant correlation between hTERTmRNA and telomerase activity. Therefore, it may be thought that expression of hTERT is an important factor in governing telomerase activity[23, 24] and that up-regulation of hTERTmRNA expression may play an important role in the formation of pancreatic cancer. However hTERTmRNA was detected in two of the pancreatic cancer samples in which no telomerase activity was found. This may be explained by the following factors: (1) The expression level of each subunit or an equilibrium state between their expression levels determines the activity of telomerase; (2) Modification of the telomerase subunit after its transcription may have a regulating effect on the enzyme activity; (3) telomerase inhibitor existing in the cell extract reduces the activity of telomerase. Furthermore, there were 3 cases whose telomerase activity was detected, while the expression of hTERTmRNA showed negative results. There may be other factors to determine the activity of telomerase in this latter situation.

This study found that though the expression level of hTR in pancreatic cancer tissue was higher than that in adjacent normal tissue, it had no statistical significance. hTR itself cannot reflect the activity of telomerase. However, its function is essential for the activity of telomerase. This point is consistent with other studies[25-28].

It was found in our study that inhibition of the growth of P_3 cells by PS-ODN1 occurred the earliest. This was probably not only due to the smaller PS-ODN1 molecules entering cells, but also due to two important basic UC groups at the junction of the closed hTR templates. No significant effect was found on the survival rate of the P_3 cells in the random sequence group, while slight inhibition of P_3 cells growth was found in the pro-sense group. This could be explained as the pro-sense oligonucleotide competed against telomerase RNA in quantity and space, thus impeding the attachment of telomere with RNA template zone to a certain degree[29]. The results showed that inhibition of PS-ODN1 and PS-ODN2 on the growth of P_3 cells was dosage-dependent. This implies that after hTR template is closed, telomerase can no longer bring its activity into full play. Therefore it can be concluded that hTR is involved in the regulation of telomerase activity[30].

FCM results showed that the apoptotic rate of P_3 cells would increase along with increase of the concentrations of antisense oligonucleotide, at the same time, cells in G_0/G_1 stage increased in quantity while those in S stage decreased. This suggests that treatment with PS-ODN1 and PS-ODN2 may block the cells at G_0/G_1 stage and induce apoptosis.

In regard to the relationship between telomerase activity and cell cycle, it was thought[31] that the tolemerase activity was regulated in the cell cycle-leading mode. It was also thought that tolemerase should be activated at the DNA replication stage as tolemerase activity was essential to maintain tolemere. This activity is not required at the non- replication stage of the cell cycle. Telomerase has different activity at different stages of the cell cycle, its highest rate is at S stage, lowest at G_2/M stage, and almost no activity at G_0/G_1 stage. Our results support this point of view.

We simultaneously observed the influence of PS-ODNs on SDH activity and proliferation of normal human fibroblasts. The results showed that it had a significantly inhibitory effect on the metabolism and proliferation of cells. Therefore, it can be assumed that the effect of antisense hTR is cell-specific, and has no harmful action on normal cells.

Our study suggested that there was no correlation between the expression of TPlmRNA and telomerase activity in pancreatic cancer. However, the function of TP1 is still not clearly known, and it may be related to interaction with protein. TP1 may play a role in the interface between telomerase and telomere conjugated proteins. Modification after transcription of TPlmRNA may regulate the telomerase activity.

In conclusion, telomerase may be taken as a subsidiary parameter for the diagnosis and outcome of pancreatic cancer. For preoperative patients, detection of the telomerase activity may be conducted on blood, or pancreatic juice and duct cells taken from ERCP on fine needle aspiration specimens for early diagnosis[32-35]. Antisense oligonucleotide can reduce the activity of telomerase in pancreatic cancer P_3 cells, inhibit the growth of P_3 cells, promote changes in cell cycle and induce their apoptosis[36, 37].

Abstract

AIM: To evaluate p53 protein overexpression and to measure serum CA19.9 concentrations in cytological diagnosis of patients with suspected pancreatic cancer.

METHODS: 24 patients with suspected pancreatic cancer due to chronic pancreatitis, had a pancreatic mass determined by imaging methods. The serum CA19.9 concentration was measured by solid phase radioimmunoassay. On laparotomy, puncture biopsy was performed, and specimens were divided into two parts for cytological diagnosis and detection of p53 protein.

RESULTS: Cytology offered a sensitivity of 0.63, a specificity of 1.00, and an accuracy of 0.63. p53 protein analysis offered a sensitivity of 0.44, a specificity of 1.00, and an accuracy of 0.73. CA19.9 offered a sensitivity of 0.44, a specificity of 0.80, and an accuracy of 0.67. The combined cytology and p53 protein analysis showed a sensitivity of 0.78, a specificity of 1.00, and an accuracy of 0.92. Cytology and CA19.9 showed a sensitivity of 0.67, a specificity of 0.80, an accuracy of 0.67. combined cytology and p53 protein analysis and CA19.9 showed a sensitivity of 0.78, a specificity of 0.80, and an accuracy of 0.79.

CONCLUSION: Superior to any single test, the combined approach is helpful for the differential diagnosis of pancreatic cancer complicated with chronic pancreatitis.The combined cytology and p53 protein analysis offers the best diagnostic efficacy.

INTRODUCTION

The differential diagnosis of pancreatic cancer (PC) complicated with and chronic pancreatitis (CP) is difficult because of their common clinical symptoms and overlapping findings. Increased pancreatic adenocarcinoma risk in chronic pancreatitis patients has renewed the interest in early tumour diagnosis and in the differentiation of neoplastic and chronic inflammatory ductal changes[1, 2]. If a pancreatic mass is discovered by the imaging method, cytological examination is required to make a conclusive diagnosis. Owing to a large number of cases without a conclusive diagnosis[3], it would be worthy to diagnose it with other methods. Genomic alterations in p53 tumour-suppressor gene and overexpression of p53 protein are frequently found in pancreatic cancer, but rarely in chronic pancreatitis. An elevated serum CA19.9 concentrations is found in a high proportion of patients with pancreatic cancer and this is considered to be the standard serum marker for adenocarcinoma of the pancreas. In the current study, we retrospectively evaluated overexpression of p53 protein, serum CA19.9, and cytology in the diagnosis of pancreatic cancer.

MATERIALS AND METHODS

Materials

24 patients,19 men and 5 women, with a mean age 58.6 years, (range 41-69 years,) with jaundice, weight loss, and abdominal pain, underwent pancreatectomy in our hospital between January 1995 and December 2001 because of high suspicion of pancreatic cancer arising from chronic pancreatitis. Preoperatively, they were found to have a mass in the pancreas by CT and ERCP. 19 masses were located in pancreatic head, two in the body, and two in the tail, 1 with three foci.

Methods

CA19.9 determination The serum samples were stored at -20 ℃ for CA19.9 by solid phase radioimmunoassay. A value of 37 U/ml was the upper limit of normal.

Cytological examination Puncture biopsy of the pancreas was performed during laparotomy, and the specimen was divided into two parts: one part was used for making fresh smears, after papanicolaou staining. The presence of malignant cells and suspicious cells were examined under microscope (Figures 1-2). The other part was employed for immunohistochemical analysis.

Immunohistochemical analysis The sample was fixed in buffered formaldehyde and paraffin-embeded. Histological sections (5 μm) were prepared, mounted on poly-L-lysine-coated slides and dried for 12 to 24 h at 37 ℃. Immunohistochemistry was performed with the avidin-biotin complex (ABC) kit[4] using the monoclonal antibody which recognizes both mutant and wild-type p53.

The result was graded as either negative or positive. The specimen was considered to positive when >5 % of the tissure component was unequivocally immunoreactive in the appropriate cellular compartment (Figure 3).

Histological examination The resected specimens were fixed in 10 % formaldehyde and sliced into 5 mm sections and stained with hematoxylin-eosin. The presence or absence of cancer was microscopically determined.

Statistical analysis

Statistical analysis was performed with STATISTICA for Windows. Differences between the results of two groups were tested with one-sided *t* test. A *P* value <0.05 was considered statistically significant.

RESULTS

Histological diagnosis

9 patients were diagnosed as pancreatic cancer complicated with chronic pancreatitis, including carcinoma of the pancreas head in 6 cases; carcinoma of the body and/or tail of pancreas in 2 cases, multifocal cancer with three foci in 1 case. The other 15 patients were confirmed to be chronic pancreatitis, including 13 cases with inflammatory mass in the head of pancreas, and two cases with adenoma in the body and/or tail of pancreas.

To compare with histological diagnosis, cytology offered a conclusive diagnosis in 5 of 24 cases. The cytological report was not conclusive in 19 cases (9 cases with suspicious cells and 8 cases with insufficient material, and two cases without non-malignant cell) (Figures 1,2).

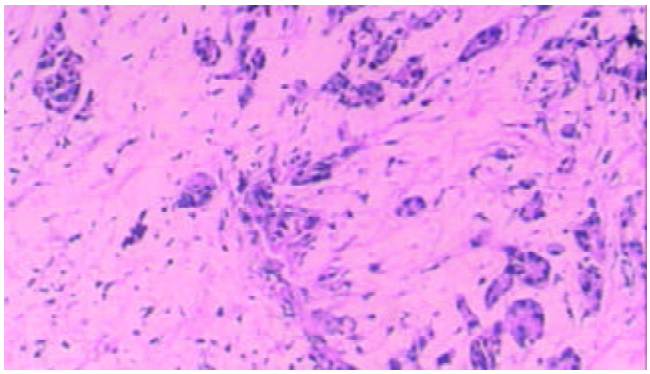

Figure 1 A little glandublar tissue and a large amount of fibrotic tissue.

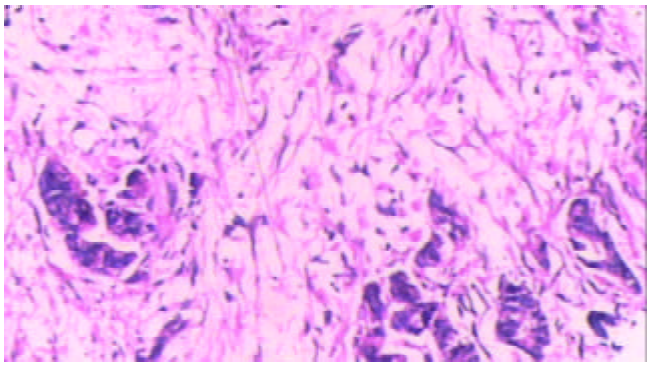

Figure 2 A few cancerous cells scattered in fibrotic gland tissue. (Papanicolaou staining, original magnification ×200).

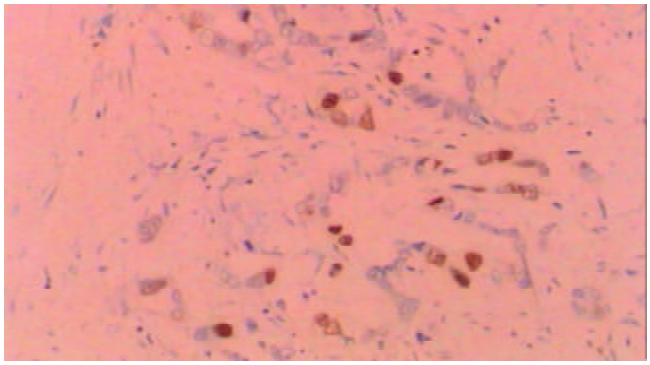

Figure 3 Yellow-brownly stained nuclei of p53 positive cells (ABC, original magnification ×400).

The presence of malignant cells in puncture samples was detected in 5 of 9 pancreatic cancer patients confirmed by histological examination. According to cytological diagnosis. The incidence of p53 protein overexpression and CA19.9 values ovre shown in Table 1.

Table 1 Patients with p53 protein overexpression and high serum CA19.9 with cytologically diagnosed pancreatic disease (*n*=24)

Histological diagnosis	Cytology				
	Patient *n*(%)	Malignant cells	Suspicious cells	Insufficient material	Non-malignant cells
Malignant diseases					
PC	9(37.5) p53(+)	2/5	1/1	1/1	0/2
	CA19.9≥37 U/ml	3/5	1/1	0/1	0/2
Benign disease					
IMH	13(54.2) p53(+)	0	0/5	0/4	0/4
	CA19.9≥37 U/ml	0	2/5	1/4	0/4
Adenoma	2(8.3)p53(+)	0	0/2	0	0
	CA19.9≥37 U/ml	0	0/2	0	0

PC: pancreatic cancer; IMH: inflammatory mass of the head of pancreas.

Table 2 Assay effectiveness in patients with pancreatic diseases (*n*=24)

Assay	Sensitivity TP/(TP+FN)	Specificity TN/(FP+TN)	Predictive value of positive test TP/(TP+FP)	Efficiency (TP+TN)/Total
Cytology alone	5/(5+3)=0.63	10/(0+10)=1.00	5/(5+0)=1.00	(5+10)/24=0.63
CA19.9>37 U/ml	4/(4+5)=0.44	12/(3+12)=0.80	4/(4+3)=0.57	(4+12)/24=0.67
P53(+)	4/(4+5)=0.44	15/(0+15)=1.00	4/(4+0)=1.00	(4+15)/24=0.79
Cytology+CA19.9	6/(6+3)=0.67	12/(12+3)=0.80	6/(6+3)=0.67	(6+12)/24=0.67
Cytology+P53	7/(7+2)=0.78	15/(15+0)=1.00	7/(7+0)=1.00	(7+15)/24=0.92
Cytology+P53+CA19.9	7/(7+2)=0.78	12(3+12)=0.80	7(7+3)=0.70	(7+12)/24=0.79

TP: true-positive; FN: false-negative; FP: false-positive; TN: true-negative.

p53 protein overexpression (shown by immunohistochemical staining) was positive in 4 of 9 patients with pancreatic cancer (Figure 3), and negative in the remaining 20 specimens. The combination of p53 protein overexpression and cytology offered a78 % sensitivity and a 100 % specificity.

Using the cut-off value of 37 U/ml as the normal upper limit, CA19.9 measurement identified 4 of 9 pancreatic carcinomas (range=41-480 U/ml). Additionally, high concentrations were also detected in 3 cases of chronic pancreatitis with a mass (range=210-1 200 U/ml). CA19.9 positivity in the chronic pancreatitis patient was related to common bile duct obstruction. The combined CA 19.9 and cytological assay showed a sensitivity of 67 % and a specificity of 80 %.

Combination of cytological analysis, P53 protein overexpression and CA19.9

Since all positive cytologies carried a final diagnosis of carcinoma, the main diagnostic contribution of p53 and CA19. 9 in the pancreatic cancer group was at the time when the cytology was suspicious or not contributory. Either test contributed to the final diagnosis of pancreatic adenocarcinoma in 4 out of 9 cases: in one case both were positive, in another case p53 protein showed overexpression but CA19.9 value was lower than 37 U/ml. None of the patients with chronic pancreatitis was positive for both markers. The sensitivity of the combined approach was 78 % with a specificity of 80 %. Both the sensitivity and efficiency of the combined approach (cytology, CA19.9, and p53 protein overexpression) were significantly higher than that of either test alone (P<0.01). Both the sensitivity and efficiency of combination of cytology and p53 were higher than that of combination of cytology, p53 and CA19.9 (P<0.05). Finally both the sensitivity and efficiency of the combined approach of cytology, p53 and CA19.9 were better than that of combination of cytology and CA19.9 (P<0.05) (Table 2).

DISCUSSION

Much effort has been devoted to achieve an optimum standard for conventional imaging procedures to increase the sensitivity and specificity of these diagnostic tools. Among which CT, ERCP are the mainstay for pancreatic cancer detection[5,6]. However, these morphologically oriented procedures, have an unsolved drawback ie, the inability to differentiate tumour tissue from pancreatic masses caused by chronic pancreatitis. Therefore, this has limited their application in patients with a suspected resectable mass for the decision of surgical exploration. FNA biopsy of the primary tumor has a significantly false negative rate due to the inflammatory response around the tumor, which accounts for the lower sensitivity[3]. According to a 1986 review, the average sensitivity was approximately 80 %[7]. A more recent, large, single-institution series reported a sensitivity of 72.5 %[8]. FNA-cytological distinction between chronic pancreatitis and pancreatic cancer is occasionally difficult because chronic pancreatitis can induce morphological changes similar to those seen in well differentiated adenocarcinoma[9]. This explains the equivocal results found in two kinds of pancreatic diseases, which can not be discriminated by clinical and imaging tests. In addition, the accuracy of cytology examination also depends on the quality and number of cells. The reported sensitivities of ERCP aspiration cytology, brush cytology, FNA biopsies, and forceps biopsies were in the range of 22 % to 71 %, and the use of multimethod samplings increased the sensitivity to 50-78 %[10]. Even with endoscopic ultrasonography-guided FNA biopsy, there were also false negative results[11]. Sometimes the accuracy of cytology might be damaged by poor staining or inadequate fixation[12]. The distinction between chronic pancreatitis and well-differentiated adenocarcinoma is difficult and it remains to find whether artificial intelligence algorithms can prove themselves useful in the cytologically differential diagnosis of carcinoma and chronic pancreatitis[9].

The greatest usefulness of carbohydrate antigen CA19.9 is its performance in detecting pancreatic cancer using a cutoff upper limit of 37 U/ml[13-16]. However, it can be confusing to interpret elevated concentrations of CA19.9, because the elevated concentration of CA19.9 used for the diagnosis of pancreatic cancer can also be seen in benign conditions such as pancreatitis[17-19], and conversely CA19.9 may be low in malignant conditions[20]. As shown in Table 1 and Table 2, the application of CA19-9 for differentiating cancer from chronic pancreatitis was disappointing in our study because of its low sensitivity and specificity, which were only 44 % and 80 %, similar to those reported by Okaga *et al*[21]. This may be explained by the elevation of CA19.9 in benign inflammatory conditions as well as in malignant diseases. According to Ker *et al*[22] CA19.9 is synthesized by normal biliary ductal cells. In benign biliary obstruction, epithelial cells will proliferate, and as a result, more CA19.9 may be secreted and leaks out into the bloodstream. The other mechanism concerning the false serum elevation of tumour markers in chronic pancreatitis has been shown to be a disturbed antigen polarity[23].

p53 gene abnormalities are considered to play an important role in the carcinogenesis of pancreatic cancer present in almost half of pancreatic cancer, but uncommon in chronic pancreatitis[24-26].

Studies on p53 abnormalities generally look for overexpression or persistence of the p53 protein, or for mutations in the genic sequence. Mutations of p53 gene lead to an accumulation of p53 protein reaching detectable concentrations by immunohistochemistry. In contrast, production of the wild type p53 gene is undetectable because of its short half-life. Thus there seems to be a good correlation between the overexpression of p53 protein and p53 gene mutations[27]. The p53 protein concentrations are correlated with percentage of p53 gene alterations[28,29]. In 40-60 % of pancreatic carcinomas, mutations of p53 gene and the increased accumulation of p53 protein have been shown by both direct sequencing and immunohistochemistry[30,31]. Both methods require tissue specimens. In comparison with cytology the, biggest advantage of gene analysis is no need to search for integrity or large number of cells. This method is sensitive enough to detect 3-30 mutant copies in the presence of 300 000 normal copies of the gene (which would be the equivalent to 0.01 ng of mutant DNA in 1 mcg of total DNA)[32]. In our series we found p53 protein overexpression in suspicious cells and insufficient materials.

In the current study, we analyzed the relative and combined contributions of the detection of p53 protein and CA19.9 concentration to the cytological diagnosis of pancreatic cancer when there was a clinical suspicion of pancreatic cancer corroborated by imaging diagnostic technique. In FNA samples, overexpressions were detected in 44 % of carcinoma. Fortunately no false-positives were detected even in the subset of chronic pancreatitis patients with a mass. Using a cut-off upper limit of 37 U/ml, the high CA19.9 concentrations were not strongly suggestive of pancreatic cancer. Although CA19. 9 is superior to any single markers elevated, it is not suitable for determining the nature of a pancreatic mass in patients with chronic pancreatitis. Similar results were also reported by other authors[33].

The combination of cytology and p53 offered the best diagnostic procedure. In four out of 9 patients with PC, the p53 protein overexpression contributed much to supporting the cytological diagnosis. Therefore, p53 protein overexpressions in FNAs are specific for pancreatic cancer, but CA19.9 values are not. Interestingly, none of the patients with chronic pancreatitis was positive for both markers,

suggesting that the combination of cytology and p53 might be useful in distinguishing PC and CP.

In conlusion, p53 protein analysis enhanced the diagnostic sensitivity of cytological evaluation in chronic pancreatitis patients with clinical suspicion of pancreatic cancer, especially in those with inconclusive cytological results such as the presence of suspicious cells or insufficient cellular material. In this case, p53 protein overexpression analysis offered a highly specific test although it was rarely employed as a clinical decision-making process.The previous clinical evidence also indicated the diagnostic benefit provided by p53 and other molecular marker analysis[34, 35], with an accumulation of more patients in such a study, there will be growing facilities for differentiating PC from CP.

Abstract

AIM: To describe the mortality rate of pancreatic cancer and its distribution in China during the period of 1991-2000.

METHODS: Based on the data of demography and death collected through China's Disease Surveillance Point System (DSPS) over the period of 1991-2000, the distribution of death rate of pancreatic cancer was described in terms of age group, gender, calendar year, rural/urban residence and administrative district.

RESULTS: A total of 1 619 death cases attributed to pancreatic cancer (975 men and 644 women) were reported by DSPS during 1991-2000. The reported, adjusted and age-standardized mortality rates increased from 1.46, 1.75, and 2.18 per 100 000 populations in 1991 to 2.38, 3.06, and 3.26 per 100 000 populations in 2000. The majority (69.62 %) of the deaths of pancreatic cancer were seen in the age group of 60 years and older. The mortality rate was higher in men than in women, but the male to female death rate ratios decreased during the 10 years. Our data also showed that the death rate of pancreatic cancer in urban areas was about 2-4 fold higher than that in rural areas, and in Northeast and East China, the death rates were higher than those in the other 5 administrative districts.

CONCLUSION: The death rate due to pancreatic cancer was rising during the period of 1991-2000 and the peak mortality of pancreatic cancer might arrive in China.

INTRODUCTION

Pancreatic cancer is one of the most formidable malignant tumors worldwide. It is difficult to diagnose at early stage, unresectable at the time of diagnosis with extremely poor survival rate due to its inaccessible location, proximity to other vital organs, and inherently aggressive pattern of growth[1,2]. The death to incidence ratio of pancreatic cancer is approximately 0.98-0.99:1[3,10]. With more than 27 000 people died from pancreatic cancer each year, it is the fourth leading cause of cancer death in the United States[4]. Some sporadic reports have shown that the mortality rates of pancreatic cancer in China have increased constantly over the last decades[5-7]. But there is little descriptive documentation countrywide on its epidemiology. By analyzing the death data from China's Disease Surveillance Point System (DSPS), we presented the first report on the mortality from pancreatic cancer and its distribution among the surveillance population during the period of 1991-2000 in China.

MATERIALS AND METHODS

Materials

All mortality data were collected from the population who resided in 145 DSPs (Disease Surveillance Points) of China. The DSPS was originated in the beginning of 1980s for the surveillance of morbidity and mortality, and the present system was established in 1989. DSPs were selected from an official list of all neighborhoods in urban areas and villages in rural areas using stratified multistage sampling. The strata was involved in geographic areas (urban or rural status: within the rural areas, stratification into 4 levels based on indicators of mortality and socioeconomic status). In 1989, 145 surveillance points with a total population of around 10 million under surveillance (Table 1) were chosen, and scattered in 31 provinces, autonomous regions, or municipalities in China. Comparisons among the DSP population and the whole population over the country showed no significant differences in terms of socioeconomic conditions, population constitution, and health status. Such comparisons were made annually[8].

The obtained information related to death in China was based on the causes of death reported by qualified physicians on medical death certificates. The underlying causes of death were ascertained following the procedures specified by the World Health Organization in the (Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death), ninth revision (ICD-9). If the death causes of the deceased were either uncertain, or out of accord with the classification standards or could not be coded with ICD-9, the registry staff would clarify and/or justify the causes of death through interviewing the relatives of the patient or consulting his or her physicians.

Evaluation on data quality

Since the beginning of the disease surveillance, the National Center of DSPs had developed a series of quality control and evaluation system to examine data quality from DSPs every year, to assure that the surveillance data over the period of 1991-2000 were reliable and valuable for estimating the mortality of surveillance population. The quality of the data was evaluated as follows: (1) The demographic data and distribution of population by age and gender were credible and suitable for a denominator for calculating the rates since the United Nations Integrated Index of Population[9] fluctuates between 15 and 20. (2) The cases with uncertain death causes accounted for around 5 % of all death cases. (3) Three types of medical evidences from medical records or files were used for

Table 1 Population distribution by age group in DSPs during 1991-2000 in China (10 000)[a]

Age group	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000

[a]Population of the surveillance points with poor quality deleted.

the diagnosis and classification of the causes of death, including autopsy or biopsy, laboratory or radiology tests (clinical diagnosis), and inference after death (without certain documentation from biopsy or radiology test, but making highly suspicious diagnosis in terms of clinical symptoms, signs and some laboratory tests). Cases of pancreatic cancer, diagnosed using pathological test and clinical test, accounted for 31.56 % and 64.13 % respectively, the remaining (4.31 %) was determined by inference diagnosis. The percentage of cases diagnosed at different levels of hospitals was as follows: 92 % by hospitals of county grade and above (36.4 % by provincial grade and 29.1 % by municipal grade). This showed that the diagnosed death causes were credible and could be used for data analysis. (4) Validation was undertaken through periodic under-reporting surveys. A stratified three-stage cluster sampling design was adopted by each DSP to obtain the under-reporting rate. The overall under-reporting rate for mortality fluctuated between 12.25 % and 22.46 %.

Analysis methods

Based on the surveillance data from the DSPs during the period of 1991-2000, the distribution of death rate of pancreatic cancer was described by age group, gender, calendar year, rural/urban residence and administrative district. The reported death rate was expressed as the reported number of deaths of pancreatic cancer per 100 000 populations per year. The adjusted death rate was calculated with the formula, reported death rate/(1-under-reporting rate) and the age-standardized rate was calculated with the indirect method in terms of World Standard Population (*http://www3.who.int/whosis/discussion_papers/htm/paper31.htm)*. All analyses were conducted using software EPI 2000.

RESULTS

During 1991-2000, 504 604 death cases were reported in DSPs population. The reported death rate fluctuated between 507.67 and 546.60 per 100 000 populations in 1991-2000. The adjusted death rate remained relatively stable in 1991-1997 and increased gradually after 1997. But the age-standardized death rate decreased slightly during the 10 years.

Table 2 Mortality rate of pancreatic cancer during 1991-2000 in China (1/100 000)

Year	Death number	Reported death rate	Adjusted death rate	Age-standardized death rate	Deaths due to tumor (%)[a]
1991	151	1.46	1.75	2.18	1.83
1992	139	1.39	1.60	1.92	1.66
1993	129	1.34	1.54	1.80	1.51
1994	142	1.43	1.63	1.90	1.69
1995	145	1.60	1.85	2.12	1.79
1996	161	1.65	1.91	2.14	1.75
1997	168	1.66	1.92	2.18	1.86
1998	183	2.06	2.66	2.92	2.10
1999	186	2.16	2.78	2.96	2.23
2000	215	2.38	3.06	3.26	2.26

[a]Calculated by reported death rate.

Eighty six thousand five hundred and fifty six patients died from tumor in the 10 years, accounting for 17.15 % of total death cases reported in DSPs population. The reported, adjusted and age-standardized death rate for tumor increased from 79.86, 95.57 and 118.74 per 100 000 in 1991 to 104.91, 135.30 and 145.63 in 2000 respectively, with a steady increase on average of 3.08 %, 3.94 % and 2.29 % per year. Tumor contributed 15.65 % of all deaths in 1991, and 19.23 % in 2000. Tumor ranked the third of death cause in all death cases during 1991-1998, and went up to the second rank in 1999-2000.

One thousand six hundred and nineteen deaths were attributed to pancreatic cancer during the 10 years, accounting for 1.87 % of all deaths due to tumors. The reported, adjusted and age-standardized mortality rate increased by 5.53 %, 6.41 % and 4.57 % annually, from 1.46, 1.75, 2.18 per 100 000 populations in 1991 to 2.38, 3.06, and 3.26 per 100 000 populations in 2000. Pancreatic cancer accounted for 1.83 %

of all deaths due to tumor in 1991 and 2.26 % in 2000, with the 6-8th rank for men and the 9-10th for women. The details and the time trend are shown in Table 2.

The death rate of pancreatic cancer was closely related to age. The majority (69.62 %) of the deaths of pancreatic cancer were seen in the age group of 60 years and more, while fewer cases (3.95 %) were found among people aged less than 40 years. Table 3 also shows the changing trend of annual mortality in all age groups during the 10 years. The annual mortality rates in the 10 years fluctuated around 2 per 100 000 populations in the age group of 45 to 54 years, but the rates were higher than 10 per 100 000 populations in the group aged 65 to 84 years, approximately 5-fold difference between these groups. Around 2-fold increase was found in the mortality in the last few years compared with that at the beginning of 1990' s in people aged over 65 years.

Table 3 Reported death rate of pancreatic cancer by age during 1991-2000 in China (1 / 100 000)

Age group	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000

75-	10.53	10.01	11.76	14.23	18.13	13.17	11.03	18.45	16.45	23.36
85+	17.82	7.74	6.89	13.01	6.32	16.36	14.79	15.98	9.08	17.10
Total	1.46	1.39	1.34	1.43	1.60	1.65	1.66	2.06	2.15	2.37

Of all the reported death cases of pancreatic cancer between 1991 and 2000, 975 were diagnosed in men and 644 in women. The mortality rates of pancreatic cancer by gender are presented in Table 4. The data showed that all the reported, adjusted and age-standardized rates in males increased during the 10 years, from 1.86, 2.23, and 2.94 per 100 000 populations in 1991 to 2.70, 3.48, and 3.87 per 100 000 populations in 2000, with an increase on average of 4.23 %, 5.07 % and 3.10 % per year respectively. All these rates in female increased from 1.05, 1.25, and 1.49 to 2.04, 2.63 and 2.68 per 100 000 populations, with an annual average increase of 7.66 %, 8.61 % and 6.74 %. The male to female standardized death rate ratios decreased from 1.97 in 1991 to 1.44 in 2000.

The distribution of pancreatic cancer differed among the administrative districts (Table 5). The reported death rates in Northeast and East China were higher than those in the other 5 districts. After adjusted by the under-reporting rates for different districts, the rates of Northeast and East China were still higher than the latter (Figure 1).

Table 5 Reported death rate of pancreatic cancer by the administrative district of DSPs, China, 1991-2000 (1 / 100 000)

Year	North China	Northeast China	East China	Central China	South China	Northwest China	Southwest China
1991	2.22	1.23	2.52	0.85	1.26	1.28	1.14
1992	1.43	2.43	2.10	0.86	0.90	1.93	1.15
1993	2.01	0.70	2.75	0.95	0.74	0.76	0.71
1994	1.27	3.18	2.62	1.13	0.60	0.88	0.92
1995	1.67	3.30	3.33	1.01	0.73	0.91	1.08
1996	1.68	3.37	3.34	1.27	1.07	0.67	0.78

1999	1.83	4.72	5.51	1.28	0.89	1.29	1.15
2000	1.55	6.96	4.31	1.26	1.48	0.73	1.79

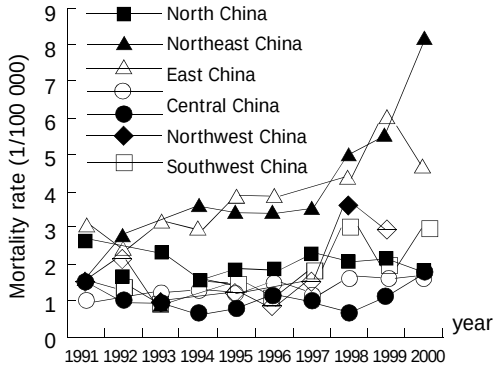

Figure 1 The adjusted mortality rate of pancreatic cancer by different districts, China, 1991-2000.

The distribution of pancreatic cancer was variable among rural and urban areas as well. The reported mortality rates in the urban areas were much higher than those in the rural areas. After adjusted by the differential under-reporting rates, the adjusted rates in the urban areas were still higher than those in the rural areas. And the death rates of pancreatic cancer displayed an increasing trend for both rural and urban areas during the period of 1991-2000 (Table 6). In 1991 the reported death rate of pancreatic cancer was 3.37 per 100 000 populations in the urban areas and 0.91 in the rural areas, and the adjusted death rates were 3.97 and 1.09, respectively. In 2000, the correspondent rates were 5.53 and 1.54, 7.32 and

Table 4 Mortality rate of pancreatic cancer by gender during 1991-2000 in China (1 / 100 000)

Year	Male				Female			
	Death number	Reported death rate	Adjusted death rate	Age-standardized rate	Death number	Reported death rate	Adjusted death rate	Age-standardized rate
1991	98	1.86	2.23	2.94	53	1.05	1.25	1.49
1992	97	1.90	2.19	2.77	42	0.86	0.99	1.13
1993	81	1.66	1.90	2.36	48	1.02	1.17	1.29
1994	79	1.56	1.78	2.24	63	1.29	1.47	1.62

2000	5.53	1.54	3.59	7.32	1.97	3.72

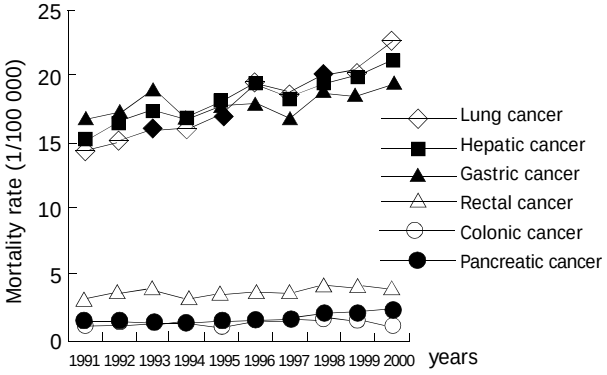

Figure 2 The trend of reported mortality of pancreatic cancer and some major cancers in DSP, China, 1991-2000.

Figure 2 shows the dynamic trend of mortality rate of pancreatic cancer and other common tumors. The increasing trend of pancreatic cancer paralleled the slight variation seen in rectal and colonic cancer, while the death rates of hepatic, stomach and lung cancers changed more remarkablely.

DISCUSSION

Our data analysis was performed based on the data of demography and death, collected through DSPs over the period from 1991 to 2000. The DSPS data were of good representative ness due to their selection by probability sampling and their rigorous management[8] and therefore the results derived from surveillance population can be inferred to health status of national population. The assessment of indicators used for data quality evaluation, including the United Nations Integrated Index on Population, the proportion of cases with uncertain death cause, the diagnosis evidence of pancreatic cancer and the under-reporting rate, demonstrates that these data are reliable and the mortality rate of pancreatic cancer derived from the DSPs data might be used to estimate the death level over the whole community. However, the mortality rates reported in this study might be lower in view of the impact of technology development in the diagnosis of pancreatic cancer and its nonspecific clinical symptoms.

Pancreatic cancer may be one of the diseases that are correlated with industrialization. Reports from the studies on the mortality of pancreatic cancer worldwide in 1990 suggested that majority deaths (66 %) occurred in developed countries[10]. WHO reported[11] the age-standardized mortality rates of pancreatic cancer in Western developed countries such as the United States, the United Kingdom, Australia, and Japan, ranged from 6 to 8 per 100 000 in males, and 4 to 6 in females, which were about 2-4 times higher than that in China (about 2 to 3 per 100 000 in males and 1 to 3 in females) in the same period. But in these countries, the mortality rate of pancreatic cancer, both in males and females, have leveled off and even dropped by the end of last century. And in some Asian countries, such as South Korea and Singapore, the age-standardized rates of pancreatic cancer are also higher than those in China, even though not reaching the peak yet[11]. In addition, we have seen a rapid increasing of death rates of pancreatic cancer in China, particularly among those aged over 65 years in the recent decade. The reported, adjusted and age-standardized death rates of pancreatic cancer have increased by 62.33 %, 74.86 % and 49.54 % respectively. This is, to some extent, explained by the improved diagnosis and cancer death registration since pancreatic cancer is difficult to be diagnosed and classified[31], but it is also probably attributed to the increased risk factors associated with industrialization, such as diet- and smoking-related factors as well as life-style changes[21,22]. At present, little is known about the etiology of pancreatic cancer. Cigarette smoking is the only firmly established factor[17, 25-28], with a 1. 2- to 3.1-fold increase in risk. Smoking, however, cannot by itself totally explain the increasing trends. There is less certainty concerning the risks associated with a range of dietary factors. Some studies have reported an increased risk with higher consumption of meat, protein and cholesterol and lower consumption of fruits and vegetables[27-30].

The role of life-style and dietary factors[27-30] in the etiology of pancreatic cancer is also supported by the higher mortality rates observed in the urban areas. Of course, the higher rates in the urban areas could be partly attributed to the improved diagnosis. Also our data showed that the death rates of pancreatic cancer were not identical in different administrative districts. The mortality rate was considerably higher in Northeast and East China than that in the other 5 districts, and the reasons led to this difference need to be discussed further, but a partial reason might be associated with higher level of industrialization and urbanization in these areas.

The mortality rate of pancreatic cancer was strongly related to age in our study. Our study indicated that the majority of death cases of pancreatic cancer occurred in the age group of 60 years or older, and the patients aged less than 45 years only accounted for 3.95 %, almost the same as the results in other studies[12-17]. Similar to the other studies[11,14,18-20], our data have also found the gender difference between male and female. And the mortality from pancreatic cancer in males was higher than that in females, but the male to female mortality rate ratio showed a decreased trend in the period of 1991-2000.

Our study indicated that the increasing trend of mortality rate of pancreatic cancer paralleled that of rectal cancer. And other studies have also shown that there are remarkable similarities between the increased incidence of pancreas cancer and breast cancer in women and prostate cancer in men, and bowel cancer in both sexes over approximately the same period[23,24]. Dietary- and smoking- factors as the common risk factors may be relevant to the similarly increased trends of breast[33], prostate[32], bowel[34] and pancreatic cancers.

It is suggested that with the entry into an aging society and urbanization in China, the peak mortality of pancreatic cancer arrive soon in the next few decades. Therefore, it is crucial to carry out further studies on the etiology of pancreatic cancer and set up screening indicators earlier to reduce the number of deaths from pancreatic cancer.

Abstract

AIM: In human sepsis, a prominent component of the hypermetabolite is impaired glucose tolerance (IGT) and hyperglycemia. Elevations in plasma glucose concentration impair immune function by altering cytokine production from macrophages. We assessed the role of glucose in the regulation of circulating levels of insulin, glucagon, cortisol, IL-6 and TNF-α in human sepsis with normal or impaired glucose tolerance.

METHODS: According to the results of intravenous glucose tolerance test, forty patients were classified into two groups: control group (n=20) and IGT group (n=20). Plasma glucose levels were acutely raised in two groups and maintained at 15 mmol/L for 3 hours. Plasma insulin, glucagon and cortisol levels were measured by radioimmunoassay, the levels of TNF-α and IL-6 were detected by ELISA.

RESULTS: In IGT group, the fasting concentrations of plasma glucose, insulin, glucagon, cortisol, IL-6 and TNF-α levels were significantly higher than those in control group (P<0.05). During clamp, the control group had a higher average amount of dextrose infusion than the IGT group (P<0.01). In control group, plasma insulin levels rose from a basal value to a peak at an hour (P<0.05) and maintained at high levels. Plasma glucagon levels descended from a basal value to the lowest level within an hour (P<0.01) and low levels were maintained throughout the clamp. In IGT group, plasma insulin was more significantly elevated (P<0.01), and plasma glucagon levels were not significantly declined. Plasma cortisol levels were not significantly changed in two groups. In control group, plasma IL-6 and TNF-α levels rose (P<0.01) within 2 hours of the clamp and returned to basal values at 3 hours. In IGT group, increased levels of plasma cytokine lasted longer than in control group (3 hours *vs*. 2 hours, P<0.05), and the cytokine peaks of IGT group were higher (P<0.05) than those of control group.

CONCLUSION: Acute hyperglycemia pricks up hyperinsulinemia and increases circulating cytokine concentrations and these effects are more pronounced in sepsis with IGT. This suggests a potential modulation of immunoinflammatory responses in human sepsis by hyperglycemia.

INTRODUCTION

Severe human sepsis is associated with hypermetabolic stress response, and affects protein, carbohydrate and lipid metabolism throughout the body[1-7]. A prominent component of hypermetabolic stress response is hyperglycemia and impaired glucose tolerance (IGT). The mechanisms of stress hyperglycemia are well known[8]. Counterreglulatory hormone and excess cytokine result in insulin resistance, and many hospitalized patients are insulin deficient for a variety of reasons (e.g. old age, pancreatitis, hypothermia, hypoxemia). Excess dextrose infusion is an often-overlooked contributor to hyperglycemia[9].

The harm of acute hyperglycemia in stress response patients has been demonstrated in several clinical and experimental conditions[10-12]. An increased susceptibility to infections in the presence of hyperglycemia has long been known in patients with diabetes[10,11,13]. And recent investigations have demonstrated that elevations in plasma glucose concentration impair immune function by altering cytokine production from macrophages, diminishing lymphocyte proliferation, and depressing intracellular bactericidal activity of leukocytes[14-17]. Furthermore, in the issue of circulation, Esposito K. argued hyperglycemia acutely increased circulating cytokine concentrations, and this effect was more pronounced in group with IGT[18]. But former researches focused on normal human being, diabetes or critically ill patients, etc. and rarely concentrated on severe human sepsis.

The present study was to test whether circulating levels of hormones and cytokines are regulated by glucose levels in sepsis, and to measure serum insulin, glucagon, cortisol, TNF-α, and IL-6 concentrations during acute hyperglycemia in septic patients with normal or impaired glucose tolerance (IGT).

MATERIALS AND METHODS

Subjects

The subjects of this study were the patients admitted from January 5 to November 1, 2002 to the medical SICU of Jinling Hospital in Nanjing. Forty patients (23 men, 17 women) with a mean (s.d.) age of 52.2 (15.6) years with abdominal or pelvic sepsis were studied. Patients with diabetes mellitus, trauma, human immunodeficiency virus disease, end-stage renal disease, end-stage hepatic disease, the patients receiving immunosuppressive agents were excluded. Forty patients were divided into two groups according to normal (control group, n=20) or impaired (IGT group, n=20) glucose tolerance (Table 1). The patients' glucose tolerance was assessed by intravenous glucose tolerance test (IVGTT). After an overnight fast each patient underwent IVGTT: a 50 % glucose solution (glucose 0.5 gm/kg of body weight) was injected into the femoral vein

for 2 minutes. Patients in IGT group had a 2-hour plasma glucose value between 7.7 mmol/L and 11 mmol/L, and the control group had normal glucose tolerance (2-hour plasma glucose value below 7.7 mmol/L). Informed consent was obtained from all participating patients or their surrogates.

Severity of sepsis and underlying diagnosis

Sepsis was defined by the American College of Chest Physicians-Society of Critical Care Medicine consensus statement by an identifiable site of infection and evidence of a systemic inflammatory response manifested by at least three of the following criteria: (1) temperature, >38 ℃ or <36 ℃; (2) heart rate, >90 beats per minute; (3) respiratory rate, >20 breaths per minute; (4) white blood cell count, >12 000/mm^3 or <4 000/mm^3[19]. Patients meeting enrollment criteria were entered within 24 h. The cause of sepsis was severe acute pancreatitis (n=11), colorectal anastomotic dehiscence (n=9), perforated diverticular disease (n=9), gastroduodenal perforation (n=7), gallbladder perforation (n=3) and spontaneous splenic abscess (n=1). Sepsis severity was scored using the method of Elebute and Stoner[20]. This scoring procedure takes into account the site of infection, bacteriology, body temperature, secondary effects (e.g. jaundice) and various haematological and biochemical variables, such as white cell count and plasma albumin concentration.

Study protocol

After 12-hour fast overnight, the patients were placed in a supine comfortable position with the sickroom temperature between 20 ℃ and 24 ℃. Intravenous lines were inserted into a large antecubital vein of one arm for infusions and into a dorsal vein of the contralateral arm for blood sampling. Patency was preserved in a slow saline infusion (0.9 % NaCl). After withdrawal of baseline blood samples, plasma glucose concentrations were acutely raised with a bolus injection of 0.25 g/kg glucose followed by a varying 30 % glucose infusion to achieve steady-state plasma glucose concentrations of about 15 mmol/L for 180 minutes.

Analysis

Samples for analysis of plasma glucose were collected in tubes containing a trace of sodium fluoride. Plasma glucose was determined according to the glucose oxidase method with an autoanalyzer (Beckman Instruments). Serum samples for measuring hormone and cytokine level were stored at -80 ℃ until assay. Commercially available kits were used for radioimmunoassay of plasma insulin, glucagon and cortisol concentrations. Serum concentrations of TNF-α, IL-6 were determined in duplicate with commercially available kits (R&D Systems). Dilution curves of serum samples were parallel to those of standard. Intra-assay and interassay coefficients of variation were 3.8 % and 5.8 % for TNF-α, 2.8 % and 3.3 % for IL-6.

Statistical analysis

Results were given as mean ±SD. One-way ANOVA was used to compare baseline data, followed by Scheffé's test for pairwise comparisons. Multiple comparison tests were made with ANOVA, followed by post hoc analysis (Student-Newman-Keuls test) to locate the significant difference indicated by ANOVA. A value of P<0.05 was considered statistically significant. Data were analysed using Statistical Package for the Social Sciences computer software (SPSS 11.0).

RESULTS

During the 7-month study period 46 patients were collected, however analysis was limited to 40 patients with complete and available data. IGT group had higher admission severity scores than control group (APACHE Ⅱ, 10 (7-15) *vs*. 7 (4-10), sepsis score, 13 (8-19) *vs*. 8 (6-13); P<0.05). In IGT group, the levels of fasting plasma glucose, insulin, glucagon, cortisol, IL-6 and TNF-α levels were significantly higher than those in control group (Table 1). During the clamp, plasma glucose became stabilized at 15 mmol/L with oscillations not exceeding 5 % of the prefixed value. The control group had a higher average amount of dextrose infusion than IGT group (0.68±0.31 g/kg *vs*. 0.42±0.16 g/kg; P<0.01).

Table 1 Details of control and IGT groups

Variable	Control group (n=20)	IGT subject (n=20)
Age, y	41±4	42±6
Sex, M/F, n	13/7	12/8
Body mass index, kg/m2	21.11±1.22	20.12±1.43
Plasma glucose, mmol/L	5.22±0.89	7.23±0.73[a]
Plasma insulin, pmol/L	72.00±14.83	82.95±10.23[a]
Plasma glucagon, pmol/L	80.75±12.98	90.90±15.54[a]
Plasma cortisol, mmol/L	0.68±0.11	0.79±0.12[b]
IL-6, pg/ml	3.18±0.64	3.63±0.43[a]
TNF-α, pg/ml	4.66±0.70	5.99±0.76[b]
APACHE Ⅱ score	7(4-10)	10(7-15)[a]
Sepsis score	10(8-16)	15(10-25)[a]

All data were the mean (s.d.), except APACHE Ⅱ score and sepsis score which were the median (range). APACHE, acute physiology and chronic health evaluation. [a]P<0.05 *vs*. control group. [b]P<0.01 *vs* control group.

Counterregulatory hormone

During the clamp, plasma insulin levels increased from a basal level of 72.00±14.83 pmol/L to a peak of 83.40±14.29pmol/L within one hour (P<0.05) and maintained at high levels in control group. Whereas, plasma insulin levels increased more significantly in IGT group (P<0.01) (Figure 1). In control group, plasma glucagon levels decreased from a basal value of 80.75±12.98 pmol/L to the lowest level of 74.70±11.40 pmol/L within an hour (P<0.01) and low levels maintained, and was not significantly declined in IGT group during the entire observation period (Figure 2). Plasma cortisol was not significantly changed in two groups (Figure 3).

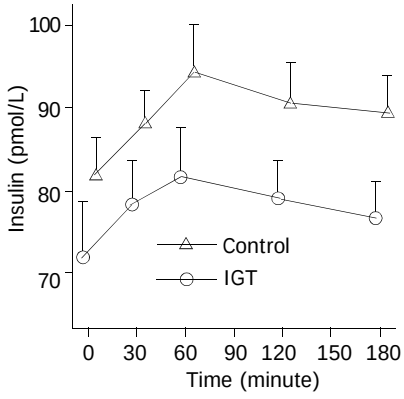

Figure 1 Circulation insulin levels during hyperglycemia clamps in 20 patients of control group (○-○) and in 20 patients of IGT group (△-△). Mean ± S.E.M. in human sepsis. Plasma insulin levels rose from a basal value to a peak within an hour (P<0.01) and high levels maintained in two groups.

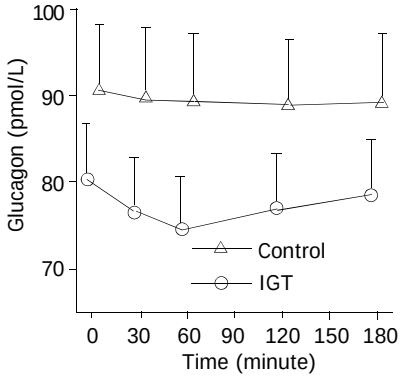

Figure 2 Circulation glucagon levels during hyperglycemia clamps in 20 patients of control group (○-○) and in 20 patients of IGT group (△-△). Mean ± S.E.M. in human sepsis. In control group, plasma glucagon levels decreased from a basal value to the lowest level within half an hour (P<0.01) and a low level maintained, and was not significantly declined in IGT group in the entire observation period.

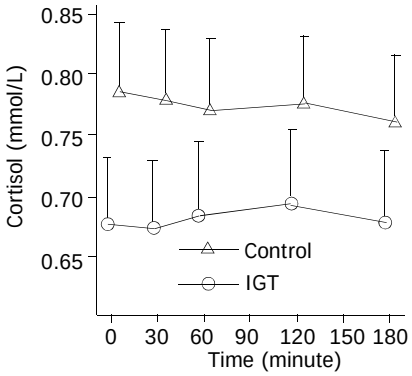

Figure 3 Circulation cortisol levels during hyperglycemia clamps in 20 patients of control group (○-○) and in 20 patients of IGT group (△-△). Mean ± S.E.M. in human sepsis. There were no significant changes in two groups.

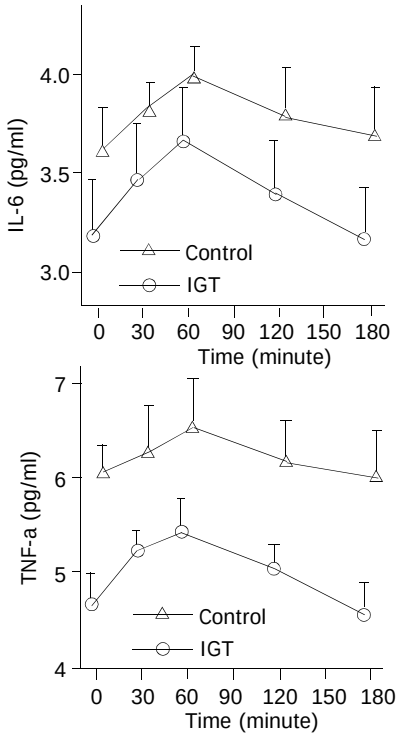

Figure 4 Circulation IL-6, TNF-α levels during hyperglycemia clamps in 20 patients of control group (○-○) and in 20 patients of IGT group (△-△). Mean ± S.E.M. in human sepsis. In two groups, plasma IL-6, TNF-α levels rose from a basal value to a peak within 1 hour (P<0.01). In IGT group, increased level of plasma TNF-α, IL-6 during the clamping lasted longer than in control group (3 hours *vs*. 2 hours; P<0.05).

Inflammatory cytokine

In control group, plasma IL-6 levels increased from a basal value of 3.18±0.64 pg/mL to a peak of 3.67±0.57 pg/mL within 1 hour (P<0.01) and returned to basal level at 3 hours. Fasting plasma TNF-α levels were 4.66±0.70 pg/mL, they peaked at 1 hour (5.4±0.64 pg/mL, P<0.01), and returned to baseline at 3 hours. In IGT group, increased levels of plasma cytokine during the clamp lasted longer than in control group (3 hours *vs*. 2 hours; P<0.05) (Figure 4, 5).

DISCUSSION

In this study, we found that IGT group had higher admission severity scores than control group, and had high plasma concentrations of counterregulatory hormones and inflammatory cytokines. During the clamp, IGT group had a less average amount of dextrose infusion than control group. In IGT patients, a short term of hyperglycemia after glucose infusion failed to adjust the plasma concentration of counterregulatory hormones to maintain glucose homeostasis. Acute hyperglycemia in control and in IGT patients induced an increase in plasma IL-6, TNF-α concentrations and insulin levels, and the effect was amplified by IGT group. These results indicate that hyperglycemia in human sepsis with IGT is more easy to be revoked, and plays a potential modulation role in immunoinflammatory responses.

The mechanisms for "stress IGT" are well known. Human sepsis is accompanied by a marked increase in plasma concentration of counterregulatory hormones, i.e. glucagons, epinephrine, cortisol and growth hormone that affect glucose homeostasis. These hormones can lead to significant reductions in insulin sensitivity through poorly understood mechanisms likely related to alterations in insulin signal pathway[21]. Counterregulatory hormones also enhance lipolysis and level of free fatty acids (FFA) which may contribute additional defects to the defective insulin action. Cytokine, TNF-α and IL-6 may exert their influence indirectly by stimulating counterregulatory hormone secretion and by direct action themselves[22-24]. TNF-α and IL-6 individually and synergistically increase net glucose flux through resistance to insulin actions in muscle and liver via poorly understood post-receptor mechanisms[25]. Hepatic insulin resistance leads to ongoing glucose production even in hyperglycemia[26]. Peripheral insulin resistance decreases sketetal muscle glucose uptake and reduces glucose clearance, which leads to the development of IGT and even hyperglycemia.

After glucose infusion, in normal group, glucagon and glucose concentrations reduced by host insulin were sufficient and inhibited hepatic gluconeogenesis and glycogenolysis and prevented glucose production[27]. In contrast, in IGT group, glucose infusion failed to suppress endogenous glucose production despite accompanying hyperinsulinemia. Using stable isotopes, it was demonstrated that hepatic glucose production was -150 % of the normal resting post-absorptive values of healthy subjects in spite of provision of total parenteral nutrition with dextrose at rates exceeding the basal energy expenditure[28].

Glucose-based nutrition in septic patients may cause marked hyperinsulinemia due to peripheral insulin resistance[29]. Hyperinsulinemia associated with glucose-based nutrition in sepsis might augment proinflammatory cytokine production and stress response in septic patients[30]. The present findings

also demonstrated that acute hyperglycemia affected concentration of plasma cytokines in human sepsis, and this effect was more pronounced in IGT patients. *In vitro* studies using supraphysiological glucose concentration (>22 mmol/l) showed an increase in TNF-α and IL-6 secretion from healthy human mononuclear cells[31]. Furthermore, increased synthesis of TNF-α has been reported both in rat uterine cells cultured *in vitro* with increasing concentrations of glucose[32] and in placental tissue explants from women with gestational diabetes incubated with high glucose (25 mmol/l)[33]. Human monocytes produced by IL-6 in healthy volunteers increased during 24-hour incubation in high-glucose medium[34]. These findings are in accordance with our observations *in vivo*, suggesting a potential modulation of immunoinflammatory response by carbohydrates.

In summary, IGT in sepsis is associated with marked changes in plasma concentrations of counterregulatory hormones and inflammatory cytokines, and these changes partially account for the fact that IGT easily develops acute hyperglycemia during glucose infusion. Acute hyperglycemia pricks up hyperinsulinemia and increases circulating cytokine concentrations. This suggests a potential role of hyperglycemia in inflammatory responses in human sepsis.

Abstract

AIM: To study the change of portal blood flow for the prediction of the status of right-sided heart failure by using non-invasive way.

METHODS: We studied 20 patients with rheumatic and atherosclerotic heart diseases. All the patients had constant systemic blood pressure and body weight 1 week prior to the study. Cardiac index (CI), left ventricular end-diastolic pressure (LVEDP), mean aortic pressure (AOP), pulmonary wedge pressure (PWP), mean pulmonary arterial pressure (PAP), mean right atrial pressure (RAP), right ventricular end-diastolic pressure (RVEDP) were recorded during cardiac catheterization. Ten patients with RAP <10 mmHg were classified as Group 1. The remaining 10 patients with RAP ⩾10 mmHg were classified as Group 2. Portal blood velocity profiles were studied using an ultrasonic Doppler within 12 h after cardiac catheterization.

RESULTS: CI, AOP, and LVEDP had no difference between two groups. Patients in Group 1 had normal PWP (14.6±7.3 mmHg), PAP (25.0±8.2 mmHg), RAP (4.7±2.4 mmHg), and RVEDP (6.4±2.7 mmHg). Patients in Group 2 had increased PWP (29.9±9.3 mmHg), PAP (46.3±13.2 mmHg), RAP (17.5±5.7 mmHg), and RVEDP (18.3±5.6 mmHg) (P<0.001). Mean values of maximum portal blood velocity (Vmax), mean portal blood velocity (Vmean), cross-sectional area (Area) and portal blood flow volume (PBF) had no difference between 2 groups. All the patients in Group 1 had a continuous antegrade portal flow with a mean percentage of peak-to-peak pulsatility (PP) 27.0±8.9 % (range: 17-40 %). All the patients in Group 2 had pulsatile portal flow with a mean PP 86.6±45.6 (range: 43-194 %). One patient had a transient stagnant and three patients had a transient hepatofugal portal flow, which occurred mainly during the ventricular systole. Vmax, Vmean and PBF had a positive correlation with CO (P<0.001) but not with AOP, LVEDP, PWP, PAP, RAP, and RVEDP. PP showed a good correlation (P<0.001) with PWP, PAP, RAP, and RVEDP but not with CI, AOP, and LVEDP. All the patients with PP >40 % had a right-sided heart failure with a RAP=10 mmHg.

CONCLUSION: The measurement of PP change is a simple and non-invasive way to identify patients with right heart failure.

INTRODUCTION

Hepatic artery and portal vein contribute to the hepatic blood inflow. In cirrhotic patients, oral nitroglycerin can reduce portal blood flow due to systemic hypotension[1-4]. Congestive heart failure, systemic hypotension and the use of hypotensive agents can decrease cardiac output. The reduced cardiac out put and systemic hypotension can decrease the portal inflow volume. Marked reduction of hepatic inflow may cause ischemic hepatitis. Patients with cardiopulmonary diseases may develop ischemic hepatitis with abnormal serum ALT levels[5,6].

On the other hand, right-sided congestive heart failure can result in the increase of pressure in inferior vena cava and hepatic veins[6,7]. The liver in passive "backward" congestion status can develop hepatomegaly and synchronous pulsation, and the liver histology shows engorged and dilated terminal hepatic veins, atrophy of hepatocytes and eventually cardiac cirrhosis. The high pressure of the hepatic veins can transmit through the liver to result in post-sinusoidal portal hypertension and cardiac ascites. The diameter of portal vein has been proved to correlate with right atrial pressure[8]. Thus, right-sided heart failure can affect portal vein flow patterns.

The role of heart function in portal blood flow remains uncertain. Therefore, we studied the changes of portal blood flow in patients with different degree of right-sided heart failure using non-invasive ultrasonic Dopper[5,8-11].

MATERIALS AND METHODS

We studied the portal blood velocity profiles in 20 patients (9 males, 11 females, mean age: 49±16 years) who underwent cardiac and/or Swan-Ganz catheterizations for cardiovascular disorders (16 rheumatic heart disease cases, 4 atherosclerotic heart disease cases) to compare the portal profiles of 20 healthy volunteers. Although all the patients took medications affecting the hemodynamics such as isosorbide dinitrate and furosemide, their systemic blood pressure and body weight were constant for at least 1 week prior to the study. Patients with fever, infection, and shock were excluded. All the patients had no past history of liver disease, alcoholism or other metabolic disorders such as chronic renal failure or diabetes mellitus. None underwent transfusion or under cardiac inotropic agents. All the patients had an abdominal sonographic examination excluding chronic liver disease or splenomegaly. Patients with severe dyspnea were excluded if they were not able to remain on supine position for the study of ultrasonic Doppler.

Cardiac profiles including cardiac index (CI), left ventricular end-diastolic pressure (LVEDP), mean aortic pressure (AOP), pulmonary wedge pressure (PW), mean pulmonary arterial

pressure (PAP), mean right atrial pressure (RAP), right ventricular end-diastolic pressure (RVEDP) were recorded during the cardiac and Swan-Ganz catheterizations. Ten patients with PAP <10 mmHg (range: 1-7 mmHg) without right heart failure were classified as Group 1. The other 10 patients with right heart failure and RAP=10 mmHg (range: 10-28 mmHg) were classified as Group 2.

We studied the portal profiles using an ultrasonic Doppler composed of a real-time mechanical sector scanner and a 3.5 mHz pulsed Doppler flowmeter (Aloka Echo Camera Model SSD-650, Tokyo) within 12 h after cardiac catheterization. After more than 8 h fasting, portal profiles were measured in supine position for more than 30 min. Portal blood flow was measured from the main portal vein with the patient in expiratory apnea. We located the cursor in the main portal vein at a site just entering or immediately after entering the liver and opened the gate of cursor as wide as possible to include the inner diameter of the main portal vein. We corrected the flow angle formed by the directions of ultrasonic beam and the portal blood flow below 55 degree to minimize the variation caused by the angle of insonation. The Doppler signal could be viewed on the screen and heard through a build-in speaker. Portal blood flow was measured by the same physician to avoid inter-observer variations[12].

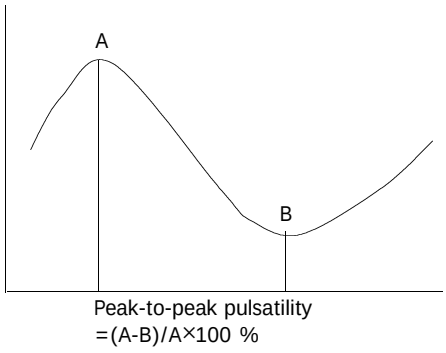

Figure 1 Mean portal blood velocity (Vmean) was calculated (cm/s) by the equation of "Vmean=0.57×maximum portal blood velocity (Vmax)".

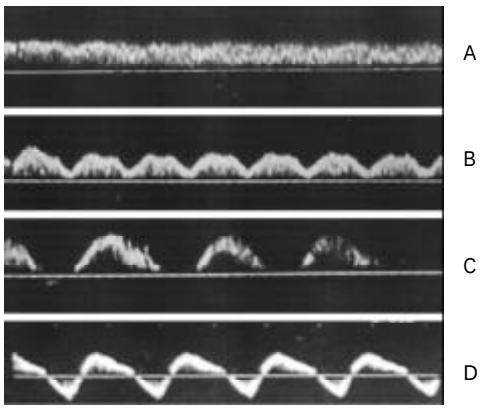

Figure 2 Representative waveform of portal blood flow from patients with normal (A; PP: 17 %), transiently reduced (B; PP: 60 %), stagnant (C; PP: 100 %) or retrograde (D; PP: 194 %) portal blood flow.

For each measurement, at least 3 reproducible patterns were made to calculate the mean maximum portal blood velocity (Vmax) over a period of 4 seconds to ensure the measurement accuracy. Mean portal blood velocity (Vmean) was calculated (cm/s) by the equation of "Vmean=0.57×Vmax" as described by Moriyasu *et al* (Figure 1)[13]. Cross-sectional area (Area) was also recorded (cm^2) at the site of main portal vein where portal blood velocity was measured. The direction of portal blood velocity, antegrade or retrograde, was also measured. Positive signal above the zero velocity indicated the flow toward the transducer and vice versa. Portal blood flow volume (PBF) was obtained (ml/min) by the equation "PBF=Area×Vmean ×60"[12,13]. The percentage of peak-to-peak pulsatility (PP) was calculated by the equation of PP=(maximum-minimum)/maximum frequency shift (Figure 1)[5,10,12]. The waveforms were classified as continuous (PP=40 %; Figure 2A), decreased (PP 41-99 %; Figure 2B), stagnant (PP=100 %; Figure 2C), and retrograde (PP >100 %; Figure 2D).

The study protocol was reviewed and approved by the Institutional Review Committee under the guidelines of the 1975 Declaration of Helsinki. Statistical analysis was performed using Student's *t*-test and linear regression as appropriate.

RESULTS

The clinical and biochemical data are shown in Table 1. All the controls had normal blood chemistries. All the patients had normal serum bilirubin, and prothrombin time. The mean serum albumin levels were lower in Group 1 (3.9±0.7 g/dL, $P<0.02$) and Group 2 (3.7±0.5 g/dL, $P<0.01$) than Controls. The serum ALT levels were all less than two times of the upper normal limit. Group 2 patients (35±20 IU/L) had a higher mean serum ALT activity than that of the controls (24±6 IU/L, $P<0.05$) but not statistically different from that of Group 1 (23±8 IU/L). Group 2 (59±29 IU/L) had a higher mean AST level than those of Group 1 (31±11 IU/L, $P=0.004$) and controls (21±6 IU/L, $P<0.001$). The higher serum AST activities, were supposed to be related to ischemic hepatitis. The other clinical and biochemical data between Group 1 and 2 showed no statistical difference.

Table 1 Clinical and biochemical data of patients with congestive heart failure ($\bar{x}\pm s$)

	Control	Group 1	Group 2
Gender (M/F)	10/10	4/6	5/5
Age (y)	46±12	50±13	47±19
Total protein (g/dL)	7.5±0.6	7.1±0.8	6.9±1.1
Albumin (g/dL)	4.3±0.2	3.9±0.7	3.7±0.5
Total serum bilirubin (mg/dL)	0.9±0.4	1.3±0.8	1.4±0.8
AST (IU/L)	21±6	31±11	59±29
ALT (IU/L)	24±6	23±8	35±20
Prolonged prothrombin time (s)	-	1.1±0.9	1.4±0.8

The CI [3.0±1.4 L/(min· m^2); range: 2.3-8.6 L/(min· m^2) *vs* 2.4±0.5 L/(min· m^2); range: 2.8-4.2 L/(min· m^2)], AOP (87.8±11.7 mmHg; range: 65-100 mmHg *vs* 87.6±16.5 mmHg; range: 65-115 mmHg), and LVEDP (12.2±9.3 mmHg; range: 4-40 mmHg *vs* 22.8±13.0 mmHg; range: 10-40 mmHg) were not statistically different between Group 1 and 2 (Table 2). All the Group 1 patients had normal PWP (mean: 14.6±7.3 mmHg; range: 5-40 mmHg), PAP (mean: 25.0±8.2 mmHg; range: 16-48 mmHg), RAP (mean: 4.7±2.4 mmHg; range: 1-10 mmHg), and RVEDP (mean: 6.4±2.7 mmHg; range: 4-14 mmHg). All the group 2 patients had abnormally higher PWP (mean: 29.9±9.3 mmHg; range: 13-38 mmHg), PAP (mean: 46.3±13.2 mmHg; range: 25-65 mmHg), RAP (mean: 17.5±5.7 mmHg; range: 12-28 mmHg), and RVEDP (mean: 18.3±5.6 mmHg; range: 9-26 mmHg) than those of Group 1 patients ($P<0.001$).

Table 2 Cardiac profiles in patients with congestive heart failure [$\bar{x}\pm s$, (n)]

	Group 1	Group2
CI [L/(min· m²)]	3.0±1.4 (6)	2.4±0.5 (7)
AOP (mmHg)	87.8±11.7 (9)	87.6±16.5 (8)
LVEDP (mmHg)	12.2±9.3(10)	22.8±13.0(9)
PWP (mmHg)	14.6±7.3(9)	29.9±9.3[a] (9)
PAP (mmHg)	25.0±8.2(10)	46.3±13.2[a] (9)
RAP (mmHg)	4.7±2.4(10)	17.5±5.7[a] (10)
RVEDP (mmHg)	6.4±2.7(10)	18.3±5.6[a] (10)

[a]P<0.001 *vs* group 1.

The mean values of Vmax (24.5±4.9 cm/s; range: 17-33 cm/s *vs* 21.5±6.1 cm/s; range: 16-33 cm/s), Vmean (14.0±2.9 cm/s; range: 9.7-18.8 cm/s *vs*12.3±3.5 cm/s; range: 8.6-13.7 mmHg), area (0.80±0.17 cm²; range: 0.64-1.13 cm² *vs* 0.94±0.18 cm²; range: 0.79-1.33 cm²) and PBF (678±239 ml/min; range: 373-1120 ml/min *vs* 684±191 ml/min; range: 432-922 ml/min) between Group 1 and 2 did not show any statistical difference (Table 3). All the 10 patients in Group 1 had a continuous antegrade portal flow with a mean PP 27.0±8.9 % (range: 17-40 %). The mean PP of the remaining 10 patients in Group 2 was 86.6±45.6 % (range: 43-194 %); all the patients had a pulsatile portal blood flow with PP >40 %. 6, 1 and 3 patients had transiently reduced, stagnant, and hepatofugal portal blood flow, respectively. The transiently reduced, stagnant and retrograde flow occurred mainly immediately after the corresponding ventricular systole. Different from earlier reports, we have observed that the decreased or reversed portal blood flow did not occur during ventricular systole in 3 patients with ventricular premature depolarizations or atrial fibrillation (Figure 3).

Table 3 Portal profiles in patients with congestive heart failure ($\bar{x}\pm s$)

	Control (n=20)	Group1 (n=10)	Group2 (n=10)
Vmax (cm/s)	20.1±3.1	24.5±4.9	21.5±6.1
Vmean (cm/s)	11.2±1.9	14.0±2.9	12.3±3.5
Area (cm²)	1.01±0.20	0.80±0.17	0.94±0.18
PBF (ml/min)	685±136	678±239	684±191
PP (%)	23.3±6.3	27.0±8.9	86.6±45.6[a]

[a]P<0.001 *vs* control and group 1.

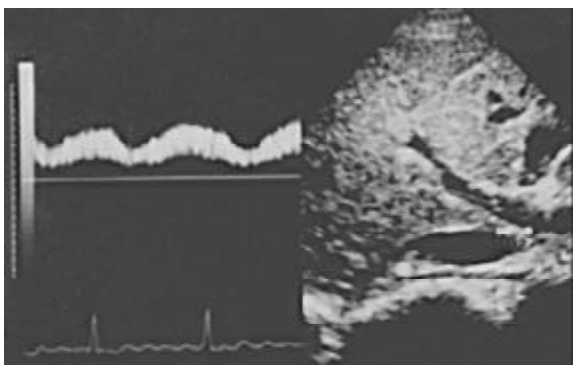

Figure 3 Occurrence of reduced portal blood flow immediately after ventricular systole.

By using linear correlation, Vmax, Vmean and PBF had a positive correlation with CI (P<0.001) but not with AOP, LVEDP, PWP, PAP, RAP, and RVEDP. PP showed a good correlation with PWP, PAP, RAP, and RVEDP (P<0.001) but did not show any correlation with CI, AOP, and LVEDP. PP had no correlation with Vmax, Vmean and PBF.

DISCUSSION

In the present study, all the 10 patients with RA=10 mmHg had a PP>40 %. On the contrary, all the patients with RAP <10 mmHg had a PP 40 % or less. It suggested these patients developed transiently reduced, stagnant or hepatofugal portal blood flow. 4 (36 %) of the patients with RAP=10 mmHg had a retrograde portal blood flow with a PP >100 %. Therefore, the portal blood flow can be retrograde during severe right heart failure[13]. Furthermore, RAP, PWP and RVEDP have a good correlation with PP. Thus, the waveforms of portal blood flow correlate well with right heart function[14]. Therefore, the measurement of PP change is a simple and non-invasive way to identify patients with right heart failure[9,15].

In the present study, AOP did not correlate with PP and "estimated" PBF[12,13,16]. Actually, all the patients had preserved AOP and only 1 patient whose AOP was 2.3 L/(min· m²) with RAP< 10 mmHg had AOP less than 2.6 L/(min· m²). Thus, right heart failure rather than reduced CI is responsible for PP changes[5,17-19]. Furthermore, "estimated" portal inflow showed no difference between patients with high and low RAP. Since the portal inflow can be transiently reduced, stagnant or hepatofugal during severe right heart failure, the "actual" portal inflow volume should be lower than the "estimated" volume[20]. As a consequence, the "estimated" volume does not represent the "actual" portal inflow volume. Hence, the correlation among "actual" PBF, AOP and RAP warrants further study.

Portal blood flow contributes to 90 % of blood flow and 50 % of oxygen supply of the liver. Therefore, portal inflow plays an important role in the delivery of oxygen to the liver[16]. It has been well known that cirrhosis with portal hypertension can result in reduced PP[16,21,22]. However, the volume of portal inflow varies due to the occurrence of collaterals or the presence of portal hypertension. In alcoholic cirrhosis, oral nitroglycerin can cause systemic hypotension to reduce portal inflow[1-4,22,23]. In the present study, all the patients did not experience systemic hypotension. Therefore, their transiently reduced, stagnant or hepatofugal portal blood flow was not likely to be related to systemic hypotension[15,24].

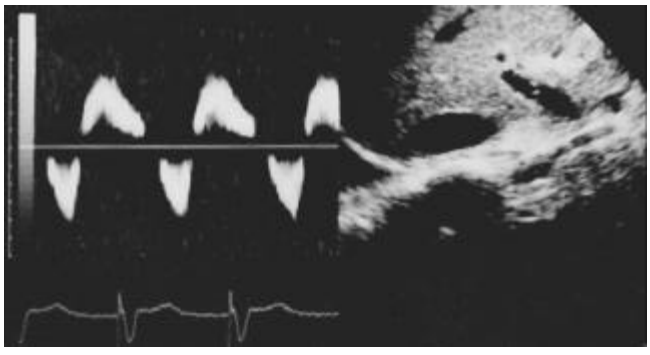

Figure 4 The occurrence of transient hepatofugal portal blood flow immediately after ventricular systole.

In the present study, the occurrence of transiently reduced (Figure 3), stagnant or hepatofugal (Figure 4) portal blood flow was immediately after ventricular systole[14,24,25]. The increased PP in those patients with RAP=10 mmHg suggests that the portal inflow is transiently reduced immediately after ventricular systole. The occurrence of transiently stagnant or hepatofugal portal blood flow may impair the delivery of

oxygen to the liver. It is well known that left heart failure and systemic hypotension can decrease hepatic inflow to cause ischemic hepatitis with a higher AST level[15,26]. However, it is not uncommon that some patients with heart failure have both abnormally higher serum ALT and LDH levels even without systemic hypotension clinically[5,6,24]. Thus, the occurrence of transiently reduced, stagnant or hepatofugal portal blood flow may in part explain the relatively higher AST levels in those patients with RAP=10 mmHg than those <10 mmHg.

ACKNOWLEDGMENT

A part of the present data was presented at the VIII World Congress of Ultrasound in Medicine and Biology, Buenos Aires, 1997, Ultrasound in Medicine and Biology 1997;23:22.

Abstract

AIM: To compare the efficacy of antibiotics therapy alone with antibiotics and saccharomyces boulardii in treatment of acute amebiasis.

METHODS: In a double blind, random clinical trial on patients with acute intestinal amoebiasis, 57 adult patients with acute amoebiasis, diagnosed with clinical manifestations (acute mucous bloody diarrhea) and amebic trophozoites engulfing RBCs found in stool were enrolled in the study. Regimen 1 included metronidazole (750 mg Tid) and iodoquinol (630 mg Tid) for 10 days. Regimen 2 contained capsules of lyophilized saccharomyces boulardii (250 mg Tid) orally in addition to regimen 1. Patients were re-examined at two and four weeks after the treatment, and stool examination was performed at the end of week 4. Student's *t*-test, χ^2 and McNemar's tests were used for statistical analysis.

RESULTS: Three patients refused to participate. The other 54 patients were randomized to receive either regimen 1 or regimen 2 (Groups 1 and 2 respectively, each with 27 patients). The two groups were similar regarding their age, sex and clinical manifestations. In Group 1, diarrhea lasted 48.0±18.5 hours and in Group 2, 12.0±3.7 hours ($P<0.0001$). In Group 1, the durations of fever and abdominal pain were 24.0±8.8 and 24.0±7.3 hours and in Group 2 they were 12.0±5.3 and 12.0±3.2 hours, respectively ($P<0.001$). Duration of headache was similar in both groups. At week 4, amebic cysts were detected in 5 cases (18.5 %) of Group 1 but in none of the Group 2 ($P<0.02$).

CONCLUSION: Adding saccharomyces boulardii to antibiotics in the treatment of acute amebiasis seems to decrease the duration of clinical symptoms and cyst passage.

INTRODUCTION

Intestinal amoebiasis is caused by the protozoan entamoeba histolytica. This organism feeds on the intestinal contents without any invasion to human tissue. It occasionally invades the intestinal wall and causes dysentery. It may also spread from the bowel to the liver and other organs and cause abscess in these organs. In addition, it may persist as cysts in the intestine and the patients become long-term cyst carriers, most of whom remain asymptomatic[1,2].

In most cases, the organism is avirulent but it may become virulent under different circumstances like immune suppression, malnutrition and alterations in intestinal flora[3,4].

Entamoeba histolytica is common all over the world but is more virulent in areas with low hygienic standards and in tropical and subtropical regions[1].

A luminal amebicide achieving high concentrations in the intestine like iodoquinol, paromomycin or diloxanide furoate is usually used to treat cysts. Tissue amebicides with high concentrations in the blood like the nitroimidazoles (especially metronidazole) are the cornerstone of treatment of invasive amoebiasis[5].

Saccharomyces boulardii is saprophytic, thermophylic yeast, which is found growing applications in the prevention and treatment of human septic enteritis[6,7]. The optimal temperature for this yeast to grow is 37 ℃. The gastric juice has no effect on it and it grows all along the gastrointestinal tract. It is used clinically as an oral lyophilized preparation[8]. No significant side effects have been reported with its consumption[9-11].

We assessed the effects of adding saccharomyces boulardii to the standard treatment for invasive amoebiasis.

To compare the routine treatment by means of metronidazole and iodoquinol with metronidazole, iodoquinol and saccharomyces boulardii in the treatment of acute amoebiasis, we performed this study on 57 patients at Shahid Beheshti Educational and Therapeutic Center in Shiraz during one-year period from March 21, 1995 to March 21, 1996.

MATERIALS AND METHODS

Patients with acute amebic dysentery who consented to participate were enrolled. The diagnosis was made according to compatible clinical presentations (acute mucous bloody diarrhea, fever and abdominal pain) and presence of amoeba trophozoite engulfing RBCs in diarrheal stool. Pregnant females, those on maintenance of hemodialysis, steroids or chemotherapy were excluded. The patients were then randomized to receive either metronidazole 750 mg and iodoquinol 650 mg thrice a day for 10 days (Group 1) or the same medication plus lyophilized saccharomyces boulardii (Ultra-levure®, Bio codex, Montrougo, France) 250 mg orally thrice a day (Group 2).

The patients were followed up at two and four weeks. At each visit in addition to recording patients' symptoms and possible adverse effects, pill count was performed. At the end of week 4, another stool examination (fresh spread and floatation) was done. Student's *t*-test, Chi-square and McNemar's tests were used for statistical analysis.

RESULTS

57 consenting patients were randomized (29 in Group 1 and 28 in Group 2). Two patients from Group 1 and one from Group

2 were excluded because of non-compliance. There were 12 (44.4 %) females in Group 1 and 10 (37 %) females in Group 2. Mean age was 29.3 years in Group 1 and 30.8 years in Group 2. Table 1 shows frequency of clinical findings in both groups. The two groups were comparable regarding their clinical presentations, too.

Table 1 Clinical manifestations in two therapeutic groups

	Regimen 1	Regimen 2	*P*
Diarrhea	27 (100 %)	27 (100%)	-
Fever	6 (22.2 %)	7 (26%)	N.S
Abdominal pain	19 (70.4 %)	22 (81.5%)	N.S
Headache	20 (74.1 %)	18 (66.7%)	N.S

N.S=Not significant.

As shown in Table 2, adding saccharomyces boulardii to the usual treatment of acute amebic dysentery decreased the mean duration of diarrhea to almost 25 % ($P<0.0001$) and the duration of abdominal pain and fever to almost half ($P<0.001$). Headache lasted almost equally in the two groups.

Table 2 Time of recovery from main clinical findings

	Regimen 1 (h)	Regimen 2 (h)	*P*
Diarrhea	48.0±18.5	12.0±3.7	<0.0001
Fever	24.0±8.8	12.0±5.3	<0.001
Abdominal pain	24.0±7.3	12.0±3.2	<0.001
Headache	24.0±8.6	24.0±7.9	N.S

N.S=not significant.

Amebic cysts were found in stool specimens of 5 patients (18.5 %) in group 1 and none in group 2 at week 4 ($P<0.02$, Table 3).

Table 3 Amebic cyst carriers in the fourth week after the treatment

	Regimen 1	Regimen 2
Cyst absent	22 (81.5 %)	27 (100 %)
Cyst present	5 (18.5 %)	0 (0 %)

DISCUSSION

Saccharomyces boulardii is a saprophytic yeast which is recommended for the prevention and treatment of septic enteritis[6,7] especially diarrhea caused by clostridium difficile[8,12,13]. It can also reduce the incidence of traveler' s diarrhea[12] and prevent the occurrence of diarrhea in acutely ill patients fed by nasogastric tube[14, 15]. Other diseases in which saccharomyces boulardii has been achieved some success include antibiotic associated colitis[11, 16] and Crohn' s disease[9]. Considering its inhibitory activity on enteropathogens and its anti-diarrheal characteristics, it has also been used in children with diarrhea[17]. Saccharomyces boulardii has been shown to have trophical effects on the small intestine in healthy human volunteers[18].

The exact mechanism by which this yeast prevents or improves diarrhea is still unclear. Saccharomyces boulardii may cause its trophic effect on the small intestine by releasing spermine and spermidine[6]. This yeast can hinder the cholera toxin excretion in the jejunum of mice.

Our data showed that co-administration of lyophilized saccharomyces boulardii with conventional treatment for acute amebic colitis significantly decreased the duration of symptoms and chances of cyst carriers after 4 weeks. This may be due to its potential to restore the beneficial normal flora of the gut, although the precise mechanism of the action remains to be elucidated. Considering the lack of any reported adverse reactions to this product, if our results are reproduced by other investigators, then lyophilized saccharomyces boulardii would be a very useful addition to the treatment of acute amebic dysentery.

ACKNOWLEDGMENT

We would like to thank Dr. Amirhossein Bagherzadeh, the member of Gastrointestinal & Liver Diseases Research Center, Guilan University of Medical Sciences, for his help in preparing and reviewing this manuscript.

Abstract

AIM: To explore the prevalence of amebiasis in inflammatory bowel disease (IBD) in Turkey.

METHODS: In this study, amoeba prevalence in 160 cases of IBD, 130 of ulcerative colitis and 30 of Crohn's disease were investigated in fresh faeces by means of wet mount+Lugol's iodine staining, modified formol ethyl acetate and trichrome staining methods and to compare the diagnostic accuracy of wet mount+Lugol's iodine staining, modified formol ethyl acetate and trichrome staining methods in the diagnosis of *Entamoeba histolytica (E. histolytica)*/ *Entamoeba dispar (E. dispar).*

RESULTS: *E. histolytica/E. dispar* cysts and trophozoites were found in 14 (8.75 %) of a total of 160 cases, 13 (10.0 %) of the 130 patients with ulcerative colitis and 1 (3.3 %) of the 30 patients with Crohn's disease. As for the 105 patients in the control group who had not any gastrointestinal complaints, 2 (1.90 %) patients were found to have *E. histolytica* /*E. dispar* cysts in their faeces. Parasite prevalence in the patient group was determined to be significantly higher than that in the control group (Fischer's Exact Test, $P<0.05$). When the three methods of determining parasites were compared with one another, the most effective one was found to be trichrome staining method (Kruskal-Wallis Test, $P<0.01$).

CONCLUSION: Consequently, amoeba infections in IBD cases have a greater prevalence compared to the normal population. The trichrome staining method is more effective for the detection of *E. histolytica* /*E. dispar* than the wet mount+Lugol's iodine staining, modified formol ethyl acetate methods.

Ustun S, Dagci H, Aksoy U, Guruz Y, Ersoz G. Prevalence of amebiasis in inflammatory bowel disease in Turkey. *World J Gastroenterol* 2003; 9(8): 1834-1835

INTRODUCTION

Amebiasis, which affects nearly 500 million people in the world, is more prevalent in developing countries in particular[1]. It is difficult to distinguish IBD from colitis associated with amoeba according to both symptomatic and endoscopic appearance of the colon. It is not even possible to establish a differential diagnosis by means of microscopic examination. Sometimes IBD can co-exist with amebiasis. This, of course, leads to confusion in the diagnosis and treatment of the disease[2].

This study was planned to consider amoeba in the cases diagnosed as IBD in the gastroenterology clinic and to compare the accuracy of wet mount + Lugol's iodine staining, modified formol ethyl acetate and trichrome staining methods in the diagnosis of *E. histolytica/E. dispar*.

MATERIALS AND METHODS

160 people who were diagnosed as IBD by endoscopic, histopathologic, radiologic and laboratory examinations at our clinic were included in this study which was carried out between January 2000 and June 2001. Of all the cases, 130 were diagnosed as ulcerative colitis and 30 as Crohn's disease. 105 people of even age and sex distribution who had not any gastrointestinal complaints and reported to the district health centre with other complaints were assessed as the control group. Fresh faeces samples taken from these people were examined immediately using the wet mount+Lugol's iodine staining, modified formol ethyl acetate and trichrome staining methods.

Fisher's exact test was applied to the groups (ulcerative colitis, Crohn's disease and control) for a comparison of amoeba frequency among them. The assessment of wet mount+Lugol's iodine staining, modified formol ethyl acetate methods used in the diagnosis of *E. histolytica/E. dispar*, was conducted by calculation of sensitivity, specificity, negative predictive value, positive predictive value and rate of accuracy.

RESULTS

In our study in which the prevalence of *E. histolytica/E. dispar* in IBD was investigated, we found *E. histolytica/E. dispar* cysts and trophozoits in 14 (8.75 %) of the 160 IBD cases. *E. histolytica/E. dispar* cysts and/or trophozoits were also determined in 13 (10.0 %) of the 130 patients with ulcerative colitis and 1 (3.3 %) of the 30 Crohn's disease patients (Table 1). Frequency of *E. histolytica/E. dispar* in patients with IBD was significantly higher than that in the control group (Fisher's exact test, $P<0.05$). When the groups of patients with IBD were compared with the control group separately, the frequency of *E. histolytica/E. dispar* in patients with ulcerative colitis was significantly higher than that in the control group. For Crohn's disease, on the other hand, it was not significantly different from the control group. A comparison between the patients with ulcerative colitis and those with Crohn's disease revealed that *E. histolytica/E. dispar* were more significantly frequent in the patients with ulcerative colitis (Fisher's exact test, $P<0.05$). When the three methods of determining parasites were compared with one another, the most effective one was found to be trichrome staining method as can be seen in Table 1 (Kruskal-Wallis test, $P<0.01$). The sensitivity of wet

mount+Lugol' s iodine staining, modified formol ethyl acetate methods was found to be quite low as compared to the trichrome staining method (36 %, 64 %, respectively) (Table 2).

Table 1 Number and methods for determination of *E. histolytica* determined in cases with IBD diagnosis and control group

	Wet mount ± Lugol's iodine staining	Modified formol ethyl acetate	Trichrome staining method	Total (none of parasite / patient)
Ulcerative colitis	5*(%3.84)	8*(%6.15)	13*(%10.0)	13 / 130
Crohn's disease	-	1*(%3.33)	1*(%3.33)	1 / 30
Control group	1*(%0.95)	2*(%1.90)	2*(%1.90)	2 / 105

*The parasite was determined by more than one method (+).

Table 2 Comparison of wet mount+Lugol's iodine, modified formol ethyl acetate methods with trichrome staining method

	Modified formol ethyl acetate (%)	Wet mount+Lugol's iodine staining (%)
Sensitivity	64	36
Specificity	99	98
False negatives	36	64
False positives	0.1	0.1
Positive predictive value	90	63
Negative predictive value	97	95
Rate of accuracy	97	93

DISCUSSION

Few studies have been performed in Turkey on this particular subject. In a study they carried out in the Province of Istanbul between April 1994 and July 1995. Bayramicli *et al*[3] explored the presence of amebiasis in 19 patients being investigated with a preliminary diagnosis of ulcerative colitis and found *E. histolytica* in 69 % of the cases. In a study they carried out in the Province of Antalya to determine the rate of amebiasis in 43 patients with ulcerative colitis. Suleymanlar *et al*[4] found *E. histolytica* cysts and trophozoites in 22 (54 %) of the patients. These values are higher than those we have found. The reason for this is the fact that the incidence of *E. histolytica/E. dispar* has been diminishing in Turkey in recent years.

Prokopowicz *et al*[5] determined 5 cases of amebiasis (4.85 %) among 103 patients with ulcerative colitis and claimed that this rate was significant in the treatment of chronic ulcerative colitis patients. We have obtained a higher rate than that of Prokopowicz in our study in which we found *E. histolytica/E. dispar* cysts and trophozoites in 13 (10.0 %) of 130 patients with ulcerative colitis**.** This was due to the environmental factors as high temperature and humidity, which are effective in and around Izmir, as well as lower immune resistance against the infection in addition to poorer hygiene. Chan *et al*[6] presented three cases with ulcerative colitis and *E. histolytica* infection and mentioned the problems to be faced during treatment.

In conclusion, amoeba infection in IBD cases, especially in patients with ulcerative colitis is more prevalent compared to the normal population. A differential diagnosis is extremely important for IBD and amebiasis cases. Therefore, we believe that *E. histolytica/E. dispar* must be explored in the faeces before planning a diagnostic scheme for cases diagnosed as IBD. In addition, the sensitivity of wet mount+Lugol' s iodine staining and modified formol ethyl acetate methods was found to be low in this study. Therefore, we think it would be necessary to use the trichrome staining method in the investigation of *E. histolytica/E. dispar* in patients with IBD diagnosis.

Abstract

AIM: To assess the effects of propranolol as compared with placebo on gastrointestinal hemorrhage and total mortality in cirrhotic patients by using meta analysis of 20 published randomized clinical trials.

METHODS: A meta analysis of published randomized clinical trials was designed. Published articles were selected for study based on a computerized MEDLINE and a manual search of the bibliographies of relevant articles. Data from 20 relevant studies fulfilling the inclusion criteria were retrieved by means of computerized and manual search. The reported data were extracted on the basis of the intention-to-treat principle, and treatment effects were measured as risk differences between propranolol and placebo. Pooled estimates were computed according to a random-effects model. We evaluated the pooled efficacy of propranolol on the risk of gastrointestinal hemorrhage and the total mortality.

RESULTS: A total of 1 859 patients were included in 20 trials, 931 in the propranolol groups and 928 as controls. Among the 652 patients with upper gastrointestinal tract hemorrhage, 261 patients were treated with propranolol, and 396 patients were treated with placebo or non-treated. Pooled risk differences of gastrointestinal hemorrhage were -18 % [95 % CI, -25 %, -10 %] in all trials, -11 % [95 % CI, -21 %, -1 %] in primary prevention trials, and -25 % [95 % CI, -39 %, -10 %] in secondary prevention trials. A total of 440 patients died, 188 in propranolol groups and 252 in control groups. Pooled risk differences of total death were -7 % [95 % CI, -12 %, -3 %] in all trials, -9 % [95 % CI, -18 %, -1 %] in primary prevention trials, and -5 % [95 % CI, -9 %, -1 %] in secondary prevention trials.

CONCLUSION: Propranolol can markedly reduce the risks of both primary and recurrent gastrointestinal hemorrhage, and also the total mortality.

INTRODUCTION

Gastrointestinal hemorrhage due to portal hypertension is a leading cause of death in patients with cirrhosis. The first episode of bleeding is fatal in 40 % to 50 % of such patients and two-thirds die within 1 year. It has been shown that treatment with propranolol can reduce portal venous pressure[1], portal blood flow[2] and superior portosystemic collateral blood flow[3] and its efficacy on preventing gastrointestinal hemorrhage has been assessed in many randomized clinical trials. Some trials have been primary, in which the drug was used to prevent hemorrhage in patients who have not bled, some have been secondary with the drug used to prevent rebleeding. Numerous primary and secondary prevention studies concluded that propranolol treatment decreased the incidence of gastrointestinal hemorrhage. Thus far, however, randomized clinical trials usually included small sample sizes and showed conflicting results, which hindered researchers drawing conclusions from the trials.

In meta analysis each treated group is compared with controls from the same study, and the treatment effect is combined across all studies, to provide information both about the presence of any significant effect and about its size. We have made extensive efforts to find all relevant studies by means of computerized and manual search. Then we combined all the studies including primary and secondary, to assess the effectiveness of propranolol as compared with placebo on the prevention of gastrointestinal hemorrhage.

MATERIALS AND METHODS

This meta analysis was performed according to a protocol determined before the study, and the widely accepted methodological recommendations[4-6]. Measurement of treatment effectiveness was determined on the basis of primary or recurrent gastrointestinal hemorrhage, and mortality.

Selection of trials

Studies that fulfilled the following criteria were included in the present meta analysis: (a) propranolol was compared with placebo; (b) patients were randomly assigned to the treatment regimen, and studies were prospective; (c) patients with cirrhosis of liver were included; (d) outcomes of primary or recurrent bleeding, and death were assessed; (e) results were published as abstracts or full reports.

Study identification

Pertinent studies were retrieved from MEDLINE database by using the search terms "propranolol", "cirrhosis" and "gastrointestinal hemorrhage" and by limiting the search to reports of clinical trials and studies with human patients. In addition, a manual search was performed by checking the reference lists from articles or reviews to identify studies not yet included in MEDLINE database. When the results of a single study were reported in more than one publication, only the most recent and complete data were included in the meta-analysis. Finally, twenty randomized clinical trials that fulfilled the criteria were identified, fifteen were published in full form[7-21], and five in abstract form[22-26].

Data extraction

Data from each randomized clinical trial were extracted by two independent reviewers (Jin-Wei Cheng, Liang Zhu). For each study and each type of treatment, the following data were extracted: number of patients, and number of each outcome. Numeric discrepancies between the two independent data extractions were resolved after discussion.

Statistical methods

All comparisons were performed according to the randomly assigned treatment (intended-treatment analysis). Because of different clinical characteristics among study groups, and varying sample sizes, we assumed that heterogeneity was present even not statistically significant, and we decided to combine data by using a random-effects model to achieve more conservative estimates[27].

For all the outcomes, the pooled estimates were computed with the method of DerSimonian and Laird[27]. Summary point estimates and 95 % confidence interval (CI) were reported. Risk differences less than zero denoted an advantage for propranolol. Those more than zero denoted an advantage for placebo. 95 % CIs of risk differences not including 0 denoted a statistically significant advantage.

RESULTS

All trials

A total of 1 859 patients were included in the twenty trials, 931 in the propranolol groups and 928 as controls.

In the 20 trials, among the 652 patients with upper gastrointestinal tract hemorrhage, 261 were treated with propranolol, and 396 were treated with placebo or not treated. The overall weighted bleeding rate was 31 % for propranolol and 48 % for controls. The pooled risk difference was -18 % [95 % CI, -25 %, -10 %], and the reduction had statistical significance (Z=-4.38, P<0.001, Table 1).

A total of 440 patients died, 188 in propranolol groups and 252 in control groups. The overall weighted bleeding rate was 17 % after propranolol treatment and 24 % after placebo treatment. The pooled risk difference was -7 % [95 % CI, -12 %, -3 %], and the reduction due to propranolol also was statistically significant (Z=-3.44, P<0.001, Table 2).

In ten trials, the overall weighted rate of death due to bleeding was 6 % in propranolol groups and 12 % in controls. The pooled risk difference was -5 % [95 % CI, -9 %, -2 %] (Z=-3.12, P=0.002).

Primary prevention

There were 964 patients in the nine primary prevention trials. Of the total 480 patients treated with propranolol, 97 patients bled from upper gastrointestinal tract, the overall weighted rate was 20 %. And 112 patients died, the overall weighted rate was 22 %. In the control groups (484 patients), the overall weighted rate of bleeding was 31 % (151 patients), and that of death was 31 % (151 patients).

The pooled risk difference of bleeding was -11 % [95 %CI, -21 %, -1 %], and that of death was -9 % [95 % CI, -18 %, -1 %]. Both of the reduction due to propranolol had statistical

significance (Table 1, Table 2).

Death due to bleeding was reported in 5 primary prevention trials, the overall weighted rate was 6 % in propranolol groups and 10 % in controls. The pooled risk difference was -4 % [95 % CI, -8 %, 0 %] (Z=-2.06, P=0.04).

Secondary prevention

Among the 895 patients in the twelve secondary prevention trials, 451 were treated with propranolol and 444 were treated with placebo.

The number of patients with bleeding was 164 in propranolol groups and 245 in control groups, the overall weighted rate was 39 % and 63 % respectively. The pooled risk difference of hemorrhage was -25 % [95 % CI, -39 %, -10 %], which had statistical significance (Z=-3.34, P<0.001, Table 1).

In all secondary prevention trials, the total number of patients died after propranolol treatment was 76, and 101 in controls. The overall weighted rate of death was 13 % and 20 % respectively. The pooled risk difference of death was -5 % [95% CI, -9 %, -1 %], and the reduction was statistically significant (Z=-2.26, P=0.02, Table 2).

In 5 recurrent prevention trials, the overall weighted rate of death due to bleeding was 6 % after propranolol treatment and 15 % in controls. The pooled risk difference was -8 % [95% CI, -15 %, -2 %] (Z=-2.53, P=0.01).

DISCUSSION

Propranolol reduces portal pressure, portal blood flow, and superior portosystemic collateral blood flow, so it can reduce the variceal pressure to prevent upper gastrointestinal hemorrhage[1-3]. However, reduction of the risk of gastrointestinal bleeding could not be replicated in some trials[7, 19, 21]. In the present meta analysis, we reviewed 20 randomized clinical trials to assess the efficacy of propranolol on gastrointestinal hemorrhage. The overall results showed that propranolol significantly reduced the risk of upper gastrointestinal tract bleeding, with a same effect on survival.

The beneficial effect of propranolol on both first and recurrent gastrointestinal hemorrhage was observed in all but six of the trials. The average rate of gastrointestinal hemorrhage was 28 % in patients treated with propranolol, but 43 % in controls, suggesting that this interventional therapy is highly effective on prevention of upper gastrointestinal tract bleeding. The results also demonstrated the efficacy of propranolol on preventing the first episode or recurrence of upper gastrointestinal tract bleeding in patients with cirrhosis. In the six trials, propranolol used to prevent variceal bleeding was proved to be ineffective, four were published in full form[7,10,19,21], and two in abstract form[25, 26].

The results of this meta analysis showed that propranolol significantly affected survival in all trials, primary prevention trials, or secondary trials. The average mortality was 20 % in patients treated with propranolol, but 27 % in controls. The reduction in total mortality was consistent with a limited effect on death due to bleeding. Other causes of death, including liver failure, sepsis, and the development of hepatocellular carcinoma, were not affected by propranolol.

Although the beta-blockade effect of propranolol can decrease hepatic blood flow, which may in turn induce deterioration of liver function in cirrhotic patients, but hepatic decompensation has been rarely encountered in patients treated with propranolol. In addition, other adverse effects of propranolol such as hypotension (3.6 %), heart failure (2.2 %), arrhythmia (1.4 %), bronchial spasm (2.7 %), dizziness (2.0 %), asthenia (3.4 %) etc were rarely encountered.

Endoscopic sclerotherapy is a conventional treatment for reducing the risk of recurrent bleeding, and long-term survival may also improve[28-33]. Another meta analysis which we conducted showed that the average recurrent bleeding rate was 42 % after endoscopic sclerotherapy, but was only 36 % in propranolol groups, and 55 % in control group in our present meta analysis. A randomized clinical trial suggested that the efficacy of combined sclerotherapy and propranolol on the primary prevention of hemorrhage in cirrhotic patients with varices was the same as propranolol alone[34]. In other words, endoscopic sclerotherapy did not consistently improve survival. Sclerotherapy, like propranolol, is associated with a low incidence of side-effects, but side effects such as esophageal perforation, may be life-threatening. The technique also is more time demanding on both physicians and patients.

In conclusion, the results of this meta analysis of the existing controlled trials show that propranolol is an effective means of reducing both the incidence of bleeding from upper gastrointestinal tract and the total mortality, and has the advantage of being safe and cost-effective. The combined data indicate that propranolol reduces the risk of bleeding or rebleeding by about 20 %, in both primary and secondary prevention and it also reduces mortality. The primary prevention trials, which included patients with obvious varices at high risk of bleeding, clearly show a beneficial effect. Based upon the analysis we would recommend a long-term treatment of gastrointestinal hemorrhage with propranolol. However, for many patients with portal hypertension without obvious varices, large prospective multicenter trials are indicated to determine the preventive benefit of propranolol. Further comparative trials of propranolol versus sclerotherapy are required to identify which is superior for secondary prevention of gastrointestinal hemorrhage.

Abstract

AIM: To explore the inhibition of β-L-D4A on hepatitis B virus (HBV) in 2.2.15 cells derived from HepG2 cells transfected with HBV genome.

METHODS: 2.2.15 cells were plated at a density of 5×10^4 per well in 12-well tissue culture plates, and treated with various concentrations of β-L-D4A for 6 days. In the end, 5 μl of medium was used for the estimation of HBsAg and HBeAg, the other medium was processed to obtain virions by a polyethlene glycol precipitation method. At the same time, intracellular DNA was also extracted and digested with HindIII. Both DNAs were subjected to Southern blot, hybridized with a ^{32}P-labeled HBV probe and autoradiographed. Intensity of the autoradiographic bands was quantitated by densitometric scans of computer and ED_{50} was calculated. Then Hybond-N membrane was washed and rehybridized with a ^{32}P-labeled mtDNA-specific probe, and effect of β-L-D4A on mitochondrial DNA was studied. 2.2.15 cells were also seeded in 24-well tissue culture plates, and cytotoxicity with different concentrations was examined by MTT method. ID_{50} was calculated. Structure-activity relationships between D2A and D4A were also studied as above.

RESULTS: Autoradiographic bands were similar between supernatant and intracellular HBV DNA. Episomal HBV DNA was inhibited in a dose-dependent manner. ED_{50} was 0.2 μM. HBsAg or HBeAg was not apparently decreased, and inhibition of mitochondrial DNA was not obvious. The experiment of cytotoxicity gained ID_{50} at 200 μM.

CONCLUSION: β-L-D4A possesses potent inhibitory effects on the replication of HBV *in vitro* with little cytotoxicity and mitochondrial toxicity, TI value is 1000. It is expected to be developed as a new clinically anti-HBV drug.

INTRODUCTION

Like interferon, nucleoside analogues have become the focus of investigations of anti-HBV drugs[1]. However, most anti-HBV nucleoside analogues tested to date have at best only transient and limited effects in a small percentage of the general population of HBV-infected individuals and exist moderately to seriously side effects[2,3]. Vidarabine, ribavirin, acyclovir, ganciclovir, famciclovir, fialuridine, etc. have not been used widely. In recent years, considerable interest has been focused on the use of 2', 3'-dideoxynucleosides (DDNs) for the treatment of chronic HBV infection[4]. DDNs are phosphorylated to triphosphate in cells, which in turn specifically inhibits the viral polymerase, terminates the elongation of HBV DNA, showing potent anti-HBV activities with relatively low cellular toxicities[5].

Lamivudine as one of DDNs has been used widely in clinic, and has a rapidly potent anti- HBV effect, but there is a rebound of HBV DNA after treatment, and drug resistance and viral mutants may appear after a long-term treatment with lamivudine[6]. Thus it is important to search for more effective agents against HBV, even with an improved therapeutic index. In this report, 2', 3'-didehydro-2', 3'-dideoxyadenine (β-L-D4A), a novel L-Nucleoside was demonstrated to effectively block the production of HBV in 2.2.15 cells *in vitro*. Mitochondrial effects and cytotoxicity were also investigated to evaluate the potential use of these compounds in treatment of HBV infection.

MATERIALS AND METHODS

Compounds and agents

β-L-D4A was synthesized by ourselves with the help of Pharmaceutic College of Wuhan University and identified by infrared, mass spectra, nuclear-magnetic resonance. Lamivudine, ddC' D-D4A, L-D2A, D-D2A were provided by Professor Cheng YC (School of Medicine, Yale University, New Haven, CT). All compounds were dissolved in phosphate-buffered saline (pH 7.4).

Determination of anti-HBV activity in 2.2.15 cells

2.2.15 cells (clonal cells derived from hepG2 cells that were transfected with a plasmid containing HBV DNA) that could secrete heptitis B virions, kindly provided by Prof. Cheng, were incubated in DMEM medium with 10 % (vol/vol) fetal bovine serum, 100 IU/mL penicillin and 100 μg/mL streptomycin at 37 ℃ in a moist atomosphere containing 5 % CO_2/95 % air. The cells were inoculated at a density of 5×10^4/ml per well in 12-well tissue culture plates. The compounds studied were added to the medium 3 days after the inoculation. The cells were grown in the presence of drugs for 9 days with changes of medium every 3 days. On the 12th day, the culture medium was havested. An aliquot of the culture medium (5 μl) was used for estimation of HBV surface antigen (HBsAg) and HBV e antigen (HBeAg). The remaining medium was processed to obtain virions by a polyethylene glycol precipitation method[7]. The viral DNA recovered from the secreted particles was subjected to Southern blot analysis. Cellular DNA was isolated according to the standard protocols. Inhibition of viral DNA replication was determined by comparison of the viral DNA from drug-treated

and nontreated cultures. The level of inhibition was determined by hybridization of the blots to an HBV-specific probe followed by autoradiography. Quantitation of the autoradiographs was performed by density scanning with a computer software.

Effect of b-L-D4A on mitochondrial DNA

Since some of the nucleosides used in the treatment of HBV, such as FIAU[8], could affect liver function, especially mitochondrial function, a detailed analysis of the effect of β-L-D4A on mitochondrial DNA synthesis was carried out. 2.2.15 cells were cultured as above and after 24 h in culture, treatment with the compounds was initiated. β-L-D4A was added at concentrations of 0.4 μM and 10 μM in DMEM. Cultures treated with 0.4 μM 2' 3' -dideoxycytidine (ddC) were maintained in parallel as positive controls for damage of mitochondrial DNA. Blank control was also set. Cellular DNA was isolated according to the standard protocols and digested with restriction enzyme BamH I. Hybridizations and detection of the mitochodrial DNA were done according to the laboratory manual of molecular cloning. The probe was cytochrome oxidase III DNA labeled by ^{32}pdCTP.

Cytotoxicity

Cells were inoculated at a density of 5×10^3/ml per well in 24-well tissue culture plates. After 24 h in culture, the cells were treated with various concentrations of β-L-D4A in DMEM for 3 days. Then 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assays were performed using the cell titer kit™ (Promega) following the standard procedure with the following exceptions. At the time points described as illustrations, 15 μl MTT reagent was added per well, allowed to incubate for 30 minutes, after which 130 μl stop/lysis buffer was added. Plates were sealed with Parafilm™ and left overnight at room temperature to allow solubilization of the formazan salt product. Absorbance was measured at 750 nm and 570 nm using a Thermomax (Molecular Devices, San Jose, CA), or a cytoFluor microplate reader (PE Biosystems, Foster City, CA). The data were normalized (A570-A750 nm) and the mean absorbance (5 wells/concentration) was plotted against drug concentration. The ID_{50} values were calculated as described above.

Determination of effects of b-L-D4A on HBsAg and HBeAg

HBsAg and HBeAg in the culture medium were determined according to the protocols supplied by the manufacturer. Essentially, the culture medium was appropriately diluted with phosphate-buffered saline and absorbed on the surface of plates coated by antibody to HBsAg or HBeAg. After an incubation period, the plates were washed and incubated in orthophenylene diamine. After a 30-min incubation, the reaction was terminated by adding 1N sufuric acid. The A_{490} of the final reaction was read. Appropriate positivity and negativity were assayed along with the samples.

RESULTS

Structure-activity relationships

The 2.2.15 cell line was used to evaluate the antiviral activities of ddA analogues: D-D4A, L-D2A, D-D2A (Structures are shown in Figure 1). The antiviral effects were measured by an analysis of extracellular HBV DNA. The experiment revealed that the inhibition of HBV DNA was more strong by L-isomer than by D-isomer and much more notable by L-D4A than by L-D2A (Figure 2).

Dosage-activity relationships

Inhibition of HBV DNA replication by β-L-D4A was evident as demonstrated by the amount of DNA obtained from the secreted viral particles as well as from the intracellular episomal particles. Concentrations of β-L-D4A ranging from 0.08 μM to 10 μM produced a dose-dependent inhibition (Figure 3). The intensity of autoradiographic bands for extracellular HBV DNA was quantitated by densitometric scans of computer and ED_{50} was calculated at 0.2 μM(Figure 4). Analysis of the intracellular episomal HBV DNA reflected similar trends in inhibition (Figure 5).

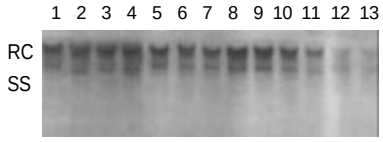

Figure 2 Inhibition of isomers of D4A and D2A on HBV DNA replication in supernatant. Lane 1 as negative control; lanes 2, 3, 4 as D-D2A at 2 μM, 4 μM and 8 μM, respectively; lanes 5, 6, 7 as L-D2A at 2 μM, 4 μM and 8 μM, respectively; lanes 8, 9, 10 as D-D4A at 2 μM, 4 μM and 8 μM, respectively; lanes 11, 12, 13 as L-D4A at 2 μM, 4 μM and 8 μM, respectively. RC: relaxed circular HBV DNA; SS: single-stranded HBV DNA.

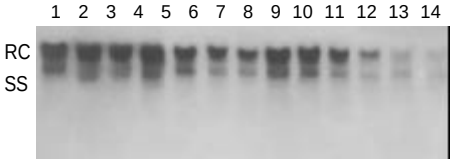

Figure 3 Inhibition on replication of extracellular HBV DNA by β-L-D4A. lanes 1, 2 as negative control; lanes 3, 4 as lamivudine at 1 μM; lanes 5, 6 as β-L-D4A at 10 μM; lanes 7, 8 as β-L-D4A at 2 μM; lanes 9, 10 as β-L-D4A at 0.4 μM; lanes 11, 12 as β-L-D4A at 0.08 μM; lanes 13, 14 as blank control ($HepaG_2$). RC: relaxed circular HBV DNA; SS: single-stranded HBV DNA.

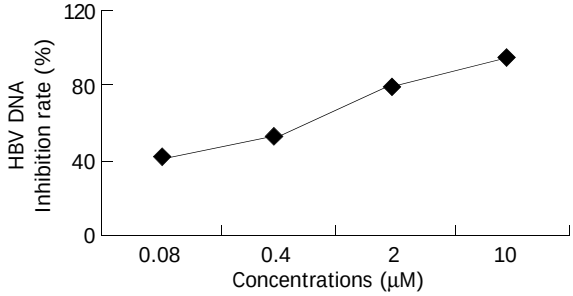

Figure 4 Inhibition on replication of extracellular HBV DNA by β-L-D4A.

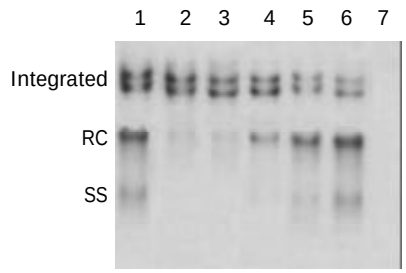

Figure 5 Inhibition on replication of intracellular HBV DNA by β-L-D4A. lane 1 as negative control; lane 2 as lamivudine at 1 μM; lane 3 as β-L-D4A at 10 μM; lane 4 as β-L-D4A at 2 μM; lane 5 as β-L-D4A at 0.4 μM; lane 6 as β-L-D4A at 0.08; lane 7 as blank control (HepaG2). RC: relaxed circular HBV DNA; SS: single-stranded HBV DNA.

Effect of b-L-D4A on mitochondrial DNA

Hybridization of intracellular DNA to a cytochrome oxidase III was done to evaluate the effect of β-L-D4A on mitochondrial DNA. Mitochondrial DNA levels treated with 0.4 μM and 10 μM β-L-D4A were nearly similar to the blank control, but were obviously lower for ddC at 0.4 μM (Figure 6).

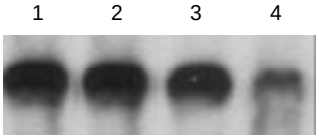

Figure 6 Toxicity of mitochondrial DNA. lane 1 as blank control; lane 2 as β-L-D4A at 0.4 μM; lane 3 as β-L-D4A at 10 μM; lane 4 as ddC at 0.4 μM.

Cytotoxicity of b-L-D4A

β-L-D4A did not show evident toxicity to 2.2.15 cells even at a concentration of 10 μM, but at high concentrations it had cytotoxicity, with 50 % inhibitory concentration (ID_{50}) of 200 μM, The data are shown in Table 1 and Figure 7.

Table 1 Effect-dosage relationship of inhibition of cell growth by β-L-D4A

Dosage (μM)	*n*	A value ($\bar{x}$±*s*)	Inhibition rate (%)
50	3	0.84±0.22	22.3

Effects of b-L-D4A on HBsAg and HBeAg

Measurements of the levels of viral surface antigen and e antigen from the media of cultures treated with β-L-D4A revealed that β-L-D4A had no significant inhibitory effect on HBsAg and HBeAg at low concentrations, but had marked effect of reducing HBsAg and HBeAg at 2 μM and 10 μM, significantly different from the blank group ($P<0.05$ or $P<0.01$, respectively) (Shown in Table 2).

DISCUSSION

One rational approach to the development of drugs for the treatment of HBV infection in patients is to identify those compounds that specifically inhibit HBV DNA replication[9,10]. Since deoxynucleoside analogues were found to be effective on a variety of viruses, several compounds have been tested *in vitro* and *in vivo* against hepadnaviruses[9-12]. The selectivity of these compounds against HBV in general is assessed by their relative potency against HBV versus cellular toxicity[13-16]. Cytotoxicity studies are usually conducted by growth retardation assays that measure cell growth in the presence of compounds tested for three or four generations[17]. This growth retardation assay could not, however, detect delayed cytotoxicity of deoxynucleoside analogues such as ddC that have an effect on cellular mtDNA synthesis. Since mitochondria play an important role in organ function, it was hypothesized that the delayed toxicity as shown by peripheral neuropathy (e.g., observed in patients treated with ddC analogs) could be due to decreases in mtDNA[18]. In this study, in addition to assessing their anti-HBV activities, compounds were examined for their effects on 4-day cell growth and on mtDNA.

Deoxynucleosides such as D2A and D4A can exist as (+)- or (-)- enatiomers. From the results we got, we could see that (-)-isomers were superior to (+)-isomers, and β-L-D4A was the most potent inhibitor of HBV replication in 2.2.15 cells, which could almost completely block HBV DNA replication at a concentration of 4 μM. However, (+) -isomers were almost inactive against HBV replication when tested up to 8 μM, mechanism of which might be in that the compounds could be deaminated intracellularly to the inactive analogues as reported before[19].

β-L-D4A was the most potent inhibitor of HBV replication in 2.2.15 cells from our results. No effects on mtDNA were observed. Cell growth retardation with the administration of β-L-D4A at low concentrations was not evident, but at high concentrations, β-L-D4A began to show cytotoxicity in a dose-dependent manner with 50 % inhibitory concentration (ID_{50}) of 200 μM. Since β-L-D4A does not inhibit mtDNA synthesis at concentrations that inhibit virus production, the delayed toxicity, such as peripheral neuropathy, associated with the treatment of ddC[20] may not occur. In addition, β-L-D4A is not toxic to proliferting cells at concentrations that completely block the synthesis of HBV virion, suggesting that acute bone

marrow toxicity may not be a concern. The study on dosage-activity relationships showed that β-L-D4A could inhibit HBV DNA replication in a markedly dose-dependent manner with 50 % inhibitory concentration (ED_{50}) of 0.2 μM. As the therapeutic index (TI value) was equal to ID_{50}/ ED_{50}, we got the TI value of β-L-D4A at 1 000. TI of lamivudine was 750 as reported in another article[21]. Therefore β-L-D4A like lamivudine possesses potent anti-HBV replication effect and has a higher TI value. In addition to that, β-L-D4A shows inhibition of expression of HBV antigens at high concentrations, indicating that β-L-D4A may be able to decrease the levels of HBsAg and HBeAg with a long term use.

About the mechanism of action of β-L-D4A, we think it is likely the inhibition of viral DNA polymerase, chain-termination resulted from incorporation into elongated DNA strand, or both. The mechanism needs to be further explored.

On the basis of the study of nucleoside analogs against HIV, human immunodeficiency virus resistant to ddC is not cross resistant to the thymidine analog zidovudine[22]. This permits the possibility of HBV treatment with β-L-D4A in the event of resistance to cytosine analogs as lamivudine. Furthermore, possibilities of a combined therapy of β-L-D4A and lamivudine for HBV can be explored.

Abstract

AIM: To establish transgenic mice expressing tamoxifen-inducible Cre-ERt recombinase specifically in the liver and to provide an efficient animal model for studying gene function in the liver and creating various mouse models mimicking human diseases.

METHODS: Alb-Cre-ERt transgenic mice were produced by microinjecting the construct with Cre-ERt fusion gene of DNA fragments into fertilized eggs derived from inbred C57BL/6 strain. Transgenic mice were identified by using PCR and Southern blotting. Expression of Cre-ERt fusion gene was analyzed in the liver, kidney, brain and lung from F1 generation transgenic mice at 8 weeks of age by reverse transcription (RT)-PCR.

RESULTS: Four hundred and fourteen fertilized eggs of C57 BL/6 mice were microinjected with recombinant Alb-Cre-ERt DNA fragments, and 312 survival eggs injected were transferred to the oviducts of 12 pseudopregnant recipient mice, 6 of 12 recipient mice became pregnant and gave birth to 44 offsprings. Of the 44 offsprings, two males and one female carried the hybrid Cre-ERt fusion gene. Three mice were determined as founders, and were back crossed to set up F1 generations with other inbred C57BL/6 mice. Transmission of Cre-ERt fusion gene in F1 offspring followed Mendelian rules. The expression of Cre-ERt mRNA was detected only in the liver of F1 offspring from two of three founder mice.

CONCLUSION: Transgenic mice expressing tamoxifen-inducible Cre-ERt recombinase under control of the liver-specific promoter are preliminary established.

INTRODUCTION

The liver plays a central role in regulation of carbohydrate, lipid, and urea metabolism as well as in production of most plasma proteins and detoxification of exogenous chemicals. The ability to create defined genetic modifications *in vitro* and *in vivo* provides a promising way to understand relevant functions of numerous hepatic genes in health and disease. Ligand-dependent chimeric Cre recombinases are powerful tools to induce specific DNA rearragements in cultured cells and mice[1-3]. To introduce defined genetic modifications in a temporally controlled manner in the liver, an alternative approach is to establish transgenic mice expressing tamoxifen-inducible Cre recombinase under control of the liver specific promoter. To this end, we constructed the fusion gene of Cre and the ligand binding domain (LBD) of a mutated human estrogen receptor (ER) that recognizes anti-estrogen 4-hydroxytamoxifen (4-OHT), Cre-ERt , under control of a liver-specific regulatory sequence from the mouse albumin gene. By using microinjection technology, two transgenic mice lines expressing Cre-ERt only in the liver were finally obtained.

MATERIALS AND METHODS

Materials

Restriction enzymes and other reagents Enzymes *Eco*RI, *Sma*I, *Sac*II *Hin*dIII, *Bam*HI, *Bgl* I, T4 DNA ligase, dNTP, Taq DNA polymerase, MMLV reverse transcriptase, etc, were purchased from NEB, Sangon and Sigma companies, respectively.
Mice C57BL/6, ICR mice (clean animal) were purchased from Laboratory Animal Center, Shanghai, China.

Methods

Construction of recombinant plasmid Construction of the Alb-Cre-ERt (Figure 1) was performed according to Sambrook *et al*[4]. In brief, a 0.6 Kb *Sma*I-*Sac*II fragment containing CMV promoter from plasmid pCMV-Cre-ERt (kindly provided by Prof. Chambon P) was replaced with a 2.3 Kb *Sac*II-*Eco*RV fragment containing albumin enhancer and promoter (alb e/p) from p2335A (kindly provided by Prof. Palmiter). Identity of the constructs was confirmed by restriction enzyme mapping and DNA sequence analysis.

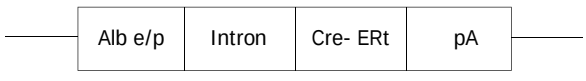

Figure 1 Structure of alb-Cre-ERt expression vector. The DNA fragments contained albumin gene promoter/enhancer (alb e/p), rabbit β-globin intron, fusion gene of Cre-ERt, and polyadenylation site (pA).

Production of transgenic mice Transgenic mice were generated by standard methods[5]. In brief, the transgene construct was linearized using *Bgl* l. The fragment was gel-purified with QIAGEN Kit. After diluted to 1 μg/ml final concentration in microinjection buffer, DNA was microinjected into the male pronucleus of fertilized C57BL/

6 mice oocytes. Then injected eggs were transplanted into the oviduct of pseudopregnant mice. Operated mice got pregnant and gave birth. Selected mice were bred with wild-type animals to establish transgenic lines that were maintained at heterozygosity.

Detection of transgenic integration Genomic DNA was extraction from transgenic mice tails (about 1-1.5 cm) at 4 weeks of age. Total DNA was extracted with the method described by Sambrook[4].

PCR assay The primers were designed on Cre gene sequence and synthesized by Cybersyn Biotechnology Company. The sequence of primers for PCR was as follows: the 5' primer for Cre was 5' -ATC CGA AAA GAA AAC GTT GA-3' and the 3' primer was 5' -ATC CAG GTT ACG GAT ATA G T-3' . The PCR reaction condition contained 2 μl of 10×PCR Buffer, 0.4 μl of 25 mM Mg^{2+}, 1 μl of 15 mM dNTP, 1 μl of 10 pmol each of primer, 2u of Taq DNA polymerase, 1 μg sample DNA. A 20 μl total reaction volume was obtained by adding sterile water, the reaction procedure of PCR was: beginning at 95 ℃ for 5 min, then 30 cycles at 94 ℃ denature for 30 s, annealing at 58 ℃ for 40 s and extension at 72 ℃ for 40 s, final extension at 72 ℃ for 10 min. 1.8 % agarose gel was prepared and 10 μl PCR products was loaded in the gel, then electrophoresed at 80 voltage for 40 min, the result of electrophoresis was observed.

Southern blot analysis Southern-blotting analysis was performed with the following standard procedures[4]: 10 μg tail DNA was digested with *Eco*RI and separated by electrophoresis on a 0.6 % agarose gel, and transferred onto a nylon membrane (Boehringer Mannheim). The nylon membrane was prehybridized for 5 h at 42 ℃ and hybridized overnight with a probe from a 0.7 kb *Bam*HI-*Xho*I Cre fragment that was a random primer labeled using α-32P dCTP (Amersham Pharmacia Biotech Inc). Bands were detected by X-ray film after 6 days of exposure.

Detection of Cre-ERt mRNA synthesis in mice The level of Cre-ERt mRNA was estimated by RT-PCR. Total RNA was isolated from F1 generation of 4 weeks old mouse tissues (liver, kidney, brain and lung) by Sambrooks method[4]. The upstream primer was 5' -CAGAACCTGAAGATGTTCG-3' and downstream was 5' -GGATCATCAGCTACACCAG-3' , resulting in a 505 bp fragment of the Cre-ERt cDNA. First stranded cDNA was synthesized as follows: The reverse transcriptase reactions contained 1 μg RNA, 5 μl of 10×PCR Buffer, 3 μl of 15 mM dNTP, 1 μl of RNasin (80 u/μl), 2 μl 10 pmol upstream primer, 1 μl MMLV(200 u). A 50 μl total reaction volume was obtained by adding sterile DEPC treated water. Reaction conditions were at 48 ℃ for 45 min for reverse transcription. The products of reverse transcriptase reactions were used directly in PCR reactions, adding 2 u Taq DNA polymerase, 3 μl of 10 pmol upstream/downstream primers, respectively. PCR denaturation was at 96 ℃ for 2 min, then for 35 cycles of reaction (denaturation at 94 ℃ for 30 s, annealing at 62 ℃ for 40 s, extension at 72 ℃ for 40 s, and a final extension at 72 ℃ for 7 min).

RESULTS

Identity of constructs

The *Sma*I-*Sac*II (blunted) fragment containing Cre-ERt of plasmid pCMV-Cre-ERt was isolated; the *Sac*II (blunted)-*Eco*RV fragment containing albumin enhancer and promoter (alb e/p) of p2335A were isolated, respectively. The two individual fragments were ligated to generate palb-Cre-ERt. The identity of palb-Cre-ERt was confirmed by restriction enzyme mapping (Figure 2) and DNA sequence analysis (data not shown), indicating that the albumin enhancer and promoter were correctly inserted and linked.

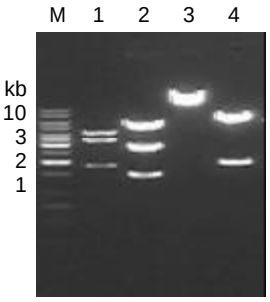

Figure 2 Identification of palb-Cre-ERt recombinant. M: GeneRuler 1 kb DNA Laddar, 1: recombinant-*Hin*dIII, 2: recombinant-*Sca*I, 3: recombinant-*Eco*RV, 4:Vector-*Hin*dIII.

Establishment of Cre-ERt transgenic mice

Recombinant Cre-ERt DNA fragment was microinjected into the male pronucleus of the 414 fertilized eggs of C57 BL/6 mice, and 312 survival eggs injected were transferred to the oviducts of 12 pseudopregnant recipient mice, 6 of 12 recipient mice became pregnant and gave birth to 44 offspring mice. The survial rate and birth rate of zygotes were 75 % (312/414) and 14 % (44/312), respectively. DNA extracted from tails of 44 offspring mice was screened by PCR assay and Southern blot analysis (Figure 3). The results showed that three mice carried the Cre-ERt gene. Three mice(two male, one female) were determined as founders. Total integration rate and efficiency of transgene were 6 % (3/44) and 0.7 % (3/414), respectively.

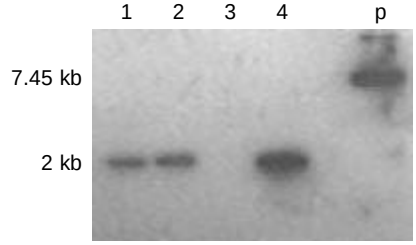

Figure 3 A part of mice was screened by Southern blot analysis. P: positive plasmid, 1,2,4: positive mice(2kb), 3: negative mice.

Stable transgenic mice of Cre-ERt

The founders were back crossed to set up F1 offsprings with other inbred C57BL/6 mice or transgenic littermates, respectively. All offsprings were screened by PCR (Figure 4), indicating that the integrated Cre-ERt gene was stably transmitted to subsequent generations (Table 1).

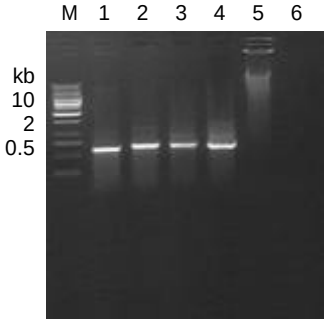

Figure 4 Electrophoresis analysis of PCR products amplified from DNA obtained from F1 mice tail tissues. Lanes 1-4 (transgenic mice) : positive bands (600 bp), lane 5: normal mouse (negative control), lane 6: blank control, M: Generuler of 1Kb DNA landar.

Table 1 Transmission rate of Alb Cre-ERt transgene to offspring

Founder line	Sex	No. of littermates	No. of offsprings	No. of transgenic mice	Ratio (%)
1	M	3	12	5	41.6
2	M	4	18	8	44.4
3	F	2	9	5	55.5

Expression of Cre-ERt gene in F1 mice

We performed RT-PCR to examine whether Cre-ERt transgene expressed only in liver tissues of F1 mice of transgenic mice lineages. The RT-PCR product (505 bp) was detected only in the liver of two of three transgenic mouse lineage (Figure 5).

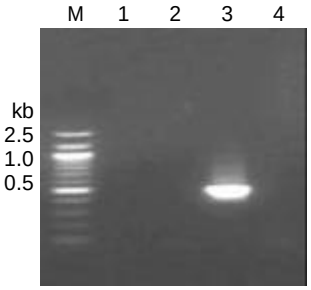

Figure 5 Electrophoresis analysis of RT-PCR products from transgenic mice. Lane 1: kidney tissue, lane 2: brain tissue, lane 3: liver (505 bp), lane 4: lung, M: Generuler of 100 bp DNA laddar.

DISCUSSION

By using transgenic mice carrying Cre recombinase under the control of a liver-specific promoter, the spatial window of gene modification can be strictly fixed to the liver. More recently, the generation and characterization of transgenic mice carrying Cre recombinase under the control of constitutive liver-specific promoters have been described[5-8]. These investigators used the constructs in which either mouse albumin regulation elements and α-fetoprotein enhancers or promoters and upstream enhancers of rat albumin gene were used to drive the Cre recombinase expression. These lines, AlfpCre, AlbCre, and Albumin-cre, allowed precise targeting of gene modifications in the liver. Nevertheless, the time of recombination remained strictly dependent on the promoter activity in these transgenic mice. In AlfpCre mice, Cre was shown to be constitutively active shortly after the appearance of the liver bud. Using the AlfpCre mice, mutagenesis of hepatic genes that serves essential functions during development could result in embryonic lethality, thus precluding analysis of their putative functions at subsequent stages. As for the temporal control of Cre expression in the liver, it was possible by using adenoviruses carrying the Cre transgene[9-11]. However, the immune response led to elimination of infected cells and could have deleterious effects on the general health status of mice[12]. An alternative approach for the temporal regulation of Cre activity is to create chimeric Cre fused to mutated ligand-binding domains of steroid hormone receptors which are insensitive to the endogenous ligands but still responsive to synthetic drugs. At present, tamoxifen-inducible Cre recombination can be achieved in many tissues of Cre-ERt transgenic adult mice and in developing mouse embryo as well as in cultured cells[13-18]. By combining the use of liver-specific promoters driving the expression of Cre and a ligand-activated Cre, gene modifications could be achieved in the liver at selected time points. Tannour-Louet *et al.*[19] established transgenic mice expressing tamoxifen-inducible Cre-mer recombinase under the control of the transthyretin promoter (TTR-Cre ind), the result showed a high recombination efficiency in the fetal and adult liver after treatment with 4-OHT. Imai *et al.*[20] established transgenic mice expressing tamoxifen-inducible Cre-ERt recombinase under control of the human 1-antitrypsin promoter, the result showed a low recombination efficiency, making it useful only to produce genetic chimeras which are not suitable for hepatic gene inactivation. In this study, the promoter and upstream enhancer of the mouse albumin gene were used to drive tamoxifen-inducible Cre-ERt recombinase expression for producing transgenic mice. After injecting the construct into oocytes, two lines expressing Cre-ERt in the liver, but not in other tested organs, were finally obtained. The results demonstrated that the promoter and upstream enhancer of the mouse albumin gene were liver-specific expression.

When the transgene results from random integration of a DNA fragment injected into a fertilized egg' s pronucleus, its level of expression in the resulting transgenic animal varied and depended upon certain factors, such as integration site, transgene cope number, genetic background of mouse, promoter/enhancer of fusion gene, etc. In this study, we only got two transgenic mice lines expressing Cre-ERt in the liver from three founder mice. The result was consistent with that of Imai *et al.*[20] in which three of 20 transgenic founder animals expressed Cre-ERt in the liver. These results indicate that not every transgenic founder mouse expresses Cre recombinase effectively, the chromosomal integration site may affect the expression pattern of transgenes.

Taken together, we have produced transgenic mice expressing Cre-ERt gene specific in the liver. This work will certainly permit a better understanding of hepatic gene functions and establish various mouse models mimicking human diseases.

ACKNOWLEDGEMENT

We thank Prof. Chambon P of Universite Louis Pasteur for providing plasmid pCMV Cre-ERt, Prof. Palmiter of University of Washington for plasmid p2335A, Prof. Orkin SH of Howard Hughes Medical Institute for Rosa26 reporter mice. This work was also supported by the Postdoctoral Foundation of China.

Abstract

AIM: The association has been established between the disorder of carbohydrate metabolism and liver cancer. However, little is known regarding the impact of concurrent hyperglycemia on prognosis of hepatocellular carcinoma (HCC). The present study aimed at solving this problem.

METHODS: A total of 225 patients included in this study, were admitted from January 1998 to December 2001 for an unresectable HCC proven by histological and imaging examinations. Most of the patients received interventional treatment, radiation and biotherapy. Response was evaluated by computerized tomography (CT) scan conducted 4-6 weeks following completion of the treatment, and then every 3 months. Survival was calculated from the beginning of treatment using the Kaplan-Meier method. Pretreatment, treatment and follow-up variables with possible prognostic significance were analyzed. A stepwise multivariate analysis was performed using the Cox regression model, and a prognostic index was obtained.

RESULTS: No differences were observed in survival parameters between the patients with and without hyperglycemia, median survival times of the patients were being 26±3.46 months and 29.5±2.04 months, respectively, and the 3-year survival rate was 8.36 % and 9.62 %, respectively. The univariate analysis indicated that there were several survival-associated variables including serum AFP level, clinical stage, Child-Pugh grade, method of treatment, size and number of tumor nodule (s). However, only the clinical stage, Child-Pugh grade and the treatment procedure were proved to be independent prognostic factors in the multivariate analysis.

CONCLUSION: This study indicates that hyperglycemia does not influence the long-term prognosis of HCC, and concurrent hyperglycemia should not be considered as an unfavorable prognostic factor during the treatment of patients with HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common cancer of human liver in the world[1]. Its increasing incidence and mortality have been observed in China and some other countries. Both case-control and cohort studies have associated chronic viral hepatitis with its development[2,3]. The majority (60-80 %) of HCCs are found in livers with cirrhosis, frequently in a macronodular type in Southeast Asia and causally linked with chronic infection of hepatitis B virus (HBV) or hepatitis C virus (HCV)[3].

A large body of evidences have demonstrated that chronic liver diseases are associated with an increased incidence of glucose intolerance and diabetes[4-7]. The glucose intolerance is one of the most frequent complications in patients with HCC. Hypoglycemia is often considered as a paraneoplastic syndrome of HCC. The incidence of hyperglycemia or diabetes, however, is also increasing[8-10], accounting for 5-15 % of cases with HCC. Hyperglycemia and HCC may be found simultaneously. In some patients, HCC occurs following hyperglycemia[11]. In fact, diabetes mellitus (DM) has been considered as a risk factor for HCC development in addition to other well known factors[11-13]. In clinical views, hyperglycemia may need specific pharmacological treatment, dietary restrictions, or both procedures. It appears logical to regard hyperglycemia as an unfavorable factor during the prognosis evaluation of HCC, but this remains unsettled. A Japanese group has described the long-term impact of diabetes mellitus on the prognosis of HCC after resection[14]. Much more HCCs, however, are found at advanced stages in this country, and hence cannot be resected. For this reason, we conducted the study to evaluate the possible impact of concurrent hyperglycemia on the peri-treatment outcome and long-term survival in a large series of consecutive patients with unresectable HCCs.

MATERIALS AND METHODS

The survey involved 230 HCC patients consecutively admitted from January 1998 to December 2001. In 2002, all the clinical records of these patients were retrospectively examined, and the following clinical and laboratory indices were collected, including the values of AST, ALT, alkaline phosphatase (AP), γ-glutamyl-transpeptidase (γ-GT), prothrombin time (PT), serum bilirubin, serum proteins, albumin, γ-globulins, platelet number and glucose control. Of these, 225 cases with a complete clinical record were included. They were comprised of 180 males and 45 females, and their ages ranged from 32 to 76 years (mean ±SD, 53.19±12 years). A diagnosis of HCC was made by the ultrasound-guided transcutaneously fine-needle aspiration and subsequently by cytological examinations in 184 cases, and for the other cases the diagnosis was made by a combined consideration of the history, physical examinations, α-fetoprotein (AFP) levels and noninvasive imaging procedures. Indications for HBV and HCV infection were found in 125 and 15 patients, respectively.

Of the 225 patients examined, 28 had hyperglycemia, as determined with the concentration of plasma glucose exceeding 6.8 mmol/L in at least 2 fasting samples for each case or with the active treatment with insulin or oral hypoglycemic drugs necessary to control blood glucose levels. No consideration was given to those who had slight alternations in glucose

metabolism, such as impaired glucose tolerance demonstrated through an oral glucose tolerance test according to the criteria of World Health Organization[15,16], and those who had no evidence of glycosuria, because the test was performed in about 20 % of cases. Of the 28 hyperglycemic patients, 8 had overt diabetes mellitus when admitted to our department, and 20 had hyperglycemia identified after the diagnosis of HCC. The clinical and laboratory data are listed in Table 1.

As treatment for HCC, 146 patients received transcatheter arterial chemoembolization (TACE), 20 received radiotherapy only, 30 were treated by TACE and local radiotherapy, 14 by percutaneous ethanol injection therapy (PEIT), 162 received biotherapy.

TACE was performed with infusion of Fluorouracil or 5-FUDR (1.0 g), cisplatin (40-60 mg), followed by chemoembolization with a mixture of iodized oil and doxorubicin (40-60 mg) or mitomycin (10-20 mg), or with gelatin-sponge particles for the embolization. Radiotherapy was performed using a Co^{60} or 18-MV linear accelerator[17]. CT scan was performed to determine the radiation fields, and then whole or partial liver irradiation was conducted using the moving-strip technique or local radiotherapy covering tumors with generous margins (2-3 cm). The irradiation dose was 40-50 Gy daily in 1.8 fractions. During the treatment, the patients were monitored weekly with a complete blood count and liver function tests. For the concurrent hyperglycemia, one patient used dietary therapy, 13 received insulin therapy, and 6 took hypoglycemic drugs.

Effects of the treatments were evaluated based on serial CT scans 4-6 weeks following completion of the therapies and then every one to three months. The complete disappearance of the tumor was regarded as complete remission (CR), a decrease of over 50 % in tumor size as partial remission (PR), a decrease of less than 50 % or no change as stable disease (SD), and progression as progressive disease (PD). The response rate was calculated for CR or PR, and the SD cases were considered as non-responsive. Survival was estimated from the starting date of treatment according to the Kaplan-Meier method.

After the procedures as described above, the outcome of patients was investigated by visiting their families. Follow-up was carried out for all the subjects regularly for more than 6 months, with a median follow-up period of 25 months. The follow-up program included measurement of serum AFP and ultrasonography or CT scan every 3 months. The patients with recurrence were managed with various therapeutic methods including TACE, PEIT and/or biotherapy.

Statistical analysis

The data collected were presented as mean ± standard deviation. Continuous laboratory values were clustered to obtain two samples of approximately equal size. Statistical comparison between groups was performed using the χ^2 test with the Yates' correction for nominal data, and the Student's *t* test for numerical data.Kaplan -Meier survival plots were built to evaluate the prognostic values of individual indices, and compared using the log rank test. The same method was used for univariate analysis of survival. The univariate analysis was also carried out with age, sex, etiology and liver function parameters measured at the beginning of observation to establish their predictive value for survival. Baseline variables included in the univariate analysis were also analyzed by multivariate analysis using the step-wise forward Cox regression model to assess their predictive value with respect to survival. To check proportionality of risk factors with time, we plotted the log of cumulative hazards against time, demonstrating parallel behaviors in the two groups of patients separately with low- and high-risk values of selected prognostic covariates. All statistical analyses were computerized using the softpackage SPSS 10.0 (SPSS Inc., Chicago, Illinois). $P<0.05$ was considered statistically significant.

RESULTS

Hyperglycemia was found in 28 of the 225 patients when they were admitted. No difference in other clinical or laboratory indices was present between the groups with and without detectable hyperglycemia at the time (Table 1). Hyperglycemia was treated by insulin alone in 13, by oral hypoglycemic agents in 9, by diet therapy in 2, and by a combination of insulin and oral hypoglycemic agents in 4 patients. Table 1 shows a comparison of the clinicopathological data between hyperglycemic and non-hyperglycemic patients under the treatment for HCC.

The mean age of hyperglycemic patients was higher than that of non-hyperglycemic patients, but the difference was not significant. The two groups were comparable regarding their pathological factors such as size of the largest tumor nodules, number of tumor nodules, clinical stage and Child-Pugh grade. No significant difference was found between these two groups in other laboratory data such as total bilirubin, platelet count, prothrombin time and initial treatment.

Table 1 Clinicopathological data of hyperglycemic and non-hyperglycemic patients with HCC

Variables	With hyperglycemia (*n*=28)	Wthout hyperglycemia (*n*=197)
Age (year)	55±1.99	51.91±1.08
HBsAg(+/-)	15/13	110/87
Cirrhosis (+/-)	20/8	133/64
Gender (male/female)	23/5	157/40
Laboratory data		
ALT (U/L)	48.91±10.41	39.82±11.21
PT (s)	12.24±0.20	12.67±0.23
Albumin (g/L)	39.63±6.35	35.81±7.86
Total bilirubin (μmmol/L)	12.32±7.15	13.54±8.97
Platelet count ($\times10^9$/L)	158.41±18.14	155.75±7.37
TNM stage (I/II/III/IVa/IVb)[a]	0/3/12/5/8	0/32/76/48/41
Child-Pugh grades (A/B/C)	22/5/1	165/30/2
Sizes of the largest tumor (cm)	3.80±6.30	3.50±6.75
Initial treatment (TACE/radiotherapy/TACE+radiotherapy/PEI/biotherapy)	18/3/5/3/15	128/17/15/11/147

[a]The criteria for TNM classification were based on the criteria of UICC(1987).

During the follow up, 73 patients, 10 with and 63 without hyperglycemia, died of the hyperglycemic complications or from liver-related causes. Intrahepatic spreading was observed in 10 of them, and extrahepatic metastases occurred in 12 of the patients. Among them, 4 were complicated with lung metastases, 2 with bone metastases, 5 with para-aortic lymph node metastases, 1 with lung and bone metastases, 1 with lung and brain metastases and 1 with bone and para-aortic lymph node metastases. All of these patients received treatments according to their liver function status.

Response rates were calculated for the groups with and without hyperglycemia, which were 21.4 % and 20 %, respectively. The difference was not significant ($P>0.05$; Table 2).

Table 2 Comparison of treatment responses between the groups with (HG) and without hyperglycemia (Non-HG)

Groups	Response rate	CR (%)	PR(%)	NC(%)	PD(%)
HG	21.4(6/28)	7.1(2/28)	14.3(4/28)	53.6(15/28)	25.0(7/28)
Non-HG	23.4(46/197)	8.1(16/197)	15.2(30/197)	48.2(95/197)	28.4(56/197)
P values	0.821	0.858	0.896	0.596	0.706

The one-, two- and three-year survival rate was 51 %, 31 % and 8 % respectively for the hyperglycemia group, and was 60 %, 30 % and 10 %, respectively for the group without detectable hyperglycemia. Median survival times of these two groups were 26.0±3.5 months and 29.5±2.0 months, respectively. Figure 1 shows the overall cumulative survival after treatment.

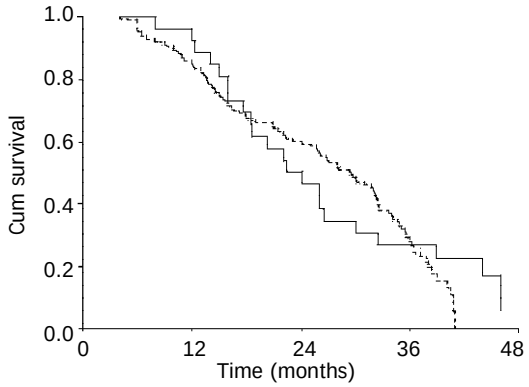

Figure 1 Kaplan-Meier survival curves for HCC patients with (green) and without hyperglycemia (red).

The incidence of complications included in this survey is shown in Table 3. The post-embolization syndrome consisted of abdominal pain, fever apparently unrelated to the tumor, and, slight or severe nausea, was seen in almost all the patients. Narcotics, anti-emetics and acetaminophen were given to relieve the symptoms. The main complications of TACE and radiotherapy included hepatic insufficiency or infarction, tumor rupture, upper gastrointestinal tract (GI) bleeding. Slight increase in serum bilirubin (n=20), elevation of serum transaminase (n=45), ascites (n=14), leukopenia (n=46) and thrombocytopaenia (n=15) were also seen during the therapies. These side effects were transient or easily controlled with medications in most cases. Two patients died of acute hepatic failure immediately after TACE, five died of hepatic encephalopathy and 2 died of severe GI bleeding. Thirty patients without hyperglycemia showed TACE- or radiotherapy-related complications, while ten with hyperglycemia showed complications after treatment and the symptoms were more severe. There was a significant difference between these two groups in the occurrence of complications.

Table 3 Incidence of complications during follow-up

Complication	With hyperglycemia		Without hyperglycemia		*P* value
	I-II	III-IV	I-II	III-IV	
Leucopoenia	6	8	22	10	0.000
Erythrocytopenia	5	1	16	2	0.049
Thrombocytopenia	2	1	10	2	0.359
Reaction of GI system	3	0	12	0	0.359
Impairment of liver function	5	1	13	0	0.008
Impairment of renal function	1	0	2	0	0.270

The univariate analysis showed that AFP level, clinical stage, Child-Pugh grade, treatment procedure, size of tumor and number of tumor nodules were independent factors predicting survival for all patients, but hyperglycemia was not. The effects of possible prognostic factors are shown in Table 4.

The Cox proportional hazards model showed that clinical stage, Child-Pugh grade and treatment procedure employed were independent factors predicting survival (Table 5). The 3-year survival rate was 1 % for Stage T4 cases and 15 % for others. The patients with T4 disease had a significantly shorter survival (P=0.0049). When the survival rates were compared according to Child-Pugh grade, patients of grade A survived significantly longer than those of grade B or C. The 3-year survival rate was 11.1 % and 0 %, respectively. The treatment procedure employed also had similar impacts on the survival. The 3-year survival rate for patients treated with TACE alone, radiotherapy alone and radiotherapy combined with TACE was 8 %, 4 % and 25 %, respectively (P=0.0042).

Table 4 Association between various clinical parameters after treatment and the survival

DISCUSSION

It is not surprising that many interactions exist between the liver and endocrine system demonstrated by some clinical and laboratory parameters. Liver diseases can result in endocrine disorders, and some endocrine disorders may affect the liver[18]. The role of the liver in glucose homeostasis is important. The regulation of hepatic glucose uptake involves a complex interaction of neural and hormonal mechanisms. HCC is often complicated with cirrhosis, and carbohydrate intolerance is seen in approximately 50 % of patients with

cirrhosis. The carbohydrate intolerance is most likely due to profound biochemical and physiologic derangements concurrent with advanced liver diseases, including portal-systemic shunting of glucose, elevated glucagon or growth hormone level, peripheral and/or hepatic resistance to insulin, malnutrition, elevated level of free fatty acids and hypokinemia[19,20]. Therefore, hyperglycemia or diabetes mellitus is often seen in HCC patients. Relatively mild hypoglycemia occurs in rapidly growing HCC among Chinese patients as a part of an end-stage illness[18], but their definite association remains lack of unequivocal evidences.

Accumulated data have associated diabetes with an increased risk for primary liver cancer[21-25]. One possible mechanism might be the proposed growth-stimulating and/or apoptosis-suppressing effects of insulin. This is particularly true for the tissues harboring preneoplastic or neoplastic lesions[26]. We observed that 68 % (153/225) of HCCs occurred in the liver with cirrhosis, and 8 of the patients had known diabetes mellitus before the diagnosis of HCC. Based on our observations, however, it is not clear whether cirrhosis and HCC were the causes or consequence of hyperglycemia and diabetes mellitus, or these two groups of disorders were merely clinically concurrent rather than causally linked.

To date, the knowledge is limited about the treatment of HCC complicated with hyperglycemia. Diabetes mellitus is regarded as an unfavorable factor in determining surgical resection for HCC patients[27-29]. Hepatic operation and anesthesia may have profound metabolic effects, potentially exacerbating the preexisting diabetes by insulin deficiency, its reduced secretion or insensitivity. This may diminish phagocyte functions, and thus impairs the resistance to infection and delays wound healing. Diabetes may also result in some cardiovascular diseases, neuropathy and nephropathy. All these factors will increase the morbidity and mortality of surgical procedures. Diabetes mellitus has been reported to be the only independent risk factor for liver failure after major hepatic resection of HCC patients with a low remnant liver volume. Ikeda *et al*[14] reported 342 hepatectomies for HCCs, the 10-year survival rate was 12.6 % and 24.6 % for diabetic and non-diabetic patients, respectively. Thus, diabetes mellitus complicated with hepatocellular carcinoma was proposed to be a high-risk condition for the higher morbidity and a shorter survival after operation. However, this notion was not approved by several recent observations carried out in Hong Kong[29], Japan[30,31] and Taiwan[27].

The impact of diabetes mellitus on the function of the liver with end-stage diseases remains obscure. Toyoda *et al*. pointed out that the presence of diabetes mellitus didn' t necessarily correlate with the severity of cirrhosis. In the present study, most of the cases of hyperglycemia did not show any symptom of diabetes, and might be simply regarded as carbohydrate intolerance, a subclinical stage to overt diabetes mellitus. Therefore, the influence of hyperglycemia on liver functions is not obvious, as indicated by the data we presented here. On the other hand, non-surgical treatments, as employed in this study, may help to reserve hepatic intracellular energy during the treatment and achieve a better peri-operational outcome, compared to those more stressful surgical procedures. Our data also showed that concurrent hyperglycemia did not significantly influence the overall survival of HCC patients after non-surgical treatment. Certainly, patients with hyperglycemia and HCC are a heterogeneous group, which is partly linked to a genetic alteration, and patients with the so-called hepatogenous hyperglycemia, are mainly associated with the acquired insulin resistance. These two conditions may have different metabolic abnormalities and possible different outcomes.

Our study was partly retrospective, and only a small number of patients underwent an oral glucose tolerance test during hospitalization, so we could not say some patients with hyperglycemia were diabetes. The prevalence of hyperglycemia in this series was higher than that reported in several previous studies. On the other hand, fasting glucose and detailed data about the treatments were available for most cases. In this survey, it was difficult to clearly identify these subgroups. Approximately 50 % of the patients had hyperglycemia before the diagnosis of HCC, whereas patients with hyperglycemia superimposed on cirrhosis were more likely to have hepatogenous hyperglycemia. Gentilini *et al*.[32] held that distinction as to either cirhhosis or diabetes occurring first did not substantially help classify patients. Carefully prospective studies are needed to answer this question.

Tumor stage was confirmed as an independent prognostic factor in our series. Patients who had non-T4 diseases survived significantly longer than those with T4 diseases. This is in agreement with a previous study[33], so we need to detect and treat liver cancer earlier[34,35]. Recently, many articles reported that combined TACE and radiotherapy might significantly increase survival rate[17,33,36].Cheng *et al*.[33]reported that the 2-year survival rate was 13 % and 55 % for patients treated with radiotherapy alone and with combined TACE and radiotherapy (P=0.0003), respectively. Our studies also confirmed this. We are currently using three dimensional conformal radiotherapy (3-DCRT) and applying the dose-volume model for every patient. With the advances in treatment planning, local radiotherapy can be more safely delivered and further studies are required to elucidate the efficacy of these regiments.

In summary, our data suggest that hyperglycemia does not significantly influence the long-term prognosis of patients who receive the proper non-surgical treatment. The T4 disease is associated with an unfavorable pognosis. Patients with Child-Pugh grade B or C have a higher risk. Further studies are needed to evaluate the impact of hyperglycemia on patients with HCC.

Abstract

AIM: To demonstrate whether class I MHC molecule, transporter associated with antigen processing (TAP), and heat-shock proteion70 (HSP70) expressed in liver cancer cells before the design and construction of CTL vaccine against hepatocellular carcinoma (HCC).

METHODS: We studied 30 HCC specimens by labeled streptavidin biotin (LSAB) method of immunohistochemistry.

RESULTS: The results showed that the majority of HCC cells investigated naturally expressed class I MHC and TAP, which were different from other tumor cells. Furthermore, we found that HSP70 expressed not only in cellular cytoplasm, but also on the cell surface in HCC.

CONCLUSION: Our findings indicate that our understanding about immune escape mechanisms employed by HCC cells may be further improved. It is important to design and construct CTL vaccine against HCC.

INTRODUCTION

It is commonly accepted that tumor rejection is mediated by lymphocytes, and most notably, by cytotoxic T lymphocytes (CTL). The recognization of a tumor cell by CTL is regulated by interactions between T-cell receptor and antigenic peptide -MHC complex. TAP, HSP70 and class I MHC molecule are important components in endogenous processing of peptides through the MHC class I pathway. Among many proteins that contribute to MHC class I assembly, TAP complex is one of the most important components. It translocates endogenously processed peptides from cytosol into ER for binding to class I MHC, resulting in surface presentation of these complexes to CTL. Most of the studies described the defect of endogenous processing function in tumors such as melanomas, cervical carcinomas, and renal cell carcinomas[1-3]. These findings suggest that TAP down-regulation might represent an important mechanism for immune escape of malignant cells in tumors. Another importantly associated presentation protein is heat-shock proteion70 (HSP70). HSP70 has long been known to be located in the cytoplasm, where it performs chaperoning function. Recent studies have also indicated that conditional over-expression of HSP70 in target cells enhances the susceptibility to CTL[4]. Moreover, HSP70 may enhance TAP function[5]. Therefore, there is an increasing realization that expression of these molecules on tumor cell surface may potentially affect CTL-mediated recognition.

HCC is one of the most malignant cancers. However, to date most of the studies that described expressions of class I MHC, TAP, and HSP70 were carried out with cell lines[6]. Limited information is available about these molecules in HCC tumor tissues. Nevertheless, it is important to demonstrate whether these molecules can also be expressed in HCC *in vivo* before the design and construction of CTL vaccine against HCC.

MATERIALS AND METHODS

Human tissues

Thirty pathological samples were obtained from surgically resected tissues of HCC patients in West China Medical Center of Sichuan University. The specimens were frozen immediately in liquid nitrogen. Cryostat sections (4 μm) were prepared and stored at -70 ℃. Pathological diagnoses were made based on routinely processed HE sections.

Main reagents

Mouse anti-human HLA-ABC (DAKO Corp., working dilutions 1:100), rabbit anti-human TAP (Chemicon International, Inc., working dilutions 1:1 000), mouse anti-human HSP70 (DAKO Corp., working dilutions 1:50), biotin labeled goat anti-mouse IgG and goat anti-rabbit IgG, HRP-labeled streptavidin and avidin biotin blocking system were all purchased from Beijing Zhongshan Corp.

Immunohistochemistry

The frozen sections were fixed in cold acetone for 10 min. 3 % H_2O_2 containing methanol was added to block endogenous peroxidase. Fixed sections were incubated with normal goat serum for blocking and subsequently with mAb (HLA-ABC, TAP and HSP70 respectively) or PBS as control at 37 ℃ for 2 h, then washed with PBS. After incubation with biotin labeled goat anti-mouse IgG or goat anti-rabbit IgG for 30 min at 37 ℃, and washed as before, HRP-labeled streptavidin was added. The following incubation and washing were exactly the same as above. Finally, freshly prepared substrate DAB was added for color development. The reaction was stopped with tap water rinse and then counterstained with hematoxylin and mounted for examination.

RESULTS

Expression of class I MHC molecule

Strongly positive staining of class I MHC molecule was presented in all cases of HCC. The staining was mainly located

on the membrane of the liver cancer cells, in the cytoplasm, and the perinuclear area. The staining showed granular pattern (Figure 1).

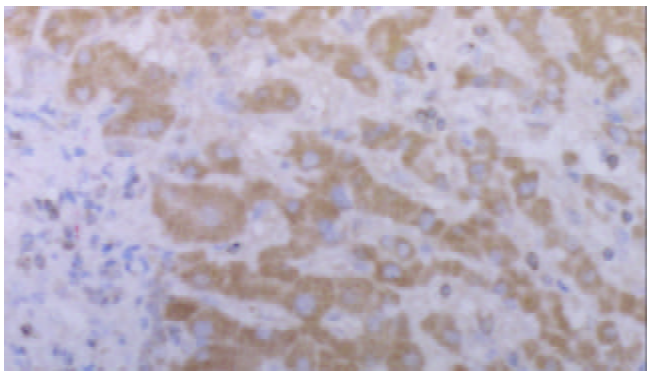

Figure 1 Displayed class I MHC molecule in hepatocellular carcinoma (×180).

The positive staining was mainly located on the membrane of the liver cancer cells. Some of the cells showed positive staining in the cytoplasm and the perinuclear area.

HSP70 expression

Tumor cells as well as adjacent non-neoplastic hepatocytes displayed intense and extensive positive staining. The staining was uniform throughout the specimen. The cytoplasmic staining showed granular pattern. The membranous staining displayed linear pattern, which made the interface between cells very clear (Figure 2).

Staining was typically uniform throughout the specimen. The cytoplasmic staining showed granular pattern. The membranous staining displayed linear pattern, which made the border between cells very clear.

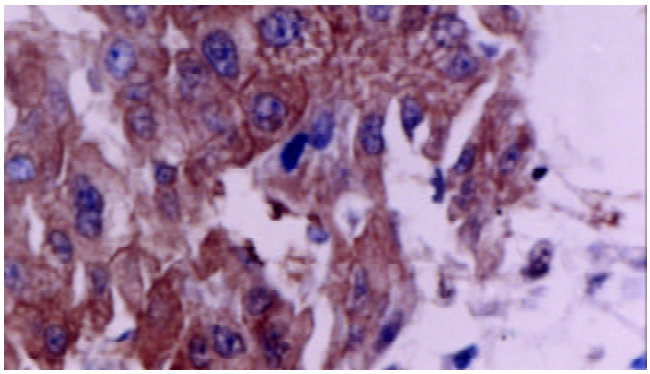

Figure 2 Hepatocellular carcinoma stained for HSP70 (×350).

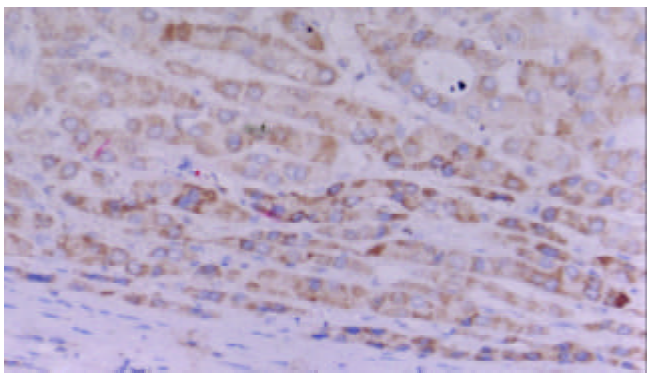

Figure 3 Hepatocellular carcinoma stained for TAP (×100).

TAP expression

Positive staining for TAP was present in 29 of 30 cases. The staining was located in the cytoplasm and the perinuclear area. It showed granular intracytoplasmic pattern accompanied by variable staining intensity. Faint or negative staining was observed within sinusoids (Figure 3).

It showed granular intracytoplasmic pattern accompanied by variable staining intensity. Hepatocytes beside the sinusoid were more intensely stained than cells in the central tissues.

DISCUSSION

In this study we examined the expressions of class I MHC, TAP, and HSP70 in 30 HCC samples by immunohistochemical methods. The results showed that the majority of HCC investigated naturally expressed TAP, which was different from other tumors. This is consistent with the results of several other groups. Kurokohchi *et al*[6] examined TAP mRNA and HLA antigen in seven HCC cell lines. They found that only one HCC cell line (HuH-7) had low expression of HLA-B and C and TAP mRNA. All the other lines expressed high levels of both TAP mRNA and HLA. They speculated posttranscriptional events or failure to transport and load peptides for MHC might allow HCC cells to escape from CTL. Whereas our results suggested HCC cells with the expression of TAP might be more susceptible to host immunity. Recently, Alimonti *et al*[7] reported that TAP expression provided a general method for improving the recognition of malignant cells. They transfected TAP gene into the TAP^- cell line and introduced it into tumor-burdened individuals. The result showed that TAP could improve tumor cell immunogenicity and host survival. This would be of a potential significance for the tumors with deficiency in components of antigen-processing molecules. However, Seliger *et al*[8,9] identified the structural alterations of TAP in the MHC class I antigen-processing pathway in melanoma after analyzing the sequence of TAP. The possibility of structural transformation of TAP in HCC cells could not be excluded and needs to be further studied.

As our understanding of the molecular aspects of the class I processing pathway has been improved, there is an increasing realization that expression of class I MHC antigen on cell surface is crucial for recognition by CTL. It is well established that many tumors escape T cell recognition by loss or down regulation of class I molecule expression on the surface of tumor cells. Previous reports described a correlation between HLA loss and TAP gene defects in some tumors[10]. So we also analyzed the expression of class I MHC on the surface of hepatocytes in HCC. Our investigation showed that most liver cancer cells in HCC tissues had strong class I MHC antigen expression. This is consistent with the results of several other groups[6,11]. The possible mechanism for the appearance of class I MHC antigen on hepatocytes remains controversial. One of the possibilities is that the expression of class I MHC antigen on HCC cells is related with viral infection. Sung *et al*[12] found that HCC patients were infected by HBV. Zhou *et al*[13] suggested cytokines such as γ-interferon released by T lymphocytes infiltrated in HCC tissues might be contributed to the expression of class I MHC molecules. The other possibility is that malignant transformation in HCC is characterized by expression of class I MHC molecules[11]. Although the underlying molecular mechanism is not well understood, the expression of class I MHC antigen on HCC cells may influence the behavior of tumor cells and has a significant effect on the reactivity of host immune system against HCC cells.

Earlier work suggested that HSP70 was shown to accumulate in the cytoplasm and the perinuclear area by cellular stress, such as non-lethal heat shock. In this study, we demonstrated

that HSP70 expressed not only in cytoplasm, but also on the surface of cells in HCC. Most members of the HSP families do not possess signal peptides. So it is still unclear how these proteins are transported to the cell membrane. Morimoto *et al*[14] postulated that some HSP might be transported to the cell surface via autoregulatory mechanism like in normal cells. Our results indicate that HSP70 may be transported to the cell surface after binding to MHC molecules. The main reason of this speculation is that class I MHC is found on the membrane of HCC cells. HSP70 is known to have strong protein-binding capacities. Therefore, it is reasonable to suggest that MHC class I may be the best candidate. It is interesting that cell-surface localization of HSP70 may make it possible to increase the immunogenicity of HCC cells. Many evidences have shown that HSPs expressing on affected cell types is recognized by the immune system[15]. Binder *et al*[16] recently identified HSP-chaperoned peptides introduced into cytosol were quite efficient as compared with free peptides. They even suggested that HSP70 was involved not only in the afferent end of this process by chaperoning partially or fully unfolded polypeptide chains, but also in chaperoning the resulting antigenic peptides to the TAP complex. These evidences indicate that HSP70 expressing on the surface of cells may be potentially promising target molecules for the immunotherapy of HCC.

On the whole, our data suggest that HCC cells express TAP, HSP70, and class I MHC. The results indicate that the mechanism of HCC cellular escape should be re-evaluated. Especially when designing immunotherapeutic strategies for HCC, it is very important to consider the potential problems associated with the ability of tumor cells to present target epitopes for immune recognition. Moreover, it needs to stress that tumor progression is dependent on multiple factors. Several scenarios have been proposed to be responsible for tumor immune-escape mechanisms, including production of suppressive cytokines by tumor cells, and expression of Fas ligand on tumor cells[17]. A recent study from Chai *et al*[18] suggested that T cell-expressed CD80 had a regulatory function and played a key role in the induction of T cell unresponsiveness by co-stimulation-deficient antigen presentation. So elucidation of the immune deficiency against cancer progression has been a difficult task because no single mechanism can explain the complicated cancer-host immune interactions. It is important to determine a more appropriate approach of combining different strategies to control the outgrowth of HCC cells.

Abstract

AIM: To summarize the experience of the diagnosis and treatment of hepatic angiomyolipoma (HAML).

METHODS: The clinical, imaging and pathological features, and treatment strategies of 26 patients with HAML treated at the authors' institute between October 1998 and January 2003 were retrospectively analyzed. All the patients received liver resection and were followed up till the study. Immunohistochemical assays were performed with a panel of antibodies.

RESULTS: There was an obvious female predominance (21:5), and most of the patients (18/26) had no symptoms. Heterogeneous high echo was found in ultrasonography and punctiform or filiform vascular distribution pattern was found in color Doppler-sonography in most of the lesions (21/26). All of the 5 lesions further enhanced with Levovist showed early and prolonged enhancement. At contrast-enhanced spiral CT, the soft-tissue components of 24 lesions were markedly enhanced in the arterial phase and 18 lesions remained enhanced in the portal venous phase. MRI was performed in 9 patients, and showed hypointensity or hyperintensity on T1-weighted images and heterogeneous hyperintensity on T2-weighted images. Histopathologically, all lesions were composed of adipose tissues, smooth muscle and blood vessels with different proportions. Most lesions showed positive immunohistochemical staining for HMB45 (26/26), A103 (24/26) and SMA (24/26). All of the 26 patients showed a benign course with no sign of recurrence.

CONCLUSION: Preoperative radiological diagnosis of HAML is possible. The demonstration of intratumoral fat and central vessels is helpful in the diagnosis. HMB45, A103 and SMA are promising markers for pathologic diagnosis of HAML, and surgical resection is effective for the treatment of HAML.

INTRODUCTION

Hepatic angiomyolipoma (HAML) is a rare benign mesenchymal neoplasm of the liver. Since its first description by Ishak in 1976[1], not more than 200 cases have been reported in the English literatures[2-7]. However, with recent progress in imaging diagnostic techniques, the reported cases of HAML are increasing in number, and the significance of accurate diagnosis is becoming more important clinically. The purpose of this study was to investigate the clinical, imaging and pathological features of HAML and to summarize our experience in the diagnosis and treatment of this disease.

MATERIALS AND METHODS

Patients and clinical data

Twenty-six patients with HAML were surgically treated in Liver Cancer Institute of Fudan University from October 1998 to January 2003. There was a marked female predominance (21/26) and the mean age was 44.3 with a range of 31 to 64 years. Most of the patients (18/26) had no symptoms and were detected incidentally by medical check-up. Seven of 26 patients had symptoms caused by tumor oppression and one patient had slight fever as a chief complaint. The average tumor size at detection was 6.1 cm ranging from 1.5 to 15 cm. None of them was found complicated with a diagnosis of tuberous sclerosis and renal AML. Concomitant hepatic hemangioma was found in one patient. None of them had the history of hepatitis virus infection. Serum alpha-fetoprotein (AFP) levels were all within normal limits.

Imaging examinations

All of the patients underwent ultrasonography, color Doppler-sonography and computer tomography (CT) examinations. Nine patients also received magnetic resonance imaging (MRI) examination.

Treatment and follow-up

Limited partial liver resections were performed in 19 patients, left lateral lobectomy in 4, left hemihepatectomy in 2, and right hemihepatectomy in 1. All the patients have been followed up till the study.

Pathological and immunochemical assays

Routine histopathological examination with hematoxylin and eosin staining was performed. Immunohistochemical studies were performed by the EnVision™ method using a panel of antibodies (HMB45, A103, smoothmuscle actin, S100, Vimentin and CK8) in all of the tumor tissues.

RESULTS

Imaging features

Most lesions (21/26) showed heterogeneous high echo in ultrasonography, and punctiform or filiform vascular distribution pattern in color Doppler-sonography. Five lesions were further enhanced with Levovist, and all of them were found to have early and prolonged enhancement.

In contrast-enhanced spiral CT examination, the soft-tissue components of 24 lesions were markedly enhanced in the arterial phase, and 18 lesions remained enhanced in the portal venous phase.

MRI was performed in 9 patients, hypointensity or hyperintensity was found on T1-weighted images and heterogeneous hyperintensity on T2-weighted images.

Histopathological and immunochemical characteristics

The tumors were well circumscribed but no obvious capsule could be found. The non-tumorous liver parenchyma was normal, and no cirrhosis was found. All tumors were composed of adipose tissues, smooth muscle and blood vessels in different proportions. In immunohistochemical studies, most tumors were positive for HMB45 (26/26), A103 (24/26), SMA (24/26), S100 (20/26) and Vimentin (16/26), but negative for CK8 (22/26).

Treatment and prognosis

All of the 26 patients received hepatectomy. Six patients were followed-up for more than one year and finally decided to receive operation because of the enlargement of the lesions. All the patients have been followed up since their surgical resection. No recurrence was found in any patient during the follow-up period.

DISCUSSION

Angiomyolipoma, which occurs relatively frequent in kidney, is a rare benign mesenchymal neoplasm of the liver. The tumor size of HAML at the first diagnosis is variable, ranging from 0.1 cm to ⩾36 cm. Clinically, most of the patients have no symptoms and are detected incidentally by medical check-ups. Patients with large tumors usually have some symptoms caused by tumor compression. The diagnosis of HAML before operation mainly depends on imaging examination.

According to our experience, typical performance of HAML is a smoothly contoured heterogeneous high echo lesion, with a well-defined border separating it from adjacent normal hepatic tissues by ultrasonography and punctiform or filiform vascular distribution pattern by color Doppler-sonography. In further enhanced imaging with Levovist, the tumor showed early and prolonged enhancement. The lesions appeared as hypodense, and adipose dense could be found in pre-contrast CT scans. In the arterial phase, the soft-tissue components of the lesions were markedly enhanced and central vessels could be found. In the portal venous phase, the lesions remained in enhancement[8]. As reported, the adipose fraction of HAML varied from 5 % to 90 %, so adipose signals could be found on MRI in most lesions. Sakamoto *et al*.[9] described MRI studies showing extensive enhancement on gadolinium-enhanced images. In addition, fat could be seen with great sensitivity on T1-weighted images as high-signal intensity. However, HAML showed various patterns of imaging features, because the relative proportions of vessels, muscle and fat varied widely from tumor to tumor. So, although diagnosis may be suggested by imaging methods, histological confirmation remains mandatory.

Histopathologically, in our study, most tumors were well-circumscribed, but not encapsulated. The lesions were composed of adipose tissue, smooth muscle and blood vessels in different proportions. The tissue components in the tumor were highly variable from case to case, and even between different areas of the same mass. According to the line of differentiation and predominance of tissue components, Tsui *et al*.[6] subcategorized the tumors into mixed, lipomatous (⩾ 70 % fat), myomatous (⩽ 10 % fat), and angiomatous types. We found that the mixed type was the most common category which comprised sheets of epithelioid muscle cells admixed with islands of adipocytes, abnormal vessels, and frequently, hematopoietic cells. Some authors advocated to diagnose HAML by fine-needle aspiration (FNA)[10], for the presence of adipocytes was a clue to the diagnosis. However, adipose tissue might be a minute fraction of HAML, in which FNA diagnosis may be difficult. So we think that immunohistochemical examination may be the only authoritative method to diagnose HAML. According to our results, all the 26 tumors were positive for HMB45, the staining was intense, granular, and concentrated in tumor cell perinuclear cytoplasm. For A103, 24 tumors showed strongly and diffusely granular cytoplasmic staining in the majority of myoid cells, the staining in the other two was only focal. Smooth muscle actin (SMA) staining was weak to moderate in epithelioid cells and strong in spindle cells in 24 tumors. So HMB45, A103 and SMA are promising markers in pathologic diagnosis of HAML.

Exclusion of hepatocellular carcinoma (HCC) is the most important issue in the diagnosis of HAML, because both kinds of the lesions show similar imaging characteristics, including rich blood flow detected in Doppler-sonography, early enhancement in CT contrast scan, etc. Most of the patients with HAML had no histories of hepatitis virus infection or negative for hepatitis marker, and had no liver cirrhosis, and AFP level was normal, which might be helpful in the differential diagnosis. In CT contrast scan, there are also differences in the peak time and duration of enhancement between HAML and HCC. Ahmadi *et al*.[11] reported that HAML showed early and prolonged enhancement (>4 min) with delayed peak enhancement at 40-80 seconds, as opposed to HCC which had peak enhancement at 10 seconds and absent or minimally delayed enhancement. Further more, differentiation from HCC with fatty metamorphosis can also be made based on the angiomyolipomas prolonged tumor enhancement (>6 min) relative to HCC. Fat suppression MRI was also reported to be successful in distinguishing HAML from HCC[12].

HAML is a benign lesion and often grows slowly without any clinical symptom, so conservative treatment with close follow-up is recommended after diagnosis. For the rarity of the cases most of which are diagnosed by pathology after operation, there has been no report about culture doubling time or growth velocity of HAML yet. In this series, one patient was followed up for five years before operation, the tumor increased from 4 cm to 10 cm in size. Another one was followed up for thirteen years before operation, the size of tumor increased from 1.5 cm to 5 cm.

Spontaneous rupture, later recurrence and vascular invasion of HAML have been reported[13-15]. So surgery may be recommended for patients with symptoms, for patients in whom diagnostic imaging can not exclude malignancy, and for patients in whom the tumor enlarges obviously in short time or shows extrahepatic growth and has a risk of spontaneous rupture. All our cases received hepatectomy and have been followed up till the study for a period between 1 month and 52 months, no mortality and serious morbidity were found in these patients. Follow-up information of the 26 cases showed a benign course with no signs of recurrences. So surgical resection is safe and effective for the treatment of HAML.

Abstract

AIM: To study the expression and significance of telomerase activity and oxidative stress in hepatocellular carcinoma (HCC) with cirrhosis.

METHODS: In this study, TRAP-ELISA assay was used to determine telomerase activity in 21 cases of HCC as well as in 23 cases of hepatic cirrhosis. Malondialdehyde (MDA), glutathione S-transferase (GST) and total anti-oxidative capacity (T-AOC) were also examined in the same samples with human MDA, GST and T-AOC kits.

RESULTS: Eighteen of 21 cases of HCC were found to have increased telomerase activity, whereas only three of the 23 non-cancerous cirrhotic samples were found to have weak telomerase activity, and the difference was significant ($P<0.001$). No significant difference in telomerase activity was detected according to different tumor size, tumor stage, histological grade, HBsAg, contents of albumin, bilirubin, ALT, AFP, r-GT and platelet. There were significant differences between HCC and cirrhosis in the expression of MDA, GST and T-AOC respectively. Telomerase activity correlated positively with the content of MDA ($P<0.05$).

CONCLUSION: Telomerase activation is the early event of carcinogenesis, which is not correlated with clinicopathological factors of HCC. The dysfunction of the anti-oxidative system is closely correlated with the progression from cirrhosis to hepatocellular carcinoma. Oxidative stress may contribute partly to telomerase activation.

INTRODUCTION

Telomeres correspond to the ends of eukaryotic chromosomes and are specialized structures containing unique (TTAGGG)n repeats[1]. Telomeres protect the chromosomes from DNA degradation, end to end fusions, rearrangements, and chromosome loss[2]. Because cellular DNA polymerases cannot replicate the 5' end of the linear DNA molecule, the number of telomere repeats decreases (by 50-200 nucleotides/cell division) during aging of normal somatic cells. Shortening of telomeres may control the proliferative capacity of normal cells[3]. Telomerase, a ribonucleicacid-protein complex, adds hexameric repeats of 5'-TTAGGG-3' to the end of telomeres to compensate for the progressive loss[4]. Although normal somatic cells do not express telomerase, immortalized cells such as tumor cells express this enzyme[5]. More recently, HeLa cells transfected with an antisense human telomerase were found to lose telomeric DNA and to die after 23 to 26 doublings[6]. Pertersen *et al*. found that the rate of shortening of telomere restriction fragments in human fibroblasts could be accelerated significantly by oxidative stress[7]. Importantly, after treatment of cells with short single stranded telomeric G-rich DNA fragments, glioblastoma cells recovered from the arrest and showed enhanced telomerase activity and elongated telomeres[8].

However, the mechanisms of activation and regulation of telomerase have not been establishednd. Cell line data indicate that a telomere length-dependent mechanism is the major pathway. On the other hand, normal lymphocytes up-regulate telomerase activity upon antigen and mitogen stimulation *in vitro* and *in vivo*. This indicates that telomere length-dependent mechanisms may be important or specific to different cell types for regulation of telomerase activation[9]. Only a few studies have specifically examined the relationship between telomerase activity in tumors and the status of oxidative stress. Our data implied that genetic defects in HCC facilitated the reactivation of telomerase activity, a process that might be associated with the increased expression of oxidative stress.

MATERIALS AND METHODS

Sample collection and processing

All 21 HCC specimens were sampled from patients who had undergone curative hepatectomy. Patients who had received radiotherapy or chemotherapy before operation were excluded. Liver cirrhosis tissues were obtained from those who had received hepatic biopsy in the operation for hypersplenia. Informed consent was obtained from all patients for subsequent use of their resected tissues. These specimens were immediately dissected into small pieces under aseptic condition within half an hour after removed, snap frozen in liquid nitrogen and stored at -80 ℃ until extracts for telomerase activity analysis and determination of oxidative stress.

Telomerase assay

Frozen tissue samples (100 μg) were homogenized in 500 μL of freshly made ice-cold lysis buffer. After 30 min incubation on ice, the lysate was centrifuged for 20 min at 16 000 g, and the supernatant was transferred to fresh tubes and used as tissue extracts for the telomerase assay. The protein concentrations were determined. Telomerase activity was assayed by the TRAP-ELISA kit, a polymerase chain reaction (PCR)-based on an improved version of the original method described by Kim *et al*[10]. In brief, aliquots of tissue extract containing 40 μg protein were added to 50 μL reaction mixtures containing

0.1 μg substrate oligonucleotide (TS) primer, TSK (internal control) template. The reaction mixtures were incubated at 25 ℃ for 20 min and then amplified for 33 cycles of PCR at 94 ℃ for 30 s, at 50 ℃ for 30 s, and at 72 ℃ for 90 s, then preserved at 4 ℃ for ELISA reaction process. 5 μg PCR product was taken for ELISA reaction. The value at A450 was read within 30 min. Telomerase activity equaled A450 for experimental well minus A450 for control well. The strength of telomerase activity was defined as follows: ++, >0.4; +, >0.2; -, <0.2.

MDA, GST and T-AOC determination

Frozen tissue samples (100 mg) were homogenized in 1.0 mL, the homogenized samples were centrifuged for 15 min at 3 000 r/min, and the supernatant was transferred to fresh tubes. After the protein concentrations were determined, MDA, GST and T-AOC were assayed with human MDA, GST and T-AOC kit (Jiancheng Biological Technical Institute, Nanjing, China).

Statistics analysis

Contingency table methods were used to analyze the univariate association between telomerase activity and clinicopathological data (age, sex, tumor grade, tumor size, and liver status). Significance was confirmed by Fisher's exact test. The association between telomerase activity and oxidative stress was investigated by Pearson correlation analysis test. All calculations were performed using the SPSS version 10.0 statistical software package, and the results were considered statistically significant at $P<0.05$.

RESULTS

Telomerase activity in HCC and hepatic cirrhosis

Telomerase positive cells were used as a positive control for assessing telomerase activity in clinical specimens. We measured telomerase activity in surgically resected specimens from 21 cases of HCC and 23 cases of liver cirrhotic tissue. Telomerase activity was detected in 18 of the 21 HCC specimens (85.7 %), but it was detected only in 3 of 23 samples of liver cirrhosis (13.4 %). There was a significant difference in telomerase activity between HCC and hepatic cirrhosis ($P<0.001$). There was no significant difference in telomerase activity in regard to different tumor size, tumor stage, histological grade, HBsAg, contents of albumin, bilirubin, ALT, AFP, r-GT and platelet (Table 1).

Table 1 Relationship between telomerase activity and clinicopathologic factors in HCC

	Telomerase activity		
	High	Low or loss	*P* value
Tumor size (cm)	7.7±3.5	7.1±3.6	0.664
Tumor grade (high / low)	9 / 4	4 / 4	0.245
Tumor stage (early / advanced)	6 / 7	3 / 5	0.327
ALT (normal / abnormal)	9 / 2	6 / 4	0.212
Bilirubin (normal / elevated)	9 / 2	9 / 1	0.414
Platelet (normal / decreased)	9 / 2	7 / 3	0.324
HbsAg (positive / negetive)	6 / 5	7 / 3	0.272
AFP (>400U / <400U)	7 / 5	5 / 5	0.309
Albumin (g / L)	39.2±5.6	39.3±4.2	0.946
Globulin (g / L)	28.6±5.3	26.8±6.5	0.423
γ-GT(U)	115.2±98.7	108.9±69.5	0.814

Expression of MDA, GST and T-AOC in HCC and hepatic cirrhosis

The content of MDA was 84.76±26.98 nM/ml in HCC, while it was 49.49±23.03 nM/ml in hepatic cirrhosis, and the difference was significant between them ($P<0.001$). Nevertheless, the contents of GST and T-AOC were lower in HCC than those in hepatic cirrhosis ($P<0.001$).

Table 2 Expression of MDA, GST and T-AOC ($\bar{x}\pm s$)

	HCC	Cirrhosis	*P* value
MDA (nM / ml)	84.76±26.98	49.49±23.03	<0.001
GST (U / mg)	8.18±5.59	18.70±5.20	<0.001
T-AOC (U / mg)	0.257±0.241	0.689±0.302	<0.001

Telomerase activity and content of MDA

The relationship between telomerase activity and oxidative stress was investigated by Pearson correlation analysis. Tumor specimes with a higher level of MDA expressed increased telomerase activity ($r=0.496$, $P<0.05$).

DISCUSSION

HCC is the most common solid tumor worldwide, being responsible for more than 1 million deaths annually, especially in Eastern Asia and South Africa[11], which ranks eighth in frequency among cancers in the world[12]. It is one of the few human cancers in which an underlying etiology can be identified in most cases, and has a background of chronic inflammatory liver disease caused by viral infection that induces cirrhosis[13]. However, it is not clear how these disorder results in HCC. The reactivation of telomerase activity may play a significant role in hepatocarcinogenesis.

Telomerase is a ribonucleoprotein complex[14] that is thought to add telomeric repeats onto the ends of chromosomes during the replicative phase of the cell cycle. Telomeres have classically been regarded as a simple linear structure, possibly capped by specific proteins. However, this simple structural view was challenged. Recent data have shown that the structure of human telomeres might be more complicated than originally thought[15]. Three different mechanisms were currently thought to contribute to telomere shortening: the so-called end replication problem, the C-strand degradation model and single-strand damage[16]. Both the end replication problem and the C-strand degradation model of telomere shortening do not take into account the possibility that the shortening rate of telomeres depends on external influences, especially oxidative stress-dependent DNA damage. von Zglonicki *et al* demonstrated that the telomere shortening rate could be either accelerated or decelerated by a modification of the amount of oxidative stress[17].

Recently, a highly sensitive PCR based TRAP assay for measuring telomerase activity that also includes an improved method of detergent lysis has been developed[10]. This assay allows more uniform extraction of telomerase from a small number of cells than conventional techniques, in which telomerase first synthesizes extension products that then serve as templates for PCR amplification. The simplicity and increased sensitivity of this assay have resulted in a dramatic increase in the investigation of telomerase expression. In this study, telomerase activity was positive in 18 of 21 HCC specimens (85.7 %), which suggested that telomerase activation was a universal event in human hepatocellular carcinoma. However, undetectable telomerase activity has been reported by others in about 10 % of tumors samples[18,19]. Some immortal cell lines without detectable telomerase activity have been described that were characterized by long and heterogenous telomeres[20,21]. These observations might indicate the presence of a telomerase-independent mechanism for telomere length maintenance in these tumors.

It is well documented that telomerase activity is detectable in the majority of cancers but rarely in normal somatic tissue. Some studies have demonstrated that some types of somatic cells express low levels of telomerase activity[22-24]. In particular physiologically regenerating somatic cells, such as hematopoietic cells, epithelial cells of skin or intestine, and endometrial cells, have been shown low levels of telomerase activity. In this study, low telomerase activity was detected in 3 of 23 cirrhotic specimens. One possible explanation for this finding was that these cirrhotic tissue samples may also contained probable cancer cell, infiltration of lymphoid cells, or dysplasia cells. Finally, demographic and clinical information of patients, such as tumor size, tumor stage, histological grade, HBsAg, albumin, bilirubin, ALT, AFP, r-GT and platelet were not correlated with the telomerase activity.

Many lines of evidence indicate that telomerase is reversibly regulated[25]. Resting lymphocytes express little telomerase activity, but stimulation of specific antigen receptors on the cell plasma membrane markedly increases telomerase activity[26-29]. High-level sun light exposure of normal human skins results in an increased incidence of telomerase activation[30]. Human hematopoietic cells with γ-rays[31], or human carcinoma cell lines with X-rays[32] induce the activation of telomerase. Activated telomerase in cancer cells is repressed when the cells leaves the cell cycle and become quiescent[33-37]. Nevertheless, the mechanisms of telomerase regulation, such as its suppression in normal human somatic cells and activation in neoplastic cells, are far from established.

Telomeres are believed to protect the ends of chromosomes against exonuclease and ligases, to prevent the activation of DNA-damage checkpoints, and to counteract loss of terminal DNA-segments that occurs when linear DNA is replicated[2,38,39]. Oikawa *et al* demonstrated that oxidative stress induced DNA damage at the 5' site of 5' -GGG-3' in the telomere sequence, and the telomeric G triplet was especially sensitive to cleavage by oxidative damage[40,41]. Moreover, it was shown that oxidative stress increased the frequency of S1 nuclease-sensitive sites, especially in telomeres[42,43]. However, it was unknown whether oxidative stress was associated with the telomerase activity in human tissue specimens. In this study, the expression of malondialdehyde, glutathione S-transferase and total anti-oxidative capacity were examined in the same samples. There were higher levels of the expression of glutathione S-transferase and total anti-oxidative capacity in hepatic cirrhosis specimens, while enhanced expression of malondialdehyde was found in HCC specimens. The difference between HCC and hepatic cirrhosis was significant (P<0.05). These findings suggested that the dysfunction of the anti-oxidative system was closely correlated with the progression from hepatic cirrhosis to hepatocellular carcinoma. Other studies also showed that HCC patients with higher anti-oxidative capacity levels survived longer after hepatectomy[44].

Henle *et al*. found that the telomeric G triplet was especially sensitive to cleavage by oxidative damage. In MRC-5 fibroblasts and U87 glioblastoma cells, oxidative stress-mediated production of single-strand damage in telomeres was concomitant to cell cycle arrest. This response can be modeled by treatment of cells with short single stranded telomeric G-rich DNA fragments. Recovery from it is accompanied by up-regulation of telomerase activity and elongation of telomeres[45]. The gene transcription of TERT is an essential rate-limiting step in telomerase activation and may be subjected to multiple levels of control and regulated by different factors in different cellular contexts[46]. In the present study we found that telomerase activity correlated positively with the content of MDA (P<0.05). One possible explanation for this observation was that telomere shortening might be accelerated by oxidative stress when telomere reached critical length, which caused the gene transcription of TERT, and telomerase was activated. Buchkovich *et al*[47] first demonstrated that in primary human leukocytes stimulated with phytohemagglutinin, telomerase activity was increased by more than 10-fold as naturally quiescent cells entered the cell cycle. In an animal model, treatment with an antagonist of growth hormone-releasing hormone dramatically decreased telomerase activity in xenografted U-87-MG human glioblastoma cells[46]. Their research was the first demonstration of a signaling pathway in normal cells that regulated telomerase, and paved the way for experimental analysis of "upstream" regulators. The possibility of a relationship between upstream regulators and oxidative stress is an important issue for future experimental studies on control of telomerase activity.

Although tumor cells have a much shorter telomere length, telomeres shorten with rates between 15 and 76 bp/PD in different culture. Too much time[48] is needed to reach the critical length of telomeres in tumor cells. However, oxidative stress may increase the rate of telomere shortening by the site-specific DNA damage in the telomere sequence. Thus, combination treatment[7] of oxidative stress and telomerase inhibitor in cancer cells will accelerate greatly the telomere shortening. Telomeres might shorten quickly to the point which is no longer able to divide.

Abstract

AIM: To investigate the association of nuclear morphometry and DNA content with resectability of pancreatic cancer.

METHODS: A total of 36 patients with pancreatic adenocarcinoma were divided into resectable group and unresectable group. The nuclear morphometry and DNA contents of tumor cells were analyzed by IBAS autoimagine analyzer from paraffin-embedded materials. Localization size, histological type and grade, and clinical stage of the tumor were evaluated. Factors influencing resectability of pancreatic cancer were investigated using stepwise regression analysis.

RESULTS: Statistical significance was found in nuclear DNA content (integrated optical density, IOD) of tumor cells (1.64±0.41 *vs* 2.96±0.55), DNA ploidy, ages (46.5±5.3 years *vs* 58.6±0.7 years) and tumor volumes (298.1±101.5 cm^3 *vs* 634.7±512.5 cm^3) in both groups ($P<0.05$), and no difference was found in the nuclear morphometry ($P>0.05$). The rates of diploid/tetraploid and aneuploid were 66.7 % and 33.3 % in resectable group respectively, and 38.9 % and 62.1 % in unresectable group, respectively ($P<0.05$). IOD (X_{12}), ploidy status (X_{13}) and clinical stage (X_3) were radical resectable indicators with statistical significance. The regression equation for resectability was $Y=-9.2053+3.5428X_{12}+2.5390X_{13}-2.3001X_3$ ($RR=0.8780$, $P<0.01$).

CONCLUSION: There is a high correlation between resectability of pancreatic cancers and their DNA contents, DNA ploidy status and clinical stage.

INTRODUCTION

Pancreatic cancer is a highly malignant tumor, and has the most dismal prognosis among abdominal malignancies[1-6]. The overall five-year survival for all the patients is only 0.4 %. Patients who undergo radical resection have five-year survival rates between 10-24 %[1,3,4]. The traditional approach to patients has been surgical procedure, but approximately 10 % to 20 % of cancers of the pancreatic head, body and tail can be resected for potential cure[7-9]. The reason is the topographical peculiarities of the pancreas and the biological aggressiveness are involved. Recent results indicated that there was a relation between DNA ploidy, DNA content of tumor cell nuclei and the biological behaviour of tumors[10-15]. The present study was to investigate the effect of the clinical characteristics, nuclear morphometry and DNA contents of pancreatic cancer on its resectability.

MATERIALS AND METHODS

Patients and group

A total of 36 patients with pancreatic carcinoma were enrolled in this study. There were 20 men and 16 women with a mean age of 52.7±8.4 years (range 32-72 years). They were followed up from 1999 to December 2002. No patient had received preoperative chemotherapy and radiotherapy. The patients were divided into: resectable group and unresectable group (18 patients per group). In resectable group, 15 patients underwent radical resection with Whipple' s procedure, 2 splenopancreatectomy and 1 total pancreatectomy. In unresectable group, palliative bypass of the biliary tree and/or the duodenum was performed in 14 patients and biopsy in 4 patients. Criteria for unresectability included definite liver metastases, tumor spread to the whole pancreas proved by needle biopsy on operation, obstruction or invasion of the portal or mesenteric veins, and/or tumor encasement of the celiac or superior mesenteric arteries. Localization size, histological type, histological grade, and clinical stage of the tumor were evaluated for each patient.

Preparation of sections

From paraffin blocks, areas with high contents of neoplastic parenchymal cells were selected. Sections about 50 to 100 μm thick were cut from these parts and deparaffinized. The two 5 μm slides were preparated, one was stained with hematoxylin and eosin for confirmation of the presence of pancreatic cancer cells in the 50 μm sections, the other was stained with Feulgen method for DNA measurement.

Feulgen reaction

The cell nuclei were stained by the classic Feulgen reaction. The sections were deparaffinized and washed with distilled water. Cells were hydrolyzed (1 N HCl at 25 ℃ for 2-3 minutes, 1N HCl at 60 ℃ for 10-12 minutes, 1 N HCl at 25 ℃ for 2-3 minutes) and washed with distilled water again, then stained with Schiff ' s reagents for 80 minutes at room temperature, treated with freshly prepared sulfurous acid rinse 3 times (3-6 minutes), and washed in running tap water for 10 minutes. After dehydration, sections were coverslipped for DNA analysis.

Image analysis

Morphological characteristics and nuclear DNA content of tumor cells were measured by IBAS image analyzer (Kontron Company, Germany). The light was a halogen lamp (12V, 100W). Measurements were made using an interferential filter centered at 546 nm. Lymphocytes admixed with the tumor cells on the sections were used as internal control cells in the

procedure. At least 100 structurally identified neoplastic cell nuclei, selected at random on three different areas, were analyzed in each specimen. The structural identification was based on conventional cytodiagnostic criteria such as nuclear shape and chromatin texture. Morphological characteristics [nuclear areas, perimeter (μm), length of minor axis (μm), length of major axis (μm), form factor (FF)] and nuclear DNA content of tumor cells (integrated optical density, IOD) were analyzed. FF was calculated using the following equation: $FF= 4\pi A/P^2$. Where A is nuclear areas (μm^2), and *P* is nuclear perimeter (μm).

DNA ploidy

The same investigator made all measurements with no previous knowledge of coded clinical data. The DNA histograms were divided into three groups[16]. Type A with one stemline within the diploid region (1.5-2.5 C) and a G_2 fraction in the tetraploid region, type B with one stemline in the tetraploid region (3.5-4.5 C) and a G_2 fraction in the octoploid region, independent of the presence of a diploid stemlione, and type C with a stemline outside the diploid/ tetraploid region or a mosaic pattern.

Statistical analysis

All the data were input into a microcomputer, and statistical evaluation was carried out using the SPSS 10.0 statistical package. Differences between the mean values were analyzed for significance using the Student' s *t* test. Fisher' s exact probability test (two tailed) was used to assess the constituent ratio between two groups because of N of valid cases <40. To establish a relation between independent variables (X_1-X_{13}, Table 1) and dependent variables (Y, resectabiliry), stepwise regression analysis was used. The difference was considered significant when *P* value was less than 0.05.

RESULTS

Histological examination

The 36 cases consisted of 33 ductal adenocarcinoma, 1 acinus cell carcinoma, 1 mucinous carcinoma, and 1 adenosquamous carcinoma.

Nuclear morphometry and DNA contents

Nuclear morphometry and DNA contents are shown in Table 1. Statistical significance was found in IOD, ages and tumor volumes between resectable group and unsectable group ($P<0.05$). No difference was found in the nuclear morphometry of tumor cells when resectable group with unsectable group were compared ($P>0.05$, Table 1).

Nuclear DNA content of tumor cells (IOD) versus *clinical pathologic parametesr*

Relationships between IOD and clinical pathologic characteristics are presented in Table 1. Except for clinical stage (correlation coefficient $r=0.683$, $P<0.05$), no statistically significant relationship was found between IOD and age ($r=0.201$, $P>0.05$), tumor cell sources ($r=0.209$), histological grade ($r=0.167$), site ($r=0.235$), size ($r=0.312$), nuclear areas ($r=0.184$), perimeter ($r=0.085$), minor axis ($r=0.202$), major axis ($r=0.206$) and form factor ($r=0.149$).

Correlation analysis of resectability

Relationships between resectability and clinical pathologic characteristics were analyzed using Pearson correlation analysis. Correlation coefficients "*r*" are listed in Table 1. Age, clinical stage, site, size, IOD and ploidy status were covariates independently associated with resectability of pancreatic cancer.

Table 1 Relationship between DNA contents, clinical characteristics and resectability

Variable Factor		Resectable group	Unresectable group	Correlation coefficient (*r*)
X_1	Age (years)	46.5±5.3	58.6±0.7[a]	0.536[b]
X_2	Tumor cells (*n*)			0.387

Stepwise regression analysis of resectability

Resectability predictors were evaluated in a stepwise regression model. In this model, stepwise regression analysis demonstrated that IOD (X_{12}), ploidy status (X_{13}) and clinical stage (X_3) were statistically significant resectable indicators after backward elimination ($F=2.80$). The regression equation for resectability was $Y=-9.2053+3.5428X_{12}+2.5390X_{13}-2.3001X_3$ ($RR=0.8780$, $P<0.01$). IOD remained to be the most important predictor, ploidy status was th second important one, followed by clinical stage according to variable *F* values.

DISCUSSION

The prognosis of pancreatic cancer though remarkable diagnosis and therapeutic advances, have led many surgeons to question whether patients with pancreatic cancer should be submitted to radical surgery[17-20]. Nevertheless, the only chance for longterm survival and cure is undoubtedly related to the feasibility of radical surgery. Therefore, many surgeons have investigated the resectability of pancreatic cancer. Although the biologic behavior and location of the tumor are the most common predictors reliable factors that may predict resectability before laparotomy are waiting to be found[21-26].

DNA aneuploidy is one of the markers of malignant tumour cells. Aneuploidy DNA pattern may be related to the development of distant organ metastases, invasion and prognosis[27-29]. Weger *et al*[16] investigated the relationship between DNA ploidy status and resectability of pancreatic cancer, in which 77 cases were studied by automatic DNA image cytometry, and the authors found that the radical resectable rates of diploid, tetraploid and aneuploid tumors were 87.5 %, 48.6 % and 25.9 % respectively. Joensuu *et al* found that only 3 of 15 resected pancreatic cancers had

aneuploid DNA content, whereas 35 of 47 nonresected pancreatic cancers had aneuploid, and the patients with diploid tumors lived longer than patients with aneupoid cancers. These findings suggested that the biological behavior of tumor could influence life span and resectability[30], which was in agreement with our study. Nuclear morphometry (nuclear area, perimeter, length of minor axis, length of major axis and form factor) was not significant between resectable group and unresectable group (P>0.05), but the tumor cellular DNA contents and ploidies in resectable group were different from those in unresectable group (P<0.05). It is suggested that there may be some difference between both groups at molecular levels, despite no difference was found in nuclear morphometry. Table 1 shows that the rates of diploid/tetraploid and aneuploid were 66.7 % and 33.3 % in resectable group, and 38.9 % and 62.1 % in unresectable group, respectively (P<0.05). The resectable rate of aneuploid tumor was lower than that of diploid/tetraploid. Compared with diploid cells, metabolism of the aneuploid cells was significantly accelerated, and the tumor cells underwent more rapid differentiation and proliferation, and had higher levels of DNA synthesis, accompanied by high DNA contents and DNA ploidy levels. According to our findings, there was a high correction between resectability of tumors and their quantitative DNA contents, DNA ploidy status. That is to say, radical or palliative resection of tumors is principally determined by DNA contents and ploidy status of tumor nuclei. Tumor tissue could be easily obtained in most cases by ultrasound guided percutaneous fine needle aspiration biopsy before operation[31]. Therefore, DNA image analysis for aspirated cellular materials may provide important preoperative information, and may help surgeons plan for radical or palliative procedure. We are convinced that the clinical application of preoperative imaging techniques and DNA measurements as a guide to select patients for surgical resection will become mature in the near future.

Abstract

AIM: To investigate the early protective effect of ischemic preconditioning on small intestinal graft in rats.

METHODS: SD rats were randomly divided into the following groups: sham operation group (S group, *n*=6), small bowel transplantation group (SBT group, *n*=12), ischemic preconditioning plus small bowel transplantation group (ISBT group, *n*=12). Heterotopic SBT was performed with a technique modified from that described by Monchik *et al*.When the graft was revascularized successfully and reperfused for 1 h, samples were obtained from the different groups. Laminin was analyzed with immunohistochemical staining. Quantitative analysis of laminin positive signals was performed using image acquiring analysis system. Apoptotic epithelia of small intestinal graft were detected by the TdT-mediated dUTP nick end labeling method. The morphological change of epithelial basement membrane was observed by transmission electron microscopy.

RESULTS: The mean optical density value of laminin positive signals was 39.52±2.60, 13.53±0.44, 25.40±1.79, respectively, in S, SBT and ISBT groups. The average optical density value of laminin positive products in SBT group was sharply lower than that in S group ($P<0.05$). However, the mean optical density value of laminin positive products in ISBT group was significantly higher than that in SBT group ($P<0.05$). The apoptotic index (AI) in S, SBT and ISBT group was 2.2±0.83,30.8±3.2, 13.2±2.86, respectively. The AI in SBT group was significantly higher than that in S group ($P<0.05$), and AI in ISBT group was sharply lower than that in SBT group ($P<0.05$). On transmission electron microscopy, the epithelial basement membrane in S group stayed normal, but in SBT group it became disrupted and collapsed, even disappeared. The lesion of epithelial basement membrane in ISBT group was slighter compared with that in SBT group.

CONCLUSION: Ischemic preconditioning has an early protective effect on epithelial cells and extracellur matrix of small intestinal graft. Inhibition of epithelial cell apoptosis may be one of the mechanisms of ischemic preconditioning.

INTRODUCTION

Small bowel transplantation (SBT) has been advocated as the preferred therapy for patients with irreversible intestinal failures such as short bowel syndrome[1-6]. In recent years, although potent immunosuppressive agents have been used, rejection rate of small intestinal grafts still amounts to 50 %[7]. Primary graft rejection and reperfusion damage involved in loss of small intestine function after transplantation are still the major obstacle to SBT[8-10]. Postischemic reperfusion damage, a nonspecific injury, may enhance graft immunogenicity and is likely to play an important role in the development of early specific and late rejection-related events, and threatens graft function and graft survival[11]. Therefore, it has important clinical significance for SBT if reperfusion injury of the graft could be ameliorated or prevented.

Studies have indicated that ischemic preconditioning can alleviate reperfusion injury of tissues or organs. Ischemic preconditioning (IPC) refers to a phenomenon in which a tissue is rendered resistant to the deleterious effects of prolonged ischemia and reperfusion by prior exposure to brief periods of vascular occlusion[12]. With regard to organ transplantation, the beneficial effect of IPC has been previously described in transplantation procedures involving in ameliorating heart preservation injury and liver reperfusion damage[13,14], but its protective capacity against reperfusion injury in small bowel transplantation has not completely defined. Lately, Sola *et al*[15]. have shown that the release of lactate dehydrogenase (marker of cell injury) decreases markedly during small intestinal graft preservation and reperfusion, and morphological change of graft improves greatly, after IPC was carried out. Extracelluar matrix is the early target of reperfusion injury[16]. Epithelial cell apoptosis of small intestinal graft is the major mode of cell death[17]. But no study has covered the effect of IPC on them. So this study was to investigate the protective effect of ischemic preconditioning on epithelial cells and extracelluar matrix of intestinal graft in rats.

MATERIALS AND METHODS

Animal preparation

Healthy male Sprague-Dawley (SD) rats, weighing 280±20 g, provided by Medical Experiment Animal Center, Xi' an Jiaotong University, were housed in standard animal facilities and fed with commercially available rat chow and tap water *ad libitum* for 1 week before test to acclimatize the laboratory. They were maintained on a 12 h light/dark cycle.

Experimental design

SD rats were used as donors and recipients. They were randomly divided into the following groups: (1) sham operation group (S group, *n*=6), in which animals were only subjected

to anesthesia and laparotomy; (2) heterotopic segmental small bowel transplantation group (SBT group, *n*=12), in which the donor and recipient were paired according to the similar body weight; (3) IPC plus SBT group (ISBT group, *n*=12). IPC was carried out before the graft was harvested. Namely, the superior mesenteric artery was occluded for 10 min with a microsurgical atraumatic vascular clamp, then it was released, and the graft was reperfused for 10 min. The following surgical procedures were the same as SBT group.

Heterotopic small bowel transplantation

Heterotopic SBT was performed with a technique modified from that described by Monchik and others scholars[18-21]. All animals were fasted for 12 h, but had free access to water before operation. They were anesthetized with pentobarbital sodium solution (2 %, 35 mg/kg) intraperitoneally. After perfused *in situ* with cold lactated Ring' s solution, the small intestine 5 cm distal to the Treitz ligament was harvested from donor rat with a vascular pedicle including portal vein (PV) and aorta segment with superior mesenteric artery, and stored at 4 ℃ in lactated Ringer' s solution for 1 h. After left nephrectomy, left renal vein and abdominal aorta of the recipient were isolated. The graft was revascularized by end-to-side anastomosis between donor aorta and recipient aorta using continuous 9-0 non-traumatic nylon suture and end-to-end anastomosis between donor PV and the left renal vein of the recipient using a cuff technique. The recipient' s own intestine was left intact. During transplantation, mean warm ischemia time of graft was 25-30 min, and the longest did not exceed 40 min[22].

Immuohistochemical staining and evaluation

When the graft was revascularized successfully and reperfused for 1 h, samples were obtained from the different groups. Specimens were fixed in 4 % paraformaldehyde, embeded in paraffin, sliced 4 μm thick, and stained by the SP methods. A polyclonal antirat laminin antibody (Boster Biotech, Wuhan, China) was used at concentration of 1:100. DAB was used for visualization. For negative control, the slides were treated with PBS instead of primary antibody.

Laminin is one of the major components of epithelial basement membrane. It was regarded as positive signals when epithelial basement membrane became brownish yellow. Quantitative analysis of positive products was performed using image acquiring analysis system (Leica QWin500CW, Germany). The image system randomly selected five visual fields per slice to measure the optical density value, using the average value as the mean optical density.

Detection of cell apoptosis

Apoptosis was detected on sections from paraformaldehyde-fixed and paraffin-embedded blocks by the terminal deoxynucleotidyl-transferase (TdTase) mediated d-UTP-biotin nick end labeling (TUNEL) method[23]. Apoptosis assay with a detection kit from Bochinger Mannheim Germany, conformed to the manufacturer' s protocol strictly. The nuclei of apoptotic cells were stained brown as detected under light microscope, and apoptotic cells were quantified by calculating the apoptotic index (apoptotic cells/10 high-power fields)[24]. Negative control was designed by PBS instead of TdTase.

Transmission electron microscopy

For transmission electron microscopy, intestinal fragments of approximately 2 mm^3 obtained from different groups, were fixed in 2.5 % glutaraldehyde for 3 h, rinsed in PBS, then postfixed in 1 % osmium tetroxide for 2 h. Samples were dehydrated in graded alcohols, and embedded in Epon 812, cut on an ultramicrotome and stained with uranyl acetate and lead citrate. Ultrathin sections were viewed using transmission electron microscopy (Hitachi H-600).

Statistical analysis

Data were expressed as mean ± standard error of the mean. One-way analysis of variance (ANOVA) was used for multiple comparisons with Student Newman Keylls (SNK) test. Significant difference was assumed when $P<0.05$.

RESULTS

Quantitative analysis of laminin expression in different groups

As seen from Table 1, the mean optical density value of laminin positive products in SBT group was sharply lower than that in S group ($P<0.05$). However, after IPC was carried out, the mean optical density value of positive products in ISBT group was higher, compared with that in SBT group ($P<0.05$). It indicated that IPC had a protective effect on the basement membrane, one of the components of extracelluar matrix.

Table 1 Expression of laminin in different groups

Group	*n*	Mean optical density value
S	6	39.52±2.60
SBT	6	13.53±0.44[a]
ISBT	6	25.40±1.79[b]

[a]$P<0.05$ *vs* S group q=29.87, [b]$P<0.05$ *vs* SBT group q=13.64.

Cell apoptosis in different groups

As shown in Figure 1 and Table 2 in S group, apoptotic epithelial cells at villus tip were found only occasionally. However, after the graft underwent 60 min of cold ischemia and 60 min of warm reperfusion, many apoptotic cells appeared at villus tip of the graft in SBT group, The AI in SBT groups was significantly higher than that in S group ($P<0.05$), but the number of apoptotic cells at villus tip of the graft decreased sharply after transient IPC was carried out. The AI in ISBT group was sharply lower than that in SBT group ($P<0.05$). It showed that the mechanism of IPC was also involved in inhibition of epithelial cell apoptosis induced by ischemia and reperfusion in small intestinal graft.

Table 2 AI of epithelial cells of small intestinal graft in different groups

Group	*n*	AI
S	6	2.2±0.83
SBT	6	30.8±3.2[a]
ISBT	6	13.2±2.86[b]

[a]$P<0.05$ *vs* S group q=25.33 [b]$P<0.05$ *vs* SBT group q=15.59.

Morphological analysis of epithelial basement membrane

Under light microscope, epithelial basement membrane was stained brownish yellow in S, SBT and ISBT groups, but there was an obvious difference in the structure of epithelial basement membrane. Basement membrane in S group showed line-shaped continuous normal structure, however, it became disrupted and collapsed, even disappeared in SBT group. The lesion of basement membrane in ISBT group was slighter compared with that in SBT group. Under transmission electron microscope, the morphological change of epithelial basement membrane was the same as that under light microscopy (Figure 2).

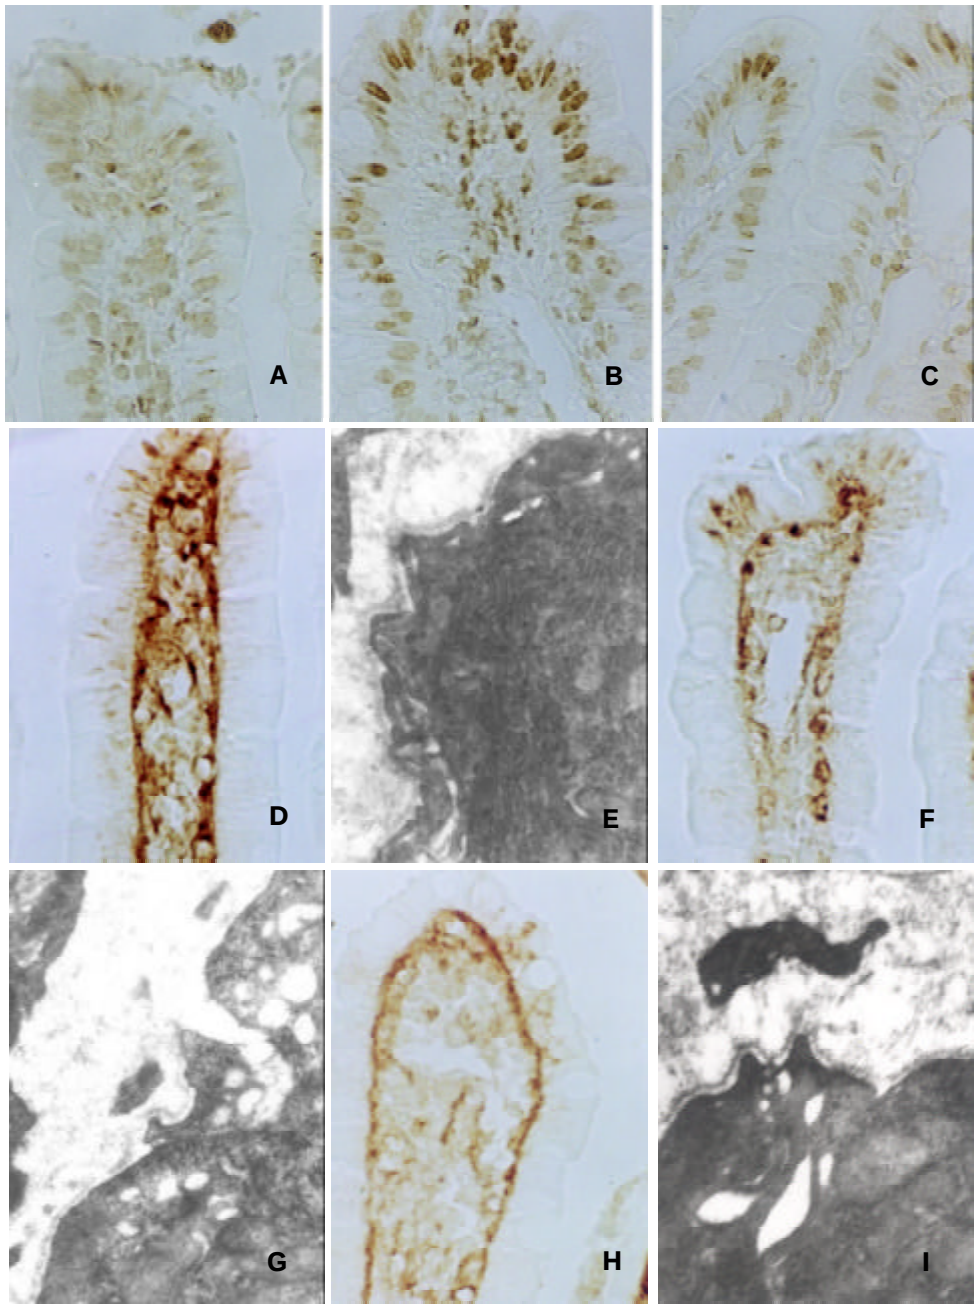

Figure 1 Light micrographs of apoptotic cells detected by TUNEL method (original magnification ×400). A: In S group, TUNEL signals were only observed accidentally at villi tip. B: In SBT group, many TUNEL signals appeared at villi tip of the graft. C: In ISBT group, after IPC was carried out, TUNEL signals decreased significantly at villi tip of the graft.

Figure 2 Light and electron micrographs (LM and EM) of morphological change of epithelial basement membrane (BM) (LM, original magnification ×400, EM, original magnification ×20 000). D and E: In S group, BM showed line-shaped, continuous normal structure. F and G: In SBT group, BM became disrupted and collapsed, even disappeared. H and I: In ISBT group, after IPC was function carried out, the lesion of BM was slighter, compared with that in SBT group.

DISCUSSION

Available evidences indicate that the small intestinal mucosa is susceptible to postischemic reperfusion, 15 minutes of ischemia alone could induce detectable mucosal injury, and reperfusion exacerbates the mucosal injury[25]. Under physiological conditions, the gut shows a remarkable rate of turnover, and a rapid regeneration of the epithelial layer has also been reported after intestinal hypoxia/reperfusion. Taguchi *et al*. have found that 15 minutes of ischemia and 1 h reperfusion could result in increase of the expression of proliferation cell nuclear antigen (PCNA) in small intestine[26]. PCNA, a kind of nuclear protein that produces or expresses in proliferative cells, is a significant cell-regulated nuclear protein for DNA-polymerase δ. So PCNA is a marker for proliferative cells[27-29]. The increase of small intestinal PCNA expression after 1 h reperfusion indicates that the repair process of epithelia is initiated by ischemia and reperfusion. In order to discover the deleterious effect of reperfusion and protective effect of IPC, respectively, on epithelia and extracelluar matrix of the small intestinal graft, and to prevent influence on graft due to the recovery of epithelia during reperfusion, the present study was designed to obtain specimens from different groups 1 h after reperfusion when the vascular anastomosis had finished.

The protective effect of IPC was first described in heart[30], and many comprehensive studies on IPC indicated that it could be divided into two major classes. One is the early phase of protection that appears 1-3 h after IPC, and the other is the late phase of protection that appears 24 h after IPC (the second

window of protection). Lately, this protective effect has been also demonstrated in the small intestine[31]. Although the effects of IPC on small intestine are not completely understood, several studies suggested that they were involved in transient increase of nitric oxide synthesis, activation of K_{ATP} channel, release of calcitonin gene-related peptide and endogenous opioid peptides, and inhibition of P-selectin expression in small intestine[32-36]. Apoptosis regulates many physiological and pathological processes. The influence of IPC on cell apoptosis in small bowel graft is not well known. Apoptosis is a major mode of epithelial death and peaks at 60 min during reperfusion period, in comparison, necrosis was relatively minor[37,38]. Therefore, loss of intestinal epithelia is a consequence of apoptosis during reperfusion. In the present experiment, apoptotic epithelial cells at villus tip were found accidentally in S group. Under physiological circumstances, apoptosis was reported to be an important mechanism of epithelial cell renewal. However, in SBT group after the graft underwent 60 min of cold ischemia and 60 min of warm reperfusion, many apoptotic cells appeared at villus tip of the graft. Compared with S group, the number of apoptotic cells was significantly higher. It indicated that apoptosis was initiated by ischemia and reperfusion in the graft. But in ISBT group, after transient IPC was carried out, the number of apoptotic cells at villus tip of the graft decreased sharply, in comparison with that in SBT group. It suggests that the mechanism of IPC may also involve the inhibition of epithelial cell apoptosis induced by ischemia and reperfusion in small intestinal graft.

Extracelluar matrix proteins provide structural support and maintenance, and also modulate a number of cell functions such as repair and immunity[39]. Laminin, an active glycoprotein with many biological functions, is one of the most abundant components of epithelial basement membrane[40]. It may play an important role in regulating cell-cell interactions, cell migration and differentiation. Laminin can be produced by epithelial and endothelial cells. In the present study, after laminin expression was evaluated by immunohistochemical staining and analyzed by quantitative analysis system, it was found that intestinal epithelial basement membrane in S group appeared line-shaped continuous structure, but it became decomposed and disrupted, even disappeared in SBT group. Compared with the average optical density value of laminin positive expression signals in S group, it was significantly lower in SBT group. Hence, it proved again that epithelial basement membrane was an early target of reperfusion injury. The small bowel contains a large reservoir of mediators, such as reactive oxygen radicals, various protease and cytokines, as well as adhesion molecules[41]. During reperfusion, laminin regulates polymorphonuclear cells to adhere and migrate to epithelial villus, and it is reactive oxygen radicals and various proteases released from polymorphonuclear cells that decompose epithelial basement membrane, meanwhile reperfusion injury damages the ability of epithelial cells to produce laminin. So, more damage and less production result in the collapse of epithelial basement membrane. In accordance with immunohistochemical results, under transmission electron microscopy, intestinal epithelial basement membrane in S group kept normal, but it showed disruption, even disappeared in SBT group. After IPC, the morphological change of epithelial basement membrane in ISBT group improved greatly, and the mean optical density value of laminin positive expression signals became higher, compared with that in SBT group. Under transmission electron microscope, the reperfusion injury degree of basement membrane in ISBT group was slighter than that in SBT group. It indicates strongly that IPC has protective effects on extracelluar matrix of small intestinal graft, and the beneficial effect may appear at early phase after IPC.

In summary, the present study demonstrates that ischemic preconditioning has an early protective effect on epithelial cells and extracelluar matrix of small intestinal graft. Inhibition of epithelial cell apoptosis initiated by reperfusion may be one of the mechanisms of IPC. With regard to organ transplantation, IPC may have a substantial impact on clinical practice. Alleviation of reperfusion injury of graft by IPC can enhance the function grafts and prolong their survival.

Abstract

AIM: To evaluate the methods and outcome of gallbladder preservation in surgical treatment of primary bile duct stones.

METHODS: Thirty-five patients with primary bile duct stones and intact gallbladders received stone extraction by two operative approaches, 23 done through the intrahepatic duct stump (RBD-IDS, the RBD-IDS group) after partial hepatectomy and 12 through the hepatic parenchyma by retrograde puncture (RBD-RP, the RBD-RP group). The gallbladders were preserved and the common bile duct (CBD) incisions were primarily closed. The patients were examined postoperatively by direct cholangiography and followed up by ultrasonography once every six months.

RESULTS: In the RBD-IDS group, residual bile duct stones were found in three patients, which were cleared by a combination of fibrocholedochoscopic extraction and lithotripsy through the drainage tracts. The tubes were removed on postoperative day 22 (range: 16-42 days). In the RBD-RP group, one patient developed hemobilia and was cured by conservative therapy. The tubes were removed on postoperative day 8 (range: 7-11 days). Postoperative cholangiography showed that all the gallbladders were well opacified, contractile and smooth. During 54 (range: 6-120 months) months of follow-up, six patients had mildly thickened cholecystic walls without related symptoms and further changes, two underwent laparotomies because of adhesive intestinal obstruction and gastric cancer respectively, three died of cardiopulmonary diseases. No stones were found in all the preserved gallbladders.

CONCLUSION: The intact gallbladders preserved after surgical extraction of primary bile duct stones will not develop gallstones. Retrograde biliary drainage is an optimal approach for gallbladder preservation.

INTRODUCTION

The gallbladder is important for digestion. Cholecystectomy can give rise to postoperative symptoms such as flatulent dyspepsia, abdominal pain, distention, heart burn, obstipation and diarrhea[1-5], and may lead to increase of incidence of carcinoma of the proximal colon[6]. Many patients with primary bile duct stones do not have stones in the gallbladders. However, as T-tube drainage after common bile duct (CBD) exploration may cause adhesion and subsequent cholecystitis and stone formation, these intact gallbladders are often concomitantly resected. Since 1991, we have adopted retrograde biliary drainage instead of T-tube drainage for primary bile duct stones. Thirty-five intact gallbladders have been thus preserved.

MATERIALS AND METHODS

Patients

Thirty-five patients with primary bile duct stones and intact gallbladders received retrograde biliary drainage (RBD) between December 1991 and December 2001. The age of the patients ranged from 29 to 70 (mean 44) years. Preoperative diagnosis was made by ultrasonography and in some cases by a combination with percutaneous transhepatic cholangiography (PTC). During the operation, the gallbladders were normal in appearance and no stones and lesions were found by intraoperative ultrasonography (IOUS). Stones extracted from the bile ducts had the typical features of pigment stones with brown color and soft quality. Stone distribution and the operation methods are shown in Table 1. Postoperatively, all the patients were routinely examined by direct cholangiography and followed up once every six months by ultrasonography. The follow-up duration ranged from 6 to 120 (mean 54 months) months.

Table 1 Stone distribution and operation methods

Stone distribution	Cases	Operation methods	Cases
Left hepatic	11	RBD-IDS&II, III segmentectomy	15
Extrahepatic	8	RBD-RP	12
Intra-and extrahepatic	8	RBD-IDS & left hepatectomy	6
Bilateral hepatic	7	RBD-IDS & III segmentectomy	1
Segment VII	1	RBD-IDS & VII segmentectomy	1
Total	35	Total	35

Notes: RBD-RP: retrograde biliary drainage by retrograde puncture, RBD-IDS: retrograde biliary drainage through intrahepatic duct stump.

Methods

RBD through intrahepatic duct stump (RBD-IDS) After partial hepatectomy for intrahepatic bile duct stones, biliary tract exploration was done by fibrocholedochoscopy through the intrahepatic bile duct stump. The CBD was incised in the patient with big concurrent extrahepatic bile duct stones which could not be extracted retrogradely. The RBD tube was placed through the hepatic duct stump and the CBD incision was closed primarily. In case of suspected residual stones, the RBD

tube was sheathed by a tube of larger bore from the abdominal wall to the lumen of the stump.

RBD by retrograde puncture (RBD-RP) After CBD exploration and stone clearance, a guide sheath was inserted into the right hepatic duct, with the tip as deep in the duct as possible. The direction was regulated with IOUS to avoid injury of large blood vessels. An 8Fr cannula fitting over a matching stylet was inserted through the guide sheath and pushed forward until the tip came out of the liver. From the other end, an 8Fr Silastic drainage tube was inserted over the guide wire which was introduced through the cannula. When the tip of the drainage tube emerged in the CBD incision, the guide wire, retrograde cannula and guide sheath were retracted together. The end of the drainage tube was brought out of the abdominal wall subcostally. The CBD incision was primarily closed. Intraoperative cholangiography was done to rule out residual stones in some suspected cases.

RESULTS

In the RBD-IDS group, postoperative drainage of bile was 340-780 ml/d (mean 440±140 ml/d). The drainage tubes were removed on postoperative day 16-42 (mean 22 days). Residual stones were found in three cases. After four weeks, stone extraction started through the tracts with the help of fibrocholedochoscope and ultrasonic lithotriptor. All patients had the stones cleared after 2-5 sessions of extraction. In the RBD-RP group, postoperative drainage of bile was 150-800 ml/d (mean 520±210 ml/d). Bile drainage was interrupted intermittently in two patients owing to blockage of the tubes and it resumed to draining after flushing with normal saline. The drainage tubes were removed on postoperative day 7-11 (mean 8 days). Hemobilia occurred in one earlier treated patient. She recovered soon after conservative therapy. No tube dislocation or residual stones occurred in this series.

Postoperative cholangiography of both methods showed that the extrahepatic bile ducts had no stricture at the sites of CBD incisions. The preserved gallbladders were well opacified, contractile and smooth (Figure 1). During the follow-up, six patients were found to have rough and mildly thickened cholecystic walls at 12-36 months after operation. However, these patients had no related symptoms and no further changes afterwards. Two patients underwent laparotomies because of adhesive intestinal obstruction and gastric cancer, respectively. Three died of cardiopulmonary diseases. No stones occurred in the preserved gallbladders.

Figure 1 Direct cholangiogram showed that the preserved gallbladder was well opacified and contractile.

DISCUSSION

A high recurrent rate of gallbladder stone after successful extracorporeal shock wave lithotripsy and dissolution has been documented by many reports[7-11]. However, the gallbladders after endoscopic sphincterotomy for common bile duct calculi rarely formed stones[12-14]. One explanation for the difference of the results is that sphincterotomy decreases fasting volume of the gallbladder and increases its contraction ability[15, 16]. Another is that the primary bile duct pigment stone is different from the cholecystic cholesterol one in both epidemiology[17-21] and pathogenesis[22-26]. It is therefore generally considered that both kinds of stones are different diseases[26]. The results of this study also showed that the gallbladders preserved during operation of the patients with primary bile duct stones had no tendency to form stones. As most gallbladders of the patients with primary intrahepatic bile duct stones are not affected, concomitant cholecystectomy during surgical extraction of stones or liver resection in these patients seems unjustified.

T-tube drainage after choledochostomy or after liver resection is a conventional method for primary bile duct stones. However, many reports in recent decades have demonstrated the problems it brought about[27,28]. The long tube-bearing not only results in inconvenience, but also causes pathological changes of the CBD[29]. T-tube tract can also adhere to the gallbladder and impair its function. Therefore, intact gallbladder is often concomitantly resected during these operations. In recent years, several alternatives to T-tube drainage have been reported[30-33]. However, preservation of the gallbladder during surgical management of primary bile duct stones and its long-term outcome have not been reported yet. After retrograde biliary drainage, the function of the gallbladder will not be impaired by tube stimulation or tube induced local adhesion because the gallbladder does not contact the drainage tube. This study also demonstrated that both methods had respective advantages over T-tube placement in residual stone management and the duration of tube-bearing.

Therefore, we conclude that retrograde biliary drainage is an optimal method for preservation of gallbladder during surgical management of primary bile duct stones.

Abstract

AIM: To observe the effects of mouse nerve growth factor (NGF), rat recombinant brain derived neurotrophic factor (rm-BDNF) and recombinant human neurotrophin-3 (rh-NT-3) on the gastrointestinal motility and the migrating myoelectric complex (MMC) in rat.

METHODS: A randomized, double-blinded, placebo-controlled experiment was performed. 5-7 days after we chronically implanted four or five bipolar silver electrodes on the stomach, duodenum, jejunum and colon, 21 experimental rats were coded and divided into 3 groups and injected NGF, rm-BDNF, rh-NT-3 or placebo respectively via tail vein at a dose of 20 $\mu g \cdot kg^{-1}$. The gastrointestinal myoelectrical activity was recorded 2 hours before and after the test substance infusions in these consciously fasting rats.

RESULTS: The neurotrophins-induced pattern of activity was characterized by enhanced spiking activity of different amplitudes at all recording sites, especially in the colon. In the gastric antrum and intestine, only rh-NT-3 had increased effects on the demographic characteristics of electrical activities ($P<0.05$), but did not affect the intervals of MMCs. In the colon, all the three kinds of neurotrophins could significantly increase the frequency, amplitude and duration levels of spike bursts, and also rh-NT-3 could prolong the intervals of MMC in the transverse colon (25±11 min *vs* 19±6 min, $P<0.05$). In the distal colon rh-NT-3 could evoke phase III-like activity and disrupt the MMC pattern, which was replaced by a continuously long spike bursts (LSB) and irregular spike activity (ISA) for 48±6 min.

CONCLUSION: Exogenous neurotrophic factors can stimulate gut myoelectric activities in rats.

INTRODUCTION

Many basic studies have shown that neurotrophins play fundamental roles in the differentiation, survival and maintenance of peripheral and central neurons[1-5] and have suggested the possible use of neurotrophins as therapeutic tools for degenerative neuronal disorders[6]. Neurotrophic factors comprise nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3), NT-4/5, and NT-6[7-9]. These factors signal their effects through specific tyrosine-kinase (trk) receptors[10,11]. In addition to the high sequence homology of neurotrophins, neurotrophic factors including NT-3, BDNF and NGF are also highly conserved across species (mouse, rat and human)[13].

In a clinical study of patients with a variety of neurologic disorders treated with rh-NT-3 or recombinant human BDNF (rh-BDNF), they were found to have alterations of bowel function, and a dose-related tendency to increasing frequency of stools or having "diarrhea"[14]. Studies also have proved that exogenous neurotrophic factors stimulate gut motility and accelerate colonic transit in health and constipation[14]. This suggests that the action of rh-NT-3 and rh-BDNF on the gastrointestinal tract parallels their effect on the central nervous system. Review of the clinical reports suggested an increased frequency of bowel movements with less impressive effects on stool consistency[15], but the mechanism is unclear so far.

All the conclusions of previous studies lead to the hypothesis that neurotrophins alter bowel motor function, leading to increased frequency of bowel movements. In order to assess the action of neurotrophins on gut motility, in the present study we injected respectively NGF, rm-BDNF and rh-NT-3 via tail vein and registered the electrical activities with chronically implanted electrodes in fasting rats.

MATERIALS AND METHODS

Animal preparation

21 healthy Sprague-Dawley (SD) rats, weighing 250-300 (mean 276±17) g, 15 male and 6 female, individually housed, fed on chow pellets and water *ad libitum*, were used for these experiments. After fasted for 24 h, the rats were intraperitoneally anesthetized with sodium pentobarbital 30 $mg \cdot kg^{-1}$ (ip) A segment of the small intestine was exposed through a midline incision. Four or five bipolar insulated silver electrodes made by teflon-coated wire (0.5 mm in outer diameter, 20 cm in length) were implanted into the muscular layer of the bowel with a needle as a trocar. 1 mm of the wire was exposed near the implanted end, and the interval between pairs of electrodes should be 2.0-3.0 mm. The electrodes were placed on the gastric antrum at 5 mm proximal to the pylorus, on the duodenum and jejunum respectively at 5 cm and 20 cm distal to the pylorus, and on the transverse colon 5 cm distal to the ileocaecal junction. Among the 21 experimental animals, 9 were implanted electrodes on the distal colon 10 cm distal to the ileocaecal junction at the same time. The bundled electrode wires were grasped by the clamp through a silastic tube (2.4 mm in diameter), which then passed

through the subcutaneous tunnel from the abdominal incision to the back of the shoulder exit. Following surgery, the rats were individually housed, and allowed 5 to 7 days to recover from the surgery.

Motility recordings

The animals were fasted for 8 h with free access to water. The experiments were performed in conscious rats. The electromyographic (EMG) recordings were monitored by using a polygraph (Biolap98, Chengdu, China), with time constant set at 0.01 s, gain set at 1 000, the filtering at lower and higher frequencies set at 0.3 Hz and 100 Hz, respectively. The amplitudes of contractions were recorded in microvolts and the paper speed was 5 cm· h^{-1}.

Experimental procedure

A randomized, double-blinded, placebo-controlled experiment was performed. The rats were coded and divided into 3 groups, 7 animals in each group. On each experimental day, at the beginning of the experiments, the gastrointestinal myoelectrical activity was recorded for 2 h for each rat, and during this period at least 3 MMCs appeared. Then, the test substances were infused through the tail vein. The substances were dissolved immediately before use in normal saline. In each group, 2 rats were placed as control that received placebo (vehicle), 0.2 mL saline containing 250 μg bovine serum albumin (BSA, Sigma), the other 5 received 0.2 ml saline containing neurotrophins at a dose of 20 μg· kg^{-1}. Of them, 3 were placed electrodes on the distal colon as well. The three groups were injected them NGF (Sigma), rm-BDNF (Sigma) and rh-NT-3 (Sigma), respectively. After tail vein injection, the gastrointestinal myoelectrical activity of the rats was continuously recorded at least for 2 h. The codes of rats were not released (sealed) for analysis until all the EMG recordings and the entire data set for statistical studies were completed.

Statistical analysis

The results were expressed as $\bar{x}\pm s$ unless otherwise stated. Student' s *t* test was used to compare the different paired values before and after the test substance administration in the 3 groups. It was considered to be statistically significant when $P<0.05$.

RESULTS

Gastrointestinal myoelectrical activity during fasting

About 1 week later, among the 93 pairs of electrodes, 2 pairs implanted on the gastric antrum failed possibly due to the their slipping off, the other 91 pairs continued to function until the study was completed. A typical pattern of myoelectrical activity in the fasting state was observed in all rats (Figure 1, Table 1). Of the totally 238 activity fronts recorded in fasting rats under control, we observed that 199 (80 %) started in the duodenum.

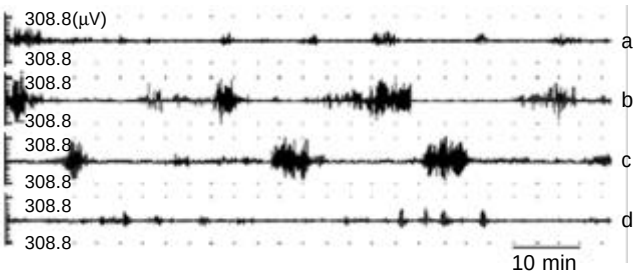

Figure 1 Electrical activity recorded directly from four electrode sites on the gastric antrum (a) at 5 mm proximal to the pylorus, on the duodenum (b) and jejunum (c) respectively at 5 cm and 20 cm distal to the pylorus, and on the transverse colon (d) at 5 cm distal to the ileocaecal junction in one fasting rat.

The antral myoelectrical activity was characterized by the presence of spike bursts, superimposed at 34.5 % of the

rhythmic oscillatory potentials corresponding to the slow wave rhythm. In fasting rats, the pattern of spike bursts of the small intestine was organized into cyclic MMCs that occurred at regular 15.6±5.4 min intervals and were propagated from the duodenum to the jejunum at 2 to 3 cm· min^{-1}. Each MMC was a cycle consisting of four phases: a period of silence (slow wave), namely phase I lasting 7.3±0.8 min, which was followed sequentially by a period of ISA (irregular spike activity), namely phase II lasting 4.1±0.9 min, and phase III of intense RSA (regular spike activity) lasting 3.6±1.1 min. Phase IV was the last period from the end of phase III to the start of phase I lasting 0.9±0.3 min. The intervals between the MMCs were measured from the end of one activity before to the end of the next one.

The pattern of colonic myoelectrical activity was characterized by randomly occurring spike bursts at a frequency of 0.6±0.07 per minute in the transverse colon and 0.5±0.09 per minute in the distal colon.

Effects of neurotrophins on the gastrointestinal and colon myoelectric activity

The effect of neurotrophins on the gastrointestinal motility was established within 2 to 4 min after commencement of the infusion. The neurotrophin-induced pattern of activity was characterized by enhanced spiking activity of different amplitudes at all recording sites, especially at the colon, which continued about 50±8 min and gradually returned to normal complexes. There was no significant difference in demographic characteristics before and after placebo treatment. Table 1 summarizes the effect of neurotrophins on the different electromyographic parameters before and after treatment.

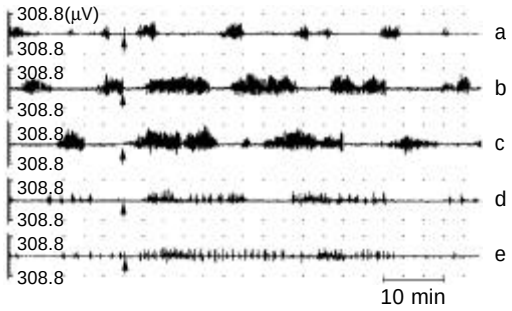

Figure 2 The effects of rh-NT-3 on the myoelectric activities respectively recorded from gastric antrum (a), duodenum (b), jejunum (c), transverse colon (d), and distal colon (e) in one case. The arrows indicated the time point of rh-NT-3 injection via tail vein at a dose of 20 μg·kg^{-1}.

In the gastric antrum and intestine of fasting rats, administration of 20 μg· kg^{-1} mouse NGF and rm-BDNF didn' t significantly increase electrical activities (P>0.05), whereas intravenous infusion of 20 μg· kg^{-1} rh-NT-3 could increase the frequency, amplitude and duration of spike bursts (P<0.05, Table 1), but did not affect the intervals of MMCs (Figure 2).

In the colon, treatment with mouse NGF and rm-BDNF prolonged the duration as well as increased the frequency and amplitude of spike bursts (P<0.05, Table 1) without alterations of MMC intervals. In the transverse colon, rh-NT-3 not only significantly increased the electrical activities, but also prolonged the intervals of MMC (25±11 min *vs* 19±6 min, P<0.05) (Figure 2). The distal colon electromyogram recordings in 3 cases implanted bipolar electrodes on the distal colon, showed that rh-NT-3 could evoke phase III-like activity and disrupt the MMC pattern that were replaced by a continuous long spike bursts (LSB) and irregular spike activity (ISA) for 48±6 min (Figure 2).

DISCUSSION

Previous studies showed that rm-BDNF and rh-NT-3 caused diarrhea in a dose-related manner[15] and that exogenous neurotrophic factors accelerated colonic transit and increased stool frequency in humans[14]. The present studies were carried out to evaluate comparatively the effects of NGF, rm-BDNF and rh-NT-3 on the gastrointestinal myoelectric activity in fasting rats. The study firstly showed that neurotrophin-induced pattern of activity was characterized by enhanced spiking activity of different amplitudes at all recording sites, especially in the colon. The MMCs were firstly described in the small intestine of fasting dogs and its presence was observed in several species, including rats. In the present studies, MMC was also observed in fasting rats and found that in gastric antrum and intestine, only rh-NT-3 had enhanced effects on demographic characteristics of electrical activities (P<0.05), but did not affect the intervals of MMCs. In the colon, not only all the three kinds of neurotrophins infusion could significantly increase the frequency, amplitude and duration of spike bursts, but also rh-NT-3 could prolong the intervals of MMC in the transverse colon (25±11 min *vs* 19±6 min, P<0.05), and in the distal colon, rh-NT-3 could evoke phase III-like activity and disrupt the MMC pattern, which was replaced by continuous LSB and ISA for 48±6 min. Thus the present results indicate that exogenous neurotrophic factors can stimulate gut myoelectric activity in rats. The recording of myoelectrical activity by means of chronically implanted electrodes in rats is a suitable experimental animal model to investigate the mechanism of action of neurotrophins on intestinal motility.

Our conclusion is consistent with the previous ones. Probably it can contribute to the explanation of the mechanisms of the rapid onset of diarrhea in clinical trials with these neurotrophins, that neurotrophins lead to increases of bowel motor, as a result the gastrointestinal contents are transmitted too quickly, leading to diarrhea for the water having not been fully absorbed.

Two mechanisms mediating the actions of neurotrophins on neuromuscular function are considered: trophic effects or a direct effect on neurotransmission[22]. The neurotrophins have long-term trophic actions, including prolongation of survival and speeding up phenotypic maturation of many types of neurons[16-19]. These functions are mediated by the Trk family of tyrosine kinase receptors[20-23]. Modulation of neurotransmission has been shown by acute or short-lived effects of neurotrophins[24,25]. For example, BDNF modulates neurotransmitter synthesis, increases neuronal excitability, and provides long-term synaptic potentiation of neurons[26], and it has been reported that NT-3 stimulates the expression of SP and neurotrophins, enhances not only synthesis but also storage of acetylcholine (Ach) in cultured septal neurons[27]. The time of the onset of effects on bowel movements with exogenous r-metHuBDNF and r-merHuNT-3 suggested direct actions on the neuromuscular apparatus or a very rapid trophic or regenerative effect on gut neuromuscular function. The other study suggested that the mechanism of rh-NT-3 excitation of colonic muscle involved increased noncholinergic contractility and decreased NANC neurotransmission with reduction in number of nitric oxide synthase (NOS) neurons. The abundance of BDNF protein in certain internal organs suggests that this neurotrophin may regulate the function of adult visceral sensory and motor neurons.

We are not quite clear why different enhancements of neurotrophins accelerating gut transition in the stomach, duodeno-jejunum and colon are possibly associated with the receptors of different neurotrophin distribution in gastrointestinal tract. Decreased trk C expression may reflect developmental abnormalities in Hirschsprung' s disease and idiopathic slow-transit constipation (STC)[28]. Further studies are needed to elucidate the precise mechanism by which neurotrophins

influence smooth muscle contractility and/or enteric nerve functions in the human gastrointestinal tract.

Gut motility disorder is common in clinical practice[29-33], and its suitable treatment should be studied[34-38]. In this respect, our data indicate that neurotrophins are the promising agents capable of modifying transit in the entire gastrointestinal tract and may provide novel treatments for patients with disturbed gut motility, such as Hirschspnmg' s disease[28, 39].

Abstract

AIM: To study the intestinal permeability (IP) following stress of abdominal operation and the different effects on IP of enteral nutrition (EN) and parenteral nutrition (PN).

METHODS: Forty patients undergoing abdominal surgery were randomized into EN group and PN group. Each group received nutritional support of the same nitrogen and calorie from postoperative day (POD) 3 to POD 11. On the day before operation (POD-1), POD 7 and POD 12, 10 g of lactulose and 5 g of mannitol were given orally, and urine was collected for 6 hours. Urine excretion ratios of lactulose and mannitol (L/M) were measured.

RESULTS: L/M ratios of EN group on POD-1, POD 7 and POD 12 were 0.026±0.017, 0.059±0.026, 0.027±0.017, respectively, and those of PN group were 0.025±0.013, 0.080±0.032, 0.047±0.021, respectively. Patients of both groups had elevated L/M ratios on POD 7 *vs*. POD-1. However the ratio returned toward control level in EN group by POD 12. In contrast, PN group still had elevated L/M ratios on POD 12.

CONCLUSION: L/M ratio increases for a period of time after surgical trauma and the loss of gut mucosal integrity can be reversed by substitution of enteral nutrition.

INTRODUCTION

Apart from the major function for digestion and absorption of nutrients, intestine also acts as "a central organ of stress". In many pathological conditions such as severe trauma, operation, chemotherapy and acute severe pancreatitis, intestine is a barrier to prevent microorganisms and toxins in the lumen from spreading to distant tissues and organs.

Nutritional support has been used in clinical care for more than forty years. Total parenteral nutrition (TPN) is the form of nutritional support most suitable to patients with gut failure, in which it is lifesaving[1]. However, studies have found that TNP has many disadvantages, such as gut barrier dysfunction and bacterial translocation. Enteral nutrition may not have these disadvantages[2-4].

Many studies have demonstrated that intestinal permeability (IP) can reflect gut barrier function[5,6]. When the integrity of gut mucosal barrier is damaged, increased intestinal permeability may occur. The excretion ratio of L/M of urine has been used to measure intestinal permeability[7]. However, few studies have directly compared the effect of EN versus PN on intestinal permeability after surgical trauma. Therefore, the present study was to observe intestinal permeability following operation and to investigate the different effects of enteral nutrition and parenteral nutrition on IP.

MATERIALS AND METHODS

Patients

A prospective and randomized study was designed. Forty patients with digestive tract tumor were enrolled. All the patients had normal liver and kidney functions but no metabolic diseases. Informed consent was obtained from all the patients preoperatively.

All the patients were randomized intraoperatively after complete resection of tumor. The groups were defined as follows. EN group: Patients received enteral nutrition via jejunostomy tube or nasojejunal tube starting from POD 3. All the tubes were placed approximately 20 cm distal to the ligament of Treitz. PN group: Patients received total parenteral nutrition via central venous catheter starting from POD 3. Control group: It consisted of twenty healthy volunteers. All controls underwent an overnight fast and took the test solution orally.

Nutrition

All the patients of the two groups received isonitrogenous (0.1728 g/Kg/d) and isocaloric (30 Kcal/Kg/d) nutritional support starting from POD 3. The aim of enteral or parenteral nutrition was to meet 50 % of nutritional requirements according to the protocol and GI tolerance of the patient on POD3, 75 % on the next day and 100 % on POD5.

EN group: Patients received Isosource (Novartis Corp, Switzerland) fluid polymeric formulation containing 14 % protein, 29 % fat, 57 % carbohydrate calories. Nutrient solution was given at a steady speed.

PN group: Patients received total parenteral nutrition. Amino acids, fat, glucose and minerals were mixed and infused steadily.

Lactulose/mannitol test

Intestinal permeability was performed on POD-1, POD7 and POD12. All the patients fasted for at least 6 hours and their bladders were emptied before the test. The test solution consisted of 10 g of lactulose and 5 g of mannitol in a total volume of 50 mL with osmotic pressure 1 200 mOsm/L. The solution was given via the jejunostomy tubes or by nasojejunal or oral routes. The urine volume was collected for the subsequent 6 hours. One hour after the test started, the patients were encouraged to drink. After 2 h, liberal intake of food was allowed. The urine volume was recorded, and 10-mL portion was frozen and stored at -80 ℃.

Analysis

Urinary lactulose and mannitol were assayed using high-

pressure liquid chromatography (HPLC) as described by Willems D and colleagues[8]. Calibration was performed on a daily basis with authentic standards at multiple concentrations, and the experimental standards were diluted so that the areas of all peaks fell within the calibration range. Fractional excretions (lactulose and mannitol) and L/M ratios were calculated. Fractional excretion was defined as the fraction of the gavaged dose recovered in the urine sample, and L/M ratio was a ratio of fractional excretions (lactulose-mannitol).

Statistical analysis

Statistical analysis was performed using analysis of variance (ANOVA) when comparing mean L/M ratios within groups and by an independent *t* test for differences between groups and *vs* control. Enumeration data were analyzed by χ^2 square test. Differences were considered significant when $P<0.05$, and obviously significant when $P<0.01$. All values were expressed as means ±SD.

RESULTS

Patients ' general data

From April 2000 to July 2001, forty patients with digestive tract tumors were randomized to receive enteral nutrition or total parenteral nutrition. Preoperative and procedure related data for the two groups are listed in Table 1.

Table 1 Comparison of preoperative and procedure related data between experimental groups

	EN group	PN group
Age (y)	50.8±14.9	53.1±15.6
Sex (M / F)	13 / 7	11 / 9
Weight (Kg)	60.0±6.8	61.3±12.3
Cancer of stomach	15	11
Cancer of colon	5	9
Complete gastrectomy	7	5
Partial gastrectomy	8	6
Left hemicolectomy	4	5
Right hemicolectomy	1	4

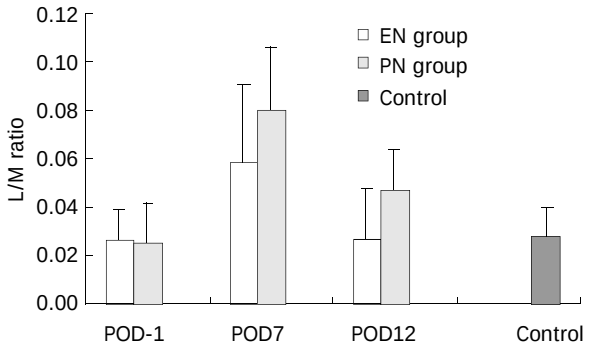

Figure 1 Mean ratio of recovered lactulose to mannitol (L / M) in the urine. A significant elevated ratio was seen on POD7 *vs* that on POD-1 in both groups ($P<0.01$). Significant decreases in the ratio were seen in both groups on POD12 *vs* POD7 ($P<0.01$). The L / M ratio of EN group was significantly lower than PN group on POD7 ($P<0.05$) and on POD12 ($P<0.01$).

Intestinal permeability

Figure 1 depicts the mean L/M ratios for all groups. On POD-1, there were no significant differences in EN group (0.026±0.017) and PN group (0.025±0.013) *vs* control (0.028±0.012) ($P>0.05$). Also there was no significant difference in EN group *vs* PN group ($P>0.05$). On POD7, there was one-fold to two-fold increase in the L/M ratios in both EN group (0.059±0.026) and PN group (0.080±0.032) *vs* that on POD-1 ($P<0.01$). However, there was a significant difference between PN group and EN group ($P<0.05$). On POD12, there was a significant difference in L/M ratios in both EN group and PN group *vs.* that on POD7 ($P<0.01$). However, there was a decreasing trend in L/M ratio in EN group (0.027±0.017) *vs.* that on POD-1 ($P>0.05$), while there was a significant difference in PN group (0.047±0.021) *vs.* that on POD-1 ($P<0.01$). There was a significant difference between PN group and EN group on POD12 ($P<0.01$).

DISCUSSION

Small intestinal permeability has been used to quantify the damage of gut mucosal barrier[9,10]. Intestinal permeability changes have been detected by oral administration of probes such as ^{51}Cr-EDTA, sucrose, lactulose, cellobiose, and polyethylene glycol[11-14]. The measurement of urinary excretion of nonmetabolized sugars has been widely used as a noninvasive method to assess mucosal integrity of the small bowel[15-17]. Monosaccharides such as mannitol and L-rhamnose pass through the transcellular routes of aqueous pores, reflecting the degree of absorption of small molecules (0.65 nm). Disaccharides, including lactulose and cellobiose, pass through the intercellular junctional complexes and extrusion zones at the villous tips, reflecting the permeability of large molecules (0.93 nm). The permeabilities of mono- and disaccharides are usually compared and expressed as an excretion ratio such as lactulose/mannitol or lactulose/L-rhamnose in urine samples. Lactulose and mannitol represent ideal compounds for measuring differential sugar absorption because they have a negligible affinity for the monosaccharide transport system and are passively absorbed and not metabolized before urine excretion. Intraindividual differences in gastric emptying, small intestinal transit, and urinary excretion are therefore eliminated[5-7,16].

Several enzymatic, colorimetric, and thin-layer chromatographic methods have been developed for the determination of lactulose and mannitol[5,6]. However, most of them are time-consuming and do not allow a simultaneous assay of both sugars. More recently, gas chromatographic and HPLC procedures have been proposed to overcome these problems[8,18]. Data from our study suggested that HPLC was a good method of measuring lactulose and mannitol. Our data also showed that L/M ratios could reflect intestinal permeability.

Sepsis, systemic inflammatory response and trauma in both animal and human are associated with gut mucosal damage and dysfunction[19-21]. Gut dysfunction is a common problem, resulting in loss of gut mucosal barrier selectivity, increased permeability to various hydrophilic solutes and translocation of bacterial products into the circulation, which may then further increase the inflammatory response in distant organs, leading to multiple organ dysfunction and death[22]. As a result, many authors considered the gut as an "engine" that drived sepsis. One possible contributory mechanism to endotoxin-induced gut mucosal damage was the increased apoptosis[11]. Inflammatory mediators enhanced apoptosis in a large number of cell lines. In intact animals, increased cardiac and hepatic apoptosis during sepsis might contribute to sepsis-related dysfunction of those organs. Thus paracellular tight junction may be injured and intestinal permeability increases. Our study showed an increased permeability after the stress of surgical trauma.

Nowadays nutritional support has become a routine therapy method. In the stress condition, proper nutritional support may provide necessary nutrients, reduce clinical complications and

promote patients' recovery from illness[3]. Total parenteral nutrition (TPN) provides significant benefits to surgical patients. However, there are still many complications. The effects of total parenteral nutrition on the gastrointestinal tract include decreasing brush-border hydrolase and nutrient-transporter activity, increasing mucosal permeability, and decreasing microvillus height[23-25]. Thus TPN is complicated by bacterial translocation (BT). Enteral nutrition after stress can maintain immunocompetence, and promote wound healing. Furthermore, it is considered that enteral nutrition can maintain gut barrier integrity, reduce septic complications[26] and the risk of death of critical care patients[3, 27]. In our study, we used L/M ratio as a marker to reflect gut mucosal barrier. On POD7, L/M ratios in both EN group and PN group were elevated, but L/M ratio of EN group was significantly lower than that of PN group. And on POD12, L/M ratio of EN group returned to the level of POD-1, while L/M ratio of PN group was still higher than that of POD-1 and EN group.

It is concluded that L/M ratio increases in a period of time after surgical trauma and institution of enteral nutrition can reverse the loss of gut mucosal integrity.

Abstract

AIM: To investigate the efficacy and safety of a single-dose daclizumab induction therapy in orthotopic liver transplantation (OLTx).

METHODS: A retrospective study was made for 54 cases of OLTx in recent three years. The daclizumab group consisted of 23 cases of OLTx who received single-dose of 2 mg/kg intravenously after postoperative 24 hours. The control group consisted of the remaining 31 patients. Additional immunosuppressors included steroids, mycomphenolate mofetil, facrolimus or microemulsion cyclosporine used in all patients. Meta-statistical analysis was made for general data, incidence of acute rejection and infection, postoperative clinical course, complications and prognosis between two groups.

RESULTS: Pretransplant demographies were not significantly different between two groups. In the induction group there were significantly less acute rejection episodes (5 of 23, 21.74 %) than those in the control group (12 of 31, 38.71 %), which were proved by pathologic diagnosis ($P<0.05$). The incidence of infection at the early stage was not significantly different between two groups.

CONCLUSION: Induction therapy with single-dose of daclizumab is safe and effective and appears to be able to reduce the incidence of acute rejection.

INTRODUCTION

One of the key elements for successful liver transplantation is to effectively prevent acute rejection in patients with liver transplantation. Even the routine immunosuppressants such as azathioprin (AZA), cyclosporin (CSA), mycomphenolate mofetil (MMF) and tacrolinous (FK506)were used, the acute rejection rate in liver transplantation was still as high as 30-40 %[1-3]. Daclizumab, a humanized form of murine monoclonal antibody, has been recently shown to be able to decrease the acute rejection in liver transplanted recipients[4-7].

In this retrospective study, whether daclizumab induction therapy was effective and safe in orthotopic liver transplantation (OLTx) was evaluated.

MATERIALS AND METHODS

General data

We retrospectively reviewed the results of 54 consecutive OLTx performed from February, 1999 to January, 2002 at the West China Hospital in Sichuan University. There were 44 males and 10 females,their age ranged from 11 to 68 years old (average 38.98 years old). 42 patients had benign hepatic diseases, 29 had cirrhosis due to hepatitis B, 2 had diffusive intrahepatic stones with liver cirrhosis, 1 had alcoholic cirrhosis, 1 had polycystic liver with cirrhosis, 2 had Budd-Chari' s syndrome, 3 had unibobar carolis syndrome, 1 had alcoholic cirrhosis and 3 had alveolar echinococcosis. 12 patients had hepatocellular carcinoma. According to the Child' s classification, 39 of the 54 patients were grade A, 2 were grade B and 13 were grade C. According to the classification of the united network of organ share (UNOS), 14 were grade I, 40 were grade II.

Among them, 14 cases were performed emergency liver transplantation because of acute hepatic failure with severe jundice (total bilirubin 129-676 nmol/L), large volume of ascites (2 500-11 000 ml) or severe coagulopathy, and 4 cases had hepatic enphacelopathy. 23 patients received induction therapy with daclizumab and 31 patients were managed with conventional immunosuppression (non induction). In the control group (non-induction), oral cyclosporin was administered at a dosage of 6-10 mg/kg/day, starting within 24 hours before the operation. Dosage adjustments were based on achieving servm level of CSA between 200 ng and 300 ng/dL. Patients received methylprednisolone during surgery 200 mg intravenously, which was decreased by 40 mg daily over a period of 5 days. On postoperative day 5, patients started to administer prednisone at 20 mg/day. MMF was administered at a dosage of 0.75 g, twice daily.

In the induction group, daclizumab was given 2 mg/kg intravenously within the postoperative 24 hours, cyclosporin, steroid and MMF were identical to the control group.

Tacrolimas was used in patients with CSA toxicity and occasionally as the primary therapy.

Diagnosis of rejection

Rejection was suspected by biochemical evidence of deteriorating liver function and/or clinical signs. Pathological examimation was done in all patients suspected of rejection. The patients in both groups received methyprednisolone every day for the treatment of acute rejection at 500 mg intravenously for 3 days.

Concomitant therapy

The patients in both groups received losec for prophylaxis of stress ulcer (40 mg, intravenously, daily). Cephaloxin was used for postoperative infection prophylaxis. HBV-DNA positive patients were given lamivudine (100 mg, orally, daily). The

patients accompanied by suspected virus infection were treated with acyclovir (800 mg, orally twice daily) or ganciclovir (5 mg/kg , intravenously twice daily).

Liver transplantation

Operative procedures were performed according to standard surgical techniques, and all grafts were perfused with the University of Wisconsin solution[8]. Veno-venous bypass was used in all cases. Buct-to-duct over a T-tube biliary anastomosis or choledochojejunostomy was performed.

Statistical analysis

All the patients received a minimum follow-up for 60 days. Values of the descriptive variables between groups were compared with a nonparainetric wilcoxon rank sum test. Chi-square test or Fisher exact test was used to evaluate the data of the independent groups.

RESULTS

Survival rate

The general data of patients in this study are shown in Table 1, which were similar in two groups.

Table 1 General data in two groups

	Induction group (n=23)	Non-induction group (n=31)
Average age(yr)	39.17(19-68)	38.76(11-57)
Male / female	21 / 2	23 / 8
Indication with		
Liver cirrhosis	15	18
Liver cancer	6	6
Other	2	7
UNOS classification		
Grade I	5	10
Grade II	18	21
Child classification		
Grade A	4	9
Grade B	2	0
Grade C	17	22
Blood type		
ABO-identical	14	23
ABO-compatible	9	8

The 1-, 3-, and 6-month survival rate in patients receiving the induction therapy with daclizumab was 91.3 %, 86.9 % and 86.9 %, respectively *vs* 90.0 %, 83.9 % and 83.9 %, respectively for patients not receiving induction therapy (P>0.05). There was a significant difference between two groups. Six months after the transplantation, 20 of the 23 patients with daclizumab induction were still alive. Deaths occurred in this group were due to the following rensons: complications of intercereberal bleeding (1case), heart failure (1case) and pulmonary infection (1case). In the non induction group, 26 of 31 patients surrived for 6 months. Deaths occurred in this group were due to the following rensons: complications of intracerebral bleeding (1case), pulmonary fungus infection (2case), MOF(1case) and recurrent of cancer (1case).

No patients in either group developed primary dysfunction or died of blood vessel complications.

Complications

Complications especially infection were less in the induction group than those in the non induction group, without significant difference (Table 2).

Table 2 Postoperative complications in two groups

	Induction (n=23)	Non-induction (n=31)
Intraperitoneal bleeding	1	3
Ascite infection	0	1
Stress ulcer bleeding	1	3
Stress ulcer perforation	0	1
Pulmonary infection	5	11
Heart failure	1	3
Biliary leakage	1	3
Chronic oral ulcer	2	3
Bowel fungal infection	1	2
Intracerebral bleeding	1	3
Total	13	32

Rejection

Overall, in the first month, acute rejection occurred less in patients of the daclizumab induction group than that in the non-induction group(21.74 % *vs* 38.71 %, P<0.05). None in either group had acute rejection after the first month and occurred chronic rejection during the first 6 months. None in the induction group and one patient in the noninduction group had OKT_3 added to their immunosuppression for intractable rejection.

Tolerance of daclizumab

None in the daclizumab group required reduction of their dose or cessation of daclizumab for side effects. Daclizumab was well tolerated without apparently clinical or biochemical toxicity.

DISCUSSION

In the recent 30-40 years, with the development of organ transplantation biology, many immunosuppressive agents have been introduced to reduce the incidence of acute rejection[9-12]. The introduction of azathioprine (AZA) was in 1960s by Starzl. Cyclosporin A has (CSA) achieved long-term survival rade since early 1980s[13-17], and occurrenc of tacrolimus (FK506)[18-22] and mycomphenolate mofetil (MMF)[23-27] has prolonged the long-term survival. In spite of these major advances in liver transplantation, there are a number of problems associated with its use. For example, the incidence of acute rejection is still as high as 30-40 %[1].

Thus, the next advance that is required in immunosuppression in recipients with liver transplantation is an agent that can either decrease the rejection without increase of toxicity or decrease toxicity with maintenance of effective immunosuppression.

Daclizumab, a humanized anti-IL-2R a-chain (CD25) antibody, is a new immunosuppressant, its proposed actions include blockade of signaling *via* the high-affinity IL-2R, down-modulation of CD25, depletion of CD25+ cells, and interaction with its FC fragments and FCRs on activated T cells[28, 29]. Induction therapy with daclizumab has been shown effective in preventing acute rejection in kidney transplantation patients[30-32]. Routine use of antibody induction therapy in liver transplantation has not gained widespread acceptance[1].

This study explored the results of adding daclizumab to conventional immunosuppressive therapy in 23 liver recipients with liver transplantation compared to the results in 31 control recipients. It was found that adding daclizumab appeared to be able to decrease the incidence of acute rejection from 38.71 % to 21.74 % without any apparent toxicity or opportunistic infections.

In this study, a different dosing schedule for daclizumab was used. Ciancio *et al* reported their dosing schedule was that daclizumab (1 mg/kg) was given on the day of surgery and every other week for a total of 5 doses[31]. Devin' s schedule

was that the first dose (2 mg/kg) was given before organ engraftment and the second dose (1 mg/kg) was given on postoperative day 5[1]. Both results suggest the efficacy of their dosing schedule. Our dosage of daclizumab was smaller than that in other transplant centers, but we still found that daclizumab appeared to be able to reduce the incidence of acute rejection singnificantly without apparent toxicity and was well tolerated. In conclusion, the induction therapy with single-dose of daclizumab is safe and effective.

Abstract

Hepatocellular carcinoma (HCC) is one of the most common malignancies in the world, responsible for an estimated one million deaths annually. It has a poor prognosis due to its rapid infiltrating growth and complicating liver cirrhosis. Surgical resection, liver transplantation and cryosurgery are considered the best curative options, achieving a high rate of complete response, especially in patients with small HCC and good residual liver function. In nonsurgery, regional interventional therapies have led to a major breakthrough in the management of unresectable HCC, which include transarterial chemoembolization (TACE), percutaneous ethanol injection (PEI), radiofrequency ablation (RFA), microwave coagulation therapy (MCT), laser-induced thermotherapy (LITT), etc. As a result of the technical development of locoregional approaches for HCC during the recent decades, the range of combined interventional therapies has been continuously extended. Most combined multimodal interventional therapies reveal their enormous advantages as compared with any single therapeutic regimen alone, and play more important roles in treating unresectable HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a highly malignant tumour with a very high morbidity and mortality, carrying a poor prognosis and presenting considerable management[1]. The treatment of patients with HCC has been evolving in the past years.

Liver resection remains a good treatment for HCC in patients with cirrhosis[2]. The best results are obtained in patients with small, non-invasive tumours[3]. However, only a small number of patients are suitable for curative resection due to many factors such as multicentric tumours, extrahepatic metastases, early vascular invasion, coexisting advanced liver cirrhosis and comorbidities[4,5]. Liver transplantation seems to be the choice for monofocal HCC less than 5 cm in diameter and in selected cases of plurifocal HCC[6], but may be limited by availability of donor organs and a long waiting time[7-9]. Cryosurgery destroys neoplastic tissue by application of cold and affords a better chance of cure because of predictable necrosis even for HCC larger than 3 cm, but its use is limited by a high complication rate[10].

Local methods for tumour ablation, which include transarterial chemoembolization (TACE), percutaneous ethanol injection (PEI), radiofrequency ablation (RFA), microwave coagulation therapy (MCT), laser-induced thermotherapy (LITT), are promising extensions of tumour therapy, especially in patients with limited liver function, unresectable tumours, or multifocal tumours[11]. Since TACE was introduced as a palliative treatment in patients with unresectable HCC, it has become one of the most common forms of interventional therapy[12-15]. TACE has been shown to reduce systemic toxicity and increase local effects and thus improve the therapeutic results[14, 16]. However, its perceived benefit for survival has not been substantiated in randomized trials, presumably because its anticancer effect is offset by its adverse effect on liver function. Its therapeutic effect is also limited by the lack of appropriate and reliable embolic agents and when the tumour is infiltrative in nature or is hypovascular, too large or too small[17-19]. PEI is widely used with excellent results for small, encapsulated tumours in livers with less than three HCCs, but it is not suitable for patients having coagulopathy or ascites[19]. While RFA results in a higher rate of complete necrosis and requires fewer treatment sessions than PEI, the complication rate is higher with RFA than with PEI[20]. MCT under local anaesthesia is a minimally invasive and effective therapy when carried out on a single occasion to treat HCC located near the liver surface[21]. MCT may be superior to PEI for the local control of moderately or poorly differentiated small HCC[22, 23]. MR-guided LITT is another local effective therapy with low morbidity in malignant liver tumours with a maximum quantity of 5 and a size of < or = 5 cm[24,25], but local recurrence can occur even in small HCC, while this drawback is infrequent[26]. Biotherapy will play a certain role in the treatment of HCC, however, the results are still controversial[27].

It is well known that improving the overall therapeutic effects of liver cancer depends on the combined therapies. The purpose of combined interventional therapies for HCC is to give full play to the merits of various therapeutic schemes, to overcome their shortcomings and to get combined effects that are impossible to obtain from any single therapeutic regimen. The general principles of combined interventional therapies for HCC are to destroy the tumour as completely as possible, to increase their therapeutic efficiencies but not the side effects and complications, to keep the liver function and immunity of patients in a better condition, and to choose the suitable combined therapeutic plan individually. In this paper, the current status of combined interventional therapies for unresectable HCC are reviewed.

COMBINATION OF TACE AND SURGERY

The role of pre- and postoperative transarterial chemoembolization (TACE)

Zhang *et al* suggested that TACE could be performed 2-4 times preoperatively within 6 months according to tumour size, range, location, hepatic function, and TACE effect. It was reported

the 5-year disease-free survival rate was 56.8 % with a mean time of 90.1 months and the 1-, 3- and 5- year survival rates were 79.7 %, 65 % and 56 %, respectively[28,29]. Gerunda *et al* suggested that TACE was able to improve HCC and significantly reduce the incidence of early and overall HCC recurrence and related death after resection[30]. It has been confirmed that pre-operative TACE can necrotize the main lesion and temporarily arrest portal diffusion of neoplastic cells by acting on microvascular infiltration[31]. Nakano *et al* recommended that preoperative TACE should be performed in HCC patients only when LHL15 (the ratio of liver to heart-plus-liver radioactivity of Tc-GSA 15 minutes after injection) was less than 0.91[32]. However, Huang *et al* and Wu *et al* suggested that preoperative TACE for resectable large HCC should be avoided because it could not provide complete necrosis in large tumours and could result in delayed surgery and difficulty in the treatment of recurrent lesions, without any benefit[33,34]. It is concluded that TACE of HCC prior to liver transplantation has no influence on the recurrent rate[35]. However, a more detailed study of this treatment for HCC has not yet been reported. Clavien *et al* demonstrated that cryosurgery after TACE was feasible for cirrhotic livers with HCC and could increase the cure rate of large tumours. TACE might reduce the risk of hemorrhage after cryosurgery, but could also increase the risk of hepatic failure in patients with poor hepatic function. The 5-year survival rate could be raised to 79 %[36].

The results of Lin *et al* indicate that postoperative TACE is useful for prevention and treatment of HCC. It helps improve survival of surgically treated HCC patients[37]. Randomized trials to accurately define the position of this combined technique are needed.

COMBINATION OF TACE AND PEI

Percutaneous ethanol injection (PEI) is widely used with excellent results for small, encapsulated tumours in livers with less than three HCCs[19,38-40]. Ethanol in PEI acts by diffusing within the cells, which causes immediate dehydration of cytoplasmic proteins with consequent coagulation necrosis followed by fibrosis, and by entering the circulation, which induces necrosis of endothelial cells and platelet aggregation with consequent thrombosis of small vessels followed by ischemia of the neoplastic tissues. Advantages for using PEI include[41-43]: no remarkable damage to the remaining parenchyma, relative safety, easy repetition when new lesions appear as in the majority of patients followed for 5 years, application anywhere due to its low cost and easy operation, and fairly good long-term results.

PEI can be carried out either in patients with HCC who have poor hepatic function or in elderly patients (age > or = 70 years)[40,44]. Long-term survival rates of PEI-treated patients are similar to those obtained in matched patients submitted to partial hepatectomy[38, 40, 42]. Livraghi *et al* reported in 746 HCCs with cirrhosis treated by PEI, the 5-year survival rates for single HCC < 5 cm were 47 % for Child A, 29 % for Child B and 0 % for Child C, respectively[45].

PEI has been performed in many hospitals and is now categorized as a potentially curative procedure for patients with HCC. However, the long-term prognosis remains disappointed because of the high recurrent rate among patients with HCC after PEI, especially in those with high levels of alphafetoprotein (AFP) and those without peritumoral capsule or with large lesions and cirrhosis[39,44]. In fact, histological examination of HCC lesions after PEI reveals that viable tissue remains in portions isolated by septa or in extracapsular or intracapsular invasion. It has been demonstrated that the high vascularity of HCC promotes an early wash-out of injected ethanol, so that PEI for patients with hypervascular tumours may be less effective than for patients with hypovascular tumours[46,47].

Combined TACE and PEI is a therapeutic option that has been recently proposed to overcome the weakness of each of the two procedures in the treatment of large HCC[48-50]. The rationale for combination of the two treatments relies on the fact that after TACE tumour consistency is markedly decreased and intratumoral septa are usually disrupted, as a result of the necrotic phenomena induced by the procedure. These histopathologic changes make subsequent treatment with PEI easier, as they provide enhanced ethanol diffusion within the tumour. Consequently, higher doses of ethanol than those used in conventional PEI can be injected, enabling complete and homogeneous perfusion even of large lesions. Moreover, treatment with PEI is facilitated by the TACE-derived fibrous wall around the lesion, which favours a better retention of the injected ethanol within the tumour[46,50,51]. The 5-year survival rate was 50 % in the TACE/PEI group and was 22 % in the TACE group[52]. A favourable outcome of this combined therapy can be expected in patients with solitary and encapsulated HCC (low Okuda stage, AFP level <100 ng/ml), compensatory cirrhosis, and absence of portal vein thrombosis[42,49,51,53].

COMBINATION OF TACE AND RFA

Radiofrequency thermal ablation (RFA) is a minimally invasive and safe technique for the nonsurgical treatment of HCC. Similar to other ablation techniques, the treatment strategy depends on several factors, such as the patient' s clinical status, the stage of liver cirrhosis and of HCC. RFA can be performed percutaneously, laparoscopically or after laparotomy[54]. RFA achieves complete tumour necrosis for small HCC (< or = 3.5 cm in diameter) with fewer treatment sessions compared with PEI, and can also create large volumes of tumour necrosis in a shorter period of time than either laser or microwave therapy. Curley and Izzo suggested that RFA could be performed for unresectable hepatic malignancies less than 6.0 cm in diameter[55]. In addition, equipments used for RFA were less expensive than either laser or microwave equipments[56]. RFA provides local control of advanced liver tumours with low recurrence and acceptable morbidity[57-62]. However, the complication rate is higher with RFA than with PEI[20].

The combination of TACE and RFA induces larger coagulation necrosis areas than RFA without any possibility of revascularization[63-66]. RFA performed after TACE effectively treats HCC larger than those suitable for segmental TACE or RFA application alone[63]. Bloomston *et al* reported that one-year survival was greater in patients undergoing TACE and RFA than TACE alone (100 % *vs* 67 %, P=0.04). Mean survival was longer after TACE with RFA compared with TACE alone (25.3 months +/- 15.9 *vs*. 11.4 months +/- 7.3, P<0.05). No patients suffered significant complications in that study[66]. For multifocal recurrence, RFA can be useful as a complementary technique for lesions not completely treated by TACE[67].

COMBINATION OF TACE AND MCT

It is well known that percutaneous microwave coagulation therapy (MCT) under local anesthesia is a palliative and effective therapy when carried out on a single occasion to treat HCC located near the liver surface, and it can be safely performed under direct visual guidance[21]. MCT may be superior to PEI for the local control of moderately or poorly differentiated small HCC[22, 23]. MCT is also superior to PEI for treating patients with HCC < or = 15 mm in diameter. In such patients with well-differentiated HCC, PEI is as effective

as MCT[68].

The combined therapy of MCT applied within 1-2 days of TACE can effectively treat HCC >2.0 cm but <3.0 cm in dimension. A few microwave electrode insertions and microwave irradiations are needed[69]. Ishikawa *et al* suggested that MCT destroyed the peripheral part of the tumour that might remain viable after TAE, but combination therapy with transarterial embolization (TAE) was preferable, especially when a viable part existed within tumours[70]. However, larger scale clinical trials are required to define the role of this combined therapy in the strategy of oncology.

COMBINATION OF TACE AND LITT

Patients with larger and more than two HCC nodules have a relatively high incidence of recurrence of HCC in the remnant liver, even when coagulation by PEI, MCT or RFA is complete[71-73].

Laser-induced thermotherapy (LITT) is another minimally invasive and attractive method for destroying relatively larger tumours within solid organs by causing carbonization and vaporization in tissue[24,72-75]. MR-guided LITT is a local effective therapy with low morbidity for malignant liver tumours with a maximum quantity of 5 and a size of < or = 5 cm[24,25]. LITT may be also equivalent to limited hepatic resection and may influence long-term survival, achieving results comparable to those of segmentectomies, but local recurrence can occur even in small HCC, while this drawback is infrequent[26].

The rationale for combination of TACE and LITT is based on the fact that LITT can reduce the volume of viable tissue and improve the lesion within the range of TACE effectiveness. Moreover, in the case of multiple lesions in the same patient, it is possible to treat the small lesions with LITT alone and to reduce the number of hepatic segments requiring TACE[74]. Pacella *et al* achieved complete response with a single segmental TACE session in 21 (70 %) of the 30 patients and reported that the 1-, 2-, and 3-year local recurrent rate was 7 % in large HCC, respectively. Complete tumour necrosis was achieved in all 15 (100 %) small HCCs. The 1-, 2-, and 3-year cumulative survival rates were 92 %, 68 %, and 40 %, respectively. The mean number of sessions needed to control large HCC was 4.2[74]. LITT seems to be more beneficial and advisable in combination with TACE for treating patients with relatively larger and multiple HCCs.

COMBINATION OF TACE AND RADIATION

A number of studies have shown the experimental and clinical therapeutic effectiveness of combination of external/interstitial radiation and TACE[76-82]. Delivering the highest irradiation dose within the tolerance of the liver is the key to improve the long-term effect.

Intra-arterial injection of radioactive lipiodol has shown promising results in patients with HCC and portal obstruction. Raoul *et al*. reported that overall survival rates at 6 months, 1, 2, 3, and 4 years were 69 %, 38 %, 22 %, 14 % and 10 %, in the ^{131}I-labeled lipiodol group and 66 %, 42 %, 22 %, 3 %, and 0 % in the chemoembolization group, respectively. In terms of patient survival and tumor response, radioactive ^{131}I-labeled lipiodol and chemoembolization were equally effective in the treatment of HCC, but tolerance to ^{131}I-labeled lipiodol was significantly better[83].

Guo *et al* and Tazawa *et al* regarded the combination of TACE and radiotherapy as an alternative and permissible treatment for large unresectable HCC, and it might be useful to reverse portal vein tumor thrombi in patients with good hepatic function reserve[79, 80]. It was reported the cumulative survival rates of 1, 3 and 5 years were 59.4 %, 28.4 % and 15. 8 %, respectively[80]. Cheng *et al* demonstrated that this combined therapy was associated with better control of HCC than radiation given alone, probably due to the selection of patients with favorable prognosis for the combined treatment[82]. However, it has been reported that the survival of patients with combined TACE and radiotherapy was similar to that with TACE as the only treatment, while a significant portion of the patients treated with radiotherapy developed extrahepatic metastasis[81]. In another study, Yasuda *et al* also confirmed that radiotherapy combined with TAE and PEI did not clearly show improvement of the survival. However, it could effectively control large HCC with minimal toxicity[84].

Whether this therapeutic method can really increase the survival rate of patients suffering from liver cancer, should be determined by further prospective and comparative studies.

COMBINATION OF TACE AND IMMUNOTHERAPY

In the past few years, combined targeting locoregional immunochemotherapy has been reported with encouraging results[85, 86].

OK-432, a biological response modifier (BRM) derived from the weakly virulent Su strain of *Streptococcus pyogenes*, has been applied in combination with locoregional chemotherapy or transarterial embolization for treating HCC in clinic. OK-432 can augment the anti-tumour effect of anticancer agents (cisplatin/mitomycin), because OK-432 itself has a direct cytotoxic and cytostatic activity against tumour cells and inhibits DNA and RNA synthesis in tumour cells. Chemotherapy can also increase the susceptibility of tumour cells to cytotoxic effector cells including lymphocytes, macrophages and neutrophils activated by OK-432 through direct damage or modulation of surface antigens by chemotherapy[87]. In addition, anticancer agents can eliminate the suppressor cells or suppressor factors in the blood or effusion, resulting in augmented anticancer activity of OK-432-activated immunopotentiating cells, especially T-cells[88, 89].

Based on the results of histologic examination in Japan, transarterial immunoembolization (TIE) seems to be more effective than conventional TAE against extracapsular invasion and intrahepatic metastasis in clinic. Data on disease-free survival and recurrence site suggest TIE may be a useful preoperative treatment[90,91]. Such combined transarterial immuno-chemoembolization merits further clinical investigation in patients with unresectable HCC and immunoincompetence.

Other BRMs such as tumor necrosis factor (TNF), cytotoxic T lymphocyte (CTL), tumor infiltrating lymphocyte (TIL) have not been used in TACE in clinic up to now.

COMBINATION OF TACE AND GENE THERAPY

Gene therapy is one of the more promising approaches for patients with advanced liver tumour. Experimental and clinical studies have been reported using cytokine genes (tumor necrosis factor, interleukin-2, interferon), suicide and p53 genes, retrovirus, adenovirus and Epstein-barr virus as vector, AFP enhancer, intraarterial administration, etc.[92-99].

Adenovirus-mediated gene therapy of experimental HCC is hindered by its low transduction efficacy *in vivo*[92]. Gene therapy for cancer requires efficient, selective gene transfer to cancer cells. The delivery of anticancer agents and iodized oil esters as embolic agents through hepatic artery is known as TACE[93]. Shiba *et al* speculated that genes might be efficiently and selectively transferred for HCC using iodized oil esters because these esters might remain together with a genetic vector within HCC selectively[93]. Clinical trials have begun to evaluate the efficacy of gene transfer of cytotoxic genes to metastatic

colorectal tumors through hepatic artery infusion[92]. The efficiency of trans-arterial gene delivery has also been compared to that of intra-tumoral injection. The results of Seol *et al* indicate that gene expression in patients with liver tumour can be enhanced by trans-arterial delivery of the liposome-DNA complex[94].

Combination of TACE and gene therapy leads to a higher transfer rate and higher concentration of drugs without major side-effects and remains an attractive field for clinical application[92,95,96].

COMBINATION OF TACE AND ANTIANGIOGENESIS THERAPY

Development of tumor angiogenesis-targeting agents is often referred to as a new concept in anticancer therapy, and antiangiogenic agents have the following clinical implications. They may overcome drug resistance in solid tumours. Identification of the angiogenic factors in serum or microvessels in tumors can allow the efficacy of the new agents to be quantified. Antiangiogenic agents have low toxicity due to their selective effect on tumour vasculature. Their combination with anticancer agents may potentiate their anticancer effects[100-104]. For the best clinical results, anti-angiogenic therapy should be used in combination with other adjuvant therapies[105-109].

TNP-470 is the first angio-inhibitor which has entered into phase III clinical trial. TNP-470 (AGM-1470) is a fumagillin analogue which inhibits proliferation and migration of endothelial cells and capillary vessel formation at cytostatic but not cytotoxic concentrations. It is believed that ischaemic hypoxia and necrosis induced by TACE stimulate angiogenesis in the residual viable HCC[110]. TNP-470 inhibits the proliferation of new microvascular channels and consequently the development of multiple arterial collaterals[111]. TNP-470 may be particularly effective in inhibiting extrahepatic collaterals and may make it possible to perform TAE repeatedly[112].

Combination treatment of animals showed that TNP-470 potentiated the anticancer effects of some cytotoxic and biological agents[113], but the terminal plasma half-life of TNP-470 was short and the drug was rapidly cleared from the circulation after a single 1-hour infusion[114]. The use of embolic substances (micropheres and medium-chain triglyceride solution), in which TNP-470 is very stable, prolonged retention of the anticancer drug at the tumour site, and augmented the efficacy of anticancer therapy[115]. TAE combined with TNP-470 may enhance the anticancer effect of TAE alone in the treatment of HCC without severe side effects on the liver or body weight gain[116]. This anticancer effect can be enhanced by coadministration of doxorubicin hydrochloride aqueous solution[117].

By combining antiangiogenic agents with TACE used in the treatment of HCC, the limitations of each therapeutic approach will be overcome, leading to enhanced efficacy with diminished toxicity. However, the optimal strategy for the use, monitoring, and validation of antiangiogenic agents in clinic remains unclear.

COMBINATION OF TACE AND TRADITIONAL CHINESE MEDICINAL THERAPY

Traditional Chinese medicinal therapy has gained wide acceptance as a safe, palliative and effective treatment even in patients with large HCC and cirrhosis in China.

Bletilla striata (BS) is a common Chinese medicinal herb and is usually used as an embolic material in TACE for HCC. Its compositions are mucilage, starch, and a little volatile oil[118]. The mechanisms of embolization by BS are attributable to the following factors such as non-absorbent property, mechanical obstruction, effect on coagulative and anticoagulative systems and secondary obstruction due to the injury to wall of blood vessels[119, 120]. Zheng *et al* have confirmed that BS powder has an adherent function and can diffuse slowly in blood flow, leading to mechanical blockade of vessels. The rough surface of BS powder can disintegrate local blood platelets and its mucilage component can make locked erythrocytes agglutinate, thus shortening the clotting time and prothrombin time and causing formation of secondary thrombi[118]. It has also been hypothesized that BS can slowly diffuse into the liver parenchyma around the tumour in colloidal forms, leading to prolonged anticancer effect and inhibition of collateralisation and metastasis of tumour[121]. Compared with gelfoam embolus, BS has the following characteristics. It can produce extensive and permanent vascular embolization, while it cannot be absorbed by body tissue. After embolization, tumour necrosis and shrinkage are significant with less collateral circulation that forms later. The mucilage component of BS is a wide-spectrum anticancer element that may inhibit tumor occurrence and development[118,121]. The 1-, 2- and 3-year survival rates were 44.9 %, 33.6 % and 33.6 % in BS group, and were 48.9 %, 31.1 % and 16.0 % in gelfoam group, suggesting that BS is superior to gelfoam as an embolizing agent, and the transarterial administration of BS may provide a beneficial therapeutic modality for HCC[122].

CONCLUSION

In summary, despite the number of treatment options, HCC usually has a poor prognosis and is one of the malignancies to be cured. The range of treatment options is fairly wide, and the choice is not always easy, given the number of variables to be assessed.

Combined interventional therapies are superior to any single therapy for improving the prognosis and survival of patients with HCC. More multi-center randomized experimental and clinical studies are required to define the indications and role of these combined modalities for treating unresectable HCC.

Abstract

AIM: To identify esophageal cancer related gene2 (ECRG2) associated proteins and their possible interactions with ECRG2 gene.

METHODS: In the yeast forward two-hybrid system, ECRG2 was fused with the DNA-binding domain (DBD) of Gal4 and human fetal liver cDNA library was fused with the transcriptional activation domain (AD) of Gal4. We performed a high-stringency scale procedure to screen ECRG2 against human fetal liver cDNA library and characterized positives by sequence analysis.

RESULTS: We found the following 9 putatively associated proteins. They were metallothionein2A, metallothionein1H, metallothionein1G, ferritin, erythrocyte membrane protein band4.2, mitochondrial ribosomal protein S12, hypothetical protein FLJ10101, and a novel gene whose cDNA was found to have no strong homology to any other previously characterized gene whose DDBJ/EMBL/GenBank accession number is AF422192 mapped to human chromosome 14q31.

CONCLUSION: MT, a potential interaction partner for ECRG2, might be involved in the regulation of cell proliferation and apoptosis, and in various physiological processes. Determination of a reliability score for each single protein-protein interaction, especially interaction of ECRG2 and MT, permits the assignment of ECRG2 and unannotated proteins to biological pathways. A further understanding of the association between ECRG2 and MT should facilitate the functions of ECRG2 gene.

INTRODUCTION

Esophageal cancer (EC) is one of the most common malignancies worldwide with the highest mortality and prevalencet in certain areas of China with a higher incidence[1-2]. It has been found some of tumor suppressor genes and oncogenes are involved in the EC initiation and development[3, 4]. However, so far no gene directly related to EC has been identified. By comparing the differential gene expression between normal esophageal epithelia and esophageal cancer using the technique of mRNA differential display, we have cloned a new gene ECRG2 (GenBank Accession No. AF268198) whose expression was found to be down-regulated in some malignant tissues such as esophageal carcinoma tissue, colon cancer and brain tumor tissues, and most common in esophageal cancer tissues. Although SMART online (http://www.smart.embl-heidelberg.de) has shown that ECRG2 gene contains a characteristic KAZAL-type conserved domain and belongs to the KAZAL-type related serine proteinase inhibitor family, little has been known about its function in normal cellur activities, other than suppressing neoplasia. In order to further reveal its biological roles, we therefore tried to identify ECRG2 associated proteins in the present study by the GAL4-based yeast two-hybrid system using the full-length ECRG2 cDNA as a bait to screen the human fetal liver cDNA library.

MATERIALS AND METHODS

Yeast strains

Matchmaker GAL4 two-hybrid system 3 and vector pACT2 containing the human fetal liver cDNA library were obtained from Clontech. Yeast strain AH109 (MATa, trp 1-901, leu2-3, 112, ura 3-52, his3-200, gal4△, gal80△, LYS2: $GAL1_{UAS}$-$GAL1_{TATA}$-HIS3, $GAL2_{UAS}$-$GAL2_{TATA}$-ADE2, URA3: $MEL1_{UAS}$-$MEL1_{TATA}$-LacZ) was used to screen the library and to verify protein-protein interactions, which could eliminate false positives by using three reporters-ADE2, HIS3, and MEL1 (or LacZ)-under the control of GAL4 upstream activating sequences (UASs) and TATA boxes. Among these reporters ADE2 provided strong nutrition selection, HIS3 gave a selection reducing false positive incidence, and MEL1 or LacZ encoding β-galactosidase could be assayed on X-α-gal indicator plates.

Plasmid constructs

Vector pGBkT7 expressing proteins were fused with amino acids 1-147 of the GAL4 DNA binding domain (DNA-BD), pGADT7 expressing proteins were fused with amino acids 768-881 of the GAL4 activation domain (AD). The control plasmids pGBKT7-53, pGBKT7-lam, pGADT7-T, pCL1 were from Clontech. Plasmid pGBKT7-ECRG2 encoding full-length (85 amino acids) ECRG2 gene fused in frame with the GAL4 DNA binding domain was constructed by inserting the PCR-generated fragment into the EcoRI and BamHI sites of pGBKT7. Plasmid pGADT7-ECRG2 encoding full-length ECRG2 gene fused in frame with GAL4 activation domain was constructed by inserting the PCR-generated fragment into the EcoRI and BamHI sites of pGADT7.

Library tittering and amplification

For tittering library, an aliquot of the library plasmid was thawed and mixed on ice by gentle vortexing. Then 1μl of library plasmid was transferred to 1 ml of LB broth, which was mixed and named dilution A ($1:10^3$). By the same way,

another library plasmid diluent dilution B ($1:10^6$) was obtained. The prewarmed LB/amp plates were prepared by inoculating them in 1 μl of dilution A mixed with 50 μl of LB broth, or 50 μl and 100 μl of dilution B where respectively incubated on LB/amp plates at 30 ℃ for 48 h. The library titer was calculated as follows: Dilution A: counted colonies$\times10^3\times10^3$=cfu/ml, Dilution B: (counted colonies/plating volume)$\times10^3\times10^3\times10^3$ =cfu/ml. For the library amplification, LB/amp plates were inoculated with the library plasmids at such a high density that the resulting colonies could be easily confluent (-20 000-40 000 cfu per 150-mm plate) and reach at least 2-3 times as the library original plasmid number to ensure the better screening results. After incubated at 30 ℃ for 48 h, colonies were scraped, mixed with adequate volume of LB broth and shake-cultured in a flask at 30 ℃ for 2 h. One-third of the library culture was set aside for plasmid preparation.

Verification of activation of reporter gene by pGBKT7-ECRG2

Plasmid pGBKT7-ECRG2 was independently transformed into strain AH109. The transformants were assayed for β-galactosidase activity by selecting them on SD/-Trp/-Leu/X-α-Gal. Positive control, pCL1, was performed in parallel.

Library transformation and screening

Plasmid pGBkT7-ECRG2 was used as a bait in two-hybrid screening of human fetal liver cDNA libraries by MATCHMAKER Two-Hybrid System 3 protocol (Clontech). The yeast strain AH109 was sequencely transformed with pGBKT7-ECRG2 and a human fetal liver cDNA library in the pACT2 vector (Clontech) was obtained by the lithium acetate method. Transformants expressing both the bait and interacting prey proteins were selected on SD/-Trp/-Leu/-His/-Ade and incubated at 30 ℃ for 5-7 days. β-galactosidase activity was tested using the filter lift assay to identify the positive colones.

Isolating plasmid DNA from putatively positive yeast clones, rescuing AD/library plasmids and retesting protein interaction in yeast

Approximately 3×10^6 colonies were screened and 146 positive clones were identified. cDNA inserts of the positive clones were amplified by PCR using primers complementary to the sequence of pACT2 vector (5' T ACC ACT ACA ATG GAT3' and 5' GTG AAC TTG CGG GGT TTT TCA GTA TCT ACG A3'). Subsequently, pACT2-cDNA constructs were isolated from positive yeast colonies, as recommended by the supplier, transformed into super-competent *E. coli* DH5α by electroporation, grown under selection, re-isolated and analyzed by restriction digests. The uniquely purified constructs were then re-tested against the original pGBKT7-ECRG2 bait construct. To ensure the interactions were specific, the positive clones were also tested against an irrelevant bait protein laminC and grown on SD/-Ade/-His/-Leu/-Trp/X-α-Gal to test the specificity of interactions.

Sequence Ad/library inserts and blast online (http://www.ncbi.nlm.nih.gov/blast)

The positive inserts were sequenced and analyzed by comparison to the GenBank sequence data bank.

RESULTS

Library tittering and amplification

The titer of human fetal liver cDNA library was 3.17×10^9cfu/ml counted by dilution method. The number of separate colonies was 1.05×10^7. We amplified it in 150 mm×500 plates, about 1×10^8 (3.5 μl original cDNA library) colonies and the library plasmids were successfully isolated.

Verification of activation reporter genes by pGBKT7-ECRG2

Plasmid pGBKT7-ECRG2 was independently transformed into AH109. After β-galactosidase activity assay, the AH109 transformed pGBKT7-ECRG2 did not appear blue colonies, but the positive control, pCL1, appeared as is shown in Figure 1. It was verified that pGBKT7-ECRG2 construct did not activate reporter genes and was suitable for the yeast two-hybrid system (Figure 1).

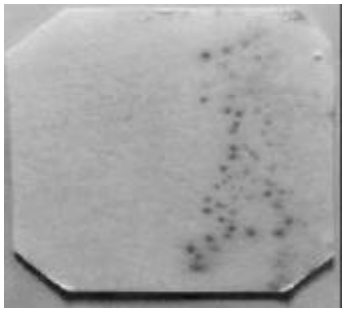

Figure 1 Colony-lift filter assay for β-galactosidase activity. Left: β-galactosidase activity of AH109 transformed with pGBKT7-ECRG2. Right: β-galactosidase activity of AH109 transformed with pCL1 (positive control). The results showed that pCL1 could activate reporter genes, but pGBKT7-ECRG2 could not.

Yeast two-hybrid screen of cellular proteins interacting with ECRG2 protein

To identify proteins associated with the ECRG2 protein, ECRG2's ORF was synthesized as a translational fusion of a DNA-binding domain (DBD) and used as the bait for screening of a human fetal liver yeast two-hybrid cDNA library. Of 3×10^6 transformants screened, 146 clones grew in the absence of tryptophan, lencine, histidine, adenine and expressed β-galactosidase activity. pACT2/cDNA plasmids were successfully isolated and duplicates were eliminated by HaeIII digestion (Figure 2). After elimination, 26 uniquely positive clones were further retested for specificity of β-galactosidase expression. After retransformation, 9 independent positive clones were identified and sequenced (Table 1).

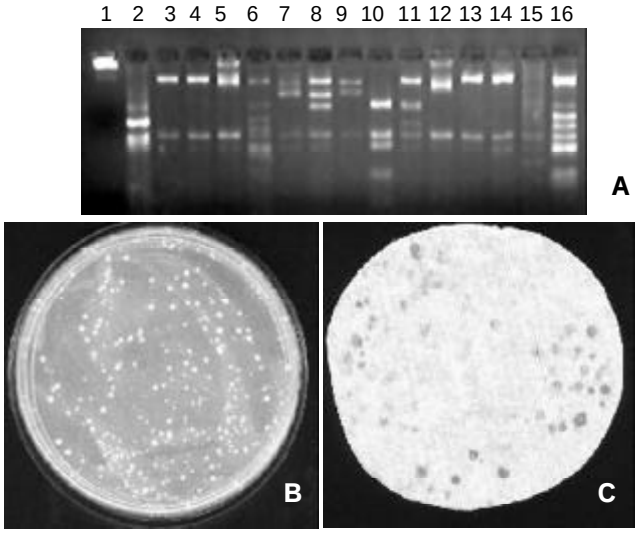

Figure 2 Positive colonies screened by yeast two-hybrid system using full-length cDNA of ECRG2 as baits. A: PCR products of positive clones digested with HaeIII restriction enzyme. Lane 1: λDNA/EcoRI+HindIII Marker, Lanes 2-16: positive colonies, B: $Trp^+/Leu^+/His^+/Ade^+$ positive clone growing on the $SD/Trp^-/Leu^-/His^-/Ade^-$ plate, C: colony-lift filter assay for β-galactosidase activity.

Table 1 Yeast two-hybrid screening using ECRG2 as baits

Yeast transformation	Transformation efficiency[a] (cfu / μg library)	Transformation yield[b]	His$^+$,Ade$^+$, Laz$^+$[c]	True positives
1	2.46×10^5	9×10^5	48	3
2	3.17×10^5	1.3×10^6	63	4
3	2.32×10^5	8×10^5	35	2
Total		3×10^6	146	9

[a]: Transformation efficiency (transformants / μg) = transformation yield ÷ amount of library DNA in μg). [b]: Transformation yield (total transformants) = [(colonies / plate) ÷ (volume / plate)] ×[(volume of total reaction) ÷ (dilution factor)]. [c]: β-galactosidase activity of the positive colonies assayed by β-galactosidase filter lift assay.

Bioinformatics

Blast online (http://www.ncbi.nlm.nih.gov/blast) showed the genes identified by the yeast two-hybrid approach were metallothionein 2A(MT2A), metallothionein 1H, metallothionein 1G, ferritin, erythrocyte membrane protein band 4.2, hemoglobin, mitochondrial ribosomal protein S12, hypothetical protein FLJ10101, and a novel gene whose cDNA was found to have no strong homology to any other previously characterized gene whose GenBank accession No.is AF422192.

DISCUSSION

Protein-protein interactions played important roles in almost all events that took place in a cell[6]. Because proteins often assembled into large complexes to perform discrete activities, the characterization of the interaction pattern of a protein could provide considerable assistance in the elucidation of the functions of that protein[7]. The availability of complete genome sequences now permits the development of tools for functional biology on a proteomic scale. Among those, the yeast two-hybrid system is the choice to detect protein-protein interactions[8,9]. The ECRG2 gene is a novel candidate of tumor suppressor gene identified from human esophageal carcinoma. Identifying the function of ECRG2 gene product may provide opportunities to elucidate the esophageal cancer mechanisms and its role in tumor development and progression. The yeast-two-hybrid approach could find novel partners for known function proteins and identify the function of a novel protein by identifying well-characterized interacting partners[10]. So, we searched for associated proteins with a yeast-two-hybrid system using the ECRG2 cDNA fragment as baits.

Our results showed that ECRG2 gene did not activate transcription by itself and was suitable for yeast two-hybrid. On screening a human fetal liver cDNA library, we identified 9 putative clones as associated proteins, which included metallothionein 2A (MT2A), metallothionein 1H, metallothionein 1G. Metallothioneins (MTs) are a family of low molecular weight, cysteine-rich, metal ion-binding proteins which are wildly distributed in various species. MTs were thought to be involved in heavy-metal detoxification, intracellular trace elements storage and scavenging free radicals. Recently, emerging data suggested that MTs had a close relationship with tumors. They might play important roles in carcinogenic and apoptotic process and differentiation of tumor cells[11-23]. In addition, MTs were attributed to affording tumor cell resistance to some important chemotherpeutic agents[24]. Using immunohistochemical-staining method, MTs have been localized intensively in various types of human tumors in organs and tissues such as skin, kidneys, prostate, tests, gallbladder, colon, breast and endometrium[25-34]. Since

human metallothioneins are closely linked with tumor, it is possible for us to understand the cellular functions of the ECRG2 protein through its linkage to MT2A. The other associated clone is a novel gene whose cDNA was found to have no strong homology to any other previously characterized gene whose GenBank Accession No.is AF422192. There are also 5 clones including ferritin, erythrocyte membrane protein band 4.2, hemoglobin, mitochondrial ribosomal protein S12 and hypothetical protein FLJ10101. Determination of a reliability score for each single protein-protein interaction, especially interaction of ECRG2 and MTs, permits the assignment of ECRG2 and unannotated proteins to biological pathways. A further understanding of the association between ECRG2 and MT should facilitate the functions of ECRG2 gene.

Abstract

AIM: To investigate the special Fourier transform infrared spectroscopy (FT-IR) spectra in normal and cancerous tissues of esophagus.

METHODS: Twenty-seven pairs of normal and cancerous tissues of esophagus were studied by using FT-IR and the special spectra characteristics were analyzed in different tissues.

RESULTS: Different spectra were found in normal and cancerous tissues. The peak at 1 550/cm was weak and wide in cancerous tissues but strong and high in normal tissues.The ratio of *I* 1 647/*I* 1 550 was 2.0 in normal tissues and 2.36 in cancerous tissues ($P<0.05$). The ratio of *I* 1 550/*I* 1 080 was 4.5 in normal tissues and 3.4 in cancerous tissues ($P<0.01$). The peak at 1453 /cm was higher than at 1 402/cm in normal tissue and lower than at 1 402/cm in cancerous tissues.

CONCLUSION: The results indicate that FTIR may be used in clinical diagnosis.

INTRODUCTION

Esophageal carcinoma is still one of the malignant tumors that challenges clinical oncologists. In China, there are about 1 300 000 new patients diagnosed as esophageal carcinoma each year[1]. At present, the best way to diagnose the disease is fiber endoscopy, which can not only look steadily at the lesion to get information of the size, location, ect, but also obtain the tissues of suspected portions for pathological examinations. Although endoscopy has been widely used in diagnosis and differential diagnosis of esophageal diseases, about 20 percent of esophageal cancer in early stage can not be detected and diagnosed by this technology because it is limited by the experience of the operator and affected by the atypical clinical manifestations of the disease[2].

Thus, it is the very goal to develop an accurate, quick, convenient, and inexpensive method for detecting early cancer of esophagus at molecular level. With the development of vibrational spectroscopic technologies, their application in cancer research has been reported. Among these technologies, Fourier transform infrared spectroscopy (FT-IR) has been extensively employed in the fields of biology and chemical engineering to get information about the structural and chemical/physical properties at molecular level. Recently, some researches about the application of FT-IR in cancer have been reported[3-8]. In fact, the results of our previous research have already shown its advantages in clinical and scientific applications[9-14]. But the study on the spectra of esophageal tissues is still preliminary. In the present work, we examined the cancerous and normal tissues of esophagus with FT-IR in order to put some light on the combination of FT-IR and endoscopy.

MATERIALS AND METHODS

Tissue preparation

Twenty-seven fresh tissues of esophageal cancer were obtained from the First Hospital of Xi' an Jiaotong University. The tissues were washed with normal saline solution and sampled immediately after removed during the operation. Two pieces of the tissues about 1 cm in diameter were taken, one was cut off from the center of the lesion and the other was from the distant edge of the removed tissues. Each tissue was divided into two equal parts, one was frozen with liquid nitrogen and the other was fixed with 10 % formalin, embedded in paraffin and stained with hematoxylin and eosin for pathological examination. All the 27 patients were diagnosed before operation as squamous cell carcinoma with endoscopic biopsy. There were 15 males and 12 females, aged 41 to 71 years old, and averaged 58 years.

Spectral measurements

The spectra were recorded on a Nicolet Magna 750 FT-IR spectrometer with a mercury cadmium telluride (MCT) detector. No special sample preparation was needed in the experiment. The sample was defrosted at room temperature, and the measurements were carried out by putting the mucosal surface and cancer side (the section side of cancer tissue) of tissue on the attenuated total reflectance (ATR) probe. A total of 64 scans were recorded at a resolution of 4/cm at the region of 900 to 4 000/cm. The samples were frozen again for reexamination after FT-IR scanning.

RESULTS

Significant differences were found between normal and malignant esophageal tissues in the FT-IR spectra except one sample.

At the range of 1 800-1 500/cm, the amide band II at about 1 550/cm was weak and broad in malignant tissues, and was

strong and sharp in normal tissues (Figure 1). The relative intensity of *I* 1 647/*I* 1 550 of malignant tissues was higher than that of normal tissues (Figure 2). The ratio of *I* 1 647/*I* 1 550 was 2.0 in malignant tissues and 2.36 in normal tissues, with a statistically significant difference ($P<0.05$). The wave number of amide band I in normal tissues was about 1-6/cm higher than that in malignant tissues, without statistically significant difference ($P>0.05$).

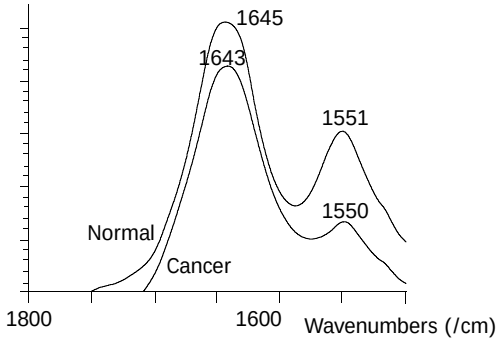

Figure 1 The spectra of the normal and cancer tissues at 1 800/cm-1 500/cm area.

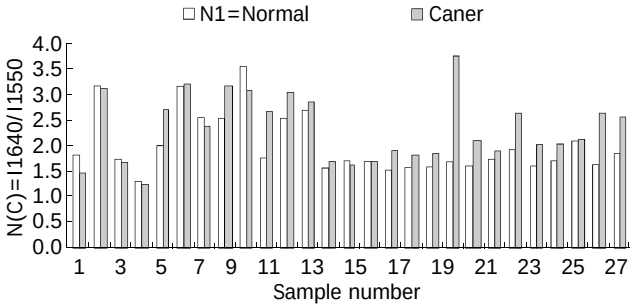

Figure 2 The ratio of *I* 1 640/*I* 1 550 of normal and cancer tissues.

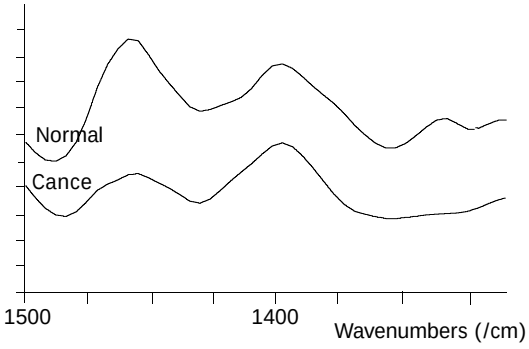

Figure 3 The spectra of the normal and cancer tissues at 1 400/cm-1 500/cm area.

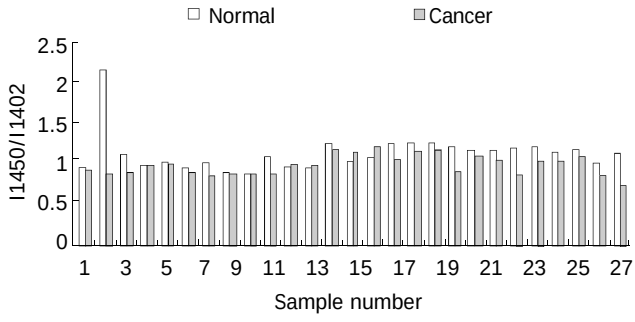

Figure 4 The ratio of *I* 1 450/*I* 1 402 of normal and cancer tissues.

At the range of 1 500-1 400/cm, two typical bands at about 1 453/cm and 1 402/cm could be seen in all the studied samples. The intensity of the band at 1 453/cm in normal tissues was higher than that in malignant tissues (Figure 3). The relative intensity of *I* 1 454/*I* 1 400 is shown in Figure 4.

The band at 1 080/cm was higher and stronger in malignant tissues than that in normal tissues. The ratio of *I* 1 080/ *I* 1540 was higher in malignant tissues. In normal tissues, a peak at 1 745/cm was seen in 6 cases, but none was seen in malignant tissues. At the range of 2 800-3 000/cm, three peaks (2 965/cm, 2 926/cm, and 2 853/cm) were seen in 25 of 27 normal tissues and only in 5 of both normal and malignant tissues. For these 5 cases, the ratio of *I* 1 226/*I* 3 380 was higher in normal tissues. For a pair of samples, in which the same spectra were found by FT-IR, the regular pathological examination showed that the two samples were normal tissues of esophagus.

DISCUSSION

The pathogenesis and development of esophageal carcinoma are a multi-step process that is controlled by many genes and affected by many factors[15-24]. The cooperation of oncogene' s activation and anti-oncogene' s inactivation causes the relative changes of contents and structures of protein, nuclear acid, sugar and fat in cells[25-31]. FT-IR could provide information about molecular structure, which makes it possible to reflect the changes of protein, nuclear acid, sugar and fat in cells and the structure changes of space array of the molecule, thus the diagnosis of cancer cells could be made at the molecular level[32-34].

Significant differences between normal and malignant esophageal tissues were seen in FT-IR spectra in this study. They might be caused by the changes of content and space array of protein, nuclear acid, sugar and fat in cells. For the bands of protein, amide bands I and II, the amide band II at about 1 550/cm was weak and broad in malignant tissues and was strong and sharp in normal tissues. The relative intensity of *I* 1 647/*I* 1 550 of malignant tissues was higher than that of normal tissues. At the range of 1 500-1 400/cm, the relative intensity of *I* 1 454/*I* 1 402 was higher in normal tissues than that in malignant tissues.

The peak at 1 745/cm was caused by the stretching vibration of carbonyl, the peaks at 2 852/cm and 2 930/cm were absorption spectra of the symmetry and asymmetry stretching vibrations of methylene, the peaks at 2 873/cm and 2 958/cm were absorption spectra of the symmetry and asymmetry stretching vibrations of methyl. Because triglyceride contains lots of methyl, methylene and carbonyl, so the differences of FT-IR spectra in normal and malignant tissues at those area were caused by the different contents of lipid substance in the tissues. The decreased lipid substance in malignant tissues might be related to the following factors. Firstly, the fast growth of cancer needs more nutrition and energy, therefore it might utilize lipid to supply nutrition and energy, which cause the lipid substance not to be accumulated in cancer cells and tissues. The second reason is that normal cell and tissues, including fat cells, are excluded mechanically by proliferating malignant tissues of the tumor.

One of the most important characteristics of cancer cells is the increased DNA content in cells caused by the endless replication of DNA, which is presented with enlarged and dark stained nuclei under light microscopy. The peak at 1 080/cm was caused by symmetry stretching vibrations of phospholipids. In this study, we found the peak at 1 080/cm was stronger and higher in malignant tissues than that in normal tissues and the ratio of *I* 1 080/*I* 1 540 was higher in malignant tissues, indicating that DNA content in malignant tissues is significantly higher than that in normal tissues.

Abstract

AIM: To investigate gene expression pattern of human γ-synuclein gene in human esophageal squamous cell carcinoma (ESCC) by using semi-quantitive reverse transcription polymerase chain reaction (RT-PCR), and to study the role of γ-synuclein in the development of human ESCC.

METHODS: Semi-quantitive RT-PCR of 27 pairs of specimens of human ESCC tissues and corresponding normal tissues was used to investigate the expression pattern of γ-synuclein in ESCC. 9706/γ-syn cells in which γ-synuclein was overexpressed were obtained through cloning γ-synuclein gene by PCR and transfecting it into ESCC 9706 cells, then selecting with G-418 for 14 days. The biological effects of γ-synuclein were measured and compared between 9706/γ-syn and 9706/vec cells by cell growth curve and soft agar assay.

RESULTS: RT-PCR showed that γ-synuclein gene was expressed in all the 27 cases of normal epithelial tissues, while downregulation of γ-synuclein was observed in 16 out of the 27 cases (59.3 %) of ESCC. There were also 6 cases of ESCC tissues with a high expression level of γ-synuclein mRNA. In functional analysis we found that over-expression of γ-synuclein in ESCC 9706 cells could inhibit the growth rate and transformation ability of ESCC 9706 cells.

CONCLUSION: The low expression level of γ-synuclein in human ESCC and the biological effects of γ-synuclein over-expression on ESCC 9706 cells suggest that γ-synuclein may play a role as a negative regulator in the development of human ESCC.

INTRODUCTION

Synucleins are a family of small, highly conserved soluble proteins that are predominantly expressed in neural tissues and certain tumors[1,2]. There are at least three members of this family in vertebrates: α-, β-, γ-synuclein. All synucleins contain a highly conserved amino-terminal domain that includes several repeated domains displaying variation of a KTKEGV consensus sequence and a less conserved carboxy-terminal domain that includes a preponderance of acidic residues[1,2]. The α- and β-synuclein proteins are found primarily in brain tissues and in association with pathological lesions of neurodegenerative diseases[3,4]. While γ-synuclein, initially termed breast cancer-specific gene 1 (BCSG1)[5], is found in the peripheral nervous system and retina, and it may affect the integrity of the neurofilament network[4-6]. Furthermore, over-expression of γ-synuclein has been recently shown in several types of cancer, including breast and ovarian cancer, suggesting that it may be involved in a certain number of human cancers[5,7].

γ-synuclein gene was first isolated from a human breast tumor cDNA library, and therefore named breast cancer-specific gene 1 (BCSG1)[5], soon after it was determined to be a new member of the synuclein family[8]. The human γ-synuclein maps to chromosome region 10q23, and is composed of five exons and transcribed into an mRNA of about 1 kb, coding 127 amino acids[8,9]. It was reported that γ-synuclein was over-expressed in infiltrating breast ductal carcinoma and ovarian cancer[7]. Other studies have shown that over-expression of γ-synuclein in breast and ovarian cancer cells may enhance the motility and invasiveness *in vitro* and metastasis *in vivo* of breast cancer[10,11].

Human esophageal squamous cell carcinoma (ESCC) is one of the most common malignant tumors in China, and its etiology and pathogenesis remain to be determined[12]. However, it has been reported that many oncogenes and tumor suppressor genes are closely related to ESCC, such as *c-myc*, cyclin D1, p53[13-15]. In the present study, we first examined the expression pattern of γ-synuclein in 27 cases of ESCC. It was unexpected that γ-synuclein was down regulated in 16 out of 27 cases of ESCC compared to their corresponding normal tissues, rather than over-expressed in tumor tissues. In order to further explore the role of γ-synuclein in the development of ESCC, we cloned human γ-synuclein gene and transfected it into ESCC 9706 cell line. Our data demonstrated that the ectopic expression of γ-synuclein in ESCC cell line could inhibit cell growth in dish and colony formation in soft agar. In conclusion, unlike in breast and ovarian cancers, γ-synuclein might play a role as a tumor suppressor in the development of human ESCC.

MATERIALS AND METHODS

Tissue sample

Twenty-seven carcinomatous tissues and the corresponding normal tissues were obtained from surgically resected esophageal carcinoma in Cancer Hospital. Fresh samples were dissected manually to remove connective tissues and stored immediately at -80 ℃ until analysis. Carcinoma tissues were obtained from poorly, moderately, and well differentiated squamous epithelial cell carcinomas. The corresponding

normal tissues were obtained from the distant edge of dissected esophagus. Each tissue sample contained over 80 % of normal or tumor epithelial cells.

RNA extraction and semi-quantitative RT-PCR

Total RNA was extracted from paired specimens of primary esophageal cancer and non-cancerous esophageal epithelial tissues with TRIZOL reagent (Invitrogen) according to the manufacturer' s protocol.

Five micrograms of total RNA extracted from paired esophageal carcinoma were used as a template respectively to synthesize cDNA in 25 μl reaction mixture with 2.5 mM oligo $d(T)_{16}$ primers and M-MLV Reverse Transcriptase (Promega) at 37 ℃ for 1 h followed by 85 ℃ for 10 min. PCR was performed in 20 μl reaction mixture [1×taq buffer (Dingguo Company), 100 ng template cDNA, 200 μM of each dNTPs, 0.5 μM of each primers and 2 U Taq] as follows: at 95 ℃ for 5 min followed by 20 cycles at 95 ℃ for 1 min, at 61 ℃ for 1 min, at 72 ℃ for 1 min, and the final step of extension was for 10 min at 72 ℃. Sequences of the PCR primers for γ-synuclein are as follows: Upper primer: 5' CGGGATCCACCATGGATGTCTTCAAGAAG 3' . Lower primer: 5' CCGCTCGAGCTAGTCTCCCCCACTCTG 3' .

The reaction products were visualized by electrophoresis of 5 ul reaction mixture at 70 V for 40 min in 2 % agarose gel containing 0.5 μg/ml ethidium bromide, and quantitated by densitometry using a dual-intensity transilluminator equipped with Gel -Pro Analyzer version 3.1. β-actin was used as internal control.

Cell culture and transfection

Human ESCC 9706 cell line (kindly provided by Dr. Mingrong Wang) was grown in Dulbecco' s modified Eagle' s medium containing 10 % heat-inactivated fetal bovine serum (Gibico BRL)[16]. Transfection was performed in 80 % confluent cells using LipofectAMINE (Invitrogen) according to the manufacturer' s protocol. Stable transfectants were obtained by G418 selection for about 14 days.

Cell lysis and Western blot

Total cell lysate was prepared in cell lysis buffer (1 % NP-40, 137 mM NaCl, 20 mM Tris pH=7.4, 1 mM DTT, 10 % glycerin, 10 μg/ml Aprotinin, 2 mM sodium orthavanadate, 100 uM PMSF). After incubation for 30 min on ice, cells were scraped from the culture dish, and the mixture was centrifuged at 12 000 g for 10 min at 4 ℃. The protein concentration of the clarified lysate was determined using a BCA kit with BSA as a standard (Periece).

Equal amounts of total protein from cell lysate were resolved on 15 % SDS-PAGE. For western blot analysis, proteins separated by SDS-PAGE were transferred to nitrocellulose (PROTRAN, Schleicher&Schuell). Firstly the filters were incubated in a blocking solution (5 % fat-free dry milk, 2 % BSA in TBS) for 1 h at room temperature. Then the filters were incubated with primary antibody, added with a blocking solution at 1:1 000 dilution, for 1 h at room temperature. After washed three times with TTBS (0.5 % Tween-20 in TBS), the filters were subsequently incubated for 40 min with HRP (horseradish peroxidase) conjugated secondary antibody (Zhongshan Company). The filters were washed as above and developed using a Luminol detection system (Santa Cruz). Before re-blotting, the filters were stripped by incubation for 30 min in stripping buffer (2 % SDS, 62.5 mM Tris.Cl pH=6.7, 100 mM 2-mercaptoethanol) at 50 ℃.

Cell growth assay

Growth on plastic culture dish 2×10^4 cells from 9706/γ-syn and 9706/vec cell line were seeded in triplicate of 24-well plates and cultured in DMEM plus 1 % FBS and 10 % FBS. At each time point, cells were trypsinized to single cell suspension and counted on a Coulter counter set at >10 μm in diameter.

Anchorage -independent growth in soft agar According to standard protocol, 200 ESCC 9706 cells were suspended in 1 mL of 0.3 % agarose medium containing DMEM plus 10 % FBS and layered onto a 2 mL bed of 0.6 % agarose in a 35 mm dish with grids. Plates were incubated for about 14 days, and the colonies were stained with 0.2 % p-iodonitroterazolium violet and photographed.

RESULTS

Expression pattern of γ-synuclein in human esophageal squamous cell carcinoma (ESCC)

Expression pattern of γ-synuclein in human ESCC was examined using semi-quantitative RT-PCR approach. Figure 1 shows a 384 bp γ-synuclein fragment from ESCC tissues and relatively normal tissues, and a 200 bp β-actin fragment as an internal control by electrophoresis in 2 % agarose gel. The γ-synuclein gene was expressed in all the 27 cases of normal esophageal epithelial tissues, while down-regulation of γ-synuclein gene was observed in 16 out of the 27 cases (59.3 %) of ESCC. There were also 6 cases of ESCC tissues with high expression level of γ-synuclein mRNA (Table 1). These results indicated that γ-synuclein might play a negative role in carcinogenesis of human ESCC.

Table 1 Expression pattern of human γ-synuclein in human esophageal squamous cell carcinoma

γ-synuclein RT-PCR	Cases (percentage)
Down-regulated	16 (59.3%)
Up-regulated	6 (22.2%)
No change	5 (18.5%)
Total	27 (100%)

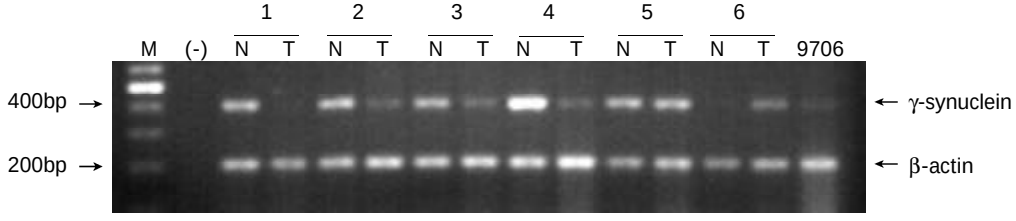

Figure 1 Simi-quantitative RT-PCR analysis of human γ-synuclein mRNA in human esophageal squamous cell carcinoma. The γ-synuclein fragment (384 bp) was amplified by 20 cycles PCR using the paired primers as indicated in Material and Methods. Five micrograms of total RNA isolated from human ESCC tissues and corresponding normal tissues were used as templates for cDNA synthesis respectively. β-actin was used as an internal control. T: esophageal squamous cell carcinoma tissue, N: corresponding normal tissue, 9706: human ESCC 9706 cell line, (-): negative control, M: 100 bp DNA marker.

Inhibition of growth rate and transformation ability of human ESCC 9706 cells by γ-synuclein

RT-PCR results led us to investigate the role of γ-synuclein in carcinogenesis of human ESCC. Firstly we amplified the γ-synuclein cDNA fragment from fetal brain cDNA and cloned it into the pcDNA3.0 vector to generate HA-tagged γ-synuclein expression plasmids. Then we transfected γ-synuclein expression plasmid and pcDNA3.0 vector into ESCC 9706 cells respectively. After 14 days selection with G418 (300 μg/ml), we obtained the stable transfectants named 9706/γ-syn and 9706/vec cells. The expression of transfected γ-synuclein was verified by Western blot analysis (Figure 2). To determine whether γ-synuclein over-expression affected the growth of ESCC 9706 cells, cells from 9706/γ-syn and 9706/vec were seeded in triplicate of 24-well plate in DMEM plus 1 % FBS and 10 % FBS. According to the growth curve we observed that 9706/γ-syn cells grew more slowly than control cells, whether in low or high serum medium in dishes (Figure 3). Furthermore, we confirmed the negative effect of γ-synuclein on ESCC 9706 cells by soft agar assay in which 9706/γ-syn cells displayed much smaller and fewer colonies than 9706/vec cells (Figure 4), indicating that γ-synuclein had the ability to inhibit the transformation activity of ESCC 9706 cells, and might act as a negative regulator in the development of human ESCC.

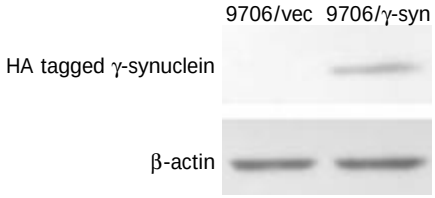

Figure 2 Identification of exogenous γ-synuclein expression in 9706/γ-syn stable cell line. Exogenous HA tagged γ-synuclein was detected by Western blot using anti-HA antibody in 9706/γ-syn cells. β-actin was used as internal control.

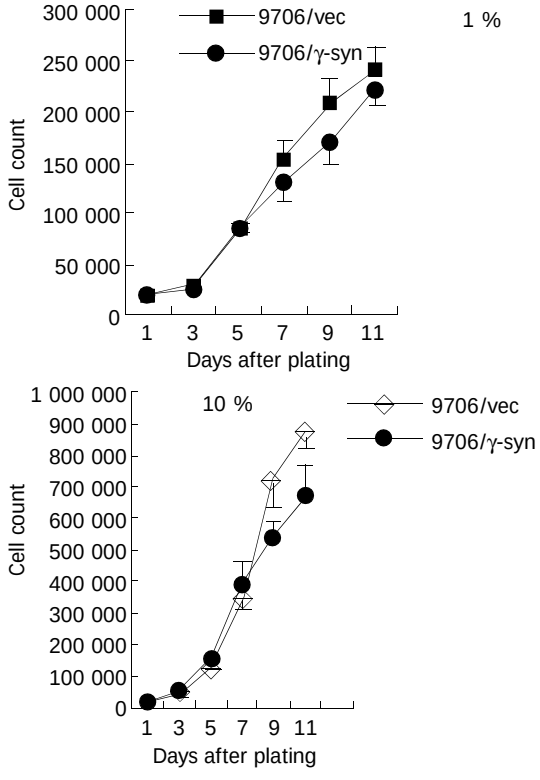

Figure 3 Effect of γ-synuclein over-expression on cell growth of 9706 cells with 1 % and 10 % FBS respectively. ESCC 9706/γ-syn and 9706/vec were seeded in triplicate of 24-well plate in DMEM plus 1 % FBS and 10 % FBS. The growth curve showed that 9706/γ-syn cells grew more slowly than that of control cells, both in low and high serum medium in dishes.

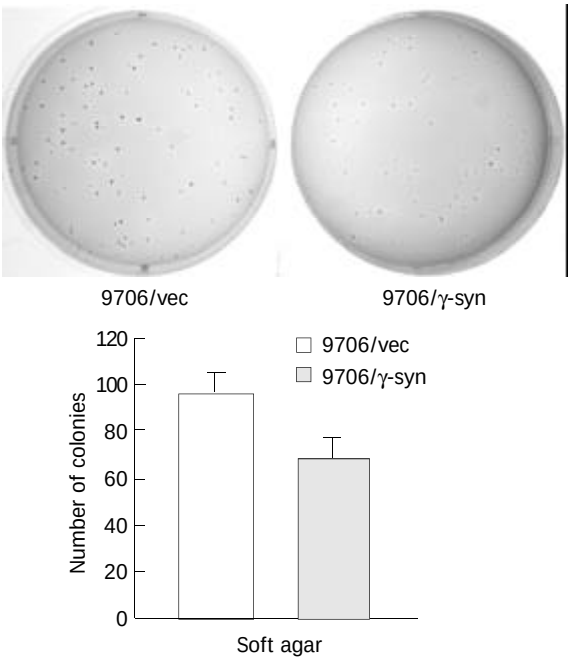

Figure 4 Colony formation of ESCC 9706 cells transfected with vector and γ-synuclein. 200 cells from each of the cell pools were plated in six-well plates. After 14 days, the colonies were stained with 0.2 % p-iodonitroterazolium violet and photographed. The number of colonies per well was quantified. Experiments were repeated three times with consistent and reproducible results.

DISCUSSION

Human esophageal squamous cell carcinoma (ESCC) is one of the most common malignant tumors in China[12]. Although the etiological agents have yet to be identified, studies have shown a series of genetic events involving the development of this cancer[13-15,17]. Identification of the genetic changes in ESCC as well as in other cancers will provide diagnostic and prognostic markers and molecular targets for treatment, intervention and prevention of human cancers.

It was reported that γ-synuclein was over-expressed in breast and ovarian cancer[5,7]. In the current study, we intended at first to detect the expression of γ-synuclein in esophageal squamous cell carcinoma (ESCC). However, γ-synuclein was unexpectedly down regulated in some 60 % tumor samples (16 out of 27 cases), compared to the corresponding normal tissues, rather than over-expressed in tumor tissues such as in breast and ovarian cancer. On the other hand, γ-synuclein was detected in all the 27 normal esophageal tissues. Furthermore, consistent with our observation that the expression of γ-synuclein was lower in tumor tissue than in surrounding non-tumor tissue in ESCC, after transfection of human ESCC cells into ESCC 9706 cells and selection with G-418, the transfectants expressing γ-synuclein (9706/γ-syn) grew remarkably slower than 9706/vec cells in low or high serum medium in dishes (Figure 3). It also displayed much smaller and fewer colonies than 9706/vec cells in soft agar (Figure 4), indicating that γ-synuclein has the ability to inhibit the transformation activity of ESCC 9706 cells. Therefore our present study suggests that γ-synuclein may be a negative regulator in tumorigenesis of human ESCC, unlike that in breast and ovarian cancer as an oncogene.

It is not unexpected to find out that the biological and

biochemical functions of the same gene are different in different cells or tissues from different tumors, since the development of tumors is a complex multigene-related phenomenon and the result of a multistep process involving a series of genetic events. As shown in our study, the manner and effect of γ-synuclein in human ESCC were different from those in breast and ovarian cancer. Moreover it was previously shown by others that in A2780 and OVCAR5 cells (ovarian cancer cell lines) with over-expressed γ-synuclein, the activated ERK1/2 was increased 2- to 3-fold. In contrast, in HEK293 cells (human embryonic kidney cells), γ-synuclein over-expression did not increase ERK activation level[18]. Likewise, the same status was also observed in many other studies, among which GKLF/KLF4 (gut-enriched Krüppel-like factor/ Krüppel-like factor 4) gene was a good example. GKLF/KLF4 encodes a zinc finger transcription factor and belongs to a big family[19]. It is the same as γ-synuclein as it is over-expressed in breast cancer[20], while down regulated in ESCC[21]. In addition, Annexin I (lipocortin I) gene is another very similar case. Annexin I is a phospholipid binding protein which is implicated in various cell activities, including proliferation, differentiation and apoptosis[22]. Studies showed that annexin I protein was actually over-expressed in human tumors including breast cancer, hepatocellular carcinoma[23,24]. However, it was also found that annexin I protein expression was decreased in human esophageal and prostate cancers[25,26]. p21 (Waf1/Cip1), one of the best broad-specificity inhibitors of CDK, acts as a suppressor in most tumors. But in some tumors, including ESCC, p21 (Waf1/Cip1) is over-expressed, acting as an oncogene to promote carcinogenesis and tumor progression[27].

Despite the fact that the mechanism by which γ-synuclein protein is involved in carcinogenesis of human tumors remains unclear, the data presented here have shown that γ-synuclein is down-regulated in ESCC, and is over-expressed in breast and ovarian cancer[5,7]. To shed new light on the role of γ-synuclein in oncogenesis, more studies are certainly needed to determine how γ-synuclein is down- regulated or up-regulated in tumors and what the physiological functions of γ-synuclein are during the development of human tumors.

ACKNOWLEDGMENT

We are grateful to Dr. Mingrong Wang for generously providing the human ESCC 9706 cell line.

Abstract

AIM: Somatostatin and its analogues may suppress the growth of various tumor cells. However, the effect of octreotide on growth of gastric adenocarcinoma is still largely unknown. This study was to explore if octreotide could inhibit the growth of gastric adenocarcinoma and its probable mechanisms.

METHODS: Proliferation of gastric cancer cell line affected by octreotide was determined by ^{3}H-thymidine incorporation. After xenografts of human gastric cancer were implanted orthotopically in stomach, nude mice were administrated octreotide for 8 weeks. The mRNA of somatostatin receptor in the SGC-7901 cells was detected by reverse transcription polymerase chain reaction technique. Extracellular signal-regulated protein kinase and c-Fos in gastric cancer tissues were measured by immunohistochemistry and Western blot. Activator protein-1 binding activity was examined by electrophoretic mobility sift assay.

RESULTS: ^{3}H-thymidine incorporation into SGC-7901 cells was significantly decreased by octreotide in a concentration dependent manner. Either size or weight of tumors treated with octreotide was significantly reduced *in vivo*. The inhibition rate for tumor was 62.3 % in octreotide group. The genes of somatostatin receptors 2 and 3 were expressed in SGC-7901 gastric cancer cell lines. Extracellular signal-regulated protein kinase and c-Fos protein level were decreased in gastric adenocarcinoma treated with octreotide. Moreover, fetal calf serum stimulated activator protein-1 binding activity could be suppressed by octreotide potentially.

CONCLUSION: Inhibition of sequential molecular events in MAPK pathway may interpret the mechanisms underlying the effect of octreotide on the growth of gastric adenocarcinoma.

INTRODUCTION

Somatostatin (SST) is a widely distributed neuropeptide that negatively regulates a number of cellular processes, including exocrine and endocrine, neurotransmission and cell proliferation[1-6]. Many studies have shown that SST and its analogues suppress the growth of normal and tumor cells in various types[7-11]. The biological effects of SST are mediated through five subtypes of SST receptors (SSTR) that belong to a family of G-protein-coupled receptors. The mechanisms responsible for the inhibitory effects of SST are related to many signal transduction pathways including control of cytosolic free calcium, adenylate cyclase, protein kinase C and SHP-1 activation[12-14]. The activator protein-1 (AP-1) family transcription factors have been implicated in the control of proliferation, apoptosis and malignant transformation. SST may inhibit the expression of c-Fos and binding of AP-1[15-18]. Advanced gastric adenocarcinoma still appears to be poor in its prognosis. Chemotherapy or radiation therapy has generally shown some clinical response but little survival advantage and is intolerable in many patients. Therefore, other therapeutic regimens for gastric adenocarcinoma need to be evaluated. The purpose of this study was to investigate the inhibitory effect of SST analog, octreotide on the growth of gastric cancer and the role of mitogen-activated protein kinases (MAPK) in cell proliferation after SSTR binding.

MATERIALS AND METHODS

Assay of [methyi-^{3}H]-thymidine incorporation

Gastric cancer cell line SGC-7901 was obtained from Cell Research Institute (Shanghai, China). The cells were cultured in RPMI1640 (Hyclon Inc, USA) containing 10 % FCS, 100 U/ml penicillin and streptomycin at 37 ℃ in 5 % CO_2 atmosphere. After incubated for 24 hours in FCS free culture, cells were treated with octreotide (Novatis Pharma AG, Switzerland) for 22 h and then exposed to [methyi-^{3}H]-thymidine (1 μCi suspended in 1 ml of RPMI1640) in the same medium for 2 h. The radioactivity was measured by a liquid scintillation counter (Becman LS1801, USA).

Animal experimental procedure

Xenografts were initiated by subcutaneous injection of 2×10^6 cells into the right flanks of nude mice (Balb/c *nu/nu*). Tumors after 4 weeks were aseptically dissected and mechanically minced. Pieces of tumor tissue in 3 mm^3 were transplanted under serosa of stomach[19]. Two groups of mice (6 each group) were given octreotide at 100 μg/kg, s.c. or saline as control each day. After 8 weeks, tumors were excised and weighed. Tumor tissue was fixed in buffer neutral formalin for histological examination. The inhibition rate (%) was expressed as (weight of tumor in control group - weight of tumor in octreotide group)/weight of tumor in control group×100 %.

Detection of mRNA for SSTR subtypes on SGC-7901 gastric carcinoma cell line with RT-PCR

Total RNA was isolated using the Tripure RNA isolation kit (Roche limited, Hong Kong). First-strand cDNA was

produced by Moloney murine leukemia virus reverse transcriptase (MBI, USA), primers for SSTR-2 (sense, 5' -ATGGACATGGCGGATGA-GCCACTC-3' ; antisense, 5' -TACTGGTTTGGAGGTCTCCATTGAG-3'), SSTR-3 (sense, 5' -TGGGCACCCTCGTGCCAGCGG-3' ; antisense, 5' -GGG-CGGCCGCTCCTGCCCG-C-3'), β-actin (sense, 5' -GACTACCTCATGAAGATCCT-3' ; antisense, 5' -GCGGAT-GTCCACGTCACACT- 3'). For SSTR-2, amplification runs consisted of an initial denaturation a 94 ℃ for 5 min, following by 35 cycles of denaturation (at 94 ℃ for 1 min), annealing (at 55 ℃ for 70 s) and extension (at 72 ℃ for 2 min), which were then linked to a final polishing step at 72 ℃ for 10 min. Cycling parameters were approximately the same as for SSTR-3 except that the annealing temperature was at 65 ℃[20].

Detection of ERK and c-Fos with immunohistochemical staining and Western bloting

Tissue sections of gastric xenografts from control or octreotide group were incubated with 0.3 % hydrogen peroxide for 30 min and then in normal goat serum for 30 min to block endogenous peroxidase activity and unspecific binding sites, respectively. Immunohistochemical staining was performed with rabbit polyclonal IgG specific for human ERK and c-Fos (Santa Cruz Biotechnology, Inc., USA) in a dilution of 1:100 overnight at 4 ℃. The tissue sections were thereafter treated with biotinylated secondary antibodies in a dilution of 1:200 (Boster, Wuhan, China) and antibody-binding sites were finally visualized by avidin-biotin peroxidase complex solution (Boster, Wuhan, China) and 3' , 3' -diaminobenzidine. Protein extracted from SGC-7901 cells was incubated in loading buffer and heated at 100 ℃ for 10 min. The samples were loaded in lane and resolved on a 8 % SDS-PAGE gel, transferred to nitrocellulose, and incubated with rabbit polyclonal antibody for either the c-Fos or ERK at 4 ℃ overnight. Filters were then washed three times in blocking solution and incubated with horseradish peroxidase-linked immunoglobulin followed by exposure to enhanced chemiluminescence Western bloting luminal reagent (Promega, USA).

Measurement of AP-1 binding activity with electrophoretic mobility shift assay (EMSA)

Nuclear protein was isolated as follows: 5×10^6 SGC-7901 cells were lysed with buffer A (0.6 % NP-40, 150 mM NaCl, 10 mM HEPES [pH 7.9, 1 mM EDTA, 0.5 mM PMSF]) on ice for 5 min, and nuclei were pelleted by centrifugation at 5 000 g for 10 min. Nuclear lyses of the pellet were performed using buffer B [25 % glycerol, 20 mM HEPES (pH 7.5), 420 mM NaCl, 1.2 mM $MgCl_2$, 0.2 mM EDTA, 0.5 mM DTT, 0.5 mM PMSF, 2 mM benzamidine, 5 μg/ml aprotin, 5 μg/ml leupeptin] for 30 min on ice. Samples were then centrifuged at 12 000 g for 10 min and the supernatant was retained. Protein determination was performed using Coomassie blue assay (Sigma).

SGC-7901 cells were grown to confluence in a 6-well plate. After serum starvation for 24 h, the cells were incubated with either 20 % FCS alone or octreotide (1×10^{-5}M) for 2 h. At the end of incubation, nuclear protein was extracted as described above. The ^{32}P-labled DNA probe was added and incubated for 30 min at room temperature. DNA binding activity was measured from free probe on a 7 % non-denaturing polyacrylamide gel (PAGE) in TBE buffer. The gel was then dried for 1 h and autoradiographed at -80 ℃. AP-1 oligonucleotide probe consensus was 5' -CGCTTGATGAGTCAGCCGGAA-3' . Bands were quantified with Image Master™ VDS analysis software.

Statistical analysis

Statistical significance was determined by the Studen' s *t*-test. Differences with P values <0.05 were considered statistically significant. All data were shown as the mean ± standard division.

RESULTS

Anti-proliferative effect of octreotide on SGC-7901 cell lines in vitro

Octreotide in 1×10^{-5}M-1×10^{-9}M potentially decreased ^{3}H-thymidine incorporation into DNA of SGC-7901 cells in a dose-dependent manner (r=-0.9, P<0.01). The inhibitory rate was 32.2 % at concentration of 1×10^{-5}M octreotide (Figure 1).

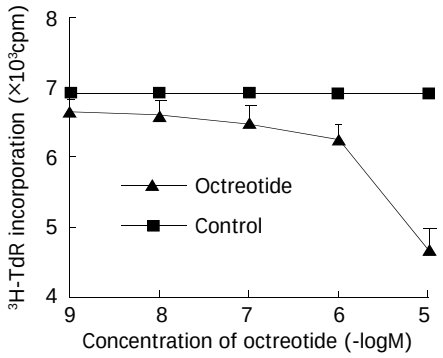

Figure 1 Effects of octreotide on ^{3}H-thymidine incorporation of SGC-7901 cell. Each value was the mean ± SD of three separate experiments in which duplicate determinations were made.

Inhibition of the growth of orthotopic tumors in nude mice in vivo

At necropsy, xenografts were found in all stomaches of nude mice. The weight of tumor in animals receiving octreotide was 0.77±0.14 g with 62.3 % reduction (P<0.01) as compared with control tumors that weighed 2.04±0.29 g. The transplanted gastric adenocarcinomas were confirmed by histological examination. Compared with control group, tissue differentiation of transplanted gastric cancer did not show notable change between two groups. No side effect was observed in all animals.

Expression of SSTR-2 and SSTR-3 in human gastric cancer

The mRNA of SSTR-2 and SSTR-3 was detected in SGC-7901 cells with RT-PCR (Figure 2). The band located between 994 bp-1 543 bp was the cDNA of SSTR-2 in 1 104 bp. The band located between 377 bp-515 bp was the cDNA of SSTR-3 in 447 bp.

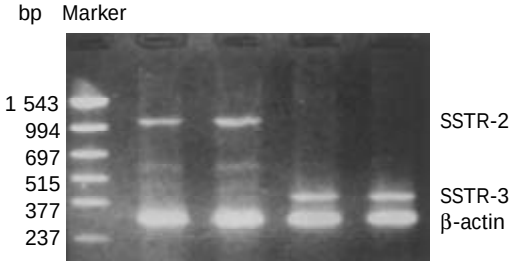

Figure 2 Expression of mRNA for SSTR-2 and SSTR-3 in SGC-7901 cells.

Inhibition of octreotide on expression of ERK

Immunohistochemical staining revealed that ERK was strongly positive in gastric adenocarcinomas. Expression of ERK in tumor tissues could be suppressed by octreotide (Figure 3). Quantitatively, ERK in SGC-7901 cells determined by Western blot was also significantly inhibited by octreotide (Figure 4).

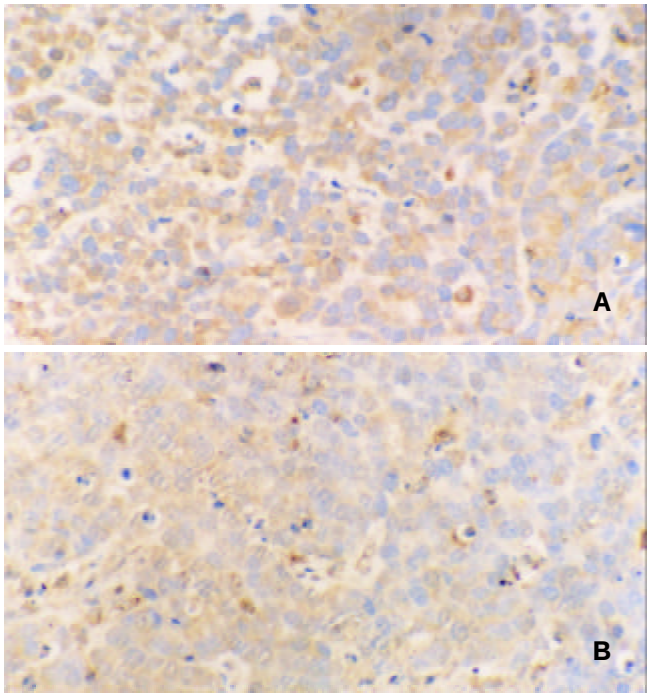

Figure 3 Immunohistochemical staining for ERK in tissues of transplanted gastric cancer in nude mice. A. control, B. octreotide group (200×).

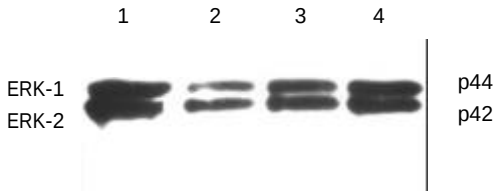

Figure 4 Western blot analysis of ERK in SGC-7901 cells. 1. control, 2. octreotide 1×10^{-5} M, 3. octreotide 1×10^{-6} M, 4. octreotide 1×10^{-7} M.

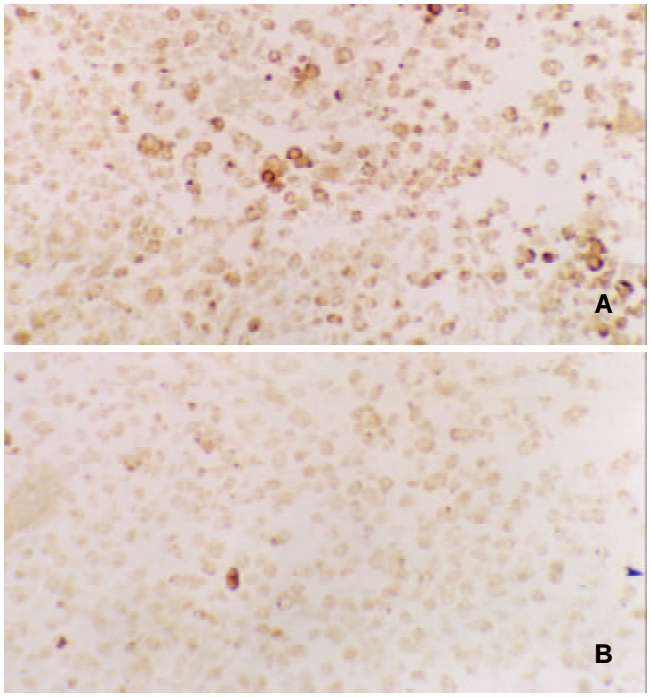

Figure 5 Immunohistochemical staining for c-Fos in tissues of transplanted gastric cancer in nude mice. A. control, B. ctreotide group (200×).

Inhibition of octreotide on expression of c-Fos

Expression of c-Fos in tumor tissues could be suppressed by octreotide (Figure 5). Quantitatively, c-Fos in SGC-7901 cells determined by Western blot was also significantly inhibited by octreotide (Figure 6).

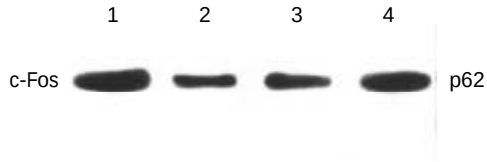

Figure 6 Western blot analysis of c-Fos in SGC-7901 cells. 1. control, 2. Octreotide 1×10^{-5} M, 3. Octreotide 1×10^{-6} M, 4. Octreotide 1×10^{-7} M.

Down-regulation of AP-1 binding activity by octreotide

As depicted in Figure 7, AP-1 binding activity could be stimulated by fetal calf serum. After addition of octreotide, the binding activity of AP-1 was reduced about 53 %.

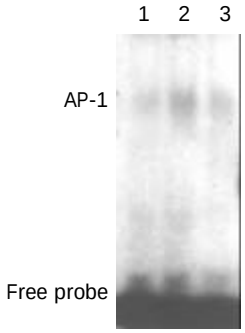

Figure 7 Effects of octreotide on AP-1 binding activity of SGC-7901 cells. 1. control, 2. FCS stimulated, 3. FCS stimulated and octreotide.

DISCUSSION

This study showed that octreotide potentially decreased ^{3}H-thymidine incorporation into gastric adenocarcinoma cell line in a dose-dependent manner. It reflected the suppression of DNA synthesis in SGC-7901 cells and reduction of tumor cells in S phase of cell cycle. Furthermore, the direct inhibitory effect of octreotory on gastric cancer *in vitro* might be attributed to the interaction of SST with its specific cellular receptors on the cell lines.

We successively established the model of *in situ* transplanted tumor in nude mice with human gastric cancer cell lines, the xenografts *in situ* were found in all stomaches of nude mice in this study. The inhibition rate for tumor was 60 % in octreotide group. This result *in vivo* was consistent with the observation *in vitro* described above. Early evidence that somatostatin analogs could inhibit the proliferation of somatostatin receptor-negative neoplasm suggested that octreotide probably acted indirectly on tumors through the inhibition of releasing some peptides or growth factors such as insulin, EGF, gastrin and IGF-1, which promote tumor growth[21-25]. Therefore, the arrested growth of transplanted gastric tumor in nude mice treated with octreotide may be either mediated directly by SST receptors or achieved indirectly via inhibition of various growth factors.

Five subtypes of SSTR, SSTR-1 to SSTR-5, have been cloned and functionally characterized during the last decade[26,27]. Natural SST is a non-selective ligand for all SSTR subtypes. Short synthetic SST analogs, however, such as octreotide and lanreotide demonstrate specific binding only to the subgroup

consisting of SSTR-2, SSTR-3 and SSTR-5[28,29]. Since no specific agonist, antagonist or antibody against individual SSTR subtype was available, detection of SSTR subtype was usually performed through analysis of corresponding mRNA. Using RT-PCR technique, to our knowledge, we demonstrated the gene expression of human SSTR-2 and SSTR-3 in SGC-7901 cell line. It afforded the further evidence for the deduction that the anti-proliferative effects of octreotide on gastric cancer might be mediated directly by SSTR-2 or SSTR-3.

The binding of SST to its receptors in native membranes triggered the intracellular signaling pathways through the activation of G proteins[30-32]. Particular interest has been devoted recently to the regulation of MAPK pathway by SSTR, which might represent an important facet of signaling. The basic assembly of the MAPK pathway was a three-component module and included three kinases that establish a sequential activation pathway[33-36]. More than a dozen of mammalian MAPK family members have been discovered, which include the ERK1/ERK2, p38 MAPK, and JNK/SAPK pathways. The activation of MAPK might be translocated to the nucleus, where these kinases phosphorylate target transcription factors such as AP-1[35,37-39]. In the present study, expression of both ERKs and c-Fos could be inhibited by octreotide. Since the expression of c-Fos is regulated by ERKs, down-regulated expression of c-Fos in gastric cancer cell lines may reflect either suppression of ERKs protein or direct effect of octreotide on c-Fos.

Accumulated data have suggested the important role of AP-1 activation in pre neoplastic-to-neoplastic transformation in cell culture and animal models. AP-1 was a critical mediator of tumor promotion in a diversity of processes[40-43]. AP-1 was best characterized as a heterodimers of c-Fos and c-Jun[44]. For this reason, the expression level and activity of c-Fos were crucial to AP-1 activation[45]. Numerous reports have confirmed that inhibition of c-Fos or c-Jun leads to inhibition of cellular proliferation. In this study, the decreased availability of c-Fos protein by octreotide led to less binding to the AP-1 site. As a result, AP-1 activity stimulated by 20 % FCS could be inhibited. The ability of AP-1 complex binding to its specific DNA elements was suppressed. Therefore, the proliferation signals of gastric cancer cell could not be transcribed.

In conclusion, the results obtained in the present study show that octreotide is able to inhibit the growth of gastric cancer *in vitro* and *in vivo*. The mechanisms may involve the down-regulation of ERKs or c-Fos expressions and binding activity of AP-1.

Abstract

AIM: To investigate the effect of *c*9, *t*11-conjugated linoleic acid (*c*9, *t*11-CLA) on the invasion of human gastric carcinoma cell line and its possible mechanism of preventing metastasis.

METHODS: Using reconstituted basement membrane invasion, chemotaxis, adhesion, PAGE substrate zymography and RT-PCR assays, we analyzed the abilities of invasion, direct migration, adhesion of intracellular matrix, as well as the activity of type IV collagenase and expression of tissue inhibitor of metalloproteinase (TIMP)-1 and TIMP-2 mRNA in SGC-7901 cells which were treated with gradually increased concentrations (25, 50, 100 and 200 μmol/L) of *c*9, *t*11-CLA for 24 h.

RESULTS: At the concentrations of 200 μmol/L, 100 μmol/L and 50 μmol/L, *c*9,*t*11-CLA suppressed the invasion of SGC-7901 cells into the reconstituted basement membrane by 53.7 %, 40.9 % and 29.3 %, respectively, in comparison with the negative control. Only in the 200 μmol/L *c*9,*t*11-CLA group, the chemotaxis of SGC-7901 cells was inhibited by 16.0 % in comparision with the negative control. C9,*t*11-CLA also could inhibit the adhesion of SGC-7901 cells to laminin, fibronectin and Matrigel, increase the expression of TIMP-1 and TIMP-2 mRNA, and reduce type IV collagenase activities in the serum-free medium supernatant of SGC-7901 cells.

CONCLUSION: *c*9,*t*11-CLA can inhibit the invasion of SGC-7901 cells at multiple procedures in tumor metastasis cascade, which may be associated with the induction of TIMP-1 and TIMP-2 mRNA expression.

INTRODUCTION

Conjugated linoleic acid (CLA) refers to a class of positional and geometrical isomers of linoleic acid (18:2) with conjugated double bonds. The conjugated double bonds are mainly located at sites 9 and 11 or 10 and 12, and each double bond may be in the *cis* or *trans* configuration[1-5]. CLA exists in dairy products and meat of ruminants, the former is the principal source of CLA, of which *c*9, *t*11-CLA is the major isomer and represents 85-90 % of total CLA in bovine milk[1]. CLA is mainly produced from linoleic acid by rumen bacteria during biohydrogenation[6], although CLA can also be synthesized in non-ruminants by Δ9-desaturase from *trans*-11 18:1, another intermediate in rumen biohydrogenation[7]. The level of CLA in human adipose tissue has been reported to be associated with the consumption of dairy fat[8]. Besides, CLA can be synthesized in the laboratory and commercially synthesized CLA is available as a dietary supplement and has been shown to be non-toxic[9].

CLA is a potent cancer preventive agent and has chemoprotective properties[10-20]. In animal models of chemical carcinogenesis, CLA has been shown to inhibit skin papillomas[10,11], forestomach neoplasia[12,13] and mammary tumors[14-20]. Several studies[21-28] suggest that CLA is cytostatic and cytotoxic to a variety of human cancer cells, including hepatoma, malignant melanoma, colorectal cancer, breast carcinomas, and gastric cancer cells. Moreover, CLA also plays a role in reducing the tumor size and inhibiting the metastasis of transplanted human breast cancer cells and prostate cancer cells in SCID mice[29,30].

Gastric cancer is one of the most common malignancies in China[31-34] and its metastasis is the major cause of death in cancer patients. Our previous studies have revealed that *c*9, *t*11-CLA is an effective agent to prevent gastric cancer[13,35,36], and could inhibit the invasion of mouse melanoma[37]. However, it is unclear whether *c*9,*t*11-CLA influences on the metastasis of gastric cancer. Thus, we investigated the effect of *c*9,*t*11-CLA on the metastasis of human gastric carcinoma cell line SGC-7901.

MATERIALS AND METHODS

Materials

*c*9,*t*11-CLA with 98 % purity, was obtained from Dr. Rui-Hai Liu (Food Science and Toxicology, Department of Food Science, Cornell University, Ithaca, NY, USA). It was dissolved in ethanol and then diluted to the following concentrations: 25 μmol/L, 50 μmol/L, 100 μmol/L and 200 μmol/L, respectively.

Methods

Cell culture Human gastric adenocarcinoma cells (SGC-7901) purchased from Cancer Research Institute of Beijing (China) were cultured at 37 ℃ in PRMI 1640 (Gibco Co.) medium supplemented with fetal calf serum (100 ml/L), penicillin (100×10^3U/L), streptomycin (100 mg/L) and L-glutamine (2 mmol/L). The pH was maintained at 7.2-7.4 by

equilibration with 5 % CO_2. The SGC-7901 cells were sub-cultured with EDTA.

In vitro invasion assay Invasion assay assessing the ability of cells to invade a synthetic basement membrane was performed in transwell chambers (Costar Co. USA) with a polycarbonate filter of 8.0 μm pore size, separating the upper and lower chambers. The top surface of the polycarbonate filter was coated with Matrigel, the bottom with fibronectin. SGC-7901 cells (2×10^5) treated with different concentration of *c*9, *t*11-CLA (25, 50, 100, and 200 μmol/L) for 24 h were added to the upper transwell chamber in 100 μl of serum-free RPMI 1640 medium containing 0.1 % bovine serum albumin (BSA, Gibco Co.) and 600 μl of serum-free BSA-RPMI 1640 medium was added to the lower chamber. After 4 h, the filters were fixed in methanol and stained with hematoxylin and eosin (HE). The noninvading cells on the top surface of the filter membrane were removed with a cotton swab. Cells on the bottom surface of the filter were counted and the cell means were obtained from five high-power fields under a light microscope. The inhibitory rate (IR) was calculated as follows:

$$IR(\%)=\frac{\text{Number of invasive cells in negative control group}-\text{Number of invasive cells in test groups}}{\text{Number of invasive cells in negative control group}}\times100$$

Chemotaxied-motion assay The assay also was performed in transwell chambers (Costar Co. USA) with a polycarbonate filter of 8.0 μm pore size separating the upper and lower chambers. The bottom surface of filter was coated with fibronectin. The lower chambers were filled with 600 μl of serum-free BSA-RPMI 1640 medium. SGC-7901 cells (2×10^5) treated with different concentrations of *c*9,*t*11-CLA (25, 50, 100, and 200 $\mu mol\cdot L^{-1}$) for 24 h were added to the upper chambers, the chambers then were treated the same as invasion assay. SGC-7901 cells that migrated from the upper chamber to the bottom surface of the filter were counted and the means of cell numbers from five high-power fields under a light microscope were calculated. The inhibitory rate (IR) was calculated as follows:

$$IR(\%)=\frac{\text{Number of cells in negative control group}-\text{Number of cells in test groups}}{\text{Number of cells in negative control group}}\times100$$

Cell adhesion assay 96-well plates (Nunc. Co.) were incubated at 37 ℃ with laminin or fibronectin or Matrigel for 1 h and then blocked with phosphate-buffered saline (PBS) containing 10 g/L BSA for another 1 h at the same temperature. The SGC-7901 cells exposed to different concentrations of *c*9,*t*11-CLA (25, 50, 100, and 200 μmol/L) for 24 h were suspended in serum-free medium at a density of 8×10^5 cells/ml. Then 0.1 ml of SGC-7901 cells suspension was added to each well, and incubated at 37 ℃ for 1 h. The plates were washed three times in PBS to remove the unattached cells, then the remaining SGC-7901 cells in 96-well plates were reacted with MTT for 4 h at 37 ℃, then were solubilized with DMSO, and the absorbance of each well was measured at 570 nm with an ELX800 microplate reader (Bio-TEK Co.). Results were expressed as the percentage of total cells, assuming that the adhesion of cells in control represented 100 %.

Zymography Zymography was used for the analysis of MMP activity secreted into the culture medium of cell lines as described[38]. SGC-7901 cells were seeded at a density of 8×10^4 cells/pore in 24 well plates (Nunc. Co.) and maintained in 400 μl of serum-free medium containing different concentrations of *c*9,*t*11-CLA (25, 50, 100, and 200 μmol/L) for 24 h. After centrifugation at 500 g for 10 min, the supernatant was collected and stored at -20 ℃. SDS-PAGE was performed on gradient gels that contained 1.0 g/L gelatin (Amresco Co.) and run for 3-4 h under nondenaturing conditions. After electrophoresis, the gels were incubated in 2.5 % Triton X-100 for 1 h and then incubated in substrate buffer [50 μmol/L Tris (pH 7.5), 10 mmol/L $CaCl_2$, 200 mmol/L NaCl and 1 μmol/L $ZnCl_2$] for 12-16 h at 37 ℃. After incubation, the gels were stained in a solution containing 1 g/L Coomassie blue R250 for 4 h, and destained with 45 % methanol and 10 % acetic acid untill clear bands were shown.

RT-PCR SGC-7901 cells were treated at different concentrations of *c*9,*t*11-CLA (25, 50, 100, and 200 μmol/L) for 24 h and collected by centrifugation. Total RNA was isolated using Trizol reagent according to the manufacturer' s instructions. The concentrations and purity of total RNA were determined by DUR 640 nucleic acid and protein analyzer (Beckman, USA). The first-strand cDNA was synthesized from 5 μg of total RNA using 50 pmol of oligo (dT) primers, 10 units of AMV reverse transcriptase XL) (TAKAKA Biotechnology, Dalian Co.), 20 units RNase Inhibitor, 5×buffer and 10 mmol/L each dNTP in a total volume of 20 μl. PCRs were performed using respectively primers for TIMP-1, TIMP-2 and β-actin. The primer sequences are described in Table1. PCR was carried out in 25 μl volume containing 4 μl of cDNA template, 10×PCR buffer, 20 μmol/L each primer, 2.5 mmol/L dNTP mixture, 2.5 unit of Taq Polymerase. After denaturation at 94 ℃ for 5 min, the reaction mixtures were subjected to 35 cycles of PCR amplification in PCT-100™ programmable thermal controller (MJ Research Inc., USA). Each cycle consisted of 1 min of denaturation at 94 ℃, a primer specific annealing temperature and period (at 58 ℃ for 45 s for TIMP-1, at 58 ℃ for 30 s for TIMP-2, at 55 ℃ for 30 s for β-actin) and extension at 72 ℃ (1.5 min for TIMP-1, 1 min for TIMP-2, 45 s for β-actin).

Table 1 Primer sequence and size of expected PCR products

Primer	Sequence	Lengh (bp)
β-actin sense	5'-AAGGATTCCTATGTGGGC-3'	532
antisense	5'-CATCTCTTGCTCGAAGTC-3'	
TIMP-1 sense	5'-CTGTTGGCTGTGAGGAATGCACAG-3'	106
antisense	5'-TTCAGAGCCTTGGAGGAGCTGGTC-3'	
TIMP-2 sense	5'-AGACGTAGTGATCGGGCCA-3'	490
antisense	5'-GTACCACGCGCAAGAACCT-3'	

The amplified products were separated in 20 $g\cdot L^{-1}$ agarose gel and stained with ethidium bromide. After electrophoresis, the gel was observed and photographed under ultraviolet reflector. The density and area of each band were analyzed using ChemiImager™ 4000 digital system (Alpha Innotech Corporation, USA).

Statistical analysis

Analysis of data was performed using the Student' s *t* test. A value of $P<0.05$ was considered as statistically significant.

RESULTS

Effect of c9,t11-CLA on invasion in SGC-7901 cells

As shown in Table 2, the invasive abilities of SGC-7901 cells treated with 50 μmol/L, 100 μmol/L, and 200 μmol/L of *c*9, *t*11-CLA were significantly lower than those of the negative control group ($P<0.01$), and the inhibitory rates were 53.7 %, 40.9 % and 29.3 %, respectively. At 25 μmol/L *c*9,*t*11-CLA, the invasive ability of SGC-7901 cells did not differ from that of the negative control group ($P>0.05$). The effect of *c9*,

t11-CLA on the invasive ability of SGC-7901 cells is shown in Figure1.

Table 2 Effect of c9,t11-CLA on invasive ability of SGC-7901 cells

Groups	Invasive cell number (x±s)	Inhibitory frequency(%)
200 μmol/L	23.2±2.9[a]	53.7
100 μmol/L	29.6±3.3[a]	40.9
50 μmol/L	35.4±2.8[a]	29.3
25 μmol/L	44.9±3.1	10.4
Negative control	50.1±4.6	0

[a]P<0.01, compared with the negative control group.

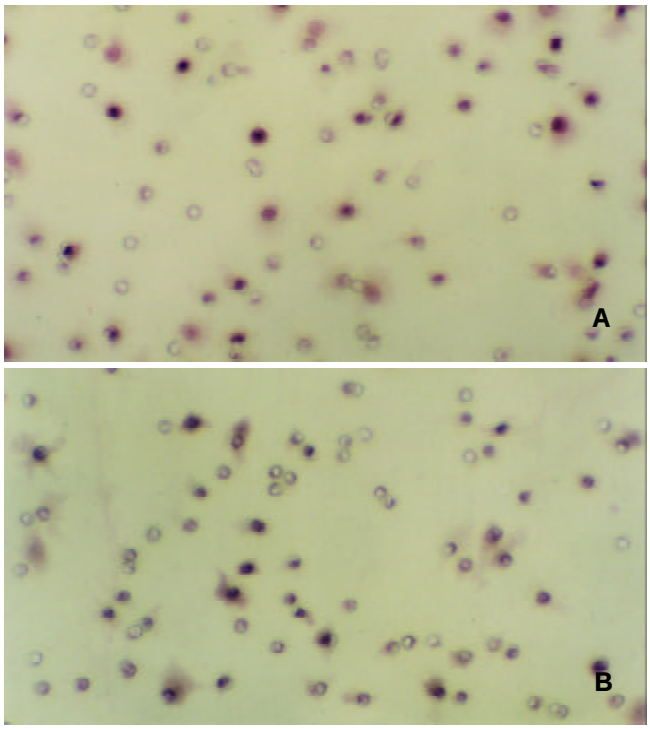

Figure 1 Effect of *c*9, *t*11-CLA on invasion of SGC-7901 cells detected by reconstituted basement membrane invasion assay (100×). A: There are more invading SGC-7901 cells in the negative control group. B: There are less invading SGC-7901 cells in the 200 μmol/L *c*9,*t*11-CLA group.

Effect of c9,t11-CLA on Chemotaxic migration ability in SGC-7901 cells

The chemotaxic ability of SGC-7901 cells at 200 μmol/L *c*9,*t*11-CLA was lower than that of the negative control group (P<0.05) and the inhibitory rate was 16.0 %. At 100 μmol/L, 50 μmol/L and 25 μmol/L of *c*9,*t*11-CLA, the chemotaxic ability of SGC-7901 cells did not differ from that of the negative control group (P>0.05). The effect of *c*9,*t*11-CLA on the chemotaxic migration ability of SGC-7901 cells is shown in Figure 2.

Table 3 Effect of *c*9,*t*11-CLA on migration ability of SGC-7901 cells

Groups	Cell number ($\bar{x}$±s)	Inhibitory frequency(%)
200 μmol/L	50.8±3.3[a]	16.0
100 μmol/L	52.5±3.1	13.2
50 μmol/L	54.4±3.9	10.1
25 μmol/L	55.0±4.4	10.1
Negative control	60.5±4.2	0

[a]P<0.05, compared with the negative control group.

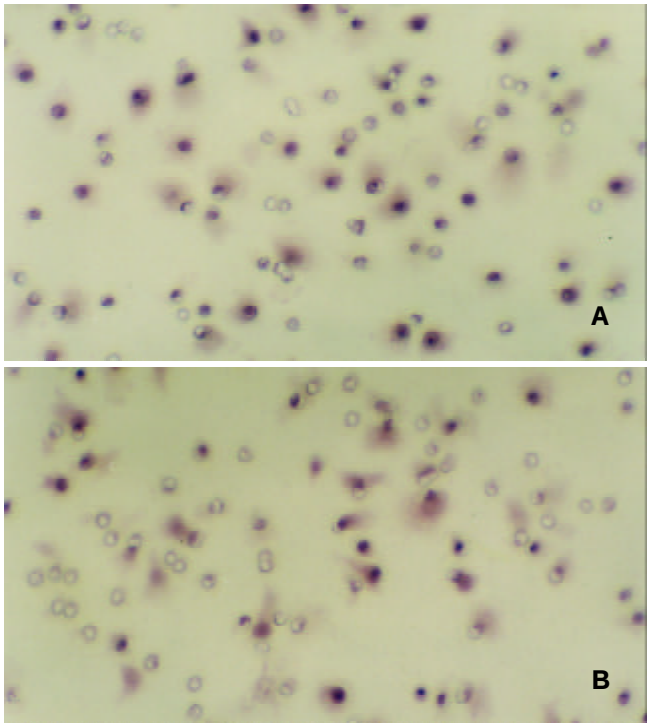

Figure 2 Effect of *c*9,*t*11-CLA on chemotaxic migration of SGC-7901 cells detected by chemotaxied-motion assay (100×). A: There are more invading SGC-7901 cells in the negative control group. B: There are less invading SGC-7901 cells in the 200 μmol/L *c*9, *t*11-CLA group.

Effect of c9,t11-CLA on attachment ability in SGC-7901 cells

As shown in Figure 3, at levels of 25 μmol/L, 50 μmol/L, 100 μmol/L and 200 μmol/L *c*9, *t*11-CLA could decrease the attachment to FN, LN or Matrigel ability of SGC-7901 cells and the inhibitory effect was positively correlated with the concentration of *c*9, *t*11-CLA.

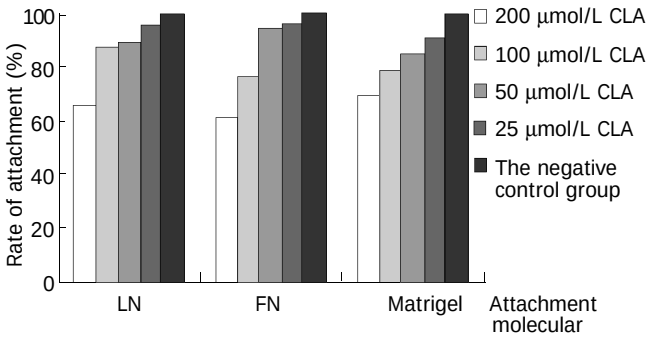

Figure 3 Effect of c9, t11-CLA on the attachment ability of SGC-7901 cells.

Effect of c9,t11-CLA on collagenase ability in SGC-7901 cells

As shown in Figure 4 and Figure 5, at levels of 200 μmol/L, 100 μmol/L and 50 μmol/L *c9, t*11-CLA significantly reduced 92 kDa type IV collagenase (MMP-9) activity in the serum-free medium supernatant of SGC-7901 cells, but at 25 μmol/L *c9, t*11-CLA, the collagenase ability did not differ from that in the negative control group. *c*9, *t*11-CLA did not influence on the 72 kDa collagenase (MMP2) activity.

Effect of c9,t11-CLA on expression of TIMP-1and TIMP-2 mRNA in SGC-7901 cells

The expression of TIMP-1 and TIMP-2 mRNA of SGC-7901 cells treated at different concentrations of *c*9,*t*11-CLA increased in comparison with that of the negative control group. As the

concentrations of *c*9,*t*11-CLA increased, the expression of TIMP-1and TIMP-2 mRNA was upregulated. Moreover, the increase of TIMP-2 mRNA expression was more obvious (Figure 6,7).

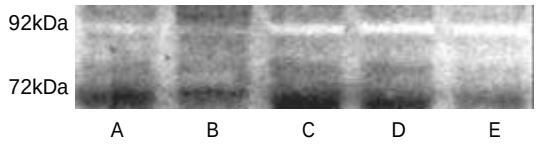

Figure 4 Effects of *c*9,*t*11-CLA on Gelatinase secretion in SGC-7901 cells detected by zymography. A, B, C, D are 200 μmol/L, 100 μmol/L, 50 μmol/L, 25 μmol/L *c*9,*t*11-CLA, respectively. E is the negative control group.

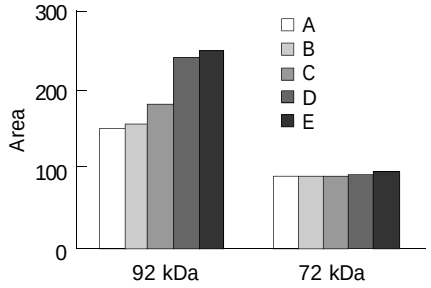

Figure 5 Quantitation of 92 and 72 kDa type IV Collagenase levels in SGC-7901 cells by ChemiImager 4000. A, B, C, D are 200 μmol/L, 100 μmol/L, 50 μmol/L, 25 μmol/L *c*9,*t*11-CLA, respectively. E is the negative control group.

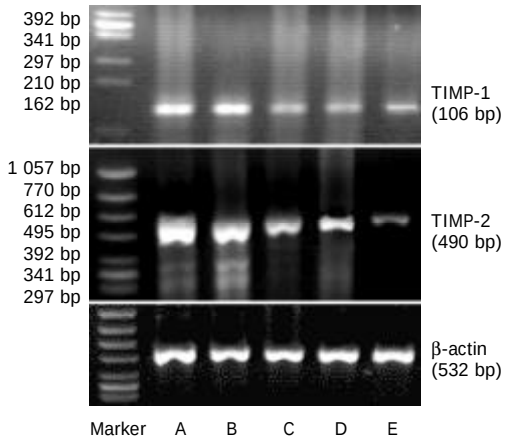

Figure 6 Effects of *c*9, *t*11-CLA on expression of TIMP-1 mRNA and TIMP-2 mRNA in SGC-7901 cells detected by RT-PCR. Top: Expression of TIMP-1 mRNA. Middle: Expression of TIMP-2 mRNA. A, B, C, D are 20 μmol/L, 100 μmol/L, 50 μmol/L, 25 μmol/L *c*9, *t*11-CLA, respectively. E is the negative control group.

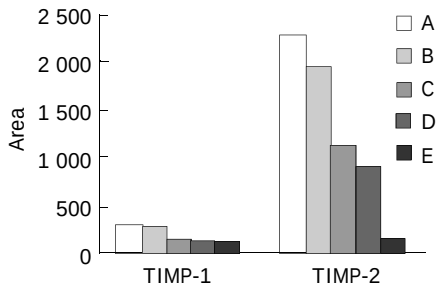

Figure 7 Quantitation of TIMP-1 and TIMP-2 mRNA levels in the SGC-7901 cells by ChemiImager 4000. A, B, C, D are 200 μmol/L, 100 μmol/L, 50 μmol/L, 25 μmol/L *c*9,*t*11-CLA, respectively. E is the negative control group.

DISCUSSION

Metastasis is a multistage process involving interactions between tumor cells and extracellular matrix (ECM). Metastasis of cancer cells required several sequent steps, including changes in cell-ECM interaction, disconnection of intercellular adhesions, separation of single cell from tumor tissue, degradation of ECM, migration of tumor cells into the ECM, invasion of lymph and blood vessels, immunologic escape in the circulatory system, adhesion to endothelial cells, extravasation from lymph and blood vessels, proliferation of cells and induction of angiogenesis[39]. The complex metastasis cascade could be described as cell attachment to the extracellular matrix, proteolytic dissolution of the matrix, and movement of cells through the digested barrier[40]. Therefore, tumor metastasis can be inhibited by blocking attachment, invasion and motility. *In vitro* invasion, attachment, proteolytic dissolution of the matrix and movement are required for tumor cell through Matrigel and polycarbonate, thus the reconstituted basement membrane invasion assay could better reflects the invasion ability of tumor. This study showed that the invasion ability of SGC-7901 cells treated with 200 μmol/L, 100 μmol/L and 50 μmol/L of *c*9, *t*11-CLA was significantly inhibited, which was consistent with the study result from mice melanoma[37]. We conclude that CLA can inhibit the invasion and metastasis of mice melanoma and human gastric adenocarcinoma.

Many studies indicated the importance of cancer cell-matrix interaction. Cell and matrix interactions promoted cell migration, proliferation, and ECM degradation[39-43]. Also, it has been shown that prevention of tumor cell adhesion and migration was related to the inhibition of tumor cell invasion into the basement membrane, and agents inhibiting cell attachment *in vitro* decreased the invasion and metastatic potential of tumor cells *in vivo*. Therefore, cellular interactions with ECM, which promote adhesion and migration, were thought to be required for tumor invasion, migration, and metastasis. We demonstrated that after incubated with 200 μmol/L, 100 μmol/L and 50 μmol/L of *c*9,*t*11-CLA for 1 h, the attachment to extracellular matrix component of SGC-7901 cells was significantly reduced, which was consistent with our previous finding[37], indicating CLA could inhibit the attachment to extracellular matrix component of tumor cells. However, in previous study we found that CLA could not affect the direct migration of B16-MB cells and in this study we observed that 200 μmol/L CLA could reduce the direct migration of SGC-7901 cells. Therefore, attachment of tumor cells to matrix inhibited by *c*9, *t*11-CLA may be a mechanism for the inhibition of invasion and needs further study.

Basement membrane is a barrier for tumor invasion and metastasis. Tumor cell invasion through the ECM was an essential process in cancer metastasis[42]. Matrix metalloproteinases (MMPs) were important enzymes for the proteolysis of extracellular matrix proteins such as collagen, laminin and fibronectin[44]. Most MMPs were synthesized and secreted from the cells as proenzymes[45]. Human MMP-2 (gelatinase A/72kD type IV collagenase) and MMP-9 (gelatinase B/92kD type IV collagenase) were thought to be the key enzymes for degrading IV collagen, which is a principal structural protein of the basement mmebrane[46]. Studies revealed that increased production of MMPs was correlated with the invasion, metastasis, and angiogenesis of tumors[47]. In this study, we found that *c*9, *t*11-CLA significantly reduced 92 kDa type (MMP9) activities in the serum-free medium supernatant of SGC-7901 cells, but had no effect on 72 kDa collagenase (MMP2), showing that CLA could inhibit the ability of tumor cells to degrade basement membrane via reduction of type IV collagenase activities. MMPs activity is regulated by tissue inhibitors of metalloproteinase (TIMPs).

There have been four members of the TIMP family determined up to date, of which TIMP-1 and TIMP-2 were best characterized as inhibitors of all known MMPs[44]. We found that TIMP-1 and TIMP-2 mRNA expression increased in SGC-7901 cells treated with *c*9,*t*11-CLA,indicating that *c*9,*t*11-CLA may inhibit the MMPs activity via inducing the expression of TIMP-1 and TIMP-2 mRNA and then inhibit the metastasis of SGC-7901 cells.

In conclusion, *c*9, *t*11-CLA inhibits several essential steps of metastasis in SGC-7901 cells. It can inhibit cell-matrix component interaction, reduce the activity of MMPs and increase the expression of TIMP1 and TIMP2 mRNA. Its mechanism in SGC-7901 cells metastasis needs to be studied further.

ACKNOWLEDGEMENTS

We are grateful to Dr. Rui-Hai Liu from Cornell University for providing 98 % purity of *c*9, *t*11-CLA.

Abstract

AIM: To investigate and determine the mechanism and signal pathway of tetradecanoylphorbol-1, 3-acetate (TPA) in degradation of RXRα.

METHODS: Gastric cancer cell line, BGC-823 was used in the experiments. The expression level of RXRα protein was detected by Western blot. Nuclear and cytoplasmic protein fractions were prepared through lysis of cell and centrifugation. Localization and translocation of RXRα were observed under laser-scanning confocal microscope through labeling specific anti-RXRα antibody and corresponding immunofluorescent antibody as secondary antibody. Different inhibitors were used as required.

RESULTS: In BGC-823 cells, RXRα was expressed in the nucleus. When cells were treated with TPA, expression of RXRα was repressed in a time-dependent and TPA-concentration-dependent manner. Meanwhile, translocation of RXRα from the nucleus to the cytoplasm occurred, also in a time-dependent manner. When cells were pre-incubated with proteasome inhibitor MG132 for 3 hrs, followed by TPA for another 12 hrs, TPA-induced RXRα degradation was inhibited. Further observation of RXRα translocation in the presence of MG132 showed that MG-132 could block TPA-induced RXRα redistribution. Conversely, when RXRα translocation was inhibited by LMB, an inhibitor for blocking protein export from the nucleus, TPA could not repress expression of RXRα.

CONCLUSION: TPA could induce the degradation of RXRα protein in BGC-823 cells, and this degradation is time- and TPA-concentration-dependent. Furthermore, the degradation of RXRα by TPA is via a proteasome pathway and associated with RXRα translocation from the nucleus to the cytoplasm.

INTRODUCTION

Retinoid receptors are nuclear receptors, and belong to members of the steroid and thyroid hormone receptor superfamily[1-4]. As retinoid receptor ligands, retinoids exert their effects on proliferation and differentiation through regulating the transcriptional and post-transcriptional activities of retinoid receptors[5-8]. Besides retinoids, other agents such as tetradecanoylphorbol-1, 3-acetate (TPA), and nerve growth factor (NGF), have an effect on retinoid receptor regulation[9-11]. Although up-regulation of retinoid receptor mRNA by retinoids has been demonstrated among a number of different types of cells[12-15], it is also indicated that retinoid receptors are degraded through a distinct pathway[16]. However, little is known how and where retinoid receptors are degraded, especially when other agents, rather than their ligands, are used to stimulate carcinoma cells.

Eukaryotic cells contain multiple proteolysis systems, which are mainly responsible for degradation of proteins in the extracellular milieu[17]. The multicomplex 26S proteasome contains two 19S regulatory complexes and a 20S catalytic core complex that may be responsible for 80-90 % of protein degradation in the cells[18,19]. It has been reported that proteasomes play an important role in thymocyte apoptosis and inflammatory response[20-23]. Proteasome inhibitors can induce cell apoptosis, accompanied by activation of several Caspases, such as Caspase-3 and Caspase-7[24,25]. In contrast, proteasome inhibitors may prevent cells from apoptosis through promoting resistance of cells at higher temperature and toxicity[26-28].

Retinoid receptors can be divided into two types, retinoic acid receptor (RAR) and retinoid X receptor (RXR)[29-32]. Usually, to regulate retinoid receptor by retinoid is preferential to measure its mRNA level, little has been done on retinoid receptor protein itself. Recently, Tanaka *et al*. pointed out that although retinoic acid caused up-regulation of RARα and RARγ mRNA, it down-regulated the expression of RARα and RARγ protein in breast cancer cell line MCF-7[16]. This evidence suggests that the mechanism of retinoic acid on transcriptional or post-transcriptional activity of retinoid receptor is quite different. In the course of investigating the effect of TPA on RXR protein expression, we found that TPA could down-regulate the expression of RXRα protein effectively in gastric cancer cells. In present study, we focused on the mechanism of TPA in RXRα degradation. The results demonstrated that degradation of RXRα by TPA was proteasome-dependent in gastric cancer cells. More importantly, both degradation and proteasome-dependency of RXRα were associated with translocation of RXRα protein. These findings may provide a novel insight into the cross-talk between degradation and translocation of retinoid receptor and TPA signaling pathway.

MATERIALS AND METHODS

Cancer cell line

Human gastric cancer cell line, BGC-823, was obtained from the Institute of Cell Biology in Shanghai. The cells were maintained in RPMI-1640 medium, supplemented with 10 % FCS, 1 mM glutamine, and 100 u/ml penicillin.

Detection of western blot[9, 33]

Cells treated by different agents were harvested, and suspended in RIPA buffer (10 mmol/L Tris (pH 7.4), 150 mmol/L NaCl, 1 % Triton X-100, 1 % deoxycholic acid, 0.1 % SDS, 5 mmol/L EDTA (pH 8.0), 1 mmol/L PMSF). Protein concentration was determined using the Bio-Rad protein assay system according to the manufacturer' s instructions (Bio-Rad Hereules, CA). Total protein (50 μg) was subjected to SDS-PAGE and transferred to nitrocellulose membrane for Western blot analysis. The membrane was subsequently blocked with 5 % dry milk in TBS-T and then immunnoblotted with the corresponding antibody. Protein was detected using the ECL kit (Peirce) according to the manufacturer' s directions. Before incubation with antibody, the same membrane was stained by ponceau S (Sigma) to show the amount of protein used in each well. The intensities of bands indicated by Western blot were quantified by a densitometer. To separate the cytoplasmic and nuclear fractions, cells were suspended in 500 μl of 10 mM Tris-Cl (pH 7.8), 1 % Nonidet P-40, 10 mM mercaptoethanol, 0.5 mM phenylmethylsulfonyl fluoride, 1 mg/L leupeptin and 1 mg/L aprotinin for 2 min at 0 ℃, then 500 μl of DDW was added, and the cells were allowed to swell for 2 min. Cells were sheared by 10 passages through a 22 gauge needle. The nuclear and cytoplasmic fraction was obtained by centrifugation at 4 000×g for 5 min. The supernatant was cytoplasmic fraction and pellet was nuclear fraction.

Immunofluorescent labeling and confocal microscopy[9, 34]

Cells were cultured on a cover glass overnight, then treated with various agents. After washed with PBS, cells were fixed in 4 % paraformaldehyde. To identify RXRα protein, cells were firstly incubated with anti-RXRα IgG antibody (Santa Cruz), and then reacted with corresponding FITC-conjugated anti-IgG (Pharmingen) as secondary antibody. To visualize nuclei, cells were stained with propidium iodine (50 mg/L) containing 100 mg of DNase-free RNase A per liter. Fluorescent images were observed and analyzed under laser-scanning confocal microscope (Bio-Rad MRC-1024ES).

RESULTS

TPA induces degradation of RXRa

Western blot analysis was carried out to investigate the effect of TPA on the expression level of RXRα protein. When BGC-823 cells were treated at different concentrations of TPA (ranging from 100-1.0 g/L) for 24 hrs, the expression of RXRα protein showed a concentration-dependent decrease (Figure 1A), 87 % reduction of RXRα protein expression was observed at the concentration of 100 g/L TPA determined by a densitometer (Figure 1B). Similar repressing tendency was also seen in time-course of TPA treatment. As shown in Figure 1A-B, treatment of cells with TPA for different time periods caused a marked down-regulation of RXRα protein in BGC-823 cells. After 24 hr of TPA treatment, the expression of RXRα protein was almost inhibited. Thus, TPA could induce the degradation of RXRα protein in BGC-823 cells. Moreover, this degradation was time- and TPA concentration-dependent.

TPA induces RXRa translocation

To determine the effect of TPA on the subcellular localization of RXRα, immunofluorescent labeling of RXRα protein was performed and observed under laser-scanning confocal microscope. The result indicated that RXRα was accumulated in the nuclei in intact BGC-823 cells (Figure 2A). Treatment of TPA resulted in redistribution of RXRα protein in a time-dependent manner. When cells were treated with TPA for 6 hrs, RXRα protein started to be translocated from the nucleus to the cytoplasm, and after 12 h of treatment, RXRα protein was completely accumulated in the cytoplasm, and after 24 h of treatment, most of the RXRα protein became localized in the cytoplasm, but little in the nucleus (Figure 2A). To further confirm this translocation, nuclear and cytoplasmic fractions were prepared from BGC-823 cells, and the protein extracts were analyzed by Western blot. It clearly showed that in the intact BGC-823 cells, RXRα was expressed mainly in the nucleus (Figure 2B). TPA treatment resulted in a time-dependent shift of RXRα protein from nuclear portion to cytoplasmic portion. The maximum cytoplasmic RXRα accumulation occurred in the 12 h TPA treatment, and after 24 h TPA treatment, trace RXRα was detected in the nucleus, mostly in the cytoplasm (Figure 2B). Accordingly, this result was in agreement with that of Figure 2A, strongly suggesting that the translocation of RXRα did occur in the course of TPA treatment.

To verify that cytoplasmic RXRα protein was originated from nuclear RXRα, rather than being synthesized in the cytoplasm, cells were pre-incubated with cycloheximide

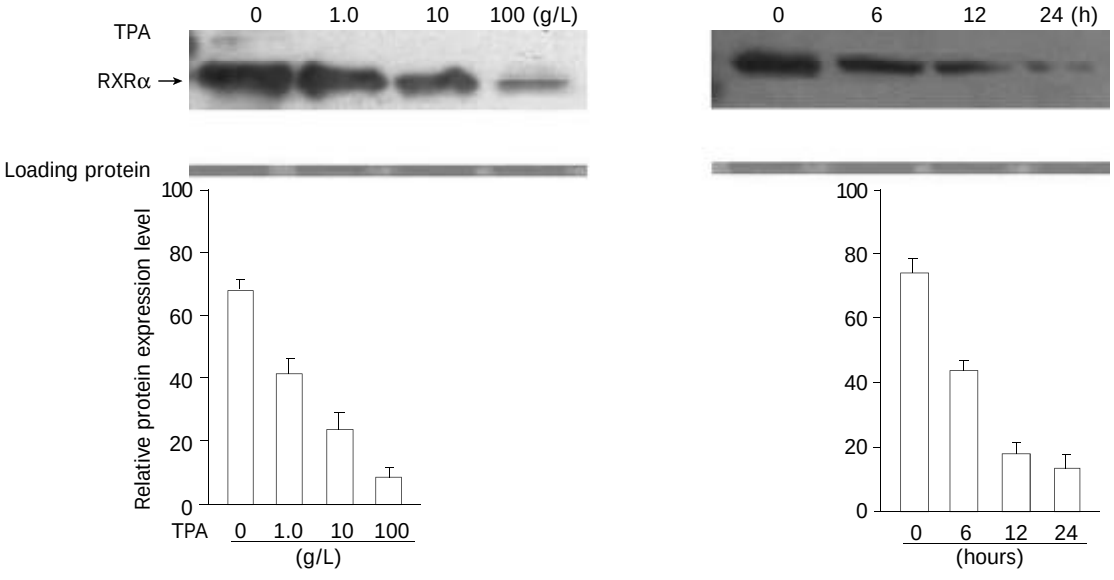

Figure 1 Effect of TPA on expression of RXRα protein. Cells were treated at different concentrations of TPA or different time periods. (A) Expression of RXRα was detected by Western blot. The amount of protein used in each lane was indicated by staining with ponceau S. (B) The intensity of each band shown in Figure 1A was quantified by a densitometer.

(CHX) for 3 hrs to specifically prevent new cytoplasmic protein synthesis[35]. Confocal microscopy observation showed that RXRα protein was seen only in the nucleus when cells were treated with CHX alone (Figure 2A), indicating that cytoplasmic protein synthesis was inhibited by CHX effectively. However, when cells were continuously incubated with TPA for another 24 hrs, RXRα protein was still translocated into the cytoplasm (Figure 2A). Therefore, it convincingly demonstrated that cytoplasmic RXRα protein was from the nucleus.

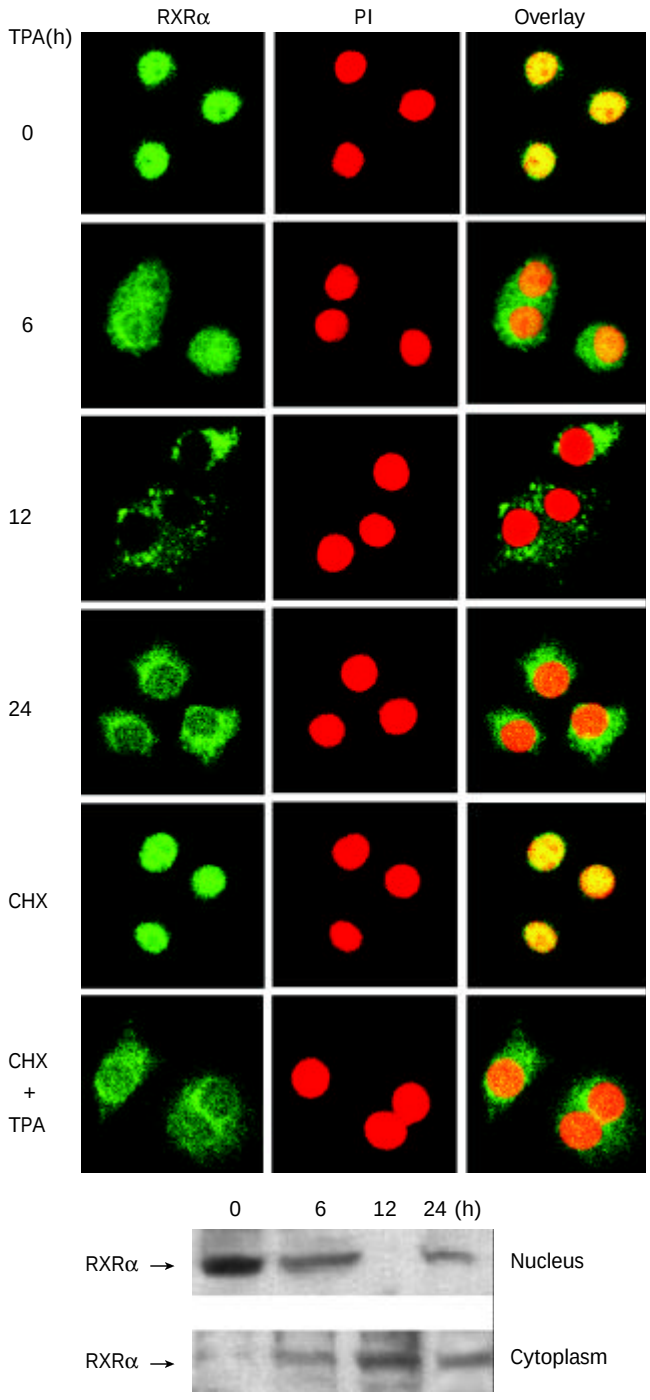

Figure 2 Translocation of RXRα from the nucleus to the cytoplasm induced by TPA. Cells were treated with TPA for different time periods or CHX (10 g/L) for 3 hrs as required. (A) Cells were immunostained with anti-RXRα antibody followed by corresponding FITC-conjugated anti-IgG secondary antibody to show RXRα protein. Simultaneously, cells were stained with PI to display the nucleus. The fluorescent image was observed under laser-scanning confocal microscope. (B) Nuclear and cytoplasmic fractions were prepared as described in the Materials and Methods. RXRα was revealed by Western blot.

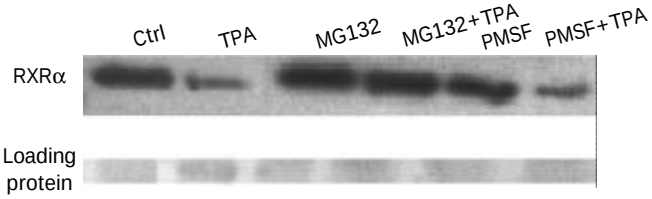

Figure 3 Effect of different agents, including TPA, MG132 (10 μmol/L) and PMSF (100 mg/L), on expression of RXRα. Cells were pre-treated with MG132 or PMSF for 3 hrs, followed by TPA for another 24 hrs. RXRα expression was analyzed by Western blot.

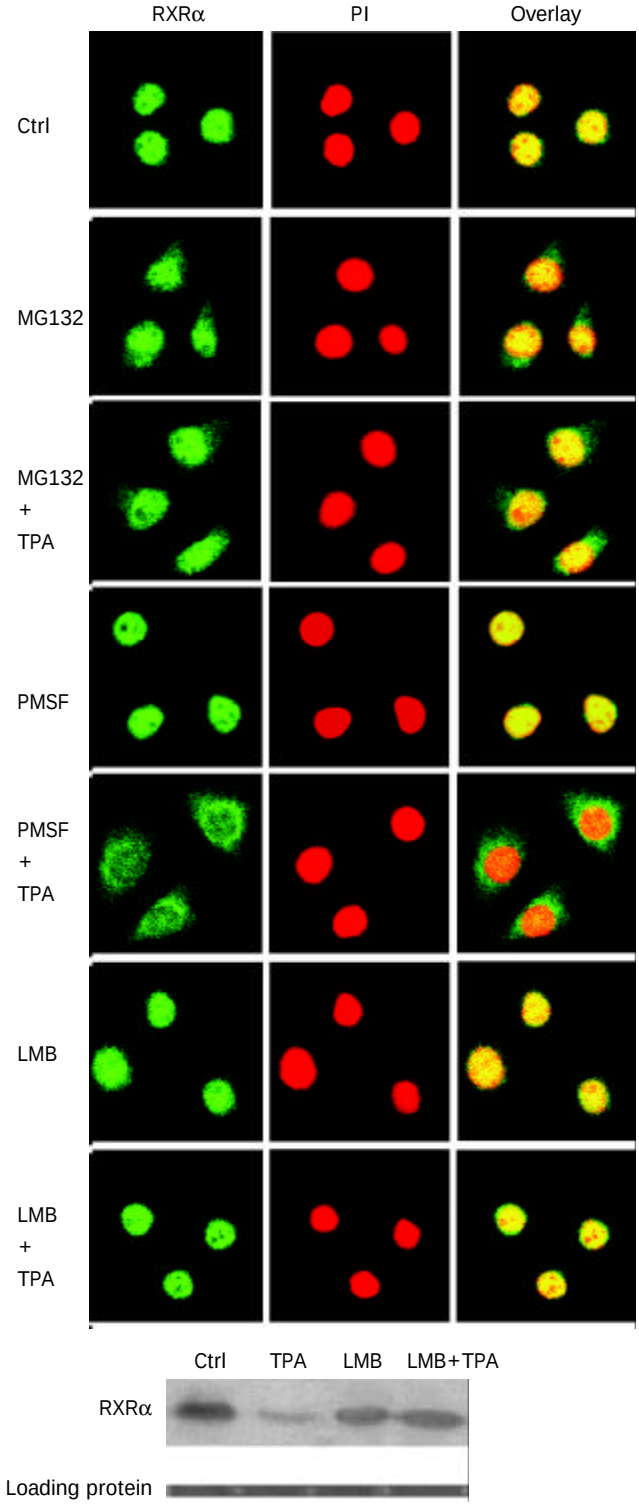

Figure 4 Effect of different agents, including TPA, MG132, PMSF and LMB (1 ng/ml), on translocation and expression of

RXRα. Cells were pre-treated with different inhibitors for 3 hrs as required, followed by TPA treatment for another 12 hrs. (A) Translocation of RXRα in response to different agents, observed under laser-confocal microscope. (B) Expression of RXRα induced by different agents, revealed by Western blot.

Effect of proteasome inhibitor on RXRa degradation

To determine whether the degradation of RXRα by TPA was 26S proteasome-dependent, BGC-823 cells were incubated with proteasome-specific inhibitor MG132[16,18] in the absence or presence of TPA. Western blot analysis showed that MG132 was able to inhibit TPA-induced RXRα degradation (Figure 3). By contrast, when PMSF, a potent inhibitor of protease but not specific-inhibitor of proteasome[36], was used as a positive control, it could not inhibit TPA-induced RXRα degradation, TPA still down-regulated expression of RXRα (Figure 3). Thus, this result suggested that TPA-induced degradation of RXRα occurred through the proteasome pathway.

RXRa translocation by TPA is proteasome-dependent

To determine the relationship between RXRα translocation and proteasome pathway, the behavior of RXRα translocation in the presence of MG132 was investigated. Confocal microscopy observation showed that cells treated with MG132 alone for 3 hrs could hardly induce RXRα protein translocation into the cytoplasm, majority of RXRα protein was localized in the nucleus, but very little in the cytoplasm. After TPA treatment for another 12 hrs, most of RXRα protein remained in the nucleus, similar to MG132 treatment alone (Figure 4A). As a positive control, when PMSF was used to treat cells alone, RXRa was not translocated, still in the nucleus. However, when cells were continuously incubated with TPA, translocation of RXRα was detected (Figure 4A). Thus, it clearly revealed that MG132 and PMSF had different effects on inducing RXRα translocation, MG132 could inhibit TPA-induced translocation of RXRa protein, and RXRα translocation induced by TPA was proteasome-dependent.

In addition, we used another inhibitor LMB, an inhibitor of protein export from the nucleus[37,38], to block RXRα protein nucleocytoplasmic translocation, and then determine whether this blockage could affect TPA-induced RXRα degradation. As shown in Figure 4A, when LMB was incubated with cells alone for 3 hrs, or followed by TPA treatment for another 12 hrs, RXRα was not translocated into the cytoplasm, indicating that LMB did block RXRα translocation no matter TPA existed or not. Under such circumstances, TPA could not repress the expression level of RXRα protein (Figure 4B). These results clearly indicated that TPA-induced RXRα degradation was not only proteasome-dependent, but also translocation-dependent.

DISCUSSION

The redistribution of proteins between nucleus and cytoplasm is an important event for the regulation of their activities and the execution of their functions[39-41]. For example, phosphorylation is needed for redistribution of some proteins. In some cases, phosphorylation of a protein promotes its entry from the cytoplasm to the nucleus[41], in other cases, it causes the protein translocation from the nucleus to the cytoplasm[41,42]. Our study showed that degradation of RXRα protein by TPA was associated with its translocation from the nucleus to the cytoplasm. In gastric cancer BGC-823 cells, TPA could down-regulate the expression of RXRα protein significantly, and this repression was time-dependent and TPA-concentration-dependent (Figure 1A). In the treatment of cells with TPA for 24 hrs, 87 % of RXRα protein expression was inhibited (Figure 1B). Moreover, we found that RXRα was translocated from the nucleus to the cytoplasm as degraded by TPA, also in a time-dependent manner (Figure 2A). However, when this translocation was blocked by LMB (Figure 4A), degradation of RXRα by TPA was not detected by Western blot (Figure 4B). Therefore, it clearly demonstrated that TPA-induced RXRα degradation was time-dependent and translocation-dependent.

Although we have detected the degradation of RXRα by TPA during the translocation of RXRα, its molecular mechanism is still largely unknown. More evidences revealed that the proteasome played not only a proteolytic role in protein degradation, but also a non-proteolytic role in transcriptional elongation, nuclear excision repair, and protein trafficking[43-48]. To determine whether degradation of RXRα was responsible for proteasome pathway, we used MG132, a specific proteasome inhibitor, to study the potential linkage among RXRα degradation, translocation and proteasome pathway. The results showed that inhibition of proteasome function by MG132 could repress TPA-induced RXRα degradation (Figure 3), and further block TPA-induced RXRα translocation (Figure 4A), which strongly supported the non-proteolytic role of the proteasome in protein translocation. Accordingly, it is likely that regulation of post-transcriptional activity of RXRα through the proteasome pathway may be involved in multiple mechanisms.

Recently, Tanaka *et al*. found that incubation of breast cancer cells MCF-7 with 10^{-6} mol/L retinoic acid induced a rapid breakdown of both RARα and RARγ in spite of the accumulation of their mRNA[16]. Eliezer *et al*. also pointed out that retinoic acid-induced degradation of RARs and RXRs could play an important role in the control of the activity of RAR/RXR heterodimer[49]. These reports, at least, provide a crucial clue: retinoid receptor (including RARs and RXRs) activity may be regulated through a distinct mechanism at transcriptional or post-transcriptional level, and formation of heterodimer/or homodimer between these receptors is essential. In our previous studies, we found that RXR could form heterodimer with RAR in the presence of retinoic acid[50]. Moreover, we have indicated that besides RAR, RXR also formed heterodimer with Nur77, an orphan receptor, bound to the RARβ (retinoic acid receptor β) promoter, and then induced RARβ expression, which is critical for inducing apoptosis and inhibiting cell growth in carcinoma cells[15,50]. Therefore, it is likely that degradation and translocation of RXRα by TPA are not a simple event. RXRα might form heterodimer with some proteins, such as Nur77 or RAR, then export from the nucleus to exert its function in the cytoplasm. But, at least, it has been confirmed that the RXRα is degraded through a proteasome pathway in the present study.

Abstract

AIM: Using a monoclonal antibody against gastric cancer antigen named MGb1 to screen a phage-displayed random peptide library fused with coat protein pIII in order to get some information on mimotopes.

METHODS: Through affinity enrichment and ELISA screening, positive clones of phages were amplified. 10 phage clones were selected after three rounds of biopanning and the ability of specific binding of the positive phage clones to MGb1-Ab were detected by ELISA assay (DNA sequencing was performed and the amino acid sequences were deduced) By blocking test, specificity of the mimic phage epitopes was identified.

RESULTS: There were approximately 200 times of enrichment about the titer of bound phages after three rounds of biopanning procedures. DNA of 10 phage clones after the third biopanning was assayed and the result showed that the positive clones had a specific binding activity to MGb1-Ab and a weak ability of binding to control mAb or to mouse IgG. DNA sequencing of 10 phage clones was performed and the amino acid sequences were deduced. According to the homology of the amino acid sequences of the displayed peptides, most of the phage clones had motifs of H(x)Q or L(x)S. And these 10 phage clones could also partly inhibit the binding of MGb1-Ab to gastric cancer cell KATO-III. The percentage of blocking was from (21.0±1.6) % to (39.0±2.7) %.

CONCLUSION: Motifs of H(x)Q and L(x)S selected and identified show a high homology in the mimic epitopes of gastric cancer associated antigen. There may be one or more clones which can act as candidates of tumor vaccines.

INTRODUCTION

Filamentous bacteriophages have been used extensively in recent years for the display large repertoires of peptides on their surface[1-3]. These peptides can be expressed by cloning random oligonucleotides at the end of the genes encoding the phage coat proteins[4]. Phage display system has many advantages such as efficacy of biopanning, ability of amplification and linkage of the displayed peptide with its encoding DNA sequence within the phage particle, enabling quick and simple elucidation of binding sequences. Numerous papers have shown that this approach is successful with an extraordinarily wide range of protein targets, such as structural proteins, signal transduction proteins, receptors, serum proteins, oncoproteins and so on. It is also possible to select phage display peptides that mimic the original characteristics of antigen binding to specific antibodies without previous knowledge of the antigen structure[5-9]. In this respect, phage display technology has been well established as an important experimental approach in the development of novel vaccines and drugs. Antigens and epitopes play important roles in immune responses to tumors. To select the possible mimotopes of gastric cancer, a random phage display peptide library constructed on pIII was screened by biopanning with MGb1-Ab, a monoclonal antibody against gastric cancer, as a selective molecule.

MATERIALS AND METHODS

Materials

Monoclonal antibody The hybridoma cell line which secretes mouse mAb MGb1 (its immunoglobulin type is IgG) against gastric carcinoma -associated antigens was established by our laboratory. This hybridoma was prepared by taking human gastric carcinoma cell line KATOIII as antigen, and the immunized mouse spleen cells were fused with SP2/0 according to routine procedures for mAb preparation[10-15]. The mAb in ascitic fluid was prepared by intraperitoneal injection of hybridoma cells into Balb/c mouse and collected at the aseptic environment. Then the mAb was purified by saturated ammonium sulfate precipitation and DEAE-52 anion exchange chromatography[16,17].

Random peptide library and bacteria The library used was purchased from New England Biolabs Company, containing approximately 2.8×10^9 different phage clones, which composed of the genome of the filamentous phage. The phages in this library were engineered to express a recombinant form of gene III containing a degenerated DNA insert encoding random 7-mer peptide. The recombinant gene III was under the control of LacZ promoter. And all the sub-major coat proteins pIII were recombinants. The ER2537 strain of *E.coli*

was used for culture of phage. Bacteria were cultured in LB medium without any antibiotics.

Methods

Amplification of phages Infections were carried out by incubating phages for 10-15 min at room temperature with ER2537 at the number ratio of 3-5:1(bacteria: phages). And the bacteria were cultured for another 4.5 h at 37 ℃. The supernatants from the culture where phages existed were collected. The culture supernatants of infected bacteria were collected, where bacteria secreted phages. The solution of 200 g· L^{-1} PEG 2.5 mol· L^{-1} NaCl was added into the supernatant at the volume ratio to supernatant of 1:5. And the mixture was incubated for 1 h at 4 ℃. After centrifuged at 10 000 g, the precipitated phages were pelleted, and then resuspended in Tris-buffered saline (TBS). The protocols of PEG precipitation were repeated. Phages from a culture supernatant volume of 5 mL were usually resuspended in a final volume of 150 μL TBS. The titer of the phages was then assayed.

Assay of phage titer The prepared phages were 10-fold serial diluted in LB with the suggested dilution ranges: 10^8-10^{11} for amplified phage culture supernatants and10^1-10^4 for unamplified biopanning eluates. A single colony of ER2537 in 5 mL LB was cultured with shaking until mid-log phase. 200 μL of bacteria culture reached mid-log phase was dispensed into microfuge tubes and then 10 μL of diluted phages per tube was vortexed quickly and incubated at room temperature for 1-5 min. Bacteria infected with phages were transfered to a culture tube containing 3 mL 45 ℃ LB/agarose at the top and immediately poured onto a pre-warmed LB/IPTG/X-gal plate and spread evenly after vortexed. Plates were cooled for 5 min, inverted and incubated overnight at 37 ℃. Plaques on plates were counted.

Biopanning Three rounds of biopanning were carried out with mAb-MGb1. During the first round, a ELISA well was used as the solid phage. It was coated by incubating overnight with aliquots of mAb (100 mg· L^{-1}) in the coating buffer (carbonate-bicarbonate buffer, pH9.6) at 4 ℃ in a humid atmosphere, then washed with TBS for 6 times, blocked in TBS-10 g· L^{-1} BSA. One aliquot of the library containing 2×10^{11} pfu phages in 100 μL TBS-0.5 g· L^{-1} BSA was added to the mAb coated well, incubated for 1 h at 37 ℃. Unbound phages were removed and the well was washed 6 times with TBS-1 g· L^{-1} Tween-20. Eluting buffer (0.2 mol· L^{-1} glycine with its pH adjusted to 2.2 by HCl) was added for 10 min, then removed and neutralized by adding of Tris-HCl (pH 9.0). Phages eluted from each round were used to infect exponential phase ER2537. After cultured for 4.5 h, phages in the supernatant were precipitated by PEG. The second and third rounds of biopanning were followed as described above except that unbound phages were washed 20 times with TBS-0.5 % Tween-20. After neutralization in the third round of biopanning, the eluted phages were planted on the LB medium directly and cultured overnight at 37 ℃.

ELISA to identify positive phage clones ELISA was carried out as routine procedures[18-26]. ELISA wells were coated by incubating overnight with mAb-MGb1 (100 mg· L^{-1}) in the coating buffer (carbonate-bicarbonate buffer, pH9.6) at 4 ℃ in a humid atmosphere, washed 6 times with TBS, blocked with TBS-50 g· L^{-1} BSA. Single clone of phage expressing the recombinant form of gene III containing the peptide insert was incubated in LB for 4.5 h. The coated wells were incubated for 1h at 37 ℃ with supernatant from such cultures and then the horseradish peroxidase (HRP) labeled mouse-anti-M13 antibody diluted to a volume ratio of 1:5 000 in blocking buffer was added. TMB was used as a substrate for HRP and the absorbance of each well was read at 450 nm.

Extraction of single strand DNA of phages and DNA sequencing Single strand DNA was prepared from 1.5 mL overnight cultures by extraction and purification by using a single strand of M13 extraction and purification kit (Huashun Bio. Com., China). The culture supernatant of infected bacteria containing phages at the volume of 1.2 mL was transferred to sterile 1.5 mL Eppendorf tubes. 200 μL precipitate buffer was added. The mixture was cooled on ice for 15 min. After centrifugation for 5 min at 10 000 g, the supernatant was discarded and the precipitate was preserved for DNA extraction. Phages were lysed in 500 μL lysis buffer for 2 min at room temperature. The product was transfered to a column containing resin that could absorb DNA. After centrifugation for 15 s, DNA absorbed in resin was washed twice with ethanol and eluted with 20 μL Tris buffer. Single strand DNA of phages was extracted and 5 μL of product was run on a 10 g· L^{-1} agarose gel in 1×TAE. DNA bands were detected by ethidium bromide staining and visualized by UV light photography. Sequencing procedures were carried out by using a auto-sequence apparatus ABI PRISMTM310 (PE Com. U.S.A.). 100 ng of such single strand DNA was used as a template. The oligonucleotide 5' -CCC TCA TAG TTA GCG TAA CG-3' , complementary to the genomic DNA of the phage and the downstream of the insert, was used as a primer.

Blocking test ELISA wells were coated with KATOIII (1×10^5 cells per well), washed 6 times with PBS, blocked for 2 h. MAb MGb1 was mixed with 1×10^{10} pfu individual phages for 1 h at 37 ℃ and then the mixture was added into the KATOIII coated wells, incubated for another 1 h. The HRP labeled goat-anti-mouse IgG diluted to a volume ratio of 1:5 000 in the blocking buffer was added then. TMB was used as a substrate for HRP and the absorbance of each well was read at 450 nm[27].

RESULTS

Biopanning

The ratios of output/input phages in three biopanning rounds are listed in Table 1. The ratio of the last round was about 100 times higher than that of the first round. It indicated that the specific phages were enriched.

Table 1 Yields of washed phages

Round	Input phages(pfu)	Output phages(pfu)	Yields/%
1	2.0×10^{11}	5.8×10^{4}	2.9×10^{-5}
2	2.0×10^{11}	3.2×10^{5}	1.6×10^{-4}
3	2.0×10^{11}	4.0×10^{6}	2.0×10^{-3}

Selection of phage clones

MGb1 mAb with specificity to gastric carcinoma was used to screen the library of phages containing random 7-mer peptide inserts. After three rounds of biopanning, some individual phage clones were isolated and screened by ELISA to identify those of interests which bound strongly to the antibody, and 10 clones of them which gave a clear positive signal and had the highest absorbance at 450 nm were selected.

Detection of antigenic specificity of the final-eluted phage by sandwich ELISA

MGb1 mAb was immobilized on the ELISA wells in which the selected phage clones were added. HRP labeled anti-M13 mAb was then used to detect the captured phages. As negative control, anti-endotoxin mAb and mouse IgG were used to replace the coating and the binding antibodies. The results revealed that the selected phages could react to mAb MGb1 specifically, and had weak ability of binding to unrelated antibodies such as anti-endotoxin mAb and mouse IgG (Figure 1).

Extraction of single strand DNA of phages

The length of all phage clones was the same as M13 single strand DNA marker, which indicated that single strand DNA of phages was prepared well and there were no other kinds of phages contaminated (Figure 2).

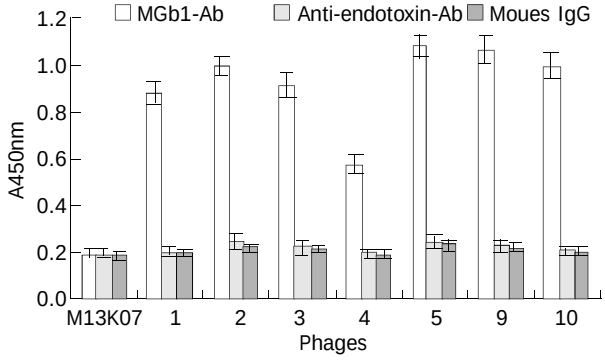

Figure 1 Binding of phages to MGb1-Ab by ELISA at the third round.

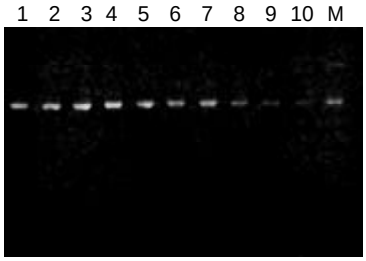

Figure 2 Electrophoresis of single strand DNA of phage clones (lanes1-10: Single strand DNA of phage clones; lane M: M13 single strand DNA marker).

Identification of motifs amongst the sequences of phage clone inserts

The selected 10 clones were sequenced and motifs could be identified amongst the deduced amino sequences of phage clone inserts for mAb MGb1. According to the homology of amino acid sequences of the displayed peptides, some preserved mimotope information was obtained. Most phage clones had motifs of H(x)Q and L(x)S (Figure 3).

Blocking test

If the selected clones contained epitopes or mimotopes of the native antigen, then they should be presented to block the binding of mAb MGb1 to gastric cancer cell-line KATOIII. To test this hypothesis, 7 of representative phage clones were used in a blocking test. Wild-type phage M13 was used as a negative control (whose absorbance at 450 nm was represented by *B*) to ensure that blocking of binding of the mAb to gastric cancer cell-line KATOIII was due to the phage insert (whose absorbance at 450 nm was represented by *A*) rather than the mere physical presence of phages. The blocking percentage of each phage was (25.6±1.3) %, (34.6±2.5) %, (32.6±1.8) %, (21.0±1.6) %, (39.0±2.7) %, (36.3±3.2) %, (29.5±1.9) %, respectively (Figure 4), compared with wells to which no phage was added (whose absorbance at 450 nm was represented by *C*), which was calculated using the formula: blocking %=[(*C*-*B*)-(*C*-*A*)]/*A*×100 %.

DISCUSSION

Gastric cancer is one kind of malignant tumors with complicated mechanism and is the leading cause of death in China[27-51]. Biotherapy is a new way for human to combat gastric cancer[52-63]. Tumor antigens play important roles in the induction of immune responses[64-66], which are predominantly focused on specific antigenic sites, known as epitopes. Identification of B-cell epitopes can be used to design peptide vaccines against tumor and is actively pursued in many laboratories. Since antibodies recognize B-cell epitopes that are mainly located on the surface of molecules, the native conformation of the antigen is a critical parameter for this interaction to occur. Early studies on the antigenicity of globular proteins suggested that antibodies recognized amino acids which either constituted a short linear stretch along the polypeptide chain (continuous or linear B-cell epitopes), or were brought together by the juxtaposition of the polypeptide chains when the protein was in its native conformation (discontinuous or conformational B-cell epitopes)[67].

Considerable attention has been paid to the difficulties in identifying the structural characteristics of B-cell epitopes. A number of empirical approaches have been employed to predict B-cell epitopes from the primary amino acid sequence of the protein including identification of regions of hydrophilicity, solvent accessibility, protrusion, atomic mobility and secondary structures. But many of them identify linear B-cell epitopes instead of discontinuous epitopes. B-cell epitopes are entities that can be defined only by their mutual complementarity. Phage display random peptide library offers a convenient way to select phage display peptides that mimic the original characteristics of antigen binding to specific antibodies[68,69]. One of the advantages of screening random peptide libraries to identify B-cell epitopes is that there is no need to know the amino acid sequence of the protein against which the antibody has been elicited. Since peptide libraries provide a rich source of mimic antigens, identification of B-cell epitopes has been greatly simplified.

In the present study, to select the possible mimotopes of gastric cancer, a random phage display peptide library constructed on pIII was screened by biopanning using MGb1-Ab as a selective molecule. After three biopanning procedures, there was a remarkable enrichment in the titer of bound phages.

Then, 10 phage clones were selected from the third biopanning and ELISA. Their single strand DNA was sequenced and the amino acid sequences were deduced. According to the homology of amino acid sequences of the displayed peptides, some preserved epitope information was obtained. Most phage clones had motifs of H(X)Q or L(X)S. The results of ELISA showed that the positive phage clones had a specific binding activity with MGb1-Ab and could inhibit the binding of MGb1-Ab to gastric cancer cell line KATO-III.

Since the binding site of an antibody is not unique for a single antigen, several mimotopes with different amino acid sequences can be recognized by binding to different subsites within the binding site[70-72]. To date, little is known about the structure and amino acid sequence of parental antigen MGb1, so we can not tell the exact characteristics of the peptides selected from the 7-mer random peptide library. Research should be done to further characterize the mimotopes recognized by mAb MGb1.

Abstract

AIM: To explore the instabilities, polymorphisms and other variations of mitochondrial D-loop region and downstream gene 12S rRNA-tRNA^{phe} in gastric cancers, and to study their relationship with gastric cancer.

METHODS: Three adjacent regions (D-loop, tRNA^{phe} and 12S rRNA) were detected for instabilities, polymorphisms and other variations via PCR amplification followed by direct DNA sequencing in 22 matched gastric cancerous tissues and para-cancerous normal tissues.

RESULTS: PolyC or $(CA)_n$ instabilities were detected in 13/22(59.1 %) gastric cancers and 9/22(40.9 %) in the control (P>0.05). There existed 2/12(16.7 %) and 6/10(60 %) alterations of 12S rRNA-tRNA^{phe} in well differentiated gastric cancers and poorly differentiated ones, respectively (P<0.05). Some new variations were found, among which np 318 and np 321 C-T transitions in D-loop region were two of the five bases for H-strand replication primer. np 523 AC-deletion and np 527 C-T transition occurred at mtTF1 binding site (mtTFBS), which were associated with the transcription of downstream mitochondrial genome. Seven samples showed the np 16 182 polyC instabilities, five of which simultaneously showed np 16 189 T-C transitions.

CONCLUSION: There is no statistic significance of instabilities and polymorphisms in mitochondrial D-loop region between gastric cancerous and para-cancerous normal tissues, which suggests that the instability might relate to heredity or be dependent on aging. There is a significant correlation between differentiation degree of gastric cancer and variant frequencies of 12S rRNA-tRNA^{phe}. The poorly differentiated gastric cancers are more prone to 12S rRNA-tRNA^{phe} variations, or gastric cancers with 12S rRNA-tRNA^{phe} variations are more likely to be poorly differentiated. np 16 189 T-C transition may be one of the important reasons for polyC instability in gastric cancer.

INTRODUCTION

Gastric carcinoma is one of the most common cancers in the world. The pathogenesis of gastric carcinoma is complex and multifactorial, among which environmental and biological factors (excessive nitrite salt intake and *Helicobacter pylori* infection) are important risk factors for gastric cancer, but no clear mechanism has been understood as that of colon cancer[1]. Mitochondrial DNA (mtDNA) is a 16 569-bp double stranded, closed circular molecule, which encodes polypeptides participating in oxidative phosphorylation and synthesis of ATP[2]. Compared to nuclear DNA, mtDNA is more susceptible to damage by mutagens and has a high mutant rate[3], because of the lack of protective action by histones and the limited capacity of damage repairing system as in yeast and most nuclear genomes[4]. 12S rRNA and tRNA^{phe} are downstream adjacently coding regions of mitochondrial D-loop region, and could reflect the molecular damage of mtDNA[5]. Mitochondrial D-loop region, containing H-strand origin, H-strand promoter, mtTF1 binding site and conserved sequence block, etc, are involved in the replication and transcription of mtDNA. Genetic instabilities, especially at the D-loop region which is associated with the replication error (RER) phenotype caused by disruption of the DNA mismatch repair system (MMR), are potentially involved in the maintenance of structure and function or even the expression of other mitochondrial genes, and probably also involved in the progressive stage of the disease[6,7].

MATERIALS AND METHODS

Materials

Gastric cancer and para-cancerous normal tissues were taken from the resected specimens of 22 patients with gastric cancer who underwent surgery between 1999 and 2002 in the First Affiliated Hospital of China Medical University. They were all diagnosed pathologically by HE-stained section and classified according to WHO' s histological classifications of gastric carcinoma.

Methods

DNA preparation 30 mg of cancerous tissues and matched normal tissues were homogenized using homogenizer for 30 s, and then digested in 1 ml of 10 mM Tris-HCl, 0.1 M EDTA (pH 7.4) containing 0.1 mg/ml proteinase K and 0.5 % sodium dodecyl sulfate. DNA was extracted twice with an equal volume of phenol/chloroform/isoamyl alcohol (25:24:1), then with chloroform/isoamyl alcohol (24:1) once. DNA was precipitated with 1/10 volume of 3 M sodium acetate (pH7.4) and two volumes of ethanol, and then rinsed with 70 % ethanol. The precipitated DNA was recovered in 50 μl of 10 mM Tris-HCl, 0.1 mM EDTA (pH 8.0).

PCR amplification of D-loop and 12S rRNA- tRNA^{phe} PCR amplification was carried out in a final volume of 50 μl containing 200 ng total DNA, 0.5 μM of each primer, 2.5 mM $MgCl_2$, 200 μM of each dNTP, and 2.5 U Taq DNA polymerase (TaKaRa Ex Taq™). Primers were as follows: Primer pair 1: F4-5' CACAGGTCTATCACCCTATTAACCA-3' , R1604-5' CTGGTTCGTCCAAGTGCA-3' ; Primer pair 2: F15974-5' ACTCCACCATTAGCACCCAAA-3' , R16564-5' TGATGTCTTATTTAAGGGGAACGT-3' . PCR (an initial incubation at 94 ℃ for 4 min, followed by 30 cycles at 94 ℃ for 30 s, at 60 ℃ for 30 s, and at 72 ℃ for 2 min; the final step at 72 ℃ was extended to 4 min) was performed in a Biometra Personal PCR system.

DNA sequencing of PCR products PCR products were sent to United Gene Technology Company, Ltd, Shanghai, China for direct sequencing.

RESULTS

Alterations in D-loop region, 12SrRNA and tRNA^{phe} of mtDNA

Two types of instabilities were detected in D-loop region, which were PolyC and $(CA)_n$ instabilities. PolyC instability existed in two regions; one was between np305 and np317, the other between np16 182 and np16 194. Some normal and cancerous tissues contained two distinct variations of mtDNA, especially the $(C)_n$ repeat number (Figures 1A-C). Instabilities including polyC and $(CA)_n$ were found in 13/22(59.1 %) gastric cancerous tissues and in 9/22 (40.9 %) normal tissues (P>0.05) (Table 1). Some new alterations were found in D-loop region, 12SrRNA and tRNA^{phe} (Table 2), among which np 318 and np 321 C-T transitions in D-loop region were two of the five bases for H-strand replication primer (GCTTC) (Figure 1C). np 523 AC-deletion and np 527 C-T transition (Figures 1D,E) occurred at mtTF1 binding site (mtTFBS), which was associated with the transcription of downstream mitochondrial genome. But no alteration was found in the major H-strand promoter (HSP1) and the minor H-strand promoter (HSP2). Seven samples showed the np 16 182 polyC instabilities, five of which simultaneously showed np 16 189 T-C transition (Figure 1F).

Relationship between instabilities of D-loop and variations of 12SrRNA-tRNA^{phe}

np523 AC deletion and np527 C-T transition in mtTFBS did not cause replication error of downstream gene 12S rRNA and tRNA^{phe}. Downstream gene of HPR containing 318 C-T and np321 C-T transitions exhibited a previously unknown np611 G insertion in tRNA^{phe} (Figure 1G) and np 716 T-G transition in 12S rRNA (Figure 1H). In addition, its downstream variations increased. Maybe, the variations of D-loop more or less influenced downstream replication. Elements of transcription and translation for D-loop and coding region 12S rRNA-tRNA^{phe} are shown in Figure 2.

Relationship between variations of 12S rRNA-tRNA^{phe} and differentiation of gastric cancer

Two of twelve well differentiated cancerous tissues (moderately and well differentiated tubular adenocarcinoma and papillary adenocarcinoma) and two of normal tissues showed variations in mitochondrial 12SrRNA-tRNA^{phe}(P>0.05); Moreover, six of ten poorly differentiated cancerous tissues (poorly differentiated adenocarcinoma, signet-ring cell carcinoma and mucinous adenocarcinoma) and four of ten normal tissues showed variations in 12SrRNA-tRNA^{phe}(P>0.05) (Table 1). Compared the data from the two groups of different cancerous tissues (2/12 and 6/10 respectively), the discrepancy was obvious (P<0.05).

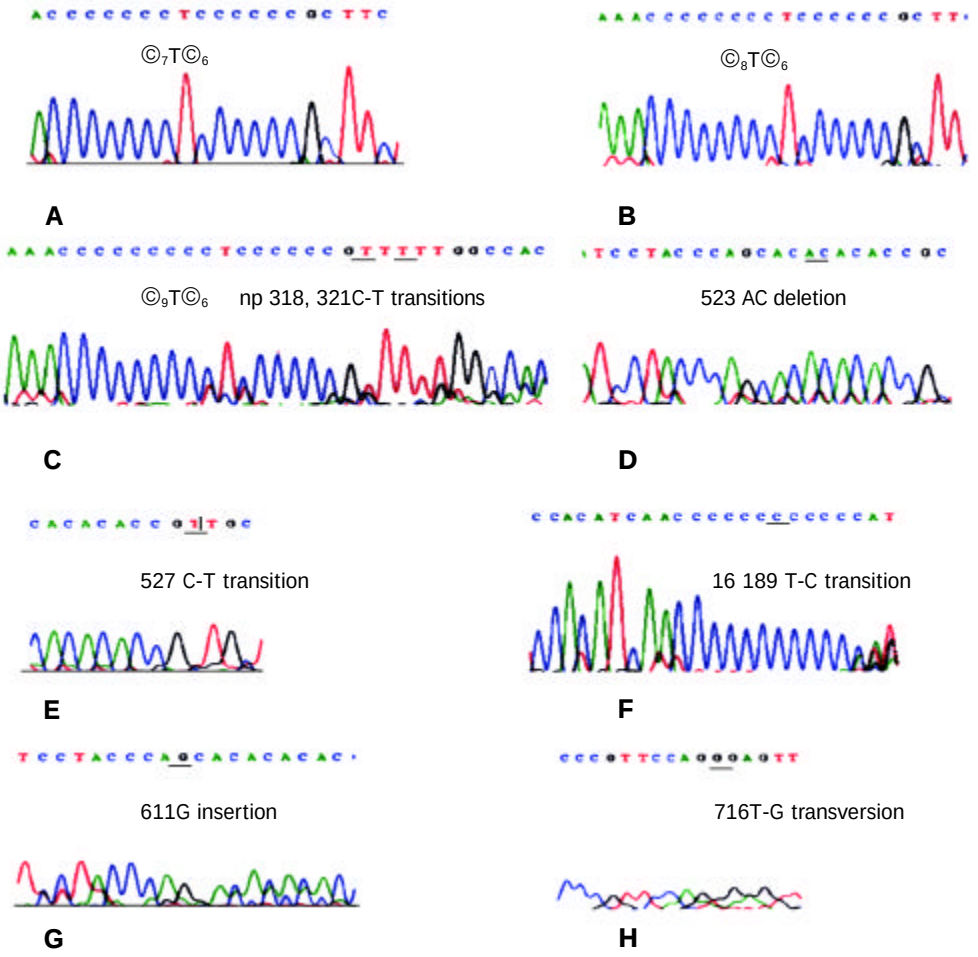

Figure 1 Sequencing results of instabilities and some variations in D-loop and 12S rRNA-tRNA^{phe}.

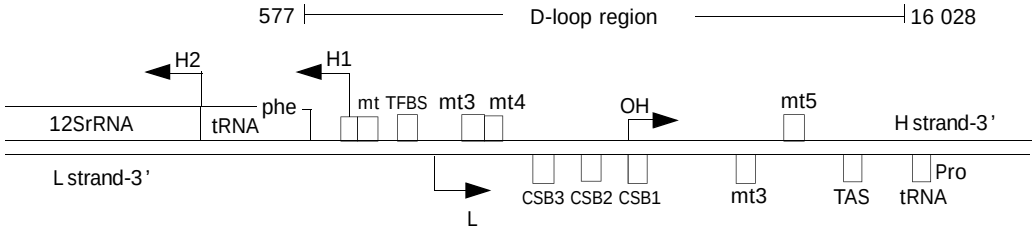

Figure 2 Elements of transcription and translation for mitochondrial coding region 12S rRNA-tRNA^{phe} and non-coding D-loop region. Non-coding D-loop region and genes encoding 12S rRNA and tRNA^{phe} are shown with boxes on the H-strand and L-strand of mtDNA. H1 and H2 are start sites for transcription of H-strand. L is start site for transcription of L-strand. O_H is the primary origin of H-strand. mt3, mt4 and mt5 are control elements. TAS: termination-associated sequence. CSB: Conserved Sequence Block.

Table 1 Variant frequencies of D-loop region, 12S rRNA and tRNA^{phe} in gastric cancers and para-cancerous tissues

Type	*n*	Variation frequency *vs* controls		
		D-loop	12S rRNA	tRNA^{phe}
Papillary adenocarcinoma	4	3/2	0/0	-[c]
Well differentiated adenocarcinoma	4	1/1	0/1[a]	-[c]
Moderately differentiated adenocarcinoma	4	2/1	2/1	-[c]
Poorly differentiated adenocarcinoma	4	3/2	3/2[b]	1/0
Signet-ring cell carcinoma	3	2/1	1/0	-[c]
Mucous adenocarcinoma	3	2/2	2/2[b]	1/0
Total	22	13/9	8/6	2/0

A: np 772 A-T transition was only found in normal tissues. B: One of variations in para-cancerous tissue was not the same as cancerous tissue. C: No variation was found.

DISCUSSION

The mitochondrial genome is particularly susceptible to mutations because of the high level of reactive oxygen species (ROS) generated in the organelle[8-10], coupled with a low level of mismatch repair gene (MMR)[11-13]. D-loop is the most variable part of human mitochondrial genome[14] and is hard to ascertain whether some variation is a mutation or not because of complex reasons such as different variations of mtDNA in different subjects[15,16], more polymorphism sites[17,18], age dependent variation[19,20], linkage disequilibrium and recombination[21-23], etc. In addition, mutated mtDNA often occurs together with wild-type mtDNA (heteroplasmic) no matter in normal tissues or in abnormal portions[24,25]. So far, most researches about the mutant positions in mtDNA have been limited to coding regions of mtDNA.

The variations, including point mutation, *per se* are mostly non-causative, and can not affect the mitochondrial function of tumor cells because sequence variation can be primarily found in individual normal tissues. These variations may occur during aging due to oxygen radical-induced mtDNA damage[8-10,26,27], mtDNA polymerase errors[28], or due to the activation of genes involved in error-prone DNA repair[11-13]. The mutations may become amplified because of an intracellular replicative advantage of mtDNA molecules. The cells with amplified mtDNA may then take over the whole population due to their clonal growth advantage[29].

The variations found in this study occurred in the middle of the promoter for mtDNA H-strand transcription, at a position with high affinity for the mtTF1 transcription factor, in the coding sequence of the RNA primer for H-strand synthesis, or within H-strand origin of DNA synthesis initiation. These variations occurred in DNA sequences that either unwound and bent because of mtTF1 binding at the same or an adjacent position, or formed persistent RNA-DNA hybrids giving rise to an R-loop with a tRNA-like cloverleaf structure at one or more origins of H-strand synthesis. These conformational changes would likely expose single stranded DNA stretches, which might be more susceptible to oxygen radical damage[10].

However, little is known about mtDNA mutation status in gastric tumors except a few reports[30-33]. Tamura *et al*[30] found two mutations, 10 polymorphisms in 45 Japanese individuals with gastric cancer, but did not find alterations of mononucleotide or dinucleotide repeats such as polyC and $(CA)_n$ in D-loop region. He thought that non-instability was related with ethnic difference. We have some doubt about Tamura' s viewpoint. First, how to explain the absence and the presence of mitochondrial instability coexisted in the same population? Second, our conclusion of mitochondrial PolyC instability is similar to the research results by Alonso[31] and Habano[32] among Westerners. According to human origin based on the mitochondrial genome[34-36], Chinese and Westerners came from different ancestors[37,38]. It supports our opinion that there is no ethnic difference regarding the absence or presence of D-loop instability in gastric cancer. And it was also found that D-loop instability occurred more often in poorly differentiated gastric cancers than in well differentiated ones, but no statistic significance existed. On the contrary, there existed a significant correlation between the differentiation degree of gastric cancer and the variant frequency of 12S rRNA-tRNA^{phe}, suggesting that poorly differentiated gastric cancers are more prone to variations of mitochondrial coding region 12SrRNA-tRNA^{phe}, or conversely, gastric cancers with more mitochondrial 12S rRNA-tRNA^{phe} variations have a tendency to become poorly differentiated with the presence of other carcinogenic factors. But, Habano *et al*[32] thought mtDNA mutations contributed to gastric tumorigenesis of intestinal type. Further studies are needed to eventually verify whether mutant mtDNA is related to degree of differentiation or to intestinal type of gastric cancer (according to Lauren' s classification of gastric carcinoma), which is closely related to environmental carcinogenic factors.

We thought that mitochondrial genome of gastric carcinoma was more subjected to mononucleotide or dinucleotide mutation, which may be resulted from functional loss of MMR. MMR system has been found in yeast strains, in which MSH1 and MSH2 are involved in mitochondrial and nuclear DNA repair systems respectively[39]. No MSH1 homologue has been found in mammalian cells. Therefore it remains uncertain whether an MMR system plays a role in the maintenance of mammalian mitochondrial genome. np 16 182 C-T transition may be an important reason for np 16 189 PolyC instability.

Endogenous and exogenous etiological factors could cause mitochondria oxidative stress by different ways, and make equilibrium disorder of oxidization and anti-oxidization[40,41], which damages mtDNA and mitochondrial double lipid membranes, thus disturbing electron transmission and ATP synthesis. Further damage may change the permeability of mitochondrial membrane, and influence the exchange of ions and macromolecules, even the process of apoptosis[42,43]. In fact, we are not sure whether some special variations and increased variant frequency of mtDNA are the causes of gastric tumorigenesis or just the results of gastric tumorigenesis. It is possible that mtDNA mutations are just the results of clonal expansion of spontaneous somatic mutations that occur at a very low frequency during previous replication of this precursor cell, and become apparent both by clonal expansion of the cell and by predominant selection and later become homoplasmic or at least somewhat predominant within the cell. It also indicates that frequencies and types of mtDNA mutation reflect hidden genetic and environmental actions. If it is true that increased frequencies of mitochondrial variations (especially the mutation) are related to differentiation level of gastric cancer, it must be the result of mtDNA genomic action on nuclear genome directly or indirectly.

Abstract

AIM: To investigate the effects of allicin on both telomerase activity and apoptosis in gastric cancer SGC-7901 cells.

METHODS: The gastric cancer SGC-7901 adenocarcinoma cells were treated with allicin and the cell cycle, inhibitory rate, apoptosis, telomerase activity and morphologic changes were studied by MTT assay, flow cytometry (FCM), TRAP-PCR-ELISA assay, light microscope, electron microscope respectively. Results were compared with that of AZT (3'-Azido-3'-deoxythymidine).

RESULTS: SGC-7901 cells were suppressed after exposure to allicin of 0.016 mg/ml, 0.05 mg/ml, and 0.1 mg/ml for 48 h. Compared with the control, the difference was significant ($P<0.05$). Allicin could induce apoptosis of the cells in a dose-dependent and non-linear manner and increase the proportion of cells in the G_2/M phase. Compared with the control, the difference was significant in terms of the percentage of cells in the G_2/M phase ($P<0.05$). Allicin could inhibit telomerase activity in a time-dependent and dose-dependent pattern. After exposure to allicin at 0.016 mg/ml for 24 hours, SGC-7901 cells showed typical morphologic change.

CONCLUSION: Allicin can inhibit telomerase activity and induce apoptosis of gastric cancer SGC-7901 cells. Allicin may be more effective than AZT.

INTRODUCTION

The relationship between telomere, telomerase and cancer has been the hotspot of study since Kim found telomerase activity in cancer in 1994. It was reported that telomerase activity and malignancy had a close association. Telomerase activity was detected in approximately 80-90 % of immortal cells. In contrast, telomerase activity was not detected in most mature somatic cells[1-3]. The observed differences in telomerase activity in normal *versus* tumor derived cells led to the hypothesis that the activation of telomerase might be essential to tumor progression and the proliferation of tumor cells, and that telomerase might represent a suitable target for highly specific anti-cancer therapies[4,5]

Gastric cancer is the most common alimentary tract cancer in China in terms of incidence. It is one of the malignancies that do serious harm to people's health with a high mortality and are short of effective therapeutic methods. Researchers are not only trying to enchance the therapeutic effects of the current methods but also working hard to find new ways and medicines to treat gastric cancer. We have studied the relationship between telomere, telomerase and malignancies, and tried to find new medicines to treat gastric cancer since 1997 in our laboratory. The results suggest that the presence of telomerase activity itself can be used as an excellent tool for the early diagnosis of cancer[6-8]. We carried out further studies to try to find out medicines from traditional Chinese herbs, which can inhibit telomerase activity and provide a new therapeutic approach on gastric cancer. Allicin is the bulb of Allium. Epidemiological studies and animal experiments have suggested that several garlic-derived compounds have potential anticarcinogens[8-13]. Allicin is one of them, but the mechanism of anticancer is not clearly demonstrated. In this paper, we first studied the effect of 3'-Azido-3'-deoxythymidine (AZT) on telomerase activity and apoptosis. Then the test was continued by using cheap allicin, instead of the expensive AZT. The results were compared between allicin and AZT.

MATERIALS AND METHODS

Materials

Allicin was obtained from HeFeng Pharmaceutical Company (15 mg/ml, Batch Number: 010101). AZT was purchased from Sigma Company. Human gastric adenocarcinoma SGC-7901 cell line was obtained from the Cell Biology Institute of Chinese Academy of Sciences. RPMI-1640 was the product of GBICO. Fetal bovine serum (FBS) was purchased from Tianjin Hematological Diseases Research Institute. Trypsin, tetrazolium bromide (MTT), ribonuclease A, DMSO and propidium iodide (PI) were purchased from the Sino-American Hua Mei Biotechnology Company of Beijing. The telomerase detection kits were obtained from the Sino-American Hua Mei Biotechnology Company of Shanghai.

Methods

Cell culture Cells were maintained in RPMI-1640 supplemented with 10 % fetal bovine serum (FBS), streptomycin (100 μg/ml) and penicillin (100 IU/ml) at 37 ℃ in a humidified atmosphere containing 5 % CO_2.

Effect of allicin on cell proliferation of SGC-7901 cells SGC-7901 cells were suspended at a concentration of 5×10^4/ml. Then 200 μl of the cell suspension was placed in each well of a replicate 96-well microtiter plate. The cells were allowed to adhere overnight. Then different concentrations (0.016 mg/ml, 0.05 mg/ml, 0.1 mg/ml) of allicin were added to the cells. MTT assay was performed after 48 h growth. 40 μl of 5 mg/ml of MTT was added to each well followed by incubation for 4 h at 37 ℃. The formazan crystals were dissolved in 200 μl DMSO and the absorbance measured by enzyme-linked immunosorbent assay (ELISA). Optical density value (OD)

was measured at a wavelength of 570 nm. Each assay was performed three times and the average results were calculated.

Effect of allicin on telomerase activity of SGC-7901 cell Cultured cells in logarithmic growth were digested by 0.25 % trypsin and suspended at a concentration of 2×10^4/ml, then 5 ml was placed into a cell culture flask of 25 ml and allowed to adhere overnight. Cells were harvested after 12 h, 24 h, and 36 h. Cells were washed once with PBS and scraped into a wash buffer, The cells were washed in the buffer, homogenized in 150 μl cell lysis buffer, and incubated on ice for 30 min. Cell homogenates were then centrifuged at 12 000×g for 20 min at 4 ℃. The supernatants were recovered and snap-frozen in liquid nitrogen and stored at -80 ℃. The TRAP-PCR-ELISA assay was performed using a telomerase detection kit. In brief, 2 μl of tissue extract and 48 μl TRAP reaction mixture were placed into tubes, PCR was then performed at 94 ℃ for 120 s and at 94 ℃ for 30 s, at 48 ℃ for 30 s, at 72 ℃ for 90 s for 35 cycles. The PCR products (25 μl) were hybridized to a digoxigenin (DIG)-labelled telomeric repeat specific detection probe. The PCR products were immobilized via the biotin-labelled primer to a streptavidin-coated microtiter plate. The immobilized PCR products were detected with a peroxidase-conjugated anti-DIG antibody and visualized following addition of the stop reagent. The microtitre plate was assessed on an enzyme-linked immunosorbent assay (ELISA) plate reader at a wavelength of 490 nm.

Effect of allicin on the cell cycle of SGC-7901 cells Cell culture was the same as before, and treated with allicin. Cultured cells were harvested after 24 h and fixed with 70 % cold ethanol for 4 h. The percentage of the cells in different cell cycle was determined by a flow cytometer. Analysis of the DNA content was done by using FACSalibur. Briefly, 1×10^5 cells were suspended in 0.2 % Triton-X-100/PBS solution containing 0.5 % ribonuclease A, After incubation for 20 min, DNA was stained with 50 ug/ml of propidum iodide (PI), then applied to flow cytometer analysis at the inspiring wavelength of 488 nm.

Effect of allicin on morphological changes of SGC-7901 cells Observations under light microscope The cells were treated with 0.016 mg/ml allicin for 24 h, 48 h, then morphological changes were observed under the inverted light microscope and photographed.

Observations under transmission electron microscope (TEM) For TEM, SGC-7901 cells were incubated in culture dishes with allicin for 24 h. A total of 5×10^6 cells were pelleted at 12 000×g for 5 min and washed twice with PBS. Cells were fixed in 2.5 % cold glutaraldehyde, 0.1 M of sodium cacodylate/ 1 % sucrose buffer for 24 h. The cells were washed three times with PBS, then postfixed in 1 % osmium tetroxide (60 min), encapsulated in 1 % agar, stained with uranyl acetate and phosphotungstic acid, and dehydrated in a series of graded ethanolic solutions, finished with propylene oxide before finally embedded in Epon 812-Araldite mixture. Ultrathin sections (50 nm) were cut on a LKL-208 ultramicrotome and placed under 200 mesh standard copper grids, examined with an HA-600 transmission electron microscope.

Statistical analysis

The oneway test was used to evaluate the significance of cell proliferation, cell cycle and apoptosis. The ANOVA was used to evaluate the significance of telomerase activity. $P<0.05$ was considered statistically significant.

RESULTS

Effects of allicin, AZT on cell proliferation

SGC-7901 cells were treated with different concentrations of allicin for 48 h. MTT assay was used to measure cell proliferation. The results are shown in Figure 1. Allicin could inhibit gastric cancer cell proliferation in A dose-dependent pattern. Allicin' s action was notably stronger than AZT (Figure 2). At the highest concentration, the inhibitory rate of allicin on SGC-7901 was 89 %, while that of AZT was only 52.6 %.

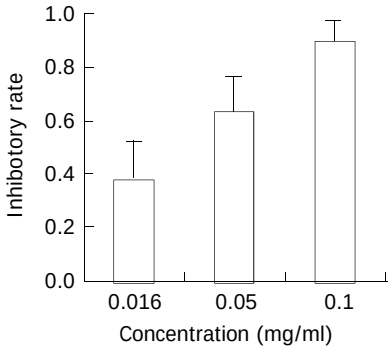

Figure 1 Effect of allicin on cell proliferation.

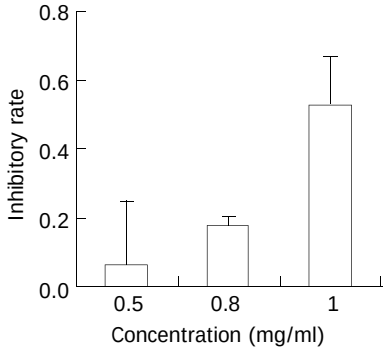

Figure 2 Effect of AZT on cell proliferation.

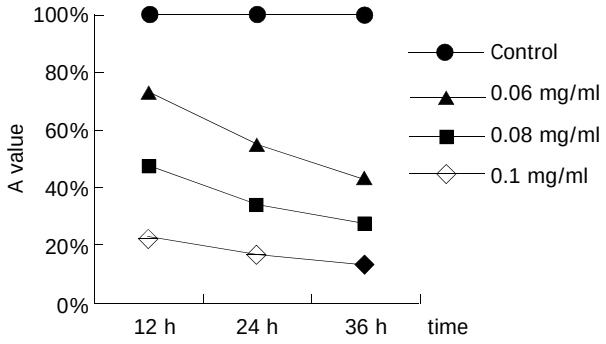

Figure 3 Effect of allicin on telomerase activity.

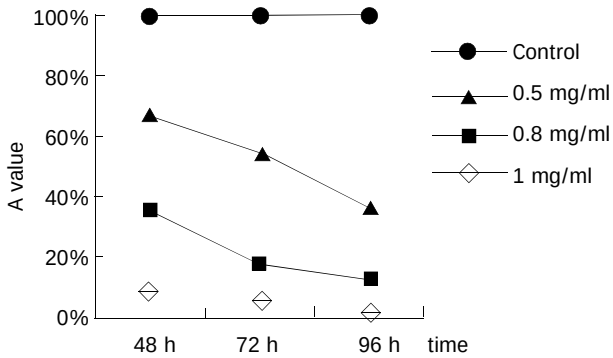

Figure 4 Effect of AZT on telomerase activity.

Effects of allicin on telomerase activity

The cells were harvested after treated at different concentrations of allicin for 12 h, 24 h, and 36 h, respectively. SGC-7901

cells were treated by AZT for 48 h, 72 h, 96 h. Then the cells were harvested. The telomerase activity was measured by TRAP-PCR-ELISA assay. The results suggested that both allicin and AZT could inhibit telomerase activity by different degrees (Figures 3 and 4).

Effects of allicin on cell cycle and apoptosis

Three different concentrations of allicin acted on SGC-7901 cells for 24 h, the flow cytometry results showed the sub-G1 wave which was the apoptosis wave. Allicin could induce apoptosis in a dose-dependent and non -linear manner (Figure 5). At the same time allicin could change the cell cycle of SGC-7901 cell. In a certain range of concentrations, when the concentration increased, the cells of G_2/M phase increased (Figure 6). As shown in Figures 7 and 8, AZT could also change the cells cycle. It could increase the cells of S phase and induce apoptosis in a dose-dependent and non-linear manner.

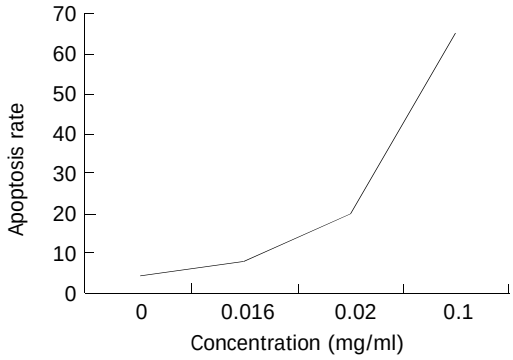

Figure 5 Effect of allicin on apoptosis.

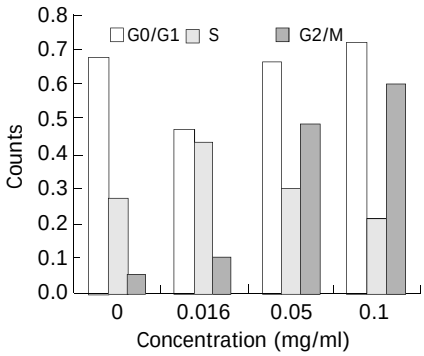

Figure 6 Effect of allicin on cells cycle.

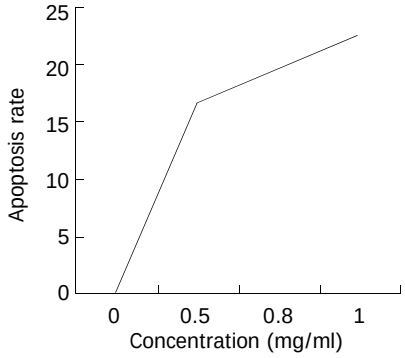

Figure 7 Effect of AZT on apoptosis.

Effect of allicin on SGC-7901 cell morphological changes

The results of light microscopy Cells became round after treated with allicin for 24 h and the intercellular gaps were loose. After 48 h, the cells were crimpled and floated. There were a lot of fragments around the cells.

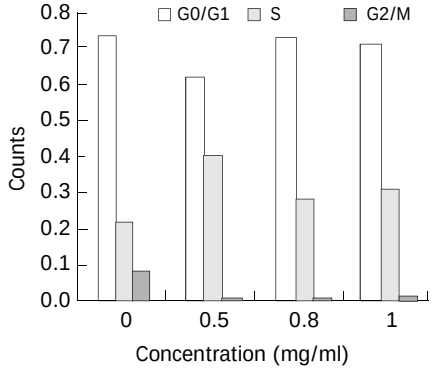

Figure 8 Effect of AZT on cell cycle.

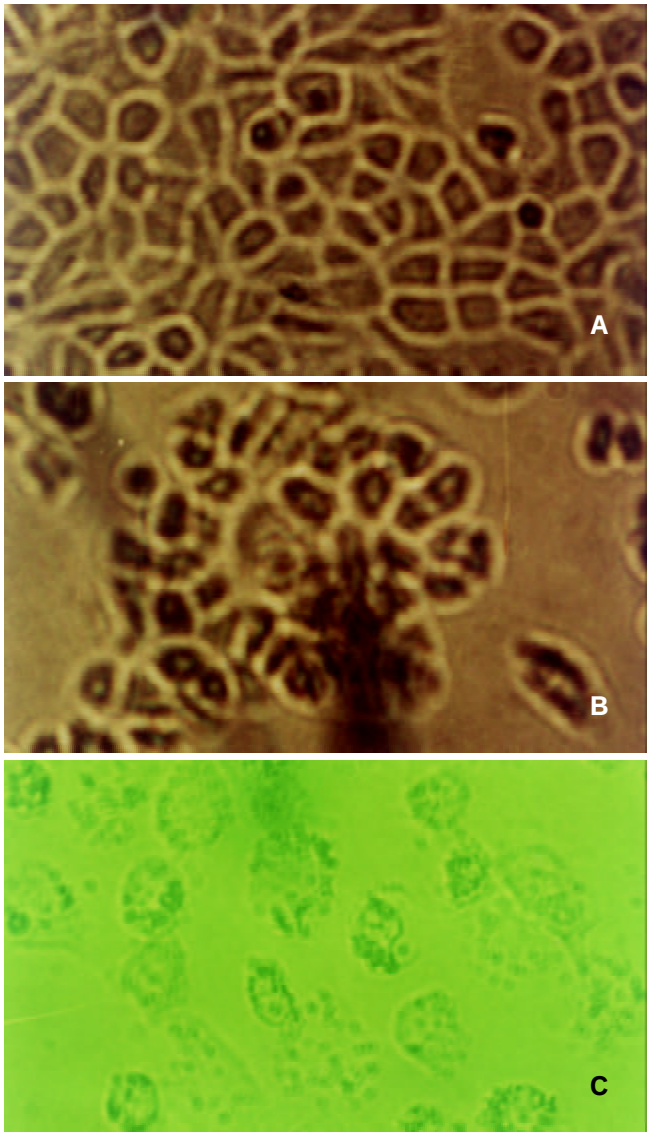

Figure 9 Allicin-induced morphological changes of SGC-7901 cells under light microscope. A: Control, ×400; B: Treated with 16 μg / ml allicin for 24 h, ×400; C: 16 μg / ml allicin for 48 h, ×400.

Results of transmission electron microscopy SGC-7901 cells had big nucleoli and aberrant nuclei. There were a lot of prominences of microvilli on the surface of cell membranes. After treated with allicin for 24 h, the prominence was disappeared and nuclei deflated, but the cell membranes were intact.

DISCUSSION

Telomeres, the ends of eukaryotic chromosomes, are composed of tandemly repeated guanine-rich sequences 5' TTAGGG3' [14]. However, due to the nature of DNA synthesis, the 5' ends of telomeres are shortened by 50-100 bp with each round of cell division. When the telomere reaches a certain critical length, the cell cannot undergo division. This has been described as the "end-replication" problem of linear chromosomes[15-17]. Telomerase is a ribonucleoprotein and its internal RNA component serves as a template for directing the appropriate telomeric sequences onto the 3' end of a telomeric primer, and then the cells can continue to divide[18]. To date, three major components of telomerase, namely, human telomerase RNA component (hTR), human telomerase-associated protein (TP) and human telomerase catalytic subunit (hTERT) have been identified[19]. Recent studies have demonstrated a close correlation between telomerase activity and hTERT expression[19,20]. In a number of laboratories, experiments have shown that down-regulation of telomerase activity can be used to treat cancer[21-28]. AZT, which has been among the most extensively studied reverse transcriptase inhibitors, is a telomerase inhibitor that works on hTERT. AZT can effectively cause telomere shortening and inhibit telomerase activity in cancer cells. The results have shown that tumor incidence is reduced and survival is prolonged, at the same time the number and size of spontaneous metastases are also decreased. But AZT has toxical effects and is so expensive that it cannot be used widely[27-29]. Allicin, which has been used to decrease blood pressure, cholesterol and as an antioxidant, antimicrobial, etc[30-33], has little toxicity and is easily available. In the current study, the SGC-7901 cells were treated at different concentrations of allicin and AZT. The results strongly suggest that allicin can effectively inhibit telomerase activity in a time- and dose-dependent manner. This study also indicates that allicin can induce cell apoptosis (arrest in G_2/M phase). The cause of apoptosis is related to decreased telomerase activity. When telomerase activity degrades, telomere shortens, mitoses of cells are arrested, which leads to cell apoptosis[34]. It was reported that apoptosis inhibitor Bcl-2 could modulate telomerase activity. Overexpression of Bcl-2 leads to a significant enchancement in the level of telomerase activity. On the other hand, with down-regulation of Bcl-2 expression, telomerase activity also decreases[35-37]. Some researches found that the mechanism of degraded Bcl-2 expression by allicin was through the secondary messengers, namely cAMP, PKC of the second signal system, which led to overexpression of Fas and Bax, and at the same time the Bcl-2 expression decreased[38]. But the telomerase activity modulation is a complex system[39]. We were unable to rigorously determine if decrease of telomerase activity after treatment by allicin was associated with the down-regulation of Bcl-2.

Furthermore, this work also provides a direct comparison between two classes of medicine, both of which can inhibit telomerase activity and induce apoptosis. Allicin is more effective than AZT. At the same time, both Allicin and AZT can arrest the cells in different cell cycle phases. Allicin arrests cells at the G_2/M phase while AZT does at the S phase, indicating that the mechanism of allicin on telomerase activity inhibition is different from that of AZT and telomerase activity is lack of cell cycle regulation[40-42]. In conclusion, our results may provide important insights into using allicin as a therapeutic approach against neoplasm.

Abstract

AIM: To investigate the apoptosis-inducing effect of Caspases-3 expressed by constructed eukaryotic vector on gastric cancer cell line SGC7901.

METHODS: PCR was employed to amplify the sequences of both small and large subunits of Caspases-3. Its products were separately cloned into the *Sma* I site of pBluescript KS$^+$ to generate both plasmids pBS/SS and pBS/LS. The small subunit fragment was excised from plasmid pBS/SS with *Bam*H I and then inserted into the *Bam*H I site of plasmid pBS/LS preceding that of the large subunit to yield plasmid pBS/Rev-Caspase-3. Rev-Caspase-3 cDNA was excised with *Kpn* I+*Xba* I and then subcloned into plasmid pcDNA3.1 (+) to construct Rev-Caspase-3 eukaryotic expression vector pcDNA/Rev-Caspase-3, which was used to transiently transfect SGC7901 cell line. Cell count, MTT assay and electron microscopy were used to confirm the antiproliferation and apoptosis-inducing effect of Rev-Caspase-3 expression on gastric cancer cells.

RESULTS: Plasmid pBS/Rev-Caspase-3 and eukaryotic expression vector pcDNA/Rev-Caspase-3 were successfully constructed. SGC7901 cells were transiently transfected by either pcDNA/Rev-Caspase-3 or pcDNA3.1 (+) for 24, 48, 72, and 96 h respectively. Cell growth was measured by cell count and MTT assay. In cell count assay, the cell numbers were 1.8×10^6, 1.55×10^6, 2.0×10^6, and 3.1×10^6 in the experimental group and 2.5×10^6, 3.1×10^6, 4.0×10^6, and 5.7×10^6 in the control group at 24, 48, 72 and 96 h respectively. The growth of SGC7901 cells was suppressed by Rev-Caspase-3 in a time-dependent manner ($P<0.05$). The results of MTT assay were similar to that of cell count ($P<0.05$). The characteristics of apoptosis such as chromatin condensation, crescent formation and margination were seen and more obvious with time in the given-experimental period in the experimental group, but not easily observed in the control group.

CONCLUSION: The expression of Rev-Caspase-3 by the constructed eukaryotic vector can significantly induce apoptosis of gastric cancer cell line SGC7901, which may exhibit a potential way in gastric cancer gene therapy.

INTRODUCTION

Apoptosis is closely related to tumor[1-10]. Although there are many factors involved in apoptotic program[11-14], Caspases are shown to play a major role in the transduction of the apoptotic signal and the execution of apoptosis in mammalian[15-19]. Caspases belong to cysteine proteases family[20] and share several common features such as all homologous to interleukin-1-β-converting enzyme (ICE)[21] containing conserved QACR/QGC sequence[22] existing as inactive zymogens activated by cleavages specific internal ASP residues in interdomain linkers being able to cleave their substrates ASP residues, and consisting of prodomain, small subunit and large subunit.

So far 15 members of Caspases have been reported in the literature. According to their structure and function, Caspases are divided into two classes, the initiator and executor Caspases. The initiator Caspases carry long prodomain, and can process and activate their own and other inactive Caspase zymogens when triggered by a death signal[23,24]. The executor Caspases such as Caspases-3, however, lack the long prodomain and remain to be dormant until the initiator Caspases activate them by direct proteolysis[25]. Once activated, they dismantle cell regulatory components rapidly, leading to the typical changes observed in cell apoptosis[26-28].

Interestingly, by making small subunit fragment preceding that of the large subunit, Srinivasula *et al*[29] constructed a recombinant Caspases-3, which could simulate the three-dimensional structure of activated Caspases-3 and was capable of being catalyzed and inducing MCF-7 cell apoptosis without initiator Caspases' proteolysis. In this study, the eukaryotic expression vector of recombinant Caspases-3 was constructed and the apoptosis-inducing effect of its expression on SGC7901 cell line was observed.

MATERIALS AND METHODS

Subclone of both small and large subunits

Plasmid pcDNA/Caspases-3 contains all the cDNA sequences of Caspases-3 gene. It was used as template to amplify the sequences of small and large subunits of Caspases-3 by PCR. The sequences of four pairs of primers were as follows: LS-forward (P1), 5' -ATG GAG AAC ACT GAA AAC TCA G-3' ; LS-reverse (P2), 5' -GTC ATC ATC AAC ACC TCA GTC T-3' ; SS-forward (P3), 5' -GGA TCC ATG ATT GAG ACA GAC AGT GG-3' ; SS-reverse (P4), 5' -ATC AAC TTC ATC GTG ATA AAA ATA GAG TTC-3' .

PCR was performed in 50 μl reactive volume containing 2 μl cDNA, 5 μl PCR buffer, 2 μl dNTP, 1 μl primer, and 1 μl Taq DNA polymerase. The samples were subjected to 30 thermal cycles for 5 min at 95 ℃ for pre-denaturation, for 30 s at 94 ℃ for denaturing, for 30 s at 56 ℃ for annealing, for 50 s at 72 ℃ for extension, and for 7 min at 72 ℃ for final extension after the last cycle. The PCR products were separately cloned into the *Sma* I site of pBluescript KS+ to construct pBS/SS and pBS/LS, which were confirmed by *Sma* I digestion and DNA sequencing.

Construction of recombinant Caspases-3 (Rev-Caspaes-3)

The small subunit fragment was excised from plasmid pBS/SS with *Bam*H I and then inserted into the *Bam*H I site of plasmid pBS/LS to yield plasmid pBS/Rev-Caspases-3 with the small subunit fragment preceding that of the large subunit, which was verified with *Bam*H I+*Kpn* I digestion and PCR method. The primers were SS-forward and LS-reverse.

Construction of Rev-Caspases-3 eukaryotic expression vector pcDNA/Rev-Caspases-3

Eukaryotic expression vector pcDNA3.1 (+) was cleaved and linearized with *Kpn* I+*Nhe* I, meanwhile, Rev-Caspases-3 cDNA was excised from plasmid pBS/Rev-Caspases-3 with *Kpn* I+ *Xba* I. Both fragments were ligated each other with T_4 DNA ligase to produce plasmid pcDNA/Rev-Caspases-3, which was proved with *Stu* I+*Kpn* I.

Cell line and cell curltrue

Cell line SGC7901 was derived from a moderately-differentiated gastric adenocarcinoma and characterized extensively. It was maintained in RPMI 1640 medium supplemented with 10 % fetal bovine serum, 200 IU· ml^{-1} penicillin and 50 μg· ml^{-1} streptomycin at 37 ℃ in a humidified atmosphere of 5 % CO_2.

Cell transfection, cell count and electron microscopy

Cells were seeded in a 6-well plate with 2×10^5 cells per well 24 h prior to transfection when they were cultured to a confluency of about 90 %. Cell transfection was performed according to the manufacturers' instructions. Briefly, a transfection mixture was prepared by adding 6 μg of plasmid DNA and 20 μl lipofectame (GIBCO BRL) to 500 μl serum-free RPMI1640. After incubated at room temperature for 20 min, the transfection mixture was added to the cells to be cultivated for 4 h at 37 ℃ when the media containing the transfection mixture was exchanged for growth medium. Cells were harvested and counted at 24, 48, 72, and 96 h after transfection. Some cells were fixed in 40 g· L^{-1} glutaraldehyde, then post-fixed in osmium tetroxide and embedded in Epon. Ultrathin sections were prepared, stained with wranyl acetate and lead citrate, examined under a transmission electron microscope to identify the morphological changes of apoptosis.

MTT assay

Antiproliferation effects of recombinant Caspases-3 were measured by MTT assay. SGC7901 cells were seeded in 96-well microtitre plates with 1×10^4 cells per well and incubated overnight in 100 μl of culture media. Then the cells were transiently transfected with 0.3 μg DNA of plasmid pcDNA/Rev-Caspases-3 for 24, 48, 72, and 96 h respectively. The cells were added with 100 μl MTT (1g· L^{-1}) and further incubated for 4 h. After supernatant was removed, the cells were added with 100 μl DMSO per well and cultivated for 30 min. The absorbance at 490 nm was measured by a micro-ELISA reader. At the same time, the SGC7901 cells transfected with plasmid pcDNA3.1 (+) were served as control. Each assay was repeated three times.

Statistics

Comparison of the data among the groups was carried out using the Bonferroni-Dun multiple comparisons. In each case, *P* values less than 0.05 were considered statistically significant.

RESULTS

Construction of Rev-Caspaes-3 and pcDNA/Rev-Caspases-3

The construction strategies of recombinant Caspases-3 and eukaryotic expression plasmid pcDNA/Rev-Caspases-3 are shown in Figure 1.

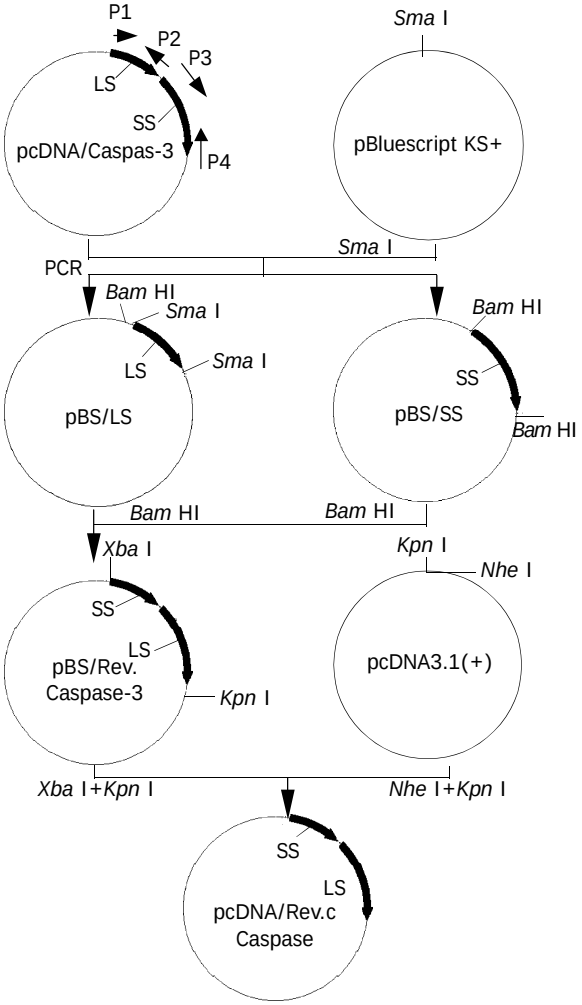

Figure 1 Schematic map of constructions of recombinant Caspases-3 and eukaryotic expression plasmid pcDNA/Rev-Caspases-3.

Both small and large subunit sequences of Caspases-3 were successfully amplified by PCR and subsequently cloned into *Sma* I site of pBluescript KS+ to yield pBS/SS and pBS/LS respectively, which were confirmed by *Sma* I digestion and DNA sequencing. The small subunit fragment was excised from plasmid pBS/SS with *Bam*H I and cloned into *Bam*H I site of plasmid pBS/LS to form recombinant plasmid pBS/Rev-Caspases-3 with the small subunit fragment located in-frame 5' to that of the large subunit, which was identified by PCR using SS-forward and LS-reverse as primers. The length of PCR product was 882 bp (Figure 2). Rev-Caspases-3 cDNA was excised from plasmid pBS/Rev-Caspases-3 with *Kpn* I+ *Xba* I and orientatively cloned into *Kpn* I and *Nhe* I site of eukaryotic expression vector pcDNA3.1(+) to construct plasmid pcDNA/Rev-Caspases-3, which was proved by the digestion of *Stu* I+*Kpn* I with a 550 bp fragment release (Figure 3).

Effect of Rev-Caspases-3 on SGC7901 cell growth

SGC7901 cells were transiently transfected by either pcDNA/Rev-Caspases-3 (the experimental group) or pcDNA3.1 (+) (the control group) for 24, 48, 72, and 96 h respectively. Cell growth was measured by cell count and MTT assay. In cell count assay, the cell numbers were 1.8×10^6, 1.55×10^6, 2.0×10^6, and 3.1×10^6 in the experimental group and 2.5×10^6, 3.1×10^6, 4.0×10^6, and 5.7×10^6 in the control group at 24, 48, 72, and 96 h respectively. The growth of SGC7901 cells was suppressed by Rev-Caspases-3 in a time-dependent manner (Figure 4, $P<0.05$). The results of MTT assay were similar to that of cell count (Figure 5, $P<0.05$).

Induction of apoptosis in SGC7901 by Rev-Caspases-3

The ultrastructural characteristics of apoptosis such as chromatin condensation, crescent formation, and margination were seen by electron microscopy in the experimental group, which were more obvious with time in the given-experimental period and not easily observed in the control group (Figure 6).

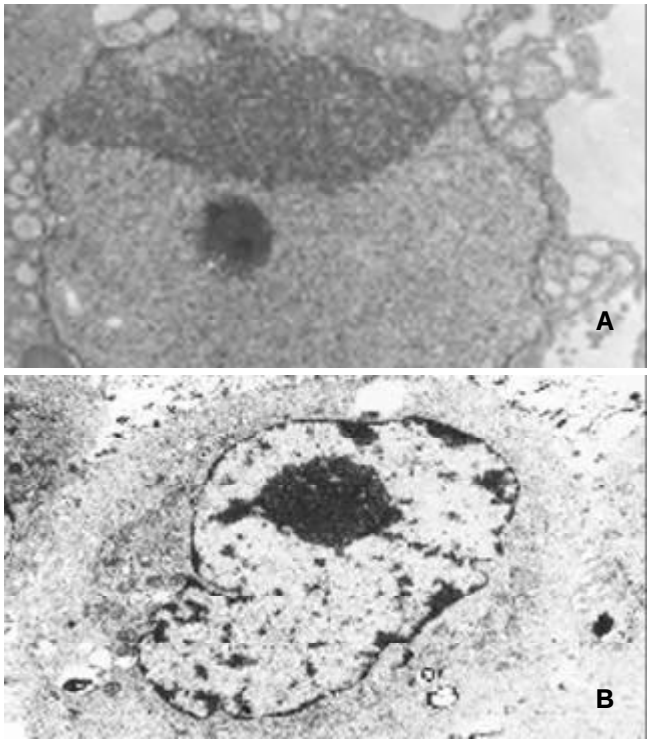

Figure 6 Electron microscopy of SGC7901 cells transfected with pcDNA3.1 (+) or pcDNA/Rev.Caspases-3. A: SGC7901 transfected with pcDNA/Rev. Caspases-3. Notice the chromatin condensation, crescent formation, original margination (×5 000); B: SGC7901 transfected with pcDNA3.1 (+), Notice no characteristics of apoptosis (×5000).

DISCUSSION

Caspases belong to cysteine protease family. So far, more than 15 members of Caspases have been reported in the literature, and most of them play a major role in apoptosis, participating in the initiation and execution of programmed cell death[30-33]. Based on their structure and function, Caspases are classified into two groups, initiator (such as Caspases-2,-8 and 10) and executor Caspases (such as Caspases-3, -6 and 7)[33-35]. Structurally, Caspase is made up of prodomain, large and small subunits, of which prodomain is located in N-terminus, small subunit in C-terminus and large subunit between. Initiator Caspases bear a long prodomain, whereas the executor Caspases do not[36-38].

Caspases are synthesized as harmless inactive zymogens and generally activated by cleavages specific internal ASP residues present in interdomain linkers, which manifests as a hierarchical process. When triggered by a death signal, the initiator Caspases are recruited through their long prodomain by specialized adaptor molecules to form the death-inducing signaling complex (DISC) or Apaf. Because of the trimeric

nature of the DISC, three Caspase molecules are brought close, which will be useful to activate initiator Caspases[39-40]. When activated, the initiator Caspase can activate itself and other inactive caspase zymogens including executor Caspases that are activated by direct proteolysis. The activated executors then rapidly dismantle important cellular components, leading to cell apoptosis.

The three-dimensional structure of activated Caspases-3 has been shown that the C-terminus of large subunit and the N-terminus of small subunit are separated far from each other, whereas the N-terminus of large subunit and C-terminus of small subunit are closed to each other[41,42]. Based on these observations, Srinivasula *et al*[29] successfully engineered recombinant Caspases-3 and -6 precursors by switching their subunits order at a gene level, in which the small subunit fragment was fused in frame N terminal to that of the large subunit. Thus the N terminus of small subunit and the C terminus of large subunit are free, while the C terminus of the small subunit and the N terminus of the large subunit are connected each other through a linker. These recombinant molecules could be activated spontaneously to induce apoptosis in MCF-7 cells independent of initiator Caspases. Jia *et al*[43] have also confirmed the apoptosis-inducing effect of recombinant Caspases-3 on HeLa cells.

Gastric carcinoma is one of the most common causes of malignancy-related death in China[44-48]. In the present study, to test the effect of recombinant Caspases-3 on gastric cancer cell, we constructed a eukaryotic expression vector of constitutively active recombinant Caspases-3 and used it to transiently transfect gastric cancer cell SGC7901. The results showed that the expressed recombinant Caspases-3 could inhibit the growth of SGC7901 in a time dependent manner. In addition, the apoptosis-inducing effect of recombinant Caspases-3 on SGC7901 was also evident. This study demonstrates the possible use of recombinant Caspases-3 in gastric cancer gene therapy. But the effects of growth inhibition and apoptosis induction conducted by recombinant Caspases-3 on other cell lines of gastric cancer or on gastric cancer cell *in vivo* need to be further investigated.

Abstract

AIM: To investigate the inhibitory effect of *in vivo* expression of expressing plasmid pCH510 of recombinant fibronectin polypeptide (CH50) on hepatocellular carcinoma and the improved therapeutic effect of pCH510 in combination with chemotherapeutic agents and Hsp70-H22 hepatocarcinoma antigen peptide on tumor.

METHODS: Mice were inoculated with H22 hepatocarcinoma cells. The chemotactic effect of the expression of plasmid pCH510 on immunocytes was observed after *in vivo* transfection, tissue slicing and HE staining. Inhibitory effect of transfection with pCH510 on murine tumor originated from different inoculative doses was observed. The inhibitory effect of immediate transfection with pCH510 after chemotherapy on tumor was compared with that of transfection 5 days after chemotherapy. The change of function and amount of mouse peritoneal macrophages and the peripheral blood immunocytes resulted from administration of chemotherapeutic agents were detected. The peptides mixture was prepared from H22 hepatocarcinoma cells. pCH510 + Hsp70-H22 antigen peptides were injected into tumor-bearing mice with or without chemotherapy, to observe the inhibitory effects on tumor.

RESULTS: At the tumor tissue site injected with pCH510, there were a great number of immunocytes which mainly were macrophages, lymphocytes and neutrophils. Transfection of plasmid pCH510 inhibited significantly the murine tumor induced by different inoculative doses. The inhibitory effect was negatively correlated with the inoculative dose. The therapeutic effect was not improved by immediate transfection with pCH510 after chemotherapy, but was significantly improved by transfection with pCH510 5 days after chemotherapy. Chemotherapeutic agent decreased the number of immunocytes and suppressed their activation *in vivo*. After injection of drug, the amount of immunocytes was the lowest from d 1 to d 3 and returned to normal level on the 10^{th} day. Transfection with plasmid pCH510 alone could inhibit tumor induced by the inoculation with 10^4 H22 cells. The tumor originated from the inoculation with 10^5 H22 cells was inhibited by pCH510+Hsp70-H22 antigen peptides and that from the inoculation with 10^6 H22 cells was inhibited by pCH510+Hsp70-H22 antigen peptides in combination with chemotherapeutic agents.

CONCLUSION: *In vivo* expression of pCH510 recruits immune cells, inhibits tumor growth, and enhances the efficacy of chemotherapy. But the proper timing of combining chemotherapy with pCH510 must be taken into great account. The synergism of pCH510 and Hsp70-H22 peptides can improve the efficacy, which could be further enhanced if they are used following chemotherapy. Chemotherapeutic agent + pCH510 + Hsp70-H22 peptides is a promising therapeutic approach of combination treatment of tumor.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a common malignant tumor with an increasing incidence, and remains a disease with a poor and dismal prognosis, and all forms of currently available conventional therapies are rarely beneficial[1]. Surgical resection is incapable of removing all HCC cells and so is chemotherapy[2]. However, in recent years, biotherapy has been reported with promising results as a new therapeutic approach of hepatocellular carcinoma[1-7]. On the other hand, the extraordinary versatility of gene therapy opens new possibilities for the treatment of hepatocellular carcinoma[8-10].

Fibronectin (FN) is an extracellular matrix glycoprotein which exists in extracellular matrix (cellular-type) and in blood (plasma-type). It is composed of multiple functional domains including cell-binding domain and heparin-binding domain, and additional regions such as EDA, EDB and V region that arise through alternative splicing. Recombinant peptides with different functional domains produce different effects on tumor cells. Hep II-V bifunctional-domain recombinant peptide can promote tumor invasion[11]. In contrast, Cell I-Hep II bifunctional-domain recombinant peptide has an inhibitory effect on adhesion, invasion, and spreading of tumor cells[12,13]. Fragments of fibronectin have chemotactic effect on immunocytes. David A.Norris[14] reported that fragments of fibronectin cleaved by enzymes were chemotactic to human peripheral blood monocytes, but intact FN was inactive. Doherty[15] also reported that FN fragments containing cell-binding domain could recruit macrophages. The chemotactic effect is mediated by the interaction between cell-binding domain and β1 integrin receptor on the cell surface[16,17]. These characteristics indicate the great potential of FN in tumor therapy. We have expressed in *E.coli* and purified recombinant

FN polypeptide containing Cell I-Hep II bifunctional-domain. The peptide has the activities of chemotaxis, macrophage activation, as well as inhibitory effect on tumor growth and metastasis[18]. On this basis, the eukaryotic expressing plasmid pCH510 of Cell I-Hep II bifunctional-domain recombinant polypeptide was constructed[19]. The main purpose of the study was to investigate the chemotactic effect on immunocytes and therapeutic effectiveness on mouse H22 hepatocellular carcinoma of *in vivo* expression of pCH510, and the role of *in vivo* expression of pCH510 in combined treatment of tumor, and to analyze the factors influencing the effect of combined treatment so as to provide experimental basis for potential use of pCH510 in tumor therapy.

MATERIALS AND METHODS

Reagents

Mouse H22 hepatocarcinoma cell line was purchased from China Center for Type Culture Collection (CCTCC, Wuhan). BALB/c mice were purchased from Medical Experimental Animal Center of Hubei Province. Eukaryotic expression plasmid pCH510 of Cell I-Hep II bifunctional-domain recombinant polypeptide CH50 of human fibronectin was constructed in our lab. Recombinant human heat shock protein 70 was expressed and purified in our laboratory. Mitomycin C (MMC) was the product of Zhejiang Hisun Pharmaceutical Corporation. IFN-γ and MTT were purchased from Sigma Co.

Inoculation of mouse with H22 cells

H22 cells were suspended in PBS at the concentrations of 1×10^8/ml, 1×10^7/ml, 1×10^6/ml, 1×10^5/ml respectively. 100 μl of the suspension was injected into the muscle of mouse at right hind limb. The inoculative doses were 1×10^7, 1×10^6, 1×10^5, 1×10^4, respectively.

Chemotaxis test for immunocytes of pCH510 transfection in hind limb muscle of tumor-bearing mice

After inoculation with 1×10^6 H22 cells, mice were randomly divided into 2 groups, 9 mice in each group, for the injection of 100 μg of plasmid pCH510, 100 μg of plasmid pcDNA3.1 respectively. The next day after inoculation, mice in each group were given an injection at the inoculation site. The tissue specimens from muscle tissue of injection site were prepared on day 1, 2, 3 after plasmid transfection, 3 mice from each group each day.

Inhibition test of tumor growth by pCH510 transfection

The mice in different groups were each inoculated with 1×10^7, 1×10^6, 1×10^5, 1×10^4 of H22 tumor cells respectively. Starting from d 2, the mice in each group were given an injection of 100 μg of plasmid pCH510 every day for 10 times at the inoculation site. The mice in control group were given an injection of control plasmid pcDNA3.1. The mice were dissected to measure the weight of tumor at different time after inoculation: on the 7th day for 1×10^7 inoculative dose, on the 10th day for 1×10^6, on the 14th day for 1×10^5, and on the 21st day for 1×10^4.

Inhibition test of pCH510 in combination with chemotherapy

The mice were inoculated with 1×10^6 H22 cells, and randomly divided into six groups designated as A, B, C, D, E, F (day 0). On day 1, the mice in group B were injected at inoculation site with 100 μg of plasmid pCH510, for 10 days. On day 2, the mice in Groups C, D, E, F were injected at inoculation site with 50 μg MMC. On day 3, the mice in group E were injected at inoculation site with 100 μg of plasmid pCH510, for 10 days. On day 6, the mice in group F were injected at inoculation site with 100 μg of plasmid pCH510, for 15 days. The mice in groups A, B, C were dissected to measure the weight of tumor on the 15th day, the mice in groups D, E, F were dissected to measure the weight of tumor on the 21st day.

Assay for function of mouse peritoneal macrophages after injection of MMC

Macrophages were collected from murine abdominal cavity 4 hours and 24 hours after ip injection of 50 μg MMC. The macrophages were cultured *in vitro* in the presence of IFN-γ and CH50. The activation and NO production of macrophages were determined after 48 hour cell culture by MTT.

Assay for amount of immunocytes in peripheral blood of mouse after injection of MMC

The mice were randomly divided into two groups for ip injection of 50 μg MMC and PBS respectively (designated as day 0). On days 1, 3, 5, 7, 9, 11, blood was collected from murine orbital vein, the cells were counted following the removal of red cells. At the same time, macrophages were collected from murine peritoneal cavity and counted.

Preparation of Hsp70-H22 antigen peptides

H22 tumor antigen peptides and Hsp70 were prepared according to the method described previously[20]. Hsp70 and peptides mixture from cells were mixed to bind each other[20]. Briefly, peptides and Hsp70, at the concentrations of 75 μg/ml and 250 μg/ml respectively, were mixed and incubated at 37 ℃ for 2 h in the presence of 1 mM of ADP and 1 mM of $MgCl_2$.

Inhibition test of pCH510 with Hsp70-H22 peptide on tumor growth

The mice were randomly divided into eight groups. Four groups were inoculated with 10^5 of H22 cells, the other four groups were inoculated with 10^6 of H22 cells (designated as day 0). On day 1, the mice in different groups were given injection of pCH510 + Hsp70-H22 antigen peptides, pCH510, Hsp70-H22 antigen peptide, and saline respectively, every other day for 9 times. The mice were dissected to measure the weight of tumor on the 21st day (for control group, on the 14th day or 10th day).

Inhibition test of chemotherapy + pCH510 +Hsp70-H22 antigen peptide on tumor growth

The mice were randomly divided into five groups and inoculated with 10^6 of H22 cells into the hind limb (designated as day 0). On day 1, the mice were injected with 50 μg of MMC at the inoculation site (the control group was given saline). On day 5, the mice injected with MMC were given injection of pCH510 + Hsp70-H22 antigen peptide, pCH510, Hsp70-H22 antigen peptide, and saline respectively, every other day for 14 times. The mice were dissected to measure the weight of tumor at different times: saline group on the 10th day, MMC group on the 15th day, MMC + pCH510 and MMC + Hsp70-H22 antigen peptide groups on the 30th day, and another MMC + pCH510 + Hsp70-H22 antigen peptide group on the 40th day. The size of tumor was observed.

Statistical analysis

The *t* test was used for statistical analysis. *P* value less than 0.05 was considered as significantly different.

RESULTS

Chemotaxis for immune cells of pCH510 expression in tumor tissue

Tumor cells in control group grew rapidly. On the 3rd day after inoculation, tumor nodes were observed. In the tissue section

of control group, there were a large amount of tumor cells which invaded muscle tissues. In the experimental group, tumor node was not observed. In the tissue section, tumor cells were distributed locally. There were a large amount of macrophages and lymphocytes in connective tissues and many neutrophils and lymphocytes on the edge of tumor and muscle tissues. Immune cells were seldom seen in normal muscle tissues which were not invaded by tumor cells (Figures 1 and 2).

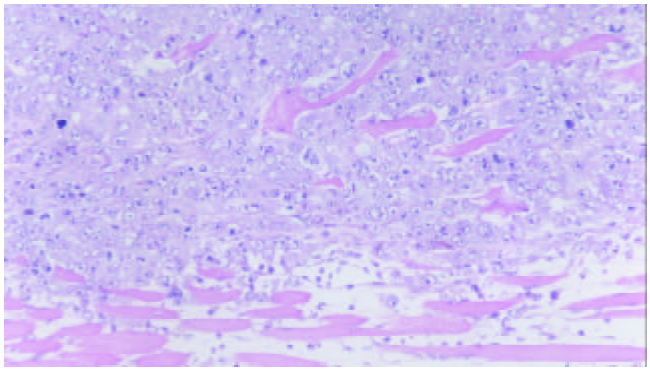

Figure 1 Control group: tumor cells grew rapidly and invaded the normal muscles (×200).

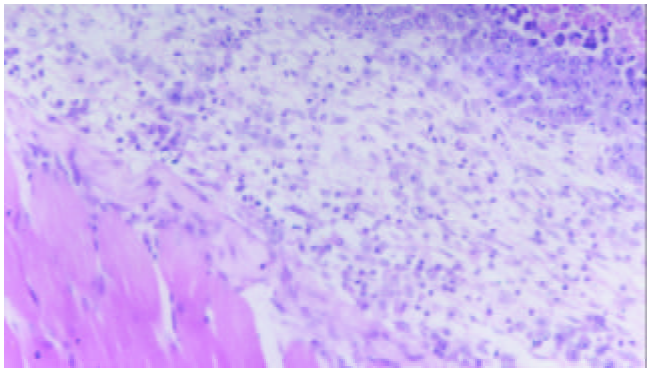

Figure 2 pCH510 group: transfection of pCH510 recruited macrophages, lymphocytes and neutrophils (×200).

Inhibitory effects of pCH510 on tumor growth

Plasmid pCH510 had inhibitory effects on murine tumor induced by different inoculative doses and the effect was negatively correlated with the inoculative dose. The lower the inoculative dose was, the more significant the effect. For 10^4 of tumor cells inoculation, pCH510 could completely inhibit the tumor growth in a period of 20 days (Table 1).

Table 1 Inhibitory effect of pCH510 on murine tumor inoculated with different doses of tumor cells

Effect of interval between injection of MMC and pCH510 on therapeutic efficacy

Chemotherapeutic agent alone or pCH510 alone could inhibit tumor growth. After chemotherapy, the effect was not improved by immediate 10-day pCH510 transfection. The tumor grew much slower if the mice were given 15-day pCH510 transfection 5 days after chemotherapy, suggesting that pCH510 in combination with chemotherapeutic agent in this way could significantly improve therapeutic effectiveness (Table 2).

Table 2 Inhibitory effect of pCH510 in combination with chemotherapy on murine tumor

Effect of MMC on the function and amount of macrophages in vivo

The metabolic activity of macrophages from murine abdominal cavity was inhibited by injection of MMC after 4 hours and 24 hours *in vivo*. The level of NO released by macrophage decreased significantly (Table 3). After injection with MMC intraperitoneally, the number of macrophage from murine peritoneal cavity and mononuclear cells from peripheral blood decreased dramatically. The number of immune cells reached the lowest from d 1 to d 3, and started recovery from d 5 and returned to normal level on the 11th day (Figure 3).

Synergic effects of pCH510 with Hsp70-H22 peptides on inhibition of H22 tumor growth

pCH510 in combination with Hsp70-H22 peptides could produce a much stronger inhibitory effect on H22 tumor in mice. Although the tumor from 10^6 of H22 cells inoculation was not completely inhibited, the tumor from 10^5 of H22 cells inoculation was completely inhibited (Table 4).

Inhibitory effects of chemotherapy+pCH510+Hsp70-H22 peptides on tumor growth

For tumor from 10^6 of H22 cells inoculation, the anti-tumor efficacy was significantly different if chemotherapeutic agent was used in combination with other agents. Compared with the protocols of chemotherapy in combination with Hsp70-H22 peptides and chemotherapy in combination with pCH510, the anti-tumor effect of chemotherapy in combination with both pCH510 and Hsp70-H22 peptides was the most powerful, which could completely inhibit the growth of residual tumor after chemotherapy (Table 5).

DISCUSSION

Tumor immuno-therapy comprises non-specific and specific immuno-therapy. The former includes some cytokines such as IL-12, IL-18, TNF-α, as well as some immune cells such as macrophages, natural killer cells and so on. The latter is cell-mediated immunity which is produced by the activation of $CD4^+$ and $CD8^+$ T cells stimulated by tumor specific antigen. Immuno-therapy holds great promise as an effective weapon against residual tumor cells after chemotherapy. Cell I-HepII double-domain polypeptide and CH50 can recruit macrophages and lymphocytes by chemotaxis, activate macrophages to inhibit the growth of tumor by non-specific immune response. It has a great potential in tumor therapy. It has been reported that fibronectin fragments containing Cell I-domain inhibited tumor invasion and metastasis[21,22]. Our results showed that recombinant FN polypeptide recruited immune cells into the local tumor tissue, increasing the local anti-tumor immunity. A large number of immune cells gathered around the tumor tissue which had been transfected with pCH510. Moreover, comparing the result of pCH510 transfection on the first day after inoculation with those of the other groups, the distribution of tumor cells was much more limited and the invasion of tumor cells to normal tissue was delayed, suggesting that transfection with pCH510 could inhibit tumor growth and invasion at the early stage of tumor growth.

Plasmid pCH510 had inhibitory effect on murine tumor from different inoculative doses and the effects was negatively correlated with the inoculative dose. The lower the inoculative dose was, the more significant the effect was. For 10^4 of tumor cells inoculation, pCH510 could completely inhibit the tumor growth in a period of 20 days. Chemotherapeutic agent kills tumor cells rapidly and powerfully. For 10^6 of tumor cells inoculation, the tumor did not grow within 11 days after chemotherapy. At the same time, the tumor weight in pCH510 transfection group was over 0.5 g, suggesting that chemotherapy should be chosen first to kill residual tumor cells after surgery.

It had an inhibitory effect on tumor growth no matter chemotherapeutic agent or pCH510 was used alone. But neither was powerful enough. When we tried to enhance the antitumor efficacy by combining anticancer drugs with immune modulator CH50, we found that the therapeutic effectiveness was not improved as we had expected by immediate 10-day transfection with pCH510 after chemotherapy. And there was no direct evidence to testify the inhibition of the expression of the plasmid by chemotherapy. CH50 plays an anti-tumor role by regulating host immune response. So we tried to find out the response pattern of host immune system to chemotherapy and the proper timing of transferring pCH510 after chemotherapy. Our results showed that chemotherapeutic agent not only decreased the number of immunocytes but also suppressed their activation. After injection of MMC, the amount of immunocytes was the lowest from d 1 to d 3 and returned to normal level on the 10^{th} day. Similar phenomenon was observed when dendritic cell (DC) counts and function were assayed in peripheral blood of lymphoma and solid tumor patients before and after chemotherapy[23]. The DC counts declined significantly within the first week from the start of chemotherapy, recovered in the second week, and exceeded the baseline values in the third week[23]. The count of immunocytes dropping to the lowest point means that the cytotoxicity of the drug is over. At this moment the host immune system is most severely damaged. If H22 cells were inoculated to the mice on the third day after chemotherapy, the tumor grew more fast than non-chemotherapy control (data not presented), suggesting that immuno-therapy was needed after chemotherapy. But immediate pCH510 transfection after chemotherapy recruited very few inactivated immune cells, as a result, the therapeutic effectiveness was not improved. In contrast, the therapeutic effectiveness was significantly improved by 15-day transfection with pCH510 5 days after chemotherapy. The proper timing of combining chemotherapy with pCH510 was on the 3^{rd} and 5^{th} day after chemotherapy.

Besides proper timing, another influential factor on

therapeutic effectiveness was the dose of chemotherapeutic drug which has also been reported recently[24-26]. One of the disadvantages of conventional chemotherapy is the cytotoxic side effect. How to make full use of the cytotoxicity to tumor cells and lower the side effects is the basis of evaluating the drug dose. In pilot experiments, four doses of MMC were set as following: 150 μg, 100 μg, 50 μg and 25 μg. Two of eight mice died from 150 μg MMC. None of the mice died from 100 μg MMC, but they were accompanied by obtuse reactions, light weight and lackluster hair. For 50 μg and 25 μg MMC, the mice were agile and no obvious side effects were found. Therefore, 50 μg of MMC was the suitable dose for mouse in our experiment. Our results were consistent with those of related reports[27, 28], which showed that combined treatment with low-dose chemotherapy could achieve better efficacy.

The growth of tumor from 10^6 of H22 inoculation was slowed down by chemotherapy in comparison with the tumor from 10^4 of H22 inoculation without treatment. Transfection with plasmid pCH510 alone did inhibit the tumor from 10^4 of H22 inoculation, but not the tumor from 10^6 of H22 inoculation with chemotherapy, suggesting that chemotherapy had a dual effect on tumor growth: on the one hand, they killed tumor cells, on the other hand, they promoted tumor growth by damaging host immune system. Furthermore, improvement of the therapeutic effectiveness by a single immune factor combined with chemotherapy was limited. The best way is the combination of chemotherapy with several kinds of synergic immune modulators. In tumor cells, there are a great amount of over-expressed proteins which can be cleaved into small peptides. These peptides can be used as tumor antigens to induce specific antitumor immune response. At present, only limited antigen peptides are identified, including MAGE-1, MAGE-3, HER-2/neu, and MUC-1[29]. On the other hand, the immunity of multi-valence CTLs induced by mixed antigen peptides from tumor cells is stronger than that of monovalence CTL induced by a given antigen peptide[30]. Heat shock protein 70, as a molecular chaperon, can bind antigen peptide to form Hsp70-peptide complex. The complex presents the antigen peptide to antigen presenting cells (APC) mediated by high affinity receptors on the surface of APC to induce CD_8^+ CTL response[31-35]. In addition to CD_8^+ CTL response, the Hsp70-peptides can also induce CD_4^+ T cell response and NK cell reaction[36]. Our experiment demonstrated that mixed antigen peptides obtained from H22 hepatocarcinoma cells, bound to Hsp70, could induce the production of $CD8^+$ CTLs which could kill specifically H22 cells and inhibit experimental tumor growth *in vivo*[20]. It is theoretically practical that immune cells recruited by pCH510 can be activated by Hsp70-H22 peptide to produce powerful anti-tumor immunity, which was verified by our experiment. The results in this paper showed that the combination of non-specific immune response with specific immune response could be a better strategy for the treatment of tumor. The Cell I-Hep II recombinant polypeptide expressed by plasmid pCH510 could recruit macrophages and other immune cells *in vivo*, activate macrophages and produce non-specific antitumor immunity. Hsp70-H22 peptides could specifically activate $CD4^+$, $CD8^+$ T cells to produce specific anti-tumor immunity. Immune cells were recruited into the tumor tissue by the expressed product of pCH510 and activated by Hsp70-H22 peptides, producing a much stronger anti-tumor immunity.

Nowadays tumor immuno-therapy is focused on specific immune response induced by antigens such as using tumor antigen peptides, tumor idiotype antibody[37]. Tumor antigen peptides can be obtained by some methods such as phage display[38], isolation from Hsp70, hsp90, and gp96-peptide complex[39, 40]. But it is difficult to get mixed antigen peptides, and the complex obtained by the latter method is very little. In this paper we provided a new method which is simple and effective, to obtain mixed antigen peptides from tumor cells by freezing and thawing, heating and acid precipitating.

Transfection with plasmid pCH510 alone could inhibit the tumor originated from 10^4 inoculative dose of H22 cells. The tumor originated from 10^5 inoculative dose of H22 was inhibited by pCH510+Hsp70-H22 antigen peptides. Following the treatment with MMC, the two factors could inhibit the tumor from 10^6 inoculative dose of H22. These results indicate that immuno-therapy is just effective on a small amount of tumor cells. The chemotherapeutic agent is the indispensable agent once the tumor load is high. Chemotherapeutic agents can kill tumor cells rapidly and powerfully, but not completely. Combination of anticancer drugs and immune modulators is necessary. And the combination of pCH510 and Hsp70-peptides has been proved to be one of the choices for the treatment of residual tumor after chemotherapy.

In summary, recombinant polypeptide CH50 is a promising non-specific immune modulator. It can be expressed *in vivo* to inhibit experimental tumor growth. The inhibitory effect can be further improved by combining pCH510 with Hsp70-tumor antigen peptides. Furthermore, the two immune modulators can synergize with chemotherapeutic agents to treat tumor. But chemotherapeutic agents damage the host immune sysytem, so that immuno-therapy has no effect within 3 or 5 days after chemotherapy. For different immuno-therapy agents, different chemotherapeutic drugs and different patients, the combining pattern is possibly different. Individualized treatment regimen should be adopted.

Abstract

AIM: To clarify the location and distribution of Kupffer cells in hepatocellular carcinoma (HCC), and to investigate their role in hepatocarcinogenesis.

METHODS: Kupffer cells were immunohistochemically stained by streptavadin-peroxidase conjugated method (S-P). The numbers of Kupffer cells in cancerous, para-cancerous and adjacent normal liver tissues of 48 HCCs were comparatively examined.

RESULTS: The mean number of Kupffer cells in cancerous, para-cancerous and adjacent normal liver tissues was 12.7±6.8, 18.1±8.2 and 18.9±7.9 respectively. The number of Kuppfer cells in cancerous tissues was significantly lower than that in para-cancerous tissues (t=2.423, P<0.05) and adjacent normal liver tissues (t=2.521, P<0.05). As tumor size increased, the number of Kupffer cells in cancerous tissues significantly decreased (F=4.61, P<0.05). Moreover, there was also a significant difference in the number of Kupffer cells among well-differentiated, moderately-differentiated and poorly-differentiated cases(F=4.49, P<0.05).

CONCLUSION: This study suggests that decrease of Kupffer cells in HCCs may play an important role in the carcinogenesis of HCC, the number of Kupffer cells in HCC is closely related to the size and differentiation grade of the tumor.

INTRODUCTION

Kupffer cells are important in maintaining homeostasis and in host anti-tumor defense mechanism[1-5]. It is thought that Kupffer cells are resident macrophages in the liver and are one kind of the sinusoidal endothelial cells[6]. Previously, Kupffer cells were not considered to exist in hepatocellular carcinoma (HCC) tissues. Recently, some studies revealed that Kupffer cells were also present in early-stage and well-differentiated HCC. Because small and well-differentiated HCCs could maintain an environment similar to that of normal sinusoids, Kupffer cells may also exist in these HCCs[7,8].

Unfortunately, whether Kupffer cells could exist in poorly-differentiated or large HCCs remaines unidentified. Nevertheless, the difference of Kupffer cells among variable tissue types is not clear. The relationship between the decrease of Kupffer cells and carcinogenesis of HCC also needs to be clarified.

In the present study, we pathomorphologically examined the localization and distribution of Kupffer cells in 48 cases of HCCs samples embracing cancerous tissues, corresponding para-cancerous tissues and adjacent normal liver tissues.

MATERIALS AND METHODS

Tissues and specimen

Tissues of forty-eight primary HCCs including cancerous tissues, corresponding para-cancerous tissues and adjacent normal liver tissues were obtained with the informed consent of patients who underwent hepatectomy at the West China Hospital of Sichuan University. The surgically resected tissues were fixed in 10 % formalin, embedded in paraffin, cut into 5 μm sections and stained with hematoxylin-eosin. Histopathological diagnosis and classification were made by the same pathologist.

Immunohistochemical staining

The SP method was used, and the first antibody was mouse-anti-human monoclonal CD68 antibody (DAKO, dilution 1: 50). The operation procedure was according to the instructions of SP kit which was purchased from DAKO, Glostrup, Denmark. DAB was used for coloration. The dark brown granules in cytoplasm were taken as CD68 positive reaction. Negative mouse serum and PBS were respectively used to replace 1st antibody as negative control and blank control.

Identification of Kupffer cells

Among the cells which were anti-CD68 antibody positive, those in the blood space of cancerous tissues or the sinusoids of noncancerous tissues with a stellate or spindle shape were evaluated as Kupffer cells.

Determination of Kupffer cell numbers

The number of Kupffer cells was counted in five randomly selected visual fields under a microscope (×200) for each specimen. Then the average Kupffer cell number of each specimen was determined.

Statistical analysis

The data of Kupffer cells were expressed as mean ± standard deviation (Mean ± SD), and the differences in the values of different groups were analyzed by t test and F test. The criterion of significance was set at P<0.05.

RESULTS

Kupffer cells in HCC specimens

Kupffer cells were present in the cancerous tissues of 45 out

of 48 cases of HCCs (93.8 %). The only 3 specimens in which no Kupffer cells were found were all poorly-differentiated HCCs. Kupffer cells were found in the para-cancerous tissues and adjacent normal liver tissues of all 48 HCCs.

Number of Kupffer cells and histological grades

The mean number of Kupffer cells in cancerous, para-cancerous and adjacent normal liver tissues was 12.7±6.8,18.1±8.2 and 18.9±7.9 respectively. The number of Kuppfer cells in cancerous tissues was significantly lower than that in para-cancerous tissues and adjacent normal liver tissues (P<0.05) (Table 1). The number of Kupffer cells in cancerous tissues of well, moderately and poorly differentiated HCCs was 18.4±4.2, 11.2±6.2 and 5.2±4.9, respectively (Table 2).The number of Kupffer cells in cancerous tissues significantly decreased as the histological grades decreased (P<0.05) (Figure 1).

Table 1 Kupffer cell number in different tissue types

Tissue type	*n*	Kupffer cell number ($\bar{x}$±*s*)
Cancerous tissue	48	12.7±6.8
Para-cancerous tissue	48	18.1±8.2[a]
Adjacent normal liver tissue	48	18.9±7.9[b]

[a]P<0.05 *vs*. cancerous tissues, [b]P<0.05 *vs*. cancerous tissues.

Table 2 Realationship between Kupffer cell number, tumor size, and differentiation degree

	n	Kupffer cell number ($\bar{x}$±*s*)
Tumor size (diameter)		
<3 cm	12	17.4±4.8[a]
3-5 cm	17	12.5±6.3[a]
>5 cm	19	7.9±5.8[a]
Differentiation degree		
Well- differentiated	11	18.4±4.2[b]
Moderately- differentiated	20	11.2±6.2[b]
Poorly- differentiated	17	5.2±4.9[b]

[a]P<0.05 *vs*. among three groups, [b]P<0.05 *vs*. among three groups.

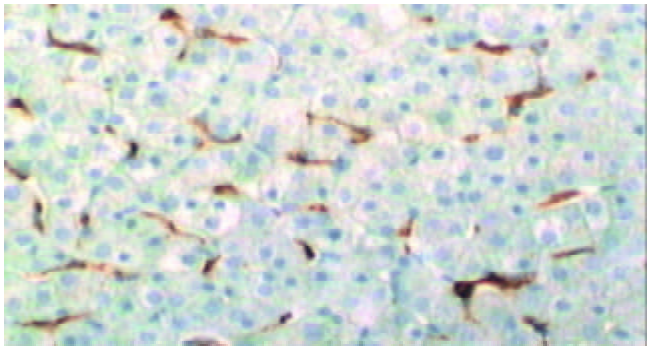

Figure 1 Kupffer cells in cancerous tissues of well-differentiated HCC ×200.

Relationship between the number of Kupffer cells and tumor size

Among the 48 HCCs, 12 cases had a tumor size <3 cm, 17 between 3-5 cm and 19 >5 cm. Mean Kupffer cell number in the cancerous tissues of the three groups was 17.4±4.8, 12.5± 6.3 and 7.9±5.8 respectively (Table 2).The three poorly-differentiated cases of HCCs in which there was no Kupffer cell in cancerous tissues all had a diameter >5 cm. Mean Kupffer cell number in cancerous tissues of HCCs which had a diameter <3 cm was significantly higher than that of the cases of HCCs which had a diameter between 3-5 cm or >5 cm (P<0.05). In addition, Kupffer cell number in cancerous tissues of tumors which had a diameter between 3-5 cm differed significantly from that of the cases of HCCs which had a diameter >5 cm (Figures 2 and 3). As the tumor size increased, the Kupffer cell number decreased significantly (P<0.05).

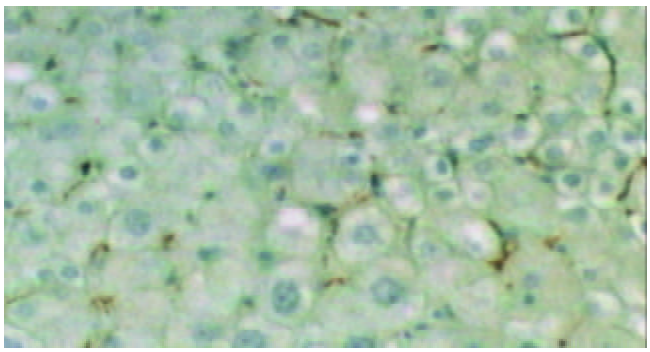

Figure 2 Kupffer cells in cancerous tissues of poorly-differentiated HCC (tumor diameter 3.5 cm) ×200.

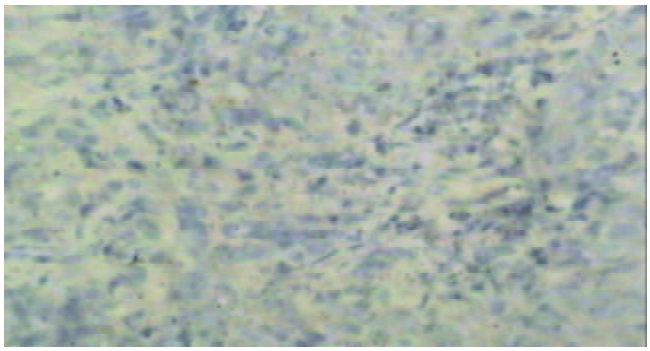

Figure 3 No Kupffer cell in cancerous tissues of poorly-differentiated HCC (tumor diameter 7.8 cm) ×200.

DISCUSSION

Kupffer cells are important in the host defense mechanism including normal metabolism, phagocytosis, cytokine generation and anti-tumor effects. They are also involved in the pathogenesis of liver diseases such as viral hepatitis, alcohoic liver injury, chemically mediated liver injury, liver fibrosis, ischemia and reperfusion injury in liver transplantation, and hepatocyte regeneration[9-23]. Functional capability of Kupffer cells is considered to decrease when the liver is impaired. Usually, light-microscope is used to identify Kupffer cells by confirming the presence of lipofuscin and hemosiderin pigments in the cytoplasm. Moreover, Kupffer cells can be identified by monitoring their unique ultra-structures. For example, they have numerous vesicles, well-developed lamillipodia in cytoplasm and lysosomes in various sizes. In this study, we used anti-CD68, an anti-human macrophage antibody, to identify macrophages. CD68 was expressed not only in the residential macrophages such as Kupffer cells, but also in the migrating macrophages. In view of this fact, Kupffer cells cannot be identified merely by being anti-CD68 positive. Morphological observations are also required to distinguish between these two cell types. For example, migrating macrophages are usually oval and contain abundant cytoplasm, while Kupffer cells usually have spindle or stellate-shaped cytoplasm and partly adhere to the sinusoidal endothelial cells[24-29].

The origin of Kupffer cells in normal liver tissues remains

unidentified. One hypothesis postulates that Kupffer cells are originated from the macrophages which have been present in the premordial liver at the embryonal stage. The other hypothesis proposes that monocytes which are originated from bone marrow arrive, settle in the sinusoids and then differentiate into Kupffer cells. There are two possible mechanisms of Kupffer cells existing in cancerous tissues of HCC. (1) Under the environmental condition similar to normal sinusoids, migrating macrophages in the blood space change into Kupffer cell-like cells. (2) Kupffer cells in normal liver tissue are maintained in the cancerous tissues. Our results showed that all the three poorly differentiated HCCs contained no Kupffer cell in cancerous tissues. Moreover, Kupffer cells in cancerous tissues of poorly differentiated HCCs were significantly less than those of well or moderately differentiated HCCs. In view of the fact that the morphology of poorly differentiated cancerous tissues is quite different from that of normal liver tissue, the former hypothesis may be more reasonable. We also found Kupffer cell number in para-cancerous and adjacent normal liver tissues had no statistical difference, probably due to the fact that para-cancerous tissues present in the blood space closer to the normal sinusoids. On the other hand, Kupffer cells were found to be activated in the pathogenesis of liver injuries such as early-stage fibrosis and fatty liver hepatitis. Under these conditions the sinusoid structures usually were not destroyed seriously and Kupffer cell number did not decrease significantly[30-32].

The mechanism responsible for the tumoricidal activities of Kupffer cells is not completely known. Kupffer cells may execute their anti-tumor effect via increasing the production of some cytotoxic molecules such as NO, TNF-α and IFN-γ, which may inhibit the growth of tumor by damaging cellular DNA and inducing apoptosis. When implanted into normal and cirrhotic rat livers, rat HCC cells grew much more progressively in cirrhotic livers than in normal livers. Meanwhile, Kupffer cells were decreased profoundly in cirrhotic livers, resulting in markedly impaired phagocytic activity. Furthermore, profound decrease production of Kupffer cell-related cytokines was found to in cirrhotic livers[1,5,33]. Previous studies also found that Kupffer cells might play an important role in controlling occurrence and progression of liver metastasis. The possible pathway of Kupffer cells against liver metastasis might be that tumor cells were apoptotic via the Fas-Fas ligand system induced by TNF-α released from Kupffer cells[34-36]. When the liver is chemically injured, Kupffer cells may release biologically active mediators that promote the pathogenic process. Though there is evidence that indicates Kupffer cells play a stimulatory role in liver regeneration, presently Kupffer cells are thought to have the potential to exert both stimulatory and inhibitory influences on hepatocyte proliferation[37-40]. Some research suggested that in viral hepatitis, Kupffer cells were activated and expressed high levels of CD80, CD40 and class-II MHC molecules, thus acquiring the phenotype of antigen presenting cells (APCs)[41].

Enhanced magnetic resonance imaging (MRI) has been used to detect hepatic tumors[42]. The method utilizes selective taken-up mechanism of superparamagnetic iron oxide (SPIO) or chondroitin sulfate iron colloid into the reticuloendothelial cells such as Kupffer cells of the liver. Our findings indicated that the number Kupffer cells in cancerous tissues decreased significantly as the tumor size increased and histological grade decreased. Therefore, the enhanced MRI which utilizes the function of Kupffer cells can be useful in estimation of histological degree of HCC. Imai *et al*[43] studied histologically proven tumors including 31 HCCs and 6 dysplastic nodules by SPIO-enhanced MRI, and proposed that SPIO-enhanced MRI reflect Kupffer cell number in HCCs and dysplastic nodules and be useful in assessing the histological grades of HCCs, especially poorly-differentiated and moderately-differentiated cases. Recently, Kitamura *et al*[44] reported 18 HCCs detected by color Doppler sonography had either a marked reduction in the number or absence of Kupffer cells. In conclusion, the present study has shown that Kupffer cells are important in preventing development of HCCs, and tumor metastases. They are also involved in the pathogenesis of chemically mediated liver injury and viral hepatitis. Further study on the biological characteristics and function of Kupffer cells will contribute to the early diagnosis of hepatic tumors and new treatment strategies.

Abstract

AIM: To investigate the expression of RhoC gene in hepatocellular carcinoma (HCC) and to evaluate the relationship between RhoC gene expression and invasion and metastasis of HCC.

METHODS: mRNA expression level of RhoC gene was examined by reverse transcription-polymerase chain reaction (RT-PCR) in 25 cases of HCC and para-cancerous normal liver tissues. In addition, mutation of RhoC gene was examined by polymerase chain reaction-single strand conformational polymorphism (PCR-SSCP).

RESULTS: The mRNA expression levels of RhoC in tumor tissues were significantly higher than those in para-cancerous normal liver tissues (1.8±1.1 *vs* 1.0±0.7, $P<0.01$). The metastatic lesions outside of liver also showed significantly higher RhoC mRNA levels than corresponding tumor tissues in liver (3.3±0.5 *vs* 2.0±0.7, $P<0.01$). There were significant associations between RhoC gene expression and certain clinical and pathological findings, including cell differentiation, vein invasion, number of tumor nodes and metastatic lesions. Mutation of RhoC gene was not found by PCR-SSCP.

CONCLUSION: The RhoC gene may be related to malignant transformation and development of HCC and may play an important role in the invasion and metastasis of HCC by overexpression but not mutation.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies in the world, and is the second-leading cause of cancer death among males in China[1]. It is generally accepted that the high incidence of recurrence and metastasis is the most crucial prognostic factor for patients with HCC[2]. Transcellular migration of tumor cells through host structures, such as endothelium of blood vessels and methothelium of visceral cavity is crucial in cancer invasion and metastasis[3].

RhoC GTPase is a member of Ras-superfamily of small guanosine triphosphatases (GTPases), which shuttles between an inactive GDP-bound state and an active GTP-bound state and exhibits intrinsic GTPase activities[4]. Activation of Rho protein leads to assembly of the actin-myosin contractile filaments into focal adhesion complexes that lead to cell polarity and facilitate motility[5]. Recently, emerging data have suggested that RhoC gene play important roles in tumorigenesis and metastasis of tumor cell[6]. The expression level of RhoC in metastatic regions of pancreas cancer has been reported to be higher than that in primary lesion[7]. Genome-wide analysis of gene expression has revealed that RhoC gene was involved in vascular invasiveness of hepatocellular carcinoma[8]. We hypothesized that RhoC might play a critical role in tumorigenesis and invasion and metastasis of HCC. In the present study, we investigated the expression of RhoC gene in HCC and evaluated the relationship between RhoC gene expression and clinical and pathological characteristics of HCC.

MATERIALS AND METHODS

Patients and tissue preparation

Twenty-five fresh HCC specimens and corresponding para-cancerous normal liver tissues were obtained by surgical resection in Xiangya Hospital between March 2002 and August 2002. Further more, four cases of corresponding metastatic lesions or hepatic vein tumor thrombosis were obtained as well. The patients with HCC were consisted of 22 men and 3 women and were ranged from 28 to 73 (mean ±SD=53). We divided the 25 patients from six aspects: tumor <5 cm in diameter 7 cases and ⩾5 cm 18 cases, I-II in cell differentiation 9 cases and III-IV 16 cases; the number of tumor nodes ⩾2 15 cases and <2 10 cases, with capsule formation 12 cases and without it 13 cases, with microscopy portal vein tumor thrombosis 13 cases and without it 12 cases, with metastatic nodes outside of liver 5 cases and without it 20 cases. All specimens were examined under a microscope after haematoxylin and eosin (H&E) staining.

RNA extraction and RT-PCR

Total RNA was isolated using Trizol reagent (GIBCO BRL, USA) and cDNA was synthesized from the RNA by M-MLV reverse transcriptase (Promega, USA) with oligodT primers (Sangon Technology, CHINA), The primer sequences of RhoC and β_2-microglobulin which was used as an internal quantitative control for the amplification were as follows: the upstream primers of RhoC and β_2-microglobulin were 5' -TCCTCAT CGTCTTCAGCAAG-3' and 5' -ACCCCCACTGAAAAAG ATGA-3' , the downstream primers of RhoC and β_2-microglobulin were 5' -CTGCAATCCGAAAGAAGCTG-3' and 5' -ATCTTCAAACCTCCATGATG-3' . The condition of PCR was as follows: 32 cycles of denaturing at 94 ℃ for 40 s, annealing at 56 ℃ for 30 s and extending at 72 ℃ for 1 min. The bands representing amplified products were analyzed by Stratagene Eagle-eye scanner. RhoC gene expression was

presented by the relative yield of PCR product from target sequence to that from β_2-microglobulin gene.

PCR-SSCP-sliver staining analysis

Because RhoC is homologous with ras gene and mutation of ras is frequent in HCC, PCR-SSCP-sliver staining analysis was performed to determine gene mutation of RhoC. We examined exon I of RhoC. The primers were designed as follows: upstream 5'-CTGCAATCCGAAAGAAGCTG-3' and downstream 5'-CTGCAATCCGAAAGAAGCTG-3'. PCR reaction was performed by denaturing at 94 ℃ for 40 s, annealing at 55 ℃ for 30 s and extending at 72 ℃ for 1 min for 35 cycles. PCR samples were denatured at 99 ℃ for 10 min and electrophoresed with 8 % non-denaturing polyacrylamide gel at 40v for 5 hours. After electrophoresis, the gel was fixed in 10 % alcohol for 10 min, washed twice with distilled water for 2 min, silver reaction was performed (silver nitrate 1 g, topped up with distilled water to 500 ml) for 10 min, then washed with distilled water for 30 s, finally the gel was developed (sodium hydroxide 3.75 g, formaldehyde 2.7 ml, topped up with distilled water to 500 ml) for 10 min.

Statistical analysis

The results of RT-PCR were statistically analyzed using the Student's *t* test. Fisher's exact test was used to determine the relationship between RhoC expression and clinical and pathological characteristics of HCC. A value of $P<0.05$ was considered statistically significant.

RESULTS

RhoC gene was expressed in HCC tissues and para-cancerous normal liver tissues of all the 25 cases. There were significant differences in the expression level of RhoC gene between carcinoma tissues and para-cancerous normal liver tissues (mean ±SD, 1.8±1.1 *vs* 1.0±0.7 respectively) (Figure 1). Metastatic lesions or hepatic vein tumor thrombosis showed significantly higher RhoC mRNA levels than primary carcinoma tissues (mean ±SD, 3.3±0.5 *vs* 1.8±1.1 respectively). Based on the ratio of RhoC expression in tumor to corresponding para-cancerous normal liver tissues ($\overline{X}_t/\overline{X}_p=1.8$), the 25 patients were divided into two groups: overexpression group (14 cases) and high-expression group (11 cases). Fisher's exact test analysis demonstrated a significant difference in some aspects between the two groups ($P<0.05$) including cell differentiation, vein invasion, number of tumor nodes and metastatic lesions. The difference in vein invasion between the two groups was statistically significant ($P<0.01$) (Table 1). Mutation of RhoC was not found in all cases of HCC.

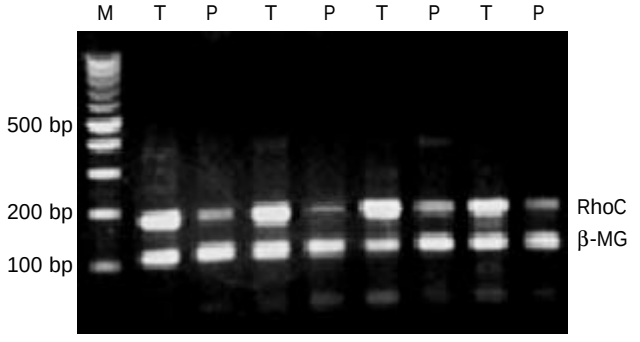

Figure 1 Expression of RhoC mRNA in hepatocellular carcinoma. M: DNA marker T: tumor P: para-cancerous normal liver tissues. PCR product of RhoC was 183 bp; PCR product of β_2-microglobulin was 120 bp. RhoC mRNA levels were significantly higher in tumor than para-cancerous normal liver tissues.

Table 1 The relationship between RhoC mRNA expression and clinical and pathological features of HCC patients

Variables	Overexpression of RhoC (*n*)	High-expression of RhoC (*n*)	Fisher's test

DISCUSSION

RhoGTPases are members of the ras superfamily of GTP-binding protein, which act as molecular switches, cycling between an active GTP-bound and inactive GDP-bound states. Eighteen members have been identified and the most extensively characterized members are Rho, Rac and cdc42[5]. Early studies showed that Rho protein regulated cell morphology and actin cytoskeleton, however it is now clear that they also affect gene expression, cell proliferation and cell survival[9]. Emerging data have showed that RhoGTPases are more important for the evolution of cancer than initially thought, and several reports indicated that RhoGTPases directly participated in the evolution of cancer. For instance, activated Rho protein mutants were capable of transforming fibroblast and dominant inhibitory mutants of Rho protein blocked transformation by ras[10]. Furthermore, Rho protein could upregulate cyclinD_1 and downregulate CDKIs through ETS, AP-1 and NF-KB[11-19]. These indicate that Rho protein is important in tumorigenesis. RhoC is a member of Rho family and it has been shown that overexpression of RhoC induce the malignant transformation of immortalized human mammary epithelial cells. RhoC is overexpressed in pancreatic ductal adenocarcinoma and inflammatory breast cancer[7,20]. Furthermore, there is a causal link between RhoC overexpression and inflammatory breast cancer. Based on these results, we hypothesized that RhoC might be involved in tumorigenesis of HCC. We detected the expression level of RhoC mRNA in 25 patients with HCC by RT-PCR. Our results showed that RhoC gene expression was significantly higher in tumor portion than that in corresponding para-cancerous normal liver tissues. Furthermore, we also found that tumor with RhoC overexpression appeared poorer in cell differentiation than those with high-expression of RhoC gene. These suggest that overexpression of RhoC gene is related to the degree of differentiation of HCC and RhoC expression level could be a useful prognostic indicator.

Metastasis and invasion of HCC were a multistep process, and the molecular and cellular mechanisms of which were not

fully understood, although cell motility has been shown to play a pivotal role in metastasis and invasion of HCC[21]. RhoC is involved in cytoskeletal reorganization, specifically in the formation of actin stress fibers and focal adhesion contacts[22]. Numerous *in vitro* studies have indicated that RhoC protein and its effector ROCK are clearly implicated in *vivo* models of tumor-cell dissemination[23]. Overexpression of RhoC gene was found in metastatic lesions of inflammatory breast cancer and pancreatic ductal adenocarcinoma. RhoC gene was also found to be correlated with vascular invasion and tumor differentiation in human HCC by using cDNA microarray[8]. In the present study metastatic lesions or hepatic vein tumor thrombosis showed significantly higher RhoC mRNA level than primary carcinoma tissues. Expression level of RhoC gene was correlated with vein invasion, number of tumor nodes and metastatic lesions. Especially, the difference between two groups in microscopy hepatic vein tumor thrombosis indicated greater significance. These results indicate that RhoC has a close relationship with invasion and metastasis of HCC. The possible reasons may be as follows: (1) Disruption of cell polarity, which plays an important role in the epithelial-mesenchymal transformation that is observed in more aggressive tumors[24,25]. (2) Contribution to the loss of adherens junctions[26-28]. (3) Increase of motility and ability to remodel ECM, which requires tumor cells to become locally invasive[29-32]. However, the exact mechanisms need to be explored further.

Given the results that RhoC protein is important in determining the behavior of cancer cells, it is surprising that mutants of RhoC-analogous of oncogenic ras have not been found in our research. Similar results were observed in pancreatic ductal adenocarcinoma[7]. In fact, several lines of evidence indicate that not mutation but the switch of Rho protein between GTP- and GDP-bound states are important in the transformation of malignant tumor[33]. Overexpression level of RhoC may contribute to a faster GTP-GDP cycling station. Taken together, our findings indicate that RhoCGTPase is related to tumorigenesis of HCC. Overexpression but not mutation of RhoC may enhance the invasion and metastasis of HCC. The molecular basis for overexpression of RhoC remains to be elucidated. What are the most important factors regulating the expression level of RhoC and how does RhoC gene regulate effector protein will be the subject of our future studies. When upstream and downstream signaling pathways are explored, these findings will provide new potential targets for the prognostication or prevention of invasion and metastasis of HCC[34].

Abstract

AIM: To increase exogenous gene expression level by modulating molecular conformations of targeting gene drugs.

METHODS: The full length cDNAs of both P_{40} and P_{35} subunits of human interleukin 12 were amplified through polymerase chain reaction (PCR) and cloned into eukaryotic expressing vectors pcDNA3.1(±) to construct plasmids of P(+)/IL-12, P(+)/P_{40} and P(-)/P_{35}. These plasmids were combined with ASOR-PLL to form two targeting gene drugs [ASOR-PLL-P(+)/IL-12 and ASOR-PLL-P(+)/P_{40} + ASOR-PLL-P(-)/P_{35}] in optimal ratios. The conformations of these two drugs at various concentrations adjuvant were examined under electron microscope (EM) and the drugs were transfected into HepG2 (ASGr+) cells. Semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) was performed with total RNA extracted from the transfected cells to determine the hIL12 mRNA transcript level. The hIL12 protein in the cultured supernatant was measured with enzyme-linked immunosorbent assay (ELISA) 48 hours after transfection.

RESULTS: Targeting gene drugs, whose structures were granular and circle-like and diameters ranged from 25 nm to 150 nm, had the highest hIL-12 expression level. The hIL-12 expression level in the group co-transfected with ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} was higher than that of ASOR-PLL-P(+)/IL-12 transfected group.

CONCLUSION: The molecular conformations of targeting gene drugs play an important role in exogenous gene expression level, the best structures are granular and circle-like and their diameters range from 25 nm to 150 nm. The sizes and linking styles of exogenous genes also have some effects on their expression level.

INTRODUCTION

In hepatoma gene therapy, the technical difficulty is that exogenous gene expression level is too low to achieve therapeutic effecets on in target cells[1]. Studies have been focused on improving gene therapeutic vector, restraining the lysosome activity in target cells, increasing exogenous gene outputs from endosomal vesicles, and modifying their transcription elements[2-7]. Whether there are some relationships between molecular conformation of gene drugs and exogenous gene expression level is not clear. Asialoorosomucoid (ASOR), the specific ligand of asialoglycoprotein receptor on the surface of hepatocytes, can be combined covalently with poly-l-lysine (PLL) to form a soluble DNA transfection vector[8-10]. Human interleukin 12 (hIL-12), also named as cytotoxin lymphocyte maturation factor or natural killer cell stimulatory factor, plays a key regulatory role in humoral immune reactions and explicits bioactivities of antivirus, antitumor and antimetastasis[11-14]. After constructing a hIL12 (human interleukin 12) double-subunit co-expressing plasmid and single-subunit gene expression plasmids, we linked them with ASOR-PLL through electrostatic interactions to form two targeting gene drugs-ASOR-PLL-DNA complexes, then examined their molecular shapes and sizes at various concentration of adjuvant under transmission electron microscope. We compared exogenous gene expression levels to select the best molecular conformation of the complexes 48 hours after transfecting them into HepG2 (ASGr+) cells, and found the means to improve the expression efficiency in target cells on the basis of molecular conformations of gene drugs.

MATERIALS AND METHODS

Materials

Eukaryotic expressing plasmids [pcDNA3.1(+/-)] and host bacteria *E. coli* JM109 were obtained from the National Laboratory of Medical Genetics of China. Plasmids purification kit 2500 was purchased from Qiagen (Chatsworth CA). All the restriction endonuclease enzymes were purchased from New England Biolabs (Beverly MA). Minimum essential medium (MEM), Trizol and lipofectamine were purchased from GibcoBRL (Grand Island NY). RT-PCR kit was purchased from Promega (Madison WI). hIL-12 (P70) ELISA kit was purchased from Pharmingen (San Diego CA). Hepatoma cells (HepG2) were obtained from China Center of Type Culture Collection (CCTCC). Newborn bovine serum was purchased from Sijiqing (Hangzhou, China). Chloroquine was a gift from Shanghai Zhong-Xi Pharmaceutical Company. All other reagents were of analytical grade from various companies in China. ASOR-PLL was prepared by ourselves.

Methods

Construction of double-subunit co-expressing plasmid of human interleukin12 The full length cDNAs of P_{40} and P_{35} subunits were amplified from human embryonic kidney by RT-PCR based on sequences deposited in Genbank (P_{40} accession number AF180563, P_{35} accession number AF180562), and cloned into pcDNA3.1(+/-) to obtain P(+)/P_{40} and P(-)/P_{35}

plasmids. The segments-P_{35}-polyA and -cmv-P_{40}-were amplified from P(-)/P_{35} and P(+)/$_{P40}$ by using the following primers IL40F, IL40R, IL35F, IL35R. They were then ligated and cloned into pcDNA3.1(+) to obtain double-subunit co-expressing plasmid P(+)/IL-12 (Table 1).

Observation under transmission electron microscope After the three plasmids were mixed and incubated with ASOR-PLL at various molecular weight ratios for 40 minutes at room temperature, the mixture was electrophoresed in a 0.8 % agarose gel retardation system to determine its optimal ratio. ASOR-PLL-P(+)/P_{40}, ASOR-PLL-P(-)/P_{35} and ASOR-PLL-P (+)/IL-12 formed in optimal ratios were the two targeting gene drugs. These two drugs (plasmid DNA 0.9 μg) were formed at various concentrations of adjuvant (0, 0.1 M, 0.2 M, 0.3 M, 0.4 M, 1.5 M), then their A_{260} values were measurated and examined under a transmission electron microscope after contrast staining by 2 % uranyl acetate (*bar*=100 nm).

Cell culture and transfection HepG2 cells were cultured to 2×10^7 in minimum essential media plus 15 % fetal bovine serum (37 ℃, 5 % CO_2), and then subcultured in 12-well plates at 1:3 ratio. After the cells were cultured to 60-70 % confluence, the 6 molecule conformations of ASOR-PLL-P(+)/IL-12 and the combined ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} were transfected into the cells using liposome transfection as positive control. There were three wells in each group and the total transfected plasmid DNA was 4.5 μg for each well. During transfection, chloroquine was used (the final concentration was 100 μM*)* to restrain lysosome activity[15,16].

Detection of hIL12 expression Total RNA of transfected HepG2 was extracted by using Trizol 48 hours after transfection. mRNA expression of P_{40} and P_{35} was determined with semi-quantitative RT-PCR using β-actin as an internal control. hIL12 protein in the supernatant was measured using ELISA.

RESULTS

Construction of P(+)P_{40}, P(-)P_{35} and P(+)IL12 plasmids

The full length cDNAs of P_{40} and P_{35} subunits were amplified from human embryonic kidney and cloned into pcDNA3.1 (+/-). P (+)/P_{40} plasmids (6.4 kb) could be cut by KpnI and Xho I to produce two bands: 5.4 kb and 1.007 kb while P (-)/P_{35} plasmids could be cut Kpn I and Nhe I to produce 5.4 kb and 823 bp bands (Figure 1). The segments of -P_{35}-polyA and -cmv-P_{40}- were ligated and cloned into pcDNA3.1 (+) to get P(+)/IL-12 (8.51 kb). P(+)/IL-12 could be cut by Nhe I and Not I (2.5 kb and 6 kb) or by BamH I (2 kb and 6.5 kb) or linearized by Avr II (8.51 kb) (Figure 2).

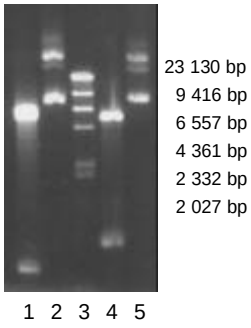

Figure 1 Electrophoresis of P(-)/P_{35}, P(+)/P_{40} and their bands after restrictive endonuclease enzyme digestion in a 0.8 % agarose gel. 1. P(-)/P_{35} plasmid digested by Kpn I and Nhe I. 2. P (-)/P_{35} plasmid. 3. Marker (λDNA/Hind III). 4. P(+)/P_{40} plasmid. 5. of P(+)/P_{40} plasmid cut by Kpn I and Xho I.

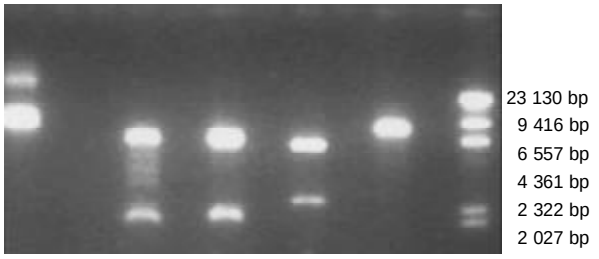

Figure 2 Electrophoresis of recombinant expression plasmid P(+)/IL-12 and the bands after restriction enzyme digestion in a 0.8 % agarose gel (Marker: λDNA/Hind III).

Molecular conformations of targeting gene drugs at various concentrations of adjuvant under transmission electron microscope

The optimal ratios of ASOR-PLL: DNA were as follow: ASOR-PLL:P(+)/IL-12=4:1, ASOR-PLL:P (+)/P_{40}[P(-)/P_{35}]=2:1. ASOR-PLL-DNA complexes which formed in 0, 0.1 M, 0.2 M, 0.3 M, 0.4 M, 1.5 M adjuvant were examined under a transmission electron microscope. The molecular conformations of gene drugs showed divarication-like (ψ-DNA) without adjuvant or in 0.3 M adjuvant, the drug molecules were condensed to granules or "doughnut"-like structures with diameters of 25 nm-300 nm in 0.1 M, 0.2 M and 0.4 M adjuvant. Their conformations varied greatly in 1.5 M adjuvant. The structure of ASOR-PLL-P(+)/IL-12 was rod-like or granule-like. The structures of ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} were both divarication-like (Figure 3).

Detection of hIL-12 expression 48 hours after drugs with different molecular conformations were transfected into HepG2 cells

Total RNA was extracted and semi-quantitative RT-PCR was performed using β-actin as an internal control. hIL12 mRNA levels were increased in both liposome-transfected and ASOR-PLL transfected groups. mRNA levels in ASOR-PLL groups varied with different concentrations of adjuvant (data not shown).

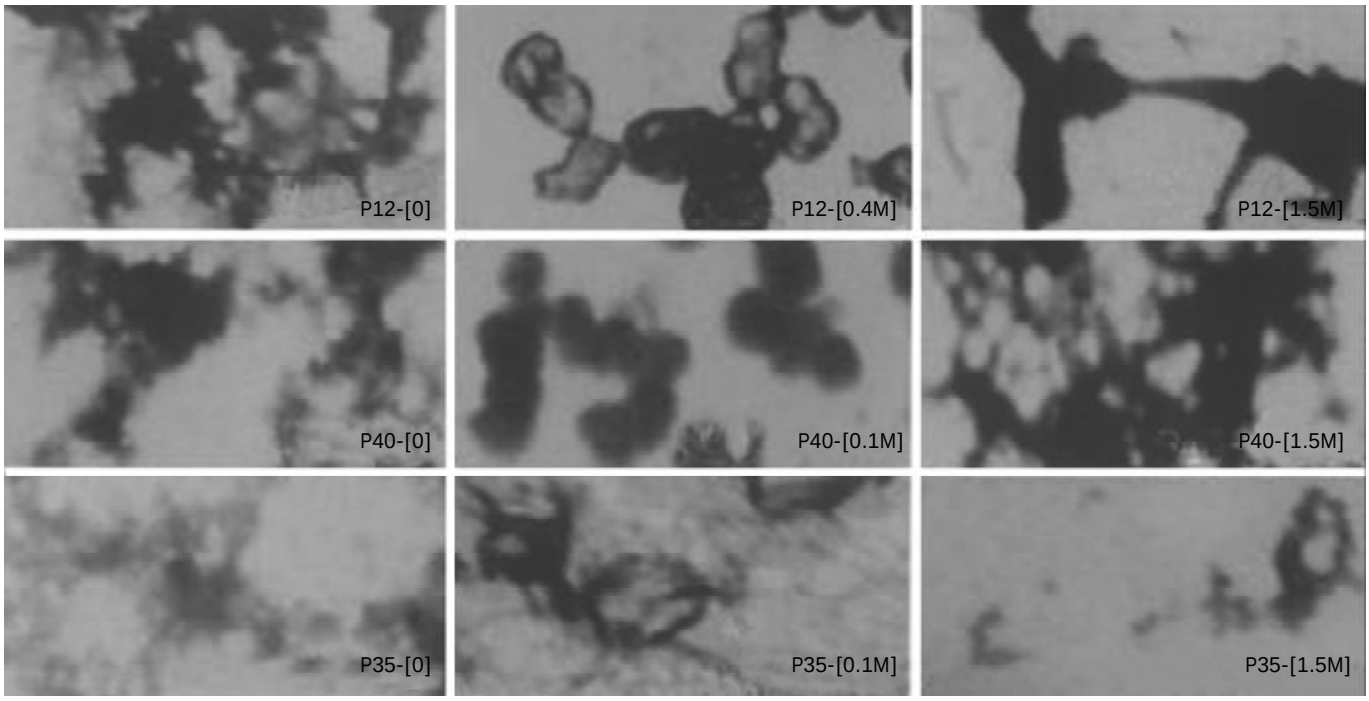

Figure 3 Differently structural features of targeting gene drugs (ASOR-PLL-DNA complexes) at various concentrations of adjuvant under transmission electron microscope. (The *bar* equals 100 nm, amplified 40 000 times).

ELISA results showed that the highest expression level of hIL12 was achieved in cells transfected with ASOR-PLL-P(+)/IL-12 in 0.4 M adjuvant, while the same level of expression was achieved when ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} were co-transfected into HepG2 cells in 0.1 M adjuvant. The expression levels in both groups went down to the lowest points in 1.5 M adjuvant. The expression levels in ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} co-transfected group were higher than those in ASOR-PLL-P(+)/IL-12 group at the same concentrations (Figure 4).

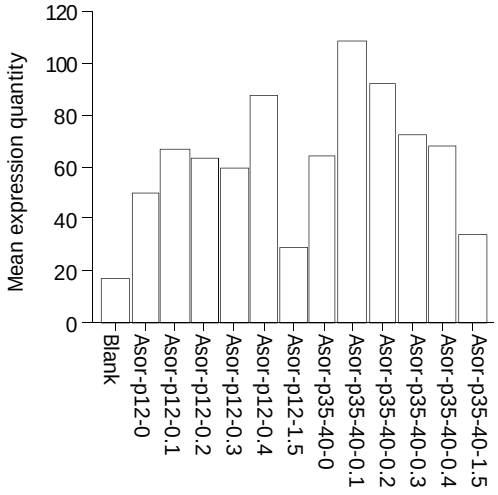

Figure 4 ELISA results of hIL-12 expressed in cell supernatant 48 hours after targeting gene drugs at various adjuvant concentrations were transfected into HepG2.

DISCUSSION

Gene transfection system mediated by receptor-ligand binding, which possesses some advantages for gene therapy, including transferring foreign genes to target cells specifically, being safer without mutation and infection caused by viral vectors, expressing functional proteins without integrating foreign genes into genomic DNA, and unlimited foreign gene size theoretically[17-19], is a potential gene therapy vector which can substitute viral vectors. ASOR is the ligand of ASG receptor (ASGr) which locates specifically on the surface of hepatocytes, and can bind to ASGr specifically[20,21]. Through the positively charged linking molecule PLL which binds to negatively charged DNA molecules through electrostatic interactions, ASOR can transfer foreign DNA molecules into hepatocytes or some hepatoma cells (ASGr+) and express the functional proteins. In 1987, Wu GY and Wu CH firstly transfected reporter gene chloramphenicol acetyltransfectase (CAT) to hepatoma cells (HepG2) by using ASOR-PLL[8]. Ever since, ASOR-PLL has been applied to various therapeutic genes targeting for hepatocytes or some hepatoma cells *in vivo* or *in vitro*[17,22,23]. However, the low expression efficiency of exogenous genes restricts its application to clinic use.

hIL-12 is a double-subunit cytokine discovered in recent years[24], which can promote Th0 cells to differentiate Th1 cells to enhance cell immunity[25]. It can also activate T cells and NK cells to proliferate and secrete IFN-γ to improve humoral immunity[26,27]. Therefore, it plays a role in antivirus, antiprimary tumors and antimetastasis[11-14]. Till now ASOR-PLL has not been used in transferring human interleukin 12 gene to HepG2. We constructed hIL12 double-subunit co-expressing plasmid P(+)/IL12 and single-subunit gene expressing plasmids P(+)/P_{40} and P(-)/P_{35}, and bound them to ASOR-PLL at various adjuvant concentrations and measured A_{260} values of the mixtures (data not shown). ASOR-PLL-P(+)/IL-12 showed the lowest A_{260} value in 0.4 M adjuvant which indicated the least dissociated DNA molecules and the highest hIL-12 expression level, while ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} showed the same result in 0.1 M adjuvant. Though ASOR-PLL-DNA complexes showed lower A_{260} values in 1.5 M adjuvant, most of the HepG2 cells could not stand such a high concentration of adjuvant and died 4 hours after they were transfected, which explained why the expression level of hIL-12 was low. These results indicate that foreign genes (hIL12) can be transferred into target cells (HepG2) through ligand (ASOR) binding to receptors (ASGr), and then endocytosed by cells as reported by Huckett *et al*[28]. The less

dissociated DNA molecules existed in the mixture, more ASOR-PLL-DNA complexes were formed, the higher efficiency of expressing hIL12 was achieved.

Pearales *et al* thought that ligand-DNA complex molecules in a receptor- mediated DNA transfection system must have a relatively high DNA concentration and certain molecule conformations to assist DNA to be transfected into target cells and express functional proteins[17]. To achieve this goal, DNA molecules need to be condensed to a smaller size, and the conformation of aggregated multiple ligand-DNA molecules (such as Ψ-DNA) inhibited gene expression. In our studies, shapes of the molecules under transmission electron microscope showed that ASOR-PLL-P(+)/IL-12 molecules were circle-like structures ("doughnut") with diameters of 50-100 nm in 0.4 M adjuvant, which produced the highest hIL-12 expression. ASOR-PLL-P(+)/P_{40} molecules were granular structures with diameters of 40-125 nm in 0.1 M adjuvant and ASOR-PLL-P(-)/P_{35} molecules were circle-like structures with diameters of 75-150 nm at the same concentration of adjuvant, both of them also achieved the highest hIL12 expression. Although ASOR-PLL-P(+)/P_{40} molecules formed granular structures with diameters of 25-75 nm in 0.2 M adjuvant, ASOR-PLL-P(-)/P_{35} molecules were concentrated to form lumps with diameters of 100-200 nm at this concentration of adjuvant. Since ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} needed to be co-transfected to express functional hIL-12, there were more factors affecting hIL-12 expression in this situation. Meanwhile, the size and the GC/AT ratio of foreign DNA molecules also affected exogenous gene expression[17]. In our studies, the smaller molecular diameters of ASOR-PLL-DNA complexes (25-150 nm), the more condensed DNA molecules and the tighter combination of DNA molecules and ASOR-PLL could lead to higher hIL-12 expression.

In general, single-subunit gene plasmids [P(+)/P_{40} and P(-)/P_{35}] co-expression mediated by ASOR-PLL could induce higher hIL12 expression than that of double-subunit genes co-expressing plasmid transfection. The possible reasons might be the following: (1) There was a certain amount of ASGr on the surface of target cells, when the same amount of DNA was used to transfect cells, ASOR-PLL-P(+)/P_{40} and ASOR-PLL-P(-)/P_{35} were co-transfected at 1:1 ratio, and ASOR could bind to ASGr more thoroughly with a relatively larger amount of ASOR, compared with ASOR-PLL-P(+)/IL-12 transfection. (2) Since the P_{40} and P_{35} subunits cDNAs were cloned in tandem into the polycloning site of pcDNA3.1(+) in which P_{40} cDNA located directly next to P_{35} cDNA, they might interfere reciprocally during transcription, and could not produce P_{40} and P_{35} subunits proportionally. However, P_{40} and P_{35} subunits must combine at 1:1 ratio to form functional hIL-12[12,25].

Another study[29], used atomic force microscope to examine DNA molecules binding to PL, ASOR-PLL and orosomucoid, and found that the optimal conformations of DNA complex molecules for foreign genes expression were solenoid-like or rod-like in diameters of 300 nm-400 nm. The condition to obtain these conformations was that ASOR was combined covalently to 10 kDa PL (Lys: nt$\geqslant$5:1), and linked to DNA molecules. In our studies, PLL was a mixture of 26 kDa, 10 kDa and 4 kDa PLL. The ratio of 10 kDa PL: nucleotide was less than 5:1 in our targeting gene drugs, so hIL-12 expression in ASOR-PLL transfection group was lower than that in liposome transfection group (data not shown).

In summary, the gene transfection system mediated by receptor-ligand binding is a prospective gene therapy strategy, and the expression level of foreign genes has a relationship with the amount of binding DNA, conformation of the complex and characteristics of the linking molecules PLL. Since hIL-12 consists of two subunits (P_{40} and P_{35}), more factors are involved in hIL-12 expression, including the way P_{40} and P_{35} genes enter into the target cells, conformations of the two ASOR-PLL-DNA complexes and interactions of the two complexes. Our studies may contribute to improving hIL-12 expression and applying hIL-12 to clinical hepatoma gene therapy research.

ACKNOWLEDEMENTS

This research work was carried out in National Laboratory of Medical Genetics of China. We sincerely thank academician Xia Jia-hui and everyone in the lab for their help.

Abstract

AIM: Hepatic cytochrome P450 isoenzymes constitute a superfamily of hemoproteins that play a major role in the metabolism of endogenous compounds and in the detoxification of xenobiotic molecules. P450 3A4 is one of the most important forms in human being, and mediates the metabolism of around 70 % of therapeutic drugs and endogenous compounds. Propofol, a widely used intravenous anesthetic drug, is known to inhibit cytochrome P450 activities in isolated rat hepatocytes. The goal of this study was to evaluate the potential efficacy of propofol on P450 3A4 in a dose-dependent manner to understand its drug-drug interaction.

METHODS: Hepatocytes were isolated from liver specimens from hepatic angioma patients undergone hepatic surgery. Primary incubated hepatocytes were treated with 0, 0.01, 0.05, 0.1, 0.5, and 1.0 mM propofol for 24 hours. P450 3A4 activity was measured with Nash's colorimetry. The protein expression was assessed by Western blot analysis.

RESULTS: A dose-dependent inhibitory effect of propofol was observed in cytochrome P450 3A4 activity. A minimal dosage of propofol (0.01 mM) induced a significant inhibition of P450 3A4 activity, although its regular dosages (0.01-0.1 mM) showed no inhibitory effect on the cellular protein expression of P450 3A4.

CONCLUSION: Propofol may be a potential CYP3A4 inhibitor as this anesthetic can inhibit isoenzyme activity significantly and reduce the metabolic rate of CYP3A4 substrates. This inhibition occurs at post-expression level, and concentration of propofol used clinically does not affect CYP3A4 protein expression. propofol may thus induce drug interaction of cytochrome P450 3A4 activity at the dosage used clinically.

INTRODUCTION

Cytochrome P450 enzymatic system is essential for the biotransformation of xenobiotics and drugs, and is a superfamily of haemoproteins[1]. One group of particular interest for those caring for the critically ill is CYP 3A4, which metabolizes many drugs used in the critical patients, including midazolam, lignocaine, alfentanil, erythromycin and cyclosporin[2,3]. Propofol (2, 6-diisopropylphenol) is widely used for anesthetic induction as well as for chronic sedation in ICU. Unlike midazolam, propofol does not undergo phase I metabolism, but is metabolized mostly through direct glucuronidation in the liver. Recent works have shown that several cytochrome P450 isoforms do participate in its metabolism, especially the CYP2B6 isoform. Both *in vitro* and *in vivo*, the inhibitory effects of propofol on cytochrome P450 activities have been already described, thus, propofol may potentially alter the metabolism of many co-administered anesthetics such as alfentanil and midazolam. However, the mechanism of propofol' s inhibitory effect still remains unclear[4-6].

Since primary cultures of human hepatocytes represent a unique *in vitro* system to study the potential of drugs to induce phase I and phase II enzymatic reaction involved in drug metabolism. Many researchers have successfully used human hepatocyte cultures to investigate the effect of various drugs on cytochrome P-450 induction and drug metabolism[7,8]. The goal of this study was to evaluate the inhibitory effect of propofol on cytochrome P450 and its 3A4 isoform activities, as well as of on protein expression of CYP3A4 isoform during 24 hours culture.

MATERIALS AND METHODS

Materials

Propofol was kindly provided by Astra-Zeneca. Rabbit anti-human CYP3A4 polyclonal antibody was purchased from Chemicon (*San Diego, CA*). HRP taged sheep anti-rabbit antibody was purchased from PharMingen (*Mannheim, Germany*). Collagenase IV glucose 6-phosphate, erythromycin, Lowry' s phenol reagent, glucose 6-phosphate transferase, acetate ammonium, acetyl-acetone, and NADP were purchased from Sigma Chemical (*St. Louis, MO*). Newborn calf serum was obtained from GIBCO (Paisley, UK). RPMI 1640 medium was purchased from Seromed (*Berlin, Germany*). dexamethasone and insulin were obtained from BioWhittaker (*Walkersville, MD*). Penicillin G/streptomycin were obtained from Gibco Laboratories (*Grand Island, NY*). All other reagents used in this study were of AR or CP grade.

Isolation and culture of human hepatocytes

Surgical liver biopsies (30-50 g) were taken from hepatic angioma patients undergone hepatic surgery after informed consent was obtained. Patients had no known liver lesions, nor had they received P450s induced medication during the weeks before surgery. None of the patients was habitual consumers of alcohol or other drugs. A total of 8 liver biopsy specimens (from ten men and two women) were used. The patients aged from 18 to 54 years. Human hepatocytes were

isolated using modified collagenase digestive technique according to the method of Liddle[9]. Liver tissues were cut into small pieces about 1 mm^3 and washed three times by 4 ℃ equilibrium liquid to remove the leftover blood, then the liver pieces were digested for 30 min by RPMI 1640 medium containing 0.05 % collagenase. The dissociated hepatocytes were placed into cold Hanks medium for 3 times and centrifugated at 600 rpm for 40 s, at 800 rpm for 50 s and at 1 000 rpm for 60 s. Percoll-gradient centrifugation (1 000-1 200 r/min,10 min) was required to get rid of remained blood thoroughly. Concentration and density of Percoll liquid were 35 % (V/V) and 1.08-1.09 g/ml respectively. Viability at plating was greater than 90 % after trypan blue elimination and hepatocytes were plated in RPMI 1640 medium supplemented with 10^{-7} M dexamethasone, 10^{-7} M insulin, 100 U/ml penicillin G, 100 μg/ml streptomycin, and 5 % bovine calf serum. The hepatocytes (3×10^6) were plated onto 60-mm culture plates previously coated with type I (rat-tail) collagen. The cells were allowed to attach for 4 h at 37 ℃ and 5 % CO2, during which the media were replaced with serum-free media with the supplements listed above and changed every 24 h thereafter.

Treatment of cultures

For CYP inhibition experiments, propofol was dissolved in dimethylsulfoxide and added to cultured human hepatocytes at a final concentration of 0.01, 0.05, 0.1, 0.5 and 1.0 mM, respectively (concentration of DMSO in culture medium was 0.1 % v/v). Treatments were started after medium renewal, and stopped after 24 hrs of co-culture in fresh RPMI 1640 medium, the control cells were run parallelily.

Cellular lysates protein and CYP3A4 activity assays

Total protein concentration of cellular lysates was determined by the method of Lowry *et al*[10]. The spectra were recorded using a Shimadzu UV-250 double-beam spectrophotometer. The final protein concentration of cellular lysates was adjusted to 0.2 mg/ml using Tris-HCl buffer (pH 7.4). CYP3A4 specific activity was determined by N-demethylation of erythromycin using the Nash method listed above[11].

Immunoquantitation of CYP3A4 isoform protein by Western blot analysis

Cellular lysates were obtained from cultured human hepatocytes, which were incubated with propofol for the indicated time points and resolved by SDS-PAGE with vertical mini-gel electrophoresis equipment. Samples of liver microsomal protein (10 μg/lane) were denatured in 10 μl loading buffer (4 ml distilled water, 1 ml 0.5M Tris-HCl, pH 6.8, 0.8 ml glycerol, 1.6 ml 10 % w/v SDS, 0.4 ml-mercaptoethanol, 0.05 ml 0.05 % w/v pyronin Y) and were separated on a 10 % w/v resolving gel. Proteins were transferred from the polyacrylamide gel to the nitrocellulose sheets by electrophoresis, and probed with rabbit anti-human CYP3A4 polyclonal antibody (not cross-reactive with other rat P450s) according to the protocol. CYP3A4 protein was detected by conjugation to the primary antibody by a HRP-linked sheep anti-rabbit second antibody using diaminobenzidine as a substrate[12].

Statistical analysis

The data were analyzed using χ^2 test. $P<0.05$ was considerd statistically significant.

RESULTS

Inhibition of CYP3A4 activity by propofol in hepatocytes primary culture

Information on the donor livers is presented in Table 1. We first determined the inhibition of propofol in primary cultures of human hepatocytes. The hepatocytes were treated with propofol at concentrations of 0.01, 0.05, 0.1, 0.5 and 1.0 mM respectively for 24 h, then we investigated the effect of propofol on Cyp3A4 activity determined by N-demethylation of erythromycin in the medium, as shown in Figure 1. A significant decrease of CYP3A4 activity was detected in hepatocytes pretreated even with 0.01 and 0.05 mM propofol which were relatively lower, and the inhibitory effect showed a dose-dependent increase when the concentration of propofol was higher. Compared with the controls, the total cellular lysate protein in the cultured medium remained unchanged in all groups.

Table 1 Informations of donors and their drug history

HH	Age (y)	Gender (F/M)	Drug history	Cell viability %
1	42	M	Fentanyl, ranitidine, dopamine	88
2	38	M	Vercuronium, fentanyl, ephedrine	86
3	18	M	Vasopressin, phenobarbital, rocuronium	90
4	26	F	Phenobarbital, fentanyl, vercuronium	92
5	39	F	Mlidozolam, fentanyl, lidocaine	80
6	54	M	Phenobarbital, rocuronium	84
7	49	M	Fentanyl, ephedrine	87
8	44	M	Fentanyl, ranitidine, dopamine	85

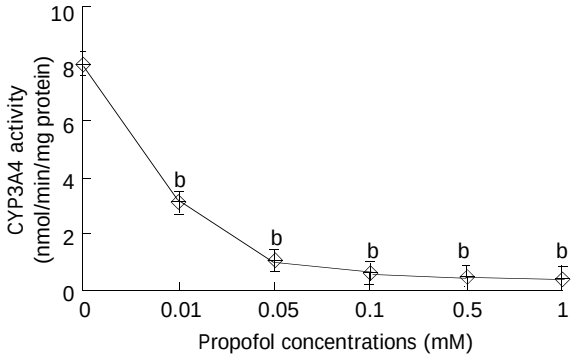

Figure 1 Effect of propofol on CYP3A4 activity in primary cultured hepatocytes. Hepatocytes prepared from donors were treated for 24 h with 0, 0.01, 0.05, 0.1, 0.5, and 1.0 mM propofol. At the end of this time, the medium was changed and erythromycin at 0.4 mM was added to the cells. After incubated for 30 min, aliquots of the medium were removed, and N-demethylation of erythromycin activity was determined as described above. Each value represented the mean of triplicate treatments with SD indicated by the vertical bars. ^{b}:$P<0.01$.

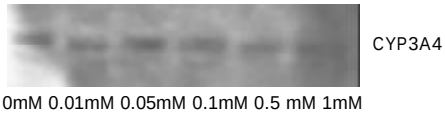

Figure 2 Effect of propofol on CYP3A protein expression. Hepatocytes prepared from donors were treated for 24 h with 0, 0.01, 0.05, 0.1, 0.5, and 1.0 mM propofol. CYP3A was analyzed in sonicates of whole cells as described in the paragraph of Materials and Methods. 20 micrograms of sonicated protein were applied per well.

Change of CYP3A4 isoform protein

Hepatocytes were treated with propofol at a concentration of 0.01, 0.05, 0.1, 0.5 and 1.0 mM, respectively for 24 hrs, and total protein synthesis was measured as described previously (Kostrubsky *et al*., 1997). The data in Figure 2 show a high expression of CYP3A4 proteins in hepatocytes, but

concentrations of propofol used clinically did not decrease total protein synthesis, even very high concentration of propofol (0.5 and 1.0 mM) could slightly reduce the hepatic CYP3A4 protein expression after 24 hours of culture. That meant the regular dosages used clinically (0.01-0.1 mM) had no significantly inhibitory effect on the cellular protein expression of P450 3A4.

DISCUSSION

In vitro studies with hepatic cells, in particular the human cultured hepatocytes, have offered a defined system for studying the direct effects of individual xenobiotic molecules on the regulation of hepatic CYP expression and activity in man[13]. This approach does not require any prior knowledge of the metabolism or disposition of the test compound, but instead uses the ability of a drug to induce or inhibit the metabolism of isoform-specific substrates, such as the conversion of testosterone to 6-hydroxytestosterone or N-demethylation of erythromycin by CYP3A[14]. This method by utilizing intact human hepatocytes for studying the metabolic activities, but not the microsomal suspensions, can provide quick and reproducible estimates of CYP3A metabolic capacity and protein levels. Primary cultures of human hepatocytes are responsive to induction of CYPs and can be used to assess the interactions resulted from the effect of CYPs during multiple drug therapy. The present study was conducted to examine the potential down-regulation by propofol on CYP expression. To this end, specific monooxygenase activities for CYP3A4 isozymes and *de novo* CYP protein synthesis were examined[15,16].

In our studies, the activity of CYP3A4 isoform in 8 Chinese patients was obviously lower than that of others reported in Caucasians. Although CYP3A4 drug metabolising activities vary widely among individuals, it has a unimodal population distribution and does not appear to be subjected to genetic polymorphism as is seen with other CYP isoforms (2D6, 2C9 and 2C19)[17-20]. The wide interrace variability is likely, in part, to be caused by ethnic or cultural differences, perhaps related to an interaction between habit and diet. Hence we could not draw any conclusion about the normal distribution character istics of CYPs in Chinese, because of the limited sample number and experimental conditions. More detailed and complete studies should be performed for analysing the distribution of CYPs among Chinese in the near future[21].

Propofol has been shown to interfere with the metabolism of alfentanil and sufentanil by inhibiting CYP2B1 and CYP1A1. Propofol inhibits CYP2E1 only to a limited extent as its molecules are too large to bind effectively to the active sites of the enzyme. Thus, propofol may potentially alter the metabolism of co-administered drugs such as alfentanil and sufentanil, but it does not effectively inhibit the metabolism of volatile agents (enflurane, sevoflurane, methoxyflurane) by CYP2E1[22-24]. This is the first report on whether different concentrations of propofol can down-regulate the protein expression of CYP3A4 in hepatocytic primary culture. According to the present result, we could see the regular dosages used clincially (0.01-0.1 mM) had no inhibitory effect on the cellular protein expression of P450 3A4, although a minimum dosage of propofol (0.01 mM) induced a significant inhibition of P450 3A4 activity. The intrinsic inhibition mechanisms of propofol on P450s have been investigated by several groups but still remain unclear[25,26]. It has been demonstrated that propofol exhibits a concentration dependent inhibitory effect on CYP2B1 and 1A1 by binding to the haemoiety of the enzymes. Some researchers have used homologic P450 models, they postulated plausible mechanisms for enzyme catalysis, inhibition, and activation, based on its 3D structure. The sites of effect that propofol binds to CYP3A4 hemeprotein maybe 214, 218 active site residues, then competitive inhibition of propofol and other CYP3A4 substrates may occur because active sites of P450s have been occupied[27] . This postulation may explain the potential inhibitory mechanism of propofol on CYP3A4.

In the present study, a dosage-dependent inhibitory effect of propofol was observed on cytochrome P450 3A4 activity, while the mean plasma concentration of propofol in clinical TCI anesthesia was 0.01-0.05 mM as described by others[28-30], indicating that a minimum clinical dosage of propofol (0.01 mM) could induce a significant inhibition of P450 3A4 activity. Since CYP3A4 is a predominant isoform of CYP3A in adult humans, change of hepatic CYP3A4 activity will change the metabolism of most therapeutic drugs. Firstly, a large number of intravenous anesthetics and sedative agents (including diazepam, midozolam, fentanyl, lidocaine, etc.) are substrates of CYP3A4 isoform, N-hydroxylation and N-dealkylation reactions of anesthetics can be reduced when propofol administration causes drug accumulation, oversedation and postoperative awake delay[31, 32]. Secondly, amiodarone, quinidine, nifedipine, berhomine and cyclosporin are also eliminated through CYP3A4, thus competitive inhibition should be noticed and avoided especially when more than one substrates are administrated by patients with impaired liver function. These findings are in accordance with pharmacokinetic studies that have shown reduced clearance of midozolam when conbined with fentanyl in cirrhotics, but overdosage of anti-arrhythmics have a greater clinical signifiance than that of other drugs[33,34]. Thirdly, as CYP3A4 also plays an important role in biotransformation and detoxification of many endogenous substrates, reduction of CYP3A4 activity may result in inactivation of endogenous substances including cholesterol, bile acid, sex hormones and glucocorticoids, thus causing more extensive physiopathologic changes in patients with hepatic diseases. These changes, in turn, will affect the drug metabolic enzymes[35,36].

Abstract

AIM: To investigate the *in vivo* anti-tumor effects of total polysaccharide (AP-0) isolated from *Angelica* sinensis (Oliv.) Diels (Danggui) on mice and the *in vitro* inhibitory effects of AP-0 and its sub-constituents (AP-1, AP-2 and AP-3) on invasion and metastasis of human hepatocellular carcinoma.

METHODS: Three kinds of murine tumor models *in vivo*, sarcoma 180 (S180), leukemia L1210 and Ehrlich ascitic cancer (EAC) were employed to investigate the anti-tumor effects of AP-0. For each kind of tumor model, three experimental groups were respectively given AP-0 at doses of 30, 100 and 300 mg/kg by *ip* once a day for 10 days. Positive control groups were respectively given Cy at a dose of 30 mg/kg for S180 and leukemia L1210, and 5-FU at a dose of 20 mg/kg for EAC. On d 11, mice bearing S180 were sacrificed and the masses of tumors, spleens and thymus were weighed. The average living days of mice bearing EAC and of mice bearing L1210 were observed, and the rates of life prolongation of each treatment were calculated, respectively. The inhibitory effects of APs on hepatoma invasion and metastasis *in vitro* were investigated by employing human hepatocellular carcinoma cell line (HHCC) with the Matrigel invasion chamber, adhesion to extracelluler matrix and chemotatic migration tests, respectively.

RESULTS: AP-0 had no obviously inhibitory effect on the growth of S180, but it could significantly decrease the thymus weights of the mice bearing S180. AP-0 could significantly reduce the production of ascitic liquids and prolong the life of mice bearing EAC. AP-0 could also increase the survival time of mice bearing L1210. AP-0 and AP-2 had significantly inhibitory effects on the invasion of HHCC into the Matrigel reconstituted basement membrane with the inhibitory rates of 56.4 % and 68.3 %, respectively. AP-0, AP-1, AP-2 and AP-3 could influence the adhesion of HHCC to extracellular matrix proteins (Matrigel and fibronectin) at different degrees, among them only AP-3 had significant blocking effect on the adhesion of HHCC to fibronectin with an inhibitory rate of 30.3 %. AP-0, AP-1 and AP-3 could partially inhibit the chemotactic migration abilities of HHCC.

CONCLUSION: The experimental findings suggest that total polysaccharide of *Angelica* sinensis (Oliv.) Diels (Chinese Danggui) possesses anti-tumor effects on experimental tumor models *in vivo* and inhibitory effects on invasion and metastasis of hepatocellular carcinoma cells *in vitro*.

INTRODUCTION

The Chinese herbal medicine Danggui, root of *Angelica sinensis* (Oliv.) is widely used in traditional Chinese medical therapy of various diseases as well as a healthful food tonic and spice for thousands of years. Being called the "female ginseng", it is excellent as an all purpose women's herb[1]. Danggui can be used for anemia due to chronic renal failure (CRF)[2] and can enhance hematopoiesis by stimulating macrophages, fibroblasts, lymphocytes in hematopoietic inductive microenvironment and muscle tissue to secrete hematopoietic growth factors. Gastrointestinal protective effects[3,4] and the mechanism[5,6] of polysaccharides from *Angelica sinensis* in rats have been reported. Effects of *Angelica* polysaccharides on blood coagulation and platelet aggregation[7] and the protective effect of the polysaccharides-enriched fraction from *Angelica sinensis* on hepatic injury[8] were also studied. A low molecular weight polysaccharide from *Angelica sinensis* (Oliv.) Diels showed strong anti-tumor activity on Ehrlich ascitic cancer bearing mice and also exhibited immunostimulating activities, both *in vitro* and *in vivo*[9] (Choy *et al*. *Am J Chin Med*, 1994; 22:137). Polysaccharides from three kinds of edible fungi showed inhibitory activities on the proliferation of human hepatoma SMMC-7721 cells and mouse implanted S180 tumor[10]. Apoptosis of hepatoma cells SMMC-7721 could be induced by polysaccharides from *Ginkgo biloba* seeds[11]. In China, hepatocellular carcinoma with high invasiveness and recurrence has ranked second of cancer mortality since 1990s. Anti-invasion and metastasis is currently one of the major targets of hepatoma studies[12,13]. Some polysaccharides involve in the process of tumor invasion and progression, such as heparin, heparan sulfate and hyaluronan[14-16]. The anti-metastasis effects and their pharmacological mechanisms of modified citrus pectin[17] and protein-bound polysaccharide (PSK) have been studied recently[18-20]. However, the anti-tumor effects on other kinds of tumors and the anti-invasion

and metastasis effects of polysaccharides from *Angelica sinensis* (Oliv.) Diels have not been studied. In the present study, the anti-tumor effects of total polysaccharide (AP-0) on mice bearing transplanted sarcoma 180, leukemia L1210 and Ehrlich ascitic cancer (EAC) were investigated. The *in vitro* inhibitory effects of AP-0 and its sub-constituents, AP-1, AP-2 and AP-3 on the abilities of invasion and metastasis of human hepatocellular carcinoma were also tested by employing HHCC cell line.

MATERIALS AND METHODS

Animals and cell lines

Male BALB/c mice, weighing 18-22 g, were used in S180 and EAC experiments, and male DBA/2 mice, weighing 18-22 g, were used in L1210 experiment. All the mice were raised in a clear room with controlled temperature and humidity. Animals were free to drink tap water. Human hepatocellular carcinoma cell line (HHCC) was purchased from Type Culture Collection of Chinese Academy of Sciences, Shanghai, China. Human embryo dermal fibroblast cell line (Fb) was kindly presented by Dr. JT Han (Department of Plastic Surgery, Fourth Military Medical University).

Polysaccharides from Angelica sinensis

Fresh roots of *Angelica sinensis* (Oliv.) were picked in autumn from Minxian County, Gansu Province, China. Total polysaccharide (AP-0) was isolated by ethanol precipitation after boiling water extraction. The sub-constituents, AP-1, AP-2 and AP-3 from AP-0 were obtained by multi-precipitation treated with CTAB, H_3BO_3, NaOH, acetic acid and ethanol according to Yamada *et al*[21]. The physical-chemical characteristics of APs were analyzed and determined (Shang P, *et al*. *Disi Junyi Daxue Xuebao*, 2001;22:1311; *Chin Pharmaceutical J*, 2000;35:332). The contents of total carbohydrate, uronic acids and proteins in AP-0, AP-1, AP-2 and AP-3 were 97.0 %, 21.0 % and 3.0 %; 97.0 %, 17.2 % and 3.0 %; 83.0 %, 25.7 % and 17 %; 97.0 %, 8.6 % and 3 %, respectively. All of APs' solution was dispensed with sterile *N S* in the laminar flow bench.

Mice transplanted tumor models and Angelica polysaccharide (AP-0) treatments

Mice model of S180 was established by inoculating 5×10^6 S180 cells into left armpit of each mouse. From the next day following tumor cells inoculation (d 1) to the 10^{th} day (d 10), mice in 3 experimental groups were administrated *ip* AP-0 at doses of 30, 100 and 300 mg/kg, once daily, respectively. Positive and negative control groups were given Cy at a dose of 30 mg/kg and *N S* of 20 mg/kg, once daily, respectively. On d 11, the mice were sacrificed, and the weights of tumor, spleen and thymus were recorded. Mice model of EAC was made by injecting *ip* 2.5×10^6 EAC cells into each mouse. From the second day of tumor cells inoculation (d 1) to the 10^{th} day (d 10), mice in 3 experimental groups were given AP-0 *ip* at doses of 30, 100 and 300 mg/kg, once daily, respectively. Positive and negative control groups were given 5-FU at a dose of 20 mg/kg and *N.S*. of 20 mg/kg, respectively. The average survival time of less than 60 days each group was observed and the effects of AP-0 on prolongation were calculated. Mice model of L1210 was made by injecting *ip* 1×10^5 L_{1210} cells into each mouse. From the next day of tumor cells inoculation (d 1) to the 10^{th} day (d 10), mice in 3 experimental groups were given AP-0 *ip* at doses of 30, 100 and 300 mg/kg, once daily, respectively. Positive and negative control groups were given Cy at a dose of 30 mg/kg and *NS* of 20 mg/kg. The average survival time of less than 30 days of each group was observed and the rates of life prolongation were calculated.

Anti-invasion tests of angelica polysaccharides in vitro

Experimental methods employed in this part were based on previous report[22] with a slight modification.

AP-0-AP-3' s inhibitory effects on HHCC invasion into reconstituted basement membrane Each inner membrane of Millicell chamber (Millipore, USA) was paved with 40 μL Matrigel (BD Bioscience, USA) and dried in the laminar bench at room temperature. The Matrigel-Millicells of co-cultured HHCC and Fb, with each Milicell containing 150 μL (1.5×10^5) cells cultured in DMEM supplemented with 1 mL/L bovine calf serum (BCS), were put into 24-well microplates (Nunc, Sweden) containing 10 μg fibronectin (FN, GIBCO, USA) as a chemotactic agent in 200 μL DMEM (GIBCO, U S A.) supplemented with 1 mL/L BCS. AP-0, AP-1, AP-2 and AP-3 at a dose of 50 μL (7.0 mg/ml) were added into the Millicell. After the microplates and Millicells were incubated for 20 hours at 37 ℃, 50 mL/L CO_2 (Heraeus, Germany), each upper surface of membrane was scrubbed 3 times with a cotton swab. All of the membranes were fixed with 950 mL/L ethanol and then taken off for HE staining. HHCC cells infiltrated into the membrane were counted under a high power microscope. All experiments were performed in triplicate.

Inhibition of AP-0-AP-3 on HHCC adhesion to extracellular matrix proteins Each well of the 96-well microplates was coated with FN and Matrigel, 2 μg for each one, respectively. The coated wells were allowed to dry, then 20 μL 10 g/L BSA was added into each well and incubated for 1 hour. The wells were washed with PBS. Each well containing 200 μL (2×10^5) HHCC and 50 μL (7.0 g/L) APs was incubated for 2 hours at 37 ℃, 50 mL/L CO_2. After each well was washed 3 times with 200 μL PBS, 40 μg MTT was added into each one and incubated for 4 hours at 37 ℃, 50 mL/L CO_2. Then the liquid was removed, and 200 μL DMSO was added into each well. The absorbance of each well was detected by a microplate Reader (Bio-Rad 450, USA) at 490 nm. Triplicate determinations were performed at each data point.

Influences of AP-0-AP-3 on HHCC chemotactic migration The outer-surface of each Millicell was paved with 10 μg FN as a chemotactic agent. 150 μL (1.5×10^5) HHCC cells cultured in DMEM supplemented with 1 mL/L BCS, was added into each Millicell. Then the Millicells were cultured in 24-well microplates containing 200 μL DMEM supplemented with 1 mL/L BCS in each well. AP-0, AP-1, AP-2 and AP-3 at doses of 50 μL (7.0 g/L) were added into the Millicells respectively. After the microplates containing Millicells were incubated for 20 hours at 37 ℃, 50 mL/L CO_2, each upper surface of the membrane was scrubbed 3 times with a cotton swab. Then the membranes were fixed with 950 mL/L ethanol and taken off for HE staining. The HHCC cells infiltrated into the membrane were counted under a high power microscope. All experiments were performed in triplicate.

Statistical analysis

Differences of weights, cell counts and absorbance between the experimental and control groups were examined by using ANOVA (analysis of variance). Differences of life prolongation rates were examined by Cox proportional hazards regression.

RESULTS

Effects of Angelica polysaccharide (AP-0) on mice transplanted tumors

Influences of AP-0 on immunological organs of mice bearing S180 Although the differences of tumor's weights between the three AP-0 groups and N.S. control group were not significant, thymus weights of mice receiving AP-0 were significantly lighter than those of mice treated by N.S. Whereas,

thymus weights of mice receiving AP-0 were significantly heavier than those of mice treated by Cy (Table 1). Thymus weights of mice receiving doses of AP-0 at 100 mg/kg (P<0.05), 30 mg/kg and 300 mg/kg (P<0.01) were lighter than those of *NS* group. The thymus weights of mice receiving doses of dAP-0 at 30 mg/kg (P<0.05), 100 mg/kg and 300 mg/kg (P<0.01) were heavier than those of Cy group.

Table 1 Masses of body, tumor, thymus and spleen of mice bearing S180 10 days after being treated with AP-0, Cy and *N S* ($\bar{x}$±s)

Group	Mice (n) (d10/d0)	m (body) (g)	m (tumor) (g)	m (thymus) (mg)	m (spleen) (g)
N S	10/10	25±3	2.6±0.8[d]	69±17	0.25±0.08[d]
Cy	9/9	19±3[b]	1.2±0.4	16±10[b]	0.06±0.02
AP-0					
30 mg/kg	9/10	22±5	2.8±1.0[d]	35±19[bd]	0.22±0.13[d]
100 mg/kg	8/10	22±3	2.7±0.5[d]	46±16[ad]	0.20±0.08[d]
300 mg/kg	7/10	22±2	3.0±1.3[d]	44±14[bd]	0.34±0.14[d]

Effects of AP-0 on mice bearing EAC The average weight of mice in each group receiving AP-0 treatment was far significantly lighter than that of *NS* group, suggesting that the amounts of ascitic fluid produced in the mice of experimental groups were less than those of *NS* groups (Table 2). The survival time of each AP-0 treated group was longer than that of *NS* group within 60 day observation. However, significant difference was found only between the AP-0 300 mg/kg treated group and *NS* group (Table 2).

Table 2 Survival and body masses of mice bearing EAC after being treated with AP-0

Group	n	Survival time (days)	Life prolongation rate (%)	m (body)/(g) ($\bar{x}$±s)	
				d 0	d 10
N S	10	14.1	0.0	19.9±0.9	42.2±1.9
5-FU	10	60.0	325.0	20.2±0.9	24.7±3.6[b]
AP-0					
30 mg/kg	10	26.5	89.7	19.8±1.6	36.5±5.2[b]
100 mg/kg	10	18.4	30.5	19.4±1.2	35.8±3.0[b]
300 mg/kg	10	36.0	155.3[a]	19.3±1.0	31.3±3.8[b]

Effects of Angelica polysaccharides on invasion and metastasis of hepatocellular carcinoma in vitro

Inhibition of AP-0-AP-3 on HHCC infiltrating into reconstituted basement membrane AP-0, AP-1, AP-2 and AP-3 could inhibit HHCC cells to infiltrate into the reconstituted basement membrane with inhibitory rates of 56.4 %, 38.6 %, 68.3 % and 26.7 %, respectively. Among them, AP-0 and AP-2 had significant inhibitory effects (P<0.05) compared with the control (Table 4).

Table 4 Inhibition of *Angelica* polysaccharides on infiltration and migration of HHCC

Group	Infiltration		Migration	
	Infiltrated cells ($\bar{x}$±s)	Inhibitory rate(%)	Migrated cells ($\bar{x}$±s)	Inhibitory rate (%)
Control	20.2±18.5	0.0	23.6±18.7	0.0

AP-3	0.098±0.020	25.2	0.069±0.008[a]	30.3

[a]P<0.05 *vs* Control.

Influences of AP-0-AP-3 on HHCC chemotactic migration abilities AP-0 had no inhibitory effect on the migration of HHCC cells, but its sub-constituents AP-1, AP-2 and AP-3 had weak inhibitory effects on the migration of HHCC cells into membranes, with no statistical significance compared with *N.S.*group (P<0.05, Table 4).

DISCUSSION

Polysaccharides from various kinds of herbal medicines or plants have extensive pharmacological activities. Since Letinan, a polysaccharide from *Lentinus edodes* (Berk.) Sing (Chihara, *et al*. *Nature*. 1969;22:687-688) was discovered to inhibit mouse sarcoma 180, a lot of plant polysaccharides have been investigated into their anti-tumor effects and the related mechanisms (Chihara, *et al*, *Nature*. 1970;225:943-944; Maeda Y, *et al*. *Nature*.1971;229:634). In the present study, we examined systematically the anti-tumor effects of polysaccharides from Chinese Danggui (*Angelica sinensis*) in mice according to the criteria of anti-tumor drug evaluation. AP-0 might have no direct inhibition on murine solid tumor S180, but it could significantly decrease the weights of thymus

of mice bearing S180. Gu *et al* (*Bull Acad Mil Med Sci*.1986;10: 401) reported that two types of polysaccharides from *Angelica* could not only decrease the weights of thymus, but also decrease the amounts of peripheral T and B lymphocytes of normal and tumor-bearing mice. Maeda believed that the tumor-inhibiting effect of Lentinan was mediated by T lymphocytes. Our results of the S180 experiments suggested that AP-0 had significant influences on thymus of mice, but the effects were not strong enough to inhibit the growth of tumor. By using body-mass as an indicator of the amount of ascitic fluid produced in EAC-mice, we discovered that AP-0 inhibited the production of ascitic fluid and prolonged the survival of the mice. Kumazawa, *et al* (*Immunology*. 1982; 47:75) previously found that AIP, which was an immunostimulating polysaccharide separated from hot water extract of *Angelica acutiloba* Kitagawa (Yamato Tohki), prolonged the survival of mice bearing EAC. Likewise, AP-0 inhibited the production of ascitic fluid and prolonged the life of mice bearing L1210. The results of *in vivo* experiments suggested that AP-0 had obvious anti-tumor effects on murine ascitic tumors (AEC and L1210), and also affected the immune organ (thymus) of mice bearing S180. Immunostimulatory activities found in the polysaccharides from *Panax ginseng*, *Spirulina platensis*, *Aphanizomenon flos-aquae and Chlorella pyrenoidosa* also suggested that immuno-mediated effects might be the main mechanism of polysaccharides' anti-tumor actions[23,24]. Polysaccharides with potent anti-tumor effects have been used clinically for cancer immunotherapy combined with radiotherapy and chemotherapy [25-27].

Invasion and metastasis are essential characteristics of malignant tumors. Tumor invasion and metastasis are a multi-step process associated with multiple-factors, such as adhesion and migration of tumor cells, degradation of exracellular matrix (ECM), and angiogenesis[28]. Molecules existing in ECM and receptors or ligands existing on the surfaces of tumor cells played critical roles in invasion and metastasis[29,30]. Polysaccharides, such as proteoglycans and glycosaminoglycans are the main constituents of ECM. Liu *et al*[15] demonstrated that heparan sulfate glycosaminoglycan coat presenting on tumor cells contained bioactive sequences that impinged on tumor-cell growth and metastasis. Hyaluronan, an extracellular polysaccharide that has been implicated in tumor invasion, was one of the major constituents of stromal myxoid changes[16]. As to the polysaccharides from herbal medicines or plants, their anti-metastatic effects have been reported. Modified citrus pectin (MCP), a nondigestible, water-soluble polysaccharide fiber derived from citrus fruit, given orally, inhibited carbohydrate-mediated tumor growth, angiogenesis, and metastasis *in vivo*[17] . Protein-bound polysaccharide PSK inhibited tumor invasiveness by down-regulation of TGF-beta1, uPA, MMP-2 and MMP-9 expressed in two human tumor cell lines, pancreatic cancer cell line (NOR-P1) and gastric cancer cell line (MK-1P3) [18]. Enhancement of HLA class-I expression on tumor cells after PSK treatment might be one of the mechanisms responsible for the induction of anti-tumor immunity by PSK[19].

The present anti-metastasis study employed human hepatocellular carcinoma cell (HHCC) co-cultured with fibroblast, a kind of important stromal cell, to test the inhibitory effects of AP-0, AP-1, AP-2 and AP-3 on metastasis *in vitro*. The results of our experiments showed that AP-0 and its sub-constituents could inhibit the infiltration, adhesion and migration of HHCC by different degrees. By analyzing the biological-effect and chemical-composition, we found that there might be some relationship between the anti-invasion activities and the uronic acids containing APs. AP-0 and AP-3 had the strongest anti-degradation effects on basement membrane, and also possessed the highest amounts of uronic acids of 210 g/kg and 257 g/kg among the 4 polysaccharides from *Angelica*. On the other hand, AP-3 with the lowest content of uronic acids had the most effective anti-adhesion action on HHCC cells to FN among the 4 polysaccharides. The polysaccharides rich in anion groups, such as heparin and heparan sulfate, are closely related to the action between cells and ECM. Based on this, it is proposed that AP rich in uronic acides act as analogues of natural polysaccharides in ECM, and exhibit their anti-metastasis effects.

The findings in the present study suggest that polysaccharides from *Angelica* not only have anti-tumor effects on murine tumors of S180, EAC and L1210 *in vivo*, but also can inhibit invasion of HHCC *in vitro*.

Abstract

AIM: To study the effect of hydroxyapatite (HAP) nanoparticles on human hepatoma cell line BEL-7402 *in vitro*.

METHODS: The human hepatoma cell line BEL-7402 was cultured and treated with HAP nanoparticles at various concentrations. Growth suppression was detected with MTT colorimetric assay, cell apoptotic alterations were evaluated by cytochemical staining (Hoechst 33258), transmission electron microscopy (TEM), and flow cytometry (FCM).

RESULTS: HAP nanoparticles inhibited the growth of hepatoma cells in a dose-dependent manner, with IC_{50} values of 29.30 mg/L. Treated with 50-200 mg/L HAP nanoparticles for 48 h, BEL-7402 cells apoptosis with nuclear chromatin condensation and fragmentation as well as cell shrinkage and the formation of apoptotic bodies were observed under cytochemical staining and transmission electron microscopy. FCM analysis showed hypodiploid peaks on histogram, the apoptotic rates at the concentrations of 50, 75, 100, 150 and 200 mg/L of HAP nanoparticles were 20.35±2.23 %, 25.35±1.92 %, 29.34±4.61 %, 44.92±3.78 % and 53.64±3.49 %, respectively, which were all significantly higher than that of control group 2.23±0.14 %. There was a significant correlation between HAP nanoparticle concentration and apoptotic rate (r=0.994, P<0.01).

CONCLUSION: HAP nanoparticles not only inhibit proliferation but also induce apoptosis of human hepatoma cell line BEL-7402 *in vitro*.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary malignant tumor of the liver. Although progress in diagnosis and treatment of hepatic carcinoma has been made in recent years, its prognosis is still poor. Exploring new materials for treatment and investigating the mechanism are important. With the development of nanometer technology, hydroxyapatite nanoparticle, a novel inorganic material, was found to be able to inhibit tumor cell proliferation. However, there was yet no report about the effects of hydroxyapatite nanoparticles on the growth and apoptosis of human hepatoma cell line BEL-7402. Therefore, the present study was designed to study the inhibitory effect of hydroxyapatite nanoparticles on human hepatoma cells and its mechanism to provide a theoretical basis for its clinical use.

MATERIALS AND METHODS

Hydroxyapatite nanoparticles were obtained from Institute of Biomaterials, East China University of Science and Technology. Stock solution was made at the concentration of 400 mg/L with RPMI 1640 and diluted to working concentration before use. RPMI 1640, fetal calf serum (FCS) and MTT were purchased from GIBCO. RNase, proteinase K, propidium iodide (PI) and Hoechst 33258 were products of Sigma Chemical Co.

Cell line and culture

Human hepatoma BEL-7402 cells were provided by China Center for Type Culture Collection of Wuhan University (CCTCC). The cells were grown as monolayers in RPMI1640 medium supplemented with 10 % heat-inactived fetal calf serum and incubated in humidified incubator with 5 % CO_2 in air at 37 ℃.

Assay of cell proliferation

MTT[3-(4,5-dimethythiazoyl-2-yl) 2,5-diphenyltetrozoliumbromide] colorimetric analysis was used to measure the cytocide rate of HAP nanoparticles. Well-growing BEL-7402 cells were collected and seeded in 96-well plates at 1×10^5/ml density 100 μl cell suspension per well. When the cells anchored to the plates, the culture medium was replaced with fresh medium containing various concentrations of HAP nanoparticles (0, 12.5, 25, 50, 75, 100, 150 and 200 mg/L). Eight duplicate wells were set up in each sample. After incubated at 37 ℃, 5 % CO_2 for 48 h, 5 g/L MTT 20 μl was added to each well and cultured for another 4 h. The MTT medium was discarded and warm dimethylsulfoxide (DMSO) 200 μl was added. Absorbance was measured at 490 nm. Cellular proliferation inhibition rate (CPIR) was calculated using the following formula: CPIR=(1-average A value of experimental group / average A value of control group)×100 %.

Cytochemical staining of apoptotic cells

Cells treated with 50, 75, 100, 150 and 200 mg/L HAP nanoparticles for 48 h were harvested and fixed with 1:3 glacial acetic acid/methanol twice, first for 5 min and then for 10 min and washed with phosphate buffer solution (PBS). Cells were resuspended in Hoechst 33258 solution (Hoechst 33258 dissolved in PBS, 5 mg/L) and incubated at room temperature for 45 min in the dark. Aliquots of 100 μl/ml were placed on a glass slide and observed under an Olympus BH-2 fluorescence microscope after dried thoroughly.

Transmission electron microscopy assay

The BEL-7402 cells were seeded in culture flasks. Three culture

bottles were divided into treatment group and control group. When the cells anchored to the plates, various concentrations (0, 50 and 100 mg/L) of HAP nanoparticles were added and the cells were incubated at 37 ℃, 5 % CO_2 for 48 h. Hepatoma cells were then digested by 0.25 % trypsinase and collected. After rinsed with PBS, the cells were prefixed with 3 % glutaraldehyde for 30 min, post-fixed with 1 % osmic acid, dehydrated in graded ethanol, embedded in Epon 812 mixture, and cut into sections on an ultramicrotome. The cells were observed under Hitachi H-600 electron microscopy.

Flow cytometric analysis

The suspended single cell solutions subjected to treatment with HAP nanoparticles at different concentrations (0, 50, 75, 100, 150 and 200 mg/L) for 48 h were harvested. Each group had three culture bottles. Cells were washed with PBS, fixed with 70 % ethanol at -20 ℃ for 30 min and stored at 4 ℃ overnight, then washed with PBS again, treated with 100 mg/L RNase 100 μl at 37 ℃ for 30 min and stained with 50 mg/L PI 100 μl at 4 ℃ for 30 min in darkness. Apoptotic cells were assayed using FACSort Becton Dickinson Flow Cytometer at 488nm and data were analyzed with CELLQuest Software. For each sample, 6000 cells were measured.

Statistical analysis

All data were expressed as mean ± standard deviation. Statistical analysis was performed by *t* test using software SPSS11.0 for Windows. $P<0.05$ was considered significant.

RESULTS

Effect of HAP nanoparticles at various concentrations on the growth of BEL-7402 cells

After 48 h treatment, HAP nanoparticles produced a dose-dependent inhibition of cell growth (Table 1). Correlation analysis displayed a significantly positive correlation between the concentration of HAP and inhibition rate (IR) (r=0.931, $P<0.01$). Regression equation was as follows: $y_{concentration}=966.09 x^3_{IR}-292.20x_{IR}+54.63$, the half effective inhibitory concentration (IC_{50}) =29.30mg/L.

Table 1 Inhibitory effect of HAP nanoparticles on hepatoma cell line BEL-7402

Concentrations (mg/L)	A_{490nm} ($\bar{x}\pm s$)	Inhibition rate (%)	*t vs* control
0(control)	0.9325±0.0337

Fluorescence microscopic observation

Hoechst 33258 is a specific DNA-binding fluorochrome and under the fluorescence microscope it exhibits a green fluorescence. As shown in Figure 1, in the control group, the nucleus was big and round, with a smooth nuclear membrane, free of condensation and fragmentation. However, smaller nuclei, increased density of nuclear chromatin, fragmentation of nucleus and apoptotic body formation were easily identified in HAP nanoparticles treated groups. The higher the concentration of HAP nanoparticles, the more apoptotic cells there were. Apoptotic rate was counted under fluorescence microscopy, there were 18.68 %, 22.27 %, 33.49 %, 49.03 %, 57.16 % at 50, 75, 100, 150 and 200 mg/L concentration, respectively.

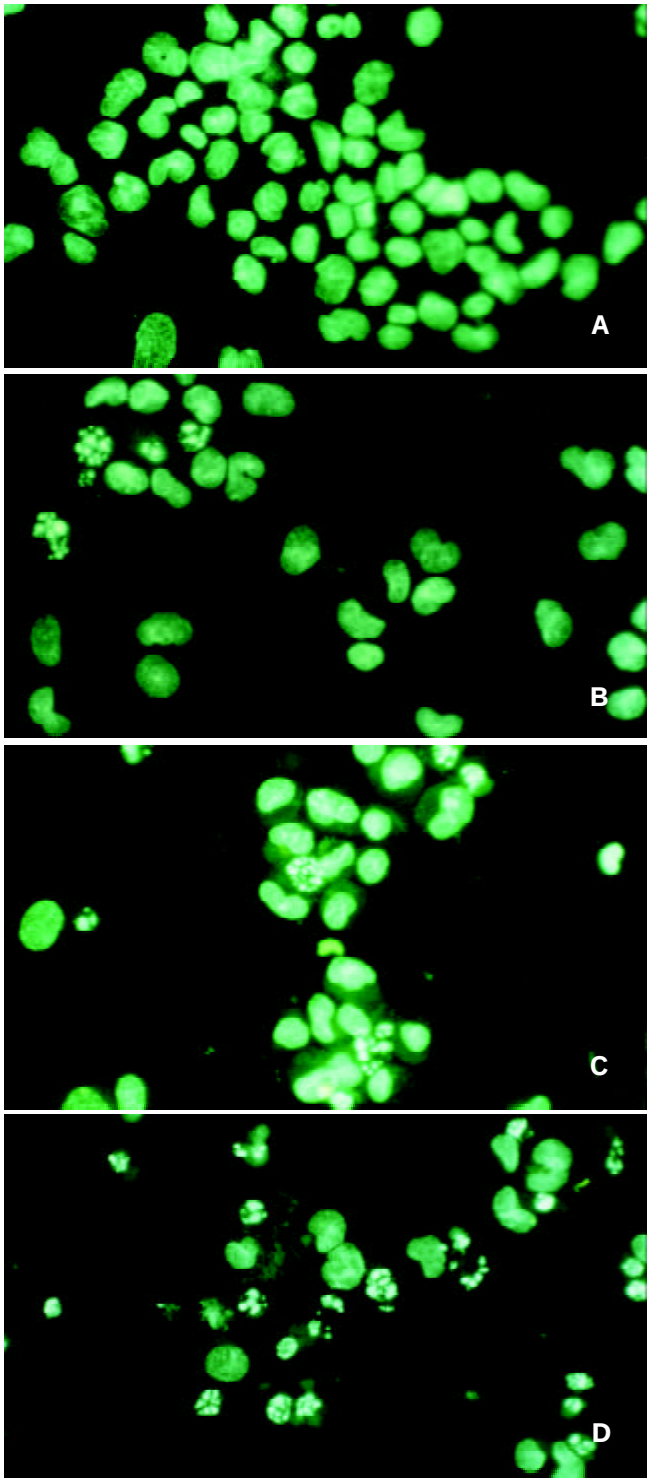

Figure 1 Fluorescence microscopy for apoptosis induced by HAP nanoparticles for 48 h (×200). A: Control; B: 50 mg/L; C: 100 mg/L; D: 200 mg/L.

Transmission electron microscopic observation

Under transmission electron microscopy, control cells were big and round, with intact nuclear membrane and low density in nuclear chromatin (Figure 2A). However, the cells treated with HAP nanoparticles exhibited characteristics of apoptosis

including cell membrane shrinkage, cytoplasm budding, condensation and fragmentation of nuclear chromatin adjacent to nuclear membrane (Figure 2B).

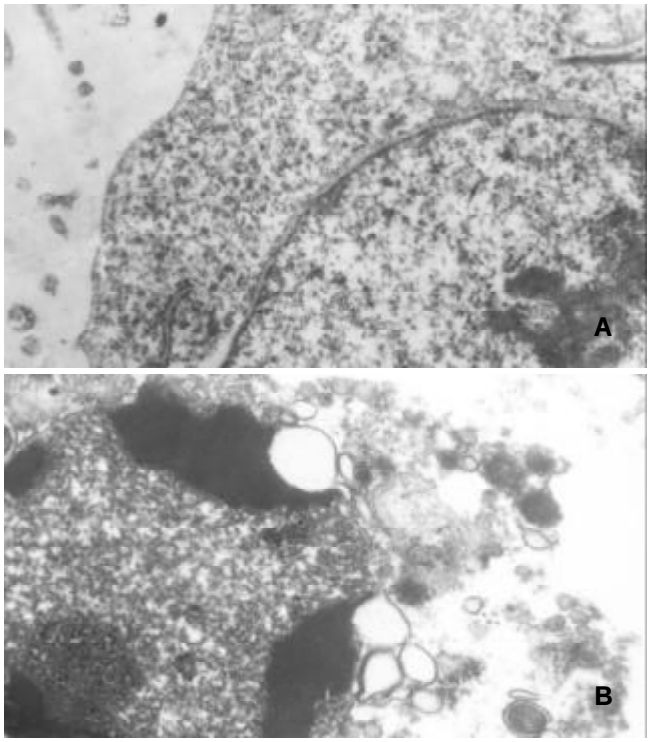

Figure 2 TEM ultrastructural changes of apoptosis induced by HAP nanoparticles for 48 h. A: Control ×15 000; B: 10 mg/L ×10 000.

Flow cytometry analysis

The hypodiploid peak appearing before the G_1 phase on histogram was called apoptotic peak, which indicated reduced DNA content in apoptotic cells in FCM analysis. Table 2 shows that apoptotic rates increased with increasing concentrations of HAP nanoparticles. Correlation analysis showed a significantly positive correlation between concentration of HAP nanoparticles and apoptotic rate (r=0.994, P<0.01).

Table 2 Apoptotic rates of HAP nanoparticles on hepatoma cell line BEL-7402

Concentrations (mg/L)	Apoptotic rate (%)	*t vs* control
0(control)	2.23±0.14	
50	20.35±2.23[b]	13.32
75	25.35±1.92[b]	22.55
100	29.34±4.61[b]	10.50

DISCUSSION

Hydroxyapatite nanoparticles used in this study was synthesized by sol-gel method, with uniform particle size of 50 nm and was well dispread. After human hepatoma BEL-7402 cells treated at various concentrations of hydroxyapatite nanoparticles for 48 h, MTT colorimetric analysis showed that nanoparticles could significantly inhibit the proliferation of BEL-7402 cells, with IC_{50} values of 29.30 mg/L. Moreover, the inhibitory rates at 25, 50, 75 and 100 mg/L concentration of HAP nanoparticles were all more than 50 %, but there was no statistical difference among the four treatment groups, which indicated the tolerance of human hepatoma BEL-7402 cells subjected to HAP nanoparticles. This would provide some experimental basis for its clinical use.

With cytochemical staining and under transmission electron microscopy, typical apoptotic alterations such as cells shrinkage, nuclear chromatin condensation and fragmentation, cytoplasmic budding and formation of apoptotic bodies were observed after BEL-7402 cells were treated by HAP nanoparticles for 48 h. Quantified by FCM, the higher the concentration of HAP nanoparticles, the more apoptotic cells there were. The apoptotic rates were in accordance with the results counted under fluorescence microscopy. At the same time, no statistical difference was found among the 50, 75 and 100 mg/L groups, in which the tolerance of BEL-7402 cells subjected to HAP nanoparticles was identified. Therefore, the present study demonstrated that HAP nanoparticles could induce human hepatoma cell apoptosis *in vitro*. This might be the first report regarding the antineoploastic mechanism of HAP nanoparticles on human hepatoma cells through apoptotic induction.

Kerr *et al* first described the concept of apoptosis. It is the programmed death of cells by fragmentation of DNA, cell shrinkage, followed by cell fragmentation and formation of membrane vesicles called apoptosis bodies. A variety of studies have revealed that the uncontrolled growth of neoplasm is not only due to the over proliferation but also due to the loss of natural apoptosis[1-19]. Therefore, exploring new medicine that could induce cancer cell apoptosis would be helpful for neoplasm treatment[20-23]. To date, chemotherapeutic medicines, growth inhibitor analogs, arsenic and various Chinese herbal medicines have been testified to suppress tumor cell growth by inducing cell apoptosis[24-38].

In this study, hydroxyapatite nanoparticles inhibited human hepatoma BEL-7402 cell growth and induced apoptosis, which may add a new way to use nanopaticles for tumor treatment. Further studies are needed to clarify the mechanism of apoptosis induced by hydroxyapatite nanoparticles.

Abstract

AIM: To investigate the expression of tumor suppressor gene p53 and spindle checkpoint gene Mad2, and to demonstrate their expression difference in colorectal cancer and normal mucosa and to evaluate its clinical significance.

METHODS: Western blot and immunohistochemistry methods were used to analyze the expression of Mad2 in colorectal cancer and its corresponding normal mucosa. The expression of p53 was detected by immunohistochemistry method in colorectal cancer and its corresponding normal mucosa.

RESULTS: Mad2 was significantly overexpressed in colorectal cancer compared with corresponding normal mucosa ($P<0.001$), and it was not related to the differentiation of adenocarcinoma and other clinical factors ($P>0.05$).The ratio of Mad2 protein in cancer tissue (C) to that in its normal mucosa tissue (N) was higher than 2, which was more frequently observed in patients with lymph gland metastasis ($P<0.05$). p53 protein expression was not observed in normal mucosa. The rate of p53 positive expression in adenocarcinomas was 52.6 %. There was a significant difference between adenocarcinomas and normal mucosa($P<0.001$), which was not related to the differentiation degree of adenocarcinoma and other clinical factors ($P>0.05$).

CONCLUSION: Defect of spindle checkpoint gene Mad2 and mutation of p53 gene are involved mainly in colorectal carcinogenesis and C/N>2 is associated with prognosis of colorectal cancer.

INTRODUCTION

Accurate chromosomal segregation is essential for cell survival and genomic stability. Genomic instability is a common feature of human cancer and is thought to be an important contributor to the malignant phenotype[1,2]. At least two categories of instability have been described: CIN and MIN. CIN is characterized by an alteration in chromosome number and is commonly detected as aneuploidy. The fact that the majority of human cancer cells exhibit gains or losses of chromosomes suggests that CIN may contribute to tumorigenesis[3-5]. In yeast, a loss of mitotic checkpoint frequently leads to abnormal chromosome number, resulting in aneuploidy or polyploidy[6]. The mitotic checkpoint, known as the spindle assembly checkpoint, detects errors occurred in the spindle structure or in alignment of the chromosomes on the spindle, and delays chromosome segregation and anaphase onset until the defects are corrected. Two major groups of mitotic checkpoint genes, budding uninhibited by benomyl (BUB) 1-3 and mitotic arrest defect (MAD) 1-3, have been identified in budding yeast[7]. Mammalian homologues of the yeast mitotic checkpoint protein have also been characterized[8-10].

To date, the vast majority of studies about mitotic checkpoint have focused on cancer cell lines. Little data are available on Mad2 in colorectal adenocarcinoma. In this study, the authors used Western blot and immunohistochemical technique to examine the expression of Mad2 and p53 in colorectal cancer to elucidate the relation of Mad2 and p53 to carcinogenesis and clinical pathological factors.

MATERIALS AND METHODS

Specimens

Cancer tissues and corresponding normal tissues were obtained from the First Affiliated Hospital of Anhui Medical University from October 2000 to May 2001. No patient had been treated with anti-neoplasm therapy before tumor removal. Thirty eight patients (21 males, 17 females, aged between 28 to 81 years, median age 54.8 years) were as follows: 25 cases of well differentiated adenocarcinoma, 5 cases of moderately differentiated adenocarcinoma, 8 cases of poorly differentiated adenocarcinoma. Parts of the tissues were embedded in OCT, immediately frozen in liquid nitrogen. The other parts were fixed in 10 % formalin, embedded in paraffin, cut into 4 μm serial sections.

Reagents

Mad2 polyclonal rabbit antibodes against human were provided by China Science and Technology University. HEPES, SDS and Polycrylamide were purchased from Sigma Biological Technology Ltd., USA. Immuno-blot nitrocellulose filter membrane was purchased from OSMONICS Biological Technology Ltd., USA. p53, goat anti-rabbit IgG-HRP and S-P immunohistochemical kit were purchased from Beijing Zhongshan Biological Technology Ltd.

Western blot

Both cancer and its corresponding normal frozen tissues were minced and homogenized in buffer (10 mM HEPES, 113 mM mannitol , 37 mM sucrose, 1mM EDTA) for 5 min on ice. After spun at 15 000 rpm for 20 min at 4 ℃, supernatants were collected and frozen at -20 ℃ until use. Protein concentration was measured by modified Lowry protein assay. Samples containing 40 μg total protein were electrophoretically separated and transferred to an immuno-blot nitrocellulose filter membrane. The membranes were blocked overnight at 4 ℃ with 5 % skim milk. The blots were incubated with rabbit polyclonal anti-Mad2 antibody at 1:200 dilution in 5 % skim milk for 1 h at 37 ℃ and were incubated with goat anti-rabbit IgG-HRP at 1:50 dilution in 5 % skim milk for 30 min at 37 ℃.

Following treatment with DAB, the blots were exposed to a gel image system and measured.

Immunohistochemistry

Immunohistochemical staining was performed using S-P method, anti-Mad2 antibody was diluted to 1:120. Anti-p53 was ready to use reagent. A negative control was dyed according to the above method with the primary antibody substituted by animal serum. The standard of positive Mad2 protein expression was stained with brown-yellow color mainly in cell plasma, p53 positive expression was stained in nucleus. A semi-quantitative evaluation was used to determine positively expressed cells by viewing 10 vision fields at ×400[11]. Negative (-) indicated cells were stained less than 10 %, mild positive (+) showed 11-25 % cells were stained, moderately positive (++) demonstrated 26-50 % cells was stained, strong positive (+++) revealed over 50 % cells were stained. The later three grades were all regarded as positive.

Statistical analysis

The data were analyzed by SPSS version 10.0. Fisher' s exact test or χ^2 test was used for statistical analysis. $P<0.05$ was considered statistically significant.

RESULTS

Expression of Mad2 protein

We analyzed the results measured by gel image system. Mad2 protein in cancer tissue was significantly overexpressed compared with that in corresponding normal tissues ($P<0.001$). (Figure4)The calculated ratio of Mad2 protein in cancer tissues (C) to that in corresponding normal tissues (N) was 2.07±1.87, ranging from 0.31 to 4.68, indicating that Mad2 expression was approximately 2-fold higher in cancer tissue than in normal tissue. Furthermore, we analyzed the association between the C/N ratio of Mad2 expression and clinicopathological parameters including histological differentiation and lymph node metastasis. The results are summarized in Table 1. No significant difference was found among well differentiated, moderately differentiated, and poorly differentiated adenocarcinomas. However, C/N>2 was found to be related with lymph node metastasis ($P<0.05$).

Table 1 Relationship between C / N ratio of Mad2 expression and histologic differentiation and lymph node metastasis

Groups	*n*	Mad2		Positive (%)	*P*
		C / N>2	C / N<2		
Differentiation					
WD	25	10	15	40 %	
MD	5	2	3	40 %	
PD	8	2	6	25 %	[a]P=0.737
Lymph node metastasis					
Absent	32	9	23	28%	
Present	6	5	1	83.3%	[b]P=0.01

A: comparison among groups of colorectal cancer, B: comparison between absent and present, WD: well differentiated adenocarcinoma, MD: moderately differentiated adenocarcinoma, PD: poorly differentiated adenocarcinoma.

The positive signals of Mad2 protein were brown-yellow stains mainly in cell plasma, and strength of color was directly proportional to positive percentage (Figures 1,2). Positive expression of Mad2 protein was detected in 33 out of 38(86.8 %) colorectal cancers, and 18 out of 38 (47.4 %) normal tissues. There was a significant difference between colorectal cancer and normal tissues ($P<0.001$). However, no significant difference was found among well differentiated, moderately differentiated, and poorly differentiated adenocarcinomas. The expression of Mad2 in colorectal cancer was not related with lymph node metastasis (Table 2).

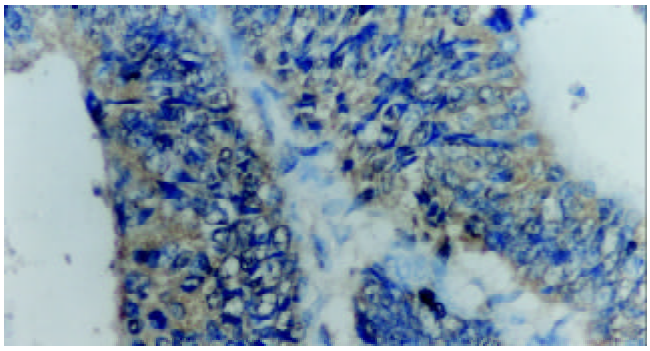

Figure 1 Strongly positive expression of Mad2 in tubular adenocarcinoma. S-P ×400.

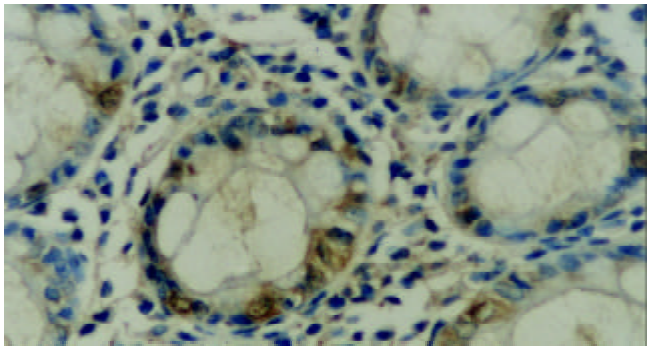

Figure 2 Weakly positive expression of Mad2 in normal mucosa S-P ×400.

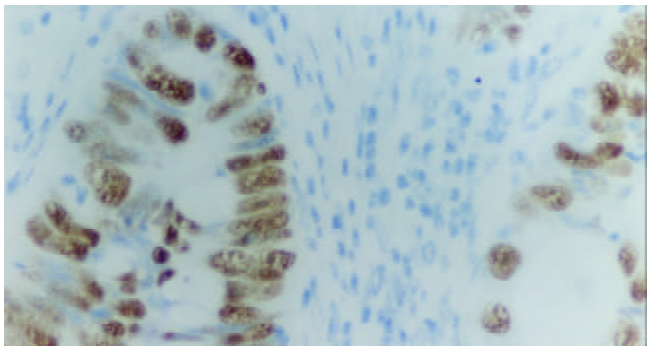

Figure 3 Strongly positive expression of p53 in tubular adenocarcinoma. S-P ×400.

Present	6	4	2	66.7 %	[c]*P*=0.169

[a]: comparison between normal tissue and adeocarcinama, [b]: comparison among groups of colorectal cancer, [c]: comparison between absence and presence.

Correlation between Mad2 protein and p53

The percentage of positive p53 expression was 52.6 % (20/38) in colorectal cancer(Figure3), no such protein expression was observed in normal tissue. We analyzed the correlation between Mad2 protein and p53 expression by χ^2 test. There was a significantly positive correlation between the expressions of Mad2 and p53(P<0.05).

DISCUSSION

Kinetochores are linked to both chromosomes and microtubules, and play an important role in the generation of mitotic checkpoint signals. The function of kinetochores was to ensure that chromosomes were not segregated until each of them was aligned and attached to the spindle[12,13]. The majority of protein associated with mitotic checkpoint function have been shown to localize at kinetochores unattached to microtubules[14,15]. It has been proposed that the mitotic checkpoint proteins, especially Mad2 be crucial for generating the "wait" signal to prevent the onset of anaphase after microtubule disruption[16-18]. Previous studies indicated that mutations of mitotic checkpoint protein gene or lower expression of mitotic checkpoint protein might lead to the failure of mitotic checkpoint function, which might in turn lead to tumorigenesis, especially aneuploid cancer. Li and benezra reported that one breast cancer cell line with a mitotic checkpoint defect expressed Mad2 at a level one-third less than that of diploid normal cell lines[8]. Recently, Takahashi *et al* reported mitotic checkpoint function was impaired in 4 (44 %) out of 9 human lung cancer cell lines[19]. In the present study, the expressions of Mad2 and p53 protein were examined in colorectal cancer and its corresponding normal tissues. Mad2 expression in colorectal cancer was higher than that in its corresponding normal tissues. Our results on the expression of Mad2 were not consistent with the reduced Mad2 expression in a breast cancer cell[8]. We speculate it might be the surrounding in which cell lived that led to the expression difference. In addition, positive expression of Mad2 was found in normal tissues to some extent. In budding yeast, the amount of Mad2 protein appeared to be constant during the cell cycle, although the level of Clb2p, a mitotic cycle cyclin, changed regularly in response to cell progression[20]. Similarly, a certain amount of Mad2 protein is thought to be required to maintain the normal checkpoint system in human cell. Loren *et al* showed that subtle differences in Mad2 protein level markedly altered checkpoint function. Therefore, inactivation of Mad2 would be sufficient to create a haplo-insufficient effect and the loss of mitotic checkpoint control[21]. The most convincing evidence of the role of mitotic checkpoint defect in CIN in mammalian cells obtained in two recent studies showed that disrupting of Mad2 expression resulted in CIN. CIN cells became aneuploidy, a hallmark of cancer associated with aggressive tumor behavior and a poor prognosis[21,22]. Very recently, Poelzl *et al* reported that estrogen receptor β, which might be involved in the regulation of cellular proliferation, interacted with Mad2 directly and specifically[23]. The Mad2 protein also interacted with the cytoplasmic domain of insulin receptors, which was thought to be a regulator of cellular growth[24,25]. Mad2 protein overexpressed in cancer tissues was exclusively present in the cytoplasm of cancer cells. We speculate that cytoplasmic Mad2 protein may enhance the positive regulatory action of estrogen receptor β and insulin receptor on cellular proliferation. We also discovered that there was a significantly positive correlation between the expressions of Mad2 and p53 (P<0.05). Orr-Weaver *et al*. thought aneuploidy resulted from defect of Mad2 and other unknown factor could increase the rate at which tumor suppressors, such as p53, were lost[17]. p53 gene was the most frequently mutated gene in human cancer[26-28]. One of its roles was to ensure that when DNA damaged cells were arrested in G1, it attempted to repair their DNA before it was replicated[29,30]. In some cell types, p53 induced apoptosis when overexpressed and was required for apoptosis in response to severe DNA damage[31,32]. p53 might directly activate death genes such as BAX, or down-regulate survival genes such as BCL-2[33-35]. So when p53 gene mutates, aneupoidy from defect of Mad2 might escape from apoptosis and go on its mitosis, finally develop to malignant tumor.

The C/N ratio of Mad2 protein was found to be associated with lymph node metastasis. A C/N ratio greater than 2 was observed more frequently in patients with lymph node metastasis. Therefore, a C/N ratio >2 may be clinically an important indicator for lymph node metastasis of colorectal cancer.

In conclusion, the protein level of Mad2 is higher in colorectal cancer tissues than in normal tissues. The higher the protein level in colorectal cancer tissues is, the more frequently lymph node metastasis. Since the difference in the protein level between colorectal cancer and normal mucosa is easily detected by immunohistochemistry, Mad2 protein might be a good marker of lymph node metastasis of colorectal cancer.

Abstract

AIM: To investigate the effects of DNA methylation on the expression of tumor suppressor genes and proto-oncogene in human colon cancer cell lines.

METHODS: Three colon cancer cell lines (HT-29, SW1116 and Colo-320) treated with different concentrations of DNA methyltransferase inhibitor, 5-aza-2'-deoxycytidine (5-aza-dC) were used to induce DNA demethylation. The expressions of $p16^{INK4A}$, $p21^{WAF1}$, *APC* and *c-myc* genes were observed by using RT-PCR. The methylation status of $p16^{INK4A}$ promoter in HT-29 cells was also determined by methylation-specific PCR (MSP).

RESULTS: Weak expressions of $p16^{INK4A}$ and *APC* in the three colon cancer cells were detected, and $p21^{WAF1}$ expression was not found in SW1116 and Colo-320 cells before treatment. After treatment of 1 μmol/L but not 10 μmol/L of 5-aza-dC, the methylation level of $p16^{INK4A}$ gene promoter decreased significantly, and the hypomethylation led to the up-regulation of $p16^{INK4A}$ gene transcription in HT-29 cells. In the cell lines of SW1116 and Colo-320, $p16^{INK4A}$ and *APC* mRNA expressions were obviously enhanced after treatment of either 10 μmol/L or 5 μmol/L 5-aza-dC for 24 h. However, no evidence was found that methylation regulated the expression of $p21^{WAF1}$ and *c-myc* genes in human colon cancer cell lines.

CONCLUSION: Expression of $p16^{INK4A}$ and *APC* genes is regulated by DNA methylation in three human colon cancer cell lines.

INTRODUCTION

DNA methylation is the main epigenetic modification after replication in humans[1]. DNA (cytosine-5)-methyltransferase (DNMT) catalyzes the transfer of a methyl group from S-adenosyl-L-methionine (SAM) to C5 of cytosine within CpG dinucleotide sequences in genomic DNA of higher eukaryotes. The expression of some genes can be frequently inactivated by reversible epigenetic events rather than genetic events[2,3].

Colon cancer is one of the most common tumors worldwide. The loss of $p21^{WAF1}$, $p16^{INK4A}$ and adenomatous polyposis coli (*APC*) gene expression, or/and the over-expression of *c-myc* gene are believed to play a crucial role in colon carcinogenesis[4]. As described in our previous review[5], mutation of $p16^{INK4A}$ was not found but the frequency of hypermethylation was 10-53 % in colon cancer. Previous studies by two independent groups of investigators have demonstrated that inactivation of $p16^{INK4A}$ in human colon tissue might be due to *de novo* methylation of promoter-associated CpG island[6-8]. Colon cancer cell lines, Colo-320[9-11] and SW1116[12-14], were frequently used in molecular biological experiments.

To date, most of these studies were focused on aberrant methylation in a single gene. However, little is known about the regulation of methylation on the expression of several tumor suppressor genes and proto-oncogenes in the same human colon cancer cell line. Furthermore, several clinical trials indicated that methylation inhibitor, 5-aza-2'-deoxycytidine (5-aza-dC) was devoid of antitumour activity in adult patients with colon cancer[15-17]. We want to know whether 5-aza-dC induces over-expression of proto-oncogene while regulates the transcription of tumor suppressor gene.

In this study, we investigated the transcriptional level of $p16^{INK4A}$, $p21^{WAF1}$, *APC* tumor suppressor genes, and *c-myc* proto-oncogenes. We examined whether the expression of these genes was influenced by methylation in colon cancer cell lines. The focus of this work was to gain a better understanding of the factors involved in regulating DNA methylation.

MATERIALS AND METHODS

Cell culture

Colon cancer-derived cell lines HT-29, Colo-320 and SW1116 were maintained by serial passages in MEM containing 10 % heat-inactivated FCS, 20 mmol/L of L-glutamine, 62.5 mg/L of penicillin, and incubated at 37 ℃ using standard tissue culture incubators as described previously[18]. The cells were plated as 10^6 cells onto per 100-mm dish.

Treatment with 5-aza-dC

5-aza-dC was a DNMT inhibitor[19]. To assess the expression of $p16^{INK4A}$, $p21^{WAF1}$, *APC* and *c-myc* genes by 5-aza-dC, colon cancer cell lines were exposed to different concentrations (1 μmol/L and 10 μmol/L for HT-29 cells; 2 μmol/L, 5 μmol/L and 10 μmol/L for Colo-320 and SW1116 cells) of 5-aza-dC (Sigma, St. Louis, MO) for 24 hours and 72 hours. The control cultures were treated simultaneously with PBS. The media were changed, DNA and RNA were harvested at various time points, respectively. We did not find cytotoxics reactions from 5-aza-dC, even at 10 μmol/L concentration.

Reverse transcription polymerase chain reaction (RT-PCR)

Total RNA was isolated by using a commercial kit (Trizol)

according to the manufacturer's instructions (Gibco BRL). Reverse transcription reactions using 5 μg of total RNA in a total reaction volume of 20 μl were performed with Superscript II reverse transcriptase (Life Technologies, Inc.). The mRNA transcription levels of *p16^{INK4A}*, *p21^{WAF1}*, *APC* and *c-myc* genes were evaluated by using RT-PCR. Primer sequence and PCR reaction for each primer are shown in Table 1. For control of RT-PCR, a 612 bp (322 bp for *p16^{INK4A}* RT-PCR in HT-29) fragment of β-*actin* cDNA was also amplified. The density of bands in RT-PCR were quantitated by using a molecular dynamics phosphorImager (Nucleo Tech Inc., San Mateo, CA), which were normalized to the amount of total RNA as determined by the density of β-*actin* band from RT-PCR[16]. RT-PCR was performed three times at least.

Methylation-Specific PCR (MSP) for p16^{INK4A}

We followed Clark's method of bisulfite treatment[20] with some modifications as follows. Two μg of total genomic DNA (from at least two independent treatments corresponding to RT-PCR experiments) was isolated by using QIAamp DNA blood mini kit (QIAGEN Inc.), then denatured by NaOH and modified by sodium bisulfite solution (2.35 mol/L) containing hydroquinone (0.04 mol/L)) freshly prepared. The bisulfite-treated DNA was desalted using Wizard DNA clean up kit (Promega). To amplify the *p16^{INK4A}* promoter, we used 0.1 μg aliquot of converted DNA. Methylation of the 5' CpG island in *p16^{INK4A}* gene was also determined in samples from HT-29 cells treated by 5-aza-dC. The bisulfite treated DNA was amplified by PCR using primers specific for the methylated or unmethylated primer. The GenBank accession number, sequences of primers and program of PCR are also shown in Table 1. PCR product was directly loaded onto 3 % agarose gels and electrophoresed. The gel was stained with ethidium bromide and directly visualized under UV illumination.

RESULTS

Methylation in p16^{INK4A} promoter in HT-29 cells treated with 5-ada-dC

We examined the methylation status of *p16^{INK4A}* following 5-aza-dC treatment using MSP. Bisulfite treatment converted the cytosine residues in the genomic DNA to uracil, which were amplified as thymine during subsequent PCR. As shown in Figure 1, HT-29 cells showed a positive 150-151 bp band for methylated and unmethylated specific primer sets for *p16^{INK4A}* respectively, indicating that *p16^{INK4A}* gene was partially methylated in this cell line. The methylated bands for *p16^{INK4A}* gene in the mock treated HT-29 cells were consistently stronger than the products of 5-aza-dC treated HT-29 cells. Thus, the product level from PCR using unmethylated primer was significantly higher, and methylated product level was correspondingly lower in HT-29 cells treated with 5-aza-dC.

Three days after treatment with 1 μm of 5-aza-dC, MSP revealed a significant increase in the amount of unmethylated product (Figure 1). These results suggested that *p16^{INK4A}* gene was a target of the decreased methylation level in HT-29 cells treated with 5-aza-dC.

Restoration of p16^{INK4A} gene expression by 5-aza-dC

We initially tried to find out whether there were expressions of several tumor suppressor genes such as *p16^{INK4A}*, *p21^{WAF1}* and *APC*, and proto-oncogene *c-myc* in human colon cancer cell lines HT-29 (*p16^{INK4A}* only), Colo-320 and SW1116. mRNA levels of the above genes were investigated by using semiquantitative RT-PCR. *p16^{INK4A}* gene was expressed in these three cell lines slightly prior to the treatment with 5-aza-dC.

In the first part of the present study, we examined the possibility of methylation on expression regulation of *p16^{INK4A}* in three colon cancer cell lines. Increased levels of *p16^{INK4A}* expression were seen in HT-29 cells treated with lower (1 μmol/L, 24 hours) but not higher (10 μmol/L, 24 hours) concentrations of 5-aza-dC (Figure 2, Table 2). In contrast, 5-aza-dC induced transcription of *p16^{INK4A}* at higher concentration (10 μmol/L)) for 24 hours or 72 hours, but not at the lower concentration (2 μmol/L or 5 μmol/L) for the same duration (Figures 3A and 3B, lanes 3 and 4, Table 3).

5-aza-dC increased transcription level of APC gene

To identify whether the transcription level of *APC* was regulated by DNA methylation in human colon cancer cell lines, we cultured Colo-320 and SW1116 cells with or without 5-aza-dC treatment for 24 hours and 72 hours. The data from RT-PCR implied that before incubation with 5-aza-dC, the levels of *APC* transcription in these cells were lower (Figure 4, line 1, Table 4). Incubation for 24 hours with 5-aza-dC resulted in the accumulation of *APC* mRNA, whose levels remained unchanged during the 72 hour incubation period. *APC* mRNA levels were normalized with respect to the level of β-*actin* mRNA, which did not change during culture with 5-aza-dC (Figure 4, Table 4). RT-PCR was repeated twice and the results were consistent.

The effectiveness of 5-aza-dC on the expression of *APC* was high even at lower concentration (2 μmol/L), suggesting that methylation-induced silencing of this gene was the primary event. Restoration of *APC* expression by 5-aza-dC treatment confirmed a causal relationship between DNA hypermethylation and *APC* silencing in colon cancer cell lines Colo-320 and SW1116.

5-aza-dC treatment failed to induce expression of p21^{WAF1} *and c-myc in Colo-320 and SW1116 cells*

To further define the modification status of *p21*^{WAF1} and *c-myc* expression in colon carcinogenesis, we attempted to observe whether their transcription levels would change after treatment with DNMT inhibitor. Although no expression of *p21*^{WAF1} and

significant over-expression of *c-myc* were seen in mock treatment. Our current study revealed that almost no change in activity was seen when these two cell lines Colo-320 and SW1116 cells were treated by 5-aza-dC. In other words, regulation of methylation on the expression of $p21^{WAF1}$ and *c-myc* genes was not found (data not shown).

Taken these together, it was suggested that the methylation silencing transcription be localized at specific regions of the chromatin. Other mechanisms might play a role in controlling the activity of $p21^{WAF1}$ and *c-myc* genes in colon cancer cell lines Colo-320 and SW1116.

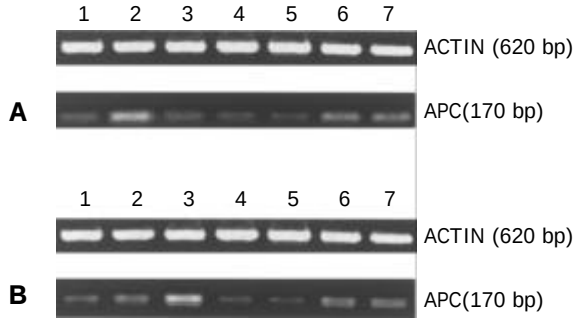

Figure 4 5-aza-dC increased the transcription of *APC* gene in Colo-320 (A) and SW1116 cells. Lane 1: mock treatment. Lanes 2-7: after 5-aza-dCtreatment; lane 2: 2 μmol/L, 24 h; lane 3: 5 μmol/L, 24 h; lane 4: 10 μmol/L, 24 h; lane 5: 2 μmol/L, 72 h; lane 6: 5 μmol/L, 72 h; lane 7: 10 μmol/L, 72 h. The density of bands shown in Table 4.

DISCUSSION

Compelling evidences for the role of epigenetic modification on the regulation of gene transcription have been published[21-26]. $p16^{INK4A}$ was a tumor suppressor gene originally identified by Serrano *et al*[27], and the methylation profile of $p16^{INK4A}$ promoter differed in each cancer type[28]. Several studies indicat that 5-aza-dC induced growth inhibition might be resulted from the release of methylation silenced cell cycle regulatory gene $p16^{INK4A}$[29]. *APC* gene hypermethylation is frequent but not universal in colon cancer cell line. Previous studies showed that $p21^{WAF1}$ transcription was regulated by histone acetylation, another modification of epigenetics in human colon cancer[30], but little is known about the effect of DNA methylation on this gene expression.

In the current study, our findings indicated firstly that $p16^{INK4A}$ was expressed in these three human colon cancer cell lines, and *APC* was expressed with $p21^{WAF1}$ inactivated in Colo-320 and SW1116 cells. 5-aza-dC induced hypomethylation of $p16^{INK4A}$ promoter and the restoration of $p16^{INK4A}$ transcription, suggesting that DNA methylation is the major regulation mechanism for $p16^{INK4A}$ in HT-29, Colo-320 and SW1116 cells. Previously it was suggested that lack of $p21^{WAF1}$ expression appeared to be the result of hypermethylation of it' s promoter region, as $p21^{WAF1}$ protein expression could be induced by growth of Rat-1 cells in the presence of 5-aza-dC[31]. However, the influence of methylation on $p21^{WAF1}$ gene expression was dependent on differentiation of cells and tissues[30]. An important finding from this study indicated that reduction of DNA methylation might not play a crucial role in the regulation of $p21^{WAF1}$ transcription in human colon cancer cell lines, Colo-320 and SW1116.

c-Myc proto-oncoprotein has been found to be deregulated in colon cancer. Over-expression of c-Myc in tissue culture caused an increase in cell proliferation with a shortened G1 phase, whereas loss of c-Myc resulted in slow growth and longer G1 phase[32]. Over-expression and abnormal intracellular location of the product of proto-oncogene *c-myc* in colon dysplasia and neoplasia might be related to the alteration in epigenetic mechanisms controlling the function of this gene [33]. Although hypomethylation of *c-myc* in human tumors has also been reported, it is not clear whether demethylation induces the over-expression of *c-myc* in human tumor cell lines. This paper reports that 5-aza-dC did not up-regulate *c-myc* transcription, while the expression of $p16^{INK4A}$ and *APC* tumor suppressor genes responded to 5-aza-dC treatment in colon cancer cell lines. The reason why 5-aza-dC failed to colon cancer treatment was not due to *c-myc* over-expression from demethylation.

In conclusion, our study results support the concept that there are significant differences in the regulatory response to DNA methylation in different genes including tumor suppressor gene and proto-oncogene, even in the same colon cancer cell lines Colo-320 or SW1116.

ACKNOWLEDGEMENTS

We are grateful to Ms.Hong-Yin Zhu and Ju-Fang Tong for performing the RT-PCR and cell culture, and Dr.Xie-Ning Wu for his assistance in preparing this manuscript.

Abstract

AIM: To evaluate the effect of human telomerase reverse transcriptase (hTERT) gene antisense oligodeoxynucleotide (As-ODN) on telomerase activity and cell apoptosis in colon cancer cell line SW480.

METHODS: As-ODN was transfected into cells SW480 by liposomal transfection. Cultured cells were divided into three groups: ASODN (5'GGAGCGCGCGGCATCGCGGG-3'), sense oligodeoxynucleotide (5'-CCCGCGATGCCGCGCGCTCC-3', S-ODN) and control. The concentration of oligodeoxynucleotide and lipsome was 10 μmol/L and 16 mg/L, respectively. The activity of telomerase was examined by telomeric repeat amplification protocol (TRAP)-enzyme-linked immunosorbent assay (ELISA), and cell apoptosis was observed by morphology and flow cytometry in each group.

RESULTS: Telomerase activity began to be down-regulated or inhibited when cells SW480 were treated with As-ODN for 72 h, and cell apoptosis was induced.

CONCLUSION: It is suggested that hTERT As-ODN might specially inhibit the activity of telomerase in colon cancer cells and it is further proved that the hTERT gene has a significant correlation with telomerase activity. Further evidence is needed to prove whether hTERT As-ODN is a potential tool for the treatment of colon cancer.

INTRODUCTION

Telomeres, the distal ends of human chromosomes, are comprised of simple, repetitive and G-rich hexameric sequences (TTAGGG) and are vital for chromosomal stability and replication. Telomerase is a ribonucleoprotein polymerase which adds telomeric sequences onto the ends of chromosomes to compensate for DNA end replication[1,2]. Telomerase activity in humans was detected in germline and tumor tissues as well as in established cultured cell lines[3]. In normal somatic cells, the absence or low expression of telomerase was thought to result in progressive telomeric shortening with each cell division[4,5]. Therefore, it has been suggested that reactivation of telomerase is a critical step in tumorigenesis and that interference with the regulation of telomerase activity may serve as a basis for cancer therapy[6,7]. Here we report the effect of SW480, a human colon cancer line, after transfected with antisense hTERT and investigated the potential value of telomerase as a target for antisense gene therapy in colon cancer.

MATERIALS AND METHODS

Cell culture

SW480 cells, a human colon cancer cell line, generously supplied by Department of Biology, Wuhan University, Wuhan, China, were maintained in RPMI 1640-10 % fetal bovine serum, supplemented with 1 mmol/L L-glutamine, 100 U/ml penicillin plus 100 μg/ml of streptomycin at 37 ℃ under 5 % CO_2.

Cell counting

Cells were counted with 5 g/L of trypan blue staining.

Oligodeoxynucleotides synthesis

Oligodeoxynucleotides synthesis was designed as described by Feng L[8,9]. Antisense oligodeoxynucleotides (As-ODN) with sequence 5' GGAGCGCGCGGCATCGCGGG-3' , which can recognize the RNA template region of telomerase, and sense oligo- deoxynucleotides (S-ODN), with 5' CCCGCGATGCC GCGCGCTCC 3' were prepared on the 391 DNA synthesizer, synthesized by SBS Bio-technology Engineering Company of Beijing. The synthesized oligodeoxynucleotides were subjected to electrophoresis (PAGE) and purified (300 V, 1.5 h).

Transfection of oligodeoxynucleotides

The phosphorothiate oligodeoxynucleotides (ODNs) transfection was performed with liposomal transfection reagent DOSPER (Roche Diagnostic GmbH) according to the manufacturer' s protocol. Briefly, cells were plated onto 6-well plates and incubated until the cells reached 70-80 % confluency. Before the transfection, DOSPER was diluted with serum-free medium. Then, the desired amount of ODNs was incubated for 15 minutes with diluted DOSPER. The ODNs/ DOSPER mixture (100 μl) was added dropwise in 900 μl serum-free RPMI 1640. After incubation for 6 hours at 37 ℃, 1 ml RPMI 1640 containing 20 % FBS was added into each well. Cells were harvested and analysed after 48, 72, 96 and 120 hours, respectively.

Table 1 Effect of telomerase activity in SW480 cells by ODNs ($\bar{x}\pm s$)

Groups	Active duration				
	24 h	48 h	72 h	96 h	120 h
As-ODN 10 μmol/L	0.648±0.057	0.324±0.029	0.283±0.072	0.189±0.093	0.172±0.114
S-ODN 10 μmol/L	1.082±0.249	1.272±0.372	1.204±0.190	0.902±0.193	0.909±0.146
Positive control	1.336±0.231	1.376±0.238	1.354±0.186	1.298±0.172	1.246±0.169
Negative control	0.339±0.181	0.312±0.139	0.283±0.086	0.072±0.039	0.057±0.028

Telomerase assay

Polymerase chain reaction enzyme linked immunosorbent assay (PCR-ELISA) was performed following the instructions from Roche Diagnostics GmbH of Germany. Briefly, 2×10^6 cells were isolated, mixed with 200 μl protein extraction buffer, and left on ice for 30 minutes. 175 μl supernatant was collected after centrifugation (16 000×g, 20 minutes, 4 ℃). PCR was performed in 50 μl supernatant containing 25 μl transfer reaction mixture, 2 μl protein extract and 2 μl primers, and added to 23 μl nuclease-free water. The PCR condition was as follows: at 25 ℃ for 30 minutes for primer elongation, and at 94 ℃ for 5 minutes for telomerase inactivation. Amplification for 30 cycles under the condition at 94 ℃ for 30 s for denaturation, at 50 ℃ for 30 for annealing, and at 72 ℃ for 90 s for polymerization. Five μl of amplified product and 20 μl denaturated reagent were incubated at room temperature, 225 μl hybridyzation buffer was then added and mixed, and 100 μl of them was distributed in the wells of a microtitering plate. After 2 hours of incubation (37 ℃, 300 rpm), the anti-DIG-POD 100 μl working solution was added and incubated for another 30 minutes followed by adding 100 μl TMB substrate solution, and 100 μl stop reagent was added at last. The OD value in each well was read at the wave length of 450 nm and 655 nm on a microtiter plate reader (Bio-RAD Model 550 microplate reader). The results OD_{450} minus OD_{655} >1.5 unit using a protein extract from immortalized telomerase-positive human embryonic kidney cell (293 cells) were judged as a positive control. The negative control was considered as OD_{450} minus OD_{655} <0.2 unit by reading the protein extract pretreated with RNase A at 65 ℃ for 10 minutes. Telomerase activity was considered positive when the value of OD_{450} minus OD_{655} of a sample was at least 0.2 units higher than that of the negative control, otherwise it would be negative. Each sample was examined for more than twice. The final value was presented as $\bar{x}\pm s$ after a statistical treatment by using *t* test.

Cytologic morphology

Cytologic morphological changes were observed under the Olympus optical microscope and Hitach transmission electron microscope.

Detection of apoptotic cells by flow cytometry

Cells were fixed and stained with propidium iodide (PI, Sigma product). The DNA content of each cell was analyzed by a FACSORT flow cytometry (Becton Dickinson). Briefly, cells were trypsinized, washed once in ice-cold PBS, and incubated with annexin-V- fluoroescein/PI, and then analyzed immediately with FACSORT flow cytometry. All data were analyzed using Cell Quest software.

Statistical analysis

Results were expressed as the means ±SD. Statistical analyses were carried out with the software package SPSS10.0. A *P* value <0.05 was considered statistically significant.

RESULTS

Effect of telomerase activity in SW480 cells by antisense hTERT ODNs

As-ODN (10 μmol/L) and S-ODN (10 μmol/L) were transfected into SW480 cells, and the cells were collected at 24, 48, 72, 96 and 120 hours after transfection, respectively. Telomerase activities were measured by TRAP-ELISA. Results were as the followings. (1) Telomerase activity of SW480, transferred with As-ODN, was greatly inhibited when compared with that in the S-ODN. (2) Telomerase activity of SW480, transferred with As-ODN, at 72 and 96 hours after transfection was significantly lower than that at 24 hours, respectively. (3) Telomerase activity of SW480, transferred with As-ODN, was significantly lower than that in the positive control, as shown in Table 1. These findings suggested that this inhibitory action was sequence specific and in a time-dependent manner.

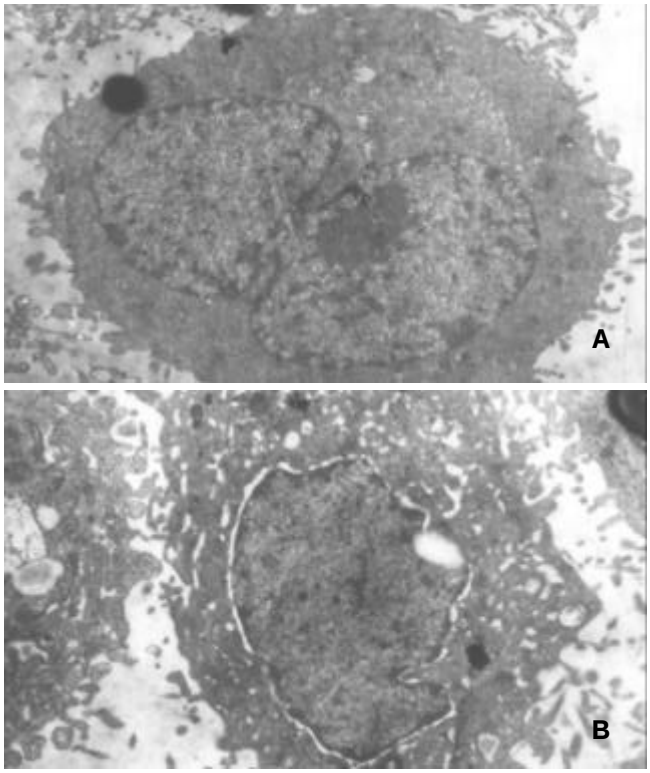

Figure 1 Morphplogic observation under transmission electron microscope. A: cell had no apoptotic features; and B: cell rounded up off the plastic, exhibiting cytoplasmic blebbing, fragmentation and chromatin condensation, features of apoptosis.

Effect of antisense hTERT ODNs on induction of SW480 cells apoptosis

Cytologic morphological changes Cytologic morphology of SW480, transferred with 10 μmol/L As-ODN for 3 days was observed under the Olympus optical microscope and Hitachi

transmission electron microscope. It was found that cells rounded up off the plaste, exhibiting cytoplasmic blebbing, fragmentation and chromatin condensation, and features of apoptosis. No apoptotic features (normal morphology) were observed in SW480 transferred with 10 μmol/L S-ODN (Figure 1).

Detection of apoptotic cells To determine the apoptotic rate, SW480 was treated with 10 μmol/L As-ODN and S-ODN for 2 days. After permeabilization, cells were stained with propidium iodide and analysed with flow cytometry. The apoptotic rate of SW480 cells transfected with As-ODN increased (at 48 hours, 4.82±0.39; 72 hours, 8.76±0.14; and 96 hours, 9.25±0.37, respectively, $P<0.001$), but no significant changes of apoptosis were observed in SW480 cells transferred with 10 μmol/L S-ODN as shown in Table 2, which indicated that this apoptotic induction was sequence specific and in a time-dependent manner.

Table 2 Effect of ODNs on induction of SW480 cells apoptosis ($\bar{x}\pm s$)

Groups	Active duration		
	48 h	72 h	96 h
As-ODN 10 μmol/L	4.82±0.39	8.76±0.14	9.25±0.37
S-ODN 10 μmol/L	2.08±0.38	2.96±0.47	2.19±0.29
hTERT blank	1.47±0.14	1.49±0.21	1.44±0.19

DISCUSSION

Three major components of telomerase, i.e. human telomerase RNA component (hTR), human telomerase-associated protein (TEP1), and human telomerase catalytic subunit (hTERT), have been identified[8,10-14]. hTR, functioning as a template for telomere elongation by telomerase, has been cloned from humans and mice[8,15] and expressed both in cancer and normal tissues, although its level was inclined to increase with tumor progression[16]. Human telomerase-associated protein (TEP1), as a human homolog of the Tetrahymena telomerase p80, was expressed ubiquitously and did not correlate with levels of telomerase activity[10,12]. hTERT, the catalytic protein subunit of human telomerase, contained the reverse transcriptase motif[12,13]. High levels of hTERT expression were observed in telomerase positive cell lines but not in telomerase negative primary fibroblasts[12]. hTERT was the limiting component necessary for the restoration of telomerase activity in normal diploid cells which was expressed transiently[17,18]. Recent studies have demonstrated telomerase activity was significantly associated with hTERT mRNA expression but not with hTR or TEP1 mRNA expression. These findings provide strong evidences that the expression of hTERT was a rate-limiting determinant of the enzymatic activity of human telomerase and that the up-regulation of hTERT expression might play a critical role in human carcinogenesis[19]. Previously, many studies[20-23] demonstrated that antisense oligonucleotides against human telomerase RNA resulted in inhibition of telomerase activity and induction of apoptosis in ovarian cancer cells and prostate cancer cells.

In our study, we found that transfection of SW480 with antisense-hTERT ODNs at a concentration of 10 μmol/L significantly inhibited the telomerase activity and induce apoptosis, when compared with positive control cells. The S-ODN with sense sequence did not affect the telomerase activity and induce apoptosis of transfected cells, indicating that this inhibitory and inducing action was sequence specific and in a time-dependent manner.

Recently, it has been shown that telomerase activity was the dominant mechanism providing telomere maintenance to human immortalized cells. The findings that the ability of cells with long telomeres to proliferate in the absence of telomerase demonstrated that telomerase activity did not require basic replicative functions of these cells, instead, telomerase activity appeared to be required to maintain a minimum telomere length[24]. However, the exact mechanisms of how telomerase activity is regulated in tumor cells remain poorly understood. Some researchers have shown that telomerase activity was correlated with the growth rate of immortal cells[25-27], whereas others found no significant association between telomerase activity and proliferative index in the tissue specimens from breast carcinoma[28], gastric carcinoma[29], and Wilm' s tumor[30]. Based on the recent findings, we did not observe any correlation between telomerase activity and proliferative index.

Some other studies, have shown that cells expressing high telomerase activity were more resistant to apoptosis than those with low telomerase expression[22,31,32], and that treatment with antisense telomerase inhibited the telomerase activity and subsequently induced either apoptosis or differentiation, and that regulation of these two distinct pathways might depend on the expression of ICE (Interleukin-1β-converting enzyme) or CDKIs (Cylin-dependent kinase inhibitors)[20]. Interestingly, inhibition of telomerase with an antisense telomerase expression vector not only decreased telomerase activity but also increased the susceptibility to cisplatin-induced apoptotic cell death in cisplatin- resistant U251-MG cells[22].

Inhibition of telomerase activity has been proposed as a potential approach to the treatment of human malignancy. It is suggested that telomerase inhibition may serve as an effective tool for eliminating tumor cells that have short telomeres. Such tumors may provide reasonable targets for the agents that inhibit telomerase. These experiments await the development of specific inhibitors for the components of the telomerase complex.

Abstract

AIM: To compare the differences in the endoscopic classification of early colorectal carcinoma (CRC) between Japan and China.

METHODS: Ten cases of early CRC were included in the study. After reviewing the color pictures of these cases, 5 Japanese endoscopists and 5 Chinese endoscopists made their classificatory diagnosis individually using the current Japanese classification, and indicated their findings on which the diagnosis was based.

RESULTS: Some lesions diagnosed by the Japanese endoscopists as IIa or IIa plus IIc, were classified as Is or Isp by the Chinese endoscopists. For superficial lesions consisting of elevation plus central depression, IIa plus depression, IIa plus IIc or IIc plus IIa were classified according to the ratio of elevated area/depressed area. However, international as well as interobserver difference still existed in the classification of such lesions. In addition, most Chinese endoscopists overlooked slightly depressed part on the top of a protruded lesion. Laterally spreading tumor, a special type of IIa, was identified as LST by some Japanese endoscopists.

CONCLUSION: Discrepancies on macroscopic classification for early CRC do exist between Japanese and Chinese endoscopists, which are found not only in terminology but also in recognition of some lesions. In order to develop a universal classification, it needs for international communication and cooperation.

INTRODUCTION

ColorectaI carcinoma (CRC) is the most common cancer of digestive system in the Western countries[1,2]. Recently, however, with the westernization of life style and dietary habits, its morbidity and mortality have also increased considerably in both China and Japan[3,4]. A series of clinical studies in many countries have all shown that both CRC incidence and mortality can be significantly reduced by a systematic screening program including endoscopic examination of the large bowel[5-8]. As a result, endoscopic diagnosis and treatment for early lesions have become more and more important in the management of CRC all over the world[9]. Undoubtedly, a worldwide agreed endoscopic classification for early CRCs will be very useful in clinical practice as well as in research[10,11].

Early CRC, according to the Japanese definition, refers to colorectal carcinoma that has not invaded beyond the submucosal layer[12]. Japanese endoscopists have developed their endoscopic classification for early CRCs since the early 1970s, and kept on modifying it. This definition of early CRC, however, has not been formally accepted in the Western countries, where Duke' s classification has been widely used for decades[13,14]. So far there has been no such classification for early CRCs in America and Europe[15]. On the contrary, Chinese doctors hold the same opinion as Japanese on the definition of early CRC, and have established a classification slightly different from the Japanese one. Up to now there has been no comparative study on endoscopic classification of early CRCs between Japan and China. lt is unclear whether Japanese classification can be easily understood and used outside of Japan[16]. This study was conducted in an attempt to clarify these questions and, particularly to evaluate the validity and feasibility of the current Japanese classification.

MATERIALS AND METHODS

Ten typical cases of early CRC were selected in this study from the Second Department of Internal Medicine in Osaka Medical College, Japan. All the diagnoses were proved pathologically, according to the results of nine adenocarcinomas and one adenoma. Five Japanese and five Chinese expert endoscopists were asked to review the colonoscopic pictures of these cases, including those before and after indigocarmine spraying. After viewing the pictures, all the endoscopists individually made their classificatory diagnosis of these cases and indicated the findings on which they based for each classificatory diagnosis. In addition, Chinese doctors were also asked for a comment on the current Japanese classification.

Doctors included in this study all majored in gastroenterological endoscopy. Hereafter their names were alphabetically listed as follows: Ichiro Hirata, Masahiro Itoh, Hiroshi Kashida, Hideki Mitooka, Seiji Shinmizu, Shu-dong Xiao, Zhao-min Xu, Zhong- lin Yu, Zhi-hong Zhang and Ren-min Zhu. The current Japanese classification, established by Japanese Research Society for Cancer of Colon, Rectum and Anus, was used as the referring classification in this study[17].

RESULTS

The results of classification are shown in Table 1. From Table

1, the following differences were indicated in macroscopic classification between Japanese and Chinese doctors.

Table 1 Differences in classification of 10 early CRCs between Japanese and Chinese endoscopists

Case	Classificatory diagnosis	
	Japanese (5)	Chinese (5)
1	IIa+IIc(5)	Is(4), IIa+IIc(1)
2	IIa+IIc(4), Isp+llc(1)	Isp(3), Isp+IIc(1), IIa(1)
3	IIc+IIa(3), IIc(2)	IIc+IIa(4), IIc(1)
4	IIc+IIa(3),IIa+IIc(1),IIa+dep.(1)	IIa+IIc(3), IIc+IIa(2)
5	IIa+dep.(3), IIa(2)	IIa+IIc(3), IIa(2)
6	Ip+IIc(4), IIa+IIc(1)	Ip(3), Ip+IIc(1), IIa+IIc(1)
7	LST(3),IIa agg. (2)	IIa
8	IIa(3), LST(2)	IIb(3), IIa(2)
9	LST(3), IIa(1), IIc(1)	IIc(3), IIb(1), IIa+IIc(1)
10	LST(3), IIa(1), IIc+IIa(1)	IIc+IIa(4), IIa(1)

[a]The numbers in parentheses are numbers of endoscopists; [b]IIa agg. IIa aggregating type.

Distinctly elevated lesions between type I and type II

Case 1 was a distinctly elevated lesion with a diameter of 15 mm and a height of 3.6 mm. The central depression became clear after indigocarmine spraying. This one was classified as IIa plus lIc by all the five Japanese and one Chinese endoscopists, while it was regarded as Is by other four Chinese endoscopists. Case 2 was a protruded lesion with a central depression. The diameter and height were 10 mm and 5.5 mm respectively (Figure 1). It was diagnosed as type IIa plus lIc by all but one Japanese endoscopist, while classified as lsp by three of five Chinese endoscopists. One Japanese and one Chinese endoscopist diagnosed it as Isp plus IIc, while one Chinese endoscopist classified it as IIa.

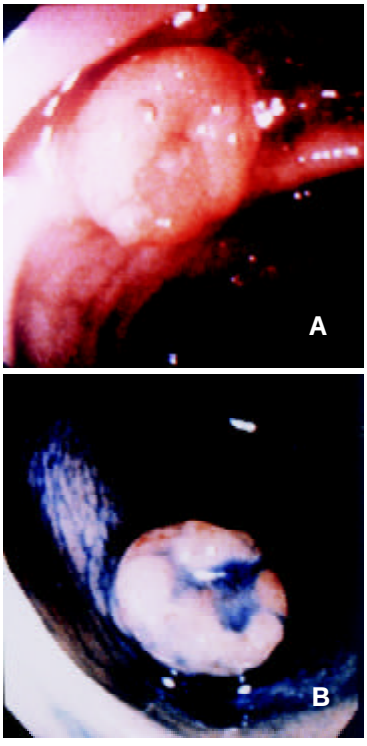

Figure 1 Submucusal adenocarcinoma with a diameter of 10 mm and a height of 5.5 mm. A: before indigocarmine staining, B: after indigocarmine staining.

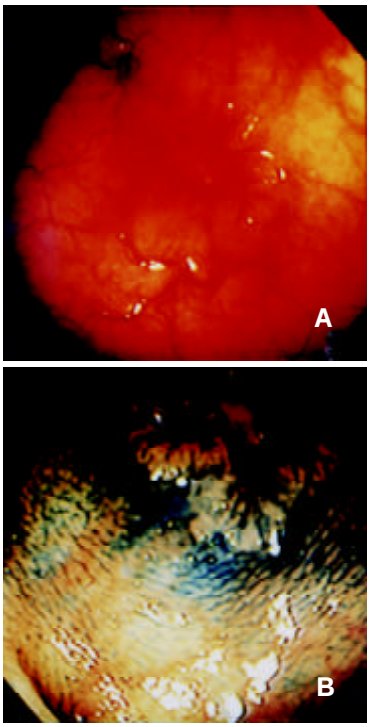

Figure 2 Mucosal adenocarcinoma with a diameter of 13 mm and a height of 1.5 mm. A: before indigocarmine staining, B: after indigocarmine staining.

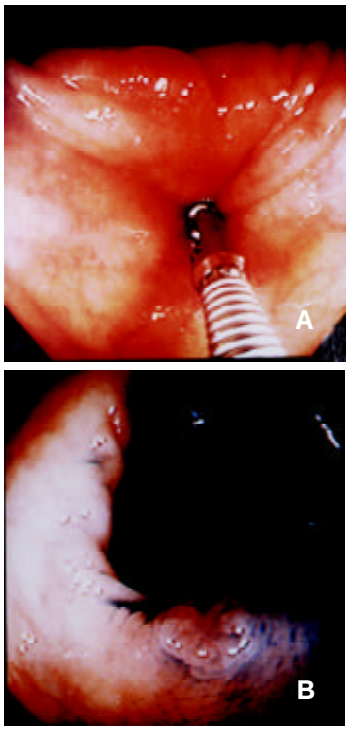

Figure 3 Adenoma with a diameter of 5 mm. A: before indigocarmine staining, B: after indigocarmine staining.

Superficial lesions consisting of elevation with depression

Case 3 was a typical superficially depressed lesion, with a slight circumferential elevation (1.5 mm), which was ambiguous before indigocarmine spraying (Figure 2). Three Japanese and four Chinese endoscopists diagnosed it as IIc plus IIa, while the rest three endoscopists classified it as IIc. Case 4 was a superficial lesion consisting of elevation plus central depression, and it was difficult to judge which part was larger even after indigocarmine spraying. Three Japanese and two

Chinese endoscopists classified it as IIc plus lIa, three Chinese and one Japanese endoscopists classified it as IIa plus IIc, and one Japanese endoscopist diagnosed it as IIa plus depression.

Superficial lesions consisting of elevation with linear depression

Case 5 was a small adenoma consisting of elevation with linear depression (Figure 3). Three Japanese endoscopists diagnosed it as IIa plus depression, while three Chinese endoscopists classified it as IIa plus IIc. The other two Japanese and two Chinese endoscopists diagnosed it as IIa.

Type I lesions with depression on the top

Case 6 was a protruded lesion with a peduncle and a depression on the center of the top (Figure 4). All but one Japanese endoscopist diagnosed it as Ip plus IIc, while three Chinese classified it as Ip. One Chinese endoscopist agreed with most Japanese, while one Japanese and one Chinese endoscopist classified it as IIa plus IIc.

Laterally spreading tumors

Case 7 was an extensively superficial elevated lesion with a diameter of 26 mm. Three Japanese doctors diagnosed it as LST granular type, and the other 2 Japanese doctors classified it as IIa aggregating type. However, five Chinese doctors all regarded it as IIa (Figure 5).

Case 8 was also a superficially elevated lesion with a diameter of 15 mm. The surface was rather smooth as compared to Case 7. Two Japanese endoscopists regarded it as LST non-granular type, three Chinese endoscopists diagnosed it as II b, while the rest five doctors classified it as IIa.

Case 9 was an extensive superficially elevated lesion with some depression, its diameter was 20 mm. Three Japanese doctors diagnosed it as LST plus "pseudo-depression", while three Chinese and one Japanese doctor regarded it as IIc. The rest doctors classified it as IIb, IIa, or IIa plus IIc, respectively.

Case 10 was also a superficial lesion extending horizontally with some depression, which was regarded as "pseudo-depression" in LST by three Japanese doctors. One Japanese and 4 Chinese doctors classified it as II c plus IIa (Figure 6).

Figure 4 Submucosal adenocarcinoma with a diameter of 8 mm. A: before indigocarmine staining, B: after indigocarmine staining.

Figure 5 Mucosal adenocarcinma with a diameter of 26 mm. A: before indigocarmine staining, B: after indigocarmine staining.

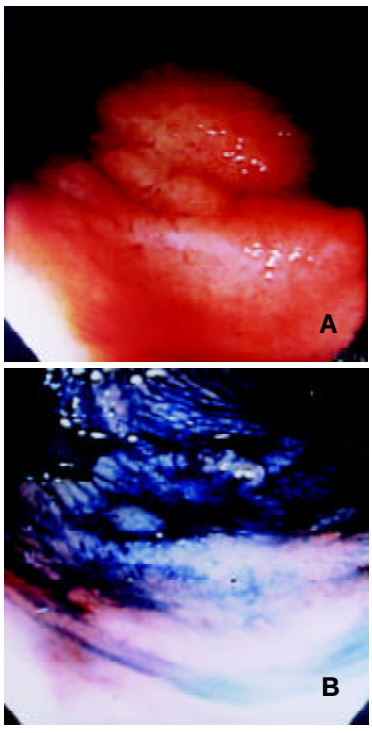

Figure 6 Submucosal adenocarcinoma with a diameter of 28 mm. A: before indigocarmine staining, B: after indigocarmine staining.

DISCUSSION

The endoscopic classification of early CRC in China was established on the basis of the Japanese classification for early gastric cancer, and has remained unchanged so far[18]. The Japanese classification, however, was developed 30 years ago and has been modified continually since then. Even so, the discrepancies are still common among Japanese colonoscopists, especially on the classification of type II lesions consisting of

elevation plus depression[19]. This was illustrated best in a recent panel discussion in Japan[20,21]. Most doctors in China regard the current Japanese classification as a comprehensive one, although some new concepts seem to be complicated and confusable. One of the differences between two classifications is that IIb, IIc and IIc plus IIa are not included in the Chinese one, for lack of such experiences in China[22]. Moreover, Chinese endoscopists are not familiar with the concept of IIa plus depression and LST. Actually, reports on superficial early CRC are few in China, which deal with depressed type. Most early CRC cases reported by Chinese endoscopists were the so-called local canceration of polyps and/or adenomas, which were diagnosed mainly after endoscopic polypectomy[23]. All these facts may explain why there are some differences in endoscopic classification of early CRC between doctors from two countries.

Some elevated lesions classified as type II in Japan might be diagnosed as Is or Isp by Chinese endoscopists. Case 1 and Case 2 were two examples. It should be emphasized that the definitions of type I and type II are exactly the same in Japan and in China. Therefore, the difference here was not in terminology but in interpretation of the same findings. In other words, the judging criteria for the height of a lesion were not the same in two countries. It is suggested that IIa should be the lesion with its height/diameter less than 1/2, therefore those with their height/diameter lager than 1/2 should be included in type I[24]. Now that the ratio for case 2 is 5.5/10, just a little bit larger than 1/2. It might be difficult to measure the accurate height of a lesion during endoscopic examination because of air-induced deformation[25]. This might be one of the reasons why international and interobserver differences occurred in the classification of such lesions.

For lesions that consist of superficial elevation plus superficial depression, many (if not all) Japanese endoscopists may classify them as IIa plus llc or IIc plus IIa, according to the ratio of elevation/depression, i.e. the large one is regarded as the main part and described first[26,27]. This is also the case in China[18]. Although international difference is not significant, interobserver differences still exist in classifying these lesions, which were indicated in case 3 and case 4.

In Japan, IIa plus depression has been used to refer to a small superficially elevated lesion with pseudo-depression or linear depression, which is always found to be adenoma pathologically[28]. This kind of lesion may appear to be IIa plus IIc or IIc plus IIa after dye spraying, although it has no well-demarcated depression. However, the current Chinese classification is not comprehensive, and does not include IIa plus depression. Furthermore, many new techniques such as chromoendoscopy or magnifying endoscopy has not been widely used in China[29,30]. Although the current Japanese classification was presented to the Chinese endoscopists, the definition of IIa plus depression might be too difficult to be understood completely in such a short time. There is no wonder that some Chinese endoscopists either overestimated the linear depression or simply neglected it, thus case 5 was diagnosed of either as IIa plus IIc or as IIa.

Similarly, to a protruded lesion with depression on the top, many Chinese endoscopists either not knew or simply neglected the depressed parts, thus diagnosed it as Is, Isp or Ip, while it should be classified as Is plus IIc, Isp plus IIc and Ip plus IIc, respectively according to most Japanese colonoscopists[31]. This tendency was indicated in case 1, case 2 and case 6.

LST, according to the definition recommended by Kudo, refers to a superficially elevated lesion that mainly grows horizontally rather than vertically, and its largest diameter is no less than 10 mm[32]. It is also suggested that LST should be classified into two subtypes, granular and non-granular, and the former may be further divided into homogeneous and mixed nodular. Our results indicated that international as well as inter-observer discrepancies were significant in the classification of such lesions. For case 7, the so-called mixed nodular LST or IIa aggregating type in Japan, Chinese endoscopists usually diagnosed it as IIa, though they also pointed out that it was a clustered nodular lesion[33]. The difference here might be just a difference in terminology.

Interestingly, three out of five Chinese endoscopists classified case 8 as IIb, which was regarded as LST non-granular type by most Japanese doctors. IIb has been defined as a lesion that is on the same level with the surrounding normal mucus in both Japanese and Chinese definition[34,35]. That is to say, Chinese endoscopists might have overlooked or simply neglected the slight elevation in case 8.

Case 9 and case 10 were rather complicated lesions, which were classified differently because the interpretations were different to the depressed parts of these lesions[36]. For those who classified them as LST, "pseudo-depression" was used to refer the depressed parts, and for those who classified them as IIc or IIc plus IIa, "authentic" rather than "pseudo" depression was interpretated, while for those who classified them as IIa, the so-called "pseudo-depression" was simply neglected.

In conclusion, differences in the endoscopic classification of early CRC do exist between Japan and China. In order to develop a universal endoscopic classification for early CRC, it needs for international communication and cooperation.

ACKNOWLEDGEMENTS

We thank Drs. Seiji Shinmizu, Masahiro Itoh, Hideki Mitooka and Hiroshi Kashida for their expert assistance in this study.

Abstract

AIM: Recent clinical epidemiological studies have demonstrated the preventive effect of non-steroidal anti-inflammatory drugs (NSAIDs) against colorectal cancer. The underlying mechanism might be the inhibition of rate-limiting enzyme cyclooxygenase-2 (COX-2) in metabolism of arachidonic acid. The role of COX-2 in carcinogenesis of colorectal cancer and its relationship with tumor biological characteristics and patients' prognosis still remain unclear. This study was to investigate the role of COX-2 expression in carcinogenesis of colorectal cancer and its relationship with tumor biological characteristics and patients' prognosis.

METHODS: A total of 139 colorectal cancers and 19 adenomas surgically treated in School of Oncology, Peking University, from January 1993 to September 2001 were retrospectively studied. COX-2 expression was detected with tissue microarray (TMA) and immunohistochemistry (IHC) procedure. The association between COX-2 expression and clinicopathological features and its influence on patients' prognosis were studied.

RESULTS: COX-2 expression was strong in colorectal cancer, moderate in adenoma and weak in normal mucosa, which demonstrated statistically significant difference (χ^2=46.997, P<0.001). COX-2 expression had no association with clinicopathological features such as gross type, differentiation, invasion depth, vessel emboli and TNM staging. Cox proportional hazards modeling analysis and Log rank test revealed no prognostic role of COX-2 expression in colorectal cancer patients.

CONCLUSION: COX-2 may play an important role in the early stage of carcinogenesis, and its expression in colorectal cancer is not associated with clinicopathological features and patients' prognosis.

INTRODUCTION

Cyclooxygenase (COX) is one of the rate-limiting enzymes in metabolism of arachidonic acid that catalyzes the arachidonic acid into a series of products such as prostaglandins and other eicosanoids. It has two isoforms, COX-1 and COX-2. COX-2 acts as both superoxidase and peroxidase that can transform arachidonic acid into PGG_2, then PGH_2. COX-2 is inducibly expressed in many human tissues by cytokines, oncogenes and tumor promoters[1-3]. Recent clinical epidemiological studies have demonstrated the preventive effect of COX inhibitors[4-6]. Cellular and animal experimental studies indicated its relevance to tumor invasion, metastasis, cell apoptosis, cell cycle, and body immunity[7]. Carcinogenesis and development of colorectal cancer are multistep and multistage processes involving cumulative effects of many genes[8,9]. It would contribute to cancer prevention and treatment to illuminate the role of COX-2 in the carcinogenesis of colorectal cancer.

MATERIALS AND METHODS

Patients and tissues

A total of 170 patients underwent surgical treatment in School of Oncology, Peking University, from January 1993 to September 2001 were retrospectively studied. All the patients including 70 males and 69 females (M:F=1.01:1) with median age 59 years (22-89) received pathological examination. There were 4, 12, 4, 3, 4, 6, 21 and 85 cases of the cancer located in ileocecum, ascending colon, hepatic flexture, tranverse colon, splenic flexture, descending colon, sigmoid colon and rectum, respectively. As to the invasion depth, one case was in mucosa, 5 in submucosa, 29 in muscularis propria, 60 in serosa or adventitia, 40 beyond serosa or adventitia or in adjacent tissue. All the patients were followed up till October 2001.

Another 19 cases of colorectal adenomas and 29 normal colorectal tissues concurrently resected were selected for study, including 8 tubular adenomas, 7 villous adenomas and 4 tubulavillous adenomas.

Tissue array preparation

Formalin-fixed and paraffin-embedded tissues were subjected to routine sectioning of 3-5 μm thickness and HE staining. Two typical tumor spots were chosen under microscopy for each case and marked on the corresponding spot on the tissue block. Then cyclinderic tissue columns were punctured with tissue arrayer (Beecher Instruments, USA) in the marked area and transferred to corresponding receiver pore of the prepared block. The tissue array block was then completed according to the predetermined scheme. The block was heated at 40 ℃ for 15 min and the surface was flattened for subsequent section of 5 μm thickness[10].

Immunohistochemical staining

Two step immunohistochemical staining was used for COX-2 detection. Tissue sections were dewaxed in xylene for 30 min, rehydrated through graded alcohol to PBS, then inmmersed in

3 % hydrogen peroxide at room temperature for 10 min to quench endogeneous peroxidase activity. After washed with PBS, the sections were subjected to antigen retrieval in boiling sodium citrite buffer (0.01M, pH 6.0) for 10 min (microwave 450W). After cooled at room temperature, and washed with PBS and distilled water sequentially, 100 μl of diluted anti-COX-2 murine antibody from Cayman Chemical, USA (1:200) was applied for each section. Then the slides were incubated overnight in a humidified chamber. After washed with PBS, each of the sections was incubated at 37 ℃ for 45 min with 100 μl of goat anti-mouse IgG from Zhongshan Biological Corp, Beijing, China. After washed with PBS again, the sections were subjected to sequential 3, 3-diaminobenzidine (DAB Kit, Zhongshan Biological Corp, Beijing, China) for immune complex visualization and then counterstained with haemotoxylin for 30 seconds. Formalin-fixed and paraffin-embedded sections of human colon carcinoma with strong staining served as positive control whereas PBS instead of antibody as negative control. The COX-2 staining was independently reviewed by two immunohistochemistry experts. Microscopically, the slides with no staining in negative control and specific dark yellow staining of cytoplasm and neuclear membrane in positive control were eligible for further analysis. Semiquantitative scoring system was adopted according to the staining intensity: 0 for no staining, 1 for weak yellow, 2 for dark yellow and 3 for brown staining with granular distribution. The mean score was used for statistical analysis and the threshold for positivity was 2[11].

Statistical analysis

All statistical analyses were carried out with SPSS software, 10.0, USA. The relationship between COX-2 expression and categorical variables was compared with χ^2 test or Fisher two-sided exact test. Continuous variables were analyzed with *t* test and $P<0.05$ was considered significant. Cox proportional hazards model and Log rank test as well as Kaplan-Meier were used for multivariate analysis of prognostic factors and survival estimation[12].

RESULTS

Localization of COX-2 protein

Immunohistochemical assay demonstrated that COX-2 protein was located in the cytoplasm and nuclear membrane. The staining was weak yellow, dark yellow and brown at a low power field and diffuse or granular staining at a high power field under microscopy (Figures 1A-C).

Expression of COX-2 in colorectal tissues

A weak staining of COX-2 was observed in normal tissue with a positive rate of 24.1 % (7/29). COX-2 expression was relatively stronger in adenoma and the rate of positivity was 57.9 % (11/19) (Figure 1D). COX-2 expression was much stronger in the tumor cells with dark yellow or brown staining with occasional granular distributions. Some sections revealed gradual staining escalation from normal mucosa, adenoma to carcinoma. 84.9 % of the cancer tissues scored not lower than 2 were considered positive, which much higher than those in normal and adenomatous tissues ($P<0.01$).

Relationship between COX-2 expression and clinicopathological factors of colorectal cancer

The study failed to find the correlation between COX-2 expression in tumor and factors such as age and gender of the patients, tumor location, size, gross type, differentiation, invasion depth, vessel emboli, lymph node metastasis, haemotogenous metastasis and TNM staging (Table 1).

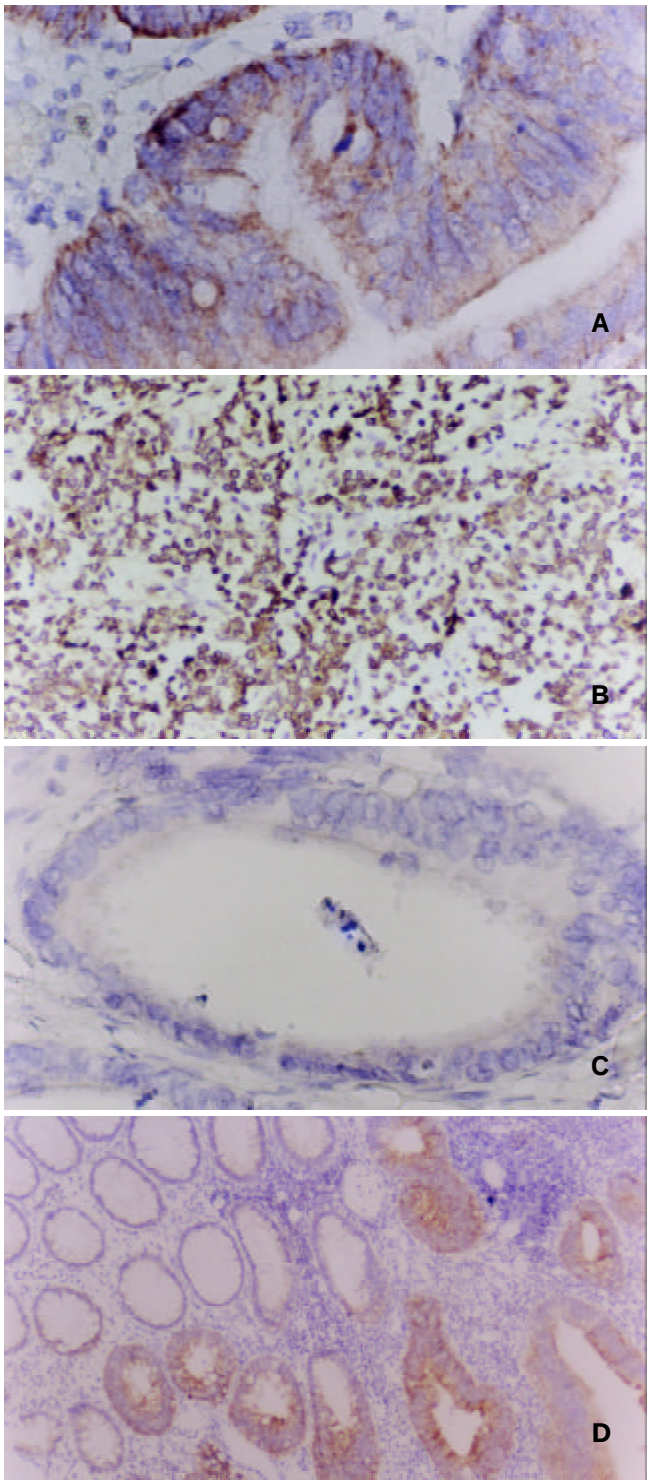

Figure 1 A: Well-differentiated adenocarcinoma of colon, COX-2 immunostaining, ×400; B: Poorly-differentiated adenocarcinoma of colon, COX-2 immunostaining, ×400; C: Negative control, COX-2 immunostaining, ×400; D: Adenoma of colon, COX-2 immunostaining, ×200.

Prognostic factor analysis of colorectal cancer patients

The median follow-up period was 55 months for the whole group (1-106 months). Two cases were missed and the follow-up rate was 98.5 %. Two and five-year survival rates of the whole group were 79.9 % and 61.6 %, respectively.

Eligible prognostic factors such as age and gender of the patients, tumor location, size, gross type, differentiation, invasion depth, vessel emboli, lymph node metastasis, COX-2 expression and TNM staging were introduced into the Cox proportional hazards model and analyzed using the backward:

wald method. The results demonstrated that TNM staging and vessel emboli were independent prognostic factors while COX-2 expression did not affect the prognosis of colorectal cancer patients (Figure 2).

Table 1 Relationship between COX-2 expression and clinicopathological factors in colorectal cancer

Item	Total	COX-2 positive	Positive rate (%)	χ^2 value	*P* value
Gender				0.557	0.455
Male	70	61	87.1		
Female	69	57	82.6

[b]refers to with *t* test, others with χ^2 test or Fisher two side exact test; [a]refers to that more than 25 % of the theoretical values were less than 5 and no statistical significance was reached even after the combination.

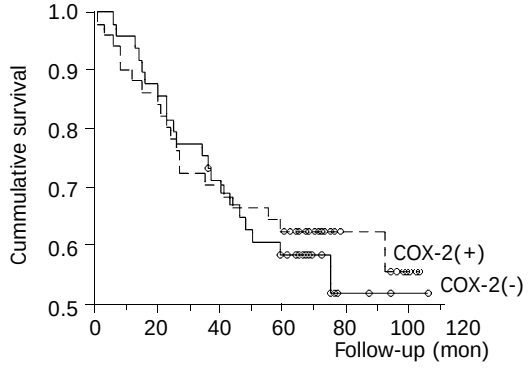

Figure 2 COX-2 expression and patients' survival (Kaplan-Meier curve).

DISCUSSION

Cumulative studies have demonstrated that COX-2 plays an important role in the carcinogenesis and development of many kinds of human cancers such as colorectal cancer[7,13], gastric cancer[14,15], lung cancer[16] and esophageal cancer[17]. Most of the colorectal cancers are derived from adenomas. Many genes are involved in the course from normal colorectal mucosa, adenoma to cancer such as APC, DCC, p53, etc[9,18-23]. The rate of COX-2 expression increases with the course of cancer development. As identified in our study, we found that most normal tissues with negative or weak positive staining had a positive rate of 24.1 % (7/29), adenomatous tissues stained stronger had a positive rate of 57.9 % (11/19), while the positive rate in cancer reached 84.9 %. A statistically significant difference existed (χ^2=46.997, P<0.001) among the three groups. In addition, some sections revealed a significant trend of gradual staining escalation from normal mucosa, adenoma to carcinoma. The present data indicated that COX-2 might be involved in early carcinogenesis, which was also supported by animal experiments. Oshima *et al*[24] found that when the COX-2 gene in a familiar adenomatous polyposis mouse model Apc Δ 716 was knocked out, the number of colon polyps decreased and the size reduced significantly. The same inhibitory effect was noted when the specific COX-2 inhibitor was used[13,25]. As stated in the prospective study on 60 000 people, the relative risk factor for colorectal cancer was reduced to 0.60 when more than 16 tablets of aspirin, a non-specific COX-2 inhibitor, was taken daily[4]. This conclusion was verified by subsequently prospective randomized trials[5,6,26,27].

The characteristics of invasion and metastasis are acquired when carcinogenesis of epithelial cells in colon mucosa occurs. Thus cancer cells might invade through the mucosa, submucosa, muscularis propria and even the adventitia to the adjacent tissues. When blood and lymphatic vessels are invaded, metastasis might occur. Invasion and metastasis are also a multistage process[28] involving many genes including COX-2. Caco-2 cell line, when transfected with COX-2, acquires increased invasiveness. It was found that COX-2 overexpressing Caco-2 cells increased about 6 times in its ability of invasion and had more lateral extension. Furthermore, metallioproteinase-2 was activated and the expression of membrane-type metallioproteinase also increased 2.8 times than the control[29], indicating the involvement of COX-2 and its metabolites in tumor invasion[30]. Tomazawa *et al*[31] injected mouse cell line colon-26 into the tail vein of VALA/C mice with simultaneous administration of JTE-52, a selective COX-2 inhibitor, into the abdominal cavity. The results showed that JTE-52 group with COX-2 overexpression had less lung metastasis than the control, but no difference was found in the group with low COX-2 expression. Therefore, COX-2 expression might be associated with metastasis of colorectal cancer, especially haematogenous metastasis.

Few clinical data are available on the relationship between COX-2 expression and clinicopathological characteristics of colorectal cancer. Thus we carried out this study in 170 colorectal cancer patients surgically treated in our institution with tissue microarray assay and tried to illustrate the relationship between COX-2 expression and clinicopathological factors of colorectal cancer. For certain reasons, only 139 cases could be analyzed and 84.9 % of the cases were positively stained according to our modified criteria of staining intensity, which combined the Masanaga' s criteria[11] with characteristics of tissue microarray technique. Among the 107 cases of advanced colorectal cancer, the expression rate of COX-2 was 86.1 %, 84.1 %, 92.3 % in stages II, III, and IV respectively. Even in stage I, COX-2 expression could reach 81.3 %. The data

indicated that COX-2 expressed high in cancer tissues. Further analysis showed that COX-2 protein expression increased with the invasion depth, its positive rate was 80 %, 82.8 %, 85 % to 86.4 % from submucosa, muscularis, serosa/adventitia to extraserosa/extraadventitia and adjacent tissues respectively, though it did not reach statistical significance (P=0.910).

Two pathways for colorectal cancer metastasis are the lymphatic and haemotogenous pathways. Masunaga *et al*[11] reported that there was a significant difference between the two groups with less or more than 3 metastatic lymph nodes based on their study in 100 patients. However, no statistical difference was found between the two groups with/without or <3 or ⩾3 lymph nodes metastasis in our study. It was inconsistent with the results of Masunaga *et al*[11]. One hundred and twenty-two colorectal cancer patients had no haemotogenous metastasis preoperatively. Forty cases of haemotogenous metastasis were found at the end of follow-up, in which 32 COX-2 positive patients had carcinoma (32/107) while 8 out of 19 COX-2 negative patients had haemotogenous metastasis. Still no correlation was found between COX-2 expression and haemotogenous metastasis. Contrary to our results, Tomozawa *et al*[32] from Japan demonstrated that COX-2 expression was correlated with haemotogenous metastasis especially in the recurrence of colorectal cancer both in clinical studies and in animal experiments. High COX-2 expression group showed a higher rate of haemotogenous metastasis. As an explanation, tumor invasion and metastasis are such a complex course that involves multiple genes. Thus, the role of one single gene should be carefully evaluated.

Few studies are available on COX-2' s role as a prognostic factor, and there are still different opinions[11,31]. Reports from Tomazawa *et al*[32] indicated that COX-2 expression was the only significant prognostic factor while the traditional TNM staging did not reach statistical significance. Our study introduced 13 eligible prognostic factors such as age and gender of the patients, tumor location, size, gross type, differentiation, invasion depth, vessel emboli, lymph node metastasis, COX-2 expression and TNM staging into the analysis, and found that TNM staging and vessel emboli could serve as independent prognostic factors instead of COX-2 expression. This was consistent to the results from Masunaga *et al* that also demonstrated that prognosis involved many factors and many genes, and expression of one single gene was not sufficient to determine the patients' prognosis.

In conclusion, our study found that COX-2 protein expression increased gradually from normal tissue, adenoma to carcinoma and no association existed between COX-2 expression and clinicopathological factors as well as prognosis of colorectal cancer patients. Therefore, it is concluded that COX-2 may play an important role in the early stage of carcinogenesis. Though involvement of COX-2 has been established, further study is needed to clarify its role in the development of colorectal cancer.

Abstract

AIM: To study the effects of non-cytotoxic concentrations of docetaxel on some important angiogenic factors of LS174T Cells.

METHODS: The non-cytotoxic concentration of docetaxel and the activity of gelatinase were determined with MTT and gelatin zymography respectively, the expression of VEGF (vascular endothelial growth factor), bFGF (basic fibroblast growth factor), MMP (matrix metalloproteinase) 2 and MMP 9 was investigated with RT-PCR and Western blot.

RESULTS: The maximum non-cytotoxic concentration of docetaxel on LS174T Cells was 1.0 ng/ml. Compared with the solvent control group, 0.1, 0.5, 1.0 ng/ml of docetaxel could downregulate the expression of VEGF, bFGF, MMP 2 and MMP 9 and suppress the activity of gelatinase.

CONCLUSION: Our study suggests that the non-cytotoxic concentrations of docetaxel have strong antiangiogenic activity on LS174T Cells, which suggests docetaxel may be a promising antiangiogenic agent.

INTRODUCTION

It has been demonstrated that angiogenesis is vital to the growth and metastasis of human cancers, thus it represents a potential therapeutic target and has become a new spotlight in tumor study fields[1-7]. Colorectal carcinoma is one of the most common malignant tumors, and the present therapeutic methods such as surgery, chemotherapy and other adjuvant methods have their own limits. Previous studies showed that the growth and metastasis of colorectal carcinoma depended intimately on angiogenesis as well[8-10], thus it is important to explore a potential way of inhibiting angiogenesis to increase its cure rate. Docetaxel, which is derived from Taxus baccata, is a cytoskeleton toxic chemotherapeutical agent. It can break the dynamic equilibrium of mitosis and cell division, hence it can induce apoptosis by preventing microtubule disassembly after binding to tubulin[11-13]. It has been proven to have positive effects on tumors such as non small cell lung cancer (NSCLC), breast cancer, ovarian cancer and some other refractory and metastatic cancerous diseases. Recently, docetaxel has been proven to hold antiangiogenic activity[14,15], but whether its antiangiogenic properties are linked to its cytotoxic role or not remains unclear, and we know little about its mechanism as yet. In this communication, our aim was to explore the effects of non-cytotoxic concentrations of docetaxel on VEGF, bFGF, MMP' s expression of LS174T Cells *in vitro*.

MATERIALS AND METHODS

Judgment of non-cytotoxic concentration of docetaxel

Docetaxel (Rhone-Poulenc Rorer, France) was disolved in solvent vehicle (13 % ethanol), then diluted to working concentrations of 0.1, 0.01 μg/ml with sterilized normal saline (NS). LS174T Cells (Shanghai Institute of Cell Biology, Chinese Academy of Sciences) were cultured in RPMI 1640 (Gibco BRL) supplemented with 10 % fetal bovine serum. The cultured cells were seeded on a 96-well plate with 5 000 cells in each well. 72 h later, at 80 % confluency, the culture medium was changed to the RPMI 1640 containing 1 % bovine serum, docetaxel solvent various concentration of docetaxel were added. The experiments were divided into docetaxel solvent control group and docetaxel 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0 ng/ml groups. 24 h later, 15 μl MTT [3-(4, 5-dimethylthiazol-2-yl)-2, 5-dipheny-ltetrazolium bromide] was added into each well, and the cells were incubated for another 4 h, then the fluid was cast, 150 μl DMSO was added. After vibrated for 10 min, the 490 nm absorpance value was determined with microplate reader apparatus (Labsystem Wellscan-MK-3, Finland). The ratio value of each group and the blank control group was taken as the relative MTT A value. Finally, we determined the maximum non-cytotoxic concentration of docetaxel on LS174T Cells and the trypan blue staining results.

Gelatin zymography

The cultured LS174T Cells at 80 % confluency were treated with docetaxel solvent and various concentrations of docetaxel. The cells were classified into docetaxel solvent control group and docetaxel 0.1, 0.5, 1.0 ng/ml group. 24 h later, we collected the supernatant of the cells, and concentrated it with Amicon filters to 10 % of initial volume. Each sample was guaranteed to contain the same amount of total protein, gelatin zymography was performed in 10 % polyacrylamide in the presence of 0.1 % gelatin as described previously[16-18]. Identification of transparent bands at 92 000 and 72 000 dalton on the Coomassie blue background of the slab gel was considered positive for the presence of enzymatic activity. The collagenase activity was semi-quantified with densitometry of Image Quant software program.

Western blot

The cell culture, drug treatment and groups classified methods

were the same as the gelatin zymography experiment. All samples containing 10 μg total proteins were loaded into 7.5 % polyacrylamide-SDS gel, electrophoresed for 3 h (apparatus of Amersham Pharmacia Biotech), and transferred onto the nitrocellulose membrane. The membrane was subjected to immunoblotting with anti-mouse monoclonal antibody MMP 2 and MMP 9 or anti-rabbit polyclonal antibody VEGF and bFGF (Oncogene corp), then conjuncted with the second antibody anti-mouse IgG-HRP or anti-rabbit IgG-HRP (Santa Cruz Biotechnology, California). Immunodetections were carried out using Western blot chemiluminescence reagent (Santa Cruz Biotechnology, California). The target bands of the gel were semi-quantified by using densitometry of image Quant software program. The ratio value of each group and the blank control group was taken as the relative value.

RT-PCR

The cell culture, drug treatment and group classified methods were the same as the gelatin zymography experiment. Total RNA (extract kit of QIAgen) extracted from LS174T Cells was transcribed into cDNA (Roche), reverse transcription reaction was performed at 42 ℃ for 60 min, then denaturated at 94 ℃ for 5 min. The cDNA was then amplified with PCR by using Taq DNA polymerase. PCR (apparatus of Hybaid) was performed for 32 cycles with denaturation at 94 ℃ for 50 s, annealing at 55 ℃ for 45 s, and elongation at 72 ℃ for 50 s, and extension for 7 min after completion of all cycles. The amplified PCR products were analyzed on 1 % agarose gel electrophoresis after stained with ethidium bromide. PCR primers (Saibaisheng, China) used to detect each factor were as follows: VEGF, sense strand 5'-CACATAGGAGAGATGAGCTTC-3', antisense strand 5'-CCGCCTCGGCTTGTCACAT-3', the length of product was 210 bp; bFGF, sense strand 5'-TGGTATGTGGCACTGAAACG-3', antisense strand 5'-CTCAATGACCTGGCGAAGAC-3', the length of product was 734 bp; MMP2, sense strand 5'-CCTGGGCAACAA ATATGAGA-3', anti- sense strand 5'-ACAGTCCGCCAA ATGAACC-3', the length of product was 426 bp; MMP9, sense strand 5'-TCCCTGGAGACCTGAGAACC-3', antisense strand 5'-GTCGTCGGTGTCGTAGTTGG-3', the length of product was 659 bp; GAPDH, sense strand 5'-ATCCCATCACCATCTTCCAG-3', antisense strand 5'-ATGAGTCCTTCCACGATACCA-3', the length of product was 310 bp. The quantified method of target PCR products was the same as above. The ratio value of each group and the GAPDH group was taken as the relative value.

Statistical analysis

Data were expressed as mean ±SD. Significant differences were determined by using ANOVA in statistical software SPSS10.0. The level of significance was $P<0.05$.

RESULTS

Non-cytotoxic concentration of docetaxel

The mean relative MTT A values of blank control group, docetaxel solvent control, 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0 ng/ml groups were 1.000±0.17, 0.995±0.28, 0.993±0.15, 0.990±0.18, 0.985±0.14, 0.981±0.11, 0.848±0.12, 0.657±0.08, 0.485±0.06 respectively. There were no significant differences between the first six groups ($P>0.05$), there were significant differences between other groups ($P<0.01$) (Table 1). Combined these with the trypan bule staining results, we determined 1.0 ng/ml as the maximum non-cytotoxic concentration of docetaxel to LS174T cells in the present study.

Gelatin zymography

Gelatin zymography result revealed prominent 92 000 and 72 000 dalton bands (Figure 1), there was expression of MMP2 and MMP9 in the LS174T cells culture supernatant. The semi-analysis results showed that 0.1, 0.2, 0.5, 1.0 ng/ml docetaxel could downregulate two matrix metalloproteases, the activity of MMP9 was higher than that of MMP2, there were significant differences between these groups.

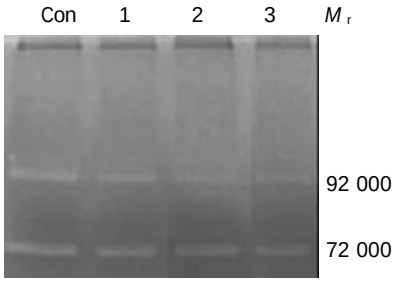

Figure 1 Inhibition of gelatinase activity of LS174T cell by docetaxel. After treated with 0.1, 0.2, 0.5, 1.0 ng / ml concentration of docetaxel,the activity of MMP2 AND 9 was inhibited. Representative results from three independent experiments: Con. docetaxel solvent control group; 1-3: 0.1, 0.5, 1.0 ng / mL concentrations of docetaxel.

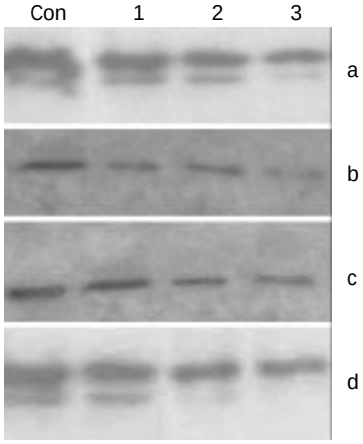

Figure 2 Inhibition of expression of proteins of LS174T cell by docetaxel. After treated with 0.1, 0.2, 0.5, 1.0 ng / ml concentration of docetaxel, the level of VEGF, bFGF, MMP2, MMP9 protein of LS174T cell was inhibited by docetaxel respectively. Representative results from three independent experiments. a. b. c. d. VEGF, bFGF, MMP2, MMP9 proteins (M_r. was 22 000, 18 000, 72 000 and 92 000) of LS174T cell; Con: docetaxel solvent control group, 1-3: 0.1, 0.5, 1.0 ng / mL concentrations of docetaxel.

Table 1 Effects of docetaxel on proliferation of LS174T ($\bar{x}\pm s$, $n=10$)

Group	Blank control	Solvent control	Docetaxel (ng / ml)						
			0.1	0.2	0.5	1.0	2.0	5.0	10.0
A Value	1.000±0.17[a]	0.995±0.28[a]	0.993±0.15[a]	0.990±0.18[a]	0.985±0.14[a]	0.981±0.11[a]	0.848±0.12[b]	0.657±0.08[b]	0485±0.06[b]

[a]$P>0.05$ *vs* between these groups, [b]$P<0.01$ *vs* other groups.

Western blot

The X-ray film was scanned (Figure 2), the semi-analysis results showed the amount of VEGF, bFGF, MMP2 and MMP9 decreased as the concentration of docetaxel increased, there were significant differences between these groups. The level of VEGF, MMP9 was higher than that of bFGF, MMP2.

RT-PCR

Agrose gel was scanned, the semi-analysis results showed the content of VEGF, MMP9 was higher than that of bFGF, MMP2, the content of bFGF was the lowest (Figure 3). The expression of VEGF, bFGF, MMP2 and MMP9 was inhibited by various concentration of docetaxel in a dose-dependent manner, and there were significant differences between these groups. However, steady state expression of GAPDH (as internal control) was observerd in all cases.

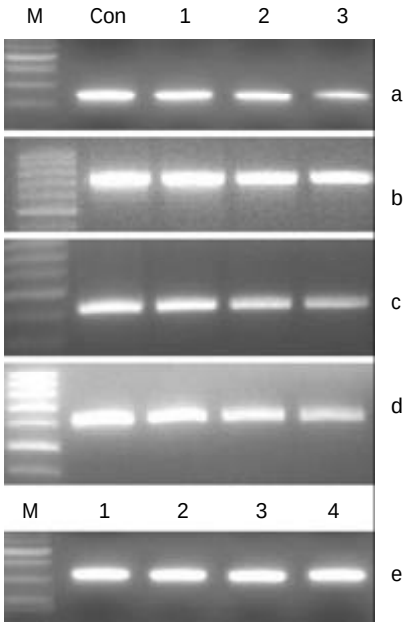

Figure 3 Inhibition of expression of mRNA of LS174T cell by docetaxel. After treated with 0.1, 0.2, 0.5, 1.0 ng/ml concentration of docetaxel, the level of VEGF, bFGF, MMP2, MMP9 protein of LS174T cell was inhibited by docetaxel respectively. Representative results from three independent experiments. a. b. c. d. e. VEGF, bFGF, MMP2, MMP9 mRNA and GAPDH (210 bp, 734 bp, 426 bp, 659 bp and 310 bp, 500 bp). Con: docetaxel solvent control group, a. b. c. d; 1-3: 0.1, 0.5, 1.0 ng/mL concentrations of docetaxel. M: marker, e; 1-4: internal control groups.

DISCUSSION

It has been demonstrated that the antitumor action of taxanes contributes to their antiangiogenic activity. Taxanes were found to inhibit angiogenesis by suppressing the proliferation, migration, and capillary formation of endothelial cells both in *in vitro* and *in vivo* models, it could inhibit the endothelial cells (HUVEC) migration with an IC50 of 0.01 nM[9,19-21]. However, little is known about the effects of docetaxel on angiogenesis related factors till now. Because of docetaxel's cytotoxic characteristic, it is important to verdict its non-cytotoxic concentration. Combined with MTT experiment and the trypan blue staining, our results indicated that 1.0 ng/ml was the maximum non-cytotoxic concentration of docetaxel in LS174T Cells.

LS174T Cells line, as a moderately differentiated adenocarcinoma with a moderately invasive ability, is one of very common colorectal carcinomas. Its characteristic is similar to that of most common carcinomas, so the present study holds definite clinical significance. And our study showed there was expression of VEGF, bFGF, MMP2 and MMP9 factors in the LS174T Cells at the gene and protein levels[22-26], which suggests angiogenesis may play a very important role in LS174T cells related tumors.

According to our current work, non-cytotoxic concentration of docetaxel could downregulate the expression of VEGF, bFGF in LS174T Cells, which are the triggers of angiogenesis. VEGF stimulates the degradation of ECM as well as the proliferation, migration and capillary formation of endothelial cells[23, 27-31], while bFGF has growth-stimulating and invasion-promoting effects on the angiogenesis process[32,33]. From the facts mentioned above, we suppose that the drug has a strong antiangiogenic action whose mechanism might be mainly related to the supressing effect on neoangiogenesis from the very beginning. Our results indicated that non-cytotoxic concentrations of docetaxel also could supress the expression of MMP2 and MMP9 and reduce their activities. MMP2 and MMP9 play a vital role in the turnover of basement membrane collagen type IV and type I which exert a crucial effect on the formation of new capillary sprouts and neoangiogenesis[15,34-36]. Baseing on the above facts, we speculate that the drug can prevent degradation of the vascular basement membrane, thus further inhibit neoangiogenesis.

We also found the inhibitory effects of docetaxel on VEGF and MMP9 are stronger than those on bFGF, MMP2. We suppose it owes to docetaxel's relative selectivity, or the higher level of VEGF and MMP9. In addition, there are complex correlating regulations among these four factors. And the direct and indirect effects of docetaxel cannot be distinguished clearly as yet, which well deserves further investigation.

Whether docetaxel's antiangiogenic property is linked to its cytotoxic role or not needs further elucidation. Schimming *et al*[37] determined whether inhibition of neoangiogenesis played a role in docetaxel's antitumor efficacy. Since no reduction in blood vessels occurred in tumors unresponsive to docetaxel, they thought the inhibition of neoangiogenesis in docetaxel responsive tumors was likely to be the result of a decrease in angiogenic stimuli due to docetaxel's cytotoxic action. Vacca *et al*[38] reported that both cytotoxic and non-cytotoxic doses of docetaxel displayed a dose-dependent antiangiogenic activity in the mouse embryo fibroblasts, human Kaposi's sarcoma, breast, endometrial carcinoma and lymphoid tumor *in vitro* and *in vivo*. Our results are in coincidence with theirs.

In conclusion, our study suggests that antiangiogenic property of docetaxel is not linked to its cytotoxicity. Docetaxel under cytotoxic concentration has strong antiangiogenic activity on LS174T Cells, with its mechanism mainly through the inhibitory effects on VEGF, bFGF and MMPs. Docetaxel in low concentration may be a promising antiangiogenic agent for tumor treatment.

Abstract

AIM: To investigate the therapeutic effect of umbilical cord blood transplantation (UCBT) on patients with severe viral hepatitis and on liver lesions in rats.

METHODS: One hundred and fifty three patients with severe viral hepatitis were included in the study between April 1990 and July 2002. The patients were treated with adult plasma transfusion (control), UCBT, plasma exchange (PE) and UCBT combined with PE (UCBT+PE) respectively. The therapeutic effectiveness was evaluated by serial determinations of liver function, lipids and immune function in all patients before and after the treatment. The model of experimental hepatic failure was constructed in SD rats by injecting carbon tetrachloride. Then, the rats were given normal saline, adult plasma or neonate cord blood intraperitoneally. After detection of liver function, the rats were killed and morphological changes of the liver were microscopically observed.

RESULTS: UCBT group and UCBT+PE group had much better improvement in liver and immune functions than control group and PE group. The patients in UCBT+PE group had the best clinical efficacy. UCBT was safe and had no side effects. The animal experiment showed significant improvements in liver function and survival rate in neonate cord blood group as compared with adult plasma group. The histopathology of rat's liver indicated that neonate cord blood application could decrease the liver injury and increase hepatocellular regeneration.

CONCLUSION: UCBT demonstrated a good therapeutic effect on severe viral hepatitis and no obvious side effects. Umbilical cord blood can attenuate the liver lesions and reproduce hepatocyte. The treatment of UCBT combined with PE was much better than that of single plasma exchange, thus UCBT can enhance the therapeutic effect of plasma exchange on severe viral hepatitis.

INTRODUCTION

In 1987, a child with Fanconi' s anaemia received an allogeneic transplant using the cryopreserved umbilical cord blood (UCB). As a result, the potential of UCB as a source of haemopoietic stem cells for transplantation rapidly became a field of intense clinical and scientific interest. Because UCB is a relatively easily available starting material, it has been increasingly used as an alternative source of hematopoietic stem cells in allogeneic transplantation. Many umbilical cord blood banks have been established. The engrafting cells in UCB are found to be significantly higher than those in adult bone marrow or in mobilized peripheral blood from normal donors. It has been found that multipotent adult progenitor cells (MAPCs) can differentiate into hepatocyte-like cells *in vitro*[1]. Neurons, astrocytes and oligodendrocytes can be propagated *in vitro* from UCB cells[2,3]. The evidences indicate that stem cells can differentiate into hepatocytes[4,5]. This study evaluated the therapeutic effectiveness of UCBT on severe hepatitis, and tried to find a new therapy for severe viral hepatitis.

MATERIALS AND METHODS

Grouping and treatment

One hundred and fifty-three inpatients with severe viral hepatitis were included in the study from April 1990 to July 2002. These patients had a history of hepatitis for more than 8 weeks, with severe hepatic dysfunction, rapidly progressive jaundice, abdominal distention, asthenia, ascites, coagulopathy, encephalopathy and hepatorenal syndrome. The patients were randomly divided into control (adult plasma) group: 39 patients (36 male and 3 female) with a mean age of 39.4 years (range 17-56 years), UCBT group: 38 patients (37 male and 1 female) with a mean age of 41.2 years (range 13-62 years), PE group: 45 patients (43 male and 2 female) with a mean age of 37.5 years (range 21-58 years), and UCBT+PE group: 31 patients (all were male) with a mean age of 43.2 years (range 13-65 years). The patients were treated with 200 ml of fresh adult plasma/ blood transfusion (in control group and PE group) or 200 ml of umbilical cord blood transplantation (in UCBT group and UCBT+PE group) intravenously each time, one to three times a week for two to four weeks. Plasma exchange given was 1 500-3 000 ml each time, one to three times every week and totally two to five times. The rate of plasma separation and the flow rate of plasma exchange were controlled at the speed of 5-15 mL/min and 15-25 mL/min, respectively.

Collection and storage of umbilical cord blood

Immediately after the birth of the baby, the umbilical cord was cut off and the baby was separated from the placenta and mother. A sterile needle was inserted into the umbilical vein and the placental blood was drawn into a sterile blood collection bag containing ACD-B anticoagulant, provided by Shanghai Blood Center. Once the collection was complete, the specimen was packaged and sent to blood bank for processing and storage at low temperatures. The maternal blood sample was also collected for infectious disease analysis.

Equipment
PE was performed with COBE Spectra™ Auto PBSC version 6.0 apheresis system (COBE BCT, Inc. Colorado, USA).

Animals and experimental design
Male SD rats, weighing 150 to 180 g, were purchased from the Laboratory Animal Center, Xiangya Medical College, Zhongnan University. On the first and second day carbon tetrachloride was injected into each rat (1 ml/100 g) intraperitoneally to establish an acute liver failure model. On the third day several rats were killed as acute liver failure models and the livers were taken for histopathological examination, the other 81 survived rats were randomly assigned to control group (n=24), normal saline group (n=16), adult plasma group (n=22), and neonate cord blood group (n=19). Rats in groups 2-4 were intraperitoneally given 1 ml/100 g· d^{-1} normal saline, adult plasma or neonate cord blood respectively for five days and no treatment was given in group 1. On the eighth day, after detection of the liver function, all survived rats were killed and sections of liver tissues were taken immediately for histopathological examination. Excised liver tissues were fixed in 10 % neutralized formaldehyde, embedded in paraffin, and then routinely stained with hematoxylin and eosin.

Statistical analysis
The data were expressed as means ± standard deviation ($\bar{x}\pm s$), and the differences between the value of different groups were analysed by the t test or χ^2 test (SPSS version 9.0). The criterion of significance was set at P<0.05.

RESULTS

Changes of patient's liver function
There was no difference in liver function (Alb, ALT, serum total bilirubin and prothrombin activity) among all the groups before treatment. Alb and prothrombin activity (PTA) were much lower than normal but serum total bilirubin (TBil) was remarkably higher than normal in all groups before treatment. Alb and PTA increased in all groups after treatment. As compared with control group, the degrees of Alb and PTA increase were higher in UCBT group, PE group and much higher in UCBT+PE group (P<0.05). The change of ALT level was not significant after treatment in all groups. Serum TBil contents significantly decreased after treatment in UCBT group, PE group and UCBT+PE group (P<0.05), (Table 1).

Influence of UCBT and PE on immune functions of the patients
Immune functions of the patients were markedly improved after treatment in UCBT group and UCBT+PE group. The values of $CD4^+$, active T lymphocytes and IL2 were significantly increased after treatment in UCBT group and UCBT+PE group (P<0.05). However no significant change of the values was observed in control group and PE group. There was no significant difference of $CD8^+$ lymphocytes before and after treatment in all groups (Table 2).

Side effect and safety
No side effect or negative response was found in UCBT group. Three patients in control group, ten patients in PE group and eight patients in UCBT+PE group had rashes during the treatment. Four patients had fever in PE group. No fatal side effect was observed in all groups.

Survival of rats
On the eighth day, 89.5 % (17/19) rats survived in neonate cord blood group, 54.5 % (12/22) in adult plasma group, 31.3 % (5/16) in normal saline group and 25.0 % (6/24) in control group respectively. The survival rate of rats in neonate cord blood group was significantly higher than that in adult plasma group (P<0.05), normal saline group and control group (P<0.01).

Biochemical parameters of rats
The serum levels of ALT and TBil in neonate cord blood group were significantly lower than those in adult plasma group (P<0.05), normal saline group and control group (P<0.01). Meanwhile the serum level of AFP in neonate cord blood group was significantly higher than that in the other three groups (P<0.01), (Table 3).

Histopathology of rats
Histopathology of model rats' livers revealed lobular disarray, ballooning degeneration, fatty degeneration, inflammatory cell infiltration in the portal zone and areas of parenchyma, cholestasis and massive necrosis of hypatocytes (Figure 1). All indicated that there was an acute liver failure in model rats. After five-day treatment of neonate cord blood, hepatocellular necrosis and mononuclear cell infiltration were greatly decreased and only spotty hepatocellular necrosis occurred. Meanwhile

obviously hepatocellular regeneration was observed in neonate cord blood group (Figure 2). There was no significant histopathological difference between control group and normal saline group. Multilobular necrosis and numerous lymphocytic infiltrations were noted, and no evident hepatocellular regeneration was demonstrated in control group and normal saline group (Figure 3). Local necrosis, moderate degree of lymphocytic infiltration and a few focal hepatocyte regenerations were observed in adult plasma group (Figure 4), (Table 4).

DISCUSSION

Severe hepatitis is the most ominous manifestation of viral hepatitis. The overall mortality rate of patients with severe hepatitis in stage III to IV coma averages 70-80 %. The management of severe hepatitis includes conventional medical management, plasma exchange, charcoal hemoperfusion, bioartificial liver system and liver transplantation, but the therapeutic effectiveness of all these therapies is not satisfactory. Thus, it is an urgent challenge to find a new reliable therapy for severe hepatitis. Umbilical cord blood (UCB) is the blood that remains in the placenta and umbilical cord after birth. Until recently the placenta and umbilical cord blood were discarded after delivery as a medical waste. The presence of hematopoietic progenitor cells (HPC) in UCB was demonstrated in 1974. Experimental evidences have shown that UCB is a rich source of hematopoietic stem/progenitor cells (HSPC). However, it was not until 1989 that experimental and clinical studies were published, indicating that human UCB could be used in clinical settings. In same year, the first hematopoietic cell transplant in which UCB was used instead of bone marrow as the source of hematopoietic cells was reported. The hematopoietic system of a child with Fanconi's anemia was reconstituted by means of UCB from an HLA-identical sibling. Since then, there has been an expanding interest in the use of UCB as an alternate source of HSPC for transplantation[6]. Some data suggested that UCB was a better source of hematopoietic stem cells than bone marrow[7]. Recipients of cord-blood transplants from HLA-identical siblings have a lower incidence of acute and chronic GVHD than recipients of bone marrow transplants from HLA-identical siblings[8]. Frozen immature human UCB cells can be stored for more than 15 years, and efficiently retrieved, and remain effective for clinical transplantation[9]. After injected into developing neonatal mouse brains, immunodepleted mouse stem cells (MSCs) differentiated into astrocytes and neurons[10].

Intravenous administration of human UCB can reduce neurological deficiency in the rat after traumatic brain injury[11]. Transplantation of genetically marked bone marrow into immunodeficient mice revealed that marrow-derived cells migrated into areas of induced muscle degeneration, underwent myogenic differentiation, and participated in the regeneration of damaged fibers[12]. Experiments demonstrated the cardiomyogenic potential of hematopoietic stem cells[13] and the presence of circulating stem cells with osteogenic and adipogenic differentiation potential in human UCB. Hematopoiesis and the hepatic environment are known to have a close relationship at the time of liver development and systemic diseases. Transplanted cells isolated from bone marrow of rodents and humans have been shown to differentiate into oval cells, which are considered to be hepatic stem cells and hepatocytes in the liver. Purified hematopoietic stem cells have been shown to be able to replace original liver cells in mice with hereditary tyrosinemia. Intravenous injection of adult bone marrow cells in the $FAH^{-/-}$ mouse rescued the mouse and restored the biochemical function of its liver[14]. Hematopoietic stem cells can contribute to the hepatocyte lineage in humans and in rodent models of liver disease and regeneration[15] and adult human liver cells can derive from stem cells originating in the bone marrow or circulation outside the liver[16-18]. Hepatocytes can derive from bone marrow cells after irradiation in the absence of severe acute injury[19]. Adult bone marrow cells have tremendous differentiating capacity as they can also differentiate into epithelial cells of the liver, lung, GI tract, and skin[20, 21]. Human mesenchymal stem cells are thought to be multipotent cells, which are present in adult marrow, that can replicate as undifferentiated cells and have the potential to differentiate to lineages of mesenchymal tissues, including bone, cartilage, fat, tendon, muscle, and marrow stroma[22]. Transdetermination consequent to cell fusion could underlie many observations attributing to an intrinsic plasticity of tissue stem cells[23,24].

UCB can easily be collected and cryopreserved and has a number of significant advantages over bone marrow such as no risk to the donor, no donor attrition, minimal risk of viral transmission, immediate availability, high rate of engraftment, more tolerant of tissue mismatches and lower rate of rejection.

In the present study, we observed that TBil content reduced and Alb, PTA increased after treatment in all groups, especially in UCBT group, PE group and UCBT+PE group. The best therapeutic effectiveness was shown in UCBT+PE group. The effects of reducing Tbil content and increasing Alb and PTA in UCBT+PE group were more significant than those in control group ($P<0.01$) and PE group ($P<0.05$). This indicates that UCBT can enhance the therapeutic effectiveness of PE on severe hepatitis. Although the effect in UCBT+PE group was also better than that in UCBT group, the difference was not significant ($P<0.05$). The therapeutic effectiveness in UCBT group was significantly better than that in control group ($P<0.05$), indicating that UCB can more effectively improve liver function than adult plasma. The reason may be that stem cells derived from UCB can differentiate into hepatocytes and cholangiocytes in a culture system simulating liver regeneration and containing cholestatic serum, which is similar to the condition of patients with severe hepatitis[25-28].

We also found that active T lymphocytes, $CD4^+$ lymphocytes and IL2 were evidently increased after treatment in UCBT group and UCBT+PE group, but no significant improvement of immune function was found in control group and PE group. The results indicate that UCB can improve the immune function of patients with severe hepatitis. It may be because stem cells derived from UCB can differentiate into lymphocytes and reconstitute thymic function[29-32].

The animal experiment demonstrated that the survival rate of rats in neonate cord blood group was significantly higher than that in adult plasma group ($P<0.05$), control group and normal saline group ($P<0.01$), and the ALT and TBil values in neonate cord blood group were obviously lower than those in control groups, saline group ($P<0.01$) and adult plasma group ($P<0.05$). The histopathological examination of rats' livers showed that only mild hepatocyte necrosis and mononuclear cell infiltration were present in the rats of neonate cord blood group after treatment, but massive hepatocyte necrosis and numerous lymphocytic infiltrations were found in other groups. There was obvious hepatocellular regeneration in neonate cord blood group after treatment. However, there was only a few local hepatocellular regenerations in adult plasma group and no hepatocellular regeneration in normal saline group and control group after treatment. All of these indicate that neonate cord blood can protect liver, decrease hepatic injury and promote hepatocellular regeneration. It implies that there are some liver regeneration stimulating factors in neonate cord plasma and some stem cells in neonate cord blood can differentiate into hepatocytes.

Moreover, no side effect or negative response was found in the patients of UCBT group during whole treatment. It showed a high safety in UCB administration. Transient fever, rash and allergic shock were noticed in some patients in control group, PE group and UCBT+PE group. The results indicate that UCBT is much safer than adult fresh plasma transfusion.

In conclusion, this study shows that UCBT can improve liver function and immune function of patients with severe hepatitis, enhance the therapeutic effectiveness of PE, alleviate hepatic injury and promote hepatocellular regeneration. The study indicates that UCBT is a new reliable and safe therapy for severe hepatitis.

Abstract

AIM: To investigate the role of hepatitis B virus (HBV) in the pathogenesis of IgA nephropathy (IgAN).

METHODS: HBV antigens (HBAg, or HBsAg, HBcAg, and HBeAg) in renal tissues with IgAN were detected by immunohistochemical technique. The distribution and localization of HBV DNA were observed by using *in situ* hybridization. Southern blot analysis was performed to reveal the state of renal HBV DNA.

RESULTS: Among 100 patients with IgAN, HBs antigenemia was detected in 18 patients (18.00 %). HBAg in renal tissues was detected in 31 patients (31.00 %), the positive rate of HBAg, HBsAg and HBcAg was 64.52 % (20/31), 32.26 % (10/31), 32.26 % (10/31), respectively in glomeruli. HBcAg was also found in tubular epithelia and interstitia, which was 45.16 % (14/31) and 6.45 % (2/31), respectively. Five out of six cases with positive HBV DNA by *in situ* hybridization were proved to be HBV DNA positive by Southern blot analysis, and all were of the integrated form. Eight specimens were demonstrated to be HBV DNA positive by *in situ* hybridization, which was localized in the nuclei of tubular epithelial cells and glomerular mesangial cells as well as in infiltrated interstitial lymphocytes.

CONCLUSION: There is a relationship between HBV infection and IgAN. In addition to the humoral immune damage mediated by HBAg-HBAb immune complex, the cellular mechanism mediated by HBV originating from renal cells *in situ* may be also involved in the pathogenesis of IgAN.

INTRODUCTION

The association between chronic hepatitis B virus (HBV) infection and glomerular diseases was first described in 1971[1], and various morphological patterns including membranous nephropathy, membranoproliferative glomerulonephritis (MN), mesangial proliferative glomerulonephritis (MPGN), minimal change nephropathy, and IgA nephropathy have been reported since then[1-28]. IgA nephropathy is considered the most common glomerular disease worldwide. Its prevalence varies considerably among and within countries, yet the pathogenetic mechanisms still remain largely uncertain[29,30]. Coexistence of mesangial proliferative glomerulonephritis with predominant mesangial IgA deposits and persistent hepatitis B virus surface antigenemia was first reported in five patients by Nagy *et al*[4], and later in some other reports[13,15,17,25,27], but the number of IgA nephropathy was fewer. Since China is an endemic area of hepatitis B virus (HBV) infection, and there is an incidence of 32 % IgA nephropathy in primary glomerulonephritis, according to a clinical analysis of 1001 cases by Li *et al*[31]. The relationship between IgA nephropathy and HBV infection is attracting increasing attention. In order to clarify the possible role of HBV infection in the pathogenesis of IgA nephropathy, we detected the serum HBV marker, HBV antigens (HBsAg, HBcAg, HBeAg) in renal tissues by immunohistochemistry technique, and HBV DNA in renal tissues by *in situ* hybridization and Southern bolt analysis.

MATERIALS AND METHODS

Patients

One hundred patients with IgA nephropathy who were admitted to our hospital during the period from 1982 to 1993 were included in the study. Their clinical data were complete and pathological diagnoses were confirmed by light microscopy and immunofluorescence examination (fresh renal tissue was used for immunofluorescence). The criteria for patients selection were no prior history of jaundice or liver disease, no previous history of blood transfusion, normal liver functions, no history of intravenous drug addiction, absence of cryoglobulinemia, and no clinical and laboratory evidences of secondary renal lesions such as lupus nephritis, *Henoch-Schonlein* purpura glomerulonephritis. All the patients received the following laboratory tests of urinalysis, serum creatinine and blood urea concentration, proteinuria, creatinine clearance at varying intervals during the study period. None had liver biopsies. Five patients without any HBV infection markers in serum or renal tissue were used as control. The following serial investigations were performed.

Serologic tests for HBV markers

Tests for HBV antigens and antibodies were performed before renal biopsy and regularly thereafter. Double antibody sandwich ELISA was used for detecting HBsAg and HBeAg, while double antigen ELISA was used for detecting anti-HBs and antibody competitive ELISA for detecting anti-HBe and anti-HBc. The kits of the test reagents were purchased from Shanghai Medical Laboratory.

Immunohistochemistry

The biopsy tissue was cut into three to four pieces. One piece

was fixed in 95 % ethanol and processed for 4 μm thick paraffin sections, which were stained by hematoxylin and eosin (HE) and periodic acid silver methanamine (PASM). The second piece was embedded in OCT compound (Miles Inc., Elkhart Inc., USA), and cut into 5 μm thick sections for detecting IgG, IgA, IgM and C_3 with direct immunofluorescence. The relevant antibodies were labelled with fluorescein (FITC) (Dako Corporation, Santa Barbara, CA, USA). The third piece was prefixed with 0.25 % glutaldehyde and postfixed with 1 % osmium and cut into ultrathin sections by conventional methods for electron microscopic observation. The fourth part was freshly preserved at -70 ℃ for Southern blot analysis.

Detection of HBVAg in renal tissue

The immunohistochemistry method was used mainly to detect the distribution of immunoglobulin, HBsAg, HBcAg, and HBeAg. The 4 μm thick tissue sections were digested with 0.05 % trypsin for 15 min at 37 ℃ to expose the epitopes of HBeAg, HBsAg and HbcAg. The ABC (Avidin-Biotin-Peroxidase) complex method kit for examining HBeAg and rabbit-anti-HBcAg in peroxidase-antiperoxidase (PAP) complex kit were purchased from Dako Company (Dakopatts, Denmark, U.S.A.). The PAP kit for HBcAg, and horseradish peroxidase-labelled goat anti-human IgG, IgA, IgM for immunofluorescence examination, and other antibodies were prepared by the Department of Pathology, Shanghai Medical University. The first antibodies for HBV antigens were goat anti-HBs, mouse anti-HBe and rabbit anti-HBcAg, respectively. The specificity of staining for HBV antigens was determined by blocking and absorption procedures as previously described by Lai *et al*[2]. Cross reactivities of anti-HBV antigen (s) with each other and with immunoglobulins, complements, and fibrinogen, normal and sclerosed glomerular tissues from HBsAg-negative controls were not found. Normal sheep and rabbit sera were used as negative control.

In situ hybridization

Paraffin fixed 4 μm thick sections were used for *in situ* hybridization. The digoxigenin labelled full-length HBV DNA probe prepared from an HBV plasmid clone of pBR322 and labelled with digoxigenin by random labelling and detection kit[32] were provided by Beijing Hepatitis Research Institute. The main procedures of *in situ* hybridization were as follows: (1) Paraffin fixed sections were dewaxed by conventional methods and digested with proteinase K (Sigma,0.5 mg/ml in Tris-HCL,0.01 mol/L pH 7.2) at 37 ℃ for 15 min and washed in 0.2 % glycine/0.01 % phosphate buffered saline (PBS) at pH 7.4. (2) The sections were fixed in 4 % paraformaldehyde at room temperature for 10 min. (3) The sections were then treated with 0.2 % acetic anhydride/triethanolamine (0.1 mol/L pH 8.0) at RT for 10 min. (4) The sections were treated with prehybridized medium (5×standard saline citrate (SSC)/0.1 % N-lauroylsarcosine/0.02 % sodium dodecylsulfate (SDS)/0.1 % blocking solution of BK) at room temperature for 15 min (5) Digoxigenin labelled HBV DNA probe was added (400 ng/mL), denatured at 100 ℃ for 10 min, hybridized at 60 ℃ for 16-20 h and washed in 2×SSC, 0.2×SSC, 0.1×SSC and 0.1 % Tween 20/buffer 1 (according to BK) sequentially, (6) Then it was pretreated with 5 % normal sheep serum/3 % bovine serum albumin (BSA) at room temperature for 20 min. (7) Sheep anti-digoxigenin labelled with alkaline phosphatase was added (BK) at 37 ℃ for 2 h, then washed in 0.1 % Tween 20/buffer III (according to BK). (8) it was then visualized by nitroblue tetrazolium salt(NBC)/5-bromo-4-chloro-3 indolyphosphate koluidium salt (BCIP;BK).

Examination of *in sit*u hybridization was retrospectively performed within several days by the same person. The specificity of *in situ* hybridization was confirmed by the negative controls. For example, the specific HBV DNA-digoxigenin probe was omitted, pBR328 DNA- digoxigenin probe was used (BK) instead of the HBV DNA- digoxigenin probe, DNase (Sigma, Chemical Co., St Louis, MO, USA 100 ug/mL) was digested.

Southern blot analysis

The fresh specimens preserved at -70 ℃ were processed for the detection of renal HBV DNA by Southern blot analysis. The ^{32}P(a)-dCTP labelled HBV DNA probe and the procedures used were the same as reported previously[18-27].

RESULTS

Serologic findings

Of the 100 patients in this study, 52 were males and 48 were females, (ranging 18-62 years, average 32.8 years). Eighteen patients were found to be HBsAg positive in their sera. Serum HBeAg was detected in four patients. Positive anti-HBe, HBcAb and anti-HBs were found in 7, 13, and 1 patients, respectively.

Detection of HBVAg in renal tissue

Detectable rate of HBAg (HBsAg, HBcAg and HBeAg) in glomeruli and renal tubules by immunohistochemistry was 31 % (31/100). The glomerular distribution of positive HBAg in 31 cases was as follows. Twenty cases were HBAg positive in the glomeruli, including HBsAg in 10 (32.26 %), and HBcAg in 10 (32.26 %). In addition, HBcAg was deposited in tubular epithelial cells (14 cases, 45.16 %) and renal interstitia (2 cases, 6.45 %). Three out of 20 cases were found to be HBeAg positive in glomerular cells (15 %). The distribution of HBAg in glomeruli varied either in capillary loops or in mesangial region or both. Both HBsAg and HBcAg were located in the cytoplasm of tubular epithelium. Occasionally HBcAg could be visualized in the nuclei of tubular cells.

Serologic and clinical findings

Among the 31 patients with positive HBVAg in renal tissues, eight were found to be HBsAg positive in their sera. Serum HBeAg was detected in one patient, HBeAb was positive in three patients, HBcAb was positive in seven patients. Clinical findings showed gross hematuria in 9 cases, microscopic hematuria in 5 cases, proteinuria in 6 cases, nephrotic syndrome in 5 cases, chronic renal failure in 2 cases and hypertension in 4 cases.

Detection of HBV DNA in renal tissue by in situ hybridization

HBV DNA was detected in eight out of the 31 specimens of renal tissues by *in situ* hybridization. Among the eight patients, four were found to be HBsAg positive in their sera. HBeAg was detected in one patient, HBeAb was positive in two patients, HBcAb was positive in four patients and HBsAb was positive in one patient. HBVAg was positive in the renal tissue, HBcAg was positive in glomerular cells and tubular cells in 7 and 3 cases respectively. HBsAg was positive in 1 and 4 cases, respectively. Eight cases were demonstrated to be HBV DNA positive in tubular epithelia by *in situ* hybridization, the positive rate was 100 % (Figure 1). The amount of HBV DNA positive cells varied in different cases. The positive signal of hybridization was localized within the nucleus. HBV DNA was detected in glomeruli in 6 out of the 8 specimens, the positive rate was 75 % (Figure 2).

Detection of HBV DNA in renal tissue by Southern blot

Five out of the 6 specimens with positive HBV DNA in glomeruli were found to be HBV DNA positive by Southern

blot analysis, the positive rate was 83.33 %. All of these positive specimens were identified to be the integrated form of HBV DNA , and none was identified as non-replicating free form of HBV DNA with a single band of signals at 3.2 Kb in length. The integrated HBV DNA by Southern blot analysis showed a high molecular weight single band before digestion, and revealed irregular multiple bands after ECoRI restrictive enzyme treatment.

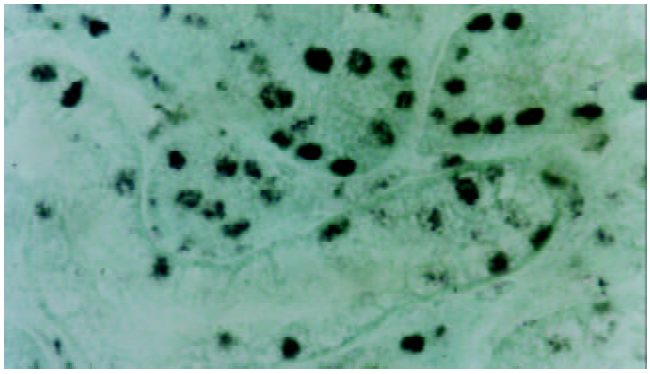

Figure 1 HBV DNA signals detected in nuclei of tubular cells by *in situ* hybridization. X200

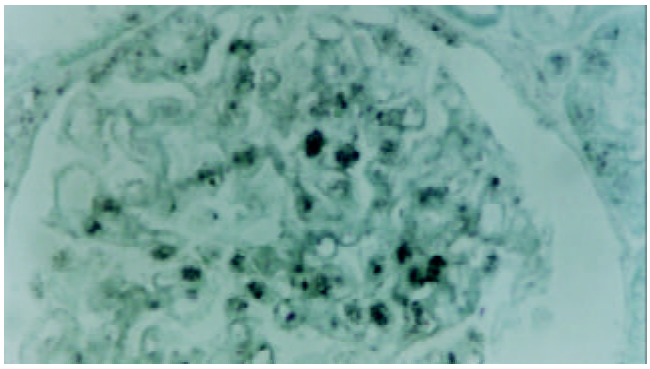

Figure 2 HBV DNA signals detected in nuclei of glomerular mesangial cells by *in situ* hybridization. X400

Relationship of positive HBV infectious markers in sera and HBAg and HBV DNA in renal tissues

The appearance of HBV infection markers in sera and HBAg and HBV DNA in renal tissues of the 8 cases of IgAN is shown in Table 1.

Neither HBAg nor HBV DNA was found in the sera or renal tissues in the five control cases of IgA nephropathy.

DISCUSSION

IgA nephropathy has been confirmed to be an immune complex-mediated glomerulonephritis defined morphologically by mesangial deposition of IgA, but the etiology is still uncertain[29,30]. The etiologic role of HBV antigenemia and HBV antigen deposition in IgA nephropathy remains speculative. It most likely involved mesangial and subendothelial trapping of circulating immune complexes (CICs), and the observations that preformed CICs primarily resulted in mesangial and subendothelial deposits supported this mechanism[29,30]. The possible role of HBV antigens was highly suspected especially in endemic areas of HBV infection such as in Southeastern Asia[13,27]. Many efforts have been contributed to this field[13,15,17,25,27], yet the data are scattered and incomplete because of the difficulty in obtaining tissue specimens, complicated clinical settings, and less specific and sensitive detection techniques. Lai *et al*[13] reported HBs antigenemia was detected in 21 out of 122 patients (17.2 %), which was significantly higher than the prevalence of HBsAg carriers in the general population ($P<0.01$). Humoral immune responses triggered by HBAg-HBAb immune complexes were traditionally regarded as the mechanism of tissue injury resulting in HBV-glomerulonephritis (GN). HBsAg, HBcAg and HBeAg with immunoglobulins and complement deposits in the glomeruli of HBV-GN have been demonstrated in many investigations[1-28]. It remains perplexing why some chronic HBsAg carriers develop IgAN whereas some develop membranous glomerulonephritis (MGN) or mesangiocapillary glomerulonephritis (MCGN). This could well be related to HBV antigens as well as the size and charge properties of HBV antigens and their antibodies. The nephrogenicity of the three different kinds of HBAg was therefore suggested. Takekosh[5], Ito[6], Hirose[8], and Zhang[15] emphasized that the molecular weight of HBeAg was the smallest (1×10^5), enabling it to pass through the glomerular basement membrane and to result in the formation of subepithelial dense deposits by microscopy. This is the well known morphologic characteristics of MGN. Local formation of antigen and antibody complexes has been well established to induce diffuse subepithelial immune deposits and proteinuria characteristic of HBV-MGN. Therefore, HBeAg is considered to be nephrogenic for MGN[5-8,15]. In contrast, the large size of HBsAg[2-4,7,9,13,15,25,27] and anionic nature of IgAN[27,29,30] favor the mesangial localization of HBsAg-anti-HBs complexes in HBV-IgAN. However, high frequencies of HBsAg (3×10^6) and HBcAg (8×10^6) were also detected in the capillary loops of glomeruli of MGN by other investigators[1,6,17,20,25,34].

Glomerular detection of HBV DNA has been reported in the kidneys of chronic HBsAg carriers with different glomerulonephritis[13,20,35], yet the consistency of these findings

Table 1 Detection results of HBV infection markers in sera and HBAg and HBV DNA in renal tissues in 8 cases of IgA nephropathy

Case	Age	Sex	Course	Serum HBVmarkers					Renal HBAg				Renal HBV DNA

remains controversial, since some investigators have been unable to detect similar findings in chronic HBV carriers with coexisting membranous nephropathy[36]. This issue is of importance in understanding the pathogenesis of HBV-related glomerulonephritis. Therefore, with the help of *in situ* hybridization (ISH) and Southern blot analysis for HBV DNA, and highly sensitive and specific biological techniques, we found evidence for the presence of viral transcription in glomerular cells and renal tubular epithelia, which supported an etiological role of HBV in some chronic HBsAg carriers who developed coexisting glomerulonephritis[18,19,23,24,26,27]. Thereafter, the question of whether the existence of HBV DNA in renal tissue of glomerulonephritis is a general phenomenon and what role HBV DNA plays in the pathogenesis of renal tissue injury has been raised. In this serial investigation of 8 cases of IgAN, we found that HBV DNA detectable rate by *in situ* hybridization was 100 %. The positive frequencies were relevant to HBV antigenaemia and the detectable renal HBAg by immunohistochemistry. Since the presence of HBcAg in glomeruli might be not only from HBV DNA positive glomerular cells but also from circulation, the detectable rate of HBcAg in glomeruli has a close correlation with serum HBV antigenaemia and HBV DNA both in serum and renal tissue. The presence of HBcAg and HBV DNA in tubular epithelia might indicate HBV replication in epithelial cells, which were consistent with other studies in transgenic mice revealing the expression of viral genome of HBcAg or HBeAg only in epithelial cells[37-39]. In our study, 5 out of 6 patients with positive HBV DNA by *in situ* hybridization were HBV DNA positive by Southern blot analysis, all of them were integrated form. Since the number and molecular weight of the bands of HBV DNA signals of integrated form varied, it was suggested that HBV DNA integration was random. The infected cells with free form of HBV DNA, consisting of full genome of HBV, might theoretically express HBAg. However, if only some fragments of HBV DNA integrated into the chromosomes of the host cells randomly, whether the cells expressed HBAg would depend on whether the integrated part was consisted of certain intact HBAg genomes and their matched promotors as the elements of franking sequence of HBV DNA. Therefore, the kidney might carry dormant HBV DNA after HBV infection[19,23,27] (as found in the liver) or expressed HBAg to trigger immune reaction and result in tissue injury, which might be mediated by HBAg-HBAb immune complexes together with complements. Meanwhile, another possibility arises that HBV infected renal cells with the target HBcAg expression might activate T lymphocytes the relevant lymphokines to result in increased permeability of glomerular epithelial cells and glomerular basement membrane (nephrotic syndrome) or proliferation of glomerular cells (proliferative glomerulonephritis or IgAN).

Immune regulation defect was hypothesized to play a key role in the pathogenesis of IgA nephropathy[29]. Immune system disorder seemed to be related with secondary infections such as HBV infection or activation of HBV infection[40-42]. In IgA nephropathy patients, the spectrum of antibodies could be extended from both fixed and circulating endogenous antigens[30]. Studies of T lymphocytes suggested that increased T help (CD4) lymphocytes and decreased T suppresser (CD8) lymphocytes occurred with exacerbation of the disease, but overproduction of IgA was probably the consequence of the involvement of both T and B lymphocytes. This might provide some clue to the elevated serum concentration of IgA in our patients. However, whether clearance impairment of IgA immune complexes in hepatic and splenic phagocytic system or elevated levels of CICs involve in the pathogenesis of IgAN are yet to be determined.

We found that HBAg in renal biopsy specimens was mainly glomerular and renal tubular HBsAg and HBcAg. They are large molecular weight antigens forming CIC after binding to appropriate antibodies. It is believed that HBsAg preferentially deposites in mesangial region and subendothelial cells, while HBeAg as a part of viral nucleoprotein is expected to be capable of inducing membranous nephropathy by preferentially depositing along capillary walls. Since HBV DNA genome was detected in glomerular mesangium of patients with HBV associated glomerulonephritis[25], the possibility of immune complex formation *in situ* couldnot be excluded. It is noteworthy that, although many previous studies described the predominant deposition of HBV in glomeruli similar to ours, HBV DNA (ISH) was confirmed to exist extensively in glomeruli, renal tubules, interstitium and capsule[26]. This phenomenon could be attributed to the sensitive and specific techniques employed. Lai *et al* noticed that HBV DNA was found mainly in cytoplasm of proximal tubular epithelia but not in glomerular cells[24]. Zhang had the similar finding[23]. Whether HBV DNA in renal tubules represents endocytosis of HBV DNA in urinary filtrates or the direct invasion of HBV needs further study. In addition, mesangial IgA deposition was possibly resulted from the structural immunological or physicochemical abnormality in IgA nephropathy[29]. Recently Zhang *et al* examined T cell subsets infiltration in interstitia of HBV-GN by immunohistochemistry with monoclonal antibodies against CD3, CD4 and CD8, and found that there were certain relationships between the expression of HBcAg in tubular epithelial cells and the amount of phenotypes of infiltrated T cells in interstitia[23]. There is a possibility that such a relationship might be involved in the frequent occurrence of tubular atrophy with prominent interstitial inflammation and persistent clinical course in some HBV-GN patients.

Our investigation by both *in situ* hybridization and Southern blot analysis revealed that the presence of HBV DNA in renal tissues of IgAN patients with coexisting HBV antigenaemia appeared to be a general phenomenon among IgAN patients in Shanghai, China. Evidences showed that the renal tissue was infected with HBV, HBAg deposited in glomeruli was not only from circulation but also from infected glomerular cells. However, this study did not provide conclusive evidences for the hypothesis. It is suggested that cellular immune mechanism might be involved in the pathogenesis of HBV-GN in addition to humoral immune injury. These concepts might better our understanding of the pathogenesis of HBV related IgAN both theoretically and clinically.

In conclusion, our findings indicate that the host tissue tropism of HBV is not limited to hepatocytes, and active viral transcription is present in glomerular cells and tubular epithelia. Hepatitis B virus might be the etiologic agent of some chronic HBsAg carriers with coexisting IgA nephropathy. There is a relationship between HBV infection and IgAN. In addition to humoral immune injury mediated by HBAg-HBAb immune complexes, cellular mechanism mediated by HBV originating from renal cells *in situ* might also be involved in the pathogenesis of IgAN.

Abstract

AIM: To evaluate the abnormal immunity and gene mutation at precore 1896 site in patients with severe hepatitis-B.

METHODS: This study included 23 patients with severe hepatitis-B, 22 patients with acute hepatitis-B and 20 controls. Mutation at precore 1896 site of HBV gene was confirmed with restriction fragment length polymorphism (RFLP) analysis. Cytokines including TNF-α, IFN-γ, IL-6, and IL-8 were measured with ELISA, and T subgroups were detected with alkaline phosphatase anti alkaline phosphatase (APAAP) technique.

RESULTS: In patients with severe hepatitis-B, the infective rate of HBV mutant strain was 52.5 % (12/23), and only one patient with acute hepatitis-B was infected with the mutant strain. The percentage of CD8+ T lymphocyte was obviously lower (0.16±0.02 %) and the ratio of CD4+/CD8+ was obviously higher (2.35±0.89) in mutant group than in wild-type group (0.28±0.05 % and 1.31±0.18 %, respectively, $P<0.01$ or $P<0.05$). The levels of cytokines in patients with severe hepatitis-B were higher (TNF-α 359.0±17.2 ng/L, IFN-γ 234.7±16.5 ng/L, IL-6 347.5±31.3 ng/L, IL-8 181.1±19.6 ng/L) than those in acute hepatitis-B (TNF-α 220.6±8.9 ng/L, IFN-γ 174.9±12.0 ng/L, IL-6 285.8±16.5 ng/L, IL-8 118.4±5.1 ng/L, $P<0.01$ or 0.05). In patients with severe hepatitis-B, the levels of IFN-γ and IL-6 were higher in mutant group (273.4±26.6 ng/L, 387.7±32.5 ng/L) than in wild-type group (207.8±12.8 ng/L, 300.9±16.3 ng/L). The mortality of patients infected with HBV mutant strain was higher (100 %) than that with wild-type (0.9 %).

CONCLUSION: In severe hepatitis-B, the infective rate of HBV mutant strain was high. The mutant strain induces more severe immune disorders in host, resulting in the activation of lymphocyte and release of cytokines. HBV DNA mutates easily in response to the altered immunity. Ultimately liver damage is more prominent.

INTRODUCTION

HBV destroys hepatocytes by changing the host immune system after its invasion into the body. Various clinical types of hepatitis are associated with different immune status of the body. The serious damage of hepatocytes constitutes the pathological basis of severe hepatitis. At present, studies about the mechanism of hepatocytic damage in severe hepatitis B focus mainly on HBV gene mutation and immunologic abnormalities. HBV gene mutation at precore 1896 site has been already detected with restriction fragment length polymorphism (RFLP). In this study, we explored the relationships between HBV gene mutation and immune status in severe hepatitis. T subgroups in peripheral blood and levels of TNF-α, IFN-γ, IL-6, and IL-8 associated with severe hepatitis were measured.

MATERIALS AND METHODS

Patients

From 1995 to 1998, 45 patients with severe hepatitis or acute hepatitis were included in this study. There were 23 cases (17 men and 6 women) of severe hepatitis and 22 cases (15 men and 7 women) of acute hepatitis. The patients with severe hepatitis aged from 8 to 62 years and those with acute hepatitis from 11 to 65 years. The diagnosis was based on the diagnostic criteria revised at the National Infectious Disease and Parasitosis Conference in 1999 (Xian, china). All samples were obtained on the day of admission. The serological markers of HBsAg and HBV DNA were positive, and those of HAV, HCV, HDV, HEV, anti-EBV-IgM, and anti-CMV-IgM were all negative.

We also studied 20 healthy blood donors aged from 25 to 43 years, including 16 men and 4 women. They had no serological markers of HAV, HBV, HCV, HDV, HEV, and their liver functions were normal.

Analysis of restriction fragment length polymorphism (RFLP)[1]

Two pairs of primers were used in the analysis of RFLP. The primers used for the first round of PCR were 5'-GGCGAGGGAGTTCTTCTTCTAGGGG-3' (2 394 to 2 370 nucleotides) and 5'-CTGGGAGGAGTTGGGGGAGG AGATT-3' (1 730 to 1 754 nucleotides). The primers for the second round of PCR were 5'-CAAGCTGTGCCTTGGGTG GCCTT-3' (1 873 to 1 895 nucleotides), which was a mismatch primer, and 5'-GGAAAGAAGTCAGAAGGCAA-3' (1 974 to 1 955 nucleotides). All of the primers were synthesized by the Shanghai Cytobiology Institute. Huamei Company provided dNTP, PGEM-7Zf(+)Hae III, and the marker of DNA molecular weight. Bsu 36 I enzyme and relevant buffer, TaqDNA polymerase and PCR buffer were from Promega Company. HBV DNA was extracted from serum samples by using the standard method. Serum (100 μl) was treated with proteinase K, phenol and chloroform, and then precipitated with ethanol. The final products served as the amplification template of PCR. The fluorescent zone after electrophoresis was observed by ultraviolet light.

Staining of T subgroups

Monocytes were purified from the samples of anticoagulant blood using lymphocytic laminated fluid. The monoclonal

antibodies to CD4+ and CD8+ were purchased from DAKO (Denmark). The percentages of CD4+ and CD8+ were counted under microscope after staining with APAAP.

Detection of cytokines

The kits of TNF-α, IFN-γ, IL-6, and IL-8 were produced by the Genzyme Company (USA). The four cytokines were detected with ELISA. The first antibody was biological antibody and the second one was peroxidase-labelled streptavidin.

Statistical analysis

All values were expressed as means ± standard deviation. Chi-square test was performed. It was considered statistically significant when the *P* value was less than 0.05.

RESULTS

Mutation at precore 1896 site of HBV DNA from patients with severe hepatitis B

Among the 23 cases of severe hepatitis, 8 were simple infection of the mutant strain, 4 coinfection of the wild and mutant strains, and 11 simple infection of the wild strain. Only 1 case had mutation in precore region among the 22 cases of the acute hepatitis.

Effects of mutation at HBV DNA precore 1896 site on status of T subgroups in peripheral blood from patients with severe hepatitis

As shown in Table 1, the percentage of CD8+ in patients with severe hepatitis in mutant group (0.16±0.02) decreased more obviously than that in patients in the wild-type group (0.28±0.05), and the ratio of CD4+/CD8+ in mutation group (2.35±0.89) increased more significantly than that in wild-type group (1.31±0.18).

Serum levels of TNF-α, IFN-γ, IL-6 and IL-8 from patients with mutation at HBV DNA precore 1896 site in severe hepatitis

Serum levels of TNF-α, IFN-γ, IL-6, and IL-8 in patients with mutation at HBV DNA precore 1896 site in patients with severe hepatitis are shown in Table 2.

The levels of IFN-γ and IL-6 in patients with severe hepatitis in mutant group (273.4±26.6 ng/L, 387.7±32.5 ng/L) increased more significantly than that in patients in the wild-type group (207.8±12.8 ng/L, 300.9±16.3 ng/L) ($P<0.05$).

The dynamic changes of the 4 cytokines are shown in Figure 1 and Figure 2. IFN-γ reached a peak and then decreased rapidly at the early stage of severe hepatitis with infection of mutant strain and acute hepatitis with infection of wild- type. TNF-α and IL-6 increased in acute stage and reached the highest level accompanied by the most severe jaundice, then decreased gradually. Both maintained a high level for a long time in severe hepatitis. IL-8, TNF-α, and IL-6 experienced the same change in severe hepatitis with mutation at HBV DNA precore 1896 site (173.5±10.7 ng/L, 356.6±18.1 ng/L, 387.7±32.5 ng/L) as in the course of acute hepatitis with infection of wild-type (173.1±11.3 ng/L, 328.4±14.6 ng/L, 300.9±16.3 ng/L).

All of the 12 patients in the mutant group died, and only 1 died among 11 patients in the wild-type group.

Table 2 The serum levels of TNF-α, IFN-γ, IL-6, and IL-8 in patients with mutation in HBV DNA precore 1896 site (ng/L, $\bar{x}\pm s$)

Group	*n*	TNF-α	IFN-γ	IL-6	IL-8

DISCUSSION

Severity of hepatitis caused by HBV varies greatly. The mechanisms determining the course and outcome of hepatitis B have not been known. Many investigations suggested that HBV was not directly cytopathic. The injury was mediated by the immune response[2]. Injury of hepatocytes in acute hepatitis was mediated by CD8+ CTLs recognizing the core protein of HBV presented in association with HLA class I proteins[3]. TNF-α and IFN-γ played indispensable roles in liver injury mediated by Th1 cells specific to HBV surface antigen[4]. Muto *et al*[5] suggested that the main immunologic abnormalities in severe hepatitis were due to TNF-α produced by monocytes in peripheral blood. Pretreatment with anti-TNF-α mAb in animal model strongly blocked Th1 cell-inducible liver injury[6]. TNF-α might be enhanced in animal models with impaired liver metabolism[7], and serum TNF-α took part in the pathogenesis of chronic hepatic failure of HBV infection[8]. The study of transgenic mice indicated that IFN-γ triggered the widespread hepatocellular necrosis. The cytopathic effect of IFN-γ was indirect, presumably due to recruitment and activation of antigen nonspecific host inflammatory cells. Immunopathological changes induced by CTL contributed to immunopathogenesis of viral hepatitis during hepatitis B virus infection in humans. IFN-γ activated the killing activity of CTL[9] and had killing activity to regenerating hepatocytes. Similarly, IL-6 was involved in the activation of NK cells and CTLs, inducing their killing activity to hepatocytes.

The serum levels of TNF-α, IFN-γ, IL-6, and IL-8 in patients with severe hepatitis were significantly higher than those in patients with acute hepatitis, and peripheral CD8+ was obviously lower, especially in mutant group. These findings suggest that cytokines and immunocytes associated with inflammation may play roles in the pathogenesis of severe hepatitis. TNF-α, IFN-γ and IL-6 may involve in hepatocytic necrosis and apoptosis. Remarkable increase of IL-8 leads to accumulation of CTL which gets direct and immediate assess to the target hepatocytes and the resident intrahepatic macrophages, and this constitutes the immunopathological basis of hepatocyte killing. CTLs that enter and reside in the liver, have the ability to bind to and kill the HBsAg-positive hepatocytes, and to activate an intrahepatic inflammatory response[4].

Omata *et al*[10] reported in 1991 that HBV DNA precore 1896 site mutation had some relationship with severe hepatitis B. Translational termination codon which was produced after

a point mutantion from G to A at nucleotide 1896 of precore region of hepatitis B virus DNA, converting tryptophan (TGG) to a stop codon (TAG) would interrupt the synthesis of HBeAg precursor protein, that may decrease or eliminate HBeAg. The presence of mutant viral strain is associated with and may be involved in the pathogenesis of severe hepatitis B and exacerbation of chronic hepatitis B. In our study the mortality was extremely high in patients with HBV DNA precore 1896 site mutation. It might be related to the immunologic abnormalities in severe hepatitis induced by HBV DNA precore 1896 site mutation[11]. It was also found that the percentages of CD8+ in the peripheral blood in patients with severe hepatitis in mutant group were much lower than those in patients in wild-type group, which was the result of the relative diminish of CD8+ infiltrating into the liver tissue in severe hepatitis. Meanwhile, the levels of IFN-γ and IL-6 increased significantly in severe hepatitis, indicating that HBeAg not only had effects on the regulation of CTL in killing hepatocytes, but also had certain effect on producing cytokines by the immunocytes. A cross-reactivition of c and e antigens at the T cell recognition sites was found by examining T cell responses to recombinant c and e antigens. When the expression of HBeAg on the surface of hepatocytes decreased or disappeared, the attacking action of specific CTL to c antigen and the target antigen through T cell-mediated cytotoxicity enhanced, resulting in massive necrosis of hepatocytes with HBV infection and deterioration of hepatitis because specific CTL bound to HBcAg which is the most possible main target for immune hepatocytolysis on hepatocytic nuclei was obviously increased[12-14]. HBV strains with mutation in the precore region that abort the translation of hepatitis B e antigen precursor, resulted in the formation of HBeAg-minus phenotype. Circulating HBeAg has been proposed as a viral strategy to induce immunotolerance[15]. Its absence, therefore, would accelerate inflammatory activity in the liver[16] which could be relevant to the pathogenesis of severe hepatitis. On the other hand, HBeAg and HBcAg were expressed simultaneously in hepatocytic membrane with HBV infection and became the target antigen of CTL[17]. Meanwhile, the activity of T suppressor cell (Ts) was weakened. As a result, the ability of Ts to regulate T cells specific to HBc/HBeAg was decreased. So the production of specific CTL to HBc/HBeAg was increased and hepatocytic necrosis exacerbated. Our investigation indicated that in severe hepatitis the abnormal immunity of patients in mutant group was due to the following aspects: (1) The levels of cytokines were abnormal compared with the wild-type, particularly IFN-γ. (2) Hepatocytic apoptosis induced by IL-6 produced by monocytes and vascular endotheliocytes might take part in the pathogenesis of fulminant hepatitis. (3) Overexpression of TNF receptors induced by IFN-γ in hepatocytes might correlate with the severe liver damage[18]. (4) Activation and aggregation of CTL in the liver enhanced the killing activity to hepatocytes and caused deterioration of liver damage. It is thus speculated that in severe hepatitis, HBV mutation might be resulted from response to immune defense reaction of the host body, or conversely, mutant HBV DNA might produce more significant immune disorders in the host body. Clinically, exploration for HBV gene mutation in patients with acute hepatitis might provide some useful hints for estimating the state of illness and predicting the prognosis.

Abstract

AIM: To investigate the clinical and virological course of coinfection by hepatitis B virus (HBV) and hepatitis C virus (HCV) in China.

METHODS: We enrolled 40 patients with chronic HBV and HCV coinfection (Group BC), 16 patients with chronic HBV infection (Group B) and 31 patients with chronic HCV infection (Group C). They infected HBV and/or HCV during 1982 to 1989. Sera of all the 87 patients were collected in 1994 and 2002 respectively. We detected biochemical and virologic markers and serum HBV DNA and HCV RNA levels of all the patients. B-type ultrasound detection was performed in some patients.

RESULTS: In Group BC, 67.5 % of the patients cleared HBsAg, and 92.5 % of the patients cleared HBeAg. The clearance rate of HBV DNA was 87.5 %. There was no significant difference of HBV clearance between Group BC and Group B. In Group BC, 85.7 % of males and 47.4 % of females cleared HBV, and males were easier to clear HBV (χ^2=6.686, P=0.010). Such a tendency was also found in Group B. The clearance rate of HCV RNA in Group BC was 87.5 %, significantly higher than that in Group C (χ^2=22.963, P<0.001). Less than 40 % of the patients in all groups had elevated liver enzyme values. The highest value of alanine aminotransferase (ALT) was 218 u/L (normal range for ALT is 0-40 u/L). In most patients the ultrasonogram presentations changed mildly.

CONCLUSION: The clinical manifestations of patients with HBV/HCV coinfection are mild and occult. High clearance rate of HBV and easy to clear HBV in male patients are the characteristics of HBV infection in adults in China. HBV can inhibit HCV replication, but no evidence has been found in our data that HCV suppresses HBV replication.

INTRODUCTION

Hepatitis B virus (HBV) and hepatitis C virus (HCV) are the most common causes of chronic liver diseases worldwide. Both viruses could induce chronic hepatitis, which may progress to cirrhosis and eventually to hepatocellular carcinoma (HCC). Because HBV and HCV share similar transmission routes, coinfection seems to be frequent. Seroprevalence studies have shown that coinfection of HCV is detected in around 10 % to 15 % of patients with chronic HBV infection, although the prevalence may vary from country to country[1-3]. Earlier studies in chimpanzees showed that replication of pre-existing HBV was inhibited by superinfection of NANB hepatitis virus (HCV)[4]. Some clinical observations indicate that HCV may inhibit HBV expression and even act as the major cause of chronic hepatitis[5-8]. And it was also reported that HBV might suppress replication of HCV[9-12]. The histopathological findings and clinical outcome in some of these cases were contradictory. Some researchers found that HBV and HCV coinfection could significantly increase the risk of development of fulminant hepatitis and also cirrhosis and HCC[2,13-16]. But others showed neither exacerbation nor diminution of histopathological changes in patients with HBV/HCV coinfection[17]. Coinfection does not play an important role in the development of HCC[18,19]. Furthermore, in patients with HBV and HCV coinfection after orthotopic liver transplantation, presence of HCV may improve their clinical outcome as compared with HBV infection alone[20].

Our previous study showed that the history of patients infected with HCV in China was different from that in Western countries[21]. At the same time, we enrolled a group of patients with chronic HBV and/or HCV infection during 1982 to 1988. Sera of all the 87 patients were collected in 1994 and 2002 respectively. We analyzed the biochemical and virologic markers and serum HBV DNA and HCV RNA levels in patients with chronic coinfection and compared the results with the patients with single HBV or HCV infection. The clinical and virological course of coinfection of HBV and HCV in China was investigated.

MATERIALS AND METHODS

Patients

Eighty seven patients with chronic HBV and/or HCV infection were native individual blood donors in Hebei Province of China, who had the history of drawing plasma from the blood and transfusion back of the blood cells during 1982-1989. The serum samples of these patients were collected in 1994 and 2002, and stored without thawing at -70 ℃. We detected the serological markers of HBV and HCV in all the patients in 1994 and 2002 respectively. All the patients were divided into 3 groups: Group BC (HBV and HCV coinfected group including 40 cases), Group B (single HBV infected group including 16 cases), and Group C (single HCV infected group including 31 cases). There was no significant difference in the number of patients, age and sex distribution, and duration of infection among the groups (Table 1). No patient had received treatment of immunosuppressors or antiviral agents such as interferon. And all the patients were negative for anti-HDV and anti-HIV. None of them had a history of auto-immune disease, and alcohol abuse.

Table 1 Clinical data for patients with HBV and/or HCV infection

	Group BC	Group B	Group C	Statistical value
Number of patients	40	16	31	
Sex (male/female)	21/19	6/10	15/16	χ^2=1.030, *P*>0.05

[a]Data were expressed as mean ±SD (range).

Serological examination

Serum anti-HBs, anti-HBe, anti-HBc and HBeAg were detected by commercially available enzyme-linked immunosorbent assay (ELISA) kits (RADIM, Italia). HBsAg, anti-HIV and anti-HDV were tested by ELISA kits (Organon Teknika China Ltd). Testing of anti-HCV was performed by the third-generation of ELISA kits (Ortho Diagnostic Systems Inc. NJ). Liver enzymes, such as alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin (TBIL), gamma glutamyl transferase (GGT) and alkaline phosphatase (ALP) were determined using HITACHI 7170 biochemistry analyzer. Serum AFP was measured by radioimmunoassay. A value greater than 20 ng/ml was considered abnormal.

Quantitative detection of HBV DNA and HCV RNA

Serum HBV DNA and HCV RNA concentrations were determined by a programmable high-speed thermal cycler (Light Cycler II; Roche Diagnostics, Mannheim, Germany) for fluorescence quantitative polymerase chain reaction (FQ-PCR) using a commercially available kit (PG Biotech Co., Ltd., China). For HBV DNA FQ-PCR, the detection limit of the method was 500 genome copies/ml. For HCV RNA, the sensitivity limit of the method was about 1 000 genome copies/ml.

Statistical analysis

All the data were presented as the mean ±SD. χ^2 test or Fisher' s exact test was used for categorical variables. The statistical package for social sciences (SPSS, Chicago, IL), version 10.0, was used for statistical analyses. Significance was set at a *P* value of less than 0.05.

RESULTS

Spontaneous clearance of HBV (Table 2)

HCV did not influence the clearance of HBV in Group BC Persistent negative HBsAg and HBV DNA in serum and liver enzyme was considered as a criterion for HBV clearance[22, 23]. In Group BC, 27 of the 40 patients (67.5 %) cleared HBV, and in Group B, 7 of the 16 patients (43.8 %) cleared HBV. No significant difference was found between the two groups (χ^2=2.703, *P*=0.100) (Table 2). It was suggested that HCV had no effect on the elimination of HBV.

Spontaneous clearance of HBV in the course of chronic HBV infection Forty patients with coinfection of HBV and HCV had acquired the viruses for 6 to 13 years. Six of them (15 %) cleared HBsAg, 29 of them (72.5 %) cleared HBeAg, and 3 of them (7.5 %) cleared HBV DNA spontaneously in 1994 (Table 2). While in Group B, all the patients were positive for HBsAg and HBV DNA, and 10 of them (62.5 %) cleared HBeAg in 1994. In Group BC, 27 patients (67.5 %) cleared HBsAg, 37 patients (92.5 %) cleared HBeAg, and 35 patients (87.5 %) cleared HBV DNA in 2002. No significant difference was found between the two groups (Table 2). It was suggested that HBV could be cleared even after 6 years of infection in adults.

Influence of sex and serum virus load on the clearance of HBV In Group BC, 85.7 % (18/21) of the males cleared HBV, but only 47.4 % (9/19) of the malas cleared HBV. The HBV clearance rate of males was significantly higher than that of females (*P*<0.05). In Group B, the spontaneous HBV clearance rates were 66.7 % (4/6) and 30 % (3/10) in males and females respectively, but no statistical difference was found between them. It showed that males seemed easier to clear HBV (Table 2). According to the criteria of HBV clearance[22,23], 10 of the 16 patients (62.5 %) in Group BC with a high HBV DNA level had cleared HBV in 2002. Among the 24 patients who had low HBV DNA level, 17 patients (70.8 %) cleared HBV. There was no significant difference between the high and low HBV DNA level groups in Group BC (*P*>0.05). In Group B, 3 of the 9 patients (33.3 %) with a high HBV DNA level cleared HBV in 2002. While in 7 patients whose serum HBV level in 1994 was lower than 10^5 genomic copies/ml, 4 patients (57.1 %) cleared HBV (*P*>0.05) (Table 2). It was suggested that the level of virus load had no effect on the clearance of HBV infection.

Spontaneous clearance of HCV RNA

In Group BC, 29 of the 40 patients cleared HCV RNA (72.5 %) in 1994. Thirty five patients (87.5 %) cleared HCV RNA in 2002. Two patients who were negative for HCV RNA in 1994 became positive in 2002. In Group C, 12 of the 31 patients cleared HCV RNA (38.7 %) in 1994, and 10 patients (32.3 %) cleared HCV RNA in 2002. Three patients who were formerly

negative for HCV RNA became positive in 2002. In 1994 and 2002, the clearance rate of HCV RNA in Group BC was higher than that in Group C (P<0.01) (Table 3).

Table 3 HCV RNA clearance rate in Group BC and Group C

	Group BC (n=40, %)	Group C (n=31, %)	Statistics value
HCV RNA clearance

Until 2002	35 (87.5%)[c]	10 (32.3%)[d]	χ^2=22.963, (c *vs.* d) P<0.001
Male	17 (80.9%)	3 (20%)	
Female	18 (94.7%)	7 (43.8%)	

Relationship between HBV DNA and HCV RNA

Forty patients with HBV and HCV coinfection were dovided into 3 groups based on their serum HBV DNA levels in 1994. Within each of the groups, the patients were reclassified based on their serum HCV RNA viral load in 1994 (Table 4). Neither inverse nor positive correlation was found between HBV DNA and HCV RNA levels in the coinfected patients. However, detection of the sera of coinfected patients collected in 2002 showed that one who was positive for HBV DNA in 1994 was negative for HCV RNA. On the contrary, one who was positive for HCV RNA in 1994 was negative for HBV DNA. The fact that HBV DNA and HCV RNA could not be found in the same patient at the same time suggested that HBV and HCV were cleared one by one.

Table 4 Relationship of serum HBV and HCV load in 1994

HCV RNA (copies / ml)	HBV DNA(copies / ml)			Total amount
	$<10^3$	10^3-10^5	$\geqslant 10^5$	
$<10^3$	2	14	12	28
10^3-10^5	1	5	3	9
$\geqslant 10^5$	0	2	1	3
Total amount	3	21	16	40

P=0.918.

Table 5 Type B ultrasonic presentations in patients with HBV and / or HCV infection

	Normal	Mild	Medium	Severe	Fatty liver	Not detected	Total
Group BC	4	0	2	1	3	30	10
Group B	8	0	2	0	3	3	13
Group C	0	13	14	1	2	1	31

Clinical outcome of patients with HBV and HCV coinfection

All the patients had no apparent symptoms and physical signs of liver diseases. In Group BC, 10 of them (25 %) had abnormal liver enzyme values, and the highest value of ALT was 218 u/L with a mean of 95±72 (u/L) (normal range for ALT is 0-40 u/L). Five patients in Group B and 12 in Group C had elevated liver enzyme values. The rate of abnormal biochemical values was similar among the groups. The mean of elevated ALT values was 69±33 (u/L) in Group B and 53±16 (u/L) in Group C. Fifty three of the patients underwent B type ultrasound detection, and most of them had mild or moderate abnormal ultrasonic manifestations according to the criteria formulated by Chinese Medical Association[24] (Table 5). Other liver enzyme values such as TBIL, ALP, GGT and AFP were in the normal range in all the patients, and no one was found to have HCC.

DISCUSSION

All the patients were individual blood donors with chronic HBV and/or HCV infection. They have never received interferon or other antiviral agent treatment, thus our data partly reflected the natural history of HBV and HCV coinfection.

High clearance rate of both viruses, and mild clinical manifestations of coinfection were the prominent findings in this study. It may have some relationship with the special characteristics of the patients. First, different from those who got HBV and HCV coinfection sporadically, the patients in our study were all individual blood donors, and had a history of taking plasma from the blood and transfusion back of the blood cells. Second, they were adults when they acquired the infection. During 1982 to 1989, they provided the blood 5-15 times, and 200 to 400 ml each time. Third, they were the natives of certain villages in Hebei Province and their blood was collected in the same hospitals. These characteristics of the patients may have some relationships with the high clearance rate of HBV in Group BC and Group B. The mechanism needs to be further studied. After 14 to 21 years of HBV and HCV coinfection, 87.5 % of the patients have cleared HCV RNA. Researchers in Western countries reported that the spontaneous clearance rate of HCV RNA was less than 15 % in adults with HCV infection, and 34 % in patients with coinfection[25]. The history of HCV infection in China was different from that in Western countries, 29 % of the patients who got HCV infection after blood transfusion for 12 to 25 years have cleared the virus, and the clinical manifestations were occult[21]. This may be the reason of different characteristics of patients with coinfection in China from those in Western countries.

With regard to the relationship of HBV/HCV coinfection and clinical outcome, most researchers found that coinfection of HBV and HCV could cause more severe liver damage than single infection[2,13-16]. While in this study, neither patients with coinfection nor patients with single HBV or HCV infection had obvious symptoms and signs of liver diseases. Twenty five percent of patients with coinfection had elevated liver enzyme values. The mean of elevated ALT values was 95±72 u/L, while other liver enzyme values such as TBIL, ALP, and GGT were in the normal range. In most patients the ultrasonic presentations changed mildly. Good clinical outcome was one of the main characteristics of the patients with coinfection in this study. It was reported that in patients with HBV and HCV coinfection after orthotopic liver transplantation, the presence of HCV might improve the clinical outcome as compared with HBV infection alone[20]. Utili *et al*[25] followed up a group of cancer survival children who acquired HBV and HCV during treatment of neoplasia for a median period of 13 years, in which the patients went though a chronic indolent course of the liver disease, 59 % of them lost one or both viruses over time.

The clearance rate of HCV RNA in Group BC was 87.5 % in 2002, significantly higher than that in Group C (32.3 %) (P<0.05), and Group BC had a higher clearance rate of HCV RNA compared with Group C (P<0.05) (Table 3) in 1994. It was suggested that in HBV and HCV coinfection group the two viruses had mutual interference, and HBV suppressed HCV replication. While in Group BC, the patients who were positive for HCV RNA in 1994 were negative for HBV DNA in 2002, and vice versa. Previous studies also found that HBV could inhibit HCV replication and took the leading role in chronic hepatitis[9-12]. Acute HBV superinfection of patients with chronic HCV infection could suppress their pre-existing HCV, and the timing or sequence of infection was a factor influencing the outcome of viral interactions[22, 26]. The mechanism might

be that antiviral cytokines such as IFN-γ and TNF-α produced by non-T cells in the event of superinfection could inhibit the pre-existing virus[27]. *In vitro* experiments showed that when HBV DNA and HCV RNA were co-transfected into HuH7 cells, HBV DNA suppressed HCV RNA secretion, and HCV RNA also suppressed HBsAg secretion in comparison with either of HCV RNA or HBV DNA transfection alone[28].

Former studies showed that HCV could inhibit HBV replication[5-8, 29], but in this study, no statistical difference was found in the clearance rate of HBsAg, HBeAg and HBV DNA between Group BC and Group B. We did not find any relationship between serum HCV RNA and HBV DNA levels in patients with coinfection. The small number of patients in Group B might result in statistical discrepancy. Anyway, no evidence was found in this study to support that HCV could affect HBV replication.

Considering that China is a highly endemic area of HBV, and most of patients with chronic HBV infection acquired the virus in their infancy, our data may partly reflect the natural history of HBV infection in adults. Its characteristics are as follows.

High clearance rate of HBV and indolent course of the infection After 14 to 21 years of infection, the clearance rates of HBsAg, HBeAg and HBV DNA in Group BC were 67.5 %, 92.5 % and 87.5 %, while in Group B, the clearance rates of these markers were 50 %, 87.5 % and 81.5 % respectively, and no significant difference was found between the two groups. It was reported that 5-10 % of chronically infected patients cleared HBV DNA and HBeAg spontaneously each year, and this might be followed by clearance of HBsAg[30,31]. In Taiwan the annual clearance rate of HBsAg was 0.43 %[32]. European Association for the Study of the Liver (EASL) reported that in Western countries, about 1-2 % of HBV carriers became HBsAg negative each year, while in endemic areas the rate of HBsAg clearance was lower (0.05-0.08 % per year)[23]. In chronic coinfection the clearance rate of HBsAg seemed higher than that in single HBV infection, and 2.03 % of patients in Taiwan cleared HBsAg annually[32]. In this study, either in patients with HBV/HCV coinfection or in HBV single infection, the clearance rate of HBsAg was higher than that ever reported. And they had mild clinical manifestations and no evidence to progress to more severe diseases.

It seemed easier for man to eliminate HBV We found in Group BC, most of the males (85.7 %) cleared HBV, and only 47.4 % of females did so ($P<0.05$). In Group B, no statistical difference was found, which might be due to a small number of cases. It was also reported in a long-term follow-up study that 88.9 % of the patients who cleared HBsAg were males[32].

The virus load did not influence the clearance rate of HBV There is no statistically significant difference of clearance rate of HBV between different virus load groups.

In short, mild and occult clinical manifestations and high clearance rate of both viruses were the characteristics of patients with HBV/HCV coinfection. High clearance rate of HBV in male patients was a clinical feature in adults with HBV infection. HBV could inhibit HCV replication, but no evidence was found that HCV could suppress HBV replication.

Abstract

AIM: To study the levels of T lymphocyte subsets and membrane interleukin-2 receptor (mIL-2R) on surface of peripheral blood mononuclear cells (PBMCs) of patients with hepatitis B and its role in the pathogenesis of hepatitis B.

METHODS: The levels of T lymphocyte subsets and mIL-2R in PBMC before and after being stimulated with PHA were detected by biotin-streptavidin (BSA) technique in 196 cases of hepatitis B.

RESULTS: In patients with hepatitis B, the levels of CD_3^+, CD_4^+ cells, and the ratio of CD_4^+ cells/CD_8^+ cells were lower, but the level of CD_8^+ cells was higher than those in normal controls (42.20±6.01 *vs* 65.96±6.54, 38.17±5.93 *vs* 41.73±6.40, 0.91±0.28 *vs* 1.44±0.31, 39.86±6.36 *vs* 30.02±4.54, $P<0.01$). The total expression level of mIL-2R in PBMC before and after being stimulated with PHA was also lower than those in normal controls (3.47±1.55 *vs* 4.52±1.49, 34.03±2.94 *vs* 37.95±3.00, $P<0.01$). In all the patients with hepatitis B, the levels of T lymphocyte subsets and mIL-2R in PBMC with HBV-DNA (+) were lower than those with HBV-DNA (-), which were significantly different (39.57±7.11 *vs* 44.36±5.43, 34.36±7.16 *vs* 40.75±5.87, 37.82±6.54 *vs* 41.72±6.21, 0.88±0.33 *vs* 0.99±0.27, 2.82±1.62 *vs* 3.85±1.47, 31.56±3.00 *vs* 35.84±2.83, $P<0.01$). In addition, the levels of CD_3^+, CD_4^+, CD_8^+ cells, the ratio of CD_4^+ cells /CD_8^+ cells and mIL-2R among different courses of hepatitis B were all significantly different ($F=3\ 723.18$, $P<0.01$. $F=130.43$, $P<0.01$. $F=54.01$, $P<0.01$. $F=2.99$, $P<0.05$. $F=7.16$, $P<0.01$).

CONCLUSION: Both cellular and humoral immune functions are obviously in disorder in patients with hepatitis B, which might be closely associated with the chronicity in patients.

INTRODUCTION

Hepatitis B virus (HBV) parasitizing in hepatocytes is a pathogen of viral hepatitis B, which easily develops into hepatic fibrosis and cirrhosis, even hepatocellular carcinoma. But the pathogenesis of hepatitis B is very complex and has not been clarified until now. Generally, it is not HBV itself that damages hepatocytes directly, but the results of function disorder of cell-mediated immunity[1-18]. Peripheral blood mononuclear cells (PBMCs), which are aggregation of abundant immunologically competent cells, such as T lymphocytes, natural killer cells and lymphokine activated killer, likely play an important role in anti-HBV infection. Interleukin-2 (IL-2) has a crucial role in several immunologic functions. Its effect is dependent on the conjugation with membrane interleukin-2 receptor (mIL-2R) expressed on surface of activated T lymphocytes and other immunocompetent cells and can release from them. Biotin-streptavidin (BSA) has a high specificity and sensitivity. In order to study possible changes of T lymphocyte subsets and mIL-2R on surface of peripheral blood mononuclear cells (PBMC) of patients with hepatitis B and its role in the pathogenesis of hepatitis B, 196 patients with acute and chronic hepatitis B were detected by the BSA methods in this study. The results suggest that there is a state of depression rather than of activation of T lymphocyte subsets and mIL-2R system in viral hepatitis B, and that the pathogenesis of viral hepatitis B is related to the cellular and humoral immune function of patients.

MATERIALS AND METHODS

Subjects

According to the diagnotic criteria passed by the 10th National Conference on Viral Hepatitis and Hepatopathy 2000 (Xi' an), 196 patients with hepatitis B (male 113 and female 83), aged 19-52 years (average 34.6 years), were chosen from our affiliated teaching hospitals. Among them, 24 patients were HBsAg-positive without symptoms, 22 with acute hepatitis B, 46 with slight chronic hepatitis, 37 with moderate chronic hepatitis, 26 with severe chronic hepatitis, 15 with severe hepatitis, 18 with posthepatitic cirrhosis and 8 with hepatocellular carcinoma. In addition, the controls were selected from HBsAb-positive volunteers (n=10) and normal blood donors from the local central blood bank (n=20), aged 10-45 years (average 32.6 years).

Reagents and instruments

Antibodies against T lymphocyte subsets were provided by Shanghai Jing' an Medical Institute, Ficoll-Hypaque sedimentation gradients were offered by Shanghai Second Reagent Factory, and HBV-DNA reagents were made in Shanghai Middle Asia Gene Institute. Carbon dioxide incubator (MDF-135) was made in Japan.

Samples

Five mL peripheral vein blood 5 mL from each patient with hepatitis B and the controls was collected at 8:00 a.m., and 2.5 ml was distributed in a sterile test tube and 2.5 mL into an anticoagulant test tube with heparin.

Separation of PBMC and detection of T cell subsets, mIL-2R

After the heparinized anticoagulant blood was mixed with equal volume of Hanks' liquid without Ca^{2+} and Mg^{2+}, PBMC were harvested from heparinized whole blood by centrifugation

on Ficoll-Hypaque sedimentation gradient and diluted to (1-3)×10^6· L^{-1}cells suspension with RPMI 1640 culture liquid. Ten μL suspension of PBMC was smeared on sheet glass pores so that the cells with CD_3^+, CD_4^+, CD_8^+ and the rest phrase of mIL-2R could be detected. Of the PBMC suspension, 0.5 mL was mixed with RPMI 1640 culture liquid, which had PHA 200 μg· L^{-1}. The cells were grown in continuous culture (37 ℃, 50 mL· $L^{-1}CO_2$ in atmosphere) for 72 h and its mIL-2R induced by PHA could be measured by the antibodies against membranes of T cells.

Immunocytochemical method of biotin- streptavidin system (BSA)

The different monoclonal antibodies (mAb) against CD_3, CD_4, CD_8 and Tac with biotin and SA-HRP were smeared on different sheet glasses. These smears were left dry naturally and fixed with acetone for 15-20 min. The cells were incubated in continuous culture (37 ℃, 50 mL· $L^{-1}CO_2$ in atmosphere) for 30 min. The immune sheet glass pores were measured after being stained with the color-developing agent and several washings with Tris buffer solution (TBS). The total number of 200 PBMCs was counted and its positive cells were statistically analyzed with the help of high power lens. The positive criterion was that the color of cell membrane was brown, if not being negative.

Detection of HBV-DNA

The levels of HBV-DNA in serum and PBMC were detected with negative, positive and vacuity controls being set up each time. After routine process, the samples were placed at 94 ℃ for 300 s for denaturation at first, then at 94 ℃ for 30 s, at 55 ℃ for 30 s and at 72 ℃ for 30 s.After 35 cycles, the samples were extended at 72 ℃ for 300 s. After electrophoresis in 2 % sepharose with ethidium bromide (EB) for 20 min, products of amplification were observed with infrared-transmission meters. Samples with orange fluorescent bands as the positive controls were considered to be positive, while the others were negative.

Statistical analysis

Statistical analysis was made by *t* and *F* tests.

RESULTS

The results showed that the percentages of CD_3^+ and CD_4^+ cells, and the ratio of CD_4^+ cells /CD_8^+ cells were lower, the percentage of CD_8^+ cells was higher, and the levels of mIL-2R before and after stimulation with PHA were lower in patients with hepatitis B than those in normal controls (P<0.01). Among different courses of hepatitis B, T lymphocyte subsets and mIL-2R were all significantly different from each other. The detailed results are shown in Tables 1 and 2.

DISCUSSION

Recently, studies have shown that patients with hepatitis B are usually accompanied by disorder of immune function, and hepatocytic damage is mainly caused by immunological

injury[15-30]. Immunologically competent cells and cytokines are the key points for body to eliminate hepatitis B virus[12]. Alterations of T lymphocyte subsets are an important reason for the disorder of immune function due to HBV infection. A lots of cytokines, especially IL-2, can facilitate proliferation of immunologically competent cells[14,31-37], such as T lymphocytes, natural killer cells and lymphokine activated killer cells. While IL-2 is conjugated with mIL-2R on surface of the proper target cells, it will be efficient in immunoregulation. In order to further explore the pathogenesis of hepatitis B, we designed a series of correlation experiments to detect the levels of T lymphocyte subsets and mIL-2R on surface of PBMC in patients with hepatitis B.

CD_3^+, CD_4^+ and CD_8^+ cells are major function subgroups of T cells and play an important role in response to HBV infection, which can reflect the situations of cellular immune function and immunoregulation and are usually regarded as a valuable index to forecast the changes of patients' immunity[11,38-47]. In this study, the percentages of CD_3^+, CD_4^+ cells and the ratio of CD_4^+ cells /CD_8^+ cells decreased, and CD_8^+ cells increased, suggesting that disorders of cellular immune function and pathologic damages occurred in the 196 patients with hepatitis B detected by the method of BSA.

PBMCs are easily infected by HBV[48,49]. When entering into PBMCs, HBV can integrate with host cells and interfere with metabolism of cells, and can depress the expression of CD_3^+ and CD_4^+. As seen in this study, the expression levels of T lymphocyte subsets between positive and negative HBV-DNA and HBV-DNA in PBMC were significantly different (P<0.01).

mIL-2R plays a key role in biologic effect of IL-2 and its expression levels can reflect the course of T cell activity and the immune situation of body[50]. From this study, we can see the expression levels of mIL-2R in PBMCs in silence and induction were lower in hepatitis B patients than in normal controls (P<0.01), and the expression levels of mIL-2R in PBMCs were lower in HBV-DNA positive patients than in HBV-DNA negative patients (P<0.01). After stimulation with PHA, the levels of mIL-2R obviously increased, which showed that mIL-2R could be induced by PHA, but its expression levels were still significantly lower than those in normal controls (P<0.001). In addition, due to deterioration and chronicity of hepatitis B, the expression levels of mIL-2R had a tendency of descent in the patients. These also showed that T cell activity was interfered and humoral immune function was decreased in patients with hepatitis B.

The levels of CD_3^+, CD_4^+, CD_8^+ cells (P<0.01), the ratio of CD_4^+ cells /CD_8^+ cells (P<0.01) and mIL-2R (P<0.05) among different courses of hepatitis B were all significantly different, which suggested that there is a close correlation between levels of T lymphocyte subsets and different courses of hepatitis B. According to the above findings, it is concluded that in patients with hepatitis B, there is an obvious disorder of cellular and humoral immune functions, and a close relationship between the body's immune function and the course of illness. While infecting PBMC, HBV can interfere with the normal metabolism of these cells, and prevent lymphocytic membranes from accepting signals from antigen presenting cells (APC), and depress the expression of mIL-2R. All of these do no good to eliminating HBV and contribute to chronicity of hepatitis B.

Abstract

AIM: *H pylori* genomes are highly diversified. This project was designed to genotype *H pylori* isolates by the polymerase chain reaction (PCR)-based randomly amplified polymorphic DNA (RAPD) fingerprinting technique and to verify its stability by Southern blotting and DNA sequencing.

METHODS: Clinical isolates of *H pylori* were cultured from gastric antra and cardia of 73 individuals, and genomic DNA was prepared for each isolate. RAPD was carried out under optimized conditions. 23S rDNA was regarded as an internal control, and a 361 bp rDNA fragment (RDF) was used as a probe to screen the RAPD products by Southern blotting. Ten RDFs from different clinical isolates and the flanking regions (both upstream and downstream) of four RDFs were amplified and sequenced.

RESULTS: *H pylori* isolates from different individuals had different RAPD profiles, but the profiles for isolates cultured from different gastric sites of a given individual were identical in all but one case. Isolates from 27 individuals were RDF positive by Southern blotting. Sequences of the RDFs and their flanking regions were almost the same between the RDF positive and negative isolates as determined by Southern blotting. There was no binding site for random PCR primer inside the sequences.

CONCLUSION: RAPD is very useful in genotyping *H pylori* grossly on a large scale. However, it seems unstable in amplification of low yield fragments, especially those that do not appear as visible bands on the agarose gel stained with EB, since the primer is partially matched to the template.

INTRODUCTION

H pylori is a spiral, Gram-negative bacterium, which chronically infects more than half of population worldwide, and is implicated in gastritis, peptic ulcer and gastric cancer[1-12]. One of its features is high genome diversity[13-15]. Clinical isolates of *H pylori* from different individuals show enormous variation in their genomic fingerprints[16-18]. Studies based on the two sequenced genomes of *H pylori* strains (i.e. 26695 and J99) have revealed that among the *H pylori* genes, 22 % are dispensable and about 6 % are unique[14,15]. Sequence variation of certain genes or regions, such as the cag pathogenicity island[19, 20], *vacA*[21], *babA* and *babB*[22], drug resistant genes[23-26] and restriction-modification genes[27-29], is also remarkable. For a given individual, the genes of the colonized strain even change over the course of colonization[17, 30]. Genotyping of the bacterium is important for the epidemiological and pathogenic investigation, and genes that are present in one strain but absent or substantially different in others can be of great interest biologically.

The polymerase chain reaction (PCR)-based randomly amplified polymorphic DNA (RAPD) method has widely applied to the distinction of *H pylori* isolates due to its sensitivity, efficiency and promptness[16, 17]. However, problems with its stability or reproducibility arise. In this study, we obtained RAPD fingerprints of clinical isolates of *H pylori* under optimized conditions, and then determined the stability of RAPD products by Southern blotting and DNA sequencing techniques.

MATERIALS AND METHODS

H pylori culture

Clinical isolates of *H pylori* cultured from gastric antra and cardia of 73 patients, 12 with gastric ulcer (GU), 18 with duodenum ulcer (DU), 8 with both GU and DU, and 25 with non-ulcer dyspepsia (NUD), were selected for this study. Each isolate preserved in the brain heart infusion broth (BHI, Gibco, Edinburgh, UK) supplemented with 100 mL/L horse serum and 200 mL/L glycerol was inoculated onto *H pylori* selective chocolate blood agar containing 40 g/L blood agar base No.2 (Oxoid, Basingstoke, UK) and 50 mL/L horse blood (Gibco, Edinburgh, UK). Antibiotics (Sigma, St. Louis, MO, USA) were used at the following concentrations: 3 mg/L vancomycin, 5 mg/L trimethoprim, 10 mg/L nalidixic acid and 2 mg/L amphotericin B. The plates were incubated in a microaerobic atmosphere (50 mL/L CO_2) in a CO_2 incubator (Forma Scientific, Marietta, OH, USA) at 37 ℃ for up to 5 days.

Extraction of genomic DNA

H pylori cells on the plates were harvested by using a sterile swab, and transferred into an Eppendorf tube containing 1.5 mL TE buffer (10 mmol/L Tris-HCl, pH 8.0; 1 mmol/L EDTA, pH 8.0). The suspension was centrifuged at 8 000 g for 10 min and washed once with TE buffer. The pellet was then suspended in 800 μL TE buffer was incubated with 10 μL of 100 g/L lysozyme (Sigma, St. Louis, MO, USA) at 37 ℃ for 30 min. The suspension was then lysed with 100 μL of 100 g/L sodium dodecyl sulfate (SDS) by incubating at 37 ℃ for another 30 min. Then 5 μL of proteinase K (10 g/L) (Boehninger, Mannheim, Germany) was added into the mixture and incubated at 56 ℃ for 1 h. Afterward, *H pylori* DNA was purified by extracting twice with equal volume of phenol and once with equal volume of chloroform, followed by centrifugation at 12 000 g for 10 min each time. The supernatant

was transferred into a new Eppendorf tube, and precipitated with 2 volume of absolute ethanol and 20 μL of 3 M sodium acetate at -20 ℃ overnight. The DNA preparation was centrifuged at 12 000 g for 20 min and washed once with 700 mL/L ethanol. The pellet was then vacuum-dried and suspended in 50 μL distilled water. RNase A was added at the final concentration of 20 mg/L. After incubated at room temperature for 30 min, DNA concentration was determined spectrophotometrically.

RAPD for genomic DNA

A universal primer was chosen for the PCR-based RAPD, according to the paper of Akopyanz, *et al*[31], to fingerprint the genomic DNA. The primer was 5-AAGAGCCCGT-3. The volume of the PCR mixture was 25 μL containing 50 ng of *H pylori* genomic DNA, 20 pmol primer, 1 unit of Taq DNA polymerase, 0.25 mmol/L dNTPs, 10 mmol/L Tris-HCl, 50 mmol/L KCl, 2 mmol/L $MgCl_2$ and 0.1 g/L gelatin (Promega, Madison WI, USA). PCR was performed with a thermal cycler (Perkin-Elmer 2400, Boston, MA, USA) consisting of an initial step at 94 ℃ for 5 min. This was followed by 39 cycles of denaturation at 94 ℃ for 1 min, annealing at 36 ℃ for 1 min and extension at 72 ℃ for 1 min. Ten microlitres of the PCR products were electrophoresed in 10 g/L horizontal agarose gel in TBE buffer at 68 V for 2 h. The gels were stained with ethidium bromide (EB, 1 mg/L) and photographed.

DNA fragment cloning and sequencing

At first, two primers were designed: RDF1-CGCAAGCTTCC ACACAGAACCAC, and RDF2-CGCGGATCCGGAC CTTTACTACAAC. A 23S rDNA fragment (RDF) was amplified according to the gene sequence reported[32]. The PCR mixture was 40 μL in volume containing 4 μL of 10×polymerase buffer, 2 μL of genomic DNA (20 ng) from the reference strain NCTC11637, 1 μL (2 units) of Taq DNA polymerase, 4 μL of 2.5 mmol/L dNTPs, and 4 μL of 10 mmol/L primers. The sample was subjected to denaturation at 94 ℃ for 3 min. The PCR program was 30 cycles at 94 ℃ for 30 s, at 55 ℃ for 45 s, and at 72 ℃ for 1 min, followed by an extra extension at 72 ℃ for 5min. The PCR product (10 μL) was then electrophoresed in a 15 g/L agarose gel. DNA was recovered by using QIAEXÐagarose gel extract kits (Qiagen, Santa Clarita, CA, USA). The purified PCR product was then cloned into the *pT-Adv* vector (Clontech, Palo Alto, CA, USA) and transformed into *E. coli Top*^{10}, which was then inoculated on the selective plates containing 20 μL of 50 g/L ampicillin, 35 μL of 100 mmol/L IPTG and 40 μL of 20 g/L X-gal. White colonies were randomly picked up, suspended in 5 mL of Luria-Bertani medium containing ampicillin (50 mg/L) and cultured at 37 ℃ overnight. The recombinant plasmid was extracted by using Qiaprep spin miniprep kit (Qiagen, Santa Clarita, CA, USA). In the same way, RDFs from different *H pylori* isolates were amplified and cloned into the *pGEM-T-Easy* Vector (Promega, Madison, WI, USA). Then, A 23S rDNA fragment (1 050 bp) containing the RDF in the middle was also amplified from different *H pylori* isolates by using the primers DMSR1-TAAGTTCGCGATAAGGTGTGC and DMSR1-GGTTCCTGCTTAGATGCTTTC. The inserts in the recombinant plasmids and the RDF flanking regions were sequenced by using the Big dye terminator DNA sequencing kit (Perkin-Elmer, Boston, MA, USA) and ABI automated sequencer (GMI, Minnesota, USA).

Southern blotting

Southern blotting was carried out following the protocol provided in the Enhanced chemiluminescence (ECL) direct nucleic acid labeling and detection system (Amersham Pharmacia Biotech, Buckinghamshire, UK). In brief, after agarose gel electrophoresis of the RAPD products, the DNA was submitted to denaturation by immersing the gel (200 cm^2) in 200 ml buffer containing 0.5 mol/L NaOH and 1.5 mol/L NaCl for 30 min. Then the gel was neutralized in 200 ml of 0.5 mol/L Tris-HCl and 1.5 mol/L NaCl (pH 7.5) for 30 min. Afterward, the DNA was transferred to the Hybond N^+ membrane (Amersham Pharmacia Biotech, Buckinghamshire, UK) by using a capillary blotting apparatus. DNA fixation was carried out by exposing the membrane to an UV transilluminator (Vilber Lourmat, Marne la Vallee Cedex 1, France) for 5 min. RDF sequenced and digested by *EcoR* I from *pT-Adv* vector was used as a probe. The pre-hybridization and hybridization were performed in a buffer containing 0.5 mol/L NaCl and 50 g/L blocking agent in a hybridization oven at 42 ℃ for 1 h and 5 h respectively. After stringency washing (twice for 20 min in 6 mol/L urea, 4 g/L SDS and 0.1×standard saline citrate, SSC; twice for 5 min in 2×SSC), chemiluminenscence signals were detected by exposing the hyperfilm to the membrane for 5 to 30 min in a dark room.

RESULTS

H pylori gene profiles identified by RAPD

For all *H pylori* isolates from the 73 individuals, bacterial growth, genomic DNA extraction and RAPD were carried out under the same conditions. RAPD products were analyzed by 10 g/L agarose gel electrophoresis (Figures 1 and 2), which showed that *H pylori* from gastric antra of different individuals had different RAPD profiles whereas the isolates from antrum and cardia of the same individual had almost identical RAPD profiles with only one exception (lanes 5C and 5A in Figure 1).

Probe preparation

The sequence of RDF from the reference strain NCTC11637 was 99 % identical to that reported in the GenBank. It was a 361 bp fragment of the 23S rDNA (from 2 133 to 2 493), which is just inside the loop (2 134-2 684) to form peptidyltransferase center in the ribosome. The fragment was then used as a probe in Southern blotting to investigate if the random PCR primer would pick up the same fragment with the same amount from genomes of different clinical isolates of *H pylori*.

Southern blotting

Firstly, the sensitivity of Southern blotting, in which the RDF was used as both target and probe, was determined by using the ECL system. The results showed that the sensitive limitation of this system was 4 pg. Then, the probe was used to screen the RAPD products of different *H pylori* isolates. Parts of the results are shown in Figure 2. *H pylori* isolates from 27 of the

73 individuals were RDF positive, and the darkness of the blots was quite different from one isolate to another. As the size of the RAPD fragment hybridized with the RDF was bigger (about 400 bp) than that of the RDF, at least one primer binding site would be outside the RDF region.

A: 10 g/L agarose gel electrophoresis of RAPD products of *H pylori* isolates; M: 1 Kb DNA ladder; 73, 27, 98, 82, 88, 05, 90, 57, 23, 09, 15, 71, 40, 33 and 93: Designations of the *H pylori* isolates; N: *H pylori* reference strain NCTC11637; R: 1 ng RDF loaded in the well; O: Template blank control; B: Southern blotting results using the RDF as a probe, the dark blots on either side of Picture B corresponding to the 1 ng RDF in the agarose gel in Picture A.

Sequencing RDFs and their flanking regions

In order to know if there were sequence differences that might facilitate the binding of the random primer, the RDFs and their flanking regions from different *H pylori* isolates were sequenced. Firstly, the RDFs from 10 different *H pylori* isolates were cloned for sequencing. The isolates with designated numbers of 15, 22, 38, 58, 90 and 93 were RDF positive and the isolates 20, 41, 84 and 90 were RDF negative in Southern blotting. Blast analysis of the sequenced results exhibited that the RDFs from the 10 isolates were quite similar.

The rates of identity were 98 % to 100 %. There was no random primer binding siteinside the RDFs. Next, the RDF flanking regions were sequenced by using the PCR products directly. Four isolates were used. Sequences of the upstream regions or the downstream regions of RDFs were also quite similar (98 % to 99 % identity) between the RDF positive isolates (numbers 38 and 93) and the RDF negative isolates (numbers 84 and 90) in Southern blotting, and there was no random primer binding site inside the upstream regions or the downstream regions.

DISCUSSION

It is known that DNA fingerprints of clinical *H pyori* isolates are highly diversified[16,17] and the fingerprinting profiles are changeable even for the isolates from different parts of the stomach in a single host[33,34]. The results in this study were basically in according with those obtained in the previous studies. The gene diversity of *H pylori* is associated with certain diseases[20, 35,36], and clinical background and geographic origin of the isolates may be responsible for the changes[37].

It is always considered that the gene of rRNA is relatively conservative, and two copies of 23S rDNA exist in *H pylori* genome[32,38]. Theoretically, when the RDF probe is used to screen the RAPD products of different clinical isolates, Southern blotting profiles should be the same. However, our results showed that the Southern blotting profiles of 23S rDNA from different *H pylori* isolates were also polymorphic. Since genomes of different *H pylori* isolates contain almost identical RDF as well as the flanking regions and the same amount of genomic DNA was used as the templates in this study, instability of using RAPD to amplify this gene fragment at the pg level might be responsible for the results.

The random primer was first proposed for fingerprinting of *H pylori* by Akopyanz *et al*[31]. They recommended the primer since it had a relative high CG content and could be used to distinguish different *H pylori* isolates. In fact, when one employs this primer, there will be numerous potentially amplifiable fragments and only a few of them are visible on agarose gels after EB staining. This depends on the matching extent of the primer to the genomic DNA. For the bright or visible bands, the primer may be completely or mostly matched, but for the light or invisible bands, the primer is probably partially matched.

In conventionally used PCR, the specificity depends mainly on the properties of the primers and the annealing temperature. However, in PCR-based RAPD, the random primer is only 10 mers and the annealing temperature is 36 ℃. Therefore, specificity of amplification is relatively low. Since we could not find any primer binding site inside or outside the RDF region in this experiment, we propose that, for amplification of the RDF, the primer be partially matched to the genomic DNA, and thus, the profiles of RAPD and Southern blotting are diversified.

From our experience, RAPD depends highly on the quality and quantity of the template. If we make a comparison between two RAPD profiles of a given *H pylori* isolate, the concentration, purity and even the integrity of the DNA templates should be considered. The RAPD results will be quite different if the genomic DNA is prepared using two different methods. Sometimes different PCR machines might also give different results. So, when we employed this method, we had tried to treat every sample under the same conditions, and handled the DNA preparation carefully. Even so, RAPD seems to be unstable in amplification of low yield fragments, especially those that do not appear as visible binds in agarose gel electrophoresis.

RAPD has reasonable discriminatory power[39] and is effective for *H pylori* genotyping grossly on large scale. But stability of this method should be taken into consideration.

Although we found many strain specific RAPD profiles in this study, using the RAPD-based methods to screen *H pylori* strain specific genes are not recommended. To identify strain specific genes, the PCR sequencing techniques are more reliable and reproducible.

ACKNOWLEDGEMENT

We are grateful to Ms. Min Gong and Yan-Wing Ho, and also Mr. Mun-Fai Loke, Department of Microbiology, National University of Singapore, for their help in the preparation of *H pylori* isolates.

Abstract

AIM: Polymorphonuclear neutrophil (PMN) plays a major role in liver ischemia/reperfusion injury. Protective effect of ischemic preconditioning (IP) has been confirmed in liver ischemia/reperfusion injury. The purpose of this study was to investigate the effect of IP on C-X-C chemokine expression and PMNs recruitment early after liver transplantation.

METHODS: Male Sprague-Dawley rats were used as donors and recipients of orthotopic liver transplantation (OLT). The donor liver was stored 24 hours in University of Wisconsin (UW) solution at 4 ℃ pre-implantation. IP was done by clamp of the portal vein and hepatic artery of the donor liver for 10 minutes followed by reperfusion for 10 minutes before harvesting. The neutrophilic infiltration in liver was quantified using a myeloperoxidase (MPO) assay. Intragraft expression of macrophage inflammatory protein-2 (MIP-2) mRNA was investigated with in situ hybridization. The serum levels of MIP-2 and tumor necrosis factor (TNF)-α were also monitored.

RESULTS: After liver transplantation without IP, the hepatic MPO increased significantly compared with sham operated group. In IP group, PMN in liver indicated by MPO was reduced significantly. In situ hybridization showed no MIP-2 mRNA in sham group but dramatic expression in hepatocytes in non-IP group. In IP group, MIP-2 mRNA was significantly down-regulated. Similarly, serum MIP-2 and TNF-α levels were significantly elevated in non-IP group and both were reduced in IP group.

CONCLUSION: IP might protect graft liver from preservation-reperfusion injury after OLT through down-regulating C-X-C chemokine expression of hepatocytes, and alleviating PMNs recruitment after reperfusion.

INTRODUCTION

Liver transplantation as an effective therapy for end-stage liver diseases has been accepted. Though preservation techniques have been greatly improved, ischemia/reperfusion injury resulting in primary liver nonfunction still poses significant clinical problems and contributes to mortality[1-2]. Jaeschke *et al*.[3-6] established that there were two distinct phases of liver injury after warm ischemia and reperfusion. The initial phase of injury which is far less than that observed at later time points is characterized by Kupffer cell-induced oxidant stress. Events occurred during the initial phase including activation of Kupffer cells, initiate a complex inflammatory pathway that culminates in hepatic accumulation of neutrophils[7]. Recruited neutrophils directly damage hepatocytes by releasing oxidants and proteases and are responsible for the later phase of liver injury induced by ischemia/reperfusion. Activated PMN has also been implicated as a vital factor in the development of ischemia/reperfusion injury in both experimental and clinical liver transplantations[8-11].

C-X-C chemokines are a group of molecules that have both inflammatory and repairable properties and are best known for their neutrophil chemotactic properties[12,13]. MIP-2, belonging to C-X-C chemokines has been shown not only to regulate PMN recruitment from vascular compartment to the tissues[14] but also to cause PMN activation[15]. Kataoka *et al*. demonstrated that MIP-2 played a crucial role in PMN recruitment and activation after liver transplantation[10].

IP is a process of a short period of ischemia and reperfusion, which leads to an unexpected resistance to a long-term ischemia/reperfusion injury. It has been documented in several organs, including the liver[16-19]. In experimental liver transplantation, IP has been confirmed as an effective strategy for protecting the grafts from ischemia/reperfusion injury[20]. But few studies have been performed on whether and how IP effects PMNs accumulation and activation in protecting grafted liver from ischemia/reperfusion injury after liver transplantation. In this study, we therefore investigated the effect of IP on PMNs recruitment, as well as MIP-2 expression in grafted livers, to determine the role of C-X-C chemokine expression and PMNs recruitment in protecting grafted liver from prolonged preservation/reperfusion injury early after OLT.

MATERIALS AND METHODS

Animals

Male Spraque Dawley rats weighing 200 to 250 g were used as donors and recipients. They were housed in pathogen-free conditions with a 12-hr light-dark cycle and were allowed to drink water and fasted for 14 hours before operation. All experiments were performed in compliance with the standards for animal use and care set by Institutional Animal Care Committee.

Surgical procedures

OLT. Liver transplantation was performed according to Kamada's cuff-technique[21] with minor modifications. Before liver harvesting, 1 mL saline containing 50 units of heparin was given intravenously, and the donor liver was perfused *in situ* via the portal vein with 20 mL of cold physiological saline

solution to which 50 units of heparin was added. Following cuff preparation, the liver was stored in a beaker containing University of Wisconsin solution at 4 ℃ for 24 hours. At the end of storage, the liver was slowly flushed with 20 mL of cold (4 ℃) Ringer' s lactate and transplanted orthotopically into a recipient animal. The hepatic artery was not reconstructed.

IP. Before harvesting donor liver, the portal vein and hepatic artery were interrupted by placing a bulldog clamp for 10 min. Reflow was initiated by removing of the clamp for another 10 min.

In sham group, the left phrenic vein and the right suprarenal vein were ligated and the hepatic artery was freed by ligating and dividing.

Experimental design

All rats were randomly divided into: sham groups, non-IP group and IP group. To obtain blood and tissue samples, six animals were killed in non-IP and IP group after 1, 2, 4 and 6 hr of reperfusion and four animals at each time point in sham group. Plasma samples were collected from inferior vena cava, and separated by centrifugation, and median lobe of the liver was carefully excised and stored at -80 ℃ for analysis. Serum levels of alanine aminotransferase (ALT) and lactate dehydrogenase (LDH) were measured using standard clinical automated analysis. Serum levels of MIP-2 (IBL Immuno-Biological Laboratories, Hamburg) and TNF-α (R & D Systems, Inc) were measured using commercial enzyme-linked immunosorbent assay kits, respectively.

MPO assay

MPO was used as a marker of pulmonary and hepatic neutrophil infiltration[22]. MPO activity was measured photometrically employing 3, 3' , 5, 5' -tetramethylbenzidine as a substrate. Frozen liver tissues were macerated, homogenized, sonicated, and centrifuged at 4 000 g for 12 minutes at 4 ℃ as described previously[22]. MPO activity was measured in the supernatant, with calculations based on the absorbance change at 460 nm. All values were normalized to tissue weight.

Hybridization

Chunks (1 cm^3) from fresh rat liver were immediately fixed in 4 % paraformaldehyde at 4 ℃ for 8 h and dehydrated through graded ethanol, then embedded in paraffin and sectioned. The sections were layered onto glass slides by standard procedures. Five μm thick sections were cut for analysis. They were deparaffinized with xylene and quickly rehydrated through graded ethanol. The deparaffinized sections were quenched from endogenous peroxidase activity in 3 % H_2O_2 diluted in methanol. Then, the expression of MIP-2 mRNA was detected in rat liver tissue sections using a commercial ISH kit (TBD biotech Co.). All solutions of it were RNase free. The sections were digested using solution I (0.4 % pepsin, 0.1 M Hcl, TBD biotech Co.), then washed in 0.5 M PBS twice for 5 minutes each. The non-specific IgG binding sites were blocked with blocking solution I (1.5 % normal blocking serum, TBD biotech Co.) at RT and excess serum was blotted from the sections. Then, the sections covered with coverslips were prehybridized with a prehybridized solution (formamide, standard saline citrate, 100×denhardt' s, SDS, sperm DNA, TBD biotech Co.) at 37 ℃ for 4 h in a sealed humidity chamber. The sections were washed twice in 0.5 M PBS and hybridized with digitoxin-labeled oligonucleotide probe synthesized by TBD cooperation Lab, (5' -CCACTCGCCAGCTCCTCAATGCTGTACTGGT CCTGCTCCT-3'). Hybridization was performed at 38 ℃ overnight in a humidity chamber, and washed in 2×SSC, 0.5×SSC, 0.2×SSC for 5 minutes each. In the following step, the sections were blocked with blocking solution II (25 μg/ml avidin, TBD biotech Co.) for 15 minutes at RT, then excess solution was blotted. The sections covered by coverslips were incubated with biotinylated mouse anti-digitoxin antibody (TBD Biotech Co.) for 1 h at 37 ℃ in a sealed humidity chamber and washed three times in 0.01 M PBS for 5 minutes each. The sections were incubated with streptavidin-biotin-peroxidase complex (TBD Biotech Co.) at 37 ℃ for 1 h and washed three times in 0.01 M PBS for 5 minutes each. The complex was detected with DAB (0.1 % diaminonbenzidine, 0.02 % hydrogen peroxide, TBD Biotech Co.) in sections and counterstained with hematoxylin (Sigma). The first negative control group was performed in which the mouse anti-digitoxin antibody was substituted with normal mouse serum and the second was performed with RNase (20 μg/ml, Sigma) before hybridization. The last one was hybridized without any oligonucleotide probe.

Histology study

Liver samples were fixed in 4 % neutral buffered formalin, paraplast-embedded and cut into 4 μm thick sections, and stained with hematoxylin-eosin according to the standard procedures.

Statistical analysis

The data were expressed as mean ± SEM. Means of different groups were compared using a one-way ANOVA. The Student *t* test was performed to evaluate the significant differences between groups. Significance was determined at $P<0.05$.

RESULTS

Serum levels of ALT, LDH

Both ALT (A) and LDH (B) were significantly elevated after OLT without IP, compared with sham-operated group. When the liver grafts were pretreated with IP, the increases in ALT and LDH were relatively reduced to the non-IP group in each time point respectively (Figure 1).

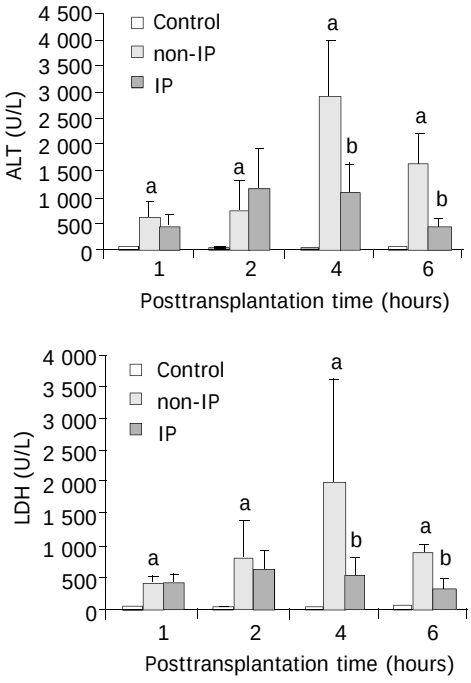

Figure 1 Changes in serum ALT (A) and LDH (B) levels. The serum ALT and LDH levels were significantly elevated in non-IP groups compared with sham-operated group ($^aP<0.01$, non-IP group *vs* sham-operated group). After IP, the increase was significantly reduced at 4 and 6 hour points after reperfusion ($^bP<0.05$, IP group *vs* non-IP group).

Hepatic PMNs accumulation

PMNs accumulation in the grafted livers was assessed by investigating the levels of MPO. Figure 2 shows changes in PMNs accumulation in three groups. The increases in non-IP groups were significantly reduced in IP group, especially at 4 and 6 hour points after reperfusion.

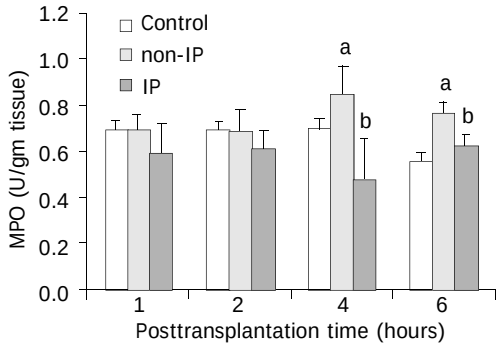

Figure 2 Changes of PMNs accumulation in grafted liver. PMNs accumulation was assessed by investigating the levels of MPO. The increase in non-IP groups was significantly reduced in IP groups, especially at 4 and 6 hour points after reperfusion ($^aP<0.05$, non-IP group *vs* sham-operated group. $^bP<0.05$, IP group *vs* non-IP group).

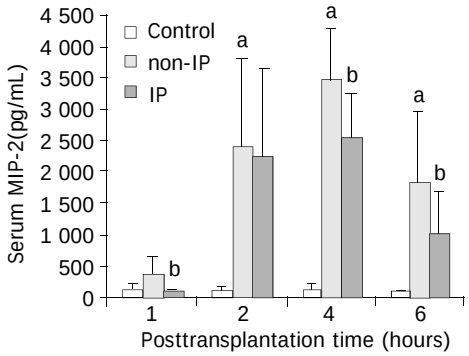

Figure 3 Changes in serum MIP-2 levels. MIP-2 was significantly increased in non-IP group compared with sham-operated group ($^aP<0.01$, non-IP group *vs* sham-operated group). After IP, the increase was significantly reduced at 1, 4 and 6 hours after reperfusion ($^bP<0.05$, IP group *vs* non-IP group).

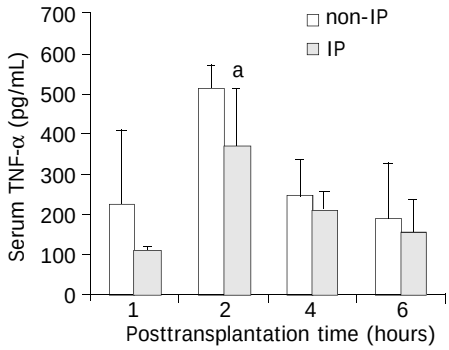

Figure 4 Changes in serum TNF-α levels. The levels of serum TNF-α were decreased to an extent in each time point respectively in IP group compared with non-IP group, especially at 2 hours after reperfusion. The decrease was significant ($^aP<0.05$, IP group *vs* non-IP group).

Serum levels of MIP-2, TNF-α

In non-IP group, MIP-2 increased significantly in each time point and peaked at 4 hours after reperfusion compared with the sham operated group. In IP group, the increases were reduced in each time point respectively (Figure 3). Similar results of TNF-α were obtained. But interestingly, the levels of TNF-α peaked at 2 hours in all three groups in this study (Figure 4).

Intragraft MIP-2 mRNA expression

In situ hybridization was performed at 4 hour point after reperfusion in all three groups (Figure 5). MIP-2 mRNA was not detectable in sham operated group (A). MIP-2 mRNA in the non-IP group (B) was remarkably up-regulated at 4 hour point and after IP(C), the expression was detectable at a lower level. It was emphasized that the MIP-2 mRNA was mostly expressed in hepatocytes in grafted livers.

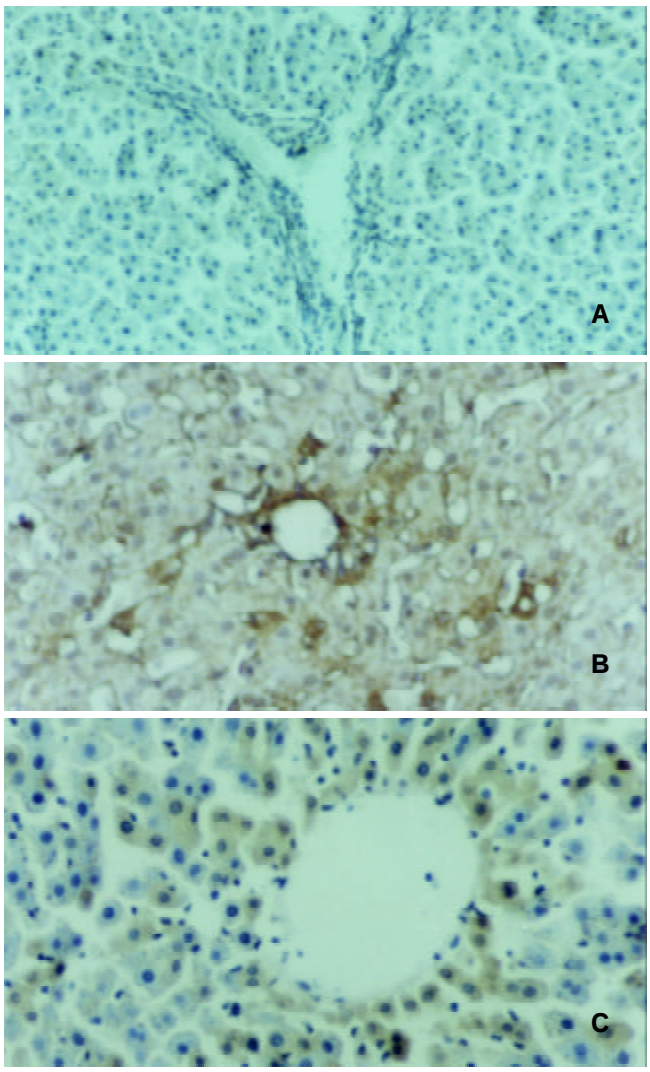

Figure 5 Intragraft MIP-2 mRNA expression. In situ hybridization was performed at 4 hours point after reperfusion in all three groups. MIP-2 mRNA was not detectable in sham operated group (A), and remarkably up-regulated in non-IP group (B), and after IP, the expression was detectable at a lower level (C). MIP-2 mRNA was mostly expressed in hepatocytes in grafted livers.

Histological changes of grafts

Similar to serum transferase indicating liver function, histological change of the graft showed that 24 hours cold storage in UW solution and reperfusion resulted in grafted liver damage. After IP and OLT, the damage was ameliated.

DISCUSSION

In this study, we demonstrated that 24 hours cold storage in

UW solution and reperfusion (OLT) resulted in grafted liver injury indicated by serum transferase and histological changes. In this process, TNF-α and C-X-C chemokines (i.e., MIP-2) were stimulated, and induced PMN-mediated tissue damage. Also we demonstrated that IP protected the grafted liver from prolonged cold preservation-reperfusion injury through down-regulation of TNF-α and MIP-2 and attenuation of PMNs accumulation. *In situ* hybridization revealed that MIP-2 mRNA was mostly expressed in hepatocytes.

IP is a phenomenon in which a short period of ischemia leads to unexpected resistance of subsequently prolonged preservation-reperfusion injury. It was found in the heart and named by Murry *et al* in 1986[16]. Recently it was reported that the phenomenon of preconditioning of the heart could be extended to the models of liver resection[19] and liver transplantation[20]. The role of IP in reducing myocardial and liver ischemic injury has been widely documented[23-26]. However, the mechanism of its protective effect remains unclear.

It is well known that accumulated PMNs in the grafted liver sinusoids might be important effector cells in the pathogenesis of liver preservation-reperfusion injury after OLT[8-11]. In this study, an increased serum level of MPO in non-IP group was synchronized with elevated serum ALT and LDH levels. The reactive oxygen and proteases released by activated PMNs might promote progressive hepatocellular damage[27]. This study demonstrated that IP decreased PMNs accumulation to protect the grafted liver from prolonged ischemia/reperfusion injury after OLT.

As the functions of cellular adhesion molecules were concerned, C-X-C chemokines (i.e., MIP-2) were intricately involved in the process of PMNs recruitment[28]. During warm hepatic ischemia/reperfusion injury, early production of proinflammatory mediators such as TNF-α has been documented[29-32]. Kataoka *et al*. revealed that TNF-α could stimulate C-X-C chemokine production in hepatocytes of prolonged ischemia-reperfusion injury after OLT[10]. Kupffer cell stimulation during extended cold preservation might result in overresponse and excessive production of TNF-α in the initial phase of reperfusion[33]. Then, TNF-α released from Kupffer cells might act locally on hepatocytes and other cells, resulting in increased C-X-C chemokine expression. This study demonstrated IP could interrupt this complex cascade of inflammatory mediators and ameliate the grafted liver damage after OLT. MIP-2 mRNA of hepatocytes performed by *in situ* hybridization was expressed in a lower level in IP group compared with non-IP group. And serum levels of TNF-α and MIP-2 in recipients also decreased significantly after IP.

In conclusion, IP can protect grafted livers from prolonged preservation-reperfusion injury in a rat liver transplantation model. One possible mechanism of its protective effect in the initial phase after reperfusion may be that IP interrupts the chain reaction of preservation-reperfusion injury in which excessive TNF-α released from activated Kupffer cells induces local expression of C-X-C chemokines of hepatocytes and accumulation of PMNs which play an important role in mediating the liver graft injury. Obviously, the preservation-reperfusion injury leading to primary nonfunction of grafted liver after OLT is multifactorial, and multi-mediators take part in it and intercross one another. Further experiments to define the protective role of IP in preservation-reperfusion injury should be performed.

Abstract

AIM: To investigate the anti-tumor mechanism of antisense oligodeoxynucleotide cantide against hTERT.

METHODS: Tumor cells were cultured overnight and grown to 50-60 % confluence. HepG2 and SMMC-7721 were treated with cantide mixed with lipofectin, or lipofectin alone. After inducted for 6 h at 37 ℃, 10 % FCS in DMEM was replaced in each well. After the treatment repeated twice to three times in each concentration of cantide, hTERT mRNA and protein expression were measured by RT-PCR and Western blot analysis, respectively. Telomerase activity was determined by TRAP-ELISA assay. CPP32- and ICE-like activity was also investigated using CasPACE assay system at 48 h after cantide treatment, and apoptosis was evaluated using the DeadEnd assay at 24, 48 and 72 h after cantide treatment.

RESULTS: Compared to the control cells, the cells treated with cantide showed a dose-dependent decrease in hTERT mRNA levels at 24 h and in protein levels at 48 h respectively. The telomerase activity was decreased as the concentration of cantide increased at 48 h. At the concentration of 800 nM, the telomerase activity in the treated HepG2 and SMMC-7721 cells was only 17.1 % ($P<0.01$) and 20.3 % ($P<0.01$) of that in untreated cells. The levels of CPP32-like protease activity in HepG2 and SMMC-7721 increased by 2.8- and 3.0-fold ($P<0.05$) at 48 h, and the levels of ICE-like protease activity also increased by 2.6- and 3.2-fold ($P<0.05$) respectively. The percentage of apoptosis in HepG2 and SMMC-7721 cells treated with 800 nM cantide at 72 h was 63 % and 52 % ($P<0.01$), respectively. By contrast, 8 % and 9 % of the cells were apoptosis after 72 h treatment with lipofectin alone.

CONCLUSION: Cantide can decrease telomerase activity by inhibiting the expression of hTERT gene and has a rapid anti-tumor effect through inducing the Caspase-dependent apoptosis. The rapid inhibitory effect of cantide on tumor growth demonstrates its feasibility in cancer treatment.

INTRODUCTION

Telomerase is a unique ribonucleoprotein enzyme responsible for adding the telomeric repeats onto the 3' ends of chromosome[1]. Telomerase plays an important role in the development of cellular immortality and oncogenesis[2,3]. Previous studies have shown that telomerase activity is found in 85-90 % of all human tumors, but not in their adjacent normal cells[4,5]. This makes telomerase a good target not only for cancer diagnosis, but also for the development of novel therapeutic agents[6,7].

The research of antisense oligodeoxynucleotides (ODN) is an area of heightened interest in the field of telomerase inhibition[8]. Antisense ODNs have been investigated on the inhibition of telomerase and suppression of tumor growth. But most of these antisense ODNs were designed to target the hTR template, and they did not reduce telomerase activity and tumor growth effectively[9-12]. It has been shown that expression of hTERT is closely associated with telomerase activity in human tumor cells while all human somatic cells constitutively contain hTR. Therefore, to significantly inhibit telomerase activity, hTERT might be more attractive as a target than hTR[13,14]. A series of antisense oligonucleotides were designed based on hTERT mRNA secondary structure. It has been demonstrated that an antisense oligonucleotide cantide has a strong inhibitory effect on tumor cell growth. The cytotoxic effect of a specific cantide antisense was also assessed by using the sense, random and mismatched ODN, only cantide had potent inhibitory effect on proliferation of tumor cells[15], and *in vivo* treatment of HepG2 tumor xenografts with cantide antisense ODN significantly retarded the growth of these tumors (data unpublished). To investigate the possible mechanism of antitumor effect of cantide, an *in vitro* study was performed in this report.

MATERIALS AND METHODS

Cell culture

Human hepatocellular carcinoma cells (HepG2, SMMC-7721) were obtained from Chinese National Cancer Institute, Chinese Academy of Medical Sciences, Beijing. Cells were cultured in Dulbecco's modified Eagle's medium supplemented with 10 % fetal bovine serum (GIBCO BRL, Grand Island, NY), 100 U/ml penicillin and 100 μg/ml streptomycin at 37 ℃ with 5 % CO_2.

Synthesis of oligonucleotides

The following specific PCR primers were synthesized by an applied biosystems 391 DNA synthesizer and purified by OPC (Perkin-Elmer, Foster city, CA). For β_2-microglobulin, sense (5'-TTCAGGTTTACTCACGTCATCC-3') and antisense (5'-CCAAATGCGGCATCTTCAAACCC-3'), amplification of 317 bp DNA fragment. For hTERT, sense (5'-TCTACCGGAAGAGTGTCTGGAGCAA-3') and antisense (5'-GCGCCCACGACGTAGTCCATGTTCA-3'), amplification of 202 bp DNA fragment. The selection of antisense ODNs against hTERT was described previously[15]. The sequence of the cantide was 5'-ACTCACTCAGGCCTC AGACT-3'. The phosphorothioate cantide was synthesized

on solid supports using Oligo Pilot II DNA (Amersham-Pharmacia, Piscataway, NJ) and purified by HPLC (Waters Delta Prep 4000) with SOURCE 15Q (Amersham-Pharmacia), and the purity of cantide was over 95 %.

Analysis of hTERT mRNA by RT-PCR

A total of 1.5×10^5 cells were seeded in a 6-well plate, and treated with 50, 100, 200, 400 or 800 nM cantide respectively mixed with 4 μl lipofectin (Invitrogen, Carlsbad, CA) according to the manufacturer' s instructions. The first day of treatment was designated as day 0. After 24 h, total RNA was isolated using TRIZOL (Invitrogen) by a single-step phenol-extraction method as templates. Subsequent RT-PCR reaction was performed using a reverse transcription system (RT-PCR kit, Promega, Madison, WI.). Briefly, first strand cDNA was synthesized using a Oligo $(dT)_{15}$ primer at 42 ℃ for 30 min. PCR reaction for hTERT and β_2-microglobulin was performed in a single reaction of 20 μl volume. The latter served as a control following 28 cycles of denaturing at 95 ℃ for 45 s, annealing at 58 ℃ for 40 s, and extending at 72 ℃ for 40 s. At this PCR condition, the amplification showed linearity as was determined experimentally (data not shown). PCR products were run on a 2.0 % agarose gel and visualized by ethidium bromide staining, and the intensities were then measured by scanning the gel with Gel Doc 1000 (Bio-Rad, Hercules, CA). Inhibition of hTERT mRNA was calculated by normalized intensity ratio hTERT: β_2-microglobulin of control sample according to the following formula:

$$\text{Inhibition percentage (\%)}=\left(1-\frac{A_{\text{sample}}\times A_{0\ \text{control}}}{A_{\ \text{control}}\times A_{0\ \text{sample}}}\right)\times 100.$$

A_{sample}: the intensity of hTERT PCR product in cells treated with cantide and lipofectin, $A_{0\ sample}$: the intensity of hTERT PCR product in cells treated with lipofectin alone, $A_{control}$: the intensity of β-actin product in cells treated with cantide and lipofectin, $A_{0\ control}$, the intensity of β-actin product in cells treated with lipofectin alone.

Analysis of hTERT protein

The levels of hTERT protein in cells treated with cantide were measured by scanning the density of bands on Western blot. The treatment of cantide was performed using the same method as for the hTERT mRNA level analysis described above. After 48 h of transfection, cells were collected by trypsinization and lysed in a lysis buffer containing 9.1 mM Na_2HPO_4, 1.7 mM NaH_2PO_4 (pH 7.4), 150 mM NaCl, 1 % NP-40, 0.5 % sodium deoxycholate, 0.1 % SDS, 100 μg/ml PMSF, 1 μg/ml aprotinin and 1 mM sodium orthovanadate for 30 min on ice. Equal amount (60 μg) of proteins was run on a 6 % SDS-PAGE gel, and transferred onto Hybond-polyvinylidene difluoride membranes (Amersham, Arlington Heights, IL). The transferred membrane was incubated first with primary antibodies against hTERT (Santa Cruz Biotechnology, Santa Cruz, CA) or primary antibodies against actin, and followed with peroxidase-linked secondary antibody, and finally the ECL Western blot system (Promega) was used for developing the bands. The intensity of the bands was scanned by Gel Doc 1 000 (Bio-Rad), and the inhibition percentage (%) was calculated according to the following formula: inhibition percent=$(1-A_{sample}/A_{control})\times100$.

Telomerase activity (TRAP-ELISA) assay

TRAP-ELISA was performed using the Telo*TAGGG* and Telomerase PCR ELISA kit (Roche, Indianapolis, IN) following the manufacturer' s instructions. Telomerase levels were determined after 48 h treatment of cantide (400 nM) transfected using the method as for the hTERT mRNA level analysis described above. These cells were grown in 24-well plates. Cells were homogenized in 200 μl lysis buffer and incubated on ice for 30 min. To determine the specificity of the assay, all protein samples were preheated for 10 min at 70 ℃ to inactivate telomerase and tested in parallel in the assay. 5 μg of each extract was assayed in 50 μl reaction mixture containing 25 μl of reaction mixture and 5 μl of the internal standard. After incubated at 25 ℃ for 30 min, the reaction mixture was then subjected to PCR amplification in a thermal cycler for 20 cycles at 94 ℃ for 30 s, at 50 ℃ for 30 s, and at 72 ℃ for 90 s. Subsequently, ELISA reaction was performed following the manufacturer' s instructions.

DeadEnd assay

Apoptosis of treated tumor cells was detected using TUNEL technique. Cells (5×10^3/well) were plated in 96-well dishes and treated with cantide at a final concentration of 400 nM. At 24, 48, and 72 h after transfection, modified TUNEL assay was performed using DeadEnd colorimetric apoptosis detection system (Promega) according to the manufacturer' s instructions. Briefly, cells were harvested, washed and fixed on silanized microscope slides. Biotinylated nucleotide was incorporated at the 3' -OH DNA ends using terminal deoxynucleotidyl transferase (TdT). Streptavidin-HRP was then bound to these biotinylated nucleotides, which were detected using hydrogen peroxide and diaminobenzidine (DAB). With this procedure, apoptotic cell nuclei were stained dark brown. Stained cells were observed under a light microscope.

Caspase activity assay

Caspase (CPP32-like and ICE-like) activity was evaluated using CaspACE assay system fluorometry (Promega) according to the protocol provided by the manufacturer. Cells were plated in flasks and treated with 400 nM cantide mixed with lipofectin. At 48 h after cantide treatment, cells were harvested and washed, lysed by subjecting to four cycles of freezing and thawing, and centrifuged at 16 000 g for 20 min at 4 ℃. The same amount of supernatant was pipetted into a 96-well plate, then the following items were added into each well, namely 32 μl buffer, 2 μl DMSO, 100 μl DTT (100 mM), 2 μl of appropriate substrate (2.5 mM). The final volume was 100 μl. Blank (without cells extracts) and negative control (with inhibitor) reaction mixtures were also prepared simultaneously. After incubated at 30 ℃ for 60 min, the fluorescence of the reactions at an excitation wavelength of 355 nm and emission wavelength of 460 nm was measured. Caspase activity was determined in duplicate cells. Relative fluorescence units (△FU) were calculated according to the formula: $\triangle FU=(FU_{assay}-FU_{blank})-(FU_{negative}-FU_{blank})$.

Statistics

The data were expressed as means ± standard deviation (SD), statistical analysis was performed by Student' s-*t*-test (two-tailed).All data represented at least two independent experiments.

RESULTS

Effect of cantide on hTERT mRNA expression

It has been suggested antisense ODNs may inhibit gene expression through diverse effects on transcription and translation, inhibition of mRNA transcription can occur through formation of triple helixes with complementary regions in DNA, and/or mRNA can be cleaved by recruitment of the endogenous nuclease RNase-H to catalyze the degradation of ODN-RNA dimmers[16]. Therefore, the mRNA level of hTERT was determined by semi-quantitative RT-PCR. A 202 bp DNA

fragment of hTERT gene and a 317 bp DNA fragment of β_2-microglobulin gene were amplified by RT-PCR with specific primers, respectively. Figure 1A shows that the mRNA expression level of hTERT was decreased as the concentration of cantide treatment increased at 24 h when compared to the untreated cells, while the mRNA level of β_2-microglobulin as a control was almost unchanged. As shown in Figure 1B, after treatment with 800 nM cantide normalized according to the levels of β_2-microglobulin, the relative inhibition rate of hTERT mRNA expression was 74.4 % (P<0.01) and 68.4 % (P<0.01) in treated tumor cells HepG2 and SMMC-7721, respectively.

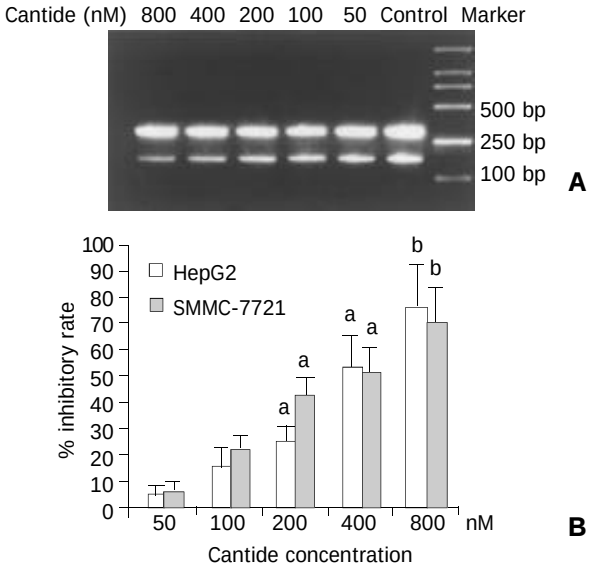

Figure 1 Inhibitory effects of cantide on mRNA level of hTERT. A: Electrophoresis of PCR products of hTERT gene and β_2-microglobulin gene in HepG2 cells treated with cantide. B: Quantitation of inhibitory percentage of hTERT mRNA in treated cells. Each level of PCR product of hTERT gene was quantitated and normalized by the level of β_2-microglobulin. Inhibitory rate was calculated by comparing to the control cells. The results were expressed as means ± SD from three independent experiments. [a]P<0.05 *vs* the cells treated with lipofectin alone, [b]P<0.01 *vs* the cells treated with lipofectin alone.

Western blot analysis was performed to determine the effect of cantide treatment on hTERT protein level in tumor cells. Figure 2A shows that the protein level of hTERT was decreased as the concentration of cantide increased at 48 h compared to the untreated cells. The relative inhibition percentage of hTERT protein was 67.8 % (P<0.01) and 66.2 % (P<0.01) in HepG2 and SMMC-7721 cells treated with 800 nM cantide, respectively (Figure 2B).

These results indicated that cantide inhibited hTERT gene expression in a dose-dependent manner after 48 h treatment.

Down-regulation of telomerase activity

It was shown that the expression of hTERT gene appeared to correlate with the level of telomerase enzymatic activity in many human tumor cells[17,18]. To investigate whether the telomerase activity was affected in tumor cells treated with cantide, a TRAP-ELISA assay was performed. Figure 3 shows that the decrease of telomerase activity was observed after 48 h of treatment at various concentrations of cantide. Moreover, the decrease of telomerase activity was approximately correlated with the concentration of cantide. At the concentration of 800 nM, the relative telomerase activity in the treated HepG2 and SMMC-7721 cells was only 17.1 % (P<0.01) and 20.3 % (P<0.01) of that in untreated cells at 48 h, respectively. These findings suggested that treatment of cantide decreased the telomerase activity in a dose-dependent manner by direct inhibition of the hTERT gene expression.

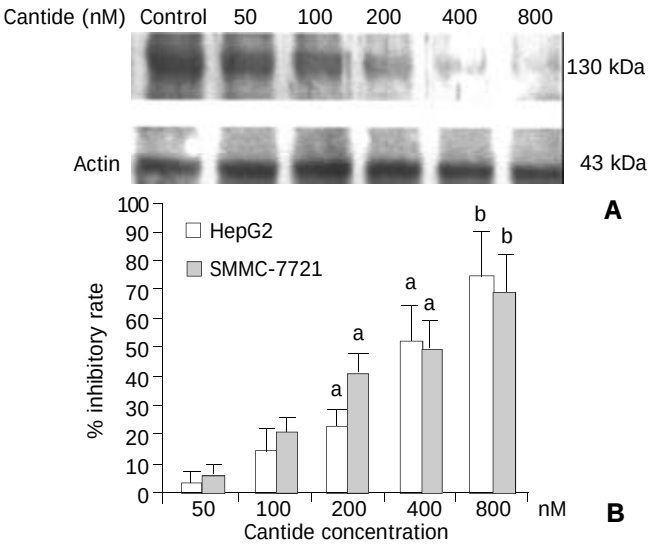

Figure 2 Inhibitory effects of cantide on protein level of hTERT. A: Western blot analysis of hTERT protein in HepG2 cells treated with cantide. B: Inhibitory percentage of hTERT protein in treated cells compared to the control cells. Each level of hTERT protein was quantitated. Inhibitory rate was calculated by comparing to the control cells. The results were expressed as means ± SD of two independent experiments. [a]P<0.05 *vs* the cells treated with lipofectin alone, [b]P<0.01 *vs* the cells treated with lipofectin alone.

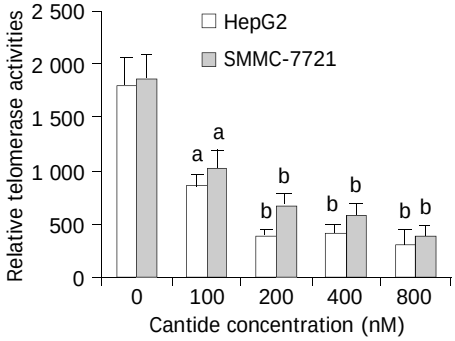

Figure 3 Comparison of telomerase activity in HepG2 and SMMC-7721 cells treated with cantide. 48 h after treatment with cantide, cells extract was tested for telomerase activity by TRAP-ELISA assay. The results were expressed as means ± SD from three independent experiments. [a]P<0.05 *vs* the cells treated with lipofectin alone, [b]P<0.01 *vs* the cells treated with lipofectin alone.

Induction of apoptosis with cantide

The DeadEnd colorimetric apoptosis detection system labeled fragmented DNA *in situ* and was used for detecting apoptosis, which was used to investigate whether cantide induced apoptosis in tumor cells. Figure 4A shows the staining of HepG2 cells 72 h after treatment. The cells treated with lipofectin alone showed very few stained cells (Figure 4 Aa). In contrast, most of the cells treated with cantide were intensively stained (Figure 4 Ab). To quantify the extent of apoptosis, the percentage of stained cells from a total of 200 cells was determined in each treatment group. As shown in Figure 4B, the percentage of apoptotic cells after cantide treatment was increased both in a time-dependent manner and in a dose-dependent manner. The percentage of stained cells in HepG2 and SMMC-7721 cells treated with 800 nM cantide at 72 h was 63 % and 52 % (P<0.01), respectively. By contrast, 8 % and 9 % cells were stained after 72 h treatment with

lipofectin alone. These results suggested that the cytotoxic effect of cantide was mainly due to induction of apoptosis.

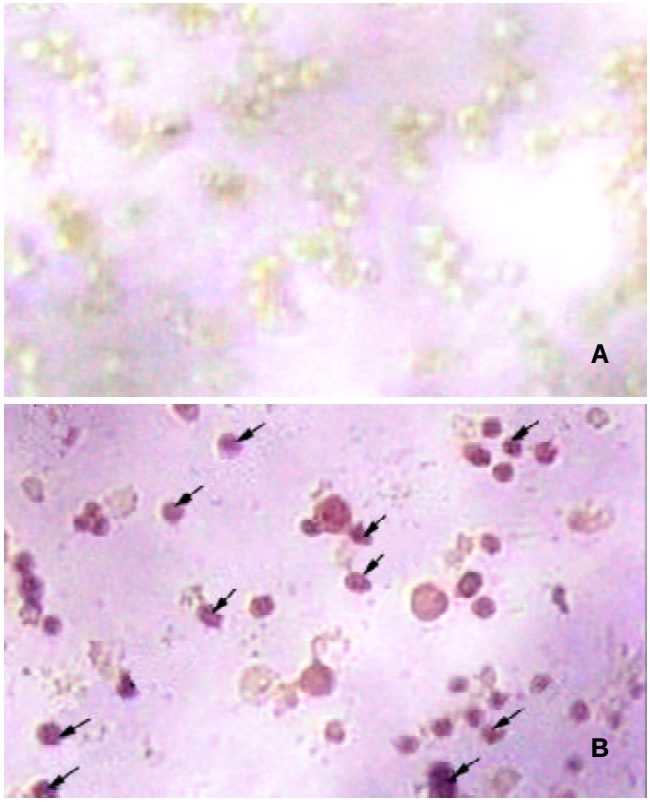

Figure 4 Apoptotic features of tumor cells. The DeadEnd kit was utilized for the assay. A: staining of the cells treated with (a) lipofectin alone and (b) cantide in combination with lipofectin. The arrows showed the representative cells with dark brown staining, 100×. B: the percentage of TUNEL-positive cells treated with cantide. c: HepG2 cells, d: SMMC-7721 cells. The results were expressed as means ± SD from three independent experiments.

Activation of Caspase

It was shown that Caspases were the main factor in the apoptotic pathway[19,20]. We investigated whether Caspase was involved in the anti-tumor effect by utilizing a Caspase activity detection assay. We observed that ICE- and CPP32-like protease activity in tumor cell treated with cantide reached the highest point at 48 h (data not shown). The levels of CPP32-like protease activity in HepG2 and SMMC-7721 were increased 2.8- and 3.0-fold respectively at 48 h ($P<0.05$) compared to the cells treated with lipofectin alone, and the levels of ICE-like protease activity were also increased 2.6- and 3.2-fold ($P<0.05$) at 48 h, respectively (Figure 5). These results clearly indicated the involvement of Caspases family (at least ICE- and CPP-like) in the induction of apoptosis by cantide treatment.

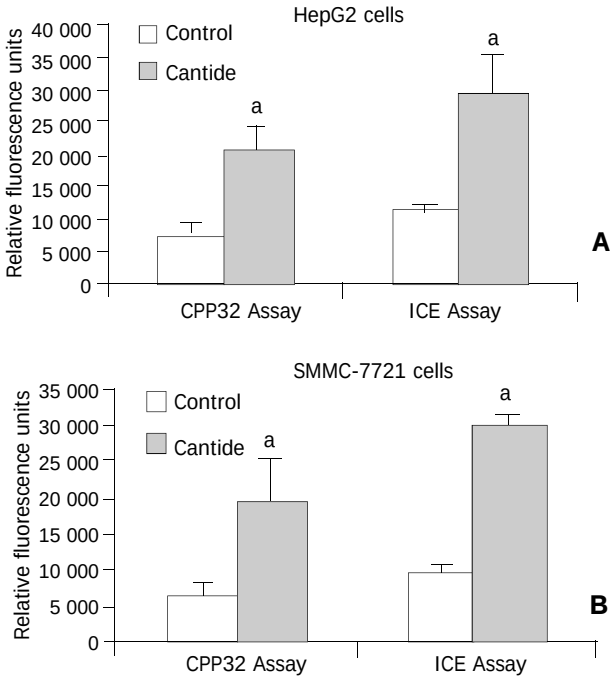

Figure 5 Measurement of CPP32- and ICE-like protease activities in tumor cells treated with cantide. Two days after treatment with cantide, cell lysates were tested for CPP32- and ICE-like protease activities.The results were expressed as means ± SD from three independent experiments. A: HepG2 cells, B: SMMC-7721 cells. $^aP<0.05$ *vs* the cells treated with lipofectin alone.

DISCUSSION

The hypothesis of telomerase mechanism is supported by the idea that progressive shortening of telomeres regulates the lifespan of cells, with each cell division, telomeres are shortened by 50-200 bp.When telomeres become critically short, the cells turn to growth arrest[21,22]. The rate of telomere DNA shortening is regulated by telomerase expression and activity[23]. Therefore, telomerase inhibitors might be useful as anticancer agents, but there will be an expected log phase between the time when telomerase is inhibited and the time when telomere of cancer cells is shortened sufficiently to produce detrimental effects on cell proliferation[24]. It takes approximately 1 month to induce cell death in tumor cells following telomerase inhibition by transfection of antisense hTR vector[25]. Our previous study has shown that cantide has a rapid inhibitory effect on tumor growth 3 days after *in vitro* treatment[15], and this striking effect is unlikely to be interpreted by the hypothesis that cantide is acting specifically through a telomere-dependent mechanism because the cells have not undergone sufficient cell divisions to significantly shorten their telomeres. It is likely that there might be other mechanisms for the antitumor effect of cantide.

In this study, we detected apoptosis in tumor cells just 3 days after cantide treatment in a dose-dependent manner. Taking previous reports on antisense hTR vector and our studies together into consideration, it is likely to raise the possibility that antitumor effect of cantide occurs through following two pathways: 1) A short-term effect on apoptosis is induced rapidly by cantide. 2) A long-term effect on

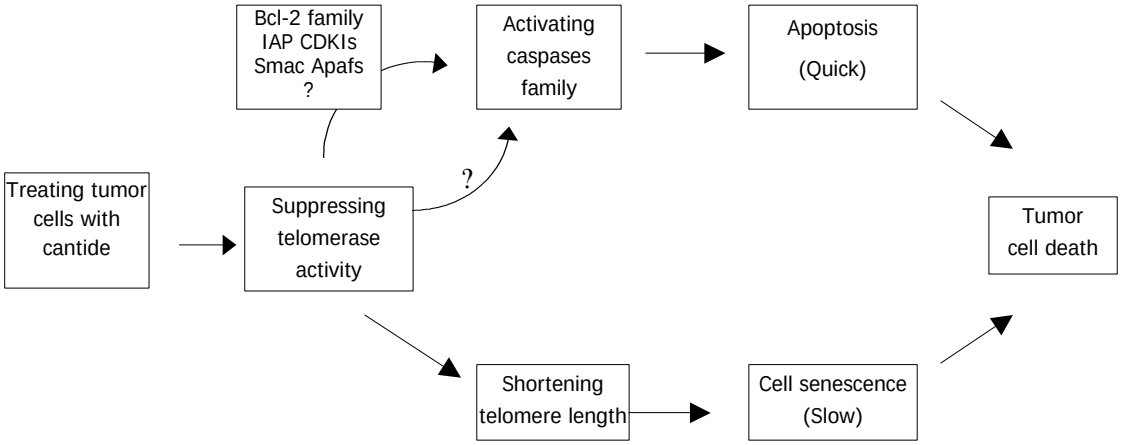

Figure 6 Two possible pathways of antitumor effect of cantide. IAP: inhibitors of apoptosis, CDKIs: cycin-dependent kinase inhibitors, Apafs: apoptotic protease activating factors.

telomerase activity is inhibited, and cell death is caused when telomere length is critically shortened by telomeric DNA.

It has been demonstrated that Caspase is a central executioner of apoptosis machinery, and over-expression and activation of Caspases in human cells lead to apoptosis[26,27]. To date, fourteen mammalian Caspases have been described. Among them, two subfamilies have been categorized based on amino acid sequence, substrate and inhibitor specificities. They are ICE-like proteases and CPP32-like proteases[28]. In this study, we found that both CPP32- and ICE-like proteases were increased 2 or 3-fold in tumor cells compared to the control cells 2 days after cantide treatment. Based on this evidence, the rapid antitumor effect of cantide may be due to active induction of Caspase-dependent apoptosis. Cantide can activate Caspase activity and lead to rapid cell death via apoptotic pathways, and might be a potential therapeutic agent for the treatment of cancer.

It has been found that 2-5A antisense ODN could cause profound cell death in prostate cancer cells and ovarian cancer cells, but not in fibroblast cells and normal ovarian epithelial cells without telomerase activity[12, 29]. Furthermore, suppression of TERT levels and function in embryonic mouse hippocampal neurons in culture could significantly increase their vulnerability to cell death induced by amyloid beta-peptide, and over-expression of TERT in pheochromocytoma cells could result in decrease of vulnerability to amyloid beta-peptide-induced apoptosis[13]. In addition, hTERT gene could be transfected into telomerase negative human embryo lung fibroblasts, the telomerase-expression cells could elongate telomeres and increase resistance to apoptosis induced by hydroxyl radicals[30]. We detected the down-regulation of hTERT mRNA gene expression, and found a significant decrease in telomerase activity after cantide treatment. The decrease was correlated with the concentration of cantide. Based on the observation above, we speculate that telomerase plays another role in addition to maintaining the telomere length, disturbance of this function will cause a rapid cell death by activating the Caspases. In accordance to that hypothesis, Cao *et al*[31] have also reported that telomerase plays roles not only in up-regulating cell proliferative life span, but also in supporting cell proliferative rate by a mechanism involving telomere lengthening-independent activity. Therefore, there should be some proteins that deliver messages between telomerase and Caspase, and further studies using techniques such as biochip or yeast two-hybrid system are necessary to find certain associated molecules.

In summary, our results have shown that cantide can effectively inhibit hTERT gene expression, decrease telomerase activity, and trigger apoptosis through activation of Caspase family. Apoptosis induction may be one of the potential mechanisms of cantide-medicated inhibition for tumor cell growth. Continuous cantide treatment might shorten the telomere to a size that leads to cell senescence (Figure 6). The treatment with cantide may be a potential strategy for cancer with telomerase activity.

Abstract

AIM: To investigate the expression of phosphorylating p38 mitogen-activated protein kinase (MAPK) in rat small intestine after ischemia-reperfusion (I/R) insult and its relationship with the localization of intestinal stem cells.

METHODS: Forty-eight Wistar rats were divided randomly into three groups, namely intestinal ischemia-reperfusion group (R), intestinal ischemia group (I) and sham-operated control group (C). In group I, the animals were killed 45 minutes after superior mesenteric artery (SMA) occlusion, while in group R the rats sustained SMA occlusion for 45 minutes and reperfusion for 2, 6, 12 or 24 hours respectively. In sham-operated control group, SMA was separated, but without occlusion. The activity of plasma diamine oxidase (DAO) was determined. Intestinal tissue samples were also taken for histological analysis and immunohistochemical analysis of MAPK p38 detection and intestinal stem cell localization.

RESULTS: The changes in histological structure and plasma DAO levels indicated that the intestinal barrier was damaged after intestinal I/R injury. In group C and I, each crypt contained 5-6 p38 MAPK positive cells, which were mainly located in the lower region of the crypts. This was consistent with the distribution of intestinal stem cells. The presence of positive cells in crypts increased with the time of reperfusion and reached its peak at 12 hours after reperfusion (35.6 %).

CONCLUSION: After intestinal I/R injury, the expression of phosphorylating-p38 MAPK in small intestine increased with the duration of reperfusion, and its distribution coincided with that of intestinal stem cells and their daughter cells, indicating that phosphorylating-p38 might be a possible marker of intestinal stem cells.

INTRODUCTION

The four principal differentiated cell lineages of the intestinal epithelium are derived from a common multipotent stem cell located near the base of each crypt. It is observed that normally there are about 1-4 stem cells in each small intestinal crypt. These crypt stem cells are divided to produce a daughter stem cell as well as more rapidly to replicate transit cells, which in turn undergo 4-6 rapid cell divisions in the proliferative zone located in the lower half of each crypt[1,2]. The mitogen-activated protein kinase (MAPK) cascade, a cytoplasm protein kinase which requires dual phosphorylation on specific threonine and tyrosine residues for their activation, can transmit the mitogen or the differentiating signals from the cell surface into the nucleus, thus regulating the gene expression. p38MAPK is an important member of the MAPK family[3-5]. There has been hardly any report to explore the expression characteristics of phosphorylating-p38 mitogen-activated protein kinase (MAPK) in rat small intestine after ischemia-reperfusion (I/R) insult and its relationship with the localization of intestinal stem cells. In the present study, we used SMA occlusion rats as an animal model to determine the expression of phosphorylating-p38 MAPK after intestinal I/R injury, and to investigate its relationship with small intestinal stem cells.

MATERIALS AND METHODS

Animal model and experimental design

Forty-eight healthy male Wistar rats (Animal Centre, Chinese Academy of Military Medical Sciences) weighing 200-250 g were used. After 1 week adaption in our animal centre and 12 hours fasting and free drinking just before the experiment, the animals were anaesthetised with 3 % sodium pentobarbital. Ischemia/reperfusion injury was produced by clamping the superior mesenteric artery (SMA) for 45 minutes and loosing the splint to form reperfusion injury. The animals were divided randomly into ischemia-reperfusion insult group (R), ischemia only group (I) and sham-operated control group (C). According to the different periods after reperfusion, group R was further divided into 2, 6, 12 and 24 hours subgroups. In group C, SMA was separated but without occlusion, and samples were taken after exposure of SMA for 45 minutes. In group I, animals were killed after occlusion for 45 minutes. In group R, rats were killed at different time points after reperfusion. Blood samples and intestinal tissue biopsies were taken. Blood samples were centrifuged and serum was frozen to measure plasma diamine oxidase (DAO). Tissue biopsies were fixed with 4 % paraformaldehyde for immunohistochemical detection of MAPK p38 and localization of stem cells.

Detection index

Plasma DAO activity Plasma DAO activity was determined according to references 6 and 7.

Histological staining Polyformalin fixed, paraffin embedded small intestinal samples were also cut into 5 μm thick sections,

deparaffinized in xylene, and rehydrated in graded ethanol, and then stained with haematoxylin-eosine (HE) for histological observation under light microscope (Olympus, Japan).

Measurement of phosphorylated forms of p38 MAPK

Formalin-fixed, paraffin-embedded small intestinal tissues were used to measure the phosphorylated forms of p38 MAPK by immunohistochemistry. Immunohistochemistry was performed according to the instructions of the Power Vision™ kit (Santa Cruze, USA). Briefly, sections (5 μm) were dewaxed and rehydrated in graded alcohols. Endogenous peroxidase activity was quenched, antigen retrieval was performed by heating for 20 minutes at 100 ℃ in 0.01 mol/L sodium citrate. The primary monoclonal antibody for p38 MAPK (Cell Signaling Technology, Inc., USA) was diluted 1:100 with the dilute buffer and incubated for 40 minutes at 37 ℃. Then sections were incubated with HRP-conjugated secondary antibody (Santa Cruz, USA) for 20 minutes at 37 ℃. Positive expression was detected with diaminobenzidine (DAB, Sigma, St. Louis, MO, USA). Sections were lightly counterstained with hematoxylin, dehydrated in graded alcohols, and mounted. As negative control, the sections were processed in the same way as above, but PBS was used as primary antibody instead of the p38 MAPK monoclonal antibodies.

Results determination

The results of positive staining cells and their distribution were observed under 10 times eyepiece and 40 times object-lens microscope. Visions of relatively good morphology of crypts were chosen to count the positive staining cells. Among the cells in the centre of crypt basement, positive staining cells and negative cells were counted upward till reaching the boundary to villus. Fifty intestinal crypts were required for counting, and then the ratio of positive cells were calculated and analyzed.

Statistical analysis

Data were expressed as mean ± standard error. Comparisons between groups of data were analyzed by Students *t* test. *P* values <0.05 were considered as statistically significant.

RESULTS

Histological changes

It was found under light microscopy that reperfusion resulted in the damage of intestinal barrier. HE staining showed that partial loss of mucosa was observed after 2 hours of reperfusion, while at 6 hours after reperfusion, the damage of epithelial cells of intestinal mucosa, hemorrhage and necrosis were observed and accompanied by inflammatory cell infiltration in intestinal wall.

Changes of plasma DAO activity

Plasma DAO levels elevated from 2 hours after reperfusion in all groups, and reached their peak at 6 hours, which was an increase of 1.7 fold as compared with those in normal controls ($P<0.05$), and then decreased gradually, almost back to normal at 24 hours after the reperfusion (Table 1).

Table 1 Changes of plasma DAO activities in different groups

Groups	DAO activity (U / ml)	Groups	DAO activity (U / ml)
Group C	0.70±0.19	Group R6	1.20±0.24[b]
Group I	0.76±0.16	Group R12	1.00±0.28[a]
Group R2	0.90±0.23	Group R24	0.80±0.17

[a]$P<0.05$, [b]$P<0.01$ compared with control.

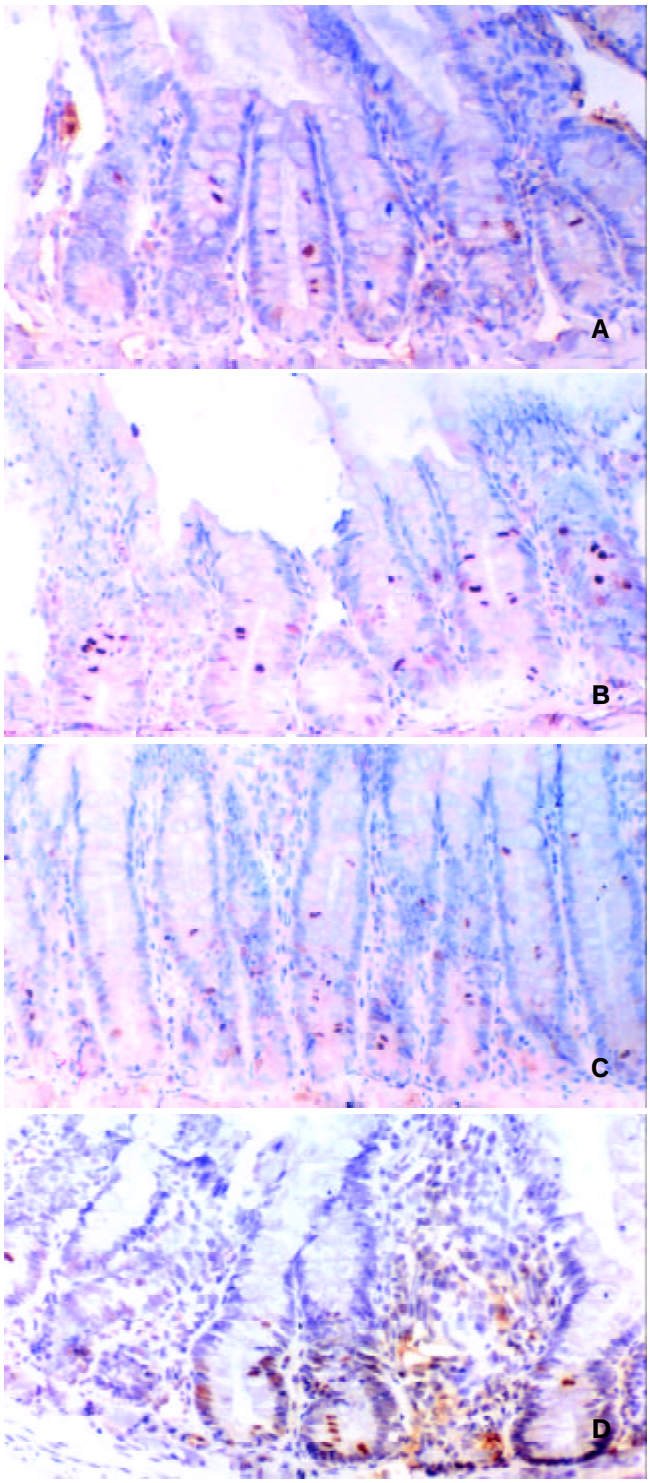

Figure 1 The expression of phosphorylated p38 MAPK in control group (A), ischemia group (B), ischemia-reperfusion 6 h (C) and 12 h (D) groups. The positive expression of p38 MAPK signals was localized mainly in the lower half of the crypts and in the cytoplasm of the crypt cells. The positively stained cells increased remarkably after 6 hours, and reached their peak at 12 hours after reperfusion, which was about 35.6 % of the total cells in crypts. At this stage, the positive staining was primarily localized in nucleus of crypt cells.

P38 MAPK expression

The immunohistochemical staining for phosphorylated forms of p38 MAPK was evaluated and summarized in Table 2. In groups C and I, there were only 5-6 p38 MAPK positive staining cells in each crypt, which were localized mainly in the lower half of the crypts and in the cytoplasm of the crypt cells. When the cell in base of crypt was regarded as layer 1,

then upward was counted till reaching the boundary to villus, there were normally about 30 cell layers. The p38 MAPK positive staining cells were mainly localized between layers 2 and 10, few positive cells were seen beyond this scale. The number was decreased slightly after 2 hours of reperfusion. The positively stained cells increased remarkably after 6 hours, and peaked at 12 hours after reperfusion, which was about 35.6 % of the total cells in crypts. At this stage, the positive staining was primarily localized in the nuclei of crypt cells. The number of positive cells was decreased and almost returned to normal after 24 hours of reperfusion. A few positive cells were found in the matrix of villus. However, no positive cells were observed in the epithelium of villus (Figure 1).

Table 2 Ratio of p38 MAPK positively stained cells to total cells in small intestinal crypts ($\bar{x}\pm s$)

Groups	Expression ratio (%)	Groups	Expression ratio (%)
Group C	15.6±1.5	Group R6	27.0±1.8[a]
Group I	14.0±1.0	Group R12	35.6±2.6[b]
Group R2	10.5±0.8	Group R24	19.3±2.1

[a]$P<0.05$, [b]$P<0.01$ compared with control.

DISCUSSION

It has become the center to study the internal organ injury and repair after severe trauma and burns in recent years and a new focus to study stem cells and intestinal organ repair[8-13]. Especially, the regulatory effects of growth factors and stem cells in internal organs are the very important field[14,15]. However, little is known about the molecular mechanisms that regulate the dynamics of stem cell replication or stem cell fate in intestinal epithelium during either normal epithelial renewal or regeneration of a functional epithelium after injury. Unfortunately, there have been no sensitive markers which can be used to identify the intestinal stem cells. In the previous studies, some positive expression of both PCNA and Ki67 in G1 phase stem cells, transit cells and other daughter cells was observed, which made them unable to act as markers for stem cells, thus becoming extremely difficult to study intestinal stem cells[16-18]. This finding raises a basic question: is there any other index which can be used as the suitable marker for stem cells?

Mitogen-activated protein kinases (MAPK) are mainly composed of the "extracellular signal regulated" p42/p44 MAPK and "stress-regulated" (SR-MAPKs) stress-activated protein kinases (SAPKs)/c-Jun N-terminal kinases (JNKs) and the p38-MAPKs. On stimulation, MAPKs translocations to the nuclei where they may phosphorylate nuclear transcription factors, thus regulating gene expression[19,20]. Philips *et al*[21] found from an *in vitro* study of mouse embryo fibroblasts, that inhibiting the activation of p38 could improve the expression of cyclin A, which is closely related to cell proliferation. p38 not only promotes the apoptosis in hematopoietic cells containing some stem cell properties, but also mediates the proliferating effect of IL-1. Various MAPK subtypes have synergetic effects[22]. p38 may have a dual function, and is tissue specific. Its effect depends on the injury degree, period and its activated condition. p38 also has a close correlation with the activation of upstream and downstream components of signaling pathways.

p38γ, a subtype of p38, is involved in myoblast differentiation[23] and its expression is enhanced with hypoxia. p38γ mediates the signaling pathway of DNA damage induced by γ ray, which protects DNA from radiative damage by stopping the cells in G2 phase. p38 may exert its effect by different subtypes.

Up to date, the studies of p38 in intestinal cells have remained on *in vitro* tissues and cultured cells. It has been concluded that p38 is related to the differentiation of intestinal crypts and villi[24]. The results of this study showed that in normal rat small intestinal cells, phosphorylated forms of p38 MAPK were mainly located in the base of crypts and cytoplasm of crypt cells, and very few in the nuclei. This localization was similar to those of intestinal stem cells demonstrated by other investigations[1,2]. These positive cells might be composed of stem cells, daughter stem cells as well as more rapidly replicating transit cells. After 45 minutes' ischemia insults, no significant difference was found in the number of p38 positive cells, indicating that ischemia can not activate p38 pathway. Positively stained p38 cells increased markedly after 6 hours of reperfusion, which might be a result of activation of p38 MAPK signaling pathway. DAO is located in the upper part of intestinal mucosa in human as well as in mammals, and is a highly active intracellular enzyme. Changes in DAO activity are an ideal index to investigate intestinal barrier function damage after trauma, especially changes in plasma DAO activity[25-28]. Our histological observations and DAO examinations showed that I/R injury induced the damage of intestinal barrier function. The activation of p38 MAPK might be mediated by LPS, TNFα and peroxides generated after small intestinal damage. However we found no positively stained p38 cells in villus epithelial cells both in normal and injured intestines, which was different from the previous *in vitro* studies. This might be related to the ischemia period, injury degree we chose in the study and the distribution of p38 MAPK and its subtypes in small intestines[29-31].

In summary, our results indicate that intestinal I/R injury can induce the activation of p38 MAPK pathway. The positively expressed cell number and their localization are more likely close to intestinal stem cells. Compared with PCNA and Ki67, the distribution and expression characteristics of p38 MAPK are similar to the intestinal stem cells. Based on these data, we suppose that p38 MAPK may not be an ideal marker for intestinal stem cells, it is more close to the goal and worthy of further investigation.

Abstract

AIM: To investigate the effect of gadolinium chloride ($GaCl_3$) and salvia miltiorrhiza compound (SMCo) on ischemia and reperfusion (I/R) injury in hepatocellular mitochondria.

METHODS: Wistar rats were randomly to divided into control group, $GaCl_3$ group, SMCo group and $GaCl_3$ + SMCo group (n=15 each). $GaCl_3$ (7 mg· kg^{-1}) was injected into tail vein on d 1 and d 2 in contrast group. SMCo (2 ml· kg^{-1}) was injected into muscle on d 1 and d 2 in SMCo group. $GaCl_3$+SMCo group received both $GaCl_3$ (iv) and SMCo (im) injection. Control group received saline injection only. On d 3, all the rats were subjected to 2 h ischemia in the middle and left lobes of the liver, followed by reperfusion for 2 h, 6 h and 18 h respectively. The level of serum alanine aminotransferase (ALT) and malondialdehyde (MDA) in hepatocellular mitochondria was measured. Pathological changes in hepatic tissue and in hepatocellular mitochondria were determined with optical microscope and electronic microscope,respectively.

RESULTS: Remarkablly pathohistological and biochemical changes were detected after 6 h of I/R. Compared with control, the level of ALT was decreased in $GaCl_3$, SMCo and $GaCl_3$+SMCo treated groups (1 314.0±278.7 *vs* 809.4±196.1, 716.6±242.8 and 837.2±190.6 IU· L^{-1}, respectively. P<0.05). Similarly, the level of MDA was decreased in $GaCl_3$, SMCo and $GaCl_3$+SMCo treated groups (293.1±51.1 *vs* 190.8±55.5, 214.3±32.9 and 221.0±47.3 nmol· g^{-1}, respectively, P<0.05). Accordingly, in control group, swelling, degeneration, focal necrosis, infiltration of leucocyte were found in reperfused tissue under an optical microscope, and mitochondria swelling, rupture and even breakdown were seen under an electronic microscope. These pathohistological and ultrastructural damages caused by I/R were greatly attenuated in $GaCl_3$, SMCo and $GaCl_3$+SMCo treated groups. However, there was no additive effect observed when $GaCl_3$ and SMCo were used together.

CONCLUSION: Both $GaCl_3$ and SMCo can alleviate the I/R injury in hepatocellular mitochondria.

INTRODUCTION

Lipid peroxide is one of the main mechanisms that cause ischemia and reperfusion (I/R) injury in the liver[1,2]. The degree of change in lipid peroxide and configuration of hepatocellular mitochondria primarily determine the severity of I/R injury[3]. Previous studies have shown that the number of Kupffer cell as well as its function are activated in response to I/R in the liver, which can be specifically inhibited by gadolinium chloride ($GdCl_3$)[4,5]. Salvia miltiorrhiza compound (SMCo) is widely used to treat many kinds of diseases in clinic, because it can scavenge oxygen free radicles, therefore reducing oxidative stress[6,7]. Reducing I/R injury constitutes a big clinical challenge and depends on the elucidation of the pathological and molecular process of I/R injury. The aim of the present study was to investigate the roles of lipid peroxide and configuration of hepatocellular mitochondria in response to I/R as well as the effect of $GaCl_3$ and SMCo on the process.

MATERIALS AND METHODS

Animals

Wistar rats (male, 8 wk old, weight 200-250 g) were randomly divided into control group, $GaCl_3$ group, SMCo group, $GaCl_3$+SMCo group (n=15 each).

Application of drugs

Gadolinium chloride hexahydrate (Wako pure medicine, Japan) was dissolved in physiological saline (2 g· L^{-1}), which was injected into tail vein at a dose of 7 mg· kg^{-1} on d 1 and d 2 in $GaCl_3$ group. Salvia miltiorrhiza compound (First Shanghai pharmacy) was injected into hind limb muscle at a dose of 2 ml· kg^{-1} on d 1 and d 2 in SMCo group. The $GaCl_3$+SMCo group received both $GaCl_3$ and SMCo injection. The control group received saline only on d 1 and d 2.

Ischemia and reperfusion

On d 3, after 12 h fasting, each rat was anesthetized with sodium thiopental at a dose of 50 mg· kg^{-1} (im). A midline incision was made to expose the liver vessels. The arteries to middle and left lobes of the liver were dissected and the blood flow was blocked with a pair of vessel clamps. The abdomen was then closed. The blood flow was restored by releasing the clamps after 2 h. The blood reperfusion in each group lasted for 2 h, 6 h and 18 h respectively (n=5 for each time point).

Assay of serum alanine aminotransferase (ALT)

The blood sample was taken from heart 2 h, 6 h and 18 h after reperfusion for ALT assay.

Preparation and observation of hepatocellular mitochondria

The liver was excised and washed with saline solution, cleaned with filter paper and then homogenized with 0.25 g· L^{-1} saccharose - EDTA solution. The homogenized solution was centrifugated for 10 min in 1 000 g of centrifugal force, and the supernatant was taken out and centrifugated again for 15 min in 7 000 g. The deposit after second centrifugation, which contained mitochondria, was reserved. All approaches were

performed at 4 ℃ and each procedure was repeated three times to make mitochondria pure.

The separated mitochondria was fixed by entering 2 ml of 25 g· L^{-1}-tris phosphoric acid glutaradehyde for 2 h and then dehydrated bleach routinely. After embedded with EPSONB for 48 h, an extreme thin slice was made and lead acetate-uranium double staining was performed. The ultrastructure of mitochondria was observed under electronic microscopy.

Determination of MDA in mitochondria

The separated mitochondria were mixed with 0.125 mol· L^{-1} kalium chloride up to 1 ml. The content of MDA in hepatocellular mitochondria was determined with biuret reaction at the 525 nm of wave.

Pathohistological observation of hepatic tissue

The hepatic tissue fixed with formaldehyde was embedded into paraffine, slices were made and stained with HE. Pathological changes were observed under optical microscopy.

Statistical analysis

Analysis of variance and Student-newman-Keuls test were used to determine the difference between groups. The results were considered statistically significant when $P<0.05$.

RESULTS

ALT assay

In control group, ALT became significantly activated 6 h after reperfusion. In $GaCl_3$, SMCo and $GaCl_3$+SMCo treated groups, ALT levels were all significantly inhibited compared with control group (Table 1).

Table 1 Change of serum ALT (IU/L, $\bar{x}\pm s$, n=5)

Group	I/R 2h	I/R 6h	I/R 18h
Control	825.8±337.5	1314.0±278.7	1071.2±201.1
$GdCl_3$	1120.8±145.5	809.4±196.1[a]	864.8±213.6
SMC	618.8±312.5	710.6±242.8[a]	899.6±227.3
$GdCl_3$ + SMC	623.8±340.9	837.2±190.6[a]	903.0±244.6

[a]$P<0.05$ *vs* contrast.

MDA assay

The dynamic changes of MDA were identical to the pattern of ALT (Table 2).

Table 2 Change of MDA in mitochondria (nmol· g^{-1}, $\bar{x}\pm s$, n=5)

Group	I/R 2h	I/R 6h	I/R 18h
Control	489.3±291.9	293.1±51.1	480.0±420.9
$GdCl_3$	440.5±581.7	190.8±55.5[a]	196.8±74.0
SMC	242.6±123.1	214.5±32.9[a]	281.4±118.8
$GdCl_3$ + SMC	191.8±44.4	221.0±47.3[a]	280.7±139.2

[a]$P<0.05$ *vs* contrast.

Pathological changes of hepatic tissue

In the control group, the major change of hepatocytes after 2 h of I/R was swelling without necrosis. The swelling became more and more severe with some scattered and focal necrosis and deposition of fibrin in central lobular vein after 6 h of I/R. In addition to obvious swelling, denaturalization and necrosis were seen after 18 h of I/R, which were associated with destroyed hepatic sinuses and infiltration of numerous white blood cells. In $GaCl_3$, SMCo and $GaCl_3$+SMCo groups, there was no necrosis 2 h and 6 h after I/R, and the hepatocyte swelling and denaturalization were much less than those in control group. In treated groups, the hepatic structure was maintained with less necrosis and infiltration of leucocyte 18 h after I/R.

Morphological changes of hepatocellular mitochondria

The I/R injury in hepatocellular mitochondria became more severe with the prolongation of I/R time in control group. It was obvious that swelling, rupture of inner membrane ridge, damage or even breakdown of mitochondrial structure with outline only (Figures 1-3). The changes in $GaCl_3$ and SMCo group were less severe than those in control group. Except for slight swelling, the structure of mitochondria was unchanged. The protective effects of $GaCl_3$ and SMCo against I/R damage on mitochondria were seen not only 2 h, 6 h, and 18 h after I/R (Figures 4-9). The effect of $GaCl_3$+SMCo combination on mitochondria was similar to that of either $GaCl_3$ or SMCo alone.

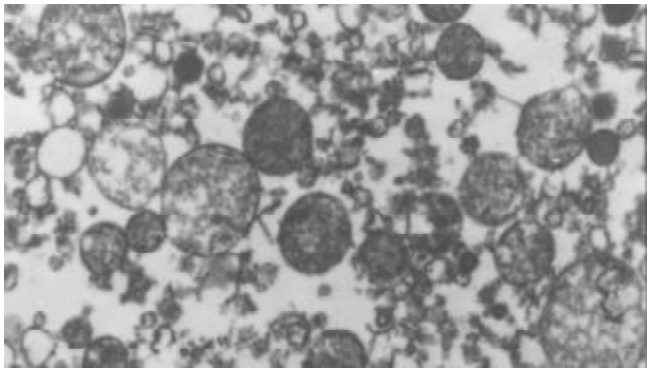

Figure 1 Hepatocellular mitochondria in I/R 2 h in control group, ×10 K.

DISCUSSION

Hepatocellular mitochondria are the place of energy metabolism in hepatocytes. In response to the process of I/R, the mitochondrion produces excessive oxidative free radicle, which in turn result in lipid peroxidation of the mitochondria membrane, therefore, causing mitochondria damage. Sammut observed that the degree of I/R injury in renal mitochondria of rabbit was associated with the preserved time of the kidney. The longer the cold preserved time was, the easier the I/R injury developed[8]. Leducq found that opening of mitochondrial permeability transition pore resulted in mitochondrial and energetic dysfunction of the liver during normothermic reperfusion[9]. These studies have directly or indirectly proved that I/R injury in hepatocellular mitochondria is closely related with the structure of hepatocellular mitochondria and the extent of damage in function[10].

Effect of $GaCl_3$ on I/R injury in hepatocellular mitochondria

The experimental results from the present study showed that ALT increased after 2 h of I/R, and reached the highest value after 6 h of I/R in control group, indicating that I/R injury in hepatic tissues is maximized 6 h after I/R. Previous studies have suggested that activation of Kupffer cells is involved in the injury process at the early stage of liver I/R. $GaCl_3$ can effectively blockade the function of Kupffer cells and reduce the secretion of cytokines and reactive oxygen species from activated Kupffer cells, so that MDA in hepatocellular mitochondria is inhibited[11]. The fact that both ALT and MDA in mitochondria in $GaCl_3$ group were markedly decreased because of the use of $GaCl_3$ suggests that inhibition of Kupffer cells can protect the hepatic function[12]. This study also showed that there was no significant decrease in ALT and MDA 18 h

after I/R, which was in agreement with the hypothesis that inhibition of Kupffer cells could only decrease the injury in the liver at the early stage of I/R. These biochemistry alterations are in parallel to the pathohistological changes. In control group, slight but detectable structural change was seen after 2 h, severe changes including necrosis and denaturalization were seen after 6 h, and more severe changes were seen after 18 h following I/R. In the mean time, by inhibiting Kupffer cells, $GaCl_3$ remarkably ameliorated those detrimental changes, in particular, 6 h after I/R. It should be pointed out that the role played by Kupffer cells is only one of the factors that is involved I/R injury in the liver. In addition to $GaCl_3$, other endogenous and exogenous compounds have also shown protective effects. For example, hepatocyte growth factor could reduce the impairment of both hepatocytes and sinusoidal endothelial cells[13]. Administration of epoprostenol could decrease hepatocellular I/R injury in transplanted liver[14], and nonselective endothelin-1 receptor antagonists could improve hepatic microcirculatory impairment[15]. Special neutrophil eastase inhibitor[16], tissue factor pathway inhibitor[17], adenosine[18], precondition of low-dose TNF-α[19] or ischemic precondition[20,21], etc, could alleviate I/R injury. All of these suggest that I/R is a complicated process. Although the potential role of Kupffer cells in I/R injury is still controversial[22,23], our data provide the strongest evidence in favor of its important role because blockade of Kupffer cells greatly reduces I/R injury in hepatocellular mitochondria.

Effect of SMCo on I/R injury of hepatocellular mitochondria

Our data showed that SMCo treatment decreased the content of MDA in mitochondria in SMCo group. As a scavenger of oxygen free radicls, the SMCo can effectively inhibit lipid peroxidation in hepatocellular mitochondria[24,25], apoptosis of cells[26], and adhesion of neutrophil[27], etc, and accordingly protect hepatocellular mitochondria. Whereas simple inhibition of lipid peroxidation is not enough to prevent entirely the occurrence of I/R injury since a lot of factors are involved. Our results imply that SMCo can protect the function and structure of mitochondria, maintain energy metabolism of hepatocytes, and thereby reduce significantly I/R injury in the liver. Because a lot of factors are involved in I/R injury, it is understandable that inhibition of lipid peroxidation by SMCo can improve, but not prevent I/R injury.

Although both $GaCl_3$ and SMCo are able to alleviate I/R injury in hepatocellular mitochondria when used separately, there is no additive effect when used in combination. We speculate that the two compounds act at different level in a same mechanism. While $GaCl_3$ inhibits mainly the functions of Kupffer cells, decreases the production of oxygen free radicls, SMCo is mainly to promote microcirculation and to restrain lipid peroxidation. Therefore, the effect of SMCo will become insignificant when oxygen free radicls are reduced when $GaCl_3$ is used.

In conclusion, both $GaCl_3$ and SMCo can ameliorate I/R injury in hepatocellular mitochondria at some extent.

Abstract

AIM: To evaluate the effects of low calorie diet (LCD) on nonalcoholic steatohepatitis (NASH) in rats with obesity and hyperlipidemia.

METHODS: 29 Sprague-Dawley (SD) rats were randomly divided into three groups. The animals in control (*n*=9) and NASH group (*n*=10) were fed on standard rat diet and high fat diet respectively for 12 weeks, ten rats in LCD group were fed on high fat diet for 10 weeks and then low calorie diet for 2 weeks. At the end of the experiment, body weight, abdominal adipose content, liver function, and hepatopathological changes were examined to evaluate the effect of different feeding protocols on the experimental animals.

RESULTS: There was no death of animal in the experimental period. All rats in the NASH group developed steatohepatitis according to liver histological findings. Compared with the control group, body weight (423.5±65.2 *vs* 351.1±43.0 g, *P*<0.05), abdominal adipose content (14.25±1.86 *vs* 9.54±1.43, *P*<0.05), liver index (3.784±0.533 *vs* 2.957±0.301 %, *P*<0.01), total serum cholesterol (1.60±0.41 *vs* 1.27±0.17 mmol/L,*P*<0.05) and free fatty acids (728.2±178.5 *vs* 429.2±96.7 mmol/L, *P*<0.01), serum alanine aminotransferase (1 257.51±671.34 *vs* 671.34±118.57 nkat/L, *P*<0.05) and aspartic aminotransferse (2 760.51±998.66 *vs* 1 648.29±414.16 nkat/L, *P*<0.01) were significantly increased in the NASH group. Whereas, when rats were fed on LCD protocol, their body weight (329.5±38.4 g, *P*<0.01), abdominal adipose content (310.21±1.52 g, *P*<0.05), liver index (3.199±0.552 %, *P*<0.05), and serum alanine aminotransferase (683.03±245.49 nkat/L, *P*<0.05) were significantly decreased, and the degree of hepatic steatosis (*P*<0.05) was markedly improved compared with those in the NASH group. However, no significant difference was found in serum lipid variables and hepatic inflammatory changes between the two groups.

CONCLUSION: LCD might play a role in the prevention and treatment of obesity and hepatic steatosis in SD rats, but it exerts no significant effects on both serum lipid disorders and hepatic inflammatory changes.

INTRODUCTION

Non-alcoholic steatohepatitis (NASH) is a hepatic disorder with the histopathological features of alcohol-induced liver disease that occurs in individuals who do not consume a large amount of alcohol. In recent years it has been believed to be a progressive liver disease that can lead to cirrhosis and even hepatocellular carcinoma. Unfortunately, up to the present its pathogenesis remains unknown. An empirical management of this disease in clinical practice, in which weight is reducted by a low-calorie diet (LCD), has been recommended to treat those patient with overweight and obesity. However, inappropriate caloric restrictions would lead to metabolic disorder, even promote hepatic portal inflammation, fibrosis, bile stasis and focal necrosis[1-8]. In the present study, we established a rat model of NASH with overwight/obesity and hyperlipidemia by chronically feeding high-fat diet to evaluate the protective effects of LCD on the metabolic changes of this disease to provide experimental evidence for the NASH treatment strategy.

MATERIALS AND METHODS

Animals

Male Spraque-Dawley rats weighing 140-160 g obtained from Shanghai Experimental Animal Center (Shanghai, China) were used in the present study. The rats were housed in plastic cages with a wire-mesh to isolate them from a hygienic bed and exposed to a 12-hour controlled light cycle. The rats were given free access to food and water under controlled humidity (55 %) and temperature (23+/-1 ℃). All protocols for animal experimentation and maintenance were approved by the Animal Ethics Committee in our university and conformed to the highest international standards of humane care.

Reagents

Cholesterol was from Huamei Company (Shanghai, China). Lard oil was prepared in our laboratory. Alanine aminotransferase (ALT) and aspartic aminotransferase (AST) assay kits were purchased from Sheneng Company (Shanghai). Free fatty acid (FFA), triglycerides (TG) and total cholesterol (TCH) assay kits were obtained from Zhicheng Company (Shanghai). Albumin (A) and total protein (TP) assay kits were provided by Shanghai Institution of Bio-products. Rabbit polyclonal anti-human lysozyme antibody was from Shanghai Biogenex Company. Mouse anti-human α-smooth muscle actin (α-SMA) was from Dako Company (Carpinteria, CA, USA). The second antibody for immunochemistry assay was from American Antibody Company (Greenwich, USA).

Experimental protocol

After fed on standard rat diet for one week, Spraque-Dawley rats were randomly divided into three groups. Animals in the control (*n*=9) and NASH group (*n*=10) were fed on standard

rat diet and high fat diet (a standard diet supplemented with 10 % lard oil and 2 % cholesterol) respectively for 12 weeks, while the rats in the LCD group (n=10) were fed on high fat diet for 10 weeks and then on low-calorie diet (70 kcal/kg/day accounting for 1/3 of the daily needs of a healthy rat) for 2 weeks. One rat of NASH group was harvested at week 10 for the demonstration of hepatopathological changes. The animals were weighed before experiment and one day prior to sacrifice. Blood samples were obtained by aorta abdominalis puncture at the time of sacrifice, and the resulting serum was stored at -20 ℃ until analysis. Meanwhile, liver samples were rapidly excised, weighed and frozen at -70 ℃, or fixed in 4 % buffered formaldehyde solution until use.

Blood biochemical analyses

Serum biochemical parameters such as ALT, AST, A, TP, TG, TCH and FFA were automatically analyzed with a multifunctional biochemistry analyzer Olympus AU1000.

Histopathological examination

Hepatic sections were prepared and stained with hematoxylin and eosin (H&E) for routine histopathological examination. Some sections were stained with VG carbazotic acid for detection of fibrosis. Ultromicrotomy was performed for transmission electron microscopy (JEM-1200EX, Japan). Hepatocytes involved in lobular fatty infiltration were counted in H&E stained sections. The severity of steatosis was graded on the basis of the extent of parenchyma involved. Grade 1 (+): <33 % of hepatocytes were involved. Grade 2(++): 33 % to 66 % of hepatocytes were involved. Grade 3(+++): >66 % of hepatocytes were involved. Normal(-): no hepatocytes were involved[4,9]. Knodell histological activity index (HAI) and modified HAI by Tailin Wang were used to determine hepatic necroinflammatory activity[9-11] scored by the severity of portal inflammation (P), intralobular inflammation(L), piecemeal necrosis (PN) and bridging necrosis (BN). The score from 1 to 4 was in accordance with the severity of lesions and the total score was calculated as P+L+2 (PN+BN). The number of Kupffer's cells and activated hepatic stellate cells was determined by immunohistochemistry using lysozyme and α-SMA antibody respectively. All samples were evaluated blindly by the same pathologist and confirmed by the other researcher.

Statistics

Data were expressed as mean ± SD unless otherwise specified. The Student t test was used to test individual differences. Rank samples were analyzed by Rank-sum test. Rate comparison was analyzed by u test. A value of P<0.05 was considered to be statistically significant.

RESULTS

General information

During the experimental period, the body weight of the rats fed on high-fat diet increased quickly. By the end of the 10th week, the body weight of high-fat fed rats was significantly increased compared with the controls. At the same time,we randomly harvested one of the high-fat fed rats for hepatopathological examination, which showed liver steatosis with mild intralobular inflammation. Biochemical analysis indicated that serum TCH, FFA, ALT, AST levels in this rat were higher than normal. However, rats in LCD group fed on low-calorie diet were fretful and inflammable, their bellicose and body weight stopped increasing.No animal died during the experimental period.

Body and liver weight changes

At the end of the experiment, the body weight of animals in the NASH group was 20 % higher than that in the control group (t=2.281, P<0.05). The liver index (liver weight/body weight ×100 %) and the abdominal adipose content in this group were also significantly increased compared with the controls (t=4.097 and 2.891, P<0.01and 0.05 respectively). Compared with the NASH group, the body weight,liver index and abdominal adipose content in the LCD group decreased significantly (t=3.928, 2.411, 2.632. P<0.01, 0.05, 0.05 respectively) (Table 1).

Table 1 Changes of body weight and liver index

Groups	n	Body weight/g	Liver index 100 %	Abdominal adipose/g
Control	9	351.1±43.0	2.957±0.301	9.54±1.43
NASH	10	423.5±65.2[a]	3.784±0.533[b]	14.25±1.86[a]
LCD	10	329.5±38.4[c]	3.199±0.552[d]	10.21±1.52[d]

[a]P<0.05, [b]P<0.01 *vs* control. [c]P<0.01, [d]P<0.05 *vs* NASH group.

Changes of serum lipids and glucose

At the end of the experiment, serum TCH and FFA in the NASH group were significantly higher than those in the controls (t=2.242 and 4.462; P<0.05 and 0.01 respectively), whereas serum TG level remained unchanged. Compared with the NASH group, serum TCH level in the LCD group was significantly increased (t=2.152, P<0.05) and FFA level was only slightly increased (P>0.05), whereas TG level was significantly decreased (t=4.435, P<0.001), even signicantly less than that in the control group (P<0.001), with a trend of decreased blood glucose (Table 2).

Table 2 Changes of major plasma lipid parameters

Groups	n	TG mmol/L	TCH mmol/L	FFA mmol/L
Control	9	0.63±0.22	1.27±0.17	429.2±96.7
NASH	10	0.62±0.10	1.60±0.41[a]	728.2±178.5[b]
LCD	10	0.39±0.13[c]	2.04±0.50[d]	771.3±124.4

[a]P<0.05, [b]P<0.01 *vs* control. [c]P<0.001, [d]P<0.05 *vs* NASH group.

Liver function

At the end of 12 weeks, serum ALT and AST levels were significantly increased in the NASH group compared with those in the controls (t=2.576 and 3.103, P<0.05 and 0.01 respectively). Compared with the NASH group, serum ALT level in LCD group was significantly decreased (t=2.541, P<0.05), whereas serum AST level only displayed a decreasing trend in plasma (P>0.05). There were no significant differences in plasma albumin levels and albumin-globulin ratio among these groups of rats (Table 3).

Table 3 Alternations of some biochemical variables in rat liver function

Groups	n	ALT nkat/L	AST nkat/L	A g/L	A/G

[a]P<0.05, [b]P<0.01 *vs* control. [c]P<0.05 *vs* NASH group.

Hepatopathological manifestations

At the end of the experiments, no specific findings were observed during the hepatohistological examination in the

controls. Under light microscope, sections stained with H&E in the NASH group showed moderate to severe macrovesicular steatosis which was diffusely distributed throughout the liver lobule, and parenchymal inflammation with both acute and chronic inflammatory cells accompanying focal necrosis. In 80 % of the samples, mild portal inflammation was noted, compared with lobular inflammation, and 20 % samples were accompanied by piecemeal necrosis. The score of HAI was significantly higher than that in the controls (3.4±2.1 *vs* 0.8±0.8, t=3.461, P<0.01) (Figures 1, 2). No obvious liver fibrosis was found in VG carbazotic acid stained sections. Immunohistochemical analysis showed that lysozyme and α-SMA positively stained cells in the NASH group were significantly increased compared with the controls.

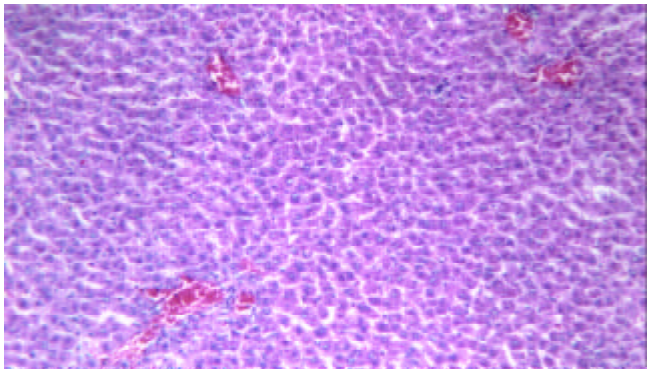

Figure 1 Light microscopy for control liver tissue, normal liver histology. H&E×100.

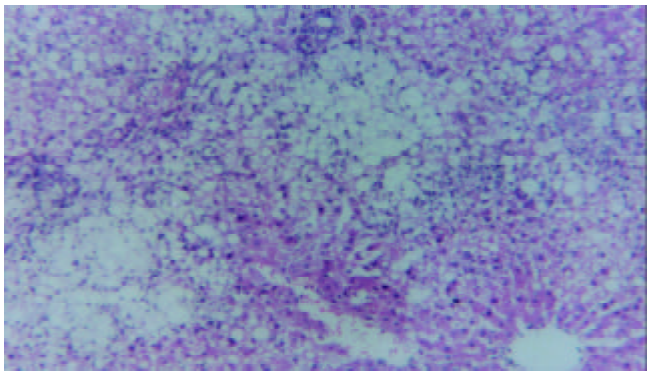

Figure 2 Light microscopy for liver tissue from a 12-week treated rat in NASH group, severe macrovesicular steatosis with mixed parenchymal inflammation and spotty focal necrosis. H&E×100.

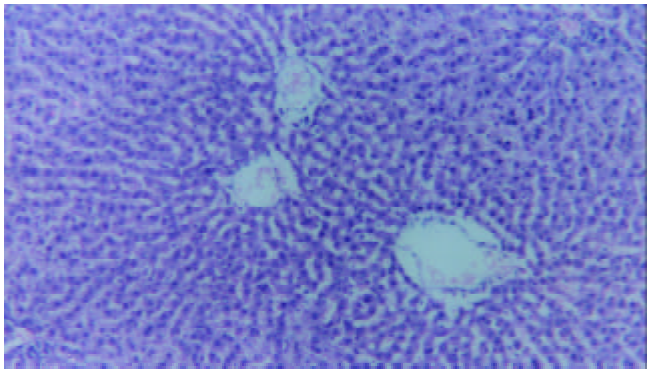

Figure 3 Light microscopy for liver tissue from a rat treated with LCD during 12-week experiment, the pathological changes of liver were obviously improved compared with the NASH group. H&E×100.

Compared with the NASH group, the liver steatosis in the LCD group was significantly reduced (P<0.05) (Figure 3, Table 4). However the score of HAI only had a trend of decrease (2.5±1.0 *vs* 3.4±2.1, P>0.05). There were no differences in the number of positive cells stained by lysozyme and α-SMA and liver fibrosis on VG stained sections between LCD and NASH groups. The liver histological findings were almost normalized in 1 sample of the LCD group.

Control	9	9			
NASH	10		3	6	1
LCD	10	3	5	2	

Rank sum test: P<0.05.

DISCUSSION

Non-alcoholic steatohepatitis (NASH) can be defined pathologically as severe steatohepatitis that is not resulted from alcohol,drug or any other singly identifiable causes. NASH is becoming a common liver disease and probably has a similar risk of progression to cirrhosis as chronic hepatitis C. No treatment has been yet proven to be efficient. Those who are overweight and suffer from NASH should be considered to employ a weight reduction program. Diet is an important component of weight-reduction regimen[1-8]. However, no controlled studies are available as for the value of diet in the management of NASH, further researches are needed to evaluate the effect of diet modalities on NASH either by clinical trial or by animal experiment[1,2,5,12].

In a recent study, liver tests and fatty infiltration were significantly improved in 15 obese patients with NASH treated with a restricted diet (25 kcal/kg· day) plus exercise for months. Improvement in the degree of inflammation and fibrosis was also achieved in some patients[13]. However, in another report, five obese patients stopped eating for some time and lost 14-30 kg within 1 month. Hepatic fat content decreased in three of them, but fibrosis became more prominent in four out of the five patients[14]. In addition, in another series, 41 morbidly obese patients with NASH had a median weight loss of 34 kg during the treatment with a very low calorie formula diet (388 kcal/day). The liver fat infiltration was also significantly improved. However, a fifth of the patients, particularly those had more pronounced reduction of liver fat and faster weight loss, developed mild portal inflammation or fibrosis[15]. It is well known that rapid weight reduction would lead to excessive fat catabolism, and marked elevation of FFA and lack of essential amino acids in serum and liver, which might finally induce or aggravate steatohepatitis and liver fibrosis[16-20].So, the adequate rate and degree of weight reduction remain to be established. Further studies are necessary to determine the appropriate caloric restrictions and the formula for obese patients with NASH[21-23].

No ideal animal model has yet been established for NASH research[24-31]. We have therefore established a model of this disease in rats by continuous feeding on a diet rich in fat and cholesterol for 12 weeks[17-19]. These animals were overweight and showed abnormal increase of abdominal fat (standing for trunk obesity), as well as markedly elevated levels of serum TCH, FFA and aminotransferase. Moderate to severe steatosis combined with intralobular inflammation and spotty necrosis was found in their hepatopathological examinations. Although fibrosis was absent on VG staining, we found that hepatic stellate cells and Kupffer cells were activated and proliferated,

suggesting that liver fibrosis might be inevitable[32,33]. Our subsequent research also demonstrated that feeding on a high fat diet for 24 weeks could induce steatohepatitis with liver fibrosis[34,35]. This animal model was easily established with low mortality (0 %) and high reproductive rate (100 %). Furthermore, this model was similar to that of the human disease, suggesting that this rat model is suitable for investigating the pathogenesis and prevention and treatment of NASH[30,33]. However, our model has some shortcomings. Firstly, the hepatopathological changes in this rat model were not entirely consistent with those in patients with NASH. Specifically, zone 3 involvement was not dominant. Moreover, no Mallory Hyaline bodies were found in sections stained by H&E. Secondly, NASH is often associated with hypertriglyceridemia which was not observed in this model.

The weight reduction diets recommended for NASH with obesity are slimming, low-calorie diet (LCD) and very-low calorie diet (VLCD). Slimming diets involve caloric intake of 1 200-1 800 kcal per day for adults, which is slightly less than that of normal diet, while LCD involves an intake of 600-1 200 kcal per day for adults and VLCD involves a caloric intake of 200-600 kcal per day[5,8,36]. Patients with moderate or severe obesity are usually put on LCD for weight reduction. In contrast, VLCD is seldom used clinically because of severe complications[5,8,36,37]. In our study, we took a caloric intake protocal for the animal model that belongs to LCD according to caloric calculation (70 kcal/kg· day *vs* 210 kcal/kg· day for rats).

While the rats fed on a high fat diet for 10 weeks were overweight and developed hyperlipidemia and fatty liver, a subsequent 2 weeks on LCD made both of their overweight and hyperlipidemia alleviated. In contrast,an additional two weeks on the high fat diet led to the development of more severe obesity,hyperlipidemia and steatohepatitis. These findings suggest that altering a high fat or high calorie diet to LCD may have markedly positive effects on obesity, hyperlipidemia and combined fatty liver, while continuation on the fat-rich diet may lead to the development of steatohepatitis. Since the rats in our LCD group developed hypercholesterolemia and hypoglyceridemia with a trend to increase serum FFA. Some of their liver samples were still found to have hepatocyte necrosis and inflammatory cell infiltration, indicating that LCD therapy for 2 weeks may be not quite enough to reverse steatohepatitis.

In summary, this study indicates that it might be difficult to resolve steatohepatitis by merely short-term LCD therapy, long-term appropriate diet control or concurrent administration of medications that can directly reduce the severity of liver damage may be reasonable alternatives for the treatment of NASH patients with obesity[2,3,5,23,24].

Abstract

AIM: To investigate the effect of Kangxian ruangan keli (KXR) on hepatic stellate cell (HSC) proliferation mediated by platelet-derived growth factor (PDGF) and the underlying mechanism.

METHODS: In a serum-free culture system, HSCs were treated with a KXR preparation for 24 hours, followed by stimulation with PDGF-BB for 24 hours. Then the cells were incubated again in the medium containing KXR for 3 hours stimulated with PDGF-BB for 5 minutes, and collected. The proliferation of HSC was examined using an MTT assay and flow cytometry. Tyrosine phosphorylation was detected with Western blotting and visualized by the enhenced chemiluminescent (ECL) method.

RESULTS: The OD values for the HSCs growing in the media without and with addition of PDGF were 0.17±0.06 and 0.82±0.05, respectively. The PDGF-induced increase was hindered remarkably by KXR preparation in a dose-dependent manner. The reaction values for the systems with 5 mg/mL, 2.5 mg/mL and 1.25 mg/mL of KXR were 0.28±0.03, 0.37±0.02 and 0.43±0.04, respectively. Moreover, the percentages of S-phase cells in these KXR-containing culture systems were 10.95±1.35, 32.76±1.07 and 43.19±1.09, respectively, all of which were significantly lower than that in the culture free of KXR (68.24±2.72). In addition, the values for tyrosine-phosphorylated protein in HSCs treated with 5 mg/mL and 1.25 mg/mL of KXR were 0.1349±0.0072 and 0.1658±0.0025, respectively, which were smaller than that in the cells treated only with PDGF-BB (0.1813±0.0117).

CONCLUSION: Within the dose range used in the present study, KXR preparation shows an inhibitory effect on HSC proliferation induced by PDGF. The mechanism of this process may involve interference with tyrosine phosphorylation mediated by PDGF.

INTRODUCTION

Hepatic fibrosis, a frequent pathologic change in a number of chronic liver diseases and an essential process during development of cirrhosis, is characterized by excessive proliferation of hepatic stellate cells (HSCs) and subsequent deposition of extracellular matrix (ECM)[1-6]. For this reason, HSC is regarded as one of the key cell types involved in progression of liver fibrosis, and is considered as a therapeutic target for treatment of hepatic fibrosis. Among several growth factors shown to be involved in the process, platelet-derived growth factor (PDGF) is the most potent mitogen for HSCs[7,8]. Hence, PDGF and its downstream target molecules or cell types may be potential targets for interventional therapies of hepatic fibrosis[9].

Kangxian ruangan keli (KXR) is an authorized granular herbal preparation, which has been used in the clinical fields for almost 30 years and is believed to be able to promote blood circulation, phlegm elimination and to soften and resolve hard mass based on traditional Chinese medicine. Our clinical and experimental data have demonstrated its effect on chronic liver diseases[10]. It may also be preventive to the fibrogensis induced by CCl_4 and inhibitory to HSC proliferation[11-14]. However, its mechanism is unknown. In this study, the effect of KXR on PDGF-mediated HSC proliferation was assessed *in vitro* using a serum-free culture system.

MATERIALS AND METHODS

Reagents

HSC-T6, a cell line from activated HSCs, was kindly provided by Prof. Liemin Xu in Institute of Liver Diseases, Shanghai University of Traditional Chinese Medicine. DMEM medium and fetal calf serum were purchased from Gibco (Life Technologies, Inc., Gaithersburg, MD, USA). PDGF-BB, propidium iodide and Fura-2/AM were purchased from Sigma (St. Louis, MO, USA). The antibody to phosphotyrosine was purchased from Santa Cruz Biotechnology Inc. (Santa Cruz, CA, USA). The SuperSignal West Pico chemiluminescent substrate was purchased from Pierce Chemicals (Rockford, IL, USA).

Cell culture

HSCs were grown in DMEM medium containing 100 mL/L fetal calf serum, 1×10^{-5} U/L penicillin, 100 mg/L streptomycin, 1 % L-glutamine and 0.1 mmol/L HEPES, and cultured at 37 ℃ in an incubator with 5 % CO_2. KXR consists of several berbs including *Radix Salviae Miltiorrhizae, Rhizoma Zedoariae, Sargassum, Carapax Trionycis*[15]. The granular preparation was made in the Affiliated Hospital of Hubei Collage of Traditional Chinese Medicine, containing 2 g of crude herbs in each gram KXR. The preparation was dissolved in DMEM medium, and sterilized by filtration through a 0.45 μm filter. Following preincubation in the serum-free medium for 24 hours, the cells were grown and incubated for 48 hours, separately in the following media: 1) Only serum-free DMEM medium as a control, 2) The serum-free medium containing 10 ng/mL PDGF-BB, 3) before the addition of PDGF-BB

(10 ng/mL), different amounts of KXR (1.25 mg/mL, 2.5 mg/mL and 5 mg/mL, separately) were extracted in the serum-free medium for 3 h.

Evaluation of cell growth

Cells were seeded in 96-well plates at a density of 1×10^8 cells/L. After treated as above, the cells were incubated with DMEM containing 1 mg/ml of 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) for 4 h at 37 ℃. The resulted precipitate was resolved by addition of dimethyl sulfoxide and incubation for 2 min. Cell growth was assessed using an enzyme-linked immunosorbent assay reader (Bio-Tek, Houston, USA) with the test wavelength at 570 nm and expressed as optical density (OD) values. The inhibition of HSC proliferation was expressed as inhibitory rate [(OD value of PDGF group - OD value of KXR group)/OD value of PDGF group]×100 %.

The cell proliferation was also described by the growth curves. HSCs were plated in 24-well dishes at a density of 1×10^5 cells/well in a complete culture medium. After 24 h (day 0), cells were washed twice with the serum-free medium and then divided and treated as described above. Cell counting was performed on triplicate wells on days 0, 2 and 4 following preparation of cell suspensions by digestion with trypsin. Fresh serum-free medium containing PDGF-BB (10 ng/ml) with or without KXR was added to the remaining wells on day 2.

The HSC proliferation kinetics was described by flow cytometry. The cells were plated in 10-cm dishes at a density of 1×10^8 cells/L in the complete culture medium. After treated as described above, cells were harvested by digestion with trypsin and washed twice with PBS. After overnight fixation with cold ethanol at 4 ℃, cells were washed twice with PBS and suspended in the buffer containing 30 μg/mL propidium iodide, 0.1 % Tritonx-100, 37 mg/mL EDTA and 0.1 % ribonuclease A. Samples were incubated in a dark chamber at room temperature for 30 minutes and stored at 4 ℃ before use. Cell fluorescence was measured by FACSCalibur flow cytometer (Becton Dickson, San Diego, CA,USA) and assessed by the Cellquest software.

Tyrosine phosphorylation assay

Subconfluent HSCs were cultured in a serum-free medium for 24 h, then in the medium with or without KXR for another 24 h. Following the culture with the presence of 10 ng/ml PDGF-BB for 24 h, cells were treated with KXR for 3 h, and incubated again in the medium containing 10 ng/ml PDGF-BB for 5 min. After washed with ice-cold PBS, the cell monolayers were harvested and suspended in a lysis buffer [1 % NP-40, 0.5 % sodium deoxycholate, 0.1 % sodium dodecyl sulfate (SDS), 150 mmol/L NaCl, 1 mmol/L ethyleneglycol-bis-(β-aminoethylether)-N, N, N', N'-tetraacetic acid, 1 mmol/L phenylmethylsulfonyl fluoride, 500 μg/mL leupepin, 1 mmol/L sodium orthovanadate, 50 mmol/L sodium fluorid, 10 mmol/L Tris-HCl, pH7.2[16]] for 30 min on ice. The lysates were clarified by centrifugation at 16 000 g for 10 min at 4 ℃, and protein concentrations were determined using Bradford' s method[16].

Proteins were electrophoresed on a 0.1 % SDS-7 % polyacrylamide gel using a Mini apparatus (Bio-Rad Laboratories, Hercules, CA, USA). The resolved proteins were transferred to a nitrocellulose filter by a transfer apparatus (Bio-Rad Laboratories, Hercules, CA,USA). After the blocking in a blocking buffer [5 % BSA,1 % hen egg albumin, 10 mmol/L Tris.Cl, pH7.4, 0.15 mol/L NaCl] for 60 min, the filter was incubated with a mouse monoclonal antibody to phosphotyrosine (1:1 000) for 120 min. Following the washing for 15 minutes respectively in a TN buffer (containing 10 mmol/L Tris pH7.4, 0.15 mol/L NaCl) and a TN buffer containing 0.05 % NP-40, the incubation was done with a peroxidase-conjugated goat antibody (1:2 000) against mouse IgG at room temperature for 60 min. The antigen-antibody complexes were visualized by an enhanced chemiluminescent (ECL) reaction[16]. The reaction intensities were assessed with an image analyzer (HPIAS-1000, Tongji Medical college Huazhong University of Science & Technology,Wuhan,China).

Statistical analysis

Results were expressed as mean ± standard deviation. Differences between groups were described by the Student *t* test. $P<0.05$ was considered significant.

RESULTS

Effect of KXR on PDGF-mediated HSC Proliferation

An inhibitory effect was observed by the MTT assay (Table 1) and cell counting (Figure 1) for KXR to PDGF-mediated HSC proliferation, which was in a dose-dependent manner. HSC growth response to PDGF stimulation with or without the presence of KXR was assessed by cell counting (Figure 1). PDGF-BB, with its concentration at 10 ng/mL, significantly increased HSC growth after 2 to 4 days of incubation, in comparison to the medium free of PDGF ($P<0.01$). This response was markedly inhibited by pretreatment with KXR ($P<0.01$), which was not associated with any detectable cytotoxic effects in the dose range used.

Table 1 Effects of KXR on PDGF-mediated HSC proliferation (mean ±s)

Groups	KXR concentration (mg/mL)	OD values	Inhibitory rate (%)
Control		0.17±0.06[b]	-
PDGF		0.82±0.05	0.00
KXR treatment before	5	0.28±0.03[b]	65.9
PDGF stimulation	2.5	0.37±0.02[b]	54.9
	1.25	0.43±0.04[b]	47.6

[b]$P<0.01$ *vs* PDGF group.

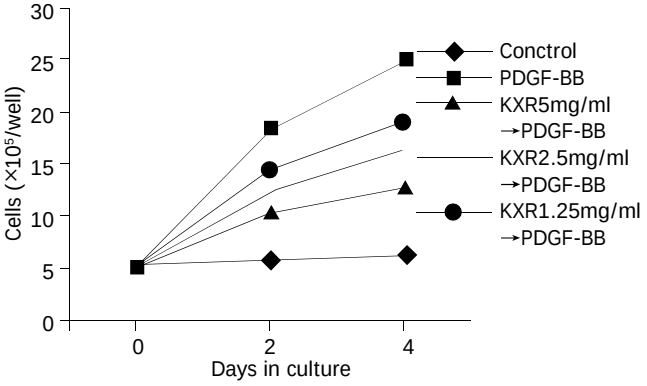

Figure 1 Effect of Kangxian Ruangan Granule on PDGF-induced cell proliferation in HSC-T6 cell line.

KXR affects cell cycle of HSC

Flow cytometry showed a reduction in G0/G1-phase cell fraction and an increase in the S-phase cell fraction for the HSCs exposed to PDGF. Pretreatment with KXR inhibited the PDGF-mediated response for the cells in S phase, the result was in agreement with the data obtained by MTT assay. However, the G0/G1-phase cell fraction was similar to that without KXR pretreatment (Table 2). It indicated that KXR treatment was inhibitory to the PDGF-induced progression of

the cell cycle beyond the G_1 phase. The effect seemed to be dose-dependent ($P<0.01$).

Table 2 Effect of KXR on cell cycle progression of HSCs mediated by PDGF (mean ±s)

Groups	*n*	HSC fractions at (%)		
		G_0-G_1 phase	S phase	G_2-M phase
Control	6	94.67±2.17	4.13±0.92	1.20±0.47
PDGF 10 ng/ml	6	20.18±1.12	68.24±2.72	11.18±1.93
KXR 5 mg/ml→PDGF	6	83.64±3.68[b]	10.95±1.35[b]	5.41±0.98[b]

[a]$P<0.05$, [b]$P<0.01$ *vs* PDGF group.

Effect of KXR on PDGF-induced tyrosine phosphorylation

As shown in Figure 2 and Table 3, treatment of KXR resulted in a reduction in the content of tyrosine-phosphorylated proteins, the result was in accordance with its effects on cell proliferation and kinetics.

Figure 2 Effect of KXR on the expression of tyrosine-phosphorylated proteins induced by PDGF (Western blot). Lanes 1 to 4 were loaded with HSC lysates from the control, PDGF groups, and the PDGF groups with pretreatment of KXR at 1.25 mg/mL and 5 mg/mL, respectively.

Table 3 Effect of KXR on the contents of tyrosine-phosphorylated proteins in HSCs stimulated by PDGF (mean ±s)

Groups	*n*	Intensities of tyrosine-phosphorylated proteins
Control	4	0.1199±0.0037
PDGF 10 mg/ml	4	0.1813±0.0117
KXR 1.25 mg/ml+PDGF	4	0.1658±0.0025[a]
KXR 5 mg/ml+PDGF	4	0.1349±0.0072[b]

DISCUSSION

KXR is a granular herb preparation mainly composed of *Salviae Miltiorrhizae, Rhizoma Zedoariae, Sargassum* and *Carapax Trionycis*. It has been reported that *Salviae Miltiorrhizae* exhibits a series of important effects including anti-inflammation, anti-oxidation and retardation of HSC proliferation[17,18]. Its extract has been shown to induce HSC apoptosis[19,20]. The oil from *Rhizoma Zedoariae* was reported to be inhibitory to the proliferation of fibroblast cells and hepatocellular carcinoma cells[21,22]. It was pointed out that *Sargassum* could be helpful for the elimination of reactive oxygen species which were believed to be important factors in the progression of fibrosis[23]. Our previous clinical and experimental observations[10-14] have approved these effects using decoction preparation of KXR in patients with chronic hepatitis or cirrhosis and in rats with CCL_4-induced liver fibrosis.

HSCs are a key cell type during liver fibrogenesis. Its activation is characterized by the myofibroblast-like phenotypes including an elevated proliferation rate, expression of α-smooth muscle actin, synthesis and excretion of some extracellular matrix components[4,24]. Recently, the phenotypic transformation has been linked to some cytokines, including PDGF, and their intracellular signal transduction pathways[6,25-30].

Among many polypeptide growth factors potentially involved in chronic hepatitis, PDGF, a dimmer of two chains referred to as A-chain and B-chain, has been shown to be the most potent mitogen for cultured HSCs isolated from rat, mouse or human liver. Of the three possible dimeric forms, including AA, AB and BB, PDGF-BB has been shown to be most effective[1,6-8,30]. Tyrosine protein kinase plays an important role in the PDGF-mediated activation and proliferation of HSCs[32,33]. PDGF binds to the extracellular domain of its receptor, PDGF-Rβ, results in the receptor molecule autophosphorylation, which allows the docking of numerous signaling cascades, such as PI3-K, Raf-MEK-MAPK, Na^+/H^+ and Ca^{2+}, leading to cell division and chemotaxis[6,34-38]. In the current study, we showed that KXR blocked PDGF-stimulated mitogenesis and DNA synthesis, and inhibited PDGF-induced autophosphorylation of tyrosine. These results suggest KXR may have the effects as those of tyrosine phosphorylation inhibitors. Clearly, more data are needed to elucidate the effect of KXR on tyrosine phosphorylation and its underlying mechanism.

Abstract

AIM: To investigate ion channel mechanism in CNP-induced relaxation of gastric circular smooth muscle in guinea pigs.

METHODS: Spontaneous contraction of gastric smooth muscle was recorded by a four -channel physiograph. The whole cell patch-clamp technique was used to record calcium-activated potassium currents and membrane potential in the gastric myocytes isolated by collagenase.

RESULTS: C-type natriuretic peptide (CNP) markedly inhibited the spontaneous contraction in a dose-dependent manner in gastric circular smooth muscle in guinea pigs. Ly83583, an inhibitor of guanylate cyclase, weakened CNP-induced inhibition on spontaneous contraction but Zaparinast, an inhibitor of cGMP sensitive phosphoesterase, potentiated CNP-induced inhibition in gastric circular smooth muscles. The inhibitory effects of CNP on spontaneous contraction were blocked by tetrathylammonium (TEA), a nonselective potassium channel blocker. CNP hyperpolarized membrane potential from -60.0 mV±2.0 mV to -68.3 mV±3.0 mV in a single gastric myocyte. CNP increased calcium-activated potassium currents ($I_{K(ca)}$) in a dose-dependent manner in gastric circular myocytes. CNP also increased the spontaneously transient outward currents (STOCs). Ly83583 partly blocked CNP-induced increase of calcium-activated potassium currents, but Zaparinast potented the effect.

CONCLUSION: CNP inhibits spontaneous contraction, and potassium channel may be involved in the process in gastric circular smooth muscle of guinea pigs. CNP-induced increase of $I_{K(ca)}$ is mediated by a cGMP dependent pathway.

INTRODUCTION

Currently, there are six members in the natriuretic peptides (NP) family, including ANP, BNP, CNP, DNP, MNP and VNP. They are distributed in the whole body[1-4], and exhibit natriuresis-diuresis and vasorelaxation, keep electrolyte homeostasis and other qualities. In gastrointestinal tract, the studies mainly focused on absorption, secretion and intestinal motility[5-7]. Our previous study[8,9] indicated that natriuretic peptide receptor (NPR) was distributed in the gastric smooth muscle of rats, and NP inhibited gastric motility in rats, guinea pigs and humans.

There are different views about the mechanism of NP physiological function. Some scholars mentioned that NP did not exert physiological function by cGMP pathway. For example, Carvajal *et al*[10] indicated that natriuretic peptide-induced relaxation of pregnant myometrium was mediated by a novel mechanism, which was independent of GC-A or GC-B activation, cGMP generation, or clearance receptor activation. However, most scholars supported the views that NP exerted many physiological functions by cyclic guanosine monophosphate (cGMP) and that ion channel participated in the process. McCann *et al*[11] showed that ANP activated guanylyl cyclase that converted guanosine triphosphate (GTP) into cGMP. cGMP activated protein kinase G (PKG), which regulated Na+ channels to reduce heart rate and the force of contraction, thus decreasing cardiac output. Carini *et al*[12] demonstrated that ANP enhanced hepatocytic resistance to hypoxia by cGMP-PKC- Na+ channels pathway in rats. Kanwal *et al*[13] showed that NP regulated release of some neurotransmitters by activating L-type calcium channel in rats. Our previous study demonstrated that CNP significarntly inhibited spontaneous contraction of gastric smooth muscle, and the inhibitory effect was mediated by cGMP pathway in rats[9].

To investigate the ionic channel mechanism in CNP-induced relaxation of gastric circular smooth muscle in guinea pigs, the conventional whole cell patch clamp technique was used to record calcium-activated potassium currents, so that the relationship between $I_{K(ca)}$ and CNP-induced relaxationship could be cleared up.

MATERIALS AND METHODS

Preparation of muscle strips and documentation of contractive activity

EWG/B guinea pigs of either sex, weighing (300±50) g bred by Experimental Animal Center of Jilin University, were anaesthetised by a lethal dose of intravenous pentobarbital sodium (50 mg/kg). The abdomen of each rat was opened along the midline and the stomach was removed and placed in a pre-oxygenated Tyrode' s solution at room temperature. The mucous layer was removed. The strips (about 2.0 mm×15.0 mm) of gastric antral circular and longitudinal smooth muscle were prepared by cutting along the vertical direction of the longer axis of the stomach and along muscle strips were placed in a chamber. One end of the strip was fixed on the lid of the chamber through glass claws, the other end was attached to an

isometric force transducer (TD-112S, JAPAN) to record the contraction. The chamber (2 ml volume) was constantly perfused with pre-oxygenated Tyrode's solution at 1 ml/min. The temperature was maintained at (37.0±0.5) ℃ by a water bath thermostat (WC/09-05, Chongqing, China). The muscle strips were incubated for at least 40 minutes before experiments. The samples of human stomach were provided by the Affiliated Hospital of College of Medicine, Yanbian University, (As the gastric sample was limited, the gastric antral of humans was used).

Cell preparation and electrophysiologic recording

Guinea pigs of either sex, weighing 250-350 g, were anaesthetised by a lethal dose of intravenous pentobarbital sodium (50 mg/kg). The antral part of the stomach was rapidly cut, then the muscosal layer was separated from the muscle layers. The longitudinal layer of muscle was then dissected from the other muscle layers using fine scissors, and then cut into small segments (1 mm×4 mm). These segments were kept in the modified Kraft-Bruhe (K-B) medium at 4 ℃ for 15 minutes. Then, they were incubated at 36 ℃ in 4 ml of digestion medium [Ca-free physiologic salt solution (Ca-free PSS)] containing 0.1 % collagenase II, 0.1 % dithioerythreitol, 0.15 % trypsin inhibitor and 0.2 % bovine serum albumin for 25-35 minutes. The softened muscle segments were transferred into the modified K-B medium, and the single cells were dispersed by gentle trituration with a wide-bore fire-polished glass pipette. Then, isolated gastric myocytes were kept in a modified K-B medium at 4 ℃ until they were ready for use.

Isolated cells were transferred to a 0.1 mL chamber on the stage of an inverted microscope (IX-70 Olympus, Japan) and allowed to settle for 10-15 minutes. Then the cells were continuously perfused with an isosmotic physiologic salt solution at a rate of 0.9-1.0 ml/min. A 8-channel perfusion system (L/M-sps-8, List Electronics, Germany) was used to exchange the solution. The $I_{K(ca)}$ was recorded using the conventional whole cell patch-clamp technique. Patch-clamp pipettes were made from borosilicate glass capillaries (GC 150T-7.5, Clark Electromedical Instruments, UK) using a two-stage puller (PP-83, Narishige, Japan). The resistance of patch pipette was 3-5 MΩ, when it was filled with pipette solution. Liquid junction potentials were cancelled prior to the seal formation. The whole-cell current was recorded with an Axopatch 1-D patch-clamp amplifier (Axon Instrument, USA), and data were filtered at 1 KHz. Command pulses, data acquisition and storage were applied by using the IBM-compatible 486-grade computer and pCLAMP 6.02 software. Spontaneously transient outward currents (STOCs) were recorded simultaneously by EPC-10-HEAKA amplifier (HEAKA Instrument, GERMAN). All experiments were performed at room temperature (20-25 ℃).

Drugs and solutions

Tyrode solution containing (mmol· L^{-1}) NaCl 147, KCl 4, $MgCl_2$· $6H_2O$ 1.05, $CaCl_2$· $2H_2O$ 0.42, Na_2PO_4. $2H_2O$ 1.81, and 5.5 mM glucose was used. Ca^{2+}-free PSS containing (mmol/L) NaCl 134.8, KCl 4.5, glucose 5, and N-[2-hydroxyethyl] piperazine-N-[2-ethanesulphonic acid] (HEPES) 10 was adjusted to pH 7.4 with Tris [hydroxymethyl] aminomethane (TRIZMA). Modified K-B solution containing (mmol/L) L-glutamate 50, KCl 50, taurine 20, KH_2PO_4 20, $MgCl_2$· $6H_2O$ 3, glucose 10, HEPES 10 and egtazic acid 0.5 was adjusted to pH 7.40 with KOH. PSS containing (mmol/L) NaCl 134.8, KCl 4.5, $MgCl_2$· $6H_2O$ 1, $CaCl_2$· $2H_2O$ 2, glucose 5, HEPES 10, sucrose 110, was adjusted to pH 7.4 with Tris. CsCl 99, HEPES 10, sucrose 90, were adjusted to pH 7.40 with Tris. The pipette solution recording $I_{K(ca)}$ contained (mmol· L^{-1}) potassium-aspartic acid 110, Mg-ATP 5, HEPES 5, $MgCl_2$· $6H_2O$ 1.0, KCl 20, egtazic acid 0.1, di-*tris*-creatine phoshate 2.5, disodium-creatine phosphate 2.5 and its pH was adjusted to 7.3 with KOH. Tetraethylammonium (TEA), C-type natriuretic peptide (CNP), Ly83583 and Zaparinast were made as stock solutions. All chemicals in this experiment were purchased from Sigma (USA).

Data analysis

All the data were expressed as means ± SD. Statistical significance was evaluated by a *t* test. Differences were considered to be significant when *P* value was less than 0.05.

RESULTS

Effect of CNP on spontaneous contraction of gastric antral circular smooth muscle

Different concentrations of CNP obviously inhibited spontaneous contraction in a dose-dependent manner and the inhibition percentage was 26.21 %±3.12 %, 52.41 %±4.21 % and 73.42 %±8.01 % (n=6) at 10^{-8} mol· L^{-1}, 10^{-7} mol· L^{-1} and 10^{-6} mol· L^{-1}, respectively (Figure 1).

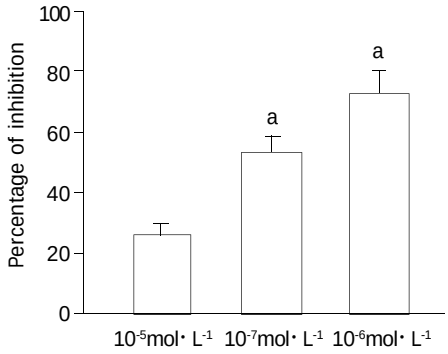

Figure 1 Effect of CNP on spontaneous contraction of gastric circular smooth muscle in a dose-dependent manner in guinea pigs. ^aP<0.01 *vs* 10^{-8} mol·L^{-1} group.

Effect of Ly83583 and Zaparinast on CNP-induced inhibition in gastric antral circular smooth muscle

To further investigate the mechanism of CNP-induced inhibition on spontaneous contraction, the effect of CNP on gastric motility was observed in the condition of administering Ly83583, a kind of inhibitor of guanylate cyclase, and Zaparinast as a phosphoesterase inhibitor to change production of cGMP. Ly83583 (10^{-7} mol· L^{-1}) markedly diminished the inhibitory effect of CNP on spontaneous contraction (P<0.05) (Figure 2), Zparinast (10^{-6}mol· L^{-1}) potentiated the inhibitory effect of CNP on spontaneous contraction (P<0.05)(Figure 3).

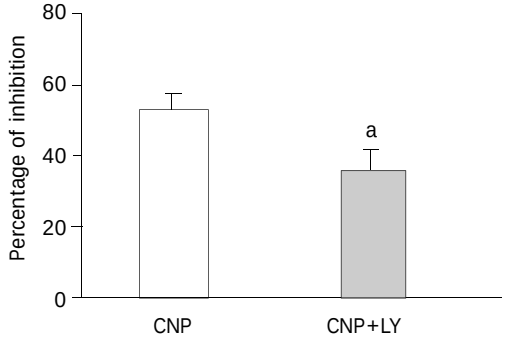

Figure 2 Effect of Ly83583 on CNP-induced inhibition in gastric circular smooth muscle of guinea pigs. ^aP<0.05 *vs* CNP group.

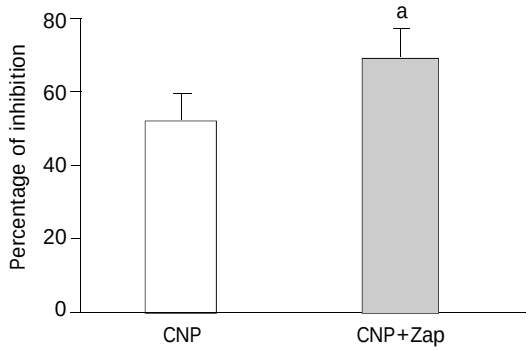

Figure 3 Effect of Zaparinast on CNP-induced inhibition in gastric circular smooth muscle of guinea pigs. [a]$P<0.05$ *vs* CNP group.

Effect of CNP on spontaneous contraction in the presence of TEA

To investigate the relationship between potassium channel and CNP-induced inhibition, the effect of TEA, a nonselective potassium channel blocker, on inhibition of gastic motility induced by CNP was observed. After muscle strips were pretreated with TEA (10 mol· L^{-1}), the inhibitory effect of CNP (10^{-7} mol· L^{-1}) on spontaneous contraction was significantly diminished (n=7) (Figure 4).

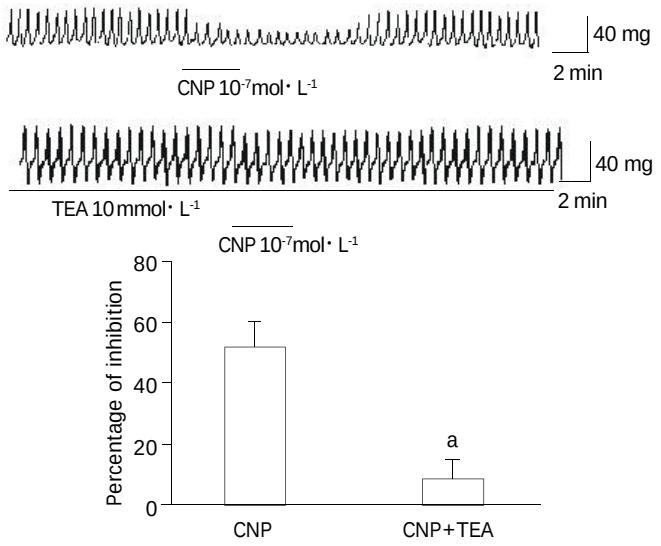

Figure 4 Effect of TEA on CNP-induced inhibition in gastric circular smooth muscle of guinea pigs. [a]$P<0.01$ *vs* CNP group.

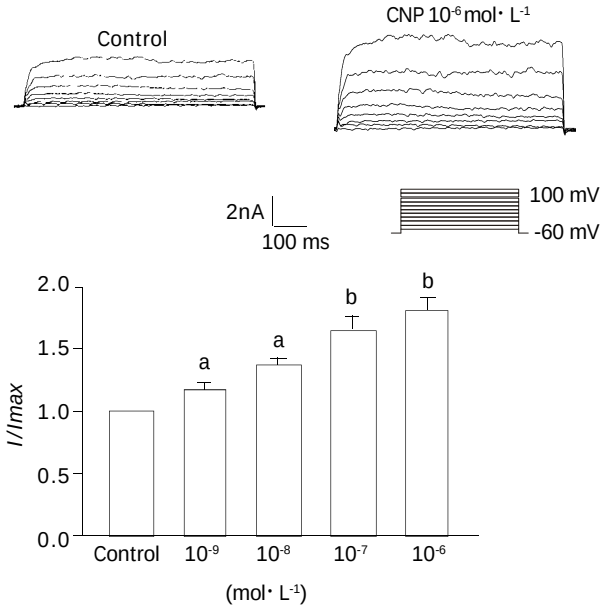

Figure 7 Dose-dependent manner of CNP calcium-activated potassium currents in gastric circular smooth muscle of guinea pigs. [a]$P<0.05$ *vs* Control group, [b]$P<0.01$ *vs* Control group.

Effect of CNP on membrane potential

To further investigate the mechanism of CNP-induced relaxation, the conventional whole cell patch-clamp technique was used. Membrane current was clamped and membrane potential was modulated to -60.0 mV, so that it was close to the resting potential of the gastric myocytes. After addtion of CNP(10^{-7} mol· L^{-1}), the membrane potential was hyperpolarized from -60.0 mV±2.0 mV to -68.3 mV±3.0 mV, and the amplitude of polarization was increased by 13.31 %±1.12 % (P<0.05) (Figure 5).

Effect of CNP on $I_{K(ca)}$

Under conventional whole cell patch clamp mode, the membrane potential was clamped at -60mV, and $I_{K(ca)}$ was elicited by step voltage command pulse from -40 mV to 100 mV for 400 ms with a 20 mV increment at 10 sec intervals.

CNP (Figure 6) (10^{-7} mol· L^{-1}) markedly increased $I_{K(ca)}$ and the increasing amplitude was 62.31 %±3.22 % at 60 mV. Different concentrations of CNP obviously increase $I_{K(ca)}$ in a dose-dependent manner, and the increasing percentage was 16.72 %±1.12 %, 37.51 %±2.32 %, 62.51 %±3.31 % and 82.32 %±3.71 % at 10^{-9} mol· L^{-1}, 10^{-8} mol· L^{-1},10^{-7} mol· L^{-1} and 10^{-6} mol· L^{-1} respectively at 60 mV (Figure 7). In conventional whole cell patch clamp mode, the holding potential was clamped at -20 mV, the spontaneously transient outward currents (STOCs) were recorded. CNP (10^{-7} mol· L^{-1}) also significantly increased STOCs (Figure 8).

Effect of cGMP on CNP-induced increase of $I_{K(ca)}$

The effect of Ly83583 and Zaparinast on CNP-induced increase of $I_{K(ca)}$ was observed. The percentage of CNP-induced increase was diminished from 64.24 %±3.32 % to 26.53 %±2.31 % at 60 mV after pretreated with Ly83583 (P<0.05) (Figure 9) at the same time, the percentage of CNP-induced increase was potentiated from 63.71 %±1.82 % to 81.13 %±2.21 % at 60 mV after pretreated with Zaparinast (P<0.05) (Figure 10).

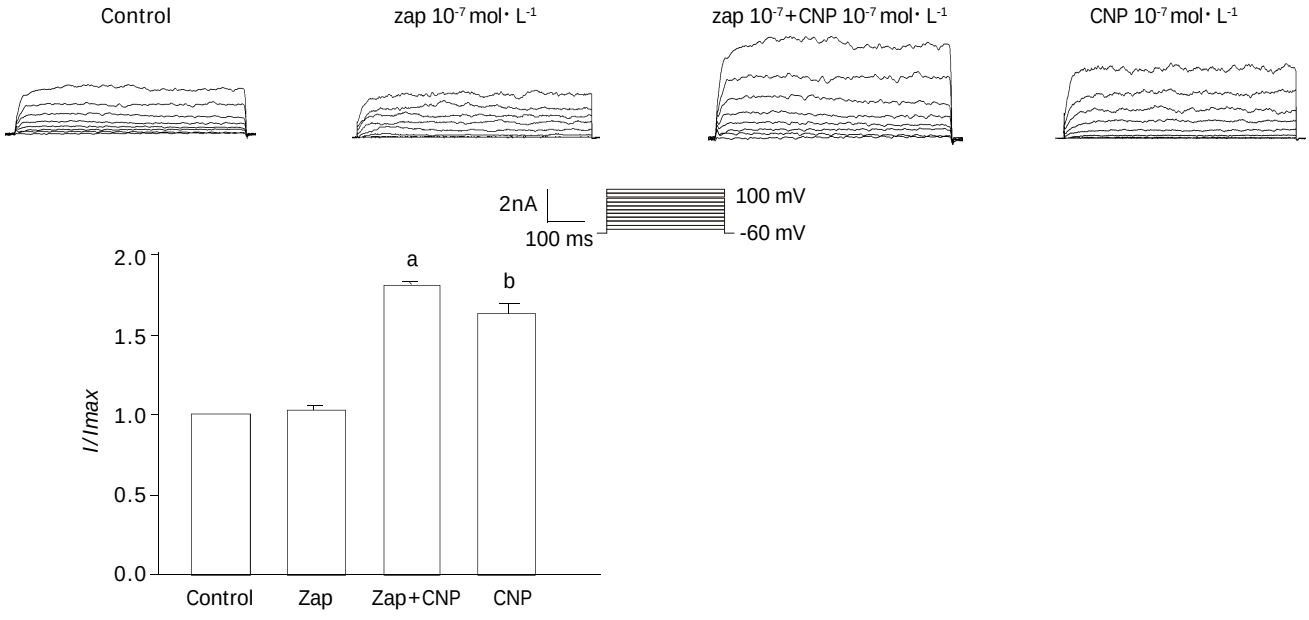

Figure 10 Effect of Zaparinast on CNP-induced increase of calcium-activated potassium currents in gastric circular smooth muscle of guinea pigs. [a]P<0.01 *vs* Zap group, [b]P<0.01 *vs* Zap+CNP group.

DISCUSSION

The present study indicated that CNP inhibited spontaneous contraction of the gastric antral smooth muscle in guinea pigs, and the inhibitory effect was markedly decreased by Ly83583 and potented by Zaparinast. TEA blocked CNP-induced inhibition. CNP hyperpolarized membrane potential and obviously increased $I_{K(ca)}$ in gastric circular myocytes in guinea pigs. CNP-induced increase of $I_{K(ca)}$ was partly blocked by Ly83583, but potentiated by Zaparinast.

Since Komatsu *et al*[14] demonstrated that CNP was distributed in the gastrointestinal tract of rats and humans, the study on the relationship between CNP and gastrointestinal function has recently become the hot topic. In the present study, CNP inhibited spontaneous contraction of gastric circular smooth muscle in guinea pigs. It was similar to many previous studies. Kim *et al*[15,16] indicated that CNP inhibited colonic motility of rabbits and both the frequency and the amplitude of basal motility of the oviduct in a dose-dependent manner. Our previous study also demonstrated that CNP inhibited spontaneous contraction of gastric circular smooth muscles in rats, guinea pigs and humans[8].

In this study, CNP-induced relaxation was mediated by cGMP pathway, since Ly83583 markedly diminished CNP-induced inhibition on spontaneous contraction, but Zaparinast obviously potentiated the effects in the gastric antral circular smooth muscle of guinea pigs. Many studies demonstrated that NP exerted a physiological function by cGMP pathway. Wellard *et al*[17] showed that atrial natriuretic peptides elevated cGMP levels in the primary cultures of rat ependymal cells. ANP and endothelin-1 (ET-1) might prevent renal dysfunction during the progression of congestive heart failure (CHF) through the cGMP pathway in dogs[18]. Tsuruda *et al*[19] demonstrated that BNP could control cardiac fibroblast function via cGMP pathway.

In our present study, TEA weakened the effect of CNP-induced inhibition on spontaneous contraction and CNP hyperpolarized membrane potential in gastric myocytes. It is well known that potassium channel has an intimate relationship with relaxation of smooth muscles. There were two kinds of potassium current, calcium-activated potassium current and delayed rectified potassium current in gastric antral smooth musle cells of guinea pigs[20,21]. This study demonstrated that CNP increased $I_{K(ca)}$ in a dose-dependent manner and CNP also increased STOCs. It could be concluded that potassium channel participates in CNP-induced relaxation. Many previous studies also reported that potassium channel was involved in NP-induced regulation of many physiological functions. Van der Zander *et al*[22] demonstrated that NO and calcium-activated potassium currents could regulate the effect of BNP-induced relaxation on vascular smooth muscles. In guinea pig sino-atrial (SA) node cells, ANP and cGMP increased the delayed rectified potassium current to exert certain physiological functions[23]. However, CNP relaxed the coronary arterial smooth muscle by activating of low conductance Ca^{2+}-activated K^+ channels, natriuretic peptide clearance receptors, and activity/regulation of phosphodiesterases in pigs[24].

NP can exert physiological functions by cGMP-PKG-ion channel pathway. Nakamura *et al*[25] indicated that ANP enhanced the level of cGMP to active cGMP-dependent protein kinase (PKG) to change the activity of inwardly rectifying K(+) channel. Nara *et al*[26] demenstrated that ANP increased $I_{K(ca)}$ by cGMP-PKG pathway in Xenopus oocytes. Our next step is to determine the relationship between CNP-induced increase of $I_{K(ca)}$ and cGMP-PKG pathway in gastric circular myocytes of guinea pigs.

In summary, CNP activated $I_{K(ca)}$ by cGMP pathway can hyperpolarize membrane potential,and gastric smooth muscle can be relaxed in guineapigs.

Abstract

AIM: To study the changes of cell proliferation and apoptosis in rat jejunal epithelium at different ages.

METHODS: Cell proliferation and apoptosis of the jejunal mucosal and glandulous epithelia from birth to postnatal 12th month were observed using immunocytochemistry (ICC), and TUNEL method. The height of villus, the thickness of muscle layer and the number of goblet cells in jejunal mucosal and glandulous epithelia were measured by BeiHang analytic software and analyzed by STAT.

RESULTS: (1) Proliferating cell nuclear antigen (PCNA) positive cells of jejunal glandulous recess were found and increased in number from birth to the postnatal 3rd month. The number of PCNA positive cells peaked in the postnatal 3rd month, and decreased from then on. (2) The number of apoptotic cells also peaked in the postnatal 3rd month, showing a similar trend to that of the PCNA positive cells. (3) The height of jejunal villus increased after birth, peaked in the postnatal 3rd month and decreased from then on. The jejunal muscle layer became thicker in the postnatal 3rd week and the postnatal 12th month. The number of goblet cells of the jejunal mucosal and glandulous epithelia had a linear correlation with age.

CONCLUSION: (1) PCNA positive cells are distributed in the jejunal glandulous recess. (2) Apoptotic cell number peaks in the postnatal 3rd month, indicating that cell proliferation and apoptosis are developed with the formation of digestive metabolism as rat grows to maturity. (3) The thickness of jejunal muscle layer increases to a maximum in the postnatal 3rd week, which may be related to the change in diet from milk to solid food. (4) The number of goblet cells increases rapidly in the postnatal 3rd week, probably due to ingestion of solid food.

INTRODUCTION

The small intestine is the primary digestive apparatus of mammals, and nutrient absorption is ongoing mostly via intestinal epithelium. Mathan *et al* in 1976[1-4] observed the embryogenesis and postnatal change of rat duodenal villi using transmission electron microscope and scanning electron microscope respectively. Weinstein *et al*[5-7] described the ultrastructure and function of intestinal epithelial lining in 1981. In 1995, Gao *et al*[8-10] studied the epithelialization, expression pattern, and transformation of some enzymes of duodenum with histological methods. However, the status of proliferation and apoptotic changes in developing jejunal epithelial lining has not yet been elucidated. The present study was to provide a digestive physiological proof more directly in proliferation and apoptotic changes at four representative developmental stages in rats: birth, postnatal 3rd week, postnatal 3rd month, and postnatal 12th month.

MATERIALS AND METHODS

Materials

Sprague-Dawly rats (male, Grade II, Certificate *No* 04036, obtained from the Experimental Animal Center of Hebei Province) were divided into four groups: newborn (n=6), postnatal 3rd week (n=6), postnatal 3rd month (n=6) and postnatal 12th month (n=6). The rats were held for 12 hours without food. The mean weight was 5.6±0.3 g for newborn, 53.5±1.2 g for postnatal 3rd week, 390±0.9 g for postnatal 3rd month and 601.7±3.4 g for postnatal 12th month. The abdominal cavity was opened immediately after the rat was killed with ether. Several segments of jejunum (1-2 cm) were removed and placed immediately in a fixative consisting of 4 % paraformaldehyde and 0.01 mol/L phosphate buffered saline (PBS, pH7.4) (4 ℃, 12 h). The segments were used for TdT-mediated X-dUTP nick end labeling (TUNEL) examination and HE staining, and other segments were placed in a fixative consisting of Bouin's solution. Fixed jejunum segments were embedded in paraffin and continuously sliced up at 6 μm thickness and mounted onto glass slides covered with 3-aminopropyl-triethoxysilane (APES). They were dried at 37 ℃, and used for immunostaining of proliferating cell nuclear antigen (PCNA).

Reagents

Rabbit anti-rat PCNA antibody and SP kit were purchased from Beijing Zhongshan Biotechnology Company. TUNEL examination kit was purchased from Wuhan Boster Biological Technology Company.

HE staining

Several segments of jejunum were fixed in formalin and embedded in paraffin. Slides were cut and stained with hematoxylin and eosin according to routine methods.

Immunohistochemistry

Immunohistochemical staining for PCNA was performed using SP technique with following procedures. Mounted specimens were washed in 0.01 mol/L phosphate-buffered saline (PBS). Endogenous peroxidase was blocked by 0.3 % H_2O_2 in methanol for 25 min. Slides were washed with PBS followed by incubation in normal goat serum for 30 min at room temperature. The primary rabbit anti-rat PCNA antibody was

diluted 1:75 and applied to sections for 12 hours at 4 ℃. Slides were washed with PBS again and incubated with biotinylated secondary antibody for 60 min at 37 ℃. After rinsed in PBS, the slides were incubated with peroxidase-conjugated streptavidin for 60 min at 37 ℃. Colour reaction was performed by incubating the sections with diaminobenzidine-H_2O_2 for 5 min. The sections were counterstained with hematoxylin, dehydrated in gradient alcohol, and hyalinized in dimethylbenzene. Finally, the sections were mounted and observed under a microscope. PBS was used as a substitute for primary antibody as negative control.

TdT-mediated X-dUTP nick end labeling (TUNEL) examination technique

Mounted specimens were dewaxed and endogenous peroxidase was blocked by 3 % H_2O_2 in methanol for 10 min. After washed with water, 20 μl labeling buffer (1 μl TdT, 1 μl DIG-UTP, and 18 μl Labeling Buffer) was added to each section and incubated for 12 hours at 4 ℃. The sections were washed with 0.01 mol/L TBS and 50 μl blocking solution was added to each slide, followed by incubation for 30 min at room temperature. Biotinylated antidigoxin antibody was added to the slides for 30 min at 37 ℃. SABC was added for 40 min at 37 ℃ followed by washing with TBS. Then the specimens were incubated with diaminobenzidine-H_2O_2 for 5 min. After rinsed in tap water, the sections were counterstained with hematoxylin. Then they were dehydrated in gradient alcohol and hyalinized in dimethylbenzene. The sections were mounted and observed under a microscope. PBS was used as a substitute for primary antibody as negative control.

Data processing

The Northern image analyzing software was employed to analyze the stained area (the percentage of immunoreaction positive cells in total number of cells within a vision field). Three sections were selected from each experimental animal, and ten fields of vision from each section were inspected by statistical random sampling. The villus height was measured, the apoptotic cells under 16×40 double OLYMPUS microscope with testing resection and the number of goblet cells in unit area were counted[11]. The proliferation index was calculated. Under 15×10 double microscope, the thickness of muscle layer was measured according to the statistical random sampling with a micrometer, then the mean value was calculated. The values were expressed as $\bar{x}\pm s$. Statistical analysis was performed using the STAT software and analysis of variance was used as appropriate. $P<0.05$ was considered significant.

RESULTS

The number of jejunal mucosal goblet cells increased from birth to postnatal 3rd week and decreased from postnatal 3rd week to postnatal 3rd month, and then increased again after the postnatal 3rd month (Figure 1, Table 1). The number of

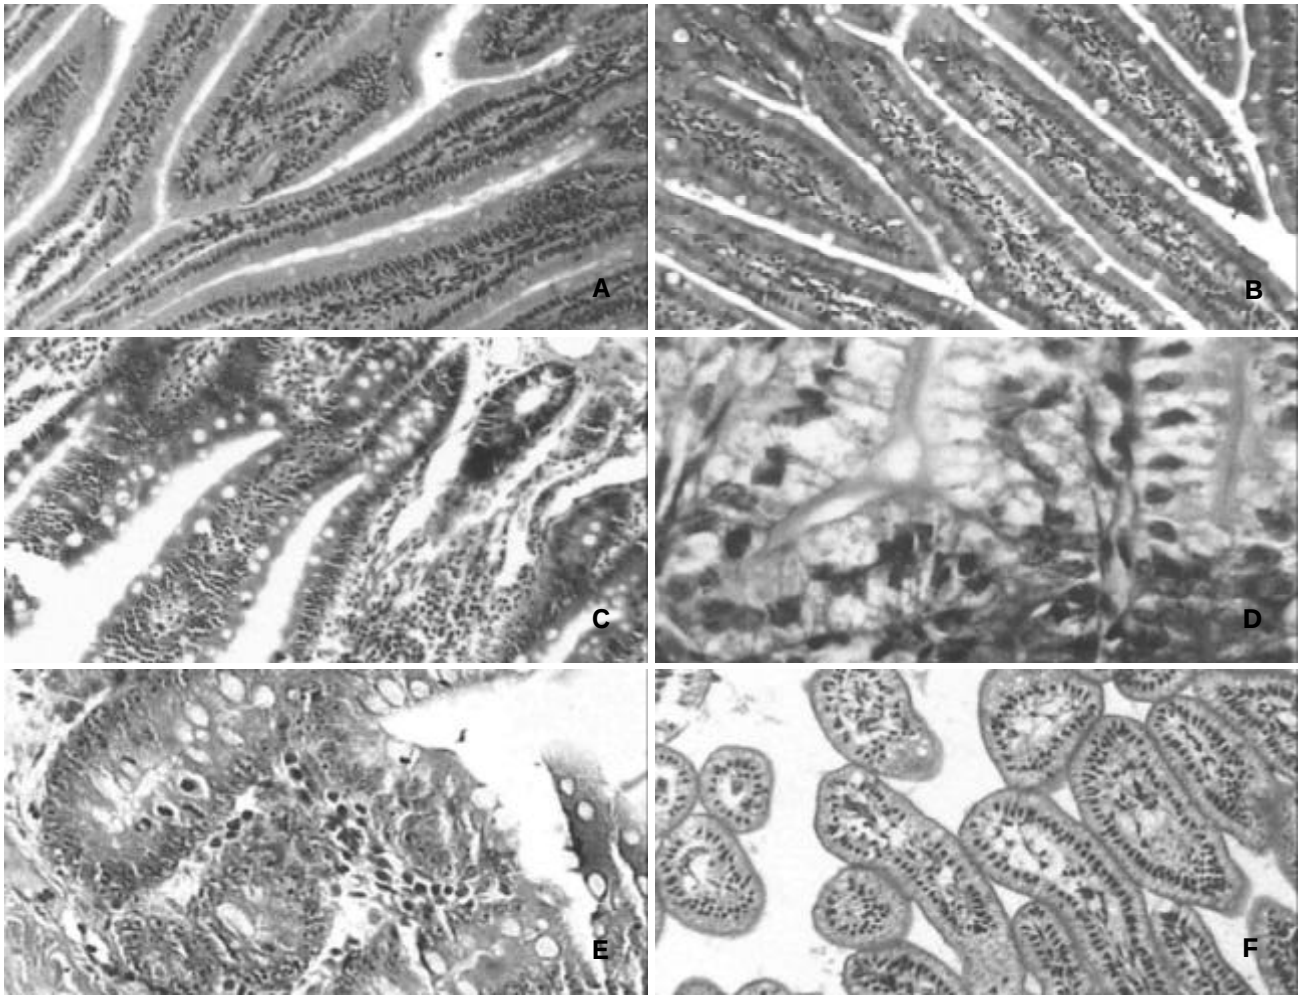

Figure 1 A: The number of goblet cells and the morphology of jejunal villi in the postnatal 3rd month ×100. B: The number of goblet cells in rat jejunal villi in the postnatal 3rd month ×100. C: The number of goblet cells and the morphology of jejunal villi in the postnatal 12th month ×100. D: There were few or no goblet cells in the jejunal glands of newborn rats ×400; E: The number of goblet cells in rat jejunal gland was much higher in the postnatal 12th month than in any other month ×400. F: The jejunal villi of newborn rats displayed ateliosis and were very small ×200.

glandulous epithelial goblet cells had a linear correlation with age (Figure 1), and there were significant differences between groups ($P<0.01$, Table 1). The height of jejunal villus increased from birth, peaked in the postnatal 3rd month and decreased from then on, and the villi were swollen in postnatal 12th month (Figure 1, Table 1). The thickness of jejunal muscle layer appeared crest on postnatal 3rd week and postnatal 12th month, the muscle fibers were quite dense in the postnatal 3rd month but very loose in the postnatal 3rd week (Table 1).

The immunostaining of PCNA positive cells was shown as light brown deposited in the nuclei. The PCNA positive cells in rat jejunum were mainly distributed in jejunal glandulous recess and proper lamina (Figure 2). The PCNA positive cells were shown to increase from birth to postnatal 3rd month, and decrease from then on (Figure 2, Table 2).

Table 2 Surface densities of PCNA-positive cells and the number of apoptotic cells at different stages ($\bar{x}\pm s$, $n=6$)

Age	Surface densities of PCNA-positive cells	The number of apoptotic cells
Newborn group	0±0	0±0
Postnatal 3rd week	0.022±0.012	9.71±2.43
Postnatal 3rd month	0.449±0.063[b]	38.83±7.41[b]
Postnatal 1 year	0.096±0.045[d]	11.36±3.14[d]

[b]$P<0.01$, *vs* Postnatal 3rd week. [d]$P<0.01$, *vs* Postnatal 3rd month.

The apoptotic cells were stained by TUNEL and positive cells were shown as dark brown in the nuclei. The apoptotic positive cells were mainly distributed in lamina propria (Figure 2). The number of apoptotic positive cells increased from newborn to postnatal 3rd month, and then decreased with aging. The pattern was similar to that of the PCNA positive cells (Figure 2, Table 2).

DISCUSSION

The goblet cell is a typical cell capable of excreting glycoprotein, containing a lot of spumous grume and granules of inhomogeneous electronic density. The jejunal glandulae of newborn rats could not develop but goblet cells can be seen in the villi. The number of goblet cells increased in the postnatal 3rd month, which might be related to the change in diet from milk to solid food. In the postnatal 12th month, the number of goblet cells increased again, and in this phase the increase of goblet cells led to the increase of mucus, which has the functions of lubricating mucosa and defending intestinal wall. The increasing change in the number of gerontic goblet cells might be a kind of protective mechanism against the weakening of excreting function of digestive gland in gerontic rat.

Cheng *et al*[12] considered that rat intestinal villi had perfectly developed on the 21st day of pregnancy, but there were only a few intestinal glands and few goblet cells. Our result was coincident with that of Cheng *et al*. We found that along with

Table 1 Developmental changes in cell type and morphology of rat villi after staining ($\bar{x}\pm s$, $n=6$)

Group	Number of villus goblet cells (entries/μm²)	Number of crypt goblet cells (entries/μm²)	Thickness of muscle layer (μm)	Villus height (μm)
Newborn group	4.89±2.67	0±0	32.0±15.71	315.20±43.74
Postnatal 3rd week	7.14±1.54[b]	4.47±1.10[b]	64.86±14.91[b]	532.75±53.36[b]
Postnatal 3rd month	4.44±1.11	5.27±0.93	56.34±15.41	629.64±48.22
Postnatal 1 year	9.31±1.50[d]	6.49±1.98	60.48±11.93	510.95±82.93[d]

[b]$P<0.01$, *vs* Newborn group. [d]$P<0.01$, *vs* Postnatal 3rd month.

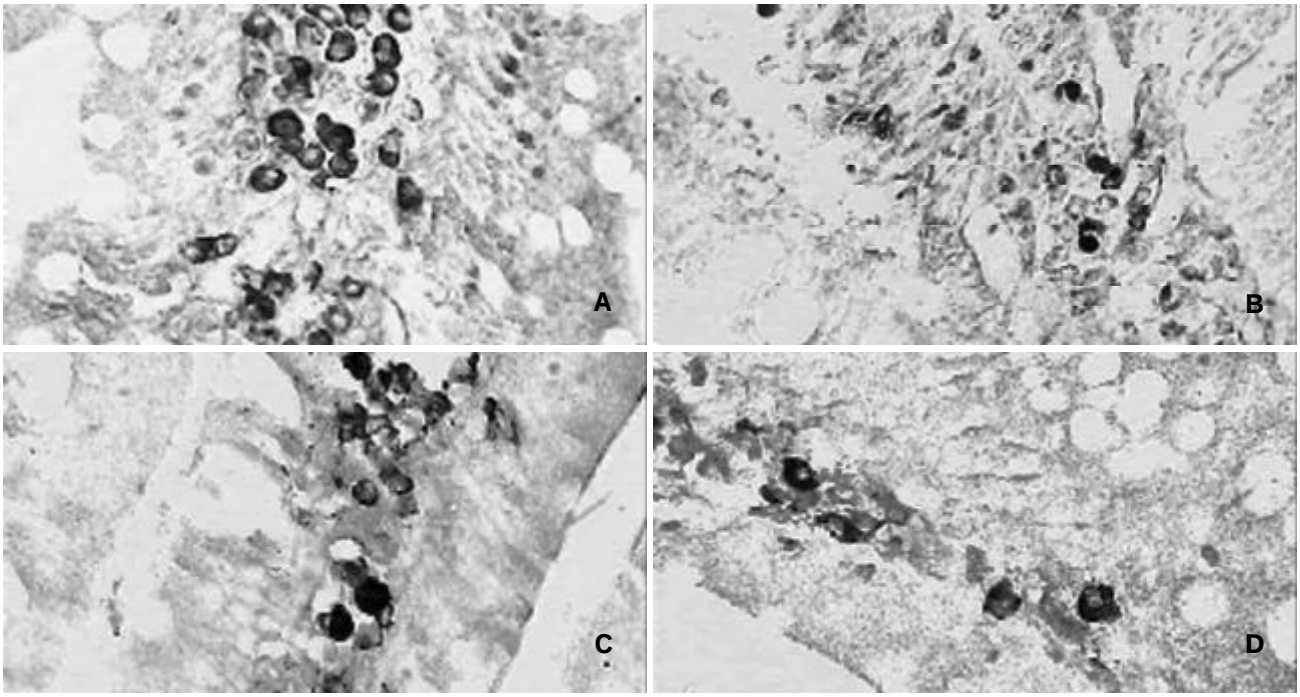

Figure 2 A: The expression of PCNA positive cells of the rat jejunum in the postnatal 3rd month ×400. B: The number of jejunal PCNA positive cells in the postnatal 12th month ×400. C: The expression of apoptotic positive cells of rat jejunum in the postnatal 3rd month ×400. D: The number of rat jejunal apoptotic positive cells in the postnatal 12th month ×400.

the development of intestinal glands the number of goblet cells in the intestinal gland gradually increased in the rat of postnatal 3rd week, postnatal 3rd month and postnatal 12th month, and this phenomenon might be corresponding to hearty digestive function in mature rats.

With the commence of sucking activity of newborn rat, the digestive tract starts its digestive activities. The newborn rat villi are very fine, and immature. In this period the intestinal digestive function is quite feeble, great molecule materials are assimilated via endocytosis with the help of lysosomes, thus the nutrients are absorbed. This absorptive manner only suits to the materials in milk[13]. Milk has balanced and all-sided nutrition, and contains many growth factors which are necessary to the development of the rat, so it can promote intestinal cells to develop[14]. To absorb various kinds of nutrients, gastrointestinal tract of rat develops rapidly and matures gradually to adapt to the digestive function[15]. In the postnatal 3rd week, villi become primarily matured. The muscle layer is quite thick, and the enteric digestive function of rat is boosted up. In this phase, endocytosis has weakened, and the rat can gradually digest food, and many absorptive mechanisms like glucide simple diffusing, solvent dragging, active ion transport and co-transport appear. In the postnatal 3rd month, villi heighten and peak, which increase the intestinal digestive areas. In this period, microvilli on the top of intestinal villus can be seen under an electron microscope, and they gather together to be known as brush border. Villi and microvilli increase the intestinal digestive area to 200 m^2 or more. There are capillary, lymphatic capillary, smooth muscle fiber and nerve net in intestinal villi, and one or more central small arteries and a central chyle vessel in each intestinal villus. The villus height increases with advancing age. The structures of capillary, lymphatic capillary, smooth muscle fiber and nerve net in intestinal villi are perfectly developed, in favor of substance countercurrent exchange in ascending and descending vessels of villi. At the same time, the muscle fiber relaxation and contraction and the pump function of central chyle vessels in villi help digestion. Besides, increase of muscle fibers which enhance the whip and rhythmic condensing movement is also helpful to digestion, and this period becomes the strongest phase of the digestive function. In the postnatal 12th month, there are effete changes like swelling and shortening of some villi, and the enteric digestive function slacks up, thus food is insufficiently digested in the enterocoelic cavity. The phenomenon of exocytosis manner assimilating large molecule substances appear again, maybe this manner is a kind of compensation for the digestion.

PCNA has a molecular weight of 36 kDa and is an assistant protein of DNA polymerase δ in terms of its physiological function. It can objectively reflect the proliferation degree of cells, and is a better proliferating marker of cells. PCNA immunostaining signal is almost completely disappeared in the nuclei. Positive substance takes on the form of dispersion or granule, or a combination of the two forms. The cell nuclei of strong positive cells are brown-yellow, nuclei of positive cells are yellow, the cell nuclei of feeble positive cells are buff. The proliferating bloom region of PCNA positive cells is distributed in jejunal glandulous recess, and the differentiation of positive cells on the top of villi is a sort of "ladder-like" movement[16-19]. The experiment showed that the proliferative index of PCNA positive cells in the recess increased from birth to postnatal 3rd month, and reached the crest in postnatal 3rd month, which made the cells in recess to be continuously hyperplastic. The proliferation index decreased at postnatal 12th month, indicating that the proliferation of cells becomes weak as the organism ages.

As the fastest renewing cells in the body, the cell cycle of small intestinal epithelia only exists for 12 h, and they also have apoptosis[20-23]. As early as the end of 19th century, the granules of epithelial cells in embryonic digestive tube under optical microscope were named "meconium corpuscles". Harmon *et al*[24-27] confirmed under the electron microscope that in fact meconium corpuscles were the apoptotic globules in digestive tract epithelia. Iwanaga *et al*[28-34] considered that macrophages in small intestinal proper lamina of adult rats could induce apoptosis of epithelia. It was observed in this experiment that the apoptotic cell number of intact jejunal villi of SD rats increased from birth to postnatal 3rd month and reached its peak in postnatal 3rd month, which may be indicated that when the rat grows up, cell proliferation and apoptosis activity became abundant with the buildup of body metabolism function. The metabolic level decreased in postnatal 12th month with the senescence of body, the number of apoptotic cells began to decline compared with that in the postnatal 3rd month.

Abstract

AIM: To evaluate the effects of prucalopride on intestinal prokinetic activity in fast rats and to provide experimental basis for clinical treatment of gastrointestinal motility diseases.

METHODS: Gastrointestinal propulsion rate was measured by the migration rate of activated charcoal, which reflexes gastrointestinal motility function. 120 Spraque-Dawley rats were randomly divided into four groups and received an intravenous injection of physiological saline (served as control), prucalopride 1 mg/kg, prucalopride 2 mg/kg and cisapride 1 mg/kg, respectively. The gastrointestinal propulsion rate was measured 1, 2 or 4 hours after intravenous injection of the drugs.

RESULTS: Significant accelerations of gastrointestinal propulsion rate in prucalopride 1 mg/kg and 2 mg/kg groups were found compared with control group at 2 and 4 hours (83.2 %±5.5 %, 81.7 %±8.5 % *vs* 70.5 %±9.2 %, $P<0.01$; 91.2 %±2.2 %, 91.3 %±3.9 % *vs* 86.8 %±2.6 %, $P<0.01$). The gastrointestinal propulsion rates at 1, 2 or 4 hours were faster in prucalopride 1 mg/kg and 2 mg/kg groups than in cisapride group (84.0 %±11.7 %, 77.1 %±11.9 % *vs* 66.3 %±13.6 %, $P<0.01$, $P<0.05$; 83.2 %±5.5 %, 81.7 %±8.5 % *vs* 75.4 %±5.9 %, $P<0.01$, $P<0.05$; 91.2 %±2.2 %, 91.3 %±3.9 % *vs* 88.6 %±3.5 %,$P<0.05$, $P<0.05$). No difference of gastrointestinal propulsion rate was found between prucalopride 1 mg/kg group and prucalopride 2 mg/kg group ($P>0.05$).

CONCLUSION: Prucalopride accelerates intestinal motility in fast rats, and has no dose dependent effect.

INTRODUCTION

Prucalopride is the first representative of the novel class of benzofurans,and is a highly specific and selective 5-HT_4 receptor agonist. Prucalopride can exert effect on intestinal prokinetic activity in fast rats.

MATERIALS AND METHODS

Experimental animals

One hundred and twenty healthy male Sprague-Dawley (SD) rats weighing 200-250 g were purchased from the Experimental Animal Center of Xi' an Jiaotong University. The rats were housed in rat cages at 22-25 ℃ with free access to standard rat pellet food and water for 10 days. They were fasted for 48 hours with free access to water.

Chemicals

Prucalopride and cisapride were kindly provided by Janssen Research Foundation. Prucalopride was dissolved in sterile, and cisapride in 0.57 mol/L ascorbic acid. Activated charcoal was purchased from the Chemical Factory of the Forestry Science Institute of China. Arabic gum powder was purchased from the Third Chemical Factory of Tianjin. Diethyl ether was purchased from Xi' an Chemical Factory.

Experimental procedure

The rats were randomly divided into four groups. Each group had 30 rats. The first group served as control and received intravenous injection of physiological saline under ether anaesthesia. The second group and the third received intravenous injection of prucalopride 1 mg/kg and 2 mg/kg under ether anaesthesia, and the fourth group received intravenous injection of cisapride 1 mg/kg in the same way. They then received intragastric injection of 100 g/L activated charcoal suspension (10 mg/kg, 100 g/L activated charcoal and 100 g/L Arabic gum powder respectively) through a specially designed orogastric cannula introduced through the mouth. The animals were killed 1, 2 and 4 hours respectively after ether anesthesia by cervical dislocation and decapitation. They had a laparotomy and migration of activated charcoal from esophagus-stomach junction to the most distal point of migration, and were expressed as distance (cm) migration by the stain. At 1 hour after injection, the most distal point of migration was in the small intestine and gastrointestinal(GI) propulsion rate was expressed as: gastrointestinal propulsion rate =the migration distance of activated charcoal(cm)÷the distance from esophagus-stomach junction to ileocecal opening (cm)×100 %. At 2 hours after injection, the most distal point of migration was all in the distal small intestine or proximal colon and at 4 hour after injection, the most distal point of migration was in the colon. So gastrointestinal propulsion rate was expressed as: gastrointestinal propulsion rate =the migration distance of activated charcoal (cm)÷the distance from esophagus-stomach junction to large intestine terminal (cm)×100 %.

Statistical analysis

Data were expressed as $\bar{x}\pm s$. Statistical analyses used were unpaired *t* test. Statistical significance was taken as $P<0.05$.

RESULTS

One hour effect of prucalopride

At 1 hour after injection, the most distal point of migration was in the small intestine. Compared with control group, in prucalopride 1 mg/kg group and prucalopride 2 mg/kg group, GI propulsion rate had no difference ($P>0.05$). Prucalopride at a

dose of either 1 or 2 mg/kg had no significant effect on gastrointestinal motility. Compared with cisapride group, GI propulsion rate had differences in prucalopride 1 mg/kg group and prucalopride 2 mg/kg group ($P<0.01$, $P<0.05$, Table 1).

Table 1 One hour effect of prucalopride on intestinal motility in SD rats ($\bar{x}\pm s$, $n=10$)

Group	GI length (cm)	Migration of activated charcoal (cm)	GI propulsion rate (%)
Control	82.9±12.2	63.8±10.5	77.9±7.5
Prucalopride (1 mg/kg)	70.9±4.1	59.7±9.5	84.0±11.7[b]
Prucalopride (2 mg/kg)	73.8±11.7	57.0±12.8	77.1±11.9[a]
Cisapride (1 mg/kg)	78.1±10.7	52.2±14.4	66.3±13.6

[a]$P<0.05$, [b]$P<0.01$, *vs* cisapride.

Two hour effect of prucalopride

At 2 hours after injection, the most distal point of migration was in the distal small intestine or proximal colon. Compared with control group, GI propulsion rate had significant differences in prucalopride 1 mg/kg group and prucalopride 2 mg/kg group ($P<0.01$).

Prucalopride at a dose of either 1 or 2 mg/kg significantly increased GI propulsion, suggesting that prucalopride might enhance gastrointestinal motility. Compared with cisapride group, GI propulsion rate had differences in prucalopride 1 mg/kg group and prucalopride 2 mg/kg group ($P<0.01$, $P<0.05$,Table 2).

Table 2 Two hour effect of prucalopride on intestinal motility in SD rats ($\bar{x}\pm s$, $n=10$)

Group	GI length (cm)	Migration of activated charcoal (cm)	GI propulsion rate (%)
Control	91.9±11.8	63.9±3.8	70.5±9.2
Prucalopride (1 mg/kg)	87.1±8.5	72.6±10.0	83.2±5.5[bd]
Prucalopride (2 mg/kg)	100.1±12.2	81.9±14.0	81.7±8.5[ad]
Cisapride (1 mg/kg)	95.4±12.3	72.0±6.9	75.4±5.9

[a]$P<0.05$, [b]$P<0.01$, *vs* cisapride; [d]$P<0.01$, *vs* control.

Table 3 Four hour effect of prucalopride on intestinal motility in SD rats ($\bar{x}\pm s$, $n=10$)

Group	GI length (cm)	Migration of activated charcoal (cm)	GI propulsion rate (%)
Control	89.9±8.6	78.0±7.3	86.8±2.6
Prucalopride (1 mg/kg)	83.7±5.1	76.3±5.2	91.2±2.2[ad]
Prucalopride (2 mg/kg)	97.4±9.8	87.3±10.4	91.3±3.9[ad]
Cisapride (1 mg/kg)	99.5±12.7	88.1±13.7	88.6±3.5

[a]$P<0.05$, *vs* cisapride; [d]$P<0.01$, *vs* control.

Four hour effect of prucalopride

At 4 hours after injection, the most distal point of migration was in the colon. Compared with control group, GI propulsion rate had significant differences in prucalopride 1 mg/kg group and prucalopride 2 mg/kg group ($P<0.01$). Prucalopride at a dose of either 1 or 2 mg/kg significantly increased GI propulsion, suggesting that prucalopride might enhance gastrointestinal motility. Compared with cisapride group, GI propulsion rate had differences in prucalopride 1 mg/kg group and prucalopride 2 mg/kg group ($P<0.05$, Table 3).

Response to different doses of prucalopride

At 1, 2 and 4 hours after prucalopride injection, GI propulsion rate in prucalopride 1 mg/kg group was not different from that in prucalopride 2 mg/kg group ($P>0.05$, Table 1, 2 and 3). The effect of prucalopride was not clearly dose related.

DISCUSSION

Prucalopride (R093877) is a newly synthesized enterokinetic agent which is a benzofuran derivative with the chemical structure of 4-animo-5-chloro-2, 3-dihydro-*N*-[1(3-methoxypropyl)-4-piperidinyl]-7-benzofurancarboxamide monochloride. It is a highly specific and selective 5-HT_4 receptor agonist[1]. *In vitro* animal experiments have shown facilitation of cholinergic[2] and excitatory non-adrenergic,non-cholinergic (NANC) neurotransmission. It is the first compound known to enhance NANC transmission in colonic preparations of guinea pig. Since cholinergic neurons and NANC neurons are known to play an important part in physiological regulation of colonic motility, it is likely that constipation will be favourably influenced by compounds facilitating NANC excitatory neurotransmission. Prucalopride is a specific and selective for 5-HT_4 receptor and is devoid of affinity to M_3 cholinoceptors, $5HT_{2A}$ and $5HT_3$ receptors, and cholinesterases. *In vivo* canine colonic studies confirmed the selectivity of the effects on 5-HT_4 receptors, as the selective and potent 5-HT_4 antagonist completely prevented the effects of prucalopride. But some 5-HT_4 agonist prokinetics stimulate $5HT_{2A}$ and $5HT_3$ receptors. *In vivo* and *in vitro* studies have shown that prucalopride can facilitate gastric, small intestinal, and colonic motility[3-5].

This study in fast rats showed that prucalopride had no significant effects on GI propulsion rate at 1 hour after intravenous injection. However, it significantly increased GI propulsion rate at 2, 4 hour after intravenous injection, suggesting that prucalopride might enhance gastrointestinal motility in the distal small intestine and colon instead of the stomach and proximal small intestine. This is consistent with the observations of Emmanuel *et al* in healthy volunteers. Emmanuel showed that 1 mg and 2 mg of prucalopride shortened orocaecal transit and whole gut transit,and suggested that prucalopride accelerated upper gut and colonic transit. Orocaecal transit was measured by lactoluse-hydrogen breath test. Whole gut transit was measured by radio-opaque markers. Bouras *et al*[6] reported that gastrointestinal and colonic transits were measured by scintigraphic techniques in healthy humans, and a daily dose of 0.5, 1, 2, or 4 mg prucalopride accelerated colonic transit, partly by stimulating proximal colonic empting, but did not alter gastric or small bowel transit. Poen *et al*[7] reported that prucalopride was well tolerated by healthy subjects and had a markedly consistent effect on stool frequency and colonic transit. Prucalopride, given orally or intravenously, altered colonic motility in the fast conscious dog in a dose-dependent manner. It induced signicant migrating contractions, stimulated proximal colon and inhihibed contractile motility patterns of distal colon by stimulating 5-HT4 receptors[4,8]. It deserves further study in patients with constipation. The fact that prucalopride did not affect stomach and proximal small intestine in fast rats does not preclude its potential beneficial effects in pathological states such as delayed gastric emptying. For example, in an animal model for delayed gastric emptying, prucalopride accelerated gastric emptying. In humans, Emmanuel *et al* observed that prucalopride shortened orocaecal transit, while Bouras *et al* found that prucalopride did not alter gastric or small bowel transit. This discrepancy probably was resulted from differences in methods used to measure transit. In Emmanuel *et al* studies, lactoluse-hydrogen breath test of a liquid marker

could measure orocaecal transit, but could not differentiate effects on stomach or small intestine. Whole gut transit was measured by radio-opaque markers. In Bouras *et al* studies, a scintigraphic technique was used to measure gastrointestinal and colonic transit[6]. The effects of prucalopride on stomach or small intestine deserves further study. Patients with idiopathic constipation had postprandial sigmoid mortor activity[9]. Prolonged colonic motility was recorded in patients with slow transit constipation[10]. Slow transit constipation was common[11-16]. Laxatives are often ineffective in treating constipation. An alternative therapeutic approach is to target serotonin-4 receptors, which are involved in initiating peristalsis[17-30]. Some Chinese herbal medicines can promote gastrointestinal motility and be used to treat constipation[31,32].

The reason for the lack of a dose-response effect of prucalopride on gastrointestinal motility is unclear. Maybe the dose groups were too few and the extent of doses was too narrow. It should design more dose groups to deserve the dose related effects. The dose dependent effects on significant colonic migrating have been more clearly shown by intravenous injection than by oral administration of prucalopride in dogs. Briejer *et al* observed a sigmoid dose-response curve in a dose of 0.001 to 1.25 mg/kg, the linear part of the curve was between 0.02 and 0.31 mg/kg. But Bouras *et al* reported that in healthy humans, a daily dose of 0.5, 1, 2, or 4 mg prucalopride was almost equally effective, and lack of dose-response effects[6]. The lack of stronger effects of 2 mg over 1 mg in this study might be resulted from turning off the signal: mechanisms that attenuate signaling by G protein-coupled receptors, by which serotonin receptors are characterized. In futher study, we shall investigate the dose related effects of prucalopride in patients with constipation and slow colonic transit.

This study showed that prucalopride whether 1 mg/kg or 2 mg/kg doses accelerated greater gastrointestinal propulsion rate compared with cisapride 1 mg/kg dose.

In conclusion, prucalopride can accelerate intestinal motility in fast rats, and maybe hold a promising new class of treatment for chronic constipation.

Abstract

AIM: To study the optical properties of human normal small intestine tissue at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm, 532 nm, 808 nm wavelengths of laser irradiation.

METHODS: A double-integrating-sphere system, the basic principle of measuring technology of light radiation, and an optical model of biological tissues were used in the study.

RESULTS: The results of measurement showed that there were no significant differences in the absorption coefficients of human normal small intestine tissue at 476.5 nm, 488 nm, 496.5 nm laser in the Kubelka-Munk two-flux model ($P>0.05$). The absorption coefficients of the tissue at 514.5 nm, 532 nm, 808 nm laser irradiation were obviously increased with the decrease of these wavelengths. The scattering coefficients of the tissue at 476.5 nm, 488 nm, 496.5 nm laser irradiation were increased with the decrease of these wavelengths. The scattering coefficients at 496.5 nm, 514.5 nm, 532 nm laser irradiation were obviously increased with the increase of these wavelengths. The scattering coefficient of the tissue at 532 nm laser irradiation was bigger than that at 808 nm. There were no significant differences in the total attenuation coefficient of the tissue at 476.5 nm and 488 nm laser irradiation ($P>0.05$). The total attenuation coefficient of the tissue at 488 nm, 496.5 nm, 514.5 nm, 532 nm, 808 nm laser irradiation was obviously increased with the decrease of these wavelengths, and their effective attenuation coefficient revealed the same trend. There were no significant differences among the forward scattered photon fluxe, backward scattered photon fluxe, and total scattered photon fluxe of the tissue at 476.5 nm, 488 nm, 496.5 nm laser irradiation. They were all obviously increased with attenuation of tissue thickness. The attenuations of forward and backward scattered photon fluxes, and the total scattered photon fluxe of the tissue at 514.5 nm laser irradiation were slower than those at 476.5 nm, 488 nm, 496.5 nm laser irradiation respectively. The attenuations of forward and backward scattered photon fluxes, and total scattered photon fluxes at 532 nm laser irradiation were obviously slower than those at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm laser irradiation. The attenuations of forward and backward scattered photon fluxes, and total scattered photon fluxe at 808 nm laser irradiation were all obviously slower than those at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm, 532 nm laser irradiation respectively.

CONCLUSION: There are significant differences in optical parameters of human normal small intestine tissue in the Kubelka-Munk two-flux model at six different wavelengths of laser radiation. The results would provide a new method of information analysis for clinical diagnosis.

INTRODUCTION

Much effort is being made in the study of light propagation in tissues due to the development and wide use of lasers in surgery and therapy[1-3]. In particular, the effectiveness of photodynamic therapy (PDT) is greatly influenced by photosensitizer content and light distribution in the irradiated tissue[4-7], and an accurate evaluation of energy fluence in depth should allow an estimate of whether the whole tumor mass is properly irradiated[8,9]. Consequently, determination of tissue optical properties is important. Photons are absorbed and scattered when they come into contact with biological tissues[10]. The depolarization degree of different biological tissues at linearly polarized light is different. All these have a correlation with the components and structures of biological tissues and optical properties. Consequently, photons have already taken the information that has a close relationship with the components and structures of biological tissues since photons came into contact with biological tissues[11-13]. Biological tissues may be looked upon as turbid media from the point of view of tissue optics. The optical properties of biological tissues change with the characteristics of living organisms[14-17]. The typical optical properties are obtained by using solutions of the radiative transport equation that expresses the optical properties in terms of readily measurable quantities. These solutions are either exact or approximate and correspond to the direct or indirect methods. A double-integrating-sphere system, the basic principle of measuring technology of light radiation, an optical model of biological tissues were used in this experiment[18-21]. In our study, we detected the optical properties of human normal small intestine tissue at 476.5 nm, 488 nm, 496.5 nm, 514.5 nm, 532 nm, 808 nm wavelengths of laser irradiation, and analyzed the experimental results.

MATERIALS AND METHODS

The optical properties of tissues describe the three-dimensional propagation of radiation. Through modeling simplifications (i.e., Kubelka-Munk Two-Flux Theory) the radial propagation

is often reduced to a one-dimensional propagation of radiation. Kubelka-Munk two-flux theory was used to calculate the absorption coefficient A_{KM}, scattering coefficient S_{KM}, total attenuation coefficient E_t and effective attenuation coefficient E_{eff} of human normal small intestine tissue at six laser wavelengths by measuring reflection R, transmission T of diffuse irradiance on a slab of thickness d of the sample.

Kubelka-Munk two-flux theory

The Kubelka-Munk two-flux theory is applied to the thin slab of scattering material without sources, and its prime advantage as compared to more complicated models is that the scattering coefficient S_{KM} and absorption coefficient A_{KM} can be directly expressed in terms of the measured reflection R, transmission T, and thickness d of the sample[22]. Consequently, it has been widely applied. Its parameters are commonly used in the field of medical physics. It regards the scattering light as none but the forward scattered photon fluxes i(x) and backward scattered photon fluxes j(x) when incident light radiates in a slab of thickness X (cm) of the turbid media. The sum of the forward and backward scattered photon fluxes is equal to the total scattered photon fluxes I(x)[23]. The scattering and absorption coefficients exist[24]. The description of A_{KM} and S_{KM} as a function of R, T, and X are given by

$$A_{KM} = \left[\left(1 + R^2 + T^2\right)/2R - 1\right]S_{KM} \qquad (1)$$

$$S_{KM} = \frac{1}{Xb} In\left[\frac{1 - R/(a + b)}{T}\right] \qquad (2)$$

The description of total attenuation coefficients E_t and effective attenuation coefficients E_{eff} as a function of A_{KM} and S_{KM} are given by[25]

$$E_t = A_{KM} + S_{KM} \qquad (3)$$

$$S_{KM} = \frac{1}{Xb} In\left[\frac{1 - R/(a + b)}{T}\right] \qquad (4)$$

The human normal small intestine tissue was regarded as a slab of turbid medium of thickness X. Then, A_{KM}, S_{KM}, E_t, E_{eff} were respectively regarded as the absorption coefficients, scattering coefficients, total attenuation coefficients, effective attenuation coefficients of human normal small intestine tissue at laser irradiation.
