### Abstract

PubMed, EMBASE, Orphanet, MIDLINE, Google Scholar and Cochrane Library were searched for articles published between 1983 and 2015. Relevant articles were selected by using the following terms: "Liver cirrhosis", "Endothelial dysfunction", "Sinusoidal remodeling", "Intrahepatic angiogenesis" and "Pathogenesis of portal hypertension". Then the reference lists of identified articles were searched for other relevant publications as well. Besides gross hepatic structural disorders related to diffuse fibrosis and formation of regenerative nodules, the complex morphofunctional rearrangement of the hepatic microvascular bed and intrahepatic angiogenesis also play important roles in hemodynamic disturbances in liver cirrhosis. It is characterized by endothelial dysfunction and impaired paracrine interaction between activated stellate hepatocytes and sinusoidal endotheliocytes, sinusoidal remodeling and capillarization, as well as development of the collateral microcirculation. In spite of the fact that complex morphofunctional rearrangement of the hepatic microvascular bed and intrahepatic angiogenesis in liver cirrhosis are the compensatory-adaptive reaction to the deteriorating conditions of blood circulation, they contribute to progression of disease and development of serious complications, in particular, related to portal hypertension.

**Key words:** Liver cirrhosis; Endothelial dysfunction; Sinusoidal remodeling; Intrahepatic angiogenesis; Pathogenesis of portal hypertension

## MORPHOFUNCTIONAL REARRANGEMENT OF THE HEPATIC MICROVASCULAR BED IN LIVER CIRRHOSIS

Besides gross hepatic structural disorders related to diffuse fibrosis and formation of regenerative nodules, the complex morphofunctional rearrangement of the hepatic microvascular bed in liver cirrhosis also contributes to the development of severe complications, in particular, associated with portal hypertension<sup>[1]</sup>. In this situation, the main place of resistance to portal blood flow is in pathologically modified sinusoids. Sinusoidal endothelial cells (SEC) become dysfunctional and among other features acquire a vasoconstrictor phenotype. It leads to increasing of SEC sensitivity to endogenous vasoconstrictors, such as endothelin, norepinephrine, angiotensin II, vasopressin, leukotrienes, thromboxane A2. In contrast, the production of nitric oxide (the most studied vasodilator involved in the regulation of hepatic vascular tone) is reduced. The reason for this may be insufficient activity of endothelial nitric oxide synthase (eNOS) due to its increased interaction with caveolin-1. Furthermore, endothelin-1 activates G-protein-coupled receptor kinase-2 which directly interacts with and inhibits protein kinase B (Akt) phosphorylation and decreases the production of nitric oxide (NO)<sup>[2]</sup>.

One of the main factors of sinusoidal endothelial dysfunction in cirrhosis is intrahepatic oxidative stress, which is associated with a decrease of eNOS expression and NO bioavailability. For example, cyclooxygenase attenuates Akt-eNOS signalization by stimulating thromboxane A2, which inhibits Akt phosphorylation in endothelial cells, as well as excessive activation of Rho-kinase. Asymmetric dimethylarginine, an endogenous inhibitor of NOS, causes uncoupling of NOS leading to generation of reactive nitrogen species such as peroxynitrite, and down-regulated tetrahydrobiopterin

expression promotes that the eNOS cannot generate NO but instead produces O<sub>2</sub><sup>-</sup>, thereby leading to further decreases in NO production. In addition, it was reported that a possible reason for the insufficient bioavailability of nitric oxide might be a reduction of superoxide dismutase ("an enzyme that saves NO") and increase of homocysteine level in the serum due to reduced expression of cystathionine-γ-lyase and cystathionine-β-synthase<sup>[3]</sup>.

Activated hepatic stellate cells (HSCs) and its paracrine interaction with SEC play very important roles in the sinusoidal microcirculation in liver cirrhosis. In pathological conditions violation of the structure and function of HSCs accompanied by a loss of retinoids reserve and HSCs transformation into myofibroblasts. Activated HSCs start to perform the functions of pericytes. This is confirmed by the expression of its phenotypic markers such as α-smooth muscle actin, desmin, NG2, glial fibrillary acidic protein, as well as emergence or increase of receptors for growth factors, cytokines and endothelin, and a number of cell adhesion molecules on its surface<sup>[4]</sup>.

HSCs, located in the subendothelial Disse spaces between the SEC and hepatocytes, are contacted because of the long branching cytoplasmic processes with nerve endings, which contains various neurotransmitters such as substance P, vasoactive intestinal peptide, somatostatin, cholecystokinin, neurotensin, NO, calcitonin gene-related peptide, and neuropeptide Y. Some vasoactive substances are able to regulate the tone of HSCs. Substances for instance endothelin-1, substance P, angiotensin II, norepinephrine, prostaglandin F2, thromboxane A2, platelet activating factor (PAF) and thrombin can trigger HSC contractility. In contrast, vasoactive substances such as acetylcholine, vasoactive intestinal peptide, NO, carbon monoxide, hydrogen sulfide, prostaglandin E2, and adrenomedullin are known for the ability to relax HSCs<sup>[5]</sup>.

Myosin II is involved in the HSCs contraction, and Ca<sup>2+</sup>-dependent and Ca<sup>2+</sup>-independent pathways mediate this process. In a Ca<sup>2+</sup>-dependent pathway, myosin light chains are phosphorylated by activated myosin light chain kinase, whose activation is induced in response to an increase in intracellular Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>i</sub>) and subsequent formation of the Ca<sup>2+</sup>/calmodulin complex. In a Ca<sup>2+</sup>-independent pathway, Rho kinase and protein kinase C inhibit the activity of myosin light chain phosphatase, an enzyme that dephosphorylates phosphorylated myosin light chains and induces relaxation<sup>[6]</sup>.

Endothelin (ET) as a powerful endogenous vasoconstrictor modulates the tone of the HSCs. ET has three kinds of isoform, ET-1, 2, and 3, which are synthesized from ET by endothelin-converting enzymes. They interact with conjugated protein G receptors A and B types, which are well expressed in the HSCs. ET-1 is the most studied. The main site of its synthesis in liver

cirrhosis is activated HSCs. Stimulation of endothelin A receptors leads to its proliferation<sup>[7]</sup>. Angiotensin II has a similar effect. In liver cirrhosis, HSCs increase its synthesis because of increased expression of angiotensin-converting enzyme. HSCs constriction may also be caused by decreased NO production and/or bioavailability in cirrhotic liver<sup>[8]</sup>. In contrast, carbon monoxide overproduction by Kupffer cells causes a dilation of the sinusoids and a decrease of hepatic vascular resistance (HVR) because of paracrine impact on HSCs and SEC<sup>[9]</sup>.

Increased HSCs mobility and migration in liver cirrhosis are required to promote enhanced coverage of HSCs around an EC-lined sinusoid, contributing to the process of sinusoidal remodeling<sup>[10]</sup>. Changes in the structure of the HSCs membrane plays an important role in this process. Cellular locomotion requires dynamic but regulated actin remodeling to form membrane structures that facilitate cell extension. These include lamellipodia, which are membrane protrusions that form the leading edge toward directed cell migration, and filopodia, which are thin, actin filament-structured spikes emanating from the plasma membrane. Small guanosine triphosphatases from the Rho family including RhoA (Rho), Rac1 (Rac), and Cdc42 in turn, closely regulate formation of actin-based structures. Proved that if Rac contributes to HSC migration due to formation of filopodia, the Rho causes a resistant to the inhibitory action of NO and restores the chemotactic response to platelet-derived growth factor (PDGF) in the absence of a functional Rac<sup>[11]</sup>.

A key molecule responsible for proliferation, migration, mobility and recruitment of HSCs is PDGF, which is secreted by endothelial cells and binds to its cognate PDGF receptor (PDGFR- $\beta$ ) on pericytes, in particular due to an ephrin-B2/EphB4 signaling pathway<sup>[12]</sup>. Moreover, activation of the PDGFR- $\beta$  causes to stimulation of Raf-1 kinase, MEK kinase and extracellular-signal regulated kinase (ERK), which leads to the proliferation of the HSCs. Phosphatidylinositol 3-kinase activation is also necessary for both mitogenesis and chemotaxis induced by PDGF<sup>[13]</sup>. In addition, it is shown that the axonal guidance molecule neuropilin-1 contributes to the chemotactic response to PDGF too<sup>[14]</sup>.

Activated HSCs are a rich source of polypeptides, eicosanoids and various other molecules with paracrine, juxtacrine, and autocrine signalization or chemoattractant activity, which include: (1) polypeptides which enhance cells proliferation in an autocrine and paracrine manner: Hepatocyte growth factor (HGF), vascular endothelial growth factor (VEGF), endothelin-1, insulin-like growth factor, transforming growth factor (TGF)- $\alpha$ , epidermal growth factor (EGF) and acidic fibroblast growth factor (aFGF); (2) members of the TGF- $\beta$  family; (3) neurotrophins; and (4) hematopoietic growth factors such as erythropoietin<sup>[15]</sup>.

When the liver is damaged, activated HSC proliferate and migrate to areas of inflammation and

necrosis of hepatocytes, producing excessive amounts of extracellular matrix components. TGF- $\beta$ 1, PDGF, connective tissue growth factor and FGF regulate this process<sup>[16]</sup>.

Overall there are three general sources of fibrogenic cells in the liver: (1) endogenous (resident) fibroblast or myofibroblast-like cells, mainly represented by HSCs, but also by portal fibroblast, vascular smooth muscle cells and pericytes; (2) the epithelial-mesenchymal transition that may occur in the liver as well as in other organs and lead to transdifferentiation of parenchymal cells; and (3) recruitment of fibrocytes from the bone marrow<sup>[17]</sup>.

## INTRAHEPATIC ANGIOGENESIS IN LIVER CIRRHOSIS

In 1983, Rappaport *et al.*<sup>[18]</sup> were among the first who had described the collateral microcirculation in cirrhotic liver. Nowadays, pathological angiogenesis well characterized in experimental liver fibrosis, as well as in patients with chronic viral and autoimmune liver diseases and nonalcoholic steatohepatitis<sup>[19]</sup>.

Angiogenesis is the complicated physiological process through which new blood vessels form from pre-existing vessels. It is accomplished by the activation of endothelial cells, expression in it proteases, destruction of the extracellular matrix, proliferation, migration of the endothelial cells and formation of high permeability primary vascular structures<sup>[20]</sup>.

### Molecular insights into the angiogenic process

The primary inducer of angiogenesis in physiological and pathological conditions is hypoxia. Cells respond to hypoxic stress through multiple mechanisms, including the stabilization of hypoxia-inducible factors (HIFs), which directly regulate the expression of angiogenic growth factors. The family of HIFs includes three  $\alpha$ -subunits, which are associated with a common  $\beta$ -subunit (HIF-1 $\beta$ ). HIF-1 $\alpha$  appears to be ubiquitously expressed, whereas HIF-2 $\alpha$  is detected in a more restricted set of cell types, including vascular endothelial cells, hepatocytes, type II pneumocytes, and macrophages. A third mammalian HIF- $\alpha$  subunit, HIF-3 $\alpha$ , has also been described, although its role in hypoxic responses is less well understood<sup>[21]</sup>.

NADPH oxidase is an important mediator of angiogenic signaling pathways. It was noted that the increased NADPH oxidase expression because of NADPH oxidase subunit p 47phox phosphorylation leads to an increase in the reactive oxygen species (ROS) levels, contributing to HIF-1 $\alpha$  induction, VEGF-receptors (VEGFR) activation and EGF-receptors transactivation<sup>[22]</sup>.

The important role of miRNA has been shown recently in the regulation of cellular response to hypoxia. In particular, Let-7 and miR-103/107 favor the VEGF induction by targeting argonaute 1 protein<sup>[23]</sup>.

The most studied angiogenic growth factors include

VEGF family consisting of five homologs: VEGF-A, B, C, D and placental growth factor (PlGF). VEGF stimulates both physiological and pathological angiogenesis. All members of this family are connected to different homologous receptors: VEGFR-1 (Flt-1), VEGFR-2 (KDR/Flk-1), VEGFR-3 (Flt-4), of which only the first and second responsible for angiogenic signals transmitting. Besides that, the binding of VEGF-A to VEGFR-2 and increasing vascular permeability through the nitric oxide are the mechanisms triggering angiogenesis and vasculogenesis.

PlGF, a homolog of VEGF binding VEGFR-1, enhances angiogenesis, but only in pathological conditions affecting, directly and indirectly, multiple cell types, including endothelial cells. In addition, it is assumed that PlGF, breaking the binding of VEGF with VEGFR-1, makes the binding of VEGF with VEGFR-2 more probable. Mass spectrometry studies showed that PlGF and VEGF each induce the phosphorylation of distinct tyrosine residues in VEGFR-1, further indicating that PlGF and VEGF transmit distinct angiogenic signals through VEGFR-1.

Different mechanisms are the basis of synergism between PlGF and VEGF. By activating VEGFR-1, PlGF induces an intermolecular cross talk between VEGFR-1 and VEGFR-2, which thereby is more response to VEGF. PlGF, as a subunit of PlGF/VEGF heterodimer, induces the formation of VEGFR-1/2 heterodimers, which transphosphorylate each other in an intramolecular reaction. By producing PlGF, endothelial cells are thus capable of enhancing their own responsiveness to VEGF but adjacent stromal or inflammatory cells may also release PlGF.

PlGF directly affects smooth muscle cells and fibroblasts, which express VEGFR-1, but may also indirectly influence its proliferation and migration through cytokine release from activated endothelial cells. Through these effects, PlGF recruits smooth muscle cells around nascent vessels, thereby stabilizing them into mature, durable and non-leaky vessels.

PlGF also mobilizes VEGFR-1 positive hematopoietic progenitor cells from the bone marrow and recruits, indirectly *via* upregulation of VEGF expression, VEGFR-2-positive endothelial progenitor cells to the ischemic tissue. PlGF is also chemoattractive for monocytes and macrophages, which express VEGFR-1<sup>[24]</sup>.

FGF family members are also able to stimulate angiogenesis. Cellular response to FGFs occurs through specific binding FGF-receptor (FGFR), which has internal tyrosine kinase activity. FGFR dimerization is a prerequisite for phosphorylation and activation of signaling molecules with the participation of heparin-binding proteins. This causes migration, proliferation, cell differentiation and destruction of extracellular matrix. It should be noted that while VEGF family members are involved mainly in the formation of the capillaries, FGFs primarily involved in arteriogenesis<sup>[25]</sup>.

Although the angiogenic effect of PDGF is not so expressed as in VEGF, PlGF and FGF, studies *in vivo*

have shown that it may induce the formation of blood vessels and regulate their tone<sup>[26]</sup>.

Tie-2 (Tek), an endothelial-specific receptor tyrosine kinase, and its ligands, the angiopoietins, have been identified as critical mediators of vascular development. Angiopoietin-1 induces endothelial cells migration, inhibits endothelial cells apoptosis and stimulates its formation, promoting stabilization of vessels. At the same time, NADPH oxidase is involved in the ang-1-mediated activation of Akt and mitogen-activated protein kinase (p42/p44 MAPK, or ERK2 and ERK1) and subsequent modulation of endothelial cell migration and angiogenesis<sup>[27]</sup>. In contrast, angiopoietin-2 causes vascular destabilization by shifting the endothelial cells from the stable state to the proliferative phenotype. However, it may also stimulate angiogenesis in the presence of VEGF<sup>[28]</sup>.

Integrin  $\alpha V\beta 3$  and  $\alpha V\beta 5$  are adhesion receptors promoting angiogenesis by mediating migration and proliferation of endothelial cells and the formation of new blood vessels<sup>[29]</sup>.

Endothelial-specific adhesion molecule vascular endothelial cadherin contributes to cell-cell junctions during neovascularization and controls the passage of molecules through the endothelial lining<sup>[30]</sup>.

Thrombospondin-1 - one of the five known thrombospondins - is an adhesive protein that regulates the interaction of cells with each other and with the extracellular matrix. Its expression increases with the progression of liver cirrhosis and strongly correlated with the severity of fibrosis and angiogenesis. However, the precise role of thrombospondin-1 is not defined in this process. It may function as a promoter or inhibitor of angiogenesis that may depend on its concentration, the type of domain being activated and the type of receptors present on endothelial cells<sup>[31]</sup>.

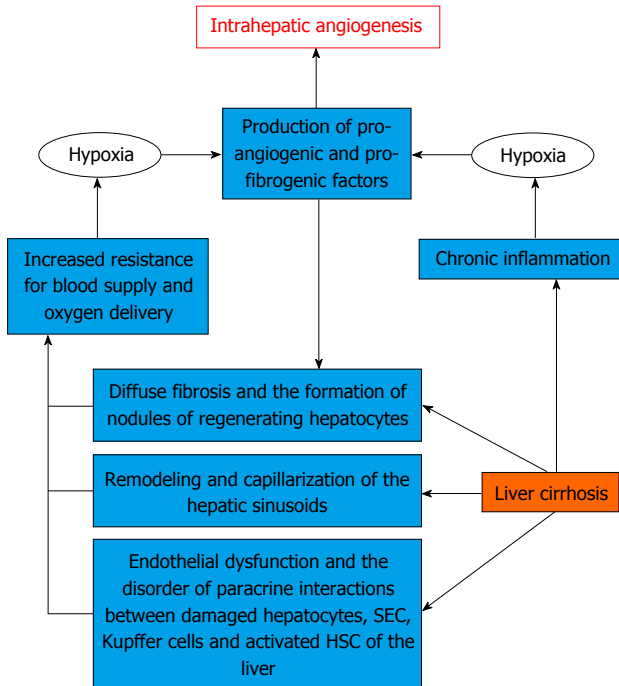

Angiostatin - a fragment of plasminogen, and endostatin - a fragment of the C-terminal part of the collagen XVIII  $\alpha 1$ -chain, inhibits the migration of human endothelial cells stimulated with FGF and VEGF and do not affect intracellular signaling pathways stimulated by FGF and VEGF<sup>[32]</sup>.

Toll-like receptor 4, which recognizes bacterial lipopolysaccharide, is expressed by SECs involved in fibrosis-associated angiogenesis in cirrhotic liver. These properties are related through the cytosolic adapter protein MyD88, which is involved in the production of extracellular protease regulating the invasive ability of SECs<sup>[33]</sup>.

Hepatic apelin system (apelin/APJ-receptor) - the connecting link between chronic inflammation and subsequent fibrogenic and angiogenic processes in liver cirrhosis. On the one hand, hypoxia and inflammation initiate expression of APJ, on the other profibrogenic activation of APJ mediates the induction of profibrogenic genes, HSCs proliferation and secretion of pro-angiogenic factors<sup>[34]</sup>.

Aquaporin-1 is an integral membrane channel pro-

**Figure 1** Two main ways of intrahepatic angiogenesis in liver cirrhosis. SEC: Sinusoidal endothelial cells; HSC: Hepatic stellate cell.

tein, overexpressed in cirrhosis, that promotes angiogenesis by enhancing endothelial invasion<sup>[35]</sup>.

It is known that chemokines from CXC family are involved in angiogenesis. ELR-positive chemokines stimulate this process, and ELR-negative suppress it<sup>[36]</sup>.

Neuropilin-1 and neuropilin-2 are transmembrane glycoproteins with large extracellular domains that interact with both class 3 semaphorins, VEGF and the classical receptors for VEGF, VEGFR-1 and -2, mediating signal transduction. Neuropilin-1 expressed mainly by arterial endothelium, whereas neuropilin-2 is only expressed by venous and lymphatic endothelium. Both neuropilins are commonly over-expressed in regions of physiological and pathological angiogenesis, but the definitive role of neuropilins in angiogenic processes are not fully characterized<sup>[37]</sup>.

### Mechanisms of intrahepatic angiogenesis in liver cirrhosis

Hepatic angiogenesis may substantially differ from homologous processes in other organs or tissue on the basis of: (1) the rather unique phenotypic profile and functional role of activated HSCs and of other liver myofibroblasts; (2) the presence of two different microvascular structures described (*i.e.*, sinusoids lined by fenestrated endothelium vs large vessels lined by a continuous one); and (3) the existence of ANGPTL3, a liver-specific angiogenic factor.

There are two main ways of forming new blood vessels in liver cirrhosis<sup>[38]</sup> (Figure 1). One of them is associated with increased expression of pro-angiogenic growth factors, cytokines and matrix metalloproteinases

on the background of chronic inflammation<sup>[39]</sup>. Proinflammatory mediators produced by Kupffer cells, mast cells and leukocytes may produce angiogenic response due to induction and increased transcriptional activity of HIF-1 $\alpha$ <sup>[40]</sup>.

It is believed that macrophages in the normal state are not directly involved in angiogenesis. In contrast, activated Kupffer cells contribute to the formation of new blood vessels through the production of cytokines, ROS and PAF in liver cirrhosis<sup>[41]</sup>.

Kupffer cells also produce tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), which induces the migration of cells and regulates apoptosis and angiogenesis<sup>[42]</sup>. The increase of ROS in the liver stimulates angiogenesis due to enhanced expression of TNF- $\alpha$ , NO, HIF-1 and VEGF<sup>[43]</sup>. PAF promotes the development of VEGF by the activation of nuclear transcription factor nuclear factor  $\kappa$ B (NF- $\kappa$ B)<sup>[44]</sup>. Mast cells involved in the formation of new blood vessels through the production of heparin, histamine, tryptase, cytokines (TGF- $\beta$ 1, TNF- $\alpha$ , interleukins) and VEGF. They can also increase the number of SECs *in vitro*<sup>[45]</sup>. Soluble mediators, in particular, pro-inflammatory cytokines, growth factors, proteases, and products of oxidative stress regulate increased expression of chemokines in chronic inflammation of the liver. Leukocytes can thereby penetrate into the liver tissue where they produce angiogenic factors such as VEGF, PlGF, PDGF, FGF, TGF- $\beta$ 1, EGF, angiopoietin-2 and different interleukins<sup>[46]</sup>.

On the one hand, hypoxia, caused by HIF-1 $\alpha$  stimulation, activates the HSCs and leads to the production of various angiogenic and fibrogenic factors (PlGF, VEGF, NO, HGF, PDGF)<sup>[47]</sup>, promoting angiogenesis and progression of hepatic fibrosis<sup>[48]</sup>. On the other hand, diffuse fibrosis, regenerative liver nodules and forming of sinusoidal capillarization cause an increase of HVR and impair the oxygen supply to the liver cells<sup>[49]</sup>. Accumulation of HIFs, in particular, HIF-1 $\alpha$ , increases the VEGF, angiopoietin-1 and their receptors expression on activated HSCs. This leads to involvement and stimulation of SECs, stabilizing the newly formed vessels and providing them with strength<sup>[50]</sup>. In turn, SECs generate PDGF and TGF- $\beta$ , helping to attract and migration of HSCs. This process includes ROS-mediated activation of ERK and c-Jun-NH2-terminal kinase (JNK) followed by a delayed- and HIF-1 $\alpha$ -dependent up-regulation and release of VEGF<sup>[51]</sup>.

Respectively there are two different phases of an angiogenic process occurring in the liver cirrhosis. Initially, the formation of blood vessels occurs in developing incomplete septa in which concomitant expression of VEGF, Flk-1, and Tie-2 is restricted by HSCs. In a later phase, angiogenesis occurs in large bridging septa and the expression of this proangiogenic panel is limited to endothelial cells and aims to stabilize the newly formed blood vessels<sup>[52]</sup>. Some of them occur mainly along areas of active inflammation and fibrous septa, probably favors inflammation, tissue repair, and gives rise to intrahepatic shunts. Some of them probably needed

for compensation of insufficient intrahepatic blood flow. Other forms intrahepatic shunts bypassing sinusoids and draining blood from the portal to the central venule. Although they perform the decompression role, they can lead to liver dysfunction due to declining oxygen delivery and nutrients to the liver tissues and limiting the free exchange between hepatocytes and sinusoids<sup>[53]</sup>.

During last years it has been found that endothelial progenitor cells produced by stem cells of the bone marrow are capable of causing *in situ* neovascularization in both physiological and pathological conditions (post-natal vasculogenesis). In particular, they may play an important paracrine role in liver angiogenesis by stimulating resident SECs through as factors as PDGF and VEGF in liver cirrhosis<sup>[54]</sup>. However, their angiogenic ability is significantly reduced in patients in this category, especially with severe hepatic dysfunction. Perhaps this is because chronic inflammation stimulates the release of angiogenic factors by resident HSCs and SECs, and inhibits the endothelial progenitor cells mobilization into the bloodstream<sup>[55]</sup>.

## CONCLUSION

Endothelial dysfunction and impaired paracrine interaction between activated HSCs and SECs, as well as sinusoidal remodeling and capillarization play an important role in improving the HVR to portal blood flow, adding structural changes associated with diffuse fibrosis and regenerative nodules in liver cirrhosis. The development of intrahepatic angiogenesis can be regarded as a compensatory mechanism that is aimed at decompression of the portal system. However, the newly formed vessels carrying blood to bypass the sinusoids are unable to provide oxygen and nutrients to the liver tissue which leads to progression of the disease. A comprehensive assessment of morphological and functional changes of hepatic vessels in the liver cirrhosis might allow to develop some new correction methods of its specific hemodynamic disorders. Moreover, it could help to enhance the effectiveness of therapeutic interventions aimed at the prevention of portal hypertension complications.

## Abstract

**AIM:** To characterize development of diet-induced nonalcoholic steatohepatitis (NASH) by performing liver biopsy in wild-type and genetically obese mice.

**METHODS:** Male wild-type C57BL/6J (C57) mice (DIO-NASH) and male *Lep<sup>ob</sup>/Lep<sup>ob</sup>* (*ob/ob*) mice (*ob/ob*-NASH) were maintained on a diet high in trans-fat (40%), fructose (22%) and cholesterol (2%) for 26 and 12 wk, respectively. A normal chow diet served as control in C57 mice (lean chow) and *ob/ob* mice (*ob/ob* chow). After the diet-induction period, mice were liver biopsied and a blinded histological assessment of steatosis and fibrosis was conducted. Mice were then stratified into groups counterbalanced for steatosis score and fibrosis stage and continued on diet and to receive daily PO dosing of vehicle for 8 wk. Global gene expression in liver tissue was assessed by RNA sequencing and bioinformatics. Metabolic parameters, plasma liver enzymes and lipids (total cholesterol, triglycerides) as well as hepatic lipids and collagen content were measured by biochemical analysis. Non-alcoholic fatty liver disease activity score (NAS) (steatosis/inflammation/ballooning

degeneration) and fibrosis were scored. Steatosis and fibrosis were also quantified using percent fractional area.

**RESULTS:** Diet-induction for 26 and 12 wk in DIO-NASH and *ob/ob*-NASH mice, respectively, elicited progressive metabolic perturbations characterized by increased adiposity, total cholesterol and elevated plasma liver enzymes. The diet also induced clear histological features of NASH including hepatosteatosis and fibrosis. Overall, the metabolic NASH phenotype was more pronounced in *ob/ob*-NASH *vs* DIO-NASH mice. During the eight week repeated vehicle dosing period, the metabolic phenotype was sustained in DIO-NASH and *ob/ob*-NASH mice in conjunction with hepatomegaly and increased hepatic lipids and collagen accumulation. Histopathological scoring demonstrated significantly increased NAS of DIO-NASH mice (0 *vs*  $4.7 \pm 0.4$ ,  $P < 0.001$  compared to lean chow) and *ob/ob*-NASH mice ( $2.4 \pm 0.3$  *vs*  $6.3 \pm 0.2$ ,  $P < 0.001$  compared to *ob/ob* chow), respectively. Furthermore, fibrosis stage was significantly elevated for DIO-NASH mice (0 *vs*  $1.2 \pm 0.2$ ,  $P < 0.05$  compared to lean chow) and *ob/ob* NASH ( $0.1 \pm 0.1$  *vs*  $3.0 \pm 0.2$ ,  $P < 0.001$  compared to *ob/ob* chow). Notably, fibrosis stage was significantly ( $P < 0.001$ ) increased in *ob/ob*-NASH mice, when compared to DIO-NASH mice.

**CONCLUSION:** These data introduce the obese diet-induced DIO-NASH and *ob/ob*-NASH mouse models with biopsy-confirmed individual disease staging as a preclinical platform for evaluation of novel NASH therapeutics.

**Key words:** Nonalcoholic steatohepatitis; Liver biopsy; Diet-induced obesity; Nonalcoholic fatty liver disease; Fibrosis

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** We characterize the development and progression of diet-induced nonalcoholic steatohepatitis (NASH) in a wild-type and a genetically obese mouse model. We confirm that a diet high in trans-fat, fructose and cholesterol, develops key histological hallmarks of NASH (steatosis, inflammation, ballooning degeneration) in conjunction with fibrosis. Concomitantly, marked alterations in NASH associated gene expression pathways can be evaluated by RNAseq analysis. In addition, we describe that performing a baseline liver biopsy enables individual disease staging for subsequent stratified randomization of animals into study groups. Finally, we show these models' utility for a chronic repeated dosing study to evaluate pharmacological intervention.

## INTRODUCTION

It is generally accepted that along with increasing rates of obesity, type 2 diabetes and metabolic syndrome, the incidence and prevalence of patients with nonalcoholic fatty liver disease (NAFLD) continues to rise<sup>[1-4]</sup>. NAFLD is considered the hepatic manifestation of the metabolic syndrome and covers a variety of pathologies ranging from simple hepatic steatosis (accumulation of triglycerides in hepatocytes) to nonalcoholic steatohepatitis (NASH), characterized by inflammation, cellular ballooning and fibrosis in varying degrees<sup>[1-3]</sup>. The pathogenesis of NASH is described by the "two-hit" hypothesis, the first hit being fat accumulation in hepatocytes, while the "second hit", *e.g.*, oxidative stress, apoptosis or mitochondrial dysfunction, causes development of inflammation and fibrosis<sup>[5]</sup>.

There are currently no pharmacological agents specifically approved for the treatment of NASH and disease management is consequently focused on the correction of underlying risk factors (*e.g.*, obesity, insulin resistance and dyslipidemia)<sup>[1,6]</sup>. A likely contributor to the absence of therapeutics is the paucity of preclinical models resembling human NAFLD/NASH<sup>[6]</sup>. Historically, several animal models have been developed to represent the pathophysiology, morphological findings, biochemical changes, and clinical features of human NAFLD/NASH. These models are usually divided into two main categories: The diet-induced models and the genetically modified models (transgenic or knockout models)<sup>[1]</sup>. Some diet-induced models are based on *ad libitum* feeding of diets enriched with various combinations of fat, cholesterol and sugars (*e.g.*, fructose) thereby developing a metabolic phenotype reflected by adiposity and hepatosteatosis, albeit only presenting mild characteristics of NASH and typically lack of liver fibrosis<sup>[7,8]</sup>. Other dietary models involve feeding nutrient-deficient diets such as the methionine- and choline-deficient diet (MCD). Methionine and choline deficiency impairs liver  $\beta$ -oxidation and the production of very-low density lipoproteins (VLDL) hereby generating a "second hit"<sup>[1]</sup>, eliciting a more severe fibrotic NASH phenotype within hepatic tissue<sup>[8,9]</sup>. However, these models fail to recapitulate a clinically relevant overall metabolic phenotype as MCD animals demonstrate pronounced weight loss and perturbed energy- and glucose homeostasis<sup>[10]</sup>. Recently, a novel wild-type diet-induced obese fibrotic NASH mouse model was introduced by Trevaskis *et al*<sup>[11]</sup>, based on the ALIOS diet model<sup>[12]</sup>. This model, generated by feeding an *ad libitum* diet high in trans-fat, fructose and cholesterol to wild-type C57Bl/6J mice [the Amylin liver NASH model (AMLN)], displayed key hallmarks of clinical NASH<sup>[11]</sup>. The AMLN mouse model was further optimized by demonstrating a liver biopsy technique for

assessing individual steatosis, inflammation, ballooning degeneration and fibrosis staging, prior to a putative study intervention<sup>[6]</sup>. Not only does the baseline liver biopsy reduce biological variability by excluding mice that fail to develop NASH prior to initiating therapy, but it also allows for within-subject comparisons over time, thereby increasing statistical power<sup>[6]</sup>.

For the genetically modified NASH models, several studies have implicated a role of individual genes involved in the development of NASH using deletion or overexpression models<sup>[7,9]</sup>. For example, mice that overexpress the transcription factor sterol regulatory element-binding proteins (SREBPs), a feedback regulatory system controlling intracellular levels of cholesterol and free fatty acids develop a hepatic phenotype resembling NASH. However, like MCD-fed mice, SREBP overexpression does not induce a metabolic profile consistent with obesity and insulin resistance<sup>[13]</sup>. In contrast, impairment of leptin signaling (e.g., *db/db* mice) results in obesity, insulin resistance and diabetes<sup>[14]</sup>. Leptin-deficient mice (*Lep<sup>ob</sup>/Lep<sup>ob</sup>*) are predisposed to develop steatohepatitis, however, when maintained on regular rodent chow they do not develop fibrosis<sup>[11]</sup>. In fact, it was previously postulated that *Lep<sup>ob</sup>/Lep<sup>ob</sup>* mice are incapable of developing hepatic fibrosis<sup>[9]</sup>. This notion was dispelled by the observation that *Lep<sup>ob</sup>/Lep<sup>ob</sup>* mice maintained on the AMLN diet for at least 12 wk do in fact develop the key hallmarks of NASH, including fibrosis<sup>[11]</sup>.

The present study assessed key NASH diagnostic characteristics (e.g., steatosis score, inflammation, ballooning degeneration and fibrosis stage), metabolic endpoints and gene expression signatures in wild-type C57Bl/6J and *Lep<sup>ob</sup>/Lep<sup>ob</sup>* mice, fed the AMLN diet for a total of 34 and 20 wk, respectively, including an eight-week repeated vehicle dosing period. In addition, we demonstrate how a baseline liver biopsy allows for individual disease staging and for stratified randomization into experimental groups with reduced biological variability and for a clear cut analysis of individual response to pharmacological intervention.

## MATERIALS AND METHODS

### Animals and experimental set-up

All animal experiments were conformed to international accepted principles for the care and use of laboratory animals and were covered by a personal license for Jacob Jelsing (2013-15-2934-00784) issued by the Danish Committee for animal research.

Male C57Bl/6J (C57) and *Lep<sup>ob</sup>/Lep<sup>ob</sup>* (*ob/ob*) mice at 5 wk of age were obtained from JanVier (JanVier labs, France), and group housed 5 animals pr. cage under a 12/12 h dark-light cycle. Room temperature was controlled to 22 °C ± 1 °C, with 50% ± 10% humidity. Animals had *ad libitum* access to diet high in fat (40%, of these 18% trans-fat), 40% carbohydrates (20% fructose) and 2% cholesterol (D09100301, Research Diet, United States) previously described as the AMLN diet<sup>[6]</sup>, or regular rodent chow (Altromin 1324, Brogaar-

den, Denmark), and tap water. Both strains had *ad libitum* access to either the AMLN diet (DIO-NASH, *n* = 110; *ob/ob* NASH, *n* = 40) or chow (lean chow, *n* = 10; *ob/ob* chow, *n* = 10). After 26 (DIO-NASH) or 12 wk (*ob/ob*-NASH) a liver biopsy was performed for histological assessment of individual fibrosis and steatosis staging at baseline. Following biopsy procedure animals were single housed. An 8-wk vehicle intervention period was conducted in a representative subset of DIO-NASH and *ob/ob*-NASH mice, and their respective chow controls. Vehicle dosing consisted of once daily per oral dose of carboxymethyl cellulose (C57 and *ob/ob*) and subcutaneous injection with PBS (C57). The rationale was to mimic repeated dosing administration and animal handling in combination with AMLN diet-maintenance. After a total of 34 and 20 wk on AMLN diet for DIO-NASH and *ob/ob*-NASH mice, respectively, animals were euthanized and liver tissue collected for histological and biochemical analysis. Total animal numbers for each experiment is indicated in the figures and table.

### Baseline liver biopsy after diet-induction

Mice were pretreated with enrofloxacin (Bayer, Germany) (5 mg/mL-1 mL/kg) one day before being biopsied. Prior to biopsy, mice were anesthetized with isoflurane (2%-3%) in 100% oxygen. A small abdominal incision in the midline was made and the left lateral lobe of the liver was exposed. A cone shaped wedge of liver tissue (50-100 mg) was excised from the distal portion of the lobe fixed in 4% paraformaldehyde for histology. The biopsy procedure previously described by Clapper *et al*<sup>[6]</sup> 2013 was refined using electrocoagulation of the cut surface of the liver by means of bipolar coagulation using ERBE VIO 100C electrosurgical unit (ERBE, United States). The liver was returned to the abdominal cavity, abdominal wall was sutured and skin stapled. Carprofen (Pfizer, United States) (5 mg/mL-0.01 mL/10 g) and enrofloxacin (5 mg/mL-1 mL/kg) were administered intraperitoneal at the time of surgery and at post-operation day one and two, to control postoperative pain relief and infection, respectively.

### Hepatic gene expression changes

Gene expression changes were measured in a representative subset of DIO-NASH mice and *ob/ob*-NASH. Liver tissue was harvested from the left lateral lobe and snap frozen in liquid nitrogen. Tissue sections (about 50 mg) were homogenized in lysis buffer containing protease inhibitors and used for RNA extraction using NucleoSpin Plus RNA columns (Macherey-Nagel). The quantity of the RNA was analyzed using a Nano Drop 2000 spectrophotometer (Thermo Scientific, United States). RNAseq libraries were prepared with the KAPA poly-A kit (Kapa Biosystems, United States) and sequenced on the NextSeq 500 (Illumina, United States) (single-end, 75 bp reads). Reads were aligned to the GRCh38 Ensembl Mus musculus genome using STAR v.2.4.0<sup>[15]</sup> and feature counts were obtained using HTseq v.0.6.1<sup>[16]</sup>, both with default parameters. Differential

expression analysis was performed with edgeR<sup>[17]</sup> and genes with a  $P \leq 0.05$  after correction for multiple testing using the Benjamini and Hochberg method was regarded as significantly regulated. Pathway analysis of WikiPathways<sup>[18]</sup> was performed using the statistics module in PathVisio<sup>[19]</sup>.

### **Body weight and body composition analysis**

Body weight was intermittently monitored during the diet-induction period and once daily during the intervention period. Whole-body fat mass was analyzed at baseline (week -1) and week 8 of the intervention period by non-invasive EchoMRI scanning using EchoMRI-900 (EchoMRI, United States). During the scanning procedure the mice were placed in a restrainer for 90–120 s.

### **Plasma biochemistry analysis**

After diet-induction, a baseline blood sample was collected from the submandibular vein in non-fasted conscious animals and blood sampling was repeated following the intervention period. Plasma levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), triglycerides (TG) and total cholesterol (TC) were measured using the auto analyzer Cobas C-111 (Roche Diagnostics, Germany). Plasma levels of insulin were measured in duplicates using an AlphaLisa kit (Perkin Elmer), according to the manufacturer's instructions.

### **Oral glucose tolerance test**

An oral glucose tolerance test (OGTT) was performed in week 4 of the intervention period. Animals were fasted for 4 h prior to OGTT. At  $t = 0$  an oral glucose load [2 g/kg glucose 200 mg/mL, (Fresenius Kabi, Sweden)] was administered *via* a gastrically placed tube. Blood samples for measuring blood glucose (BG) were collected from the tail vein at  $t = 0, 15, 30, 60$  and 120 min. Glucose area under the curve (AUC) calculations were determined as total AUC from the sampling period of 0 to 120 min.

### **Whole blood glucose analysis**

Blood samples for BG analysis were collected into 10  $\mu$ L heparinized glass capillary tubes and immediately suspended in buffer [0.5 mL of glucose/lactate system solution (EKF-diagnostics, Germany)] and analyzed for glucose using a BIOSEN c-Line glucose meter (EKF-diagnostics, Germany) according to the manufacturer's instructions.

### **Terminal hepatic hydroxyproline content**

Formalin fixed (50 mg) liver tissue was homogenized in 500  $\mu$ L water. Five hundred microliter concentrated HCl was added to the samples and hydrolyzed at 120 °C for three hours. Supernatants were transferred to a 96 well plate and wells were allowed to evaporate dry overnight. Total collagen content in the liver was measured by colorimetric determination of hydroxyproline residues

by acid hydrolysis of collagen (Cat no. MAK008, Sigma Aldrich).

### **Terminal hepatic triglyceride and total cholesterol content**

A liver piece (about 100 mg) was collected in FastPrep tubes and snap-frozen in liquid nitrogen. One milliliter 5% NH<sub>4</sub>OH/ddH<sub>2</sub>O solution (ab142227, Abcam) was added to the FastPrep tube. The tubes were homogenized in a FastPrep homogenizer and shaken for 2  $\times$  60 s. After homogenization the samples were slowly heated to 80 °C–100 °C in a heating block for three minutes. Samples were allowed to return to room temperature prior to a second round of heating. Next, samples were centrifuged for two minutes at top speed using a microcentrifuge to remove any insoluble material. TG and TC content in liver homogenates are measured in single determinations using auto analyzer Cobas C-111 with commercial kit (Roche Diagnostics, Germany) according to manufacturer's instructions.

### **Histology assessment and digital image analysis**

Baseline liver biopsy and terminal samples were collected from the left lateral lobe (about 100 mg) and fixed overnight in 4% paraformaldehyde. Liver tissue was paraffin embedded and sectioned (3  $\mu$ m thickness). To assess hepatic morphology and fibrosis, sections were stained with Hematoxylin and Eosin and Sirius Red, respectively, followed by analysis with Visiormorph software (Visiopharm, Denmark). Histological assessment and scoring was performed by a pathologist blinded to the study. NAFLD activity score (NAS) (steatosis/inflammation/ballooning degeneration) and fibrosis stage were performed using the clinical criteria outlined by Kleiner *et al.*<sup>[20]</sup>.

### **Statistical analysis**

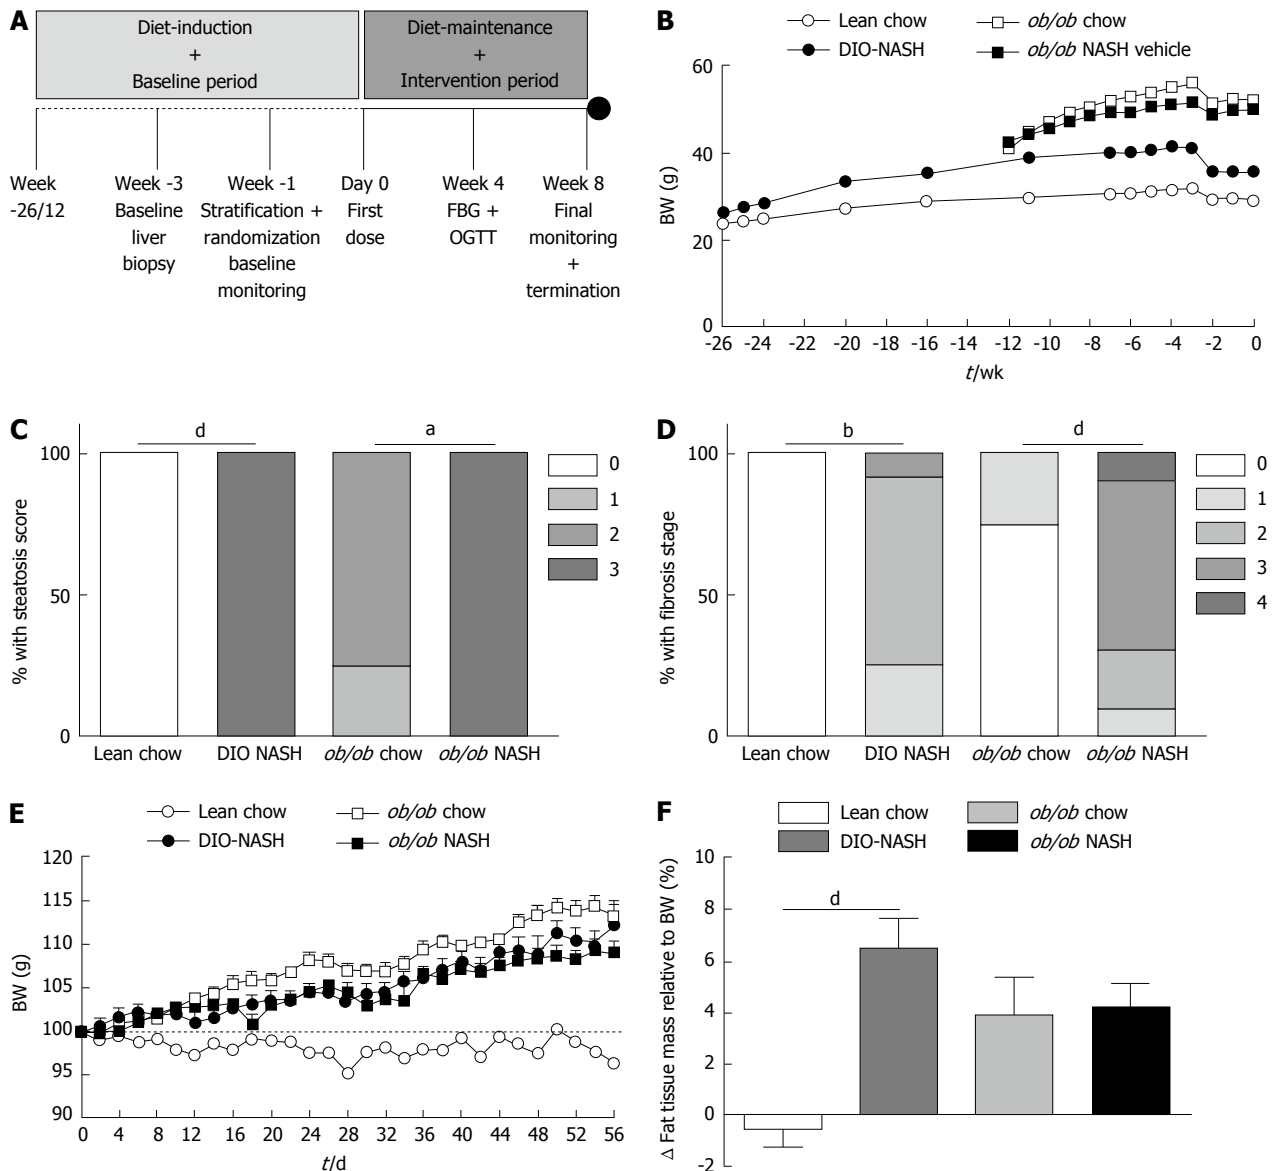

All data were analyzed using GraphPad Prism 5.0. The results are presented as mean  $\pm$  standard error of the mean. Statistical significance was evaluated using One-way analysis of variance with Turkey's multiple comparison test, and for histological analysis using Kruskal-Wallis test with Dunn's multiple comparison test.  $P < 0.05$  was considered statistical significant.

## **RESULTS**

### **Male C57 and ob/ob mice developed adiposity and elevated plasma metabolic parameters after AMLN diet-induction**

The overall study design is outlined in Figure 1A. Following a diet-induction period of 26 wk, C57 (DIO-NASH) mice demonstrated increased body weight (adiposity), when compared to lean chow animals. In the already obese *ob/ob* strain there was no additional effect on body weight noted in *ob/ob*-NASH mice relative to chow controls. Whereas all mice experienced slight weight loss following the biopsy, they returned

A: Study design of the DIO-NASH and *ob/ob* NASH mouse models; B: BW during diet-induction and baseline period (monitoring and biopsy-recovery); C and D: Liver biopsy-derived histopathological assessment of (C) steatosis score (0-3), and (D) fibrosis stage (0-4); E and F: Change in BW (E), and change in adiposity (F), during diet-maintenance and intervention period (repeated vehicle dosing). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>c</sup> $P < 0.001$ . The results are presented as mean  $\pm$  SEM. Lean chow ( $n = 9$ ), DIO-NASH ( $n = 12$ ), *ob/ob* chow ( $n = 8$ ), *ob/ob* NASH ( $n = 10$ ). NASH: Nonalcoholic steatohepatitis; BW: Body weight; OGTT: Oral glucose tolerance test; FBG: Fed blood glucose; SEM: Standard error of the mean.

to a weight stable state within one week (Figure 1B). After diet-induction, DIO-NASH and *ob/ob*-NASH mice demonstrated a metabolic NAFLD phenotype, as reflected by elevated levels of plasma total cholesterol (TC) and liver enzymes ALT and AST, when compared to respective chow fed animals. Overall, the *ob/ob*-NASH mice demonstrated an accelerated and more pronounced metabolic phenotype, when compared to DIO-NASH mice (Table 1).

**Male C57 and *ob/ob* mice demonstrated biopsy-proven hepatic steatosis and fibrosis after AMLN diet-induction**  
Histological assessments of biopsied liver tissue revealed that lean chow animals did not develop hepatic steatosis or fibrosis over the 26-wk diet-induction (Figure

1C and D). In contrast, DIO-NASH mice presented with high levels of steatosis (score 3) (Figure 1C) and fibrosis stage ranging from 1-3 (Figure 1D). The *ob/ob* chow phenotype displayed mild steatosis (score 1-2) and lack of or only mild fibrosis (stage 1) whereas all *ob/ob*-NASH mice displayed a steatosis score of 3 (Figure 1C) and a fibrosis stage ranging from 1-4 (Figure 1D).

#### Altered hepatic gene expression in male C57 and *ob/ob* mice after AMLN diet-induction

To characterize the effect of 26 wk diet-induction on global liver gene expression, the transcriptome of lean chow vs DIO-NASH mice were analyzed by RNAseq<sup>[21]</sup>. Principal component analysis identified a clear separation between the two groups along the first component,

indicating that the NASH diet markedly alters the overall gene expression profile (Figure 2A). We identified a total of 1378 differentially expressed genes, composed of 510 repressed and 868 induced genes (Figure 2B). To explore biological processes affected, sets of significantly altered signaling pathways were extracted (Figure 2C and D). Many of these pathways are consistent with the observed NASH phenotype including focal adhesion, toll-like receptor (TLR) signaling pathway, matrix metalloproteinases and inflammatory response pathway. Consistent with the identification of focal adhesion as the top affected pathways multiple collagen subtypes showed increased expression (Figure 2E).

Similar analyses were conducted on a subset of samples from *ob/ob*-NASH animals which confirmed the exaggerated expression levels of collagen types (Figure 2E). The pathway analysis also highlighted TLR signaling as one of the primary affected signaling processes, an observation supported by the increased expression of TLR4, which was recently demonstrated as an important pro-inflammatory mediator in the pathogenesis of NASH<sup>[22,23]</sup>. Notably, mRNA expression levels of a number of other TLR subtypes (TLR7, TLR8, TLR12 and TLR13) were upregulated to greater extent than TLR4 (Figure 2F). Furthermore, a large collection of pro-inflammatory factors ranging from chemokines, such as monocyte chemoattractant protein-1 (MCP-1), to chemokine receptors, such as C-C motif chemokine

receptor-2 (Ccr2) and macrophage markers (*i.e.*, CD68, CD86, F4-80 and MAC-2) (Figure 2G) were significantly induced. Finally, in line with observed hepatosteatosis, expression levels of genes involved in triglyceride biosynthesis were significantly increased in C57 and *ob/ob* animals exposed to the AMLN diet. Conversely, cholesterol biosynthesis expression was significantly decreased in the DIO-NASH and *ob/ob*-NASH mice (Figure 2H).

#### **Male C57 and *ob/ob* mice sustained adiposity and elevated plasma metabolic parameters after AMLN diet-maintenance and repeated dosing intervention period**

During the intervention period with diet-maintenance and repeated vehicle dosing for a total of 8 wk, DIO-NASH mice progressively gained body weight (adiposity), when compared to lean chow animals. Leptin-deficient mice also gained fat mass during the 8-wk intervention period (Figure 1E and F). Fat gain was somewhat less in the *ob/ob*-NASH mice, however, these mice began the study with a higher % adiposity (37%, *n* = 10) relative to DIO-NASH mice (14%, *n* = 12). At study end (termination), DIO-NASH and *ob/ob*-NASH animals sustained the elevated levels of plasma liver enzymes and hypercholesterolemia, when compared to respective chow-fed mice (Table 1). In contrast, terminal plasma TG levels were unchanged in DIO-NASH mice, and were significantly decreased for *ob/ob*-NASH animals,

**Figure 2 Gene expression analysis by RNAsequencing and bioinformatics.** A: Principal component analysis of the 500 most variable genes, [principal component (PC)]; B: Hierarchical clustering of the differentially expressed genes, bars on the right indicate the induced and repressed genes; C: Pathways enriched for the induced (up-regulated) genes, filtered for  $P < 0.01$  and  $n > 4$ ; D: Same as (C) for the down-regulated genes; E-H: Expression levels of selected differentially expressed genes shown as mean  $\pm$  SEM. Lean chow ( $n = 5$ ), DIO-NASH ( $n = 5$ ), *ob/ob* NASH ( $n = 5$ ). NASH: Nonalcoholic steatohepatitis; BW: Body weight; TLR: Toll-like receptor; IFN: Interferon; IL1: Interleukine 1; MCP-1: Monocyte chemoattractant protein-1; GPCRs: G protein-coupled receptors; IFNG: Interferon gamma; RPKM: Reads per kilobase of transcript per million mapped reads; SEM: Standard error of the mean.

when compared to chow (Table 1). Collectively, terminal plasma levels of ALT, AST and TC were markedly elevated in *ob/ob*-NASH, when compared to DIO-NASH mice (Table 1).

An OGTT was performed four weeks into the intervention period. Fasting blood glucose and OGTT AUC for blood glucose were unchanged in DIO-NASH and *ob/ob*-NASH mice, as compared to respective chow fed animals (Table 1). Diet effects on glycemic status are supported by the elevation in plasma insulin levels of about 3-fold (NS) in DIO-NASH when compared to lean chow, whereas *ob/ob*-NASH showed a surprisingly decrease in plasma insulin levels at study end when

compared to *ob/ob* chow animals (Table 1).

#### Male C57 and *ob/ob* mice demonstrated hepatomegaly with increased hepatic lipids and collagen content after AMLN diet-maintenance and repeated dosing intervention period

At study end, terminal liver weight was significantly increased in DIO-NASH and *ob/ob*-NASH mice, when compared to respective chow animals (Figure 3A). Additionally, liver weight of *ob/ob*-NASH was significantly higher than liver weight of DIO-NASH animals (Figure 3A). Both strains demonstrated increased deposition of liver TG and TC when compared to respective chow mice

**Figure 3 Liver weight and hepatic lipid and collagen content at study end.** Liver weight at termination (A), hepatic triglyceride content (B), hepatic total cholesterol content (C), and hepatic hydroxyproline (collagen) content (D) at study end. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>d</sup> $P < 0.001$ . The results are presented as mean  $\pm$  SEM. Lean chow ( $n = 9$ ), DIO-NASH ( $n = 12$ ), *ob/ob* chow ( $n = 8$ ), *ob/ob* NASH ( $n = 10$ ). NASH: Nonalcoholic steatohepatitis; BW: Body weight; SEM: Standard error of the mean.

(Figure 3B and C). Furthermore, liver TG and TC content were significantly increased in *ob/ob*-NASH mice, when compared to DIO-NASH animals (Figure 3B and C). Notably, DIO-NASH and *ob/ob*-NASH mice showed elevated levels of liver hydroxyproline (collagen) content, when compared to chow controls (Figure 3D). Overall, levels of liver hydroxyproline content were higher in *ob/ob*-NASH animals relative to DIO-NASH mice (Figure 3D).

#### **Histopathological scoring of liver steatosis, inflammation and ballooning degeneration after AMLN diet-maintenance and repeated dosing intervention period in male C57 and *ob/ob* mice**

Blinded histological assessment of NAS was performed on hematoxylin and eosin stained terminal hepatic tissue (Table 1). No evidence of steatosis, inflammation and ballooning degeneration was observed in lean chow controls (Figure 4A). In *ob/ob* chow mice steatosis was categorized as pronounced microvesicular with mild microvesicular steatosis (Figure 4B). Despite increased steatosis when maintained on chow diet, neither ballooning degeneration nor inflammation was observed in *ob/ob* chow animals (Figure 4B). In contrast, DIO-NASH mice developed micro- and macro-vesicular steatosis, with inflammation and ballooning degeneration (Figure 4C). Similarly, *ob/ob*-NASH mice developed micro- and macro-vesicular steatosis, and more pronounced inflammation and ballooning degeneration (Figure 4D). Thus, the NASH phenotypes of both strains of mice were clearly reflected in significantly increased NAS,

when compared to respective chow animals (Figure 4E). Finally, image analysis confirmed hepatic steatosis in DIO-NASH and *ob/ob*-NASH mice (Figure 4F).

#### **Histopathological scoring of liver fibrosis after AMLN diet-maintenance and repeated dosing intervention period in male C57 and *ob/ob* mice**

Fibrosis stage was assessed by blinded histological evaluation using Sirius red staining of terminal liver tissue (Table 1). Hepatic fibrosis was not observed in lean chow or *ob/ob* chow mice (Figure 5A and B). In contrast, fibrosis was observed in DIO-NASH mice (Figure 5C) and to a greater extent in *ob/ob*-NASH animals who progressed to bridging fibrosis (Figure 5D). Fibrosis was most evident at tissue margins, but also penetrated into the tissue (Figure 5A-D). The fibrotic phenotypes of the DIO-NASH and *ob/ob*-NASH mice were mirrored by an increase in fibrosis stage compared to respective chow animals (Figure 5E). Increases in fibrosis stage were reflected by our image analyses showing an increase in % fractional area of Sirius Red (Figure 5F). Notably, the *ob/ob*-NASH animals were more fibrotic than DIO-NASH mice (Figure 5E and F).

## **DISCUSSION**

In the present study two obese mouse models of diet-induced NASH were evaluated; the C57 DIO-NASH and the *ob/ob*-NASH. We confirm that a diet high in trans-fat, fructose and cholesterol produces a metabolic NASH phenotype with elevated plasma liver enzymes,

**Figure 4** Histological assessment of non-alcoholic fatty liver disease activity score and liver lipid at study end. hepatomegaly and recapitulates multiple clinical features including key hallmarks of NASH (steatosis, inflammation, ballooning degeneration and fibrosis). These changes were associated with marked alterations in associated gene expression pathways implicated in NASH and development of fibrosis. The mouse models are also suitable for pharmacological intervention studies, with a paired baseline liver biopsy procedure enabling individual disease stage before a repeated dosing period as is customary in NASH preclinical studies. Whereas all mice experienced slight weight loss following the biopsy, they returned to a weight stable state within one week moreover DIO-NASH and *ob/ob*-NASH sustained hepatomegaly, hepatic steatosis, inflammation, ballooning degeneration and fibrosis following repeated dosing intervention for a total of 8 wk.

DIO-NASH and *ob/ob*-NASH mice developed key hallmarks of fibrotic NASH including marked hepatosteatosis with evident inflammation and ballooning degeneration, as assessed by a clinical-derived histological NAS and fibrosis stage classification system developed by Kleiner *et al.*<sup>[20]</sup>. This is in line with recent findings by Clapper *et al.*<sup>[6]</sup> and Honda *et al.*<sup>[24]</sup> in C57 AMLN mice, thus supporting the wild-type C57 DIO-NASH mouse as a suitable preclinical model for diet-induced obesity and NASH. In addition, the genetically obese *ob/ob* mouse model was also recently demonstrated to exhibit fibrotic NASH when fed AMLN diet<sup>[11,25]</sup>. In the leptin-deficient model superimposing the NASH diet high in trans-fat, fructose and cholesterol represents a “second hit” in development of preclinical NASH. The present study demonstrates that the NAS

**Figure 5** Histological assessment of fibrosis stage and liver collagen at study end. Liver fibrosis stage performed by a blinded pathologist at study end (E), and quantitatively image analysis of collagen (% area) from sirius red staining using visiomorph software (F). Fibrous band formation indicated by black arrows. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>d</sup> $P < 0.001$ . The results are presented as mean  $\pm$  SEM. Lean chow ( $n = 9$ ), DIO-NASH ( $n = 12$ ), *ob/ob* chow ( $n = 8$ ), *ob/ob* NASH ( $n = 10$ ). NASH: Nonalcoholic steatohepatitis; SEM: Standard error of the mean.

and fibrosis stage can also be integrated in analyses of the *ob/ob*-NASH mouse - and in conjunction with the excessive accumulation of hepatic lipids and collagen content - introduces an accelerated and aggressive diet-induced NASH phenotype relative to the C57 DIO-NASH model.

In accordance with histological observations of hepatic inflammation, mRNA analyses revealed within inflammatory pathways that toll-like receptors and downstream pro-inflammatory effectors (e.g., IL1b, MCP-1) were markedly upregulated after the diet-induction period in DIO-NASH and *ob/ob*-NASH. In line with previous findings in diet-induced NASH mouse models<sup>[26]</sup>, we observed increased expression of TLR4, a key receptor in fibrogenic development as demonstrated in high-fat diet-induced TLR4 knockout<sup>[22]</sup>, and bile duct

ligation models<sup>[23]</sup>. In addition, TLR4 KO in *ob/ob* mice was protective against NASH development as evinced by reduced NAS compared to regular *ob/ob* mice<sup>[27]</sup>. Interestingly, we observed higher expression levels of four additional TLRs: TLR7, TLR8, TLR12 and TLR13, which could be of relevance in future elucidation of the pathogenesis of NASH and for pharmacological intervention.

CCR2 mRNA levels were also increased in *ob/ob*-NASH mice. CCR2 has been implicated in the development of liver fibrosis, with *Ccr2*<sup>-/-</sup> mice showing reduced fibrosis following bile duct ligation or CCl<sub>4</sub> exposure<sup>[28]</sup>. CCR2 is a functional receptor for MCP-1, and is involved in the migration of macrophages during obesity<sup>[29]</sup>. Together, the impact on TLR signaling and macrophage abundance indicates an accelerated inflammatory NASH

phenotype in the *ob/ob*-genotype. Furthermore, markers of macrophage infiltration CD68 and F4-80, were up-regulated in DIO-NASH and to a larger extent in *ob/ob*-NASH mice, hereby corroborating the histological finding of increased inflammation in the two models.

In accordance with histological observations of hepatic fibrosis, our mRNA analyses also revealed increased expression of fibrillary collagens. Of particular interest is the increased diet- and strain-induced regulation of type I, III and type IV collagen, as these are known to be abundantly increased in liver fibrosis<sup>[30,31]</sup>. Interestingly, we also report altered expression of type I collagen  $\alpha 1$  and  $\alpha 2$  chain, type III collagen  $\alpha 1$ , as well as type XIV collagen  $\alpha 1$ , which could be of relevance in development/progression from NASH to fibrosis and future design of anti-fibrotic agents.

Pathway analyses also shed light on the transcriptional regulation of the main enzymes involved in triglyceride and cholesterol biosynthesis induced by the AMLN diet in DIO-NASH and *ob/ob*-NASH mice. Expression of these enzymes are all regulated by SREBP transcription factors, with SREBP1 regulating triglyceride synthesis and SREBP2 regulating cholesterol synthesis<sup>[32]</sup>. We report significantly increased levels of total cholesterol in plasma and livers of DIO-NASH and *ob/ob*-NASH mice compared to respective chow groups. Interestingly, the gene markers for biosynthesis of cholesterol in the liver appear to be dramatically reduced for DIO-NASH and *ob/ob*-NASH, presumably to compensate for the intake of high level of cholesterol in the diet. However, to our surprise the same was not observed for the triglyceride synthesis as the main lipid enzymes showed increased expression (data not shown), albeit plasma levels of triglycerides were significantly decreased for *ob/ob*-NASH mice compared to *ob/ob* chow. This could be caused by impairment in VLDL secretion from the liver<sup>[6]</sup>, as relative triglyceride content in the liver was significantly increased in livers of *ob/ob*-NASH compared to levels in livers from *ob/ob* chow. Dysfunctional VLDL synthesis and secretion has been suggested to be a key factor in the progression of simple steatosis to NASH<sup>[33]</sup>. The mechanism(s) of action involved in the perturbed lipid metabolism awaits further investigations.

In conclusion, the diet-induced DIO-NASH and *ob/ob*-NASH mouse models demonstrate metabolic and histological key hallmarks of NASH. A clinically-derived histopathological scoring system can be applied in the DIO-NASH and *ob/ob*-NASH mouse models, thereby introducing a preclinical platform for evaluation of novel NASH therapeutics. Finally, a liver biopsy procedure at baseline allows for evaluation of individual disease staging prior to pharmacological intervention hereby reducing biological variability.

## COMMENTS

### Background

Nonalcoholic steatohepatitis (NASH) is an emerging liver disease with

increasing prevalence. There are currently no pharmacological agents specifically approved for the treatment of NASH and disease management is consequently focused on the correction of underlying risk factors such as obesity, insulin resistance and dyslipidemia.

### Research frontiers

The lack of approved therapeutics has to some degree been attributed to the failure of animal models to faithfully represent the clinical condition (e.g., disease progression and metabolic background) and the way NASH is assessed clinically (paired biopsies and validated histological methods). Hence, novel diet-induced NASH models that develop the appropriate metabolic phenotype with improved liver sampling methods are highly desirable as a preclinical platform for exploring novel NASH treatments.

### Innovations and breakthroughs

The authors describe and characterize a wild-type C57 and a genetically (*ob/ob*) obese diet-induced mouse model of NASH and confirm previous findings demonstrating key hallmarks of metabolic deregulation and fibrotic NASH using biochemical, histological and gene expression endpoints. Notably, a liver biopsy-confirmed and clinically-derived histological NASH scoring and fibrosis staging are being performed in *ob/ob* mice, which the authors are the first to report. Finally, the utility of the diet-induced NASH mouse models for pharmacological investigations is being demonstrated by performing a chronic intervention period with repeated dosing following a baseline liver biopsy procedure.

### Applications

A baseline liver biopsy performed after diet-induction allows for individual disease staging for stratification and randomization into study groups and for evaluation of novel NASH therapeutics.

### Peer-review

The results of this study demonstrated a useful animal model for evaluation the disease progression and treatment of NASH. The data were appropriately presented and interpreted. The manuscript was well prepared.

## Abstract

**AIM:** To elucidate causes for false negative magnetic resonance imaging (MRI) exams by identifying imaging characteristics that predict viable hepatocellular carcinoma (HCC) in lesions previously treated with locoregional therapy when obvious findings of recurrence are absent.

**METHODS:** This retrospective institutional review board-approved and Health Insurance Portability and Accountability Act-compliant study included patients who underwent liver transplantation at our center between 1/1/2000 and 12/31/2012 after being treated for HCC with locoregional therapy. All selected patients had a contrast-enhanced MRI after locoregional therapy within 90 d of transplant that was prospectively interpreted as without evidence of residual or recurrent

tumor. Retrospectively, 2 radiologists, blinded to clinical and pathological data, independently reviewed the pre-transplant MRIs for 7 imaging features. Liver explant histopathology provided the reference standard, with clinically significant tumor defined as viable tumor  $\geq 1.0$  cm in maximum dimension. Fisher's exact test was first performed to identify significant imaging features.

**RESULTS:** Inclusion criteria selected for 42 patients with 65 treated lesions. Fourteen of 42 patients (33%) and 16 of 65 treated lesions (25%) had clinically significant viable tumor on explant histology. None of the 7 imaging findings examined could reliably and reproducibly determine which treated lesion had viable tumor when the exam had been prospectively read as without evidence of viable HCC.

**CONCLUSION:** After locoregional therapy some treated lesions that do not demonstrate any MRI evidence of HCC will contain viable tumor. As such even patients with a negative MRI following treatment should receive regular short-term imaging surveillance because some have occult viable tumor. The possibility of occult tumor should be a consideration when contemplating any action which might delay liver transplant.

**Key words:** Hepatocellular carcinoma; Transarterial chemoembolization; Tumor recurrence; Locoregional therapy; Imaging surveillance

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Hepatocellular carcinoma (HCC) is often treated with locoregional therapy such as transarterial chemoembolization as a bridge to transplantation. Detecting residual or recurrent tumor within these treated lesions is challenging and some treated lesions that do not demonstrate any magnetic resonance imaging (MRI) evidence of HCC will contain foci of viable tumor. Regular, short-term imaging surveillance is clinically important for patients being considered for liver transplantation even when prior MRIs have been negative and the possibility of a false negative MRI exam needs to be considered when managing these patients.

Becker-Weidman D, Civan JM, Deshmukh SP, Roth CG, Herrine SK, Parker L, Mitchell DG. Hepatocellular carcinoma after locoregional therapy: Magnetic resonance imaging findings in falsely negative exams. *World J Hepatol* 2016; 8(16): 685-690 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i16/685.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i16.685>

## INTRODUCTION

The American College of Radiology developed the liver imaging reporting and data system (LI-RADS) to standardize how hepatocellular carcinoma (HCC) is

diagnosed<sup>[1]</sup>. These criteria were validated in untreated lesions and therefore do not apply to lesions after treatment with locoregional therapy. Although certain imaging findings are associated with the presence of viable HCC in a treated lesion there is currently no formal system to assess the probability of viable tumor.

Magnetic resonance imaging (MRI) is commonly used status post locoregional therapy to evaluate for recurrent or residual viable tumor. Because the hallmark of HCC is avid arterial-phase enhancement, dynamic imaging following gadolinium-based contrast administration should be a core component of the examination. Arterial-phase enhancement following locoregional therapy has a reported sensitivity and specificity of 82% to 100% and 79% to > 90% respectively<sup>[2,3]</sup>. Subtle arterial-phase enhancement can be obscured in treated lesions as they often demonstrate heterogeneous high signal on T1-weighted images due to the presence of blood products (Figure 1). HCC is a very cellular tumor<sup>[4]</sup> and will typically restrict the diffusion of water molecules giving it high signal on diffusion-weighted imaging (DWI) and corresponding low signal on the computer generated apparent diffusion coefficient map. Diffusion restriction following locoregional therapy has a reported sensitivity and specificity of 61% to 75% and 88% to > 90% respectively<sup>[2,3]</sup>. Identifying restricted diffusion in treated areas is complicated by the fact that these areas typically demonstrate high signal on T2-weighted images due to fibrosis (Figure 2), appearing as T2 shine through on DWI. Signal intensity on T2-weighted images is not typically helpful as it is affected by treatment and can be variable, although it is typically mildly to moderately hyperintense. Signal intensity on precontrast T1-weighted images is quite variable and generally not helpful. HCC is usually hypointense or isointense but can be hyperintense with intratumoral fat.

Unresectable HCC is often treated with locoregional therapy to decrease disease burden and as a bridge to transplant. In these patients accurate assessment of tumor response is integral to directing patient care. False negative MRI exams are due to a number of factors including technical limitations and inherent MR signal alteration of the treated areas. In addition there is no formal system for evaluating treated lesions. The goal of this study was to retrospectively determine which MRI features were most predictive of histological findings of residual or recurrent HCC in a population that does not demonstrate obvious recurrence.

## MATERIALS AND METHODS

### Patient and lesion inclusion criteria

This retrospective study was approved by our institutional review board and was compliant with the Health Insurance Portability and Accountability Act. Our study included patients with HCC who underwent liver transplantation at our center between 1/1/2000 and 12/31/2012 after being treated with locoregional therapy. Inclusion criteria selected patients that had a

**Figure 1 Treatment-related signal alterations on T1-weighted images.** A 59-year-old man with HCV cirrhosis and a segment V LI-RADS 5B lesion measuring up to 3.6 cm. Fat-saturated T1-weighted precontrast (A) and arterial-phase (B) images demonstrate a 3.6 cm enhancing focus of viable tumor (B, arrow) within an area previously treated with TACE. Mass could not be visualized upon selective angiography so repeat TACE was not performed. Non-contrast CT from a radiofrequency ablation procedure (C) demonstrates an electrode positioned within the tumor. One month later a fat-saturated T1-weighted precontrast image (D) demonstrates peripheral high signal related to hemorrhage from coagulative necrosis (D, arrow). LI-RADS: Liver imaging reporting and data system; TACE: Transarterial chemoembolization; HCV: Hepatitis C virus.

**Figure 2 Treatment-related signal alterations on T2-weighted images.** A 63-year-old man with HCV/EtOH cirrhosis and a segment VII LI-RADS 5B lesion measuring 2.4 cm × 1.8 cm. T2-weighted image (A) just superior to the segment VI lesion before treatment demonstrates a cirrhotic liver with homogeneous low signal intensity. Non-contrast CT (B) performed immediately after a TACE procedure shows high attenuation Lipiodol® in segment VII confirming that the appropriate segment was treated. T2-weighted image (C) from an MRI performed one month later shows high signal intensity in the area that was treated due to fibrotic change. Precontrast (D) and arterial-phase images (E) from that exam demonstrate that the treated area is completely necrotic. LI-RADS: Liver imaging reporting and data system; TACE: Transarterial chemoembolization; HCV: Hepatitis C virus; CT: Computed tomography; MRI: Magnetic resonance imaging.

contrast-enhanced MRI after locoregional therapy within 90 d of transplant that was prospectively interpreted as without evidence of residual or recurrent tumor. Patients were identified through our electronic medical record.

While HCC is a radiologic diagnosis, subcentimeter lesions cannot be designated as “definite” HCC by either the American Association for the Study of Liver Diseases or the LI-RADS criteria in recognition of the fact that

early tumors may not demonstrate hypervascularity and technical limitations preclude adequate assessment of lesions below this threshold<sup>[1,5]</sup>. Therefore, we considered foci of HCC identified on explant significant for the purpose of our study only if it measured  $\geq 1.0$  cm in maximal diameter.

Foci of viable tumor detected histologically on explant, distinct from a previously treated lesion were

not included in our analysis. These foci were treated as incidental findings as our current analysis regards the MRI findings in lesions previously identified as HCC subsequently undergoing treatment.

### MR image analysis

All MRI data sets were reviewed on a workstation equipped with image review software (iSite, version 3.6; Philips, Andover, MA). Retrospective image interpretations were performed independently by two body MRI specialists, each with more than 10 years of experience. The study coordinator, a radiology resident, prepared the exams for review by correlating the lesions described in the explant pathology report with the treated lesions on the MRI, marking the lesions to be evaluated with an arrow. Exams were reviewed in random order by the interpreting radiologists, who were blinded to all other patient history, including pathology and other imaging results.

Each liver lesion was assessed by the interpreting radiologist for the presence or absence of: Arterial-phase nodular enhancement, arterial-phase non-nodular enhancement, gradual enhancement, partial or complete T1 signal hypointensity, partial or complete T2 signal hyperintensity, lipid as determined by comparison of in-phase and opposed-phase images, and restricted diffusion if DWI was performed. Findings were recorded in prepared data sheets.

### Gross pathology and histopathologic analysis

All explanted livers were received as surgical resection specimens. Each explant was serially sectioned in contiguous slices at 5 mm intervals, and processed for routine Hematoxylin and Eosin stains. These slides were prospectively reviewed for the presence of viable HCC and the pathology report produced was used to retrospectively correlate the histologic findings with the pretransplant MRI.

### Statistical analysis

Statistical review of the study was performed by a biomedical statistician. Statistical software (SAS version 9.4; SAS Institute, Cary, NC) was used for all data analysis. Fisher's exact test was first performed to identify significant imaging features in a bivariate analysis followed by a step-wise logistic regression if more than one variable was significant. The significance threshold was set at a *P*-value of 0.05 and any variable with *P* > 0.05 was removed from the model and determined to be insignificant. The agreement level between readers was measured by using *k* coefficient. We defined *k* values for level of agreement as follows: 0.81-0.99, almost perfect agreement; 0.61-0.80, substantial agreement; 0.41-0.60, moderate agreement; 0.21-0.40, fair agreement; and 0.01-0.20, slight agreement<sup>[6]</sup>.

## RESULTS

### Patients

A search of our electronic medical record showed

that 488 patients had a liver transplant at our center between 1/1/2000 and 12/31/2012, of which 167 (34.2%) had HCC, all of whom were treated with locoregional therapy prior to transplant. Of these patients, 84 (50.3%) had findings suspicious for recurrent or residual HCC on the pre-transplant MRI, 24 (14.4%) underwent locoregional treatment between the pre-transplant MRI and transplant, 16 (9.6%) had the pre-transplant MRI over 90 d before transplant, and 1 (0.6%) did not receive intravenous contrast and were excluded from our study. Patient accrual details are presented in Figure 3. The final cohort of 42 patients (mean age, 59 years; age range, 46-73 years) included 34 men (mean age, 59 years; age range, 46-73 years) and 8 women (mean age, 59 years; age range, 53-70 years). Patients had cirrhosis secondary to hepatitis C (*n* = 29), hepatitis C and alcohol abuse (*n* = 5), alcohol abuse (*n* = 4), nonalcoholic steatohepatitis (*n* = 1), or an unknown cause (*n* = 3). MRI was performed an average of 40 d before transplant (range, 1-89 d).

Prior to transplant 33 (79%) patients were treated with transarterial chemoembolization (TACE) only, 3 (7%) were treated with radiofrequency ablation only, 2 (5%) were treated with radioactive embolization only, 1 (2%) was treated with bland transarterial embolization only, and 3 (7%) were treated with TACE and radiofrequency ablation.

### Reference histopathologic analysis

The 42 patients who met our inclusion criteria included 18 (43%) who had no viable tumor, 10 (24%) who had viable tumor that was considered clinically insignificant, and 14 (33%) who had at least one focus of clinically-significant viable tumor on explant pathology. Two patients had two foci of clinically-significant viable tumor. The explant Pathology report mentioned a single lesion in 27 patients (64%), 2 lesions in 9 patients (21%), 3 lesions in 3 patients (7%), 4 lesions in 2 patients (5%), and 5 lesions in 1 patient (3%) for a total of 65 treated lesions. Sixteen treated lesions (25%) had clinically significant viable tumor (mean size, 1.5 cm; range, 1.0-3.5 cm), 13 treated lesions (20%) had a focus of tumor < 1.0 cm (mean size, 0.5 cm; range, 0.1-0.9 cm), and 36 (55%) treated lesions had no viable tumor.

### MR image and statistical analysis

Of the 42 patients, 15 received gadoxetate disodium (Eovist) (36%), 13 received gadopentate dimeglumine (Magnevist) (31%), 8 received gadobutrol (Gadavist) (19%), and 6 received gadobenate dimeglumine (MultiHance) (14%). DWI was only performed in 19 patients (45%) as DWI was not included as a part of our routine MRI exam of the abdomen until 2011.

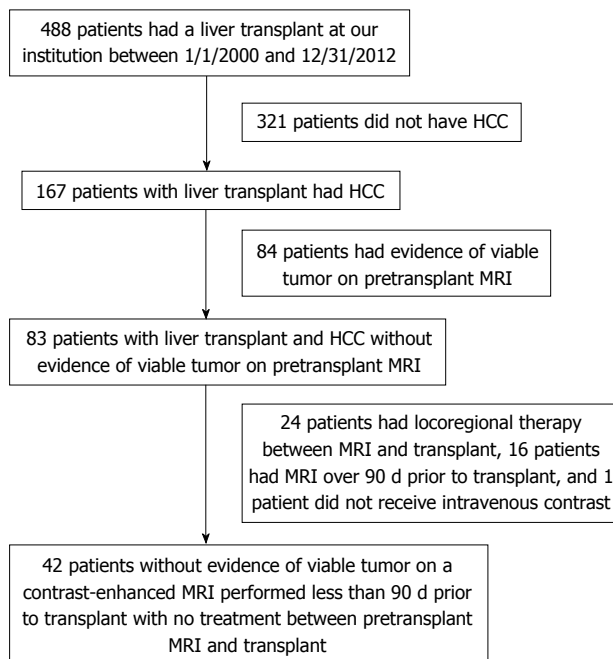

For reader #1 "arterial-phase non-nodular enhancement" and "partial or complete T1 signal hypointensity" were significant predictors of viable tumor. For reader #2 "partial or complete T2 signal hyperintensity" was the sole significant predictor of viable tumor.

**Table 1** *P*-values and Kappa values associated with the 7 different imaging features

	<i>P</i> -values		Kappa values
	Reader #1	Reader #2	
Arterial-phase nodular enhancement	0.44	0.14	0.37 (fair agreement)
Arterial-phase non-nodular enhancement	0.25	0.008 <sup>b</sup>	0.23 (fair agreement)
Gradual enhancement	0.47	0.15	0.10 (slight agreement)
Partial or complete T1 signal hypointensity	0.21	0.001 <sup>b</sup>	0.15 (slight agreement)
Partial or complete T2 signal hyperintensity	0.047 <sup>a</sup>	0.47	0.07 (slight agreement)
Lipid	0.56	0.44	-0.03 (no agreement)
Restricted diffusion	N/A <sup>1</sup>	N/A <sup>1</sup>	N/A <sup>1</sup>

<sup>a,b</sup>*P*-values reached significance; <sup>1</sup>Could not be assessed due to collinearity. N/A: Not applicable.

**Figure 3 Patient accrual flowchart.** HCC: Hepatocellular carcinoma; MRI: Magnetic resonance imaging.

There was fair agreement for arterial-phase nodular enhancement and non-nodular enhancement ( $k = 0.37, 0.23$  respectively); slight agreement for gradual enhancement, partial or complete T1 signal hypointensity, and partial or complete T2 signal hyperintensity ( $k = 0.07, 0.10, 0.15$  respectively); and no agreement for the presence of lipid ( $k = -0.03$ ). The *P*-values and kappa values are presented in Table 1.

### Patient outcomes

There was a single post-transplant recurrence in the 18 patients without viable tumor (mean length of followup, 4.9 years; range, 1.1-9.0 years). There was a single recurrence in the 10 patients with clinically insignificant cancer (mean length of followup, 5.2 years; range, 2.6-13.4 years). There was a single recurrence in the 14 patients with clinically significant viable tumor (mean length of followup, 3.4 years; range, 0.2-7.1 years). One patient with only 0.2 years of followup died from a stroke.

## DISCUSSION

Retrospective review of true negative and false negative MR exams did not identify any subtle findings that can reliably and reproducibly indicate the presence of viable HCC in studies that were prospectively interpreted as negative. T1 and T2 signal intensity are highly variable after locoregional therapy and are not reliable indicators of viable tumor. Delayed enhancement is often seen after treatment and indicates fibrosis. Arterial-phase enhancement is associated with viable tumor but may be subtle or absent and has a reported sensitivity of as low as 82%<sup>[2]</sup>. In other words, some patients who do not have evidence of HCC on MRI will have viable tumor on explant pathology.

A limitation of this study was the low level of agreement between readers. This can be partially explained due to the low number of "positive" imaging features. When there is a low base rate a small number of discordant findings will have a disproportionately large effect on Cohen's kappa coefficient<sup>[7]</sup>. Agreement regarding enhancement characteristics is only slight to fair because any case that demonstrated obvious enhancement was prospectively read as suspicious for viable HCC and excluded from our study. The only cases that remained were those that demonstrated subtle enhancement. Agreement for signal intensity on T1- and T2-weighted images is only slight due to the inherent difficulty in classifying a highly heterogeneous area. That being said the low kappa value limits the value and reliability of any imaging finding that was positively associated with viable HCC. Therefore, we do not propose that signal intensity on unenhanced T1-weighted or T2-weighted images is predictive of viable tumor. It is possible that non-nodular arterial-phase enhancement is predictive of viable tumor but this finding was not reliable enough in our study for clinical use.

Another limitation was the inconsistency of the explant pathology reports. Some pathology reports measured the size of the viable component or state the percentage of necrosis within the measured treated lesion, whereas, other reports used subjective terminology such as "partially necrotic" or "largely necrotic" which made exact measurement of the viable component difficult. Another problem was that some of

the treated lesions demonstrated partial diffuse necrosis and contained only microscopic islands of tumor. These lesions are considered viable by histology but impossible to identify by imaging.

Noting the limitations above it is clear that occasionally treated lesions without evidence of viable HCC by MRI can contain foci of viable tumor. This supports the utilization of regular short-term imaging surveillance even when prior MRIs have been negative and is clinically important for patients being considered for liver transplantation. For example, a decision to delay transplant to allow treatment of underlying chronic viral hepatitis C should be made with caution, without over-reliance on a sense of security suggested by surveillance imaging with no definite evidence of viable HCC. The possibility of a false negative MRI exam needs to be considered when managing patients after locoregional therapy.

## COMMENTS

### Background

Unresectable hepatocellular carcinoma (HCC) is often treated with locoregional therapy to decrease disease burden and as a bridge to transplant. After locoregional therapy magnetic resonance imaging (MRI) interpretation can be more difficult due to a number of factors. Several imaging findings have been shown to correlate with the presence of viable HCC in this setting including diffusion restriction and arterial-phase enhancement.

### Research frontiers

Liver imaging reporting and data system (LI-RADS) was not developed to be applied to treated lesions and as such these lesions are designated "LR-treated". Further investigation into the imaging characteristics of treated lesions could lead to the development of a version of LI-RADS that can be applied to these lesions.

### Innovations and breakthroughs

In this study, the authors demonstrate that treated lesions can harbor foci of viable HCC but demonstrate no MRI findings.

### Applications

The research supports the utilization of regular short-term imaging surveillance

in patients with HCC treated with locoregional therapy even when prior MRIs have been negative due to the possibility of a false negative exam.

### Terminology

Diffusion-weighted imaging: MRI sequence that measures random Brownian motion of water molecules within a voxel of tissue; LI-RADS: Set of terminology developed by the American College of Radiology to standardize the reporting of imaging findings of liver lesions; Locoregional therapy: Transarterial and/or local ablative therapy.

### Peer-review

This is an interesting manuscript providing information for an easily neglected field. It is thus of value to be considered for publication.

### Abstract

**AIM:** To re-examine whether hepatic vein thrombosis (HVT) (classical Budd-Chiari syndrome) and hepatic vena cava-Budd Chiari syndrome (HVC-BCS) are the same disorder.

**METHODS:** A systematic review of observational studies conducted in adult subjects with primary BCS, hepatic vein outflow tract obstruction, membranous obstruction of the inferior vena cava (IVC), obliterative hepatocavopathy, or HVT during the period of January 2000 until February 2015 was conducted using the following databases: Cochrane Library, CINAHL, MEDLINE, PubMed and Scopus.

**RESULTS:** Of 1299 articles identified, 26 were included in this study. Classical BCS is more common in women with a pure hepatic vein obstruction (49%-74%). HVC-BCS is more common in men with the obstruction often located in both the inferior vena cava and hepatic veins (14%-84%). Classical BCS presents with acute abdominal pain, ascites, and hepatomegaly. HVC-BCS presents with chronic abdominal pain and abdominal

wall varices. Myeloproliferative neoplasms (MPN) are the most common etiology of classical BCS (16%-62%) with the JAK2V617-F mutation found in 26%-52%. In HVC-BCS, MPN are found in 4%-5%, and the JAK2V617-F mutation in 2%-5%. Classical BCS responds well to medical management alone and 1<sup>st</sup> line management of HVC-BCS involves percutaneous recanalization, with few managed with medical management alone.

**CONCLUSION:** Systematic review of recent data suggests that classical BCS and HVC-BCS may be two clinically different disorders that involve the disruption of hepatic venous outflow.

**Key words:** Budd-Chiari; Hepatic vein outflow tract obstruction; Membranous obstruction of the inferior vena cava; Obliterative hepatocavopathy; Hepatic vein thrombosis

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** With improved diagnostic methods, the terminology for Budd-Chiari syndrome (BCS) has expanded discordantly. This systematic review discusses recent population studies of BCS and proposes the delineation of two clinically unique syndromes.

## INTRODUCTION

Budd-Chiari syndrome (BCS) was originally described as a rare vascular disorder that encompasses an array of symptoms due to obstruction of hepatic blood outflow at the level of the hepatic veins or hepatic portion of the inferior vena cava (IVC)<sup>[1]</sup>. The symptoms resulting from this type of occlusion of the hepatic outflow, "classical BCS", were first described by Budd<sup>[2,3]</sup> in 1845 and later by Hans Chiari in 1899. With the advancement of diagnostic and therapeutic techniques, providers have expanded upon these initial characterizations<sup>[4]</sup>. Historically, identifying the precise location of the obstruction was challenging, leading to the propagation of simplified descriptions. The precise location of the obstruction(s) is however clinically and prognostically significant. As Valla<sup>[5]</sup> proposed, the clinical manifestations of BCS (the selective group of symptoms that characterize the syndrome) can be explained by the location of the obstruction: Within the hepatic veins vs within the IVC at the level of the hepatic ostia. Over time, in order to incorporate novel and more detailed findings associated with BCS, the lexicon has evolved discordantly. The

lexicon now includes a myriad of ambiguous terms or eponyms: Budd's disease, Chiari's disease, Chiari's syndrome, Rokitansky's disease, von Rokitansky disease, Hepatic vein outflow tract obstruction, membranous obstruction of the IVC, obliterative hepatocavopathy, Hepatic vena cava disease, Budd-Chiari syndrome with occlusion of hepatic vein, or hepatic vein thrombosis<sup>[6-8]</sup>. These eponyms have been used at some point during the course of further discovery; this disarray of terms, some of which are unclear and nonspecific, reflects not only the heterogeneous presentation of BCS, but also the possibility of distinct entities within this syndrome.

The currently accepted definition of primary BCS is hepatic outflow obstruction regardless of the cause or level of obstruction<sup>[6,9]</sup>. The obstruction can range from the small hepatic veins to the orifice of the IVC into the right atrium. Sinusoidal obstruction syndrome is excluded from this definition<sup>[6,9]</sup>. Secondary BCS is defined as a hepatic venous outflow obstruction due to compression or invasion by extravascular lesions, including benign or malignant diseases such as abscesses, hepatocellular carcinomas, and renal cell carcinomas, or secondary to cardiac or pericardial diseases<sup>[6,9]</sup>.

In 1998, Okuda *et al*<sup>[4]</sup> proposed that primary hepatic venous thrombosis (classical BCS) and thrombosis of the IVC at the level of the IVC were two separate syndromes. Recent studies continue to suggest a clear division within the definition of "primary BCS" based on the location of the obstructive lesion<sup>[4,10]</sup>. Obstruction of the hepatic veins or "classical BCS" appears to be more common in Western patient populations and usually has a known etiology<sup>[11,12]</sup>, acute onset of symptoms, and a greater severity of symptoms requiring a different therapeutic approach than obstruction of the IVC at the level of the hepatic veins<sup>[4,13,14]</sup>. In comparison with "classical BCS", hepatic vena cava (HVC)-BCS appears to be more common in East Asian patient populations, and is more often idiopathic or due to membranous obstruction. HVC-BCS more commonly presents with a chronic onset of less severe symptoms, thus requiring a different therapeutic approach than "classical BCS"<sup>[15]</sup>. The location, size, and chronicity is clinically important as it dictates the patient's symptoms and directs the therapeutic approach for patient management<sup>[10]</sup>.

## Precedence

Historically, hepatic sinusoidal obstruction syndrome (SOS) or veno-occlusive disease was included under the general term BCS<sup>[1,16-18]</sup>. SOS is specifically defined as obstruction of the sinusoids or hepatic veins resulting from sinusoidal wall injury. Several distinct clinical characteristics differentiate SOS from BCS and the two conditions are now considered separate entities as the distinct etiology and pathophysiology of SOS necessitates different management strategies. SOS is caused by pyrrolizidine alkaloid toxicity, whereas BCS is caused by multifactorial prothrombotic condition(s) or membranous obstruction of the IVC and/or HV<sup>[18]</sup>. Pyrrolizidine alkaloids include over 150 compounds that

occur naturally in several plant families<sup>[18]</sup>. Historically, they were ingested in indigenous herbal teas or inadvertently *via* crop contamination in developing countries. Currently, pyrrolizidine alkaloids are used as myeloablative regimens for patients preparing for hematopoietic stem cell transplantation. Thus, SOS almost exclusively affects hematopoietic stem cell transplant patients, while BCS can affect a wide range of patient populations<sup>[9]</sup>. Clinically, both SOS and BCS can present with abdominal pain, portal hypertension, jaundice, and non-cirrhotic ascites. Management of SOS is challenging and involves preventive measures (avoiding pyrrolizidine alkaloids in susceptible patients) and a few interventional therapeutic options (defibrotide, heparin, shunt procedures, *etc.*). In contrast, management of BCS ranges from medical management (*e.g.*, anticoagulation) to interventional procedures (angioplasty, stents, shunt procedures, *etc.*)<sup>[19]</sup>.

Due to the low incidence of “BCS” in many countries, published data tended to include only small case series. Recently, there have been an increasing number of larger observational studies (both retrospective and prospective), particularly from Asia (China) and Europe. Advancing imaging technologies, such as computed tomography (CT) angiography, magnetic resonance (MR) angiography, Doppler ultrasound (US), and angiography have allowed for better identification and delineation of this disease. This may signal the start of prospective, randomized, controlled therapeutic trials which can differentiate classical BCS from HVC-BCS and their management strategies. Other investigators have suggested various novel classification systems, including those that forego the eponym “Budd-Chiari” altogether<sup>[8-16]</sup>. However, given that both classical and HVC-BCS reflect an obstruction in hepatic venous outflow, we propose a clarification of the general BCS term into classical BCS and HVC-BCS.

## MATERIALS AND METHODS

A systematic literature search yielded 818 results in the PubMed database; 428 in the Scopus database; 18 in the CINAHL database; and 17 in the Cochrane database. All duplicates were removed. After 18 additional studies (from the references within included studies) were added, 1178 study abstracts were screened. Of these, 591 were excluded because of the publication type and/or subject (reviews, case reports including less than 20 patients, non-human studies, or studies not on BCS (*e.g.*, Chiari malformations, acute liver failure, *etc.*)). The full text articles of the remaining 587 studies were acquired to determine eligibility.

### Inclusion criteria

Clinical trials and observational studies (prospective or retrospective) conducted in predominantly adult subjects with primary BCS were included in this study. All of the included studies needed to explicitly delineate diagnostic methods for BCS (namely standard imaging

studies such as US, CT, MR imaging, or venography) and to explicitly describe inclusion and exclusion criteria to ensure the focus on primary BCS (vs secondary BCS). For multiple studies published from the same institution(s) within a close time frame, we reviewed years of subject recruitment, methodology specifics, and results. In addition, we also investigated if there were possible overlapping subjects and/or results. Only the most recent eligible studies were included in this review, unless distinctly specific and separate findings were previously reported<sup>[20,21]</sup>.

Of the 587 studies, the following were excluded: 390 were missing key clinical information (*e.g.*, clear inclusion and exclusion criteria) or focused on a subpopulation within the BCS population (*e.g.*, only BCS patients requiring liver transplantation, *etc.*); 71 studies were not limited to primary BCS; 86 studies were not mainly focused on BCS, but rather broader topics associated with BCS (*e.g.*, causes of liver transplantation, *etc.*); 17 studies were older versions of recently published subject populations with similar study aims. Twenty-six studies were included for analysis in this review (Figure 1).

## RESULTS

### Epidemiology

Many observational studies have recently been published on “BCS” (Table 1). For clarity and compromise, only the terms classical BCS and HVC-BCS will be used to differentiate between the two types of BCS in this review. After considering the location of the obstruction and clinical manifestations of the subjects, studies were grouped as majority-classical BCS or majority-HVC-BCS studies in Table 1. It has previously been suspected that classical BCS is more likely to present in women with a pure hepatic vein obstruction<sup>[9,13]</sup>. This review continues to support this observation as 13 of the 14 included studies reported a higher incidence of classical BCS in women; 55%-76% of the reported population is female. In addition, recent studies continue to report pure obstruction in the majority of cases 49%-85%. Most studies reported pure hepatic vein obstruction in > 71% of patients (Table 1). Compared with classical BCS, HVC-BCS is more common in men (51%-66%) and more likely to present with an IVC obstruction with or without involvement of the HVs (69%-100%) (Table 1).

### Clinical manifestations in classical BCS vs HVC-BCS

Classical BCS typically presents with an acute onset of symptoms with most studies reporting the duration of symptoms < 6 mo (Table 2) with 60%-85% of patients having an acute presentation of symptoms; however, one study from Egypt designated 80% of their 94 patients as chronic, but the definitions of chronic vs acute were not explicitly delineated<sup>[22]</sup>. Classical BCS typically presents with abdominal pain (45%-86% of patients), ascites (76%-100%), and hepatomegaly (43%-83%) (Table 2). In comparison, HVC-BCS typically presents

**Table 1** Epidemiology of classical Budd-Chiari syndrome and hepatic vena cava-Budd Chiari syndrome

**Figure 1** Flow diagram of studies selection. <sup>1</sup>Searches conducted with MEDLINE results removed; <sup>2</sup>Studies missing key clinical information including clear inclusion and exclusion criteria, clear diagnostic parameters, *etc.*, and studies that investigated subpopulations (*e.g.*, BCS patients requiring liver transplantation, BCS patients without MPN, *etc.*); <sup>3</sup>Studies focused on other categories (*e.g.*, causes of liver failure). BCS: Budd-Chiari syndrome; MPN: Myeloproliferative neoplasms.

with chronic onset of symptoms (75%-86% of patients), with an average duration of symptoms prior to diagnosis ranging from 44-96 mo. Nine to seventy percent of patients (most studies reporting < 29%) with HVC-BCS present with abdominal pain, 32%-90% with ascites, and 28%-95% with hepatomegaly. Splenomegaly, abdominal wall varices, lower extremity varices, and discoloration are more commonly associated with HVC-

BCS (Table 2)<sup>[13,23]</sup>. The severity of disease depends upon both the extent of disease (the number of occluded vessels, complete or incomplete occlusion), the presence of associated symptoms (refractory ascites, portal vein thrombosis, *etc.*), and the chronicity of symptoms. Patients with the chronic variation of disease generally have several milder episodes of vague symptoms (abdominal pain or leg swelling), providing sufficient time for

the development of collateral vessels<sup>[13,24]</sup>. In contrast, acute onset and/or significant obstruction (e.g., complete occlusion of several hepatic veins) increases the risk of acute hepatic failure.

### Obstruction characteristics

Patients with classical BCS typically have an obstructing thrombus within the hepatic veins (Figure 2)<sup>[5,24]</sup>. In contrast, patients with HVC-BCS typically have a membranous or segmental obstruction involving the IVC<sup>[24]</sup> (proximal to the ostia of the hepatic veins), but the obstruction can extend into, or secondarily involve the hepatic veins themselves (Figure 3). Observational studies continue to reflect this difference between classical BCS and HVC-BCS patients; several studies from Europe to northern Africa consistently describe a thrombotic obstruction (87%-95%) limited to the hepatic veins (49%-85%) and rarely describe a membranous obstruction (1%-5%) located at only the IVC (0%-14%). However, in HVC-BCS patients, many studies report a membranous obstruction (30%-61%) only located at the IVC (57%-72%) or both the IVC and HV (63%-84%). Obstructions in HVC-BCS patients are not commonly isolated in the hepatic veins (0%-31%)<sup>[24-26]</sup>. The development of collateral circulation takes time; given that the chronic form of BCS is more commonly associated with HVC-BCS, it is not surprising that the development of collateral circulation is more typical with HVC-BCS patients (63%-65%) than with classical BCS patients (Table 3).

### Etiology

Uncovering the etiology of BCS can be challenging. In classical BCS, however, thrombotic risk factors are consistently identified in the majority of patients<sup>[1]</sup>. Findings reported in recent studies continue to report myeloproliferative neoplasms [MPN, previously called myeloproliferative disorders (MPD)] as the most common etiology of classical BCS; 9 out of 14 studies found that it is the most common cause of classical BCS affecting 16%-62% of patients, with many reporting between 41%-62% (Table 4). The most commonly observed MPNs include polycythemia vera (PV) and essential thrombocythemia (ET) found in 18%-43% and 6%-14% of classical BCS patients, respectively. The JAK2V617-F mutation is a sensitive marker for MPN and has been observed in 26%-52% of patients with classical BCS<sup>[27-34]</sup>. In contrast, in several large Chinese studies,

**Figure 2** Classical Budd-Chiari syndrome - Occlusions are within the hepatic veins themselves and usually thrombi. RHV: Right hepatic vein; MHV: Middle hepatic vein; LHV: Left hepatic vein; IVC: Inferior vena cava.

**Figure 3** Hepatic vena cava-Budd Chiari syndrome - Occlusions are thin or thick (membranous or segmental) and within the inferior vena cava and occlusion can extend into the hepatic veins and generally involve the ostia to the inferior vena cava. RHV: Right hepatic vein; MHV: Middle hepatic vein; LHV: Left hepatic vein; IVC: Inferior vena cava.

MPN were only found in 4%-5% of patients (PV in 2% and ET in 1%-2%) and the JAK2V617-F mutation in only 0%-5% of patients diagnosed with primary HVC-BCS (Table 4)<sup>[13,35,36]</sup>.

Hereditary prothrombotic conditions such as factor V Leiden mutation (FVL), prothrombin (PT) 20210A mutation, protein C deficiency (PCD), protein S deficiency (PSD), antithrombin deficiency (ATD), plasminogen activator inhibitor [PAI-1 (4G-4G)], and the 5,10-methylenetetrahydrofolate reductase enzyme mutation (MTHFR C677T) often also play a significant role in the development of classical BCS. Following MPNs, the FVL mutation is the second most common cause of classical BCS and was found in 2%-53% of patients. Thrombophilic conditions also may contribute to the development of classical BCS. Mutations in PT were found in 2%-8% of patients with classical BCS vs 0% of patients with HVC-BCS. PCD, PSD, and ATD were found in 3%-26%, 1%-9% and 3%-15% of patients with classical BCS, respectively, vs 0% of patients with HVC-BCS (Table 4). Interestingly, this pattern is not apparent with MTHFR C677T mutations; these mutations were found in 26%-52% of patients with classical BCS and 71%-72% of patients with HVC-BCS. Less common but established prothrombotic or associated conditions further include antiphospholipid antibodies (classical BCS: 3%-29% vs HVC-BCS: 0%-17%), hyperhomocysteinemia (10%-18% vs 21%-50%), and paroxysmal nocturnal hemoglobinuria (0%-19% vs 0%-4%). Several systemic conditions (classical BCS: 5%-24% vs HVC-BCS: 1%-19%) including connective tissue disorders such as systemic lupus erythematosus (5%-12% vs 1%) are generally associated more frequently with classical BCS. Hormonal factors such as oral contraceptives, pregnancy, or puerperium can also increase the risk of thrombosis as can local insults such as recent surgery. Of these numerous differences between classical BCS and HVC-BCS, one consistent difference is the greater influence of hormonal changes (be it oral contraceptive use or pregnancy) in classical BCS patients (4%-52% of the female population) (Table 4)<sup>[29,37-39]</sup>.

Membranous obstruction of the IVC (and/or HV) is consistently listed as the etiology of a significant number of HVC-BCS patients (52%-61%). In classical BCS patients, membranous obstruction is rare (1%) or rarely explicitly delineated, except in one study of 23 consecutive patients diagnosed with BCS in Germany where 5 patients (22%) were found to have a membranous obstruction of the IVC<sup>[24]</sup>. Furthermore, despite comprehensive work-up, an etiologic factor is often not identified in HVC-BCS patients (19%-29% vs classical BCS: 5%-30%) (Table 4).

Data from recent studies continues to support the possibility of two different types of BCS with separate etiologies: Classical BCS, where thrombophilic risk factors and often multiple concomitant factors are common vs HVC-BCS, where thrombophilic risk factors are uncommon, but membranous obstruction and idiopathic hepatic venous outflow obstruction are more common.

### Management and outcomes

Treatment and prognosis of BCS depends on a few key factors: Acuity of symptoms, location and extent of the obstruction, and etiology<sup>[24]</sup>. In 2013, Seijo *et al.*<sup>[11]</sup> outlined a step-wise management approach for BCS patients from the analysis of the extended follow-up data of 157 patients from 9 European countries. This management approach starts with medical management alone (*e.g.*, salt-restriction, anticoagulation, diuretics), including concomitant management of any underlying etiological processes. Diagnostic work-up for classical BCS patients generally includes hematologic work-up for MPN, JAK2V617F mutation screening for MPN<sup>[29-31,33]</sup>, testing for FVL mutation<sup>[28]</sup>, and the aforementioned thrombophilic risk factors. In addition, some studies recommend continued monitoring of JAK2-mutation-positive-patients for occult MPNs<sup>[5,9,33]</sup>. In general, the medical management of classical BCS patients involves anticoagulation and ascites management with diuretics. Patients with MPN require additional aspirin and cyto-

reductive medications (e.g., hydroxyurea). Patients with autoimmune diseases (e.g., antiphospholipid syndrome, Behçet's disease, etc.) require additional corticosteroids and/or immunosuppressive drugs. If patients fail medical management, therapy is then escalated to minimally invasive procedures including percutaneous transluminal angioplasty (PTA) and/or thrombolysis. If patients fail to respond to these measures, developing refractory ascites, variceal bleeding, or liver failure, they are then treated with transjugular intrahepatic portosystemic shunt (TIPS) or other shunt operations<sup>[11,40,41]</sup>, with liver transplantation as a final option<sup>[32]</sup>. Such an approach appears to result in good long-term survival (Table 5)<sup>[11]</sup>.

Recent studies continue to support that medical management alone can be appropriate for classical BCS patients; 33%-54% of the classical BCS patients treated with medical management alone have good outcomes. In contrast, only 0%-7% of HVC-BCS patients are treated with medical management alone. While both classical and HVC-BCS patients benefit from interventional therapy, the specific interventions are different. Classical BCS patients commonly undergo TIPS (classical BCS: 4%-62% vs HVC-BCS: 1%-4.5%) and liver transplantation (9%-55% vs 0%-1%). In a study of 62 predominantly classical BCS patients from Turkey, none of the patients underwent liver transplantations, but that was due to a lack of donor availability<sup>[42]</sup>. In contrast, first line management of HVC-BCS with percutaneous re-canalization (with or without stent deployment) has good outcomes<sup>[43]</sup>. In one large study from China, Han *et al.*<sup>[44]</sup> found that all 187 consecutively diagnosed primary BCS patients at one institution were eligible for percutaneous recanalization, regardless of the location of the obstruction. Recent studies report that HVC-BCS patients undergo PTA more frequently compared to classical BCS patients (HVC-BCS: 43%-92% vs classical BCS: 3%-18%). After percutaneous recanalization, patients are anticoagulated with an international normalized ratio goal of 2-3 for a minimum of 6-8 mo per standard post-endovascular intervention management guidelines<sup>[44]</sup>.

Median follow-up for both classical BCS and HVC-BCS patients were similar (classical BCS: 17-58 mo and HVC-BCS: 12-103 mo). Both groups of patients fared well with their respective management strategies. One-year and five-year survival was 79%-96% and 56%-79% among classical BCS patients, respectively. One-year and five-year survival for HVC-BCS patients was 67%-99% and 75%-86%, respectively (Table 5). Poor prognostic factors for classical BCS patients include: Severe BCS (e.g., ascites requiring diuretics or paracentesis, pleural effusion, higher Clichey Prognostic index score), older age, cirrhosis at diagnosis of BCS, and chronic kidney disease<sup>[37,38]</sup>. Development of cirrhosis or hepatocellular carcinoma (HCC) are poor prognostic factors for HVC-BCS patients<sup>[23]</sup>.

## DISCUSSION

This systematic literature review highlights the numerous differences between classical BCS and HVC-BCS. Despite the growing cognizance of this difference<sup>[4,5]</sup> and despite

the abundance of recent publications on BCS, there is still a paucity of large, randomized clinical trials with regard to classical and/or HVC-BCS. The vast heterogeneity of these recent publications with regards to recruitment of solely primary vs secondary BCS, of solely classical or HVC-BCS, and of patients who have not previously been recruited and described, may lead to disparate and skewed patient populations that preclude certain data analyses and conclusions. Thus, this review specifically sought out studies that recruited BCS subjects that were representative of the indigenous BCS patient population. We attempted to minimize selection bias by excluding studies that focused on a particular subgroup of patients (e.g., BCS patients requiring liver transplantation, exclusion of patients with specific previously diagnosed etiologies, etc.). We also attempted to minimize multiple representations of the same patient population by comparing recruitment periods from studies that were similar in geographic location (institution, city, and country) or similar in authorship. The selected studies thereby provide an unadulterated presentation of the differences between classical vs HVC-BCS according to geography, patient demographics, location of obstruction, and treatment strategies and outcomes. The examination of these differences is important as they impact the diagnostic work-up and the therapeutic management strategies for individual patients and healthcare communities alike.

<sup>1</sup>Medical management includes anticoagulation, diuretics, and medical treatment of any underlying causes; <sup>2</sup>After PTA failed; <sup>3</sup>Of the 22 patients who initially were treated with PTA/thrombolitics, 12 subsequently underwent TIPS and 2 underwent OLT; <sup>4</sup>Among the 62 patients who underwent TIPS, 4 subsequently underwent OLT; <sup>5</sup>Patients who failed medical management (namely anticoagulation with heparin and warfarin and diuretics) as defined by persistent transaminitis, resistant ascites or worsening hepatic function) moved on to receive stenting, shunting, or TIPS; <sup>6</sup>50% success rate (16/32); <sup>7</sup>Per study, 7 out of 21 patients died before hospital discharge; <sup>8</sup>No patients underwent liver transplantations due to a lack of donor availability; <sup>9</sup>Median follow-up post liver transplantation was 40 mo and median follow-up of patients with MPN was 73 mo; <sup>10</sup>Mean survival time was 65 mo; <sup>11</sup>10 patients died by the 5-yr follow-up period; <sup>12</sup>At the end of the follow-up period, 2 patients were waiting to receive OLT from another hospital; <sup>13</sup>Mean, not median values provided. Interventional therapy includes both endovascular and surgical procedures. OLT: Orthotopic liver transplant; TIPS: Transjugular intrahepatic portosystemic shunt; PTA: Percutaneous transluminal angioplasty; BCS: Budd-Chiari syndrome; HVC: Hepatic vena cava; IVC: Inferior vena cava.

Differentiation between classical and HVC-BCS is important because it dictates what constitutes comprehensive and appropriate diagnostic strategies. Given the likelihood of multiple pro-thrombotic risk factors contributing to the development of classical BCS, recommendations for extensive routine work-up for multiple possible etiologies include testing for MPN; JAK2V617F mutation screening for MPN<sup>[42,45]</sup>; continued monitoring of JAK2-mutation-positive-patients for occult MPN<sup>[5,9,24,31]</sup>; further testing for TET2 mutation when the JAK2 screening is negative<sup>[32]</sup>; FVL mutation<sup>[28]</sup>; PT 20210A mutation; protein C and S deficiencies; AT deficiencies; PAI-1 and MTHFR C677T mutations<sup>[24]</sup>. Since more than one thrombophilic condition often manifests in classical BCS patients, such an extensive work-up is appropriate, but recent data continues to suggest that those same recommendations may not be appropriate for HVC-BCS patients<sup>[24]</sup>. For instance, screening for the JAK2V617F mutation is important for classical BCS patients because it has been reported to be a better diagnostic test for MPN when compared to traditional hematologic tests<sup>[42]</sup>. The JAK2V617F mutation has consistently been found in a significant number of "idiopathic" cases of classical BCS (although this is not observed in "idiopathic" HVC-BCS). In a study of 41 classical BCS patients from England, the JAK2V617F mutation was detected in 58.5% of idiopathic BCS cases<sup>[32]</sup>. Furthermore, 93% of the patients who later developed latent MPN were positive for the mutation suggesting that the JAK2V617F mutation is a highly sensitive marker to detect overt or covert MPN<sup>[33]</sup>. Given the possible geographic distribution of classical and HVC-BCS in regions with limited healthcare resources, a clear delineation of standard of care would benefit patients and providers alike. Historically, it has been speculated that there is association between lower standards of living and HVC-BCS. However, a recent prospective study including 53 consecutive BCS patients from Western India found no association between socioeconomic status and location of hepatic venous outflow obstruction although, a correlation between living in mud houses and IVC membranous obstruction was observed<sup>[28]</sup>. Therefore, according to this review, balancing the costs of diagnostic work-up for numerous potential genetic or acquired pro-thrombotic factors

with the actual benefit the patient may gain should be BCS-type specific.

Treatment and prognosis of BCS depends on a few key factors: Acuity and severity of the symptoms, location and the extent of the obstruction, and etiology of the obstruction<sup>[24]</sup>. While anticoagulation (initially with heparin and chronically with warfarin) is the initial treatment of choice for both classical BCS and HVC-BCS patients<sup>[45]</sup>, the expected response and course of therapy differs dramatically. Classical BCS patients often present with acute thrombosis of the hepatic veins. This rapid blockage of hepatic venous outflow precludes the ability to adapt *via* the development of collateral circulation. It is not surprising then that acute fulminant liver failure (with its sequelae) is more common among classical BCS patients, thus requiring shunt operations and liver transplantations more frequently than in HVC-BCS patients<sup>[13]</sup>. In contrast, HVC-BCS patients generally present with chronic symptoms that may lead to the transformation of an old thrombus into a fibrous, membranous obstruction<sup>[7,25]</sup>. Depending on the thickness and the extent of the obstruction, early interventional therapy (most commonly PTA with or without stent deployment), is very effective and thus more commonly utilized among HVC-BCS patients<sup>[13,46]</sup>. The thrombotic nature of obstruction observed in classical BCS may explain why these obstructions are more susceptible and responsive to medical management (namely anticoagulation) alone. As noted in two long-term follow up studies by Perelló *et al.*<sup>[40]</sup> and Darwish Murad *et al.*<sup>[24]</sup> (with median follow-ups of 58 and 17 mo respectively) of predominantly classical BCS patients, 33%-44% of patients that were maintained on medical management alone had good outcomes: 100% and 44% (at 12 mo), respectively. In both studies, very few classical BCS patients (5%-9%) required percutaneous recanalization. In HVC-BCS patients, the role of anticoagulation is often adjunctive and temporary; the use of warfarin before angioplasty can improve outcomes in patients with IVC obstruction<sup>[47]</sup>. Few HVC-BCS patients are managed with medical management alone because of previously reported poor outcomes<sup>[38]</sup>. In terms of the pathophysiology, Simonetto *et al.*<sup>[48]</sup> recently used a murine model to demonstrate that hepatic venous outflow obstruction as seen in congestive heart failure or veno-occlusive disease led to liver fibrosis not *via* an inflammatory pathway, but *via* sinusoidal thrombosis and mechanical strain, while also showing that anticoagulation may have a beneficial effect in decreasing fibrosis. This aids our understanding of the mechanism by which BCS and HVC-BCS can result in fibrosis, and emphasizes the need for relief of obstruction for proper management. Given the different presentations and treatment courses of the two entities, it would be relevant to further study the pathophysiology of these conditions to better optimize management.

Factors that contribute poor prognosis in classical BCS include: Increasing age, cirrhosis at the time of diagnosis, chronic kidney disease, and portal vein

thrombosis<sup>[25,38]</sup>. The Child-Pugh and MELD scores also play an unclear role in terms of practical management, while asymptomatic patients generally have better prognoses<sup>[45,49]</sup>. For HVC-BCS patients, factors that contribute to poor prognosis include the development of cirrhosis and HCC. Recent studies have suggested that the risk of developing HCC in HVC-BCS patients (unlike classical BCS patients) is directly attributable to the disease vs Hepatitis B or C infections<sup>[7]</sup>. Furthermore, the incidence of developing HCC in HVC-BCS patients is similar to those of cirrhotic patients<sup>[50,51]</sup>. These findings suggest that HVC-BCS patients, unlike classic BCS patients, should be routinely monitored for the development of HCC. Specific interventions to address and reduce the high pressure gradient in BCS patients may reduce the risk of HCC development.

In conclusion, clarification in the terminology describing hepatic venous outflow obstruction would enable both clinicians and investigators to identify patients with comparable signs and symptoms, thus enabling the execution of sound (randomized and controlled) and separate research studies on pathogenesis, therapy, and prognosis of what seems to be two different etiologies of Budd-Chiari syndrome. As summarized in this review, recent studies continue to support that classical and HVC-BCS have distinct demographics, characteristics, etiologies, therapeutic strategies, and prognoses. To address gaps in knowledge within classical BCS and HVC-BCS patients, these differences should be acknowledged and future research should be performed on these two conditions separately.

## COMMENTS

### Background

Budd-Chiari syndrome (BCS) encompasses a wide array of symptoms that are caused by hepatic venous outflow tract obstruction and has been known by many different names. While reviewing the recent literature, this paper delineates the difference between primary hepatic venous thrombosis and thrombosis of the inferior vena cava (IVC), which have both previously been referred to as BCS.

### Research frontiers

With the influx of new studies examining the wide spectrum of BCS, there has been a growing argument for the separation of primary hepatic venous thrombosis (classical BCS) and thrombosis of the IVC at the level of the IVC (hepatic vena cava-BCS) given the difference in their etiology and management.

### Innovations and breakthroughs

This paper supports the clarification of terminology used to describe hepatic venous outflow obstruction, which will help guide future research and allow for more specific treatment modalities for this condition.

### Applications

The evidence presented helps clinicians to understand the difference in etiologies of this syndrome and their influence in the management of the separate entities of this condition.

### Terminology

Classical BCS refers to primary hepatic venous thrombosis. HVC-BCS refers to thrombosis of the IVC at the level of the IVC.

# Peer-review

This review is well organized and comprehensive, has a good clinical message about BCS, and should be of great interest to the readers.

*Thomsen KL, Møller HJ, Graversen JH, Magnusson NE, Moestrup SK, Vilstrup H, Grønbaek H*

**Clinical Trials Study**

- 731** Therapeutic usability of two different fiducial gold markers for robotic stereotactic radiosurgery of liver malignancies: Pilot study  
*Marsico M, Gabbani T, Livi L, Biagini MR, Galli A*

**Prospective Study**

- 739** Circulating insulin-like growth factor-binding protein 3 as prognostic biomarker in liver cirrhosis  
*Correa CG, Colombo BS, Ronsoni MF, Soares e Silva PE, Fayad L, Silva TE, Wildner LM, Bazzo ML, Dantas-Correa EB, Narciso-Schiavon JL, Schiavon LL*

**ABOUT COVER**

Editorial Board Member of *World Journal of Hepatology*, Leonardo L Schiavon, MD, PhD, Associate Professor, Department of Internal Medicine, Federal University of Santa Catarina, Florianópolis, Santa Catarina 88051150, Brazil

**AIM AND SCOPE**

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

**INDEXING/  
ABSTRACTING**

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

## Abstract

Therapeutic management of hepatocellular carcinoma (HCC) is quite complex owing to the underlying cirrhosis and portal vein hypertension. Different scores or classification systems based on liver function and tumoral stages have been published in the recent years. If none of them is currently "universally" recognized, the Barcelona Clinic Liver Cancer (BCLC) staging system has become the reference classification system in Western countries. Based on a robust treatment algorithm associated with stage stratification, it relies on a high level of evidence. However, BCLC stage B and C HCC include a broad spectrum of tumors but are only matched with a single therapeutic option. Some experts have thus suggested to extend the indications for surgery or for transarterial chemoembolization. In clinical practice, many patients are already treated beyond the scope of recommendations. Additional alternative prognostic scores that could be applied to any therapeutic modality have been recently proposed. They could represent complementary tools to the BCLC staging system and improve the stratification of HCC patients enrolled in clinical trials, as illustrated by the NIACE score. Prospective studies are needed to compare these scores and refine their role in the decision making process.

**Key words:** Scoring system; Hepatocellular carcinoma; Barcelona Clinic Liver Cancer staging system; NIACE; Transarterial chemoembolization

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Different scores or classification systems have been proposed to refine hepatocellular carcinoma prognosis and better guide medical treatment. The Barcelona Clinic Liver Cancer (BCLC) system has become the reference classification in Western countries. Its treatment algorithm is based on randomized studies, but only offers one recommendation for BCLC stages B and C, whereas they include a broad spectrum of tumors. In clinical practice, many patients are treated out of the scope of these recommendations. In this context, alternative scores or classifications, which have been opposed for a long time, could be complementary tools for the benefit of the treatment.

Usefulness of staging systems and prognostic scores for hepatocellular carcinoma treatments. *World J Hepatol* 2016; 8(17): 703-715 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i17/703.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i17.703>

## INTRODUCTION

Most hepatocellular carcinomas (HCC) develop upon chronic diseases of the liver, mainly B or C viral hepatitis. HCC is a frequent and serious cancer, often diagnosed at an inoperable stage<sup>[1]</sup>. It is singular as its prognosis not only relies on the tumor characteristics but also on the underlying liver disease, frequently at a cirrhotic stage. The tumor-node-metastasis (TNM) classification of solid tumors failed to impose itself as the reference system for such a dual pathology, despite its recognized prognostic value even for non-operated tumors<sup>[2]</sup>. In order to refine the prognosis and provide better medical care, different scores or classifications originating from Asian or Western countries have been published recently. Most of them use regression models based on the prognostic variables of the studied populations. If they all share common parameters including liver function, tumor characteristics, age-related clinical consequences, comorbidities or cirrhosis (Figure 1), there is no universally recognized score or classification to date.

In the first part, we will focus on the main scores and classification systems published in the recent years, following a chronological order and revealing the differences between Western and Asian countries, the corresponding affected populations, treatment modalities and recommendations being distinct. The second part highlights the complementarity between the two systems in the decision making process (excluding graft), as successively exemplified by the sorafenib,

the transarterial chemoembolization (TACE), the radio-frequency ablation (RFA) and the surgical resection treatments.

## HCC PROGNOSIS: SCORES OR CLASSIFICATIONS?

The OKUDA score, published in the eighties, was the first to combine tumor-associated parameters (more vs less than 50% of invaded parenchyma) and liver function (ascites, albumin, bilirubin) (Tables 1 and 2). It classifies patients into three stages [lowly ( I ), moderately ( II ) or highly advanced ( III )] with different outcomes, depending on their number of positive variables (0 vs 1-2 vs 3-4, respectively). This score was initially validated on a population of 850 patients, either non-treated or treated according to the modalities applicable at that time (surgery, intra-arterial or systemic chemotherapy, arterial embolization)<sup>[3]</sup>. Although approximative and hardly differentiating the less advanced patients (e.g., the median survival of stage I patients was 11.5 mo independently of the treatment vs 25.6 mo when operated), this score has been widely used.

Published in the late nineties, the Italian Cancer of the Liver Italian Program (CLIP) score was calculated from the prognostic values of 435 patients originating from 16 centers (Tables 1 and 2)<sup>[4]</sup>. It includes other tumor-linked parameters such as portal vein thrombosis or alpha-fetoprotein (AFP) serum levels and better estimates the liver function using the Child-Pugh score. Easy to calculate (4 variables to add), it is well correlated with survival (CLIP 0, 1, 2, 3, 4, 5-6: 42.5 vs 32 vs 16.5 vs 4.5 vs 2.5 vs 1.0 mo). The CLIP score was first assessed on a prospective cohort<sup>[5,6]</sup> and subsequently validated on Asian cohorts<sup>[7]</sup>. Still recently ranked first for its ability to predict survival<sup>[8]</sup>, it was criticized for its lack of treatment offer, approximation in tumor morphology and extension, for the absence of clinical status consideration and its inability to classify intermediate stages. Another issue is that studies evaluating the CLIP system mainly included patients with scores only ranging from 0 to 2<sup>[7-9]</sup>.

French speaking teams have created the GRETCH score in 1999. Quite similar to the CLIP, it further includes the patients' overall condition but lacks tumor morphology information<sup>[10]</sup>. Also determined from a multivariate analysis including 761 patients (mainly non-treated) from 24 centers, it identifies 3 different groups (A: 0, B: 1 to 5 and C: 6 to 11 points) with distinct prognosis [overall survival after a year: A (72%), B (34%), C (7%), respectively]. Less evaluated than the CLIP, it faces the same limitations.

The BCLC classification was published at the same time<sup>[11]</sup>. Differently built as it is not based on a regression model but results from the combination of different studies, it distinguishes 4 different stages [A: (very) early, B: intermediate, C: advanced, D: terminal] with different prognosis, according to the liver function, the

extent of the tumor and its consequences (Figure 2). As opposed to the previous scores, the early stages are well defined according to the number and size of nodules, the

associated comorbidities and the portal vein pressure. The BCLC staging system was assessed on Western and Asian cohorts<sup>[12,13]</sup> and demonstrated a better ability to predict survival than most other scores<sup>[9,14]</sup>. This classification has imposed itself from its practical aspect and for being the only one linked to a treatment algorithm relying on a high level of evidence for each modality. Endorsed by both the European Associations for the Study of the Liver (EASL)<sup>[15]</sup> and the American Associations for the Study of the Liver (AASLD)<sup>[16]</sup>, it has become the reference classification in Western countries and is being used in day-to-day practice and clinical trials.

However, BCLC is not the reference classification in Asia, notably as HCC treatment modalities differ according to the countries (*e.g.*, external radiotherapy, intra-arterial and systemic chemotherapy or TACE being indicated for advanced HCC despite a low level of evidence<sup>[17]</sup>). Such recommendations are based on studies but, as opposed to the BCLC, also rely on personal experience, experts advice and consensus conferences. Alternative scores or classifications have thus been proposed.

The Japan Integrated Staging (JIS) score was published in 2003 (Table 3)<sup>[18]</sup>. Also easy to calculate, it associates the Child-Pugh score and the Japanese TNM,

**Figure 2** Barcelona Clinic Liver Cancer system. HCC: Hepatocellular carcinoma; PS: Performance status; TACE: Transarterial chemoembolization.

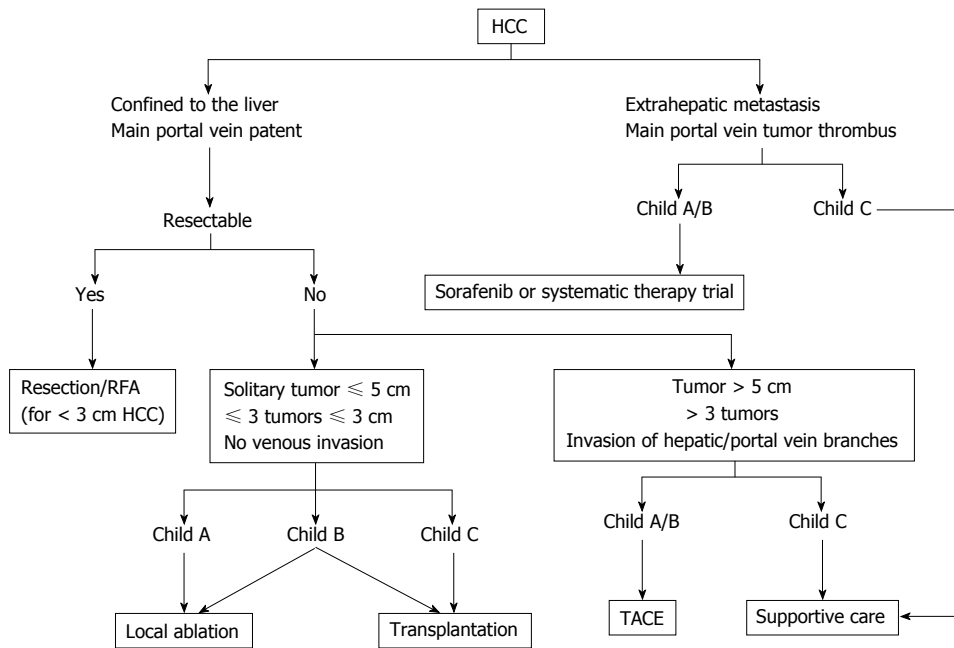

Table 3 Definitions of the c-Japan Integrated Staging score and the biomarker combined Japan Integrated Staging score

which is based on three parameters (vascular invasion, unique vs multiple nodules, diameter  $\leq$  vs  $>$  20 mm) determined from a population of 13772 operated patients. It defines six groups with different prognosis (excluding JIS 4-5). This score has demonstrated a better ability to predict survival than the CLIP and was further improved a few years later with the modified-JIS<sup>[19]</sup>, in which the encephalopathy item is replaced by the indocyanine green clearance, due to an early HCC screening in Japan and a preferred surgical orientation. In 2008, the JIS score became the biomarker combined

JIS with the inclusion of three HCC serum markers [AFP, AFP-L3 (AFP-Lens culinaris agglutinin-reactive) and des-gamma-carboxy prothrombin], which allowed better survival predictions (Table 3)<sup>[20]</sup>. However, two of those markers are not frequently used in Western countries where HCC is also often being diagnosed at more advanced stages. Thus, this score, without treatment guidelines, has not been evaluated on patients from Western countries.

The Taipei Integrated Scoring system (TIS) was published in 2010<sup>[21]</sup> arising from the lack of a reference classification and the opposite results from studies regarding the performance of classification systems. TIS is a point scoring system combining AFP levels (< 400 vs > 400 ng/mL: 0 vs 1 point), Child-Pugh score (A, B and C : 0, 1 and 2 points, respectively) and the sum of the volume of each tumor (total tumor volume), calculated from the following formulae:  $[(4/3) \times 3.14 \times (\text{radius of tumor in cm})^3]$ , and which defines 4 different groups (< 50 cm<sup>3</sup>, 50-250 cm<sup>3</sup>, 250-500 cm<sup>3</sup>, > 500 cm<sup>3</sup>: 0, 1, 2 or 3 points, respectively). From a cohort of 2030 patients, mainly with viral hepatitis (hepatitis B virus 51%, hepatitis C virus 27%), the score identified six distinct prognostic groups, with a score evolution inversely correlated to survival. The predictive ability of the TIS score was better than the JIS and the BCLC for the whole cohort, independently of the treatment modality (curative or palliative), but not as good as the CLIP for the 936 patients treated with curative intent.

**Figure 3** Asian Pacific Association for the Study of the Liver guidelines on the treatment algorithm for hepatocellular carcinoma. HCC: Hepatocellular carcinoma; TACE: Transarterial chemoembolization; RFA: Radiofrequency ablation.

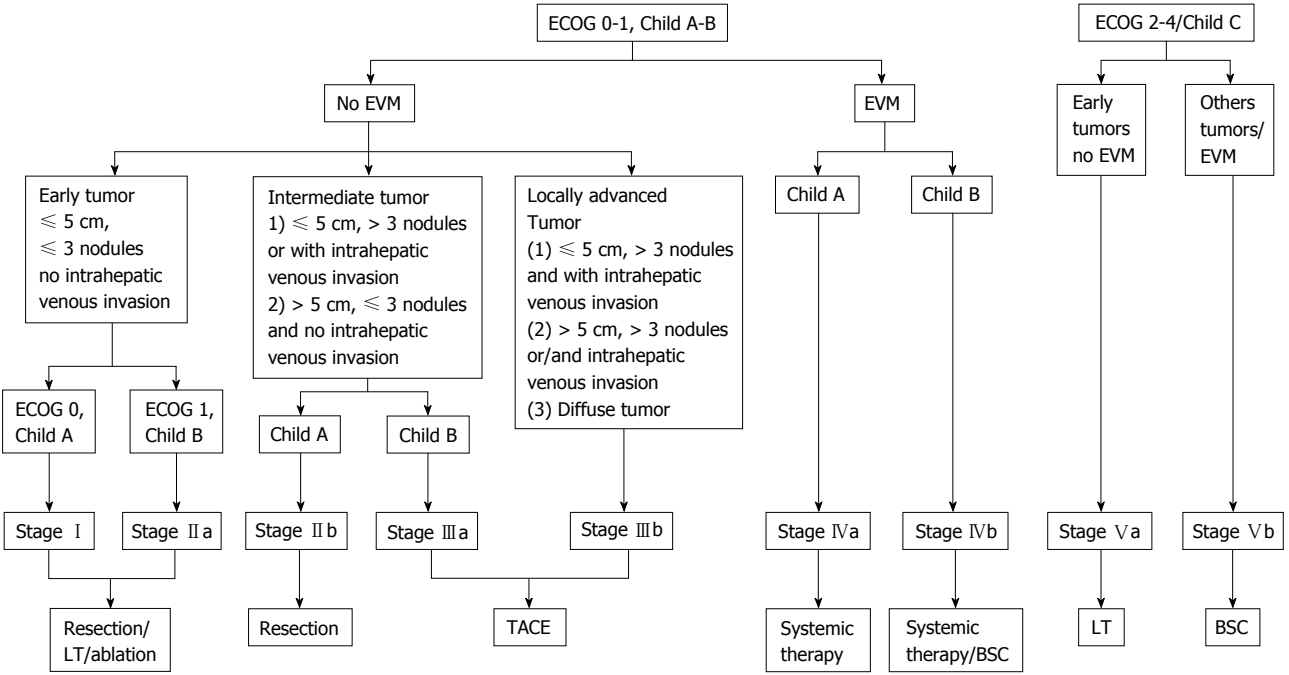

Vascular invasion that was observed in 36.7% of the patients is taken into account in the CLIP but not in the TIS, which probably participates in this discrepancy. Again, this score appears promising, but lacks a linkage to any treatment decision choice and has not been validated on any Western country patient.

In 2011, an Asian experts meeting has suggested to adopt a common classification and common recommendations. TACE was then proposed for HCC with limited vascular invasion, despite a low level of evidence (Figure 3)<sup>[17]</sup>. The competing Hong Kong Liver Cancer (HKLC) classification, which is close to the BCLC system, was published in 2014<sup>[22]</sup>. Built from a population of 3856 patients (median age: 58 years old), mainly affected by viral hepatitis B, with Child-Pugh A scores (73%), it identifies five groups and nine sub-groups to further refine the prognosis (Figure 4). The associated treatment algorithm recommended surgery at more advanced stages and subsequently increased survival according to the authors. However, its prognostic value was comparable to the BCLC system for a European cohort of HCC linked to viral hepatitis C or alcohol, the II a/II b, IIIb/IVa, IVb/Vb subgroups presenting similar survival<sup>[23]</sup>, which limits the impact of such a stratification within this population. A prospective study is currently on-going to further evaluate this score.

Overall, the BCLC classification has become the reference in Western countries and has replaced the other prognostic scores. Limitations have however been highlighted since several years. The intermediate BCLC B stage, which gathers multifocal tumors lacking vascular invasion and excludes unique and large HCC, now part of the BCLC A group in newer version of the BCLC classification<sup>[24]</sup>, remains heterogeneous<sup>[25]</sup>. Thus, a diffuse multinodular HCC or four nodules of one

centimeter in size within the same lobe are categorized within the same BCLC B group, and only a single therapeutic option is offered (*i.e.*, chemoembolization). Advanced (BCLC C) stages encompass a broad spectrum of tumors, including cancers with or without symptoms, metastatic or locally advanced diseases, eventually associated with portal thrombosis, nodular or infiltrating tumors, uni- or multi-nodular tumors, associated with Child-Pugh A or B grade, which are, again, only associated with a single treatment (sorafenib)<sup>[24]</sup>. It has thus been suggested to extend the indication for surgery<sup>[26-28]</sup> or chemoembolization to some advanced stages<sup>[29,30]</sup>. Stage C HCC were defined using a population limited to 102 patients<sup>[31]</sup>. Furthermore, comparative studies have shown lower prognostic ability for the BCLC than the CLIP score regarding advanced HCC<sup>[32-34]</sup>, and several studies have suggested a possible stratification for the BCLC C HCC<sup>[35-37]</sup>. For example, Yau *et al.*<sup>[36]</sup> have proposed a new score called Advanced Liver Cancer Prognostic System (ALCPS), separating 3 groups according to their survival after 3 mo, and aiming at improving patients selection before their enrollment into clinical trials (Table 4). However, the ALCPS score is too complex for daily clinical practice as it includes eleven variables with different coefficients, as is the Chinese University Prognostic Index score<sup>[37]</sup>.

Conversely, the recently published NIACE score<sup>[38]</sup> (Table 5) was determined from a population of advanced HCC and validated using an external Asian cohort, independently of the BCLC stage<sup>[39]</sup>. Easy to calculate and well correlated to survival, it distinguishes 2 subgroups with different prognosis within BCLC stage C patients. Advanced HCC are classified according to their morphology as infiltrating or diffuse (hardly delimited lesion, with a heterogeneous enhancement, more easily

CLIP	87.2785	< 0.0001	430.3872	< 0.0001	10749.848	0.716 (0.687-0.746)

BCLC: Barcelona Clinic Liver Cancer; CLIP: Cancer of the Liver Italian Program; HKLC: Hong Kong Liver Cancer; LR: Likelihood ratio; LT:  $\chi^2$  linear trend test.

**Figure 5** Evolution of the median overall survival according to the NIACE score in Barcelona Clinic Liver Cancer stage C patients from a French multicenter study, treated by sorafenib (black bars center 2, grey bars center 3, white bars center 4)<sup>[38]</sup>. BCLC: Barcelona Clinic Liver Cancer.

CLIP 0, 1, 2 and 3 groups ( $P < 0.0001$ ). As opposed to the HKLC, when applied to the various HKLC groups with similar survival (*i.e.*, II a/II b, IIIb/IVa, IVb/Vb), the NIACE score highlighted 2 different prognosis sub-groups using a threshold value of 3 ( $P < 0.0001$ ). The same results were obtained when investigating the HKLC I group using a threshold value of 1 ( $P < 0.0001$ )<sup>[45]</sup>.

In conclusion, the use of additional prognostic scores improves the stratification of HCC selected according to the BCLC system.

## HCC CLASSIFICATION AND PROGNOSTIC SCORES: A USEFUL COMPLEMENTARITY FOR TREATMENT CHOICE

### Prognostic scores benefit in HCC treatment: Before sorafenib

Sorafenib is recommended for BCLC stage C HCC<sup>[46,47]</sup> and is also a possible alternative for some BCLC stage B HCC being either progressive or confronted with chemoembolization contraindication<sup>[48]</sup>. The NIACE score allows to further stratify the BCLC stage C patients

treated with sorafenib (Figure 5), by separating two distinct groups with different survival using a threshold value of 3<sup>[38]</sup>. The survival of patients with a NIACE score  $> 3$  is limited to around 5.0 mo, despite a median treatment duration of 2 mo. Thus, this population does not seem to really benefit from the treatment and the NIACE score could be helpful in the treatment choice process or even earlier, to better classify patients before their enrollment into clinical trials.

### Prognostic scores benefit in HCC treatment: Before chemoembolization

As chemoembolization is mainly recommended for intermediate BCLC stage B HCC<sup>[24]</sup>, the usefulness of any additional prognostic score for such cases appears limited to some experts. However, if TACE remains the main treatment modality in most countries confronted with this disease<sup>[1]</sup>, it is controversial. Its validation relies on two randomized studies with limited patients groups, mainly including intermediate and advanced HCC, and each offering a different treatment option<sup>[49,50]</sup>. Metadata analyses show contradictory results<sup>[51,52]</sup> and, despite the improvement of the selection criteria, the radiological response (according to the EASL or the mRECIST criteria)<sup>[53,54]</sup>, the existing contraindications<sup>[55]</sup>

**Table 7** Prognostic scores before the first transarterial chemoembolization

HAP (0 to 4 points)		NIACE (0 to 7 points)		STATE
Before the first TACE				
Albumin < 36 g/dL	1 point	≥ 3 nodules	1 point	Albumin (g/L)
Bilirubin > 17 mcmol/L	1 point	infiltrative HCC <i>vs</i> nodular HCC	1.5 points	-12 (tumour load exceeding the up-to-7 criteria)
			0	
AFP > 400 ng/mL	1 point	AFP ≥ 200 ng/mL	1.5 points	
		Child-Pugh A <i>vs</i> Child-Pugh B	0	
			1.5 points	
Size of dominant tumour > 70 mm	1 point	ECOG PS ≥ 1	1.5 points	-12 (if CRP ≥ 1 mg/dL)
No chemoembolization				
≥ 2 points		> 3 points		< 18 points

HAP: Hepatoma arterial-embolisation prognostic; AFP: Alpha-fetoprotein; TACE: Transarterial chemoembolization; HCC: Hepatocellular carcinoma; ECOG: Eastern Cooperative Oncology Group; PS: Performance status; CRP: C reactive protein; STATE: Selection for transarterial chemoembolisation treatment.

**Figure 6** Evolution of the median overall survival according to the NIACE score in hepatocellular carcinoma patients from a French multicenter study treated by transarterial chemoembolization (grey bars center 1, black bars center 2)<sup>[60]</sup>. TACE: Transarterial chemoembolization.

or treatment termination criteria<sup>[56]</sup>, there is still no consensus regarding the treatment strategy (on-demand or sequential), the number of treatments before reassessment<sup>[57]</sup>, the overall aim (stability or response)<sup>[55,56]</sup> or concerning the TACE mode (using conventional techniques or calibrated drug-eluting beads). An additional score could thus facilitate the treatment strategy choice.

### Before the first treatment

Several scores have been proposed recently to improve candidate patient selection (Table 7), as TACE is a potentially toxic treatment, with limited survival benefit. Among these pre-therapeutic scores, the Hepatoma Arterial-embolisation Prognostic (HAP) and the selection for transarterial chemoembolisation treatment (STATE) scores were determined from the prognostic variables of around a hundred of BCLC stage A, B (HAP, STATE) or even C (HAP) patients treated by TACE<sup>[58,59]</sup>. The NIACE score was also evaluated on two cohorts adding up 321 BCLC A, B or sometimes C (with distal portal vein thrombosis) patients treated by TACE. Using a threshold value of 3, the NIACE score identified two

groups presenting a significantly different survival (NIACE ≤ 3: 27 mo (24-31) *vs* NIACE > 3: 7 mo (6-10),  $P < 0.0001$ ), even without any stage C patients (Figure 6)<sup>[60]</sup>. It also separated two subgroups with distinct prognosis from an Asian cohort of patients treated by TACE<sup>[39]</sup>, as opposed to the HAP score which failed to prove its ability to select all the “good” candidates for TACE from a multicenter European cohort (with similar survival between the subgroups)<sup>[61]</sup>. Such a result could be anticipated as the same rating (1 point) is attributed to each variable and only HCC > 70 mm are taken into account, whereas the efficiency of the TACE treatment relies on the size (generally < 50 mm) and the number of nodules. The more recent STATE score, which mainly focuses on multinodular (BCLC B) HCC, still needs to be evaluated. The list presented here is not exhaustive and some relatively new scores now include indocyanine green clearance to better evaluate the liver function before TACE<sup>[29]</sup>, but often at the expense of simplicity, which should remain a priority.

The continuation of a TACE treatment is determined by the radiological response (which is correlated to

**Table 8** Pronostic scores before retreatment with transarterial chemoembolization

ART (0 to 8 points)		ABCR (-3 to 6 points)	
Before the second, the third TACE.....			
No radiological response	1 point	AFP < 200 ng/mL	0
		AFP ≥ 200 ng/mL	1 point
AST increased > 25%	4 points	BCLC A/B/C	0/2/3 points
Child-Pugh increased: 1 point	1.5 points	Child-Pugh increased ≥ 2 points	2 points
Increased: ≥ 2 points	3 points	Radiological response	-3 points
No chemoembolization			
ART ≥ 2.5 points		ABCR > 2 points	

TACE: Transarterial chemoembolization; ART: Assessment for retreatment with TACE; AST: Aspartate aminotransferase; AFP: Alpha-fetoprotein; BCLC: Barcelona Clinic Liver Cancer.

survival after TACE<sup>[53]</sup>, a decrease in AFP levels and the impact of the treatment on the liver function.

**After the first TACE:** Two scores easy to calculate were proposed to improve the selection of patients before repeating the treatment: The Assessment for Retreatment with TACE (ART) and the ABCR scores, both defined using regression models<sup>[62,63]</sup>. The ART score associates its higher coefficient with a possible increase in ASAT levels (4 points), the lower being associated with the radiological response (1 point). It is recommended not to repeat the treatment in case of a score worsening ≥ 2.5 points (Table 8). Conversely, the ABCR system assigns a higher coefficient to the radiological response (-3 points), which is correlated to survival after TACE and to the initial stage of the disease (BCLC A/B/C: 0/2/3 points). The associated threshold value is a score worsening > 2 points. Both scores are usable after the second treatment. From a European multicenter cohort, the ART score calculated before the second or the third TACE failed to orientate the treatment option for all the patients<sup>[61,63]</sup>. If, unlike the ABCR, it did discriminate two different prognosis subgroups, the evolution of the ART score was not correlated with survival. As expected, patients with an ART score of 1 (*i.e.*, no radiological response) presented a lower survival than the ART 4 (ASAT levels increase > 25%) patients. Among the ABCR score limitations stands the possible absence of radiological response after the first TACE, which affects almost 25% of the "late responders", depending on the series<sup>[64]</sup>. The score being contributory after the second TACE, it is recommended to repeat the treatment in the absence of obvious progression and in case of worsening hepatic function.

The prognostic ability of the ABCR score was higher than the HAP and ART systems on both Western<sup>[65]</sup> and Asian cohorts<sup>[66]</sup>.

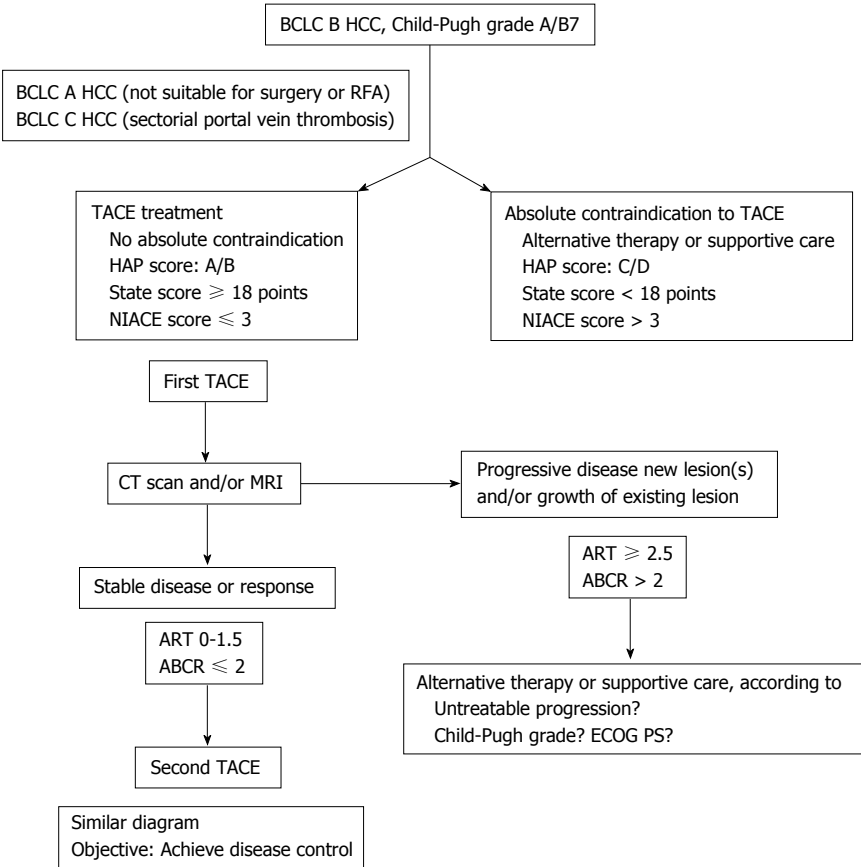

Overall, these pre-chemoembolization scores are not able to embrace all the patients or situations and cannot replace a multidisciplinary meeting. However, owing to the high number of patients treated following this modality, the heterogeneity of HCC and day-to-day practices, such scores could help in the therapy decision making process (Figure 7).

### Prognostic scores benefit in HCC treatment: Before surgical resection or radiofrequency

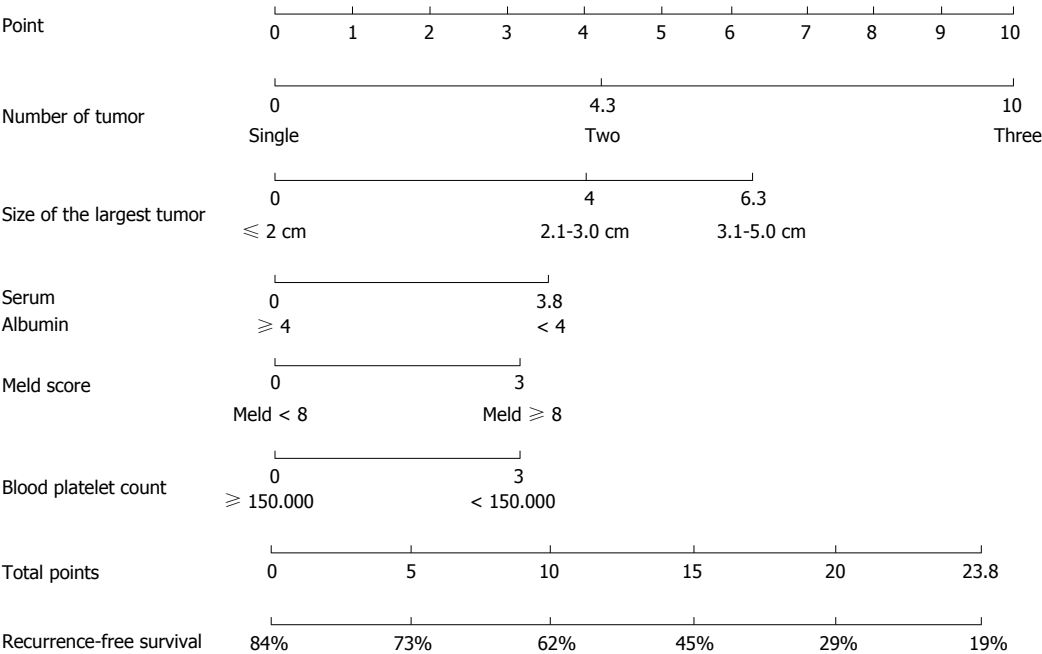

Surgical resection and radiofrequency ablation are curative treatments for HCC. In such cases, a score is not meant to exclude patients from the treatment when they meet the Barcelona criteria, early (BCLC A) stages being more homogeneous (single nodule or 3 nodules ≤ 3 cm), but to further evaluate their prognosis (overall survival and recurrence), in the prospect of a possible complementary treatment. This is illustrated by the nomogram recently proposed by Liu *et al.*<sup>[67]</sup> which orientates stage A HCC towards surgery or RFA according to the risk of recurrence (Figure 8). However, some experts have proposed to extend the indication for surgery beyond the Barcelona criteria to some intermediate or advanced HCC, which are more heterogeneous<sup>[27]</sup>. Despite some interesting results, only a proper randomized comparative study could address this question using a prognostic score to improve patient classification.

The NIACE score was tested on two French cohorts, both including around one hundred BCLC A/B and even C (single nodule with segmental portal vein thrombosis or above) HCC patients treated by surgery, thus beyond the scope of the BCLC recommendation, but in agreement with day-to-day practice. Using the more stringent threshold value of 1, it identified two different prognosis groups regarding the median overall survival (NIACE ≤ 1: 61 mo (36-81) vs NIACE > 1: 18 mo (9-73),  $P = 0.0005$ ) and the mean time to progression (NIACE ≤ 1, 26.9 ± 16.3 mo vs NIACE > 1, 9.2 ± 9.7 mo,  $P < 0.0001$ )<sup>[68]</sup>. The score evolution was inversely correlated to survival (Figure 9). Similar results were observed using an Asian cohort comprising around one hundred BCLC A/B/C HCC patients treated by surgery<sup>[39]</sup>.

When tested on a group of BCLC A HCC patients treated by surgery, selected from a French multicenter cohort, the NIACE score also highlighted two subgroups with distinct prognosis (median OS NIACE ≤ 1: 80 (58-81) mo vs NIACE > 1: 39 (28-58) mo,  $P = 0.0011$ ), notably among patients with a single tumor exceeding 50 mm in the longest axis (median OS NIACE ≤ 1: 80 (58-80) mo vs NIACE > 1: 35 (18-58) mo,  $P = 0.0024$ )<sup>[44]</sup>.

**Figure 7** Prognostic scores designed to transarterial chemoembolization, an aid to the decision making process: In practice. BCLC: Barcelona Clinic Liver Cancer; HCC: Hepatocellular carcinoma; TACE: Transarterial chemoembolization; CT: Computed tomography; ART: Assessment for Retreatment with TACE; ECOG (PS), Eastern Cooperative Oncology Group (Performance Status); RFA: Radiofrequency ablation; HAP: Hepatoma Arterial-embolisation Prognostic; MRI: Magnetic resonance imaging.

**Figure 8** Nomogram for hepatocellular carcinoma recurrence after radiofrequency ablation<sup>[67]</sup>.

These results should be further confirmed by a prospective study but, again, an additional prognostic score could provide complementary information to the BCLC system.

### Abstract

Approximately 400 million people are chronically infected with hepatitis B virus (HBV) globally despite

the widespread immunization of HBV vaccine and the development of antiviral therapies. The immunopathogenesis of HBV infection is initiated and driven by complexed interactions between the host immune system and the virus. Host immune responses to viral particles and proteins are regarded as the main determinants of viral clearance or persistent infection and hepatocyte injury. Innate immune system is the first defending line of host preventing from virus invasion. It is acknowledged that HBV has developed active tactics to escape innate immune recognition or actively interfere with innate immune signaling pathways and induce immunosuppression, which favor their replication. HBV reduces the expression of pattern-recognition receptors in the innate immune cells in humans. Also, HBV may interrupt different parts of antiviral signaling pathways, leading to the reduced production of antiviral cytokines such as interferons that contribute to HBV immunopathogenesis. A full comprehension of the mechanisms as to how HBV inactivates various elements of the innate immune response to initiate and maintain a persistent infection can be helpful in designing new immunotherapeutic methods for preventing and eradicating the virus. In this review, we aimed to summarize different branches the innate immune targeted by HBV infection. The review paper provides evidence that multiple components of immune responses should be activated in combination with antiviral therapy to disrupt the tolerance to HBV for eliminating HBV infection.

**Key words:** Hepatitis B virus; Infection; Targets; Innate immune response; Signaling pathway

**Core tip:** The pathogenesis of hepatitis B virus (HBV) infection is initiated and driven by complicated interplays between the virus and the host immune system. HBV DNA and different HBV proteins have various effects on different arms of innate immune system. The extent of HBV replication as well as the amounts of circulating

HBV antigens and different source of HBV proteins have heterogeneous effects on innate immune responses and antiviral signaling pathways. Other factors, such as liver inflammation may also have impact on innate immune response. Multiple components of immune responses should be activated in combination with antiviral therapy to disrupt the tolerance to HBV for eliminating HBV infection.

## INTRODUCTION

Though hepatitis B virus (HBV) vaccine has been available for several decades and much progress has been made on anti-HBV therapeutics, there are still more than 350 million people chronically infected with HBV worldwide. The immunopathogenesis of HBV infection is initiated and propelled by complicated interactions between the host immune system and the virus<sup>[1]</sup>.

It is recognized that host immune responses to HBV antigens are the major determinants of HBV pathogenesis and hepatocytes damage in the liver. On the contrary, viruses also exert immune regulatory effects to favor their replication. HBV has evolved active tactics to escape innate immune recognition and induce immunosuppression<sup>[2]</sup>. This has been displayed through the fact that HBV particles and proteins can be detectable around 5 wk postinfection, after which viral loads reach a logarithmic amplification stage<sup>[3]</sup>. The reason of the lag of viral replication is that the virus manages to evade being sensed by the innate immune system in the early phase of infection when the adaptive immune system has not been fully activated. HBV genome is 3.2 kbp in length and contains four overlapping genes that encode for the nucleocapsid (precore and core), polymerase, envelope (pre S and S), and hepatitis X proteins. The abundant HBV particles and viral proteins in the circulation in chronic HBV-infected patients allow multiple interactions among the virus, its viral proteins, and the immune system. HBV DNA and different HBV proteins have various effects on different parts of host immune systems, including immune cells and signaling pathways. The extent of HBV replication as well as the amounts of circulating HBV antigens, especially surface antigen (HBsAg), leads to heterogeneous profiles of the immune response, particularly in the context of chronic infection manifested as patients' different clinical profiles<sup>[4-6]</sup>. The immune tolerance phase has the highest level of serum HBsAg and hepatitis B e antigen (HBeAg) quantitation<sup>[7]</sup>. High levels of viremia, particularly high amounts of HBsAg, not only suppress innate immune cells, including monocytes, dendritic cells (DCs), natural

killer (NK) cells, and NKT cells, through direct interaction, but also lead to exhaustion of cytotoxic T lymphocytes (CTLs) and helper T (Th) cells<sup>[8]</sup>. HBsAg mutations which enhanced the capability to avoid immune response were associated with HBV reactivation in a quite different clinical profiles<sup>[9]</sup>. Also, reduced viremia through antiviral therapy partially restores the impaired immune response<sup>[10]</sup> and the restored immune response status correlated with the levels of HBV infection parameters<sup>[11]</sup>, which indirectly demonstrated the immune suppressive effect of HBV and its proteins.

A full understanding of the mechanisms as to how the virus inactivates various components of the immune system to maintain a persistent infection can help establish a new theory for designing novel immunotherapeutic methods and aid the eradication of the virus in chronic HBV infection.

Innate immune pathways are the targets of HBV to evade host antiviral responses contributing to chronicity of infection. The components of the innate immune system targeted by HBV include pattern-recognition receptors (PRRs), DCs, NKs, NKT cells, and antiviral signaling pathways<sup>[2]</sup>. In addition to directly regulating the innate immune response, HBV also modulates the innate immunity through alteration of the expression of microRNAs (miRNAs)<sup>[12]</sup>.

### PRRs

PRRs, including toll-like receptors (TLRs), retinoic acid-inducible gene I (RIG-I) - like receptors, and NOD-like receptors (NLRs), are crucial for sensing invading pathogens, initiating innate immune responses, restricting the spread of infection, and facilitating effective adaptive immune responses<sup>[13]</sup>. The early inhibition of the innate immune response by HBV is mainly through TLR-3 and RIG-I /melanoma differentiation-associated gene 5 (MDA5) signaling pathways, which leads to decreased expression of several proinflammatory and antiviral cytokine genes<sup>[14]</sup>. In the setting of chronic HBV infection, reduced TLR expression and interference of PRRs signaling pathways lead to the impairment of host innate immune response.

### TLRs

TLRs sense pathogen-associated molecule patterns (PAMPs), including nucleic acid sequences in degraded viral particles, and activate antiviral mechanisms, including intracellular antiviral pathways, production of antiviral effector interferons (IFNs) and proinflammatory cytokines, and initiation of adaptive immunity<sup>[15]</sup>. TLR signaling pathways are important parts of the innate immune response in HBV infection. It has been demonstrated that TLR ligands could suppress HBV replication<sup>[16]</sup>. Also, the activation of TLRs plays an important part in preventing intrauterine HBV transmission<sup>[17]</sup>. Accumulating evidence has consistently shown that the expression and function of TLRs in immune cells reduced during chronic HBV infection<sup>[18]</sup>. Expressions of TLR2 mRNA and protein were remarkably reduced

in peripheral blood monocytes (PBMCs) derived from chronic hepatitis B (CHB) patients<sup>[19]</sup>.

HBV virions or proteins such as HBsAg and HBeAg may reduce TLR expression and abrogate TLR-induced antiviral activity. The inhibitory mechanisms include suppressing IFN- $\beta$  production and induction of IFN-stimulated genes (ISG) and transcription factors, such as IFN regulatory factor 3 (IRF3) and nuclear factor- $\kappa$ B (NF- $\kappa$ B)<sup>[20]</sup>. HBsAg, HBeAg, and HBV particles could inhibit the activation of nonparenchymal liver cells by TLR3 ligands<sup>[20]</sup>. Jiang *et al.*<sup>[21]</sup> demonstrated that TLR-induced the expression of IFN- $\gamma$ , ISGs, and proinflammatory cytokines in murine Kupffer cells (KCs) and liver sinusoidal endothelial cells (LSECs), and the activation of NF- $\kappa$ B, IRF3, and mitogen-activated protein kinases (MAPKs) in hepatocytes were strongly suppressed by HBsAg. TLR3-stimulated KCs and LSECs mediated T-cell activation was also suppressed by HBsAg. Visvanathan *et al.*<sup>[22]</sup> first showed that TLR2 expression on liver cells, KCs, and PBMCs significantly reduced in HBeAg-positive CHB patients compared with HBeAg-negative CHB and controls. TLR2 detects several microbial PAMPs and subsequently activates NF- $\kappa$ B in a myeloid differentiation primary response gene 88 (MyD88)-dependent manner. Therefore, decreased TLR2 expression may lead to impairment of immune responses to HBV infection<sup>[23]</sup>. In addition to directly inhibits the TLR2-mediated c-Jun N-terminal kinase/MAPK pathway, HBsAg may also induce interleukin (IL)-10 production in monocytes indirectly<sup>[24,25]</sup>. Thus, TLR2 is an important immune target of HBV infection.

Toll/IL-1 receptor (TIR) domain-containing adapter protein inducing IFN- $\beta$  (TRIF) is an important component in innate immune signaling pathways. It is one of the main intracellular adapter proteins required for TLR3 and TLR4 signaling. Ayoobi *et al.*<sup>[26]</sup> suggested that the expression of TRIF significantly decreased in PBMCs isolated from CHB patients compared with those isolated from healthy subjects. TRIF protein was also downregulated in human hepatoma cell lines and liver tissue specimens infected with HBV<sup>[27]</sup>. HBeAg interacted with TRIF-related adaptor molecule (TRAM), Mal, and TLR2 at the subcellular level, and mutated HBeAg not only may disrupt the interaction between Mal and MyD88 but also ablate homotypic TIR:TIR interaction, which is crucial for TLR-mediated signaling<sup>[28]</sup>. Furthermore, HBeAg can suppress TIR and IL-1 $\beta$ -mediated activation of the inflammatory transcription factors, such as NF- $\kappa$ B and inhibit NF- $\kappa$ B and IFN- $\beta$  promoter activity<sup>[29]</sup>. These results suggest the presence of intracellular precore protein in addition to secreted extracellular HBeAg.

Hepatitis B virus X (HBx) and polymerase (Pol) are the proteins that interfere with the PRRs pathways most frequently<sup>[2,30]</sup>. For instance, HBx reduced TRIF protein expression *via* the proteasomal pathway in a dose-dependent manner<sup>[31]</sup>. However, no direct convincing evidence indicating that HBV RNAs, DNAs and proteins are authentically recognized by TLRs is available up to date. The interplay between HBV proteins and TLRs

should be verified directly *in vivo* through further investigation<sup>[15]</sup>.

### RIG- I - MDA5 pathway

MDA5 and RIG-1 as the PRRs play important roles in viral mRNA recognition. HBx and HBV Pol are involved most frequently in the inactivation of the RIG- I pathways and ultimately impaired IFN production. HBx is a pivotally protein involved in HBV-associated liver diseases. Studies<sup>[32]</sup> indicate that HBx can interact with the mitochondrial membrane protein virus-induced signaling adapter (VISA), which is a key adapter protein downstream RIG- I and MDA5, and interrupts the association of VISA with its upstream and downstream parts. This inhibits the induction of type I IFNs through the activation of transcription factors, including NF- $\kappa$ B and IRF3. Human cell line studies<sup>[33]</sup> have also suggested that adapter protein mitochondrial antiviral signaling (MAVS) is another target for HBx. The RIG- I /MDA5 pathway and IFN- $\beta$  induction is inhibited due to degradation of MAVS promoted by HBx. A recent study<sup>[34]</sup> showed that mRNA levels of MDA5 and RIG- I dramatically decreased in CHB patients in comparison with healthy controls. However, these mRNA levels have little alteration among CHB patients with different states of HBeAg and HBV DNA viral loads. Moreover, RIG- I could also offset the interaction of HBV Pol with the 5'- $\epsilon$  region, which suggest that RIG- I dually actions as an HBV sensor activating innate signaling and counteracting viral Pol in human liver cells<sup>[35]</sup>. Therefore, the mechanism underlying the downregulation of MDA5 may attribute to several reasons in patients with CHB<sup>[34]</sup>. DDX3, an HBV Pol binding protein, belonging to the DEAD-box RNA helicase family, is associated with mRNA metabolism. HBV Pol blocks PRRs signaling *via* interaction with DDX3<sup>[36]</sup>. This may explain the mechanism of how HBV evading the innate immune response.

In contrast, Luangsay *et al.*<sup>[14]</sup> found that the early inhibition of dsRNA-mediated response resulted from the HBV inoculum, but not HBsAg or HBeAg itself. Whereas, the significance of these results in the human needs to be confirmed.

### DCs

DCs are key cells in the initiation of adaptive immune responses because of their ability of processing foreign antigens and presenting them to effector cells. Also, mature DCs can efficiently induce T-cell polarization to Th1 and generate HBcAg-specific CTLs<sup>[37]</sup>. A long-lasting debate exists on the functionality and phenotypes of DCs in chronic HBV infection. Several studies demonstrated that DCs functions were impairment in CHB patients, which included decreased expression of co-stimulatory molecules, defective cytokine production, and reduced allostimulatory capacity compared with healthy people<sup>[38,39]</sup>.

However, Gehring *et al.*<sup>[40]</sup> suggested that the fre-

quency and function of myeloid DCs (mDCs) and plasmacytoid DCs (pDCs) were largely intact *ex vivo* in HBV infected patients except for the reduced IFN- $\alpha$  production compared with those of healthy donor DCs. They found that reduced IFN- $\alpha$  production did not correlate with viral titer, which suggested that viral antigens had slight impact on DCs function. The major confusion about the function of DCs resulted from studies which indicated that function of healthy donor DCs was impaired exposing to various sources of HBV *in vitro*, which are in contrast to the results obtained from CHB patients. Tavakoli *et al.*<sup>[41]</sup> also demonstrated that phenotypes and functionality of circulating total DCs, mDCs, or pDCs are unaffected in chronically HBV infected patients whether experimented *ex vivo* or after *in vitro* activation and maturation. They demonstrated that isolated mDCs and pDCs from chronic HBV carriers showed the similar expression of co-stimulatory molecules and alloreactive T cell stimulation as that of the control DCs.

However, other studies showed that pDCs were the targets of HBV. Both HBV virions and purified HBsAg have immune modulatory functions and may directly contribute to the impairment of mDCs functions in chronic HBV infection<sup>[42]</sup>. HBV particles and HBsAg were capable of abrogating TLR9-induced IFN- $\alpha$  gene transcription *via* combining to TLR9-triggered pDC directly<sup>[43]</sup>. HBV not only directly interfered with pDC function, but also indirectly disturbed monocyte-pDC interaction. In addition, the ability of inducing the cytolytic activity of NK cells by TLR9-activated pDCs from CHB patients were also compromised<sup>[44]</sup>. Virus-like particles (VLPs) comprising small HBV envelope protein (HBsAgS) impaired IFN- $\alpha$  production of pDCs in response to CpG *in vitro*<sup>[45]</sup>. Op den Brouw *et al.*<sup>[42]</sup> suggested that in the presence of HBV or HBsAg, cytokine-induced maturation resulted in a more tolerogenic mDC phenotype, as demonstrated by a significantly reduced upregulation of co-stimulatory molecules and a decreased T-cell stimulatory capacity, as demonstrated by T-cell proliferation and production of IFN- $\gamma$  and IL-12. It has been shown that DCs from immune tolerant patients showed a prominently lower expression of CD80, CD86, and HLA-DR and demonstrated an injured stimulatory capacity in mixed lymphocyte reactions and decreased production of IL-12, compared with those in the inactive HBsAg carrier state. Also, no remarkable difference was observed between the indexes from inactive carrier and healthy controls<sup>[46]</sup>. Several studies<sup>[47,48]</sup> revealed that mDC frequency could return to the level of healthy donors, IL12p70 production increased, and lower expression of phenotypic molecules was restored with antiviral therapy of adefovir and lamivudine. These results indirectly demonstrated the suppressive effect of high loads of HBV particles and proteins on DCs.

Though with suppressive effect on DCs functions, HBsAg is also a component of HBV vaccine. HBsAg-pulsed DCs might promote HBV-specific immune response in CHB patients<sup>[49]</sup>. HBsAgS VLPs can deliver an

antigen to both major histocompatibility complex (MHC)-I and MHC-II in primary DCs and facilitate cytotoxic and helper T-cell priming<sup>[45]</sup>. Also, Ag-Ab immune complexes could be easily captured and taken up by DCs<sup>[50]</sup>, and could efficiently induce HBs-specific T cells. A clinical study showed that the immunity was enhanced by autologous HBsAg-activated DC-cytokine-induced killer cells as adoptive immunotherapy<sup>[51]</sup>. Martinet *et al.*<sup>[52]</sup> showed that the vaccination of Hepato-HuPBL mice with the HBc/HBs peptide-loaded pDCs induced HBV-specific T cells with specific ability of lysing the transfected hepatocytes. In addition, HBeAg might have a negative effect on the generation of DCs from bone marrow precursors<sup>[53]</sup>.

The mechanism underlying the suppressive influence of HBV and HBV proteins on the function of DCs has not been fully elucidated. Some reports indicated that HBV and HBsAg can enter the DCs and cause damage, leading to a decline in the number of DCs and functional impairment<sup>[45,54]</sup>. However, Tavakoli *et al.*<sup>[41]</sup> found that viral mRNA was not detectable by reverse transcription-polymerase chain reaction in both DC populations, which argues against viral replication in DCs.

The arguments regarding the functions and phenotypes of DCs result from the heterogeneous source of HBV antigens, variability of patients, and assay methods of DC maturation and cytokine production *in vitro* across studies<sup>[40]</sup>. In addition, liver pathology also likely affects the function of pDCs. Studies show that IFN- $\alpha$  production by pDCs is negatively correlated with the serum alanine aminotransferase (ALT) level in patients with CHB<sup>[39,43]</sup>. Furthermore, the expression of inhibitory molecule programmed death-ligand 1 (PD-1) in mDCs tended to more closely relate to ALT level than to viral load<sup>[55]</sup>.

## NK AND NKT CELLS

NK cells, the main innate immune cells, play indispensable roles in the clearance of HBV from hepatocytes. Although the numbers, subset distribution, and cytotoxic capacity of NK cells were retained, their activation and IFN- $\gamma$  and tumor necrosis factor (TNF)- $\alpha$  production, particularly of the CD56(dim) subset, were strongly hampered in patients with CHB compared with healthy controls<sup>[56]</sup>. NK cells express several kinds of stimulatory and inhibitory receptors, which interact with their respective ligands results in functional activation and suppression<sup>[57]</sup>. Activation status and surface receptor expression patterns of NK cells may be altered in HBV infection<sup>[2]</sup>. Natural killer group 2D (NKG2D) is a well-characterized activating receptor expressed on NK cells, NKT cells, and CD8(+) cytotoxic T cells, which binds to a diverse group of ligands that resemble the MHC-class I molecules. Accumulating evidence has shown that NKG2D-ligand interactions play a crucial role in the persistence of HBV infection and the development of liver injury and hepatocellular carcinoma. The expression of NKG2D ligands may be modulated post-trans-

criptionally by HBV<sup>[1]</sup>. Also, high serum HBV DNA loads upregulate the expression of inhibitory receptors such as NKG2A, but downregulate activating receptors, CD16, NKp30, NKG2D, and NKp46<sup>[56,58,59]</sup>. One study showed that the expression of NKp46 negatively correlated with the HBV DNA level and was much higher in inactive HBsAg carriers compared with active infection patients. NKp46 activation may restore NK cell cytolytic activity to HepG2 and HepG2.215 cell lines *in vitro*<sup>[59]</sup>. Furthermore, NK cell phenotype and functionality may partially be restored by viral load reduction through antiviral therapy, as shown by downregulated expression of NKG2A and improved IFN- $\gamma$  production as a result of an increased ability of CD56(dim) NK cells<sup>[56]</sup>. And the recovered function of NK cells was strongly associated with HBsAg clearance<sup>[60]</sup>. Under the combination treatment of pegylated IFN- $\alpha$ -2a and adefovir, compared with nonresponders, responders had a remarkably lower expression of NKG2A on CD56(dim) NK cells and higher CD56 (bright) TNF-related apoptosis-inducing ligand expression and IFN- $\gamma$  production at the end of the treatment. These results were not observed in HBeAg-positive patients who developed HBeAg seroconversion without HBsAg clearance<sup>[60]</sup>. The spontaneous reduction of HBV loads had similar results<sup>[61]</sup>.

In addition, HBeAg may inhibit IFN- $\gamma$  production by NK cells mediated by IL-18 in a dose-dependent manner<sup>[62]</sup>. HBV may specifically suppress pDC-induced IFN- $\gamma$  production by NK cells without affecting their cytolytic ability through pDC-NK cell cross-talk<sup>[63]</sup>. Although NK cell IFN- $\gamma$  production was impaired in response to TLR9 stimulation in CHB patients compared with controls, the upregulation of CD69 expression in response to TLR9 was maintained<sup>[64]</sup>.

NKT cells are a unique subgroup of T-cells expressing both NK cell surface marker-CD56 and a T-cell receptor CD3 - which are stimulated by lipid antigens. NK and NKT are the two cell types that are promptly activated in the early phase of HBV infection, which probably contribute to controlling the HBV invasion and allowing timely induction of adaptive immune responses<sup>[65]</sup>. While, it has demonstrated that the frequency of hepatic NKT cells from HBV transgenic mice was low and the capability of producing IFN- $\gamma$  was impaired<sup>[66]</sup>. Reports by Jiang *et al*<sup>[67]</sup> and Zhu *et al*<sup>[68]</sup> indicated that the frequency of peripheral invariant NKT (iNKT) cells is lower in patients with chronic HBV infection than in healthy subjects, and returns to normal levels during viral control with telbivudine. In patients treated with PEG-IFN- $\alpha$ , the ratio of peripheral blood NKT cells in T lymphocytes before, during, and after treatment significantly elevated in the significant-effect group compared with the effect and no-effect groups<sup>[69]</sup>. This implies that NKT cells modulate the innate immune response against HBV infection and play a major role in effective antiviral treatment.

The mechanism underlying the decrease in the number and function of circulating iNKT cells in patients with CHB remains unclear. It is believed that this

reduction is at least partially due to trafficking to the liver<sup>[70]</sup> because iNKT cells express a high level of CC chemokine receptor 5 (CCR5) and CCR6<sup>[67]</sup> which enable iNKT cells migrate toward the liver. Other mechanism may involved in the high expression of inhibitory molecules PD-1 and Tim-3, and lower the expression of CD28<sup>[66,71]</sup>. In addition, HBV-induced lipid alterations also contributed to a change in NKT cell function<sup>[72]</sup>.

## IMMUNE TARGET OF SIGNALING PATHWAYS OF THE ANTIVIRAL RESPONSE AND CYTOKINES

Recognition of viral infections by PRRs, such as TLRs and RIG- I /MDA5, activates signaling pathways and leads to the induction of inflammatory and antiviral cytokines, such as type I IFN, that limit viral replication and initiation of adaptive immunity. The expression of TLR signaling molecules, such as MyD88, IL-1 receptor-associated kinase 1 (IRAK1), and IRAK4, significantly decreased in PBMCs from CHB patients compared with healthy controls<sup>[73,74]</sup>.

HBV proteins, such as HBV Pol and HBx, could interfere with multiple sites of intracellular signaling pathways triggered by HBV infection, preventing IFN production and antiviral responses in hepatocytes<sup>[30,75]</sup>. HBV Pol can inhibit TANK-binding kinase 1 (TBK1)/IkappaB kinase-epsilon (IKKi), the effector kinases of IRF signaling. It can block IRF signaling activation mediated by TLR-3 or RIG- I recognizing dsRNA in the endosomes or in the cytosol through interaction with DDX3, a transcriptional factor of the IFN- $\beta$  promoter in human hepatoma cell lines<sup>[30,32,36]</sup>. HBV Pol mediates blockage of IFN- $\alpha$  signaling through suppressing IFN- $\alpha$ -induced signal transducers and activators of transcription 1 (STAT1) serine 727 phosphorylation and STAT1/2 nuclear accumulation<sup>[76]</sup>. Pol also affects STAT methylation through increasing protein phosphatase 2A (PP2A) expression, which inhibits protein arginine methyltransferase 1, the enzyme that catalyzes the methylation of STAT1<sup>[77]</sup>. This may be responsible for HBV resistance to PEG-IFN- $\alpha$  therapy<sup>[78]</sup>. However, HBV Pol does not interfere with STAT1 degradation and phosphorylation<sup>[79]</sup>. The cytosolic DNA sensor and key adaptor stimulator of IFN genes (STING) has been suggested to be critical in multiple foreign DNA-elicited innate immune signaling. Screening analysis demonstrated that the reverse transcriptase and the RNase H (RH) domains of HBV Pol were responsible for the inhibition of STING-stimulated IRF3 activation and IFN- $\beta$  induction<sup>[80]</sup>. One study has demonstrated that HBV Pol preferentially suppresses TNF- $\alpha$ -, TLR3- or TLR4-induced NF- $\kappa$ B signaling by inhibiting the activity of IKK complex through disrupting the association of IKK/NF- $\kappa$ B essential modulator (NEMO) with Cdc37/Hsp90 $\beta$  in hepatoma cells<sup>[81]</sup>. Therefore, in addition to its inherent catalytic function, HBV Pol has multifunctional immunomodulatory effects. It may counteract the innate

HBs: Hepatitis B surface antigen; HBe: Hepatitis B e antigen; HBx: Hepatitis B x protein; HBV Pol: Hepatitis B polymerase; TLRs: Toll-like receptors; ISG: Interferon-stimulated genes; IFN: Interferon; NF- $\kappa$ B: Nuclear factor  $\kappa$ B; KCs: Kupffer cells; LSECs: Liver sinusoidal endothelial cells; MAPKs: Mitogen-activated protein kinases; JNK: c-Jun N-terminal kinase; mDCs: Myeloid dendritic cells; pDCs: Plasmacytoid DCs; PBMCs: Peripheral blood mononuclear cells; TRAM: TRIF-related adaptor molecule; TIR: Toll/interleukin-1 receptor; RIPK2: Receptor-interacting serine/threonine protein kinase 2; TRIF: TIR domain-containing adapter protein inducing IFN- $\beta$ ; RIG-I: Retinoic acid inducible gene I; IRF: Interferon-regulatory factors; MDA5: Melanoma differentiation associated gene 5; VISA: Virus-induced signaling adapter; MAVS: Mitochondrial antiviral signaling; TBK1: TANK-binding kinase 1; IKKi: KappaB kinase-epsilon; STAT1: Signal transducers and activators of transcription 1; PP2A: Protein phosphatase 2A; STING: Stimulator of IFN genes; NK: Natural killer; NKG2D: NK group 2D; NKG2A: NK group 2A; NKT: NK T cell; CTHRC1: Collagen triple helix repeat containing 1; HBV: Hepatitis B virus; MAPK: Mitogen-activated protein kinase; NEMO: NF- $\kappa$ B essential modulator.

responses at different steps.

Similar to HBV Pol, HBx can target multiple points of signaling pathways negatively regulating type I IFN production. In addition to RIG-I, TNF receptor-associated factor 3, and TRIF, HBx also interacts with NEMO, TBK1, kinase-epsilon (IKKi), and IRF3<sup>[75]</sup>. HBx can also transactivate multiple transcription factors including NF- $\kappa$ B that regulates inflammatory-related genes. A recent report has suggested that HBx-evolutionarily conserved signaling intermediate in toll pathways interaction plays an important role in IL-1 $\beta$  induction of NF- $\kappa$ B activation<sup>[82]</sup>.

In addition to HBV Pol and HBx proteins, HBeAg may also modulate the intracellular signaling pathways. HBeAg may target receptor-interacting serine/threonine protein kinase 2 through inhibiting its expression and interacting with it<sup>[83]</sup> which may results in inactivation of NF- $\kappa$ B. Experiments indicate that collagen triple helix repeat containing 1 (CTHRC1) expressed in HBV-transfected cells facilitates HBV replication in cultured cells and BALB/c mice. On the other hand, HBV increases CTHRC1 expression, which downregulates the activity of type I IFN, the transcription of ISGs, and the phosphorylation of STAT1/2<sup>[84]</sup>.

However, some of the signaling pathways are important in restraining HBV replication. Tzeng *et al.*<sup>[85]</sup> demonstrated that not IFN- $\alpha/\beta$  receptor, RIG-I, MDA5, MyD88, NLR pyrin containing 3, caspase recruitment domain, and IL-1R but TNF- $\alpha$  is essential for HBV eradication. In the absence of TNF- $\alpha$ , or early treatment

with the soluble blocker of TNF receptor in mice leads to HBV persistence<sup>[86]</sup>. This may explain the mechanism of HBV reactivation during TNF blockage agents therapy.

In contrast to HBeAg, research has reported that the treatment of human monocyte-derived DCs with HBsAg resulted in enhanced cell surface expression of CD80, CD83, CD86, and MHC-II, and increased IL-12 p40, IL-12p70, and IL-10 production through decreasing inhibition of  $\kappa$ B $\alpha$  concentrations and MAPK phosphorylation<sup>[87]</sup>.

## CONCLUSION

The suppression of various innate immune components targeted by HBV and HBV proteins may result in virus spread and subsequent inefficient adaptive immune responses, leading to HBV persistence. However, still controversies exist regarding the effects of HBV on the functionalities and phenotypes of innate immune cells, especially DCs. The conflicting results may be due to patient diversity, divergence of antigen sources, and inconsistent assay methods. Some of the findings derived from cell line and animal models remain to be defined for the human HBV infection. Furthermore, the knowledge of the exact mechanism of action of HBV and HBV proteins on some of the sites of the complicated innate signaling pathways is lacking. The updated findings of innate immune cells, molecules and signaling pathways targeted by HBV and HBV proteins are summarized in Table 1. The present study

provides evidence that multiple components of immune responses should be activated in combination with antiviral therapy to disrupt the tolerance to HBV for eliminating HBV infection.

### Abstract

**AIM:** To study the effect of a new anti-CD163-dexamethasone conjugate targeting activated macrophages on the hepatic acute phase response in rats.

**METHODS:** Wistar rats were injected intravenous with either the CD163 targeted dexamethasone-conjugate (0.02 mg/kg) or free dexamethasone (0.02 or 1 mg/kg) 24 h prior to lipopolysaccharide (LPS) (2.5 mg/kg intraperitoneal). We measured plasma concentrations of

tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interleukin 6 (IL-6) 2 h post-LPS and liver mRNAs and serum concentrations of the rat acute phase protein  $\alpha$ -2-macroglobulin ( $\alpha$ -2-M) 24 h after LPS. Also, plasma concentrations of alanine aminotransferase and bilirubin were measured at termination of the study. Spleen weight served as an indicator of systemic steroid effects.

**RESULTS:** The conjugate halved the  $\alpha$ -2-M liver mRNA ( $3.3 \pm 0.6$  vs  $6.8 \pm 1.1$ ,  $P < 0.01$ ) and serum protein ( $201 \pm 48$   $\mu$ g/mL vs  $389 \pm 67$   $\mu$ g/mL,  $P = 0.04$ ) after LPS compared to low dose dexamethasone treated animals, while none of the free dexamethasone doses had an effect on liver mRNA or serum levels of  $\alpha$ -2-M. Also, the conjugate reduced TNF- $\alpha$  ( $7208 \pm 1977$  pg/mL vs  $21583 \pm 7117$  pg/mL,  $P = 0.03$ ) and IL-6 ( $15685 \pm 3779$  pg/mL vs  $25715 \pm 4036$  pg/mL,  $P = 0.03$ ) compared to the low dose dexamethasone. The high dose dexamethasone dose decreased the spleen weight ( $421 \pm 11$  mg vs  $465 \pm 12$  mg,  $P < 0.05$ ) compared to controls, an effect not seen in any other group.

**CONCLUSION:** Low-dose anti-CD163-dexamethasone conjugate effectively decreased the hepatic acute phase response to LPS. This indicates an anti-inflammatory potential of the conjugate *in vivo*.

**Key words:** Acute phase response; Dexamethasone; Endotoxin; Hemoglobin scavenger receptor CD163; Cytokines; Inflammation; Rats

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** We aimed to study the effect of a new anti-CD163-dexamethasone conjugate targeting activated macrophages on the hepatic acute phase response in rats. The central finding of the study was a reduction in liver mRNA and plasma levels of the acute phase protein  $\alpha$ -2-macroglobulin, and plasma tumour necrosis factor- $\alpha$  and interleukin 6 by administration of the conjugate prior to a lipopolysaccharide-induced inflammatory response. This anti-acute phase effect exceeded that of the therapeutic dexamethasone dose and did not cause systemic adverse effects. Thus, the antibody conjugate may be a potential candidate in future anti-inflammatory macrophage-directed therapy, *e.g.*, in liver diseases with Kupffer cells activation.

Thomsen KL, Møller HJ, Graversen JH, Magnusson NE, Moestrup SK, Vilstrup H, Grønbaek H. Anti-CD163-dexamethasone conjugate inhibits the acute phase response to lipopolysaccharide in rats. *World J Hepatol* 2016; 8(17): 726-730 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i17/726.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i17.726>

## INTRODUCTION

In conditions with macrophage proliferation and activation, CD163, a haemoglobin-haptoglobin scavenger

receptor expressed exclusively on monocytes and macrophages<sup>[1,2]</sup>, is up-regulated<sup>[3,4]</sup>. Following toll-like receptor activation by inflammatory stimuli like lipopolysaccharide (LPS), receptor shedding to circulation as soluble CD163 (sCD163) is increased, and within hours upregulated on the cell surface<sup>[5]</sup>. As an example, hepatic macrophages (Kupffer cells) are activated and sCD163 is increased in patients with liver cirrhosis who chronically experience some degree of endotoxemia and acute phase response<sup>[6,7]</sup> and this may be involved in the development of the serious cirrhosis complications<sup>[6,8]</sup>.

We have recently constructed a conjugate of CD163 antibody and the potent corticosteroid dexamethasone (anti-CD163mAb-dexa) specifically targeting dexamethasone to activated macrophages<sup>[9]</sup>. The conjugate reduces the LPS-stimulated cytokine release from activated macrophages *in vitro* and *in vivo* in rats and pigs<sup>[9,10]</sup>. The effect is obtained with very low concentration of dexamethasone, thereby minimizing steroid-induced systemic effects. A fifty-fold higher concentration of non-conjugated dexamethasone is needed to obtain the same anti-inflammatory response<sup>[9]</sup>.

Exposure to LPS is a standard method to induce an acute phase response with a large increase in pro-inflammatory cytokines and hepatic synthesis and release of acute phase proteins<sup>[11,12]</sup>. While the conjugate reduces the LPS-mediated cytokine response in rats it remains unknown whether it also inhibits the hepatic acute phase protein synthesis response.

To approach this issue we measured the gene expression in liver tissue and serum concentrations of the prevailing acute phase protein  $\alpha$ -2-macroglobulin ( $\alpha$ -2-M) 24 h post-LPS exposure in rats.  $\alpha$ -2-M is a hepatocyte-derived inhibitor of a wide range of proteinases that can be activated during inflammation<sup>[13]</sup>. Further, we compared plasma concentrations of tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interleukin 6 (IL-6) 2 h post-LPS exposure. Spleen weight served as an indicator of systemic steroid effects.

## MATERIALS AND METHODS

### Animals

The animal protocol was designed to minimize pain or discomfort to the animals. Female Wistar rats (body weight 190-210 g; Taconic M and B, Ejby, Denmark) were housed at  $21^{\circ}\text{C} \pm 2^{\circ}\text{C}$  with a 12-h artificial light cycle. Two or three animals were housed in each cage, with free access to tap water and standard food (Altromin, Lage, Germany) and acclimatized for one week. Food intake and body weight were registered at the beginning and at the end of the experimental procedures. The study was performed in accordance with local and national guidelines for animal welfare and approved by the national Animal Ethics Committee, protocol No. 2010/561-1918.

### Design

Forty animals were allocated in 5 groups of 8: One

**Table 1** Weights, liver function tests, and cytokines.

	Controls	LPS	Anti-CD163-dexa plus LPS	High dexa plus LPS	Low dexa plus LPS
Body weight	199 ± 1	196 ± 2	207 ± 2 <sup>b</sup>	204 ± 3	206 ± 3 <sup>b</sup>
Weight loss	11 ± 1	14 ± 3	22 ± 2 <sup>a</sup>	23 ± 2 <sup>a</sup>	21 ± 1 <sup>a</sup>
Spleen weight	465 ± 12	512 ± 31	492 ± 23	421 ± 11 <sup>a</sup>	483 ± 23
ALT	42 ± 3	61 ± 16	57 ± 20	48 ± 9	77 ± 31
Bilirubin	3.0 ± 0.0	3.3 ± 0.3	3.1 ± 0.1	3.6 ± 0.4	4.0 ± 0.4
TNF- $\alpha$	0 ± 0	26817 ± 9780 <sup>a</sup>	7208 ± 1977 <sup>a,c</sup>	16891 ± 4210 <sup>a</sup>	21583 ± 7117 <sup>a</sup>
IL-6	0 ± 0	23075 ± 6758 <sup>a</sup>	15685 ± 3779 <sup>a,c,e</sup>	32964 ± 8294 <sup>a</sup>	25715 ± 4036 <sup>a</sup>

Body weight (g), body weight loss (g), spleen weight (mg), plasma alanine aminotransferase (U/L), and bilirubin ( $\mu$ mol/L) in controls ( $n = 8$ ) and in animals injected with LPS 24 h after vehicle ( $n = 8$ ), anti-CD163mAb-dexa ( $n = 8$ ), high dose ( $n = 8$ ) and low dose ( $n = 8$ ) dexamethasone at termination of study. Plasma TNF- $\alpha$  (pg/mL) and IL-6 (pg/mL) are measured 2 h after saline (controls) or LPS injection. <sup>a</sup> $P < 0.05$  vs controls; <sup>b</sup> $P < 0.05$  vs low dose free dexamethasone group; <sup>c</sup> $P < 0.05$  vs high dose free dexamethasone group; <sup>d</sup> $P < 0.05$  vs vehicle. ALT: Alanine aminotransferase; TNF- $\alpha$ : Tumor necrosis factor- $\alpha$ ; IL-6: Interleukin-6; LPS: Lipopolysaccharide.

control group receiving only vehicle (PBS pH 7.4) intravenously and four groups injected intravenously with either vehicle, anti-CD163mAb-dexa (0.02 mg/kg dexamethasone), high dose free dexamethasone (1 mg/kg) (Sigma-Aldrich, Brøndby, Denmark), or low dose free dexamethasone (0.02 mg/kg). The high ("therapeutic") dose gives maximal steroid efficacy in other rat studies<sup>[14,15]</sup> and the low dose was the same as in the anti-CD163mAb-dexa. After 24 h, 0.5 mL of saline (controls) or LPS dissolved in 0.5 mL saline (2.5 mg/kg) (from *Escherichia coli* 0111:B4 obtained from Sigma-Aldrich, Brøndby, Denmark; product No. L2630) was injected intraperitoneally. Two hours later and following anaesthesia with inhalation of isofluran 2%-3% (Forene<sup>®</sup>, Abbott Laboratories, Gentofte, Denmark), a blood sample for determination of plasma TNF- $\alpha$  and IL-6 was drawn from a retrobulbar venous plexus using heparinised micropipettes. After an overnight 12-h fast the animals were anaesthetised with a subcutaneous injection of fentanyl/fluanisone (Hypnorm<sup>®</sup>, Jansen Pharma, Birkerød, Denmark) 0.5 mL/kg and midazolam (Dormicum<sup>®</sup>, La Roche, Basel, Switzerland) 2.5 mg/kg. All blood was collected for blood analyses and approximately 200 mg of liver tissue was snap-frozen in liquid N<sub>2</sub>, and stored at -80 °C. Finally, the spleen was weighed. In all animals we measured liver mRNA levels and serum concentrations of  $\alpha$ -2-M and plasma concentrations of alanine aminotransferase and bilirubin at termination of the study.

#### Liver tissue

mRNA levels of  $\alpha$ -2-M were determined by slot blot hybridization as previously described<sup>[16]</sup>.

#### Blood analyses

The concentrations of  $\alpha$ -2-M in serum were evaluated by rat ELISA (Immunology Consultants Laboratory, Newberg, OR, United States). The plasma concentrations of TNF- $\alpha$  and IL-6 were determined by immunoassay (R and D Systems, Minneapolis, MN, United States, both). Samples were analysed in duplicate and all assays had

intra- and inter-assay coefficients of variance below 5% and 10%, respectively. Plasma concentrations of alanine aminotransferase and bilirubin were determined by standard clinical biochemical analytical methods.

#### Statistical analysis

Data were analysed using the Kruskal-Wallis One Way Analysis of Variance on Ranks; when significant, post-hoc tests were performed among groups by the Mann-Whitney rank sum test. Data are presented as the mean  $\pm$  SEM. Differences were considered significant with  $P$ -values  $< 0.05$ . A statistical review of the study was performed by a biomedical statistician.

## RESULTS

#### Body and spleen weight

LPS induced a body weight loss in all the intervention groups ( $P < 0.05$ ) (Table 1) and there was no difference among these groups. The high dose dexamethasone dose decreased the spleen weight ( $P < 0.05$ ), an effect not seen in any other group (Table 1).

#### Acute phase protein liver mRNA and serum levels

LPS increased the liver mRNA and serum levels of  $\alpha$ -2-M several fold in all groups ( $P < 0.01$ ) (Figure 1). Anti-CD163mAb-dexa approximately halved the  $\alpha$ -2-M liver mRNA ( $P < 0.01$ ) and serum response ( $P = 0.04$ ) compared to low dose dexamethasone treated animals, while no free dexamethasone dose had any effect on liver mRNA or serum levels of  $\alpha$ -2-M compared to vehicle (Figure 1).

#### TNF- $\alpha$ and IL-6

LPS markedly increased plasma TNF- $\alpha$  and IL-6 in all groups ( $P < 0.001$ ). There was a trend for reduced TNF- $\alpha$  ( $P = 0.08$ ) after anti-CD163mAb-dexa compared to vehicle and significantly so vs the low dose dexamethasone ( $P = 0.03$ ). Also, the anti-CD163mAb-dexa decreased IL-6 compared to both dexamethasone doses ( $P < 0.05$ ). None of the free dexamethasone doses had

**Figure 1** Relative levels of serum levels (A) and liver mRNA (B) of  $\alpha$ -2-macroglobulin. Changes in serum levels ( $\mu$ g/mL) (A) and liver mRNA (% of controls) (B) of  $\alpha$ -2-macroglobulin ( $\alpha$ -2-M) in controls ( $n = 8$ ) and in animals injected with LPS 24 h after vehicle ( $n = 8$ ), anti-CD163mAb-dexa ( $n = 8$ ), high dose ( $n = 8$ ) and low dose ( $n = 8$ ) dexamethasone. mRNA results from LPS-injected animals are presented as relative levels compared to control animals. Bars represent the mean and SEM. <sup>a</sup> $P < 0.05$  vs controls. LPS: Lipopolysaccharide; SEM: Standard error of mean.

an effect on TNF- $\alpha$  or IL-6 (Table 1).

#### Plasma-alanine transferase and bilirubin

LPS had no effect on these measures at termination of the study (Table 1).

## DISCUSSION

The central finding of this study was the reduction in liver mRNA and plasma  $\alpha$ -2-M, and plasma TNF- $\alpha$  and IL-6 by the administration of the anti-CD163-dexa conjugate prior to the LPS-induced inflammatory response. This anti-acute phase effect much exceeded that of the therapeutic dexamethasone dose and did not cause systemic adverse effects, as evidenced by reduced spleen weight in the group treated with high dose free dexamethasone. This study completes the chain of evidence that the conjugate not only suppresses the LPS elicited IL signaling but also the ultimate effect on synthesis and release of hepatic acute phase proteins that effectuate the acute phase response.

The increase in plasma  $\alpha$ -2-M after LPS reflects *de novo* synthesis as almost no such protein is present under non-induced conditions<sup>[17]</sup> in contrast to conditions with ongoing low grade inflammation such as cirrhosis<sup>[18]</sup>. LPS as assumed caused a marked systemic acute phase response reflected in increased liver mRNA and plasma  $\alpha$ -2-M, TNF- $\alpha$ , and IL-6. In contrast to the equal amount of free dexamethasone, the anti-CD163mAb-dexa efficiently suppressed this response. Still, however, the acute phase response to some extent serves to restore homeostasis and one needs to be aware that suppression of the response might not be entirely beneficial entailing a potential risk using the conjugate long term.

The anti-inflammatory effects of glucocorticoids are related to a decrease in lymphocyte expansion and cell survival and also a reduction in the expression of pro-inflammatory cytokines originating from macro-

phages<sup>[19]</sup>. However, as glucocorticoids bind to the ubiquitous intracellular glucocorticoid steroid receptor present in most cell types they also exert serious systemic metabolic side effects. Thus dexamethasone causes the spleen to undergo a corticosteroid-induced weight reduction due to lymphocyte depletion<sup>[20]</sup>. Accordingly, the high dose dexamethasone in our study decreased the spleen weight as compared with the other groups reflecting systemic non-macrophages effects. In contrast, the conjugate did not affect spleen weight and was still found to exert a potent anti-inflammatory effect.

In our animal model, the conjugate was given as a pre-emptive dose prior to the induction of the acute phase response as we aimed at establishing a proof-of-concept position of the conjugate's effects. We believe our findings support further studies on interference with on-going inflammation in relevant experimental models. Such studies are also essential for monitoring of long term effects of the conjugate.

In conclusion, the anti-CD163-dexa conjugate demonstrated potent effects in reducing the acute phase proteins without evident systemic side effects during an endotoxin-induced acute phase response in rats. The effect much exceeded that of a therapeutic dose of dexamethasone. Thus, the antibody conjugate may be a potential candidate in future anti-inflammatory macrophage-directed therapy, *e.g.*, in liver diseases with Kupffer cells activation<sup>[7]</sup>.

## COMMENTS

### Background

In conditions with macrophage proliferation and activation, CD163, a scavenger

receptor expressed exclusively on monocytes and macrophages, is up-regulated. As an example, hepatic macrophages (Kupffer cells) are activated and CD163 is increased in patients with liver cirrhosis who chronically experience some degree of endotoxemia and acute phase response.

### Research frontiers

The authors have recently constructed a conjugate of CD163 antibody and the potent corticosteroid dexamethasone (anti-CD163mAb-dexa) specifically targeting dexamethasone to activated macrophages.

### Innovations and breakthroughs

The anti-CD163-dexa conjugate exerts an anti-inflammatory effect, which is obtained with very low concentration of dexamethasone, thereby minimizing steroid-induced systemic effects.

### Applications

The antibody conjugate may be a potential candidate in future anti-inflammatory macrophage-directed therapy, *e.g.*, in liver diseases with Kupffer cells activation.

### Peer-review

This is an experimental report written by Thomsen *et al.*, which indicates an efficacy of dexamethasone-conjugated anti-CD163 against lipopolysaccharide-induced acute inflammatory reaction. The well-designed study was carried out using firm methods.

## Abstract

**AIM:** To assess how the application of different types of markers affects the tracking accuracy of CyberKnife's.

**METHODS:** Fifteen patients were recruited and subjected to the ultrasound-guided placement of markers. Two different type of needles 25 gauge (G) and 17 G containing two different fiducial marker, gold notched flexible anchor wire 0.28 mm × 10 mm (25 G needle) and gold cylindrical grain 1 mm × 4 mm (17 G), were used. Seven days after the procedure, a CyberKnife planning computed tomography (CT) for the simulation of radiation treatment was performed on all patients.

A binary CT score was assigned to the fiducial markers visualization. Also, the CT number was calculated for each fiducial and the values compared with a specific threshold.

**RESULTS:** For each patient from 1 to 5, intra-hepatic markers were placed (one in 2 patients, three in 8 patients, four in 3 patients, and five in 2 patients). A total of 48 needles were used (thirty-two 17 G and sixteen 25 G) and 48 gold markers were placed (32 Grain shaped markers and 16 Gold Anchor). The result showed that the CT visualization of the grain markers was better than the anchor markers ( $P = 5 \times 10^{-9}$ ). Furthermore, the grain markers were shown to present minor late complications ( $P = 3 \times 10^{-6}$ ), and the best CT threshold number ( $P = 0.0005$ ).

**CONCLUSION:** The study revealed that the Gold Anchor fiducial marker is correlated with a greater number of late minor complications and low visualization by the CT.

**Key words:** Robotic radiosurgery; Fiducial markers; Liver malignancies; CyberKnife; Radiation therapy; Stereotactic radiosurgery

**Core tip:** Robotic radiosurgery can employ different systems for the localization of the neoplastic targets to treat. The purpose of this study is to assess how the application of different types of markers affects the tracking accuracy of CyberKnife's. Fifteen patients have been recruited and analyzed for the study and two types of markers were used for the procedure. The computed tomography (CT) visualization of grain markers was better than anchor markers  $P = 5 \times 10^{-9}$ . Grain markers presented minor late complications of  $P = 3 \times 10^{-6}$ , and the best CT threshold number. The study revealed that the Gold Anchor fiducial marker is correlated with a greater number of late minor complication.

Marsico M, Gabbani T, Livi L, Biagini MR, Galli A. Therapeutic usability of two different fiducial gold markers for robotic stereotactic radiosurgery of liver malignancies: A pilot study. *World J Hepatol* 2016; 8(17): 731-738 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i17/731.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i17.731>

## INTRODUCTION

The stereotactic robotic radiosurgery is able to administer high-dose radiation that could reach any anatomic point with a sub-millimeter precision<sup>[1-4]</sup>. The high accuracy is achieved by the image-guidance system robotic technology and the dynamic tracking of targets,

that remove the effect of breathing. The use of these techniques permits the CyberKnife system's to hit the lesion with high-dose radiation and to safeguard the surrounding critical organs which could suffer irreversible damage<sup>[5-13]</sup>. Robotic radiosurgery can employ different systems for the localization of the neoplastic targets to treat. In particular, for the treatment of the parenchymatous organ tumors, CyberKnife uses a localization system based on specific gold markers<sup>[14]</sup>. Various types of gold markers can be employed in relation to the characteristics of the lesion and the different technique of placement. In particular, the type of gold markers to use often depends on the choice of needles of different calibers and length. The choice of the needle is influenced by the type and site of the lesion to treat and its proximity to critical organs or vascular structures<sup>[15,16]</sup>. The physical characteristic (dimensions and length) of the gold markers strongly depends on the characteristics of the needle. The gold markers (Gold Anchor) contained in fine needle [25 gauge (G) and 22 G] must be smaller in dimension and longer than those contained in larger needles. Markers contained in fine needles, in order to reach an appropriate density for a normal computed tomography (CT) number and to be correctly recognized by the CyberKnife system, must assume a correct array in the parenchyma, when they are inserted. In fact, they have the advantage of being flexible and to curl up when they are pushed against the parenchyma tanks to the spindle and carried by the needle. Therefore, after their placement, the Gold Anchor reached some similar dimensions to those in grain and so, an appropriate density and a normal CT number. Therefore, if they are too crowded or shatter during their release, they do not achieve the proper density to have a normal CT number, and to be well recognized as a fiducial by the CyberKnife System. The markers (cylindrical markers) contained in larger gauge needles (17 G and 18 G) can not break and do not need to mass during their placement. Therefore they can not change their CT number (Figure 1)<sup>[17-21]</sup>. The placement of fiducial markers may be burdened by complications due to puncture or related to the gold markers. For instance, the major complications related to the gold markers could be the migration of fiducials from the positioning site and the physical alterations of the markers, like marker not deployed or shattered, that may occur during or after placement<sup>[22-26]</sup>. These complications determine the lack of fiducials recognition by CyberKnife and result to failure in targeting the lesions that prevented the execution of the treatment<sup>[27,28]</sup>.

The aim of this prospective pilot study was to assess, how the use of two different types of gold fiducial markers: Grain type and Anchor type, affects the accuracy of tracking by the CyberKnife System, and consequently, the therapeutic efficacy of the treatment of primary or metastatic liver malignancy. We also aimed to identify which type of fiducial can ensure better viability of the SRR.

**Figure 1** Types of gold fiducial markers. A: Twenty five gauge and 17 G needle and their gold markers: Grain cylindrical gold marker, 1 mm × 4 mm and flexible wire notched gold marker 0.28 mm × 10 mm, Gold Anchor Marker respectively; B: Grain cylindrical gold marker, 1 mm × 4 mm flexible wire notched gold marker 0.28 mm × 10 mm, Gold Anchor marker after massing.

## MATERIALS AND METHODS

Fifteen consecutive patients, who were scheduled to receive robotic radiotherapy treatment for primary or metastatic liver malignancy, were recruited for percutaneous ultrasonography (US)-guided placement of intra-hepatic fiducial markers, from March 2014 to June 2014 (Figure 1). A written informed consent was obtained from the patients. Two different types of needles, 25 G and 17 G containing two different fiducial markers, gold notched flexible anchor wire of 0.28 mm × 10 mm (25 G needle) and gold cylindrical grain of 1 mm × 4 mm (17 G), were used. The needle type to use was selected according to the site of the lesion (deep or superficial liver lesion) and physical structure. The choice of the different fiducial markers depends mainly on the choice of the needle caliber. The number of fiducial markers to place was evaluated according to the acoustic window, the compliance of the patients and morphological characteristics of the lesions. The examination was performed by two expert ultrasonographers with the same echograph, ProSound Alfa7, (Hitachi-Aloka, Tokyo, Japan) with a 3.75–7.5 MHz hemispheric sound technology (HST) 91–30 Multi Frequency Convex Abdominal HST probe.

Local anesthesia was achieved *via* the subcutaneous administration of 1% lidocaine. All the gold fiducial markers were placed with US-guidance through sub or intercostals access. After confirming that the needle tip had reached the target lesion, the fiducial marker was deployed, and then the needle was removed. We placed in each patient from 1 to 5 fiducial markers, and when at least two or more fiducials were placed, it was at a distance of about 1.5–2 cm apart, in a way to occupy the perpendicular edges of a cube containing the tumor inside. The Gold Anchor markers were always placed with the same technique to take advantage of their mass effect. Fiducial positioning was confirmed with ultrasound image. A marker was usually seen as a hyperechoic structure. The two different fiducial markers used were sonographically undistinguishable (Figure 2). Technical success was defined when the implantation enables adequate treatment planning and CT simulation. Fiducial migration was defined as seed dislodgement outside the volume of the original injection site that is unusable for guiding stereotactic body radiation therapy (SBRT) as determined by planning CT. Clinical success was defined as the completion of SBRT. Seven days after the procedure, a CyberKnife planning CT for the simulation of radiation treatment was performed on all patients.

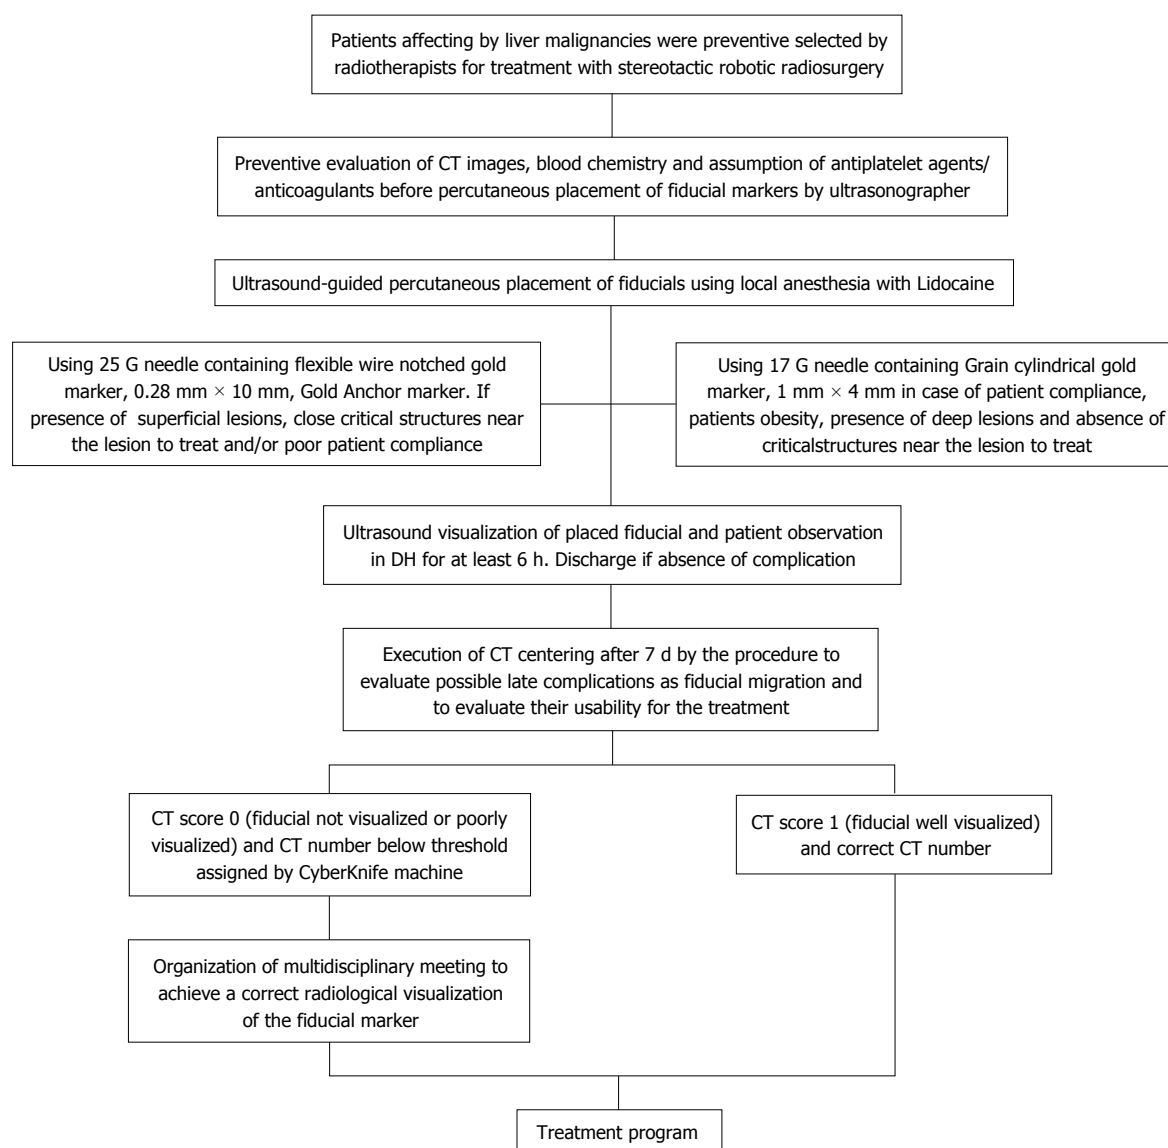

**Figure 3 Well visualized fiducial markers.** A: CT displaying of Grain cylindrical gold marker, 1 mm × 4 mm. This marker exhibits good contrast on X-ray images with typical "star effects"; B: CT displaying types of flexible wire notched gold marker, 0.28 mm × 10 mm, Gold Anchor marker. This marker exhibits good contrast on X-ray images demonstrating less artifacts. CT: Computed tomography.

A binary CT score for the fiducial markers visualization was assigned (not visualized or poorly visualized = 0; well visualized = 1) (Figure 3). In the case of CT score of zero (0) which prevented treatment, we organized a series of multidisciplinary meetings (with regards to the procedure, the physician and the radiation oncologist responsible for the radiosurgery treatment) to achieve the correct radiological visualization of the fiducial marker. Moreover, for the execution of treatment with CyberKnife, it is necessary that each fiducial reaches a CT number above a specific threshold (CT number threshold). The CT number of the fiducial is assigned in an automated manner by the CyberKnife machine (Figure 4). Database construction and data analysis were performed using Office Excel 2007, XLSTAT 2016 (microsoft) and SPSS for Windows (SPSS Inc., Chicago, United States). We examined the data with the use of appropriate parametric and non-parametric statistical tests (Student's *t*-test two-tailed and a  $\chi^2$  test according to Fischer considering  $P < 0.05$  as significant). A Lilliefors (Kolmogorov-Smirnov) test for normality has been previously performed. Statistical analysis was performed by Tommaso Gabbiani, MD, and reviewed by Principal Investigator, Maria Marsico, MD.

## RESULTS

Fifteen consecutive patients (men: 9, women: 6, mean age: 72.9 years old, range: SD ± 7.9) who had already undergone percutaneous ultrasound-guided fiducial marker implantations for CyberKnife therapy were employed for this study. Eleven patients (8 males) presented liver metastasis from a note primary neoplasm (2 right colon carcinoma, 2 sigmoid carcinoma, 2 rectum carcinoma, 1 gastric carcinoma, 1 lung carcinoma, 1 ovarian carcinoma and 2 pancreatic carcinoma). Four patients (2 males) showed liver primary malignancy [2 hepatocellular carcinoma (HCC), 1 cholangio-carcinoma, 1 hepatic cholangio-carcinoma]. Among 11 patients who presented liver metastasis, 9 patients had previously undergone radical surgery of primary neoplasm. Among these 9 patients, 4 had submitted to adjuvant therapy,

2 to metastasectomy and adjuvant therapy, 2 to neo-adjuvant and adjuvant therapy and 1 to metastasectomy without chemotherapy. Moreover among these 9 patients, 7 developed new liver metastasis during or at the end of the treatment, while 2 patients presented a metastatic recurrence. Only 2 patients of the 11 affected by liver metastasis undergone treatment by chemotherapy and not surgery, one performed a palliative chemotherapy and the other performed an effective chemotherapy with failure of treatment. In the group of patients with primary hepatic neoplasm, patients affected by HCC and hepato-cholangiocarcinoma were treated by chemoembolization, while another one affected by cholangiocarcinoma undergone chemotherapy. Patients treated with chemoembolization showed relapse of neoplasm, while the patient treated with chemotherapy showed no response to the treatment. In the group of patients with hepatic metastasis, 8 of them have a single nodule, 2 of them have two nodules, and 1 has three nodules so the total of liver lesions treated was 15. These 15 liver lesions presented a maximum diameter between 2 to 4 cm. In the group of patients with primary liver lesions, 3 patients showed a single nodule and another one presented two nodules so the total primary lesion treated was 5. Four of these measured a maximum diameter from 2 to 4 cm and only one measured a maximum diameter over 4 cm. 2 patients showed a moderate ascites at the moment of the procedure. The 20 liver lesions were localized into the VII liver segment ( $n = 7$ ), VI liver segment ( $n = 3$ ), VIII segment ( $n = 3$ ), V segment ( $n = 1$ ), IV segment ( $n = 1$ ), III segment ( $n = 1$ ), between V-VI segment ( $n = 1$ ), between V-VI-VII segments ( $n = 1$ ) and between VI-VII segments ( $n = 2$ ). Five lesions were localized close to vascular structures and 2 lesions close to critical organs. Considering the closeness of the critical organs or vascular structures and the patients' compliance, 8 patients undergone a combined placement of the two types of gold markers. Two patients presented severe compliance problems (panic attack), so they received only anchor markers (placed with fine needles). Five patients received only cylindrical grain markers. For each

**Figure 4** Flow chart of the study conducted tank to a prospective collection of data (compliance, demographic and clinic characteristics of the patients, liver lesions characteristics, type of needle and markers used, ultrasonographic and computed tomography visualization of fiducial markers, usability of the markers and immediate and late complications) and a retrospective statistical analysis. CT: Computed tomography.

patient about 1 to 5 intra-hepatic markers were placed (one in 2 patients, three in 8 patients, four in 3 patients, and five in 2 patients). A total of 48 needles were used (thirty-two 17 G and sixteen 25 G) and 48 gold markers were placed (32 Grain shaped markers and 16 Gold Anchors). In 47 cases, the gold markers were placed through subcostal access and only in a single case with an inter-costal access. Every patient received a local anesthesia with lidocaine. All fiducials placement were sonographically confirmed right after the procedure. No patient presented any major complication related to the procedure.

After the placement of markers, 14 patients underwent the planning simulation CT scan to allow fiducials to settle. One patient did not perform the CT because of a complication related to the primary tumor (hepatic failure). Removing the latter patient who was excluded from the treatment for causes not correlated to the

fiducial placement, the technical and clinical success rate was 100%. The CT scan revealed that 14 markers (11 Gold Anchors and 3 Grain shaped markers) showed late complications. Few markers showed more than one complications at the same time for a total of 27 complications. Shattered markers ( $n = 2$ ; 2 Gold Anchors), extra-hepatic migration ( $n = 4$ ; 1 Gold Anchor and 3 Grain markers), extra-hepatic migration and marker not visualized ( $n = 1$ ; 1 Gold Anchor), intra-hepatic migration ( $n = 5$ ; 5 Gold Anchors), not massed markers ( $n = 5$ ; 5 Gold Anchor). The Gold Anchor marker presented more frequent late minor complications (68.75% vs 9.375%,  $P = 3 \times 10^{-6}$ ). Moreover, 38 markers were visualized with CT score = 1 and 10 markers with CT score = 0, the markers visualized with CT score = 0 were all Gold Anchors and we demonstrated that the CT subjective visualization of Grain shaped markers was significantly higher than the CT subjective visualization for Gold

Anchor (100% vs 37.5%,  $P = 5 \times 10^{-9}$ ). For 5 patient it was necessary to organize multidisciplinary meetings to identify the correct intra-hepatic localization of the markers visualized with CT score = 0. Finally, 5 markers showed a CT number below the threshold (5 Gold Anchors). The 5 markers with the CT number below the threshold were not recognized by the CyberKnife system and so were not used for the treatment (one marker not recognized for 5 patients). Forty-three markers (32 Grain shaped markers and 11 Gold Anchors) with regular CT number were recognized by CyberKnife system and were used for the treatment. The clinical success achieved was 89.6%. We demonstrated that the Gold Anchor marker is associated with a threshold below the CT number (31.25% vs 0%,  $P = 0.0005$ ) that is not suitable for treatment. A total of 14 patients underwent radiosurgery treatment, only one patient was excluded because of a complication related to his primary tumor.

## DISCUSSION

The CyberKnife Robotic Radiosurgery System is a non-surgical option for patients who have inoperable or surgically complex tumors or who may be looking for an alternative to surgery. It is an option in the case where no response and/or relapse is observed after chemotherapy and standard radiotherapy<sup>[29-31]</sup>. In our study, we compared the therapeutic usability of the two different gold fiducial markers for robotic radiosurgery treatment of primary and metastatic liver malignancies. We used the two different gold markers according to the necessity to either use 17 or 25 G needle, depending on the patient's compliance, patient physical structure and the proximity of critical or vascular structures. This pilot trial demonstrate that the Anchor marker (0.28 mm × 10 mm) is correlated with a greater number of late minor complications that results from a frequent association with a CT number below threshold and a low subjective CT visualization, resulting in a delay or a difficulty in starting the treatment. In our opinion, the use of the Gold Anchor marker should be limited to use of the 25 G needle and in combination with the other types of markers. Only few studies have compared the use of different fiducial in the terms of efficacy and complications<sup>[32,33]</sup>. Our study differs from others because it compares the two different types of gold fiducial markers in terms of usability for CyberKnife treatment. In our study, we identified some of the factors related to the type of fiducials (the Gold Anchor) that may prevent the treatment with CyberKnife. The identification and knowledge of these factors allows us to limit the use of Gold Anchor marker type, to specific cases and preferably, in combination with the other marker types, in order to reduce the tracking problems of CyberKnife. Infact, CyberKnife tracking problems are causes of increasing costs and delay in treatment execution. Contrary to what is shown in our study, other trials have demonstrated the advantage of Gold Anchor fiducial than the other types of fiducial markers for the

treatment with CyberKnife. Nevertheless, in these other studies, inserting of the fiducial markers was executed by endoscopic ultrasonography technique to treat tumors of the pancreas and lung. Therefore, it is our opinion that the different techniques for positioning, and the different localization of the lesions may be the basis of the different results obtained in the study. Furthermore, we must consider the variable offered by the needle. The percutaneous placement of Gold Anchor (0.28 mm × 10 mm) occurred with the 25 G needle that originally contained the gold marker. In the cases of endoscopic ultrasound guided placement of fiducial gold markers (in particular, for treatment of pancreas lesion), the 25 G needle originally containing the marker, serves only as a carrier to put the fiducials inside the other needles (22 G or 19 G) usually used for the fiducial placement. The use of needles with a greater caliber (22 G and 19 G) and less flexibility than the 25 G needle, may facilitate the placement of Gold Anchor limiting the complications.

## COMMENTS

### Background

The treatment of liver malignancies has evolved over the years. Although surgery is the current standard treatment for localized surgically operable lesions. Alternative treatment approaches for unresectable liver metastasis and primary liver cancer include: Chemoembolization, radiofrequency ablation, cryotherapy, and the oral multikinase inhibitor sorafenib, chemotherapy and standard radiotherapy. The CyberKnife Robotic Radiosurgery System is a non-surgical option for patients who have inoperable or surgically complex tumors or who may be looking for an alternative to surgery. It also provides an option in the case where no response and/or relapse is observed after standard treatment.

### Research frontiers

Many points still remain unclear in literature to ameliorate the treatment by CyberKnife and a lot of them seem to correlate with the type of fiducial to be use, the technique of placement and the number of fiducial to use. Nowadays, there are many different types of gold fiducial markers with different dimensions, lengths and physical characteristics. Therefore, many other studies of fiducial comparison, like the authors', should be conducted. This is necessary to identify the basis of compliance, demographic and clinical characteristics of the patients and liver lesions characteristics, the best type of fiducial and needle to use. Percutaneous fiducial marker placement could be under computed tomography (CT) fluoroscopic guidance or ultrasonographic (US) guidance. In this study, fiducial placement was entirely conducted under US guidance demonstrating a great safety and efficacy. Cost-effectiveness studies should also be conducted to compare the CT and the US percutaneous fiducial placement to identify the best method in the terms of cost-effectiveness. Nowadays, there is yet no consensus in literatures on the exact number of fiducials necessary to effectively perform the treatment with CyberKnife. Many studies define the technical success as the ability to place more of a fiducial near the tumor target before the treatment; other studies have resulted in higher clinical success placing a unique fiducial marker for patient. In this study, the authors also demonstrated a high clinical success from using one to five fiducial for each patient, in relation to which fiducials were really recognized and used by the CyberKnife system (fiducial with correct relegated CT number). Therefore, many studies should be conducted regarding the different analysis of tracking accuracy resulting from the use of a different number of fiducial for treatment. This is important to establish the best number of fiducials to use in terms of cost effectiveness.

### Innovations and breakthroughs

The study differs from others because it compares the two different types of gold fiducial markers in terms of usability for CyberKnife treatment of liver

malignancies. The study also differs for describing other possible complications related to Gold Anchor - their wrong stacking and their break after the placement. In this study, the authors identified some factors related to the type of fiducial, (the Gold Anchor) that may prevent the treatment with CyberKnife. The identification and knowledge of these factors allows them to limit the use of Gold Anchor marker type, to specific cases and preferably in combination with other marker types, in order to reduce tracking problems of CyberKnife. In fact, CyberKnife tracking problems are causes of increasing costs and delay in treatment execution. Contrary to what is shown in the study, other trials have demonstrated the advantage of Gold Anchor fiducial over the other types of fiducial markers for the treatment with CyberKnife. Nevertheless, in these other studies, the inserting of fiducial markers was executed by endoscopic ultrasonography technique for treating tumors of the pancreas and lung. Therefore, it is the authors' opinion that the different techniques of positioning, and the different localization of the lesions and the different needles (generally of higher caliber) used for the placement of Gold Anchor may be the basis of the different results obtained in this study.

### Applications

In the authors' opinion, the use of Gold Anchor marker type has to be limited to specific cases; in order to reduce tracking problems of CyberKnife treatment which is the major cause of increasing costs and delay in treatment execution. Therefore, the authors suggest that the use of the Gold Anchor marker should be limited to the necessity to use the 25 G needle and in combination with the other type of markers. In particular, the 25 G needle should be used in the case of low patient compliance, absence of obesity and in the presence of superficial lesions at critical structure near the liver lesions.

### Terminology

Stereotactic robotic radio surgery: Ability to dispense high doses of focused radiation in a minor number of fractions respect to the standard treatment (2-5 vs 30-40). Ability to reach any point with anatomical precision and extreme sub-millimeter accuracy thanks to a target localization computerized system offered by CyberKnife system; CyberKnife: Robot with a complete autonomy characteristic with more than 1500 dispensing positions of X-ray; Variable diameter collimator; Synchrony Respiratory Tracking System to preserve the near organs from toxicity; Fiducial gold markers: Markers exploited by CyberKnife for the target localization in the treatment of parenchymatous organs lesions. This marker is made from gold, which makes it biocompatible and ensures it exhibits good contrast on X-ray images; CT number: A normalized value of the calculated X-ray absorption coefficient of a pixel (picture element) in a computed tomogram, expressed in Hounsfield units, where the CT number of air is -1000 and that of water is 0.

### Peer-review

In this work, the authors reported a comparison study of two different types of fiducial markers for robotic radiosurgery. In this study, 15 patients have been recruited, in which 48 gold markers were placed (32 Grain shaped markers and 16 Gold Anchor). All these patients except one were scanned with CT for visualization and identification of these markers. The data of these patients were analyzed and reported in this work. The work intended to address an interesting clinical issue.

### Abstract

**AIM:** To investigate the prognostic significance of insulin-like growth factor-binding protein 3 (IGFBP-3) in patients with cirrhosis.

**METHODS:** Prospective study that included two cohorts: outpatients with stable cirrhosis ( $n = 138$ ) and patients hospitalized for acute decompensation ( $n = 189$ ). Development of complications, mortality or liver transplantation was assessed by periodical phone calls and during outpatient visits. The cohort of stable cirrhosis also underwent clinical and laboratory evaluation yearly (2013 and 2014) in predefined study visits. In patients with stable cirrhosis, IGFBP-3 levels were measured at baseline (2012) and at second re-evaluation (2014). In hospitalized subjects, IGFBP-3 levels were measured in serum samples collected in the first and in the third day after admission and stored at  $-80^{\circ}\text{C}$ . IGFBP-3 levels

were measured by immunochemiluminescence.

**RESULTS:** IGFBP-3 levels were lower in hospitalized patients as compared to outpatients (0.94 mcg/mL *vs* 1.69 mcg/mL,  $P < 0.001$ ) and increased after liver transplantation (3.81 mcg/mL *vs* 1.33 mcg/mL,  $P = 0.008$ ). During the follow-up of the stable cohort, 17 patients died and 11 received liver transplantation. Bivariate analysis showed that death or transplant was associated with lower IGFBP-3 levels (1.44 mcg/mL *vs* 1.74 mcg/mL,  $P = 0.027$ ). The Kaplan-Meier transplant-free survival probability was 88.6% in patients with IGFBP-3  $\geq 1.67$  mcg/mL and 72.1% for those with IGFBP-3  $< 1.67$  mcg/mL ( $P = 0.015$ ). In the hospitalized cohort, 30-d mortality was 24.3% and was independently associated with creatinine, INR, SpO<sub>2</sub>/FiO<sub>2</sub> ratio and IGFBP-3 levels in the logistic regression. The 90-d transplant-free survival probability was 80.4% in patients with IGFBP-3  $\geq 0.86$  mcg/mL and 56.1% for those with IGFBP-3  $< 0.86$  mcg/mL ( $P < 0.001$ ).

**CONCLUSION:** Lower IGFBP-3 levels were associated with worse outcomes in patients with cirrhosis, and might represent a promising prognostic tool that can be incorporated in clinical practice.

**Key words:** Liver cirrhosis; Acute decompensation; Insulin-like growth factor binding protein 3; Acute-on-chronic liver failure; Prognosis

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Insulin-like growth factor-binding protein 3 (IGFBP-3) levels are decreased in cirrhosis and seem to correlate with the intensity of hepatic dysfunction, but its prognostic significance is uncertain. In this prospective cohort study, IGFBP-3 levels correlated with variables associated with the intensity of liver dysfunction in both outpatients with stable cirrhosis and in subjects hospitalized for acute decompensation. IGFBP-3 levels increased significantly after discharge and after liver transplantation. Lower IGFBP-3 levels were associated with poor outcomes in both outpatients with stable cirrhosis and in those hospitalized for acute decompensation, suggesting that it can be used in clinical practice as a prognostic biomarker in cirrhosis.

## INTRODUCTION

Cirrhosis is a late stage progressive hepatic fibrosis

characterized by distortion of hepatic architecture and the formation of regenerative nodules. Although considered potentially reversible in some clinical scenarios, in its advanced stages, liver cirrhosis is associated with high mortality and the only treatment option may be liver transplantation<sup>[1]</sup>. Patients with cirrhosis are susceptible to a variety of complications such as variceal bleeding, ascites, spontaneous bacterial peritonitis (SBP), hepatic encephalopathy, hepatocellular carcinoma, hepatorenal syndrome, hepatopulmonary syndrome and portal vein thrombosis<sup>[1]</sup>. The prognosis of cirrhosis is highly variable because it is influenced by a number of factors including etiology, severity, presence of complications, and comorbidities. Mortality rate increases significantly once decompensation occurs<sup>[2]</sup>.

Changes in the growth hormone-insulin-like growth factor (GH-IGF) axis occur as a result of liver disease and has been reported in cirrhosis<sup>[3,4]</sup>. GH and IGF-I have important anabolic effects on the metabolism of proteins, carbohydrates and lipids<sup>[5]</sup>. GH is a peptide hormone released from anterior pituitary that stimulates growth, cell reproduction and regenerations while exerting metabolic effects on bone, cartilage, fat, muscles, heart and the immune system<sup>[6-8]</sup>.

In the liver, GH activation of GH receptors induces IGF- I gene transcription, and the subsequent synthesis and release of IGF- I to plasma<sup>[9]</sup>. However, the actions of IGF- I are tightly controlled by the binding of IGF to binding proteins (IGFBP-1 to -6). The IGFBPs carry IGFs in the serum and regulate their activity and bioavailability<sup>[10]</sup>. IGFBP-3 is the major binding protein of IGF and carries 80%-90% of circulating IGF- I. The IGFBP-3 is predominantly produced in the liver and synthesized in Kupffer cells. It forms a 150 kDa ternary complex with IGFs and the acid-labile subunit<sup>[7,9]</sup>.

Low serum concentrations in both IGF- I and IGFBP-3 have been reported in patients with cirrhosis *vs* healthy controls. This likely reflects decreased hepatic synthesis function<sup>[5,11-13]</sup>. In fact, some studies reported that IGFBP-3 serum levels are abnormally low in patients with liver cirrhosis and correlated with several variables associated with the intensity of liver dysfunction<sup>[5,7]</sup>. Even though these reports suggest the clinical utility of monitoring circulating IGFBP-3 in cirrhosis, there is little data on the prognostic significance of this biomarker. The aim of this study was to investigate the relationship between serum IGFBP-3 levels and prognosis in both outpatients with stable cirrhosis and in patients hospitalized for acute decompensation (AD).

## MATERIALS AND METHODS

### Patients

This prospective study included two cohorts of adult patients ( $\geq 18$  years of age) with liver cirrhosis in the University Hospital of the Federal University of Santa Catarina. The diagnosis of cirrhosis was established either histologically (when available) or by combination of clinical, imaging and laboratory findings in patients

with evidence of portal hypertension. The first cohort was comprised of patients with stable cirrhosis in the outpatient clinic. In this case, patients in the following situations were excluded: Diagnosis of hepatocellular carcinoma; interferon-based therapy over the last 30 d; or refusal or inability of the patient to understand the terms of the informed consent.

The second cohort included patients admitted to the emergency room due to AD of liver cirrhosis. In this group, the following exclusion criteria were adopted: Hospitalization for elective procedures; admissions not related to complications of liver cirrhosis; and hepatocellular carcinoma outside Milan criteria. Exclusion criteria for both groups also included: Pregnancy; chronic renal failure requiring hemodialysis; severe heart disease; severe chronic pulmonary disease; and active extrahepatic cancer. The study protocol complies with ethical principles of the Declaration of Helsinki and was approved by the Ethics Committee on Human Research of the Federal University of Santa Catarina.

## Methods

This initial cohort was initially evaluated from June to October 2012. The development of complications, mortality, or liver transplantation was assessed by periodic phone calls and during outpatient visits. Patients also underwent clinical and laboratory evaluation yearly (2013 and 2014) in predefined study visits. The second cohort included subjects hospitalized for AD between January 2011 and November 2013. AD was defined by acute development of hepatic encephalopathy, large ascites, gastrointestinal bleeding, bacterial infection or any combination of these. Patients were evaluated within 24 h of admission by one of the researchers involved in the study. They were followed during their hospital stay and 30- and 90-d mortality was evaluated by phone call in case of hospital discharge. In case of more than one hospital admission during the study period-only the most recent hospitalization was considered.

The following clinical variables were collected for all patients: Age, gender, etiology of cirrhosis, history of previous decompensation, current complications of cirrhosis, active alcoholism and regular propranolol and omeprazole use. All subjects underwent laboratory evaluation including total leukocytes, serum sodium, creatinine, international normalized ratio (INR), albumin, C-reactive protein (CRP), total bilirubin and IGFBP-3. In patients hospitalized for AD of cirrhosis, blood samples were obtained on the first and third day after admission.

Active alcoholism was defined as an average overall consumption of 21 or more drinks per week for men and 14 or more drinks per week for women during the 4 wk before enrollment (one standard drink is equal to 12 g absolute alcohol)<sup>[14]</sup>.

Hospitalized individuals with a suspected infection at admission received a clinical examination to confirm this diagnosis and to establish the primary source of infection. Diagnosis of infection was made according to

the criteria of Center for Disease Control<sup>[15]</sup>. A diagnostic paracentesis was performed in all patients with ascites at admission. SBP was diagnosed when the neutrophil count in the ascitic fluid was  $\geq 250$  neutrophils/mm<sup>3</sup> in the absence of an intra-abdominal source of infection regardless of negative culture<sup>[16]</sup>. All patients with SBP received ceftriaxone plus weight-based intravenous albumin in the first and third day after diagnosis. Hepatic encephalopathy was graded according to West-Haven criteria<sup>[17]</sup>. If this was present, a precipitant event was actively investigated and lactulose was initiated, and the dose was adjusted as needed. All subjects with acute variceal bleeding received intravenous octreotide, an antibiotic (either oral quinolone or intravenous ceftriaxone), and underwent urgent therapeutic endoscopy after stabilization.

The severity of liver disease was estimated using the Child-Pugh classification system<sup>[18]</sup> and model for end-stage liver disease (MELD)<sup>[19]</sup> calculated based on laboratory tests performed at admission in the case of hospitalized patients. Acute-on-chronic liver failure (ACLF) was defined as proposed by the EASL-CLIF Consortium<sup>[20]</sup>.

## IGFBP-3 serum levels

In patients with stable cirrhosis, IGFBP-3 levels were measured at baseline (2012) and at second re-evaluation (2014). In hospitalized subjects, IGFBP-3 levels were measured in serum samples collected in the first and in the third day after admission and stored at -80 °C until use. The IGFBP-3 levels were measured by immunochemiluminescence (Immulite® 2000, Diagnostic Products Corp., Los Angeles, CA, United States). The reported analytical sensitivity of this assay is 0.50 mcg/mL.

## Statistical analysis

The normality of variable distribution was determined using the Kolmogorov-Smirnov test. The correlation between numerical variables was evaluated using Spearman's correlation coefficient. Continuous variables were compared using the Student's *t*-test in case of a normal distribution or Mann-Whitney test in the remaining cases. Categorical variables were evaluated with a  $\chi^2$  test or Fisher's exact test, as appropriate. Multiple logistic regression analysis (forward stepwise regression) was used to investigate factors independently associated with death or liver transplantation during follow-up period. The best cutoffs of IGFBP-3 for predicting mortality, in both cohorts, were chosen based on the receiver operating characteristics (ROC) curves. Survival curves were calculated using the Kaplan-Meier method and survival differences between groups were compared using a log-rank test. Wilcoxon signed rank-test was used for comparing IGFBP-3 at two times. All tests were performed using SPSS software, version 22.0 (SPSS, Chicago, IL, United States). A *P* value of less than 0.05 was considered statistically

## RESULTS

### Characteristics of included patients

The study included 138 patients with stable cirrhosis and 189 subjects hospitalized for AD of cirrhosis. Table 1 lists the characteristics of the included patients. In the cohort of stable cirrhosis, the mean age was 53.6  $\pm$  12.5 years, 92.8% were Caucasians with a predominance of men (70.3%). A previous history of cirrhosis decompensation was observed in 75.4% of the sample and only 3.6% of subjects reported active alcoholism during the past month. Regular propranolol and PPI use was 63.0% and 50.0% of the patients, respectively. The mean MELD score was 9.84  $\pm$  2.28 and 66.7% of subjects were Child-Pugh A.

In the group hospitalized for AD, the mean age was 53.6  $\pm$  11.6 years, 68.6% were Caucasians and 73.0% were males. Previous decompensation was

reported by 63.5% of the sample, and active alcoholism was present in 36.0% of the sample. Upon admission, upper gastrointestinal bleeding was observed in 52.4% of cases, ascites in 48.7%, hepatic encephalopathy in 59.3%, bacterial infections in 26.6% and ACLF in 23.8%. In hospitalized patients, propranolol and PPI use prior to admission was reported in 40.2% and 23.4% of the patients, respectively. The mean MELD score was 16.32  $\pm$  6.53 and 39.7% of subjects were Child-Pugh C. Patients hospitalized for AD of cirrhosis exhibited significantly lower median IGFBP-3 vs outpatients (0.94 mcg/mL vs 1.69 mcg/mL,  $P < 0.001$ ).

### IGFBP-3 in outpatients with stable cirrhosis

In patients with stable cirrhosis, IGFBP-3 levels were positively correlated with total leukocytes ( $r = 0.215$ ,  $P = 0.011$ ) and albumin levels ( $r = 0.579$ ,  $P < 0.001$ ). A negative correlation was observed between IGFBP-3 levels and INR ( $r = -0.412$ ,  $P < 0.001$ ), total bilirubin ( $r = -0.329$ ,  $P < 0.001$ ), CRP ( $r = -0.265$ ,  $P = 0.002$ ) and MELD ( $r = -0.327$ ,  $P < 0.001$ ). No significant correlations were observed between IGFBP-3 and other studied variables.

Significantly lower IGFBP-3 median levels were observed in Child-Pugh B/C patients (1.38 mcg/mL vs 1.88 mcg/mL,  $P < 0.001$ ), in those with previous decompensation of cirrhosis (1.58 mcg/mL vs 2.19 mcg/mL,  $P = 0.012$ ), hospitalization secondary to complications of cirrhosis (1.57 mcg/mL vs 1.95 mcg/mL,  $P = 0.052$ ), and those with a history of ascites (1.53 mcg/mL vs 1.85 mcg/mL,  $P = 0.024$ ). Previous variceal bleeding or hepatic encephalopathy as well as an etiology of cirrhosis had no impact on IGFBP-3 levels ( $P > 0.05$ ).

The median follow-up of patients with stable cirrhosis was 20 mo. During the study period, 17 patients died and 11 received liver transplantation. Bivariate analysis showed that progression to death or liver transplantation was associated with previous ascites (70.4% vs 42.3%,  $P = 0.009$ ), history of hospitalization for complications of cirrhosis (88.9% vs 65.8%,  $P = 0.018$ ), and Child-Pugh B/C (70.4% vs 24.3%,  $P < 0.001$ ) (Table 2). In addition, those with unfavorable outcome showed a higher median total bilirubin (1.80 mg/dL vs 0.90 mg/dL,  $P < 0.001$ ), INR (1.27 vs 1.16,  $P < 0.001$ ), CRP (4.51 mg/L vs 3.50 mg/L,  $P = 0.014$ ), MELD score (11.98  $\pm$  2.24 vs 9.32  $\pm$  1.97,  $P < 0.001$ ) and lower sodium (136.00 mEq/L vs 138.00 mEq/L,  $P = 0.022$ ), albumin (3.11  $\pm$  0.39 g/dL vs 3.52  $\pm$  0.44 g/dL,  $P < 0.001$ ) and IGFBP-3 values (1.44 mcg/mL vs 1.74 mcg/mL,  $P = 0.027$ ). A stepwise forward logistic regression analysis was performed including the following variables with  $P < 0.05$  in bivariate analysis: Previous ascites, history of hospitalization for complications of cirrhosis, albumin, INR, total bilirubin, CRP, sodium, and IGFBP-3. Multivariate analysis showed that only albumin (OR = 0.183, 95%CI: 0.053-0.631,  $P = 0.007$ ) and total bilirubin (OR = 2.482, 95%CI:

PPI: Proton-pump inhibitors; INR: International normalized ratio; CRP: C-reactive protein; IGFBP-3: Insulin-like growth factor-binding protein 3; MELD: Model for end-stage liver disease.

**Figure 1** Kaplan-Meier transplant-free survival of 138 outpatients with cirrhosis stratified according to insulin-like growth factor-binding protein 3 cut-off level of 1.67 mcg/mL. Survival probability after a median follow-up of 20 mo was 88.6% for patients with IGFBP-3  $\geq$  1.67 mcg/mL and 72.1% for those with IGFBP-3 < 1.67 mcg/mL ( $P = 0.015$ ). IGFBP-3: Insulin-like growth factor-binding protein 3.

1.358-4.538,  $P = 0.003$ ) were independently associated with death or liver transplantation during follow-up. However, at the end of follow-up, Kaplan-Meier survival probability was 88.6% for patients with IGFBP-3  $\geq$  1.67 mcg/mL and 72.1% for those with IGFBP-3 <

1.67 mcg/mL. The survival was significantly shorter for those with lower IGFBP-3 values (20.24 mo, 95%CI: 18.32-22.17) as compared to the remaining subjects (23.06 mo, 95%CI: 21.72-24.40) ( $P = 0.015$ ) (Figure 1).

Twenty-seven patients developed variceal bleeding during follow-up. Those patients exhibited similar baseline IGFBP-3 levels when compared to those who did not develop this complication (1.74 mcg/mL vs 1.69 mcg/mL,  $P = 0.478$ ).

One-hundred and nine patients underwent laboratory evaluation in 2014, and 12 subjects refused blood collection. Of those who did not receive liver transplantation, IGFBP-3 significantly decreased at the second assessment (1.67 mcg/mL vs 1.74 mcg/mL,  $P = 0.013$ ). However, in patients who underwent liver transplantation, a significant increase in IGFBP-3 was observed (3.81 mcg/mL vs 1.33 mcg/mL,  $P = 0.008$ ). Actually, IGFBP-3 increased in all nine patients, and its levels were restored to normal after transplantation in five subjects.

### Prognostic significance of IGFBP-3 in patients hospitalized for AD of cirrhosis

In hospitalized patients, IGFBP-3 levels were positively correlated with sodium ( $r = 0.173$ ,  $P = 0.018$ ) and albumin levels ( $r = 0.422$ ,  $P < 0.001$ ). A negative correlation was observed between IGFBP-3 levels and

SpO <sub>2</sub> /FiO <sub>2</sub> ratio, median	461.9	442.86	< 0.001

INR: International normalized ratio; CRP: C-reactive protein; IGFBP-3: Insulin-like growth factor-binding protein 3; MELD: Model for end-stage liver disease; MAP: Mean arterial pressure; SpO<sub>2</sub>/FiO<sub>2</sub>: Oxygen saturation to fraction of inspired oxygen ratio; ACLF: Acute-on-chronic liver failure.

INR ( $r = -0.437$ ,  $P < 0.001$ ), total bilirubin ( $r = -0.278$ ,  $P < 0.001$ ), CRP ( $r = -0.365$ ,  $P < 0.001$ ), MELD ( $r = -0.373$ ,  $P < 0.001$ ), and CLIF-SOFA ( $r = -0.410$ ,  $P < 0.001$ ). Significantly lower levels of IGFBP-3 were observed in Child-Pugh C patients (0.73 mcg/mL vs 1.13 mcg/mL,  $P < 0.001$ ), in those with ascites (0.76 mcg/mL vs 1.22 mcg/mL,  $P < 0.001$ ), hepatic encephalopathy (0.85 mcg/mL vs 1.12 mcg/mL,  $P = 0.001$ ), ACLF (0.78 mcg/mL vs 1.02 mcg/mL,  $P = 0.007$ ) and bacterial infection at admission (0.66 mcg/mL vs 1.11 mcg/mL,  $P < 0.001$ ). The etiology of cirrhosis had no impact on IGFBP-3 levels ( $P > 0.05$ ).

Overall 30-d mortality was 24.3%, and it was associated with active alcoholism in bivariate analysis (Table 3) (50.0% vs 31.5%,  $P = 0.023$ ) as well as ascites (76.1% vs 39.9%,  $P < 0.001$ ), hepatic encephalopathy (84.8% vs 51.0%,  $P < 0.001$ ), bacterial infection (48.9% vs 19.6%,  $P < 0.001$ ), Child-Pugh C (73.9% vs 28.7%,  $P < 0.001$ ), ACLF at admission (63.0% vs 11.2%,  $P < 0.001$ ), lower median SpO<sub>2</sub>/FiO<sub>2</sub> ratio (442.86 vs 461.90,  $P < 0.001$ ), and higher MELD

score (22.44 ± 6.95 vs 14.35 ± 5.00,  $P < 0.001$ ). The 30-d mortality was also related to higher median leucocyte count (8.46 × 10<sup>9</sup>/L vs 6.59 × 10<sup>9</sup>/L,  $P = 0.005$ ), creatinine (1.80 mg/dL vs 1.00 mg/dL,  $P < 0.001$ ), INR (1.60 vs 1.38,  $P < 0.001$ ), CRP (24.80 mg/L vs 8.40 mg/L,  $P = 0.002$ ), total bilirubin (3.10 mg/dL vs 1.51 mg/dL,  $P < 0.001$ ) as well as lower mean albumin (1.98 ± 0.51 g/dL vs 2.47 ± 0.70 g/dL,  $P < 0.001$ ), lower median sodium (134.00 mEq/L vs 136.00 mEq/L,  $P = 0.011$ ), and IGFBP-3 levels (0.63 mcg/mL vs 1.05 mcg/mL,  $P < 0.001$ ).

A stepwise forward logistic regression analysis was performed including the following variables with  $P < 0.010$  in the bivariate analysis: Ascites, hepatic encephalopathy, infection at admission, SpO<sub>2</sub>/FiO<sub>2</sub> ratio, leucocyte count, creatinine, INR, albumin, CRP, total bilirubin, and IGFBP-3. In this regression analysis, the 30-day mortality was independently associated with creatinine (OR = 5.331, 95%CI: 2.563-11.090,  $P < 0.001$ ), INR (OR = 5.830, 95%CI: 1.492-22.785,  $P = 0.011$ ), SpO<sub>2</sub>/FiO<sub>2</sub> ratio (OR = 0.985, 95%CI: 0.975-0.995,  $P = 0.004$ ), and IGFBP-3 (OR = 0.332, 95%CI: 0.120-0.915,  $P = 0.033$ ).

Fifty-four patients died and three subjects underwent liver transplantation during 90 d of follow-up. The Kaplan-Meier survival probability at 90-d was 80.4% in patients with IGFBP-3 ≥ 0.86 mcg/mL and 56.1% for subjects with IGFBP-3 < 0.86 mcg/mL ( $P < 0.001$ ) (Figure 2A). For the prediction of 90-d mortality, the IGFBP-3 at a cutoff of 0.86 mcg/mL showed a sensitivity of 63% and a specificity of 65%. The negative predictive value was 80% with a positive predictive value of only 44%. Figure 2A exhibited Kaplan-Meier curves for mortality during the follow-up period according to the presence of ACLF and IGFBP-3 categories. The Kaplan-Meier survival probability at 90-d was 89.5% in patients without ACLF and IGFBP-3 ≥ 0.86 mcg/mL. It was 70.7% for those with IGFBP-3 < 0.86 mcg/mL only, 42.9% for those with ACLF only, and 20.8% for patients with both ACLF and IGFBP-3 < 0.86 mcg/mL ( $P < 0.001$ , long-rank test). Similarly, the 90-d survival was 90.8% in patients with Child-Pugh A/B and with IGFBP-3 ≥ 0.86 mcg/mL, 78.9% for those with IGFBP-3 < 0.86 mcg/mL only, 54.8% for those with Child-Pugh C only, and 36.4% for Child-Pugh C patients with IGFBP-3 < 0.86 mcg/mL ( $P < 0.001$ ) (Figure 2B).

The MELD score was dichotomized as ≥ 17 and < 17 based on ROC curve. The 90-d Kaplan-Meier survival probability was 90.7% in patients with MELD < 17 and IGFBP-3 ≥ 0.86 mcg/mL, 80.5% for those with MELD < 17 and IGFBP-3 < 0.86 mcg/mL, 56.3% for those with MELD ≥ 17 and IGFBP-3 ≥ 0.86 mcg/mL, and 31.7% for patients with both MELD ≥ 17 and IGFBP-3 < 0.86 mcg/mL ( $P < 0.001$ ) (Figure 2C).

The IGFBP-3 levels were available for 163 patients at the third day of hospitalization and showed a significant decline vs admission values (0.76 mcg/mL vs 0.94 mcg/mL,  $P < 0.001$ ). However, neither the magnitude

**Figure 2** Cumulative 90-d transplant-free survival of hospitalized patients with cirrhosis according to insulin-like growth factor-binding protein 3, acute-on-chronic liver failure, Child-Pugh and model for end-stage liver disease. The 90-d survival was 89.5% in patients without ACLF and with IGFBP-3  $\geq 0.86$  mcg/mL, 70.7% for those with IGFBP-3  $< 0.86$  mcg/mL only, 42.9% for those with ACLF only and 20.8% for patients with both ACLF and IGFBP-3  $< 0.86$  mcg/mL (A:  $P < 0.001$ ). Similarly, survival probability was 90.8% in patients Child-Pugh A/B and with IGFBP-3  $\geq 0.86$  mcg/mL, 78.9% for those with IGFBP-3  $< 0.86$  mcg/mL only, 54.8% for those Child-Pugh C only and 36.4% for Child-Pugh C patients with IGFBP-3  $< 0.86$  mcg/mL (B:  $P < 0.001$ ). The 90-d Kaplan-Meier survival probability was 90.7% in patients with MELD  $< 17$  and IGFBP-3  $\geq 0.86$  mcg/mL, 80.5% for those with MELD  $< 17$  and IGFBP-3  $< 0.86$  mcg/mL, 56.3% for those with MELD  $\geq 17$  and IGFBP-3  $\geq 0.86$  mcg/mL and 31.7% for patients with both MELD  $\geq 17$  and IGFBP-3  $< 0.86$  mcg/mL (C:  $P < 0.001$ ). ACLF: Acute-on-chronic liver failure; IGFBP-3: Insulin-like growth factor-binding protein 3; MELD: Model for end-stage liver disease.

nor the occurrence of IGFBP-3 decline was related to the severity of cirrhosis or bad prognosis (data not shown). In addition, IGFBP-3 measured at the third day showed similar performance to admission levels when used at its best cutoff for prediction of 90-d mortality (0.68 mcg/mL). These metrics offered a sensitivity of 64%, specificity of 65%, negative predictive value of 83% and positive predictive value of 41%.

#### IGFBP-3 levels after hospital discharge

The 30 patients evaluated during hospitalization underwent laboratory analysis within a median 105 days after discharge. These were compared at two time points to investigate the impact of AD on IGFBP-3 levels. Vs inpatient assessment, significantly higher median IGFBP-3 levels were observed with outpatient evaluation (1.51 mcg/mL vs 1.07 mcg/mL,  $P < 0.001$ ). Likewise, an increase in IGFBP-3 levels at outpatient evaluation

were observed in 24 out of 30 patients included in this analysis (80%).

## DISCUSSION

Even though the course of cirrhosis varies according to several factors, the need for prognostic markers and scoring systems is critical to manage individuals facing different therapeutic options<sup>[21]</sup>. It was previously shown that IGFBP-3 levels in cirrhosis are related to the severity of liver dysfunction. This marker undergoes only slight influence from other factors not related to liver synthesis capacity. Therefore, IGFBP-3 is a potential and underexplored prognostic biomarker in liver cirrhosis.

Here, the IGFBP-3 levels correlated with several variables directly or indirectly associated with the intensity of liver dysfunction in both stable and decom-

pensated patients. These findings agree with previous studies, which demonstrated an association between lower IGFBP-3 levels and the severity of liver disease<sup>[5,7,10,21-24]</sup>. In a recent study including patients with AD of cirrhosis, we showed that patients with more severe liver dysfunction exhibited lower IGFBP-3 levels - these levels were not influenced by other parameters such as gender, etiology of cirrhosis and comorbidities<sup>[25]</sup>. In addition, this study showed that IGFBP-3 increased significantly after liver transplantation as well as after hospital discharge. These findings reinforce the impact of hepatic synthetic function on IGFBP-3 levels and support its utility as a potential biomarker for assessment of liver function.

In patients with stable cirrhosis, death or liver transplantation during follow-up was associated with lower IGFBP-3 levels in bivariate analysis. In addition, transplant-free survival was significantly shorter in subjects with IGFBP3 < 1.67 mcg/mL. Data about the prognostic significance of IGFBP-3 in cirrhosis are scarce. IGFBP-3 was evaluated in 354 patients with alcohol-induced liver disease from a large multicenter trial of the effect of malotilate on survival<sup>[26]</sup>. The mean follow-up period was 569 d and low IGFBP-3 levels were associated with poor prognosis, especially at a cutoff of 1.35 mcg/mL<sup>[26]</sup>. The difference between this cutoff and that in the present study probably reflects methodological issues or disparities in the severity of the disease across the cohorts. It is important to note that the European study included both patients with and without cirrhosis-no detailed analysis of only those with cirrhosis was provided<sup>[26]</sup>. In our data, IGFBP-3 was not associated with death or liver transplantation in the logistic regression analysis in stable cirrhosis. This can be explained by the relatively low number of events in this cohort. Nevertheless, these results indicate the potential of IGFBP-3 as a prognostic marker in stable cirrhosis.

In patients hospitalized for AD of cirrhosis, lower IGFBP-3 levels were associated with short-term mortality in both bivariate and multivariate analysis. There is no data about IGFBP-3 prognostic value in this setting. It is possible that suppressed IGFBP-3 reflects the acute deterioration of hepatic function as suggested by its lower levels in hospitalized cirrhosis vs outpatients. The Kaplan-Meier survival probability at 90 d was significantly worse in patients with IGFBP3 < 0.86 mcg/mL vs control subjects (56.1% vs 80.4%,  $P < 0.001$ ). This cutoff is markedly lower than the limits suggested by Møller *et al.*<sup>[26]</sup> as well as in our study for stable cirrhosis. This likely reflects the severe deterioration of hepatic function in AD of cirrhosis.

The significance of IGFBP-3 in AD of cirrhosis was evaluated according to two of the most important prognostic parameters in this setting: The presence of ACLF and Child-Pugh Classification. The ACLF definition used here was based on a modified version of the SOFA score (CLIF-SOFA) and was first proposed by the

EAS-CLIF Consortium in a large multicenter trial and subsequently validated<sup>[20,27]</sup>. Patients who presented with higher IGFBP-3 and without ACLF showed good prognosis (90-d survival approximately 90%). However, even in the absence of ACLF, low IGFBP-3 was associated with worse prognosis and a 90-d survival of 70.7%. Similarly, in the presence of ACLF, higher IGFBP-3 was associated with 90-d survival of 42.9% vs 20.8% for those with both ACLF and low IGFBP-3. These results indicate that combining IGFBP-3 and ACLF definition provided a well-defined four-level stratification for short-term prognosis in patients with cirrhosis hospitalized for AD. Similar results were observed for Child-Pugh Classification and MELD score although with a less clear stratification than that observed by using ACLF.

This study does have some limitations. The relatively small number of events in the stable cohort may have influenced the results - especially concerning regression analysis. In fact, regarding stable patients with cirrhosis there is still a need for validation of our results in larger cohorts with a longer follow-up before this biomarker is incorporated into clinical practice. Another limitation that we should highlight is the fact that we included a very heterogeneous population in distinct clinical scenarios and no specific treatment guidelines were created for the purpose of this study. Therefore, variations in the approach to specific cases are expected. In addition, the underlying liver disease status (if active or not) was not investigated. However, this issue is common in almost all studies investigating biomarkers in clinical settings. In addition, patients were evaluated according to standardized charts developed specifically for the purpose of the study and were followed both in outpatient clinic and in the ward by the same medical team. This minimized the impact of non-standardized approach.

In conclusion, in patients with cirrhosis IGFBP-3 levels correlated with several variables associated with severity of liver disease and improved significantly after discharge and after liver transplantation, indicating the impact of impaired hepatic function on its levels. Lower IGFBP-3 levels were associated with worse long-term prognosis in outpatients with stable cirrhosis and worse short-term prognosis in those hospitalized for AD. These findings suggest that measurement of circulating IGFBP-3 is of prognostic relevance and can be incorporated into clinical practice to improve the care of patients with liver cirrhosis.

## COMMENTS

### Background

Insulin-like growth factor-binding protein 3 (IGFBP-3) is the major binding protein of insulin-like growth factor (IGF) system, carrying 80%-90% of circulating IGF-1. IGFBP-3 has predominantly hepatic production and decreased IGFBP-3 serum levels have been reported in patients with cirrhosis and seem to correlate with hepatic dysfunction intensity. Although preliminary reports indicate a clinical applicability for the assessment of circulating IGFBP-3 in cirrhosis, there are very few data on prognostic significance of this biomarker

in this context.

### Research frontiers

Defining the prognosis of patients with cirrhosis is of great relevance in order to select appropriate candidates for distinct therapeutic approaches, such as liver transplantation.

### Innovations and breakthroughs

In the present study, IGFBP-3 levels correlated with several variables associated with hepatic dysfunction. Lower IGFBP-3 levels were associated with worse long-term prognosis in outpatients with stable cirrhosis and worse short-term prognosis in those hospitalized for acute decompensation.

### Applications

These data suggested that IGFBP-3 levels can be used solely or in combination with other models (including Child-Pugh, model for end-stage liver disease and acute-on-chronic liver failure definition) to evaluate the prognosis of patients with liver cirrhosis.

### Peer-review

This prospective study investigated the prognostic significance of IGFBP-3 in patients with cirrhosis. This is an interesting study, and this manuscript could provide useful information to readers.

Editorial Board Member of *World Journal of Hepatology*, Reem Al Olaby, BSc, MSc, PhD, Pharmacist, Research Associate, Research Fellow, Department of Biotechnology, The American University in Cairo, Doha 22188, Qatar

**AIM AND SCOPE**

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

**INDEXING/  
ABSTRACTING**

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

### Abstract

Quality of life (QoL) after deceased donor liver transplantation is increasingly recognized as a major outcome parameter. We reviewed recent publications in this rapidly evolving field in order to summarize recent achievements in the field and to define opportunities and perspectives for research and improvement of patient care. QoL does improve after liver transplantation according to a typical pattern. During the first year, there is a significant improvement in QoL. After one year, the improvement does stabilise and tends to decline slightly. In addition to the physical condition, different psychological parameters (such as depression, anxiety, sexual function) and socio-demographic elements (professional state, sex, marital state) seem to impact QoL. Opportunities for further research are the use of dedicated questionnaires and identification of influencing factors for QoL.

**Key words:** Epidemiologic factors; Liver transplantation; Demographic factors; Quality of life; Mental health; Sociological factors

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Quality of life (QoL) after deceased donor liver transplantation (LT) is increasingly recognized as a major outcome parameter. This review summarizes a broad spectrum of factors that influence QoL in LT and elucidates the evolution in time of physical and mental QoL after LT. Furthermore attention is given to areas for further investigation and the use of self-report QoL questionnaires in LT. This way, we want to offer a recent and complete overview in this rapidly evolving field.

Onghena L, Develtere W, Poppe C, Geerts A, Troisi R, Vanlander A, Berrevoet F, Rogiers X, Van Vlierberghe H, Verhelst X. Quality of life after liver transplantation: State of the art. *World J Hepatol* 2016; 8(18): 749-756 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i18/749.htm> DOI: <http://dx.doi.org/10.4254/>

## INTRODUCTION

In 1967, Thomas Starzl performed the first successful liver transplantation. Over the past few decades liver transplantation (LT) has become a widely accepted treatment for end-stage liver disease, acute liver failure and selected cases of hepatocellular carcinoma with excellent long-term results<sup>[1,2]</sup>. The first years after the introduction of liver transplantation were characterized by a marked increase of survival rates, due to better pre- and post-operative care, refinement of explanting techniques and organ preservation, better surgical techniques, the development of potent immunosuppressive drugs and improved patient selection. Therefore, mortality and morbidity have decreased<sup>[3,4]</sup>. Today liver transplantation has a three-month survival rate of about 91.2%, a five-year survival of about 73.3% and a ten-year survival of about 60%<sup>[3,5-7]</sup>.

Survival is the main outcome parameter after liver transplantation and a *conditio sine qua non*. However, once survival is granted, the real outcome parameter to address the success of liver transplantation on the long term is quality of life (QoL). QoL can be defined as "an overall sense of well-being, including aspects of happiness and satisfaction with life as a whole, which is measurable through mental well being, physical functioning and overall health status"<sup>[8]</sup>. The World Health Organization defines health as a "state of complete physical, mental and social well-being and not merely the absence of disease and infirmity". A shift of the focus from life expectancy to QoL can be observed in an increasing number of medical fields and is also taking place in organ transplantation research<sup>[9]</sup>. The goal of liver transplantation is to achieve a health status that is at least as good as it was before liver transplantation.

Since 2010 many authors have addressed the issue of QoL after LT. Our goal was to collect and compare these new insights and controversies in this research area.

## METHODOLOGY

We searched for articles in major databases (PubMed, Google Scholar and Science Direct) from 2009 to 2015. English, French and Dutch manuscripts were eligible.

Search terms "Quality of life" and "Liver transplantation" were used as MeSH terms or searched in the title of the article. Exclusion criteria were paediatric LT, living donor liver transplantation (LDLT) and articles published before 2009. Paediatric patients were excluded due to different interpretation of QoL, reliance on parents and difficult data collection. LDLT patients were excluded due to a different psychosocial process pretransplantation. Only articles between 2009 and 2015 were eligible for inclusion.

## STUDY RESULTS

### Description of selected manuscripts

Thirty-one publications met our criteria for the PubMed search, including 24 original articles and 7 reviews (Figure 1 and Table 1). The last search was performed September 1<sup>st</sup>, 2015.

### Components of QoL

**Overall QoL:** In general, health related QoL (HRQoL) improves and remains stable throughout the years after transplantation, but does not reach the level of the general population. This can be explained by the presence of comorbidities, the severity of the disease and the transplant procedure<sup>[3,8,10-14]</sup>.

HRQoL tends to increase rapidly during the first two years, and remains stable afterwards once almost normal values have been reached<sup>[8,15]</sup>. Some authors report a more fluctuating evolution with a rapid increase of QoL during the first six months, followed by a stabilization during the remainder of the first year and a rebound effect during the second year due to adaption to certain psychosocial conditions. Patients are confronted with their new health status and can experience problems with re-enrolment in society and more particular difficulties in their professional life. The rebound effect is due to the fact that patients slowly retrieve peer acceptance and can participate in professional and social activities. After two years, in these patients, an improvement can be found until the fifth year after LT<sup>[10]</sup>.

Overall, many studies have proven significant improvements in general and mental health, vitality, social and physical functioning<sup>[1,16]</sup>.

**Physical QoL:** Overall, physical health starts improving after the first month after transplantation. This effect lasts the first six months, up to 2 years after transplantation<sup>[17]</sup>. Fluctuations are not uncommon due to the rebound effect<sup>[10,13,16]</sup>. A lower physical activity can be seen 10 to 30 years post-transplantation in comparison to the general population. This can be explained by the effect of ageing<sup>[11,14]</sup>. Due to the rapid evolution in the field of LT, older studies do not reflect the common medical practice and should be read with caution.

In summary, an improvement is seen in physical functioning after LT after the first year, if major medical complications are absent, *e.g.*, cytomegalovirus reactivation, rejection and revision<sup>[1,18-22]</sup>.

**Mental QoL:** The World Health Organisation defines mental health as "a state of well-being in which every individual realizes his or her own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to her or his community"<sup>[23]</sup>. This vague definition complicates the assessment of mental health QoL after liver and impedes the comparison of different studies. Some authors assessed the mental QoL by measuring anxiety

**Figure 1** Summary of the search method. LT: Liver transplantation; LDLT: Living donor liver transplantation; QoL: Quality of life.

and depression, because of the high correlation with these mental diseases. Burra and Germani<sup>[14]</sup> showed in their systematic review an increase of depression and anxiety scores during the first year, followed by a decrease afterwards. However, another study reported a significant improvement of depression and anxiety rates especially during the first year after LT in the absence of complications such as biliary events, endocrine disorders, physical and psychiatric problems<sup>[11,15]</sup>. The relief of the stressful time-lapse awaiting transplantation combined with a better physical health status could be a logical explanation. Furthermore, differences might be related to the presence of underlying psychiatric morbidities. Affective illness, maladjustment and severe anxiety have been diagnosed in 19%-54% of patients during psychiatric evaluation. Obsessive-compulsive, somatization, anxiety and depression symptoms were frequently found. The transplantation and stay at intensive care unit have been considered as traumatic stressors that diminish QoL and can cause overall mental distress. These patients are prone to some psychiatric disorders (e.g., anxiety and affective disorders, post-traumatic stress disorder) and a low QoL after LT<sup>[21,24-31]</sup>.

The short form-36 questionnaire (SF-36) is extensively used to assess the health-related QoL, which is a reliable and standardized tool comparing as well the mental [the mental component summary score (MCS)] as the physical [physical component summary score

(PCS)] aspects of QoL. During the first month after liver transplantation, studies show a rapid improvement of the MCS; the improvement of the PCS is slower though more durable and remains at higher levels six to twelve months after transplantation<sup>[13,15]</sup>. Side effects of immunosuppressive drugs and unmet expectations after liver transplantation can also hamper the improvement of MCS<sup>[17]</sup>.

In summary an improvement is seen in the mental health status within the first months after transplantation and can be influenced by complications such as rejection, infections and biliary events. These are interesting targets for improvement<sup>[13-15,27]</sup>.

### Factors influencing QoL after transplantation

**Aetiology of liver disease:** The original liver disease leading might influence QoL afterwards. Patients transplanted for non-cholestatic liver diseases report a significantly lower QoL after LT in comparison to those with a cholestatic liver disease<sup>[12]</sup>. Patients with viral hepatitis tend to suffer more from anxiety after LT than patients with alcoholic liver disease<sup>[13]</sup>. However, others challenge these data<sup>[10,14,21]</sup>. The influence of aetiology on QoL needs further investigation, since it influences all aspects of QoL<sup>[2,14]</sup>.

**Socio-demographic factors:** The influence of gender on QoL remains a matter of debate, and data are conflicting<sup>[8,11,18]</sup>.

Relational status however, does impact QoL. Married patients have a better QoL after liver transplantation than single or non-married patients<sup>[8,19,28]</sup>. This might be explained by a better social support.

Employment after LT is a crucial factor influencing QoL. Unfortunately, only 25% will return to work after two years. Restarting an active professional life after LT generates an income, but also restores the functional role of the patient in society. In employed patients, physical functioning is also improved and this results in an overall better QoL<sup>[10,12-14,21]</sup>.

Early retirement, which is often observed in these patients, negatively impacts QoL. Patients with former alcoholic liver disease have a lower chance to return to work after transplantation, compared to other aetiologies, which can be related to the psychosocial burden present before liver transplantation. This can be explained by the psychosocial burden attached to addiction.

Professional activity before transplantation has a major impact on the general outcome after LT, which improves the activation grade after LT. As one might expect, the type of activities will determine the possibility to return to work, favouring higher educated patients compared to lower educated patients involved in physically demanding manual labour<sup>[1,3,13]</sup>.

Patients regaining professional activities after only one year had a better QoL on the long term with less emotional problems<sup>[1,3,8,10,28]</sup>. A possible bias could be that only patients in good general condition will resume

Table 1 Summary of used articles

Ref.	Title	Study design	Population (n)	Instruments used to assess QoL	Main conclusions
Masala <i>et al</i> <sup>[1]</sup>	Quality of life and physical activity in liver transplantation patients: Results of a case-control study in Italy	Case-control	45 transplant patients 108 controls	SF-36 IPAQ	Transplant recipients are more subject to psychological/emotional distress and low physical function than the general population
Lankarani <i>et al</i> <sup>[2]</sup>	Outcomes of liver transplantation for patients with acute liver failure	Retrospective cross-sectional study	12 ALF patients 20 cirrhotic patients	N/A	Liver transplantation is safe, effective and should be considered in patients diagnosed with ALF
Drent <i>et al</i> <sup>[3]</sup>	Symptom experience, nonadherence and quality of life in adult liver transplant recipients	Review	N/A	N/A	Health-related quality of life is satisfactory, but below the level of the general population
O'Mahony <i>et al</i> <sup>[4]</sup>	The future of liver transplantation	Review	N/A	N/A	Improvements in surgical techniques, postoperative care, and donor and recipient selection have all contributed to the increased success of OLT and to higher survival rates in patients with advanced liver disease
Saidi <sup>[5]</sup>	Current status of liver transplantation	Review	N/A	N/A	New problems that include severe organ shortage, recurrence of primary disease, opportunistic infections, and development of de novo malignancies are the major problems affecting further implementation of LT
Butt <i>et al</i> <sup>[6]</sup>	Quality of life, risk assessment, and safety research in liver transplantation: New frontiers in health services and outcomes research	Review	N/A	N/A	Recipient quality of life is an area that has grown in importance in the published literature, but several important questions remain unanswered in these areas that merit programmatic, interdisciplinary research
Jay <i>et al</i> <sup>[9]</sup>	A review of quality of life instruments used in liver transplantation	Review	N/A	N/A	There are no available instruments that allow for the precise and reliable assessment of the full QoL impact of liver transplantation
Wang <i>et al</i> <sup>[10]</sup>	Health-related quality of life after liver transplantation: The experience from a single Chinese center	Case-control	60 post-LT, 55 benign end-stage liver disease, 50 controls	SF-36	LT patients generally have a good HRQoL although some respects of their HRQoL remains to be improved. Lower family income and poor education are important factors relating to the poor HRQoL of LT patients
Chen <i>et al</i> <sup>[11]</sup>	Health-related quality of life of 256 recipients after liver transplantation	RCT	256	SF-36, BAI, SDS	Age > 45 yr at time of transplant, DDLT, full-time working, no complications, anxiety and depression were possible factors influencing postoperative HRQoL in liver recipients
Braun <i>et al</i> <sup>[12]</sup>	Quality of life after liver transplantation	Case-control	123 recipients, 40 patients on the waiting list and a cohort of healthy controls	EORTC QLQ C30 and a liver transplant specific module	Retransplantation was accompanied by a significant loss of QoL. Cyclosporine-treated recipients displayed a better QoL compared with those treated with tacrolimus. The influence of medical parameters, such as co-morbidity or immunosuppression, needs to be further established with reference to QoL. The global perception of quality of life increases after liver transplantation, but remains lower than in healthy subjects
Cannesson <i>et al</i> <sup>[13]</sup>	Vie quotidienne, grosseesse, qualité de vie après transplantation hépatique	Review	N/A	N/A	Liver transplantation is associated with an improvement in overall QoL. However, this improvement is lower than expected. QoL improves significantly early after liver trans-plantation, but it seems to decrease after the first year after transplantation
Burra <i>et al</i> <sup>[14]</sup>	Vie quotidienne, grosseesse, qualité de vie après transplantation hépatique	Review	N/A	N/A	High-dose steroid use for post-transplant immunosuppression in liver transplant recipients is associated with reduced physical and mental HRQoL and increased symptoms of anxiety
Zaydfudim <i>et al</i> <sup>[15]</sup>	Reduction in corticosteroids is associated with better health-related quality of life after liver transplantation	Retrospective analysis of prospective, longitudinal data	186	SF-36, BAI, and Center for Epidemiologic Studies Depression Scale	OLT improved HRQoL of end-stage liver patients and their spouses or caregivers
Sirivatanauskorn <i>et al</i> <sup>[16]</sup>	Quality of life among liver transplantation patients	Case-control	57 pre-LT 95 post-LT	SF-36, CLDQ	

Telles-Correia <i>et al</i> <sup>[17]</sup>	When does quality of life improve after liver transplantation? A longitudinal prospective study	Cohort study	60	SF-36	Our findings suggested that quality of life improved early after liver transplantation (1 mo). Between the first and the sixth months, there only was a significant improvement in the physical quality of life
Bownik <i>et al</i> <sup>[18]</sup>	When does quality of life improve after liver transplantation? A longitudinal prospective study	Review	N/A	N/A	Greater attention must be paid to patients' postoperative expectations and the effects of social influences (such as gender, education level, and socioeconomic and ethnic background)
Duffy <i>et al</i> <sup>[19]</sup>	When does quality of life improve after liver transplantation? A longitudinal prospective study	Prospective, cross-sectional study	168	SF-36, liver disease quality of life	More than 50% of LT recipients survive 20 yr, achieve important socioeconomic milestones, and report quality of life superior to patients with liver disease or other chronic conditions
Narumi <i>et al</i> <sup>[20]</sup>	Importance of awareness of perioperative social and physical situations of living donors for liver transplantation	Case-control study	31	SF-36, Hamilton's depression and anxiety scores	We must pay attention to depression and anxiety among living donors
Thiel <i>et al</i> <sup>[21]</sup>	Contributors to individual quality of life after liver transplantation	Cross-sectional study	71	SF-36, SEIQoL-DW	The five most nominated areas related to QoL are not related to health. By focusing on health, the importance of health-related factors is overrated, and the impact of non-medical effects is under-represented
Volk <i>et al</i> <sup>[22]</sup>	Organ quality and quality of life after liver transplantation	Retrospective cross-sectional study	171	SF-36	No association between organ quality and QoL after liver transplantation is found
Baranyi <i>et al</i> <sup>[24]</sup>	Overall mental distress and health-related quality of life after solid-organ transplantation: Results from a retrospective follow-up study	Retrospective follow-up	123	TERS, SCL-90-R SF-36	Transplantation recipients may face major transplantation- and treatment-related overall mental distress and impairments to their HRQoL. Further, overall mental distress is a high-risk factor in intensifying impairments to patients' overall quality of life
Jurado <i>et al</i> <sup>[23]</sup>	Coping strategies and quality of life among liver transplantation candidates	Observational	93	SF-36, MCMQ	Cirrhosis etiology is not a determinant factor of quality of life, whereas the acceptance-resignation coping strategy might lead to lower self-perception of quality of life
Lobo <i>et al</i> <sup>[26]</sup>	Care complexity, mood, and quality of life in liver pre-transplant patients	Cross-sectional	60	SF-36, HADS, INTERMED, EuroQoL	High frequency of complexity in liver transplant candidates in European hospitals, but wide between-center differences suggest that local studies in specific hospitals and/or countries may be necessary to document care needs
Martín-Rodríguez <i>et al</i> <sup>[27]</sup>	Affective status in liver transplant recipients as a function of self-perception of general health	Cross-sectional	168	SF-36, HADS	Transplant recipients with worse self-perception of general health presented the same anxiety-depressive levels as patients with severe liver disease in the pretransplantation phase
Santos <i>et al</i> <sup>[28]</sup>	Affective status in liver transplant recipients as a function of self-perception of general health	Observational, descriptive and transversal	73	SF-36, BDI, structured interviews	Psychological aspects related to transplants require psychological intervention because they can affect the recuperation process, the quality of life, and the adherence to treatment for potential transplant patients
Stille <i>et al</i> <sup>[29]</sup>	Pathways of psychosocial factors, stress, and health outcomes after liver transplantation	Longitudinal	130	N/A	A number of strong bidirectional relationships exist between coping style, self-regulatory ability, hostility, the caregiver relationship and family environment, personal and transplant-related stress over the second half of the first post-transplant year, and health (especially mental) outcomes at 12 mo post-transplant
Telles-Correia <i>et al</i> <sup>[30]</sup>	Predictors of mental health and quality of life after liver transplantation	Cross-sectional	60	SF-36	Quality of life improved early after liver transplantation (1 mo). Between the first and the sixth months, there only was a significant improvement in the physical quality of life
Telles-Correia <i>et al</i> <sup>[31]</sup>	Mental health and quality of life in alcoholic liver disease patients after liver transplantation: A prospective controlled study	Cross-sectional	45	SF-36, HADS, brief coping inventory	There is a favorable adjustment of alcoholic liver disease patients after transplantation as shown in coping mechanisms evolution, which might explain the improved mental health and quality of life dimensions

Poppe <i>et al</i> <sup>[32]</sup>	Improving quality of life in patients with chronic kidney disease: Influence of acceptance and personality	Cross-sectional	99	SF-36, ICQ, NEO-FFI	Acceptance is an important positive variable in accounting for health-related quality of life
Åberg <i>et al</i> <sup>[33]</sup>	Cost of a quality-adjusted life year in liver transplantation: The influence of the indication and the model for end-stage liver disease score	Cross-sectional	333	15D	The cost/QALY ratio for LT appears favorable, but it is dependent on the assessed time period and the severity of the liver disease
Fernández-Jiménez <i>et al</i> <sup>[34]</sup>	Comparison of quality of life between two clinical conditions with immunosuppressive therapy: Liver transplantation and multiple sclerosis	Cross-sectional	62	SF-36	Transplant recipients belong to a population that still requires special health care. Bio-psychosocial functioning is not fully restored

IPAQ: International Physical Activity Questionnaire; ALF: Acute liver failure; LT: Liver transplantation; QoL: Quality of life; HRQoL: Health related QoL; CLDQ: Chronic liver disease questionnaire; SF-36: Short form-36; OLT: Orthotopic liver transplantation; DDLT: Deceased donor liver transplantation; BAI: Beck anxiety inventory; SDS: Sheehan disability scale; EORTC QLQ: European Organization for Research and Treatment of Cancer, quality of life questionnaire; RCT: Randomized controlled trial; SEIQoL-DW: The schedule for the evaluation of individual quality of life - direct weighting; MCMQ: Medical coping modes questionnaire; SCL-90-R: Symptom checklist-90-revised; TERS: Transplant evaluation rating scale; HADS: Hospital anxiety and depression scale; BDI: Beck depression inventory; QALY: Quality-adjusted life year; ICQ: Illness cognition questionnaire; NEO-FFI: Neuroticism-extraversion-openness five-factor inventory; N/A: Not available.

work. Unemployment leads to a circulus vitiosus: Unemployed patients are less active, therefore less motivated which leads to reduced physical functioning and to lower employment. Professional reactivation should be stimulated after liver transplantation and is an interesting target for improvement of QoL.

**Depression and anxiety:** Patients with anxiety disorders or depression before LT report a lower QoL. Generally, it is assumed that mental disorders such as anxiety disorders and depression are mostly correlated with the severity of the disease pre-transplant and the occurrence of complications. However, some studies show that the acceptance of the disease is more predictive for a good or bad QoL than the severity of the disease<sup>[13,32]</sup>.

Importantly, high levels of depression may double the chances of mortality. More than half of the recipients experience at least one episode of anxiety disorder or depression within the first two years after transplantation. This negatively impacts MCS<sup>[8,11]</sup>.

**Sexual function:** An aspect of QoL that often remains taboo, is sexual function after LT. We found some conflicting results. As expected, sexual dysfunction seems to be related to old age, a positive post-transplant status and the presence of depression<sup>[14]</sup>. In a study of Cannesson *et al*<sup>[13]</sup>, 70% of the liver transplant recipients declare to have a satisfactory sexual life after LT, even though a decrease is seen in libido, sexual potency and starting of new sexual relationships, caused by bodily changes and immunosuppressive side effects. This high percentage may be caused by a reserve of patients to communicate openly about this topic. Sexual function after liver transplantation is a research area with unmet needs.

**Immunosuppressive therapy:** Intensified immunosuppressive therapy during the first six months after transplantation can cause uncomfortable side effects<sup>[5]</sup>. These side effects are common and remain a challenge on the long term<sup>[3]</sup>. Transplant recipients take a variation of immunomodulating drugs, such as mTOR and calcineurin inhibitors. Their side effects include diabetes mellitus, renal failure, hypertension, tremor, obesity and hypercholesterolemia<sup>[4,11,15]</sup>. Furthermore, corticosteroids, often used in the first 3 mo can cause insomnia, mood swings and anxiety<sup>[15]</sup>. Especially high doses of corticosteroids are associated with physical and mental health, however this correlation is not seen with low-dose corticosteroids. Corticosteroid restricting strategies can reduce long-term complications and support QoL<sup>[4,15]</sup>. Noteworthy, some observations report better QoL in patients using cyclosporines than patients using tacrolimus<sup>[8]</sup>. However, rejection and re-transplantation affect QoL, and should be avoided by proper immunosuppressive therapy<sup>[8,12,13]</sup>. We can conclude that the maximal reduction of side effects has a beneficial effect on QoL<sup>[12,33,34]</sup>.

**Waiting list:** Waiting for a liver transplantation can be long and stressful. The QoL of patients on the waiting list is significantly lower than the QoL of the general

population. Length of time spent on the waiting list has a negative impact on QoL. Thirty-eight percent of these patients are fearful (for rejection, death, recurrence of illness), 53% struggle with keeping up with their work-related functions and 23% experience social isolation. Anxiety and negative mood are known to get worse with increasing waiting time<sup>[13]</sup>. Nevertheless, some authors do not describe an increase in psychosocial stress<sup>[28]</sup>. More than half of the patients on the waiting list express a need for psychological counselling, which decreases during the waiting time<sup>[27]</sup>.

### Areas of controversy

**Areas for further investigation:** Although QoL has been extensively studied, we identified several areas of ambiguity. Identifying influencing factors of QoL is crucial to increase QoL after liver transplantation and needs further research<sup>[3,12]</sup>. In this line some interesting areas of research are: The influence of the underlying condition on QoL, gender, length of stay, immunosuppressive regimens, the influence of the recurrence of the initial liver disease, sexual function and professional reactivation. The development of more liver transplant specific outcome measures could be helpful<sup>[13,14]</sup>.

**Self-report QoL questionnaires:** For the assessment of QoL more than 50 different instruments are used, measurement is not standardized and generic health assessment questionnaires are very commonly used. The largest part of these instruments has not been designed to evaluate the health status of liver transplant patients. Consequently it is difficult to interpret the results of these questionnaires in a meaningful way<sup>[9,14]</sup>. The SF-36 is the most commonly used generic questionnaire. It offers broad-spectrum questions applicable to a variety of patient groups and enables comparison between different populations<sup>[1,9]</sup>. These questionnaires can be distributed before and after LT.

Alternative questionnaires are the Transplant Effects Questionnaire, the Positive Effects of Transplant Scale, the schedule for the evaluation of individual expects of QoL - direct weighting (SEIQoL-DW)... The SEIQoL-DW allows patients to name areas important for him/herself and weigh each area to the relative importance and fulfilment level. On the downside, it is a qualitative interview-based assessment with his inherent disadvantages<sup>[21]</sup>. This complicates its use in clinical studies and does not enable repeated questioning of the same patient. Other questionnaires are the International Physical Activity Questionnaire and the Chronic Liver Disease Questionnaire. Only 16% of the reported authors used disease-specific instruments<sup>[1,9,16]</sup>.

In conclusion, the best way to measure QoL after LT is the combination of generic questionnaires and disease-specific questionnaires, which offers a broad and thorough assessment of QoL. Jay *et al*<sup>[9]</sup> proposed the consistent use of validated, treatment-specific QoL instruments. This will result in a more accurate assessment of QoL in LT and lead to an increasing number of

studies with comparable endpoints.

## DISCUSSION

Quality of life should be a major concern for health workers involved in transplant medicine and should be the final "major outcome" to evaluate the success of liver transplantation on the long term. Fortunately, authors report a significant increase in QoL during the first year after liver transplantation, which remains stable afterwards. In general an improvement is seen both in physical and mental QoL. However, they express distinct dynamics after transplantation with a slower but more durable increase for the physical QoL compared to the mental QoL. An integrated biopsychosocial approach is the preferred model to evaluate QoL after liver transplantation.

QoL in liver transplantation is definitely influenced by numerous factors: Mental health, sociodemographic factors, underlying liver disease, immunosuppressive therapy, time on the waiting list, *etc*.

Our minireview has several limitations. Studies with different endpoints were used, since a lot of studies use different questionnaires to measure QoL. A general image of QoL in LT is given. Consequently not all aspects of QoL are reviewed in detail.

The latter could also be seen as strength of this article since we looked into almost all the aspects of QoL in liver recipients.

We can conclude that in order to further increase the QoL in LT recipients, multidisciplinary interventions of biosocial and psychological treatment are needed. An integrated approach of rehabilitation programs, psychological treatment and thorough repetitive medical follow-up seems to be helpful in these patients with physical and social problems, and stimulates the rehabilitation progress<sup>[8,10,28]</sup>. Longitudinal monitoring of QoL could increase insight into dynamics of QoL after LT and identify patients at risk for more thorough and individualized follow-up. This is a growing field of research with a lot of unanswered questions and opportunities for improvement strategies.

## Abstract

**AIM:** To evaluate the clinical characteristics and progression of liver abscess caused by toxocara.

**METHODS:** We retrospectively reviewed the medical records of patients with serum IgG antibody to *Toxocara canis* and liver abscess diagnosed using abdominal computed tomography between February 2010 and February 2015. Among 84 patients exhibiting serum IgG antibody to *Toxocara canis*, 34 patients were diagnosed with liver abscess and treated with albendazole. A follow-up period of 1 year was conducted.

**RESULTS:** Mean patient age was 53 (34-79) years, with 26 (76.5%) patients being male. Twenty-one (61.7%) patients were moderate or heavy drinkers, 23 (67.6%) patients had a history of eating raw meat or liver and 6 (17.6%) patients owned pet dogs or cats. Main patient symptoms consisted of right upper quadrant pain, fever, and fatigue; 18 (52.9%) patients, however, presented with no symptoms. Lung involvement was detected in 444 (11.7%) patients. The eosinophil count increased in 29 (85.3%) patients at initial diagnosis, and decreased in most patients after albendazole treatment. The initial serum IgE level increased in 25 (73.5%) patients, but exhibited various response levels after albendazole treatment. Liver abscess formation improved in all patients.

**CONCLUSION:** The liver abscess was improved with albendazole treatment.

**Key words:** Toxocariasis; Liver abscess; Eosinophilia

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** This is a retrospective study to evaluate the clinical characteristics and progression of liver abscess caused by toxocara. Eating uncooked food was a more common route of infection than contact with pet animals. Alcohol consumption, sex (male), and ingestion of raw meat or liver were considered to be significant risk factors for toxocariasis. Patients can present with no specific symptoms, eosinophilia, and/or increased levels of serum IgE. Liver abscess caused by toxocara has characteristic radiologic findings. Even if a few patients experience relapse or migration of abscess posttreatment, a good prognosis exists for the overall clinical course.

## INTRODUCTION

Toxocariasis is a parasitic infection caused by *Toxocara canis* or *Toxocara cati*. It is known as a main cause of eosinophilia<sup>[1]</sup>. Clinical manifestations of toxocariasis range from asymptomatic infection to involvement of various organs. Visceral larva migrans (VLM) means toxocara infection associated with various internal organs of the body<sup>[2]</sup>. Liver abscess represent one type of VLM, which differs from pyogenic liver abscess in displaying specific histologic and radiologic findings<sup>[3,4]</sup>. Hepatic VLM or liver abscess caused by toxocara can occasionally be detected as an abnormal finding at ultrasonography screening and therefore be misdiagnosed as a malignancy in patients with chronic liver disease or a history of other cancer(s)<sup>[5]</sup>. A thorough understanding of the clinical characteristics and progression of hepatic VLM or liver abscess caused by toxocara is necessary in order to determine potential factors that may help improve diagnosis, as well as avoid unnecessary testing and improper disease treatment.

## MATERIALS AND METHODS

We retrospectively reviewed the medical records of patients with serum IgG antibody to *Toxocara canis* and liver abscess diagnosed by abdominal computed tomography (CT) at Daegu Catholic University Hospital between February 23, 2010 and February 24, 2015. We investigated patients about a history of moderate

or heavy alcohol consumption, raw meat or cow's liver ingestion, and owning pet dogs or cats. We obtained liver transaminase levels, peripheral blood eosinophil counts, serum IgE levels, hepatitis B surface antigen and antibody and anti-hepatitis C virus antibody results. In addition, we obtained any history of underlying disease and other organ(s) involvement. Eosinophilia was defined as an absolute peripheral blood eosinophil count  $\geq 500/\mu\text{L}$ . Elevated serum levels of IgE were defined as IgE levels  $\geq 100$  IU/mL. We treated patients with liver abscess with 400 mg orally twice daily for 5 d. The follow-up protocol consisted of obtaining repeat eosinophil counts and serum IgE levels, as well as performing abdominal CT scans at various intervals for 1 year.

## RESULTS

Among a total of 84 patients exhibiting serum IgG antibody to *Toxocara canis*, 34 patients were diagnosed with liver abscess. Mean patient age was 53 years, with serum IgG antibody to *Toxocara canis* being three times more prevalent in men than in women (Table 1). Twenty-three (67.6%) patients had a history of eating raw meat or liver and 6 (17.6%) patients owned pet dogs or cats (Table 1). Four patients had no specific history of eating uncooked food or owning pet animals. Main patient symptoms consisted of right upper quadrant pain, fever, and fatigue. Eighteen (52.9%) patients were asymptomatic (Table 1). Five patients revealed involvement of other organs including the lung, a leg muscle, and the brain in addition to liver involvement (Table 1). One of four patients with lung involvement demonstrated concomitant brain involvement. Aspartate transaminase and alanine transaminase levels were normal in all patients except one who had alcoholic hepatitis. Twenty-nine (85.3%) patients initially presented with eosinophilia. Among these 29 patients, 17 had mild eosinophilia, 7 had moderate eosinophilia, and 5 had severe eosinophilia (Table 1). Twenty-five of 26 patients who had repeat serum IgE levels had initially increased IgE levels (Table 1). The remaining patient demonstrated an upper normal serum IgE level of 99 IU/mL. Liver abscess on dynamic CT included multiple lesions in 19 patients and a single lesion in 15 patients (Table 1). The lesions were seen as ill-defined, low-attenuating, oval nodules. They were faintly seen on arterial and equilibrium phase images and best seen on the portal venous phase. All of these 34 patients were treated with albendazole. After treatment, the eosinophil count was normal in 16 patients, decreased in 8, and remained the same in one (Table 2). The eosinophilic response pattern was divided into two groups: Continuously decreasing (15 patients, 62.5%) and fluctuating (9 patients, 37.5%). We were unable to evaluate the eosinophilic response in 9 patients. Among those patients, 5 had normal eosinophil counts at initial diagnosis and 4 did not participate in the follow-up protocol posttreatment. Fifteen of 24 patients who showed an eosinophilic response did so within 1 mo posttreatment. Six months after treatment, the serum

**Table 1** Baseline characteristics of patients with liver abscess caused by toxocara

Patients, <i>n</i>	34
Mean age, yr	53
Male, <i>n</i> (%)	26 (76.5)
Underlying disease, <i>n</i> (%)	
Hypertension	9 (26.5)
Diabetes	4 (11.8)

Severe (> 5000/ $\mu$ L)	5 (14.7)
Serum IgE, <i>n</i> (%)	
Normal (< 100 IU/mL)	1 (2.9)
Mild elevated (100-500 IU/mL)	10 (29.4)
Severe elevated (> 500 IU/mL)	15 (44.1)
Unknown	8 (23.5)
Liver abscess, <i>n</i> (%)	
Single	15 (44.1)
Multiple	19 (55.9)

Liver abscess caused by toxocara was related to sex (male), alcohol drinking, eating raw meat or liver. Laboratory characteristics showed normal liver enzymes, peripheral blood eosinophilia, and elevated level of serum IgE. RUQ: Right upper quadrant; CNS: Central nervous system; AST: Alanine aminotransferase; ALT: Aspartate aminotransferase.

IgE level increased in 7 patients, decreased in 8, and remained the same in 3 (Table 2). We were unable to evaluate the serum IgE response in 16 patients. Among these patients, 8 patients did not undergo check serum IgE level tests initially and the other 8 patients did not participate in the follow-up protocol. A follow-up CT was performed for 22 patients. Among these patients, 15 demonstrated disappearance of liver abscess within 3 mo and 21 within 6 mo. Relapse or migration of liver abscess was observed in 3 patients.

**Table 2** Therapeutic response after treatment with albendazole *n* (%)

Eosinophilia ( <i>n</i> = 25)	
Normalized	16 (64)
Decreased	8 (32)
No change	1 (4)
Serum IgE ( <i>n</i> = 18)	
Increased	7 (38.9)
Decreased	8 (44.4)
No change	3 (16.7)
Liver abscess ( <i>n</i> = 22)	
Improved	22 (100)
Not improved	0

Most eosinophil counts were normalized or decreased and all of the abscesses were improved on computed tomography after 1 year, but the levels of serum IgE showed variable response after 6 mo.

## DISCUSSION

Toxocariasis is a worldwide disease. The overall seroprevalence of toxocariasis has been reported as 13.9% in United States<sup>[6]</sup>, 2%-5% and 14%-37% respectively in the urban and rural areas of France<sup>[7]</sup>, 18% in China, 20% in Malaysia, 68% in Indonesia, and 81% in Nepal<sup>[8]</sup>. In South Korea the seroprevalence has been reported as 5% in Gangwon-do<sup>[9]</sup>, 6% in Seoul, and 11% in Gyeongsangnam-do<sup>[10]</sup>. The seroprevalence of toxocariasis in patients with eosinophilia has been reported as 64.9%-86.7% in Seoul<sup>[8,11]</sup>, 50.5% in Chungcheongnam-do<sup>[12]</sup>, and 62% in Pohang<sup>[13]</sup>. These reports confirm that toxocariasis is known to be a main cause of eosinophilia. Toxocara infection is caused by ingestion of embryonated eggs from the soil and pet animals or by ingestion of encapsulated larva while eating uncooked paratenic hosts<sup>[14]</sup>. In this study, eating uncooked food was a more common route of infection than contact with pet animals (67.6% vs 17.6%). Choi *et al*<sup>[8]</sup> suggested that ingestion of raw cow liver was related to an increased risk of toxocariasis, but not ingestion of raw meat or animal blood and owning dogs. Based on the results of our epidemiologic study, demonstrating that men are three times more susceptible to toxocariasis than women, and revealing that approximately 60% of the patients consumed alcohol, we consider sex (male) and alcohol consumption as risk factors for toxocariasis.

The most commonly utilized serologic test for toxocariasis is the detection of the serum IgG antibody to the toxocara excretory/secretory antigen (TES Ag) with a toxocara ELISA kit (Bordier Affinity Products, Crissier, Switzerland)<sup>[15]</sup>. Eosinophilia, elevated serum IgE levels or increased eosinophil cationic protein is helpful for the diagnosis of active toxocariasis<sup>[16-18]</sup>. Although the toxocara ELISA test possesses high sensitivity and specificity<sup>[15]</sup>, the test cannot differentiate present from past infections<sup>[16]</sup> and may produce cross-reactivity with other parasites such as *Clonorchis sinensis*, *Sparganum*, *Fasciola hepatica*, and *Paragonimus westermani*<sup>[2]</sup>. Infected larva can penetrate the intestinal wall through vessels and invade various organs such as the liver, lung, muscle,

eye, heart and central nervous system, etc<sup>[19,20]</sup>. We investigated other organ(s) involvement in 84 patients who had the IgG antibody for *Toxocara canis*, and found the organs involved, displayed in order of frequency, were the liver (40.5%), lung (27.4%), eye (8.3%), skin (3.6%), muscle (1.2%), and brain (1.2%). Lung involvement occurred in 11.8% of patients with liver abscess (Table 1). This occurrence, therefore, creates the necessity of assessing the possibility of lung involvement in patients with liver abscess caused by toxocariasis. TES Ag secreted from the epicuticle of the moving larva causes an immune reaction, which produces increased serum IgE and eosinophilia<sup>[21]</sup>. Liver abscess, histologically described as eosinophilic abscess or granuloma, results from eosinophilic inflammation which develops when larva remain in the liver<sup>[22]</sup>.

Approximately 50% of patients were asymptomatic. A small number of patients had right upper quadrant pain, fever, and fatigue (Table 1). It remains impossible to rule out liver abscess in patients with toxocariasis using only symptom information. In contrast to patients with hepatic visceral larva migrans or liver abscess caused by toxocara, approximately 90% of patients with pyogenic liver abscess have fever and approximately 70% have abdominal pain<sup>[23]</sup>. The possibility of abscess caused by toxocara must be considered if liver abscess is inadvertently detected upon abdominal ultrasonography during routine medical exams. CT findings of liver abscess caused by toxocara usually include lesions that measure approximately 1-1.5 cm in diameter; possess an oval shape, obscure margin, multiplicity, and hypodensity<sup>[3]</sup>. In contrast to hepatocellular carcinoma, CT findings for liver abscess include lesions that are regular, not round, and striking at portal venous phase<sup>[24]</sup>. We can confirm the CT findings cited in this study; however, one finding that differs from the previous study<sup>[24]</sup> is that data from this study reveal that a relatively high number of patients with single abscess existed.

Toxocariasis is a self-limiting disease; therefore, patients with mild symptoms do not necessarily require medication<sup>[2]</sup>. However, if patients have moderate or severe symptoms due to visceral larva migrans, they should be treated with albendazole<sup>[24]</sup>. Previous literature has recommended treating liver abscess regardless of symptom status because, compared with the control group, the albendazole group demonstrated accelerated liver abscess healing<sup>[5]</sup>. Twenty-four of 25 patients who presented with eosinophilia and had been treated with albendazole displayed decreased eosinophil counts. Fifteen of these patients (62.5%) had checked their eosinophil count within 1 mo posttreatment. All patients experienced decreased eosinophil counts. Previous literature has reported an eosinophilic response occurred 1 mo posttreatment<sup>[16]</sup>; therefore, we concluded that the eosinophilic response could be evaluated 1 mo posttreatment. In addition, if the eosinophilic count initially decreases, but continually increases during the posttreatment period, relapse or migration of lesions should be considered. Transient eosinophil count fluctuations, which can occur among eosinophilic response patients

as observed in this study, must also be considered. Abdominal CT and repeat eosinophil counts at follow-up can help distinguish relapse or migration from eosinophilic fluctuation. Repeat serum IgE levels at follow-up provides an inadequate evaluation measurement of treatment response because serum IgE responds unpredictably<sup>[16]</sup>. CT follow-up was performed within 3 mo for 68.2% of patients and liver abscess disappeared in all of them. We therefore concluded that CT scan results could be evaluated 3 mo posttreatment. We encountered relapse or migration of lesions in three patients at 4, 6 and 8 mo posttreatment. Eosinophilia developed in only one of these patients, while the other two experienced continuously decreasing eosinophil levels despite relapse or migration of lesions. Two of these three patients were retreated with albendazole, while the other was only observed. Subsequently, all lesions of all three patients disappeared. If this phenomenon is observed posttreatment, the possibility of reinfection also needs to be considered. No evidence exists confirming that patients who are experiencing relapse or migration of liver abscess, regardless of clinical symptoms or eosinophilia, should be retreated with albendazole. It is reasonable, however, to retreat relapsed or migrated lesions with albendazole because albendazole is inexpensive, easily available over the counter and has no significant side effects. Existence of toxocara-specific IgG antibody can persist for years after the disappearance of liver abscess. One study reported that the mean duration of IgG antibody existence in the body was 2.7 years<sup>[25]</sup>. IgG antibody detection was conducted at 3, 9, 18, 24 mo and 5 years each in five patients from this study. All patients persistently displayed IgG antibody during the follow-up period, therefore, excluding detection of serum IgG antibody testing from the follow-up protocol<sup>[16]</sup>.

The study has limitations as a retrospective study, so our recommendations about the evaluation measurement of treatment response are based on the literature data and not on the results of this study.

Liver abscess caused by toxocara is a disease resulting from the ingestion of uncooked food, which causes an immune reaction in the liver. Patients can present with no specific symptoms, eosinophilia, and/or increased levels of serum IgE. Toxocariasis has characteristic radiologic findings and may involve other organs such as the lung. Treatment of toxocariasis consists of taking albendazole for 5 d. After treatment, the eosinophil count starts to decrease within 1 mo and the abscess begins to disappear within 3 mo as displayed on CT scan. Complete disappearance of liver abscess can occur after 1 year. Even if a few patients experience relapse or migration of abscess posttreatment, a good prognosis exists for the overall clinical course of this disease.

## COMMENTS

### Background

Toxocariasis is a parasitic infection caused by *Toxocara canis* or *Toxocara cati*. It is known as a main cause of eosinophilia. Clinical manifestations of

toxocarasis range from asymptomatic infection to involvement of various organs. Liver abscess caused by toxocara can occasionally be detected as an abnormal finding at ultrasonography screening and therefore be misdiagnosed as a malignancy in patients with chronic liver disease or a history of other cancer(s). The authors evaluated the clinical characteristics and progression of liver abscess caused by toxocara.

### Research frontiers

This study contributes to determining potential factors that may help improve diagnosis of liver abscess caused by toxocara, as well as avoid unnecessary testing and improper treatment.

### Innovations and breakthroughs

In this study, all patients (62.5%) who had checked their eosinophil count within 1 mo posttreatment experienced decreased eosinophil counts. And all patients (68.2%) who had checked computed tomography (CT) follow-up within 3 mo posttreatment experienced disappearance of liver abscess. Therefore, the authors concluded that the eosinophilic response could be evaluated 1 mo posttreatment and CT scan could be evaluated 3 mo posttreatment.

### Applications

Human toxocarasis can clinically present as liver abscess. If a patient with a history of eating raw meat or liver presents peripheral eosinophilia and abnormal liver imaging, liver abscess caused by toxocara should be considered for diagnosis.

### Terminology

Toxocarasis: An infection transmitted from animals to humans caused by the parasitic roundworms commonly found in the intestine of dogs (*Toxocara canis*) and cats (*Toxocara cati*).

### Peer-review

Studies exploring toxocarasis in liver abscess have been infrequent. The author of this paper evaluated the clinical characteristics and progression of liver abscess caused by toxocara. This study is useful for diagnosing and monitoring the disease in the clinical practice.

## Abstract

**AIM:** To investigate Chinese physicians' awareness of the 2010 guidelines on the treatment of chronic hepatitis B virus (HBV) infection.

**METHODS:** This was a quantitative survey that investigated the characteristics and practices of physicians who were treating patients with hepatitis B, the profile of their patients and physician practices regarding the diagnosis and treatment of HBV at the time of the survey. Participants were randomly selected from available databases of Chinese physicians and requested to complete either an online or paper-based survey. Data from the survey responses were analysed. For data validation and interpretation, qualitative in-depth interviews were conducted with 39 of the respondents.

**RESULTS:** Five-hundred completed surveys, from 663 physicians were available for analysis. A mean of 175 chronic hepatitis B (CHB) patients was seen by each physician every month, of whom 85 (49%) were treated in line with therapeutic indications stated in the 2010 guidelines. A total of 444 (89%) physicians often (> 60% of the time) adhered to the guidelines. Most physicians used antiviral medications as recommended. For patients with compensated and decompensated cirrhosis, 342 (68%) and 336 (67%) of physicians, respectively, often followed the recommendation to use potent nucleos(t)ide analogues with a high genetic barrier to resistance, using the appropriate treatment more than 60% of the time. Physicians from infectious disease or liver disease departments were better informed than those from gastrointestinal or other departments.

**CONCLUSION:** The majority of Chinese physicians often adhere to Chinese 2010 CHB guidelines and are well-informed about the use of antiviral medications for hepatitis B.

**Key words:** Chronic hepatitis B; Practice guidelines; Awareness; China; Physicians

**Core tip:** In general, the majority of Chinese physicians often adhere to Chinese 2010 chronic hepatitis B guidelines and they are well-informed about the use of antiviral medications for hepatitis B. Most of the physicians who participated in our survey used antiviral medications as recommended. For patients with compensated and decompensated cirrhosis, more than two-thirds of physicians, often followed the recommendation to use potent nucleos(t)ide analogues with a high genetic barrier to resistance. Our survey also showed that physicians from infectious disease or liver disease departments were better informed than those from gastrointestinal or other departments.

## INTRODUCTION

The clinical management of chronic hepatitis B (CHB) has undergone dramatic changes over the past two decades following the registration worldwide of several antiviral agents that effectively suppress hepatitis B virus (HBV) loads<sup>[1-4]</sup>. Currently, the primary aim of CHB treatment is the permanent suppression of HBV replication to decrease viral infectivity and pathogenicity<sup>[5]</sup>. Two different classes of drug are used to treat HBV: Conventional interferon (IFN) or pegylated IFN, and oral nucleos(t)ide analogues (NAs). Nucleoside analogues include lamivudine, telbivudine, clevudine and entecavir, while nucleotide analogues include adefovir dipivoxil and tenofovir dipivoxil fumarate<sup>[5]</sup>. Guidelines have been developed to help standardise the prevention, diagnosis and treatment of CHB. Key clinical practice guidelines have been developed by the Asian Pacific Association for the Study of the Liver (APASL; 2012 update)<sup>[6]</sup>, the European Association for the Study of the Liver (EASL; 2012 update)<sup>[6]</sup> and the American Association for the Study of Liver Diseases (AASLD; 2009 update)<sup>[7]</sup>. In March 2015, the World Health Organization issued its first-ever guidance for the treatment of CHB<sup>[8]</sup>.

Chinese CHB guidelines were first developed in 2005 by the Chinese Society of Hepatology, Chinese Medical Association and Chinese Society of Infectious Diseases<sup>[9]</sup>, and updated in 2010<sup>[10]</sup>. The 2010 guidelines state that no antiviral treatment is recommended for chronic and inactive HBV carriers, although regular diagnostic tests should be performed to ensure criteria for antiviral therapy are not met. For hepatitis B e antigen (HBeAg)-positive and HBeAg-negative patients with CHB, both IFNs and NAs are recommended as first-line treatments. However, due to these patients' need for long-term treatment, it is recommended that those with HBeAg-negative CHB or CHB with cirrhosis (compensated or decompensated) receive treatment with NAs that have a high genetic barrier to resistance<sup>[10]</sup>.

It is known that the implementation of treatment guidelines in clinical practice can improve the outcome of patients, but despite wide promulgation, many guidelines are not readily accepted by physicians or incorporated in clinical management strategies<sup>[11]</sup>. There is some evidence of poor adherence to HBV treatment guidelines among healthcare providers in the United States who treat HBV/human immunodeficiency virus (HIV) co-infected patients<sup>[12]</sup>, but in general, real-world clinical practice with CHB guidelines is not well understood. In China, the prevalence of HBV is high<sup>[13,14]</sup> and physician adherence to CHB treatment guidelines could potentially have an important impact on the long-term outcome of a large

proportion of the CHB population. To date, there are limited available data on how CHB is treated in real-world clinical practice in China and whether physicians adhere to available guidelines. Therefore, the aim of this study was to investigate Chinese physicians' awareness of the updated 2010 Chinese CHB treatment guidelines<sup>[10]</sup>, to improve understanding of guideline use in clinical practice, and to assist with the development of future CHB clinical practice guideline updates.

## MATERIALS AND METHODS

### Study design

This was a quantitative survey to investigate the characteristics of physicians who treat patients with HBV, the profile of their patients and physician practices regarding the diagnosis and treatment of HBV. Three study dimensions were therefore included. The first captured physician gender, location, affiliation and professional position. The second captured number of CHB patients treated, proportion of HBeAg-positive and HBeAg-negative patients and the proportion of patients with cirrhosis. The third captured physician reference to the Chinese 2010 CHB guidelines<sup>[12]</sup>, as well as specific data on physician prescription, treatment and follow-up practices.

### Participants

Participants were randomly selected from internal databases of Chinese physicians, belonging to either SmithStreet (Shanghai, China) or Bristol-Myers Squibb (BMS; Shanghai, China). SmithStreet has proven experience in healthcare survey development, a focus on China growth strategies, and relevant experience in consumer health and prescription medicines. For survey data capture, physicians working in Chinese grade III hospitals and in liver disease or infectious disease departments were targeted, with appropriate segmentation to obtain an even distribution of physicians by region, city tier and professional position. In China, the Ministry of Health grades hospitals according to a three-grade system, which assesses a hospital's ability to provide medical care and medical education, and to conduct medical research. In general, grade III hospitals are considered the highest level in China. These hospitals are able to provide high quality, specialized care in well-equipped facilities. Considering the availability of medical education and specialized care at grade III hospitals, in general, physicians at these hospitals are thought to be at the forefront of clinical medicine.

Participants were approached by SmithStreet *via* phone or email, and also face-to-face for qualitative follow-up questions. There was a target sample size of 500 respondents, which was deemed sufficient to allow nationwide representation of the data. Participants were required to be physicians currently treating patients with HBV, but there were no other pre-specified eligibility criteria or screening questions prior to enrolment.

### Research setting

Survey questions were developed by SmithStreet. Contributions were made by leading physicians, who reviewed and provided feedback on the questions prior to survey initiation. Data were collected remotely online, *via* the SurveyMonkey® platform (<https://www.surveymonkey.com>). Physicians who were unable to complete the survey online were provided an offline survey by SmithStreet, which was distributed by post or fax; offline surveys were subsequently returned by email to SmithStreet for data collection and analysis.

### Data collection

Instruction guides for online and offline surveys were provided to participating physicians. A pilot online survey was tested on five randomly selected representative physicians outside of the target pool to obtain feedback on language, content and interface structure. Participant responses were captured by the SurveyMonkey® platform. For consistency during data extraction and analysis, data from the offline surveys were entered into SurveyMonkey® by SmithStreet. Respondents who completed the survey offline were given the opportunity to review their responses.

### Data analyses

All coding and data analyses were conducted by SmithStreet. Responses were reviewed to eliminate repeat submissions and incomplete responses. Follow-up phone calls were conducted with 25 randomly selected online respondents to verify their participation. Responses that were deemed invalid or defective were eliminated from the analyses. To assist with data validation and interpretation, qualitative in-depth interviews were conducted with 39 respondents of the quantitative survey. The statistical methods of this study were reviewed by Qing-Qing Dai of SmithStreet. No statistical tests were performed. The data are presented as percentages and described.

## RESULTS

### Characteristics of physicians

The first participant was screened on 21 March 2013 and the last participant completed the survey on 1 September 2013. Participant flow through the study is shown in Figure 1. Of 663 physicians who completed the survey, 500 were available for analysis (472 from online surveys); of these, 194 were recruited through BMS' physician database and 306 were recruited *via* SmithStreet's physician database. Demographics and background characteristics of the responding physicians are shown in Table 1. The majority were female, from South, North or East China, held attending level positions or above, and worked in an infectious diseases department (Table 1).

### Characteristics of treated HBV patients

Segmentation of physicians by number of CHB patients

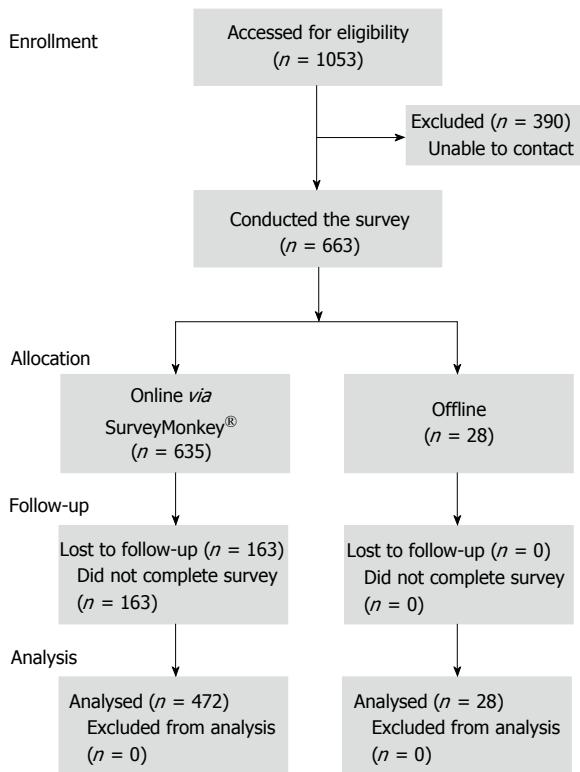

Figure 1 Participant flow through the study.

seen per month is shown in Figure 2. A mean of 175 CHB patients was seen by each physician every month, of whom 85 (49%) were treated with antiviral therapy in line with the therapeutic indications as stated in the Chinese 2010 CHB guidelines<sup>[12]</sup> and 46 (26%) had cirrhosis (27 with compensated cirrhosis). Among treatment-naïve CHB patients, 25 (14%) were HBeAg-positive and 21 (12%) were HBeAg-negative. The number of patients seen each month varied by physician rank, hospital grade, city tier and region; however, the number of treatment-naïve HBeAg-positive and HBeAg-negative patients seen by physicians each month was similar across different regions and city tiers. (In China, cities are ranked into tiers (tier I through IV) according to size and economic development, with tier I cities generally the largest economical hubs).

#### Physician awareness of guidelines

A total of 444 (89%) surveyed physicians indicated that they "often" (defined as more than 60% of the time) adhered to the Chinese 2010 CHB guidelines. In particular, more than 90% of physicians from infectious disease or liver disease departments often adhered to the guidelines (Figure 3).

Most physicians used antiviral medications consistent with guideline recommendations. However, in patients older than 40 years, who were HBV DNA-positive (but with  $< 1 \times 10^4$  copies/mL), and with alanine aminotransferase (ALT) levels above the upper limit of normal (ULN), 196 (39%) of the surveyed physicians did not consider antiviral medication necessary (Figure 4). The guideline recommends that in these patients, the

Figure 2 Segmentation of physicians. Segmentation of physicians by number of chronic hepatitis B (CHB) patients seen per month (A) in total, and (B) according to indications stated in the Chinese 2010 CHB guidelines<sup>[12]</sup>. A: Physicians ( $n = 500$ ) were asked, "how many CHB patients do you treat per month?"; B: Physicians ( $n = 500$ ) were asked, "amongst the CHB patients that you treat per month, how many of them are in line with the therapeutic indications as stated in the (Chinese 2010 CHB) guidelines?".

presence of liver fibrosis (as judged by the physician), should be an indication for antiviral therapy.

A total of 354 (71%) physicians could identify the distractor (HBeAg-positive, HBV DNA  $\geq 10^5$  copies/mL,  $1 \times \text{ULN} < \text{ALT} < 2 \times \text{ULN}$ ), including 194 (73%) of those from infectious disease departments, 106 (76%) from liver disease departments, 49 (62%) from gastroenterology departments, and five (29%) from other departments.

When asked for a response regarding the reasonable treatment course for antiviral medications, 422 (84%) physicians considered that more than 12 mo (responses for "12 to 18 mo" and "more than 18 mo") of consolidation treatment was needed for HBeAg-positive patients following serological conversion. However, this proportion was lower among physicians from gastroenterology ( $n = 54$ ; 68% of all physicians from gastroenterology departments) or other ( $n = 11$ ; 65%) departments, than among physicians from infectious disease ( $n = 236$ ; 89%) or liver disease ( $n = 121$ ; 87%) departments. For HBeAg-negative patients following serological conversion, 302 (60%) physicians considered that more than 18 mo of consolidation treatment was needed. However, this proportion was lower among physicians from gas-

**Figure 3 Physician adherence to the Chinese 2010 chronic hepatitis B guidelines.** Proportion of physicians adhering to Chinese 2010 chronic hepatitis B (CHB) guidelines<sup>[12]</sup> by (A) region, or (B) by hospital department or grade. "Often" defined as > 60% of the time, "sometimes" defined as > 30% to < 60% of the time and "seldom" defined as < 30% of the time.

troenterology ( $n = 40$ ; 51% of all physicians from gastroenterology departments) or other ( $n = 8$ ; 47%) departments, than among physicians from infectious disease ( $n = 169$ ; 64%) or liver disease ( $n = 85$ ; 61%) departments.

For patients with compensated and decompensated cirrhosis, 342 (68%) and 336 (67%) physicians, respectively, followed guidelines recommending the use of potent NAs with a high genetic barrier to resistance, using the appropriate treatment more than 60% of the time. This recommendation was followed most frequently by physicians from liver disease departments for patients with compensated and decompensated cirrhosis (both  $n = 100$ ; 72%). A low proportion of physicians did not follow this recommendation (use of the appropriate treatment less than 30% of the time) for compensated cirrhosis ( $n = 17$ ; 3%) and decompensated cirrhosis patients ( $n = 20$ ; 4%).

## DISCUSSION

Our survey results show that the majority of Chinese physicians often adhered to Chinese 2010 CHB guide-

lines<sup>[10]</sup>. Physicians from liver disease and infectious disease departments were most familiar with the guidelines, but physicians from other departments adhered to the guidelines less frequently, indicating that access to, or awareness of CHB treatment guidelines in China could be improved.

The physicians in this survey saw a mean of 175 CHB patients every month. This was below the number expected, especially for physicians working in tier I cities and grade III hospitals (210 and 184 patients per month, respectively; data not shown). We found 26% of patients to have cirrhosis, 29% to be HBeAg-positive and 23% to be HBeAg-negative. Nearly half (49%) of patients were treated in line with guidelines for various indications, and nearly nine out of 10 (89%) responding physicians often adhered to the guidelines; based on our clinical experience, this number is higher than expected.

In China, most patients with HBV are treated in infectious disease or liver disease departments, with physicians working in these departments generally regarded as specialists. Accordingly, when our survey results were analysed by hospital department, we found that adherence was greatest among physicians from infectious disease or liver disease departments. Adherence was slightly lower among physicians working in gastroenterology departments, but much lower among physicians from other departments. In Northwest China, the percentage of physicians who adhered to the guideline was noticeably lower than in other regions. Although

**Figure 4 Physician familiarity with various indications for antiviral medication.** Physician familiarity with the different indications for antiviral medication as described in the Chinese chronic hepatitis B (CHB) guidelines<sup>[12]</sup> is depicted here. The various indications are listed on the left. Physicians were asked, “does antiviral medication apply to the following cases?” and the proportion of physicians who would consider antivirals, no antivirals, and follow-up for each indication, is depicted in each horizontal bar. According to the Chinese 2010 CHB guidelines, general indications for antiviral treatment include: (1) hepatitis B e antigen (HBeAg)-positive and hepatitis B virus (HBV) DNA ≥ 105 copies/mL, or HBeAg-negative and HBV DNA ≥ 104 copies/mL; (2) alanine aminotransferase (ALT) ≥ 2 × upper limit of normal (ULN); or (3) ALT < 2 × ULN, but hepatic histology show Knodell histology activity index (HAI) ≥ 4, inflammation necrosis grade ≥ 2, or fibrosis stage ≥ 2. If HBV DNA is consistently positive but the above general indications cannot be reached, then antiviral treatment should be considered under the following circumstances: (1) ALT > ULN and age > 40 years; (2) ALT consistently normal and age > 40 years (can be closely monitored, but liver biopsy is recommended; antiviral treatment is indicated when Knodell HAI ≥ 4, or inflammation necrosis grade ≥ 2, or fibrosis stage ≥ 2); or (3) evidence of disease progression following dynamic observation (hepatic histology examination is recommended and antiviral treatment should be administered as necessary). For the distractor (HBeAg-positive, HBV DNA ≥ 105 copies/mL, 1 × ULN < ALT < 2 × ULN), liver biopsy tests are also needed to determine whether antiviral treatment is required. <sup>1</sup>Hepatic histology shows Knodell HAI ≥ 4, or inflammatory necrosis grade ≥ 2, or fibrosis stage ≥ 2; <sup>2</sup>HBV DNA < 104 copies/mL was considered HBV positive; <sup>3</sup>Equivalent to 2000 IU/mL; <sup>4</sup>Equivalent to 20000 IU/mL.

speculative, this may be due to a higher proportion of respondents who were residents, and a lower proportion of respondents who were chief physicians in Northwest China compared with other regions (data not shown). In addition, Northwest China had the second highest proportion of respondents from other departments (6%) and the second lowest combined proportion of respondents who were specialists (48% from infectious disease departments plus 23% from liver disease departments; data not shown).

Previous publications have demonstrated inadequacy of CHB management and need for improved education among Chinese physicians<sup>[15,16]</sup>. Even with the availability of CHB guidelines from key international associations, continual advancement in our understanding of CHB and availability of new data can create ongoing challenges regarding who should be treated and for how long<sup>[17]</sup>. Chao *et al.*<sup>[16]</sup> (2010) previously reported that there is a lack of basic knowledge surrounding HBV natural history, prevention and transmission. They identified critical gaps in HBV knowledge; in particular, 34% of physicians surveyed in their study did not know that CHB is often asymptomatic, 29% did not know that CHB infection confers a high risk of cirrhosis, liver cancer and premature death, and only 31% knew the recommended protocol for testing liver function and screening for liver cancer in CHB<sup>[16]</sup>.

In contrast, in our study, the majority of physicians were found to be well-informed about the importance of antiviral medication and were educated on the appropriate indications for their use. However, there was some inconsistency among physicians regarding the use of antiviral treatment for patients older than 40 years, who present with HBV DNA of < 1 × 10<sup>4</sup> copies/mL, and ALT levels above the ULN. The guideline recommends that these patients be initiated on antiviral therapy if they have liver fibrosis (as judged by the physician). For these patients, liver biopsy is clearly important when making treatment decisions.

As expected, and in line with the proportion of physicians who adhered to the Chinese 2010 CHB guidelines, physicians from infectious disease and liver disease departments were better able to identify the distractor, followed by those from gastroenterology departments and physicians from other departments.

According to the Chinese 2010 CHB guidelines, the endpoint for antiviral treatment in HBeAg-positive patients should be HBV DNA levels below the lower limit of detection, normalisation of ALT levels, HBeAg seroconversion, at least 1 year of consolidation therapy and a total treatment duration of at least 2 years. In HBeAg-negative patients, these criteria are the same for HBV DNA and ALT levels, but at least 1.5 years of consolidation therapy and a total treatment duration of at least 2.5 years is recommended<sup>[10]</sup>. We found that 84% and 60% of physicians often followed recommendations for consolidation therapy for HBeAg-positive and HBeAg-negative patients, respectively. Physicians from infectious disease or liver disease departments again showed greatest awareness of the guidelines in this context. For HBeAg-negative patients, the optimal duration of NA treatment is unknown unless hepatitis B surface antigen seroclearance has occurred, and the decision to stop therapy can be based upon clinical response and severity of the underlying liver disease<sup>[5]</sup>; this flexibility may explain the lower adherence to recommended endpoints for HBeAg-negative patients compared with HBeAg-positive patients.

As CHB requires long-term treatment, the Chinese

2010 CHB guidelines recommend that HBeAg-negative CHB patients and CHB patients with cirrhosis (compensated or decompensated) receive treatment with NAs that have a high genetic barrier to resistance<sup>[10]</sup>. We found that, in both patients with compensated and decompensated cirrhosis, over two-thirds of physicians often followed guidelines recommending the use of potent NAs with a high genetic barrier to resistance. While this finding is promising for the appropriate antiviral treatment of patients with CHB, this alignment with the guidelines was higher than expected.

Although the majority of Chinese physicians in our survey often adhered to Chinese 2010 CHB guidelines, our results also showed that there is a need to improve physicians' awareness and knowledge of CHB guidelines. This was particularly evident among non-specialists, where a need for education on CHB and its treatment was confirmed. Although physicians from gastroenterology departments were relatively well-informed about CHB, their awareness of CHB guidelines was lower than that of specialist physicians from infectious disease or liver disease departments, implying that Chinese gastroenterologists may require additional training on HBV antiviral recommendations. The delay and reduction of liver cirrhosis is one goal of CHB treatment<sup>[5]</sup> and the Chinese 2010 CHB guidelines provide specific recommendations for antiviral treatment and follow-up in CHB patients with cirrhosis<sup>[10]</sup>. Since patients with cirrhosis are frequently referred to gastroenterologists, consensus statements for treatment of cirrhotic HBV patients with antiviral therapy should help educate Chinese gastroenterologists moving forward.

Other than general limitations associated with the acquisition of data using a survey design, the respondent pool in our survey could be considered a potential limitation leading to over- or underestimation of guideline awareness and uptake. In particular, our survey included only one grade I hospital, the majority of physicians came from grade III hospitals and physicians from Southwest China or other departments may have been under-represented. In addition, this survey was based upon the latest update to the Chinese CHB guidelines; because this update was published in 2010, and this survey was completed at the end of 2013, this survey may not reflect changes in physician attitudes or education in the past few years.

This survey has shown that the majority of Chinese physicians often adhered to Chinese 2010 CHB guidelines and were well-informed about the use of antiviral medication for HBV. However, there is a need to further educate non-specialist physicians who treat patients with CHB and to promote physician adherence to future CHB guidelines or updates.

The majority of Chinese physicians often adhere to Chinese 2010 CHB guidelines and they are well-informed about the use of antiviral medications for hepatitis B. In general, the physicians who participated in our survey used antiviral medications as recommended. For patients with compensated and decompensated cirrhosis, more

than two-thirds of physicians, often followed the recommendation to use potent nucleos(t)ide analogues with a high genetic barrier to resistance. We found that physicians from infectious disease or liver disease departments were better informed than those from gastrointestinal or other departments.

## ACKNOWLEDGMENTS

The survey that formed the basis of this study was sponsored by Bristol-Myers Squibb. The survey was executed by SmithStreet. Editorial support for this manuscript was provided by Manette Williams, PhD, from Nucleus Global.

## COMMENTS

### Background

The implementation of treatment guidelines in clinical practice can improve the outcome of patients, but despite wide promulgation, many guidelines are not readily accepted by physicians or incorporated in clinical management strategies. In China, the prevalence of hepatitis B virus (HBV) is high and physician adherence to chronic hepatitis B (CHB) treatment guidelines could potentially have an important impact on the long-term outcome of a large proportion of the CHB population. There are limited available data on how CHB is treated in real-world clinical practice in China and whether physicians adhere to available guidelines. The authors investigated Chinese physicians' awareness of the updated 2010 Chinese CHB treatment guidelines.

### Research frontiers

CHB patients require long-term treatment and it is recommended that those with hepatitis B e antigen negative CHB or CHB with cirrhosis (compensated or decompensated) receive treatment with nucleos(t)ide analogues that have a high genetic barrier to resistance. Despite these recommendations, many treatment naïve CHB patients do not receive appropriate treatment because physicians do not adhere to the treatment guidelines. The authors assessed how well Chinese physicians adhere to the Chinese CHB treatment guidelines, released in 2010.

### Innovations and breakthroughs

The authors show that in China, the majority of Chinese physicians often adhere to Chinese 2010 chronic hepatitis B guidelines and they are well-informed about the use of antiviral medications for hepatitis B.

### Applications

Despite high adherence rates, there was some inconsistency among physicians regarding the use of antiviral treatment for patients older than 40 years, who present with HBV DNA of  $< 1 \times 10^4$  copies/mL, and alanine aminotransferase levels above the upper limit of normal. The guideline recommends that these patients be initiated on antiviral therapy if they have liver fibrosis (as judged by the physician). For these patients, liver biopsy is clearly important when making treatment decisions.

### Terminology

HBV DNA levels, measure in copies/mL indicates the rate of viral replication. Low or undetectable levels (about 300 copies/mL) indicate "inactive infection", whereas higher levels indicate "active infection".

### Peer-review

It is a well-designed study and provides useful information to physicians especially treating patients with hepatitis B about the trends in the treatment of CHB.

### Abstract

**AIM:** To compare the efficacy and safety of yttrium-90 radioembolization (Y90RE) and transarterial chemoembolization (TACE) in hepatocellular carcinoma patients.

**METHODS:** Bibliographic research was conducted on main scientific databases. When there was no statistically significant heterogeneity, pooled effects were calculated using a fixed-effects model by means of Mantel-Haenszel test, otherwise, a random-effects model was used with DerSimonian and Laird test. Summary estimates were expressed in terms of odds ratios (ORs) and 95%CI. The probability of publication bias was assessed using funnel plots and with Begg and Mazumdar's test. Sensitivity analysis was finally conducted using the method of excluding extreme data.

**RESULTS:** A total of 10 studies were analyzed, of which 2 randomized controlled trials. Survival rate (SR) assessed at 1 year showed an absolute similarity between the two treatment groups (OR = 1.01, 95%CI: 0.78-1.31,  $P = 0.93$ ). As long as time elapsed since the treatment, ORs for survival rate tended to significantly increase, thus meaning better long-term outcomes in patients who underwent Y90RE (2-year SR: OR = 1.43, 1.08-1.89,  $P = 0.01$ ; 3-year SR: OR = 1.48, 1.03-2.13,  $P = 0.04$ ). Meta-analysis of plotted hazard ratios (HRs) determined a non-significant overall estimate in favor of Y90RE (HR = 0.91, 0.80-1.04,  $P = 0.16$ ). Y90RE showed a statistically significant benefit as compared to TACE in terms of higher progression-free survival rate

assessed at 1 year (OR = 1.67; 95%CI: 1.10-2.55;  $P = 0.02$ ). Pooled analyses do not revealed a statistically significant increase in OR for tumor objective responses after Y90RE with respect to TACE (OR = 1.22, 95%CI: 0.69-2.16,  $P = 0.50$ ). A non-significant trend in favor of Y90RE was observed according to adverse event rate (OR = 0.70, 0.38-1.30,  $P = 0.26$ ).

**CONCLUSION:** Our meta-analysis reveals that Y90RE and TACE show similar effects in terms of survival, response rate and safety profile, although tumor progression is delayed after radioembolization.

**Key words:** Yttrium-90 radioembolization; Transarterial chemoembolization; Hepatocellular carcinoma; Survival; Prognosis; Recurrence

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** A clear evidence in support of the superiority of yttrium-90 radioembolization (Y90RE) over chemoembolization (TACE) in hepatocellular carcinoma patients is still lacking. Results of our meta-analysis reveal that Y90RE and TACE show similar effects in terms of survival, response rate and safety profile, although tumor progression is delayed after radioembolization. Similar results were found as for objective response rate and safety profile. The sole statistical difference was with regard to 1-year progression-free survival, which resulted significantly in favor of Y90RE (OR = 1.67,  $P = 0.02$ ).

## INTRODUCTION

Hepatocellular carcinoma (HCC) is a global health problem, representing the third most common cause of cancer-related death and the leading cause of mortality among patients with cirrhosis<sup>[1,2]</sup>. Thanks to the recent improvements in surveillance protocols, diagnostic tools and therapeutic armamentaria, nowadays early HCC diagnosis is feasible in 30%-60% of cases in developed countries<sup>[3]</sup>. However, a substantial proportion of patients develop tumoral portal vein thrombosis (PVT) or a multifocal pattern as a result of HCC recurrence or progression, leading to an advanced disease stage not amenable to curative treatments.

Transarterial chemoembolization (TACE) is the most widely used primary treatment for unresectable HCC and the recommended first line-therapy for patients in intermediate stage<sup>[2,4,5]</sup>. The rationale for TACE is that

intra-arterial infusion of a cytotoxic agent followed by embolization of the tumor-feeding blood vessels will result in a strong cytotoxic and ischemic effect<sup>[4,5]</sup>.

A novel technique in the field of loco-regional treatments for HCC is called transarterial radioembolization with yttrium-90 (Y90RE), which induces tumor necrosis by means of injection of glass or resin microsphere loaded with yttrium-90<sup>[6,7]</sup>. Y90RE, which is in fact a novel form of liver-directed brachytherapy, has already demonstrated its efficacy in HCC patients leading to delayed time to progression (TTP) and prolonged overall survival (OS)<sup>[8,9]</sup>. Commonly adopted Y90-loaded microspheres present usually a small size (< 40  $\mu\text{m}$ ), therefore due to their microembolic effect they can be used even in patients with portal vein occlusion. Furthermore, because of absence of flow obstruction, in the case of Y90RE there is no hypoxia-initiated cascade and therefore typical post-TACE sequelae as post-embolization syndrome are less common<sup>[6,7]</sup>.

Although several studies comparing the two loco-regional techniques have been recently published, whether there is a clear superiority of one treatment over the other is still debated.

In this study, we performed a meta-analysis to compare the efficacy of Y90RE and TACE in treating patients with unresectable HCC considering as main endpoints survival rate (SR), progression-free survival (PFS) and adverse events rate. We think that the comparison of these two procedures could help to better define the treatment strategy in intermediate/advanced HCC patients.

## MATERIALS AND METHODS

### Inclusion and exclusion criteria

This meta-analysis only included studies meeting the following criteria: (1) studies comparing Y90RE and TACE in HCC patients; (2) studies published in English; and (3) articles reporting at least one of the following data: TTP, survival and adverse events.

### Search strategy

Figure 1 reports the search strategy followed in the meta-analysis.

Bibliographic research was conducted on PubMed, EMBASE, Cochrane Library and Embase including all studies fulfilling inclusion criteria published until January 2016. Keywords used included "transcatheter arterial chemoembolization", "TACE", "transcatheter arterial radioembolization", "TARE", "liver cancer", "hepatocellular carcinoma" and "HCC". Relevant reviews and meta-analyses of loco-regional treatments in unresectable HCC were examined for potential suitable studies. Authors of included studies were contacted to obtain full text or further information when needed.

### Data extraction and management

Data extraction was conducted by two reviewers (Facciorusso A and Muscatiello N) using a standardized

**Figure 1** Flow chart summarizing study selection. HCC: Hepatocellular carcinoma; TACE: Transarterial chemoembolization; Y90RE: Yttrium-90 radioembolization.

approach (PRISMA Statement)<sup>[10]</sup>. Data on publication details (year of publication, name of first author and country), study characteristics (patients' age and sex, study design, sample size, Child-Pugh stage, interventions, follow-up duration), OS, TTP, and 1-year SR were gathered. Case reports and abstracts or studies with insufficient data were excluded. In case of repetitive publications from the same population, only most recent and complete articles were included.

The quality of the included studies was assessed by two authors independently (Facciorusso A and Muscatiello N) according to the currently accepted criteria described elsewhere<sup>[11,12]</sup>.

Disagreements were resolved by discussion and following a third opinion (Serviddio G).

### Statistical analysis

$\chi^2$  and  $I^2$  tests were used for across studies comparison of the percentage of variability attributable to heterogeneity beyond chance.  $P < 0.10$  for  $\chi^2$  test and  $I^2 < 25\%$  were interpreted as low-level heterogeneity.

When there was no statistically significant heterogeneity, pooled effects were calculated using a fixed-effects model by means of Mantel-Haenszel test; otherwise, a random-effects model was used with DerSimonian and Laird test. Summary estimates were expressed in terms of odds ratios (ORs) and 95%CI.

Probability of publication bias was assessed using funnel plots and with Begg and Mazumdar's test. To explore eventual sources of heterogeneity, we compared summary results obtained from subsets of studies grouped according to their design or quality. Sensitivity analysis was finally conducted using the method of excluding extreme data (the maximum or the minimum).

All statistical analyses were conducted using RevMan version 5 from the Cochrane collaboration. For all calculations a two-tailed  $P$  value of less than 0.05 was considered statistically significant.

## RESULTS

### Selection of studies

After initial screening, 66 potentially relevant articles were identified; 34 were excluded because dealing with non-HCC patients and 22 due to missing or incomplete data. Clinical data of 1557 patients from 10 studies were finally pooled to compare Y90RE and TACE (Figure 1).

### Characteristics of included articles

A total of 10 studies published from 2005 to 2015 were analyzed, which included 461 HCC patients treated with Y90RE and 1096 who underwent TACE<sup>[13-22]</sup> (Table 1).

Among these articles, 8 were retrospective studies<sup>[13-18,20,22]</sup> and 2 were randomized controlled trials (RCTs)<sup>[19,21]</sup>. Overall, 5 studies (of which 1 RCT) were judged high quality<sup>[14,16-19]</sup> and 5 (of which 1 RCT) moderate quality<sup>[13,15,20-22]</sup> (Table 2). In all the studies, the two treatment cohorts were well-balanced in terms of either clinical parameters and tumoral stage (Table 2).

### Survival

Data on overall survival were available for 1481 patients enrolled in 9 studies<sup>[14-22]</sup>, which estimated this outcome by means of Kaplan-Meier curves and compared the two groups using log-rank test. Table 3 describes summary estimates for SR at three consecutive time-points, specifically at 1, 2 and 3 years. SR at 1 year was reported in all the aforementioned nine studies and showed an absolute similarity between the two treatment groups (OR = 1.01, 95%CI: 0.78-1.31,  $P = 0.93$ ). As long as time elapsed since the treatment, ORs for survival rate tended to significantly increase, thus meaning better long-term outcomes in patients who underwent Y90RE (2-year SR: OR = 1.43, 1.08-1.89,  $P = 0.01$ ; 3-year SR: OR = 1.48, 1.03-2.13,  $P = 0.04$ ). Notably, the number of studies reporting long-term outcomes tended to decrease with 7 studies assessing 2-year SR<sup>[15-20,22]</sup> and only 5 reporting 3-year SR<sup>[15,16,18-20]</sup>. No evidence of heterogeneity was found at any time points (Table 3).

In order to obtain a more robust and reliable estimate of patient survival, we performed a meta-analysis of plotted hazard ratios (HRs) from 7 studies which provided data to calculate this parameter<sup>[14-20]</sup>, obtaining as result a non-significant overall estimate in favor of Y90RE (HR = 0.91, 0.80-1.04,  $P = 0.16$ ; Figure 2). There was only a low level of heterogeneity among studies [ $\chi^2 = 7.32$ ,  $df = 6$  ( $P = 0.29$ ),  $I^2 = 18\%$ ] and no publication bias was detected by using funnel plot (Figure 3) and performing Begg and Mazumdar's test ( $P = 0.51$ ). Subgroup analysis retrieving separately results of the only RCT and observational studies did not alter the final findings of our meta-analysis ( $P = 0.77$  and 0.16, respectively). Sensitivity analysis was also performed by restricting analysis to high-quality

**Table 3** Odds ratios and heterogeneity of 1-year, 2-year and 3-year survival rate

Survival estimate	No. of studies	No. of patients	OR (95%CI)	P-value	Heterogeneity	
					I <sup>2</sup>	P
1-yr SR	9	1481	1.01 (0.78-1.31)	0.93	0%	0.71
2-yr SR	7	1382	1.43 (1.08-1.89)	0.01	0%	0.93
3-yr SR	5	1261	1.48 (1.03-2.13)	0.04	0%	0.44

SR: Survival rate; OR: Odds ratio.

studies and by excluding each article once per time and it showed that the outcome effect was coherent (data not shown).

### PFS

Data on tumor progression was available in 4 studies<sup>[16,19-21]</sup>. Y90RE showed a statistically significant

**Figure 2 Forest plot of hazard ratios for overall survival after yttrium-90 radioembolization and transarterial chemoembolization.** Overall estimate was non-significantly in favor of Y90RE (HR = 0.91, 0.80-1.04,  $P = 0.16$ ). There was only a low level of heterogeneity among studies [ $\chi^2 = 7.32$ ,  $df = 6$  ( $P = 0.29$ ),  $I^2 = 18\%$ ]. Y90RE: Yttrium-90 radioembolization; TACE: Transarterial chemoembolization; HR: Hazard ratio.

**Figure 3 Funnel plot for detection of publication bias with regard to overall survival.** No evidence of publication bias was detected. HR: Hazard ratio.

benefit in terms of higher PFS rate assessed at 1 year (OR = 1.67; 95%CI: 1.10-2.55;  $P = 0.02$ ) (Figure 4). There was no evidence of heterogeneity among individual studies ( $P = 0.66$ ;  $I^2 = 0\%$ ), hence a fixed model was used. Furthermore, there was no publication bias detected using funnel plot and Begg and Mazumdar's test was not significant ( $P = 0.304$  and  $P = 0.412$ , respectively). A low sensitivity to individual studies resulted after performing sensitivity analysis.

### Objective response rate

There were eight studies containing information about objective response rate<sup>[13-16,18,20-22]</sup> enrolling 407 and 1041 patients treated with Y90RE and TACE, respectively. Pooled analyses did not reveal a statistically significant increase in OR for tumor objective responses after Y90RE with respect to TACE (OR = 1.22, 95%CI: 0.69-2.16,  $P = 0.50$ ) (Figure 5). There was, however, evidence of heterogeneity across these studies ( $P = 0.004$ ;  $I^2 = 67\%$ ), therefore we performed a subgroup analysis in order to explore the cause of this heterogeneity, which was mainly due to some outlier studies<sup>[13,15,20,21]</sup>. In fact, tumor response assessment is dependent on a number of variables, such as radiologic criteria adopted, local expertise, imaging technique used (whether computed tomography-scan or magnetic

resonance imaging) and time of response evaluation. Unfortunately, conducting a meta-regression analysis taking into account all these variables was not possible due to the small number of studies. No evidence of publication bias was detected.

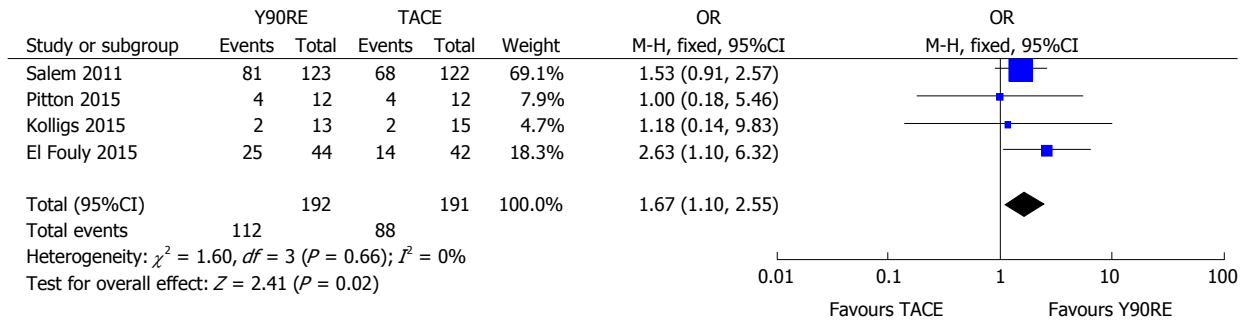

### Toxicity

Seven studies reported toxicity data of their treated patients<sup>[13,14,16-18,21,22]</sup>. A non-significant trend in favor of Y90RE was observed (OR = 0.70, 0.38-1.30,  $P = 0.26$ ), but with high evidence of heterogeneity ( $I^2 = 52\%$ ,  $P = 0.05$ ) (Figure 6). Major responsible of heterogeneity was the study by Salem *et al.*<sup>[16]</sup>, since  $I^2$  dropped to 13% after exclusion of this article. No evidence of publication bias was detected.

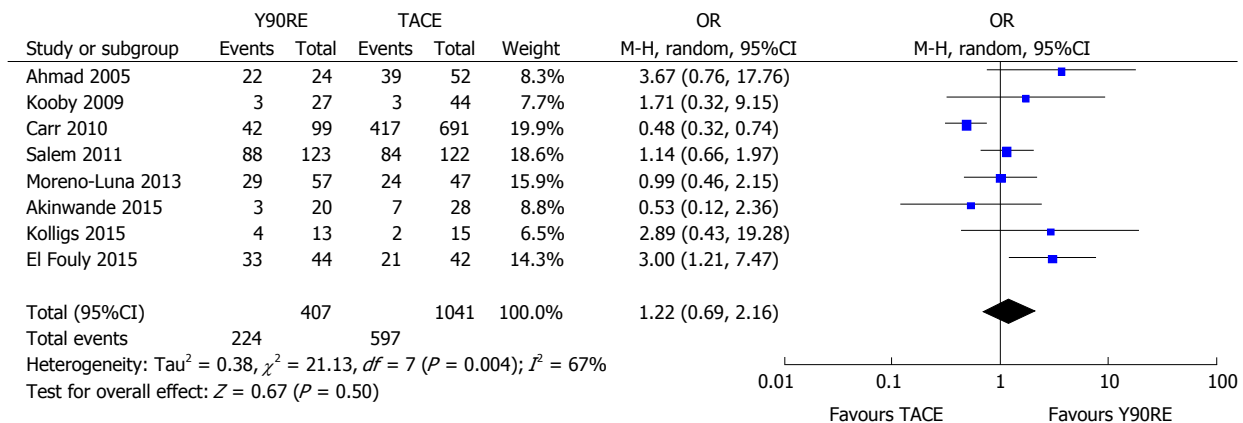

## DISCUSSION

TACE is actually the recommended first-line therapy for patients with unresectable intermediate HCC<sup>[2-4]</sup>. In this setting where curative surgical or ablative treatments are not feasible, palliation with TACE has been found to improve survival as compared to best supportive care<sup>[23,24]</sup>. The pressing need for novel therapeutic regimens able to improve response rates and survival while reducing treatment-related complications led to the development of new drug-delivery systems, such as drug-eluting beads (DEBs)<sup>[4,25]</sup>. Although whether there is a clear superiority of DEB-TACE over conventional TACE using lipiodol is still matter of debate<sup>[12,26,27]</sup>, increasing interest has been recently raised on smaller DEBs which seem able to induce wider necrosis of the target lesion since they achieve a more distal embolization, thus also obstructing collateral channels<sup>[28]</sup>. As a consequence, survival estimates after TACE has considerably improved in the last years, reaching more than 40 mo of median OS in two recent studies<sup>[29,30]</sup>.

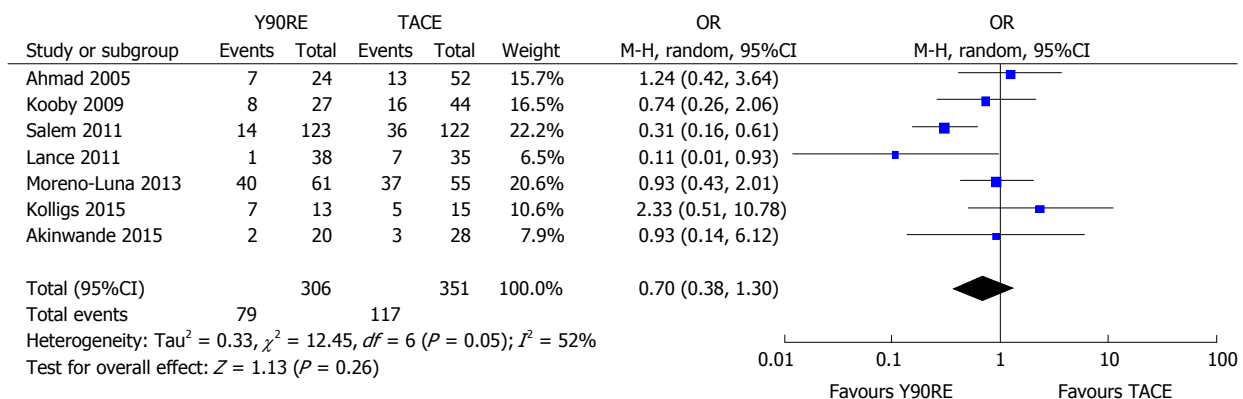

On the other hand, Y90 transarterial radioembolization is a form of brachytherapy in which intra-arterially injected 90Y-loaded microspheres serve as sources for internal radiation purposes, with no significant vessel occlusion thus rendering this treatment

**Figure 4 Forest plot for 1-year progression-free survival after yttrium-90 radioembolization and transarterial chemoembolization.** Y90RE showed a statistically significant benefit in terms of higher progression-free survival rate assessed at 1 year (OR = 1.67, 1.10-2.55,  $P = 0.02$ ). There was no evidence of heterogeneity among individual studies ( $P = 0.66$ ;  $I^2 = 0\%$ ). Y90RE: Yttrium-90 radioembolization; TACE: Transarterial chemoembolization; OR: Odds ratio.

**Figure 5 Forest plot for objective response rate after yttrium-90 radioembolization and transarterial chemoembolization.** Pooled analyses do not revealed a statistically significant increase in odds ratio for tumor objective responses after Y90RE with respect to TACE (OR = 1.22, 95%CI: 0.69-2.16,  $P = 0.50$ ). There was, however, evidence of heterogeneity across these studies ( $P = 0.004$ ;  $I^2 = 67\%$ ), mainly due to some outlier studies. Y90RE: Yttrium-90 radioembolization; TACE: Transarterial chemoembolization; OR: Odds ratio.

**Figure 6 Forest plot for serious adverse event rate after yttrium-90 radioembolization and transarterial chemoembolization.** A non-significant trend in favor of Y90RE was observed (OR = 0.70, 0.38-1.30,  $P = 0.26$ ), but with a high evidence of heterogeneity ( $I^2 = 52\%$ ;  $P = 0.05$ ). Y90RE: Yttrium-90 radioembolization; TACE: Transarterial chemoembolization; OR: Odds ratio.

feasible even in patients with PVT, which is a well-known contraindication to TACE<sup>[6,7]</sup>.

In particular radioembolization produces average disease control rates above 80% and is usually very well tolerated. Main complications do not result from the microembolic effect, even in patients with portal vein occlusion, but rather from excessive irradiation of non-target liver tissue<sup>[6,7,9]</sup>.

Although several studies comparing the two therapies have been published so far, a clear evidence in support of the superiority of one technique over the other in terms of OS is still lacking. Therefore, given the similarity in survival outcomes between the two procedures, post-hoc analyses indicated that a randomized study with > 1000 patients would be required to establish equivalence of survival times between patients treated with Y90RE

and TACE<sup>[16]</sup>.

Aim of our meta-analysis was hence to compare these two trans-arterial treatments in terms of overall survival, progression-free survival, objective response rate and safety profile in unresectable HCC patients.

A total of 10 studies were identified and statistically analyzed, which included 461 HCC patients treated with Y90RE and 1096 treated with chemoembolization. Of note, all the included studies were from the West and in particular 70% from United States. Average quality was moderate-high.

Survival rate assessed at 1 year was similar between the two therapeutic groups (OR = 1.01,  $P = 0.93$ ), but as long as time elapsed since the treatment ORs for survival rate tended to significantly increase, thus meaning better long-term outcomes in patients who underwent Y90RE ( $P = 0.01$  and  $0.04$  at 2 and 3 years, respectively). Notably, the number of studies reporting long-term outcomes tended to decrease from 10 (all the included studies) which reported 1-year SR to only 5 reporting 3-year SR<sup>[15,16,18-20]</sup> (Table 3).

In order to obtain a more robust and reliable estimate of patient survival, we performed a meta-analysis of plotted HRs, obtaining as result a non-significant overall estimate in favor of Y90RE (HR = 0.91, 0.80-1.04,  $P = 0.16$ ; Figure 2).

Therefore, our analysis seem to confirm the non-superiority of one treatment over the other as found in previous papers<sup>[16,18]</sup>.

Unfortunately, subgroup analysis performed on the basis of baseline tumor stage or other clinical prognostic factors known to influence HCC patients' survival, such as ferritin level<sup>[31]</sup> or drug therapy used<sup>[32]</sup>, was not feasible due to the low number of available studies and the absence of outcomes stratification in most of them.

In the above cited study by Salem *et al.*<sup>[16]</sup>, time to progression was significantly longer after Y90RE (13.3 mo vs 8.4 mo,  $P = 0.023$ ), but it did not translate directly into improved survival. Such a finding was confirmed in our meta-analysis where OR for 1-year PFS resulted significantly in favor of Y90RE (OR = 1.67,  $P = 0.02$ ) (Figure 4).

No significant difference according to the other two analyzed outcomes (response rate and major adverse event rate) was found.

The apparent discrepancy between the significant benefit of Y90RE in terms of progression-free survival and the non-significant trends found with regard to the other outcomes are likely due to the complex multistep pathogenesis of HCC and the different course of underlying liver cirrhosis<sup>[33-35]</sup>. In this regard, a post-progression survival analysis would be interesting and represents in our opinion one of the most important targets of incoming clinical research in hepato-oncology<sup>[36,37]</sup>.

There are some limitations to our study. First, we included both RCTs and observational studies, thus resulting in greater heterogeneity (as seen with regard to response rate analysis) and higher risk of

selection and reporting bias. This, in addition to the aforementioned lack of data stratification and subgroup analysis, calls for a carefully interpretation of our findings. Moreover, technical details varied widely throughout the included studies either in TACE cohorts (for instance some studies adopted conventional TACE whereas others DEB-TACE) and in Y90RE arms (for instance as for dosimetry protocol)<sup>[38]</sup>.

In conclusion, our meta-analysis reveals that Y90RE and TACE show similar effects in unresectable HCC patients in terms of OS, response rate and safety profile, although tumor progression is delayed after radioembolization. Further properly sized RCTs are warranted in order to confirm these results.

## COMMENTS

### Background

Transarterial chemoembolization (TACE) is the most widely used primary treatment for unresectable hepatocellular carcinoma (HCC) and the recommended first line-therapy for patients in intermediate stage. A novel technique in the field of loco-regional treatments for HCC is called transarterial radioembolization with yttrium-90 (Y90RE), which induces tumor necrosis by means of injection of glass or resin microsphere loaded with yttrium-90. Although several studies comparing the two loco-regional techniques have been recently published, whether there is a clear superiority of one treatment over the other is still debated.

### Research frontiers

This meta-analysis reveals that Y90RE and TACE show similar effects in unresectable HCC patients in terms of overall survival, response rate and safety profile, although tumor progression is delayed after radioembolization. Further properly sized randomized controlled trials are warranted in order to confirm these results.

### Innovations and breakthroughs

The authors' findings stand for a similarity in treatment effects between Y90RE and TACE in HCC patients. Their meta-analysis constitutes the most up-to-date overview of studies comparing the two techniques.

### Applications

The present report allows understanding the role of two transarterial treatments in HCC patients.

### Terminology

TACE: Transarterial treatment whose rationale is that the intra-arterial infusion of a cytotoxic agent followed by embolization of the tumor-feeding blood vessels will result in a strong cytotoxic and ischemic effect; Y90RE: Novel form of liver-directed brachytherapy which induces tumor necrosis by means of injection of glass or resin microsphere loaded with yttrium-90.

### Peer-review

This meta-analysis aims to compare the efficacy and safety of Y90RE and TACE in HCC. It is a nicely written manuscript. The analysis is well performed.

### Abstract

Classically, hepatic artery pseudoaneurysms (HAPs) arise secondary to trauma or iatrogenic causes. With an increasing prevalence of laparoscopic procedures of the hepatobiliary system the risk of inadvertent injury to arterial vessels is increased. Pseudoaneurysm formation post injury can lead to serious consequences of rupture and subsequent hemorrhage, therefore intervention in all identified visceral pseudoaneurysms has been advocated. A variety of interventional methods have been proposed, with surgical management becoming the last step intervention when minimally invasive therapies have failed. The authors present a case of a HAP in a 56-year-old female presenting with jaundice and pruritis suggestive of a Klatskin's tumor. This presentation of HAP in a patient without any significant past medical or surgical intervention is atypical when considering that the majority of HAP cases present secondary to iatrogenic causes or trauma. Multiple minimally invasive approaches were employed in an attempt to alleviate the symptomology which included jaundice and associated inflammatory changes. Ultimately, a right hepatic trisegmentectomy was required to adequately relieve the mass effect on biliary outflow obstruction and definitively address the HAP. The presentation of a HAP masquerading as a malignancy with jaundice and pruritis, rather than the classic symptoms of abdominal

pain, anemia, and melena, is unique. This presentation is only further complicated by the absent history of either trauma or instrumentation. It is important to be aware of HAPs as a potential cause of jaundice in addition to the more commonly thought of etiologies. Furthermore, given the morbidity and mortality associated with pseudoaneurysm rupture, intervention in identifiable cases, either by minimally invasive or surgical interventions, is recommended.

**Key words:** Klatskin tumor; Cholangitis; Hepatic artery pseudoaneurysm; Biliary obstruction; Trisegmentectomy

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Hepatic artery pseudoaneurysms (HAPs) typically arise from secondary trauma or iatrogenic causes. Most of HAPs are asymptomatic but can be complicated with rupture and bleeding. Biliary obstruction due to HAPs is a rare phenomenon and can present clinically as Quinke's triad (hematobilia, abdominal pain, and jaundice). Most cases can be managed with non-operative vascular and endoscopic interventions. This case report presents an atypical presentation of HAP with a multidisciplinary approach to a complex problem.

Atypical presentation of a hepatic artery pseudoaneurysm: A case report and review of the literature. *World J Hepatol* 2016; 8(18): 779-784 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i18/779.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i18.779>

## INTRODUCTION

Hepatic artery pseudoaneurysms (HAPs), or false aneurysms, classically arise secondary to trauma or iatrogenic causes and pose a serious risk of exsanguinating hemorrhage and subsequent death<sup>[1,2]</sup>. Numerous case reports have been published addressing the occurrence of HAPs subsequent to a variety of interventional procedures including cholecystectomy, pancreaticoduodenectomy, and orthotopic liver transplant. It has been hypothesized that with the increasing frequency of laparoscopic procedures, such as cholecystectomy, which can result in inadvertent injury to the right hepatic artery, the overall incidence of HAPs will continue to rise<sup>[1,3]</sup>. Due to the increased risk of rupture compared with true aneurysms, some have advocated intervention in all cases of identifiable visceral pseudoaneurysm<sup>[4]</sup>. It has been reported that HAPs have been successfully treated using a variety of interventional methods, including endovascular embolization, coiling embolization, and arterial stent grafting<sup>[1,2]</sup>. Because of the increased morbidity associated with surgery in this setting, surgical management is the final treatment option when these subsequent methods have failed. Although in most cases interventional technologies can quench the risk of hemorrhagic rupture of HAP and

alleviate biliary obstruction<sup>[5]</sup>, surgical management of impairment to adjacent structures such as the bile duct and portal vein have to our knowledge ever been reported.

Here we provide a unique case of HAP, initially presenting as a Klatskin tumor (tumor at the confluence of the right and left hepatic biliary confluence) mimic and with no identifiable cause. Furthermore, the aforementioned treatment options were inadequate to address this persistent and recurrent chronic HAP, ultimately requiring surgical intervention.

## CASE REPORT

A 65-year-old female with no significant past medical history was transferred from an outside institution for further management of painless jaundice and pruritis, with suspicion for a Klatskin's tumor. At this outside institution, non-contrast computed tomography (CT) imaging studies revealed a 5 cm dense lesion within the hilar region of the liver and intrahepatic biliary duct dilatation. Subsequent endoscopic retrograde cholangiopancreatography showed a hilar obstructive lesion that was concerning for cholangiocarcinoma/Klatskin's tumor. A temporary hepatic duct stent was placed and sphincterotomy was performed. Cytology results from this procedure were negative. On the day of her transfer, she was afebrile but was placed on empiric antibiotic coverage. Her total and direct bilirubin levels were elevated (total bilirubin 24.3 mg/dL, direct bilirubin 18.6 mg/dL), as was her serum alkaline phosphatase (432 U/L), liver transaminases (AST 132 U/L, ALT 148 U/L), and CA 19-9 (891 U/mL). Other pertinent labs included a positive ANA and CEA within the reference range.

At transfer to our institution, a triphasic computed tomography angiography demonstrated a right branch HAP measuring 2.1 cm, a suspected hematoma measuring 5 cm in diameter (Figure 1A and B) and significant biliary duct dilatation (Figure 1C). Further studies including esophagogastroduodenoscopy and colonoscopy demonstrated hemobilia with the 2 cm biliary stent protruding into the lumen of the small bowel. Therapeutic strategies to control pseudoaneurysmal bleeding included embolization procedures encompassing percutaneous ultrasound and fluoroscopic guided thrombin injections into the HAP (Figure 2). Multiple sub-centimeter smaller pseudoaneurysms were noted to be extending off of the right hepatic artery. Due to lack of trauma or interventions that could be a likely etiology for pseudoaneurysm, an autoimmune work up, including C-ANCA, P-ANCA, anti-smooth muscle antibodies, double-stranded DNA antibody, anti-smooth muscle antibody, anti-RNP antibody, to establish etiology of these multiple pseudoaneurysms was performed and was largely negative. Rheumatology was consulted and ruled out systemic vasculitides including polyarteritis nodosa (PAN), systemic lupus erythematosus, and cryoglobulinemia. The patient continued to have a complicated long hospital course and even after attempts to alleviate

**Figure 1** Computerized tomography scan demonstrating pseudoaneurysm and significant biliary ductal dilatation. A: Triple contrast computerized tomography scan of abdomen demonstrates hepatic artery pseudoaneurysm; B: With significant thrombus formation adjacent to aneurysm; C: Significant biliary ductal dilatation in the right and left hepatic ducts.

obstructive jaundice with stent procedures, the patient had recurrent episodes of cholangitis with septic shock. Blood cultures demonstrated pan-sensitive *Klebsiella pneumoniae* likely from biliary source.

Non-operative strategies included fluoroscopic and ultrasound-guided embolization of re-emergent right HAP with multiple coils, gelfoam, and thrombin. During this procedure it was noted that a portion of thrombosed aneurysm was exerting significant mass effect, effectively occluding multiple right biliary branches and compressing vascular flow in her right portal vein thereby potentially rendering her right lobe ischemic. It was determined that surgical intervention was required for inability to completely address the obstructing nature of this pseudoaneurysm. The patient underwent right hepatic trisegmentectomy with Roux-en-Y hepaticojejunostomy.

Pathology demonstrated the presence of a porta hepatis hematoma (5.0 cm) and organized thrombus dissecting into the hepatic artery wall (Figure 3). Although the liver specimen was negative for malignancy, the liver was microscopically consistent with centrilobular cholestasis (Figure 4A) and bile ductular reaction with bile plugs (Figure 4B) all of which were consistent with chronic biliary obstruction.

The patient was discharged home without any events. She is three years from surgery with no complaints, doing well.

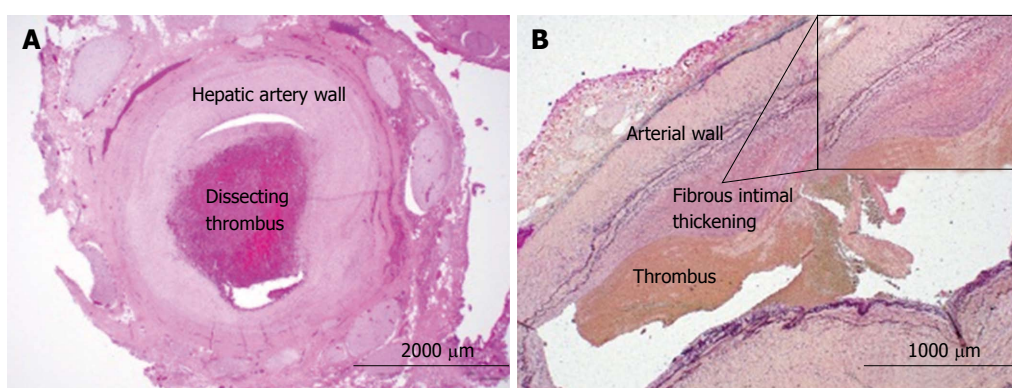

## DISCUSSION

While visceral artery aneurysms and pseudoaneurysms (VAP) may be a rare finding in the general population, with a reported incidence of approximately 0.1%-2%, timely diagnosis is imperative because of the risk of rupture and subsequent mortality<sup>[6]</sup>. In their retrospective review, Tulsyan *et al*<sup>[7]</sup> reported that of the 28 patients found to have VAPs between 1997 and 2005 at the Cleveland Clinic Foundation, 39% involved the celiac axis or its branches, 39% arose from the hepatic arteries, 18% from the splenic artery and 4% from the superior mesenteric artery. In this review, the majority of VAPs, including HAPs arose secondary to arterial trauma, intrabdominal or retroperitoneal inflammation or malignancy, and manipulation of the biliary tract<sup>[7]</sup>. Other non-iatrogenic causes of HAPs include trauma, acute and chronic pancreatitis, arteriosclerosis, PAN, necrotizing vasculitis, infection and hepatocellular carcinoma<sup>[2,3,8-10]</sup>.

Recent increases in the incidence of HAPs have been attributed to a rise in the number of liver transplantations, percutaneous liver and gallbladder interventions and the use of laparoscopic surgery<sup>[1,4,9,11]</sup>. Advances in imaging techniques have enhanced the detection rate of asymptomatic HAPs<sup>[1]</sup>. While HAPs may be an incidental finding in an asymptomatic patient, more commonly patients present with abdominal pain, anemia, hemobilia, melena, and can present as life-threatening hemorrhage following rupture<sup>[2,8,11]</sup>. Although we advocate interventional attempts such as angioembolization or stenting to stop hemorrhage immediately, failures in these attempts or chronic sequel on adjacent structures such as the biliary system and portal vein can require further investigations with possible surgical intervention. We advocate the use of non-invasive assessments, such as CT and/or MRI-MRCP radiographic imaging, to determine the possible etiology of biliary obstruction with then focused therapies toward alleviating the problem. To our knowledge, this is the first presentation of a patient presenting with classic picture of a Klatskin's tumor, specifically jaundice and pruritis secondary to biliary system compression by HAP that could not be managed with a non-operative approach. This unique presentation and atypical history for HAP initially masked the diagnosis. Despite a thorough diagnostic workup, no identifiable cause was uncovered for this patient's HAP,

**Figure 2** Interventional attempts to embolize the hepatic artery pseudoaneurysm. A: Angiogram of common hepatic artery demonstrates pseudoaneurysmal formation off right hepatic artery; B and C: Interventional fluoroscopic and ultrasound-guided embolization of right hepatic artery pseudoaneurysm with multiple coils, gelfoam, and thrombin.

**Figure 3** Histochemical analyses of resected hepatic artery. A: H and E of hepatic artery with organized thrombus dissecting into the vessel wall, 40 × magnification; B: Verhoeff-Van Gieson (VVG) staining of the hepatic artery with eccentric fibrous intimal thickening with adherent thrombus, 20 × magnification (B, inset). Internal elastic lamina is highlighted by the VVG stain with notable fibrous intimal thickening, 100 × magnifications.

**Figure 4** Histologic analyses of hepatic artery pseudoaneurysm and adjacent liver. A: H and E of fibrous capsule of the contained pseudoaneurysmal rupture adjacent to liver, 20 × magnification (A, inset). Liver with centrilobular cholestasis, 200 × magnification; B: Liver with bile duct reaction and bile plugs consistent with biliary obstruction, 200 × magnification.

which further adds to the complexity and atypical nature of the case.

While HAPs can thrombose and resolve without intervention, the risk of rupture and subsequent hemorrhage are high enough that the general consensus has been in favor of intervention<sup>[1,2,4]</sup>. At this time, numerous minimally invasive techniques have proven to be successful, including coiling, covered stent exclusion, thrombin injection,

gelfoam injection, plug deployment, polyvinyl alcohol injection, and surgical intervention<sup>[1,3,4]</sup>. The literature has supported all of these techniques as viable options for management of HAPs. Nagaraja *et al*<sup>[12]</sup> retrospectively analyzed 29 patients with HAP were successfully managed with angioembolization not surprisingly resulting in more rapid bleeding control, shorter hospital stay, and lower transfusion requirements although a 14%

mortality rate in the angioembolization group with no mortality in the surgical group. Currently, minimally invasive management is favored, although indications still exist for surgical intervention. Of note, recurrence of HAPs following embolization has been reported to be significant, and therefore current recommendations involve follow-up imaging with potential need for secondary intervention<sup>[9]</sup>. In the case of our patient, standard minimally invasive endovascular (HAP) and biliary (obstructive jaundice) management was attempted on several occasions with the use of multiple modalities, but ultimately failed to palliate her symptoms. This specific case presented multiple complications including inability to decompress the right biliary system secondary to mass effect and subsequent ischemia as portal vein. Therefore, surgical intervention, specifically right hepatic trisegmentectomy and bile duct resection, was required to address the biliary outflow obstruction and the inherent risk of rupture and hemorrhage of the HAP itself.

In conclusion, we present a unique case of HAP of unknown etiology, initially presenting with jaundice and pruritus. While the presenting symptoms were inconsistent with the typical presentation of HAPs, it is important to be aware of this as a potential cause of jaundice in addition to the more commonly thought of etiologies. The risk of morbidity and mortality secondary to HAP rupture and subsequent hemorrhage requires immediate identification and intervention. Currently, the literature supports the use of minimally invasive endovascular, endoscopic, and percutaneous approaches in the initial management of HAPs, with the potential need for future open surgical intervention if these techniques are inadequate.

## COMMENTS

### Case characteristics

A 65-year-old female with no significant past medical history with a history of painless jaundice and pruritis.

### Clinical diagnosis

Computed tomography imaging studies revealed a 5 cm dense lesion within the hilar region of the liver and intrahepatic biliary duct dilatation.

### Differential diagnosis

Klatskin's tumor, extrahepatic cholangiocarcinoma, pancreatic cancer.

### Laboratory diagnosis

Total and direct bilirubin levels were elevated (total bilirubin 24.3 mg/dL, direct bilirubin 18.6 mg/dL), as was her serum alkaline phosphatase (432 U/L), liver transaminases (AST 132 U/L, ALT 148 U/L), and CA 19-9 (891 U/mL). Other pertinent labs included a positive ANA and CEA within the reference range.

### Imaging diagnosis

Triphasic computed tomography angiography demonstrated a right branch hepatic artery pseudoaneurysm (HAP) measuring 2.1 cm, a suspected hematoma measuring 5 cm in diameter and significant biliary duct dilatation.

### Pathological diagnosis

Right hepatic trisegmentectomy pathology specimen demonstrated the presence

of a porta hepatis hematoma (5.0 cm) and organized thrombus dissecting into the hepatic artery wall, negative for malignancy and microscopically consistent with centrilobular cholestasis and bile ductular reaction with bile plugs all of which were consistent with chronic biliary obstruction.

### Treatment

Complete surgical excision of locally involved right hepatic artery pseudoaneurysm.

### Related reports

HAPs classically arise secondary to trauma or iatrogenic causes and pose a serious risk of exsanguinating hemorrhage and subsequent death. Numerous case reports have been published addressing the occurrence of HAPs subsequent to a variety of interventional procedures including cholecystectomy, pancreaticoduodenectomy, and orthotopic liver transplant. Due to the increased risk of rupture compared with true aneurysms, HAPs have been successfully treated using a variety of interventional methods. Because of the increased morbidity associated with surgery in this setting, surgical management is the final treatment option.

### Term explanation

HAPs are "false" aneurysms that do not have the presences of layers of the arterial wall, communicates with the vessel in question and has blood confined by the surrounding tissues.

### Experiences and lessons

HAPs are typically managed with a variety of interventional methods such as endovascular embolization, coiling embolization, and arterial stent grafting. Because of the increased morbidity associated with surgery in this setting, surgical management is the final treatment when impairment to adjacent structures such as the bile duct and portal vein cannot be alleviated.

### Peer-review

This manuscript presents a rare case of pseudoaneurysm of hepatic artery. The management of the case is informative, and useful for the readers.

## Contents

Three issues per month Volume 8 Number 19 July 8, 2016

### EDITORIAL

- 785 Sofosbuvir/velpatasvir: A promising combination  
*Bonaventura A, Montecucco F*

### MINIREVIEWS

- 790 Could there be light at the end of the tunnel? Mesocaval shunting for refractory esophageal varices in patients with contraindications to transjugular intrahepatic portosystemic shunt  
*Davis J, Chun AK, Borum ML*

### ORIGINAL ARTICLE

#### Basic Study

- 796 Assembly and release of infectious hepatitis C virus involving unusual organization of the secretory pathway  
*Triyatni M, Berger EA, Saunier B*

#### Prospective Study

- 815 Is neutrophil gelatinase associated lipocalin a useful marker in hepatitis C virus infection?  
*Strazzulla A, Coppolino G, Di Fatta C, Giancotti F, D'Onofrio G, Postorino MC, Mazzitelli M, Mammone SV, Gentile I, Rivoli L, Palella E, Gravina T, Costa C, Pisani V, De Maria V, Barreca GS, Marascio N, Focà A, Fuiano G, Gulletta E, Torti C*

### LETTERS TO THE EDITOR

- 825 Lot to give, got to live - the restless minds of the "Liver on Tour" project  
*Macedo G, Peixoto A, Lopes S*

**ABOUT COVER**

Editorial Board Member of *World Journal of Hepatology*, Sandro Vento, MD, Professor, Department of Medicine, School of Medicine, Nazarbayev University, Astana 010000, Kazakhstan

**AIM AND SCOPE**

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

**INDEXING/  
ABSTRACTING**

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

### Abstract

Hepatitis C virus (HCV) affects 3% of the world population. It represents the main cause of chronic liver

disease and is responsible for extra-hepatic complications, such as type 2 diabetes and cardiovascular diseases. HCV includes 7 genotypes differing in the nucleotide sequence variability, the geographic distribution, the rates of viral clearance, the risk of progression to liver fibrosis and to hepatocellular carcinoma, and the response to therapy. Last years have seen remarkable advances in the field of HCV infection with the approval of direct antiviral agents (DAAs) targeting key viral proteins involved in the HCV replication. Several oral regimens combining DAAs from different families have been developed and these regimens showed increased and sustained virological response rates to above 90% reducing the treatment duration to 12 wk or less. In particular, sofosbuvir, a nucleotide analogue nonstructural (NS)5B polymerase inhibitor, and velpatasvir, a NS5A inhibitor, have been tested in two phase 3 trials, the ASTRAL-2 (against HCV genotype 2) and the ASTRAL-3 (against HCV genotype 3), demonstrating to be effective, safe, and well tolerated in patients who were 18 years of age or older and had at least a 6-mo history of HCV infection with a compensated liver disease.

**Key words:** Hepatitis C virus; Sofosbuvir; Velpatasvir; NS5A inhibitor; NS5B inhibitor

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Hepatitis C virus (HCV) spread all over the world. In the last years, new therapies with direct antiviral agents draw a great revolution thanks to several oral regimens combining different drugs of this class. The present editorial provides a brief overview on the association between two direct antiviral agents, sofosbuvir and velpatasvir, and their implication in the treatment of HCV infection.

Bonaventura A, Montecucco F. Sofosbuvir/velpatasvir: A promising combination. *World J Hepatol* 2016; 8(19): 785-789 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i19/785>.

## INTRODUCTION

Hepatitis C virus (HCV) infects approximately 3% of the world population and leads to cirrhosis and hepatocellular carcinoma<sup>[1]</sup>. HCV is a member of the Flaviviridae family of RNA viruses and is classified into 7 genotypes; each genotype is different from the others in its nucleotide sequence. This remarkable genetic diversity represents a challenge for the development of new therapies<sup>[2]</sup>. HCV genotypes differ not only in the nucleotide sequence variability, but also in their geographic distribution, rates of viral clearance, risk of progression to liver fibrosis and to hepatocellular carcinoma, and response to therapy<sup>[3]</sup>.

In last years, HCV treatment has undergone substantial advances. Direct antiviral agents (DAAs), when combined with pegylated interferon (PegIFN) and ribavirin (RVR), demonstrated increased rates of cure in chronic HCV infections when compared to PegIFN and RVR alone<sup>[4]</sup>. The first class of DAAs to be approved for treatment of HCV was that of protease inhibitors targeting the nonstructural protein (NS)3/4A serine protease, responsible for the processing of the nascent viral polyprotein<sup>[4]</sup>. The search for new key viral targets continued and compounds against two additional targets - NS5A replication scaffold and the NS5B RNA-dependent RNA polymerase (RdRp) - have been generated<sup>[5]</sup>. Drugs inhibiting NS5B include two subclasses: Nucleos(t)ide inhibitors (NIs) and non-nucleoside inhibitors (NNIs). NS5B is strictly required during the HCV replication both to copy the RNA genome and to transcribe messenger RNA: These steps are essential and the inhibition of NS5B is able to block viral propagation (Figure 1).

Many phase 2 trials have been conducted with promising results. Two phase 3 trials have done encouraging results with the combination of the nucleotide polymerase inhibitor sofosbuvir and the NS5A inhibitor velpatasvir in patients chronically infected with HCV genotype 2 and 3<sup>[6]</sup>.

## A BRIEF PRESENTATION OF SOFOSBUVIR AND VELPATASVIR

### Sofosbuvir

Sofosbuvir (SOF) (formerly known as GS-7977; Gilead Sciences, Foster City, CA, United States) is a NS5B NI<sup>[7]</sup>. It is converted into a pharmacologically active form (GS-461203) within hepatocytes, inhibits RdRp activity by competing with uridine, and blocks RNA synthesis by acting as "chain terminator"<sup>[8]</sup>. Given the high conservation of the catalytic site of the NS5B protein, this drug is believed to have pangenotypic activity<sup>[8]</sup>. The combination of SOF and RVR achieved sustained virologic response (SVR) rates of 100% for genotype 2 infection and 91% for genotype 3 infection<sup>[9]</sup>. On December 6, 2013, the United States Food and Drug Administration (FDA) approved SOF (Sovaldi™) for the

treatment of chronic HCV, genotypes 1, 2, 3 and 4, in combination with Peg-IFN and RVR or with RVR alone. SOF is also highly effective in HCV patients who are co-infected with human immunodeficiency virus (HIV). It should not be administered with potent inducers of intestinal P-glycoprotein, such as rifampin and Saint John's wort, resulting in reduced absorption<sup>[10]</sup>. Moreover, co-administration of SOF with select anticonvulsants, rifabutin, rifapentine, or tipranavir/ritonavir is not recommended<sup>[5]</sup>. SOF showed no clinically significant drug interactions with many of the common medications metabolized by CYP3A enzymes, such as tacrolimus, cyclosporine, and methadone, as well as with the common combination therapies for HIV<sup>[5]</sup>.

### Velpatasvir

Velpatasvir (VEL) (formerly GS-5816; Gilead Sciences; Foster City, CA, United States) is a new NS5A protein inhibitor with pan-genotypic activity *in vitro*<sup>[11]</sup>. In phase 2 trials, it demonstrated high rates of SVR in patients with HCV genotypes 2 and 3 in combination with sofosbuvir for a period of 12 wk of treatment<sup>[12,13]</sup>. Regimens including an NS5A inhibitor have demonstrated high tolerability and high antiviral efficacy in phase 3 studies<sup>[11]</sup>.

## SOF AND VEL IN PHASE 2 AND 3 STUDIES

### The phase 2 studies

In phase 2 studies, the SOF/VEL combination administered for 12 wk showed high rates of SVR and was well tolerated in all HCV genotype infections<sup>[12,13]</sup>.

In the phase 2 study by Everson *et al.*<sup>[12]</sup>, treatment-naïve non-cirrhotic patients achieved high rates of SVR at 12 wk with SOF/VEL, independently of HCV genotypes. Virologic failure was rare; the nonresponse of 1 patient with HCV genotype 3 infection and the relapse in a patient with HCV genotype 1 infection, both receiving 25 mg of VEL, may suggest that the 100 mg dose could have a clinical advantage over the 25 mg one. In general, the therapy with SOF/VEL with or without RVR was well tolerated. In the other phase 2 study by Pianko *et al.*<sup>[13]</sup>, SOF/VEL demonstrated to be safe, effective, and well-tolerated for treatment-experienced patients with HCV infection genotype 1 or 3, including those with compensated cirrhosis, which are the most common genotypes accounting for approximately 46% and 22% of all global infections, respectively<sup>[14]</sup>. In particular, the SVR at 12 wk in patients with genotype 3 HCV infection under VEL 100 mg compared favorably with those previously reported for other regimens<sup>[15-17]</sup>.

### The ASTRAL-2 and the ASTRAL-3 trials

The ASTRAL program aimed to evaluate the safety and the efficacy of the association SOF/VEL in patients with HCV genotype 1-6 infection including patients with decompensated liver disease. ASTRAL-2 and ASTRAL-3 trials are two randomized, controlled, phase 3 trials, in which a fixed-dose combination tablet of SOF/VEL for

**Figure 1 Structure of hepatitis C virus and mechanisms of action of direct antiviral agents<sup>[29]</sup>.** The open reading frame of hepatitis C virus (HCV) encodes 11 proteins: 3 structural proteins (core, E1, and E2); 6 nonstructural (NS) proteins (NS2, NS3, NS4A, NS4B, NS5A and NS5B); the p7 protein; and the frameshift (F) protein (not illustrated). The core protein has a role in viral capsid formation and can directly interact with many cellular proteins and pathways implicated in the HCV lifecycle. Envelope glycoproteins, E1 and E2, are fundamental components of the virion envelope and are essential for HCV entry and fusion; in particular, E2 has a central role in the early steps of infection because it functions as a host receptor binding protein and mediates the attachment to host cells. The F protein is probably produced during viral infection and could be involved in viral persistence, but the exact role has not been fully elucidated. The p7 protein is an integral membrane protein belonging to the viroporin family and maybe acts as a calcium ion channel, but further studies are needed to confirm its function. NS2 is a non-glycosylated transmembrane protein having a protease activity, which may interact with host cell proteins. NS3 is a multi-functional protein owning a serine protease domain and a helicase/nucleoside triphosphatase domain, while NS4A is a cofactor of NS3 protease activity. The 2 proteins can interact with host cell pathways and proteins involved in HCV lifecycle and for this reason they are an appealing viral target for anti-HCV therapies. NS4 is an integral membrane protein serving as a membrane anchor for the replication complex; moreover, it can inhibit cellular synthesis and modulate the HCV RdRp activity. NS5A is a zinc-metalloprotein playing a role in virus replication, cell growth replication, and in mediating interferon-resistance, even if some of these functions need to be still clarified. NS5B belongs to the class of tail-anchored proteins. Its crystal structure showed that the RdRp has a "fingers, palm and thumb" structure; interactions between the fingers and thumb subdomains create a fully surrounded catalytic site ensuring both HCV RNA strand synthesis. For this reason, the RdRp is an attractant target for new anti-HCV drugs.

12 wk was compared to standard treatment with SOF plus RVR for 12 or 24 wk in patients already treated for HCV genotype 2 and 3 infection and in those who had not received this treatment, including the ones with decompensated cirrhosis<sup>[6]</sup>.

The two studies shared the same eligibility criteria, except for HCV genotype. Patients who were 18 years of age or older and with at least a 6-mo history of HCV infection could enter the study, whilst patients with clinical evidence of hepatic decompensation were excluded. In the two trials, patients with chronic HCV infection were randomly assigned to receive a fixed-dose combination tablet containing 400 mg of SOF and 100 mg of VEL once daily for 12 wk or 400 mg of SOF plus RVR for 12 wk (for patients with HCV genotype 2) or 24 wk (for patients with HCV genotype 3). RVR was administered orally twice daily, with body weight-determined doses. The primary endpoint was a SVR, defined as an HCV RNA level of less than 15 IU per milliliter at 12 wk after the end of treatment.

In the ASTRAL-2 trial, patients who had received SOF/VEL met the primary endpoint with no virologic failures. In the ASTRAL-3 trial, patients who were administered with SOF/VEL gained a SVR, but 4% of them showed virologic failure after the end of treatment. Overall, the rate of SVR was higher among patients without cirrhosis and who did not receive any previous treatment.

### Safety

In both trials, rates of adverse events (AEs) were lower among patients who received SOF/VEL than those who received SOF/RVR. In both trials, only 1 patient receiving SOF/VEL stopped the treatment prematurely because of an AE (anxiety, headache, and difficulty in concentrating). Common AEs, such as headache, fatigue, and nausea have been reported in 10%-38% of SOF/VEL patients, together with insomnia, irritability, pruritus, nasopharyngitis, cough, and dyspnea<sup>[6]</sup>. Serious AEs in the SOF/VEL group of the ASTRAL-2 included enteritis, pneumonia, and abdominal pain, whereas in the ASTRAL-3 acute myocardial infarction, acute cholecystitis, food poisoning, hematochezia, intracranial aneurysm, and rupture of ovarian cyst have been described<sup>[6]</sup>. In both trials, only 1 patient receiving SOF/VEL stopped the treatment prematurely because of an AE (anxiety, headache, and difficulty of concentration). Death after treatment occurred in two patients in the ASTRAL-2 (1 from cardiac arrest and one from metastatic lung cancer complications); in the ASTRAL-3, two deaths occurred during treatment (1 from unknown cause and 1 from gunshot wounds) and one in the post-treatment period (from unknown cause).

### Comparison between NIs and NNIs

NIs inhibit the RdRp by mimicking NS5B protein sub-

strate leading to the termination of the new viral RNA chain; they possess a high-resistance barrier, are highly effective, and own a pan-genotypic activity<sup>[18]</sup>. NNIs behave as allosteric inhibitors by binding to the RdRp blocking polymerase function through conformational change; this results in a lower barrier to resistance and lower anti-viral activity with respect to NIs<sup>[18]</sup>.

SOF is the only NI approved and was associated with high SVR rates in all kind of patients. The addition of SOF to PegIFN and RVR demonstrated to be the most effective IFN-containing regimen in HCV patients with compensated cirrhosis. In the NEUTRINO and FISSION studies, patients receiving SOF had rapid and substantial decreases in serum HCV RNA levels. Moreover, AEs were uncommon among patients receiving SOF regimens as well as severe AEs were few in all study groups<sup>[19]</sup>. In IFN-free regimens, SOF was tested in combination with the first generation NS5A inhibitor ledispavir both in treatment-naïve and pre-treated patients and showed good response in terms of SVR<sup>[20,21]</sup>. Nonetheless, among all patients, the majority had at least one, mild-to-moderate AE (fatigue, headache, insomnia, and nausea), but also serious AEs occurred in 6%-8% of patients of the 24 wk-SOF regimens<sup>[20,21]</sup>. AEs were higher and more serious in the groups concomitantly treated with RVR. Finally, some mild modifications of the haemochrome were present, whilst the increase in bilirubin and transaminases were more frequently in the group treated with RVR.

Among NNI, dasabuvir is the only drug approved and is usually administered in combination with ritonavir/paritaprevir and ombitasvir. Dasabuvir is mainly effective against HCV genotype 1. When used in combination, these three drugs showed excellent SVR rates at 12 wk in patients with HCV-1-compensated cirrhosis. Mild AEs were recorded in nearly 80% of patients, especially when treated with RVR and included nausea, fatigue, pruritus, and headache. A modest decrease of hemoglobin was reported, sometimes reaching the lower limit of the normal range<sup>[22-26]</sup>. Serious AEs were rare. However, in the post-marketing surveillance many cirrhotic were found developing hepatic decompensation and/or liver failure. For this reason, the United States FDA issued a warning in which it was noted that this treatment could cause serious liver injury in cirrhotic patients<sup>[27]</sup>.

## CONCLUSION

The development of DAAs revolutionized the therapeutic weapons against HCV infection. These advances have been possible thanks to the increased knowledge of the structures of HCV protease and HCV polymerase, which permitted to design structure-based drug inhibiting key viral enzymes. Indeed, HCV drug development was fast for different reasons, such as a shorter treatment duration, no need for control arms, and the short period to evaluate the SVR (12-24 wk)<sup>[28]</sup>.

Since 2014, many drugs were approved: The first one was SOF, followed by simeprevir and daclatasvir. In 2015, ledipasvir in combination with SOF, and paritaprevir in combination with ombitasvir and dasabuvir were

approved in several countries. In 2016/2017, three other combinations could be approved, such as grazoprevir in combination with elbasvir, SOF with VEL, and ABT-493 plus ABT-530 combination therapy<sup>[28]</sup>.

The combination SOF/VEL was extensively studied in phase 2 and 3 studies. In the ASTRAL-2 and ASTRAL-3 studies, SOF/VEL showed great efficacy against HCV infections genotype 2 and 3 (except for a virologic failure after the end of treatment for 11 patients in the ASTRAL-3) and a reasonable safety<sup>[6]</sup>. The treatment of patients with HCV genotype 3 is still a challenge, even in the era of DAAs and further researches are needed to increase the rate of SVR in this subtype of patients. As the same researchers of ASTRAL-2 and ASTRAL-3 state, the generalizability of the results are limited by the small number of black patients included in the trials, considering that genotype 2 is present in sub-Saharan Africa<sup>[14]</sup>. Moreover, the exclusion of patients with decompensated cirrhosis represents another pivotal point to cope with, given the huge importance of HCV in the natural history of cirrhosis and hepatocellular carcinoma, never forgiving the extrahepatic complications, such as type 2 diabetes mellitus and cardiovascular diseases.

Further trials evaluating new DAAs should focus on the prolongation of the SVR and the inclusion of patients such as those abovementioned, which can get a real benefit from these new therapies, if safe, effective, and well tolerated.

## Abstract

Cirrhotic patients with recurrent variceal bleeds who have failed prior medical and endoscopic therapies and are not transjugular intrahepatic portosystemic shunt candidates face a grim prognosis with limited options. We propose that mesocaval shunting be offered to this group of patients as it has the potential to decrease portal pressures and thus decrease the risk of recurrent variceal bleeding. Mesocaval shunts are stent grafts placed by interventional radiologists between the mesenteric system, most often the superior mesenteric vein, and the inferior vena cava. This allows flow to bypass the congested hepatic system, reducing portal pressures. This technique avoids the general anesthesia and morbidity associated with surgical shunt placement and has been successful in several case reports. In this paper we review the technique, candidate selection, potential pitfalls and benefits of mesocaval shunt placement.

Mesocaval shunting for refractory esophageal varices in patients with contraindications to transjugular intrahepatic portosystemic shunt. *World J Hepatol* 2016; 8(19): 790-795 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i19/790.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i19.790>

## INTRODUCTION

Patients with cirrhosis and recurrent variceal bleeding face a high mortality, 20% in the first year vs 5.4% for compensated patients<sup>[1]</sup>. Current standard of care for variceal bleeding includes three primary modalities: Medical therapy with beta blockade, endoscopic therapy with ligation of varices and shunt therapy with transjugular intrahepatic portosystemic shunting (TIPS). Each of these have been shown to improve rebleeding rates and mortality<sup>[2-4]</sup>.

For an unfortunate cohort of patients with varices who fail medical and endoscopic therapy and are not TIPS candidates, there are limited options in the face of a grim prognosis. Historically, these patients have been offered surgical shunt approaches, however, mortality of surgical shunt placements is high - 20%-50% if emergent - and many patients may not be suitable surgical candidates<sup>[5]</sup>. First described in 1996 by Nyman *et al*<sup>[6]</sup>, mesocaval shunting may provide an alternate route to alleviate portal hypertension in these challenging patients. This paper will review the technique, candidate selection, potential pitfalls and benefits of mesocaval shunting. While there are not enough data to comment on a mortality benefit, we believe that mesocaval shunting is a feasible procedure for the prevention of variceal bleeding. It will likely be most useful for patients whose anatomy prohibits TIPS to provide a bridge to transplant.

## TECHNIQUE

Mesocaval shunting involves the creation of a shunt from the mesenteric vasculature, typically the superior mesenteric vein (SMV), into the inferior vena cava (IVC). Similar to TIPS, this provides relief of portal pressures by allowing blood to bypass the congested hepatic vasculature. Shunt placement is performed by interventional radiologists. There have been both femoral and transabdominal approaches reported (Table 1)<sup>[6-9]</sup>.

Fluoroscopy from a recent case of refractory variceal bleeding in a patient with a portal vein thrombus (PVT) from our institution will be used to graphically illustrate the basic technique (Figure 1). Our patient had cirrhosis and prior medical and endoscopic attempts to control her varices were limited by significant chest pain attributed

to her banding procedures that required inpatient admission. Her PVT prohibited TIPS placement and she consented to undergo endovascular mesocaval shunt placement.

In our patient, and, in general, first, a needle is directed, in our case transabdominally, through the SMV, or, in this instance, a portal vein remnant, at a target placed *via* internal jugular (IJ) access (Figure 2A). Then, a wire is threaded from this needle through the IVC and out the IJ access so that, when the needle is removed, the distal tip of the the wire is in the splenic vein and its proximal end functions as a guidewire exiting the IJ access (Figure 2B). Finally, a stent graft, in our case a covered VIATORR stent, is passed over the guidewire *via* IJ access using Seldinger technique and placement is confirmed with fluoroscopic guidance (Figure 2C).

In the initial case report<sup>[6]</sup>, contrast-enhanced computed tomography (CT) was first performed to define cross-sectional anatomy. The patient underwent bowel preparation pre-procedurally and was given prophylactic antibiotics as a transcolonic approach was anticipated. Using CT and fluoroscopic guidance, a needle was inserted through and through the transverse colon and SMV into the IVC to a retrieval basket. The retrieval basket had been placed in the IVC *via* the right internal jugular vein. A guide wire was then passed from the abdominal access through the SMV to IVC and jugular access. A stent was placed under angiographic guidance from the internal jugular access across the IVC to SMV and the wire was removed.

Another case report, by Moriarty *et al*<sup>[9]</sup>, used similar methodology but opted for a transgastric rather than transcolonic approach to reduce the risk of infection. Interestingly, the case reported by Moriarty *et al*<sup>[9]</sup> required a cardiac transseptal needle to puncture the IVC as attempts made with a Rosch-Uchida TIPS needle were unsuccessful. The final published percutaneous approach to date was remarkable for the ability to avoid luminal puncture; Bercu *et al*<sup>[8]</sup> were able to approach transabdominally without perforating the bowel and relied on fluoroscopic rather than CT-guidance for visualization of the patient's anatomy during the procedure.

Hong *et al*<sup>[7]</sup> reported an interesting series of three cases in which they were able to place mesocaval shunts but avoid a transabdominal approach. Using techniques similar to direct intra-hepatic portosystemic shunt (DIPS) placement, they describe a series of cases in which they relied on intravascular ultrasound to avoid transabdominal puncture to access the SMV. The stent itself is extra-hepatic (and thus distinct from DIPS) and possible in patients who are not candidates for TIPS or DIPS given portal vein thrombi. In short, sheaths were placed both femorally and in the internal jugular vein. A guide wire was used to couple the jugular and femoral sheaths. Following guide wire placement, a longitudinal side-firing intravascular ultrasound (IVUS), akin to those used in placement of DIPS, was introduced through the femoral sheath so that the SMV could be cannulated using a needle introduced at the jugular access. In this

**Table 1** Summary of published mesocaval shunt placements

Ref.	Case history	Details and outcomes	
Nyman <i>et al</i> <sup>[6]</sup> 1996	37-year-old male with history of recurrent massive variceal bleeds attributed to congenital PVT and failed prior surgical shunt attempt	Visualization Approach Duration of follow-up Thrombosis Recurrent bleeding Hepatic encephalopathy	CT angiography Transcolonic 5, 12 and 14 mo Yes <sup>1</sup> No NR
Moriarty <i>et al</i> <sup>[9]</sup> 2012	57-year-old male with history of metastatic CRC and extrahepatic PVT who failed prior TIPs and was thought not to be surgical candidate	Visualization Approach Duration of follow-up Thrombosis Recurrent bleeding Hepatic encephalopathy	CT and fluoroscopy Transgastric 3 mo Yes <sup>2</sup> Yes <sup>2</sup> NR
Bercu <i>et al</i> <sup>[8]</sup> 2015	58-year-old female with history of HCV cirrhosis, PVT with recurrent ascites who failed prior TIPs attempt and was a poor surgical candidate	Visualization Approach Duration of follow-up Thrombosis Recurrent bleeding Hepatic encephalopathy	Fluoroscopy Transabdominal 3 and 6 mo No No Yes <sup>3</sup>
Hong <i>et al</i> <sup>[7]</sup> 2012	16-year-old female with history of chronic PVT and hematemesis who was felt to have high surgical risk	Visualization Approach Duration of follow-up Thrombosis Recurrent bleeding Hepatic encephalopathy	Fluoroscopy and IVUS Endovascular 1 mo No No NR
Hong <i>et al</i> <sup>[7]</sup> 2012	60-year-old female with history of HBV, HCV, HCC with thrombus obliterating PV	Visualization Approach Duration of follow-up Thrombosis Recurrent bleeding Hepatic encephalopathy	Fluoroscopy and IVUS Endovascular 2 and 10 mo No No NR
Hong <i>et al</i> <sup>[7]</sup> 2012	53-year-old male with history of pancreatic teratoma treated with Whipple with clot at SMV and splenic veins	Visualization Approach Duration of follow-up Thrombosis Recurrent bleeding Hepatic encephalopathy	Fluoroscopy and IVUS Endovascular 1 and 3 mo No No NR

<sup>1</sup>The shunt was found to be thrombosed on POD #1 so the patient underwent ballooning of his stent and directed thrombolysis and was started on a therapeutic heparin. His hematocrit began to fall on the heparin but stabilized when the anticoagulation was held; <sup>2</sup>The shunt was found to be thrombosed on POD #2 and on POD #3 the patient had a recurrent upper gastrointestinal hemorrhage. A new shunt was placed and the patient had no further bleeding; <sup>3</sup>The patient had no encephalopathy at a 3-mo follow-up visit but was noted by an outside hospital to have encephalopathy 6 mo after shunt placement when the patient was hospitalized for concern for partial small bowel obstruction. The patient's home lactulose and rifaximin had been held; when these medicines were resumed her encephalopathy resolved. NR: Not reported; PVT: Portal vein thrombus; CRC: Colorectal cancer; TIPs: Transjugular intrahepatic portosystemic shunting; HCV: Hepatitis C virus; HBV: Hepatitis B virus; HCC: Hepatocellular carcinoma; SMV: Superior mesenteric vein; PV: Portal vein; CT: Computed tomography.

way, they were able to avoid a percutaneous transabdominal approach altogether. It should be noted that the third patient included in this series was not a cirrhotic patient but rather had portal and SMV clots due to a pancreatic tumor; we chose to include this patient in our review to demonstrate the feasibility of the procedure but appreciate that his underlying pathophysiology may be different from the others presented.

## SELECTION OF CANDIDATES

Candidates likely to benefit from mesocaval shunting include those with recurrent variceal bleeds who have failed prior medical and endoscopic therapies. Traditionally, TIPS has been employed in these patients to alleviate portal pressures. We propose that mesocaval shunting be offered to patients who are not TIPS can-

didates, particularly the group awaiting transplant, as there are not yet mortality data for mesocaval shunting and the mortality benefit of other portosystemic shunts, including TIPs, has been questioned<sup>[10]</sup>.

As in our illustrative case, PVT, for example, are known to make TIPS more difficult and result in lower success rates, ranging from 40%-75%<sup>[11]</sup>. In some cases, when PVT is chronic, TIPS is not only difficult but actually technically impossible as in order to re-establish flow, there must be functional vessels surrounding the planned recanalized clot segment. This intact vasculature is often absent in those with chronic PVT as intrahepatic vessels may have atrophied while extrahepatic vessels form collaterals at high risk of bleeding<sup>[6]</sup>. Given the relatively high prevalence of PVT in cirrhotics, up to 5% to 16% of patients at the time of liver transplantation, mesocaval shunting has the potential to offer a therapy

Figure 1 Grade III varices in distal esophagus on pre-procedure esophagogastroduodenoscopy.

to a large group of patients who were previously thought to be without options, particularly in those patients whose PVT prohibits them from receiving a liver transplant<sup>[12]</sup>.

Prior to endovascular placement of mesocaval shunts, the other option for patients in this scenario was surgical shunt placement. Historically, surgically placed portosystemic shunts have had high mortality<sup>[5]</sup>. While experienced centers are reporting improved operative mortality<sup>[13,14]</sup>, the ability to replicate these lower mortality rates at smaller, less experienced centers remains to be seen. Furthermore, several of the patients in published percutaneous mesocaval shunt cases to date were thought to be poor surgical shunt candidates due to a history of prior abdominal surgeries and/or anatomy of their PVT<sup>[6,8,9]</sup>.

If a patient is felt to be appropriate for consideration of mesocaval shunt placement, assessment of cross-sectional anatomy should be undertaken with computed tomography or magnetic resonance imaging of the abdomen to assist in procedural planning. For successful shunt placement, the IVC and SMV should be aligned and proximal in an anatomic window without any significant vasculature or viscera interposed between the two vessels<sup>[8]</sup>. The IVC and SMV (or a large collateral) must be patent for shunt placement.

## POTENTIAL PITFALLS

There are a few potential pitfalls we consider with placement of a mesocaval shunt. First, similar to the surgical expertise required for safe surgical shunt placement, institutional interventional radiologic expertise will be required to safely recommend this procedure and this may not be available at all centers. This procedure, unlike TIPS, has not been reported to be performed in the setting of active variceal bleeding and thus there are no data to support its safety in that setting.

The most serious risk is that of procedure-related hemorrhage due to puncture of proximal vasculature. As noted by Hong *et al.*<sup>[7]</sup> both the SMV and infrahepatic IVC lack any surrounding solid organs that could provide tamponade during shunt placement, creating a risk of major hemorrhage. Of the published cases to date, one noted intraabdominal hemorrhage-multiple small

bowel hematomas - which was successfully treated conservatively with intravenous fluid, transfusion support and discontinuation of anticoagulation<sup>[6]</sup>. If the cannulated vessels require predilation prior to shunt placement, this risk of bleeding is likely increased<sup>[7]</sup>. Finally, while they did not experience intrabdominal hemorrhage despite use of an uncovered stent, Moriarty *et al.*<sup>[9]</sup> note that use of an uncovered stent certainly increases risk of bleeding and recommend using covered stents and/or balloons to minimize this risk. In addition to procedural technique, we anticipate that, similar to other invasive procedures in cirrhotic patients, platelet counts influence the risk of hemorrhage. The cases reviewed here unfortunately do not provide patient platelet counts or other measures of clotting function.

In addition to the potential for vessel perforation, depending on each individual patient's anatomy, there are risks of perforation of different structures. If an intestinal perforation is created, risk of sepsis, hemorrhage and/or abscess formation will certainly be increased<sup>[8]</sup>. In two reported cases, the transabdominal approach necessitated intestinal puncture<sup>[6,9]</sup>. In one case the track was transcolonic while the other approach was transgastric. Bowel preparation and antibiotic prophylaxis were administered in the transcolonic case and neither case resulted in sepsis. Although there were no reported infectious complications in the cases we reviewed, this risk should be underscored as it is likely not negligible in cirrhotic patients with impaired immunity. In addition to the risk of intestinal perforation, other nearby viscera are at risk of puncture as well. If the pancreas is punctured, both hemorrhage and pancreatitis are potential risks<sup>[8]</sup>. One published case to date notes pancreatic bisection and reports that serum amylase levels were within the normal range for at least five days post-operatively<sup>[7]</sup>.

In the six cases reviewed, two cases reported subsequent shunt occlusion and need for further revision, a rate of 33% in our, appreciably, small series. Shunt thrombosis is an important outcome as it presumably puts the patient at risk for further portal hypertension, variceal formation and variceal bleeding. In the first of the two cases complicated by occlusion, lack of flow through the shunt was noted on both Doppler and CT on POD #2<sup>[6]</sup>. The patient underwent repeat angiography and had ballooning and directed thrombolysis of his stent with subsequent patency on 5 mo follow-up angiogram. The stent was again noted to be occluded on 12 mo follow-up angiography but he had no further gastrointestinal bleeding and no attempt to revise the shunt further was made. In the second case complicated by shunt occlusion, lack of flow through the shunt was noted on POD #2 on CT<sup>[9]</sup>. This was attributed to the severe angle of the initial shunt placement and its proximity to the wall of the IVC. This patient experienced upper gastrointestinal bleeding on POD #3 and underwent repeat angiography with stent replacement and had a patent stent and no further bleeding at 3 mo follow-up.

Finally, as with any form of portosystemic shunting, we anticipate that these patients will have higher rates

**Figure 2** Intra-procedure steep oblique fluoroscopy of upper abdomen during mesocaval shunt placement. First, a needle is inserted percutaneously (black arrowhead) and directed through the portal vein remnant at a target snare placed in the inferior vena cava (white arrowhead) via internal jugular (IJ) access sheath (red arrowhead) (A). The wire is then threaded from its original percutaneous entry via the needle through the IJ sheath (red arrowhead) so that it extends from the IJ and is seen coiling in the splenic vein (black arrowhead) (B). The unexpanded stent graft (white arrowhead) is passed over the wire using Seldinger technique with fluoroscopic guidance (B). Coils are placed in varices (blue arrowhead) (B). Shuntogram with contrast 22 mo post-procedure shows functioning mesocaval shunt (white arrowhead) with tip in the splenic vein (black arrowhead) and absent varices (C). Previous coils in the varices are still visible (red arrowhead).

of hepatic encephalopathy (HE) than patients without portosystemic shunting. Given the limited numbers of patients who have undergone percutaneous or endovascular mesocaval shunt placement, there are no data to evaluate rates of HE with these shunts vs TIPS or surgical shunt creation but presumably the rate is similar, around 30%<sup>[15,16]</sup>. In the cases reviewed above, only one case reported on the presence or absence of encephalopathy. In that case, the patient was noted to have no encephalopathy during index hospitalization or at 3 mo follow-up but was noted to be encephalopathic 6 mo post-operatively when her lactulose and rifaximin were held at an outside hospital for partial small bowel obstruction<sup>[8]</sup>. Her encephalopathy reportedly resolved with resumption of these medications.

## BENEFITS

As above, mesocaval shunting offers a treatment for bleeding varices for patients who otherwise face a high mortality with virtually no options. It can be offered to patients with PVT who cannot undergo TIPS and may be best utilized as a bridge to transplant. Furthermore, if an IVUS is utilized, vessels are directly visualized, avoiding the blind puncture method used in TIPS<sup>[7]</sup>. As with other similar endovascular procedures, we anticipate a lower mortality with this less invasive approach vs surgical shunt placement. Regardless, the majority of the published patients to date were not felt to be surgical candidates<sup>[6,7,9]</sup>.

In the six adult cases published to date, two stents thrombosed within two days post-operatively while the remaining four remained patent<sup>[6,9]</sup>. Of the two patients with shunt thrombosis, one had a recurrent upper gastrointestinal bleed. In this case, it was postulated that the severe angle of the initial stent placement may have contributed to turbulence and subsequent thrombosis<sup>[9]</sup>. In both cases, subsequent shunt revision was performed and the revised shunts remained open during five and

three months follow-up respectively. One shunt ultimately lacked patency at 12 mo follow-up but the patient had no further bleeding up to 14 mo follow-up. In summary, all reported cases have follow-up ranging from 1 to 14 mo in which, with the exception of the post-operative day 2 bleed noted above, there were no further variceal bleeding episodes. These are promising results in light of the known 60% 1-year risk of rebleeding and 33% 1-year mortality in patients who survive an episode of variceal hemorrhage<sup>[17]</sup>.

In addition to offering a rescue therapy for a group of patients with minimal options, mesocaval shunting has an advantage compared to local variceal therapy, it will result in lower portal pressures and thus will reduce recurrent ascites as well reducing the risk of variceal bleeding. As noted by Garcia-Tsao and Bosch in a recent review, judgment of treatment success of varices should include mindfulness about the impact of variceal treatment on other complications of portal hypertension—ascites, jaundice, encephalopathy—rather than artificially isolating the treatment's impact on variceal bleeding alone<sup>[17]</sup>. Finally, given that the presence of portal vein thrombosis is no longer thought to be an absolute contraindication to transplant<sup>[18]</sup>, for those patients that are transplant eligible, placement of a mesocaval shunt may enable survival to the operating room table for transplant, a pressing concern given that our most recent national statistics are dire. In 2014, 1821 patients died while awaiting transplant and an additional 1290 were removed from the waiting list as they were felt to be “too sick” for transplant<sup>[19]</sup>.

## CONCLUSION

As reviewed above, endovascular mesocaval shunting is a feasible procedure that offers a promising intervention to a patient population with few options and one-year mortality as high as 20%<sup>[1]</sup>. TIPS has been shown to be an effective intervention to prevent recurrent variceal

bleeding<sup>[2]</sup> and mesocaval shunting provides similar physiologic relief of portal pressure in patients who are not TIPS candidates. Like TIPS, mesocaval shunting avoids major surgery and may require less anesthesia than a surgical shunt approach. Furthermore, it can be offered to patients who are not surgical candidates. Mesocaval shunting alleviates portal hypertension, a key component of reducing the rate of variceal bleeding, and one that will potentially reduce recurrent ascites as well. The patient who stands to gain the most from this procedure has recurrent variceal bleeds, has failed endoscopic and medical therapies, cannot undergo TIPS due to anatomy and needs a bridge to transplant to minimize the chance of further decompensating while awaiting an organ. In order to have successful shunt placement, these patients must have alignment between IVC and SMV or SMV collaterals. Potential procedural complications include perforation of nearby vessels or viscera which could result in hemorrhage, sepsis, pancreatitis or abscess formation as well as stent thrombosis. Placement of a portosystemic shunt will also increase the risk of hepatic encephalopathy although there is little data to compare mesocaval shunts to surgical shunts or TIPS. To date, several approaches and imaging techniques have been utilized by reporting groups, notably including one approach that avoids transabdominal puncture<sup>[7]</sup>. In the cases reported, all have prevented rebleeding for the post-procedural monitoring period after initial shunt or initial shunt revision<sup>[6,8,9]</sup>. Further research should be performed to better assess outcomes - variceal bleeding, hepatic encephalopathy rates and mortality - in these patients compared to standard-of-care controls so that the benefits of this promising technique may be maximized.

## Abstract

**AIM:** To determine if calnexin (CANX), RAB1 and alpha-tubulin were involved in the production of hepatitis C virus (HCV) particles by baby hamster kidney-West Nile virus (BHK-WNV) cells.

**METHODS:** Using a siRNA-based approach complemented with immuno-fluorescence confocal microscope and Western blot studies, we examined the roles of CANX, RAB1 and alpha-tubulin in the production of HCV particles by permissive BHK-WNV cells expressing HCV structural proteins or the full-length genome of HCV genotype 1a. Immuno-fluorescence studies in producer cells were performed with monoclonal antibodies against HCV structural proteins, as well as immunoglobulin from the serum of a patient recently cured from an HCV infection of same genotype. The cellular compartment stained by the serum immunoglobulin was also observed

in thin section transmission electron microscopy. These findings were compared with the JFH-1 strain/Huh-7.5 cell model.

**RESULTS:** We found that CANX was necessary for the production of HCV particles by BHK-WNV cells. This process involved the recruitment of a subset of HCV proteins, detected by immunoglobulin of an HCV-cured patient, in a compartment of rearranged membranes bypassing the endoplasmic reticulum-Golgi intermediary compartment and surrounded by mitochondria. It also involved the maturation of N-linked glycans on HCV envelope proteins, which was required for assembly and/or secretion of HCV particles. The formation of this specialized compartment required RAB1; upon expression of HCV structural genes, this compartment developed large vesicles with viral particles. RAB1 and alpha-tubulin were required for the release of HCV particles. These cellular factors were also involved in the production of HCVcc in the JFH-1 strain/Huh-7.5 cell system, which involves HCV RNA replication. The secretion of HCV particles by BHK-WNV cells presents similarities with a pathway involving caspase-1; a caspase-1 inhibitor was found to suppress the production of HCV particles from a full-length genome.

**CONCLUSION:** Prior activity of the WNV subgenomic replicon in BHK-21 cells promoted re-wiring of host factors for the assembly and release of infectious HCV in a caspase-1-dependent mechanism.

**Key words:** Membrane rearrangements; Hepatitis C virus; Flavivirus replicon; Virus assembly and secretion; Host cellular factors

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Our system for production of authentic infectious hepatitis C virus (HCV) in non-humanized, non-hepatic cells involves the rearrangement of inner cellular membranes triggered by the replication of flaviviruses. The present results suggest that this feature relies on the re-wiring of host factors that usually contribute to the secretion of glycoproteins to generate an unusual secretory pathway. This model offers a new way to study the properties of free HCV particles, *i.e.*, independently from lipoproteins.

Assembly and release of infectious hepatitis C virus involving unusual organization of the secretory pathway. *World J Hepatol* 2016; 8(19): 796-814 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i19/796.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i19.796>

## INTRODUCTION

Hepatitis C virus (HCV) genotype 1 has accounted for up to 70% of HCV infections worldwide and is more often

resistant than the other genotypes to the combination of pegylated interferon plus ribavirin, the standard of care until recently<sup>[1]</sup>. New antiviral drugs specifically target either the viral protease NS3, the protein NS5A or the RNA polymerase NS5B and are able to clear HCV infections in a higher number of individuals with a shorter duration of treatment than the standard of care<sup>[2]</sup>. However, a significant proportion of patients requiring treatment still cannot be cured<sup>[3]</sup>, does not have access to treatment<sup>[4]</sup> and/or will need the development of a vaccine<sup>[5]</sup>. Experimental models are being developed<sup>[6]</sup>, but may not cover all aspects of the pathogenesis of hepatitis C, such as the mechanism by which antibodies prevent the spread of infection<sup>[7]</sup>.

In an effort to develop alternative systems, we have established a model in which infectious HCV production is independent from its replicon-mediated RNA replication<sup>[8]</sup>, hence circumventing limitations inherent to existing cell culture models<sup>[9]</sup>. For instance, the replication of HCV genotype 1 isolates in hepatocellular carcinoma cell lines is inefficient or generates adaptive mutations interfering with viral fitness *in vivo*. Briefly, our system relies on the amplification provided by a dual bacteriophage RNA polymerase plasmid system (referred to as P2B) that generates large amounts of HCV RNA transcripts from a T7 promoter-driven plasmid in the cytoplasm of baby hamster kidney (BHK)-21 cells conditioned by a lineage II West Nile virus (WNV) subgenomic replicon<sup>[8]</sup>. We observed that the WNV replicon in this cell line created an environment permissive for the assembly and release of infectious HCV of various genotypes, including virions of strains H77 (genotype 1a)<sup>[10]</sup> or Con1 (genotype 1b)<sup>[11]</sup>; these virions infected human liver slices *ex vivo*<sup>[8]</sup>.

BHK-WNV cells produce infectious HCV particles independently from lipoprotein biosynthesis. The fact that these particles retain the possibility to interact with lipoproteins *in vitro*<sup>[8]</sup> is in line with previous results<sup>[12-14]</sup> and supports the view that HCV particles may interact with lipoproteins in a second step (*e.g.*,<sup>[15,16]</sup>) and not necessarily co-assemble with them (*e.g.*,<sup>[17]</sup>). Potential mechanisms for WNV-conditioned BHK cells producing highly infectious HCV virions could relate to common genomic features between the *Flavivirus* and *Hepacivirus* genera within the *Flaviviridae* family<sup>[18]</sup>. In addition, several flaviviruses infect hepatocytes<sup>[19,20]</sup> and may use similar host factors as HCV for their production<sup>[21-25]</sup>.

Our previous results showed that after curing BHK cells from the WNV subgenomic replicon, the production and release of infectious HCV particles were still observed for a while<sup>[8]</sup>. In addition, although recombinant expression of HCV structural genes in cultured cells, including in human hepatocytes<sup>[26]</sup>, usually leads to their retention in the endoplasmic reticulum (ER)<sup>[27]</sup>, BHK-WNV cells released infectious HCV particles even in the absence of HCV non-structural genes<sup>[8]</sup>. These findings suggested that, while the viral replication machineries played no direct role in the secretion process, the reorganization of intracellular membranes induced by the WNV subgenomic replicon contributed to the permissiveness

of BHK cells.

In mammalian cells, conventional protein traffic from the ER to the Golgi complex passes through the membrane clusters of the ER-Golgi intermediate compartment (ERGIC), the marker of which is the lectin ERGIC-protein of 53 kDa (ERGIC-53). ER-derived cargo is first shuttled to the ERGIC in a coat protein (COP) II-dependent step and subsequently to the Golgi apparatus in a second vesicular transport step involving COP I-coated vesicles, RAB and ARF GTPases, as well as cytoskeletal networks; incoming vesicles can also be recycled to the ER in a COP I-mediated process<sup>[28]</sup>. The ERGIC contributes to the concentration, folding, and quality control of newly synthesized proteins and is required for the production of several viral pathogens<sup>[29]</sup>. N-linked glycosyl antenna are matured by Golgi-resident enzymes along with glycoproteins' progression from the proximal to the distal Golgi *cisternae*, then across the plasma membrane for their secretion, *via* the *trans*-Golgi/endosomal network.

In the present work, we studied the potential involvement of components of this secretory machinery in the production of HCV particles by BHK-WNV cells and compared this model with the JFH-1 strain/Huh-7.5 cells model. We show that, upon expression of an HCV genome of genotype 1a in these cells, a subpopulation of HCV proteins were recruited through calnexin (CANX) to a cytoplasmic compartment of rearranged membranes. The small GTPase RAB1 was involved in the formation of this compartment. The secretion of HCV particles produced from a full-length genome required also the N-linked glycosylation of HCV envelope glycoproteins and  $\alpha$ -tubulin ( $\alpha$ -TUB), a component of microtubules and, surprisingly, the activity of cysteine protease caspase-1. As our understanding of the HCV virus life cycle has recently widened to alternative routes of transmission, elucidating mechanisms at work in BHK-WNV cells could shed some light on the production of HCV *in vivo*.

## MATERIALS AND METHODS

### Cell cultures

BHK-21 cells were grown in E-MEM supplemented with 10% fetal bovine serum (FBS; HyClone, United States), Glutamax-I (Gibco, Life Technologies, United States); BHK cells harboring WNV lineage II SG-replicon encoding *Renilla* luciferase<sup>[30]</sup>, herein called BHK-WNV cells, were propagated in D-MEM supplemented with 10% FBS, Glutamax-I and 5  $\mu$ g/mL blasticidin. Huh-7.5 cells were maintained in D-MEM supplemented with 10% FBS, Glutamax-I, non-essential amino acid mix (Gibco, Life Technologies, United States).

### Plasmid constructs

A previously described system of two plasmids (P2B = dual phage RNA polymerases plasmid system for generation of T7 RNA polymerase in the cytoplasm) was used to amplify the cytoplasmic transcription of a plasmid encoding HCV bicistronic particles (HCVbp) under the control of bacteriophage T7 DNA-dependent

RNA polymerase's cognate promoter<sup>[8]</sup>; a sequence encoding an HDV antigenomic ribozyme<sup>[31]</sup> was added at its C termini; as a consequence, HCV transcripts were uncapped and have correct 5'- and 3'-ends. p90 HCVcon-FLlongpU<sup>[10]</sup> and pH-SGNeo (L + I) encoding a SG-replicon of the same strain with cell-culture adaptive mutations<sup>[32]</sup> were used as templates to construct HCVbp-coding plasmids. pHCV STp7 is a pcDNA3.1(+)-based plasmid (Life Technologies, United States) encoding the structural genes (*core*, *E1*, *E2*) plus *p7* of HCV genotype 1a linked to the human cytomegalovirus (CMV) immediate early promoter. HCVbp-4cys are HCVbp particles with a sequence encoding a tetracysteine tag<sup>[33]</sup> inserted in the part of their genome encoding NS5A<sup>[8]</sup>.

### Antibodies and cellular markers

Anti-E2 (ALP98 and AP33)<sup>[34]</sup>, and anti-E1 (A4) monoclonal antibodies were used for Western blot (WB) analysis. Conformational AP33 monoclonal antibody, human serum from an HCV patient (genotype 1a) that recognizes conformational HCV core and E2 protein subspecies by WB and anti-HCV core peptides 9-21 (C1) or 7-50 (Thermo Scientific, United States) monoclonal antibodies were used for confocal microscopy analysis. Neutralizing monoclonal antibody E16 recognizes WNV E by WB<sup>[35]</sup>. Antibodies against various cellular proteins are as followed: ERGIC-53 (Alexis Biochemicals, United States), GDI (Life Technologies, United States); RAB1 and atlastin (Santa Cruz Biotechnology, United States); CANX and GM130 (Abcam, United States); and calreticulin (Cell Signaling Technology, United States). For immunofluorescence analysis, the secondary antibodies used were Alexa Fluor 488-, 594- or 635-conjugated goat anti-mouse and anti-human antibodies, and Alexa Fluor 594-, 635- or -680 conjugated goat anti-rabbit antibodies from Molecular Probes (Life Technologies, United States). Mito Tracker Orange CMTMRos, TC-ReASH II In-Cell Tetracysteine Tag detection kit and Paclitaxel (Taxol) Oregon Green® 488 Conjugate were obtained from Molecular Probes (Life Technologies, United States). Nuclei were counterstained with DAPI (blue). The cells were observed with a laser-scanning confocal microscope and the pictures were deconvoluted. Bar scales = 5  $\mu$ m.

### Production of HCV particles in mammalian cells

One day before transfection, BHK-WNV cells were seeded at a density of  $6 \times 10^6$  cells per 162 cm<sup>2</sup> flask. Plasmids encoding the HCV sequence under the control of the CMV early promoter or the bacteriophage T7 promoter were transfected using Lipofectamine® LTX with Plus™ Reagent according to the manufacturer's protocol (Life Technologies, United States). Culture medium after transfection was D-MEM supplemented with 10% FBS, non-essential amino acid mix, Glutamax-I, 25 mmol/L Hepes and 3.7 g/L sodium bicarbonate. Cells were incubated at 37 °C for 3 d in an incubator with a 95% air/5% CO<sub>2</sub> atmosphere saturated in humidity. Culture media were harvested, centrifuged at 30000  $\times$  g for 30

min at 4 °C to remove cell debris; then clarified supernatants (SN) were filtered with 0.45 µm PVDF membrane (Millipore, United States) and centrifuged at 100000 × g for 3 h at 4 °C. Pellets were suspended in ice-cold Tris-buffered saline solution (TBS; Quality Biologicals, United States) containing protease inhibitor cocktail (Roche, United States). HCVcc (Huh-7.5-produced JFH-1) was obtained by electroporating IVT RNA into Huh-7.5 cells as described<sup>[36]</sup>; the SN was concentrated, and aliquots of the virus stock were stored at -80 °C.

### Gene knockdown in BHK-WNV cells using siRNAs

CANX, melanocortin 5 receptor (MC5R), α-TUB were analyzed for their effects on HCV release. BHK-WNV cells were treated with the corresponding siRNA (2 siRNAs per target gene; Dharmacon, United States) for 2 d, re-seeded and transfected the next day with HCV-coding plasmid. Cells and supernatants were harvested 48 h later, and analyzed by WB. To verify the effects of these genes on HCV release, CANX and α-TUB cDNAs were synthesized from BHK-WNV mRNA, and cloned into pTracer-CMV/Bsd (Invitrogen, United States). The corresponding pTracer plasmid was co-transfected with HCV-coding plasmid in siRNA-treated BHK-WNV cells to show the specificity of their knockdown.

### Effect of RAB1 on HCV production by BHK-WNV cells

To study co-localization of HCV and RAB1 in the producer cells, BHK and BHK-WNV cells were transfected with HCVbp-coding plasmid, and the following day, re-seeded on 8-well chambered coverglass (5 × 10<sup>3</sup> cells/well). Two days later, cells were fixed and permeabilized as above, then incubated with serum from an HCV-infected patient (HCV genotype 1a) and anti-RAB1 antibodies. BHK-WNV cells were then treated with siRNA against RAB1 (2 siRNA per target gene; Dharmacon, United States) for 2 d, re-seeded, and the following day were transfected with HCVbp-coding plasmid. Cells and SN were harvested 3 d after transfection; cell lysates and particles released into SN were analyzed by WB.

### Electron microscopy

BHK-WNV cells seeded in a 6-well plate (2.5 × 10<sup>5</sup> cells) were transfected with HCVbp-coding plasmid. Three days later, cells were fixed in 2% glutaraldehyde in 0.1 mol/L sodium cacodylate for 1 h at RT, then at 4 °C, overnight. Cells were subsequently processed for transmission electron microscopy (TEM) as described<sup>[37]</sup>.

### Effects of siRNAs on HCVcc production and release in Huh-7.5 cells

Cells were treated with the siRNAs (CANX, α-TUB, RAB1A, RAB1B, or non-target) for 48 h; the same number of cells was reseeded on 24-well plates, and the next day was inoculated with HCVcc at MOI 0.5. Cells were harvested daily, total RNA was extracted using lysis buffer of TaqMan Gene Expression Cells-to-ct kit (Life Technologies, United States) and HCV RNA was analyzed by RT-TaqMan<sup>TM</sup> PCR with a StepOne Plus

thermocycler (Applied Biosystems, United States).

### IF experiments

For live staining after inoculation with HCVbp-4cys, Huh-7.5 cells were incubated with two cell-permeant reagents: The arsenical ReASH-ethane dithiol (Life Technologies) that fluoresces upon binding a tetra-cysteine tag<sup>[33]</sup>, and Oregon Green 488 paclitaxel bis-acetate (TubulinTracker Green Reagent; Life Technologies, United States) that binds to polymerized alpha tubulin. Immuno-fluorescence studies on fixed cells were performed on stacks of images (a dozen cells per IF condition); co-localization was analyzed using Coloc 2 Plugin ([http://imagej.net/Coloc\\_2](http://imagej.net/Coloc_2)) with ImageJ software (<https://imagej.nih.gov/ij/>).

### Experimental reproducibility

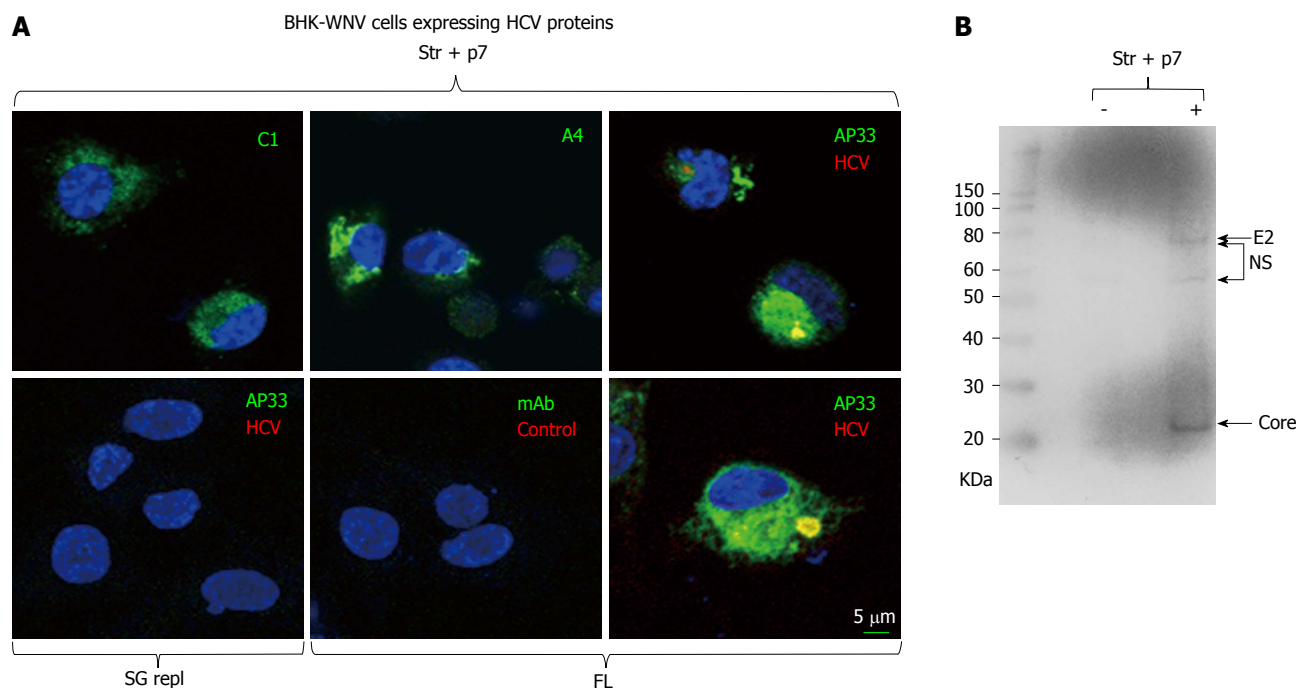

Unless specified otherwise, all shown results are representative of at least three independent experiments.

## RESULTS

### Identification of a compartment possibly linked to the assembly of HCV particles in the cytoplasm of BHK-WNV cells

To gain insight regarding the mechanisms by which BHK-WNV cells produce HCV particles, we transfected the cells with either of three different plasmids based on HCV genotype 1a (HCV1a): (1) HCV structural and p7 genes<sup>[38]</sup> linked to a CMV promoter (Str + p7); (2) HCV subgenomic replicon (SG repl); or (3) full-length HCV genome (FL) linked to the bacteriophage T7 promoter; for (2) and (3), the cells were also co-transfected with the P2B (dual phage RNA polymerases) plasmid system for generation of T7 RNA polymerase in the cytoplasm. The cells were then permeabilized and incubated with monoclonal antibodies (mAbs) against HCV1a core (C1), E1 (A4) and E2 (AP33) or a control mAb. Like in hepatic cells expressing a HCV genome<sup>[22]</sup>, we observed that the three HCV1a mAbs stained a large and heterogeneous area in the cytoplasm of BHK-WNV cells expressing the structural genes, while the control mAb did not stain these cells (Figure 1A). AP33 is a neutralizing mAb that targets a linear epitope within a flexible region of E2<sup>[34]</sup> and, as expected, did not stain cells not expressing HCV1a structural genes (Figure 1A). In contrast, a neutralizing IgG from the serum of a patient (HCV1a sIgG) who had been cured from hepatitis C of this genotype<sup>[8]</sup> stained a more limited and heterogeneously shaped compartment of the cytoplasm of BHK-WNV cells expressing a full-length genome of HCV1a, which was also stained by AP33 but not by control human sIgG (Figure 1A); of note, HCV1a sIgG did not stain BHK-WNV cells expressing a HCV1a subgenomic replicon. A mitochondrion-specific staining surrounded this compartment (Figure 2A). By WB, beside non-specific bands (NS), HCV1a sIgG specifically recognized bands with apparent molecular weights of 21 kDa and 75 kDa (Figure 1B) whose sizes coincided with those reported for HCV core and E2, both known to

**Figure 1** Immunodetection of hepatitis C virus proteins of genotype 1a expressed in baby hamster kidney-West Nile virus cells. **A:** A plasmid encoding Str + p7 of HCV strain H77 (genotype 1a) from an early human cytomegalovirus promoter or a system of plasmids (P2B) expressing a subgenomic replicon or genome (FL) of same genotype in the cytoplasm (8) were transfected in BHK-WNV cells; after 2 d, IF study was performed with monoclonal antibodies (green) targeting core 9-21 (C1), envelope E1 (A4) and E2 (AP33) (28) glycoproteins of strain H77 (all IgG1a), or anti-rabbit Ig mouse Ab (mAb) of same isotype; and with human serum IgG (red) obtained from a patient recently cured from an infection of same genotype (HCV) or uninfected (control). Nuclei were counterstained with DAPI (blue) and cells were observed with a laser-scanning confocal microscope; **B:** BHK-WNV cells were either mock transfected (-) or transfected with a system of plasmids expressing the genome of H77 strain (+); after 3 d, cell lysates were prepared and human anti-HCV IgG tested in (a) were used as a Western blot probe. The scale on the left shows molecular weight markers. HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus; Str + p7: Structural and p7 genes.

display most HCV epitopes recognized by human B cell (<http://www.iedb.org/>).

To further characterize the cytoplasmic compartment stained by HCV1a sIgG, thin sections of BHK-WNV cells expressing HCV genome of genotype 1a were observed by TEM. The sub-compartment was easily identified due to the presence of mitochondria in its periphery (Figure 2B)<sup>[39]</sup>. As previously, it was comprised of large vesicles containing viral-like particles - not observed in cells expressing an HCV1a subgenomic replicon, *i.e.*, without structural genes - as well as membranous web with vesicle packets, both typical of membrane rearrangements triggered by WNV replication<sup>[8]</sup>. This time, we also observed a mix of rearranged cellular organelles (ER, Golgi *cisternae*) with a few additional viral-like particles (Figure 2B). Altogether, these results support the view that HCV particles assembled in BHK-WNV cells were specifically recognized by sIgG from a cured patient.

#### **CANX recruits a subset of HCV proteins into a compartment of BHK-WNV cells for the release of HCV particles**

Classically, the secretion of glycoproteins involves lectins of the ER, CANX and calreticulin (CRT), microtubule-dependent ER-to-Golgi vesicular traffic<sup>[40,41]</sup>, maturation of their carbohydrates in the Golgi apparatus and the secretion machinery of the trans-Golgi network<sup>[42]</sup>. We

had previously observed that brefeldin A prevented the secretion of HCV by BHK-WNV cells, while it did not affect that of exosomes<sup>[8]</sup>. Brefeldin A is an inhibitor of GBF1 that activates small-sized GTPase ARF1 and, in turn, COPI-dependent traffic<sup>[43]</sup>. The effect of brefeldin A was consistent with HCV particles being released *via* a classical secretion path. Two components of the classical secretion path, CANX and microtubules, have been previously implicated in HCV life cycle in other systems<sup>[27,44,45]</sup>. Since what appeared to be the assembly compartment displayed major membrane rearrangements, we explored whether a classical secretion path was involved in the production of HCV particles by BHK-WNV cells.

In BHK-WNV cells expressing an HCV1a genome, most CANX was unexpectedly detected in the same compartment as HCV proteins stained by HCV1a sIgG (Figure 3A, left panels). After a treatment of BHK-WNV cells by CANX siRNA, which decreased the level of CANX (Figure 3A, right panels, and Figure 3C, top panels), HCV1a sIgG staining was no longer localized in this compartment but, instead, displayed a scattered pattern in the cytoplasm (Figure 3A, right panels). The effect of knocking down CANX and  $\alpha$ -TUB expression on HCV production was analyzed. Figure 3B shows WB analysis of E2 glycoprotein in particles purified from the supernatants and cell lysates as a marker for HCV production. Treatment of BHK-WNV cells by control or

**Figure 2** Transmission electron microscopy view of a hepatitis C virus compartment forming in baby hamster kidney-West Nile virus cells. BHK-WNV cells were transfected with a mix of HCVbp-expressing and P2B plasmids (8). HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus.

MC5R siRNA did not alter the production or release of HCV (Figure 3B). In contrast, siRNA-mediated down-regulation of CANX or  $\alpha$ -TUB significantly reduced the secretion of HCV (Figure 3B). Albeit incomplete, the siRNA effect on CANX expression was sufficient to abolish BHK-WNV permissiveness for HCV production (Figure 3C, top panels).

Hsp70 or Hsp90 were chosen as controls since they associate with exosomes<sup>[46,47]</sup>, which are particulate materials secreted by BHK cells yet distinct from HCV particles<sup>[8]</sup>. After a treatment of BHK-WNV cells with  $\alpha$ -TUB siRNA, the releases of Hsp70- and Hsp90-containing particles in the supernatant decreased (Figure 3B and C, bottom panels), in accordance with the requirement for a functional cellular traffic to release exosomes and consistent with an accumulation of Hsp70 in the producer cells. In contrast, HCV E2 did not accumulate in BHK-WNV cells (Figure 3B).

To evaluate whether inhibition of HCV release could result from an off-target effect, CANX and  $\alpha$ -TUB cDNAs cloned from BHK-WNV cells were inserted into mammalian expression plasmids. In BHK-WNV cells treated by CANX siRNA, expression of recombinant CANX gene partially restored both CANX levels (Figure 4) and HCV

secretion (Figure 3C, middle panels). A similar result was observed with  $\alpha$ -TUB cDNA expressed in  $\alpha$ -TUB siRNA-treated BHK-WNV cells (Figure 3C, middle panels). The release of WNV particles upon expression of WNV structural genes was minimally affected by either siRNA treatment (Figure 3C, bottom panels). These results show that HCV production in BHK-WNV cells specifically involved CANX and  $\alpha$ -TUB.

#### ***N-glycans of HCV envelope proteins are required for the non-classical secretion of HCV particles by BHK-WNV cells***

Together with CANX, CRT usually ensures the proper conformation of nascent glycoproteins in the ER lumen. However, CRT expression was lower in BHK-WNV cells than in parental cells (Figure 5A) and did not co-localize with HCV proteins detected by the immune sIgG (Figure 5B). An additional C-type lectin, ERGIC-53, transports properly folded glycoproteins from the ER to the Golgi apparatus. Its expression was also slightly lower in BHK-WNV cells (Figure 5A) and did not co-localize with this pool of HCV proteins (Figure 5B).

Treatment of producer cells with deoxynojirimycin (DNJ), which prevents the binding of nascent glyco-

**Figure 3** Involvement of calnexin and alpha-tubulin in the release of hepatitis C virus particles by baby hamster kidney-West Nile virus cells. A: BHK-WNV cells were treated, or not, with CANX siRNA and, three days later, transfected with the HCV-coding and P2B plasmids. Two days later, IF was performed with anti-HCV serum of Figure 1 (green) and anti-CANX antibody (red) followed by confocal microscopy analysis; nucleus were counterstained with DAPI (blue); B: Top panels: BHK-WNV cells were treated with the indicated siRNA for 2 d, then transfected with a plasmid encoding full length HCV (HCVbp) in the cytoplasm. Contents in E2 envelope protein of both supernatant (SN) and cell lysate (Cells) were analyzed 2 d later by Western blot (WB); Bottom panel: Densitometry analysis; C: Left panels: BHK-WNV cells were treated with the indicated siRNA for 2 d and content in CANX was analyzed by WB; Hsp90 was used as a control; Middle panel: BHK-WNV cells were transfected with the indicated siRNA for 2 d and cells were then reseeded and transfected the next day with the HCV-coding plasmid together with a control plasmid (-) or one expressing the cDNA of the knocked-down transcript (+). Two days later, HCV materials released in SN were analyzed by WB; Right panels: BHK-WNV treated as in (B) were transfected with a plasmid encoding West Nile virus (WNV) structural genes (core, prM and E). Two days later, materials released in the SN were analyzed by WB with an antibody recognizing WNV E (29); Hsp90 was used as a control; Bottom panels: Densitometry analyses. **Figure 4** Baby hamster kidney-West Nile virus cells treated with the indicated siRNA (on top). After 2 d, cells from both conditions were reseeded and transfected the next day with either a control plasmid or plasmid expressing CANX cDNA, respectively in control or CANX siRNA-treated BHK-WNV cells. The following day, content in CANX was analyzed by Western blot in cell lysates. CANX: Calnexin; BHK-WNV: Baby hamster kidney-West Nile virus.

proteins to CANX<sup>[42]</sup>, modified the glycosylation and stability of HCV envelope proteins in BHK-WNV cells (Figure 5C, bottom panel), which was accompanied by a lower amount of HCV particles released (Figure 5C, top panels). As expected, DNJ treatment resulted in decreased resistance of carbohydrates on E1 to a digestion by endo- $\beta$ -N-acetylglucosaminidase H (Endo-H). In contrast, O-glycosylation<sup>[48]</sup> inhibitors PAG and ALL did not display any effect on HCV production or E1 glycosylation (Figure 5C, middle panels). A similar pattern was observed with BHK cells bearing a Dengue 2 subgenomic replicon (Figure 6). Therefore, the decreased production of HCV in the presence of DNJ resulted from a lack of maturation of N-linked glycosyl antenna on HCV envelope proteins, consistent with the effect of CANX siRNA observed.

#### **RAB1 and conformational HCV protein subspecies co-localize within a compartment of reorganized ER and Golgi components**

We looked for additional cellular factors that could contribute to the secretion of HCV particles. RAB1 exerts a key control on the ER-to-Golgi traffic. In parental BHK-21 cells, RAB1 was spread in the cytoplasm, but co-localized with HCV proteins expressed after transfection (Figure 7A). The WNV subgenomic replicon enhanced RAB1 staining, coalescing into a few membranous-like spots within which most HCV proteins detected by HCV1a sIgG were localized (Figure 7B). Treatment of BHK-WNV cells with RAB1 siRNA greatly reduced HCV protein expression (Figure 7D); concomitantly, fewer HCV particles were released (Figure 7D).

Although maturation of HCV envelope glycoproteins did not involve a classical secretory pathway, some carbohydrate residues at the surface of released HCV particles became resistant to a treatment by Endo-H<sup>[42]</sup>. This indicates that the ER-to-Golgi machinery as well as the Golgi apparatus contributed to HCV production in BHK-WNV cells. Interestingly, in these cells, the

expression of RAB1 GDP dissociation inhibitor (GDI)<sup>[49]</sup> was enhanced and co-localized with HCV proteins in a pattern reminiscent of RAB1's (Figure 8). In addition, the expression of Atlastin 1, a high molecular weight GTPase that is involved in maintenance of the ER compartment<sup>[50]</sup> and fusion of ER tubules<sup>[51]</sup>, as well as in ER-to-Golgi trafficking<sup>[52]</sup>, was up-regulated in BHK-WNV cells compared to parental BHK-21 cells (Figure 9). We detected its presence within the CANX-enriched compartment formed in BHK-WNV cells (Figure 10), as well as that of p115/USO1<sup>[53]</sup>, required for membrane fusion of ERGIC vesicles with the Golgi apparatus. We also detected the presence of GM130/GOLGA2 (Figure 11), which contributes to the progression of glycoproteins between Golgi cisternae<sup>[41]</sup>, which in turn correlates with the maturation of their carbohydrate residues<sup>[54]</sup>.

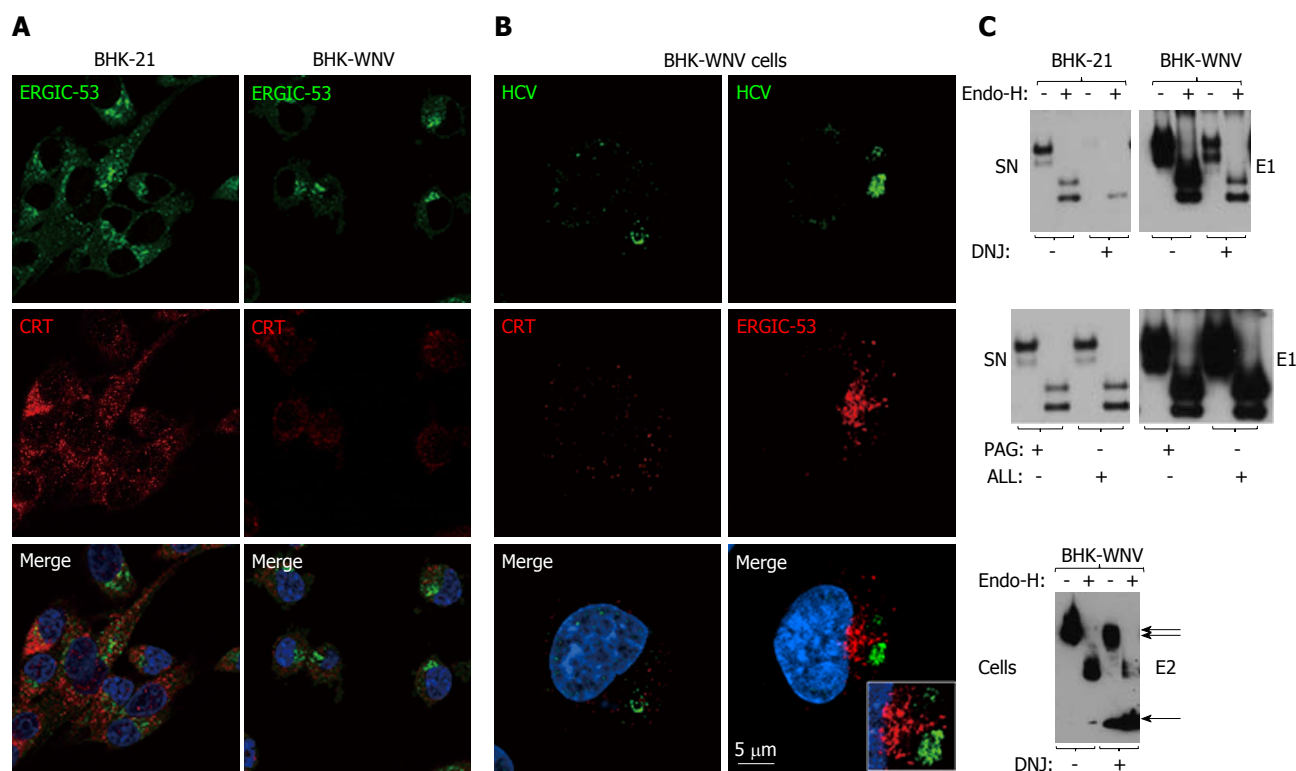

#### **Similarities between HCV productions in BHK-WNV and Huh-7.5 cells**

We next tested whether host factors assisting HCV production in BHK-WNV cells also play a role in the JFH-1 strain of genotype 2a/Huh-7.5 hepatocarcinoma cell paradigm. Mock transfection and non-target siRNA slightly decreased HCV production in Huh-7.5 cells infected with HCVcc. All other siRNAs tested further decreased the amount of HCV RNA, the inhibition ranging between 1 and 3 logs; HCV particle release in the supernatant was diminished as well (Figure 12A).

The human HCV serum used in BHK-WNV cells was of a different genotype than JFH-1; hence, for our IF studies we used a different antibody recognizing HCV core 7-50 peptide. There was not obvious co-localization of the staining it elicited in Huh-7.5 cells inoculated with HCVcc and that of the studied cellular factors. It has been reported that the localization of HCV proteins changed with time<sup>[55]</sup>. Therefore, we examined Huh-7.5 cells infected with the JFH-1 strain for over two weeks. HCV core staining was more widely spread within the cytoplasm and several hot spots were observed, similar to HCV proteins detected with the immune human serum in BHK-WNV cells. Core preferentially co-localized with CANX and RAB1 (Figure 12B); it did less so with tubulin.

Huh-7.5 cells were then inoculated with HCVbp-4cys particles (encoding a tetra-cysteine tag on NS5A) of genotype 1a produced in BHK-WNV cells (Figure 12C). In a live-cell immunofluorescence study, the pattern of NS5A-4cys was reminiscent of that observed with the same construct expressed in BHK-WNV cells<sup>[8]</sup>. However, this pattern was different from the staining of NS5A (without a tag) detected with an in-house antibody against a 48 aa-long peptide<sup>[8]</sup>, suggesting that distinct NS5A protein species were observed with two detection methods; each species could differentially affect HCV particle assembly and secretion. Interestingly, in Huh-7.5 cells, NS5A-4cys closely associated with microtubules (Figure 12C)<sup>[56]</sup>.

With minor differences, these results suggest that cellular factors involved in permissiveness of BHK-WNV cells are also required for long term HCV production in Huh-7.5 cells.

**Figure 5** Calnexin and N-linked glycosylation are involved in the release of hepatitis C virus particles via a non-classical secretion path in baby hamster kidney-West Nile virus cells. A: BHK-21 and BHK-WNV cells were transfected with the HCV expression plasmid system. IF was performed three days later with anti-ERGIC-53 (green) and anti-CRT (red) antibodies, followed by confocal microscopy analysis; B: Same protocol as in (A) with BHK-WNV cells transfected with the HCV-coding plasmids; C: Twelve hours after transfection with the HCV expression plasmid mix, parental BHK cells or BHK-WNV cells were treated, or not, with N- (DNJ) or O- (PAG, ALL) glycosylation inhibitors; materials released in SN (top and middle panels) or cell lysates (bottom panel) were collected, incubated with or without Endo-H and analyzed by Western blot. HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus; ERGIC-53: Endoplasmic reticulum-Golgi intermediate compartment-protein of 53 kDa; CRT: Calreticulin; SN: Supernatants; DNJ: Deoxynojirimycin; Endo-H: Endo- $\beta$ -N-acetylglucosaminidase H.

**Figure 6** Huh-7.5 cells were incubated with hepatitis C virus reporter particles produced either in parental baby hamster kidney cells or in baby hamster kidney cells chronically replicating a dengue 2 subgenomic replicon (similar to the West Nile virus's). Infectivity was measured in target cells with a Firefly luciferase (FFL)-based reporter system, as previously described<sup>[6]</sup>. Error bars represent the SD in a representative experiment. BHK: Baby hamster kidney.

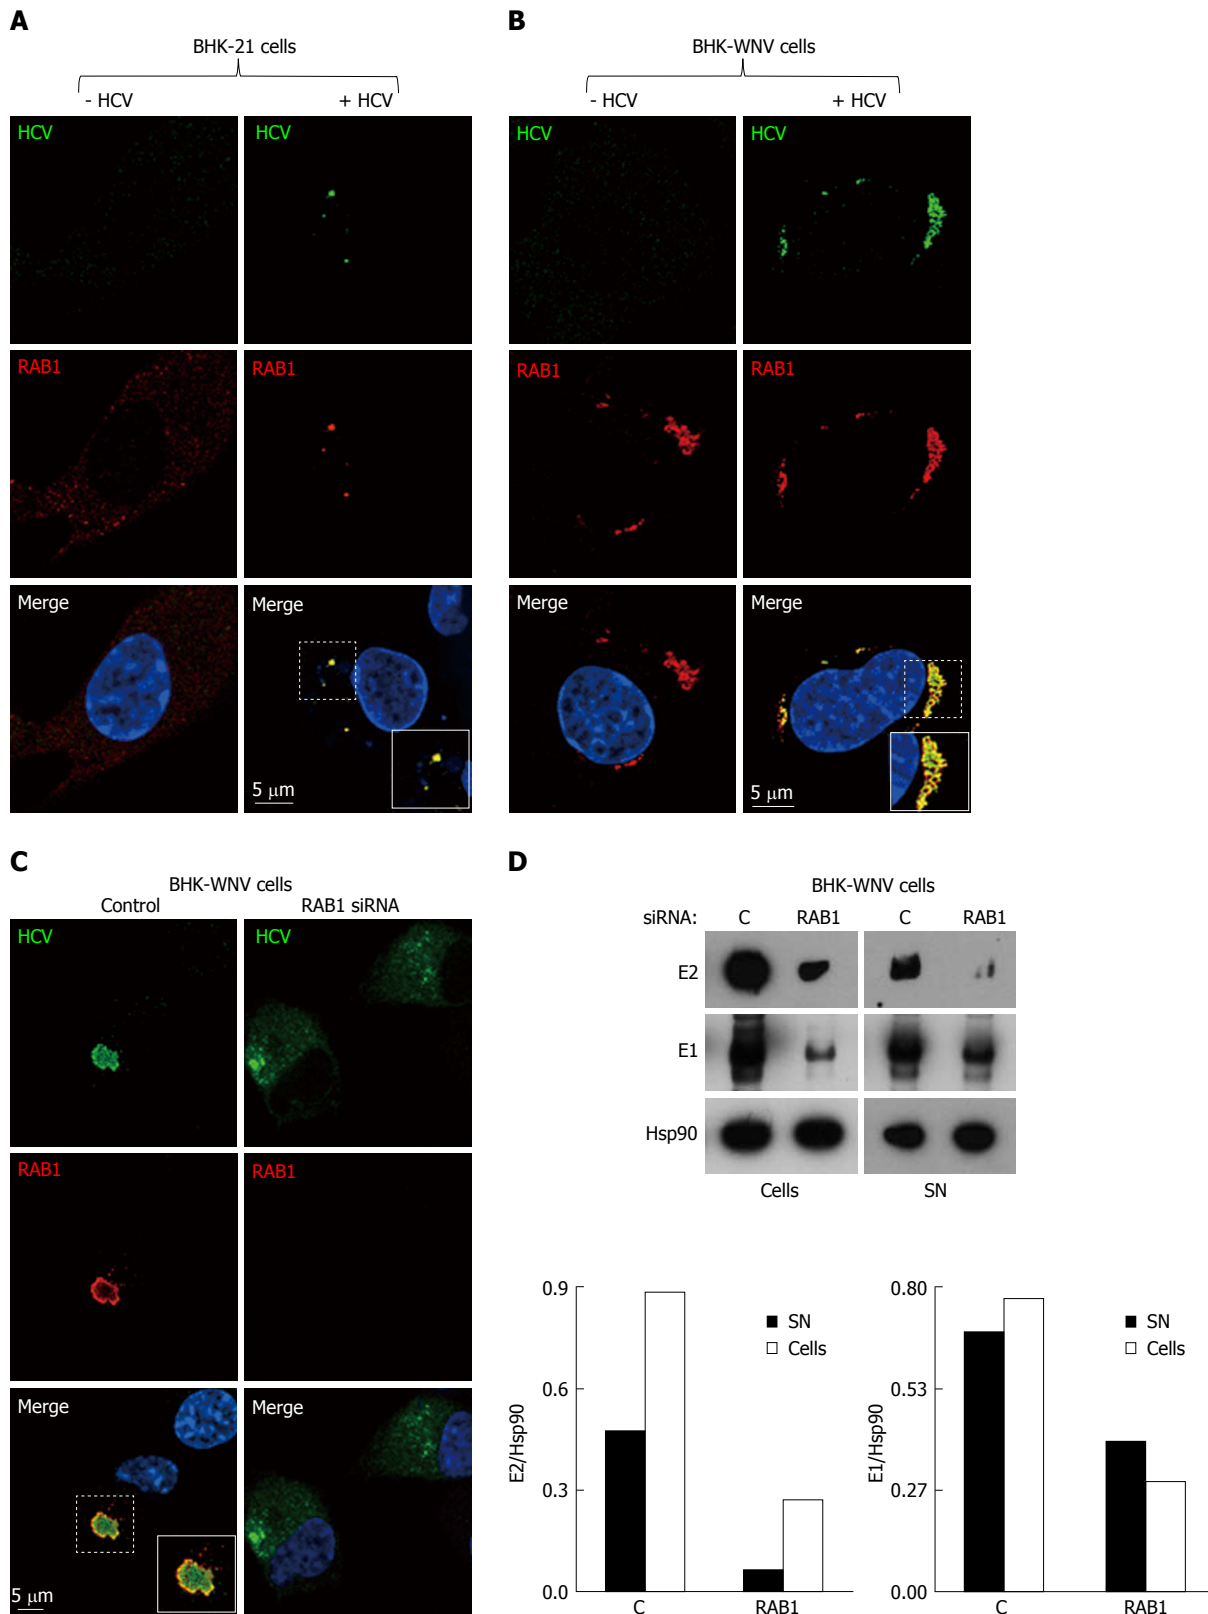

### Caspase-1 is required for the release of HCV particles via interplay with viral non-structural genes

Caspase-1 is a cysteine protease and the common denominator of some twenty NLR/ALR inflammasome

complexes identified so far and that contribute to host defenses against infections<sup>[57]</sup>. Cleavage sites for caspase-1 are present on HCV E2, NS2 and NS3 ([http://web.expasy.org/peptide\\_cutter/](http://web.expasy.org/peptide_cutter/)). They are well conserved between genotypes, but those on E2 and NS2 are generally missing in genotypes 6 and 2, respectively. Additional sites on E1, NS3, NS4B or NS5A are found only in particular HCV strains/isolates. Overall, an average of 3 (2 to 5) cleavage sites are found in HCV polyproteins.

The HCV strain H77 polyprotein displays cleavage sites for caspase-1 at aspartate residues 728 (E2), 989 (NS2) and 1302 (NS3), but none for other caspases. This prompted us to test whether this protease could interfere with the production of HCV particles by BHK-WNV cells. We tested the effect of an inhibitor preferentially targeting caspase-1 (ZVAD-FMK) on the production of this strain of HCV by BHK-WNV cells. While neither production of envelope E1 protein nor its release by parental BHK cells changed with the inhibitor, the release of HCVbp particles by BHK-WNV cells was dramatically reduced (Figure 13A). This was associated with a different processing of the core protein, with a predominant size of 21 kDa in treated vs 23 kDa in untreated cells (Figure 13A). This observation is reminiscent of the shorter core protein in HCVcc released by Huh7.5.1 cells, compared to that of HCV progenies produced in human liver slices or primary

**Figure 7** Release of hepatitis C virus particles by baby hamster kidney-West Nile virus cells requires RAB1 in a cytoplasmic subcompartment. Three days after transfection with the HCV-coding and P2B plasmids, or not, IF of BHK-21 (A) or BHK-WNV (B) cells was performed with anti-HCV serum (green) and anti-RAB1 antibody (red), followed by confocal microscopy analysis; C: BHK-WNV cells treated (right panels) or not (left panels) with RAB1 siRNA were transfected with the HCV expression plasmid system; IF was performed as in (B); A-C: Nuclei were counterstained with DAPI (blue); D: BHK-WNV cells treated with RAB1 siRNA were transfected with the HCV expression plasmid system. Cells and SN were harvested 3 d later, and analyzed by Western blot; Hsp90 = control; bottom: Densitometry analysis. HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus; SN: Supernatants.

hepatocytes<sup>[58]</sup>. In contrast, no clear effect of the inhibitor was observed on HCV production with BHK-WNV cells

**Figure 8** Parental or baby hamster kidney-West Nile virus cells were transfected to express hepatitis C virus genome in the cytoplasm and IF experiment was performed and analyzed as described throughout the manuscript. HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus; GDI: GDP dissociation inhibitor.

expressing only HCV structural genes, with or without p7 (Figure 13B).

## DISCUSSION

A classical secretion pathway has been implicated in the release of HCV virions<sup>[59]</sup> that are associated with apolipoprotein E (apoE) in Huh-7.5 cells<sup>[60]</sup> or other cell types<sup>[61]</sup>. In spite of a fully functional secretion pathway, parental BHK-21 cells, which do not express apoE, released only trace amounts of HCV particles<sup>[8]</sup>. Lack of apoE was overcome by the prior reorganization of intracellular trafficking by the replication of WNV (or dengue virus) for the production of infectious HCV particles (Figure 14). Epitopes detected by IgG from a patient cured of an infection of same genotype as the HCV strain used in this study (H77), are likely to be

amongst those displayed on native HCV virions. This pool of HCV protein isoforms/conformers represented only a fraction of the HCV structural proteins stained by monoclonal antibodies. It overlapped with a compartment of rearranged membranes. The presence of virus particles in this compartment supports the hypothesis that it could be the HCV assembly site in permissive BHK-WNV cells.

Some arguments are consistent with the involvement of a conventional secretion pathway in the production of HCV particles by BHK-WNV cells; other arguments suggest otherwise. On one hand, an involvement of the ERGIC implies a requirement for RAB1, which was the case for the formation of the assembly compartment, as well as for the production of HCV particles. In accordance, RAB1 and p115/USO1 were co-enriched in this compartment<sup>[43,62]</sup>. GBF1, an additional component of

**Figure 9** Parental or baby hamster kidney-West Nile virus cells were transfected to express hepatitis C virus genome in the cytoplasm and IF experiment was performed and analyzed as described throughout the manuscript. HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus.

**Figure 10** Endoplasmic reticulum-Golgi membrane remodelers (RAB1, p115 and atlantin) are recruited into the hepatitis C virus assembly compartment in baby hamster kidney-West Nile virus cells. Three days after transfection of BHK-WNV cells with the HCV expression plasmid system, IF was performed with anti-HCV serum (green) and anti-p115 (red), RAB1, Atlantin-1 or CANX (white) antibodies. Mitochondria were labeled with Mito-Tracker-Orange-CMTMRos (red). HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus; CANX: Calnexin.

**Figure 11** This experiment was performed with baby hamster kidney-West Nile virus cells transfected to express hepatitis C virus genome in the cytoplasm and IF experiment was performed and analyzed as described throughout the manuscript (anti-GM130 monoclonal antibodies have been reported to cross-react with an unidentified protein of lower molecular weight). HCV: Hepatitis C virus.

**Figure 12** Hepatitis C virus produced in cultured human hepatic cells involves same cellular factors as those enhancing hepatitis C virus production in baby hamster kidney-West Nile virus cells. **A:** Huh-7.5 cells were seeded on 24-well plates and the next day were transfected, or not, with siRNA, as indicated. After 2 d, cells were reseeded into 24-well plates and, the next day, incubated at a MOI = 0.5 with HCVcc produced with the JFH-1 strain in Huh-7.5 cells. At 3 dpi, HCV RNA contents were determined in the cells (closed bars) and SN (open bars) by RT-qPCR (TaqMan). Results are plotted on a log-scale; errors bars represent maximum variations observed in this assay; **B:** Huh-7.5 cells were electroporated with *in vitro*-transcribed genome of the JFH-1 strain and passaged for two weeks, then were seeded onto coverslips. Two days later, IF was performed with anti-HCV core 7-50 (green) and anti-human CANX, tubulin (TUB) or RAB1 antibodies (red); **C:** Huh-7.5 cells were inoculated with HCVbp-4cys produced in permissive BHK-WNV cells (8); 2 d later, the cells were incubated with both ReASH (red) and Taxol fluorophore conjugate (green); result representative of two independent experiments; **B** and **C:** Nuclei were counterstained with DAPI and cells were observed by confocal microscopy. CANX: Calnexin; HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus; SN: Supernatants.

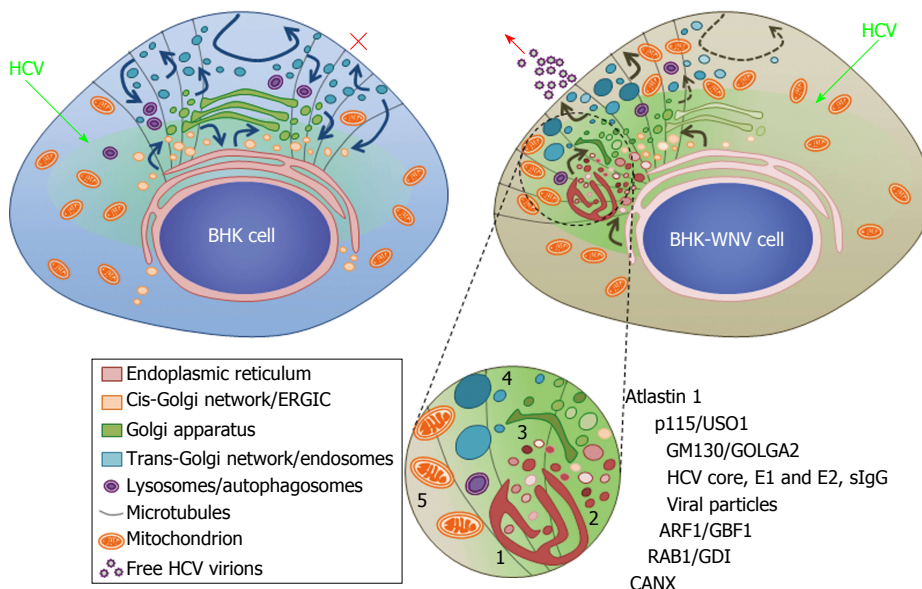

the ERGIC that activates small-sized GTPase ARF1 and, in turn, COPI-dependent traffic<sup>[43]</sup>, was also involved in the production of HCV particles<sup>[8]</sup>. On the other hand, another feature of the ERGIC, the lectin ERGIC-53, was excluded from the assembly compartment. As observed in TEM, the latter directly brought together membranes

from the ER and the Golgi apparatus, which was consistent with an enrichment of this compartment in, respectively, Atlastin 1<sup>[50-52]</sup> and GM130/GOLGA2<sup>[41]</sup>, both reported to reorganize and/or maintain membranes of their organelle. In addition, an enrichment in both RAB1 and its GDI, like what was observed in the assembly

**Figure 13** Caspase-1 inhibitor conditionally inhibits the secretion of hepatitis C virus particles by baby hamster kidney-West Nile virus cells. **A:** BHK-21 and BHK-WNV cells were transfected with a mix of HCVbp-coding and P2B plasmids; the next day, a caspase-1 inhibitor was added in the culture medium and the cells were incubated for 2 more days; cell lysates and HCV particles were harvested and analyzed by Western blot (WB); **B:** BHK-WNV cells were transfected with a plasmid coding for the structural (*core*, *E1*, *E2*) genes of HCV H77 strain, plus (+) or minus (-) p7, then were analyzed as in (A); **C:** Quantification of WBs: Top panels for (A) and bottom panels for (B); bar inside patterns are displayed underneath corresponding data; error bars represent standard deviations; inserts = results in cells. HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus.

**Figure 14** Model of a hepatitis C virus assembly compartment in baby hamster kidney-West Nile virus cells. Schematic organization of cell traffic in parental BHK-21 (top left) and BHK-WNV (top right) cells; curved arrows represent cell traffic; HCV genome is produced by the P2B plasmid system (green arrows) and expressed (greenish areas) in the cytoplasm of BHK cells. Bottom, sketches' legend and close up of a HCV assembly site (cf. also Figure 2B): (1) convoluted membranes; (2) vesicular packets; (3) Golgi cisternae; (4) large vesicles filled with viral particles; and (5) mitochondrion; host and viral factors identified within this compartment. sIgG: Antibodies from the serum of a cured HCV patient; CANX: Calnexin; HCV: Hepatitis C virus; BHK-WNV: Baby hamster kidney-West Nile virus; ERGIC: Endoplasmic reticulum-Golgi intermediate compartment; GDI: GDP dissociation inhibitor.

compartment, has been reported to initiate a cascade of events involving GBF1, ARF1 and phosphatidylinositol

4-kinase III alpha (PI4KIII $\alpha$ )<sup>[43]</sup>, which may increase the local proportion of phosphatidylinositol 4-phosphate<sup>[63]</sup>

and subvert endocytic trafficking<sup>[64]</sup>. In Huh-7.5 cells, this role is normally devoted to HCV NS5A that brings together PI4KIII $\alpha$  and TBC1D20, an activator of RAB1<sup>[65]</sup>. Therefore, replication of the genomic RNA of flaviviruses in BHK-21 cells may pre-position components - or their equivalent - HCV establishes by itself in the cells in which it usually replicates. Although excluding ERGIC as we know it in the classical secretion pathway, such reorganization of the secretion machinery in BHK-21 cells (Figure 14) could explain why a BFA treatment inhibited HCV particle production.

Finally, if CANX was required for the production of HCV particles, most of it shuttled a pool of HCV protein subspecies to the assembly compartment of BHK-WNV cells, instead of co-localizing with CRT for the proper folding of glycoproteins. How CANX really assists these cells to produce HCV virions is not fully understood. CANX still probably requires binding N-linked glycans on the HCV envelope proteins. The reported slow dissociation rate between CANX and HCV envelope proteins<sup>[27]</sup> could contribute to unusual involvements of CANX, such as what is observed with proteins targeted to mitochondria-ER associated membranes (MAMs) for the formation of inflammasome and autophagy compartments<sup>[66]</sup>. HCV has previously been shown to target MAMs in hepatocytes<sup>[67]</sup>. However, mitochondria were excluded from the assembly compartment in BHK-WNV cells. And, upon expression of HCV structural genes, this coincided with the appearance within the assembly compartment of large vesicles containing particles<sup>[8]</sup>.

Oxidative stress, inflammation and/or infection can lead to the appearance in the cytoplasm of large vesicles, often indiscriminately referred to as multivesicular bodies, releasing extracellular particles of very different compositions depending on their origin. They are formed by the fusion of late endosomal vesicles with membranes from lysosomal and/or autophagosomal compartments, or originating from the periphery of the ER-Golgi complex assembling - independently from a COP II - and COP I -mediated membrane transport - into a compartment of unconventional protein secretion<sup>[68]</sup>. Unconventional pathways are used by intracellular pathogens reorganizing the vesicular traffic to secrete proteins (*e.g.*,<sup>[69]</sup>). The reorganization of the secretion machinery required for the production of HCV particles by BHK-WNV cells displayed similar features.

Knocking down  $\alpha$ -TUB expression not only resulted in a lesser release of HCV particles, but also of particulate materials containing Hsp70 and Hsp90, a feature of exosomes. Such extracellular vesicles have been shown to participate in the transfer of viral materials<sup>[46]</sup>. Recently, exosomes have also been implicated in the propagation/dissemination of HCV genome, proteins and replication complexes, although in the former case with a weaker effectiveness than lipoprotein-associated virions<sup>[70,71]</sup>. However, the production of HCV particles by BHK-WNV cells cannot be reduced to the secretion of exosomes. We

had previously shown that, albeit overlapping, the peaks of particles containing HCV structural and heat-shock proteins released by BHK-WNV cells did not coincide after ultracentrifugation on a density gradient<sup>[8]</sup>. In addition, while the secretion of HCV particles was blocked, the release of heat-shock proteins was insensitive to a treatment by brefeldin A (BFA), an inhibitor of GBF1<sup>[8]</sup>. In this work, the secretions of Hsp70 and Hsp90-containing particles and HCV particles displayed different patterns. Therefore, the dual effect of  $\alpha$ -TUB siRNA on the secretions of exosomes and HCV particles probably reflects separate needs for microtubules taking place at different steps. For exosomes, it could relate to effects on the BFA-insensitive *trans*-Golgi network, which is consistent with an accumulation of hsp70 inside producer cells following knockdown of  $\alpha$ -TUB expression. Conversely, the production of HCV particles could be inhibited at the level of a GBF1/ARF1-dependent traffic, within the assembly compartment, or later during their secretion.

Treatment of BHK-WNV cells with a caspase-1 inhibitor abolished the release of HCV particles. Caspase-1 has been shown to activate IL-1 $\beta$  and IL-18 proinflammatory cytokine precursors<sup>[57]</sup>. It has long remained unknown how their matured species translocate across the plasma membrane. Recent results support the idea that their secretion involves a cytosolic compartment containing vesicles and their exocytosis<sup>[72]</sup>. It could be the mechanism by which a caspase-1-dependent secretory pathway contributed to the production of HCV particles by BHK-WNV cells. However, inhibition of HCV production with the caspase inhibitor occurred only in the context of a full-length genome, suggesting the existence of interaction(s) between caspase-1 and HCV non-structural genes, here NS2 and/or NS3. Although the catalytic activity of NS2 is dispensable, this viral cysteine protease is required for the production of HCV particles<sup>[73]</sup>, as is the helicase/serine protease NS3<sup>[74]</sup>. Therefore, the cleavage(s) of NS2/3 by caspase-1, in addition, could prevent the maturation of non-structural proteins required for RNA replication and/or remove interactions, either of them or both being detrimental to the formation and secretion of HCV particles.

At variance with the JFH-1/Huh-7.5 cell model<sup>[59,75]</sup>, infectious HCV particles released by BHK-WNV cells did not require lipoproteins or exosomes. It is still unclear whether discrepancies between models<sup>[9]</sup> could not also relate to active HCV replication in a non-physiological environment<sup>[76]</sup>, differences between viral genotypes<sup>[12]</sup> and/or differential processing of some HCV proteins<sup>[58]</sup>. Nevertheless, host factors involved in BHK-WNV cells were also required in Huh-7.5 cells that, over time, developed a cytoplasmic compartment<sup>[26]</sup> enriched in HCV core, CANX and RAB1. Infectious HCV particles are assembled in the cytoplasm of Huh-7.5 cells<sup>[13]</sup> before their association to lipoproteins<sup>[8,77]</sup> or exosomes<sup>[75,78]</sup>. The associations to lipoprotein particles and extracellular particles have been proposed as mechanisms to regulate

vertebrate Hedgehog dispersion during development<sup>[79]</sup>. In addition, ApoE<sup>[25,80]</sup> and extracellular particles<sup>[47]</sup> are suspected to contribute also to the pathogenesis of viruses unrelated to HCV. Therefore, rather than having evolved a unique mechanism of viral propagation, HCV may have instead subverted existing cellular processes. It could involve intrinsic properties of its envelope proteins, since HCV E1 interacts with apoE<sup>[81]</sup> and possibly lipids<sup>[82]</sup>, which is believed to help the virus escape from immune recognition<sup>[83]</sup>.

The release of HCV particles by BHK-WNV cells, instead, involved an unusual, if not unconventional secretion pathway. The present data suggest that their mechanism of assembly and egress could be a mean by which HCV circumvents intracellular defenses. These infectious particles are not those usually observed as such in infected patients. Therefore, as for other HCV particles produced *in vitro*<sup>[9]</sup>, we are not sure of their relationship to the normal viral cycle. Are they merely a precursor for the main HCV species, which will eventually associate to lipoproteins, or do they represent different viral species of higher buoyant density? In patients, the proportion of circulating HCV particles associated to lipoproteins varies between individuals and during the course of infection. Denser viral species can amount up to half of the circulating HCV genome<sup>[84]</sup>; they are usually opsonized by IgG in the serum of infected patients, making the study of free virions difficult. At least during the assembly process in BHK-WNV cells, HCV particles exposed epitopes that were recognized by neutralizing sIgG from a patient previously chronically infected by HCV of same genotype. We propose that the BHK-WNV cell model could be useful to study the structure of free HCV virions and their immunological properties.

## ACKNOWLEDGMENTS

We thank Charles M Rice (Center for the Study of Hepatitis C, the Rockefeller University) for his generosity in providing plasmids encoding HCV RNA of genotype 1a (wild type and adaptive mutants) and Huh-7.5 cells; Theodore C Pierson (LVD, NIAID, NIH) for kindly provided BHK-21 cells bearing a WNV subgenomic replicon as well as a plasmid encoding WNV structural genes; Takaji Wakita (Department of Virology, National Institute of Infectious Diseases, Tokyo) provided plasmids encoding HCV RNA of genotype 2a; anti-HCV antibodies were generous gifts from Arvind H Patel (anti-E2; MRC Virology Unit, Institute of Virology, University of Glasgow), Ramsey C Cheung (anti-E1; Division of Gastroenterology and Hepatology, Stanford University School of Medicine), Stanislas Pol (HCV serum; Hôpital and Institut Cochin, Paris). We are indebted to the staff of the Biological Imaging Section (RTB, NIAID, NIH) for their assistance with the confocal microscopy and Kunio Nagashima (SAIC/NCI, NIH Frederick) for the EM analyses.

## COMMENTS

### Background

The production of infectious hepatitis C virus (HCV) particles by model human hepatocellular carcinoma Huh-7.5 cells is believed to involve a classical secretion pathway; it has also been reported to involve lipoproteins and exosomes. The authors previously demonstrated that the intracellular environment generated by a West-Nile virus (WNV) subgenomic replicon rendered non-human, non-hepatic mammalian cells [here referred to as baby hamster kidney-WNV (BHK-WNV) cells] permissive for assembly and release of infectious HCV particles of various genotypes wherein the HCV genome is generated in the cytoplasm independently of its replication machinery. HCV production did not require ongoing activity of the WNV replicon, but instead was associated with persisting replicon-induced changes in the cellular environment. Since secretion of HCV particles by BHK-WNV cells neither involved lipoproteins nor exosomes, could it still follow a conventional pathway? Activity of the small GTPase ARF1 and the maturation of carbohydrates on envelope proteins of released HCV particles were both required for the production of infectious HCV by permissive BHK-WNV cells, suggesting that, indeed, it followed a classical secretion pathway. The authors, therefore, examined the possibility that the endoplasmic reticulum (ER)-bound lectin calnexin (CANX), the small GTPase RAB1 and microtubule-associated alpha-tubulin, which all contribute to the secretion of several glycoproteins by BHK-21 cells, were involved in the production of HCV particles by BHK-WNV cells. Surprisingly, the results show that secretion of HCV particles went through a re-organized and re-wired pathway bypassing the conventional ER-to-Golgi intermediary compartment and involving components of the inflammasome.

### Research frontiers

The structure of HCV virions/progenies remains elusive. The fact that infectious HCV particles are produced independently from lipoprotein biosynthesis, yet retain the possibility to interact with lipoproteins *in vitro* supports the view that, *in vivo*, HCV particles may interact with lipoproteins in a second step and not necessarily co-assemble with them. This has probably important consequences regarding the way HCV interacts with producer cells and the immune system.

### Innovations and breakthroughs

The authors' results suggest that the HCV production made possible by the prior WNV replication in BHK cells could be related to that observed in human hepatocytes. It is unclear whether this reflects an organization of HCV production more complex than expected in hepatocytes or the existence of additional route(s) of HCV secretion.

### Applications

Although no immediate application of these findings is foreseen, the production of free HCV virions could pave the way for identifying the most important epitopes for HCV neutralization and the development of an effective vaccine.

### Terminology

Subgenomic replicon: Fragment of a viral RNA genome encoding the non structural genes required for its own replication in the cytoplasm, but not the structural genes required for the formation of virions.

### Peer-review

In this manuscript, the authors aimed to examine whether the cellular factors including CANX, RAB1 and alpha-tubulin were involved in the production of HCV particles by BHK-WNV cells. Moreover, it brings an interesting contribution to the current literature.

## Abstract

**AIM:** To evaluate neutrophil gelatinase associated lipocalin (NGAL) in patients infected by hepatitis C virus (HCV) before and during treatment with directly acting antivirals (DAAs).

**METHODS:** NGAL was measured in a group of patients with chronic HCV infection ranked, at baseline, by age, gender, anti-hypertensive therapy, HCV viral load, liver fibrosis stage and, either at baseline or after 1 year, estimated glomerular filtration rate (eGFR). Then, NGAL and eGFR evolutions were monitored in a subgroup of patients who started antiviral therapy with DAAs. Differences of median NGAL levels were evaluated through Wilcoxon-Mann-Whitney test for non-parametric data. Differences in dichotomous variables were evaluated through  $\chi^2$  test. At baseline, a univariate regression analysis was conducted to verify if NGAL values correlated with other quantitative variables [age, fibrosis four (FIB-4), AST to platelet ratio index (APRI), and eGFR].

**RESULTS:** Overall, 48 patients were enrolled, 8 of them starting HCV treatment. At baseline, statistically significant differences were found in median NGAL values only between patients with eGFR < 60 mL/min *vs* patients with eGFR  $\geq$  90 mL/min. Differences in NGAL were not significant among patients ranked by HCV viral load, FIB-4 score and APRI, when patients with NGAL > 118.11 ng/dL were compared with those of NGAL  $\leq$  118.11 ng/dL, not statistically significant differences were present for age, gender, chronic kidney disease classification and liver fibrosis ( $P > 0.05$ ). Linear correlation was found between NGAL and both age ( $P = 0.0475$ ) and eGFR ( $P = 0.0282$ ) values. Not statistically significant predictions of NGAL at baseline were demonstrated for eGFR evolution 1 year later. Interestingly, in the 8 patients treated with DAAs, median NGAL significantly increased at week 12 compared to baseline ( $P = 0.0239$ ).

**CONCLUSION:** Our results suggest that NGAL should be further evaluated as an adjunct marker of kidney function in these patients.

**Key words:** Directly acting antivirals; Hepatitis C virus; Inflammation; Neutrophil gelatinase lipocalin; Tubular impairment

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** For the first time, we evaluated the evolution of neutrophil gelatinase associated lipocalin (NGAL), a novel biomarker of renal impairment, in patients infected by hepatitis C virus before and during treatment with directly acting antivirals (DAAs). In our study, we documented a significant increase of NGAL during the first 12 wk of therapy with DAAs and a correlation of NGAL with both age and estimated glomerular filtration

rate before starting treatment. In a context of paucity of information about safety of the new DAAs, we believe that these data are both informative and novel, provoking urgent investigations.

Is neutrophil gelatinase associated lipocalin a useful marker in hepatitis C virus infection? *World J Hepatol* 2016; 8(19): 815-824 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i19/815.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i19.815>

## INTRODUCTION

Estimated prevalence of renal insufficiency is increased by 40% in patients infected by hepatitis C virus (HCV) compared to the HCV negative population<sup>[1]</sup>. Renal disease, ranging from mild to end-stage renal disease (ESRD), often complicates prognosis and treatment of HCV infection with haemodialysis being required in some cases. Moreover, in the context of liver disease, kidney function is one of the key predictors of death and serum creatinine, is a component of both King's college criteria and model for end-stage liver disease scoring systems that are used for prognostic stratification in patients with acute and chronic liver failure<sup>[2]</sup>.

Virus related kidney diseases mainly show up as a glomerular impairment, predominantly a membranoproliferative glomerulonephritis with type 2 crioglobulinaemia and sub-endothelial or intra luminal deposits of IgG, IgM and complement components<sup>[3]</sup>. Moreover, HCV core proteins were isolated in both glomerular and tubular tissues, suggesting the presence of a parallel tubular-interstitial damage<sup>[4]</sup>.

Treatment of HCV infection in patients with renal impairment has always been challenging due to the side effects of the past treatment used as standard, an association of pegylated-interferon (PEG-IFN) and ribavirin (RBV), which was more difficult to manage in patients with renal impairment than in patients with normal renal function. In 2014, with the advent of first generation directly acting antivirals (DAAs), efficacy of anti HCV treatment was substantially improved. However, the first generation DAAs, boceprevir and telaprevir (TVR), were not recommended in patients with severe renal impairment or ESRD because these patients were excluded from registrational trials<sup>[5]</sup>. Moreover, in real-life patients without renal impairment, an increase of serum creatinine was observed during treatment with TVR, even if it was not associated with more severe renal impairment<sup>[6]</sup>. In March 2015, second generation DAAs were available in Italy for the treatment of HCV. Even if second generation DAAs are better tolerated, there is a paucity of information about the possible impact of these

drugs on renal function<sup>[7]</sup>. Therefore, the evidence of kidney impairment may make clinicians less comfortable to begin an antiviral treatment.

Estimated glomerular filtration rate (eGFR) can be calculated by creatinine values, however in circumstances such as toxic drug dosage, kidney disease improving global outcome (KDIGO) guidelines suggest to add at least another biomarker. In fact, GFR estimating equation alone is biased in many situations, such as acute kidney disease (AKI), high GFR, non-GFR determinants of serum creatinine and interferences with creatinine assays<sup>[8]</sup>. Additionally, creatinine-based measures are even more limited in cirrhotic patients due to a decrease in hepatic synthesis of creatinine, reduced skeletal muscle mass and increased tubular secretion<sup>[9]</sup>.

Among novel kidney biomarkers, one of the most promising is neutrophil gelatinase associated lipocalin (NGAL) either in urine and serum (or plasma)<sup>[10]</sup>. This is a small glycoprotein in three different forms: A monomer (25 kDa), a homodimer (45 kDa) and a heterodimer (135 kDa). It is secreted by many human cells, such as epithelial cells (liver, kidney, lungs) and blood cells (neutrophils, monocytes and macrophages), filtered in the glomerulus and reabsorbed by the proximal tubules<sup>[11,12]</sup>. It is removed by hemodialysis<sup>[13]</sup>. In general, NGAL urinary levels increase after a tubular injury and reveal a kidney damage earlier than the increased levels of creatinine<sup>[14]</sup>. On the other hand, plasmatic or serum NGAL are more extensively adopted in AKI contexts, because their measurement is less limited by availability of samples when patients are anuric<sup>[15]</sup>. Remarkably, an increase of plasmatic NGAL is considered to be an early predictor of AKI in various critical settings such as cardiac surgery, septic shock, contrast induced nephropathy, renal and liver transplantation<sup>[16-22]</sup>. However, NGAL is increased also in case of epithelial damage or inflammation outside the kidney<sup>[10]</sup>.

In cirrhotic patients, NGAL is a marker of AKI and urinary NGAL that can help distinguish among different causes of renal impairment<sup>[10]</sup>. Recently, a significant difference in plasmatic NGAL levels amongst HCV positive patients with cirrhosis and eGFR < 60 mL/min vs ≥ 60 mL/min has been demonstrated<sup>[23]</sup>. Also, recent data showed that NGAL is a good marker of renal damage due to drug toxicity. For example, urinary NGAL is a good predictor of tacrolimus induced AKI in liver transplanted patients and nonsteroidal anti-inflammatory drug (NSAID) associated AKI in cirrhotic patients<sup>[24,25]</sup>. To our best knowledge, no published data on NGAL during HCV treatment with DAAs are available so far.

The objectives of this study were to explore: (1) whether there is a difference in plasmatic NGAL between HCV positive patients and HCV negative people; (2) whether there is a difference in plasmatic NGAL among HCV positive patients ranked by age, gender, viral load, eGFR and liver fibrosis stage; (3) whether NGAL levels at baseline correlate with modification of eGFR after 1 year; and (4) the evolution of renal function in patients

treated with DAA including regimens.

## MATERIALS AND METHODS

### Recruitment of patients and data collection

A prospective study was conducted. Patients with chronic hepatitis C who attended the Outpatient Service of the Infectious Diseases Unit and the Hepatology Unit of the "Mater Domini" Teaching Hospital in Catanzaro (Italy) from February 1, 2014 to April 30, 2014 were included in this study. Exclusion criteria included: Leukocytosis (leukocyte count higher than 12000 cells/ $\mu$ L), variceal bleeding, primary kidney diseases (glomerular nephropathy), KDIGO classification of chronic kidney disease (CKD) ≥ G4 (eGFR < 30 mL/min), ongoing HCV therapy (with or without interferon or DAA). Approval from local ethical committee was obtained. All enrolled patients signed an informed consent.

All patients underwent physical examination and history taking at baseline. The following blood tests were collected: AST, ALT, total and fractioned bilirubin, albumin,  $\gamma$ GT, alkaline phosphatase, prothrombin time, total blood cell count (including neutrophil and platelet count) and urea. Serum creatinine levels were measured at baseline and after 1 year. For patients who started anti-viral therapy, serum creatinine levels and GFR were studied at week 4 and week 12 after baseline.

Glomerular filtration rate was estimated through Chronic Kidney Disease Epidemiology Collaboration formula (CKD-EPI, 2009) since CKD-EPI is less biased and more accurate for eGFR ≥ 60 mL/min than MDRD (Modification of Diet in Renal Disease) and Cockcroft-Gault formulas<sup>[7]</sup>. The following formula was used:  $141 \times \min(\text{SCr}/k, 1)^a \times \max(\text{SCr}/k, 1)^{-1.209} \times 0.993^{\text{Age}}$  × (1.018 if female or 1.159 if black), where SCr is serum creatinine (in mg/dL), k is 0.7 for females and 0.9 for males, a is 0.329 for females and 0.411 for males, min is the minimum of SCr/k or 1, and max is the maximum of SCr/k or 1.

Liver fibrosis was estimated at baseline by either fibrosis four (FIB-4) score or AST to platelet ratio index (APRI) which are the most used formulas for estimating stage of liver disease. FIB-4 has a negative predictive value of 94.7% to exclude severe fibrosis with a sensitivity of 74.3% when < 1.45 and a positive predictive value to confirm the existence of a significant fibrosis (F3-F4) of 82.1% with a specificity of 98.2% when ≥ 3.25. The following formula was used:  $\text{Age} \times \text{AST}/(\text{platelets} \times \sqrt{\text{ALT}})$  where AST and ALT were measured as IU/L, platelets were measured as number × 10<sup>6</sup>/ $\mu$ L and age was measured in years<sup>[26]</sup>. An APRI value ≤ 0.5 rules out significant fibrosis and cirrhosis while values ≥ 1.5 indicates significant fibrosis<sup>[27]</sup>. More specifically, when APRI score is greater than 1.0 it has a sensitivity of 76% and a specificity of 72% for predicting cirrhosis<sup>[28]</sup>. The following formula was used:  $[(\text{AST}/\text{AST upper normal limit})/\text{platelets}] \times 100$  where AST was measured as IU/L, platelets were measured as number

$\times 10^6/\mu\text{L}$  and AST upper normal limit was fixed at 35 IU/L.

### NGAL measurement

Peripheral venous blood samples were taken from each patient at baseline and then processed for NGAL measurement. Plasmatic NGAL was measured in all patients at baseline. For patients who started anti-viral therapy, NGAL was measured at different endpoints (baseline, week 4 and 12). NGAL assay was performed using human NGAL Rapid Elisa Kit (BioPorto Diagnostic). A 96-well microtiter plate coated with purified anti-human NGAL monoclonal antibody was used. In each well 50  $\mu\text{L}$  of each sample, diluted 1:100 with sample diluting buffer, undiluted calibrators and controls were added; then 50  $\mu\text{L}$  of horseradish peroxidase -conjugated NGAL antibodies were added. During this first step of incubation at room temperature for 30 min, NGAL bind either the specific antibody adsorbed to microwells or the second antibody; an aspiration-washing step (3 times with 300  $\mu\text{L}$  of wash solution) was performed to remove excess and unbounded reagents; 100  $\mu\text{L}$  of tetramethyl-benzidine solution were added to each well and a second step of incubation performed at room temperature for 15 min; at end of incubation 100  $\mu\text{L}$  of stop solution was added and the color developed in each well was measured at 450 nm. The values of samples were determined on the basis of a standard curve. The methodology was performed using a Triturus automatic analyzer. The commercial kit, that is validated by Pedersen *et al.*<sup>[29]</sup> is used in our study. The reference range (41.19-118.11 ng/mL) had been previously validated in our laboratory on a group of healthy volunteers.

### Groups of patients

Differences of NGAL values were evaluated in patients ranked by age (< 65 years vs  $\geq$  65 years), gender (female vs male), anti-hypertensive therapy (present vs absent), HCV viral load (< 1000000 copies/mL vs  $\geq$  1000000 copies/mL), FIB-4 score ( $\leq$  1.45 vs 1.45 to 3.25 vs  $\geq$  3.25), APRI ( $\leq$  0.5 vs 0.5 to 1.5 vs  $\geq$  1.5), and eGFR ( $\geq$  90 mL/min vs  $\geq$  60 mL/min to < 90 mL/min vs < 60 mL/min). Patients were ranked by eGFR worsening vs stable/improved with respect to baseline values after 1 year. Any reduction of eGFR was considered as worsening. Viral load cut-off was set at 1000000 HCV RNA copies/mL because this value is commonly considered to be high<sup>[30]</sup>. Cut-off for age was set at 65 years because that is the threshold discriminating adulthood and elderly life in many western countries<sup>[31]</sup>. We analyzed eGFR as a continuous measure and did not consider any specific-cut off for change of eGFR.

Differences in dichotomous variables (gender, FIB-4  $\geq$  3.25, APRI  $\geq$  1.5, KDIGO CKD classification  $\geq$  G3a, KDIGO CKD classification  $\geq$  G2, age  $\geq$  65 year) were evaluated in patients ranked at baseline by NGAL values (> 118.11 ng/dL vs  $\leq$  118.11 ng/dL).

Evolution of NGAL at different time points (baseline, week 4 and week 12) was evaluated separately in

patients who started antiviral treatment with DAA containing regimens during the first twelve weeks of therapy.

### Statistical analysis

Differences of distribution NGAL levels from baseline to one year in the overall population and differences of NGAL and eGFR distribution in patients prescribed HCV therapy (evaluated at baseline, week 4 and week 12) were evaluated through Wilcoxon-Mann-Whitney test for non parametric data. Also, at baseline, a Spearman correlation analysis was conducted to verify if NGAL values correlated with other quantitative variables (age, FIB-4, APRI, and eGFR). Differences in dichotomous variables (age, gender, CKD classification and liver fibrosis) in patients with NGAL > 118.11 ng/dL or NGAL  $\leq$  118.11 ng/dL were evaluated through  $\chi^2$  test. Statistical analysis was performed using Graphpad Prism 6.01 (GraphPad Software, La Jolla, CA, United States). Nominal statistical significance was set at  $P < 0.05$ .

## RESULTS

### Patient characteristics at baseline

Forty-eight HCV RNA positive patients were enrolled with median NGAL of 68.5 ng/dL (range: 136-27). Main characteristics of the population are summarized in Table 1. Seventeen (35%) patients were < 65 years old, 25 (52%) patients were females, 10 (21%) patients suffered from blood hypertension. Median NGAL was: 63 ng/dL (111-27) for patients < 65 years old and 77 ng/dL (136-28) for patients  $\geq$  65 years old ( $P = 0.1353$ ); 70 ng/dL (132-27) for males and 63 ng/dL (111-27) for females ( $P = 0.7822$ ); 72.5 ng/dL (102-28) for patients with hypertension and 66.5 ng/dL (136-27) for patients with normal blood pressure ( $P = 0.7756$ ).

Differences in NGAL were not significant among patients ranked by HCV viral load, FIB-4 score and APRI. Quantitative HCV RNA was available in 36 patients, 19 (53%) of them having HCV RNA < 1000000 copies/mL (*i.e.*, low HCV RNA group). Median NGAL at baseline was 70 ng/dL (range: 132-27) vs 63 ng/dL (121-28), respectively. For FIB-4, 8 (17%) patients with FIB-4  $\leq$  1.45 had median NGAL of 60.5 ng/dL (111-27), 16 (33%) with FIB-4 from 1.45 to 3.25 had median NGAL of 82 ng/dL (136-36) and 24 (50%) with FIB-4  $\geq$  3.25 had median NGAL of 74.5 ng/dL (132-28). Regarding APRI, 10 (21%) patients were  $\leq$  0.5, 22 (46%) were between 0.5 and 1.5, and 16 (33%) were  $\geq$  1.5. Median NGAL values were 60.5 ng/dL (range: 136-27), 74.5 ng/dL (124-36) ng/dL and 80 ng/dL (132-28) in the three APRI groups, respectively.

According to eGFR ranking, 25 (52%) patients had eGFR  $\geq$  90 mL/min, 19 (40%) had eGFR  $\geq$  60 but less than 90 mL/min and 4 (8%) had eGFR < 60 mL/min. Median NGAL was 63 ng/dL (range: 136-36), 70 ng/dL (124-27) and 102.5 ng/dL (132-88) in the three groups, respectively. Statistical analysis showed significant

**Table 1** Characteristics of the population at baseline *n* (%)

Patients' characteristics	Overall population ( <i>n</i> = 48)	Patients treated with DAAs ( <i>n</i> = 8)
Qualitative variables		
Gender		
Female	25 (52)	1 (12)

HCV-RNA (copies/mL)	776500 (90100-19500000)	2330000 (793000-3250000)

HCV: Hepatitis C virus; eGFR: Estimated glomerular filtration rate; FIB-4: Fibrosis four index; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; PLT: Platelet; WBC: White blood cell; DAAs: Directly acting antivirals.

**Figure 1** Plasmatic neutrophil gelatinase associated lipocalin at baseline according to estimated glomerular filtration rate ranking. eGFR: Estimated glomerular filtration rate; NGAL: Neutrophil gelatinase associated lipocalin.

differences in median NGAL values only in patients with eGFR < 60 mL/min vs patients with eGFR ≥ 90 mL/min (Figure 1;  $P = 0.0288$ ).

Spearman correlation analysis showed statistically significant positive correlation between NGAL and age (Spearman  $r = 0.341$ ; 95%CI: 0.05450-0.5759; two-tailed  $P = 0.0088$ ) and a negative correlation between NGAL and eGFR values (Spearman  $r = -0.257$ ; 95%CI: -0.5164 to 0.04421; two-tailed  $P = 0.0419$ ) (Figure 2). Not statistically significant results were obtained when NGAL was correlated FIB-4 score ( $P = 0.413$ ) or APRI ( $P = 0.7430$ ).

In 6 (12.5%) patients, NGAL exceeded the upper limit of the reference interval (NGAL > 118.11 ng/mL). When patients with NGAL > 118.11 ng/dL were compared with patients with NGAL ≤ 118.11 ng/dL, no statistically significant differences were present for age,

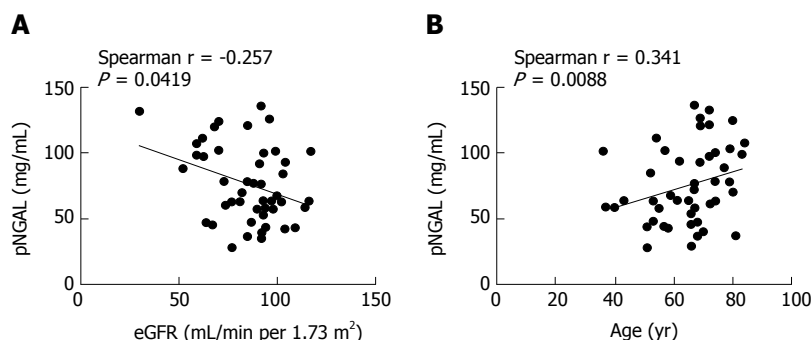

gender, CKD classification and liver fibrosis ( $P > 0.05$ ). In fact: 6/6 (100%) patients with NGAL > 118.11 ng/mL vs 25/42 (60%) patients with NGAL ≤ 118.11 ng/mL were ≥ 65 years old; 3/6 (50%) patients with NGAL > 118.11 ng/mL vs 20/42 (48%) patients with NGAL ≤ 118.11 ng/mL were males; 1/6 (17%) patients with NGAL > 118.11 ng/mL vs 7/42 (17%) patients with NGAL ≤ 118.11 ng/mL had a KDIGO CKD ≥ G3a; 4/6 (67%) patients with NGAL > 118.11 ng/mL vs 26/42 (62%) patients with NGAL ≤ 118.11 ng/mL had a KDIGO CKD classification ≥ G2; 4/6 (67%) patients with NGAL > 118.11 ng/mL vs 19/42 (45%) patients with NGAL ≤ 118.11 ng/mL had a FIB-4 ≥ 3.25; 3/6 (50%) patients with NGAL > 118.11 ng/mL vs 13/42 (31%) patients with NGAL ≤ 118.11 ng/mL had an APRI ≥ 1.5.

#### Evaluation of renal parameters after one year

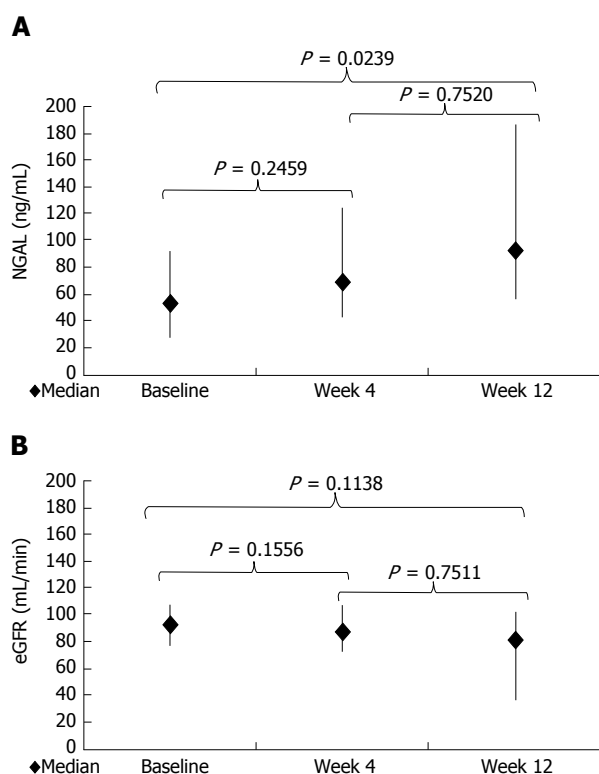

Serum creatinine and eGFR were collected after 1 year for 40 patients, while the remaining 8 were analyzed separately because they started HCV treatment in the meanwhile. No statistically significant differences were demonstrated in median NGAL values at baseline between patients with worsening eGFR vs patients with stable/improved eGFR at year 1. Indeed, median NGAL at baseline was 71.5 ng/dL (range: 136-36) in patients with worsening eGFR after 1 year, while it was 73.5 ng/dL (132-27) in patients with stable/improved eGFR after 1 year ( $P = 0.4898$ ).

#### Evolution of renal parameters during HCV treatment

A separate prospective analysis was conducted in the 8 patients who started with antiviral therapy. Baseline

**Figure 2** Univariate linear correlations between plasmatic neutrophil gelatinase associated lipocalin (NGAL) at baseline and estimated glomerular filtration rate (A) and NGAL at baseline and age (B). Data are represented as a scatter plot in which each point represents a patient. Correlation coefficient, Pearson  $r$  values, and statistical significance are indicated.  $n = 48$  patients. eGFR: Estimated glomerular filtration rate; NGAL: Neutrophil gelatinase associated lipocalin.

**Figure 3** Evolution of plasmatic neutrophil gelatinase associated lipocalin (A) and estimated glomerular filtration rate (B) during the first 12 wk of hepatitis C virus therapy with directly acting antiviral containing regimens. eGFR: Estimated glomerular filtration rate; NGAL: Neutrophil gelatinase associated lipocalin.

characteristics of these patients are summarized in Table 1. Two patients started simeprevir (SMV) + daclatasvir (DCV) for 24 wk, while 6 patients started PEG-IFN + RBV + TVR for 12 wk followed by PEG-IFN + RBV for other 24 wk (36 wk overall). Three patients were relapser to previous treatments with PEG-IFN + RBV, while 5 were partial responders. At week 4, 2 patients had negative but detectable HCV RNA ( $\leq 15$  UI/mL) while 6 had undetectable HCV RNA. At week 12, HCV RNA was undetectable in all patients. Median NGAL was 53 ng/dL (range: 92-28) at baseline, 69 ng/dL (125-43) at week 4, and 93 ng/dL (186-56) at week 12 ( $P = 0.0239$  compared with baseline value) (Figures 3A and 4A).

Median eGFR was 93 mg/dL (109-77) at baseline, 86.5 mg/dL (108-72) at week 4, and 82.5 mg/dL (103-72) at week 12; no statistically significant differences were found for eGFR along the time points of the study (Figures 3B and 4B).

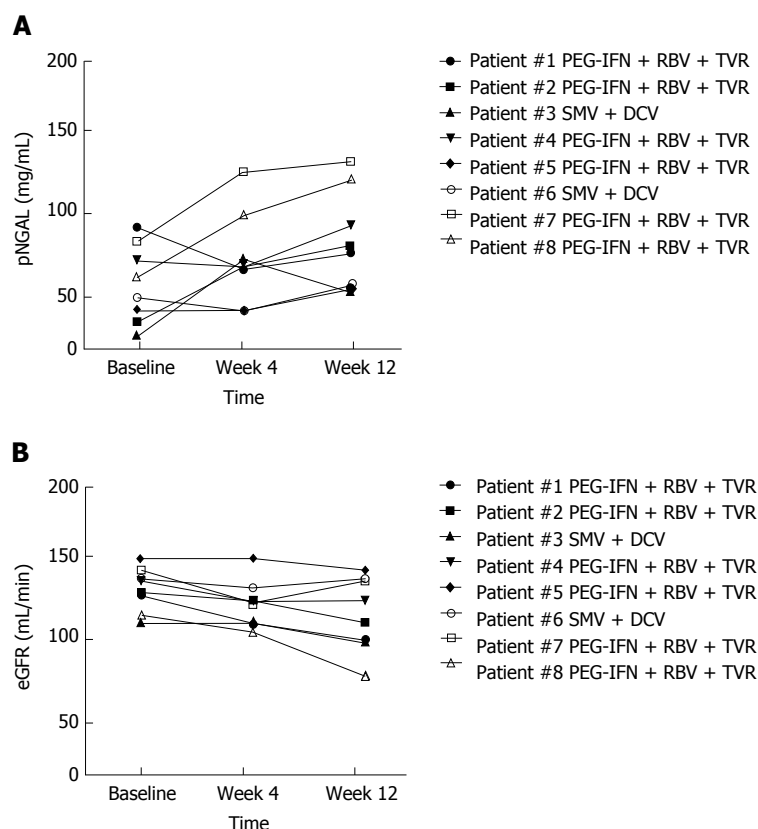

## DISCUSSION

This is the first study which investigated NGAL, both before and during the first twelve weeks of therapy with DAA including regimens. Until now, other investigators evaluated NGAL but only in HCV positive patients with cirrhosis and before treatment with DAA containing regimens<sup>[23]</sup>.

We found that, in patients not exposed to DAA, eGFR was below normality around 50%, while NGAL was in the range of normality in most individuals. Moreover, among the six patients with increased NGAL, two cases had eGFR normal. These results suggest that a discordance between the two methods exists when interpretation is "categorical". Despite these findings, in the overall population plasmatic NGAL was statistically correlated with eGFR. Particularly, NGAL was significantly higher in patients with eGFR  $< 60$  mL/min than those with eGFR  $\geq 90$  mL/min. It is difficult to explain apparent discrepancies with the current literature data because Alhaddad *et al.*<sup>[23]</sup> previously demonstrated that HCV positive cirrhotic patients with eGFR  $< 60$  mL/min had a significantly lower plasmatic NGAL than HCV positive cirrhotic patients with eGFR  $\geq 60$  mL/min. Inclusion of both cirrhotic and non-cirrhotic patients in our study could be an explanation. In conclusion, we think that further studies should evaluate the rate of concordance between the two methods in diverse stages of liver disease. Also, it has to be seen whether these markers provide useful insights on the glomerular (especially detected by e-GFR) or tubular (especially detected by NGAL) damage in these conditions.

We were not able to find any correlations explaining the variability in NGAL values apart from age and in contrast with Bolignano *et al.*<sup>[11]</sup> who, however, selected patients with non-terminal CKD of various etiologies. The correlation found in our study (increasing NGAL with increase in age) was consistent with the inverse

**Figure 4** Evolution of neutrophil gelatinase associated lipocalin (A) and estimated glomerular filtration rate (B) in 8 patients during the first 12 week of hepatitis C virus therapy with directly acting antiviral containing regimens. Number of patients and respective treatment for hepatitis C virus infection are specified. PEG-IFN: Pegylated-interferon; RBV: Ribavirin; TVR: Telaprevir; SMV: Simeprevir; DCV: Daclatasvir; eGFR: Estimated glomerular filtration rate; NGAL: Neutrophil gelatinase associated lipocalin.

and expected correlation between eGFR and age. Importantly, NGAL was not correlated with stage of liver disease or burden of HCV RNA, suggesting that further mechanisms are implicated. Similarly, in their study, Gungor *et al*<sup>[22]</sup> did not find differences between cirrhotic patients and healthy controls but, at the same time, they found that a high plasmatic NGAL was associated with a higher risk of mortality in cirrhotic patients. Our data support the fact that NGAL is not influenced by HCV RNA, suggesting that glomerular and tubular damages have different pathogenic and clinical significances.

We did not find any signals pointing to a predictive role of NGAL for eGFR evolution during the follow-up. Indeed, contrary to this hypothesis, patients with a reduction of eGFR at 1 year had lower NGAL than patients with an improvement of eGFR at 1 year. Bolognani *et al*<sup>[11]</sup> found that patients with non-advanced CKD who progressed in their kidney disease during the follow-up period (median 18.5 mo, range 1-20) had a significantly higher urinary and serum NGAL levels at baseline than patients with non-advanced CKD who did not progress. Our patients did not suffer from significant CKD and renal function did not decrease significantly during the follow-up. These considerations, together with the small sample size and limited length of follow-up may have limited our possibility to demonstrate a significant prediction in this study.

We measured NGAL for the first time during therapy with DAA. Importantly, NGAL increased significantly from baseline to week 12, whereas eGFR did not change significantly, suggesting that tubular damage induced by drugs is not accompanied by glomerular impairment. An alternative hypothesis could be that NGAL increase is induced by a pro-inflammatory status, so this increase in NGAL would be a consequence, at least in part, of inflammation due to activity of antiviral drugs and consequent reduction of HCV RNA. Until now, data about relationship of HCV RNA and inflammation have been controversial. Indeed, some studies pointed to a pro-inflammatory role of HCV RNA, highlighting the enhanced activity of tumor necrosis factor- $\alpha$  and the consequent increase of some pro-inflammatory interleukins (ILs), such as IL-10, in presence of detectable HCV RNA<sup>[32,33]</sup>. Instead, other studies showed that a higher HCV RNA load was correlated with a lower value of C-reactive protein (CRP) and that levels of other ILs, such as IL-6, were correlated with liver fibrosis rather than with HCV RNA load<sup>[34]</sup>. Lastly, successful IFN-free regimens resulted in improved functional responses by natural killer cells (such as degranulation and TRAIL expression) to *in vitro* stimulation with IFN $\alpha$ <sup>[35]</sup>. Further studies are necessary to understand evolutions of immunologic or inflammatory markers (including NGAL) after DAA treatment and the underlying mechanisms.

According to this hypothesis that increase of NGAL during HCV treatment is due to drug toxicity, it is likely that our results were scarcely affected by the use of PEG-IFN and RBV. In fact, these two molecules did not demonstrate significant nephrotoxicity, while the reverse may be true because renal impairment reduces excretion of both PEG-IFN and RBV, leading to an increased risk of side effects, such as hemolytic anaemia due to intra-erythrocyte accumulation of RBV<sup>[5,36]</sup>.

All regimens analyzed in our study included a NS3/4A protease inhibitor (*i.e.*, TVR or SMV). Currently, far more data are available about renal safety of TVR than renal safety of SMV or other DAAs. The available data showed that TVR causes a significant but reversible reduction of eGFR which may be associated with an increase of side effect related to the drug<sup>[37,38]</sup>. Our study showed that, aside reduction of eGFR, there was also an increase of NGAL which could be a consequence of tubular damage. Currently, there is a paucity of data about renal safety of interferon free regimens including DAAs different from TVR. Particularly, it is unknown if second or third generation DAAs have a direct nephrotoxic effect. In our study, both patients treated with SMV + DCV experienced an increase of NGAL with a concomitant eGFR decrease during the first 12 week of treatment. Our results need to be confirmed by further and larger studies, however.

Several limitations may affect the study conclusions: (1) sample size was small and length of follow-up was limited; (2) correlations of NGAL with other factors which could have impaired renal function, such as diabetes, cryoglobulinaemia, treatment with non NSAIDs or diuretics were not evaluated; and (3) we did not measure urinary NGAL or inflammatory molecules such as CRP and ILs which could confirm or disprove the hypotheses above. Notwithstanding these limitations, we feel that our results are important and should provoke further investigations. In particular, we hypothesize that NGAL reveals kidney damage earlier than eGFR during DAA containing regimens.

However, many questions still remain to be answered. Indeed, it has to be established whether a clinical cut-off of NGAL may guide clinical decisions (*e.g.*, dosage modification or stopping of the offending drug). Also, it has to be evaluated whether NGAL could predict AKI during HCV treatment, especially in most-at-risk patients such as those with advanced cirrhosis and a high risk of renal complications (*e.g.*, hepato-renal syndrome). Lastly, cost-effectiveness studies need to be conducted to verify the hypothesis that NGAL should be routinely used to monitor kidney function during HCV treatment instead of (or in addition to) creatinine.

## COMMENTS

### Background

Neutrophil gelatinase associated lipocalin (NGAL) is a novel biomarker of renal impairment but also a marker of inflammation. For the first time, the authors evaluated the evolution of NGAL in patients infected by hepatitis C virus (HCV)

before and during treatment with directly acting antivirals (DAAs).

### Research frontiers

Kidney toxicity of new DAAs has not been established until now. The authors' results suggest that NGAL could provide information complementary to estimated glomerular filtration rate in monitoring the kidney toxicity of DAAs.

### Innovations and breakthroughs

The literature suggests that NGAL is a good marker of acute kidney injury but no data are available about NGAL in HCV positive patients. This article adds to literature data about evolution of NGAL before and during HCV treatment with DAA containing regimens.

### Applications

This study serves as an additional evidence supporting the fact that NGAL can reveal the presence of a kidney impairment before creatinine.

### Terminology

NGAL is a small glycoprotein secreted by multiple human cells, such as epithelial cells (liver, kidney, lungs) and blood cells (neutrophils, monocytes and macrophages), filtered in the glomerulus and reabsorbed by the proximal tubules. An increase of plasmatic NGAL is considered to be an early predictor of acute kidney disease in various critical settings.

### Peer-review

This study examined the measures of a novel biomarker for kidney function, NGAL, before and after HCV treatment with direct acting antivirals among 48 patients. The authors have performed a good study, the manuscript is interesting.

## TO THE EDITOR

The Liver on Tour (LOT) was a special Project devoted to increase the public awareness on Liver Health and Liver Diseases that the Portuguese Association for The Study of Liver Diseases (APEF) launched throughout the country, between mid-April and mid-June 2010, and consisted of a road show, travelling through and reaching all 18 district capitals of Portugal. It was mainly focused on giving simple, reliable and practical information about liver problems with emphasis in messages trying to raise public attention on Liver Health. "Meet the liver", "Care for your Liver", "Mind the Liver", were repeatedly announced sound bites, and had a professional media support so that liver problems reached the level of widespread lay public interest and, of course, politicians rule makers, while members of the APEF Board were literally on the road, claiming for help and protection for the liver.

Although pointing out the need for understanding and for taking care of the Liver, the deep goal was directed to the knowledge of the social and individual threats of Hepatitis, Alcoholic Liver Disease and The Obesity Epidemics. Hepatitis B and Hepatitis C were major players in these topics, and all efforts were made to promote public to decide to look (individually) for serological markers of infection to, give referral and guidance to liver specialists, creating an environment of highly awareness and concern on liver problems.

We believe that policy makers, in these times of funding constraints, will only be sensible to these matters if the public itself realizes how deep and broad impact liver diseases may cause either individually or collectively.

The scientific responsibility of all the pedagogical messages and contents of this Road Show (which included small conferences and media interviews) was from the Board of Direction of APEF.

It was one of our tasks to show how liver diseases may lead to social exclusion and how social exclusion can promote liver diseases. The stigmata and inadequate understanding and misperception often associated with liver diseases are truly cumbersome and there is an urgent need to overcome these misconceptions: Liver diseases were shown not to be caused only by self-inflicted deviated behaviors, previous drugs use and alcohol abuse, but instead that there is a wide spectrum

of causes, chances and risk factors, that may affect each and any one of us, regardless social, cultural or, economic status.

Our itinerant road show, located in central areas of the main Portuguese towns, addressed precisely these topics, stressed the fact why liver diseases are generally referred as "silent killers", how the liver itself copes with inflammation and regeneration, which ubiquitous factors challenge our livers. The hepatotropic viruses of course, alcohol consumption, excess weight and medical conditions as diabetes that cooperate to damage liver cells, were object of description, thorough but simple, clear enough to raise the public curiosity and awareness without frightening but with plenty of hope and need for global commitment.

Several thousands of people, from teens to elderly, walked through the exhibition displayed in the truck, reading carefully all the texts and pictures, from historical trivia to the most advanced virtuosity of liver technology. A small questionnaire was distributed, trying to promote the understanding of eventual individual risk factors for liver diseases and to evaluate a possible previous perception of the exposed topics.

The media came along and had different approaches depending on the places and towns we visited. Local radios interviewed liver specialists, national TVs broadcasted several messages regarding liver health. Underage drinking and alcohol marketing were actively challenged. Our presence in several students' parties, the recruitment of local doctors to get themselves to be available for questioning and even for some counselling, were extremely important to bring everyone together. We were able to gather thousands of in loco measurements of body mass index, and thousands of leaflets with simple knowledge on viral hepatitis were widely distributed.

In a ten million people country where there is evidence of more than 10% being affected with some form of liver diseases<sup>[1]</sup>, all efforts need to be made to enroll everyone in this never ending battle. High priority to education, gathering on board committed doctors with expertise in mass communication and engage reluctant policymakers (pressured by well-informed voters): A formula that could be a brighter way to raise the standards in prevention, detection and management of liver diseases.

**ABOUT COVER**

Editorial Board Member of *World Journal of Hepatology*, Andres F Carrion, MD, Assistant Professor, Texas Tech University Health Sciences Center El Paso, Paul L Foster School of Medicine, El Paso, TX 79905, United States

**AIM AND SCOPE**

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

**INDEXING/  
ABSTRACTING**

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

## Abstract

Genetics plays an important role in determining the susceptibility of an individual to develop a disease. Complex, multi factorial diseases of modern day (diabetes, cardiovascular disease, hypertension and obesity) are a result of disparity between the type of food consumed and genes, suggesting that food which does not match the host genes is probably one of the major reasons for developing life style diseases. Non-alcoholic fatty liver is becoming a global epidemic leading to substantial morbidity. While various genotyping approaches such as whole exome sequencing using next generation sequencers and genome wide association studies have identified susceptibility loci for non-alcoholic fatty liver disease (NAFLD) including variants in patatin-like phospholipase domain containing 3 and transmembrane 6 superfamily member 2 genes apart from others; nutrient based studies emphasized on a combination of vitamin D, E and omega-3 fatty acids to manage fatty liver disease. However majority of the studies were conducted independent of each other and very few studies explored the interactions between the genetic susceptibility and nutrient interactions. Identifying such interactions will aid in optimizing the nutrition tailor made to an individual's genetic makeup, thereby aiding in delaying the onset of the disease and its progression. The present topic focuses on studies that identified the genetic susceptibility for NAFLD, nutritional recommendations, and their interactions for better management of NAFLD.

**Key words:** Transmembrane 6 superfamily member 2 gene; Patatin-like phospholipase domain containing 3 gene; Genotyping; Nutrient interactions; Non-alcoholic fatty liver disease; Genetic susceptibility

**Core tip:** Various genome wide association and replication studies across ethnicities have consistently associated variants in patatin-like phospholipase domain containing 3 gene with a higher risk of non-alcoholic fatty liver disease (NAFLD). More recently a variant in transmembrane 6 superfamily member 2 gene was also associated with susceptibility to the disease. Functional studies have established the role of these genes in NAFLD. Gene and nutrient interactions should be the focus of future research in the management of NAFLD.

## INTRODUCTION

Genetic susceptibility carried by an individual determines the risk of developing a disease. However, not all individuals who carry the risk manifest with the disease, suggesting that, most of the complex multifactorial diseases are the result of interactions between genes and environment. Disease occurrence (onset) or severity may differ in individuals with same genotype exposed to different environmental conditions or vice versa, reiterating the fact that phenotype is the consequence of genotype and environment interactions (Figure 1). Diet, life style, exposure to chemicals and toxins form the major part of environmental risks. Majority of the modern day life style diseases such as diabetes, cardiovascular disease, hypertension, obesity are typically inherited with multifactorial mode of inheritance. It refers to a complex pattern of inheritance where a combination of both genetic and other factors including environmental are involved. Multifactorial conditions do not always manifest despite the fact that the individual carries a genetic variant that increases the risk of disease, putting the emphasis on favorable environment.

Non-alcoholic fatty liver disease (NAFLD) is one of the most important lifestyle based complex and multifactorial diseases. The prevalence of the disease varies markedly in various populations. It ranges between 20%-30% in the Western countries<sup>[1]</sup>, 20%-30% in Europeans<sup>[2]</sup>, 8% in Japanese<sup>[3]</sup> and 25%-30% in Indians<sup>[4]</sup>. The spectrum of the disease ranges between steatosis alone on one hand and non-alcoholic steatohepatitis (NASH)/cirrhosis/hepatocellular carcinoma on the other. However, the progression through the spectrum involves multiple risks including genetic and environmental interactions, in addition to other risk factors (Obesity, advancing age, diabetes, hypertension, and hypertriglyceridemia).

Therefore, understanding genetic susceptibility has been the major focus of recent research in addition to alterations in dietary habits and life style modifications which have been demonstrated to benefit the patients and aid in better management of the disease.

It is imperative for organisms from bacteria to humans to regulate their metabolism vis a vis availability of nutrients for better survival of the species. Nutrient-gene interactions have therefore been an ancient and omnipresent mechanism across species. However research started to explore these interactions only lately and the topic has been of prime importance in the context of disease including NAFLD. This review focuses on the genetic susceptibility identified till date employing various approaches (Exome sequencing, GWAs, candidate gene) thus far and the nutrient risks and the interactions between the two wherever studies are available.

## WHOLE EXOME SEQUENCING AND NAFLD

Recent advances in sequencing the human genome have transformed methods of identifying genetic susceptibility for complex, multifactorial diseases. With whole exome sequencing studies, it is now possible to sequence protein coding regions of the genome and identify genetic susceptibility for complex diseases in an unbiased manner. Although very few studies are available that exploited this technology, important loci have been identified. A quick search on PubMed revealed a single whole exome sequencing study in morbidly obese patients of Caucasian origin with NAFLD, that revealed novel damaging mutations in Bardet-Biedl syndrome 1 gene and Melanocortin 3 receptor gene (*MC3R*). *MC3R* gene encodes MC3 a G-protein coupled receptor for melanocyte stimulating hormone and adrenocorticotrophic hormone. Studies have identified that mice deficient for this gene product have increased fat and play a critical role in weight regulation ("Entrez gene: *MC3R* melanocortin 3 receptor"). Further another patient with NAFLD-related cirrhosis was compound heterozygous for rare and damaging mutations in patatin-like phospholipase domain containing 3 (*PNPLA3*)<sup>[5]</sup>. It is only recently that researchers have started to harness NGS technology to identify genetic susceptibility for complex diseases. In future by exploiting this technology many more important loci may be identified for NAFLD that may aid in better management of the disease.

## GENOME WIDE ASSOCIATION STUDIES AND NAFLD

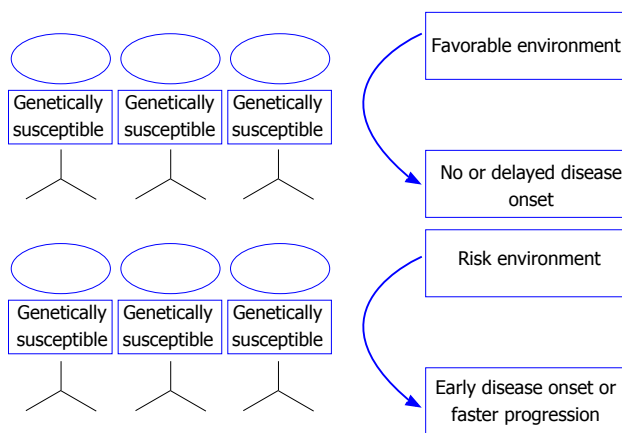

Genome wide association studies (GWAS) are employed to identify genetic susceptibility for complex diseases in an unbiased way. One of the first GWA studies for NAFLD was performed by Romeo *et al.*<sup>[6]</sup> that used a custom chip of approximately 9000 non-synonymous variants across

**Figure 1** Genetic and environmental interactions to produce a phenotype.

the genome. The sample included patients with and without NAFLD of various ethnicities including European, Hispanic and African-American. The liver fat was measured by proton magnetic resonance spectroscopy. One variant (rs738409), a G allele encoding I148M in *PNPLA3* gene was associated with increased fat level in the liver across all the ethnicities. A list of various GWA studies and the variants identified are given in Table 1. Subsequently various groups have replicated the association of this variant in different ethnicities including Japanese<sup>[3,7]</sup>, Indian<sup>[8,9]</sup>, Chinese<sup>[10,11]</sup>. Further the variant was also associated with higher levels of ALT, histologic NAFLD including steatosis<sup>[7,8]</sup>.

A meta-analysis of 24 studies that included 9915

patients from different ethnicities, identified that *PNPLA3* rs738409 variant was associated with fibrosis severity (OR = 1.32, 95%CI: 1.20-1.45)<sup>[12]</sup>. Another meta-analysis of 16 studies<sup>[13]</sup>, showed that rs738409 had a strong influence on liver fat accumulation. Individuals with GG homozygous genotype showed 77% higher lipid fat content compared to CC genotype and were susceptible to 3.24 fold aggressive disease and NASH. Further, when the risk associated with heterozygosity was evaluated for the variant, additive genetic model was better at explaining the effect of the variant on the susceptibility to develop NAFLD. However the analysis suggested that carrying two G alleles did not seem to increase the risk of severe histological features. Also, meta-regression showed a negative correlation between male sex and the effect of rs738409 on liver fat content (slope:  $-2.45 \pm 1.04$ ;  $P < 0.02$ ). Importantly, the rs738409 GG genotype vs the CC genotype was associated with a 28% increase in serum alanine aminotransferase levels. Xu *et al*<sup>[14]</sup> recent meta analysis of the rs738409 variant that included 23 case-control studies (6071 NAFLD and 10366 controls) showed a significant association of the variant with NAFLD, NASH. The subgroup and sensitivity analysis revealed that the changes were not influenced by the ethnicities and age of the subjects.

A GWA study conducted<sup>[15]</sup> in 236 non-Hispanic white woman who were genotyped for 3,24,623 single nucleotide polymorphisms (SNPs) on the Illumina platform and were assessed for various histologic parameters revealed that NAFLD activity score was associated with

rs2645424 in farnesyl diphosphate farnesyl transferase 1. Further analysis revealed that degree of fibrosis was associated with rs343062, lobular inflammation with rs1227756 in COL13A1), rs6591182, and rs887304 in EFCAB4B. SNPs associated with serum levels of alanine aminotransferase included rs2499604, rs6487679, rs1421201 and rs2710833. However, no significant associations were found between genotypes and steatosis, ballooning degeneration, portal inflammation, or other features of NAFLD.

A meta-analysis<sup>[16]</sup> carried out across four groups of European ancestry and one of the largest GWA studies for NAFLD was tested for associations with computed tomography (CT) measured steatosis initially in the 4 groups independently followed by a meta-analysis. The study involved 7176 individuals that were controlled for age, gender and all the principal components. Variants in or near *PNPLA3*, *LYPLAL1*, *PPP1R3B*, *NCAN*/transmembrane 6 superfamily member 2 (*TM6SF2*) and *GCKR* genes were found to be associated with hepatic steatosis. These above variants but for *PPP1R3B* were also associated with NASH and fibrosis.

Few GWA studies identified loci associated with the associated parameters of NAFLD and most importantly the liver function tests. Two such studies<sup>[17,18]</sup> have identified four loci namely SNPs in or near *PNPLA3* (rs2281135, rs738409), *SAMM50* (rs2143571, *CPN1-ERLIN1-CHUK* gene cluster (rs10883437, rs11597390, rs11591741, rs11597086), *TRIB1* (rs2954021) and near *HSD17B13/MAPK10* (rs6834314) that were associated with elevated levels of ALT.

Our pooled genetic study<sup>[8]</sup>, where 19 variants were selected that were associated with NAFLD from 4 GWA studies conducted until 2013 and replicated in patients with and without ultrasound detected NAFLD in Indians. The study identified variants in *PNPLA3*, *PZP*, *SAMM50* and *PARVB* were associated with NAFLD. Furthermore, the haplotype data suggested that variants in *PNPLA3*, *SAMM50* and *PARVB* on chromosome 22 were linked, suggesting that this loci is very important in Indian context. Studies from Japan<sup>[3]</sup> also associated these loci with NAFLD suggesting that it is an important loci conferring susceptibility in Asian population.

## WHOLE EXOME ASSOCIATION STUDY AND NAFLD

Two studies published during the same time reported the association of a variant (rs58542926) in *TM6SF2* gene with susceptibility to NAFLD<sup>[19]</sup> and influencing total cholesterol and myocardial infarction risk<sup>[20]</sup>. The first study identified that the variant in *TM6SF2* gene was associated with hepatic triglyceride content (HTGC) and is a adenine to guanine substitution in coding nucleotide 499, replacing glutamate with lysine at position 167 (c.499A > G; p.Glu167Lys). The frequency of this variant was higher in three ancestries studied (European, African-American and Hispanics). The study suggested

that the variant carriers had elevated mean and median HTGC in European and African-American ancestries. The study also identified that there was a reduction in the expression of recombinant protein in cultured hepatocytes by almost 50% by the Glu167Lys *TM6SF2* variant compared to the wild type. Further knockdown of the gene by Adeno-associated virus-mediated short hairpin RNA in mice increased the liver triglyceride content by threefold and decreased very-low-density lipoprotein (VLDL) secretion by half. Based on the above, the study suggested that *TM6SF2* activity may be required for normal VLDL secretion and that impaired function of the *TM6SF2* gene causally contributes to NAFLD<sup>[19]</sup>. Further, the function of the gene was also clearly established, where it is now known to be a regulator of liver fat metabolism influencing triglyceride secretion and hepatic lipid droplet content<sup>[21]</sup>. The second study<sup>[20]</sup>, systematically assessed coding variants at the genome-wide level to identify novel lipid genes and also evaluate whether low frequency variants with large effect exist, identified a coding variant (p.Glu167Lys) in *TM6SF2* gene that modifies total cholesterol levels and further was associated with myocardial infarction. The functional role of few of the genes identified employing GWAS and exome wide association studies are as given in Table 2.

In an ongoing study at our center, we have replicated these variants (rs58542926 in *TM6SF2* and rs2281135 in *PNPLA3* genes) in 220 patients with NAFLD and 185 controls to date. Both the variants are significantly associated with the disease (*TM6SF2*  $P = 0.00008$ ; *PNPLA3*  $P = 0.002$ ) with a higher risk of the disease (Odds - 2.17, 95%CI: 1.34-3.52 and 1.85, 95%CI: 1.24-2.76). Further both the variants were significantly associated ( $P > 0.05$ ) with higher ALT and AST levels (data unpublished).

## CANDIDATE GENE STUDIES (OTHER GENES) AND NAFLD

Based on the two hit hypothesis as discussed earlier<sup>[22]</sup>, studies have explored genes that have an important role in mechanisms related to lipid metabolism, insulin signaling, oxidative stress, inflammation and fibrogenesis.

While *APCO3* gene is the major gene studied for its role in lipid metabolism (association with higher triglyceride levels), *MTP* gene was studied for its role in regulating synthesis, storage and export of hepatic triglyceride content. A loci on the long arm of chromosome 11 (11q23) harbors genes coding for apolipoproteins, including apolipoprotein A1 (*APOA1*), A4 (*APOA4* and *APOC3*<sup>[23]</sup>). Two polymorphisms T455C (rs2854117) and C482T (rs2854116) in the *APOC3* gene either singly or in combination had 30% higher levels of fasting plasma *APOC3* and triglyceride levels as compared to the wild type<sup>[24]</sup>. Subsequent studies failed to replicate these associations<sup>[25,26]</sup>, including our own study<sup>[27]</sup>. However we found that the SNPs were associated with higher triglyceride levels. *MTP* gene (microsomal triglyceride

Table 2 Functional role of major genes associated with non-alcoholic fatty liver disease identified by genome/exome wide association studies

Gene	Protein	Cellular location <sup>1</sup>	Function <sup>1</sup>	Chromosome location <sup>2</sup>	No. of exons and size <sup>2</sup>	Pathway/biologic function <sup>1</sup>	Tissues expressed <sup>1</sup>
<i>PNPLA3</i>	Patatin-like phospholipase domain-containing protein 3	Lipid droplets	Triacyl glycerol lipase and acylglycerol O-acyltransferase activities	Chromosome 22: 43,923,739-43,964,488 (forward strand)	9 (2805 bp)	Triacyl glycerol degradation and in glycerol-lipid metabolism	Liver, gall bladder, kidney, exocrine pancreas, seminal vesicles, intestine and salivary glands
<i>TM6SF2</i>	Transmembrane 6 superfamily member 2	ER and the ER-golgi intermediate compartment	Regulation of fat in liver influencing triglyceride secretion and lipid droplet content	Chromosome 19: 19,264,364-19,273,391 (reverse strand)	10 (1505 bp)	Promotes very low density lipoprotein export	Liver and intestine
<i>SAMM50</i>	Sorting and assembly machinery component 50 homolog	Outer mitochondrial membrane	Assembly of beta-barrel proteins	Chromosome 22: 43,955,421-44,010,531 (forward strand)	15 (1717)	Transport to the Golgi and subsequent modification and mitochondrial protein import	Liver, muscle, skeletal, lung adipocyte, colon and other tissues
<i>PARVB</i>	Parvin, beta	Cytoplasm	Involved in the reorganization of the actin cytoskeleton and formation of lamellipodia	Chromosome 22: 44,024,277-44,172,949 (forward strand)	13 (5429 bp)	ERK signaling and focal adhesion	Liver, muscle, skeletal, lung adipocyte, colon and other tissues
<i>NCAN</i>	Neurocan	Extracellular, Golgi lumen	Modulates neuronal adhesion and neurite growth during development	Chromosome 19: 19,211,973-19,252,233 (forward strand)	15 (6387 bp)	Developmental	Liver, muscle, skeletal, lung adipocyte, colon and other tissues
<i>PPP1R3B</i>	Protein phosphatase 1, regulatory subunit 3B	Glycogen granule	Acts as glycogen targeting subunit for phosphatase PP1	Chromosome 8: 9,136,255-9,151,574 (reverse strand)	2 (5548 bp)	Regulating glycogen synthesis	Liver, skeletal muscle
<i>GCKR</i>	GCKR	Cytoplasm, nucleus	Inhibits glucokinase by forming an inactive complex with this enzyme. The affinity of GCKR for GK is modulated by fructose metabolites	Chromosome 2: 27,496,842-27,523,684 (forward strand)	19 (2186 bp)	Carbohydrate metabolism	Liver, pancreas, colon and other tissues
<i>LYPLAL1</i>	Lysophospholipase-like 1	Cytoplasm	Depalmitoylating activity	Chromosome 1: 219,173,844-219,212,865 (forward strand)	5 (1898 bp)	Negative regulation of golgi to plasma membrane protein transport	Liver, muscle, skeletal, lung adipocyte, colon and other tissues

<sup>1</sup>Data extracted from <http://www.genecards.org/>; <sup>2</sup>Data extracted from ENSEMBL <http://asia.ensembl.org/index.html>; ER: Endoplasmic reticulum; PP1: Protein phosphatase 1; GCKR: Glucokinase (Hexokinase 4) regulator; GK: Glucokinase; ERK: Extracellular signal-regulated kinase.

transfer protein), located at 4q24<sup>[28]</sup> is critical for the synthesis and secretion of VLDL (very low density lipoprotein) in the liver. A meta-analysis<sup>[29]</sup> of most studied polymorphism -493G > T (rs1800591 G > T) in the *MTP* gene suggested that the SNP was significantly associated with higher risk of NAFLD.

Genes influencing inflammation and immune responses are known to modify susceptibility to NAFLD. Cytokines not only play an active role in the development of disease, but also in the progression by regulating the inflammatory process<sup>[30]</sup>. Studies identified a positive correlation between increasing degree of liver fibrosis and levels of TNF- $\alpha$ <sup>[31-33]</sup> including pediatric NAFLD<sup>[34]</sup>. Further, polymorphism studies associated a promoter SNP (-238G > A) in *TNFr*- $\alpha$  gene with susceptibility to NAFLD in Chinese

population<sup>[35]</sup>. transforming growth factor-beta (TGF- $\beta$ ), known to regulate cell death and lipid metabolism<sup>[36]</sup>, has been shown to be up-regulated and is considered an early event in steatohepatitis that is progressive.

Expression of interleukin-6 (IL-6), a major pro-inflammatory cytokine was shown to be increased in animal models of NAFLD, while in mice, sustained selective up-regulation in the liver resulted in systemic insulin resistance<sup>[37]</sup>. This was subsequently confirmed in humans<sup>[38]</sup>. Further, a positive correlation was observed between the expression levels and degree of inflammation and stage of fibrosis. A study identified that -174G/C in the IL-6 gene was involved in inflammation and insulin resistance and associated with NASH<sup>[39]</sup>, chronic liver disease and Hepatocellular carcinoma<sup>[40]</sup>.

Interleukin-10 (IL-10), an anti-inflammatory cytokine coded by IL-10 gene<sup>[41]</sup> has a role in regulating inflammation and its anti-inflammatory properties are well known<sup>[42]</sup>. T cell, monocyte and macrophage mediated functions are inhibited by IL-10. Different types of the cells in liver including stellate cells, hepatocytes and kupffer cells have shown the presence of IL-10. Few studies that explored the role of the gene, identified the protective role of endogenous role of IL-10 against hepatic steatosis, however they suggested that it does not improve hepatic or whole body insulin sensitivity during high-fat feeding<sup>[43]</sup>. Furthermore, in an animal model of diet-induced fatty liver disease, inhibition of IL-10 promoted increased expression of inflammatory cytokines, worsened insulin signaling and activated gluconeogenic and lipogenic pathways<sup>[44]</sup>.

Hepatic insulin resistance is associated with NAFLD and is one of the contributory factors in the pathogenesis of metabolic syndrome. Genetic screening of insulin signaling cascade identified a substitution (Glycine-Arginine) at codon 972 of the insulin receptor substrate-1 gene with a prevalence of approximately 9% in Caucasians that was associated with reduced insulin sensitivity. Furthermore, obese individuals heterozygous for this mutation have 50% reduced insulin sensitivity as compared to wild type obese subjects<sup>[45]</sup>. This variant is known to affect insulin receptor activity predisposing to liver damage and decreased hepatic insulin signaling in patients with NAFLD. It is suggested that insulin signaling might play a causal role in the progression of liver damage in NAFLD<sup>[46]</sup>.

NAFLD pathogenesis is a complex mechanism with involvement of free fatty acid (FFA) oxidation<sup>[47,48]</sup> and genes encoding proteins that are involved in the oxidation process of FFAs influence the oxidation load in individuals with obesity, insulin resistance and metabolic syndrome<sup>[22]</sup>. Genes harboring polymorphisms involved in generation and degradation of reactive oxygen species play a crucial role that could be due to excessive oxidation of FFA leading to oxidative stress causing apoptosis and liver injury<sup>[49]</sup>. Namikawa *et al.*<sup>[50]</sup> reported that the TT genotype in the *MnSOD* gene, the main ROS scavenger in mitochondria, leads to decreased efficiency

in the transport of MnSOD to the mitochondria and therefore confers susceptibility for NAFLD. Apart from the *MnSOD* gene, substantial evidence is now available on the role of polymorphisms in genes namely *GSTM1*, *GSTT1* and *GSTP1* genes that are involved in the generation or degradation of ROS. These genes are known to be involved in the progression to cirrhosis<sup>[51]</sup>.

## NUTRITIONAL RECOMMENDATIONS

Currently in clinical practice, a combination of vitamin D, vitamin E and omega-3 fatty acids have shown promise in the treatment of NAFLD and seem to be beneficial in patients with NAFLD. Studies further suggests that apart from nutritional counseling that includes a multi-disciplinary team (dietician, psychologist, and physical activity supervisor) aerobic exercises, gradual weight loss, management of NAFLD associated conditions namely diabetes, obesity and metabolic syndrome, nutritional recommendations namely use of 400-800 IU/d vitamin E, 1000 IU/d vitamin D, 1 g/d omega-3 fatty acids, and olive oil containing omega-9 fatty acids seem to benefit in reducing the severity of NAFLD. Also, restricting calorie intake to less than 30 kcal/kg per day and including a balanced diet with low levels of saturated and trans fats and simple sugars, avoiding soft drinks with high fructose corn syrup, fast food (trans fats, and reduce red and processed meats), and genetically modified crops seem to be beneficial<sup>[52]</sup>.

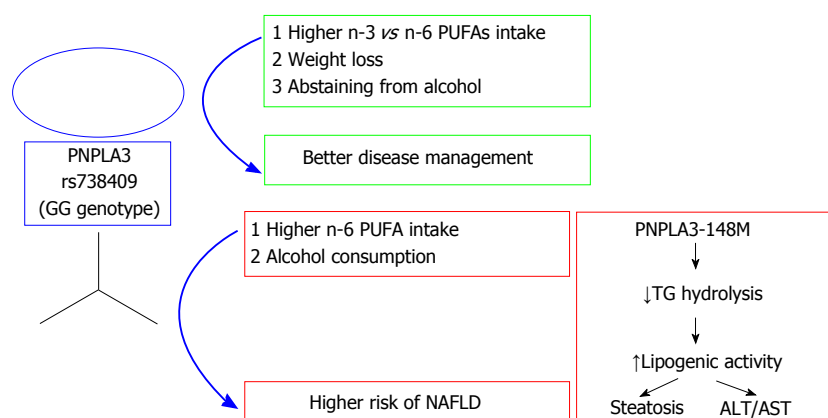

## MANAGEMENT OF NAFLD

Lifestyle modification usually by way of weight reduction through diet and exercises is currently the only proven strategy for managing NAFLD. As obesity is a strong risk and influencing factor for NAFLD, weight loss ( $\geq 8\%$  of body weight) is effective and is also the first line of therapy. A low caloric diet with reduction in the intake of total fat, saturated fatty acids, trans fatty acids and fructose, increase in physical activity and abstaining from smoking is advantageous and the patients are encouraged to follow these. Antioxidants, anti-inflammatory, insulin sensitizers, lipid lowering agents apart from wide range of drugs and supplements have been evaluated in various studies, both animal and human, however none of these have efficacy on long term use<sup>[53,54]</sup>.

## GENETIC AND NUTRIENT INTERACTIONS

It is almost imperative that all living organisms either simple or complex multicellular, regulate their metabolism vis a vis nutrient availability. Thus, interactions between nutrition and gene are widespread and an ancient feature across species. However, this aspect has not been explored and it is only recently that research started to uncover the mechanism. In view of the rapid advances made in sequencing human genome enormous amount of genetic data is being generated, particularly with

**Figure 2** Genotype (rs738409) in patatin-like phospholipase domain containing 3 gene and its interactions. PNPLA3: Patatin-like phospholipase domain containing 3; PUFA: Polyunsaturated fatty acid; NAFLD: Non-alcoholic fatty liver disease; ALT/AST: Alanine aminotransferase/aspartate aminotransferase.

respect to common multigenic, multifactorial conditions including obesity, diabetes, NAFLD, *etc.* It is becoming more and more obvious that an individual's susceptibility to lifestyle disease represents a complex interaction between genetics and environmental interactions. Food and nutrient intake are the important environmental factors and their interactions with genes play a key role in the pathogenesis and progression of polygenic diseases. Therefore, research should be focused on identifying such interactions of genes with nutrients and identifying susceptible genotypes to particular nutrients. This will help us optimize nutrient/diet intake (personalized nutrition) to reduce disease risk<sup>[55]</sup>. However, there are challenges in analyzing these interactions in the form of genetic heterogeneity and complex nature of human genome, complexity of environmental factors including diet, *etc.*<sup>[56]</sup>.

NAFLD is considered to be the hepatic manifestation of the metabolic syndrome<sup>[57]</sup>. The "thrifty genotype" a possible explanation for the steep increase in obesity and diabetes, where periods of famine in the history of modern humans has exerted natural selection in favor of selecting genes favorable for fat storage and this is likely mediated through fertility and not viability selection<sup>[58]</sup>.

Hepatic lipase gene (*HL*) is a lipolytic enzyme that regulates triglyceride levels. Insulin is known to up-regulate the activity of HL through the insulin-responsive elements in the promoter region. It is suggested that higher intake of total and saturated fat is associated with higher activity of *HL* gene. A study reported that this activity is influenced by the -514 C > T polymorphism in the *HL* gene, with significantly stronger associations noted between total dietary fat intake and HL activity in individuals with CT and TT genotypes as compared to the wild type (CC)<sup>[59]</sup>. Another study<sup>[60]</sup> that explored epidemiologic genotype-nutrient interactions in obesity, where a total of 42 SNPs in 26 candidate genes were genotyped identified an interaction between -514 C > T in *HL* gene and fiber intake. Further they also suggested that the -681 C > G polymorphism in *PPARG3* gene might interact with the percentage of energy derived

from fat in the diet for the development of obesity. However, this was a case-only study with only adult obese women as part of the analysis. A study<sup>[61]</sup> that examined the interactions between the -514 C > T in *HL* gene, dietary fat and HDL-related measures in 1020 men and 1110 women from the farmingham study reported that individuals with the "TT" genotype may have an impaired adaptation to higher animal fat diets. Furthermore, they suggested that dietary fat intake modifies the effect of the polymorphism in *HL* gene on HDL-C concentrations and subclasses, where the T allele was significantly associated with greater HDL-C concentrations only in subjects consuming < 30% of energy from fat and the reverse is true when total fat intake was  $\geq$  30% of energy.

It is well established that apolipoprotein A5 (*APOA5*) gene is an important determinant of plasma triglyceride levels. Further it is a component of several lipoprotein fractions including high density lipoprotein (HDL), VLDL<sup>[62]</sup>. A study<sup>[63]</sup>, investigated the interaction between variants in *APOA5* gene and dietary fat in determining plasma fasting triglycerides, remnant-like particle concentrations and lipoprotein particle size in 1001 men and 1147 women from farmingham heart study reported significant gene-diet interactions between the -1131T > C polymorphism in *APOA5* gene and polyunsaturated fatty acid (PUFA) intake were found that determined fasting TGs, RLP concentrations and particle size. However, these interactions were not found for the other polymorphism (56C > G). Further they noted that the -1131C allele was associated with higher fasting TGs and RLP concentrations in only individuals who consumed a high-PUFA diet with > 6% of total energy. The study concluded that individuals who are carriers of -1131C polymorphism in *APOA5* gene and take higher n-6 but not n-3 PUFA, have increased fasting TGs, RLP concentrations, and VLDL size and decreased LDL size, suggesting a more atherogenic lipid profile in these individuals because of the n-6 PUFA-rich diet.

A study<sup>[64]</sup> that recruited 8 subjects with homozygous genotype for the rs738409G allele in *PNPLA3* gene and

10 with C allele, explored the influence of the variant on the ability to lose weight thereby reducing liver fat or change insulin sensitivity. The study identified that the fasting serum insulin and C-peptide concentrations were significantly lower in rs738409G as compared to rs738409C group. Although weight loss was not significantly different between the groups (approximately 3.1 kg), liver fat decreased by 45% in rs738409G as compared to 18% in the rs738409C group, suggesting weight loss is more effective in decreasing liver fat in rs738409G carriers. Another study<sup>[65]</sup> that explored the influence of PNPLA3 (rs738409) genotype on hepatic fat and modulation by dietary factors such as PUFAs identified that the ratio of n-6 to n-3 PUFAs interacted with the GG genotype to promote hepatic steatosis (Figure 2).

## FUTURE TRENDS

In future, testing for variants that pre-dispose to NAFLD along with their nutrient interactions would help identify the type of nutrition to be taken based on individual's genetic makeup thereby minimizing the risk of fatty infiltration.

## CONCLUSION

Among all the loci identified thus far, there is a compelling evidence of the association of variants in PNPLA3 with NAFLD and functional role of TM6SF2 in the regulation of liver fat metabolism and hepatic lipid droplet content. It may be prudent to genotype these well characterized variants (PNPLA3) as part of the diagnostic workup for NAFLD, to assess the risk of an individual. Further genotyping in asymptomatic individuals will help in making lifestyle based recommendations, including nutrition to minimize the risk of future disease. As the genetic susceptibility risk cannot be changed, it is important to identify the risk at an early age and manage/lower the other modifiable risks/modifiable triggers to efficiently manage the disease without progressing to subsequent pathologies. Finally, the genetic information along with personalized environment exposures will help in stratifying risk of NAFLD in an individual.

### Abstract

**AIM:** To determine whether hepatocyte lipogenesis, in an *in vitro* cell culture model, is modulated by adjusting culture media monosaccharide content and concentration.

**METHODS:** Hepatocytes (Huh7), demonstrating glucose and fructose uptake and lipid biosynthesis, were incubated in culture media containing either glucose alone (0.65-0.72 mmol/L) or isosmolar monosaccharide (0.72 mmol/L) comprising fructose:glucose (F:G) molar ratios ranging from 0.58-0.67. Following a 24-h incubation, cells were harvested and analyzed for total protein, triglyceride (TG) and cholesterol (C) content. Significant differences ( $P < 0.05$ ) among groups were determined using analysis of variance followed by Dunnett's test for multiple comparisons.

**RESULTS:** After a 24 h incubation period, Huh7 cell mass and viability among all experimental groups were not different. Hepatocytes cultured with increasing concentrations of glucose alone did not demonstrate a significant change either in C or in TG content. However, when the culture media contained increasing F: G molar ratios, at a constant total monosaccharide

concentration, synthesis both of C and of TG increased significantly [F:G ratio = 0.58, C/protein ( $\mu\text{g}/\mu\text{g}$ ) = 0.13; F:G = 0.67, C/protein = 0.18,  $P < 0.01$ ; F:G ratio = 0.58, TG/protein ( $\mu\text{g}/\mu\text{g}$ ) = 0.06; F:G ratio = 0.67, TG/protein = 0.11,  $P < 0.01$ ].

**CONCLUSION:** In an *in vitro* hepatocyte model, glucose or fructose plus glucose support total cell mass and lipogenic activity. Increasing the fructose:glucose molar ratio (but not glucose alone) enhances triglyceride and cholesterol synthesis. These investigations demonstrate fructose promotes hepatocellular lipogenesis, and they provide evidence supporting future, *in vivo* studies of fructose's role in the development of hepatic steatosis and non-alcoholic fatty liver disease.

**Key words:** Hepatocytes; Cholesterol; Triglycerides; Fructose; Glucose

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Employing an *in vitro* hepatocyte culture model, these data demonstrate fructose promotes intracellular synthesis both of cholesterol and of triglyceride. The results support the requirement for future, *in vivo* investigations to determine whether diets high in fructose are risk factors for hepatic steatosis and development of non-alcoholic fatty liver disease.

## INTRODUCTION

Fructose, a five-carbon monosaccharide, comprises an increasing component of the Western diet, particularly in the form of high fructose corn syrup (HFCS). In the United States, this sweetener is both readily available from domestically grown corn and inexpensive, when compared to imported, granulated sugar. It was introduced in the 1960's, with subsequent expansion into a vast array of foods and beverages. HFCS is made from corn starch, processed by glucose isomerase to convert a portion of its glucose fraction into fructose. HFCS preparations contain approximately 25% water, fructose (up to 55% of the water-free fraction), glucose and 0%-5% unprocessed glucose oligomers. HFCS's use as a commercial sweetener has doubled in the last decade and, as a consequence, fructose intake in developed countries has increased five-fold<sup>[1]</sup>.

In several human studies to date, increased fructose intake has been linked both to abnormal plasma lipid profiles and to the development of non-alcoholic fatty liver disease (NAFLD)<sup>[2-4]</sup>. However, because the effects

of fructose, *per se*, are difficult to distinguish from the influences of other dietary carbohydrates and fats, current clinical evidence does not establish the precise contribution of fructose-containing food and beverage products to the etiology and/or the exacerbation of specific biochemical, clinical and histopathologic abnormalities. Further, since the causes of dietary carbohydrate and lipid-related problems (e.g., hyperlipidemia, type II diabetes, NAFLD, metabolic syndrome) are multifactorial and also related to age, gender and lifestyle, additional investigations are required to determine the relative contributions of dietary and other co-factors.

In attempting to identify the importance of fructose in hepatocellular lipid metabolism, available *in vitro* studies indicate fructose may preferentially promote *de novo* lipogenesis<sup>[5]</sup>. Since fructose bypasses the glycolytic rate-limiting enzyme phosphofructokinase, it is metabolized efficiently and provides a readily available substrate for hepatic lipid synthesis<sup>[6]</sup>. In addition, fructose has been shown to inhibit peroxisome proliferator-activated receptor (PPAR)-alpha mediated hepatocellular fatty acid beta-oxidation and lipid clearance<sup>[7]</sup>.

The potential lipogenic role of fructose also may be related to its relationship to endogenous insulin activity. Insulin insensitivity has been implicated in the pathogenesis and progression of NAFLD<sup>[8]</sup>. Impaired insulin responsiveness to circulating carbohydrate is associated both with increased adipocyte lipolysis and with increased levels of circulating free fatty acids (FFA). Thus, insulin resistance promotes lipolysis, particularly in intra-abdominal, white adipose tissue. This phenomenon occurs as a consequence of dysregulation of lipid regulatory transcription factors (e.g., PPAR-gamma), instability of adipocyte lipid and impaired lipogenesis. Released FFA lead to upregulation of inflammatory cytokines and chemokines<sup>[8,9]</sup>. Subsequently, liberated adipocyte FFA are taken-up by the liver and re-esterified to triglyceride. As fructose does not promote insulin secretion, it may therefore exacerbate the effects of insulin resistance on hepatic lipid synthesis, steatosis and the development of NAFLD<sup>[10]</sup>. Further evidence of fructose' role in the development of NAFLD derives from a recently reported rat model of hepatic steatosis. A high fructose-containing diet promoted not only lipogenesis leading to steatosis, but also increased expression of lipocalin-2, a ubiquitous glycoprotein involved in the response to inflammation and oxidative stress<sup>[11]</sup>.

Despite evidence linking fructose to the development of altered lipid dynamics, hepatic steatosis and NAFLD, a recent meta-analysis concluded that studies examining the hepatocellular effects of fructose were confounded by the co-stimulation of lipogenesis resulting from increased total energy intake<sup>[12]</sup>. This observation suggests the deleterious effects of HFCS are merely a reflection of overall calorie excess in the Western diet.

In light of the above clinical and experimental data, the present study seeks to establish the influence of fructose on hepatocyte lipogenesis and provide a basis for future, translational investigations of fructose-

Protein (μg/mL)	635.0 ± 52.7	608.6 ± 35.3	543.2 ± 126.6
Fructose:glucose (mmol/L: mmol/L)	0.58:1 <sup>1</sup>	0.61:1 <sup>1</sup>	0.67:1 <sup>1</sup>
Protein (μg/mL)	626.6 ± 95.2	610.2 ± 30.6	521.9 ± 38.7

<sup>1</sup>Total monosaccharide concentration = 0.72 mmol/L, Huh7 cell homogenates, means ± SD after 24 h of incubation in culture media containing only glucose or glucose plus fructose as the nutrient monosaccharide(s). All experiments comprise samples at a fixed volume of 10 mL/plate.

mediated lipid biosynthesis. These experiments employ an established, immortal and metabolically active human hepatocellular carcinoma cell line, Huh7, used extensively in studies of hepatocyte metabolism<sup>[13-15]</sup>. Since facilitated uptake of glucose and fructose by the transmembrane GLUT2 transporter is demonstrated in Huh7 cells<sup>[16]</sup>, these cells provide an excellent model for studies of carbohydrate-induced lipogenesis. Accordingly, the studies herein were carried out to determine whether hepatocyte lipogenesis, in an *in vitro* cell culture model, is modulated by adjusting culture media monosaccharide content and concentration.

## MATERIALS AND METHODS

### Cell culture

Huh7 cells (American Type Culture Collection, Manassas, VA) were maintained in Dulbecco's Modified Eagle Medium (DMEM) containing 10% Fetal Bovine Serum (FBS), 1% penicillin-streptomycin and 1% L-glutamine, in a 37 °C, 5% CO<sub>2</sub> cell culture incubator on 100 mm × 200 mm tissue culture dishes (BD Falcon Durham, NC). Once 80% confluence was achieved (cell count -  $1 \times 10^5$ ), cells were incubated for 24 h in culture media (DMEM) with 10% FBS containing either glucose alone (0.65, 0.68 and 0.72 mmol/L) or isosmolar monosaccharide (0.72 mmol/L) comprising fructose:glucose (F:G) molar ratios of 0.58, 0.61, and 0.67. For all experiments, total media osmolality was 400 mOsm/L. All incubations were performed in triplicate. Following the 24 h incubation, as described above, culture media was removed, plates were washed with phosphate buffered saline, and cells were lysed and collected in 750 microliters isopropanol, as previously described<sup>[17]</sup>. The cell lysates were kept at 4 °C for 12 h. Each sample was then centrifuged at 4 °C for 10 min at 10000 rpm. Supernatants were removed for lipid studies and the remaining cellular precipitate was re-suspended in 0.1N NaOH for protein quantification, employing a previously validated method<sup>[17]</sup>.

### Protein and lipid analyses

Cholesterol and triglyceride were measured utilizing samples from the isopropanol supernatant<sup>[18]</sup>. The samples were placed in a 96 well plate for lipid quantification, using established spectrophotometric methods<sup>[19,20]</sup>. Spectrophotometric absorbancies of each cell lysate sample were compared to known lipid standards, and the concentrations of cholesterol and triglyceride

were calculated from the derived measurements<sup>[19,20]</sup>. Protein was quantified in triplicate utilizing samples from the NaOH suspension, employing standard spectrophotometric methods<sup>[21]</sup>.

### Cell mass determination

For these cell culture studies, estimates of cell mass in all experimental groups were made using total protein measurements in Huh7 lysates<sup>[22]</sup>. All single cell-line incubations were performed concurrently, under the same environmental conditions, thereby synchronizing cell cycles among experimental groups. Accordingly, as previously described, calculation of total cell protein content was employed to estimate relative cell biomass among incubations<sup>[23]</sup>.

### Statistical analysis

Differences among all experimental groups were assessed by analysis of variance, followed by Dunnett's test for multiple comparisons. A *P*-value of < 0.05 was considered significant.

## RESULTS

### Cell mass

Cultured Huh7 cells incubated in glucose-only supplemented media (0.65, 0.68, and 0.72 mmol/L) and in media containing varying F:G molar ratios (total monosaccharide concentration 0.72 mmol/L), did not show any statistically significant differences in protein content among all study groups. These data indicate total cell mass was not affected by varying the monosaccharide concentration or distribution (Table 1).

### Glucose-mediated lipogenesis

As shown in Figures 1 and 2, triglyceride and cholesterol content (μg/mg cell protein) did not differ significantly among Huh7 cells incubated for 24 h in media containing 0.65, 0.68 or 0.72 mmol/L glucose per plate. Further increases (> 0.72 mmol/L) in glucose molar concentration did not result in any additional enhancement in cellular lipid content (data not shown).

### Fructose-mediated lipogenesis

For these experiments, all cells were incubated in media containing 0.72 mmol/L monosaccharide (total media osmolality = 400 mOsm/L), the maximum sugar concentration employed in the "glucose-only" experiments, described above. To determine the effects of fructose on lipogenesis, cells were incubated in the presence of increasing molar ratios of F:G (0.58, 0.61 and 0.67). Following a 24 h incubation, Huh7 cell cholesterol content (μg/μg cell protein) increased significantly at a F:G molar ratio of 0.67:1 (Figure 3), compared both to a 0.61:1 ratio (0.18 μg/μg vs 0.14 μg/μg protein, *P* < 0.05) and to a 0.58:1 ratio (0.18 μg/μg vs 0.13 μg/μg protein, *P* < 0.01). Triglyceride analyses (Figure 4) demonstrated fructose-mediated Huh7 triglyceride synthesis also increased significantly in step-wise fashion. Thus, increased triglyceride content was

**Figure 1** Cholesterol content of Huh7 cells ( $\mu\text{g}/\mu\text{g}$  cellular protein) following a 24-h incubation, in culture media containing 0.65, 0.68 and 0.72 mmol/L glucose.

**Figure 2** Triglyceride content of Huh7 cells ( $\mu\text{g}/\mu\text{g}$  cellular protein) following a 24-h incubation, in culture media containing 0.65, 0.68 and 0.72 mmol/L glucose.

**Figure 3** Cholesterol content of Huh7 cells ( $\mu\text{g}/\mu\text{g}$  cellular protein) following a 24-h incubation, in culture media containing fructose and glucose, at fructose:glucose molar ratios of 0.58:1, 0.61:1 and 0.67:1. All incubations were carried out in media containing 0.72 mmol/L total monosaccharide.

**Figure 4** Triglyceride content of Huh7 cells ( $\mu\text{g}/\mu\text{g}$  cellular protein) following a 24-h incubation in culture media containing fructose and glucose, at fructose:glucose molar ratios of 0.58:1, 0.61:1 and 0.67:1. All incubations were carried out in media containing 0.72 mmol/L total monosaccharide.

noted at a F:G ratio of 0.61:1 (compared to the ratio of 0.58:1,  $0.08 \mu\text{g}/\mu\text{g}$  vs  $0.06 \mu\text{g}/\mu\text{g}$  protein,  $P < 0.05$ ) and at a ratio of 0.67:1 (compared to the ratio of 0.61:1,  $0.11 \mu\text{g}/\mu\text{g}$  vs  $0.08 \mu\text{g}/\mu\text{g}$  protein,  $P < 0.05$ ; to 0.67:1,  $0.11 \mu\text{g}/\mu\text{g}$  vs  $0.06 \mu\text{g}/\mu\text{g}$  protein,  $P < 0.01$ ).

## DISCUSSION

The results presented in this report demonstrate Huh7 cells, an immortal hepatocellular carcinoma cell line, grown in standard culture media containing increasing glucose concentrations (up to 0.72 mmol/L), exhibit no differences in relative cellular TG and C, as a consequence of increased media glucose content. However, when the nutrient monosaccharides comprise fructose plus glucose (at increasing F:G molar ratios), significant promotion of lipogenesis is demonstrated by increased hepatocellular TG and C concentrations. For these studies, the cell culture media monosaccharide content of 0.72 mmol/L (glucose alone or glucose plus fructose) was found to maximize hepatocellular lipogenesis. This molar amount was determined following a series of experiments, employing a step-wise increase in sugar content and based on previous human studies showing serum total monosaccharide concentrations of approximately 0.50 mmol/L following a fructose-rich

meal<sup>[24]</sup>. Higher amounts of monosaccharide ( $> 0.72$  mmol/L) in the Huh7 incubating media did not yield statistically significant increases either in cellular TG or in cellular C content, while further increases ( $> 400$  mmol/L) in media osmolality resulted in decreased cell viability.

These results are consistent with a prior clinical report, suggesting hepatic fat (estimated by magnetic resonance imaging) in subjects fed fructose, in addition to a specific weight maintenance diet, was increased compared to a study group fed the same diet supplemented with glucose alone<sup>[4]</sup>. Conversely, another report failed to demonstrate any promotion of lipogenesis following four weeks of a fructose supplemented diet. As stated previously, a recent meta-analysis concluded the potential association between fructose and NAFLD was confounded by the concurrent consumption of hypercaloric diets<sup>[12]</sup>. The influence of fructose on lipogenesis, as a consequence of excess energy intake, may be mediated by this monosaccharide's direct attenuation of post-prandial ghrelin suppression<sup>[24]</sup>. On the other hand, another study examining the effects of dietary sucrose vs HFCS on endogenous hormone levels, failed to demonstrate any significant differences in serum insulin, leptin and ghrelin levels<sup>[25]</sup>. These combined *in vivo* studies therefore suggest the amount of carbohydrate taken up by hepatocytes is increased (thus leading

to enhanced lipogenesis) as a consequence of total calorie intake, rather than resulting directly from the lipogenic effects of any specific dietary substrate.

In contrast to available clinical data examining fructose mediated steatosis (often derived from imprecise imaging techniques), considerable biochemical evidence supports the role of fructose in promoting *de novo* lipogenesis. Since fructose is more efficiently utilized intracellularly, as compared with glucose, it may provide a more readily available substrate for lipid synthesis<sup>[26]</sup>. Interestingly, one recent study failed to demonstrate any effects of fructose on regulating hepatocellular lipogenic genes, thus providing further, indirect evidence linking the lipogenic role of this monosaccharide to its ability to provide increased amounts of carbon fragments for lipid synthesis<sup>[27]</sup>. The present results extend this observation by demonstrating that lipogenesis, in cultured hepatocytes, is not solely related to the provision of carbon precursors, since all incubations contained similar total monosaccharide concentrations. Thus, fructose, in this experimental model, appears to exert a direct effect on promotion of lipogenesis, and this effect is independent of carbon supply.

Because fructose metabolism is insulin-independent and does not stimulate pancreatic insulin secretion<sup>[28]</sup>, this monosaccharide was previously thought to be a superior dietary substrate, as compared with other sugars<sup>[29]</sup>. However, more recent experimental data, while confirming these metabolic characteristics, also demonstrate fructose promotion of insulin resistance<sup>[12]</sup>. Fructose stimulates Jun-N-terminal kinase-1 (JNK-1), an intracellular mitogen activated protein kinase. JNK-1 in turn phosphorylates insulin receptor substrate-1 resulting in suppression of cellular glucose uptake, increased blood glucose levels and increased insulin secretion<sup>[30-32]</sup>. These findings, therefore, suggest another potential pathway for fructose-mediated steatosis.

Despite results presented in this report and published previously, the precise mechanisms by which fructose increases hepatic TG are not completely understood. Carbohydrate responsive element binding protein (ChREBP) and sterol regulatory element binding protein 1c (SREBP1c) are two transcription regulators of hepatic lipogenesis induced by glucose and insulin, respectively. Animal knockdown studies of peroxisome proliferator-activated receptor gamma co-activator-1 beta, a transcriptional co-activator of SREBP1c, have demonstrated improved hepatic lipid profiles in fructose fed rats. In a separate study<sup>[7]</sup>, fructose fed rats showed increased expression of ChREBP hepatic mRNA, compared with a glucose fed group. Because recent data shows fetal bovine serum (FBS) contains factors that promote cellular lipogenesis, independent of insulin<sup>[33]</sup>, and because FBS concentrations were held constant in our studies, stimulation of either SREBP1c or ChREBP represents an unlikely contributor to the observation of fructose-mediated *de novo* lipogenesis.

Our preliminary study certainly has several important limitations. These observations, in an *in vitro* cell culture model, cannot accurately predict the metabolic fate of

fructose, in terms of its ability to enter lipogenic pathways. While the data clearly suggest direct effects of fructose on hepatocellular synthesis of triglyceride and cholesterol, they do not provide further elucidation of the underlying mechanisms leading to these findings. Nevertheless, the observation that fructose exerts a promoting influence on lipid synthesis, confirms prior studies suggesting the significant role of this monosaccharide in the development and/or exacerbation of hepatic steatosis. These data, therefore, warrant further investigations into the mechanisms and extent of fructose-mediated, *de novo* hepatic lipogenesis.

## COMMENTS

### Background

Available studies, both *in vitro* and in clinical trials, indicate the dietary monosaccharide, fructose, may be an important substrate for hepatic lipid synthesis, and may promote the development of hepatic steatosis. However, whether fructose-associated lipogenesis is related to dietary intake of fructose, *per se*, or merely reflects excess total energy consumption, remains unclear. The present study seeks to establish the effects of fructose on hepatocyte lipogenesis and provide a basis for future, translational investigations of fructose-mediated lipid biosynthesis. These experiments employ an established, immortal and metabolically active human hepatocellular carcinoma cell line, Huh7, used extensively in studies of hepatocyte metabolism. The studies herein were carried out to determine whether hepatocyte lipogenesis, in an *in vitro* cell culture model, is modulated by adjusting culture media monosaccharide content and concentration.

### Innovations and breakthroughs

The results of these experiments clearly demonstrate, in a stable, *in vitro* hepatocyte culture model, at constant monosaccharide concentrations (glucose  $\pm$  fructose), by increasing the culture medium fructose to glucose molar ratio, but not by increasing glucose alone, significant enhancement of lipogenesis.

### Applications

The observation that fructose exerts a promoting influence on lipid synthesis, confirms prior studies suggesting the significant role of this monosaccharide in the development and/or exacerbation of hepatic steatosis. These studies, therefore, support the need for further investigations into the mechanisms and extent of fructose-mediated, *de novo* hepatic lipogenesis. Most important, these results provide a basis for future, clinical studies of fructose's role in development of hepatic steatosis and non-alcoholic liver disease.

### Terminology

Huh7 cells, an immortal, stable hepatocyte line, derived from human hepatocellular carcinoma. These cells take-up both glucose and fructose, and have been used extensively in studies of hepatic metabolism.

### Peer-review

This is an interesting study that reveals fructose is linked to lipogenesis in a concentration dependent way.

## Abstract

**AIM:** To show that aluminum potassium sulfate and tannic acid (ALTA) sclerotherapy has a high success rate for Grade II and III hemorrhoids.

**METHODS:** This study was based on the clinical data of 604 patients with hemorrhoids who underwent ALTA sclerotherapy between January 2009 and February 2015. The objective of this study was to assess the efficacy of this treatment for Grades II and III hemorrhoids. Preoperative and postoperative symptoms, complications and success rate were all assessed retrospectively. Follow-up consisted of a simple questionnaire, physical examination and an anoscopy. Patients were followed-up at one day, one week, two weeks, one month, one year, two years, three years, four years and five years after the ALTA sclerotherapy.

**RESULTS:** One hundred and sixty-nine patients were diagnosed with Grade II hemorrhoids and 435 patients were diagnosed with Grade III hemorrhoids. The one year, three year and five year cumulative success rates of ALTA sclerotherapy for Grades II and III hemo-

rrhoids were 95.9% and 93.1%; 89.3% and 83.7%; and 89.3% and 78.2%, respectively. No significant differences were observed in the cumulative success rates after ALTA sclerotherapy between Grades II and III hemorrhoids ( $P = 0.09$ ). There were forty-seven post-operative complications (low grade fever; anal pain; urinary retention; rectal ulcer; and others). No serious or life-threatening complications occurred and all cases improved through conservative treatment. At univariate analysis there were no predictive factors of failure.

**CONCLUSION:** ALTA sclerotherapy has had a high success rate for Grade II and III hemorrhoids during five years of post-operative treatment. However, additional studies are needed to evaluate the efficacy of this ALTA sclerotherapy in the management of hemorrhoidal disease.

**Key words:** Sclerotherapy; Aluminum potassium sulfate and tannic acid; Goligher grade III; Minimally invasive treatment; Hemorrhoid

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Since 2000, aluminum potassium sulfate and tannic acid (ALTA) sclerotherapy has been frequently performed in Japan for internal hemorrhoids as a minimally invasive treatment. This study affirms that ALTA sclerotherapy is an effective and safety treatment for Goligher Grades II and III hemorrhoids because of the high cumulative success rate and no serious complications during post-operative treatment.

Aluminum potassium sulfate and tannic acid sclerotherapy for Goligher Grades II and III hemorrhoids: Results from a multicenter study. *World J Hepatol* 2016; 8(20): 844-849 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i20/844.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i20.844>

## INTRODUCTION

Hemorrhoids are the most common anorectal disease world-wide. The term "hemorrhoidal disease" can be employed when hemorrhoidal tissue gives rise to symptoms such as bleeding, prolapse, or pruritus<sup>[1]</sup>. Etiologic factors are multi-factorial and include prolonged straining, irregular bowel habits and heredity. Supporting connective tissue degenerates and hemorrhoidal cushions slide as a consequence.

Conservative treatment based on lifestyle changes such as dietary and exercise and laxatives can help the majority of patients, and rubber band ligation, sclerotherapy and phlebotonic drugs can effectively treat Grades I and II hemorrhoids<sup>[2]</sup>. Surgical treatment is required for the most advanced stages, Grade III or IV and bleeding. There are several methods of surgical treatment for hemorrhoids: Conventional hemorrhoidectomy

(CH), stapled hemorrhoidopexy (PPH), and trans-anal hemorrhoidal dearterialization (THD)<sup>[1-4]</sup>.

Among them, PPH and THD aim to correct the underlying pathophysiological mechanisms involved in the etiology of hemorrhoids. These treatments are painless treatment, because of the sparing of the anoderm. Although an increased risk of recurrence is the price to pay for these minimally invasive treatments, a rapid return to normal life without pain are greatly appreciated by patients<sup>[5]</sup>.

On the other hand, new and effective sclerosant named aluminum potassium sulfate and tannic acid (ALTA) has been developed in Japan. ALTA sclerotherapy has been frequently performed in Japan for internal hemorrhoids as a minimally invasive treatment<sup>[6-9]</sup>. Nowadays in Japan, ALTA sclerotherapy for internal hemorrhoids has been performed in over 300000 cases.

In this report, we present effective results of ALTA sclerotherapy for Grades II and III hemorrhoids, according to the five year follow-up for this multi-center study.

## Indication for ALTA sclerotherapy

ALTA sclerotherapy was performed on all patients with internal hemorrhoids except for the following: Patients with associated acute inflammatory internal hemorrhoids and acute irreducible hemorrhoids; patients with serious cardiac, hepatic, renal, and hematological diseases; pregnant women or women who may be pregnant; nursing mothers; and patients with a past history of hypersensitivity to local anesthetics.

## MATERIALS AND METHODS

The medical records of 604 patients with hemorrhoidal disease who underwent ALTA sclerotherapy at four institutions from January 2009 to February 2015 were analyzed. All patients underwent clinical evaluation and physical examination including digital examination and proctoscopy for diagnosis of hemorrhoid engorgement and easy-bleeding, prolapsing hemorrhoids. The severity of hemorrhoidal disease was graded according to Goligher's classification.

Patients assumed the lithotomy position or Sims' position. Zero point five percent Lidocaine 10 mL was injected around sphincter muscle. The concentration of ALTA solution is set by, Mitsubishi Tanabe Pharma Corporation, Osaka, Japan. Procedures were undertaken under local anesthesia using the Z-type proctoscope (ARAKAWA SEISAKUJO, Tokyo, Japan) with a distally opening window that allowed for the application of an injection into the rectal mucosa. An ALTA four-step injection was performed<sup>[7]</sup>. The method used for the ALTA four-step injection was to inject four times, once into each of the following parts of the primary hemorrhoid: The superior part; the central deep and slight parts; and the inferior part above the dentate line.

## Assessment and post-operative follow-up

All data were retrospectively collected from medical

**Table 1** The characteristics of patients with Grades II and III hemorrhoids

Goligher classification	Grade II	Grade III	Statistical significance
Number	169	435	
Gender			
Male	103	231	NS
Female	66	204	
Age (yr)	58 ± 18	59 ± 16	NS
Injection dose of ALTA (mL)	13.4 ± 5.2	21.5 ± 6.8	$P < 0.0001$
Operative time	14 ± 8	16 ± 7	$P = 0.0020$

NS: Not significant; ALTA: Aluminum potassium sulfate and tannic acid.

**Figure 1** The cumulative success rate of aluminum potassium sulfate and tannic acid sclerotherapy. At one year, three years and five years after ALTA sclerotherapy, the cumulative success rate of Grades II and III were 95.9% and 93.1%; 89.3% and 83.7%; and 89.3% and 78.2%, respectively. ALTA: Aluminum potassium sulfate and tannic acid.

record. Patients took oral analgesia (loxoprofen or acetaminophen) at three days post operation. They were followed-up at one day, one week, two weeks, one month, one year, two years, three years, four years and five years after the ALTA sclerotherapy. Follow-up consisted of a simple questionnaire, physical examination and an anoscopy. Effects were defined as follows: (1) cure (after bowel movement there is no prolapse of the hemorrhoids, hemorrhage or other discomfort; and on examination with an anoscope, atrophied internal hemorrhoids have disappeared); (2) improvement (after bowel movement, some hemorrhoids prolapse but return into the anal canal spontaneously; occasional blood or hemorrhage with bowel movements; and an anoscopic examination reveals some internal hemorrhoids still visible); and (3) failure (no improvement, or some hemorrhoids prolapsed and did not return into the anal canal spontaneously).

### The action mechanism of ALTA

ALTA compounds with aluminum potassium sulfate and tannic acid. The aluminum ion induces a strong local inflammatory reaction, resulting in fibrosis<sup>[10,11]</sup>. Tannic acid has a strong astringent effect on tissue, promoting protein coagulation and the contraction of blood vessels, while reducing exudation into tissue from the inflammatory reaction<sup>[10,11]</sup>. These actions tend to prevent tissue necrosis, and promote sclerosis, adhesion of hemorrhoidal

**Table 2** Prognostic factors associated with the recurrence of hemorrhoids after aluminum potassium sulfate and tannic acid sclerotherapy

Prognostic factor	Relative risk (95%CI)	P value
Age	0.997 (0.981-1.012)	0.6567
Gender	0.800 (0.469-1.365)	0.4124
Goligher grade	1.768 (0.897-3.483)	0.0997
Operation time	0.974 (0.941-1.010)	0.1542
ALTA injection dose	0.976 (0.941-1.012)	0.1901
Complication	1.293 (0.469-3.564)	0.6189

ALTA: Aluminum potassium sulfate and tannic acid.

tissue and immediate hemostasis and are also effective for the prolapse and bleeding of internal hemorrhoids early after injection.

## RESULTS

The characteristics of the patients involved in this study are shown in Table 1. From January 2009 until February 2015 ALTA sclerotherapy was performed on 604 patients with second or third degree hemorrhoids. There were three 334 men and 270 women. The age range (mean ± SD) of the patients with Grades II and III hemorrhoids was 58 ± 18 years and 59 ± 16 years, respectively. Overall, 169 patients had Grade II hemorrhoids and 435 had Grade III hemorrhoids. The total injection dose of ALTA (mean ± SD) for Grades II and III was 13.4 ± 5.2 mL and 21.5 ± 6.8 mL, respectively. The operative time (mean ± SD) of Grades II and III was 14 ± 8 min and 16 ± 7 min, respectively. All the operations were performed under local anesthesia during either day surgery or a one day hospital stay.

Prolapses and bleeding disappeared immediately after ALTA sclerotherapy. All cases with bleeding or prolapses were cured or there was improvement after the first post-operative month. At one year after treatment, the rate of successful resolution of bleeding or prolapse of Grades II and III was 95.9% and 93.1%, respectively. The three year and five year cumulative success rates of ALTA sclerotherapy for Grades II and III hemorrhoids were 89.3% and 83.7%; and 89.3% and 78.2%, respectively. At one year after treatment, the rate of failure of Grades II and III was 4.1% and 6.9%, respectively. The three year and five year cumulative failure rates of ALTA sclerotherapy for Grades II and III hemorrhoids were 10.7% and 16.3%; and 10.7% and 21.8%, respectively. No significant differences were observed in the cumulative success rates after ALTA sclerotherapy between Grades II and III hemorrhoids ( $P = 0.09$ ) (Figure 1). There were 47 post-operative complications (low grade fever; anal pain; urinary retention; rectal ulcer; and others). No serious or life-threatening complications occurred and all cases improved through conservative treatment. At univariate analysis there were no predictive factors of failure (Table 2). However, the only factor associated with a recurrence may be the grade of hemorrhoids ( $P = 0.09$ ).

THD: Trans-anal hemorrhoidal dearterialization; DGHAL: Doppler-guided hemorrhoidal arterial ligation; SH: Stapled hemorrhoidopexy; RAR: Rectoanal repair; CH: Conventional hemorrhoidectomy; ALTA: Aluminum potassium sulfate and tannic acid.

## DISCUSSION

The ideal operation for hemorrhoids should be effective with a low rate of recurrence; minimal post-operative pain to allow early return to normal activities; and safe with minimal morbidity<sup>[12]</sup>. The treatment for internal hemorrhoids is gradually shifting to minimally invasive surgery. CH has been used to be the most widely performed surgical procedure till now. Although CH was very effective, it was painful and potentially affected the mechanism of anal continence. Over the years, alternative minimally invasive techniques have been developed including stapled hemorrhoidopexy, also known as PPH, and trans-anal hemorrhoidal dearterialization, also known as THD<sup>[1,3-5]</sup>. In Japan, new sclerosant, ALTA, has been developed. Takano *et al*<sup>[6]</sup> reported that ALTA (OC-108) sclerotherapy was effective for Grades II, III, and IV internal hemorrhoids. In recent years in Japan, ALTA sclerotherapy has become gradually recognized as minimally invasive treatment for internal hemorrhoids.

In Japan, ALTA sclerotherapy is popular with patients with symptomatic internal hemorrhoids, because unpleasant symptoms disappear immediately on the first post-operative day in almost all cases<sup>[7]</sup>, and patients experience little post-operative pain and no serious complications<sup>[6-9]</sup>. ALTA sclerotherapy could be performed on patients with Grades II and III hemorrhoids in an outpatient clinic. Patients are highly satisfied with ALTA sclerotherapy as a treatment for internal hemorrhoids. Our previous study demonstrated that overall patient satisfaction at one month and one year after ALTA sclerotherapy was 97.7%<sup>[13]</sup>. In the Japanese literature, Matsuda *et al*<sup>[14]</sup> reported that the overall satisfaction of ALTA sclerotherapy was over 90% and concluded that ALTA sclerotherapy matched the needs of patients with symptomatic internal hemorrhoids. Minimally invasive treatments such as PPH, THD, or Doppler-guided hemorrhoidal arterial ligation (DGHAL) are acceptable

treatments. But, if recurrence is the main consideration, CH is still considered the best<sup>[15]</sup>. A recent systematic review of 27 randomized controlled trials demonstrated that, compared with CH, PPH had less pain, shorter operative time, and quicker patient's recovery of patient, but a significantly higher rate of prolapse and reintervention for prolapse<sup>[16]</sup>. The recurrence rate and additional operation rate related to each technique were summarized in Table 3. Although the follow-up time was different, the recurrence rate and/or additional operation rate of CH, stapled hemorrhoidopexy, THD, DGHAL with rectoanal repair and ALTA was 0%-2%, 7.5%-13%, 0%-14%, 4%-10.34% and 3.6%-16%, respectively<sup>[4-7,17-24]</sup>. In this study, the one year cumulative rate for the successful resolution of bleeding or prolapse of Grades II and III was 95.9% and 93.1%, respectively. The five year cumulative success rate of ALTA sclerotherapy for Grades II and III hemorrhoids was 89.3% and 78.2%, respectively. ALTA sclerotherapy has had a high success rate for Grades II and III hemorrhoids during the five years post treatment.

Vidal *et al*<sup>[25]</sup> reported a new concept for the treatment of hemorrhoids with arterial embolization. Fourteen patients with disabling chronic rectal bleeding were treated using the emborrhoid technique. Although 10 patients had coagulation disorders (anticoagulants or cirrhosis), coil embolization of the superior rectal arteries is technically feasible, safe and well tolerated. Yano *et al*<sup>[26]</sup> reported that among patients with hemorrhoids receiving anticoagulant, ALTA sclerotherapy was recommended for those in whom it was difficult to discontinue anticoagulant. Miyamoto *et al*<sup>[27]</sup> reported the efficacy and safety of ALTA sclerotherapy for hemorrhoidal patients with liver cirrhosis.

In conclusion, ALTA sclerotherapy is an effective treatment for Grades II or III hemorrhoids. ALTA sclerotherapy might revolutionize the present state of hemo-

hemorrhoid treatment and be the ideal method for symptomatic internal hemorrhoids needed surgery. However, additional studies are needed to evaluate the efficacy of this ALTA sclerotherapy in the management of hemorrhoidal disease.

## COMMENTS

### Background

Aluminum potassium sulfate and tannic acid (ALTA) sclerotherapy is intended to shrink and harden internal hemorrhoids to eliminate hemorrhoidal prolapse and bleeding. ALTA sclerotherapy has been recognized as minimally invasive treatment for symptomatic internal hemorrhoid in Japan. The effectiveness of ALTA sclerotherapy, which shrinks and hardens internal hemorrhoids, is permanent.

### Research frontiers

There are few reports of clarifying long time follow-up after ALTA sclerotherapy. The results of this study contribute to clarifying the effectiveness of ALTA sclerotherapy for Grade II or III hemorrhoids with five-year follow-up.

### Innovations and breakthroughs

In this study, ALTA sclerotherapy is an effective treatment for Grades II or III hemorrhoids. The one-year, three-year and five-year cumulative success rates of ALTA sclerotherapy for Grades II and III hemorrhoids were 95.9% and 93.1%; 89.3% and 83.7%; and 89.3% and 78.2%, respectively. ALTA is an epoch-making sclerosant. ALTA sclerotherapy might be an effective sclerotherapy for symptomatic internal hemorrhoids needed surgery.

### Applications

This study suggests that ALTA sclerotherapy is an effective treatment for Grades II or III hemorrhoids. If a patient is diagnosed with Grade II or III hemorrhoids, ALTA sclerotherapy can be chosen.

### Peer-review

This is an interesting manuscript describing a relatively new minimally invasive treatment of hemorrhoids. The paper has a good number of cases and it is well designed.

## Abstract

**AIM:** To evaluate the efficacy and safety of transjugular intrahepatic portosystemic shunt (TIPS) combined with stomach and esophageal variceal embolization (SEVE) in cirrhotic patients with a large gastroduodenal vessel shunt (GRVS).

**METHODS:** Eighty-one cirrhotic patients with gastric variceal bleeding (GVB) associated with a GRVS were enrolled in the study and accepted TIPS combined with SEVE (TIPS + SEVE), by which portosystemic pressure

gradient (PPG), biochemical, TIPS-related complications, shunt dysfunction, rebleeding, and death were evaluated.

**RESULTS:** The PPGs before TIPS were greater than 12 mmHg in 81 patients. TIPS + SEVE treatment caused a significant decrease in PPG (from  $37.97 \pm 6.36$  mmHg to  $28.15 \pm 6.52$  mmHg,  $t = 19.22$ ,  $P < 0.001$ ). The percentage of reduction in PPG was greater than 20% from baseline. There were no significant differences in albumin, alanine aminotransferase, aspartate aminotransferase, bilirubin, prothrombin time, or Child-Pugh score before and after operation. In all patients, rebleeding rates were 3%, 6%, 12%, 18%, and 18% at 1, 3, 6, 12, and 18 mo, respectively. Five patients (6.2%) were diagnosed as having hepatic encephalopathy. The rates of shunt dysfunction were 0%, 4%, 9%, 26%, and 26%, at 1, 3, 6, 12, and 18 mo, respectively. The cumulative survival rates in 1, 3, 6, 12, and 18 mo were 100%, 100%, 95%, 90%, and 90%, respectively.

**CONCLUSION:** Our preliminary results indicated that the efficacy and safety of TIPS + SEVE were satisfactory in cirrhotic patients with GVB associated with a GRVS (GVB + GRVS).

**Key words:** Transjugular intrahepatic portosystemic shunt; Cirrhosis; Gastric varices; Variceal embolization; Gastroduodenal shunt

**Core tip:** The optimal treatment of gastric variceal bleeding (GVB) + gastroduodenal vessel shunt (GRVS) remains uncertain. Transjugular intrahepatic portosystemic shunt (TIPS) alone cannot be widely used in the treatment of GVB + GRVS. Some studies have evaluated the short-term outcomes of cirrhosis treated with TIPS combined with variceal embolization. In this study, we found that the efficacy and safety of TIPS + stomach and esophageal variceal embolization were satisfactory for patients with GVB + GRVS.

Jiang Q, Wang MQ, Zhang GB, Wu Q, Xu JM, Kong DR. Transjugular intrahepatic portosystemic shunt combined with esophagogastric variceal embolization in the treatment of a large gastroduodenal shunt. *World J Hepatol* 2016; 8(20): 850-857 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i20/850.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i20.850>

## INTRODUCTION

Although the rate of gastric variceal bleeding (GVB) is significantly lower than that of esophageal variceal bleeding (EVV)<sup>[1,2]</sup>, it is usually more severe, requires more transfusions, and is associated with higher mortality than EVV<sup>[1-3]</sup>. Currently, the optimal treatment of GVB re-

mains a difficult issue for clinicians. In terms of recommended therapy for gastric varices, there are various primary options, including surgery, endoscopic variceal obturation with tissue adhesive, Transjugular intrahepatic portosystemic shunt (TIPS) placement, and balloon-occluded retrograde transvenous obliteration<sup>[4,5]</sup>. First-line therapies for gastric varices are endoscopically administered tissue adhesives and TIPS placement.

GVB is often associated with a gastroduodenal vessel shunt (GRVS)<sup>[6]</sup>. The safety of endoscopically-administered tissue adhesives in patients with GVB + GRVS is controversial, due to potential cerebral or pulmonary embolism secondary to migration of cyanoacrylate into the systemic circulation through GRVS<sup>[7]</sup>. TIPS placement has been widely accepted as an effective and safe treatment for GVB in cirrhotic patients<sup>[4,8]</sup>. However, because the portosystemic pressure gradient (PPG) in patient with GVB + GRVS is lower than that in patient with EV, TIPS placement alone is seldom used in the treatment of GVB + GRVS<sup>[9-13]</sup>.

Recent years, some studies have shown that TIPS combined with variceal embolization prevented recurrent variceal bleeding and improved liver function<sup>[14,15]</sup>. However, there are no similar studies to evaluate the effectiveness of a combination of these two methods for patients with GVB + GRVS. The aim of this study was therefore to evaluate the efficacy and safety of TIPS + SEVE for patients with GVB + GRVS.

## MATERIALS AND METHODS

### Patients

Between October 2013 and December 2015, a total of 107 patients in whom TIPS + SEVE had been successfully performed in our hospital were recruited for this study. Inclusion criteria were as follow: (1) age > 18 years; (2) history of cirrhosis and GVB (based on findings of histological or typical cross-sectional imaging, such as ultrasound, endoscopy, computed tomography, or magnetic resonance imaging); and (3) patients was diagnosed as having GRVS by computed tomography angiography (CTA). Exclusion criteria were: (1) hepatocellular carcinoma or other malignancies; (2) chronic renal failure; (3) portal vein thrombosis; (4) infection; and (5) coagulation disorder. Of the 107 patients, 26 with EVB or GVB without GRVS were excluded from this study. Thus, the final population for study consisted of 81 patients. The main clinical and biochemical characteristics of these 81 patients are presented in Table 1. All patients provided their informed written consent. The study was conducted in accordance with the ethical principles of the Declaration of Helsinki and was approved by the Ethics Committee of Anhui Medical University.

### Procedural protocol

Procedures were performed with general anesthesia in the angiography suite. The procedure of TIPS + SEVE has been described previously<sup>[14-16]</sup>. Briefly, before cath-

PPG: Portosystemic pressure gradient.

terization of the hepatic vein was performed through the right internal jugular vein, inferior vena cava pressure was measured when the tip of the catheter floated in the inferior vena cava at the junction with the hepatic vein. A needle and guide-wire were advanced through the liver parenchyma into a branch of the portal vein with fluoroscopic guidance, which was then followed by direct portography and measurement of portal vein pressure. A catheter was passed into the gastroesophageal collateral vessels and embolization of the collateral vessels was initiated, which formed coils of varying diameters and resulted in the disappearance of varices at post-embolization angiography. The catheter was then exited *via* the liver parenchyma. After the parenchymal tract between the hepatic vein and portal vein was dilated with an angioplasty balloon catheter, the patency of the TIPS was facilitated by deployment of a covered stent (8 mm in diameter, BARD E LUMINEXX Vascular Stent, France). The PPG was determined *via* the difference between the portal vein pressure and inferior vena cava pressure. The mid-chest was used as the external zero reference. Pressure tracings must remain stable for at least 30 s to be considered satisfactory. The mean value of two PPG measurements was used for analysis.

All patients received intravenous antibiotic prophylaxis 1 d before the procedure. Intravenous heparin was given as an anti-coagulate during the procedure and for 1 wk post-procedure, which then changed to oral aspirin and warfarin for 1 year. Oral lactulose was used to prevent

hepatic encephalopathy (HE).

### Follow-up

All patients were asked to enroll in the follow-up protocol. PPG, biochemical examination, TIPS-related complications, post-HE, primary patency, rebleeding, and death were recorded respectively. Patients were examined during follow-up with Doppler ultrasound, endoscopy, and CTA at 1, 3, 6, and 12 mo after TIPS placement and then every 6 mo thereafter. Patients suffering from HE, rebleeding, or any other severe complications were invited to our TIPS unit at any time. Liver functions were assessed by testing albumin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), bilirubin, prothrombin time (PT) levels, and Child-Pugh score at 1 wk before and 1 mo after TIPS. TIPS patency could be assessed by Doppler ultrasonography. Endoscopy confirmed sources of bleeding and variceal disappearance. CTA was used to define the GRVS. Patients were followed until death or liver transplantation, while first rebleeding, first HE, and first shunt insufficiency were followed-up on to a maximum of 2 years after the procedure (closure date: December 31, 2015).

### Definitions

The following definitions were used: (1) rebleeding: Any subsequent hematemesis or melena confirmed endoscopically; (2) HE: Diagnosis of HE was made according to the final report of the 1998 Working Party at the 11<sup>th</sup> World Congress of Gastroenterology in Vienna<sup>[17]</sup>, and patients with clinical evidence of HE were classified according to the West Haven criteria grades: HE  $\geq$  grade I; (3) shunt dysfunction<sup>[18]</sup>: Doppler criteria for shunt insufficiency was that maximal flow velocity was less than 50 cm/s or that there was an absence of flow within the shunt. Suspected shunt dysfunction was confirmed by portography that showed shunt stenosis > 50%; (4) primary patency: The absence of shunt insufficiency without intervention during TIPS surveillance; and (5) endoscopic findings of esophagogastric varices were recorded as proposed by the Japanese Society for portal hypertension<sup>[19]</sup>.

### Statistical analysis

The data were expressed as means  $\pm$  SD. Quantitative variables were compared using Student's *t* test. The rates of primary patency, HE, survival, and variceal rebleeding were analyzed using Kaplan-Meier analyses. A statistically significant difference was assessed for any of the analyses with results of *P* < 0.05. Analyses were performed using the SPSS 10.0 software package.

## RESULTS

### Basic data

Table 2 summarizes the basic clinical and biochemical characteristics of patients. As shown, the PPG before TIPS placement was greater than 12 mmHg in all patients. The mean PPG dropped from 37.97  $\pm$  6.36 mmHg to

**Table 2** Comparison of main biochemical data and porto-systemic pressure gradient before and after the transjugular intrahepatic portosystemic shunt + stomach and esophageal variceal embolization

	Before TIPS	After TIPS	P
Albumin (mg/dL)	32.24 ± 5.88	33.90 ± 7.26	0.199
ALT (u/L)	30.00 ± 17.51	30.85 ± 20.60	0.806
AST (u/L)	38.00 ± 25.95	41.88 ± 24.03	0.318
Bilirubin (mg/dL)	1.41 ± 0.76	1.45 ± 0.65	0.561
PT (%)	52 ± 14	51 ± 15	0.903
Creatinine (mg/dL)	1 ± 0.3	1 ± 0.4	0.58
Child-Pugh score	6.91 ± 1.44	6.79 ± 1.34	0.563
PPG (mmHg)	38.0 ± 6.4	28.2 ± 6.5	< 0.001

PPG: Portosystemic pressure gradient; TIPS: Transjugular intrahepatic portosystemic shunt; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; PT: Prothrombin time.

28.15 ± 6.52 mmHg after TIPS ( $t = 19.22$ ,  $P < 0.001$ ), with reductions in PPG greater than 20% from baseline. There were no significant differences in albumin, ALT, AST, bilirubin, PT, or Child-Pugh score 1 wk before or 1 mo after operation.

### Rebleeding

Rebleeding from the upper gastrointestinal tract occurred in ten patients (12.3%) after TIPS placement. One patient had 4 U of blood transfused within 24 h after the TIPS procedure, with no symptoms of rebleeding observed thereafter. The cumulative rates of rebleeding (Kaplan-Meier estimation) after 1, 3, 6, 12, and 18 mo were 3%, 6%, 12%, 18%, and 18%, respectively. The actual probability of rebleeding is presented in Figure 1. One patient underwent tissue adhesive administration 6 mo after TIPS implantation and is, at the time of writing, alive and free of rebleeding. One patient was found to have portal hypertensive gastropathy, which resulted in rebleeding. The other rebleeding patients were found to have shunt stenosis or obstruction.

### Survival

Five patients died within the follow-up period because of procedure-related complications. In one patient, a shunt obstruction was observed 6 mo after TIPS placement; the patient refused intervention treatment and died seven months after TIPS due to recurrent bleeding. The other four patients died 5 to 12 mo after TIPS placement. The cumulative rates of survival (Kaplan-Meier estimation) after 1, 3, 6, 12, and 18 mo were 100%, 100%, 95%, 90%, and 90%, respectively. Survival curves are shown in Figure 2.

### HE

Five patients experienced HE sometimes before the operation and were also diagnosed as having HE after TIPS placement. A protein-restricted diet and/or lactulose treatment were given to prevent the recurrence of HE. The cumulative rates of HE (Kaplan-Meier estimation) after 1, 3, 6, 12, and 18 mo were 9%, 13%, 18%, 18%,

and 18%, respectively (Figure 3).

### Primary shunt patency

The cumulative rates of primary shunt patency (Kaplan-Meier estimation) after 1, 3, 6, 12, and 18 mo were 100%, 96%, 91%, 74%, and 74%, respectively (Figure 4). During the follow-up period, 10 (12.3%) patients were diagnosed as having shunt stenosis or obstruction, of which 8 patients successfully underwent shunt recanalization with balloon angioplasty. Although one patient with shunt obstruction died 7 mo after TIPS (as previously mentioned), at the time of writing, the remaining patients are alive and well, albeit with one patient who had to receive anticoagulant therapy.

### Other complications

During the follow-up period, the rare complication of hepatic myelopathy (HM) occurred in two patients 6 to 8 mo after the TIPS procedure, which exerted a significant impact on their mobility and quality of life. Due to economic factors, the patients received conservative medical treatment and are, at the time of writing, alive.

## DISCUSSION

The rate of GVB is significantly lower than that of EVB<sup>[1,2]</sup>, but is usually more severe, requires more transfusions, and is associated with higher mortality than EVB<sup>[1-3]</sup>. Currently, the optimal treatment of GVB remains a difficult issue for clinicians.

Variceal embolotherapy has been recognized as an efficient method for preventing bleeding caused by portal hypertension<sup>[19,20]</sup>, while TIPS is used worldwide for the prevention of variceal bleeding<sup>[4,5,8]</sup>. Previous studies have advocated TIPS combined with variceal embolization in the prevention of recurrent variceal bleeding and improvement of liver function<sup>[14,15]</sup>. However, there are no similar studies evaluating the combination of these two methods in patients with GVB + GRVS.

In the current study, we found that the PPG before TIPS placement was greater than 12 mmHg in patients with GVB + GRVS. All included patients had previously experienced at least one instance of bleeding. Ou *et al*<sup>[21]</sup> found that 35% (14/40) of patients with GVB had a PPG ≤ 12 mmHg at the time of TIPS<sup>[22]</sup>. The differing results may be related to the number of cases and the size of spontaneous GRVS in our study, despite previous studies illustrating that PPG appears to correlate inversely with the presence and size of spontaneous GRVS<sup>[6,21]</sup>; to date, there have been no attempts to measure the size of GRVS and the definition of GRVS size remains as yet undetermined.

It has been reported that patients with strong GVB have a lower PPG than those with EV, which may be a result of GRVS development<sup>[6,23]</sup>. Several studies have found that decompressive methods such as TIPS do not seem to confer much of a benefit for GVB + GRVS<sup>[9-13]</sup>. Our results suggest that the rebleeding rate after TIPS was 12% after 1 year, which was similar to the typically

Figure 1 Graph of Kaplan-Meier estimation of cumulative percentages of rebleeding.

Figure 2 Kaplan-Meier plot shows the rates of survival after transjugular intrahepatic portosystemic shunt placement.

reported result of between 10% to 40%<sup>[24,25]</sup>, while the reduction in PPG was greater than 20% from the baseline. Moreover, we noticed that TIPS + SEVE may reduce the risk of rebleeding. It should be noted that previous studies of TIPS differed from our own in that they used bare stents with TIPS alone placement or did not limit the stent diameter. In our study, all patients underwent decompressive operation and embolotherapy *via* coil, as well as the embolization of extensive collateral circulation (such as that of the short or posterior gastric vein), which may contribute to the occlusion of GRVS. All covered stents were dilated to 8 mm, which may be regarded as limited shunts that accord with natural hemodynamic features.

Survival is usually regarded as the strongest evidence

Figure 3 Actuarial probability of hepatic encephalopathy in 81 patients treated with transjugular intrahepatic portosystemic shunt + stomach and esophageal variceal embolization.

Figure 4 Graph of Kaplan-Meier estimation of cumulative percentages of patients with primary shunt patency in all patients undergoing transjugular intrahepatic portosystemic shunt + stomach and esophageal variceal embolization.

for evaluating the effectiveness of a therapy. In previous studies, total survival 1-year post-TIPS ranged from 58% to 80% and depended mainly on the severity of the underlying liver disease<sup>[25,26]</sup>. The survival rate was 94% at 1 year in our study; such a high rate may be related to the patients' liver function (76.5% patients with Child-Pugh class A or B). Although our results support patients with Child-Pugh class C as well, TIPS placement should be used with extreme caution. Taken together, improving liver function before TIPS may increase the survival rates.

TIPS has been extensively used within the last 20 years. Previous studies showed that TIPS increases the

incidence of HE without improving survival<sup>[27-29]</sup>, which may be the reason why it is currently only recommended as a rescue therapy. HE has been reported to occur in 16%-31% of patients who receive a TIPS in the presence of GVB + GRS<sup>[30]</sup>. Our results indicated that 15% of our patients were diagnosed as having HE after TIPS placement, which is very similar to the reports of other studies, and that only one patient required admission. Importantly, our results were attributed to three effective improvements. First, oral lactulose was used to prevent HE after operation. Second, the left portal vein could be successfully punctured in 58% patients. As we know, the left portal vein receives blood from the splenic vein and inferior mesenteric vein, which have fewer digestive products but more electrolytes. Most recent studies have illustrated that introducing TIPS to the left portal vein instead of the right portal vein could decrease the risk of HE<sup>[31-33]</sup>. Third, 8 mm stents were used in patients. It has been previously reported in the literature that the incidence of portosystemic HE increased with increasing diameter of the stent<sup>[31]</sup>.

It has been shown that occlusion and stenosis are the main disadvantages of TIPS. Studies have demonstrated that stent insufficiency occurs in 14% to 82% of patients by 1 year post-TIPS<sup>[25,33]</sup>. Our findings suggest that 12% of patients in our study were diagnosed as having stenosis or obstruction one year after TIPS; our results therefore showed higher patency rates when compared to historical data. It was reported that the routine administration of anticoagulants and the use of covered stents play important roles in the improved patency rate<sup>[34-36]</sup>. Thus, the higher patency rate of our patients was partially attributed to the use of covered stents and anticoagulant therapy. Other possible reasons for our results are that patients were regularly followed-up on and that TIPS was placed in the left portal vein.

During the follow-up period, two patients were diagnosed with HM, in which the spontaneous shunt found by CTA was not completely closed. Embolization only with coils may be an insufficient embolization factor that was thought to be secondary to the increased systemic circulation of shunting portal venous toxins from the hypoperfusion and ischemia of the hepatocytes. Studies showed that a liver transplant could fully reverse the effects of HM in patients with early stage disease<sup>[37,38]</sup>, however, due to economic factors, patients only received conservative medical treatment. Despite previous studies advocating TIPS combined with variceal embolization to improve liver function<sup>[15,39]</sup>, there were no significant differences in liver functions before and after TIPS placement in our study.

In spite of these results, we may conclude that PPG before TIPS placement may be greater than 12 mmHg in patients with GVB + GRVS, and that the efficacy and safety of TIPS + SEVE were satisfactory in these patients.

## ACKNOWLEDGMENTS

The authors thank all patients involved in this study. We

would also like to thank Professor Keyang Chen, from the Temple University School of Medicine, for language assistance.

## COMMENTS

### Background

The optimal treatment for gastric variceal bleeding (GVB) + gastroduodenal vessel shunt (GRVS) is still controversial. Transjugular intrahepatic portosystemic shunt (TIPS) alone cannot be widely used in the treatment for GVB + GRVS. Previous studies have advocated TIPS combined with variceal embolization in order to prevent recurrent variceal bleeding and improve liver function. However, the efficacy and safety of TIPS + stomach and esophageal variceal embolization (SEVE) in patients with GVB + GRVS was unclear.

### Research frontiers

In recent years, more and more patients have undergone TIPS procedure to prevent variceal bleeding. For the use of the TIPS procedure, the research hot spot is how to increase the patient survival rate and reduce complications by bettering the patient selection and improving techniques. Interestingly, TIPS + SEVE may decrease portal pressure and embolize extensive collateral circulation, thereby potentially reducing the risk of rebleeding.

### Innovations and breakthroughs

Most GVB is associated with a GRVS. The efficacy of tissue adhesives in patients with GVB + GRVS is controversial, due to the potential for systemic embolism secondary to migration of cyanoacrylate into the systemic circulation through a GRVS. TIPS alone cannot be widely used in the treatment of GVB + GRVS. In the study, all patients underwent TIPS + SEVE with via coil, with extensive collateral circulation, such as short or posterior gastric vein, potentially contributing to the occlusion of GRVS. In this study, the authors found that the efficacy and safety of TIPS + SEVE were satisfactory in patients with GVB + GRVS.

### Applications

The results suggest that the efficacy and safety of TIPS + SEVE were satisfactory in patients with GVB + GRVS. Additional studies with long-term follow-up are needed to confirm the results.

### Peer-review

The authors have provided a well-designed study that shows the satisfactory efficacy and safety of combination TIPS + SEVE in cirrhotic patients with gastric variceal bleeding associated with a gastroduodenal vessel shunt.

### Abstract

The United States Food and Drug Administration recently warned that the direct acting antiviral (DAA) combination hepatitis C virus (HCV) treatment of Paritaprevir, Ombitasvir, Dasabuvir, Ritonavir, and Ribavirin (PODr + R) can cause severe liver injury in patients with advanced liver disease. Drug induced liver injury was observed in a small number of patients with decompensated cirrhosis treated with other DAAs, but has not been reported in patients with compensated cirrhosis. We report a case of a 74-year-old woman with chronic HCV and Child-Pugh class A cirrhosis (compensated cirrhosis) treated with PODr + R. The patient presented on day 14 of PODr + R therapy with jaundice and new-onset ascites. Her total bilirubin level increased to 23 mg/dL and international normalized ratio rose to 1.65, while aminotransferase levels remained relatively stable. Hepatitis C treatment was discontinued on day 24 and she gradually recovered. Follow-up testing showed that she achieved a sustained virologic response. In conclusion, hepatic decompensation developed within two weeks of starting treatment with

PODr + R in a patient with Child-Pugh class A cirrhosis and was characterized by jaundice and ascites with stable aminotransferase levels. Careful monitoring is warranted in patients with HCV-related cirrhosis treated with PODr + R.

**Key words:** Direct antiviral agent; Drug-induced liver injury; Hepatitis C; Mathematical modeling; Sustained virological response; Viral kinetics

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** To the best of our knowledge, this is the first report of hepatic decompensation in a hepatitis C patient with Child Pugh class A cirrhosis due to treatment with Paritaprevir, Ombitasvir, Dasabuvir, Ritonavir and Ribavirin (PODr + R). Liver aminotransferase levels did not increase prior to decompensation, depriving us of our usual alarm signs heralding hepatic decompensation. The patient achieved sustained virologic response despite very early discontinuation of therapy (day 24).

Hepatitis C virus cures after direct acting antiviral-related drug-induced liver injury: Case report. *World J Hepatol* 2016; 8(20): 858-862 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i20/858.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i20.858>

## INTRODUCTION

Globally, it was estimated that in 2005, more than 185 million people were anti-hepatitis C virus (HCV) seropositive (prevalence 2.8%)<sup>[1]</sup>. End-stage liver disease due to HCV is a leading indication for liver transplantation and accounts for almost 500000 deaths annually<sup>[2]</sup>. The growing proportion of patients with chronic HCV infection and cirrhosis has the highest priority for treatment, but are at risk for complications of liver disease<sup>[3]</sup>.

The interferon-free, 12-wk Paritaprevir, Ombitasvir, Dasabuvir, Ritonavir and Ribavirin (PODr + R) regimen is approved for the treatment of patients with Child's-Pugh class A cirrhosis and was shown to achieve a sustained virologic response (SVR) rate exceeding 90% in such patients<sup>[4]</sup>. However, on 10/22/15, an Food and Drug Administration (FDA) Drug Safety Communication warned that PODr + R can cause severe drug-induced liver injury (DILI) in patients with advanced liver disease<sup>[5]</sup>. Since December 2014, 26 cases of severe liver injury in patients with advanced liver disease were reported to the FDA Adverse Event Reporting System database that were considered probably or possibly related to PODr + R. Ten patients developed liver failure resulting in death or liver transplantation. The pattern of liver injury consisted of an acute increase in bilirubin level without alanine aminotransferase (ALT) elevations. The FDA

Drug Safety Communication emphasized that PODr + R is contraindicated in patients with Child's class B and C cirrhosis. More recently, four cases of severe DILI were identified in patients who had decompensated cirrhosis at pre-treatment baseline who were treated with sofosbuvir and a NS5A inhibitor, with or without Ribavirin<sup>[6-8]</sup>. Three of the patients were human immunodeficiency virus-co-infected and were receiving anti-retroviral therapy. To date, severe DILI has not been reported in patients with compensated cirrhosis who receive direct acting antiviral (DAA).

## CASE REPORT

A 74-year-old woman presented to Shaare Zedek Medical Center in Jerusalem on 12/30/14 for management of HCV genotype 1b infection with compensated cirrhosis (Child's Pugh class A-score 6, MELD score 7), and a 5.6 cm × 6.8 cm right lobe liver lesion with diagnostic features of hepatocellular carcinoma (HCC) on ultrasonography and contrast-enhanced computed tomography. Her baseline laboratory data are shown in Figure 1.

On 1/1/15 she underwent transcatheter arterial chemoembolization (TACE) as treatment for HCC. Her ALT and aspartate transaminase levels increased transiently and then declined to baseline (Figure 1B). She showed no signs of hepatic decompensation before or after the procedure. Treatment with Ombitasvir, Paritaprevir, Ritonavir (2 tablets daily), Dasabuvir (250 mg twice daily, and Ribavirin (400 mg, twice daily) was initiated on 3/1/15, two months after TACE. The HCV RNA level declined from a pre-treatment baseline of 2000000 IU/mL to 474 IU/mL in 7 d (Figure 2). However, on day 14 of treatment, she presented with nausea and increased abdominal girth. Her medications were limited to PODr + R and Ramipril for hypertension, which she had taken for four months. She reported taking no other prescription, over the counter, or alternative medications during the four months prior to the onset of liver injury. She did not drink alcohol. On physical examination, she had icteric sclera and moderate ascites. She developed vomiting and anorexia. Serial laboratories showed a rising total bilirubin (maximum 23 mg/dL) and international normalized ratio (maximum 1.65) levels and her albumin level decreased to 2.5 g/dL (Figure 1A). Of note, her aminotransferase levels remained stable (Figure 1B). An abdominal ultrasound with Doppler study showed flow in the portal and hepatic veins and no new mass lesions in the liver.

Antiviral therapy was discontinued on treatment day 24 (3/24/15) for suspected DILI. The patient was hospitalized on 4/1/15 for management of ascites. After hospital discharge, she was treated with weekly intravenous albumin and Furosemide until November 2015. Her ascites slowly improved and her liver biochemistries normalized (Figure 1). Seven months after discontinuation of antiviral therapy, she has recovered and her HCV RNA remains undetectable (Figure 2). She

**Figure 1** Change in laboratories in relation to antiviral therapy (A) and in aminotransferase and Alkaline Phosphate levels over time (B). A: Change in laboratories in relation to antiviral therapy. Shortly after initiation of hepatitis C treatment, and after 4 mo of stable levels, laboratory values deteriorated indicating a decline in hepatic synthetic function; peak bilirubin - 23 mg/dL, PT/INR - 1.65, lactate-2.44 mg/dL, lowest albumin - 2.5 g/L. Shortly after treatment discontinuation, laboratory values slowly returned to baseline; B: Change in aminotransferase and alkaline phosphate levels over time. There was a spike in aminotransferase levels after the TACE procedure. Following HCV treatment initiation, aminotransferase levels declined over time, reaching plateau levels of AST = 40 U/L and ALT = 25 U/L. Aminotransferase levels remained stable when total bilirubin and PT/INR levels increased (shown in Figure 1A above). AST: Aspartate transaminase; ALT: Alanine aminotransferase; TACE: Transcatheter arterial chemoembolization; INR: International normalized ratio; PODr + R: Paritaprevir, Ombitasvir, Dasabuvir, Ritonavir, and Ribavirin; IV: Intravenous; PO: By mouth.

has no evidence of viable HCC by magnetic resonance imaging.

The time to reach cure, or SVR, was previously defined as the time to reach less than one hepatitis C virion in the extracellular fluid volume (approximately  $13.5\text{--}15\text{ L}$ )<sup>[9–12]</sup>. Thus a value of approximately  $3 \times 10^5$  IU/mL is the threshold for viral clearance (termed here cure boundary). The fact that the patient achieved SVR despite a very short course of therapy (24 d) was striking since her viral load level 10 d before DAA therapy stopped (3/15/15) was 97 IU/mL, which is several log IU/mL higher than the cure boundary. To estimate, retrospectively, when the patient reached cure we used the standard biphasic HCV treatment model<sup>[11,12]</sup> and the multiscale HCV treatment model<sup>[13,14]</sup>. Both these models predicted that cure occurred 3 to 6 wk after therapy was stopped (not shown).

## DISCUSSION

Herein we detail hepatic decompensation in a patient treated with PODr + R. The patient had Child's-Pugh class A cirrhosis prior to initiation of treatment and presented with jaundice and ascites 14 d after DAA therapy was started. Treatment was discontinued on day 24. She had a prolonged recovery and gradually returned to her baseline condition. She achieved SVR despite a truncated course of therapy. No causes of liver injury other than DAA were identified in the present case and the available data are consistent with the minimal elements for reporting DILI<sup>[15]</sup>.

The patient's presentation is consistent with the pattern of PODr + R-related liver injury reported by the FDA with an early onset of hyperbilirubinemia without a rise in ALT level<sup>[5]</sup>. Similarly, two cases of severe liver

**Figure 2** Hepatitis C virus RNA measurements over time. HCV RNA levels (circles) declined rapidly during treatment reaching not detected levels by the first measurement after treatment discontinuation and the patient achieved a sustained virologic response (SVR) defined as no detectable viral RNA 12 wk post treatment (purple line). HCV: Hepatitis C virus; PODr + R: Paritaprevir, Ombitasvir, Dasabuvir, Ritonavir, and Ribavirin.

injury in patients with decompensated cirrhosis treated with sofosbuvir and a NS5A inhibitor were characterized by a rising bilirubin level with stable ALT levels<sup>[6]</sup>. Aminotransferase levels were not reported in the other two sofosbuvir/NS5A inhibitor DILI cases<sup>[7,8]</sup>. It is critical that clinicians be aware that aminotransferase levels do not tend to rise prior to, or in parallel with bilirubin levels in patients with DAA-related DILI, as failure to recognize this pattern could delay recognition of severe liver injury and discontinuation of therapy.

The most novel and important feature of the present case is that the patient had well compensated liver disease before starting treatment with a Child Pugh score of 6 and a MELD score of 7. In contrast, the FDA Drug Safety Communication emphasized that PODr + R is contraindicated in patients with Child's Pugh class B and C cirrhosis. The current case provides evidence that patients with Child's Pugh class A cirrhosis are at risk for severe DILI with PODr + R.

Of interest, HCV was eradicated with only 24 d of treatment. Both the standard biphasic and the multiscale models of HCV kinetics during therapy suggest that cure might have occurred between 3 to 6 wk after therapy was stopped. While it is not feasible that the drugs had a prolonged direct antiviral effect, in theory the ongoing liver injury (*i.e.*, cell loss) and/or resulting inflammation might have exerted an immune mediated antiviral effect. Alternatively, cure might have occurred by the end of DAA therapy if the DAAs affected the ratio between non-infectious and infectious viral particles (*i.e.*, viral infectivity) as previously observed during HCV DAA treatment in cell culture<sup>[16]</sup>. That is, DAAs may reduce the infectivity of the virus particles produced such that only a small fraction of the viral RNA detected 10 d before drug cessation was infectious. This alternative explanation is also consistent with reports in which some patients treated with DAAs were documented to achieve SVR despite having detectable HCV RNA at end of treatment<sup>[17,18]</sup>. Further experimental and modeling efforts are needed to provide insights into the biological and/or immunological aspects that gave rise to HCV cure

after such short durations of DAA therapy<sup>[19]</sup>.

Our study has several limitations. Blood samples during therapy are not available for further measurements to test for superimposed acute viral infections such as hepatitis A or B or to measure paritaprevir concentration at the time of the rise in bilirubin. However, the temporal relation between PODr + R therapy and hepatic decompensation and recovery following discontinuation of therapy provides strong evidence for DILI.

Careful laboratory and clinical monitoring, beginning early in the course of therapy, is prudent in patients with compensated cirrhosis treated with PODr + R.

## COMMENTS

### Case characteristics

Patient suffered from jaundice, nausea and vomiting 14 d following treatment with Paritaprevir, Ombitasvir, Dasabuvir, Ritonavir, and Ribavirin (PODr + R).

### Clinical diagnosis

Aminotransferase levels did not increase. Despite that, Nausea, Vomiting, Ascites, Jaundice, hypoalbuminemia and coagulopathy occurred.

### Differential diagnosis

Ribavirin induced hemolysis, possible drug induced liver injury, recurrence of hepatocellular carcinoma (HCC), or vascular causes for hepatic failure. The authors performed liver ultrasonography to exclude Recurrence of HCC and vascular causes. Blood tests to exclude hemolysis as cause for jaundice were performed.

### Laboratory diagnosis

The authors witnessed increase in bilirubin levels, decrease in albumin levels and impaired coagulation tests with no increase in aminotransferase levels. Despite the above, eradication of hepatitis C virus was achieved (Figures 1 and 2).

### Imaging diagnosis

The authors performed liver ultrasonography to rule out recurrence of HCC or vascular causes as the cause of decompensation. Eventually magnetic resonance imaging scan was also performed as follow-up on HCC.

### Treatment

The main treatment in this case was discontinuation of PODr + R treatment. Albumin infusions and IV furosemide were administered.

## Term explanation

All acronyms are explained in the main text.

## Experiences and lessons

The new direct acting antiviral have an excellent safety record. Still, careful clinical and laboratory monitoring, beginning early in the course of therapy, is warranted especially in compensated cirrhotic patients treated with PODr + R because decompensation can occur without aminotransferase flareup.

## Peer-review

The author presents an interesting and valuable case report.

## Contents

Three issues per month Volume 8 Number 21 July 28, 2016

### EDITORIAL

- 863 New horizon for radical cure of chronic hepatitis B virus infection  
*Tajiri K, Shimizu Y*

### THERAPEUTIC ADVANCES

- 874 Hepatocellular carcinoma beyond Milan criteria: Management and transplant selection criteria  
*Elshamy M, Aucejo F, Menon KVN, Eghtesad B*

### TOPIC HIGHLIGHT

- 881 Contribution of alpha-fetoprotein in liver transplantation for hepatocellular carcinoma  
*Charrière B, Maulat C, Suc B, Muscari F*

### REVIEW

- 891 Acute renal injury after partial hepatectomy  
*Peres LAB, Bredt LC, Cipriani RFF*

### ORIGINAL ARTICLE

#### Basic Study

- 902 Anti-hepatitis C virus potency of a new autophagy inhibitor using human liver slices model  
*Lagaye S, Brun S, Gaston J, Shen H, Stranska R, Camus C, Dubray C, Rousseau G, Massault PP, Courcambeck J, Bassisi F, Halfon P, Pol S*

**ABOUT COVER**

Editorial Board Member of *World Journal of Hepatology*, Giovan Giuseppe Di Costanzo, Director, Division of Hepatology, AORN A Cardarelli, 80131 Napoli, Italy

**AIM AND SCOPE**

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

**INDEXING/  
ABSTRACTING**

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

### Abstract

About 250 to 350 million people worldwide are chronically infected with hepatitis B virus (HBV), and about 700000 patients per year die of HBV-related cirrhosis

or hepatocellular carcinoma (HCC). Several anti-viral agents, such as interferon and nucleos(t)ide analogues (NAs), have been used to treat this disease. NAs especially have been shown to strongly suppress HBV replication, slowing the progression to cirrhosis and the development of HCC. However, reactivation of HBV replication often occurs after cessation of treatment, because NAs alone cannot completely remove covalently-closed circular DNA (cccDNA), the template of HBV replication, from the nuclei of hepatocytes. Anti-HBV immune responses, in conjunction with interferon- $\gamma$  and tumor necrosis factor- $\alpha$ , were found to eliminate cccDNA, but complete eradication of cccDNA by immune response alone is difficult, as shown in patients who recover from acute HBV infection but often show long-term persistence of small amounts of HBV-DNA in the blood. Several new drugs interfering with the life cycle of HBV in hepatocytes have been developed, with drugs targeting cccDNA theoretically the most effective for radical cure of chronic HBV infection. However, the safety of these drugs should be extensively examined before application to patients, and combinations of several approaches may be necessary for radical cure of chronic HBV infection.

**Core tip:** Among the agents used to treat chronic hepatitis B virus (HBV) infection are nucleos(t)ide analogues, which have been shown to strongly suppress HBV replication. HBV replication, however, may be reactivated after cessation of treatment, because complete removal of covalently-closed circular DNA (cccDNA) from hepatocyte nuclei is extremely difficult. Immune responses have been shown to destroy cccDNA, but immune response alone is insufficient for complete eradication of template DNA. Several drugs were

recently developed to block the HBV life cycle in hepatocytes, with drugs targeting cccDNA being, at least theoretically, the most effective for radical cure of chronic HBV infection. The safety of these agents should be extensively examined before their use in patients. Combinations of two or more classes of agent may be necessary for radical cure of chronic HBV infection.

## INTRODUCTION

About 250 to 350 million people worldwide are chronically infected with hepatitis B virus (HBV)<sup>[1,2]</sup>, with about 700000 patients per year dying from HBV-related cirrhosis or hepatocellular carcinoma (HCC)<sup>[3]</sup>. Several anti-viral agents, including interferons and nucleos(t)ide analogues (NAs), have been shown effective, with NA-based treatment strongly suppressing the replication of HBV-DNA and normalizing serum alanine aminotransferase activity, resulting in little or no progression of liver disease<sup>[4-6]</sup>. NAs target the viral reverse transcriptase, effectively reducing serum HBV-DNA concentrations. However, intrahepatic HBV-DNA, such as converted covalently closed circular DNA (cccDNA), is not a direct target of NAs. cccDNA is a template for all viral RNAs and HBV-DNA replication can be induced to start from residual cccDNA after cessation of treatment with NAs<sup>[7]</sup>. Small amounts of HBV-DNA can be found in serum long after patients recover from acute HBV infection, suggesting that cccDNA may persist for decades<sup>[8]</sup>. Thus, cccDNA is difficult to eradicate once infection is established, and should be the main target for the complete eradication of HBV infection. However, measuring intrahepatic cccDNA concentrations is difficult in a clinical setting<sup>[9]</sup>. The cccDNA levels in HBV-infected human hepatocytes are low, ranging from 1 to 50 copies per hepatocyte<sup>[10]</sup>. Real-time polymerase chain reaction (PCR) amplification with specific primers for cccDNA or Southern blotting can be used for the detection. However, PCR amplification may be hampered by other co-extracted viral DNA and Southern blotting needs much time and effort. Moreover, the form of cccDNA may be changed during the DNA extraction procedure. Therefore, further investigation should be required to establish the precise evaluation of intrahepatic cccDNA. As an alternative, the reduction in HBV surface antigen (HBsAg) concentration has been reported to partly reflect the decrease in intrahepatic cccDNA, with the goal of treatment for chronic HBV infection being the complete disappearance of HBsAg<sup>[11]</sup>. Fewer than 10% of patients receiving interferon-based therapy<sup>[4-6]</sup>, and few patients treated with NAs<sup>[12,13]</sup>, achieve complete loss of HBsAg. Various trials have tested agents targeting the life cycle of HBV in hepatocytes, including the elimination of cccDNA.

This review summarizes and discusses the radical cure (Table 1) of chronic HBV infection, mainly focusing on the elimination of cccDNA.

## HBV REPLICATION CYCLE AND THE PRODUCTION OF HBV-RELATED PROTEINS

### HBV replication cycle

HBV is a DNA virus that belongs to the family *Hepadnaviridae*, with a 3.2 kb-long partially double-stranded relaxed circular DNA (rcDNA) genome<sup>[14]</sup>. The life cycle of HBV is shown in Figure 1. HBV virions are thought to enter hepatocytes through a high-affinity interaction between the myristoylated preS1 region of HBV and the surface structures of hepatocytes, including sodium taurocholate cotransporting polypeptide (NTCP)<sup>[15-17]</sup>. After entry into hepatocytes, uncoated rcDNA is released into the cytoplasm and then enters the nucleus, where it is converted to cccDNA. The cccDNA remains for a long time in the nucleus, where it serves as a template for the transcription of viral mRNA<sup>[17,18]</sup>. All viral RNAs, pregenomic RNAs (pgRNA) and RNAs encoding the surface proteins, precore and HBx of HBV, are transcribed from cccDNA, with efficient transcription regulated by liver-specific transcription factors<sup>[19]</sup> and the HBx protein itself<sup>[20]</sup>. Epigenetic control of cccDNA transcriptional activity, such as acetylation, methylation or phosphorylation, appears to occur<sup>[21]</sup>. Cytoplasmic pgRNA and polymerase protein are subsequently packaged into envelope proteins, with rcDNA produced from the reverse transcription of pgRNA. Nucleocapsids packaging rcDNA are encapsulated by HBsAg as the envelope protein and released from hepatocytes as virions. The precise understanding of these processes is important for the development of new strategies for the radical cure of chronic HBV infection.

### HBV-related proteins and their roles in hepatocarcinogenesis

The HBV-related proteins translated from cccDNA consist not only of the envelope, core and polymerase proteins of HBV, but may play a role in hepatocarcinogenesis itself.

Studies analyzing the role of HBx proteins in hepatocellular transformation and HCC progression have found that low levels of HBx protein are present in non-tumor tissues of HBV-infected liver, whereas high levels of HBx protein are present in HCCs arising in HBV infected individuals, suggesting that this protein has an oncogenic function<sup>[22,23]</sup>. Moreover, HBx transgenic mice often develop liver cancer<sup>[24,25]</sup>, and HBx protein has been found to accumulate in hepatocytes, affecting the expression of genes associated with signal transduction, cell cycle control, transcription, and immune response<sup>[23,26]</sup>. Expression of genes on the X-chromosome is regulated epigenetically, including by DNA and histone methyltransferases<sup>[27,28]</sup>, and by microRNAs<sup>[29,30]</sup>.

**Table 1** Cure status of hepatitis B virus infection

	Serum HBV-DNA	Serum HBsAg	Intraheptic cccDNA	HBV-DNA-integrated hepatocytes
Functional cure (clinical cure)	Low	(-)(-++)	(+)	(-)(+)
Radical cure (virological cure)	(-)	(-)	(-)	(-)

HBV: Hepatitis B virus; cccDNA: Covalently-closed circular DNA; HBsAg: Hepatitis B virus surface antigen.

**Figure 1** Simplified schema of the hepatitis B virus life cycle and possible targets of therapy. HBV: Hepatitis B virus; cccDNA: Covalently-closed circular DNA; HBsAg: Hepatitis B virus surface antigen; rcDNA: Relaxed circular DNA; siRNAs: Small interfering RNAs; pgRNA: Pregenomic RNAs.

HBx is not only involved in carcinogenesis but in the progression of HCC. HBx has been shown to increase beta-catenin signaling through epigenetic control or micro-RNA<sup>[31,32]</sup> and to be an independent predictor of survival after HCC resection<sup>[33]</sup>.

HBsAg is also involved in hepatocarcinogenesis. The ground glass appearance of hepatocytes was shown to be a typical histological finding in HBV-infected livers, with this ground glass appearance resulting from the accumulation of HBsAg with preS mutations<sup>[34-36]</sup>. PreS-mutated HBsAg, especially large HBsAg, was found to accumulate in cytoplasm, leading to the induction of ER stress and oxidative DNA damage<sup>[35-37]</sup>. Furthermore preS mutations upregulated intracellular signaling *via* hepatocyte proliferation<sup>[35,38]</sup>. High serum HBsAg levels showed a definite correlation with HCC development in patients with controlled HBV-DNA<sup>[39-41]</sup>. Like HBV-related proteins, spliced HBV proteins were found to activate intracellular signaling *via* hepatocyte proliferation<sup>[42,43]</sup>. These findings suggest that not only HBV replication, but the production of HBV-related proteins, should be suppressed to efficiently prevent hepatocarcinogenesis.

## IMMUNE RESPONSE AGAINST HBV INFECTION

Immune responses against HBV are involved in both the pathogenesis and control of HBV infection<sup>[44-47]</sup>. There-

fore, understanding the immune response against HBV may result in better control of HBV infection.

### Acute infection

Analysis of immune responses that occur during acute HBV infection may provide valuable information on strategies by which immune responses control HBV infection.

A mouse model of acute viral hepatitis B was established by injecting HBsAg-specific T-cell clones into HBV transgenic mice<sup>[48]</sup>. Although HBsAg-specific T-cells were found to kill small numbers of HBV-replicating hepatocytes, these T cell clones destroyed intracellular HBV-RNA and HBV-DNA in most infected hepatocytes without killing these cells. This effect was found to be due to interferon (IFN)- $\gamma$  and tumor necrosis factor (TNF)- $\alpha$ <sup>[40,49-51]</sup>. Because HBV transgenic mice do not have cccDNA<sup>[52]</sup>, the effects of these cytokines on cccDNA were unclear. In cccDNA-expressing cultured cells, however, IFN- $\gamma$  and TNF- $\alpha$  inhibited HBV replication and reduced cccDNA in an additive manner<sup>[53]</sup>. Moreover, the decay of cccDNA was found to require activation of APOBEC3 deaminases<sup>[53]</sup>, which are expressed in liver tissues of individuals with acute, but not chronic, HBV infection. These observations indicate that HBV-specific T-cell activation followed by treatment with anti-viral cytokines, such as IFN- $\gamma$  and TNF- $\alpha$ , could eradicate HBV without cytotoxicity.

In a chimpanzee model, cccDNA was found to dis-

appear during the course of acute hepatitis B, and HBV-DNA was found to be susceptible to noncytolytic control by cytokines<sup>[54]</sup>. Moreover, HBV-DNA titers in these livers were reduced before T-cell influx, suggesting that non-T-cells, possibly natural killer cells, may have an important role in the noncytolytic destruction of HBV-DNA in liver during early phases of acute HBV infection<sup>[54]</sup>.

Broad and vigorous CD4<sup>+</sup> and CD8<sup>+</sup> T-cell responses have been reported in patients with acute hepatitis B<sup>[55]</sup>. Moreover, HBV-specific T-cell responses were observed during the incubation period of acute hepatitis, with HBV-DNA reduced before alanine aminotransferase concentration peaked, indicating that noncytolytic eradication of HBV also occurs in acute hepatitis B in humans<sup>[56]</sup>. However, recovery from acute hepatitis B does not imply complete eradication of HBV, as small amounts of HBV-DNA can be detected in the blood for a long time after resolution of acute hepatitis B<sup>[8]</sup>. T-cell responses are therefore not sufficient to completely eradicate cccDNA from infected livers, even in acute hepatitis B.

### Chronic infection

Immune responses in patients chronically infected with HBV were found to consist of four phases: The immunotolerant, immune-active, inactive carrier, and reactivation phases<sup>[57]</sup>. Although the exact mechanism by which HBV induces immune tolerance is unclear, it may arise from central deletion or peripheral non-recognition of HBV-specific T-cells<sup>[58]</sup>. Immune tolerance may be broken after several decades by as yet undetermined mechanisms, but these may involve the maturation of dendritic cell (DC) function<sup>[59]</sup>. Breaking immune tolerance to HBV can lead to the immune-active phase, resulting in some degree of hepatitis. During this phase, suppression of HBV replication is observed in 85% to 90% of patients, leading to an inactive carrier state. Most patients in an inactive carrier state do not need antiviral treatments, but cccDNA may be present in their livers. The cccDNA persisting in inactive carriers may be a template for reactivation of HBV replication. The 10% to 15% of patients who remain in the immune-active phase continue to experience liver inflammation with active replication of HBV, and may be at high risk for progression to liver cirrhosis and the development of HCC. The number of HBV-specific CD8<sup>+</sup> T-cells was found to be the same in livers with low HBV replication and little hepatitis and in livers with high HBV replication and severe hepatitis<sup>[60]</sup>. These findings suggest that HBV replication is suppressed by immune surveillance of HBV-specific T-cells in the liver and that these T-cells are important in controlling HBV replication in a noncytolytic manner in inactive carriers. In contrast, HBV-specific immune responses are thought to be dysregulated in livers with active hepatitis, and several possible mechanisms have been proposed.

### Impairment of innate immune response

Innate immune system such as pattern recognition receptors, macrophages, DCs, natural killer cells or natural killer T cells are involved in the pathogenesis of HBV

infection especially at an early stage of infection<sup>[61,62]</sup>. HBV has been shown to alter the function of macrophages by modulating the secretion of cytokines<sup>[63,64]</sup> or type-1 IFN gene expression<sup>[64]</sup>. Hepatitis B e antigen was shown to directly suppress toll-like receptor (TLR) signaling via interaction with Toll/IL-1 receptor-containing proteins such as TRAM and Mal<sup>[65]</sup>. HBV has been shown to downregulate TLR-2 expression in patients with chronic HBV infection<sup>[66]</sup>. Thus, innate immunity alteration plays a role, at least in part, in the pathogenesis of chronic HBV infection and TLR-7 agonists have been applied as immune-modulatory components<sup>[67,68]</sup>. On the other hand, the effect of IFN- $\alpha$  on intrahepatic cccDNA has been recently explored<sup>[69]</sup>, and IFN- $\alpha$  in addition to lymphotoxin- $\beta$  receptor (LT $\beta$ R) activation has been shown to induce cccDNA degradation through upregulation of nuclear APOBEC3 deaminases<sup>[70]</sup>. APOBEC3 can deaminate double-stranded DNA cytidines to uridines<sup>[71]</sup> and induce cccDNA degradation. IFN- $\gamma$  and TNF- $\alpha$  produced from T-cells can induce deamination of cccDNA without cytolysis, supporting the essential role of APOBEC3 in reduction of cccDNA<sup>[53]</sup>. Collectively, type-1 IFN-mediated effects, especially APOBEC3 upregulation, will be a key subject for development of new therapeutics.

### Dysfunction of dendritic cells

DCs are the most potent antigen-presenting cells, stimulating both T- and B-cells. In patients with chronic hepatitis, the cytokine-induced maturation of circulating myeloid DCs is impaired, possibly by exposure to high amounts of HBV or HBsAg<sup>[72,73]</sup>. Dysfunctional DCs may act as tolerogenic antigen-presenting cells, resulting in a failure to induce HBV-specific immune responses.

### Alteration of the hierarchy of epitope-specific CD8<sup>+</sup> T-cell responses

In acute hepatitis B, the CD8<sup>+</sup> T-cell response to the immunogenic epitope HBc18-27 (HLA-A2 restricted epitope) is dominant. In contrast, HBc18-27-specific CD8<sup>+</sup> T-cell responses are low and CD8<sup>+</sup> T-cell responses against less immunogenic envelope (183-191) are dominant in chronic hepatitis B<sup>[74]</sup>. Although the mechanisms underlying changes in the major epitope to CD8<sup>+</sup> T-cell response are not yet known, they may account, at least in part, for the different CD8<sup>+</sup> T-cell responses observed in patients with acute and chronic hepatitis.

### Regulatory T-cells

Regulatory T-cells (Tregs) expressing the forkhead family transcription factor, Foxp3, are specialized cells that have a major role in the maintenance of immunological self-tolerance by suppressing self-reactive cells<sup>[75]</sup>. Tregs express CD25 [interleukin (IL)-2 receptor  $\alpha$ -chain] and/or cytotoxic T-lymphocyte antigen-4 (CTLA-4), which are excellent inhibitors of IL-2 production or downregulation of CD80 and CD86 on DCs by a CTLA-4-dependent mechanism<sup>[76]</sup>.

The numbers of CD4<sup>+</sup>CD25<sup>+</sup>FoxP3<sup>+</sup> Tregs were higher in the livers of patients with chronic hepatitis B,

suggesting that these cells suppress intrahepatic HBV-specific T-cell responses, leading to insufficient immune control of HBV replication in the liver<sup>[77]</sup>.

### **Inhibitory receptors**

Program death (PD)-1 is a surface receptor critical for the regulation of T-cell function<sup>[78,79]</sup>. Binding of the ligand PD-L1 to PD-1 on T-cells results in the antigen-specific inhibition of T-cell proliferation, with a molecule related to T-cell exhaustion found in the livers of patients with chronic hepatitis B. T-cell exhaustion is characterized by poor cytotoxic activity and cytokine production, as well as by the expression of inhibitory receptors, including not only PD-1 but lymphocyte activation gene-3, CTLA-4, T-cell immunoglobulin domain and mucin domain-3, and CD244<sup>[66]</sup>. These inhibitory receptors are thought to be induced by persistent exposure of intrahepatic T-cells to HBV or HBV-related proteins<sup>[80]</sup>. Exhaustion of T-cells could also account for impaired T-cell responses in the livers of patients with chronic hepatitis B, and blockade of these receptors could be therapeutic.

Patients with high serum HBV-DNA concentration have been reported likely to progress to cirrhosis and eventually HCC<sup>[81]</sup>. Transition of immune-active patients to an inactive state with low HBV-DNA replication by the direct stimulation of HBV-specific T-cells or removal of immunosuppressive factors, may be sufficient to inhibit progression to cirrhosis or HCC. Inactive HBV carriers may not require specific treatment, because spontaneous HBsAg develops at a rate of 1% to 1.9%/year in these patients, making the development of HCC rare<sup>[82]</sup>. Therefore, an inactive HBV carrier may be regarded as in a state of functional cure (Table 1). However, HBV replication may be reactivated, either spontaneously or during treatment with an immunosuppressive or anticancer agent, resulting in a higher risk of hepatocarcinogenesis than in the general population<sup>[83]</sup>. The rate of HCC development was recently reported to be greater in patients with high than with low serum HBsAg concentrations, even in inactive HBV carriers with low serum HBV-DNA concentrations<sup>[36,37]</sup>.

Collectively, these results suggest that induction of immune control against HBV infection may result in functional cure of HBV infection. Functional cure, however, may be an unstable condition, allowing progression to cirrhosis or HCC under various conditions. Although radical cure (Table 1) is desirable, it is problematic because of the difficulty in eliminating HBV cccDNA from the liver.

## **THERAPEUTIC STRATEGIES FOR HBV INFECTION**

### **Immunotherapy**

Radical cure of HBV infection could be achieved by both the elimination of cccDNA in the liver and the destruction of HBV-DNA-integrated hepatocytes. The primary goals of immunotherapy in HBV-infected individuals include the induction or stimulation of HBV-specific immune re-

sponses, leading to the killing of infected cells or the degradation of HBV-RNA and HBV-DNA in a noncytolytic manner, inhibiting progression to liver cirrhosis and hepatocarcinogenesis. Although immune responses involving cytokines such as IFN- $\gamma$  and TNF- $\alpha$  can eliminate cccDNA<sup>[50,53]</sup>, cccDNA is not completely eliminated even after resolution of acute hepatitis B<sup>[8]</sup>, suggesting that immune responses alone may be insufficient to achieve radical cure of HBV infection.

### **Induction or stimulation of HBV-specific immune responses**

Efforts to stimulate HBV-specific T-cells have included immunizations with HBV-peptides, viral proteins, DCs, and DNA, as well as treatment with cytokines<sup>[84]</sup>. Because HBV-specific T-cells in patients with chronic hepatitis B are exhausted by long-term exposure to high levels of HBV-related antigens, activation of those cells by immunization would be ineffective without functional restoration of the cells by blocking the inhibitory signals responsible for T-cell exhaustion. Blockade of PD-1, CTLA-4 or Tim-3 has been shown to restore exhausted HBV-specific T-cells<sup>[80]</sup>, suggesting that the combination of immunization and blockade of inhibitory signals would be effective in activating HBV-specific T-cells.

Other immunotherapeutic approaches to HBV infection include administration of cytokines, such as IFN- $\gamma$ , IL-6, IL-1 $\beta$ , LT $\beta$ R-agonists and/or TLR-7 agonist, as well as IFN- $\gamma$  and TNF- $\alpha$  which were shown to cause silencing or degradation of cccDNA<sup>[67]</sup>. This strategy may be more effective in the complete eradication of HBV infection than strategies involving the activation of HBV-specific cells, suggesting that only cytokine administration results in the elimination of cccDNA.

### **Elimination of HBV-infected hepatocytes by a novel approach**

A novel approach to eliminate HBV-core containing hepatocytes<sup>[85]</sup> was based on findings showing that elimination of HBV is impaired by cellular inhibitor of apoptosis proteins (cIAPs), which inhibit the TNF- $\alpha$ -mediated death of HBV-infected cells<sup>[86]</sup>. This led to testing the effects of inhibitors of cIAPs, including birinapant and other Smac mimetics, on HBV-infected hepatocytes. These inhibitors of cIAPs resulted in the rapid reduction in serum HBV-DNA and HBsAg concentrations, possibly by eliminating HBV-core containing hepatocytes. However, the effects of those drugs on cccDNA are unclear.

### **Immunotherapeutic strategies for HBV-DNA-integrated hepatocytes**

Three main mechanisms are responsible for hepatocarcinogenesis: (1) the oncogenic potential of the HBV-related proteins, HBsAg and HBx; (2) HBV-DNA integration into the host genome, dysregulating the cell cycle by the introduction of deletions, cis/trans-activations, and/or translocations, and/or inducing generalized genomic instability; and (3) persistent inflammation in the

liver causing rapid turnover of hepatocyte regeneration, enhancing the instability and/or mutagenesis of host genomes.

Therefore, if future advances in therapeutic modalities result in the complete elimination of cccDNA, hepatocarcinogenesis resulting from HBV-DNA integration into the host genome should be addressed. HBV-DNA integration into the hepatocyte genome has been observed in 86.4% of HBV-related HCCs and in 30.7% of adjacent liver tissue<sup>[87]</sup>. Integration of HBV-DNA into areas of the host genome encoding genes that regulate cellular proliferation, such as telomerase or proliferation signal transduction genes, may lead to cis-/trans-activation, inducing malignant transformation<sup>[88]</sup>. Furthermore, integration of HBV-DNA may induce genetic instability by altering the expression of oncogenes, tumor suppressor genes and microRNAs<sup>[87,89]</sup>. In addition, a viral-human chimeric transcript was reported to function as a noncoding RNA and promote hepatocarcinogenesis<sup>[90]</sup>. Integration of HBV-DNA into the host hepatocyte genome of transiently infected individuals has been reported to be a rare event, occurring in 0.01%-0.1% of hepatocytes<sup>[91]</sup>. Further investigations are needed to determine the mechanism by which HBV-DNA integration into the host genome induces carcinogenesis. The immune cytotoxicity of cells expressing HBV-related peptides may be the only strategy that effectively eliminates HBV-DNA-integrated hepatocytes. However, if non-immunogenic regions of HBV-DNA are integrated, elimination of those cells by immune attack would be impossible.

Taken together, these findings indicate that immunotherapy against HBV can control viral replication and reduce cccDNA, but may not be sufficient to completely eradicate HBV-infected or -integrated hepatocytes.

### **Inhibition of HBV replication**

Currently available NAs can efficiently reduce viremia but cannot eliminate intracellular cccDNA. However, complete suppression of HBV polymerase can result in the complete elimination of cccDNA through the death of cccDNA-containing hepatocytes after one natural lifespan of these cells<sup>[92]</sup>. Among the agents being tested are prodrugs of HBV polymerase inhibitors<sup>[93]</sup>. These include prodrugs of tenofovir, such as AGX1009 (Agenix) and TAF (GS-7340, Gilead Sciences), which have been evaluated in phase 3 trials<sup>[93,94]</sup>, and CMX157, a lipid conjugate of tenofovir, which has been evaluated in phase 1/2 trials<sup>[93,95]</sup>. RNase H inhibitors are also being tested, based on the specificity of HBV replication, which depends on the RNase H activity of HBV polymerase to degrade pgRNA<sup>[10]</sup>. Evaluations of selective inhibitors of HBV polymerase RNase H activity<sup>[96]</sup> suggest that they might be more effective when combined with NAs<sup>[93]</sup>.

### **Destruction of cccDNA**

Eradication of cccDNA in hepatocytes is essential to achieve radical cure of established HBV infection. Several trials have targeted cccDNA. For example, gene silencing techniques, such as small interfering RNAs (siRNAs) or

antisense oligonucleotides (ASOs), have been evaluated for their ability to reduce viremia and cccDNA. Although siRNAs may have promising activity, methods to effectively deliver them to hepatocytes have not been determined<sup>[97]</sup>. RNAi can inhibit all steps of HBV replication, and ARC-520 has been tested in a phase 2 trial in patients with chronic hepatitis B<sup>[95]</sup>. In contrast, a single injection of ASO, consisting of liver-targeted peptides, into a mouse model of chronic HBV infection was shown to reduce HBV-RNA, proteins and HBV-DNA for a long time, suggesting that ASO may become a promising treatment in patients with chronic HBV<sup>[98]</sup>. Furthermore, disubstituted sulfonamide was shown to selectively inhibit the formation of cccDNA<sup>[99]</sup>.

In addition, several genome editing technologies have been developed to silence sequence-specific cleavage of cccDNA. These include zinc finger nucleases (ZFNs)<sup>[100,101]</sup>, transcription activator-like effector nucleases (TALENs)<sup>[102,103]</sup>, and the clustered regularly interspaced short palindromic repeat (CRISPR)/CRISPR associated system (Cas). These sequence-specific genome editing technologies could induce double-stranded breaks at certain DNA sites. ZFNs consist of a zinc finger domain, which contains a sequence-specific binding site, and a *Fok I* nuclease domain. ZFNs form heterodimers and induce double-stranded breaks at targeted sites. These breaks are subsequently repaired by homology-directed repair or non-homologous end joining. The specificity of ZFNs may be context-dependent, resulting from interactions between DNA binding domains and neighboring zinc fingers<sup>[104]</sup>. TALENs have transcription activator-like effector specific DNA binding activity, with DNA-binding sites more specific than those of ZFNs<sup>[105]</sup>. However, both ZFNs and TALENs require pairs of site-specific nucleases for each target to produce customized proteins<sup>[9]</sup>. In contrast, CRISPR/Cas technology is a novel genome-editing method, which is more useful than ZFNs or TALENs<sup>[106]</sup>. CRISPR/Cas loci encode RNA guided endonucleases, which are induced by immune responses against foreign genetic elements such as bacteriophages and plasmids<sup>[107]</sup>. The type 2 CRISPR/Cas system from *Streptococcus pyogenes* is a chimeric single-guide RNA with Cas9 protein<sup>[108]</sup>. The CRISPR/Cas9 system was shown to suppress HBV replication in cultured cells and in mouse models<sup>[109-117]</sup>, reducing both HBsAg<sup>[109,110,112-116]</sup> and cccDNA<sup>[110,113-115,117]</sup>. These findings suggest that genome editing technology, such as a CRISPR/Cas system, may be a potential therapeutic option for the complete eradication of HBV infection in future. However, cleavage of cccDNA and subsequent DNA repair may introduce mutations into the host genome. These mutations may be harmful to the host, resulting in the possible development of malignancy<sup>[9,118,119]</sup>, suggesting the need for further improvements in efficacy and safety prior to the therapeutic use of these systems.

### **Future perspectives on radical cure of chronic HBV infection**

Various trials have assessed agents that can terminate

**Table 2** Tgераaptic agents against hepatitis B virus currently in clinical development

Mode of actions	Target	Stage of development	Ref.
Entry inhibitions	NTCP	Myrcludex in phase 2	[14,123]
cccDNA			
Formation inhibitions	DSS	Preclinical	[99]
Transcription inhibitions	ASO	IONIS-HBVRx in phase 1	[98]
Destabilization/degradation	ZFN	Preclinical	[100,101]
	TALEN	Preclinical	[102,103]
	CRISPR/Cas9	Preclinical	[109-117]
SiRNA	PgRNA	ARC-520 in phase 2	[95]
Nucleocapsid assembly inhibitions	Capsid formation	BAY4109 in phase 1	[93,95]
		NV1221 in phase 1	[93,95]
Reverse transcription inhibitions	Polymerase	TAF in phase 3	[93,94]
		Cmx157 in phase 1/2	[93,95]
HBsAg release inhibitions	HBsAg secretion	Preclinical	[109]
	HBsAg secretion	Rep2139 in phase 1/2	[110]
Immune modulating	TLR-7 agonist	GS-9620 in phase 2	[67,68]
	HBV-specific	Preclinical	[84]
	cIAPS	Preclinical	[86]

cccDNA: Covalently-closed circular DNA; ZFN: Zinc finger nuclease; TALEN: Transcription activator-like effector nuclease; CRISPR: Clustered regularly interspaced short palindromic repeat; Cas: CRISPR associated system; pgRNA: Pregenomic RNAs; HBsAg: Hepatitis B virus surface antigen; TLR: Toll-like receptor; HBV: Hepatitis B virus; cIAPS: Cellular inhibitor of apoptosis proteins; DSS: Disubstituted sulfonamide; ASO: Antisense oligonucleotides; TAF: Tenofovir Alafenamide; NTCP: Na<sup>+</sup>/taurocholate cotransporting polypeptide.

the HBV life cycle in hepatocytes, including inhibitors of HBV-DNA polymerase, virus entry, core assembly and HBsAg secretion (Table 2)<sup>[93,95,120,121]</sup>. Especially Myrcludex B, a synthetic lipopeptide that targets NTCP, has been shown to efficiently prevent viral spread and has been applied in clinical trials<sup>[15,17,122,123]</sup>. These agents, including Myrcludex, are not themselves sufficient to eliminate HBV from chronically infected hepatocytes, as shown by the remaining cccDNA in the nuclei and HBV-DNA-integrated hepatocytes. Immunotherapy may potentially eliminate both cccDNA and HBV-DNA-integrated hepatocytes, but its effects would be limited. Although drugs targeting cccDNA in hepatocytes are theoretically ideal for complete eradication of HBV, no single drug or strategy, whether currently available or under development, has shown the ability to completely eliminate HBV with established safety and efficacy. Future trials, testing combination of different agents or strategies, will be necessary.

### Abstract

Liver transplantation (LT) for hepatocellular carcinoma (HCC) has been established as a standard treatment in

selected patients for the last two and a half decades. After initially dismal outcomes, the Milan criteria (MC) (single HCC  $\leq 5$  cm or up to 3 HCCs  $\leq 3$  cm) have been adopted worldwide to select HCC patients for LT, however cumulative experience has shown that MC can be too strict. This has led to the development of numerous expanded criteria worldwide. Morphometric expansions on MC as well as various criteria which incorporate biomarkers as surrogates of tumor biology have been described. HCC that presents beyond MC initially can be downstaged with locoregional therapy (LRT). Post-LRT monitoring aims to identify candidates with favorable tumor behavior. Similarly, tumor marker levels as response to LRT has been utilized as surrogate of tumor biology. Molecular signatures of HCC have also been correlated to outcomes; these have yet to be incorporated into HCC-LT selection criteria formally. The ongoing discrepancy between organ demand and supply makes patient selection the most challenging element of organ allocation. Further validation of extended HCC-LT criteria models and pre-LT treatment strategies are required.

**Key words:** Hepatocellular carcinoma; Milan criteria; Liver transplantation; Expanded criteria; Locoregional therapy; Down staging

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Numerous expanded selection criteria for hepatocellular carcinoma (HCC)-liver transplantation (LT) have been proposed worldwide. Surrogates of favorable tumor biology such as Post-locoregional therapy strategies which observe tumor behavior, and the addition of HCC biomarkers to selection criteria have been explored. Further investigation is encouraged to identify patients beyond MC with the most favorable tumor biology for LT.

selection criteria. *World J Hepatol* 2016; 8(21): 874-880 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i21/874.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i21.874>

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver, with over 700000 new cases diagnosed yearly worldwide<sup>[1]</sup>. HCC continues to be a global health problem due to insufficient screening and surveillance and poorly controlled risk factors<sup>[2]</sup>. HCC arises most frequently in patients with chronic liver disease from diverse etiologies, and liver transplantation (LT) has been established as a standard treatment in selected patients for the last two and a half decades<sup>[3]</sup>. However, an ongoing conundrum is the discrepancy between organ demand and supply, making patient selection the most challenging piece of the puzzle to prevent organ misutilization<sup>[4]</sup>.

Poor patient selection (excessive tumor burden, unknown tumor biology) made initial results of LT for HCC quite dismal<sup>[5]</sup>. It wasn't until 1996, when Mazzaferro *et al*<sup>[6]</sup> defined tumor criteria for patient selection (single lesion  $\leq 5$  cm, or up to 3 lesions  $\leq 3$  cm each in the absence of tumor vascular invasion or evidence of extra-hepatic metastases) associated with comparable outcome to patients undergoing LT without HCC. The study revealed 4 year post-LT survival  $> 75\%$  and post-LT recurrence rate in the order of 8%. These criteria have since been known as the Milan criteria (MC), and have been adopted worldwide to select HCC patients for LT<sup>[7]</sup>.

Patients who present with HCC beyond MC can be down-staged *via* loco-regional therapy (LRT). LRT are trans-catheter, needle based or radiation treatments which target the tumor and induce selective tumor necrosis<sup>[8]</sup>. The efficacy of these treatments is gauged radiologically by the modified Response Evaluation Criteria in Solid Tumors<sup>[9]</sup>. Tumor response to LRT, post LRT observation before LT, and HCC biomarkers have been described for selecting the most favorable tumor biology in patients presenting with HCC beyond MC<sup>[9-11]</sup>.

Although strict adherence to MC can produce outcomes comparable to LT for non-HCC, cumulative experience over the last two decades have shown that MC can be too strict, and that select patients beyond MC may benefit from LT with adequate survival<sup>[12]</sup>. This has led to the development of numerous HCC expanded criteria worldwide, applied for both cadaveric and live donor liver transplantation.

Herein, we review various expanded HCC criteria and outcomes, impact of tumor response to LRT in post-LT outcome and emerging HCC molecular signatures that may be incorporated into patient selection criteria in the near future.

## EXTENDED LT-HCC CRITERIA

In 2001, Yao *et al*<sup>[13]</sup> published one of the most popular

expanded LT-HCC criteria. The University of California, San Francisco (UCSF) criteria considered a single lesion  $\leq 6.5$  cm, or 2-3 lesions  $\leq 4.5$  cm each, with total tumor diameter  $\leq 8$  cm.

Tumor recurrence was 11.4% and 5 years post-LT survival was in the order of 72.4%<sup>[13]</sup>. The original UCSF criteria were developed based on explant histopathological analysis, but subsequently have been validated utilizing pre-LT imaging. In 2007, Yao *et al*<sup>[14]</sup> published a prospective study utilizing the UCSF criteria revealing 80% 5 years post-LT recurrence free survival (RFS). Alongside MC, UCSF criteria have been the most widely recognized transplant criteria for HCC, and can expand 5%-20% the indication of LT for HCC patients<sup>[14]</sup>. Currently, some worldwide transplant centers utilize UCSF as the standard selection LT criteria for HCC<sup>[15]</sup>.

The Navarro extended criteria described by Herrero *et al*<sup>[16]</sup> in 2001 can expand the MC by considering LT for a single lesion  $\leq 6$  cm, or 2-3 lesions  $\leq 5$  cm each. In their analysis, 12.7% of the cohort experienced tumor recurrence. Post-LT 5 years overall survival and RFS was 79% and 70% respectively.

Silva *et al*<sup>[17]</sup> published the Valencia criteria in 2008. These would consider LT in HCC patients with 1-3 lesions  $\leq 5$  cm each, and total tumor  $\leq 10$  cm. Two hundred and fifty-seven patients undergoing LT for HCC were analyzed, however only 10% were beyond MC based on pre-LT imaging. Patients who fell within the Valencia criteria demonstrated post-LT 5 year survival comparable to patients within MC. The Valencia criteria expands LT to a higher maximum tumor burden compared to both MC and UCSF criteria, without detriment to patient survival, however similar to the Navarro criteria, due to the small number of patients in this cohort, these criteria require further validation.

Correlation of tumor size and number according to explant pathology and post-LT survival in 1206 patients from the International Registry of Hepatic Tumors, led to the recommendation of LT for a single lesion  $\leq 6$  cm, or 2-4 lesions  $\leq 5$  cm each by Onaca *et al*<sup>[18]</sup> in 2007. Survival in patients exceeding MC but meeting these criteria were not significantly lower than for patients meeting MC. Five years post-LT RFS with a single lesion 5.1-6.0 cm in diameter, or with 2-4 lesions (largest 3.1-5.0 cm) were 63.9%, and 64.6% respectively, compared to 5 years post-LT RFS of 61.8% if MC were met<sup>[18]</sup>.

Other proposed extended criteria do not put a limit to number of tumors recommended for LT. Roayaie *et al*<sup>[19]</sup> in 2002, demonstrated 55% 5 years post-LT RFS for patients with lesions 5-7 cm in diameter. In 2004, Kneteman *et al*<sup>[20]</sup> reported the outcomes of LT utilizing extended criteria described as a single lesion  $< 7.5$  cm, or multiple lesions  $< 5$  cm each. Four year post-LT survival was 82.9% vs 87.4% in the MC group.

One of the more recently proposed extended criteria is the Up-to-7 criteria proposed by Mazzaferro *et al*<sup>[21]</sup> in 2009. A cohort of 1556 patients undergoing cadaveric LT and LDLT for HCC from 36 transplant centers was analyzed, 71.5% of the cohort had HCC exceeding MC. The Up-to-7 criteria are defined as the sum of the

size of the largest tumor in cm and the total number of tumors in the absence of tumor microvascular invasion. Five years post-LT survival for patients within the Up-to-7 criteria compared to MC were 71.2% vs 73.3%<sup>[21]</sup>. The major limitation of these criteria is the lack of pre-LT information about microvascular invasion. Currently, this can only be partially projected *via* assessment of alpha-fetoprotein (AFP) level.

### Extended LT-HCC criteria using living donors

Outcomes in HCC patients undergoing living donor liver transplantation (LDLT) were shown to be equivalent to cadaveric liver transplantation<sup>[22]</sup>. Soejima *et al*<sup>[23]</sup> reported that tumor diameter > 5 cm was associated with worse prognosis; however the number of tumors was not. In the cohort of 60 patients who underwent LDLT for HCC, 67% were beyond MC based on pre-LT imaging. Three years post-LT survival of 68.6% was reported for patients beyond MC<sup>[23]</sup>.

Jonas *et al*<sup>[24]</sup> also described their extended criteria based on a cohort of 21 patients undergoing LDLT for HCC. Three year survival rates for patients not meeting MC or UCSF criteria were 62% and 53% respectively. Sugawara *et al*<sup>[25]</sup> proposed an expansion of selection criteria to include up to 5 HCC lesions,  $\leq 5$  cm each. In their cohort of 78 patients, post-LT RFS at 3 years was 94%.

Table 1 demonstrates an overview of proposed morphometric based expanded selection criteria.

## INCORPORATION OF SURROGATES OF TUMOR BIOLOGY TO SELECTION CRITERIA

### Tumor markers

Post-LT outcomes in patients with HCC are in part a consequence of tumor biology. As a result of the impossibility to unveil this feature solely through morphometric imaging characteristics, multiple studies have attempted to include other indicators of tumor behavior as selection criteria. AFP and des- $\gamma$ -carboxyprothrombin (DCP) both have established correlations with post treatment prognosis<sup>[26,27]</sup>. A pre-LT AFP level > 1000 ng/mL has been demonstrated as a significant predictor of HCC recurrence post-LT<sup>[26]</sup>. A large scale analysis of United Network for Organ Sharing (UNOS) data has demonstrated that patients transplanted beyond MC with an AFP level of 0 to 15 ng/mL (normal range) had improved survival<sup>[28]</sup>.

One of the most popular HCC-LT extended criteria including biomarkers as surrogates of tumor biology are the Hangzhou criteria (absence of macrovascular invasion and total tumor diameter  $\leq 8$  cm. If the tumor burden is > 8 cm, histopathology *via* tumor biopsy should be non-poorly differentiated HCC and AFP level should be  $\leq 400$  ng/mL<sup>[29]</sup>.

In the original cohort of 195 patients, fulfilling Hangzhou criteria led to a 5 year survival of 70.7% and DFS: 62.4%. On the other hand, patients beyond Hangzhou

criteria had a 5 year survival of 18.9% and DFS: 4.7%<sup>[29]</sup>. A large scale comparative study of multiple extended criteria confirmed post LT survival associated with LT beyond MC but meeting Hangzhou at 1-, 3-, 5- and 10-years was 89.5%, 70.8%, 62.4% and 52.9% respectively. Additionally, 1-, 3-, 5- and 10-year RFS was 81.6%, 64.3%, 56.5%, and 37.2% respectively. Compared to MC, expanded criteria expanded transplantable patients by 12.4% for Valencia, 16.3% for UCSF, 19.6% for Navarro, and 51.5% for Hangzhou. RFS rates were comparable to MC<sup>[30]</sup>.

In 2012, Lai *et al*<sup>[31]</sup> also suggested that the combination of total tumor diameter > 8 cm and an AFP level  $\leq 400$  ng/mL would result in favorable survival outcomes. The 5 year DFS rate was 74.4%. It was also noted that patients with increased AFP values in response to LRT had higher recurrence rates<sup>[31]</sup>. Duvoux *et al*<sup>[32]</sup> have suggested a predictive scoring model that combines the AFP level at listing with MC. In their model, an AFP level  $\leq 100$  ng/mL in the setting of patients beyond MC (1-3 lesions with a maximum tumor diameter of 6 cm) demonstrated 5- year survival near 70%<sup>[32]</sup>.

Similar criteria have been applied to LDLT as well. In a multicenter study from Japan, Todo *et al*<sup>[33]</sup> suggested that the combination of an AFP cut of level  $\geq 200$  ng/mL and protein induced by vitamin K absence or antagonism factor II (PIVKA II)  $\geq 100$  mAU/mL are significant predictors for poor post LT survival. These combined were described as the A-P level. Five year DFS for beyond MC HCC patients and within the A-P cutoff level was similar to those within MC at 78.7% and 90.4% respectively.

Kwon *et al*<sup>[34]</sup> demonstrated their outcomes incorporating an AFP level  $\leq 400$  ng/mL as a selection criteria along with any number of lesions  $\leq 5$  cm each. In a cohort of 139 patients, 5 year survival was noted at 79.9%, without a significant difference between patients within or beyond MC<sup>[34]</sup>. More recently in 2015, Toso *et al*<sup>[35]</sup> in a prospective study suggested extended LT criteria described as a combination of a total tumor volume  $\leq 115$  cm<sup>3</sup> and an AFP level  $\leq 400$  ng/mL. Four year post LT survival was similar between the extended criteria group and the MC group at 78.7% and 74.6% respectively<sup>[35]</sup>.

A lower AFP cut off rate of < 100 ng/mL as a criteria for HCC-LT was recommended by Grāt *et al*<sup>[36]</sup>. A retrospective analysis of a 121 patients demonstrated significant prediction of recurrence in patients transplanted within UCSF and Up-to-7 criteria who surpassed this limit. Five year RFS for patients meeting UCSF and within the AFP cut off was superior to those meeting USCF but beyond the cut off limit at 100% vs 69% respectively. Similarly, when applied to the Up-to-7 criteria, 5 year RFS for those meeting both the criteria and cut off limit was noted at 100% vs 71.9% for beyond the cut off limit<sup>[36]</sup>.

DCP, often utilized as a tumor marker for HCC in Japan, has been incorporated into the Kyoto criteria published by Fujiki *et al*<sup>[37]</sup> in 2009: A DCP level of  $\leq 400$  mAU/mL in addition to morphometric criteria of up

**Table 1** Expanded morphometric criteria for hepatocellular carcinoma-liver transplantation

Ref.	Year	Description	Donor type	n	Survival
Yao <i>et al</i> <sup>[13]</sup>	2001	1 lesion $\leq$ 6.5 cm, or 2-3 lesions $\leq$ 4.5 cm each. Total tumor diameter $\leq$ 8 cm	Cadaveric	70	5 yr OS: 72.4%
Herrero <i>et al</i> <sup>[16]</sup>	2001	1 lesion $\leq$ 6 cm, or 2-3 lesions $\leq$ 5 cm each	Cadaveric	47	5 yr OS: 79%
Roayaie <i>et al</i> <sup>[19]</sup>	2002	Any number of lesions, 5-7 cm each	Cadaveric	43	5 yr RFS: 55%
Keneteman <i>et al</i> <sup>[20]</sup>	2004	1 lesion $<$ 7.5 cm, or multiple lesions $<$ 5 cm each	Cadaveric	40	4 yr OS: 82.9% 4 yr RFS: 76.8%
Onaca <i>et al</i> <sup>[18]</sup>	2007	1 lesion $\leq$ 6 cm, or 2-4 lesions $\leq$ 5 cm each	Cadaveric	1206	5 yr RFS: 1 lesion $\leq$ 6 cm: 63.9%/or 2-4 lesions 3.1 cm-5 cm each: 64.6%

Silva <i>et al</i> <sup>[17]</sup>	2008	1-3 lesions $\leq$ 5 cm each. Total tumor diameter $\leq$ 10 cm	Cadaveric	257	5 yr OS: 67%
Mazzaferro <i>et al</i> <sup>[21]</sup>	2009	The sum of the size and number of tumors not exceeding 7 in the absence of microvascular invasion	Both	1556	5 yr OS: 71.2%

RFS: Recurrence free survival; OS: Overall survival.

to 10 nodules  $\leq$  5 cm each. Five year recurrence was similar for patients within MC, and patients beyond MC but meeting Kyoto criteria at 7% and 4% respectively. Five year survival for patients meeting Kyoto criteria was 89%<sup>[37]</sup>. Takada *et al*<sup>[38]</sup> also propose similar selection criteria. In their cohort of 136 patients, those who met the proposed selection criteria demonstrated a 5 year survival rate of 87%.

Lee *et al*<sup>[39]</sup> proposes the incorporation of 18F-Fluoro-deoxyglucose positron emission tomography (PET) to HCC-LT selection criteria. Retrospective analysis of 2806 patients demonstrated that patients with PET negative scans preoperatively in combination with a total tumor diameter  $\leq$  10 cm demonstrated 5 year overall survival and DFS rates of 73.4% and 80.4% respectively, which was not significantly different from those within MC<sup>[39]</sup>.

Table 2 demonstrates an overview of proposed expanded selection criteria which incorporate biomarkers to morphometric tumor measurements.

### Downstaging and response to LRT

LRT in HCC-LT candidates is considered an element of two approaches: For patients listed/to be listed within MC, LRT is applied neo-adjuvantly as bridging therapy to halt tumor progression<sup>[40]</sup>. Patients who present initially beyond MC are downstaged to reduce tumor size to meet MC<sup>[41]</sup>. Both strategies provide the opportunity to evaluate radiological and laboratory surrogates of tumor response, which could unveil more aggressive tumors with less favorable biology in order to be excluded from LT.

Since tumor behavior over time is a surrogate of tumor biology, LRT followed by a required waiting time before LT can help to unveil tumor biology and has been coined as the "ablate and wait" strategy<sup>[10]</sup>.

A systematic review and pooled analysis of 13 studies revealed the success rate of downstaging ranging between 11%-77%. There was no significant difference in utilizing Transarterial Chemoembolization or Transarterial Radioembolization. Post LT recurrence rates were noted to be as high as 16%, however survival outcomes could

not be calculated due to heterogeneity of the data which prevented adequate analysis. Further investigation is required to determine the effect of heterogeneous downstaging protocols in term of LRT modality, frequency, and waiting period pre- LT<sup>[42]</sup>.

The correlation between the AFP expression in response to LRT and post LT survival has also been investigated. A multicentric study which included 422 patients who underwent LRT before LT for HCC (306 within MC, 116 beyond MC) demonstrated an increased risk for HCC recurrence and death with an AFP slope  $>$  15 ng/mL per month<sup>[43]</sup>.

### Future directions: Molecular signatures

Genetic molecular signatures have been explored for their potential as biomarkers for HCC<sup>[44]</sup>. Dvorchik *et al*<sup>[45]</sup> assessed fractional allelic imbalance rates in a panel of 9 tumor suppressor genes. A higher rate of tumor suppressor gene mutation correlated with worse post-LT outcome independently of tumor vascular invasion or tumor burden<sup>[45]</sup>.

MicroRNA (miRNA) signatures detected in serum exosomes have also been described as potential biomarkers for HCC. In a cohort of 6 HCC patients miR-718 was described as significantly linked to HCC; and this was further validated in a cohort of 59 LDLT HCC cases. In the validation cohort, miR-718 expression levels were significantly lower in patients beyond MC, and with poorer histological differentiation. However, due to the small incidence of recurrence in this cohort, no direct association could be linked to miR-718<sup>[46]</sup>.

Another study analyzed paraffin embedded tissue from 69 HCC LT patients (which included 40 post LT recurrences) for miRNA expression. The biomarker proposed by this study consisted of 67 miRNAs, this biomarker had significantly identified the HCC recurrent cases, and it also displayed significance when applied to patients within and beyond MC<sup>[47]</sup>.

A predictive scoring system was recently published combining MC with miRNA markers to identify the risk of

**Table 2** Expanded criteria that incorporate tumor biomarkers for hepatocellular carcinoma-liver transplantation

Ref.	Year	Morphometric criteria	Biomarker criteria	Donor type	n	Survival
Kwon <i>et al</i> <sup>[34]</sup>	2007	Any number of lesions ≤ 5 cm each	AFP ≤ 400 ng/mL	Living	139	5 yr OS: 79.9%
Takada <i>et al</i> <sup>[38]</sup>	2007	Up to 10 lesions ≤ 5 cm each	PIVKA-II ≤ 400 mAU/mL	Living	136	5 yr OS: 87%

Lee <i>et al</i> <sup>[39]</sup>	2015	Total tumor diameter ≤ 10 cm	PET/CT negative uptake	Living	280	5 yr OS: 73.4%, 5 yr DFS: 80.4%

AFP: Alpha fetal protein; UCSF: University of California, San Francisco; DFS: Disease free survival; PIVKA-II: Protein induced by vitamin K absence or antagonism factor II; OS: Overall survival.

HCC recurrence post- LT. Two miRNA markers significant of tumor recurrence (miR-214, miR-3187) were identified *via* microarray analysis of paraffin explant samples of 40 patients. In another validation cohort of 22 patients, high expression of miR-214 and low expression of miR-3187 were significantly associated with HCC recurrence. A predictive score including levels of these miRNAs and MC status was successful in identifying patients with a lower risk for tumor recurrence and death<sup>[48]</sup>.

## CONCLUSION

Although there remains a large discrepancy between cadaveric organ availability and demand, numerous selection criteria for HCC exceeding the well-established MC have been proposed worldwide. Only a few of these criteria have been validated by multiple independent studies. The current direction of incorporating biomarkers and other surrogates of tumor biology to morphometric criteria is highly encouraged, however this is not without challenge. The most commonly used HCC biomarker AFP, is not a reliable indicator for HCC. AFP levels are not elevated in up to 40% of cases<sup>[49,50]</sup>, furthermore AFP is challenged by its poor sensitivity and specificity<sup>[51]</sup>. Pre-LT tumor biopsy is somehow discouraged, due in part to tumor heterogeneity when multifocal HCC is present, as well as the risk of needle-tract seeding<sup>[52]</sup>.

In light of the current organ shortage, hepatic resection followed by salvage LT has also been suggested as a treatment strategy for HCC. A systematic review by Chan *et al*<sup>[53]</sup> demonstrated median overall survival at 1-, 3- and 5-years post LT was 89%, 80%, and 62% respectively. Additionally, tissue specimens obtained from a pre-LT resection can assist in selection of tumors with a favorable histopathological profile for LT<sup>[53]</sup>.

Monitoring radiologic and laboratory (tumor markers) tumor response post-LRT has been utilized to identify tumors with favorable biology; and in line with this current UNOS guidelines for organ allocation in the United States require listing HCC patients for 6 mo before qualification for HCC exception points<sup>[54]</sup>.

miRNAs are stable in blood and resistant to RNAases,

which makes them promising HCC biomarkers<sup>[46]</sup>. Further validation of extended HCC-LT criteria models that incorporate predictors of tumor biology are needed to optimize organ utilization in an ongoing era of organ shortage.

### Abstract

Alpha-fetoprotein (AFP) is the main tumor biomarker available for the management of hepatocellular carcinoma (HCC). Although it is neither a good screening test nor an accurate diagnostic tool for HCC, it seems to be a possible prognostic marker. However, its contribution in liver transplantation for HCC has not been fully determined, although its use to predict recurrence after liver transplantation has been underlined by international societies. In an era of organ shortages, it could also have a key role in the selection of patients eligible for liver transplantation. Yet unanswered questions remain. First, the cut-off value of serum AFP above which liver transplantation should not be performed is still a subject of debate. We show that a concentration of 1000 ng/mL could be an exclusion criterion, whereas values of < 15 ng/mL indicate patients with an excellent prognosis whatever the size and number of tumors. Monitoring the dynamics of AFP could also prove useful. However, evidence is lacking regarding the values that should be used. Today, the real input of AFP seems to be its integration into new criteria to select patients eligible for a liver transplantation. These recent tools have associated AFP values with morphological criteria, thus refining pre-existing criteria, such as Milan, University of California, San Francisco, or "up-to-seven". We provide a review of the different criteria submitted within the past years. Finally, AFP can be used to monitor recurrence after transplantation, although there is little evidence to support this claim. Future challenges will be to draft new international guidelines to implement the use of AFP as a selection tool, and to determine a clear cut-off value above which liver transplantation should not be performed.

**Core tip:** Alpha-fetoprotein (AFP) is the main biomarker available for the management of hepatocellular carcinoma (HCC). Yet, its contribution in liver transplantation for HCC has not been fully determined. We discuss the interest of AFP as a prognostic factor to predict tumor recurrence after liver transplantation, and as a selection tool to assess the best candidates to receive a graft. We also provide an overview of the different ways that AFP could be included in decisional algorithms before liver transplantation, through its static and dynamic values.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the second most common cause of death from cancer worldwide. It is estimated to have caused nearly 745000 deaths in 2012<sup>[1]</sup>. It represents a frequent indication for liver transplantation (LT). Good results are now achieved by accurate selection of patients. The Milan criteria (MC) are considered as the reference by health systems worldwide and are currently used by the United Network for Organ Sharing<sup>[2-4]</sup>. The overall survival rates after LT for HCC range from 65% to 80% at 5 years for patients fulfilling these criteria<sup>[5-7]</sup>. As the incidence of HCC is currently rising, several teams have attempted to extend the selection criteria in order to treat more patients: *i.e.*, University of California, San Francisco (UCSF), "up-to-seven", or "5/5" criteria<sup>[8-11]</sup>. These criteria are all based on the number and the size of nodules, but other features can influence recurrence rate after LT. Among these, histopathologic findings, poor differentiation, and microvascular invasion are negative prognostic factors<sup>[12-14]</sup>. However, data on these are difficult to obtain before transplantation. Therefore, we need preoperative prognostic elements to help improve the selection of patients eligible for LT. Today, alpha-fetoprotein (AFP) is the main tumor biomarker available to manage HCC<sup>[15]</sup>. It has many advantages, as it is simple to use, relatively inexpensive, and is widely available. In this article, we discuss the contribution of AFP in LT in HCC. First we assess its value as a screening and diagnosing tool, then we focus on its prognostic relevance, and finally we analyze its interest for the selection of the best candidates to receive a graft.

## AFP: WHAT IS IT?

AFP is a 67-kDa glycoprotein that is produced in early

fetal life by the liver and by a variety of tumors including HCC, hepatoblastoma, and non-seminomatous germ-cell tumors of the ovary and testis (*e.g.*, yolk sac and embryonal carcinoma). Tumor cells synthesize fetal proteins because of the "de-differentiation" of adult hepatocytes<sup>[16]</sup>. During fetal life, AFP is synthesized at first by the yolk sac, then by the liver. By the end of the first trimester, the fetal liver produces nearly all of the AFP. Although synthesis is reduced markedly shortly after birth, small amounts of AFP continue to be produced during adulthood<sup>[17]</sup>. Normal concentrations of AFP in adult serum are  $\leq 20$  ng/mL. AFP can increase temporarily in cases of liver injury or regeneration, particularly after liver resection, during fulminant viral hepatitis, or chronic viral hepatitis<sup>[18,19]</sup>. Patients with chronic hepatitis or cirrhosis and persistently elevated AFP levels are at higher risk of developing HCC<sup>[20-22]</sup>. More than the AFP rate at a given time, it is the increased expression of AFP that suggests the presence of HCC<sup>[23]</sup>.

Up to 20% of cases of HCC do not produce AFP<sup>[24]</sup>. For others, AFP can raise from normal to  $\geq 100000$   $\mu\text{g/L}$ <sup>[25]</sup>. AFP concentrations do not differ if HCC is developed on a cirrhotic liver or not. Serum AFP levels increase by 20%-80% in patients with HCC and are strongly related to tumor aggressiveness<sup>[26-28]</sup>. Its concentrations are correlated with tumor size, microvascular invasion and poorly differentiated HCC<sup>[15,20,29,30]</sup>. However, the utility of AFP is restricted by the existence of non-AFP-secreting tumors<sup>[24]</sup>.

## AFP: A POOR MARKER FOR SCREENING AND DIAGNOSING HCC AMONG PATIENTS ON A LT-WAITING LIST

### Use of AFP for HCC screening

Literature has shown that serum AFP ( $> 15$  or  $20$  ng/mL) as a screening test for HCC had a sensitivity of between 39% and 64%, and a specificity of between 76% and 91%. The positive predictive value is estimated at between 9% and 33%<sup>[20,31-33]</sup>.

The association of AFP with ultrasonography only improved the sensitivity by 6%-7% and the specificity by 2% compared to ultrasonography alone<sup>[31,34]</sup>, while also increasing the cost of HCC screening<sup>[35]</sup>.

These results clearly show that AFP is not a useful screening tool for HCC<sup>[36]</sup>. The first reason is that fluctuating levels of AFP in patients with cirrhosis can reflect flare-ups of HBV or HCV infection, or exacerbation of an underlying liver disease other than HCC development<sup>[7,37]</sup>. In addition, only a small proportion of tumors at an early stage (10%-20%) present with abnormal AFP serum levels<sup>[7]</sup>.

Current guidelines from the American Association for the Study of Liver Disease and the European Association for the Study of the Liver (EASL) have stopped recommending the use of AFP anymore to screen for HCC in cirrhotic patients. Only ultrasonography must be performed every 6 mo<sup>[7,38]</sup>.

### AFP for the diagnosis of HCC

In a case-control study of 340 cirrhotic patients, Trevisani *et al.*<sup>[39]</sup> have shown that AFP levels of > 20 ng/mL had a sensitivity of 60% and a specificity of 91% to diagnose HCC. At this threshold, 40% of all cases of HCC would be missed. An increase in this cut-off value would result in a lower rate of HCC detection whereas a lower cut-off value would increase the false-positive rate. These results demonstrate that AFP should not be used to diagnose HCC. Thus, AFP is no longer part of the diagnostic algorithm for HCC<sup>[7,38]</sup>.

## AFP: A PREDICTOR OF RECURRENCE AFTER LT

Although AFP is no longer used to diagnose HCC, several teams have shown that it could be a very interesting tool for prognosis<sup>[40,41]</sup>.

Thus, it could prove useful when discussing LT. Shetty *et al.*<sup>[42]</sup> in 2004, were among the first to suggest the potential prognostic usefulness of AFP when used specifically for patients who have received a liver graft. In their study, they have shown that elevated serum levels of AFP before LT were significantly associated with poorer recurrence-free survival and overall survival. In the following years, multiple studies have confirmed the prognostic role of AFP to predict outcomes after LT. Most of them are based on small cohorts of patients<sup>[28,43-47]</sup> and their main drawbacks are their retrospective designs. Yet all of them display the same tendency: Elevated AFP at the time of LT is associated with a worse prognosis after LT. Between 2008 and 2011, three large cohort studies that included thousands of patients, also showed the same pattern<sup>[48-50]</sup>. As a result, the EASL-EORTC advises on the prognostic relevance of AFP in their Clinical Practice Guidelines for the management of HCC<sup>[7]</sup>. Nevertheless, AFP alone is not sufficient to predict recurrence. Its interpretation must be associated with other demonstrated prognostic factors such as histopathologic findings, tumor differentiation, and microvascular invasion<sup>[12-14]</sup>.

## USE OF AFP TO SELECT LT CANDIDATES

Although the prognostic value of AFP seems well established today, one issue remains: How can we use AFP to improve the selection of LT candidates and ensure acceptable outcomes?

This question raises other issues: What cut-off value must we use to define an “elevated” level of AFP? Is it important to consider the evolution of AFP over time? Can AFP be included in an algorithm to help assess the best candidates for LT?

### Defining a cut-off value for AFP

To this day, there is no clear consensus regarding the level of AFP above which a patient should not be a

candidate for LT. The international consensus report regarding liver transplantation, published in 2012, mentions that “AFP concentration adds prognostic information in HCC patients and may be used for making decisions regarding transplantation”<sup>[4]</sup>, but with a weak level of evidence. According to these recommendations, whatever the level of AFP, LT can be considered as long as a patient fits within the Milan, UCSF, “up-to-seven” or “5/5” criteria<sup>[2,8,11,51]</sup>.

More than 20 studies have tried to define a cut-off value for pre-LT AFP, above which the prognosis would be too impaired to propose a LT. The main studies are reported Table 1. Several values have been studied, ranging from 15 ng/mL<sup>[52,53]</sup> to 1000 ng/mL<sup>[30,45,54-57]</sup>. Three reviews have also focused on the static values of AFP in an attempt to synthesize these various findings<sup>[58-60]</sup>, but none have been designed as a meta-analysis and thus no clear conclusion could be drawn.

However, three values appear repeatedly in the different studies: 15 ng/mL, 400 ng/mL and 1000 ng/mL.

The value of 15 ng/mL is interesting because it could indicate a population with a very good prognosis, even for patients with HCC graded beyond the MC. Lai *et al.*<sup>[52]</sup> and Berry *et al.*<sup>[53]</sup> report almost identical conclusions regarding this 15 ng/mL cut-off point: Patients outside the MC but with AFP < 15 ng/mL and no other adverse prognostic factors have excellent outcomes after a LT. This suggests that, in some cases, AFP could be used to select people with excellent outcomes and who would have been unfairly excluded from receiving a LT because they exceeded the MC.

The value of 1000 ng/mL appears as a value that should exclude patients from receiving a LT, at least in the absence of downstaging. Yao *et al.*<sup>[8]</sup>, when defining UCSF criteria in 2001, had already pointed out that an AFP of > 1000 ng/mL was related to a worse outcome, but only in univariate analyses. Later, the same team published a study concluding that AFP > 1000 ng/mL was an independent predictor of vascular invasion and should be an exclusion criterion for LT<sup>[30]</sup>. According to their study, using this cut-off value could have led to the exclusion of 4.7% of patients from receiving a LT, while decreasing tumor recurrence by 20%. Other publications observed that an AFP > 1000 ng/mL was a predictor of recurrence after a LT<sup>[45,55,61]</sup>. In 2012, Duvoux *et al.*<sup>[57]</sup> proposed a score that integrated AFP for the selection of patients eligible for LT. The value of 1000 ng/mL automatically led to the exclusion of these patients. In France, Duvoux’s algorithm is currently in use and an AFP value of 1000 ng/mL is recognized as a limit over which a LT should not be performed. The UCSF team now applies a similar policy<sup>[62]</sup>.

What about the values in between 15 and 1000 ng/mL? Several cut-off values have been studied over the last few years. The endpoints differ between studies: Some teams have studied the relationships between AFP and recurrence, whereas other have focused on the relationships between AFP and microvascular

AFP: Alpha-fetoprotein.

invasion, or AFP and drop-out rates from waiting lists. The most frequent cut-off value reported in the literature is 400 ng/mL. This has been reported by authors from various countries in Asia<sup>[63]</sup>, Europe<sup>[64,65]</sup> and the United States<sup>[49,59,66]</sup>. It appears to be linked to recurrence but also to the risk of dropout while on a waiting list. However, it seems difficult to use the cut-off value of 400 ng/mL to directly exclude patients from a waiting list, because this value has been mostly studied as part of algorithms that include tumor volume, tumor size, the MC, and/or the UCSF-criteria. Moreover, many other cut-off values have been suggested, such as 100 ng/mL<sup>[47,57,67]</sup> and 200 ng/mL<sup>[10,68]</sup>. The level of evidence to define an optimal value is very weak and thus calls for further studies.

As to which AFP value should be considered, Merani *et al*<sup>[66]</sup> showed that only the last pre-transplant value of AFP independently predicted survival, unlike the AFP at the time of listing. Most of the studies cited above also used the last pre-transplant value of AFP to perform their analyses.

### Evolution of AFP over time: A critical marker

Studies have tried to assess the impact of the dynamic behavior of AFP. They are presented Table 2. The first team to address this issue was Han *et al*<sup>[69]</sup> in 2007. Although focusing on only 47 patients, this Canadian study found out that the preoperative AFP slope was an independent prognostic factor for recurrence, with a

cut-off at 50 ng per month. Later, Vibert *et al*<sup>[70]</sup> studied the outcomes of 153 patients in a monocentric French cohort, and concluded that a progression of AFP of > 15 ng per month was associated with decreased overall survival. Lai *et al*<sup>[52]</sup> in 2013, in a multicentric European study, obtained the same results. A fourth study proposed the cut-off value of 0.1 ng per day<sup>[71]</sup>. The main drawback of these four studies was the small number of data points used to determine the slope of AFP: Only two values were used by Vibert *et al*<sup>[70]</sup> (lowest and highest) and by Lai *et al*<sup>[52]</sup> (time of listing and time of LT). Han *et al*<sup>[69]</sup> used a median of 4 values (ranging from 2 to 11).

Other studies have focused on AFP dynamics, but with a different goal. They have evaluated the prognostic value of AFP evolution after loco-regional therapy. One of the first teams to address this question was Riaz *et al*<sup>[72]</sup> in 2009. They showed that a drop in AFP following loco-regional therapy was associated with better outcomes after LT. Bhat *et al*<sup>[73]</sup> used a logistic regression model to show that a decrease in AFP value after trans-arterial chemoembolization was significantly associated with better overall survival<sup>[73]</sup>. Wong *et al*<sup>[59]</sup> also obtained similar results. These studies enabled AFP to be part of the definition of a successful downstaging, along with radiological features. In fact, Yao *et al*<sup>[62]</sup> in California require that patients with an initial AFP > 1000 ng/mL have AFP decreased to < 500 ng/mL after loco-regional therapy, before undergoing LT. Similarly, in

AFP: Alpha-fetoprotein.

France, the use of the Duvoux algorithm enables a patient with an AFP of > 1000 ng/mL to be back on the waiting list if AFP drops below this value<sup>[57]</sup>. Yet, to this day, the international recommendations only mention the number and size of viable tumors as criteria for successful downstaging<sup>[4]</sup>. The AFP concentrations before and after downstaging are just considered as giving “additional information” because evidence is not strong enough to enforce the wider use of AFP dynamics in the management of LT candidates. These recommendations date back from 2012 and they may evolve based on the recent studies mentioned above.

### Designing new scores that integrate AFP: The end of the MC?

If AFP can be used to obtain additional information to select LT candidates, then it appears logical to integrate it into an algorithm, along with other prognostic factors. Since Mazzaferro’s study in 1996<sup>[2]</sup>, attempts have been made to improve the MC. Including AFP to create a new selection tool could be a key.

This idea arose as early as 2007, when a Korean team designed a score based on tumor size, number of tumors, and value of AFP in order to select the best candidates for living donor LT<sup>[56]</sup>. For each feature, the patient was awarded between 1 and 4 points. In this small study ( $n = 63$ ), the different values of AFP used were < 20 ng/mL, 200 ng/mL, and 1000 ng/mL. According to the authors, this score allowed a slight expansion of the MC with comparable outcomes. Five years later, Duvoux *et al*<sup>[57]</sup> developed a very similar score. Their multicentric French study was based on a much larger cohort of patients ( $n = 492$ ), and used the same three characteristics for the selection of patients: *i.e.*, tumor size, number, and AFP. However, the number of points awarded for each feature was different; as were the cut-off values for AFP: *i.e.*, 100 ng/mL and 1000 ng/mL. It is interesting to note that in this latter score, an AFP > 1000 ng/mL provided enough points for patients to be excluded directly from LT, whatever the size and number of tumors. This means that, according to this score, AFP overpowers the MC. In France, Duvoux *et al*<sup>[51]</sup>’s study precluded to a radical change in the allocation policy for LT: This score is now used to select candidates for LT. Patients exceeding the criteria are classed as having a temporary contra-indication as long as a downstaging is not successfully performed. A recent study by Varona *et al*<sup>[74]</sup> has confirmed the accuracy of this model for the

prediction of recurrence and survival after a LT.

Other teams have come up with different scoring systems that include AFP when selecting LT candidates. The main ones are presented in Table 3. In 2008, a Chinese team designed the Hangzhou criteria<sup>[63]</sup>, based on total tumor diameter, AFP, and histopathologic grade. The main issue with this score was the necessity for histopathologic evaluation prior to LT, which is not easy to obtain and may be inaccurate as it is based on a biopsy. Nevertheless, this work raised the idea of total tumor size, rather than maximum size of tumor, or number of tumors. Lai’s team simplified the Hangzhou score and suggested using a score that featured only AFP and total tumor diameter (TTD), with a cut-off value at 400 ng/mL for AFP and 8 cm for TTD<sup>[64]</sup>. Various teams have developed slightly different scores, still using an AFP cut-off value of 400 ng/mL but replacing TTD with total tumor volume<sup>[49,75]</sup> or actual tumor volume<sup>[76]</sup>. More recently, a Korean team suggested that a combination of AFP and F-FDG PET data could be a very interesting selection tool<sup>[77]</sup>: A positive PET (cut-off at 1.10) and an AFP of > 200 ng/mL defined a group of patients with a high risk of recurrence and who should not be selected for LT. The main drawback of this study is the cost of F-FDG PET, but the authors point out the usefulness of PET to predict tumor aggressiveness, rather than sheer size and number.

Despite a few discrepancies, these studies share many common points: All of them agree that an AFP value of > 1000 ng/mL should lead to exclusion of these patients from receiving a LT; most suggest an association between AFP and morphological characteristics (size, number, and/or volume of tumors); and a few of these studies suggest the probable need for another marker for aggressiveness, such as histopathologic findings or PET.

## MONITORING AFP AFTER LIVER TRANSPLANTATION: A WISE POLICY OR A WASTE OF TIME (AND MONEY)?

In the absence of HCC recurrence, AFP levels decrease to < 20 ng/mL within 2 mo post-transplantation<sup>[78]</sup>. Hepatocellular carcinoma recurs in 10%-20% of transplant recipients, despite careful patient selection<sup>[2,7,78-80]</sup>. There is no evidence-based recommendation to be applied after transplantation in order to promptly detect and treat HCC recurrence.

Because few recurrences after LT can benefit from curative treatment, this raises questions about the usefulness of active surveillance after LT<sup>[81,82]</sup>. Roberts<sup>[82]</sup> suggest that screening all patients for HCC recurrence after transplantation, using both imaging and serum biomarkers, is probably not cost effective. However, AFP monitoring, in itself, is not very costly and may be appropriate at regular intervals<sup>[83]</sup>. Yamashiki *et al*<sup>[78]</sup> proposed to measure AFP at monthly periods for the first two years after LT, to detect any HCC recurrence. When a cut-off level of 20 ng/mL was used, the sensitivity and

specificity of AFP to detect HCC recurrence after liver transplantation were 67% and 100%, respectively<sup>[78]</sup>. Several other studies suggest that active surveillance with AFP should be performed, but the optimal frequency is not clear<sup>[83-85]</sup>. Since 2010, international guidelines state that post-transplant monitoring may be performed every 6 to 12 mo, using contrast-enhanced computed tomography or magnetic resonance imaging in addition to AFP measurements<sup>[4]</sup>.

## CONCLUSION

Today, AFP is a key element to consider in the management of patients with HCC and who are eligible for LT. Although it does not contribute to screening or obtaining a diagnosis of HCC among patients on a LT waiting list, it can help predict the aggressiveness of the tumor and its risk of recurrence after LT.

The main usefulness of AFP regarding LT for HCC is its ability to assess the best LT candidates. It can be considered as an excellent selection criterion in association with the size and number of HCC nodules. This enables a reasonable enlargement of the MC while also guaranteeing satisfactory outcomes. Integrating an upper limit of 1000 ng/mL to the selection criteria would also allow exclusion of the few patients within the MC but who have a high risk of recurrence after LT. Furthermore, AFP can be used to monitor the evolution of HCC while on a waiting list, particularly in cases where there is downstaging.

Future challenges lie in the drafting of new international guidelines to implement the use of AFP as a selection tool, and to clarify the exact values that must be considered when using this biomarker in LT for HCC.

### Abstract

Currently, partial hepatectomy is the treatment of choice for a wide variety of liver and biliary conditions. Among the possible complications of partial hepatectomy, acute kidney injury (AKI) should be considered as an important cause of increased morbidity and postoperative mortality. Difficulties in the data analysis related to postoperative AKI after liver resections are mainly due to the multiplicity of factors to be considered in the surgical patients, moreover, there is no consensus of the exact definition of AKI after liver resection in the literature, which hampers comparison and analysis of the scarce data published on the subject. Despite this multiplicity of risk factors for postoperative AKI after partial hepatectomy, there are main factors that clearly contribute to its occurrence. First factor relates to large blood losses with renal hypoperfusion during the operation, second factor relates to the occurrence of post-hepatectomy liver failure with consequent distributive circulatory changes and hepatorenal syndrome. Eventually, patients can have more than one factor contributing to post-operative AKI, and frequently these combinations of acute insults can be aggravated by sepsis or exposure to nephrotoxic drugs.

**Key words:** Hepatectomy; Liver resection; Acute renal injury; Hepatorenal syndrome; Kidney

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** In the specific scenario of liver resections, there are limited and heterogeneous data regarding the occurrence of acute kidney injury (AKI) in the post-operative period, and its clinical relevance (mortality, morbidity and hospital stay) were not conclusively explored and clarified. Difficulties in the data analysis related to postoperative AKI after liver resections are mainly due the scarce data published on the subject.

## INTRODUCTION

Currently, partial hepatectomy is the treatment of choice for a wide variety of primary liver tumors (benign or malignant), tumors of the bile ducts and secondary malignant liver tumors. The partial liver resections may also be necessary in the management of complex cystic liver diseases, benign biliary structures, some cases of hepatic trauma and more recently with living donor liver transplantation<sup>[1]</sup>. With the refinement of surgical techniques, improved selection of patients to procedure, advances in anesthetic support and perioperative care, this traditionally complex and feared operation has become a routine procedure in the past 20 years, with acceptable mortality rates ranging from 3.1% to 4.5%<sup>[2-4]</sup>.

Among the possible complications of major surgical procedures, including the partial hepatectomy, acute kidney injury (AKI) should be considered as an important cause of increased morbidity and postoperative mortality<sup>[5,6]</sup>, with an incidence ranging from 10% to 30% after major operations<sup>[7,8]</sup>. Literature data report an incidence of 1% of AKI in the postoperative major non-cardiac surgery without liver resection<sup>[6]</sup> about 20% after cardiac surgery<sup>[9-11]</sup> and 50% after liver transplantation<sup>[12-18]</sup>.

In the specific scenario of liver resections, there are limited and heterogeneous data regarding the occurrence of AKI in the postoperative period, with an incidence ranging from 0.9% to 15.1% of the patients<sup>[19-23]</sup>, and its clinical relevance (mortality, morbidity and hospital stay) were not conclusively explored and clarified.

Difficulties in the data analysis related to postoperative AKI after liver resections are mainly due to the multiplicity of factors to be considered in this surgical patients, such as general medical conditions and comorbidities, nutritional disorders, metastatic malignancy with low physiological reserve systems, immunological disorders, chemotherapy treatment, functional capacity and volume of liver parenchyma to be preserved, and the perioperative hemodynamic effects of the different modalities of partial hepatectomy. Moreover, there is no consensus of the exact definition of AKI after liver resection in the literature, which hampers comparison and analysis of the scarce data published on the subject<sup>[22]</sup>.

Despite this multiplicity of risk factors for postoperative AKI after partial hepatectomy, there are main factors that clearly contribute to its occurrence. First factor relates to large blood losses with renal hypoperfusion during the operation<sup>[20]</sup>, that very often can be associated by the deleterious renal effects of red blood cell transfusion<sup>[23]</sup>, and in some occasions this renal hypoperfusion occurs in patients with increased

renal susceptibility to ischemia, usually elderly patients with underlying cardiovascular or renal disorders, or eventually it may be drug-induced<sup>[21-24]</sup>. Second factor relates to the occurrence of post-hepatectomy liver failure (PLF) with consequent distributive circulatory changes and hepatorenal syndrome (HRS)<sup>[20]</sup>. Eventually, patients can have more than one factor contributing to post-operative AKI, and frequently these combinations of acute insults can be aggravated by sepsis<sup>[20-24]</sup> or exposure to nephrotoxic drugs, such as aminoglycosides<sup>[25]</sup>.

The aim of this review is to present the definition of postoperative AKI after partial hepatectomy, the different pathophysiological mechanisms for its occurrence and methods for preventing these events.

## DEFINITION OF POSTOPERATIVE AKI AFTER PARTIAL HEPATECTOMY

AKI is characterized by the deterioration of kidney function over a period of hours to days, resulting in the failure of the kidney to excrete nitrogenous waste products and to maintain fluid and electrolyte homeostasis<sup>[26]</sup>. In recent years, several criteria have been proposed for the diagnosis of AKI in general population, particularly the "Risk, Injury, Failure, Loss of Renal Function and End-Stage Renal Disease" (RIFLE) criteria<sup>[27]</sup>, the "Acute Kidney Injury Network" (AKIN) criteria<sup>[28]</sup> and more recently, the criteria suggested by a panel of experts, which combine the AKIN and the RIFLE criteria, thus proposing a new classification: The "Kidney Disease Improving Global Outcomes" criteria<sup>[29]</sup> (Table 1).

The first question regarding the definition of postoperative AKI after partial hepatectomy, would be determining which of these proposed AKI criteria is most appropriate for these patients undergoing liver resection. Whereas acute tubular necrosis (ATN), resulting from hypoxic damage to the renal medulla, is considered as a major cause of postoperative AKI<sup>[30]</sup>, different from general population, liver resections are often performed in the presence of functional deficit of the hepatic parenchyma, as in fibrosis, steatosis, cirrhosis, chemotherapy-induced injury and also in biliary obstruction<sup>[2]</sup>. Moreover, the recent technical improvements in liver surgery have resulted in an expansion and more liberal indications for major hepatectomies in patients with these underlying liver conditions<sup>[2,3,31-34]</sup>, however, the risk of postoperative complications, such as AKI, have remained important concerns<sup>[3,31,35]</sup>.

In the specific case of hepatocellular carcinoma, the tumor generally appears in a cirrhotic liver, which is a contributor to unfavorable postoperative results in large procedures<sup>[36]</sup>, regarding renal dysfunction, AKI is a common and potentially fatal event in patients with cirrhosis<sup>[37-39]</sup>, with a reported prevalence of 14%-50% in patients with cirrhosis<sup>[40-45]</sup>, this wide range in prevalence is likely due to different study populations and varying definitions of renal dysfunction. Studies evaluating survival predictors in cirrhosis, renal dysfunction was a

**Table 1** Current diagnostic criteria for acute kidney injury in general population

	RIFLE criteria <sup>[27]</sup>	AKIN criteria <sup>[28]</sup>	KDIGO criteria <sup>[29]</sup>
Diagnostic criteria	Increase in sCr to $\geq 1.5$ times baseline, within 7 d; or GFR decrease $> 25\%$ ; or urine volume $< 0.5$ mL/kg per hour for 6 h	Increase in sCr by $\geq 0.3$ mg/dL (26.5 mmol/L) within 48 h; or increase in sCr $\geq 1.5$ times baseline within 48 h; or urine volume $< 0.5$ mL/kg per hour for 6 h	Increase in sCr by $\geq 0.3$ mg/dL (26.5 mmol/L) within 48 h; or increase in sCr to $\geq 1.5$ times baseline, which is known or presumed to have occurred within the prior 7 d; or urine volume $< 0.5$ mL/kg per hour for 6 h
	Risk: sCr increase 1.5-1.9 times baseline; or GFR decrease 25%-50%; or urine output $< 0.5$ mL/kg per hour for 6 h	Stage 1: sCr increase 1.5-1.9 times baseline; or sCr increase $\geq 0.3$ mg/dL (26.5 mmol/L); or urine output $< 0.5$ mL/kg per hour for 6 h	Stage 1: sCr increase 1.5-1.9 times baseline; or sCr increase $\geq 0.3$ mg/dL (26.5 mmol/L); or urine output $< 0.5$ mL/kg per hour for 6-12 h
Staging	Injury: sCr increase 2.0-2.9 times baseline; or GFR decrease 50%-75%; or urine output $< 0.5$ mL/kg per hour for 12 h	Stage 2: sCr increase 2.0-2.9 times baseline; or urine output $< 0.5$ mL/kg per hour for 12 h	Stage 2: sCr increase 2.0-2.9 times baseline; or urine output $< 0.5$ mL/kg per hour for $\geq 12$ h
	Failure: sCr increase $\geq 3.0$ times baseline; or GFR decrease 50%-75%; or sCr increase $\geq 4.0$ mg/dL (353.6 mmol/L) with an acute increase of at least 0.5 mg/dL (44 mmol/L); or urine output $< 0.3$ mL/kg per hour for $\geq 24$ h; or anuria for $\geq 12$ h	Stage 3: sCr increase 3.0 times baseline; or sCr increase $\geq 4.0$ mg/dL (353.6 mmol/L) with an acute increase of at least 0.5 mg/dL (44 mmol/L); or urine output $< 0.3$ mL/kg per hour for $\geq 24$ h; or anuria for $\geq 12$ h	Stage 3: sCr increase 3.0 times baseline; or sCr increase to $\geq 4.0$ mg/dL (353.6 mmol/L); or initiation of renal replacement therapy; or urine output $< 0.3$ mL/kg per hour for $\geq 24$ h; or Anuria for $\geq 12$ h

AKIN: Acute Kidney Injury Network; GFR: Glomerular filtration rate; KDIGO: Kidney Disease Improving Global Outcome; RIFLE: Risk, Injury, Failure, Loss, End stage renal disease; sCr: Serum creatinine.

powerful predictor of death, as Child-Pugh score<sup>[46-48]</sup>.

Along with parenchymal dysfunction, the portal hypertension levels and its hemodynamic consequences are directly related to the degree of underlying liver injury<sup>[49-51]</sup>, as it is observed in cirrhosis and others conditions, such as severe steatosis and chemotherapy-induced injury<sup>[52]</sup>. The types of chemotherapy-induced liver toxicity include steatosis<sup>[53]</sup>, sinusoidal changes<sup>[54]</sup>, steatohepatitis<sup>[55]</sup>, and hemorrhagic central lobular necrosis<sup>[52]</sup>. Steatosis represents fatty changes in the liver, with the presence of fat droplets within the hepatocytes<sup>[56]</sup>, and it has been shown that steatosis may interfere with circulation through sinusoids and impair regeneration, and in addition the liver's protective mechanism against oxidative stress appear to be impaired<sup>[57,58]</sup>. The morbidity following liver resection associated with steatosis has been reported by Belghiti *et al*<sup>[2]</sup>, in this study with 747 patients, the mortality rate was higher in patients having steatosis than in those with no steatosis, 22% vs 8%, respectively ( $P = 0.003$ ). Likewise, according to Behrns *et al*<sup>[32]</sup> in 135 liver resections, morbidity was seen in 29% and 10% of the patients with steatosis and without steatosis, respectively.

Besides the fact that a significant portion of patients eligible for partial hepatectomy have underlying chronic liver disease or were exposed to systemic therapies with liver toxicity, the hemodynamic changes in patients after major liver resections may have similarities with those of patients with cirrhosis or acute liver failure, and depending on the remnant liver volume and functional quality of parenchyma (steatosis/cirrhosis) the clinical effects may be more evident<sup>[59]</sup>.

In 1953, Kowalski and Abelmann<sup>[60]</sup> reported the results of a study which have demonstrated that cardiac output in cirrhotic patients was significantly higher compared with healthy volunteers. The reason for this

so-called hyperdynamic state is that patients with cirrhosis develop portal hypertension with resultant splanchnic vasodilation and pooling of blood secondary to increased resistance to portal flow. This is due to (1) vasodilators such as nitric oxide, carbon monoxide, and endogenous cannabinoids<sup>[61,62]</sup>; and (2) vasodilation from inflammatory cytokines such as tumor necrosis factor- $\alpha$  and interleukin-6 induced by bacterial translocation from the gut<sup>[63]</sup>. As a result, the concentration of cyclic guanosine monophosphate cyclic is increased, resulting in splanchnic vasodilation, decrease in central and arterial blood volume, low capillary pressure, low central venous pressure (LCVP), low systemic vascular resistance, and reduction of mean arterial pressure<sup>[64]</sup>. This compensatory increase in cardiac output *via* activation of the sympathetic nervous system by carotid baroreceptors maintains sufficient renal perfusion, however, with decompensation of cirrhosis and increasing severity of portal hypertension, the compensatory increase in cardiac output is inadequate to maintain circulatory blood volume and adequate renal perfusion<sup>[65]</sup>. Therefore, it would be reasonable that diagnostic and staging AKI criteria that consider this circulatory impairment could be better applied in patients undergoing liver resections, particularly large resections and those with chronic liver disease.

It is extremely important to point out that in the case of patients with chronic liver disease, isolated dosages of serum creatinine (sCr) levels can not reveal the actual renal function of the patient, because: (1) there is decreased creatine formation in the secondary muscles loss of muscle mass<sup>[66]</sup>; (2) is increased renal tubular secretion of creatinine (Cr)<sup>[67]</sup>; (3) increasing the circulating volume of distribution in cirrhosis can dilute the sCr<sup>[68]</sup>; and (4) interference in the measurement of Cr due to elevated bilirubin<sup>[69]</sup>. As a result, the serum levels of Cr in patients

with cirrhosis overestimate glomerular filtration rate (GFR). Therefore, a dynamic definition referring to the elevation of serum Cr of  $\geq 50\%$  of preoperative levels to a final value  $\geq 1.5$  mg/dL (133  $\mu$ mol/L) could be more suitable for these patients, and clinical studies have shown that AKI according to these criteria was a strong predictor of hospital mortality in patients with liver disease<sup>[70-72]</sup>.

Another situation relates to the measurement of urine output of patients with chronic liver disease and ascites, since these patients can often present oliguria with high sodium retention, but they can still maintain a relatively normal GFR<sup>[73]</sup>. On the other hand, these patients can also have an increased diuresis because of diuretics therapy.

Thus, the current criteria suggested by the "International Ascites Club" for definition of AKI in cirrhotic patients do not include unreal measurements for these patients<sup>[68]</sup> (Table 2), and apparently would be the most appropriate criteria for the diagnosis and management of AKI after partial hepatectomy, especially in cases of large resections and underlying chronic liver disease.

## HEMODYNAMIC INSTABILITY AND RENAL HYPOPERFUSION

Although the extent of liver resection correlates with the magnitude of the procedure, and patients undergoing resection of more than three segments or an additional extrahepatic procedure have an increased risk of complications<sup>[74-76]</sup>, this is not a rigid rule. For example, an isolated resection of segment I is technically more demanding than a right hepatectomy, similarly, resection of segments IV, V, VIII or posterior right segments (segments VI, VII) may be technically more difficult than the left or right hepatectomy, although the transection area is larger. Therefore, a minor hepatectomy should not be considered as an operation of less magnitude, and most important, the prevention of intraoperative hemorrhage should not be neglected. If excessive blood loss persists and a reduction in oxygen delivery is not corrected, the renal medulla may be susceptible to ischemic ATN<sup>[77]</sup>, and as a result, patients may suffer from AKI. The results of two large studies<sup>[3,31]</sup> suggest that a blood loss of 1250 mL is the cutoff value for major complications after liver resections, such as AKI. Furthermore, red blood cell transfusion, that can be necessary in the case of haemorrhage, can be an additional risk factor for postoperative AKI<sup>[78]</sup>.

### **Increased susceptibility to renal hypoperfusion**

The kidneys are most vulnerable to moderate hypoperfusion when autoregulation is impaired. Factors increasing susceptibility to renal hypoperfusion may be seen in elderly patients or in patients with atherosclerosis, hypertension, or chronic renal failure, in whom hyaline and myointimal hyperplasia cause structural narrowing of the arterioles<sup>[79-81]</sup>. Increased susceptibility to renal

ischemia may also occur in malignant hypertension because of intimal thickening and fibrinoid necrosis of the small arteries and arterioles<sup>[82]</sup>. In addition, in chronic kidney disease, afferent arterioles in the functioning glomeruli become dilated with impairment of the kidney's ability to autoregulate the glomerular filtration rate in low-perfusion states<sup>[83]</sup>.

Impaired decreasing of afferent arteriolar resistance can occur when a patient is receiving nonsteroidal anti-inflammatory drugs or cyclooxygenase-2 inhibitors, which reduce the synthesis of prostaglandins in the kidneys, as consequence a decreasing in glomerular capillary pressure occurs in occasions of low-perfusion states<sup>[82,84-86]</sup>. In other situations, calcineurin inhibitors<sup>[87]</sup>, and radiocontrast agents<sup>[88]</sup> can act through various vasoconstrictor mediators to increase afferent arteriolar resistance, the later may have direct toxic effects on the tubules as well<sup>[81,82,88-92]</sup>. Decreased renal perfusion may also have an exaggerated drop in the GFR in low-perfusion states as a consequence of not raising efferent arteriolar resistance by angiotensin II in patients who are receiving angiotensin-receptor blockers or angiotensin-converting-enzyme inhibitors.

### **Red blood cell transfusion and postoperative AKI**

Despite the deleterious effect of hemodynamic instability in renal perfusion, red blood cell transfusion, that can be necessary in the case of haemorrhage, can be an additional risk factor for postoperative AKI<sup>[78]</sup>. Although the exact causal link between red blood cell transfusion and postoperative AKI is not fully elucidated, there are several mechanisms that may be implicated: Deficiency in 2,3-diphosphoglycerate with impaired oxygen unloading from hemoglobin, less deformability of stored red blood cells with obstruction of smaller capillaries<sup>[93]</sup> stored red blood cells hemolysis with an increase in circulating free iron<sup>[94]</sup>. Other mechanisms might include loss of the ability to generate nitric oxide, release of procoagulant phospholipids, increased adhesiveness to vascular endothelium, and accumulation of proinflammatory phospholipids<sup>[93,95-98]</sup>.

## POSTHEPATECTOMY LIVER FAILURE AND HEPATORENAL SYNDROME

Apart from blood loss, that can lead to ATN because of severe hemodynamic instability, others risk factors for postoperative AKI after partial hepatectomy would be those that favor PLF, characterized by jaundice, coagulopathy, encephalopathy, ascites, and renal and pulmonary failure, all of which may become apparent only 3 to 5 d after surgery<sup>[1]</sup>. These risk factors for PLF are well described, such as a small volume of remaining liver with marked volume reduction of organ parenchyma<sup>[35,99,100]</sup> associated to parenchymal cell injury due portal hyperperfusion<sup>[59,101]</sup>, liver cirrhosis or steatosis<sup>[102,103]</sup>, and liver toxicity induced by chemotherapy<sup>[104]</sup>. In patients with liver cirrhosis, the postoperative liver failure may occur

**Table 2** International Club of Ascites new definitions for the diagnosis and management of acute kidney injury in patients with cirrhosis<sup>[68]</sup>

Baseline sCr	A value of sCr obtained in the previous 3 mo, when available, can be used as baseline sCr. In patients with more than one value within the previous 3 mo, the value closest to the admission time to the hospital should be used. In patients without a previous sCr value, the sCr on admission should be used as baseline
Definition of AKI	Increase in sCr $\geq 0.3$ mg/dL ( $\geq 26.5$ mmol/L) within 48 h; or a percentage increase sCr $\geq 50\%$ from baseline which is known, or presumed, to have occurred within the prior 7 d
Staging of AKI	Stage 1: Increase in sCr $\geq 0.3$ mg/dL (26.5 mmol/L) or an increase in sCr $\geq 1.5$ -fold to twofold from baseline Stage 2: Increase in sCr > two to threefold from baseline Stage 3: Increase of sCr > threefold from baseline or sCr $\geq 4.0$ mg/dL (353.6 mmol/L) with an acute increase $\geq 0.3$ mg/dL (26.5 mmol/L) or initiation of renal replacement therapy
Progression of AKI	Progression: Progression of AKI to a higher stage and/or need for RRT Regression: Regression of AKI to a lower stage
Response to treatment	No response: No regression of AKI Partial response: Regression of AKI stage with a reduction of sCr to $\geq 0.3$ mg/dL (26.5 mmol/L) above the baseline value Full response: Return of sCr to a value within 0.3 mg/dL (26.5 mmol/L) of the baseline value

AKI: Acute kidney injury; RRT: Renal replacement therapy; sCr: Serum creatinine.

due the compromised liver microcirculation, with less resistance to ischemia-reperfusion injury<sup>[105]</sup> and impaired regeneration<sup>[106]</sup>, in addition, portal hypertension, if present, is associated with a poor outcome because of compromised portal flow and the risk of postoperative upper gastrointestinal bleeding<sup>[107]</sup>.

Liver steatosis is usually related to obesity, the presence of metabolic disorders, or the intake of alcohol or drugs, and this liver disorder increases the operative risk of partial hepatectomy<sup>[2,53,108]</sup>. The extent of liver resection in these patients with steatosis in order to avoid PLF is unclear, but the severity of fatty infiltration must be considered: Mild steatosis (up to 30% of hepatocytes containing fat) represents a minimal additional risk, in moderate steatosis (30% to 60% containing fat) caution is necessary, thus, a conservative resection should be favored, and patients with severe steatosis (more than 60% of hepatocytes containing fat) should undergo only limited resection<sup>[108]</sup>.

Regarding the chemotherapy-induced liver aggression, the rates of complications and death after major liver resection are likely to be increased<sup>[55,109]</sup>. Oxaliplatin can induce a veno-occlusive syndrome, occasionally associated with nodular regenerative hyperplasia, these vascular obstructions result in a bluish appearance of the liver (blue liver syndrome)<sup>[54,110,111]</sup>, and irinotecan can cause chemotherapy associated steatohepatitis<sup>[112]</sup>, and liver impairment can be amplified after partial hepatectomy in both situations, triggering PLF<sup>[113]</sup>.

A major concern regarding PLF is the onset of HRS. HRS is a reversible functional renal impairment that occurs in patients with advanced liver cirrhosis or hepatic failure. It is characterized by marked decrease in GFR and renal plasma flow in the absence of other cause of renal failure<sup>[114]</sup> (Table 3). The pathophysiological alterations of SHR consist of intravascular hypovolemia with activation of the renin-angiotensin-aldosterone system and vasoconstrictive sympathetic nervous system, leading to renal vasoconstriction of the afferent vessels and subsequent decrease in GFR<sup>[20]</sup>. Two subtypes of

HRS have been identified: SHR type 1 is characterized by a rapidly progressive renal insufficiency defined as a doubling of the initial serum creatinine to a level greater than 2.5 mg/dL or 220  $\mu$ mol/L in less than 2 wk, it is associated with very poor prognosis, and SHR Type 2 is characterized by a moderate renal insufficiency (Cr greater than 1.5 mg/dL or 133  $\mu$ mol/L), follows a steady course or slowly progressive, often associated with refractory ascites<sup>[114]</sup>.

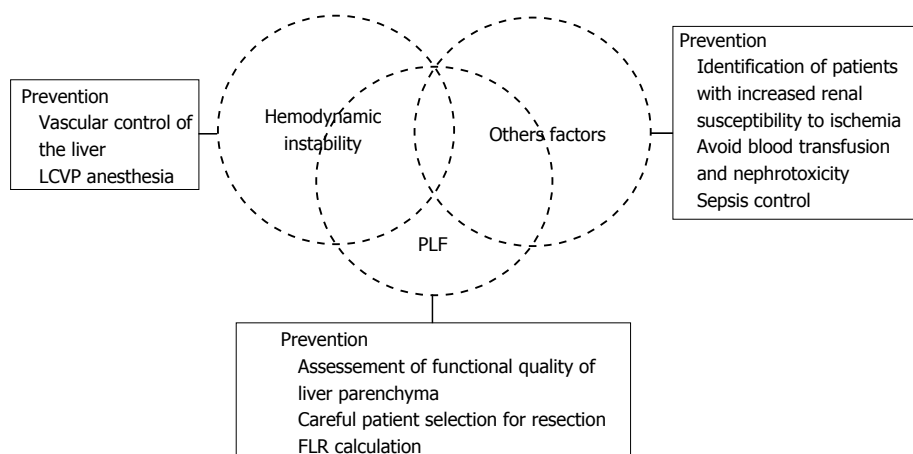

## KEYPOINTS FOR PREVENTION OF AKI AFTER PARTIAL HEPATECTOMY

Despite the fact that patients can have more than one factor contributing to post-operative AKI after partial hepatectomy, eventually aggravated by sepsis<sup>[20,21-24]</sup> or exposure to nephrotoxic drugs<sup>[25]</sup>, there are particular risk factors that must be controlled and specific operative and non-operative procedures that must be undertaken for prevention of post-operative renal injury in these patients (Figure 1).

### Vascular control of the liver

For prevention of intraoperative blood loss with consequent hemodynamic instability during the partial hepatectomy, there are intraoperative maneuvers that may be crucial in the moment of parenchymal transaction, such as vascular control of the liver<sup>[21]</sup>.

The vascular control of the liver is an effective method to reduce bleeding during the hepatectomy. While various techniques have been proposed, the two most widely used methods are the vascular inflow occlusion and complete vascular exclusion<sup>[115,116]</sup>. Occlusion of the hepatic vascular inflow<sup>[117]</sup> by the application of tourniquet in hepatoduodenal ligament<sup>[118]</sup> is the oldest and simplest way to reduce blood loss during hepatectomy. The "Pringle maneuver" can be used continuously to normal livers under normothermic conditions for a maximum of 60 min, and for 30 min in cirrhotic or steatotic livers, although longer periods have already been described<sup>[119-122]</sup>.

**Figure 1 Main risk factors and prevention of acute kidney injury after partial hepatectomy.** LCVP: Low central venous pressure; PLF: Posthepatectomy liver failure; FLR: Future liver remnant.

**Table 3 Diagnostic criteria of hepatorenal syndrome type of acute kidney injury in patients with cirrhosis<sup>[68]</sup>**

#### HRS-AKI

Diagnosis of cirrhosis and ascites  
Diagnosis of AKI according to ICA-AKI criteria (Table 2)  
No response after 2 consecutive days of diuretic withdrawal and plasma volume expansion with albumin 1 g/kg bodyweight  
Absence of shock  
No current or recent use of nephrotoxic drugs (NSAIDs, aminoglycosides, iodinated contrast media, etc.)  
No macroscopic signs of structural kidney injury, defined as  
Absence of proteinuria (> 500 mg/d)  
Absence of microhaematuria (> 50 RBCs per high power field)  
Normal findings on renal ultrasonography  
Patients who fulfil these criteria may still have structural damage such as tubular damage. Urine biomarkers will become an important element in making a more accurate differential diagnosis between HRS and acute tubular necrosis

HRS: Hepatorenal syndrome; AKI: Acute kidney injury; ICA: International club of ascites; NSAIDs: Non-steroidal anti-inflammatory drugs; RBCs: Red blood cells.

According Belghiti *et al.*<sup>[123]</sup> there is no significant difference in blood loss during surgery using the Pringle maneuver continuously or intermittently (15 min of ischemia for 5 min reperfusion). These concerns about longer periods of hepatic vascular inflow is mainly because that obstruction of the portal blood flow causes venous congestion of the bowel, and in combination with warm ischemic liver injury it results in a flush of anaerobic metabolites and cytokines back into the circulation on the clamp release<sup>[124]</sup>. In the total vascular exclusion<sup>[125]</sup>, the occlusion of the hepatic vascular inflow is combined to hepatic venous exclusion. The complete hepatic ischemia can be associated to hypothermic perfusion with cooled preservation solution<sup>[126]</sup> and extracorporeal venovenous bypass, with "ex situ" liver resection<sup>[127]</sup> or "in situ" liver resection<sup>[128]</sup>.

#### LCVP anesthesia

During the parenchymal transaction, a LCVP prevents

the back bleeding from hepaticveins<sup>[19,129,130]</sup>, and along with vascular control of the liver, these techniques test the patients cardiovascular reserve<sup>[21]</sup>. LCVP anesthesia is based on patients being maintained in hypovolaemic state until liver resection has been completed<sup>[19,129]</sup>, this is in contrast to most other major surgical procedures, where patients receive large volumes of crystalloid and colloid during the peri-operative period<sup>[21]</sup>. Moreover, vasodilators are often used to further reduce central venous pressure (CVP), leading to distributive changes in blood flow<sup>[129]</sup>, and whereas these techniques are applied for haemorrhage control and consequently promoting AKI prevention, a potential consequence of such circulatory changes is ATN, with subsequent renal impairment or failure<sup>[20]</sup>. The kidneys are at greater risk with abrupt fall in blood pressure, if the mean arterial pressure reaches values below 80 mmHg, there is a significant decrease in GFR<sup>[24]</sup>.

In the study of Wang *et al.*<sup>[131]</sup>, the maintenance of CVP  $\leq 4$  mmHg has reduced blood loss during partial hepatectomy, and has shortened the length of hospital stay, with no detrimental effects on hepatic or renal function. According to Melendez *et al.*<sup>[19]</sup>, in 496 liver resections with an anesthetic protocol of fluid restriction, with the use of nitroglycerin, furosemide, and with the maintenance of a systolic blood pressure of 90 mmHg, the median volume blood loss was 645 mL and the incidence of AKI was 3.1%. A study with 2116 LCVP-assisted hepatectomies reported an estimated mean blood loss of 300 mL (IQR: 200-600 mL), 90-d mortality of 2%, and postoperative AKI of 16% in the whole cohort (13% at risk, 2% at injury and 1% experienced failure)<sup>[132]</sup>. A study reported a low incidence of AKI requiring renal replacement therapy after liver resection (< 1%), confirming that the routine use of LCVP anaesthesia in combination with intermittent inflow occlusion is safe<sup>[21]</sup>.

Although there are strong evidences that LCVP during partial hepatectomy can minimize blood loss and mortality<sup>[19]</sup>, it is not clear whether it would play a role

in AKI prevention, as renal perfusion pressure can be decreased during relative hypovolemia, thus, further studies are required to prove this hypothesis.

### Prevention of post-hepatectomy liver failure

In order to reduce the incidence of PLF, a careful pre-operative planning and patient selection is mandatory. In the case of underlying cirrhosis, the best candidates for surgical resection are the exclusive Child-Pugh A patients with normal bilirubin values, the absence of clinical signs of portal hypertension (platelet count, splenomegaly and esophageal varices), only tumor diameter < 5 cm (without vascular invasion), asymptomatic and MELD < 8<sup>[107,133,134]</sup>. Hyperbilirubinemia, portal hypertension and clinical deterioration criteria are considered signs of poor postoperative course, despite the tumor resectability<sup>[135]</sup>.

Analyzing the issue of remnant liver volume after partial hepatectomy, the functional quality of parenchyma should not be ignored. In obtaining the computed tomography images, it enables the calculation of the future liver remnant (FLR), in patients with normal liver function, it must be greater than 25% of the liver total volume, corresponding to 0.5 of the patient weight. In patients with cirrhosis, prolonged exposure to chemotherapy and biliary obstruction, this value is 40%, corresponding to 0.7 of the patient weight<sup>[136]</sup>. The occlusion of a branch of the portal vein can be performed in order to minimize the occurrence of hepatic insufficiency after major resections. This procedure makes possible the treatment of tumors previously classified as unresectable, providing contralateral liver hypertrophy, thereby increasing the FLR<sup>[137,138]</sup>. In some situations resectability only occurs when performing two sequential hepatectomies associated with portal ligation for manipulation of the FLR, the two-stage hepatectomy<sup>[139]</sup>.

## FINAL CONSIDERATIONS

In the context of liver resections, the risk assessment of postoperative AKI requires the analysis of multiple variables involved in this complex universe, but probably there are main factors which significantly influence these patients for the occurrence of AKI: The massive blood loss during operation with or without an increased renal susceptibility to ischemia, and the occurrence of PLF. Certainly, the key interventions for preventing postoperative AKI after partial hepatectomy would be an appropriate preoperative work up, careful patient selection for surgery and rigorous perioperative control of the patient hemodynamic status by the surgical team.

## Abstract

**AIM:** To evaluate the antiviral potency of a new anti-hepatitis C virus (HCV) antiviral agent targeting the cellular autophagy machinery.

**METHODS:** Non-infected liver slices, obtained from human liver resection and cut in 350  $\mu\text{m}$ -thick slices ( $2.7 \times 10^6$  cells per slice) were infected with cell culture-grown HCV Con1b/C3 supernatant (multiplicity of infection = 0.1) cultivated for up to ten days. HCV infected slices were treated at day 4 post-infection with GNS-396 for 6 d at different concentrations. HCV replication was evaluated by strand-specific real-time quantitative reverse transcription - polymerase chain reaction. The infectivity titers of supernatants were evaluated by foci formation upon inoculation into naive Huh-7.5.1 cells. The cytotoxic effect of the drugs was evaluated by lactate dehydrogenase leakage assays.

**RESULTS:** The antiviral efficacy of a new antiviral drug, GNS-396, an autophagy inhibitor, on HCV infection of adult human liver slices was evidenced in a dose-dependent manner. At day 6 post-treatment, GNS-396 EC<sub>50</sub> was 158 nmol/L without cytotoxic effect (compared to hydroxychloroquine EC<sub>50</sub> = 1.17  $\mu\text{mol/L}$ ).

**CONCLUSION:** Our results demonstrated that our *ex vivo* model is efficient for evaluation the potency of autophagy inhibitors, in particular a new quinoline derivative GNS-396 as antiviral could inhibit HCV infection in a dose-dependent manner without cytotoxic effect.

**Key words:** Host antiviral therapy; Hepatitis C virus; Tissue culture; Autophagy; Quinoline derivative

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Hepatitis C virus (HCV) infection (or spread) is a serious public health challenge counting approximately 170 million people that are chronically infected worldwide. Efficient interferon-free treatments with new direct acting antivirals are expected to cure more than 90% of HCV-infected patients but they are not available in all the countries. Autophagy machinery is required to initiate HCV replication. Host antiviral therapy is an additional option for the treatment of HCV infection. The new autophagy inhibitor GNS-396 demonstrated significant efficacy and additive activity in inhibiting HCV replication and might be an additional option to treat HCV infected individuals.

Anti-hepatitis C virus potency of a new autophagy inhibitor using human liver slices model. *World J Hepatol* 2016; 8(21): 902-914 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i21/902.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i21.902>

## INTRODUCTION

Approximately 170 million people worldwide are chronically infected with hepatitis C virus (HCV)<sup>[1]</sup>. Until recently, the most effective treatment against HCV infection was the combination of pegylated interferon- $\alpha$  2a or b and ribavirin (PR) which achieved sustained virological response (SVR) in about 45% of individuals infected by HCV genotype 1, 65% by HCV genotype 4, 70% by HCV genotype 3 and more than 85% by HCV genotype 2<sup>[2,3]</sup>. The frequent side effects associated with PR and the rates of non response to PR includes partial or null virologic response and breakthrough or relapse after PR discontinuation. Thus, development of novel and more effective antiviral treatments were essential<sup>[4]</sup>.

Two HCV NS3 protease inhibitors (PI), boceprevir (BOC) and telaprevir (TVR) have been approved and combined with PR, have increased the SVR to about 75% in therapy naïve HCV genotype 1 infected patients<sup>[5-9]</sup>. Over the past few years, other direct acting antivirals (DAAs) were developed<sup>[10-14]</sup> as second generation of PI with higher antiviral potency, HCV NS5A replication complex inhibitors and nucleotide analogue HCV NS5B polymerase inhibitors<sup>[13]</sup> as well as host-targeted indirect antivirals like cyclophilin inhibitors<sup>[15]</sup> and lambda interferon<sup>[15]</sup>. Interferon-free treatments with new DAAs are expected to cure more than 90% of HCV-infected patients<sup>[16]</sup>. But they are not available in all the countries<sup>[17]</sup>. At the present time, triple therapy combining PR with NS3 PI (TVR or BOC) is going to remain the main treatment for HCV patients<sup>[16-21]</sup>. That is why it appears important to continue research in limiting virus replication and the autophagy inhibition could be a new additional pathway because of recent evidences obtained regarding to an increased autophagic response in the liver of chronically HCV infected patients<sup>[22]</sup>.

Autophagy is a catabolic process which degrades a cellular own component through the lysosomal machinery<sup>[23]</sup>. It has been shown that autophagy is activated during virus and bacterial infection<sup>[24]</sup> and that some viruses can use the autophagy system to facilitate their own replication<sup>[25-29]</sup>. Previously, several studies evidenced that HCV infection resulted in endoplasmic reticulum stress and autophagy responses, that HCV regulated the autophagy pathway, that the autophagy machinery was required to initiate HCV replication, and finally, that the suppression of autophagy inhibited HCV replication<sup>[30-35]</sup>. Interestingly, it has been demonstrated that HCV induces autophagosomes *via* a Class III PI3K-independent pathway and uses autophagosomal membranes as sites for its RNA replication<sup>[36]</sup>.

The lysosomotropic anti-malarial drugs, chloroquine (CQ) and hydroxychloroquine (HCQ), belonging to the quinoline family, are among the autophagy inhibitors, which act by preventing the acidification of lysosomes, leading to the inhibition of both fusion of autophagosome with lysosome and lysosomal protein degradation<sup>[23]</sup>. In fact, CQ exerts an inhibitory effect for several RNA viruses including coronaviruses, flaviviruses and human

immunodeficiency virus<sup>[37-39]</sup>. Recently, it has been shown that a treatment with CQ of HCV infected cells suppressed the replication of the virus in a dose-dependent manner by preventing the autophagic proteolysis<sup>[40]</sup>.

In the present study, we used the established *ex vivo* model of primary human liver slices culture which allows to the *de novo* replication of primary viral isolates and production of high titer infectious HCV particles<sup>[41]</sup> to evaluate the potential antiviral potency GNS-396<sup>[42]</sup>, a new autophagy inhibitor in comparison with a well-known autophagy inhibitor, HCQ. Presented results might be additional options to treat HCV infected individuals.

## MATERIALS AND METHODS

### Human liver tissue specimens

Adult human primary liver tissue samples were obtained from HCV and also hepatitis B virus, and human immunodeficiency virus seronegative patients who underwent liver resection surgery, mainly for liver metastasis in the absence of underlying liver disease. Experimental procedures were carried out in accordance with French laws and Regulations.

### Liver slices preparation, culture and infection

Slices were prepared and cultured as described<sup>[41,43]</sup>. Briefly, uninfected human liver slices, obtained from human liver resection, were cut into 350  $\mu\text{m}$  thick slices of ( $2.7 \times 10^6$  cells per slice) with a vibratome (Leica, VTS1200) and transferred to 0.4  $\mu\text{m}$  organotypic culture inserts (Millipore) in 12-wells plates (1 slice/well) containing 2 mL of complete Dulbecco's modified eagles's medium (DMEM) culture media and maintained at 37 °C under a constant flow of humidified 95% O<sub>2</sub>/5% CO<sub>2</sub> for up to 24 h before viral infection. Cell number for tissue slices was estimated at approximately  $2.7 \times 10^6$  cells per slice based on a 14-cell thick slice (cell diameter approximately 25  $\mu\text{m}$ )<sup>[41]</sup>. The complete culture medium consisted of DMEM with 4.5 g/L D-glucose and glutamine (Life Technologies) supplemented with 10% fetal calf serum (Life Technologies, 16000-044), 5% penicillin-streptomycin (Life Technologies, 10378-016), 1% amphotericin (Sigma Aldrich), 5  $\mu\text{g/mL}$  insulin (Life Technologies, 51500-056), 0.4  $\mu\text{g/mL}$  dexamethasone (Sigma Aldrich, D4902), 10 mmol/L HEPES (Life Technologies, 15630080), non-essential amino acids (Life Technologies), 20 mmol/L sodium pyruvate (Life Technologies) and 50  $\mu\text{g/mL}$  ascorbic acid (Sigma Aldrich). One day post-culture in twelve-transwell plates, human primary liver slices were inoculated with HCV Con1/C3 at a multiplicity of infection equal to 0.1 at 37 °C in the same culture conditions as described above, for overnight. The infectious clone Con1/C3 (genotype 1b) (JFH1-derived chimeric viruses whose structural proteins are encoded by the genotype 1b-HCV sequence Con1)<sup>[44]</sup> could efficiently infect human liver slices which maintain their hepatocyte differentiation and retain normal physiological and biochemical parameters for at least 10 d. The inoculum was then removed; the slices were

washed three times with PBS and then supplemented with complete culture medium. Then, liver slices were cultured without medium replacements, as previously described<sup>[41]</sup>.

### HCV RNA transfection and virus production

To produce HCVcc, viral RNAs were transcribed *in vitro* and electroporated into Huh-7.5.1 cell line (kindly provided by Professor Francis V Chisari, The Scripps Research Institute, La Jolla, CA), as described previously<sup>[45]</sup>. The infectious titer of cell culture supernatants was evaluated by classical titration assay<sup>[45]</sup>. In brief, the HCV infection of Huh-7.5.1 cells was performed with serial 10-fold dilution of viral supernatants. Seventy-two hours later, the formation of infected cells foci were detected by staining with human HCV positive sera or mouse monoclonal antibodies directed against HCV core (Ozyme) and non-structural (NS5A) (Virostat, clone1877) proteins. Titrations were performed in duplicate.

### Quantification of HCV strands RNA by real-time quantitative reverse transcription- polymerase chain reaction

A strand-specific real-time quantitative reverse transcription-polymerase chain reaction technique to quantify the intracellular levels of positive and negative strand HCV RNA was performed as previously described<sup>[46-49]</sup>. The quantification of 28S rRNA was used as an internal standard to quantify HCV in total liver RNA, as previously described<sup>[46]</sup>, (threshold of detection: 25 copies/reaction). Briefly, reverse transcription was carried out using oligo(dT) primer (Life Technologies) and Moloney murine leukemia virus reverse transcriptase (Promega) as recommended by the manufacturer. Real-time polymerase chain reactions were performed using the Light CyclerR (Roche Applied Science) and Fast Start DNA Master SYBR Green I kit (Life Science, Roche) according with the manufacturer's protocol.

Reverse transcription was performed using primers located in the 5' NCR region of HCV genome, tag-RC1 (5'-GGC CGT CAT GGT GGC GAA TAA GTC TAG CCA TGG CGT TAG TA-3')<sup>[47]</sup> and RC21 (5'-CTC CCG GGG CAC TCG CAA GC-3')<sup>[48]</sup> for the negative and positive strands, respectively, as described previously<sup>[46]</sup>. After a denaturation step performed at 70 °C for 8 min, the RNA template was incubated at 48 °C for 5 min in the presence of 200 ng of tag-RC1 primer and 1.25 mmol/L of each deoxynucleoside triphosphate (dNTP) (Promega) in a total volume of 12  $\mu\text{L}$ . Reverse transcription was carried out for 60 min at 60 °C in the presence of 20 U RNaseOutTM (Life Technologies) and 7.5 U ThermoscriptTM reverse transcriptase (Life Technologies), in the buffer recommended by the manufacturer. An additional treatment was applied by adding 1  $\mu\text{L}$  (2U) RNaseH (Life Technologies) for 20 min at 37 °C. The first round of nested PCR was performed with 2  $\mu\text{L}$  of the cDNA obtained in a total volume of 50  $\mu\text{L}$ , containing 3 U Taq polymerase (Promega), 0.5 mmol/L dNTP Mix (Promega), and 0.5  $\mu\text{mol/L}$  RC1 (5'-GTC TAG CCA TGG CGT TAG TA-3')

**Figure 1** GNS-396 and hydroxychloroquine structures. HCQ: Hydroxychloroquine.

and RC21 primers for positive-strand amplification, or tag (5'-GGC CGT CAT GGTGGC GAA TAA-3') and RC21 primers for negative strand amplification. The PCR protocol consisted of 18 cycles of denaturation (94 °C for 1 min), annealing (55 °C for 45 s), and extension (72 °C for 2 min). The cDNA obtained was purified using the Quick-clean kit (Qiagen), according to the manufacturer's instructions, and 2 µL of the purified product suspended in 10 µL nuclease free water (Promega) were then subjected to real-time PCR. The reaction was carried out using the DNA Fast Start SYBR Green Kit (Life Science, Roche), with Lightcycler<sup>TM</sup> instruments and technology (Roche Diagnostics). PCR amplifications were performed in a total volume of 20 µL, containing 3 mmol/L MgCl<sub>2</sub>, 2 µL DNA Master green (Life Science) and 50 ng of the 197 R (5'-CTTTCGCGACCCAACACTAC-3') and 104 (5'-AGAGCCATAGTGGTCTGCGG-3') primers<sup>[48,49]</sup>. The PCR protocol consisted of one step of initial denaturation for 10 min at 94 °C, followed by 40 cycles of denaturation (95 °C for 15 s), annealing (57 °C for 5 s), and extension (72 °C for 8 s). After amplification, the specificity of PCR products was checking by a melting curve analysis.

### Western blotting

Western blotting was performed as following. Each liver slice was washed 3 times in PBS, incubated in Laemmli buffer<sup>[50]</sup> at 100 °C for 10 min. The lysate was passed through a 26 G needle, 10 times and kept at -80 °C. Before electrophoresis in pre-cast sodium dodecyl sulfate polyacrylamide gel 4%-12% (Life Technologies), the samples were incubated at 95 °C for 5 min. After electrophoresis, proteins were transferred to a 0.22 µm Protran membrane BA83 (Schleicher and Schuell) and HCV proteins were detected by Western blotting using mouse monoclonal antibodies to core (C7-50, 1:10000) (Ozyme), to NS5A (1:2000) (Virostat, clone 1877), to

LC3 proteins (Sigma-Aldrich) and to glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (Abcam), and to β-actin (Pierce biotechnology). Horseradish peroxidase-conjugated anti-mouse IgG (GeHealthCare Life Sciences) at the dilution of 1:50000 were used as secondary antibodies. The reactions were developed using enhanced chemiluminescence detection reagents (GeHealthCare Life Sciences), followed by exposure to X-OMAT film (GeHealthCare Life Sciences). LC3-II protein expression analysis was performed with Image J software.

### Drugs inhibition of HCVcc Con1/C3 replication and cytotoxicity assays

The HCVcc Con1/C3 inhibition either by pegylated-interferon α-2a (peg-INF) (Roche, Pegasys) or/and ribavirin (RBV) (Schering Plough, Rebetol) or TVR (Janssen-Cilag, Incivo) or BOC (Schering-Plough, Boceprevir) or SOF (Gilead Sciences Intl Ltd, Sofosbuvir) or GNS-396 (Figure 1) (Genoscience Pharma, Marseille, France) or HCQ (Figure 1) (Genoscience Pharma, Marseille, France) or 0.5% dimethylsulfoxide (DMSO) (Sigma Aldrich) as a carrier control, and the cytotoxicity assays were performed as following. At day 4 post-infection with HCVcc Con1/C3 the human liver slices were treated by addition of different concentrations of the following drugs: peg-INF or/and RBV or TVR or BOC or SOF or HCQ (0.1, 1, 2.5, 5 µmol/L or a new quinoline derivative, GNS-396 (0.1, 1, 2.5, 5 µmol/L) alone or 0.5% DMSO as a carrier control, to culture medium, twice daily, up to day 10 post-infection. The infectivity (ffu/mL) was measured at day 2, day 4 or day 6 post-treatment depending on the experiment as described<sup>[41]</sup>. All the experiments were performed in triplicate. The cytoTox 96R Non-Radioactive Cytotoxicity Assay (Promega, G1780) was used to assess the potential cytotoxicity of the drugs. Results of lactate dehydrogenase (LDH) leakage were compared to the carrier control calculated (Figure 2) as described previously<sup>[51]</sup>.

### Evaluation of autophagy modulation and inhibition

Autophagy modulation was evaluated on HeLa cells treated with GNS-396, a new quinolone derivative. For tracking different stages of autophagy the tandem fusion of mRFP and EGFP fused to LC3 make a pH-sensitive sensor (mRFP-EGFP-LC3) that is used to monitor autophagy in live cells<sup>[52]</sup>. The EGFP tag is acid-sensitive while the mRFP tag is not. The double tagged LC3 can be used to label autophagosomes, amphisomes and autolysosomes. In autophagosomes, both tags emit yellow light. However, the fusion of autophagosomes to acidic lysosomes results in acidic autolysosomes where the green fluorescence from GFP is lost. Subsequently, the red fluorescence from mRFP is lost when the double tagged protein is degraded. The autophagic flux inhibition was shown using a SkBr3 mRFP1-EGFP-LC3 stable breast cancer cell line treated with 100 µmol/L GNS-396 or 100 µmol/L HCQ during 6 h. HCQ was used as a positive control of autophagy inhibition. Cell images were obtained using an epifluorescence microscope (Nikon,

**Figure 2** Cytotoxicity assays of the drugs used hydroxychloroquine (A) and GNS-396 (B). Percentages of lactate dehydrogenase (LDH) leakage are relative to DMSO control-treated liver slices. Drugs cytotoxicity is significant at % of control > 120. All experiments were performed on triplicate. Values are expressed as means  $\pm$  SE, comparisons were performed using the Mann-Whitney rank-sum test ( $P < 0.001$ ). HCQ: Hydroxychloroquine; DMSO: Dimethylsulfoxide.

Eclipse Ci).

Autophagy inhibition was evaluated on HeLa cells treated with GNS-396, at different drug concentrations (1, 10, 100  $\mu$ mol/L) during 4 h or 6 h in the presence or absence of bafilomycin A1 (100 nmol/L) (Sigma-Aldrich) added for the last 2 h. Bafilomycin A1 (BafA1) is an autophagy inhibitor as endosomal acidification inhibitor. It is a known inhibitor of the late phase of autophagy. Bafilomycin A1 prevents maturation of autophagic vacuoles by inhibiting fusion between autophagosomes and lysosomes. Bafilomycin A1 acts by inhibiting vacuolar H<sup>+</sup> ATPase<sup>[53,54]</sup>. HCQ was used as a positive control of autophagy inhibition. The LC3-II protein expression in cell lysates was evaluated by Western-blot assay [anti-LC3 antibody (Sigma-Aldrich)] compared to either GAPDH protein expression [anti-GAPDH antibody (Abcam)] or  $\beta$ -actin protein expression [anti-actin antibody (Pierce biotechnology)]. LC3-II protein expression analysis was performed with Image J software.

### Statistical analysis

At different days of the kinetics, the results were obtained from the mean of the three slices culture. Statistical tests were performed using the GraphPad Prism 5.0 software (GraphPad Software, La Jolla, CA, United States). Values are expressed as means  $\pm$  standard errors of the mean. The data were compared using an unpaired two-tailed student's *t*-test or the Mann-Whitney rank-sum test. *P*-value < 0.05 was considered significant.

## RESULTS

### Validation of GNS-396, a new quinoline derivative, as inhibitor of autophagy

We evaluated the effect of GNS-396 (Figure 1)<sup>[42]</sup>, a new quinoline derivative, on autophagy by treatment of HeLa cells with various concentrations of GNS-396 during 6 h. HCQ was used as a positive control of autophagy inhibition. The microtubule-associated protein 1A/1B-

light chain 3 (LC3) is a soluble ubiquitin-like protein with a molecular mass of approximately 17 kDa that exists ubiquitously in mammalian tissues and cultured cells, as an unconjugated form (LC3-I) or conjugated to autophagosomes membranes (LC3-II: lipidated form). During autophagy, a cytosolic form of LC3 (LC3-I) is conjugated to phosphatidylethanolamine to form LC3-phosphatidylethanolamine conjugate (LC3-II), which is recruited to autophagosomal membranes allowing for the closure of the autophagic vacuole. Autophagosomes fuse with lysosomes to form autolysosomes, and intra-autophagosomal components are degraded by lysosomal hydrolases. At the same time, LC3-II in autolysosomal lumen is degraded. Thus, lysosomal turnover of the autophagosomal marker LC3-II reflects autophagic activity. Analysis of LC3 intracellular expression by Western blotting demonstrated an increase of normalized LC3-II protein expression when HeLa cells were treated with GNS-396, in a dose-dependent manner (Figure 3A), reflecting the accumulation of autophagosomes in cells, and therefore an effective modulation of the autophagy. Consequently, GNS-396 is a dose-dependent autophagy modulator with a magnitude of normalized LC3-II similar to which achieved with HCQ treatment, a well-known autophagic inhibitor (Figure 3B). Similar results were obtained on Huh7.5.1 cell line (data not shown).

To evaluate if the observed accumulation of autophagosomes after GNS-396 treatment was a consequence of either a stimulated production of new autophagosomes (in this case, GNS-396 would be an autophagy inducer) or a result of autophagosome clearance blockage (in this case, GNS-396 would be an autophagy inhibitor), HeLa cells were treated with different concentrations of GNS-396 in the absence or presence of a lysosomal protease inhibitor, Bafilomycin A1, that increases lysosomal pH and blocks autophagosome-lysosome fusion (Figure 3C) and LC3 protein levels were measured. HCQ was used as a positive control of autophagy inhibition (Figure 3D). After 4 h exposure of HeLa cells to GNS-396 (100  $\mu$ mol/L),

the accumulation of LC3-II was observed (Figure 3C) which was not enhanced in the presence of BafA1, supporting the idea that GNS-396 inhibits autophagic flux as HCQ (Figure 3D). To confirm that GNS-396 is an autophagy inhibitor, the autophagic flux was monitored by fluorescence microscopy, using the mRFP-EGFP-LC3 tandem-tagged fluorescent protein in SkBr3 mRFP-EGFP-LC3 stable cell line (Figure 4). In green/red merged images, yellow dots (*i.e.*, mRFP+EGFP+) indicate autophagosomes or non-acidic autolysosomes, while red dots (*i.e.*, mRFP+EGFP-) indicate autolysosomes. The autophagy flux is increased when both yellow and red puncta (dots) are increased in cells while the autophagic flux is blocked when only yellow puncta (dots) are increased without an accompanying increase of red puncta in cells. SkBr3 mRFP-EGFP-LC3 stable cell line was treated during 6 h with either GNS-396 (Figure 4C) or HCQ, a well-known autophagic inhibitor (Figure 4B) (100  $\mu\text{mol/L}$ ). An accumulation of yellow puncta (dots) corresponding to autophagosomes or non-acidic autolysosomes was noticeable (Figure 4B and C), indicating that GNS-396 blocks the autophagic flux, and may act as lysosomotropic agent as HCQ.

#### **Modulation of autophagy and inhibition of HCV infection in human liver slices model by GNS-396 treatment**

The level of LC3 and viral proteins expression were analysed by Western blotting after 1, 4, 6 and 10 d post-infection (Figure 5). HCV infection induced autophagy with an increase of protein LC3-II expression (Figure 5B) as compared to non-infected liver slices (Figure 5A), along with an increase of intracellular expression of the core and NS5A proteins consistent with the previous reports<sup>[22,36]</sup>. Intracellular expression of the viral proteins was decreased significantly at day 6 post-treatment with HCQ (1  $\mu\text{mol/L}$ ) or GNS-396 (1  $\mu\text{mol/L}$ ) (Figure 5D) in comparison with HCVcc infected liver slices not treated (Figure 5B). The HCQ- and GNS-396-treatment induced an accumulation of LC3-II protein in HCV infected liver slices treated with 1  $\mu\text{mol/L}$  HCQ or 1  $\mu\text{mol/L}$  GNS-396 (Figure 5D) in comparison either with not infected liver slices treated (Figure 5C) or not (Figure 5A), or with HCV infected liver slices without treatment (Figure 5B). At day 10, the normalized LC3-II protein expression increased when liver slices infected (Figure 5D) or not (Figure 5C) were treated either with GNS-396 (1  $\mu\text{mol/L}$ ) or HCQ (1  $\mu\text{mol/L}$ ). The GNS-396 and HCQ effects were tested on the *de novo* viral production of HCVcc Con1 infected liver slices (Figures 6 and 7). At day 4 post-infection, HCVcc Con1 infected liver slices were treated for 6 d with different concentrations either of GNS-396 or HCQ. From day 1 to day 6 post-treatment, the HCV RNA replication (Figure 6A and B) and the infectivity (Figure 7A and B) were inhibited in a dose-dependent manner. The addition of RBV with the new drug GNS-396 showed no significant difference in the viral inhibition (data not shown).

#### **EC50 analysis of HCV replication with GNS-396 treatment compared to that of validated antiviral drugs**

The ability of various concentrations of different antiviral

drugs to inhibit HCV replication was measured by detecting the replication of negative strands HCV RNA (Figure 6A and C) (Table 1). The calculated EC50 of different antiviral drugs is listed as Table 1 and compared to GNS-396. In summary, our model confirms that the antiviral activity of triple therapy was higher than that of the dual therapy by PR as extensively reported in clinical trials<sup>[5,6]</sup>. The new quinoline derivative GNS-396 has about 10-fold lower EC50 than HCQ (0.158  $\mu\text{mol/L}$  as compared to 1.17  $\mu\text{mol/L}$ ) (Figure 6B and D). No significant cytotoxic effects were observed when evaluated by the lactate dehydrogenase leakage (LDH) assays (Figure 2A and B). A 50% cytotoxic concentration (CC50 value) of 25  $\mu\text{mol/L}$  was obtained for GNS-396 in the human liver slices culture at day 6 post-treatment. Similar CC50 values were obtained in proliferating Huh-7-5-1 replicon cells (23  $\mu\text{mol/L}$ ).

## **DISCUSSION**

Our study evidenced that: (1) the *ex vivo* model of human liver slices HCVcc Con1 infection may be efficiently used for the assay of the antiviral potency of a new inhibitor (GNS-396 compared to HCQ) which interfered with autophagy; and (2) GNS-396 was a potent autophagy inhibitor, acting as "lysosomotropic agent" which was able to inhibit HCV replication in primary human adult HCVcc infected liver slices culture.

The establishment of the *ex vivo* model (feasibility, rapidity, specificity, potency) was already described in detail in 2012<sup>[41]</sup> with comparison between primary human hepatocytes, Huh-7.5.1 cell line. The Huh-7 cell system has several limitations that includes the inability to study the effects of pharmacologic inhibitors targeting the non-structural proteins of the most prevalent and problematic viral strains (*e.g.*, genotypes 1a and 1b). Moreover, the study of virus/host cell interactions is limited since the permissive cell lines are transformed and poorly differentiated. Firstly, the human liver slices culture maintains the original three-dimensional structure of the liver that allows cell crosstalk: The extra-cellular matrix and Kupffer cells essential for the normal function of the hepatocytes and the lobular structure. Secondly, the gene expression profiles in liver tissue slices were similar to that of the *in vivo* gene expression. Thirdly, primary hepatocytes preparations undergo treatment with collagenase (a treatment might have a negative effect on integrity of the proteins repertoire on the cell surface), but not the liver slices. Noteworthy, using established procedures, the tissue slices remained viable for, at least 10 d as it was shown by the secretion of albumin and urea. Moreover, the Huh-7 cell infection with primary isolates from patients are not very efficient. The infection of adult human liver slices culture allowed to achieve the robust replication of HCVcc genotype 2a, 1a and 1b genome and to obtain infectivity titers above 105 ffu/mL. In addition, we reported robust and productive infection using human primary isolates HCV genotype 1b. Stem cell-derived hepatocytes (hESC-Heps) displayed

**Figure 3** Modulation and inhibition of autophagy by treatment with GNS-396 in HeLa cells. A and B: Autophagy modulation was evaluated using HeLa cells treated either with (A) GNS-396 or (B) HCQ at different concentrations (1, 10 and 100  $\mu\text{mol/L}$ ) during 6 h. HCQ was used as a positive control of autophagy modulation. Intracellular expression of proteins LC3 was evaluated by Western-blot assay and normalized for LC3- II; C and D: Autophagy inhibition by treatment with GNS-396 in HeLa cells. Autophagy inhibition was evaluated using HeLa cells treated either with (C) GNS-396 or (D) HCQ at different concentrations (1, 10 and 100  $\mu\text{mol/L}$ ) during 4 h in the presence or absence of 100 nmol/L bafilomycin A1. HCQ was used as a positive control of autophagy inhibition. LC3- II intracellular expression was evaluated by Western-blot assay and normalized. HCQ: Hydroxychloroquine; LC3: Microtubule-associated protein 1A/1B-light chain; DMEM: Dulbecco's modified eagles's medium; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; BafA1: Bafilomycin A1.

equivalence to primary adult hepatocytes. HESC-Heps were capable of supporting the full HCV life cycle (JFH1), including the release of infectious virions. Although supportive, hESC-Hep viral infection levels were not as great as those observed in Huh7 cells. Up to now, the hESC-Heps were not infected with primary isolates<sup>[55]</sup>. Currently, we are establishing a culture of liver slices for 21 d, which allows us to follow the variation of different

parameters and in particular, complete inhibition of viral production (data not shown).

Previous studies have reported that autophagy proteins are required to initiate HCV replication and translation<sup>[28,30-36]</sup>. Some data demonstrated that the suppression of LC3 protein lipidation, a necessary step for the formation of autophagosomes could also suppress HCV replication<sup>[30]</sup>. CQ is a well-known autophagic inhibitor

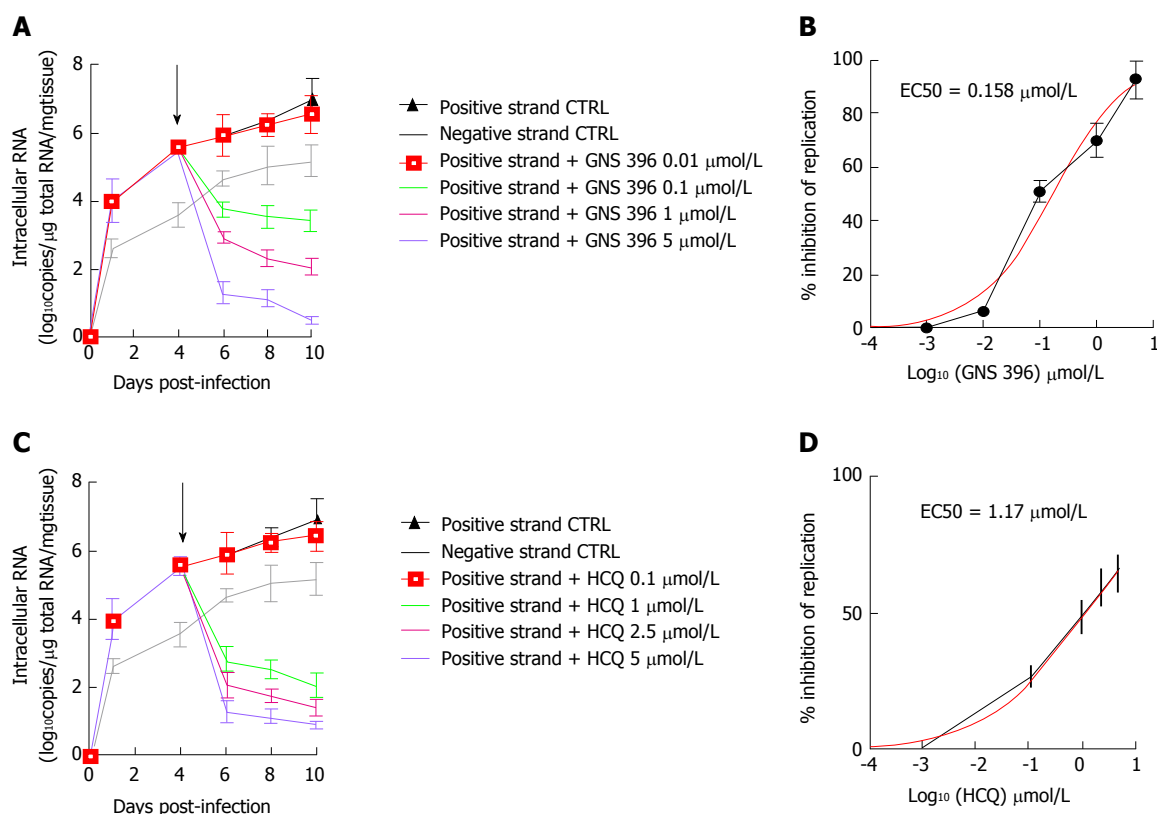

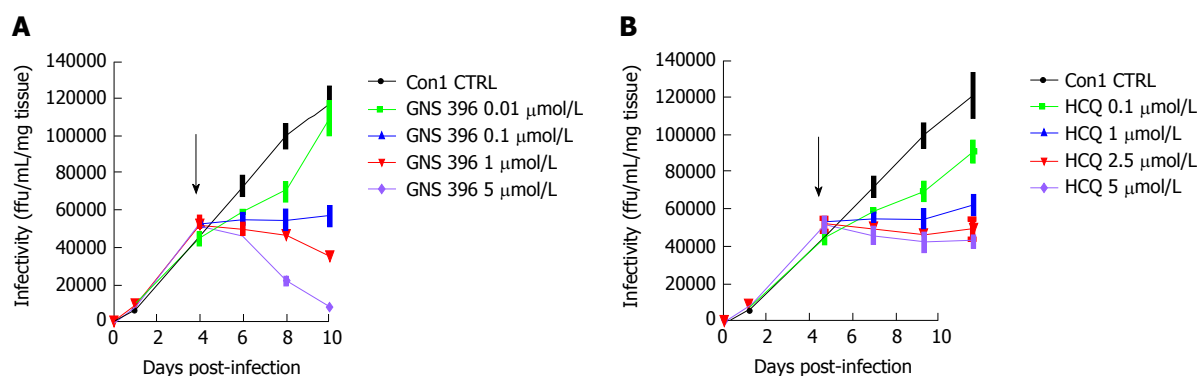

**Figure 4** Inhibition of autophagic flux by treatment with GNS-396 in SkBr3 mRFP-EGFP-LC3 stable cell line. Autophagic flux was monitored using the mRFP-EGFP-LC3 tandem-tagged fluorescent protein in SkBr3 mRFP-EGFP-LC3 stable cell line. A: SkBr3 mRFP-EGFP-LC3 stable cell line without any treatment is representative of basal autophagy; SkBr3 mRFP-EGFP-LC3 stable cell line was treated either with (B) 100  $\mu\text{mol/L}$  HCQ or (C) 100  $\mu\text{mol/L}$  GNS-396 during 6 h. In green/red merged images, yellow puncta (*i.e.*, mRFP+EGFP+) indicate autophagosomes or non-acidic autolysosomes, while red puncta (*i.e.*, mRFP+EGFP) indicate autolysosomes. HCQ is used as a positive control of autophagy inhibition. HCQ: Hydroxychloroquine; DMEM: Dulbecco's modified eagles's medium; LC3: Microtubule-associated protein 1A/1B-light chain.

LC3: Microtubule-associated protein 1A/1B-light chain; HCVcc: Cell culture-grown hepatitis C virus; NS5A: HCV nonstructural protein 5A.

**Figure 6** Inhibition of hepatitis C virus RNA replication by treatment either with GNS-396 or hydroxychloroquine in a dose-dependent manner in primary adult human cell culture-grown hepatitis C virus Con1 infected liver slices. Human liver slices were infected overnight with HCVcc Con1 (MOI = 0.1). The supernatant is then removed, the human liver slices washed and cultured. The liver slices and culture supernatants were collected different times post-infection. At day 4 post-infection, the liver slices were treated with increasing concentrations either of GNS-396 (0.01, 0.1, 1, 5 μmol/L) (A, B) or HCQ (C, D) for 6 d (black arrow: Start of the treatment either with GNS-396 or HCQ). Human HCVcc Con1 infected liver slices were lysed to evaluate intracellular levels of positive- and negative-strand HCV RNA by specific strand RT-qPCR at 1, 4, 6, 8, 10 d post-infection. The results were compared using the two-paired Student's test. Values are expressed as means ± standard errors: (A) HCV RNA replication by treatment with GNS-396: Positive strand (black line),  $P < 0.03$ ; negative strand (grey line),  $P < 0.013$ ; GNS-396 0.01 μmol/L (red line),  $P < 0.04$ ; GNS-396 0.1 μmol/L (green line),  $P < 0.05$ ; GNS-396 1 μmol/L (pink line),  $P < 0.05$ ; GNS-396 5 μmol/L (blue line),  $P < 0.05$ ; (C) HCV RNA replication by treatment with HCQ: Positive strand (black line),  $P < 0.03$ ; negative strand (grey line),  $P < 0.015$ ; HCQ 0.1 μmol/L (red line),  $P < 0.0001$ ; HCQ 1 μmol/L (green line),  $P < 0.0001$ ; HCQ 2.5 μmol/L (pink line),  $P < 0.01$ ; HCQ 5 μmol/L (blue line),  $P < 0.03$ . The detection of negative strand of HCV RNA evidences active replication as well as the increase overtime of both positive and negative strands of HCV RNA; B: Inhibition of HCV replication (%) with GNS-396 treatment  $P < 0.0038$ ; D: Inhibition of HCV replication (%) with HCQ treatment  $P < 0.0013$ . The replication was significantly inhibited in a dose-dependent manner in presence of increasing concentrations either of GNS-396 (B) or HCQ (D) for 6 d. HCVcc: Cell culture-grown hepatitis C virus; HCQ: Hydroxychloroquine; qRT-PCR: Quantitative technique consisting of reverse transcription followed by real-time polymerase chain reaction; MOI: Multiplicity of infection; CTRL: Control-treated liver slices.

**Figure 7** Dose-dependent inhibition of primary-culture-derived virus infectivity in primary adult human cell culture-grown hepatitis C virus Con1 infected liver slices by treatment either with GNS-396 (A) or hydroxychloroquine (B). Kinetics of infectivity of culture supernatants from human liver slices infected by HCV Con1 (MOI = 0.1) and treated either GNS-396 (A) or with HCQ (B) or at day 4 post-infection for 6 d. A: Con1 (black line),  $P < 0.0001$ ; GNS-396 0.01 μmol/L (green line),  $P < 0.0003$ ; GNS-396 0.1 μmol/L (blue line),  $P < 0.019$ ; GNS-396 1 μmol/L (red line),  $P < 0.05$ ; GNS-396 5 μmol/L (purple line),  $P < 0.05$ ; B: Con1 (black line),  $P < 0.0001$ ; HCQ 0.1 μmol/L (red line),  $P < 0.0001$ ; HCQ 1 μmol/L (green line),  $P < 0.0001$ ; HCQ 2.5 μmol/L (red line),  $P < 0.0001$ ; HCQ 5 μmol/L (purple line),  $P < 0.0003$ . Each curve represented the average of 2 independent infections performed in triplicate from 2 different donors. Values are expressed as means ± SE. The results were compared using the two-paired student's test. HCV: Hepatitis C virus; HCQ: Hydroxychloroquine; MOI: Multiplicity of infection; CTRL: Control-treated liver slices.

**Table 1** Inhibition of hepatitis C virus infectivity and 50% effective concentration of hepatitis C virus replication with direct active antivirals and autophagy inhibitors

Drugs <sup>1</sup>	Infectivity inhibition (%)	Average (SD) <sup>2</sup>	Replication inhibition (EC50) <sup>3</sup>	Average (SD) <sup>4</sup>	CC50 (SD) <sup>5</sup>
INF (2.6 to 260 nmol/L) <sup>6</sup>	Up to 95%	5	17 ng/mL	7.2	40 ng/mL (± 4)

<sup>1</sup>Drugs added at day 4 post-infection for 6 d; <sup>2</sup>Average (SD) of infectivity inhibition at day 6 post-treatment; <sup>3</sup>EC50 of the drugs written in bold at day 6 post-treatment; <sup>4</sup>Average (SD) of EC50 at day 6 post-treatment; <sup>5</sup>CC50 (SD): 50% cytotoxic concentration of the drugs written in bold at day 6 post-treatment (standard deviation); <sup>6</sup>INF 26 nmol/L: Peg-INF concentration corresponding to SOC; <sup>7</sup>DAAs and autophagy inhibitors in bold. EC50: 50% effective concentration; BOC: An inhibitor of the HCV-encoded NS3 protein; TVR: An inhibitor of the HCV-encoded NS3/4A hepatitis C protease; SOF: An uridine analogue inhibitor of the HCV NS5B polymerase; HCV: Hepatitis C virus; TVR: Telaprevir; BOC: Boceprevir; SOF: Sofosbuvir; RBV: Ribavirin; SD: Standard deviation; Peg-INF: Pegylated-interferon  $\alpha$ -2a; DAAs: Direct acting antivirals; HCQ: Hydroxychloroquine.

which is often used as an anti-malarial agent. HCQ is a "lysosomotropic" weak base that raises the lysosomal pH quickly<sup>[37]</sup>. Furthermore, many studies have reported the antiviral effect of CQ on other positive strand RNA viruses, such as polioviruses, coxsackieviruses, dengue viruses, coronaviruses (SARS-CoV virus)<sup>[24-29]</sup>, HIV-1<sup>[56]</sup>. In our study, we demonstrated the antiviral effect of HCQ and the new quinoline derivative GNS-396 on HCVcc replication in a dose - dependent manner. Compared to the treatment with HCQ alone, HCQ inhibition was more pronounced in combination with RBV or with other direct antivirals, suggesting a synergistic effect of the combined drugs on HCVcc infection in human liver slices. This result is consistent with a previous study which demonstrated the antiviral effect of CQ in combination with peg-IFN in HCV infected Huh-7 cell line<sup>[33]</sup>. Similarly, on Huh-7 cells infected with HCVpp (genotype 1a and 3a), it has been shown that CQ reduced by 50% virus infectivity at 50 µmol/L concentration, when the antiviral effect was tested<sup>[57]</sup>. Recently, ferroquine (FQ), an antimalarial ferrocenic analog of CQ, has been described as a novel inhibitor of HCV. FQ potently inhibited HCV infection of hepatoma cell lines<sup>[58]</sup>. Compared to these investigations, our study using the quinoline derivative GNS-396, revealed an inhibition of the virus infectivity up to 93% respectively at day 6 post-treatment with lower drug amounts (EC50 = 0.158 µmol/L). This demonstrates that GNS-396 is a stronger antiviral than HCQ (EC50 = 1.17 µmol/L). EC50 is a measure of the effectiveness of the drug in inhibiting the biochemical function. In our study, we evaluated the EC50 of HCV replication at day 6 post-treatment. The lower EC50 value indicates the greater potency of inhibiting HCV replication. As shown in Table

1, the infectivity inhibition, consistent with the inhibition of HCV replication, demonstrated that the new drug evaluated in the human HCV infected liver slices culture model, had a potent antiviral effect compared to the well-known established antivirals. In combination with the other well established drugs like DAA or inhibitors of other host targets (cyclophilin), quinoline derivatives could be additional therapeutic options for HCV infected patients.

In conclusion, this study demonstrated the relevance of the human HCV infected liver slices culture in preclinical studies of the new anti-viral drugs. New host-targeted therapies inhibiting autophagy (GNS-396, HCQ) have demonstrated significant efficiency and additive activity in inhibiting HCV replication. The *ex vivo* model of culture of human HCV infected liver slices might allow further evaluation of the efficacy of new antiviral drugs in single or in combined therapy and their potential toxicity in particular for patients "difficult to treat". Moreover, the infection of human liver slices culture with primary viral isolates from patients that we succeed to establish<sup>[41]</sup>, should allow highlighting the potential of early emergence of drug resistant viral variants during the anti-viral treatments.

## ACKNOWLEDGMENTS

The authors are grateful to Professor Francis V Chisari, for the kind gift of Huh-7.5.1 cells and to Professor Ralf Bartenschlager for kindly providing the chimeric pFK-Con1/C3 plasmid. We are also grateful to the members of the Departments of Digestive Surgery in the Groupe Hospitalier La Pitié Salpêtrière and Cochin-Hôtel Dieu

as to the members of the Department of Hepatology in Groupe Hospitalier Cochin-Hôtel Dieu, APHP, Paris, France, for the technical assistance. We are deeply indebted to Doctor Vladimir A. Morozov and Doctor Matthew Albert for the critical reading of the manuscript.

## COMMENTS

### Background

Hepatitis C virus (HCV) infection (or spread) is a serious public health challenge counting approximately 170 million people that are chronically infected worldwide. Host antiviral therapy is an additional option for the treatment of HCV infection.

### Research frontiers

Interferon-free treatments with new direct acting antivirals are expected to cure more than 90% of HCV-infected patients. But they are not available in all the countries. At the present time, triple therapy combining pegylated interferon- $\alpha$  2a or b and ribavirin with NS3 protease inhibitors (telaprevir or boceprevir) is going to remain the main treatment for HCV patients. That is why it appears important to continue research in limiting virus replication and the autophagy inhibition could be a new additional pathway because of recent evidences obtained regarding to an increased autophagic response in the liver of chronically HCV infected patients.

### Innovations and breakthroughs

This is the first study evaluating a new autophagy inhibitor as antiviral that could inhibit HCV infection in a dose-dependent manner without cytotoxic effect using the relevant ex vivo model of the human liver slices culture.

### Applications

This study highlight the relevance of the *ex vivo* model of the human HCV infected liver slices culture in preclinical studies of the new anti-viral drugs in single or in combined therapy and their potential toxicity in particular for patients "difficult to treat". Moreover, the infection of human liver slices culture with primary viral isolates from patients that the authors succeed to establish, should allow highlighting the potential of early emergence of drug resistant viral variants during the anti-viral treatments.

### Terminology

Autophagy is a catabolic process which degrades a cellular own component through the lysosomal machinery. It has been shown that autophagy is activated during virus and bacterial infection and that some viruses can use the autophagy system to facilitate their own replication.

### Peer-review

The manuscript is clear and comprehensive.

# World Journal of *Hepatology*

*World J Hepatol* 2016 August 8; 8(22): 915-956

## Editorial Board

2014-2017

The *World Journal of Hepatology* Editorial Board consists of 474 members, representing a team of worldwide experts in hepatology. They are from 52 countries, including Algeria (1), Argentina (6), Armenia (1), Australia (2), Austria (4), Bangladesh (2), Belgium (3), Botswana (2), Brazil (13), Bulgaria (2), Canada (3), Chile (1), China (97), Czech Republic (1), Denmark (2), Egypt (12), France (6), Germany (20), Greece (11), Hungary (5), India (15), Indonesia (3), Iran (4), Israel (1), Italy (54), Japan (35), Jordan (1), Malaysia (2), Mexico (3), Moldova (1), Netherlands (3), Nigeria (1), Pakistan (1), Philippines (2), Poland (1), Portugal (2), Qatar (1), Romania (6), Russia (2), Saudi Arabia (4), Singapore (1), South Korea (12), Spain (20), Sri Lanka (1), Sudan (1), Sweden (1), Switzerland (1), Thailand (4), Turkey (21), Ukraine (3), United Kingdom (18), and United States (55).

*World Journal of Hepatology*  
Volume 8 Number 22 August 8, 2016

### ABOUT COVER

Editorial Board Member of *World Journal of Hepatology*, Dr. Neil L Julie, MD, Department of Gastroenterology, Shady Grove Adventist Hospital, Bethesda, MD 20850, United States

### AIM AND SCOPE

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

### INDEXING/ ABSTRACTING

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

### Abstract

Acute liver failure, also known as fulminant hepatic failure (FHF), embraces a spectrum of clinical entities characterized by acute liver injury, severe hepatocellular dysfunction, and hepatic encephalopathy. Cerebral edema and intracranial hypertension are common causes of mortality in patients with FHF. The management of patients who present acute liver failure starts with determining the cause and an initial evaluation of prognosis. Regardless of whether or not patients are listed for liver transplantation, they should still be monitored for recovery, death, or transplantation. In the past, neuromonitoring was restricted to serial clinical neurologic examination and, in some cases, intracranial pressure monitoring. Over the years, this monitoring has proven insufficient, as brain abnormalities were detected at late and irreversible stages. The need for real-time monitoring of brain functions to favor prompt treatment and avert irreversible brain injuries led to the concepts of multimodal monitoring and neurophysiological decision support. New monitoring techniques, such as brain tissue oxygen tension, continuous electroencephalogram, transcranial Doppler, and cerebral microdialysis, have been developed. These techniques enable early diagnosis of brain hemodynamic, electrical, and biochemical changes, allow brain anatomical and physiological monitoring-guided therapy, and have improved patient survival rates. The purpose of this review is to discuss the multimodality methods available for monitoring patients with FHF in the neurocritical care setting.

**Key words:** Fulminant hepatic failure; Cerebral edema; Multimodality methods; Intracranial hypertension; Liver transplantation

**Core tip:** Cerebral edema and intracranial hypertension are common causes of mortality in patients with fulminant hepatic failure (FHF). The management of

patients who present acute liver failure starts with determining the cause and an initial evaluation of prognosis. Regardless of whether or not patients are listed for liver transplantation, they should still be monitored for recovery, death, or transplantation. The purpose of this review is to discuss the multimodality methods available for monitoring patients with FHF in the neurocritical care setting.

Paschoal Jr FM, Nogueira RC, Ronconi KDAL, de Lima Oliveira M, Teixeira MJ, Bor-Seng-Shu E. Multimodal brain monitoring in fulminant hepatic failure. *World J Hepatol* 2016; 8(22): 915-923 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i22/915.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i22.915>

## INTRODUCTION

Fulminant hepatic failure (FHF) is a complex clinical condition that is only partially understood and remains a major clinical challenge<sup>[1,2]</sup>. Hepatic encephalopathy (HE) associated with intracranial hypertension is a severe neurologic complication and the leading cause of death among patients with FHF<sup>[3]</sup>.

The management of patients who present acute liver failure starts with determining the cause and an initial evaluation of prognosis<sup>[3]</sup>. In the past, neuromonitoring was restricted to serial clinical neurologic examination and, in some cases, intracranial pressure (ICP) monitoring. Over the years, this monitoring has proven insufficient because brain abnormalities were detected at late and irreversible stages<sup>[4]</sup>. The need for real-time monitoring of brain functions to favor prompt treatment and avert irreversible brain injuries led to the concepts of multimodal monitoring and neurophysiological decision support. New monitoring techniques, such as brain tissue oxygen tension, continuous electroencephalogram (cEEG), transcranial Doppler (TCD), and cerebral microdialysis (MD), have been developed. These techniques enable early diagnosis of brain hemodynamic, electrical, and biochemical changes, allow brain anatomical and physiological monitoring-guided therapy, and have improved patient survival rates<sup>[4,5]</sup>.

The purpose of this review is to discuss the multimodality methods available for the monitoring of patients in the neurocritical care setting.

## MONITORING INTRACRANIAL PHYSIOLOGICAL VARIABLES

### Invasive ICP monitoring

ICP monitoring is indicated for brain swelling due to FHF and involves the use of catheters, which can be implanted into epidural, subdural-subarachnoid, or intraventricular spaces through a burr hole. The latest catheters allow real-time and continuous ICP data acquisition. The objective of ICP monitoring is to maintain ICP below 20 mmHg and have adequate cerebral perfusion pressure

(CPP) = arterial blood pressure (ABP) - ICP. The ideal management of CPP should take cerebral metabolic and hemodynamic data into account in order to avoid excessive cerebral hyperemia, as well as uncoupling of cerebral blood flow and metabolism<sup>[6,7]</sup>. Despite a lack of evidence that treatment of elevated ICP can improve survival rates of patients with FHF, it is generally accepted that Grade 3-4 HE patients, especially those awaiting liver transplantation, should undergo ICP monitoring<sup>[6,7]</sup>. ICP higher than 40 mmHg and prolonged low CPP < 50 mmHg are strongly associated with poor neurological recovery in FHF patients who are traditionally bad candidates for liver transplantation<sup>[8]</sup>.

Continuous perioperative measurement of ICP has been associated with a FHF survival rate of 54%-74%. Invasive ICP monitoring is especially risky in FHF patients with coagulopathy, for whom the incidence of intracranial bleeding due to catheter placement ranges from 5% to 22%<sup>[9,10]</sup>. Recombinant factor VII (rFVIIa) can be an alternative method for preventing intracranial hemorrhage associated with ICP placement. Acidosis can lead to low effectiveness of rFVIIa, therefore requiring its correction before use<sup>[5,11]</sup>.

Cerebral edema and intracranial hypertension (IH) are complications in approximately 75% to 80% of patients with FHF and grade III or IV encephalopathy, which remains a leading cause of death. The pathophysiology of these two complications still remains poorly understood, but may be related to vasogenic edema, cytotoxic edema, or cerebral hyperemia<sup>[8,12]</sup>. Vasogenic edema is the consequence of a breakdown of the blood brain barrier, while cytotoxic edema is related to the glutamine osmotic effects in the astrocytes that results in cerebral edema. On the other hand, hyperemia can be caused by failure of the sodium-potassium adenosine triphosphatase pump<sup>[8]</sup> and/or the accumulation of certain substances such as cytokines, products of the necrotic liver, or glutamine, which lead to vasodilatation of the microcirculation. Brain edema and hyperemia can lead to IH, with decreased cerebral perfusion pressure, cerebral ischemia, and herniation<sup>[8,12]</sup>.

## NON-INVASIVE ICP MONITORING

### Optic nerve ultrasound

The optic nerve has a sheath which is continuous with the dura mater of the brain. The subarachnoid space of the optic nerve sheath communicates with the brain and the subarachnoid space, meaning that optic nerve sheath diameter (ONSD) can be influenced by changes in the pressure of cerebrospinal fluid in the cranial cavity. ONSD has been increasingly used to monitor ICP in many different clinical settings, and is measured by an ultrasound probe placed on the eyes<sup>[13,14]</sup>. A linear correlation between ICP and ONSD measurements has been reported, and a significant reduction in ONSD occurs after draining the cerebrospinal fluid. The cut-off value of ONSD suggested to indicate ICP greater than 20 mmHg was 5.2 mm<sup>[15]</sup>. However, scant information

is available regarding the use of ONSD in patients undergoing liver transplantation. Kim *et al.*<sup>[13]</sup> concluded that patients undergoing liver transplantation are susceptible to severe bleeding disorders and elevated ICP during the procedure, reporting two cases of patients who underwent liver transplantation at different stages. In one case with severe hepatic encephalopathy, ONSD was measured before transplantation, yielding a value of 6.4 mm. Meanwhile, measurements made in the other case after reperfusion of the graft yielded a value of 5.7 mm. These data demonstrate that measurement of ONSD is a useful method for evaluating patients with FHF undergoing liver transplantation.

### **Transcranial color-coded duplex ultrasonography**

Midline shift (MLS) is a known prognostic factor for unfavorable outcome after the development of intracranial hemorrhage in patients with severe brain injury<sup>[16]</sup>. In clinical practice, the repetition of computed tomography is mostly used to monitor MLS. However, the examination leads to increased radiation exposure and requires the transport of critically-ill patients, which are associated with increased morbidity and mortality in these patients<sup>[17]</sup>. Transcranial color-coded duplex sonography (TCCD) represents a non-invasive bedside alternative to radiological methods. TCCD measurements are valid for the diagnosis and monitoring of various neurological diseases, including IH<sup>[18,19]</sup>. Furthermore, monitoring MLS *via* TCCD safely predicts early mortality and prognosis of conservative clinical treatment of hemispheric ischemic stroke<sup>[18]</sup>. Unlike ischemic stroke, intracranial hemorrhage MLS is caused by both the volume of hematoma and the formation of edema, which can make outcomes difficult to predict<sup>[20]</sup>. Patients with FHF who develop brain swelling and IH can benefit from this method, although it has not yet been described in the literature.

### **Brain computer tomography and magnetic resonance images**

Brain images have traditionally been used to diagnose strokes, but are also useful in ruling out other causes of changes in mental status<sup>[21]</sup>. Furthermore, a non-contrast computer tomography (CT) scan of the brain can disclose brain swelling, compressed basal cisterns, hydrocephalus, mass effect, and midline shift, which can be indicative of increased ICP. However, the absence of these findings does not exclude the presence of brain swelling<sup>[22]</sup>, which may be better visualized through magnetic resonance imaging (MRI) of the brain<sup>[21]</sup>. The imbalance in the homeostasis of cell volume consequent to elevation of cerebral ammonia concentration can be disclosed in MRI by the proton spectroscopy findings of decreased myo-inositol and choline signals<sup>[23]</sup>. Moreover, magnetization transfer ratio measurements of fast fluid-attenuated inversion recovery sequences and diffusion-weighted images can be used to detect abnormalities in white matter, thereby reflecting elevated ammonia concentrations in the central nervous system that

facilitate the diagnosis of brain swelling in patients with FHF<sup>[23,24]</sup>.

### **Cerebral blood flow monitoring**

Cerebral blood flow (CBF) can generally be maintained in the presence of varying CPP. However, this relationship is not linear in severe brain injury due to impaired cerebral autoregulation<sup>[25,26]</sup>. In such cases, assessment based on CPP alone can be inaccurate, as measurements assume that cerebral vascular resistance remains constant, which is not the case in serious brain injuries<sup>[24]</sup>. Therefore, direct monitoring of CBF can help in the management of patients with severe brain injury.

The gold standard method for CBF study is the Kety-Schmidt technique. This technique assesses the area between the curves of arterial and venous washout of a freely diffusible indicator such as nitrous oxide and calculates global CBF from the absorption rate of the indicator in brain tissue<sup>[26,27]</sup>. Radioisotopes such as krypton-85 and xenon-133 can also be used for CBF study in combination with compact scintillation detectors and microprocessors, as well as the indocyanine green dye dilution technique, which involves non-invasive near-infrared spectroscopy (NIRS) and the thermodilution method<sup>[28,29]</sup>. The principle of spectroscopy is based on the application of light in the near-infrared wavelength to assess, quantitatively and qualitatively, the molecular components related to tissue oxygenation. Based on deoxyhemoglobin and oxyhemoglobin concentrations in the tissue, NIRS is a non-invasive method which allows for the gathering of information for calculating tissue oxygenation<sup>[30]</sup>. Other techniques that evaluate CBF include: CT with xenon, CT by single photon emission tomography (SPECT), positron emission oxygen-15 tomography (PET), perfusion CT, and perfusion imaging by MRI<sup>[31,32]</sup>. SPECT studies the spatial distribution of the radioactive isomer technetium-99 (Tc-99) and its local metabolism in the brain. Since these radionuclides are unusual in the human body, Tc-99 metabolism or its connection may not be identical to the native molecule, and therefore difficulties in the interpretation of results may occur<sup>[33]</sup>. SPECT provides only a relative measurement of radioactivity and allows for the comparison of physiological parameters such as blood flow in different areas of the brain<sup>[34,35]</sup>.

Cerebrovascular resistance, according to Davies *et al.*<sup>[10]</sup>, tends to decrease during the course of FHF and can be influenced by the use of pharmacological agents (*i.e.*, sedatives and inotropes). Previous studies have shown increased blood flow in the basal ganglia of patients with minimal HE, which suggests an increased supply of ammonia to these areas, with resultant astrocyte dysfunction and cognitive impairment.

Nielsen *et al.*<sup>[36]</sup> evaluated CBF of FHF patients *via* the NIRS method. This method detects changes in cerebral perfusion pressure and constitutes a non-invasive method that, in conjunction with transcranial Doppler, may detect brain hyperperfusion before the manifestation of increased intracranial pressure.

TCD is a non-invasive method that measures cerebral blood flow velocity (CBFV). Access of ultrasound waves to the intracranial environment is possible through the "ultrasonic windows", namely the temporal, orbital, suboccipital, and submandibular windows. Thus, placing one transducer against these ultrasonic windows allows the obtention of the spectra of blood flow velocity vs time for some cerebral arteries<sup>[37]</sup>.

The previously mentioned arteries can be assessed every 1 mm to 2 mm along their lengths given the pulsed emission ultrasonic waves, which allow controlled modulation depth of the sampling area<sup>[38]</sup>. The examiner should acquire the most intense audible signal and best blood flow velocity spectra possible by adjusting the position and transducer angle so that the incidence angle between the emitted ultrasound beam and blood vessel is close to zero<sup>[39]</sup>; thus, more accurate measurements of blood flow velocity can be made.

TCD has proven a valuable method in studies of cerebral hemodynamics due to its high temporal resolution, non-invasiveness, portability, and ability to measure CBFV in real time. CBFV indirectly represents CBF if the cross-sectional area of the vessel is assumed to remain constant with fluctuations in arterial pressure. There is evidence that, despite variations in ABP, the caliber of the vessel does not change significantly<sup>[40,41]</sup>, thereby validating the method for clinical use.

TCD can provide indirect information on CBF and ICP in patients with FHF<sup>[22]</sup>. Changes in the shape of the spectral diastolic wave can be an early sign of IH and impaired cerebral perfusion pressure. In addition, the final stages of IH can lead to large attenuation of diastolic blood flow velocity (BFV)<sup>[42]</sup>.

ICP changes can influence cerebral blood circulation, which may be assessed with TCD. Currently, TCD publications are trying to predict ICP curves in a non-invasive manner. The pulsatility index (PI) is defined by the following formula: Systolic velocity - diastolic velocity/mean velocity, and is increased when cerebrovascular resistance is elevated. Increased ICP may lead to PI elevation, especially if there is an impairment of cerebral autoregulation. In this case, when diastolic blood pressure equals ICP, there is cessation of intracranial diastolic flow<sup>[43]</sup>; a further increase in ICP (oscillating flow) may appear during flow progress in the systole. During diastole, critically high ICP, CVR, and distended intracranial arteries eject the blood in a retrograde direction. When net forward flow is seriously reduced, severe ischemic brain damage or brain death may occur. In critical IH, the intracranial waveform degrades to become a small systolic spike and then disappears altogether<sup>[44]</sup>. The relationship between TCD-hemodynamic patterns and the different states of ICP reinforces the idea that TCD can be useful for determining the optimal range of arterial blood pressure for adequate cerebral blood flow dynamics in FHF patients<sup>[45,46]</sup>.

Cerebral autoregulation (CA) is impaired in patients with FHF, and CBF has been described as correlating with ICP in FHF<sup>[23]</sup>. CA is characterized by CBF remaining

relatively constant despite variations in CPP. This physiological response acts to protect the brain from the harmful effects (*i.e.*, ischemia or hyperemia) of large oscillations in perfusion pressure. Lassen *et al.*<sup>[47]</sup> use the term "autoregulation" to explain the relatively constant values of blood flow encountered during hypotension induction. However, autoregulation has been confused with other dynamic adjustment processes. Strictly speaking, autoregulation refers only to the brain's vascular response to changes in CPP, and is sometimes referred to specifically as pressure autoregulation. Brain vessels also dilate or contract as a physiological response to cellular metabolic activity, but should not strictly be called autoregulation. The influence of neuronal metabolism on CBF should be referred to as metabolic regulation of the flow-metabolism coupling<sup>[47,48]</sup>.

The methods used to estimate changes in cerebral perfusion are TCD ultrasound and clearance of xenon-133, while CT demonstrates stable CBF. Other techniques reflect tissue perfusion and estimate changes in CBF such as jugular arteriovenous difference in oxygen (AVDO<sub>2</sub>), electromagnetic flow meters, near-infrared spectroscopy, laser Doppler flowmetry, and venous occlusion plethysmography<sup>[49]</sup>.

With changes in technology, particularly the advent of TCD and high temporal resolution examination, it has become possible to calculate an index for static CA<sup>[50]</sup>, which relates cerebrovascular resistance to blood pressure, according to the following formula<sup>[51]</sup>:  $\Delta\text{CVR}\% / \Delta\text{CPP}\%$  (CVR - cerebrovascular resistance); where it is assumed that  $\text{CPP} = \text{ABP} - \text{ICP}$ , with the value of ICP being negligible and thus ABP replacing CPP<sup>[50]</sup>.

However, the nature of the estimates, the need for invasive procedures to change ABP, the inherent risk of exposing the patient to exhaustion of self-regulatory reserves, and the emergence of new dynamic CA study methods has reduced the use of the static method for evaluating CA in clinical studies<sup>[51,52]</sup>.

Abdo *et al.*<sup>[46]</sup> evaluated BFV by TCD in five patients with FHF and compared the results against a control group who had associated critical neurological conditions without FHF. Despite the limitations of the study, the authors concluded that patients with FHF may have a dominant pattern of brain hypoperfusion, with an average velocity below normal values and an increased pulsatility index, possibly due to an increase in ICP. The authors suggested that proper measurement by this method improves brain perfusion and prevents hypoxia in these patients. Another study that used TCD demonstrated that CA of CBF was re-established after the onset of HE improvement in patients with FHF<sup>[53]</sup>.

## NEUROPHYSIOLOGICAL MONITORING

### Electroencephalogram

Electroencephalogram (EEG) is a non-invasive method which analyzes spontaneous brain electrical activity and is performed by placing electrodes on the scalp with the aid of a conductive paste which, besides affixing the

electrodes, allows for the proper acquisition of the signals that constitute the brain's electrical activity<sup>[54]</sup>. Initially, a spontaneous recording of brain electrical activity is made while the patient is awake and conscious. If possible, this activity is also recorded during drowsiness and sleep. Recording during these different states increases the sensitivity of the method in detecting various defects, including patients with severe brain pathologies<sup>[21,54]</sup>.

Continuous video EEG (cEEG) provides long-term monitoring of brain electrical activity in critically-ill patients with altered mental status and in those at risk of secondary ischemia following acute brain injury. The main indications of cEEG are the detection of non-convulsive seizures or status epilepticus in order to investigate causes of impairment of consciousness, and to determine the prognosis of brain injury. EEG changes in hepatic encephalopathy may range from low alpha-rhythm frequency (8 Hz) mixed with bilateral theta activity, which can later develop into theta-delta with deceleration throughout both hemispheres, with or without three-phase curves. With increasing stupor, sleep activity disintegrates. In severe coma, arrhythmic delta activity diminishes, both in frequency and amplitude, and progresses to electrocerebral silence<sup>[54]</sup>.

The presence of subclinical seizure is often poorly recognized in patients with grade III and IV HE, emphasizing the importance of EEG monitoring in these patients. Cerebral ischemia has often been known to precede the onset of seizures in patients with FHF<sup>[54]</sup>. Seizures are susceptible to cerebral hypoxia and contribute to the development and perpetuation of brain swelling. During FHF, the increase in extracellular brain glutamate concentrations predisposes patients to epileptic activity<sup>[21]</sup>. Although no definitive recommendations can be made at the time of writing, the morbidity of untreated subclinical crisis should be considered concomitant with the prudent administration of anti-epileptic drugs until additional studies are established.

### Bispectral index

The bispectral index (BIS) is a neurophysiological monitoring system that continuously analyzes electroencephalograms to determine the level of consciousness of patients undergoing general anesthesia. The notion of "anesthetic depth" is usually associated with training experiences or memories during surgery, in which anesthesia does not prevent consciousness or even waking-up during general anesthesia. Although EEG is the gold standard used to determine electrical activity in comatose patients, standard EEG monitoring may not be feasible for all patients who require intensive care during pretransplant<sup>[55,56]</sup>.

Studies show that monitoring by BIS, which was developed in order to assist with the clinical evaluation of the degree of hypnosis with anesthesia, is useful for monitoring cases of FHF<sup>[55-57]</sup>. The BIS monitor uses the EEG signal derived from electrodes placed on the forehead that provide continuous monitoring. While monitoring for BIS has been developed to assess the

level of awareness during anesthesia, this method may also be useful to assess the degree of recovery of consciousness alongside improved liver function after liver transplantation. Hwang *et al*<sup>[9]</sup> showed that the BIS may be useful for evaluating state of consciousness during the peritransplant and intensive care periods for FHF patients who develop HE.

## BRAIN OXYGENATION MONITORING

Brain oxygenation monitoring after brain injury can lead to the detection or prevention of secondary ischemic episodes. The four methods used to measure cerebral oxygenation are: Jugular bulb oximetry, measurement of direct tissue oxygen tension, NIRS, and PET oxygen-15<sup>[32]</sup>.

### Jugular bulb oximetry

Catheterization of the jugular bulb and obtention of venous blood samples allow for an estimate of blood flow and cerebral metabolism. Monitoring blood oxygen saturation in veins that drain the brain provides an estimate of overall metabolic demand compared to oxygenation deprivation<sup>[32]</sup>. The parameter can be used as a measure of jugular venous oxygen content, as well as arteriovenous oxygen difference<sup>[57]</sup>.

Monitoring the oxygen saturation of the jugular vein provides an estimate of overall metabolic demand compared to oxygenation. The parameter used can be jugular venous oxygen content or arteriovenous oxygen difference ( $AVDO_2 = CMRO_2/CBF$ ;  $CMRO_2$  = cerebral metabolic rate of oxygen consumption). The extent of arteriovenous oxygen difference indicates the amount of oxygen extracted by the brain. Under normal conditions, this value is a 2.8  $\mu\text{mol/mL}$  (range 2.2-3.3  $\mu\text{mol/mL}$ ) or 6.3% volume (volume varies from 5%-7.5% oxygen) change in  $CMRO_2$  or cerebral blood flow extraction<sup>[24]</sup>. A reduction in cerebral blood flow, without changes in the energetic demands, increases oxygen extraction in the cerebral tissue. Thus, the jugular vein oxygen decreases and the difference between arterial and jugular venous oxygen increases. On the other hand, a disproportionate increase in cerebral blood flow or a decrease in energy consumption decreases  $AVDO_2$ <sup>[57]</sup>. The limitation of the method is the non-detection of oxygen consumption changes in small brain regions<sup>[58]</sup>.

### Brain tissue oxygen

Quantitation of tissue oxygen pressure ( $PtIO_2$ ) in the brain reflects the partial pressure of oxygen at the end of the capillary circuit. In ischemic situations, a fall in  $PtIO_2$  is accompanied by a decrease in pH (lactic acidosis) and an increase in tissue carbon dioxide pressure, with a lack of metabolic exchange between cells and the capillary circuit. Low values indicate  $PtIO_2$  tissue hypoxia and help guide therapy<sup>[59]</sup>. The patient should exhibit adequate hemoglobin content, balanced hemoglobin affinity for oxygen, and appropriate systemic arterial oxygen

content. Commonly-used sensors determine mean tissue oxygen pressure in an area of 17 mm<sup>3</sup>. The catheter is introduced into the cerebral white matter to a depth of 25 mm below the dura mater. The cathode comprises a gold and silver anode immersed in an electrolyte solution<sup>[58,59]</sup>. The oxygen molecules diffuse into the catheter, producing a reversible reaction at the cathode in which oxygen combines with water and forms ions (OH<sup>-</sup>). These reactions generate an electric current detected by a voltmeter, with the electrical signal subsequently digitized and transformed into a numeric value on the monitor display panel. Positioning the catheter in a circulatory border territory between the anterior and middle cerebral arteries allows for the early detection of changes in this area, which is more sensitive to flow variations<sup>[59]</sup>.

Based on previous studies, the cutoff point value for cerebral ischemia monitoring with PtIO<sub>2</sub> appears to lie within the 8 to 25 mmHg range. PtIO<sub>2</sub> monitoring can provide real-time information on the regulation of brain blood flow and has been shown to have a clear impact on the management of patients with severe brain injuries, such as traumatic brain injury and hemispheric infarcts<sup>[60]</sup>. Patients with FHF who develop brain swelling and IH can benefit from this method.

### Near infrared spectroscopy

As described above, this is a non-invasive technique for measuring regional cerebral oxygen saturation, as well as analyzing the difference in oxygenated hemoglobin and deoxygenated absorption spectra<sup>[61]</sup>.

Studies in patients with FHF demonstrate that the monitoring of brain oxygenation provides valuable data for the clinical management of this population<sup>[62]</sup>. Oxygen and cerebral glucose consumption have been observed before signs of brain swelling, suggesting that cerebral oxygen metabolism is intact at this stage<sup>[62]</sup>. In another study, CMRO<sub>2</sub> was found to be decreased in all patients with FHF<sup>[61]</sup>. There was also evidence of cerebral ischemia, as indicated by increased AVDO<sub>2</sub>. In the study, it was concluded that hyperemia alone was not related to the outcome, despite having occurred more frequently during elevated ICP. All patients with malignant intracranial hypertension previously had hyperemia<sup>[62,63]</sup>. Nielsen *et al.*<sup>[36]</sup> reported that both pressure and arterial oxygen saturation were maintained during infusion with norepinephrine. Additionally, hemoglobin concentration in blood flow was not compromised. Cerebral arterial oxygenation is capable of detecting brain perfusion changes during norepinephrine infusion in patients with acute liver failure. This suggests that NIRS can be valuable in monitoring critical changes in the cerebral oxygenation and blood volume of these patients.

## METABOLIC MONITORING

Brain metabolism can be evaluated by PET and MR spectroscopy, jugular oxygen saturation, monitoring of CBF, and MD. PET scans provide an estimate of the topographic view of glucose metabolism, while MRI

spectroscopy qualitatively shows the lactate content of a particular brain structure<sup>[58]</sup>.

MD techniques provide information on tissue metabolism, including the availability of substrates such as glucose and the production of local metabolites. This technique is based on the exchange of solutes through a semipermeable membrane that simulates the operation of a capillary and has the basic objective of monitoring the tissue availability of the different metabolites released by cells<sup>[64]</sup>.

The tip of the catheter contains a semipermeable membrane that separates a solution of known composition from the extracellular fluid space. MD fluid is then analyzed to quantify metabolites. This technique allows for the study of the release of excitatory neurotransmitters such as glutamate and aspartate, as well as other neuro-modulators, thereby indirectly analyzing the ischemic excitotoxicity phenomenon. It also allows for the analysis of the concentration of tissue degradation products such as glycerol. The catheter's semipermeable membrane used to study the cited substances only allows for the passage of ions of molecules with a molecular weight of less than 20000 daltons<sup>[64,65]</sup>.

Glucose is most frequently determined as the cellular energy substrate. In conditions where there is a decrease in both cerebral tissue glucose and PtIO<sub>2</sub>, a reduction of capillary blood flow may be inferred<sup>[63,64]</sup>. Lactate studies can indicate the intensity of anaerobic metabolism, while glycerol studies can evaluate tissue damage since glycerol is one of the structural components in the tissue lipid layer of cell membranes<sup>[66]</sup>. Glutamate is an important excitatory neurotransmitter in the mammalian nervous system, with aspartate following in importance. These amino acids are released in the synaptic cleft after neuronal depolarization. This depolarization can be associated with tissue ischemia in states of massive release<sup>[67]</sup>. In situations of excitotoxicity, massive release of glutamate into the synaptic cleft can be seen. Thus, large inputs of calcium into the cell are observed; as a consequence, there is production of oxygen free radicals in cell membranes and the release of more fatty acids and glycerol<sup>[66]</sup>. It is recommended that the MD catheter be placed in so-called "penumbra" areas adjacent to focal lesions in order to allow monitoring of potentially recoverable brain regions<sup>[68,69]</sup>. MD is currently considered one of the most important *in vitro* sampling methods in physiology and pharmacology. Applied in neurointensive care, it is the only tool that allows continuous measurement of chemicals in the brain extracellular space and elucidation of non-ischemic forms of cerebral hypoxia<sup>[67]</sup>.

The tissue volume evaluated by the MD catheter is a cylinder equivalent to the length of the dialysis membrane (10 mm) with a diameter of a few millimeters (0.6 mm). MD pumps perfuse the catheter with an artificial cerebrospinal fluid, which equilibrates with the interstice around the catheter. Balance occurs by diffusion through the dialysis membrane. Using a dialysis membrane with a 10 mm 0.3 perfusion flow L/min, the

concentration of dialyzed glucose, lactate, pyruvate, and glutamate is approximately 70% of the concentration of interstitial fluid. Samples are continuously collected and analyzed at the bedside every hour, or as needed, with the results being analyzed on trend curves<sup>[70]</sup>. When monitoring biochemical markers it is established that: Lactate/pyruvate ratio is the best marker of cerebral cortex state and early biomarkers in secondary ischemic injury glycerol and glutamate are additional markers of tissue hypoxia<sup>[70]</sup>.

Brain swelling predominantly involving glial cells is often reported as a serious complication of FHF. The swelling of astrocytes may result in elevated ICP and cerebral herniation syndrome in patients with FHF<sup>[70]</sup>. Tofteng *et al.*<sup>[71]</sup> found brain chemical changes in the MD of a young man with severe acute liver failure and brain swelling in the liver transplant, and found that both extracellular glutamate and glycerol levels were elevated before liver transplant, and tending to decrease after grafting. These results indicate changes in glutamate neurotransmission, arachidonic acid metabolism, lactate, and flow through the blood-brain barrier in patients with FHF.

In another study, Tofteng *et al.*<sup>[72]</sup> investigated whether an increased concentration of glutamate and brain extracellular lactate preceded episodes of elevated ICP in patients with FHF (7 women and 3 men; age range 20-55 years) by inserting MD and ICP catheters into the brain. A total of 352 MD samples were collected for a median of 3 d, allowing for the analysis of approximately 1760 dialyzed samples at the bedside. It has been shown that patients with FHF feature elevated concentrations of extracellular glutamate and cerebral lactate. However, high levels of glutamate are not correlated with increased intracranial pressure, while high levels of lactate precede episodes of elevated ICP. Hyperglycolysis to lactate accumulation is involved in brain microvascular vasodilation and ICP increase in patients with FHF. Therefore, it can be concluded that brain MD at the bedside can be a valuable tool for monitoring these patients.

## CONCLUSION

Patients with FHF are usually submitted for brain monitoring after undergoing liver transplantation or when they have a neurological decline. Brain monitoring in this critical phase is essential for maintaining hemodynamic, metabolic, and electrical parameters at acceptable levels. There are a myriad of methods for real time measuring of the aforementioned parameters, with each method having a particular contribution in the detection of "a brain at risk". The key point for proper patient management in order to prevent neurological complications is to combine the different methods in a multimodal approach.

The multimodal technique of extended neuro-monitoring offers an advanced option for further development and investigations in animal models of FHF. Furthermore, identification of patients at risk for neurologic complications before and after liver transplant

may allow for prompt neuroprotective interventions, including the optimal control of blood pressure.

## Abstract

The aim of this review is to enlighten the critical roles that the liver plays in cholesterol metabolism. Liver transplantation can serve as gene therapy or a source of gene transmission in certain conditions that affect cholesterol metabolism, such as low-density-lipoprotein (LDL) receptor gene mutations that are associated with familial hypercholesterolemia. On the other hand, cholestatic liver disease often alters cholesterol metabolism. Cholestasis can lead to formation of lipoprotein X (Lp-X), which is frequently mistaken for LDL on routine clinical tests. In contrast to LDL, Lp-X is non-atherogenic, and failure to differentiate between the two can interfere with cardiovascular risk assessment, potentially leading to prescription of futile lipid-lowering therapy. Statins do not effectively lower Lp-X levels, and cholestasis may lead to accumulation of toxic levels of statins. Moreover, severe cholestasis results in poor micellar formation, which reduces cholesterol absorption, potentially impairing the cholesterol-lowering effect of ezetimibe. Apolipoprotein B-100 measurement can help distinguish between atherogenic and non-atherogenic hypercholesterolemia. Furthermore, routine serum cholesterol measurements alone cannot reflect cholesterol absorption and synthesis. Measurements of serum non-cholesterol sterol biomarkers - such as cholesterol precursor sterols, plant sterols, and cholestanol - may help with the comprehensive assessment of cholesterol metabolism. An adequate cholesterol supply is essential for liver-regenerative capacity. Low preoperative and perioperative serum cholesterol levels seem to predict mortality in liver cirrhosis and after liver transplantation. Thus, accurate lipid profile evaluation is highly important in liver disease and after liver transplantation.

**Key words:** Cholesterol metabolism; Cholestasis; Liver transplantation; Non-cholesterol sterols; Cholestanol; Donor; Low density lipoprotein receptor mutation; Apolipoprotein B-100; Lipoprotein-X

**Core tip:** The liver plays key roles in cholesterol metabolism. Cholestatic liver disease leads to alterations of cholesterol metabolism: Cholesterol homeostasis is disturbed and cholesterol synthesis and especially cholesterol absorption are reduced, and lipoprotein X may develop. The latter can interfere with cardiovascular risk assessment. Apolipoprotein B-100 measurement may be useful in such cases. Cholesterol metabolism in cholestasis could be better described using cholesterol precursor sterols, diet-derived plant sterols, and cholestanol (the liver-synthesized derivative of cholesterol). Accurate lipid profile evaluation is particularly important after liver transplantation, when both atherogenic and non-atherogenic hypercholesterolemia may co-exist.

## INTRODUCTION

Abundant in the bloodstream and in cell membranes, cholesterol is a critical component of vertebrate cell-membrane structure and function, allowing cells to maintain the permeability and fluidity that is fundamental for all animal life<sup>[1,2]</sup>. Cholesterol biosynthesis defects, such as Smith-Lemli-Opitz syndrome and lathosterolosis, reveal cholesterol's importance in normal embryonic development. Lathosterolosis is a defect of postsqualene cholesterol biosynthesis that results in deficient transformation of lathosterol into 7-dehydrocholesterol by sterol-C5-desaturase/dehydrogenase. This disorder is characterized by high serum levels of the cholesterol precursor lathosterol, and low cholesterol levels in cells, plasma, and tissues-which causes multiple congenital anomalies, including microcephaly and progressive cholestasis leading to liver failure<sup>[3]</sup>.

The tightly inter-regulated whole-body cholesterol homeostasis includes the following main components: Intestinal cholesterol absorption, hepatic *de-novo* cholesterol synthesis, and cholesterol excretion from the body. Recent advances in the field have further clarified the mechanisms of intestinal transporters and regulatory pathways<sup>[4-11]</sup>. The brain is home to about 23% of total body cholesterol, which is mainly synthesized *in situ* following blood-brain barrier establishment since dietary cholesterol does not cross this boundary<sup>[3]</sup>. In contrast

to other species, humans exhibit a high cholesterol synthesis rate in the brain only after birth<sup>[3]</sup>.

Under normal circumstances, the liver is the primary site of cholesterol biosynthesis and storage<sup>[12]</sup>. The liver is also the principal site of cholesterol excretion, converting cholesterol to bile acids and removing free cholesterol as neutral sterols *via* biliary excretion<sup>[4,5,13,14]</sup>. Since the liver plays a central role in cholesterol metabolism, liver disease can impact cholesterol metabolism, depending on the type of liver injury (parenchymal, cholestatic, or mixed)<sup>[15]</sup>. In one case of lathosterolosis, liver transplantation (LT) removed the liver disease, reversing the cholesterol metabolism defect and somewhat improving the postnatal neurological symptoms<sup>[3]</sup>. Conversely, various changes in cholesterol metabolism can be indicators of hepatic and biliary dysfunction.

In the present review, we aimed to summarize current concepts regarding the regulation of cholesterol metabolism in health and in cholestatic liver disease. We discuss difficulties in assessing cholesterol metabolism, and summarize the cholesterol metabolism disturbances seen in cholestatic liver disease and before and after LT. Cholesterol metabolism in the setting of non-alcoholic steatohepatitis was recently reviewed<sup>[16]</sup>, and is not discussed here.

## OVERVIEW OF CHOLESTEROL METABOLISM

The following are the main components involved in liver-related cholesterol metabolism and the control of plasma cholesterol levels: (1) intestinal absorption of dietary and biliary cholesterol; (2) bile acid synthesis; (3) endogenous cholesterol synthesis; (4) biliary excretion of cholesterol; (5) low-density lipoprotein (LDL) receptor activity; (6) very-low-density lipoprotein (VLDL) particle synthesis and transport into circulation; and (7) reverse cholesterol transport from peripheral tissues for biliary or non-biliary excretion [trans-intestinal cholesterol efflux (TICE)], the latter of which has been demonstrated only in animal models<sup>[4-11,13,17-19]</sup>.

## ABSORPTION OF DIETARY AND BILIARY CHOLESTEROL IN THE SMALL INTESTINE

Intestine-driven pathways are an important component of cholesterol homeostasis, through which cholesterol is both taken up from and pumped back to the intestinal lumen. Intestinal cholesterol absorption is a selective multistep process that is regulated by multiple sterol-transporter genes at the enterocyte level<sup>[17,18]</sup>. Uptake of free cholesterol from mixed micelles in the intestinal lumen to enterocytes occurs *via* the specific transporter protein Niemann-Pick C1 Like 1 (NPC1L1), which is highly expressed in the brush-border membrane of small-intestinal enterocytes<sup>[10,11,18,19]</sup> (Figure 1). These enterocytes then selectively efflux about half of the free cholesterol and about 90% of plant sterols back to the

**Figure 1 From the gut to the circulation: An overview of the pathways involved in cholesterol absorption and synthesis.** IDL: Intermediate density lipoprotein; HDL: High density lipoprotein; LDL: Low density lipoprotein; VLDL: Very low density lipoprotein; NPC1L1: Niemann-Pick C1 like 1; ABCG5: Adenosine triphosphate-binding cassette transporter G5 heterodimer; HMGCoA: 3-hydroxy-3-methyl-glutaryl CoA; FXR: Farnesoid X receptor.

intestinal lumen *via* the adenosine triphosphate (ATP)-binding cassette (ABC) G5/G8 transporters<sup>[20]</sup>.

Lipoproteins synthesized in the liver and intestine play central roles in mediating the cholesterol transport to and from tissues through the bloodstream. Within enterocytes, free cholesterol is esterified and assembled - together with triglycerides, phospholipids, and apolipoproteins - to form chylomicrons (lipoproteins). Chylomicrons next enter the lymphatic system and the blood circulation at the thoracic duct, such that chylomicron remnants can be transported to the liver<sup>[21]</sup> (Figure 1). Some of the cholesterol in enterocytes is generated by endogenous synthesis<sup>[4,22]</sup>. Cholesterol is also reportedly secreted *via* an apolipoprotein A1-dependent pathway to form high-density lipoproteins (HDL) in the extracellular milieu, which then enter circulation<sup>[21]</sup>.

## CHOLESTEROL SYNTHESIS IN THE LIVER AND PERIPHERAL TISSUE

Cholesterol primarily enters blood circulation from two sources: From intestinal cholesterol absorption, and from the *de novo* cholesterol synthesis that is ubiquitous in all nucleated cells<sup>[1]</sup>. The majority of the body's endogenous cholesterol is produced by the liver<sup>[4]</sup>. Through a complex 37-step process, cholesterol is synthesized from simpler precursor molecules, starting with acetyl CoA<sup>[12]</sup>. The rate-limiting factors in the cholesterol synthesis pathway

include two enzymes: The target of statins 3-hydroxy-3-methyl-glutaryl CoA reductase and squalene mono-oxygenase, which oxidizes the precursor squalene to lanosterol<sup>[1,23]</sup> (Figure 1).

The membrane of the endoplasmic reticulum (ER) contains an intracellular feedback system-a tightly controlled protein network that modulates the transcription of genes that mediate cholesterol synthesis and uptake (Figure 2). Sterol regulatory element-binding protein isoform 2 (SREBP-2) is an ER membrane-bound transcription factor that activates genes encoding the enzymes required for cholesterol synthesis<sup>[1,6-8,24]</sup>. A key event in cholesterol synthesis is the gated movement of SREBP-2 from the ER to the Golgi complex. A crucial ER membrane component, the cleavage-activating protein (SCAP), acts as both an escort for SREBP-2 and a sterol sensor. Immediately after SREBP-2 synthesis in the ER, its COOH-terminal regulatory domain binds to the COOH-terminal domain of SCAP. When cells become cholesterol depleted, SCAP escorts SREBP-2 from the ER to the Golgi apparatus, where SREBP-2 is cleaved by two proteases and then trans-located to the nucleus, where it activates transcription of multiple target genes for cholesterol synthesis. Upon accumulation of excess cellular cholesterol, the SCAP-SREBP complex binds to the resident ER protein INSIG-2, remaining in the ER in a sterol-regulated manner and thereby blocking cholesterol synthesis<sup>[25]</sup> (Figure 2). Interactions between cholesterol, SCAP, and the SCAP-binding protein INSIG-2

**Figure 2** One key event in cholesterol homeostasis is the gated movement of sterol regulatory element-binding protein isoform 2 from the endoplasmic reticulum to the Golgi complex, involving the cleavage-activating protein, and INSIG-2. create a sensitive switch that can respond to minor alterations of intracellular cholesterol levels, thus exerting precise control over the cholesterol composition of cell membranes.

In liver cells, free cholesterol can be excreted as neutral sterols into bile or transformed into bile acids, or it can be esterified and either stored in the liver as cholesterol esters or assembled into VLDL and secreted into circulation. The microsomal transfer protein assembles VLDL from cholesterol esters, triglycerides, phospholipids, free cholesterol, and apolipoprotein B-100 (apo B-100) as its structural protein. Triglycerides in VLDL are subsequently broken down by the enzymes lipoprotein lipase and hepatic lipase, producing intermediate-density lipoproteins (IDLs), followed by LDLs that transport cholesterol to peripheral tissues<sup>[21]</sup>.

## CHOLESTEROL ELIMINATION

Free cholesterol is toxic and mammalian somatic cells cannot catabolize it; thus, the removal of excess intracellular cholesterol by a distinct regulatory system is crucial (Figure 3). Liver X receptors (LXRs) act as whole-body cholesterol sensors. Under physiological conditions, cholesterol pool expansion and high intracellular cholesterol levels raise the intracellular concentration of oxygenated cholesterol metabolites termed oxysterols, which are important intermediate or end products in cholesterol excretion pathways. Oxysterols trigger liver-specific LXR activation, generating a transcriptional response that results in net elimination of cholesterol from the body *via* mobilization of cholesterol from peripheral tissues and promotion of hepatic excretion<sup>[4]</sup>. Quantitatively, the most important oxygenation reactions are those involved in the early steps of converting cholesterol into bile acids, a metabolically strictly controlled process. Cholesterol 7 $\alpha$ -hydroxylase (CYP7A1) is the initial and rate-limiting enzyme of bile-acid synthesis<sup>[7,26]</sup>. CYP7A1 gene transcription is inhibited by the farnesoid X nuclear receptor, thereby producing negative feedback that reduces the bile acid synthesis from cholesterol. The farnesoid X receptor-agonist obeticholic acid is currently

under investigation for possible use in therapy for primary biliary cholangitis (PBC)<sup>[27]</sup>.

The most important target genes of LXRs include ABCG5/G8, NPC1L1, acetyl-CoA cholesterol acyltransferase 2 (ACAT-2), and ATP-binding cassette transporter sub-family member A 1 (ABCA1; also known as the cholesterol efflux regulatory protein)<sup>[4]</sup>. Activation of these genes can increase intestinal and hepatic cholesterol excretion (ABCG5/G8), reduce cholesterol absorption (NPC1L1), and reduce cholesterol storage (ACAT-2). ABCA1 is involved in reverse cholesterol transport, in which surplus free cholesterol from peripheral tissues is eliminated from the body *via* biliary excretion or through the non-biliary TICE pathway<sup>[4,5]</sup> (Figure 3).

HDL mediates the transfer of cholesterol from peripheral tissues to the liver. Nascent cholesterol-poor pre- $\beta$  HDL particles take up free cholesterol from peripheral tissues *via* ABCA1, after which this free cholesterol is esterified by lecithin-cholesterol acyltransferase. The esterified cholesterol is moved to the HDL particle's hydrophobic core, and progressive lipidation of the HDL particle causes it to mature, enlarge, and become more spherical. The cholesterol esters in mature HDL particles can be removed from circulation by hepatic scavenger receptor B1, or *via* transfer to apo B-100-containing lipoproteins (VLDL, IDL, and LDL) in a manner mediated by the cholesterol-ester transfer protein. By means of the LDL receptor and the LDL receptor-related protein, the liver can take up the apo B-100-containing lipoprotein particles from circulation<sup>[21]</sup>.

## DIFFICULTIES OF ASSESSING CHOLESTEROL METABOLISM IN CHOLESTASIS

Changes in cholesterol metabolism are not mirrored by routine serum cholesterol and lipoprotein measurements<sup>[28]</sup>. Moreover, the direct methods available to evaluate cholesterol metabolism are complex and laborious, and require labeling techniques, feces collection, and dietary recalls over several days.

In clinical research under steady state conditions, several non-cholesterol sterols that are measurable in serum can serve as valid biomarkers of cholesterol metabolism, especially when expressed as ratios to cholesterol<sup>[13,29-31]</sup>. Cholesterol precursor sterols, such as desmosterol and lathosterol, are markers of cholesterol synthesis<sup>[29]</sup>. On the other hand, diet-derived plant sterols (e.g., campesterol and sitosterol) and the liver-synthesized cholesterol metabolite cholestanol are markers of cholesterol absorption efficiency<sup>[30]</sup>. These markers have been investigated in PBC before and after LT<sup>[15,28,32-34]</sup>. Compared to that in healthy controls, intestinal cholesterol absorption is reportedly reduced by 2/3 in cases of prolonged severe intrahepatic cholestasis leading to cirrhosis and end-stage liver failure, as seen in PBC<sup>[35]</sup>. Cholestasis impairs the intestinal absorption of all types of sterols due to poor micellar formation secondary

**Figure 3 Cholesterol elimination- mechanisms and key transporters.** Expansion of the cholesterol pool activates liver X receptor, thereby generating transcriptional responses resulting in cholesterol excretion and catabolism. NPC1L1: Niemann-Pick C1 like 1; ABCA1: ATP-binding cassette transporter sub-family member A 1, also known as the cholesterol efflux regulatory protein; ACAT2: Acetyl-CoA acyltransferase 2; ABCG5: Adenosine triphosphate-binding cassette transporter G5 heterodimer; HDL: High density lipoprotein.

to reduced bile formation and excretion. However, striking increases of serum and hepatic plant sterol and cholestanol levels are also observed, indicating that the serum levels of plant sterols and cholestanol do not correctly mirror cholesterol absorption in cholestasis<sup>[15,28]</sup>. These changes can be used as biomarkers of the degree of cholestasis, with serum cholestanol/cholesterol being an even more sensitive marker of cholestasis among early-stage PBC patients than serum bilirubin<sup>[33]</sup>. Moreover, in end-stage cholestasis, serum cholestanol levels increase to levels that are otherwise only seen in the rare genetic disorder cerebrotendinous xanthomatosis<sup>[36]</sup>. This genetic disorder manifests with extremely high cholesterol deposits in tissues, including nerve tissues, resulting in severe neurologic symptoms<sup>[36]</sup>.

The liver is almost solely responsible for the secretion of sterols (*e.g.*, cholesterol, plant sterols, and cholestanol) from the human body *via* bile, which is regulated by hepatic proteins, including ABCG5/G8, NPC1L1, and LXRs<sup>[4-11]</sup>. ABCG5/G8 is active in cholesterol and sterol excretion across the canalicular membrane into bile. To our knowledge, no human studies have been performed to clarify how these sterol transporters function on the biliary canalicular level in intrahepatic cholestasis. Mutations in the genes of these transporters cause phytosterolemia, characterized by increased intestinal absorption and reduced biliary secretion of plant sterols, cholesterol, and cholestanol. Interestingly, Miettinen *et al.*<sup>[37]</sup> reported the case of a patient with phytosterolemia who presented with cholestatic liver disease necessitating LT. Following LT, the grossly elevated pre-transplant serum levels of plant sterols decreased to values only slightly above normal. This case highlights that the liver apparently plays a predominant role in maintaining sterol balance, since the intestinal ABCG5/G8 defect was not

altered by LT<sup>[37]</sup>.

## LIPOPROTEIN X

Despite reduced cholesterol synthesis, high serum total and LDL cholesterol concentrations and even xanthomata are common features in PBC and other forms of cholestatic liver disease<sup>[35,38-47]</sup>. In PBC, serum total cholesterol varies widely, ranging from 2.9 to 46.1 mmol/L (112-1779 mg/dL), and even up to 83 mmol/L (3204 mg/dL)<sup>[43]</sup>.

High serum LDL cholesterol concentration is associated with atherosclerosis. Apo B-100 is present in all liver-derived atherogenic lipoproteins-including VLDL, IDL, LDL, and lipoprotein (a). However, in chronic cholestasis, LDL cholesterol measured using standard hospital laboratory methods is frequently elevated due to abnormal lipoprotein X (Lp-X), which is distinct from apo B-100-containing lipoproteins. Lp-X is characterized by a vesicular structure comprising a 30- to 70-nm lipid bilayer enclosing an aqueous compartment. Lp-X possesses strikingly high contents of unesterified cholesterol and phospholipids; low contents of cholesterol esters and triglycerides; small amounts of albumin and apolipoproteins C, E, and A-1; and no or a low concentration of apo B-100. Lp-X and LDL have the same density and are thus indistinguishable by standard lipoprotein ultracentrifugation. On the other hand, the physical size of Lp-X is in the range of VLDL or larger. Routine clinical laboratory methods currently used to measure LDL cholesterol are markedly affected by the presence of Lp-X, leading to false interpretations of elevated LDL cholesterol levels. Nuclear magnetic resonance spectroscopy measurements of lipoproteins reveal that Lp-X exist in PBC patients more commonly than currently recognized<sup>[48]</sup>. This phenomenon explains

**Figure 4** Algorithm for assessing hyperlipidemia in the setting of chronic liver disease. LDL: Low density lipoprotein; ALP: Alkaline phosphatase.

why high LDL cholesterol concentrations within the context of PBC, when actually caused by Lp-X, show no association with atherosclerotic events<sup>[38-41]</sup>.

Lp-X formation is typically associated with a low apo B-100 concentration together with a high total cholesterol concentration<sup>[44]</sup>. The usual target level of apo B-100 is below 90 mg/dL, corresponding to a true LDL cholesterol concentration of below 3.0 mmol/L (116 mg/dL)<sup>[49-51]</sup>. The ratio of apo B-100 to total cholesterol is normally around 1:2, but may be 1:10 in cases of severe Lp-X formation<sup>[45]</sup>. Since an elevated apo B-100 concentration is a risk factor for atherosclerosis<sup>[49-51]</sup>, apo B-100 concentrations should be measured when considering lipid-lowering treatment in PBC and other cholestatic conditions (Figure 4). Even when LDL cholesterol levels are high, cholesterol-lowering medication is unnecessary in cases where apo B-100 is below 90 mg/dL, since this suggests prevalence of non-atherogenic Lp-X. Lp-X resolves after successful cholestasis treatment<sup>[52]</sup>.

Importantly, most statins are excreted into bile and, thus, cholestatic liver disease may lead to toxic levels of drug accumulation<sup>[41]</sup>. Furthermore, in Lp-X-related hypercholesterolemia, statin therapy does not effectively lower cholesterol levels because Lp-X does not undergo LDL receptor-mediated hepatic clearance<sup>[43,48]</sup>. Therefore, statins must be used cautiously in cholestatic conditions. Moreover, cholesterol absorption is low in severe cholestasis due to poor micellar formation, potentially diminishing the effect of ezetimibe, which lowers cholesterol levels by decreasing intestinal cholesterol absorption. In severe cholestasis, a lipid phenotype suggesting high cardiovascular risk necessitates accurate evaluation with consultation of a lipidologist. An additional caveat is that elevated Lp-X may affect various laboratory tests - for instance, potentially leading to pseudohyponatremia<sup>[45]</sup>. Although hypercholesterolemia is well-acknowledged in

PBC, Lp-X formation is often neglected<sup>[53]</sup>.

## CHOLESTEROL AND LIVER REGENERATION

An ample cholesterol supply is critical for liver regeneration and for hepatocyte, stellate cell, and Kupffer cell function<sup>[54]</sup>. The importance of a circulating cholesterol supply for liver regeneration is exemplified following liver resection, where declining serum cholesterol coincides with intrahepatic cholesterol accumulation. In parallel, a serum total cholesterol concentration of below 2.8 mmol/L (108 mg/dL) in decompensated liver cirrhosis is associated with reduced transplant-free survival<sup>[55]</sup>. Additionally, among patients with non-cholestatic cirrhosis who underwent LT, a recipient serum total cholesterol level of below 1.8 mmol/L (69 mg/dL) at LT was associated with reduced post-LT graft outcome, independent of relevant donor, graft, and pre-operative recipient variables<sup>[56]</sup>. Both recipient cholesterol levels and the expressions of cholesterol metabolism genes in the liver graft could conceivably influence liver graft cholesterol availability and graft regeneration<sup>[56]</sup>.

## DONOR-DERIVED HYPERCHOLESTEROLEMIA

The LDL receptor is critical in mediating the catabolism of cholesterol-enriched particles and is abundant in the liver, with hepatocytes expressing up to 70%-80% of all LDL receptors in humans<sup>[57]</sup>. Pathogenic mutations in the LDL receptor gene cause familial hypercholesterolemia (FH) characterized by markedly elevated serum total and LDL cholesterol levels, tendon xanthomas, and early atherosclerosis. LT presents an effective therapy for homozygous FH.

On the other hand, we recently reported a case in which an LDL receptor mutation was unintentionally transmitted from a donor to an LT recipient, causing severe hypercholesterolemia in the recipient<sup>[58]</sup>. Prior to LT, the patient had hepatic epithelioid hemangioendothelioma without cirrhosis or cholestasis and exhibited no dyslipidemia. Following LT, the recipient's lipid levels were similar to those observed in FH, but her genomic DNA was normal in this regard. DNA was extracted from biopsy specimens of the liver allograft, and subjected to sequencing of the LDL receptor coding region, revealing a heterozygous splicing mutation in intron 9 that was previously reported as an FH-associated pathogenic mutation<sup>[58]</sup>. This finding essentially represents a transgenic model, consistent with previous evidence suggesting that most LDL cholesterol uptake in the body occurs in the liver and is mediated by LDL receptors. Since heterozygous FH is not extremely rare (prevalence 1/200 to 1/500<sup>[59]</sup>), our report raises concern of LT recipients acquiring unidentified FH from LT donors, especially

since FH manifestations are extrahepatic and thus easily overseen during donor evaluation<sup>[60]</sup>.

## POST-TRANSPLANT FOLLOW-UP

Hyperlipidemia reportedly occurs in 40%-66% of patients following LT<sup>[61]</sup>. Many mechanisms contribute to post-LT hypercholesterolemia and hypertriglyceridemia, including genetic susceptibility, diet, obesity, metabolic syndrome, diabetes, cholestatic problems, and immunosuppressive medication. The immunosuppressive drug cyclosporine induces hypercholesterolemia by inhibiting sterol 27-hydroxylase, a key enzyme in the bile synthesis pathway. Corticosteroids are usually tapered in the early post-LT period, and thus have minimal long-term influence on serum lipids<sup>[61]</sup>. Post-transplant cholestasis is also relatively common, and often secondary to anastomotic or non-anastomotic biliary stricturing<sup>[62]</sup>. Prolonged cholestasis may lead to Lp-X formation, but very few post-LT cases are reported<sup>[52,63,64]</sup>.

Compared to the general population, LT recipients more commonly experience cardiovascular events, especially LT recipients with metabolic syndrome and/or diabetes<sup>[65]</sup>. The overall lipoprotein profile in LT recipients is generally proatherogenic, but variation exists<sup>[66]</sup>, warranting an individualized detailed assessment of cardiovascular risk. Hepatic steatosis is considered a manifestation of metabolic syndrome and/or diabetes and is associated with a proatherogenic profile. Importantly, liver graft steatosis is increasingly detected. Thus, lipid profile assessment should include apo B-100 quantification in addition to the routine measurements of total, LDL, and HDL cholesterol, and total triglycerides. It is assumed that reducing intrahepatic lipids reduces the risks of hepatic and cardiovascular complications. Recent data suggest that treatment with a combination of dietary intervention, weight loss, and ezetimibe (which is well tolerated and can be combined with a statin) can reduce LDL cholesterol and apo B-100 concentrations in these patients<sup>[22,67-70]</sup>.

## CONCLUSION

Various liver disorders, particularly cholestasis, affect cholesterol metabolism and can cause variable hypercholesterolemia, including Lp-X appearance. Mistaking Lp-X for LDL cholesterol may interfere with cardiovascular risk assessment, leading to the prescription of futile lipid-lowering therapy. Lipid panel assessment should be regularly performed in all LT recipients, and at LT evaluation. Apo B-100 measurement can help in distinguishing between atherogenic and non-atherogenic hypercholesterolemia. Therefore, the measurement of apo B-100 can help in evaluating overall cardiovascular risk, as well as the effects of therapy during follow-up. This is particularly important after LT, when cholestasis and Lp-X may coexist with true atherogenic hypercholesterolemia and increased cardiovascular risk.

## ACKNOWLEDGMENTS

I recently changed my name from Katriina Nikkilä to Katriina Nemes. My previous publication history has been released by using the name Katriina Nikkilä (e.g., Nikkilä K) partly shown also in the actual references.

## Abstract

**AIM:** To examine the effects of the endothelin type A receptor antagonist ambrisentan on hepatic steatosis and fibrosis in a steatohepatitis mouse model.

**METHODS:** Fatty liver shionogi (FLS) FLS-*ob/ob* mice (male, 12 wk old) received ambrisentan (2.5 mg/kg orally per day;  $n = 8$ ) or water as a control ( $n = 5$ ) for 4 wk. Factors were compared between the two groups, including steatosis, fibrosis, inflammation, and endothelin-related gene expression in the liver.

**RESULTS:** In the ambrisentan group, hepatic hydroxyproline content was significantly lower than in the control group ( $18.0 \mu\text{g/g} \pm 6.1 \mu\text{g/g}$  vs  $33.9 \mu\text{g/g} \pm 13.5 \mu\text{g/g}$  liver, respectively,  $P = 0.014$ ). Hepatic fibrosis estimated by Sirius red staining and areas positive

for  $\alpha$ -smooth muscle actin, indicative of activated hepatic stellate cells, were also significantly lower in the ambrisentan group ( $0.46\% \pm 0.18\%$  vs  $1.11\% \pm 0.28\%$ , respectively,  $P = 0.0003$ ; and  $0.12\% \pm 0.08\%$  vs  $0.25\% \pm 0.11\%$ , respectively,  $P = 0.047$ ). Moreover, hepatic RNA expression levels of procollagen-1 and tissue inhibitor of metalloproteinase-1 (TIMP-1) were significantly lower by 60% and 45%, respectively, in the ambrisentan group. Inflammation, steatosis, and endothelin-related mRNA expression in the liver were not significantly different between the groups.

**CONCLUSION:** Ambrisentan attenuated the progression of hepatic fibrosis by inhibiting hepatic stellate cell activation and reducing procollagen-1 and *TIMP-1* gene expression. Ambrisentan did not affect inflammation or steatosis.

**Key words:** Endothelin; Ambrisentan; Steatohepatitis; Hepatic stellate cell; Hepatic fibrosis; Oxidative stress; Hepatic hydroxyproline

**Core tip:** Endothelin (ET) can activate hepatic stellate cells, leading to the progression of hepatic fibrosis. Furthermore, ET-1 may increase the inflow of free fatty acids from the fat tissue into the liver and exacerbate hepatic steatosis. Therefore, ET-1 antagonism may be a novel target for steatohepatitis. The present study showed that ambrisentan, an ET type A receptor antagonist, attenuated hepatic fibrosis by inhibiting hepatic stellate cell activation, without affecting hepatic steatosis, in a non-alcoholic steatohepatitis mouse model.

## INTRODUCTION

Non-alcoholic steatohepatitis (NASH) is characterized by hepatic fat deposition, inflammation, and differing degrees of fibrosis<sup>[1]</sup>. In the pathophysiology of NASH, the deposition of fat in liver cells, which occurs in association with obesity and insulin resistance, is a benign process in most patients but is followed by inflammation and fibrosis in the liver in response to multiple insults, such as oxidative stress and various adipokines or cytokines acting in parallel<sup>[2]</sup>. In NASH, the serum endothelin-1 (ET-1) level is elevated and is correlated with hepatic fibrosis severity<sup>[3]</sup>. The development of hepatic fibrosis is mediated to a large extent by the activation of hepatic

stellate cells (HSCs). ET-1 is released from sinusoidal endothelial cells and HSCs, which serves to activate the HSCs and accelerate collagen fiber synthesis in them<sup>[4]</sup>. Furthermore, ET-1 acts as a mediator and is elevated in conditions such as insulin resistance, hyperglycemia, oxidative stress, and endothelial cell dysfunction<sup>[5,6]</sup>. ET-1 also increases vascular superoxide production and promotes cell proliferation by inducing reactive oxygen species<sup>[7]</sup>.

Ambrisentan is a selective ET type A receptor (ETAR) antagonist approved for the treatment of patients with pulmonary arterial hypertension<sup>[8]</sup>. ETAR antagonists improve liver fibrosis in cirrhotic rats<sup>[9]</sup>, but their effects on NASH are unknown. Fatty liver shionogi (FLS)-*ob/ob* mice are characterized by hyperphagia, obesity, hyperlipidemia, and diabetes mellitus<sup>[10]</sup>. As described in our previous study using these mice<sup>[11]</sup>, FLS-*ob/ob* mice are generated by transferring the *Lep<sup>ob</sup>* gene into the FLS mouse genome, causing FLS mice to spontaneously develop chronic hepatic steatosis but not obesity. The resultant FLS-*ob/ob* mice show severe steatosis, hepatocellular ballooning, and advanced hepatic fibrosis histologically. They also display increased oxidative stress, elevated production of inflammatory and profibrotic cytokines, and increased apoptosis of hepatocytes, and eventually develop cirrhosis and liver tumors<sup>[12,13]</sup>. For these reasons, FLS-*ob/ob* are considered to be animal model the most closely represents human metabolic syndrome-related NASH. Against this background, this study investigated the therapeutic effects of ambrisentan on hepatic steatosis and fibrosis in NASH using FLS-*ob/ob* male mice.

## MATERIALS AND METHODS

### Animals

A total of 13 male FLS-*ob/ob* mice (age, 8 wk; body weight,  $42.88 \pm 1.74$  g) were obtained from Shionogi Research Laboratories (Shiga, Japan) and housed in a controlled environment ( $24^\circ\text{C} \pm 2^\circ\text{C}$ ; 12:12-h light:Dark cycle). Mice were provided *ad libitum* water and a standard powdered diet (CE-2, 4.6% fat; CLEA Japan, Tokyo, Japan). To maintain dietary intake in both groups at an equal level, food consumption and body weight were monitored throughout observation. All experiments were performed in accordance with the Animal Experimentation Guidelines of Tottori University (Yonago, Japan). The study was reviewed and approved by the ethics committee of Tottori University. All procedures involving animals were reviewed and approved by the Institutional Animal Care and Use Committee of Tottori University (approval number, 14-Y-8) and the animal protocol was designed to minimize pain and discomfort to the animals.

### Administration of ambrisentan

At the age of 12 wk, male FLS-*ob/ob* mice were randomly assigned to the ambrisentan ( $n = 8$ ) or control ( $n = 5$ ) group. Intragastric gavage administration was carried out in conscious animals with an appropriately

sized gastric tube. Ambrisentan (2.5 mg/kg per day; ADooQ BioScience, Irvine, CA) was orally administered every afternoon for 4 wk as a bolus through a gastric tube. Water was administered to the control group. At week 4, animals were fasted for 4 h and tail vein blood was drawn and subjected to blood glucose determination. Animals were killed by pentobarbital anesthesia injection (Dainippon Sumitomo Pharma, Osaka, Japan) after 4 wk and blood was collected from the right ventricle. Plasma samples were frozen and stored at -80 °C. Liver and visceral fat were then weighed, snap-frozen in liquid nitrogen, and stored at -80 °C. Additional liver specimens were fixed in 10% buffered formalin (Wako Pure Chemical Industries, Ltd., Osaka, Japan) and embedded in paraffin (Wako Pure Chemical Industries, Ltd.) for histological analysis.

#### **Analysis of hepatic cholesterol and triglycerides**

Snap-frozen liver samples (50 mg) were homogenized and extracted using chloroform-methanol (2:1 v/v; Wako Pure Chemical Industries, Ltd.). The organic phase was then dried and resuspended in 2-propanol containing 10% Triton X-100. Total cholesterol and triglyceride contents were measured with the Cholesterol E-test (Wako Pure Chemical Industries, Ltd.) and Triglyceride E-test (Wako Pure Chemical Industries, Ltd.), respectively.

#### **Biochemical analysis**

Blood samples were immediately separated by centrifugation at 2000 *g* for 15 min at 4 °C and stored at -80 °C until further use. Serum samples were analyzed to determine the levels of aspartate aminotransferase (AST) and alanine aminotransferase (ALT).

#### **Measurement of hepatic hydroxyproline content**

Hepatic tissue (400 mg wet weight) was hydrolyzed in 4 mL of 6 mol/L HCl at 105 °C overnight. The hydrolysate was then thoroughly evaporated under vacuum. The sediment was resuspended in distilled water, decolorized with activated charcoal, and filtered; the filtrate was then acidified to pH 5.0 and evaporated under vacuum. The sediment was resuspended in distilled water, mixed with 2 mL of isopropanol, and then incubated with 1 mL of 7% chloramine-T for 5 min at room temperature. After addition of Ehrlich's solution (2 mL; 1.76 g p-dimethylaminobenzaldehyde dissolved in 4.08 mL 60% perchloric acid and 95.5 mL of isopropanol), the mixture was incubated at 60 °C for 10 min. The absorbance of the cooled mixture was measured at 562 nm.

#### **Measurement of hepatic fibrosis area**

As in our previous study<sup>[11]</sup>, formalin-fixed, paraffin-embedded liver sections (4- $\mu$ m-thick) were stained with picrosirius red (Chroma-Gesellschaft Schmid GmbH and Co., Munster, Germany) and counterstained with fast green (Chroma-Gesellschaft Schmid GmbH and Co.). The areas of hepatic fibrosis were subsequently measured in 10 randomly selected fields in each specimen (magnification,  $\times$  400) using WinROOF ver.5.71 software and the Olympus BX51N-34 microscope.

fication,  $\times$  400) using WinROOF ver.5.71 software and the Olympus BX51N-34 microscope.

#### **Measurement of hepatic steatosis area**

Following the staining of neutral lipids in frozen-fixed, cryostat-embedded liver sections (4-mm-thick) with oil red O (Sigma-Aldrich, St. Louis, MO), areas of hepatic steatosis were measured using WinROOF version 5.71 software (Mitani Corporation, Tokyo, Japan) in 10 randomly selected fields (magnification,  $\times$  400; Olympus BX51N-34; Olympus Corporation, Tokyo, Japan) per specimen<sup>[11]</sup>.

#### **Immunostaining for $\alpha$ -smooth muscle actin**

Immunostaining for  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA) was used for the detection and counting of activated HSCs. As described previously<sup>[11]</sup>,  $\alpha$ -SMA was detected by staining with mouse monoclonal anti- $\alpha$ -SMA antibody (cat. No. MS-113-R7; Thermo Fisher Scientific, Fremont, CA) without dilution. Goat anti-mouse Ig from the Histofine Mouse Stain kit (cat. No. 414322; Nichirei Biosciences, Inc., Tokyo, Japan) was used without dilution as the secondary antibody. HSCs activation was assessed by using WinROOF ver.5.71 software to measure the areas of  $\alpha$ -SMA staining in 10 randomly selected fields (magnification  $\times$  400; Olympus BX51N-34) per specimen.

#### **Analysis of inflammatory cell infiltration of hepatic tissue**

F4/80, a mature mouse cell surface glycoprotein expressed at high levels on Kupffer cells, was immunohistochemically stained using a rat monoclonal anti-mouse F4/80 antibody (cat. No. ab6640; Abcam, Tokyo, Japan) diluted to 1:100 with 0.01 mol/L PBS according to the manufacturer's instructions. Goat anti-rat secondary antibody from the Histofine Simple Stain Mouse MAX-PO (Rat) kit (cat. No. 414311; Nichirei Biosciences, Inc.) was used without dilution. Immunopositive cells were analyzed in 10 intralobular ocular fields (magnification,  $\times$  400; Olympus BX41N-34) per specimen<sup>[11]</sup>.

#### **Analysis of oxidative stress**

Immunohistochemical staining for 8-hydroxy-2-deoxyguanosine (8-OHdG), a marker of oxidative DNA damage, was used to assess oxidative stress<sup>[11]</sup>. A monoclonal mouse anti-8-OHdG antibody (cat. No. MOG-020P; Nikken SEIL, Shizuoka, Japan) diluted in 200  $\mu$ L distilled water was used, following the manufacturer's instructions. Goat anti-mouse Ig from the Histofine Mouse Stain kit served as the secondary antibody without dilution. WinROOF ver.5.71 software was used to analyze immunopositive cells using 10 intralobular ocular fields (magnification  $\times$  400; Olympus BX41N-34) per specimen, and values are expressed as the ratios (%) of fields. Also, 4-hydroxynonenal (4-HNE) was semi-quantified *via* immunohistochemical staining using a monoclonal mouse anti-4-HNE antibody (cat. no. MHN-020P; Nikken SEIL) diluted in 200  $\mu$ L distilled water following the

manufacturer's instructions. Goat anti-mouse Ig from the Histofine Mouse Stain kit was used as the secondary antibody without dilution. Ten randomly selected fields (magnification,  $\times 400$ ) in each 4-HNE-stained specimen were classified into immunopositive grades 1, 2, 3 and 4 (0%-10%, 11%-20%, 21%-30%, and  $> 30\%$ , respectively) and the mean values of 10 fields were calculated.

#### RNA extraction and reverse transcription-PCR analysis

As described previously<sup>[11]</sup>, total RNA was extracted from homogenized hepatic tissue samples using the RNeasy Lipid Tissue Mini kit (Qiagen, Hilden, Germany). Absorbance at 260 nm was measured using a NanoDrop 1000 spectrophotometer (Thermo Fisher Scientific), to determine RNA concentrations and RNA quality was confirmed by electrophoresis on ethidium bromide-stained 1% agarose gels. Total RNA (2  $\mu\text{g}$ ) was reverse transcribed in a final volume of 11.5  $\mu\text{L}$  containing 4  $\mu\text{L}$  of 5  $\times$  standard buffer, 2  $\mu\text{L}$  of 0.1 mol/L dithiothreitol, 1  $\mu\text{L}$  of SuperScript II RNase H reverse transcriptase (Invitrogen Life Technologies, Carlsbad, CA), 2  $\mu\text{L}$  of 10 mol/L MdNTP (Promega, Madison, WI), 1  $\mu\text{L}$  of 50 pmol/ $\mu\text{L}$  Random Primer (Promega), 0.5  $\mu\text{L}$  of 100 pmol/ $\mu\text{L}$  Oligo (dT)15 Primer (Promega), and 1  $\mu\text{L}$  of 40 U/ $\mu\text{L}$  ribonuclease inhibitor (Wako Pure Chemical Industries, Ltd.). Mixtures were incubated at 37  $^{\circ}\text{C}$  for 60 min and 95  $^{\circ}\text{C}$  for 5 min, and were then cooled to 4  $^{\circ}\text{C}$  for 5 min using a MyCycler Thermal Cycler (Bio-Rad Laboratories, Inc., Hercules, CA).

#### Real-time PCR

Quantitative real-time PCR assays (7900HT Fast Real-time PCR system; Applied Biosystems, Carlsbad, CA) proceeded as described previously<sup>[11]</sup>. The assays were used a final volume of 10  $\mu\text{L}$  containing 250 nmol/L Universal ProbeLibrary probe (Roche, Basel, Switzerland), 900 nmol/L forward primer, 900 nmol/L reverse primer, 5  $\mu\text{L}$  EXPRESS qPCR Supermix with Premixed Rox (Invitrogen), and 2  $\mu\text{L}$  cDNA. mRNA level of transforming growth factor- $\beta 1$  (TGF- $\beta 1$ ; GenBank: NM\_011577), procollagen-type I (GenBank: U08020), connective tissue growth factor (CTGF; GenBank: NM\_010217), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ; GenBank: NM\_013693), monocyte chemoattractant protein-1 (MCP-1; GenBank: NM\_100127112), tissue inhibitor of metalloproteinases-1 (TIMP-1; GenBank: NM\_011593), peroxisome proliferator-activated receptor (PPAR- $\alpha$ ; GenBank: NM\_007988.3), sterol regulatory element-binding protein 1c (SREBP1c; GenBank: NM\_011480), microsomal triglyceride transfer protein (MTP; GenBank: NM\_008642), endothelin-1 (ET-1; GenBank: NM\_010204), endothelin-converting enzyme (ECE; GenBank: NM\_199307), endothelin-1 type A receptor (ET-1A; GenBank: NM\_010332), and endothelin-1 type B receptor (ET-1B; GenBank: U32329) were assessed using the 7900HT Fast Real-Time PCR System with SDS2.3 software (Applied Biosystems) and with  $\beta$ -actin (GenBank: NM\_007393) as an internal standard.

Thermal cycle conditions were 95  $^{\circ}\text{C}$  for 20 s, followed by 45 cycles of 1 s at 95  $^{\circ}\text{C}$  and 20 s at 60  $^{\circ}\text{C}$ . The relative mRNA expression levels were calculated using the  $2^{-\Delta\Delta\text{CT}}$  method.

#### Statistical analysis

Differences between groups were statistically analyzed using unpaired Student's *t*-tests. All statistical analysis was performed using StatFlex ver.6.0 for Windows software (Artech Co. Ltd., Osaka, Japan). All data are expressed as means  $\pm$  SD, with *P* values less than 0.05 considered to indicate significant differences.

## RESULTS

#### Characteristics of FLS-ob/ob mice

As shown in Table 1, the two groups of mice did not differ in terms of food consumption, bodyweight, liver weight, liver-to-bodyweight ratio, visceral fat weight, or levels of serum AST and ALT. There was no difference in hepatic histology with hematoxylin-eosin staining between the two groups (Figure 1A and B).

#### Effects of ambrisentan on hepatic steatosis

To assess the effects of ambrisentan on lipid metabolism, we determined the hepatic steatosis area, hepatic lipid contents, and gene expression of hepatic lipogenesis, lipolysis, and lipid transporter genes. Oil red O staining showed no differences in area of hepatic steatosis between the groups (ambrisentan vs control; 15.0%  $\pm$  6.0% vs 17.0%  $\pm$  7.7%; *P* = 0.614; Figure 1C-E). Steatosis-related mRNA expression levels (PPAR- $\alpha$ , SREBP-1c, FAS, and MTP) were not different between the two groups (Table 2). Hepatic total cholesterol and triglyceride contents also revealed no differences between the two groups (Table 1). These findings suggested that ambrisentan did not affect lipid metabolism and accumulation in the liver of FLS-ob/ob mice.

#### Effects of ambrisentan on hepatic fibrosis

To assess whether ambrisentan attenuated hepatic fibrosis, we determined the antifibrotic effects of ambrisentan in the FLS-ob/ob mice. Sirius red staining showed that the area of fibrosis was decreased by ambrisentan compared with the control (0.46%  $\pm$  0.18% vs 1.11%  $\pm$  0.28%, respectively, *P* = 0.0003; Figure 1F-H). Hepatic hydroxyproline (Hyp) content was significantly reduced by ambrisentan compared with the control (18.0  $\mu\text{g/g}$   $\pm$  6.1  $\mu\text{g/g}$  liver vs 33.9  $\mu\text{g/g}$   $\pm$  13.5  $\mu\text{g/g}$  liver, respectively, *P* = 0.014; Figure 1I). Moreover, the area of positive  $\alpha$ -SMA immunostaining was significantly reduced by ambrisentan (0.12%  $\pm$  0.08% vs 0.25%  $\pm$  0.11%, respectively *P* = 0.047; Figure 1J-M).

In relation to extracellular matrix metabolism in the liver, as shown in Table 2, ambrisentan reduced the mRNA expression levels of procollagen-1 by 60% and TIMP-1 by 45% but the mRNA expression of TGF- $\beta 1$  and CTGF did not differ between the two groups.

**Table 1** Effects of ambrisentan administration on various parameters in fatty liver shionogi-*ob/ob* mice

Parameters	Control group ( <i>n</i> = 5)	Ambrisentan group ( <i>n</i> = 8)	<i>P</i> value
Body weight (g)	47.3 ± 3.6	47.0 ± 4.6	0.27
Liver weight (g)	5.4 ± 1.2	5.1 ± 1.1	0.75
Liver/body weight ratio	0.11 ± 0.02	0.11 ± 0.01	0.68
Visceral fat weight (g)	2.5 ± 0.3	2.7 ± 0.3	0.32
Weekly dietary intake (g)	31.7 ± 9.3	29.4 ± 9.0	0.66
Serum AST (U/L)	143 ± 20	155 ± 43	0.59
Serum ALT (U/L)	120 ± 52	151 ± 65	0.38
Hepatic cholesterol (mg/dL)	24.5 ± 1.56	27.2 ± 2.58	0.06
Hepatic triglyceride (mg/dL)	1152 ± 500	929 ± 210	0.28

AST: Aspartate aminotransferase; ALT: Alanine aminotransferase.

### Effects of ambrisentan on the inflammatory reaction in the liver

The process of hepatic fibrosis is driven primarily by inflammation in response to liver damage. There were fewer F4/80-positive cells in the ambrisentan group than in the control group, but not significantly so ( $6.5 \pm 3.9$  vs  $15.2 \pm 11.5$ , respectively,  $P = 0.055$ ; Figure 2A-C). Levels of inflammation-related mRNA (TNF- $\alpha$  and MCP-1) did not differ between the two groups (Table 2).

### Effects of ambrisentan on oxidative stress

Oxidative stress is involved in the development of NASH. We determined oxidative stress by two methods: 8-OHdG as an index of DNA damage and 4-HNE as an index of lipid peroxidation. Ambrisentan did not affect the ratio of 8-OHdG-positive cells in the liver compared with the control ( $73.8\% \pm 12.4\%$  vs  $78.2\% \pm 11.5\%$ , respectively,  $P = 0.538$ ; Figure 2D-F) and did not alter the immunostaining grade for liver 4-HNE ( $2.36 \pm 0.37$  vs  $2.35 \pm 0.41$ , respectively,  $P = 0.958$ ; Figure 2G-I).

### Effects of ambrisentan on ET-related mRNA in the liver

Finally, we measured ET-related gene expression in FLS-*ob/ob* mice. The levels of ET-related mRNAs (ET-1, ECE, ETAR, and ETBR) were not different between the two groups (Table 2).

## DISCUSSION

This study had two important findings. First, ambrisentan did not affect lipid metabolism. Second, it significantly attenuated the progression of hepatic fibrosis. Thus, ET-1 antagonism reduced hepatic fibrosis without improving hepatic steatosis. Ambrisentan did not reduce body weight, blood glucose levels, or hepatic steatosis compared with the control group. ET-1 is reported to increase lipolysis in human and bovine adipocytes<sup>[14]</sup>. Therefore, ET-1 may increase the inflow of free fatty acids from the fat tissue into the liver and exacerbate hepatic steatosis. ET-1 reduced the cholesterol efflux in macrophages, resulting in exacerbation of lipid accumulation in macrophages<sup>[15]</sup>. However, the present study showed that ambrisentan did not affect lipid accumulation

**Table 2** Hepatic mRNA expression levels of various genes in the control and ambrisentan groups

mRNA	Control group ( <i>n</i> = 5)	Ambrisentan group ( <i>n</i> = 8)	<i>P</i> value
Procollagen-1	1.76 ± 0.58	1.06 ± 0.43	0.024
TGF- $\beta$ 1	1.60 ± 0.80	1.14 ± 0.17	0.13
CTGF	1.43 ± 0.49	1.52 ± 0.40	0.36
TIMP-1	2.98 ± 1.58	1.34 ± 0.61	0.02
TNF- $\alpha$	2.37 ± 2.65	2.37 ± 3.02	1
MCP-1	10.20 ± 10.06	8.14 ± 8.90	0.39
SREBP1c	0.69 ± 0.19	0.80 ± 0.17	0.29
FAS	0.76 ± 0.34	0.87 ± 0.46	0.67
PPAR- $\alpha$	0.81 ± 0.16	0.98 ± 0.27	0.24
MTP	0.95 ± 0.09	0.99 ± 0.09	0.45
ET-1	1.40 ± 0.57	1.47 ± 0.50	0.82
ECE	1.02 ± 0.13	1.23 ± 0.23	0.09
ETAR	3.74 ± 3.35	2.55 ± 1.56	0.4
ETBR	2.07 ± 0.76	1.87 ± 0.49	0.59

TGF: Transforming growth factor; CTGF: Connective tissue growth factor; TIMP: Tissue inhibitor of metalloproteinase; TNF: Tumor necrosis factor; MCP: Monocyte chemoattractant protein; SREBP: Sterol regulatory element-binding protein; FAS: Fatty acid synthase; PPAR: Peroxisome proliferator-activated receptor; MTP: Microsomal triglyceride transfer protein; ET: Endothelin; ECE: Endothelin-converting enzyme; ETAR: Endothelin type A receptor; ETBR: Endothelin type B receptor.

in hepatocytes or the contents of hepatic cholesterol and triglyceride. Furthermore, the expression levels of lipid metabolism-related genes such as SREBP-1c and FAS, which are involved in hepatic lipogenesis<sup>[16]</sup>, PPAR- $\alpha$ , which is involved in  $\beta$ -oxidation of fatty acids, and MTP, which transports triglyceride to very low-density lipoprotein-were not affected by ambrisentan. From these findings, our *in vivo* experiments using FLS-*ob/ob* mice indicated that ETAR antagonism was not involved in hepatic lipid metabolism. Hyperleptinemia is reported to regulate the sensitivity of ET-1 for steatosis in NASH cirrhotic rats<sup>[16]</sup>. Because the FLS-*ob/ob* mice used in our study are leptin deficient<sup>[12]</sup>, FLS-*ob/ob* mice may have low sensitivity for ET-1 in steatosis, and ET-1 may be less involved in hepatic steatosis in these mice.

Second, we investigated the effect of ambrisentan on hepatic fibrosis. The present study showed that ETAR antagonism reduced the hepatic Hyp content and the area of hepatic fibrosis through the inhibition of HSC activation. Several studies have implicated ET-1 in fibrogenesis of the kidney, cardiovascular system, and liver<sup>[2,9,17,18]</sup>. HSCs express ETAR and ET type B receptors. ET-1 is secreted from HSCs and acts in HSCs and other cells in an autocrine and paracrine manner. Our previous *in vitro* experiments showed that ET-1 increased fibrogenic gene expression *via* ETAR<sup>[17]</sup>. Furthermore, Cho *et al.*<sup>[19]</sup> reported that an oral ETAR antagonist attenuated collagen synthesis in rat liver fibrosis due to cholestasis. The present study confirmed that the ETAR antagonist also inhibited hepatic fibrosis in a mouse NASH model. HSCs are activated by several factors and stimulants and produce extracellular matrix proteins. Rocky *et al.*<sup>[9]</sup> and Pinzani *et al.*<sup>[20]</sup> showed that ET-1 increased DNA synthesis and cell growth *via* ETAR in cultured HSCs.

## Hematoxylin-eosin staining

## Oil red O staining

## Sirius red staining

 $\alpha$ -SMA staining

**Figure 1** Histological analyses of liver tissues. Representative images of hematoxylin-eosin staining (magnification,  $\times 100$ ) in the (A) control and (B) ambrisentan groups; representative images of oil red O staining (magnification,  $\times 100$ ) in the (C) control and (D) ambrisentan groups; E: The proportion (%) of the hepatic steatosis area stained with oil red O was measured using image analysis. Hepatic fibrosis was determined by Sirius red staining. Representative images of Sirius red staining (magnification,  $\times 400$ ) of the (F) control and (G) ambrisentan groups; the proportion (%) of the hepatic fibrosis area stained with Sirius red was measured using image analysis ( $P < 0.01$ ); H: The area of fibrosis was significantly decreased in the ambrisentan group compared with the control group; I: Comparison of hepatic hydroxyproline content between groups; representative images of  $\alpha$ -SMA immunostaining (magnification,  $\times 400$ ) in the (J) control and (K) ambrisentan groups; L: Shows a higher magnification ( $\times 1000$ ) of an  $\alpha$ -SMA-positive cell (arrow); M: Quantitation of an area of  $\alpha$ -SMA immunostaining measured by image analysis ( $P < 0.05$ ). The area of  $\alpha$ -SMA immunostaining was significantly reduced in the ambrisentan group compared with the control.  $\alpha$ -SMA:  $\alpha$ -smooth muscle actin.

## F4/80 staining

## 8-OHdG staining

## 4-HNE immunostaining

**Figure 2 F4/80 immunostaining.** Representative images of F4/80 immunostaining (magnification,  $\times 400$ ) of Kupffer cells in the (A) control and (B) ambrisentan groups; C: Numbers of immunopositive F4/80 cells (arrows) in both groups; representative immunostaining for 8-OHdG (magnification,  $\times 400$ ) in the (D) control and (E) ambrisentan groups; F: Comparison of 8-OHdG-immunopositive cells between the groups; immunostaining for 4-HNE (magnification,  $\times 400$ ) in the (G) control and (H) ambrisentan groups; I: Comparison of 4-HNE-immunopositive cells between the groups. 4-HNE: 4-hydroxynonenal.

Our study showed that ETAR antagonism reduced HSC activation. Therefore, in the NASH model, ET-1 is involved in the activation of HSCs *via* ETAR. HSCs are activated by cytokines, oxidative stress, and inflammation. However, ambrisentan did not affect oxidative stress, as assessed by 8-OHdG and 4-HNE, or the inflammatory reaction, as assessed by *TNF- $\alpha$*  and *MCP-1* gene expression or F4/80-positive cells. Therefore, ET-1 may directly activate HSCs.

ET-1 stimulates extracellular matrix protein production by HSCs. In an HSC culture study, ET-1 increased the production of procollagen-1 and TGF- $\beta$ 1 *via* ETAR<sup>[17]</sup>. However, although the present study indicated that ETAR antagonism attenuated the gene expression of procollagen-1, it did not influence the gene expression of

TGF- $\beta$ 1 and CTGF, which is downstream of TGF- $\beta$ 1. This discrepancy may be attributable to the model of liver injury. A previous report<sup>[9]</sup> showed that ET antagonism reduced TGF- $\beta$ 1 mRNA levels in the carbon tetrachloride model, but its levels were not altered in cholestatic-induced liver injury. Such data showed that the effects of ET-1 antagonism in TGF- $\beta$ 1 may depend on the liver injury model. Therefore, ET-1 might not play a major role in TGF- $\beta$ 1 expression in mild liver injury models such as cholestasis or steatohepatitis.

The present study showed that ETAR antagonism reduced TIMP-1 gene expression. TIMP-1 is a high-affinity inhibitor of many matrix metalloproteinases and suppresses matrix degradation, resulting in the progression of liver

fibrosis. ET-1 is reported to increase TIMP-1 mRNA in fibroblasts<sup>[21]</sup>. In our study, ETAR antagonism attenuated TIMP-1 expression and might improve hepatic fibrosis by increasing fibrolysis. From these results, it appears that ambrisentan improved hepatic fibrosis by inhibiting HSC activation and suppressing procollagen-1 and *TIMP-1* gene expression.

The present study has some limitations. First, it involved a small number of mice and a relatively short duration of ambrisentan treatment. We included only 8 ambrisentan-treated mice and 5 controls and the study duration was only 4 wk. Therefore, examination of a larger number of mice and a longer administration period is required to validate these results. Second, our experiments did not include non-NASH mice arms because we could not obtain DS mice, the original wild-type of FLS-*ob/ob* mice. Therefore, further study is needed using another NASH mouse model.

In conclusion, ambrisentan attenuated the progression of hepatic fibrosis by suppressing the activation of HSCs and reducing procollagen-1 and TIMP-1 expression.

## COMMENTS

### Background

In non-alcoholic steatohepatitis (NASH), the serum endothelin-1 (ET-1) level is elevated and is correlated with hepatic fibrosis severity. The development of hepatic fibrosis is mediated to a large extent by the activation of hepatic stellate cells (HSCs). ET-1 serves to activate the HSCs and accelerates collagen fiber synthesis in them. Furthermore, ET-1 acts as a mediator and is elevated in conditions such as insulin resistance, hyperglycemia, oxidative stress, and endothelial cell dysfunction.

### Research frontiers

Ambrisentan, a selective ET type A receptor (ETAR) antagonist improves liver fibrosis in cirrhotic rats, but their effects on NASH are unknown. ET-1 may become a novel target for the treatment of NASH.

### Applications

The present study has shown ambrisentan improved hepatic fibrosis by inhibiting HSC activation and suppressing procollagen-1 and tissue inhibitor of metalloproteinase-1 (*TIMP-1*) gene expression, but did not affect hepatic steatosis. The combination therapy of ambrisentan with other drugs for lipid accumulation may be more effective for NASH.

### Terminology

NASH: Nonalcoholic steatohepatitis is characterized by hepatic fat deposition, inflammation, and differing degrees of fibrosis.

### Peer-review

This is an interesting study. The authors report that "ambrisentan" attenuates the progression of hepatic fibrosis by inhibiting the activation of HSCs and reducing procollagen-1 and *TIMP-1* gene expression. According to them it did not affect inflammation and steatosis. No doubt these results are interesting.

### Abstract

**AIM:** To assess the impact of model for end-stage liver disease (MELD) score on patient survival and morbidity post living donor liver transplantation (LDLT).

**METHODS:** A retrospective study was performed on 80 adult patients who had LDLT from 2011-2013. Nine patients were excluded and 71 patients were divided into two groups; Group 1 included 38 patients with a MELD score < 20, and Group 2 included 33 patients with a MELD score > 20. Comparison between both groups was done regarding operative time, intra-operative blood requirement, intensive care unit (ICU) and hospital stay, infection, and patient survival.

**RESULTS:** Eleven patients died (15.5%); 3/38 (7.9%)

patients in Group 1 and 8/33 (24.2%) in Group 2 with significant difference ( $P = 0.02$ ). Mean operative time, duration of hospital stay, and ICU stay were similar in both groups. Mean volume of blood transfusion and cell saver re-transfusion were  $8 \pm 4$  units and  $1668 \pm 202$  mL, respectively, in Group 1 in comparison to  $10 \pm 6$  units and  $1910 \pm 679$  mL, respectively, in Group 2 with no significant difference ( $P = 0.09$  and  $0.167$ , respectively). The rates of infection and systemic complications (renal, respiratory, cardiovascular and neurological complications) were similar in both groups.

**CONCLUSION:** A MELD score  $> 20$  may predict mortality after LDLT.

**Key words:** Living donor liver transplantation; Model for end-stage liver disease score; Morbidity; Mortality; Infection

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** We assessed the impact of model for end-stage liver disease (MELD) score on patient survival and morbidity after living donor liver transplantation (LDLT). A total of 71 patients were included and divided into two groups: Group 1 had 38 patients with a MELD score  $< 20$  and Group 2 had 33 patients with a MELD score  $> 20$ . We compared between both groups regarding operative time, intra-operative blood requirement, duration of intensive care unit and hospital stay, infection, and patient survival. We found that a MELD score  $> 20$  could predict mortality after LDLT.

Living donor liver transplantation for high model for end-stage liver disease score: What have we learned? *World J Hepatol* 2016; 8(22): 942-948 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i22/942.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i22.942>

## INTRODUCTION

Orthotopic liver transplantation (OLT) is now considered an established treatment option for patients with end-stage liver diseases (ESLD). However, the increasing scarcity of grafts in comparison to the number of waiting patients, as well as the high procedure cost, lead to difficult decisions about how to distribute such scarce organs<sup>[1,2]</sup>. This highlights the need to identify patients who are likely to have good outcome following liver transplantation<sup>[3,4]</sup>. The Child-Turcotte-Pugh (CTP) score was originally developed for assessing the outcome of patients with liver cirrhosis and portal hypertension and was extended to stratify patients on the waiting list for liver transplantation<sup>[5]</sup>. The use of CTP in prioritizing potential liver transplant recipients is limited by several factors. Ascites and hepatic encephalopathy

are subjective variables and are affected by medical treatment; also CTP score lacks renal function assessment which strongly affects prognosis in cirrhotic patients<sup>[6]</sup>. The model for end-stage liver disease (MELD) was first described by Malinchoc *et al.*<sup>[7]</sup> as a mathematical model for predicting postoperative three-month survival for patients who underwent transjugular intrahepatic porto-systemic shunt. The MELD score was then validated as a predictor of mortality for a wide variety of liver diseases<sup>[8]</sup>, including cirrhotic patients awaiting liver transplantation<sup>[9]</sup>. Afterwards, MELD score was incorporated as a clear and objective system based on easily measurable laboratory parameters to reduce mortality among patients on the waiting list<sup>[10,11]</sup>. The ideal allocation system should allocate livers to candidates who are most likely to die without transplantation, and also to those who have a high probability of survival after OLT<sup>[12]</sup>. In February 2002, the United Network for Organ Sharing introduced a new allocation policy for cadaveric liver transplants based on the MELD score<sup>[13]</sup>. This new policy stratified patients according to the risk of death while they are on the waiting list<sup>[14]</sup>. The impact of the MELD score on postoperative mortality is still elusive.

The aim of this retrospective study was to assess the impact of the MELD score on patient survival and morbidity post living donor liver transplantation (LDLT).

## MATERIALS AND METHODS

Between January 2011 and January 2013, 80 adult patients with ESLD had received LDLT at the Ain Shams Center for Organ Transplant, Cairo, Egypt. Nine patients were excluded: Three had small-for-size grafts; one recipient had a combined organ (liver and kidney) transplant and 5 recipients had incomplete follow-up records. The remaining 71 transplants were included in this retrospective study. Seventy patients had LDLT with a right liver graft, and one patient had a left liver graft. The graft recipient weight ratio was between 0.8 and 1.7. The immunosuppressive regimen included cyclosporine or tacrolimus, mycophenolate mofetil (MMF), and corticosteroids in all patients except those transplanted for hepatocellular carcinoma (HCC). In patients transplanted for HCC, the regimen included calcineurin inhibitor and steroids only. Trough levels of cyclosporine were maintained between 200 and 300 ng/mL. Trough levels of tacrolimus were maintained between 8 and 12 ng/mL. Rapid withdrawal of corticosteroids within three months was routine in all patients (all transplanted for hepatitis C virus). In cases of acute rejection, the first-line therapy consisted of optimization of the maintenance level of immunosuppression. If there was no response, then MMF or rapamycin were added to the patient's regimen, if not already being taken. In some cases, a shift from cyclosporine to tacrolimus was beneficial. A small dose of steroids was used if all other measures failed.

The seventy one patients included in this study were

**Table 1** Demographic data, Child classification, and cold and warm ischemia time among the studied groups *n* (%)

Variable	MELD < 20 ( <i>n</i> = 38)	MELD > 20 ( <i>n</i> = 33)
Age (yr) (mean ± SD)	47.8 ± 7.8	46.2 ± 7.9
Sex		
Male	34 (89.5)	32 (97)
Female	4 (10.5)	1 (3)

C	35 (92.1)	33 (100)
Cold ischemia time (min)	47 ± 23	42 ± 30
Warm ischemia time (min)	54.4 ± 20.2	53.7 ± 16.9

ESLD: End-stage liver disease; HCC: Hepatocellular carcinoma; MELD: Model for end-stage liver disease.

divided into two groups. Group 1 included 38 patients with a MELD score less than 20, and Group 2 included 33 patients with a MELD score more than 20.

The MELD score was calculated using laboratory results collected immediately before liver transplantation with no adjustments for malignancy. We calculated the MELD score using the following formula: MELD =  $[0.957 \times \ln(\text{creatinine mg/dL}) + 0.378 \times \ln(\text{bilirubin mg/dL}) + 1.12 \times \ln(\text{INR}) + 0.643 \times 10^8]$ . We reported the age, sex of the recipient, diagnosis, indication for liver transplantation, modified CTP score as well as cold and warm ischemia time. The diagnosis of chronic liver disease was confirmed by histopathology of the explanted liver. The modified CTP score was calculated and each patient was categorized as A, B, or C. Operative data (including operative time and intra-operative blood transfusion) and early post-operative outcomes [including intensive care unit (ICU) stay, hospital stay, incidence of infection and other morbidities including renal impairment, cardiovascular, respiratory and neurological complications] were compared between the two groups. Overall patient survival was also compared between the two groups. Survival was calculated using the date of transplant to either 5 years post-transplant or to the end-point of this study in January 2016.

### Statistical analysis

Categorical data were presented as numbers and percentages. Quantitative data were presented as the mean, standard deviations, ranges, median and interquartile ranges. For qualitative data, the comparison between the two groups was performed by using the  $\chi^2$  test and Fisher exact test. For quantitative data, the comparison between the two groups was performed using an independent *t*-test for parametric data and a Mann-Whitney test for non-parametric data. The Kaplan-Meier survival analysis was used to assess the overall survival of both groups. The confidence interval was set to 95%,

and the margin of error that was accepted was set to 5%. All data were analyzed using SPSS version 17. A *P*-value more than 0.05 was considered to indicate a non-significant (NS) difference between the two groups; a *P*-value less than 0.05 was considered to be statistically significant (S).

The statistical methods of this study were reviewed by Ahmed Mukhtar, Department of Anesthesia and Critical Care, Diploma of Medical Biostatistics, Faculty of Medicine, Cairo University, Cairo, Egypt.

## RESULTS

This retrospective study included 71 patients classified into two groups according to their preoperative MELD score. Demographic data, Child classification, and cold and warm ischemia time were comparable between both groups (Table 1).

### MELD score and survival

Overall patient survival was compared between both groups from the date of transplant to 5 years post-transplant or to the end-point of this study in January 2016. Eleven patients (15.5%) died during this study: Three patients out of 38 (7.9%) in Group 1 with a MELD less than 20 and 8 patients out of 33 (24.2%) in Group 2 with a MELD more than 20.

The 1, 3 and 5-year survival rates in Group 1 were 94.7%, 94.7% and 92.1% respectively, in comparison to 81.8%, 81.8% and 75.8% respectively in Group 2 with statistically significant difference between both groups (*P* = 0.02). Mortality occurred mainly in the early postoperative period in ICU because of respiratory failure due to weak respiratory muscles with poor weaning capability from mechanical ventilation (two patients in Group 1 and six patients in Group 2).

Figure 1 shows the Kaplan-Meier curve for overall survival of both groups, where Group 1 patients had a statistically significant higher overall survival rate compared to Group 2 patients.

### MELD score and hospital stay

In this study, there was no statistically significant difference observed among the two groups with regard to mean hospital and ICU stay. In Group 1, the mean hospital stay was 30 ± 14 d in comparison to 29 ± 18 d in Group 2 (*P* = 0.937). The mean ICU stay in Group 1 was 7 ± 3 d, while in Group 2, it was 9 ± 4 d (*P* = 0.315).

### MELD score and operative data

There was no statistically significant difference between the groups with respect to operative time, blood loss, and intra-operative blood transfusion (cell saver, blood product). The mean operative time in Group 1 was 11.1 ± 2 h (with a range of 7-15 h), and in Group 2, it was 10.6 ± 1.4 h (with a range of 9-14 h), (*P* = 0.292). The mean volume of blood transfusion and cell saver re-transfusion were 8 ± 4 units and 1668 ± 202 mL, respectively, in Group 1 in comparison to 10 ± 6 units and

**Figure 1** Kaplan-Meier curve for overall survival of both groups. The Group 1 patients that had a MELD score < 20 had higher overall survival rates than the Group 2 patients that had a MELD score > 20. MELD: Model for end-stage liver disease; Cum survival: Cumulative survival.

**Figure 2** Infection rates in both groups. MELD: Model for end-stage liver disease.

1910 ± 679 mL, respectively, in Group 2 ( $P = 0.09$  and  $0.167$ ).

#### MELD score and postoperative complications

**Infection:** The overall incidence of infection in this study was 42.3% (30 out of 71 patients). In Group 1, the incidence of infection was 39.5% (15/38 patients). Bacterial infection was the most common representing 23.6% of the patients, while viral infection [cytomegalovirus (CMV)] was detected in 2.6%, fungal in 2.6% and combined infection in 10.5%. In Group 2, the incidence of infection was 45.5% (15/33 patients). Bacterial infection was the most common type of infection, representing 30.3%, while viral infection (CMV) was detected in 6%, fungal in 0% and combined infection in 9.1%. No statistically significant difference was detected between the groups regarding infection rates ( $P = 0.79$ ) (Figure 2).

**Systemic complications:** There were no significant differences observed between groups with regard to the incidence of systemic complications including renal,

respiratory, cardiovascular, and neurological complications (34.2% and 45.5% in Groups 1 and 2, respectively,  $P = 0.869$ ).

Renal impairment was the most common complication in both group (10.5% in Group 1 and 15.2% in Group 2), followed by cardiovascular complications (13.2% in Group 1 and 12.1% in Group 2) consisting of mainly hypertension in most patients and arrhythmia in 2 patients. Neurological complications occurred in 2.6% and in 3% of the patients in Groups 1 and 2, respectively. Respiratory complications (basal atelectasis, pleural effusion, adult respiratory distress syndrome and respiratory infection) occurred in 7.9% of the patients in Group 1 compared to 15.2% in Group 2. Two patients in Group 1 (5.3%) and 2 patients in Group 2 (6.1%) had a combined respiratory and other system complications (Figure 3).

## DISCUSSION

The large imbalance between patient demand and donated organs is a pressing problem in LDLT. The best solution to this problem is still a matter of debate. Unfortunately, prioritizing extremely sick patients makes it likely that patients who are not as sick will be forced to wait until getting worse and their chances for success become also diminished<sup>[15]</sup>. Patients who are very sick may have worse post-transplant outcomes than healthier patients<sup>[16]</sup>. Thus, the optimal system would offer grafts to those who are sufficiently sick to justify the transplantation but not too sick to benefit from it<sup>[17]</sup>. The urgency of need should be optimized with the likelihood of satisfactory postoperative outcomes so as to avoid "ineffective transplantation"<sup>[18]</sup>.

An accurate prognostic model could also help potential transplant recipients and their families make decisions by providing them with information on the patient's survival probability post-transplantation<sup>[19,20]</sup>. The MELD score was achieved to help prioritizing prospective liver allograft recipients. Its accuracy to predict short-term mortality

Figure 3 Incidence of systemic complications in both groups. MELD: Model for end-stage liver disease.

among patients with end-stage liver disease has been largely established<sup>[21]</sup>. However, an ideal selection system should incorporate predictions for survival while the patient is on the waiting list as well as following transplantation. The development of a model that may predict post-transplant outcomes based on pre-transplant variables is difficult because of variation in surgical skills and chance events that occur in the perioperative period. In addition to other factors such as graft rejection, biliary and vascular complications which are independent of pre-transplant events. Although it seems reasonable that pre-transplant variables which constitute the MELD score may influence the immediate post-transplant phase, their ability to predict long term outcome appears less likely. Recently, several investigators examined the predictive value of MELD for post-transplantation outcome, but with conflicting results and limited follow-up period; thus, a clear consensus has not emerged yet<sup>[22,23]</sup>.

In a systematic review about the performance of MELD score in the setting of liver transplantation, Cholongitas *et al*<sup>[9]</sup> concluded that the MELD is not a good predictor for short-term mortality following liver transplantation, and further studies were needed to assess its long term performance. Additionally, Batista *et al*<sup>[24]</sup> demonstrated that the preoperative MELD score showed low overall accuracy for predicting survival after liver transplantation; similar to what was described in other Brazilian studies. On the other hand, worse survival rates in recipients with higher MELD scores has been reported by some authors<sup>[25-27]</sup>. The current study confirms the relation between MELD score and post liver transplantation survival. The incidence of mortality was 7.9% in patients with a MELD score less than 20 compared to 24.2% in patients with a MELD greater than 20, with significant difference

between both groups ( $P = 0.02$ ).

Our study shows no significant impact of MELD score on the duration of hospital and ICU stay; these findings are comparable with those of Poon *et al*<sup>[28]</sup>, while many studies such as Foxton *et al*<sup>[29]</sup>, demonstrated that liver transplantation of patients with higher MELD scores resulted in an increased ICU and hospital stay as well as increased need for renal replacement therapy. Additionally, Buchanan *et al*<sup>[30]</sup> showed that patients in the highest MELD group had a longer ICU stay than those in the lower MELD group ( $P = 0.008$ ). Lee *et al*<sup>[31]</sup> and Massicotte *et al*<sup>[32]</sup> concluded that the MELD score did not predict blood loss or blood product requirements during liver transplantation, while others such as Feng *et al*<sup>[33]</sup> demonstrated that massive blood transfusion during liver transplantation can be predicted by preoperative MELD score. In our study, no definite relation was detected between MELD score and intra-operative blood loss or requirements of blood transfusion.

In the current study, the incidence of infection was comparable between both groups with no significant difference between a MELD score that was less or more than 20. This conclusion is the same finding of Li *et al*<sup>[34]</sup> in which a univariate analysis of risk factors for post-operative bacterial and fungal infections showed no statistically significant difference in regards to the MELD score. However, in the study of Selzner *et al*<sup>[35]</sup>, high MELD score recipients had more frequent postoperative pneumonia in comparison to those with low MELD ( $P = 0.003$ ), while no differences were observed in rates of biliary complications or overall infections.

In conclusion, a MELD score more than 20 can predict poor overall survival post LDLT. No significant relation was found between MELD score and intra-operative blood

loss or blood requirement, hospital and ICU stay, or post LDLT morbidity.

## COMMENTS

### Background

Orthotopic liver transplantation has become an established treatment approach for patients with end-stage liver disease, but the growing scarcity of grafts compared to numbers of waiting patients, and the high cost of this procedure, make it difficult to make decisions about how to distribute such scarce organs. The impact of the model for end-stage liver disease (MELD) score on postoperative mortality and morbidity following liver transplantation is not well-established yet.

### Research frontiers

The authors assessed the impact of MELD score on patient survival and morbidity post living donor liver transplantation (LDLT) in the current retrospective study that was performed on 71 adult patients who had LDLT from 2011-2013. They were divided into two groups: Group 1 included 38 patients with a MELD score < 20, and Group 2 included 33 patients with a MELD score > 20. They found that MELD score > 20 can predict poor overall survival post LDLT. No significant relation was found between MELD score and intra-operative blood loss or blood requirement, hospital and intensive care unit stay, or post LDLT morbidity.

### Innovations and breakthroughs

This is the first Egyptian study that addresses the impact of MELD score on patient survival and morbidity post living donor liver transplantation.

### Applications

The findings of this study may represent a future strategy that may help prioritize prospective liver allograft recipients and predict post-transplantation outcome.

### Terminology

The MELD score is a mathematical model based on easily measurable laboratory tests. It is calculated immediately prior to liver transplantation through the following formula:  $MELD = [0.957 \times \ln(\text{creatinine mg/dL}) + 0.378 \times \ln(\text{bilirubin mg/dL}) + 1.12 \times \ln(INR) + 0.643 \times 10^3]$ .

### Peer-review

The authors have done a retrospective study on impact of MELD score on patient survival and morbidity after living donor liver transplantation. The data may be useful for liver transplantation.

## Abstract

**AIM:** To check the safety and efficacy of boceprevir/telaprevir with peginterferon/ribavirin for hepatitis C virus (HCV) genotype 1 in the real-world settings.

**METHODS:** This study was a non-randomized, observational, prospective, multicenter. This study involved 47 centers in Italy. A database was prepared for the homogenous collection of the data, was used by all of the centers for data collection, and was updated continuously. All of the patients enrolled in this study were older than 18 years of age and were diagnosed with chronic infection due to HCV genotype 1. The HCV RNA testing was performed using COBAS-TaqMan2.0 (Roche, LLQ 25 IU/mL).

**RESULTS:** All consecutively treated patients were included. Forty-seven centers enrolled 834 patients as follows: Male 64%; median age 57 (range 18-78), of whom 18.3% were over 65; mean body mass index 25.6 (range 16-39); genotype 1b (79.4%); diagnosis of cirrhosis (38.2%); and fibrosis F3/4 (71.2%). The following drugs were used: Telaprevir (66.2%) and PEG-IFN-alpha2a (67.6%). Patients were naïve (24.4%), relapsers (30.5%), partial responders (14.8%) and null responders (30.3%). Overall, adverse events (AEs) occurred in 617 patients (73.9%) during the treatment. Anemia was the most frequent AE (52.9% of cases), especially in cirrhotic. The therapy was stopped for 14.6% of the patients because of adverse events or virological failure (15%). Sustained virological response was achieved in 62.7% of the cases, but was 43.8% in cirrhotic patients over 65 years of age.

**CONCLUSION:** In everyday practice, triple therapy is safe but has moderate efficacy, especially for patients over 65 years of age, with advanced fibrosis, non-responders to peginterferon + ribavirin.

**Key words:** Boceprevir; Telaprevir; Chronic hepatitis; Antiviral therapy; Peg-interferon; Ribavirin

**Core tip:** This study describes the role of antiviral therapy for chronic hepatitis C virus infections in everyday practice. Boceprevir or telaprevir, in combination with pegylated interferon and ribavirin, were

used in this multicenter study organized by the Italian Association of Hospital Hepatologists (CLEO). A total of 834 patients were enrolled with this first available combination of direct-acting antiviral drugs. The data on the efficacies were quite similar to those produced by the registration studies; however, in the real world experience, patients were older and had more advanced liver disease. In this category of patients, the sustained virological response was less than 50%.

Boceprevir or telaprevir in hepatitis C virus chronic infection: The Italian real life experience. *World J Hepatol* 2016; 8(22): 949-956 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i22/949.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i22.949>

## INTRODUCTION

Chronic hepatitis C virus (HCV) infection is one of the main causes of liver cirrhosis, end-stage liver disease, hepatocellular carcinoma (HCC) and liver transplantation worldwide. Pegylated interferon-alpha (P) and ribavirin (R) have been the backbone of HCV treatment for more than a decade. In 2011, the approval of telaprevir (TVR) and boceprevir (BOC), two protease inhibitors (PI), opened the first generation of direct antiviral agents (DAAs) for the treatment of genotype 1 HCV infection.

In many randomized studies, triple therapy (the combination of P plus R with PI, such as TVR or BOC) is demonstrated to be more effective than P plus R alone, with an increased likelihood of sustained virological response (SVR) of more than 30%, when compared with the dual therapy (P + R), reaching 68%-75% of naïve patients and 29%-83% of the experienced patients depending on the previous response to P + R<sup>[1-4]</sup>. The increase in SVR is associated with more side effects, and some of them, such as anemia and rash, were frequently causes of the withdrawal from treatment. However, as is well known, in the registered trials, the number of difficult-to-treat patients is rather small (cirrhotic, elderly, null responders to previous treatments and patients with comorbidities). However, even with restricted criteria for enrollment in phase 3 studies, a number of patients had

to stop the triple therapy due to either viral failure or adverse events (12%-15%).

TVR/BOC, approved for reimbursement in Italy in December 2012, have been used since January 2013. Since then, the group of the Association of Hospital Hepatologists (CLEO DAAs Study Group) was deeply involved in using these drugs, and the Governing Board of the Association decided to collect data from the Hospital centers belonging to the CLEO. The aim of our study was to determine what happens in everyday practice in terms of safety and efficacy using the triple therapy.

## MATERIALS AND METHODS

### Study design

This study was a non-randomized, observational, prospective, multicenter. This study involved 47 centers in Italy. A database was prepared for the homogenous collection of the data, was used by all of the centers for data collection, and was updated continuously.

### Subjects

All of the patients enrolled in this study were older than 18 years of age, were diagnosed with chronic infection due to HCV genotype 1, and were consecutively seen in at least one of the centers between January 2013 and June 2014. No distinction was made between naive and previously treated patients. With regard to age, patients were divided into the following three groups: (1) less than 50; (2) between 50 and 65; and (3) over the age of 65. In this manner, we tried to avoid the division into only two categories (under 65 and over 65), which is presented in many papers and flattens the differences. Hepatitis B virus/human immunodeficiency virus positive patients or patients suffering from chronic liver disease due to other etiologies were excluded.

### Treatment

Each center made the choice between TVR or BOC and Peg-IFN- $\alpha$ 2a or Peg-IFN- $\alpha$ 2b; patients were also treated with ribavirin (dose depending on the type of P chosen). The drugs were administered according to the manufacturer's instructions. TVR was administered with P + R for 12 wk followed by 36 wk of P + R; while patients treated with BOC received 4 wk of P + R (lead-in phase) followed by 44 wk of BOC + P + R. Patients treated with BOC or TVR had to respect the stopping rule concerning the kinetics of the viral load as follows: BOC patients with an HCV-RNA at week 12 greater than or equal to 100 IU/mL or detectable at 24 wk had to stop the therapy, while TVR patients with an HCV-RNA greater than 1000 IU/mL at week 4 or 12 or detectable at week 24 had to stop the treatment. They were classified as non-responders because of the virological failure.

### Methods

Fibrosis was evaluated by a liver biopsy or by measuring the liver stiffness according to the manufacturer's in-

structions (Fibroscan<sup>®</sup>, Echosens, Paris, France). The results were expressed in kilopascal (kPa), and the cut-off values according to the literature were as follows: F1 was defined by a liver stiffness < 7.0 kPa; F2 was defined by a liver stiffness between 7.1-9.5; F3 was defined by a liver stiffness between 9.6-12.4; F4 (cirrhotic patients) was defined by liver stiffness values of up to 12.5 kPa<sup>[5]</sup>. Patients, according to their response to the previous treatment, were categorized as naive (never treated with antiviral drugs); relapsers (patients who were HCV RNA negative at the end of treatment and HCV RNA positive during the follow-up); partial responders (those with a reduction of HCV RNA during the treatment, but never become HCV RNA negative); and null responders (patients without any change in HCV RNA during the treatment and thereafter)<sup>[6]</sup>.

AEs were graded by the investigators, according to the NIH grading system (CTCAE version 4.0). Hematological disorders, mainly anemia, were managed by reducing the ribavirin dose, giving erythropoietin, and/or with a blood transfusion, at the discretion of the physicians of each center. Hepatic decompensation during the therapy was defined by the new onset of one of the following clinical manifestations: Ascites, variceal hemorrhage, hepatic encephalopathy and onset of HCC.

A quantification of the HCV-RNA level was performed at baseline, 4 wk, 8 wk, 12 wk, the end of treatment, and 12 wk after the end of treatment. The HCV-RNA level was detected using real-time polymerase chain reaction (COBAS<sup>®</sup> TaqMan<sup>®</sup> HCV Test v2.0, Roche Diagnostics, Basel, Switzerland) with a lower limit of detection of 25 IU/mL. SVR was defined as HCV-RNA below the level of quantification 12 wk after the end of treatment.

### Statistical analysis

All consecutively treated patients were included; data were analyzed according to the intention-to-treat principle. A preliminary descriptive analysis of the main demographic, virological and clinical baseline variables [gender, age, body mass index (BMI), HCV genotype, HCV RNA level, fibrosis grade, IL-28B, type of response to previous antiviral therapy, biochemical laboratory tests, concomitant diseases, side effects, and virological response during, at the end, and 12 wk after the end of therapy] of the entire population under investigation was carried out. Statistics measurements were as follows: Mean and standard deviation, mean standard error and 95%CI, median and range (when appropriate). At a later stage, univariate analysis and one-way ANOVA were conducted to verify the relationships between each independent variable and the dependent variable (SVR12). A  $\chi^2$  test for categorical variables and a *t*-test or Mann-Whitney test (when appropriate) for quantitative variables was used. A two-tailed *P*-value < 0.05 was considered to indicate statistical significance. Then, we looked for multicollinearity between those independent variables that statistically associated with SVR12. Finally, a multivariable logistic-regression analysis (step-

wise selection procedure) was conducted to assess the relationship between the SVR and the pre-specified demographic and baseline clinical characteristics.

We have not carried out a statistical analysis comparing the two treatments. The reasons are as follows: (1) as already mentioned, this comparison was not one of the purposes of the study; and (2) each center not only chose BOC or TVR in its absolute discretion but also the type of pegylated interferon. This aspect would determine the division into the four groups with a very different dimension and would not provide acceptable results. Moreover, other studies similar to ours did not make any comparative analysis between the two treatments because of the same reasons<sup>[7,8]</sup>.

All statistical analyses were performed using the software package SPSS for Windows (Rel SPSS 15.0; SPSS Chicago, IL, United States).

## RESULTS

Eight hundred and thirty-four Caucasian patients observed in the 47 participating centers from January 2013 to June 2014 were enrolled, of whom 12.1% were also alcohol abusers, and 11.5% were affected by type 2 diabetes.

The two treatments (BOC/TVR) were analyzed to-

gether. The characteristics of the patients are reported in Table 1.

The majority of our patients were affected by genotype 1b (79.4%) and cirrhosis (38.2%). Among these 319 cirrhotic patients, 70.8% had a Child-Turcotte-Pugh Score of A5, 23.1% had A6; while 4.5% were B7 and 1.6% were B8. According to the response to previous treatments, 24.4% were naive, 30.5% were relapsers, 14.8% were partial responders and 30.3% were null-responders. According to the fibrosis grade, 7.7% of patients were F1, 21.1% were F2, 33.0% were F3 and 38.2% were F4.

HCV genotype 1b (79.4%) infections were more frequent than HCV 1a (19.2%), but the HCV genotype was not defined as 1b or 1a in 1.4% of the cases. As expected, in this population of relapsers and non-responders to prior antiviral therapy, only 13.5% of the patients had an IL-28B genotype CC. However, not all of the centers had this test available, but it was carried out on 61.5% of treated patients. Each center decided the choice of therapy, with the following percentage: TVR 66.2%, BOC 33.8%, Peg-IFN alpha2a 67.6% and Peg-IFN alpha2b 32.4%.

Overall, 70.4% of the patients completed a full course of therapy, while the treatment was stopped due to virological failure in 15% of the cases and for adverse events in 14.6%.

The overall SVR rate was 62.7% (95%CI: 59.1-66.3), while 70.1% of the patients had undetectable HCV-RNA levels at the end of triple therapy with a rate of relapse of 7.3% (Table 2). According to age, SVR was observed in 67.4% of patients < 50 years, 63.1% of the patients whose ages ranged from 50 to 65, and 55.3% of patients > 65 years ( $P = 0.037$ ). SVR was observed in 65.7% of the naive patients, 73.7% of relapsers, 67.2% of partial responders and 55.1% of the null responders ( $P = 0.012$ ). Only 53.4% of the cirrhotic patients had an SVR vs the 72.7% of patients with fibrosis F1 ( $P = 0.003$ ), 73.4% with F2 ( $P = 0.0001$ ), and 63.3% with F3 ( $P = 0.013$ ); the lower rate of SVR of 43.8% was observed in cirrhotic patients over 65 years of age ( $P = 0.0001$ ). When we compared the SVR observed in the categories F0/1/2 and 3 (68.1%) vs F4 (53.4%), there was a statistically significant difference ( $P = 0.0001$ ). As for the relationship between SVR and the IL28B, the CC (70%), CT (57.5%), and TT (45.7%) groups, there was a statistically significant difference ( $P = 0.029$ ) in favor of the CC group. Alcohol did not affect the percentage of SVR, while type 2 diabetes was statistically associated with SVR (OR = 0.55; 95%CI: 0.34-0.87,  $P = 0.006$ ). The univariate analysis showed that six factors were independently associated with SVR. These factors were as follows: (1) a relapse after P + R treatment; (2) the stage of fibrosis; (3) age; (4) gender; (5) diabetes; and (6) the IL-28B status; while BMI, HCV-RNA at baseline, biochemistry at baseline and genotype subtype were not associated with SVR. The multivariate analysis with logistical regression revealed that only fibrosis F0/F1/F2 stages, IL-28B-CC and the absence of diabetes are independently associated

**Table 2** Percentage of sustained virological response according to demographics and clinical characteristics

RVR <sup>1</sup>	66.5%

with SVR ( $P < 0.05$ ). The odds ratios for fibrosis stages F0/F1/F2 and F3 vs F4 (the reference category) were 2.3 (95%CI: 1.3-3.8;  $P = 0.002$ ) and 1.5 (95%CI: 0.9-2.3;  $P = 0.096$ ), respectively. The OR for IL28B-CC and IL-28B-CT vs IL-28B-TT (the reference category) were 3.2 (95%CI: 1.5-6.7;  $P = 0.003$ ) and 1.5 (95%CI: 0.9-2.4;  $P = 0.11$ ), respectively. As for diabetes, the odds ratio was 1.8 (95%CI: 0.9-3.5;  $P = 0.075$ ).

### Safety

Overall, AEs occurred in 617 patients (73.9%) during the treatment (Table 3). A total of 122 (14.6%) of the patients suspended the therapy due to AEs. In general, females stopped the treatment more often than males (16% vs 11%;  $P = 0.043$ ). With increasing age, there was a statistically significant increase in AEs (9.4% vs 12.6% vs 18.4%;  $P = 0.040$ ). There was no statistically significant difference in relation to subtype (1b 13.7% vs 9.3% 1a;  $P = 0.18$ ); nor was there a statistically significant difference in relation to the histological diagnosis ( $P = 0.58$ ) even if the F4 class showed the highest percentage (13.8%) of AEs compared to the other classes as follows: F3 (12.9%), F2 (9.8%), F1 (11.7%) and F0 (0.6%, four patients only in this group).

Anemia was the most frequent AE (52.9% of cases), especially in cirrhotic as already described<sup>[9]</sup>, followed by asthenia (39.6%), neutro-thrombocytopenia (29.6%), rash/itching (23.2%), dysgeusia (8.6%), psychiatric disorders (6.7%), anorectal discomfort (5.9%) and others (14.9%). Among this last group, we recorded the following: Gastrointestinal disorders (23 cases), pulmonary infections (9), ascites (3), pancreatitis (2), thrombosis of retina (2), and new onset of cancer as follows: Hepatocellular carcinoma (1), breast (1), and

**Table 3** Adverse events (%) and treatment discontinuation

Adverse events (73.9%)	
Anemia	52.9
Asthenia	39.6
Neutro/thrombopenia	29.6
Dysgeusia	8.6
Psychiatric disorders	6.7
Anorectal symptoms	5.9
Others (see text)	14.9
Treatment discontinuation (122 cases; 14.6%)	Number of cases
Rash/Itch	36 (29.5%)
Anemia	28 (22.9%)
Asthenia	18 (14.7%)
Psychiatric disorders	6 (5%)
Pancytopenia	3 (2.5%)
Neutro/thrombopenia	3 (2.5%)
Others (see text)	28 (22.9%)

kidney (1). Anemia was observed regardless of the DAA used, while rash was more frequently observed in the TVR treated patients. The main AEs that led to treatment discontinuation were rash (29.8%) and anemia (23.4%). There were no fatalities as the included patients had cirrhosis, but not as advanced as in the French study<sup>[8]</sup> where the 2.2% of the patients died.

### DISCUSSION

This study, conducted in 47 hospital centers in Italy, enrolled 834 patients consecutively seen in clinical settings. Because there was no selection of the cases, all of the patients seen and judged to be treatable by each center were included. For this reason, we can safely assume that this study mirrors what happens in real life. This is the main reason of the need for studies that monitor the safety after registration of the authorization of the prescription of new drugs. It is at this stage that many older patients with morbidity, concurrently taking other medications, are enrolled. Observational studies, such as those already published and our own, serve not only to validate the results of pivotal trials but also to provide information on safety and predictors of response that helps to more appropriately use the new drugs. Some aspects should be underlined, such as the age of the patients (18.3% more than 65), the percentage of advanced liver disease (Fibrosis score F3 plus F4 = 70.9%) and the high percentage (75.6%) of patients previously treated with P + R. It is quite remarkable that the percentage of patients with compensated cirrhosis was 37.1%; while in the registration studies, this group of difficult-to-treat patients did not exceed 15%.

When we analyzed the differences between the major registration studies conducted using TVR/BOC and our findings, the first observation was that the AEs causing discontinuation of drugs were different from those reported in the phase 3 trials, where these percentages ranged between 8%-15%. The true strength of "real life" studies is the inclusion of patients who visit the clinics in every day practice and represent HCV-related disease at every stage. The only weakness is that they are not

randomized, and specialized centers in different parts of the country are involved, which favors a certain degree of heterogeneity. However, this aspect is also present in the pivotal studies in which many centers participate, often scattered in different countries. Analyzing other studies similar to ours, the percentages of drug discontinuation varies from a minimum of 8% to a maximum of 38%<sup>[7-10]</sup>. However, it is difficult to entirely blame DDAs for some AEs, as in addition to BOC and TVR, there were two drugs, including P and R, with AEs well known for many years, especially anemia, itching, and nervousness.

In this study, among the AEs causing withdrawal from treatment, rash (29.5%) was the most frequent, although we did not observe DRESS syndrome or toxic epidermal necrolysis.

Rash was detected in both treatment groups, although it was more frequent in patients treated with TVR. Anemia was the second most important AE leading to discontinuation of therapy. In 11% of the patients, it was necessary to perform blood transfusions, while in 25%, epoetin was administered. Other cases were simply treated with a dose reduction of ribavirin. As for the AEs not causing withdrawal from therapy, we did not find remarkable differences with the pivotal trials (Table 3).

The SVR at 12 wk after the end of treatment was achieved by 62.7%, more than that achieved by the other similar studies. The high number of patients with cirrhosis and the presence of older patients explain the results, such as SVR, which was a percentage lower than that obtained from the pivotal studies. In naive patients, the results were similar to those previously obtained by partial responders, while those who had the best performance (SVR = 73.7%) were those who had a relapse at the end of the previous treatments. Similar data for this category of patients were achieved by the other studies<sup>[9,11,12]</sup> for experienced patients. Null responder patients to previous treatments had an SVR of 55.1%, better than that reported in other similar studies, whereas in one study<sup>[10]</sup>, the SVR was less than 20%. The most relevant finding of this study was the negative correlation between the SVR and fibrosis grade. This result has been recently confirmed<sup>[13]</sup>. In fact, as reported in Table 3, the worst result (SVR = 43.8%) was achieved in patients with cirrhosis, who were older than 65 years of age. Indeed, these categories of patients (elderly, with cirrhosis and with many failures to previous treatments) represent the majority of patients requiring treatment today. Multivariate analyses showed that the most important factors linked to SVR were the grade of fibrosis, IL-28B-CC and not being diabetic.

In conclusion, the treatment with first generation PI (BOC/TVR) plus P + R is quite safe, but its efficacy is limited, especially for elderly cirrhotic patients. This information is very useful as DDA IFN-free drugs may change the antiviral therapy options for HCV, and there is no doubt that in many countries, these drugs will only be selectively available due to cost. Therefore, real life studies on "old" less expensive DDAs could be very

useful for establishing drug delivery policies in relation to the resources available in each country.

## ACKNOWLEDGMENTS

The CLEO Study Group thanks Michele Imparato, MD, for the data management, Massimo De Luca, MD, for the statistical analysis and Antonio Ascione, MD, for writing the draft.

## COMMENTS

### Background

Protease inhibitors (boceprevir or telaprevir) in combination with pegylated interferons and ribavirin are the first direct antiviral therapy for chronic infections with hepatitis C virus (HCV) genotype 1. They were introduced in 2011 and since then have been a step forward in the development of this therapy. In Italy, these therapies were introduced in 2013 and the Italian Association of Hospital hepatologists (CLEO) has begun, among the members of the association, the data collection.

### Research frontiers

This study represents one of the few real-life studies with high number of cases, published in the international field and the only one regarding the Italian patients. Compared to the registration studies, the collection of data from patients who are treated every day provides valuable data to validate in clinical practice this treatment.

### Innovations and breakthroughs

Therefore, the present study tested in practice the first two innovative drugs in chronic infections with HCV therapy that were expected at least for ten years. With their arrival in the therapeutic baggage of hepatologists, the authors have obtained results certainly better than the performance of conventional therapy with interferon and ribavirin alone, which has represented the standard of care for about fifteen years.

### Applications

The data generated from this study show that these drugs have an acceptable safety profile but their effectiveness, especially in cirrhotic patients and with over 65 years of age, is quite modest. Their greater efficacy is obtained in patients with non-advanced liver damage. The new drugs, which are currently on the market for hepatitis C, are more active than the triple therapy, but their cost is extremely high. Therefore, these studies are of great social importance because, in countries that do not have an economy that allows the purchase of these drugs, the triple therapy can be offered with excellent results, choosing carefully the categories of patients to be treated.

### Terminology

The letter "F" expresses the degree of fibrosis in the liver. In this study this aspect was defined by liver biopsy or by the Fibroscan tool, which, in a non-invasive way, is able to define the degree of rigidity and, therefore, the actual degree of fibrosis in the liver. The physical principle is that the higher the number in kilopascals, the higher the degree of fibrosis.

### Peer-review

This topic of study is very topical and important. The authors' concept and ideas for this investigation is very note worthwhile and studies of real life experiences are most useful for the field.

## Contents

*World Journal of Hepatology*  
Volume 8 Number 23 August 18, 2016

### ABOUT COVER

Editorial Board Member of *World Journal of Hepatology*, Oliver Ebert, MD, Attending Doctor, II. Medizinische Klinik und Poliklinik, Klinikum rechts der Isar, Technical University of Munich, D-81675 Muenchen, Germany

### AIM AND SCOPE

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

### INDEXING/ ABSTRACTING

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

### Abstract

Recurrence rate of hepatocellular carcinoma (HCC) is very high even after curative surgery, and no postoperative therapies have been definitively shown to prevent HCC recurrence. Sorafenib is proved to be effective for advanced HCC by two large randomized controlled trials in 2008 and 2009. Therefore it stands to reason to expect that adjuvant sorafenib may improve post-surgery outcomes of patients with HCC. However, many questions still exist about the value of sorafenib for patients with HCC after surgery or transarterial chemoembolization. In this editorial, we comprehensively reviewed the safety and efficacy of adjuvant sorafenib for patients with hepatocellular carcinoma after surgery or transarterial chemoembolization. We emphasized the positive and negative role of sorafenib.

**Key words:** Adjuvant; Hepatocellular carcinoma; Tumor recurrence; Sorafenib

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Sorafenib is effective for advanced hepatocellular carcinoma (HCC). However, its positive role as adjuvant therapy for HCC after surgery or transarterial chemoembolization is controversy.

Zhong JH, Du XK, Xiang BD, Li LQ. Adjuvant sorafenib in hepatocellular carcinoma: A cautionary comment of STORM trial. *World J Hepatol* 2016; 8(23): 957-960 Available from:

## INTRODUCTION

Large randomized controlled trials have shown transarterial chemoembolization (TACE)<sup>[1,2]</sup> and sorafenib<sup>[3,4]</sup> monotherapy to extend median overall survival by approximately 3 mo over best supportive care in patients with hepatocellular carcinoma (HCC) in Barcelona Clinic Liver Cancer (BCLC) stage B or C. Though hepatic resection is the mainstay treatment for HCC, tumor recurrence is very high after surgery<sup>[5]</sup>. Therefore it stands to reason to expect that sorafenib may improve post-resection outcomes of patients with multinodular HCC or patients at high risk of HCC recurrence.

## STUDY ANALYSIS

In the recent issue of the *World J Gastroenterol*, Li *et al*<sup>[6]</sup> reported a small retrospective study which enrolled 36 male patients with BCLC stage C HCC after hepatic resection. Twelve patients received resection plus sorafenib while other 24 patients received resection alone. The authors found patients in the resection plus sorafenib group had a significantly longer time-to-tumor progression (TTP) and median overall survival compared to patients in the resection alone group.

However, the phase III placebo-controlled study STORM trial<sup>[7]</sup>, which included 1602 patients from 28 countries with early-stage HCC following surgical resection or local ablation, found that adjuvant sorafenib did not significantly affect recurrence-free survival, time to recurrence or overall survival. The authors concluded that no evidence of clinical benefit exists for adjuvant sorafenib therapy in such patients.

Also, the phase II SPACE trial comparing the efficacy and safety of TACE with or without sorafenib failed to meet its endpoint of prolonging TTP<sup>[8]</sup>. This raises important questions about the use of adjuvant sorafenib in the clinic.

The SPACE trial<sup>[8]</sup>, which involved 307 Asian and non-Asian patients with multinodular HCC in BCLC stage B, showed that the combination of TACE and sorafenib did not significantly increase TTP or overall survival over TACE alone. This negative result adds to another previous study calling into question the clinical benefits of adjuvant sorafenib. A phase III trial involving 458 Asian patients with HCC in stage B or C found that sorafenib did not significantly prolong TTP or overall survival in patients who responded to TACE<sup>[9]</sup>. In addition to non-efficacy, sorafenib add the incidence of adverse events or may worsen outcomes in certain patients<sup>[3,7,10]</sup>.

## REASONS OF NEGATIVE RESULTS

These negative results (Table 1) call for caution in the

adjuvant use of sorafenib. Why the results would be negative when our therapeutic aim shifts from control of established tumor cells to the eradication of occult micrometastases? One reason for caution lies in the mechanism of sorafenib, which inhibits tumor angiogenesis. Preclinical studies suggest that anti-angiogenic therapy can, in principle, increase the likelihood of tumor invasion and spread<sup>[11]</sup>, and that tumor angiogenesis can rapidly recover when anti-angiogenic therapy is halted<sup>[12]</sup>. Another reason for caution is that sorafenib may not be effective against recurrent or metastatic tumors, even if it is effective against primary tumors. The two types of tumors behave differently, and it is possible that recurrent or metastatic tumors are more malignant because they were not eliminated by initial therapy (TACE, resection, ablation). In fact, studies suggest that sorafenib has poor efficacy against intrahepatic metastases (derived from the primary tumor) as well as multicentric tumors arising spontaneously in the residual liver<sup>[7]</sup>.

While previous works strengthens the arguments for re-assessing adjuvant use of sorafenib, some of their results should be interpreted with caution. For example, the findings of Li *et al*<sup>[6]</sup> were based on a very small retrospective study; Lencioni *et al*<sup>[8]</sup> reported that the combination of TACE and sorafenib showed greater benefit in Asian patients than in non-Asian ones, yet median TTP was nearly the same (24 mo) in Asian and non-Asian subgroups as well as the total study population<sup>[8]</sup>. This TTP is substantially longer than the 5.4 mo reported in another phase III trial involving only Asian patients<sup>[9]</sup>.

Lack of efficacy with sorafenib has been attributed to insufficient duration of therapy<sup>[8]</sup>, such as because of delays in starting sorafenib after TACE, as well as to insufficient daily sorafenib doses<sup>[9]</sup>. These explanations seem less likely given that all published phase II or III multicenter randomized controlled trials concur that adjuvant anti-angiogenic agents, including sorafenib, are associated with negative TTP, overall survival, or recurrence-free survival for solid cancers<sup>[7-9,13]</sup>. In fact, a large dosing study involving 1943 patients with non-metastatic renal-cell carcinoma supports the notion that disease-free survival does not depend on treatment duration<sup>[13]</sup>.

## PERSPECTIVE

The growing evidence for lack of adjuvant sorafenib efficacy against HCC<sup>[7-9]</sup>, and substantial evidence against adjuvant anti-angiogenic therapy against solid cancers in general<sup>[13-16]</sup>, should lead clinicians to re-assess their treatment approaches. In this sense, some ongoing trials of adjuvant anti-angiogenic agents for solid cancers (*e.g.*, NCT00908752, NCT01009801) are already terminated.

Nowadays, more and more trials revealed the definite efficacy of postoperative antiviral treatment with nucleot(s)ide analogs for hepatitis B virus-related HCC<sup>[17-19]</sup>. Adjuvant adoptive immunotherapy may also improve recurrence-free and overall survival<sup>[20]</sup>. But more rando-

**Table 1** Adjuvant sorafenib for hepatocellular carcinoma

Ref.	Recruited period	Sample size (T/C)	HCC characteristics	First therapy	Adjuvant therapy	Outcomes
Li <i>et al</i> <sup>[6]</sup> , 2016	2009-2013	12/24	With portal vein thrombus	Hepatic resection	Sorafenib (200-800 mg/d)	TTP, <i>P</i> = 0.041 OS, <i>P</i> = 0.01
Bruix <i>et al</i> <sup>[7]</sup> , 2015	2008-2010	556/558	Early stage HCC	Hepatic resection or ablation	Sorafenib (400 mg) twice a day	RFS, <i>P</i> = 0.26 OS, <i>P</i> = 0.48
Lencioni <i>et al</i> <sup>[8]</sup> , 2016	-	154/153	Intermediate stage multinodular HCC	TACE with doxorubicin-eluting beads	Sorafenib (400 mg) twice a day	TTP, <i>P</i> = 0.07 OS, <i>P</i> = 0.29
Kudo <i>et al</i> <sup>[9]</sup> , 2011	2006-2009	229/227	Unresectable HCC who responded to TACE	Conventional TACE	Sorafenib (400 mg) twice a day	TTP, <i>P</i> = 0.25 OS, <i>P</i> = 0.79

C: Control group; HCC: Hepatocellular carcinoma; OS: Overall survival; RFS: Recurrence-free survival; T: Adjuvant treated group; TACE: Transarterial chemoembolization; TTP: Time-to-tumor progression.

mized trials are warranted because of inconsistent findings from new randomized trials<sup>[21,22]</sup>. For HCC patients with high risk of recurrence, adjuvant TACE has positive effect in terms of improving overall survival<sup>[23]</sup>. However, each postoperative or adjuvant therapy has its own indication, revealing that not all patients with HCC after surgery should receive specific postoperative or adjuvant therapy. New drugs may help further define therapeutic directions for the future.

dynamics that involves transport lipoproteins which levels are tightly dependent on how the liver and the intestine regulate cholesterol and biliary acid metabolism. Regulation of cholesterol and biliary acids by the liver and the intestine is in turn coupled to a large array of enzymes and transporters that largely influence the inflow and the outflow of cholesterol and biliary acids through these organs. The activity of the key regulators of cholesterol and biliary acids may be influenced by several external factors such as pharmacological drugs and the nutritional status. In recent years, more information has been gathered about the impact of estrogens on regulation of cholesterol in the body. Exposure to high levels of estrogens has been reported to promote cholesterol gallstone formation and women are twice as likely as men to develop cholesterol gallstones. The impact of estrogen withdrawal, such as experienced by menopausal women, is therefore of importance and more information on how the absence of estrogens influence cholesterol regulation is started to come out, especially through the use of animal models. An interesting alternative to metabolic deterioration due to estrogen deficiency is exercise training. The present review is intended to summarize the present information that links key regulators of cholesterol and biliary acid pathways in liver and intestine to the absence of estrogens in an animal model and to discuss the potential role of exercise training as an alternative.

### Abstract

Plasma cholesterol level is determined by a complex

**Core tip:** The liver is considered the master piece in regulation of plasma cholesterol levels. Together with

the intestine they control the influx and the efflux of cholesterol and biliary acids in the body. Cholesterol and its conversion into biliary acids are regulated by an extended network of enzymes and transporters that largely influence plasma cholesterol levels. The key regulators of cholesterol and biliary acids in liver and intestine are in turn affected by several factors including estrogens levels and more recently exercise training. Low estrogenic levels, such as seen in post-menopausal women, are associated with higher plasma cholesterol levels. In recent years more information has been accumulated on the extent to which low estrogenic levels, such as seen in an ovariectomized animal model, influence cholesterol and biliary metabolism at the molecular level. As an alternative to a deficiency in estrogens, exercise training has been reported to exert a beneficial effect on these key regulators of cholesterol and biliary acids.

## INTRODUCTION

The importance of estrogens in regulating cholesterol and biliary acid metabolism in liver is enlightened by clinical studies confirming that women are twice as likely as men to develop cholesterol gallstones<sup>[1,2]</sup>. Oversaturation of biliary cholesterol is the requisite defect for the formation of gallstones<sup>[1]</sup>. This pathophysiological state is induced by either hypersecretion of biliary cholesterol or decreased secretion of bile acids. Therefore, both the cholesterol secreted into bile and the bile acids synthesized from cholesterol in liver are involved in the disease<sup>[3]</sup>. Exposure to high levels of estrogens has been reported to promote cholesterol gallstone formation<sup>[4]</sup>. Similarly, the estrogen receptor  $\alpha$ -selective agonist propylpyrazole and tamoxifen treatment, that have estrogen-like activity, augment biliary cholesterol secretion in mice<sup>[4]</sup> and increase gallstone prevalence in women<sup>[5]</sup>. On the whole, these findings indicate that there is a close relationship between estrogens, cholesterol and biliary acid metabolism in liver. This in turn raises the question of the extent to which a deficiency in estrogens, as happens with menopause, affects cholesterol and biliary acid regulation in liver. The first element to take into consideration is the fact that estrogen withdrawal in animals decreases gene expression of HMGCoA-reductase (-r), the rate-limiting enzyme in hepatic cholesterol biosynthesis<sup>[6]</sup>.

Estrogen-deficient state in Ovx animals has been repeatedly reported to result in substantial liver fat accumulation indicating that fat metabolism is perturbed

by the absence of estrogens<sup>[7,8]</sup>. The information on the impact of the absence of estrogens on cholesterol metabolism, however, is scarce. An increase in plasma cholesterol levels in Ovx rats has been reported 30 years ago<sup>[9,10]</sup>. This has been confirmed in more recent studies in Ovx animals<sup>[6,11]</sup> as well as in post-menopausal women<sup>[12]</sup>. The situation of liver cholesterol levels in Ovx animals is more controversial. Liver total cholesterol level was reported not to be affected by estrogen withdrawal in some studies<sup>[11,13]</sup> while it has been found to be increased in rats ovariectomized for 5-8 wk<sup>[14,15]</sup>. Large cholesterol accumulation has also been found in liver of Ovx rats fed with a high-fat diet, that was not observed in liver of Ovx rats fed a standard diet and in Sham rats fed a high-fat diet<sup>[6]</sup>. The authors suggested a vulnerability to cholesterol accumulation in liver of Ovx animals fed a high fat diet. These findings have, at least, the merit of raising questions on the impact of the lack of estrogens on regulatory pathways involved in liver cholesterol metabolism. Cholesterol homeostasis in liver depends on cholesterol synthesis, uptake, and clearance. One of the aims of the present review is to summarize our present knowledge of the extent to which the lack of estrogens in an ovariectomized animal model affects the regulation of molecular pathways of cholesterol and bile acids in liver and intestine.

One of the best non-pharmacological strategies for the treatment of metabolic disturbances leading to coronary artery disease is exercise training<sup>[16,17]</sup>. In recent years, there has been a fair amount of studies indicating that exercise training is also beneficial in circumventing the detrimental effects of estrogen removal on metabolic pathways involved in liver fat accumulation<sup>[18]</sup>. Treadmill exercise for 12 wk has also been reported to reduce plasma low density lipoprotein (LDL)-cholesterol (-C) and total cholesterol in Ovx rats<sup>[19]</sup> while plasma LDL-C was decreased in 6-wk trained Ovx rats fed a high fat diet for 10 mo<sup>[20]</sup>. Although limited, there is recent information on the impact of exercise training on regulation of cholesterol pathways in liver and intestine in response to metabolic disturbances. For instance there are reports indicating an increased fecal cholesterol excretion in exercising animals<sup>[21]</sup>. There is also a recent report of changes with exercise training in gene expression of intestinal nuclear receptors involved in the defense system against endobiotic and xenobiotic insults suggesting that regular exercise contributes to the intestinal maintenance of cholesterol and bile acid homeostasis<sup>[22]</sup>. In the present review, a consideration will be given to the effects of exercise training on cholesterol and bile acids pathways, especially in the context of estrogens deficiency.

The present review is divided in two large sections related respectively to the pathways involved into hepatic cholesterol influx and efflux and how estrogen deficiency affects key regulators of these pathways. This will be followed by a discussion of the known effects of exercise training on these pathways.

## HEPATIC CHOLESTEROL INFLUX

Western-type diets provide approximately 400 mg of cholesterol per day while our body synthesizes approximately 1 g *de novo*<sup>[23,24]</sup>. Hence, blood cholesterol levels reflect both dietary and endogenously synthesized cholesterol. The liver is a central component in regulation of cholesterol metabolism. This organ is able to acquire cholesterol through *de novo* synthesis and from all classes of circulating lipoproteins<sup>[25]</sup>.

### Cholesterol biosynthesis

The total body content of cholesterol is approximately 100 g, of which approximately 90% are found at the cellular levels and 10% in circulation<sup>[26]</sup>. Cholesterol is synthesised virtually in all nucleated cells<sup>[27]</sup>. For instance, the central nervous system contains approximately 25% of the unesterified cholesterol present in the body and it comes almost entirely for *in situ* synthesis<sup>[28]</sup>. It is assumed that approximately 24% of cholesterol synthesis occurs in small intestine of rats and a significant fraction of it is transported to liver where nearly 50% of total cholesterol synthesis occurs<sup>[29]</sup>. Cholesterol synthesis starts, similarly to *de novo* lipogenesis, by the transfer of acetyl CoA from mitochondria to cytosol. The further condensation of three units of acetyl CoA forms an HMG-CoA that is transported to the endoplasmic reticulum (ER) where it is reduced to mevalonate by the enzyme HMGCoA-r follows by several steps leading to the formation of isoprene, squalene, lanosterol, and finally cholesterol. The action of the enzyme HMGCoA-r is the rate-limited step in endogenous cholesterol synthesis.

**Regulation of cholesterol biosynthesis:** The view that cholesterol is randomly distributed within cell membrane no longer holds. For instance the distribution of lipids and cholesterol in the outer leaflet is organized into domains so-called rafts and caveolae playing intricate roles to maintain cellular homeostasis<sup>[30,31]</sup>. On the other hand, membranes of the endoplasmic reticulum and the Golgi apparatus contain comparatively little cholesterol, an important factor in cholesterol homeostasis<sup>[32]</sup>. Maintenance of cholesterol homeostasis is orchestrated mainly by a feedback regulatory system that senses the level of cholesterol in cell membranes and modulates cholesterol biosynthesis and uptake from plasma lipoproteins<sup>[33]</sup>. The molecular mechanism of how hepatocytes maintain cholesterol homeostasis has become more precise with the discovery of the transcription factors sterol regulatory element binding proteins (SREBPs)<sup>[32]</sup>.

Short-term regulation of the enzyme HMGCoA-r is operated by mechanisms such as phosphorylation/dephosphorylation of the catalytic domain (serine 871) by specific kinases (AMPK) and phosphatases (protein phosphatase 2A)<sup>[34,35]</sup>. HMGCoA-r is physiologically present in the cell in unphosphorylated active form (30%) and phosphorylated inactive form (70%)<sup>[36]</sup>.

Long-term regulation of HMGCoA-r relies on synthesis and degradation rate of the enzyme. The cholesterol system is unique in that the regulated end-product, cholesterol, is sequestered entirely within cell membranes. Sterol regulatory elements (SREs) are nucleotidic sequences in the gene promoters, encoding proteins involved in cholesterol homeostasis such as HMGCoA-r and LDL receptor (LDL-R). These sequences are recognized by a family of transcription factors called SREBP<sup>[37]</sup>. The SREBP family members, SREBP-1 (a and c) and SREBP-2, are synthesized as membrane protein in the endoplasmic reticulum.

SREBP-2 is considered to be largely involved in the regulation of cholesterol metabolism. In ER, SREBP interacts with a cargo protein called SREBP cleavage-activated protein (SCAP), which acts as a transporter and cholesterol sensor<sup>[37,38]</sup>. The complex formation is essential for the exit of SREBPs from the ER and subsequent proteolytic activation<sup>[39]</sup>. The SREBP/SCAP containing vesicles from the ER also contain a membrane anchored serine protease of the subtilisin family called Site-1 protease (SIP-1). Sip becomes activated only during its transport to the Golgi<sup>[40]</sup>. SCAP escorts SREBP from the ER to the Golgi apparatus where the SREBPs are proteolytically processed by SIP-1 to yield active fragments that migrate to the nucleus encoding its target genes<sup>[33]</sup>. To release active SREBP, another enzyme is required, Site-2 protease. Interestingly, the nuclear action of SREBP induces new SREBP mRNA through SREs located in the promoter regions of their own genes<sup>[41]</sup>. When cholesterol builds up in the ER membrane, a conformational change in SCAP occurs through the direct cholesterol binding to the sterol domain and triggers SCAP to bind to Insig, another ER membrane protein<sup>[42]</sup>. This association hampers the transport of the SREBP/SCAP complex to the Golgi apparatus, resulting in a reduced proteolytic activation of precursor SREBP. For instance, high dietary cholesterol prevents maturation of SREBPs and cuts off cholesterol and LDL receptor synthesis.

**Estrogen deficiency and HMGCoA-r regulation:** Since plasma cholesterol level is increased in Ovx animals<sup>[6,11]</sup> one might expect an increase in cholesterol synthesis. However, HMGCoA-r mRNA secondary to Ovx was found to be decreased in several studies in rats<sup>[6,11,43,44]</sup> and in mice fed a high-fat high-cholesterol diet<sup>[13]</sup>. Along with HMGCoA-r, gene expression of SREBP-2, the transcription factor involved in the regulation of HMGCoA-r, was also decreased in Ovx animals<sup>[14,43]</sup>. On the opposite, an increase in HMGCoA-r protein content has been reported in frog and rat after 5 d of estrogen administration<sup>[45,46]</sup>. On the whole these results strongly suggest that an increased cholesterol biosynthesis is not responsible for the increased higher plasma cholesterol found with estrogen deficiency in animals and in post-menopausal women. They also suggest an accumulation of cholesterol in the ER membrane.

### Receptors involved in hepatic uptake of cholesterol from lipoproteins

**Lipoprotein remnant receptors:** Upon completion of hydrolysis (approximately 50% of TG removal) chylomicrons and VLDL lose affinity for lipoprotein lipase (LPL) and dissociate<sup>[47]</sup>. The apoproteins A1 and C are then transferred to high-density lipoprotein (HDL) in exchange for apo E upon what they are then called chylomicrons and VLDL remnants<sup>[48,49]</sup>. The acquisition of apo E is crucial since it will serve eventually as ligands for receptor mediated clearance. Intermediate density lipoproteins (IDL) which are VLDLs that interact for prolonged period with LPL are also remnants particles. The remnant lipoproteins are then small enough to enter the space of Disse. Once into the space of Disse, remnant lipoproteins small enough to fit between the endothelial cells are sequestered by high-molecular-weight heparin proteoglycan (HSPG) molecules. Within the space of Disse the particles are remodeled by hepatic lipase. Final uptake by the hepatocytes is receptor mediated that include LDL-R, LDL related protein (LRP), a complex LRP-HSPG or HSPG alone<sup>[25,50]</sup>. These mechanisms are efficient so that half-life of remnants in plasma is 30 min. The apoB-48 containing chylomicron remnants are completely cleared from the plasma. However the presence of apoB-100 in VLDL alters their metabolism so that only 50% of VLDL remnants are cleared by lipoproteins remnant receptors.

**Receptors involved in hepatic uptake of LDL-cholesterol:** VLDL remnants that are not taken up by the remnant receptors are metabolized to a greater extent by LPL, become increasing smaller, relatively deficient in TG and enriched in cholesterol esters. These particles are called IDL. Because IDL contains apoE a fraction of these particles may be taken up by the liver through the remnant receptors<sup>[51]</sup>. However, the remainder will be changed to LDL following further hydrolysis of the TG by the hepatic lipase. The apoE and apoC- II molecules will then transfer to HDL and leave apoB as their only apolipoprotein<sup>[52]</sup>. The LDL-R is the only receptor able to clear up LDL from the circulation. Because of the lack of apoE, the LDL particle is a relatively weak ligand for the LDL receptor<sup>[53]</sup>. As a result, the half-life of the LDL particle is relatively long (two to four days) thus accounting for 65%-75% of total plasma cholesterol. Interaction of apoB with the LDL-R facilitates the internalisation and the further degradation of LDL<sup>[53]</sup>. Inside the cell, the LDL particle is hydrolysed to release unesterified cholesterol. The LDL-R is expressed on the cell surface of several tissues including liver, macrophages, lymphocytes, adrenal cortex, gonads, and smooth muscle<sup>[25]</sup>.

**Metabolism of the LDL-R:** The LDL-R is a cell surface receptor that mediates specific uptake and catabolism of plasma lipoproteins containing apoB or apoE<sup>[53]</sup>. The primary function of this receptor is the removal of highly atherogenic LDL particles from circulation<sup>[53]</sup>. Since the liver contains approximately 70% of total

LDL-R found in the body<sup>[54]</sup>, hepatic LDL-R activity is an important contributor to regulation of plasma cholesterol LDL levels. The LDL-R activity is downregulated post-transcriptionally by a protease, proprotein convertase subtilisin kexin type 9 (PCSK9)<sup>[55]</sup>. PCSK9 is highly expressed in liver and intestine<sup>[56]</sup>. However, circulating PCSK9 originates exclusively from hepatocytes<sup>[57]</sup>. The gene expressions of LDL-R and PCSK9 as well as HMGCoA-r are regulated by a transcription factor, SREBP-2<sup>[58]</sup>. Within the endoplasmic reticulum, PCSK9 undergoes an auto catalytic cleavage<sup>[56]</sup> that results in a tightly bound secretable heterodimeric complex<sup>[59]</sup>. PCSK9 is, therefore, readily measured in plasma. PCSK9 binds to the LDL-R at the surface of the hepatocytes and/or within the cell<sup>[60]</sup>. LDL-R is then directed from the cell surface recycling toward degradation in the endosome/lysosome pathway<sup>[61]</sup>. Mutations leading to a loss of function or genetic invalidation of PCSK9 largely reduce circulating LDL-C levels and reduce cardiovascular events (88%) in humans (for a review see<sup>[60]</sup>).

The co-regulation of PCSK9 and HMGCoA-r by the same transcription factor has consequences. As discussed by Poirier *et al*<sup>[60]</sup>, statins that lower LDL-C by inhibiting HMGCoA-r also increase the expression of PCSK9<sup>[62]</sup> which decreases their capacity at increasing LDL-R. This may explain why LDL-C levels do not reach therapeutic goals in many patients with statins therapy. Hepatocyte nuclear factor 1 alpha, a key mediator of the effects of bile acids on gene expression, also regulates PCSK9<sup>[63]</sup>.

**Estrogen deficiency and LDL-R:** In line with the reduction in HMGCoA-r, gene expression of hepatic LDL-R has been repeatedly reported to be reduced in Ovx animals<sup>[11,13,14,43,64]</sup>. Along with LDL-R, PCSK9 transcripts in liver and PCSK9 plasma levels have also been shown to be reduced in Ovx rats<sup>[14]</sup>. These results concord with the reports that estrogens administration upregulates *LDL-R* gene expression in rat liver<sup>[46,65]</sup>. In a recent study, Roubtsova *et al*<sup>[66]</sup> showed, using PCSK9 KO mice, that the interaction between PCSK9 and LDL-R was sex-specific, thus depending on estrogens. The similar decrease in PCSK9 and LDL-R in Ovx animals is, however, puzzling considering that a decrease in PCSK9 should lead to an increase in LDL-R. It has been proposed that the rate of cycling of hepatic LDL-R on cell surface might be an explanation. When hepatic cholesterol increases, as it is observed in Ovx animals<sup>[11,14]</sup>, the transcriptional regulation of PCSK9 and LDL-R both mediated by SREBP-2 would be inhibited, and the rate of cycling of the hepatic LDL-R slowed down leading to higher levels in circulating LDL-cholesterol. The transcriptional regulation of the LDL-R is, however, paradoxical since SREBP-2 also regulates the transcription of PCSK9, thus leading to two opposing effects initiated by the same signal. In a recent publication, Starr *et al*<sup>[67]</sup> proposed a more dynamic role for PCSK9, suggesting that phosphorylated PCSK9 promotes degradation of LDL-R, whereas nonphosphorylated PCSK9 is in an LDL-R-protective state. Taken together, these results emphasize

the need to a better understanding of the sex specific interaction between LDL-R and PCSK9, especially in view of a new class of cholesterol lowering drugs, the PCSK9 inhibitors<sup>[68]</sup>.

**Metabolism of the LRP1 receptor:** LRP1 is a member of the *LDL-R* gene family which also includes receptors such as LRP2 (megalin), LRP8 (apoE receptor 2), and the VLDL receptor (VLDLR)<sup>[69]</sup>. LRP1 is expressed in several types of cells including hepatocytes, fibroblasts, smooth muscle cells, and neurons<sup>[70]</sup>. This transmembrane protein displays both scavenging and signaling functions. LRP1 mediates removal of at least 30 different ligands, including VLDL remnants or IDL and chylomicron remnants from the circulation<sup>[71]</sup>, but also several molecules unrelated to lipid homeostasis including proteases, protease inhibitor complexes, extracellular matrix proteins, growth factors, toxins, and viral proteins<sup>[72]</sup>. LRP1 also acts as an endocytic receptor for several intracellular proteins released by necrotic cells, which failure to be efficiently cleared may be associated with the onset of autoimmune disease<sup>[73,74]</sup>. Interestingly, LRP1, by regulating cell signaling through several mechanisms, may change the activity of other receptors by controlling the abundance of these receptors in the plasma membrane<sup>[75]</sup>. For instance, disruption of the LRP gene in adult normal mice resulted in a compensatory upregulation of the LDL-R in the liver<sup>[76]</sup>.

The gene expression of LRP1 is complex and appears to be regulated by hormones and growth factors<sup>[77]</sup>. LRP1, as well as other members of the LDL-R family, are bound by a molecule called receptor-associated protein (RAP) that blocks the bindings of ligands to these receptors<sup>[78]</sup>. RAP functions as a molecular chaperone that assists in the trafficking of the LRP1 to the cell surface<sup>[79]</sup>. In different tissues, LRP1 gene expression has been reported to be affected by factors such as hypercholesterolemia, lipopolysaccharides, growth factors, and hypoxia (for a review see<sup>[80]</sup>). Hepatic LRP1 expression has been reported to be negatively associated with intracellular cholesterol level and positively associated with expression of SREBP-2<sup>[81]</sup>. On the whole, LRP1 may be seen as a complex biosensor allowing the cells to answer to micro-environmental variations<sup>[80]</sup>.

**Estrogen deficiency and LRP1 receptor:** A reduction in gene expression of LRP1 in Ovx rats was first reported by Ngo Sock *et al*<sup>[14]</sup> and confirmed in recent studies at the protein levels<sup>[15]</sup>. This decrease in LRP1 in Ovx animals may be associated with the decrease in the SREBP-2 transcription factor<sup>[81]</sup>. Interestingly, it has been recently reported that LRP1 is also a target for PCSK9 in HepG2 cells<sup>[82]</sup>. These authors postulated that LDL-R can effectively compete with LRP1 for PCSK9 activity. A reduction in *LRP1* gene expression could contribute to the increase in plasma cholesterol in Ovx rats by reducing the uptake of circulating lipoprotein remnants. Finally, inducible degrader of the low-density lipoprotein receptor an ubiquitin ligase that also me-

diates the degradation of the LDL-R was found not to be affected by an ovariectomy<sup>[66]</sup>.

### VLDLR

In addition to LRP, the LDL-R gene family includes a further member that functions as receptor for VLDL<sup>[83]</sup>. The VLDLR is expressed in several tissues including heart, muscle, adipose tissue, and macrophages but barely detectable in liver under normal conditions<sup>[83,84]</sup>. This receptor has been suggested to be important for the metabolism of apoE-containing triacylglycerol-rich lipoproteins, such as VLDL and IDL.

Interestingly, circulating PCSK9 originating from liver can regulate VLDLR in adipose tissue, which tissue does not express PCSK9<sup>[57]</sup>. In that manner, the absence of circulating PCSK9 resulted in an increase in the level of surface of VLDLR in the perigonadal tissue<sup>[57]</sup>. Interestingly, the increase was 10 times higher in female than in male mice<sup>[57]</sup>. This response was in line with the typical female pattern in mice that implies a high surface VLDLR levels in perigonadal fat and low surface LDLR levels in hepatocytes<sup>[66]</sup>.

### Hepatic cholesterol uptake from HDL

HDL is a class of lipoproteins that is able to remove excess cholesterol from cells and transport it through plasma to the liver. The apoA1 is the major structural determinant of HDL. It is involved in the formation as well as in the interaction with its receptor, scavenger receptor class B, type 1 (SR-B1)<sup>[85]</sup>. HDL formation occurs mainly in the liver and to a lesser extent in the intestine<sup>[85]</sup>. The events start when lipid-poor apoA1 is secreted by the liver or the intestine<sup>[86]</sup> or dissociates from lipoprotein particles in the plasma<sup>[87]</sup>. ApoA1 interacts with the membrane-embedded ATP binding cassette A1 (ABCA1) and incorporates small amount of phospholipids and unesterified cholesterol into the apoA1 molecule<sup>[88]</sup>. Maturation of these pre $\beta$ HDL in the plasma occurs due to two enzymes, lecithin: Cholesterol acyl transferase (LCAT) that esterifies cholesterol and phospholipid transfer protein (PLTP) that transfers phospholipids from remnant particles to HDL.

HDLs have the ability of removing excess cholesterol from cells. The first mechanism involved the action of pre $\beta$ HDL interacting with ABCA1 that in addition of forming a new HDL by the liver is used to remove excess cholesterol from macrophages<sup>[89]</sup>. Spherical mature HDL may remove cholesterol from cells using several mechanisms. The particle may interact with SR-B1 on the plasma membrane. Macrophages also express ABCG1 transporters that mediate transfer of excess cholesterol to HDL. Finally excess cholesterol from cells may also efflux in absence of binding to transport protein, travels short distance through plasma and be taken up by HDL<sup>[25]</sup>. The activity of LCAT and PLTP prevents the HDL from being saturated with cholesterol. The enzyme cholesterol ester transfer protein (CETP) that transfer cholesteryl ester molecules from HDL to remnant particles in exchange for TG also increases the capacity of HDL to accept

unesterified cholesterol from cells.

HDLs circulating to the liver interact with SR-B1 the main HDL receptor<sup>[90]</sup>. SR-B1 in the liver facilitates the uptake of cholesterol and cholesterol esters from the HDL particle without the apoA1<sup>[86]</sup>. ApoA1 may then be recycled to form a new pre $\beta$ HDL. The action of SR-B1 is facilitated by the hydrolysis of TG by the hepatic lipase. The adrenal gland and gonads also highly express SR-B1 most likely due to their requirement in cholesterol<sup>[86]</sup>.

HDLs are considered limiting for the reverse cholesterol transport because it is assumed that they deliver peripheral cholesterol to the liver for biliary secretion and eventually fecal excretion<sup>[91,92]</sup>. As discussed by Temel and Brown<sup>[93]</sup>, however, there is evidence that HDL-driven cholesterol efflux does not correlate with how much is lost in bile or in the feces. Mice genetically lacking ApoA1 or ABCA1 and, therefore having very low circulating levels of HDL, or showing different steady-state concentrations of HDL-C have normal biliary and fecal cholesterol loss<sup>[94,95]</sup>. Some authors argue that apoB-containing lipoproteins and particularly the activity of CETP play a substantial role in reverse cholesterol transport<sup>[96]</sup>.

#### Estrogen deficiency and hepatic HDL receptor:

SR-B1 mRNA in liver that allows the return of cholesterol to liver *via* HDL was reported to be higher in Ovx compared to Sham rats<sup>[14]</sup>. Interestingly, *ABCA1* gene expression, involved in biosynthesis of nascent HDL was also found to be increased in Ovx rats<sup>[14]</sup>. An increase in gene expression of *ABCA1* was also found in jejunum of Ovx rats<sup>[14]</sup>. Although limited, these findings point to the direction as if the hepatic contribution to HDL metabolism was increased with estrogen withdrawal.

## HEPATIC CHOLESTEROL EFFLUX

There are essentially two ways by which liver can excrete cholesterol: (1) secretion of unmodified cholesterol or after its transformation in bile salts into bile caniculi; and (2) through VLDL secretion.

#### Hepatic cholesterol-bile acid metabolism

The liver is the only organ that has ability to eliminate cholesterol through its secretion into bile or its transformation into bile salts. Bile acids synthesis from cholesterol is stimulated by the nuclear factor liver X receptor (LXR) through its target gene cytochrome P450, family 7, subfamily a, polypeptide 1 (CYP7A1), the main enzyme in the conversion of cholesterol into bile acids<sup>[97]</sup>. The synthesis of a full complement of bile acids requires 17 enzymes<sup>[98]</sup>. The bile acid pool size is reduced by 75% in mice deficient in CYP7A1<sup>[99]</sup>. An alternative biosynthetic pathway is initiated by the enzyme cholesterol 27 $\alpha$ -hydroxylase (Cyp27 $\alpha$ 1<sup>[99]</sup>). Bile salts are highly soluble in water. They form aggregate with phospholipids derived from hepatocyte membranes and solubilize cholesterol in bile for transport from liver to intestine<sup>[100]</sup>. Nuclear factor farnesoid X receptor (FXR) activated by bile acids, stimulates bile and cholesterol

efflux from liver. Opposite to LXR, FXR suppresses bile acids synthesis by inhibiting Cyp7A1. At the canalicular membrane of the hepatocytes, bile salts are pump into bile by a membrane transporter, ABCB11, also referred to as bile salt export pump (BSEP) and to a lesser extent by the multidrug resistance-associated protein 2 (MDR2; ABCC2<sup>[101]</sup>), which activates two other transporters, ABCB4 involved in the transport of phospholipids and ABCG5/G8 a heterodimer involved in the secretion of cholesterol<sup>[102-104]</sup>. Alternative mechanisms to ABCG5/G8 cholesterol secretion involve ATP8B1 and diffusion<sup>[105]</sup>. Altogether bile salts and phospholipids form micelles which are stored in the gall bladder during fasting. In addition, bile salts may be exported to the blood at the sinusoidal membrane mediated by MRP3 (ABCC3) and MRP4 (ABCC4), as well as the organic solute transporter OST  $\alpha/\beta$ <sup>[106]</sup>. Conversion of cholesterol to bile salts accounts for about 50% of daily cholesterol excretion<sup>[107]</sup>.

#### Estrogen deficiency and hepatic cholesterol-bile acid metabolism:

Cyp7A1 and Cyp8b1 transcripts have been reported to be decreased in Ovx rats and mice<sup>[6,11,13,43]</sup> suggesting a reduction in cholesterol elimination *via* bile acid formation. This decrease has been found in Ovx rats fed a standard diet and even more so when Ovx rats were fed a high-fat (42%) diet<sup>[6]</sup>. On the opposite, estrogen treatment has been reported to result in an increase in biliary cholesterol hypersecretion in mice<sup>[4]</sup>.

Estrogen deficiency was associated with lower transcript levels of BSEP and MDR2 suggesting that, in addition to synthesis, excretion of bile acids from hepatocytes to caniculi was decreased in Ovx rats<sup>[15,43]</sup>. Furthermore, the gene expression of nuclear receptors FXR and LXR was found to be lower in Ovx compared to Sham animals<sup>[43]</sup>. The decrease in gene expression of FXR suggests that bile acids did not accumulate in liver of Ovx rats. FXR mRNA levels are controlled by bile acids<sup>[108]</sup>. The specific role of hepatic FXR is to prevent bile acid hepato-toxicity by initiating the expression of a gene network involved in the synthesis and excretion of bile acids. Accordingly, FXR-null mice show massive accumulation of cholesterol in hepatocytes<sup>[109]</sup>. The indication that bile acid metabolism is disrupted in Ovx rats may in turn favours cholesterol accumulation in liver since bile acid secretion exerts a driven force for biliary cholesterol excretion<sup>[110]</sup>. Supporting the hypothesis that biliary metabolic pathways are indeed disrupted in Ovx animals is the finding of a decrease in total bile production in Ovx rats<sup>[111]</sup>.

Gene expression of ABCG5/G8 transporters involved in exportation of cholesterol from the liver to the bile ducts was unchanged in Ovx compared to Sham rats<sup>[6,15,43]</sup> and in aromatase knockout mice<sup>[112]</sup> suggesting that these transporters are not regulated by estrogens.

#### Hepatic excretion of cholesterol through VLDL

VLDL assembly in liver is initiated by the entry of apoB100 in the lumen of the endoplasmic reticulum<sup>[113]</sup>.

The apoB protein is lipidated by the action of microsomal transfer protein (MTP) accumulating TG as well as cholesterol esters molecules. Besides MTP and apoB100, other molecular markers of VLDL assembly include diacylglycerol acyltransferase 2 (DGAT2), involved in the reesterification of TG<sup>[114]</sup>, and acyl-CoA: Cholesterol acyltransferase 2 (ACAT2) that converts free cholesterol into cholesterol esters<sup>[115]</sup>. Further lipidation of the VLDL particles after they exit the endoplasmic reticulum compartment is carried on by a lipid droplet-associated protein, cell death-inducing DNA fragmentation factor alpha-like-effector B (Cideb)<sup>[116]</sup>. The importance of Cideb has been enlightened by the finding of a reduction in plasma LDL levels in Cideb-null mice<sup>[117]</sup>. However, hepatic cholesterol storage was increased in liver of these animals due to its increased LDL-R and ACAT expression. Finally, small GTP binding protein (Sar1a), an intracellular vesicular trafficking protein, facilitates the movements of VLDL particles between the endoplasmic reticulum and the Golgi apparatus where they are secreted in the plasma.

#### **Estrogen deficiency and hepatic VLDL metabolism:**

The observation that plasma cholesterol level is increased in OvX animals<sup>[6,11]</sup> might suggest an increased cholesterol excretion through VLDL. On the opposite, a decrease in VLDL-TG production has been reported in estrogen-deficient animals<sup>[118,119]</sup>. Supporting such a decrease in VLDL production at the molecular level is the repeatedly reported decrease in gene expression of MTP, the rate-limiting molecule for VLDL assembly and secretion, in OvX animals<sup>[15,43,118]</sup>. Transcripts of other genes involved in VLDL synthesis, including apoB, DGAT2, ACAT2, Cideb, and Sar1a have also been reported to be decreased in OvX rats fed a standard diet<sup>[15,43]</sup> and even more so for some genes (MTP and apoB100) in OvX rats fed an enriched-cholesterol diet<sup>[15]</sup>. The additive effect of estrogen withdrawal and high-cholesterol diet on reducing markers of VLDL production was corroborated by an accumulation of total cholesterol and TG in liver and lower levels of these two forms of lipids in plasma<sup>[15]</sup>. In search of an explanation for the postulated reduced VLDL production in OvX rats fed the cholesterol diet, it has been suggested that cholesterol may induce ER stress through cholesterol accumulation<sup>[120]</sup> and that ER stress limits VLDL assembly and secretion through apoB degradation<sup>[121]</sup>. Collectively, these results points toward the interpretation that VLDL assembly is disrupted upon ovariectomy leading to reduced excretion of TG and cholesterol from the liver, thus contributing to exacerbate liver fat and cholesterol accumulation<sup>[14,15]</sup>.

Molecular mechanisms by which estrogens regulate transcription of target genes involved in VLDL pathway are not well known. The classical genomic mechanism of estrogen action involves activation of its nuclear receptor (ER $\alpha$  and  $\beta$ ) and subsequent binding to estrogen response elements located in the promoters of target genes<sup>[122,123]</sup>. Estrogens have also been shown to have non-genomic actions mediated through a subpopulation

of ER $\alpha$  and  $\beta$  located at the plasma membrane<sup>[124]</sup>. It is thus possible that estrogens affect expression of target genes involved in different metabolic pathways through interaction in the nucleus and/or activation of signal transduction pathways at the plasma membrane.

#### **Intestinal excretion of biliary cholesterol**

As mentioned above, hepatic cholesterol is secreted into bile unmodified or after its conversion into bile salts. These bile salts participate in cholesterol transport and eventually in fat digestion in the intestine. However, rather than being lost in the feces, most of the bile salts are recycled when they are taken up by transport proteins in the distal ileum. FXR controls the absorption of bile acids in the intestine through the regulation of bile acid transporters from the intestine to the portal system<sup>[125]</sup>. These include apical sodium-dependent bile acid transporter, the ileal bile acid binding protein, and at the basolateral membrane of enterocytes the heterodimeric organic solute transporters  $\alpha$  and  $\beta$  (OST $\alpha$ , OST $\beta$ )<sup>[126,127]</sup>. Bile salts picked up by these transporters enter the portal circulation and are transported back to the liver where they are eventually re-secreted into bile. This process of recycling back the bile salts between the intestine and the liver is called the enterohepatic circulation<sup>[128]</sup>. The Na<sup>+</sup>-taurocholate cotransporting polypeptide (NTCP) is the major uptake system to transport bile salts from the blood into parenchymal cells<sup>[129]</sup>. Together with several organic anions transporting polypeptide, it controls bile salt uptake at the sinusoidal membrane<sup>[130]</sup>. Bile salt accumulation down-regulates NTCP at the transcriptional level mediated by FXR and the short heterodimer partner 1<sup>[131]</sup>.

Less than 10% of transported bile salts are lost in the feces (0.4 g/d)<sup>[132]</sup>. Therefore, dietary cholesterol (0.4 g/d) constitutes only 25% compared to endogenous cholesterol (1.2 g/d) that passes through intestine in one day<sup>[133]</sup>. Coordination between intestinal bile acids levels and hepatic bile acids biosynthesis is assured through the intestinal secretion of fibroblast growth factor 15/19 that inhibits Cyp7 $\alpha$ 1 in liver under FXR activation<sup>[134]</sup>.

**Excretion of intestinal absorbed cholesterol:** The cellular mechanisms by which chylomicrons in the intestine and VLDL in the liver are assembly are very similar. Their assembly depends of the availability of apoB, triglycerides, and the TG transfer protein MTP. However, opposite to liver, enterocytes express a protein called apoB editing complex-1<sup>[135]</sup>. As a result of the action of this enzyme, translation of apoB comes to a premature stop making intestinal apoB in the intestine 48% as long as the protein expressed in the liver (apoB100). Cholesteryl esters added to the core molecule of chylomicrons come from biliary acids (75%) and from dietary sources. During digestion, cholesteryl esters in food are hydrolyzed to form unesterified cholesterol<sup>[136]</sup>. Dietary and biliary cholesterol from micelles enter the enterocytes mainly (80%) *via* a protein channel, Neimann-Pick C-1 like 1 protein (NPC1L1)<sup>[137]</sup>. Some of

this cholesterol is immediately pumped back into the lumen by the heterodimer transporter ABCG5/G8<sup>[138]</sup>. A portion of cholesterol is also transferred to apoA1 by the ABCA1 transporter to form a nascent HDL. The fraction of cholesterol remaining is esterified to a long-chain fatty acid by ACAT2<sup>[139]</sup>.

**Estrogen deficiency and intestinal bile acid-cholesterol metabolism:** The information is rather limited in regard to biliary cholesterol metabolism in the intestine. A greater faecal excretion of bile acids has been reported in Ovx rats<sup>[11]</sup>. The authors explain this response by suggesting a decreased reabsorption of bile acids from the ileum through a decrease in bile acid transporters. Gene expression of Ntcp, the major uptake system to transport bile salts from the blood into parenchymal cells, was found to be unchanged in Ovx compared to Sham rats<sup>[15]</sup>. On the other hand, gene expression of ABCA1 was reported to be increased in jejunum of Ovx rats, suggesting an increased efflux of intestinal cholesterol through HDL synthesis in Ovx animals<sup>[14]</sup>.

#### **Transintestinal cholesterol excretion**

The hepatobiliary pathway also referred to as the reverse cholesterol transport pathway is considered the major elimination cholesterol route. Nevertheless, fecal cholesterol excretion was observed in several states of disturbances in cholesterol biliary excretion supporting the existence of a new route for cholesterol excretion<sup>[140-142]</sup>. In other words, a large part of the cholesterol found in the feces originates from a source other than bile and diet. The non-biliary alternative called the transintestinal cholesterol excretion pathway implies the direct secretion of plasma lipoprotein-derived cholesterol by the small intestine<sup>[94,143,144]</sup>. Among the numerous studies on transintestinal cholesterol excretion (TICE), there is some agreement that under normal conditions TICE contributes to less than 30% of cholesterol found in the feces (for a review see<sup>[93]</sup>). However, the TICE pathway may be stimulated under pathophysiological or pharmacological conditions. For instance, intestinal cholesterol excretion is inducible by a high-fat diet<sup>[145]</sup> or pharmacologically by ligands of LXR<sup>[146]</sup>. The importance of the role of TICE has been recently highlighted by the demonstration that TICE is essential to macrophage reverse cholesterol transport in mice<sup>[142]</sup>.

It seems that the liver initiates the activation of the TICE<sup>[93]</sup>. Findings in mice with impaired hepatobiliary cholesterol excretion indicate that cholesterol is first transported to the liver before being delivered to the intestine<sup>[93]</sup>. Temel and Brown<sup>[93]</sup> summarized evidence that indicate that it is the subsequent steps within the liver that determine the amount of cholesterol eliminated through the biliary and non-biliary excretory mechanism. The excess cholesterol is most likely repacked into apoB rich lipoproteins secreted by the liver. These liver-derived apoB-containing lipoproteins are recognized by the proximal small intestine through LDL-R and probably

other mechanisms<sup>[147]</sup>. Le May *et al*<sup>[147]</sup> provided data suggesting that PCSK9 is a repressor of TICE dependent on the LDL-R. They also demonstrated that both LDL and HDL (possibly through SR-B1 transporter) provided cholesterol to TICE. Once the free cholesterol is liberated from the TICE lipoproteins, it may efflux from the apical side of the enterocyte through the ABCG5/G8 transporters or the multidrug transporter ABCG1a/b<sup>[93]</sup>.

## **EFFECTS OF EXERCISE TRAINING ON LIVER AND INTESTINAL CHOLESTEROL METABOLISM**

The main finding supporting the contention that exercise training improves lipid and cholesterol metabolism is the reported increase in plasma HDL levels and the concomitant decrease in LDL-cholesterol and triglycerides in human studies<sup>[148,149]</sup>. In animals, positive effects of exercise training on the outcome of disturbances in lipid and cholesterol metabolism has been demonstrated by Ramachandran *et al*<sup>[150]</sup> who reported a 50% reduction in pre-existing atherosclerotic lesions in LDL-R KO mice. Similarly, Matsumoto *et al*<sup>[151]</sup> reported that exercise training in LDL-R KO mice prevented aortic valve sclerosis. These authors specified that exercise exerted several numerous favourable effects that include preservation of valvular endothelial integrity, reduced recruitment of inflammatory cells, and oxidative stress. A decrease in aortic lesion size was also reported by Meissner *et al*<sup>[21]</sup> after 12 wk of voluntary running wheel in LDL-R deficient mice.

However, as mentioned by Meissner *et al*<sup>[152]</sup>, the molecular pathways behind such exercise-induced improvements in plasma lipids are not well defined. In addition, the analysis of the effects of exercise training on the molecular components of cholesterol metabolism in liver is complicated by the variety of animal models used.

#### **HMGCoA-r and exercise training**

There is a paucity of information on the effects of exercise training on cholesterol biosynthesis. Ngo Sock *et al*<sup>[14]</sup> reported that training (8 wk) did not appear to have any effect on HMGCoA-r as well as on SREBP-2 transcripts whether in Sham or in Ovx rats. Previously, Meissner *et al*<sup>[152]</sup> reported an increase in lanosterol/cholesterol ratio in mice submitted to two weeks of voluntary exercise suggesting an increase in cholesterol biosynthesis. However, the same group of authors reported a decrease in HMGCoA-r after 12 wk of voluntary wheel running in LDL-R deficient mice<sup>[21]</sup>. On the whole, there is no clear indication that hepatic cholesterol biosynthesis is changed with exercise training.

#### **LDL-R and exercise training**

Using CETP transgenic mice, an animal model that simulates reverse cholesterol transport (RCT) in human, Rocco *et al*<sup>[153]</sup> found an increase in hepatic LDL-R protein

levels following 6 wk of treadmill exercise. Using this animal model they also found that exercise training improved macrophage RCT. An increase in *LDL-R* gene expression in liver of normal mice exercised for two weeks had been previously found<sup>[154]</sup>. At the same time, Wilund *et al*<sup>[155]</sup> reported an increase in *LDL-R* gene expression and a reduction in gallstone development in gallstone-sensitive mice fed a lithogenic diet after 12 wk of exercise training.

In a recent study, Wen *et al*<sup>[156]</sup> found that treadmill exercise for 8 wk resulted in an increase in PCSK9, *LDL-R*, and SREBP-2 mRNA in high-fat fed mice. On the other hand, they found a reduction in plasma PCSK9 levels and no difference in *LDL-R* protein abundance. They attributed these latter responses to the lower levels of circulating *LDL-C* in trained animals.

In other respects, exercise training (8 wk) did not alter *LDL-R*, *PCSK9*, and *LRP1* gene expression in Sham rats as well as being ineffective in correcting reductions in these molecular markers in Ovx rats<sup>[14]</sup>. On the opposite, Pinto *et al*<sup>[157]</sup> recently reported an increase in *LDL-R* protein levels in male mice trained for 6 wk. Taken together, there is indication that exercise training may favour liver cholesterol uptake from circulation through *LDL-R* thus, supporting the general finding of a reduction in circulating *LDL-C* in human<sup>[149]</sup>.

#### **HDL metabolism and exercise training**

Exercise training (8 wk) did not influence SR-B1 and ABCA1 responses in Sham as well as in Ovx rats<sup>[14]</sup>. On the other hand, an increase in ABCA1 mRNA had previously been reported following 6 wk of treadmill exercise in rats accompanied by an increase in plasma HDL-C concentration<sup>[158]</sup>.

Two weeks of exercise training resulted in an increase in SR-B1 in livers of exercised mice<sup>[154]</sup>. Wilund *et al*<sup>[155]</sup> also reported an increase in *SR-B1* gene expression and a reduction in gallstone development in gallstone-sensitive mice fed a lithogenic diet after 12 wk of exercise training. An increase in SR-B1 protein level in liver has also been reported in male mice trained for 6 wk along with the demonstration of an increased macrophage cholesterol flux to the liver<sup>[157]</sup>.

In CETP transgenic mice, Rocco *et al*<sup>[153]</sup> found an increase in hepatic ABCA1 protein levels following 6 wk of treadmill exercise but no effects on SR-B1. On the whole, it appears that exercise training stimulates positive adaptations of molecular markers of HDL metabolism that would tend to support the finding of an increase circulating HDL levels with exercise training in human<sup>[149]</sup>.

#### **Bile acids and exercise training**

Wilund *et al*<sup>[155]</sup> reported an increase in gene expression of Cyp27A1 in mice fed a lithogenic diet after 12 wk of exercise training. On the opposite, Meissner *et al*<sup>[21,152]</sup> did not observe any effects of exercise on key genes expression involved in bile acid synthesis (*CYP7A1*, *CYP8B1*, and *CYP27A1*) in mice despite an increased fecal bile acid and cholesterol excretion, leading the authors to assume

a posttranscriptional regulation of these genes. The authors hypothesized that physical activity might increase bile acid synthesis to increase the capacity for micelle formation, thus increasing fatty acid absorption<sup>[21]</sup>. More recently, Pinto *et al*<sup>[157]</sup> reported an increase in *CYP7A1* gene expression in male mice trained for 6 wk. On the whole the existing molecular data would tend to support the physiological finding of an increase in fecal bile acid and cholesterol excretion in exercise trained animals.

#### **VLDL and exercise training**

There is a report that VLDL-TG secretion rate is reduced in human following exercise training<sup>[159]</sup>. A decrease in VLDL-TG accumulation and apoB mRNA after exercise training has also been reported in male Wistar rats<sup>[160]</sup>. Accordingly, liver MTP protein content has been found to be decreased with exercise training in mice<sup>[21]</sup> and in standard and high-fat fed female Sprague-Dawley strain rats<sup>[161]</sup>. Since liver fat accumulation is reduced with exercise training<sup>[162]</sup>, the latter authors argue that the reduced liver VLDL production induced by regular exercise is a consequence of an increased lipid disposal through oxidation<sup>[163]</sup>. It is also possible that an increased hepatic insulin sensitivity following exercise training may have resulted in a decrease in VLDL-TG synthesis and secretion. It is well documented that insulin suppresses the secretion of VLDL particles by the liver<sup>[164]</sup> and *MTP* gene expression has been reported to be reduced by insulin in culture liver cells<sup>[165]</sup>.

Plasma VLDL-TG levels have also been reported to be reduced following exercise training in Ovx rats for which VLDL-TG levels were already reduced<sup>[118]</sup>. This suggests that the effects of exercise training and estrogen withdrawal on VLDL-TG synthesis and/or secretion are additive and most likely take place through different pathways. On the other hand, the reduction in VLDL-TG production with exercise training in Ovx rats did not result in an accumulation of liver TG<sup>[118]</sup>. This was explained by the fact that exercise training increases the use of lipids, therefore, reducing fat delivery to the liver.

#### **Intestinal markers and exercise training**

Gene expression of ABCA1 was reported to be increased in jejunum of Ovx rats but unchanged by exercise training (8 wk)<sup>[14]</sup>. On the other hand, the same group of authors found an increase in ABCA1 in ileum of 8-wk trained rats<sup>[22]</sup>. An increase in ABCA1 mRNA in the upper part of the small intestine in Wistar rats trained for 6 wk had been previously reported<sup>[166]</sup>. Although limited, these findings concord with what has been found in liver and suggest that HDL synthesis from the intestine is increased following exercise training.

Wilund *et al*<sup>[155]</sup> found a decrease in *NPC1L1* and *ABCG5/G8* gene expression in duodenum of mice after 12 wk of exercise training. The authors explain that the reduction in *ABCG5/G8* might have been the consequence of the reduction in *NPC1L1* and less cholesterol transported into the enterocytes. A decrease in *NPC1L1* and *ABCG5/G8* was also recently reported in the ileum of

8-wk trained rats<sup>[22]</sup>.

On the other hand, Meissner *et al*<sup>[152]</sup> reported an increase in fecal bile and cholesterol loss and a decrease in jejunal NPC1L1, suggesting a decrease intestinal cholesterol absorption, in male mice submitted to voluntary exercise for two weeks. Running mice also displayed lower ileal OST $\alpha$ , OST $\beta$ , and NTCP transporters, all involved in the enterohepatic circulation of bile acids. However, running did not affect mRNA levels of cholesterol efflux ABCG5/G8 in jejunum. On the whole these authors<sup>[152]</sup> reached the conclusion of an increase cholesterol turnover with regular exercise. In a subsequent study, Meissner *et al*<sup>[21]</sup> found a massive fecal bile acid loss in hypercholesterolemic LDL-R deficient mice trained for 12 wk. Decreases in ileal OST $\alpha$  and OST $\beta$  mRNA have also been reported in 8-wk trained rats along with a decrease in FXR transcription factor indicating that the need to protect the intestine against bile acid overload is reduced in trained animals<sup>[22]</sup>. Finally, Ngo Sock *et al*<sup>[22]</sup> found a decrease in pregnane X receptor (PXR) mRNA in ileum of trained rats. Since PXR receptors protect organisms from exogenous chemical insults, and several endobiotics such as lipids, steroids, and bile acids<sup>[167]</sup>, the authors advocate that exercise training contributes to the maintenance of cholesterol and bile acid homeostasis<sup>[22]</sup>.

On the whole it appears that, at the molecular level, exercise training would contribute to the maintenance of normal circulating cholesterol levels by increasing hepatic LDL-R and HDL metabolism and by favouring adaptations to bile acid metabolism that stimulate fecal bile and cholesterol excretion. When discussing the effects of exercise training on cholesterol metabolism one has to consider that on contrary of fatty acids and glucose or glycogen, cholesterol is not metabolized during exercise. Therefore, it might be an interesting avenue to look at the impact of exercise training on cholesterol metabolism through its link with lipid and glucose metabolism such as intestinal lipid absorption or hepatic *de novo* lipogenesis.

## IN SUMMARY (ESTROGEN DEFICIENCY EFFECTS)

*HMGCoA-r* gene expression in liver along with its transcription factor SREBP-2 is decreased in Ovx animals suggesting a decrease in cholesterol synthesis. There are also indications that bile acid synthesis (*i.e.*, CYP7A1) and transporters of bile acid excretion into caniculi (*i.e.*, BSEP) are also decreased with estrogen deficiency. The reduction in hepatic bile acid metabolism would support the finding that total bile production is reduced in Ovx rats<sup>[111]</sup>.

Although it has been shown that hepatic PCSK9 as well as SREBP-2 and LDL-R mRNA levels are reduced in estrogen deficient animals, there is on the whole data supporting the contention that LDL-R protein levels are increased in Ovx animals most likely associated with a reduction in *PCSK9* gene expression. Although it is

difficult at the present time to reconcile clearly the impact of the absence of estrogens on the dynamics of hepatic PCSK9 and LDL-R and its consequence on plasma LDL-cholesterol, it is evident that estrogen levels play a critical role. The sex specific interaction between LDL-R and PCSK9 would be particularly relevant to post-menopausal women, especially in view of a new class of cholesterol lowering drugs, the PCSK9 inhibitors<sup>[68]</sup>.

There are also data supporting the finding that VLDL and HDL metabolism are changed with the absence of estrogens. VLDL production and its main regulatory factor (MTP) have been repeatedly reported to be decreased in Ovx animals. On the other hand, increases in SR-B1 and ABCA1 mRNA in liver of Ovx animals support the contention that HDL metabolism is increased in these animals. An increase in ABCA1 in intestine suggesting an increase in HDL biosynthesis has also been reported<sup>[14]</sup>.

Although it is obvious that more work has to be done to clearly understand the changes in cholesterol and bile acid metabolism in liver and intestine with the absence of estrogens, the data actually available in Ovx models tend to indicate an increase in cholesterol influx into the liver and a decrease in cholesterol efflux.

### Abstract

**AIM:** To investigate the effect of microRNA on insulin-like growth factor binding protein-3 (IGFBP-3) and hence on insulin-like growth factor- II (IGF- II) bioavailability in hepatocellular carcinoma (HCC).

**METHODS:** Bioinformatic analysis was performed using microrna.org, DIANA lab and Segal lab softwares. Total RNA was extracted from 23 HCC and 10 healthy liver tissues using mirVana miRNA Isolation Kit. microRNA-17-5p (miR-17-5p) expression was mimicked and antagonized in HuH-7 cell lines using HiPerFect

Transfection Reagent, then total RNA was extracted using Biozol reagent then reverse transcribed into cDNA followed by quantification of miR-17-5p and IGFBP-3 expression using TaqMan real-time quantitative PCR. Luciferase reporter assay was performed to validate the binding of miR-17-5p to the 3'UTR of IGFBP-3. Free IGF- II protein was measured in transfected HuH-7 cells using IGF- II ELISA kit.

**RESULTS:** Bioinformatic analysis revealed IGFBP-3 as a potential target for miR-17-5p. Screening of miR-17-5p and IGFBP-3 revealed a moderate negative correlation in HCC patients, where miR-17-5p was extensively underexpressed in HCC tissues ( $P = 0.0012$ ), while IGFBP-3 showed significant upregulation in the same set of patients ( $P = 0.0041$ ) compared to healthy donors. Forcing miR-17-5p expression in HuH-7 cell lines showed a significant downregulation of IGFBP-3 mRNA expression ( $P = 0.0267$ ) and a significant increase in free IGF- II protein ( $P = 0.0339$ ) compared to mock untransfected cells using unpaired *t*-test. Luciferase assay validated IGFBP-3 as a direct target of miR-17-5p; luciferase activity was inhibited by 27.5% in cells co-transfected with miR-17-5p mimics and the construct harboring the wild-type binding region 2 of IGFBP-3 compared to cells transfected with this construct alone ( $P = 0.0474$ ).

**CONCLUSION:** These data suggest that regulating IGF- II bioavailability and hence HCC progression can be achieved through targeting IGFBP-3 *via* manipulating the expression of miRNAs.

**Key words:** Insulin-like growth factor binding protein-3; Insulin-like growth factor signaling pathway; MicroRNA; Insulin-like growth factor- II ; Hepatocellular carcinoma

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** microRNA-17-5p (miR-17-5p) was extensively underexpressed in hepatocellular carcinoma tissues, while insulin-like growth factor binding protein-3 (IGFBP-3) mRNA showed significant upregulation in the same set of patients. In HuH-7 cell line, miR-17-5p directly targets and downregulates IGFBP-3, consequently elevating the level of free insulin-like growth factor- II (IGF- II). Thus, manipulation of microRNAs can potentially control the activation of the oncogenic IGF axis.

## INTRODUCTION

The insulin-like growth factor (IGF) signaling pathway

is composed of IGF ligands, IGF receptors and insulin-like growth factor binding proteins (IGFBPs) which work in unison to regulate cell growth, differentiation, proliferation, and apoptosis. This axis is activated when the IGFs, IGF- I and IGF- II , bind to the insulin-like growth factor-1 receptor (IGF-1R) and activate a series of downstream signaling pathways controlling the cell cycle<sup>[1,2]</sup>. IGFBPs are transport proteins which bind to IGF- II with high affinity thereby prolonging their half-life and circulation turnover, and negatively regulate the activity of IGFs by controlling their binding to IGF receptors<sup>[3]</sup>. The levels of IGFBPs are modulated by various IGFBP proteases, such as matrix metalloproteinases (MMPs), which regulate the bioavailability and activity of IGFBPs, by mediating their proteolytic cleavage<sup>[4]</sup>.

Multiple IGF axis members were found to play an important role in hepatocellular carcinoma (HCC) pathogenesis. IGF- II was found to be overexpressed in HCC and to promote tumor cell migration, proliferation and extra-hepatic metastasis<sup>[5-8]</sup>. Moreover, our research group has shown IGF- II to be overexpressed in peripheral blood monocytes of HCC patients, and this aberrant expression was directly correlated with elevated serum levels of alfa-fetoprotein and poor prognosis<sup>[9]</sup>. IGF-1R was reported to be upregulated in 59% of HCC tissues in which it was associated with poor prognosis and tumors exceeding the Milan criteria<sup>[10]</sup>. The tumorigenic effect of IGF-1R was reversed through its efficient blockage by combination of two IGF-1R antibodies which dramatically reduced liver tumor growth<sup>[11]</sup>. On the other hand, IGFBP-3 expression was found to be inversely correlated to HCC metastasis and proliferation<sup>[12,13]</sup>.

The potential regulation of IGF axis members by microRNAs is an appealing subject of investigation. We have previously shown that miR-615-5p downregulates IGF- II expression and forcing its expression reduces tumorigenesis in HCC<sup>[14]</sup>. miR-122 was found to suppress IGF-1R expression thus inhibiting HCC progression<sup>[15,16]</sup>. Conversely, we have demonstrated that forcing the expression of the oncomiR miR-96 leads to the up-regulation of IGF-1R and IGFBP-3 expression, while forcing the expression of the oncomiR-182 leads to the downregulation of IGF-1R and the upregulation of IGFBP-3 expression<sup>[17]</sup>. On the other hand, our research group reported that miR-155 induces the expression of IGF- II and IGF-1R and downregulates IGFBP-3 expression<sup>[18]</sup>. Nevertheless, the regulation of IGF-axis members by microRNAs still needs further investigation, particularly for the IGFBP-3. *In silico* analysis revealed IGFBP-3 as a potential downstream target for several microRNAs, one of which is microRNA-17-5p (miR-17-5p). This microRNA is an oncomiR that belongs to miR-17-92 cluster<sup>[19]</sup>. We have previously shown miR-17-5p to be significantly downregulated in non-metastatic HCC tissues compared to healthy tissues, where forcing its expression in HuH-7 cells resulted in enhancement of tumor cell growth, proliferation, migration, and colony-formation<sup>[20]</sup>. Therefore, this study aimed at identifying the impact of this important microRNA on IGFBP-3 expression, and

consequently on the IGF- II bioavailability, and hence on HCC tumorigenesis.

## MATERIALS AND METHODS

### Bioinformatics

Bioinformatics algorithms microrna.org, DIANA Lab, and Segal lab were used to predict microRNAs that may target IGFBP-3.

### Study subjects

This study included 23 HCC patients who underwent liver transplantation surgery in the Kasr Al Aini Hospital, Cairo University, Egypt. Ten healthy liver tissues were obtained from the healthy liver donors. Healthy donors were non-diabetic, non-hypertensive and negative for hepatitis B and C viruses (Table 1). The study was approved by the ethical review committees of the German University in Cairo and Cairo University, and is in accordance with the standards set by the Declaration of Helsinki. All participants gave their written informed consent. All patients were non-metastatic with no extrahepatic manifestations and no vascular invasion. Most of the patients (65.5%) had more than one focal lesion as indicated in the pathology report and were subjected to clinical assessment as shown in (Table 2).

### Cell cultures and transfection of microRNA oligonucleotides

HuH-7 cells were maintained in Dulbecco's modified Eagle's medium (Lonza, Switzerland) supplemented with 4.5 g/L glucose, 4 mmol/L L-glutamine, 10% fetal bovine serum and Mycozap (1:500, Lonza, Switzerland) at 37 °C in 5% CO<sub>2</sub> atmosphere. HuH-7 cells were transfected with mimics and inhibitors of miR-17-5p (Qiagen, Ger-

many) (Qiagen ID: MSY0000070 and MIN0000070, respectively). All transfection experiments were carried out in triplicates using HiPerFect Transfection Reagent (Qiagen, Germany), according to the manufacturer's protocol; the experiments were repeated three times. Cells that were only exposed to transfection reagent are designated as mock. Cells transfected with miR-17-5p mimics are designated as miR-17-5p, whereas cells transfected with miR-17-5p inhibitor are designated as anti-miR-17-5p.

### mRNA and microRNA isolation from liver tissues and HCC cell lines

mRNAs and microRNAs were extracted from liver tissues and HCC cell lines. Fresh liver samples (HCC and healthy tissues) were collected during surgery and were immediately snapfrozen in liquid nitrogen. The specimens were manually pulverized in liquid nitrogen, and about 100 mg of tissues powder were used for large and small RNA extraction using mirVana miRNA Isolation Kit (Ambion, United States), according to the manufacturer's protocol. HCC cell lines were harvested 48 h after transfection according to HiPerFect Transfection Reagent protocol and total RNA was extracted using Biozol Reagent (Bioer Technology, China).

### miRNA and mRNA quantification

The extracted microRNAs were reverse transcribed into single stranded complementary DNA (cDNA) using TaqMan MicroRNA Reverse Transcription Kit (ABI, United States) and specific primers for has-miR-17-5p and RNU6B. mRNA was reverse transcribed into cDNA using the high-capacity cDNA reverse transcription kit (ABI, United States)

**Table 3** The forward and reverse primer sequences used in the wild type 1 and 2, and the mutant type 1 and 2 insulin-like growth factor binding protein-3 3'UTR constructs

WT: Wild type; MUT: Mutant type.

according to the manufacturer's instructions. Relative expression of miR-17-5p and RNU6B (for normalization) as well as IGFBP-3 and beta-2 microglobulin (B2M; as housekeeping gene for normalization) was quantified using TaqMan Real-Time quantitative PCR (ABI Assay IDs: 002308, 001093, Hs00365742\_g1 and Hs00984230\_m1, respectively) using StepOne™ Systems (ABI, United States). Relative expression was calculated using the  $2^{-\Delta\Delta CT}$  method. All PCR reactions including controls were run in duplicate reactions.

#### IGFBP-3 3'UTR construct and luciferase assay

The two predicted target sites for miR-17-5p on IGFBP-3 3'UTR were each designed as sticky ended oligonucleotides flanked by *Sac* I and *Xba* I restriction sites, and ligated into the pmirGLO Dual-Luciferase miRNA Target Expression Vector (Promega, Germany) to form the two wild-type (WT) constructs. Also, two mutant constructs (MUT) were designed where 3 nucleotides from the binding region had been deleted from each site. The first target site is denoted as WT1 and its mutant form as MUT1; the second target site is WT2 and its mutant form is MUT2. The forward and reverse primer sequences for each construct are as shown in (Table 3). HuH-7 cells were seeded in 24-well plates and either WT or MUT constructs were transfected by lipofection technique using SuperFect Transfection Reagent (Qiagen, Germany). The following day, the cells were co-transfected with miR-17-5p mimics using HiPerFect according to the protocol (Qiagen). After 48 h, luciferase assay was performed using Steady-GLO Luciferase Reporter System (Promega, Germany) according to the manufacturer's protocol. After 5 min, luminescence was measured at 545 nm. Luciferase experiments were done in triplicates.

#### Quantitative detection of free IGF-II protein

Free IGF- II protein was measured in the cell culture supernatant from miR-17-5p mimicked, miR-17-5p antagonized, and mock untransfected HuH-7 cells, using the human IGF- II ELISA kit (CUSABIO, China), according to the manufacturer's instructions. Absorbance was measured at 450 nm in a microplate reader.

#### Statistical analysis

miRNA and gene expression data analysis was performed

according to the  $2^{-\Delta\Delta CT}$  method. An assessment of the normality of data was done as a prerequisite for all the statistical tests to identify the correct statistical methods to analyze our data with. We used Shapiro Wilks test since the size of the sample is less than 50. The normality test for miR-17-5p and IGFBP-3 screening experiments of "Healthy controls" and "HCC patients" showed that the dependent variable, "RQ", isn't normally distributed since the significant value of the Shapiro Wilks test is less than 0.05, so the data significantly deviate from a normal distribution, with an exception in the data obtained from IGFBP-3 expression in the healthy controls were found to be normally distributed. In view of this fact the statistical significance of the data was analyzed by performing the non-parametric Mann-Whitney test. The degree of the relationship between linear related variables was measured by the Pearson *r* correlation test. The normality test for the transfection and binding confirmation experiments showed that the data are normally distributed; therefore the parametric unpaired *t*-test was used. The specific types of tests, when applicable, are indicated in the figure legends. All data are presented as mean  $\pm$  standard error of the mean (SEM). All tests were 2-tailed and a two-tailed *P* value  $< 0.05$  was required for statistical significance. All the data were statistically analyzed using GraphPad Prism 5 software.

The statistical methods of this study were reviewed by Dr. Nihal Aly Etman, Department of Statistics, Mathematics and Insurance, Faculty of Commerce, Ain Shams University.

## RESULTS

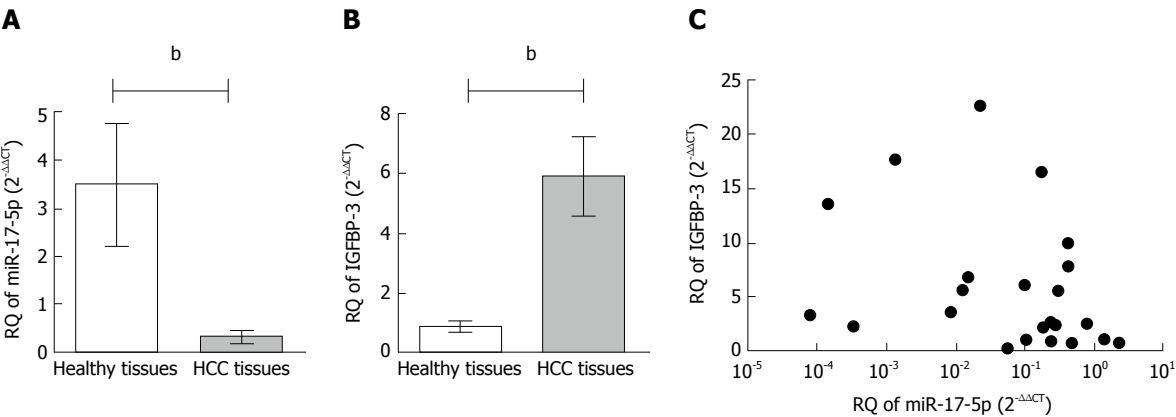

#### Bioinformatics

miR-17-5p accession number and mature sequence were retrieved using miRBase database (<http://www.mirbase.org/>). *In silico* predictions were carried out using three different softwares, and results showed IGFBP-3 to be a potential downstream target to miR-17-5p, where the microRNA was predicted to bind to the 3'UTR of IGFBP-3 at two different regions. The interactions between miR-17-5p seed sequence and its target sequence on the 3'UTR of IGFBP-3 are as shown in (Table 4). Where, the seed sequence of miR-17-5p

IGFBP-3: Insulin-like growth factor binding protein-3; miR-17-5p: MicroRNA-17-5p.

**Figure 1** Expression profile of microRNA-17-5p and insulin-like growth factor binding protein-3 and their correlation in liver tissues. The expression of miR-17-5p and IGFBP-3 were investigated in 10 healthy and 23 HCC liver tissues using TaqMan qRT-PCR and normalized in each sample to RNU6B endogenous control for miR-17-5p and B2M for IGFBP-3. A: miR-17-5p expression was down-regulated in non-metastatic HCC patients compared to healthy liver tissues ( $P = 0.0012$ ); B: Regarding IGFBP-3, its mRNA expression showed a significant higher expression in HCC tissues compared to healthy tissues ( $P = 0.0041$ ). Statistical analysis was performed using the Mann-Whitney test; C: Relative quantitation (RQ) values of miR-17-5p and IGFBP-3 mRNA in HCC tissues were analyzed using Pearson's method of correlation. A non-significant inverse correlation was found with Pearson's  $r = -0.3244$  ( $P = 0.1310$ ). <sup>b</sup> $P < 0.01$ . HCC: Hepatocellular carcinoma; IGFBP-3: Insulin-like growth factor binding protein-3; miR-17-5p: MicroRNA-17-5p; qRT-PCR: Real-time quantitative PCR.

is shown in bold and italic, while the target sequence of the 3'UTR of IGFBP-3 is underlined. The lines indicate complementarity between the binding region of the mRNA and the seed sequence of the microRNA, while the dots indicate mismatches or GU wobbles.

**Expression profile of miR-17-5p and IGFBP-3 in non-metastatic HCC liver tissues**

Expression of miR-17-5p in non-metastatic HCC tissues ( $n = 23$ ) ( $0.318 \pm 0.109$ ) was significantly lower compared to healthy tissues ( $n = 10$ ) ( $3.488 \pm 1.267$ ,  $P = 0.0012$ ; Figure 1A). On the other hand, the expression of IGFBP-3 in the same non-metastatic HCC tissues ( $5.913 \pm 1.294$ ) was significantly higher compared to healthy tissues ( $1.352 \pm 0.272$ ,  $P = 0.0041$ ; Figure 1B).

**Correlation analysis between miR-17-5p and IGFBP-3 mRNA expression in HCC tissues**

IGFBP-3 mRNA was quantified in all HCC tissues and correlated to miR-17-5p expression in the same patients. Using Pearson's statistical method of correlation, miR-17-5p expression was found to be moderately inversely correlated but not statistically significant with IGFBP-3 transcript levels in all HCC tissues studied ( $r = -0.3244$ ,  $P$

$= 0.1310$ ; Figure 1C).

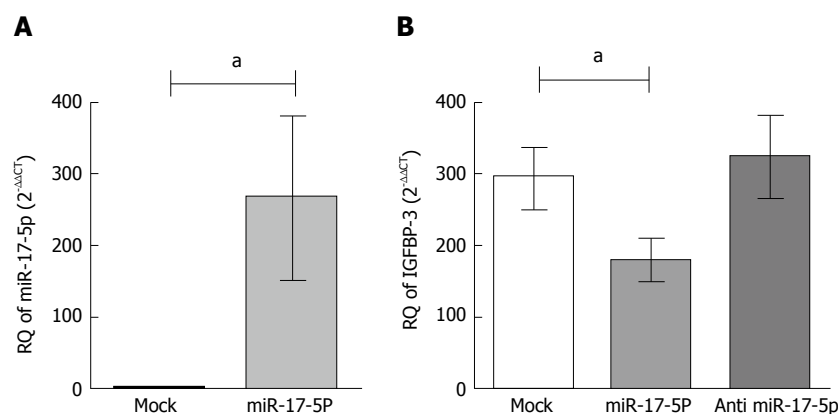

**Impact of miR-17-5p on IGFBP-3 mRNA in HuH-7 cells**

HuH-7 cells were transfected with miR-17-5p mimics and transfection efficiency was achieved with an observed 250 fold increase ( $P = 0.0470$ ) in miR-17-5p levels in transfected cells ( $266.6 \pm 113.2$ ) compared to their respective untransfected mock cells ( $1.069 \pm 0.1927$ ) (Figure 2A). Mimicking of miR-17-5p in HuH-7 resulted in a significant downregulation of IGFBP-3 mRNA levels ( $0.6527 \pm 0.1021$ ) compared to mock untransfected cells ( $1.069 \pm 0.1502$ ,  $P = 0.0267$ ). Conversely, inhibitors of miR-17-5p in HuH-7 cells showed a tendency of increase compared to mock untransfected HuH-7 cell lines (Figure 2B).

**Impact of miR-17-5p on free IGF-II protein in HuH-7 cells**

In miR-17-5p mimicked HuH-7 cells, there was a significant upregulation in the amount of the free IGF- II protein ( $1.045 \pm 0.05255$ ) compared to mock untransfected HuH-7 cells ( $0.8344 \pm 0.06783$ ,  $P = 0.0339$ ). Antagonizing the expression of miR-17-5p had no effect on the amount of the free IGF- II protein compared to the mock HuH-7 cells (Figure 3).

**Figure 2** Impact of microRNA-17-5p on insulin-like growth factor binding protein-3 mRNA expression in HuH-7 cell line. A: The expression of miR-17-5p was determined by TaqMan qRT-PCR in HuH-7 cells transfected with oligonucleotide mimics of miR-17-5p, 48 h post-transfection, relative to their expression in mock untransfected HuH-7 cells. The expression of miR-17-5p was normalized to RNU6B endogenous control. A: Transfection of miR-17-5p mimics increased miR-17-5p levels in HuH-7 by 250 fold compared to mock cells ( $P = 0.0470$ ). Unpaired *t*-test was performed; B: HuH-7 cells were transfected with miR-17-5p mimics or inhibitors, and the relative expression of IGFBP-3 was determined using TaqMan qRT-PCR, relative to mock untransfected cells, and gene expression was normalized to endogenous control B2M. IGFBP-3 mRNA expression was dramatically suppressed upon mimicking of miR-17-5p compared to mock cells ( $P = 0.0267$ ), while inhibitors of miR-17-5p showed a tendency of increase compared to mock cells. Unpaired *t*-test was performed. <sup>a</sup> $P < 0.05$ . IGFBP-3: Insulin-like growth factor binding protein-3; miR-17-5p: MicroRNA-17-5p; qRT-PCR: Real-time quantitative PCR.

**Figure 3** Impact of microRNA-17-5p on free insulin-like growth factor-II protein in HuH-7 cells. HuH-7 cells were transfected with miR-17-5p mimics or inhibitors. The free IGF- II protein was measured in media of mimicked and antagonized HuH-7 cells using an IGF- II ELISA Kit. Free IGF- II protein, measured at  $\lambda_{max} = 450$ , was found to be significantly increased upon mimicking of miR-17-5p expression compared to mock untransfected cells ( $P = 0.0339$ ), while inhibitors of miR-17-5p showed no effect on the levels of free IGF- II protein levels compared to mock cells. Unpaired *t*-test was performed. <sup>a</sup> $P < 0.05$ . IGF- II: Insulin-like growth factor- II; miR-17-5p: MicroRNA-17-5p.

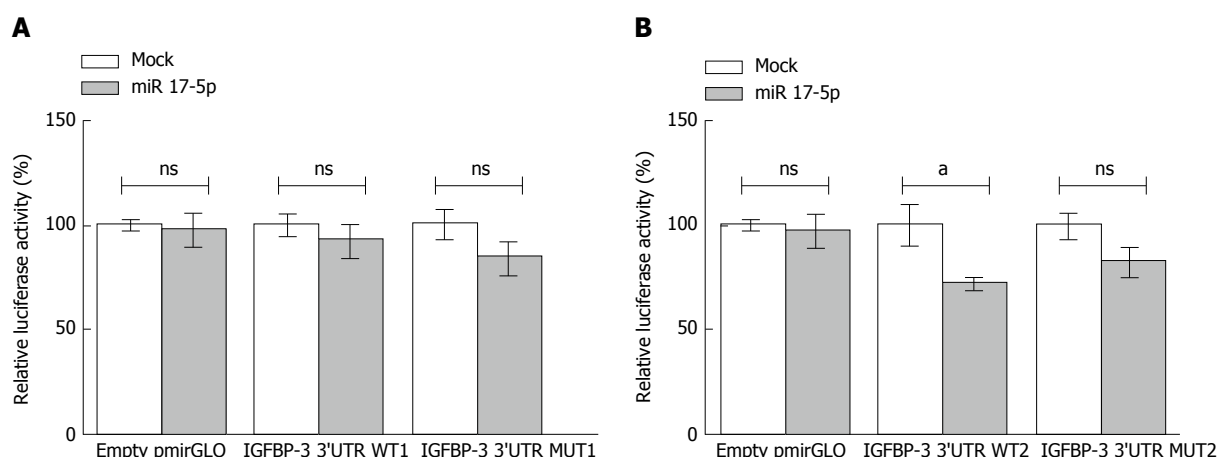

### Confirming IGFBP-3 as a direct target of miR-17-5p

To confirm that miR-17-5p directly targets the 3'UTR of IGFBP-3, wild-type constructs (WT1 and WT2) were designed where each of the two predicted 3'UTR target regions were inserted downstream to a luciferase reporter gene in pmiRGLO vector. To assess that the effects were due to specific binding to these binding regions, a mutant construct for each binding site was also prepared in which 3 base pairs were deleted from the predicted binding sequence in the 3'UTR of IGFBP-3, to form mutant constructs MUT1 and MUT2, respectively. Also, in a set of cells, empty pmiRGLO vector was transfected as a control to ensure that miR-17-5p mimics have no effect

on the vector itself. For each binding region, experiments were performed by transfecting HuH-7 cells with either the construct containing the WT 3'UTR binding region of IGFBP-3, or the construct containing the MUT 3'UTR binding region. Then miR-17-5p mimics were co-transfected with the vectors or constructs and luciferase reporter activity was assessed. In cells transfected with WT1 construct, luciferase activity was not affected upon co-transfection with miR-17-5p mimics (Figure 4A). On the other hand, luciferase activity was inhibited by 27.5% in cells co-transfected with miR-17-5p mimics and WT2 construct ( $72.48 \pm 2.383$ ) compared to cells transfected with the WT2 construct alone ( $100.0 \pm 9.432$ ,  $P = 0.0474$ ) (Figure 4B). In contrast, in cells transfected with either MUT1 or MUT2, no change in luciferase activity was observed upon mimicking with miR-17-5p (Figure 4). The inhibition in the luciferase activity observed only in the WT2 construct indicates direct targeting and transcriptional inhibition of IGFBP-3 by miR-17-5p mimics through only one of the two predicted target regions.

## DISCUSSION

The regulation of IGFBP-3 by microRNAs has not been extensively studied but recently our research group showed that the oncomiR miR-155 represses IGFBP-3 expression in HCC cell lines<sup>[18]</sup>. In addition, we showed an increased expression of IGFBP-3 upon forcing the expression of miR-96 and miR-182<sup>[17]</sup>. To the best of our knowledge the IGF- II bioavailability has never been investigated after targeting IGFBPs with microRNAs, therefore in this study, we aimed at identifying a new microRNA which could regulate the IGFBP-3 and consequently the IGF- II bioavailability, and hence influence HCC tumorigenesis. *In silico* analysis revealed IGFBP-3 as a potential downstream target for miR-17-5p (Table 4), a microRNA which we have previously shown to have

**Figure 4** Insulin-like growth factor binding protein-3 is a direct target of miR-17-5p. For each target sequence, experiments were performed by transfecting HuH-7 cells with either empty pmirGLO vector, or the construct with the wild-type (WT) miR-17-5p target region insert, or the construct with the mutant (MUT) miR-17-5p target region insert. Then miR-17-5p mimics were co-transfected with the vectors or constructs. A: Luciferase activity was not affected in cells co-transfected with miR-17-5p mimics and WT1 construct compared to cells transfected with the WT1 construct alone; B: On the other hand, luciferase activity was inhibited by 27.5%, in cells co-transfected with miR-17-5p mimics and WT2 construct compared to cells transfected with the WT2 construct alone ( $P = 0.0474$ ). The cells transfected with either of the mutant constructs (MUT1 or MUT2) show no change in the luciferase activity upon mimicking with miR-17-5p. Unpaired *t*-test was performed. <sup>a</sup> $P < 0.05$ . NS: Not significant; IGFBP-3: Insulin-like growth factor binding protein-3; miR 17-5p: MicroRNA-17-5p.

oncogenic properties in HCC<sup>[20]</sup>.

No correlation analysis was previously done between miR-17-5p and IGFBP-3 expression in HCC patients, therefore non-metastatic liver tissues of HCC patients were screened for that purpose. miR-17-5p was markedly downregulated (Figure 1A) while IGFBP-3 was significantly upregulated (Figure 1B) in the non-metastatic liver tissues of HCC patients compared to healthy controls. This goes in line with previous studies showing IGFBP-3 to be highly expressed in breast and esophageal cancer<sup>[21,22]</sup>. But on the other hand, it contradicts other studies that reported reduced IGFBP-3 mRNA expression and protein levels in metastatic HCC patients<sup>[12,13]</sup>. Moreover, the repression of miR-17-5p in HCC tissues (Figure 1A) corroborates our previous results that showed a significant downregulation of miR-17-5p expression in non-metastatic HCC patients<sup>[20]</sup>, but nonetheless it contradicts other studies in metastatic HCC tissues<sup>[23]</sup>. These disparities can, however, be attributed to differences in the cohorts of patients included in the various studies, with regards to stage and etiology of the disease as well as other factors such as ethnicity, gender and age. Of note, the results of the correlation analysis revealed a moderate negative correlation between miR-17-5p and IGFBP-3 expression in HCC patients (Figure 1C), suggesting that IGFBP-3, as predicted by *in silico* analysis, may in fact be under the posttranscriptional regulation of miR-17-5p.

In order to investigate the effect of miR-17-5p on IGFBP-3, transfection experiments were performed by forcing miR-17-5p expression in HuH-7 cell lines and the expression of IGFBP-3 mRNA was assessed, where it was found that upon forcing miR-17-5p expression in HuH-7 cells, there was a significant downregulation in IGFBP-3 expression (Figure 2B). This finding further implies that miR-17-5p may target and regulate IGFBP-3

expression. As revealed by *in silico* analysis, the 3'UTR of the IGFBP-3 transcript contains two exclusive putative binding sites for miR-17-5p. In order to validate IGFBP-3 as a direct downstream target of miR-17-5p, a WT and a MUT luciferase reporter gene construct was prepared for each binding region on the 3'UTR of IGFBP-3. Using these microRNA-target expression constructs, it was demonstrated that forcing the expression of miR-17-5p significantly decreased luciferase activity only in the construct harboring the WT2 binding region of the 3' UTR of IGFBP-3 target gene (Figure 4). This interesting finding indicates that only one of the two putative binding sites is in fact functionally active and that miR-17-5p effectively targets and inhibits the transcription of IGFBP-3 by directly associating with this specific target region. This unusual observation has also been found in colon cancer where bioinformatic tools predicted two target sites on the oncogene Friend leukemia virus integration 1 (Fli-1) for the tumor suppressor miR-145; however, upon measuring the luciferase activity only the construct harboring one of these two predicted target sites of Fli-1 showed a decrease in luciferase activity by more than 50% upon miR-145 mimicking, while the other construct harboring the second target site did not respond to miR-145<sup>[24]</sup>.

Since IGFBP-3 is a crucial negative regulator of the bioavailability of IGF- II, therefore the levels of free IGF- II protein were quantified in the media of miR-17-5p mimicked and mock untransfected HuH-7 cells. The results showed a significant increase in unbound IGF- II in miR-17-5p mimicked HuH-7 cells compared to mock untransfected cells (Figure 3). This in turn confirms that miR-17-5p regulates IGF- II bioavailability through direct targeting of IGFBP-3. In this regard, the biological function of miR-17-5p appears to simulate the effect of another regulator of the IGF pathway, the MMPs, whose

overexpression leads to the decrease in IGFBP-3 and subsequent increase in IGF- II bioavailability<sup>[25]</sup>.

In conclusion, the findings of this study shed light on the important role of the oncogenic miR-17-5p in hepatocarcinogenesis, where this microRNA was found to increase IGF- II bioavailability by directly targeting and repressing IGFBP-3 expression. Hence, manipulating microRNA expression might be a compelling potential therapeutic approach in preventing HCC progression.

## ACKNOWLEDGMENTS

The authors would like to thank the English instructor, Ms. Gilan Hamdi, and the English Department at the German University in Cairo for revising the manuscript. We would like to thank Ms. Nihal Etman, from the Department of Statistics, Mathematics and Insurance at Ain Shams University, Cairo, Egypt for reviewing the statistics of the manuscript.

## COMMENTS

### Background

Insulin-like growth factor-II (IGF-II) is a major activator of the oncogenic IGF axis, often overexpressed in hepatocellular carcinoma leading to the promotion of tumor cell migration, proliferation and metastasis. IGF-II protein bioavailability is controlled by a class of insulin-like growth factor binding proteins (IGFBPs) 1-6 which regulate the binding of IGF-II to its receptor, IGF-1 receptor. Very few studies have investigated the regulation of IGFBPs by microRNAs.

### Research frontiers

Recently, microRNAs have entered the first clinical trials investigating their therapeutic potential in primary liver cancer.

### Innovations and breakthroughs

This is the first study to investigate the effect of a microRNA on an IGFBP and consequently on the IGF- II bioavailability.

### Applications

microRNA-17-5p affected IGFBP-3 and consequently the level of free IGF- II which could allow for the activation of the oncogenic IGF axis. This suggests that microRNAs can be manipulated to regulate the activation of this axis.

### Terminology

microRNAs are approximately 22 nucleotide long single stranded, small, non-coding RNA sequences that post-transcriptionally regulate gene expression by binding to the 3'UTR of their target mRNA, suppressing its translation or causing its degradation.

### Peer-review

The study is well planned involves proving of a concept by bioinformatics tools and then confirming *in vitro* and patient's tissues.

### Abstract

**AIM:** To interfere with the activation of nuclear factor-κB (NF-κB) with metformin and explore its effect in reversing multidrug resistance (MDR) of hepatocellular carcinoma (HCC) cells.

**METHODS:** Expression of P-glycoprotein (P-gp) and NF-κB in human HepG2 or HepG2/adriamycin (ADM) cells

treated with pCMV-NF- $\kappa$ B-small interference RNA (siRNA) with or without metformin, was analyzed by Western blot or fluorescence quantitative PCR. Cell viability was tested by CCK-8 assay. Cell cycle and apoptosis were measured by flow cytometry and Annexin-V-PE/7-AnnexinV apoptosis detection double staining assay, respectively.

**RESULTS:** P-gp overexpression in HepG2 and HepG2/ADM cells was closely related to *mdr1* mRNA ( $3.310 \pm 0.154$ ) and NF- $\kappa$ B mRNA ( $2.580 \pm 0.040$ ) expression. NF- $\kappa$ B gene transcription was inhibited by specific siRNA with significant down-regulation of P-gp and enhanced HCC cell chemosensitivity to doxorubicin. After pretreatment with metformin, HepG2/ADM cells were sensitized to doxorubicin and P-gp was decreased through the NF- $\kappa$ B signaling pathway. The synergistic effect of metformin and NF- $\kappa$ B siRNA were found in HepG2/ADM cells with regard to proliferation inhibition, cell cycle arrest and inducing cell apoptosis.

**CONCLUSION:** Metformin *via* silencing NF- $\kappa$ B signaling could effectively reverse MDR of HCC cells by down-regulating MDR1/P-gp expression.

**Key words:** Metformin; Reversal; Multidrug resistance; Hepatocellular carcinoma

© The Author(s) 2016. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Metformin might target AMP-activated protein kinase mammalian target of rapamycin pathway, suppress hypoxia-inducible factor-1 $\alpha$  and transcriptionally down-regulate P-glycoprotein (P-gp) and multidrug resistance (MDR)-associated protein 1, suggesting that metformin may reverse MDR by targeting the AMP-activated protein kinase/mammalian target of rapamycin/hypoxia-inducible factor-1 $\alpha$ /P-gp and MDR-associated protein 1 pathways. In the present study, HepG2/ADM cells pretreated with metformin were sensitized to doxorubicin and P-gp was decreased through the nuclear factor- $\kappa$ B (NF- $\kappa$ B) signaling pathway. The synergistic effects were found in the cells with regard to proliferation inhibition, cell cycle arrest and inducing apoptosis, and inhibiting P-gp expression *via* the NF- $\kappa$ B signaling pathway effectively reversed MDR by down-regulating MDR1/P-gp expression.

Reversal of multidrug resistance of hepatocellular carcinoma cells by metformin through inhibiting NF- $\kappa$ B gene transcription. *World J Hepatol* 2016; 8(23): 985-993 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i23/985.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i23.985>

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common cancers and causes of cancer-related mortality

worldwide<sup>[1-3]</sup>. Due to the lack of specific symptoms, the vast majority of HCCs are diagnosed at late and/or advanced stages<sup>[4,5]</sup>. Although recent advances in surgical techniques and interventional therapy have improved survival, the emergence of multidrug resistance (MDR) to a series of clinical chemotherapeutics with different structures or different target sites severely blocks the successful management of HCC<sup>[6,7]</sup>. The well recognized mechanism of classical MDR is the significant overexpression of human *MDR1* gene encoding MDR1/P-glycoprotein (P-gp) that acts as an efflux pump on cell surface<sup>[8,9]</sup>. Intracellular anti-cancer drugs increasingly flow from cells through the efflux pump, thus drug concentrations become lower and cancer cells become resistant to chemotherapeutic drugs such as doxorubicin<sup>[10,11]</sup>.

Recently, some studies have found diverse anticancer effects of metformin in the cells of lung, gastric, endometrial, breast, and other types of cancer<sup>[12,13]</sup>. Metformin exhibits anti-proliferative effects in tumor cells *in vitro* and *in vivo*<sup>[14,15]</sup>. Metformin might target the AMP-activated protein kinase (AMPK)/mammalian target of rapamycin (mTOR) pathway<sup>[16,17]</sup>, suppress the hypoxia-inducible factor-1 $\alpha$  (HIF-1 $\alpha$ )<sup>[18,19]</sup> and transcriptionally down-regulate P-gp and MDR-associated protein 1 (MRP1), suggesting that metformin may reverse MDR by targeting the AMPK/mTOR/HIF-1 $\alpha$ /P-gp and MRP1 pathways<sup>[20,21]</sup>. In addition, the activation of nuclear factor-kappa B (NF- $\kappa$ B) pathway plays an important role in the development of HCC<sup>[22-24]</sup>, but whether it is related to MDR and the underlying molecular mechanisms remain to be explored<sup>[25,26]</sup>. In this study, we silenced NF- $\kappa$ B gene transcription with specific small interference RNA (siRNA) in human resistant HepG2/adriamycin (HepG2/ADM) cells, and explored the impact of metformin and NF- $\kappa$ B silencing, alone or in combination, on MDR1 regulation and MDR in HCC cells.

## MATERIALS AND METHODS

### Cell culture

Human hepatoma cell line HepG2, HepG2/ADM cell line and hepatocyte cell line LO2 were purchased from Aibio Biotech Company (Shanghai, China). LO2 cells were cultured in Dulbecco's modified Eagle's medium (DMEM, KeyGen Biotech Co., Ltd, Nanjing, China) containing 10% fetal bovine serum (FBS, Invitrogen, United States), penicillin (100 U/mL)/streptomycin (100 U/mL), at 37 °C with 5% CO<sub>2</sub>. HepG2 and HepG2/ADM cells were cultured in RPMI 1640 (KeyGen Biotech Co., Ltd, Nanjing, China) complete medium supplemented with 10% FBS, penicillin (100 U/mL)/streptomycin (100 U/mL) at 37 °C in a humidified incubator containing 5% CO<sub>2</sub>.

### Western blot

The cultured cells were washed with phosphate buffered saline (PBS) twice and lysed in phenylmethane sulfonyl fluoride (PMSF, Beyotime, Nantong, China) cell lysis buffer (1:1000), and the protein concentrations were determined with the bicinchoninic acid (BCA, Beyotime,

Nantong, China) protein assay kit. The protein samples were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred onto polyvinylidene fluoride (PVDF, Millipore, United States) membranes. After blocking with 5% skim milk in Tris-buffered saline with tween (TBST) at room temperature for 3 h, the membranes were incubated with the primary antibody overnight at 4 °C. The primary antibodies were diluted as follows: p65 and P-p65 (rabbit anti-human, 1:1000, Cell Signaling, United States), MDR1 (rabbit anti-human, 1:500, Abcam, United States) and  $\beta$ -actin (mouse anti-human, 1:2000, internal reference, Proteintech, United States). Then the membranes were washed three times with TBST and incubated with a horseradish peroxidase-conjugated secondary antibody (mouse or rabbit anti-human, 1:1000, Univ-bio, Nanjing, China) for 2.5 h at room temperature. Finally, the samples were detected with Quantity One software using the electrochemiluminescence kit (Millipore, United States). All Western blot experiments were repeated three times.

### Real-time quantitative PCR

The cultured cells were digested with trypsin. Total RNA was extracted with TRIzol (Invitrogen, United States) reagent according to the protocol of the manufacturer. The quantity of total RNA was determined based on absorbance at 260 nm, and the purity of total RNA was analyzed based on the absorbance ratio at 260 and 280 nm ( $A_{260}/A_{280}$ ). Reverse transcription of total RNA to complementary DNA (cDNA) was performed with RevertAid™ First Strand cDNA Synthesis Kit (MBI Fermentas, CA, United States). PCR was carried with an SYBR Premix Ex Taq™ II kit (TaKaRa, Dalian, China), and GAPDH was used as an internal reference. The sequences of the primers used<sup>[27]</sup> were: NF- $\kappa$ B/p65 (forward: 5'-CTATCAGTCAGCGCATCCAG-3' and reverse: 5'-GCCAGAGTTTCGGTTCCTC-3'); mdr1 (forward: 5'-CCGGTT TGGAGCCTACTTG-3' and reverse: 5'-TCCAA TGTGTTCCGGCATTAG-3'); and GAPDH (forward: 5'-CAAGTTCATCCATGACAAC TTTG-3' and reverse: 5'-GTCCACCACCCTGTTGCTGTAG-3'). Real-time PCR cycling parameters consisted of initial denaturation at 94 °C for 2 min and 40 cycles of 95 °C for 10 s, 55 °C for 30 s, and 70 °C for 45 s. The amplification specificity was confirmed by the melting curves. Ct values were calculated based on duplicates and normalized to GAPDH. The relative expression was calculated using the  $2^{-\Delta\Delta Ct}$  method. All PCR experiments were repeated three times.

### Cell viability assay

Cell viability was evaluated with CCK-8 kit (Dojindo, Japan). Cells were divided into blank, negative control and experimental groups. Briefly, cells in logarithmic growth phase were digested with trypsin, and the cell suspension liquid (100  $\mu$ L) was seeded in 96-well plates. Toxicity tests were performed with different concentrations of ADM added to 96-well plates in the experimental group. The micro-plates were pre-cultured

at 37 °C in a humidified incubator containing 5% CO<sub>2</sub>, and liquid was changed at a fixed time interval. Then 10  $\mu$ L/well CCK-8 solution was added and incubated at 37 °C for 4 h. The absorbance (A) was measured with a microplate reader at a wavelength of 450 nm. Cell survival rate was calculated as  $A_{exp}/A_{con} \times 100\%$ . Values of IC<sub>50</sub> were evaluated with the Graphpad Prism5 software. Each individual experiment was performed at least three times.

### Metformin treatment

HepG2/ADM cells were divided into three groups: Blank, control and experiment. The experimental group was treated with 1  $\mu$ mol/L metformin for 24 h, and then continued to be cultured for 48 h with 1.5  $\mu$ mol/L doxorubicin. The control group was only treated with doxorubicin, and the blank group did not undergo any treatment.

### Analysis of cell apoptosis

HepG2/ADM cells were treated with drugs for 48 h, and then continued to be cultured for 24 h with another culture solution. Cells were harvested using trypsin without EDTA and washed with cold PBS twice. Cell cycle and apoptosis ( $n = 3$ ) were measured by flow cytometry and Annexin-V-PE/7-AnnexinV apoptosis detection double staining assay (BD, United States), respectively.

### Plasmid construction and cell transfection

NF- $\kappa$ B-siRNAs were designed according to the previously reported sequences<sup>[28]</sup> and synthesized by the Biomix Company (Nantong, China) according to Rel A sequence obtained from Gene ID 5970. The sequences of siRNAs were: NF- $\kappa$ B/p65 siRNA (forward, 5'-TGCTGTTCATCTCCTG AAAGGAGGCCGTTTTGGCCACTGACTGACGGCCTCCT CAGGAGATGAA-3' and reverse, 5'-CCTGTTTCATCTCCT GAGGAGGCCGTGCTAGTCAGTGGCCAAAACGGCCTCC TTTCAGGAGATGAAC-3'; and negative-siRNA (forward, 5'-TGCTGAAATGTACTGCGCGTGGAGACGTTTTGGCCA CTGACTGACGTCTCCACGCAGTACATTT-3' and reverse, 5'-CCTGAAATGTACTGCGTGGAGACGTGCTAGTCAGTGGCC AAAACGTCTCCACGCAGTACATTT-3'). Each siRNA was inserted to a pcDNA™ 6.2-GW/EmGFPmiR vector (Invitrogen, United States). HepG2/ADM cells were divided into blank control, negative siRNA control and NF- $\kappa$ B/p65 siRNA transfection groups. After cells were planted into microwell plates at a density of 70%, the plasmids were transfected into cells for incubation for 24 h according to the manufacturer's instructions. The medium was removed on another day and replaced with the fresh one, and the transfection efficiency was observed with a fluorescence microscope. These experiments were performed in triplicate.

### Statistical analysis

Data are expressed as the mean  $\pm$  SD. Statistical analyses were done using the SPSS21.0 software package. Differences between groups were assessed using analysis of variance or *t*-test.  $P \leq 0.05$  was regarded as

## RESULTS

### Expression of P-gp, *mdr1*, and NF- $\kappa$ B in different liver cell lines

The levels of P-gp, *mdr1*, and NF- $\kappa$ B expression in different liver cell lines are shown in Figure 1. The proliferation of HepG2 and HepG2/ADM cells was decreased along with the increase of the concentration of doxorubicin, and the ability of proliferation was higher in HepG2/ADM cells than in HepG2 cells. At 24, 48 and 72 h, the IC<sub>50</sub> values of doxorubicin against HepG2 cells were 0.489, 0.221 and 0.224  $\mu$ mol/L, respectively, and the IC<sub>50</sub> values of doxorubicin against HepG2/ADM cells were 4.166, 1.522 and 1.380  $\mu$ mol/L, respectively. The resistance index (RI,  $\mu$ mol/L) of HepG2/ADM cells was 8.519 at 24 h, 6.874 at 48 h and 6.166 at 72 h. There was almost no P-gp expression in LO2 cells. Different degrees of expression of P-gp protein were observed in HepG2 and HepG2/ADM cells, but the P-gp expression in HepG2/ADM cells was significantly higher than that in HepG2 cells (Figure 1A and B). The p-p65 expression was significantly increased, while the expression of p65 was significantly decreased in HepG2/ADM cells (Figure 1C and D). The levels of *mdr1* mRNA and NF- $\kappa$ B mRNA were  $3.310 \pm 0.154$  and  $2.580 \pm 0.040$ , respectively, in HepG2/ADM cells, and  $0.084 \pm 0.038$  and  $0.607 \pm 0.032$ , respectively, in HepG2 cells; the former was significantly higher than the latter ( $P < 0.01$ ). Relative transcript levels ( $2^{-\Delta\Delta Ct}$ ) of *mdr1* mRNA and NF- $\kappa$ B mRNA were  $9.381 \pm 0.750$  and  $3.927 \pm 0.069$ , respectively (Figure 1E).

### Effect of metformin on HepG2/ADM cells

The effect of metformin on the proliferation of HepG2/ADM

cells was concentration- and time-dependent (Table 1). Metformin showed no significant effect on HepG2/ADM cells when its concentration was less than 3 mmol/L, but had different degrees of inhibition on the proliferation of HepG2/ADM cells when its concentration was between 3–10 mmol/L ( $P < 0.05$ ). The HepG2/ADM cells were divided into experimental and control groups. After pretreatment with metformin, the experimental group cells were treated with different concentrations of doxorubicin. The effect of adriamycin combined with metformin on the proliferation of HepG2/ADM cells is shown in Table 2. After treatment with metformin, HepG2/ADM cells were more sensitive to adriamycin.

### Metformin promotes HepG2/ADM cell apoptosis

The levels of HepG2/ADM cell apoptosis in the experimental (treated with metformin plus adriamycin), control (only treated with adriamycin) and blank (without adriamycin or metformin) groups are shown in Figure 2. After the cells were pretreated with 1 mmol/L metformin for 24 h, adriamycin was added. MDR1 in HepG2/ADM cells was down-regulated, the cell cycle was blocked at G<sub>0</sub>/G<sub>1</sub> phase, and apoptosis was enhanced. Significant differences in the apoptosis rates were found among different groups ( $F = 3726.97$ ,  $P < 0.001$ ), and the apoptosis rate was significantly higher in the experimental group ( $22.17\% \pm 0.37\%$ ) than in the control group ( $14.86\% \pm 0.21\%$ ) or the blank group ( $4.17\% \pm 0.13\%$ ).

### Metformin reverses MDR via the NF- $\kappa$ B signaling pathway

Metformin reversed the MDR of HCC cells via the NF- $\kappa$ B signaling pathway (Figure 3). The levels of P-gp expression in the HepG2/ADM cells were decreased with

**Figure 1** The levels of P-glycoprotein, mdr1 and nuclear factor- $\kappa$ B expression in different cell lines. A and C: The levels of P-gp and NF- $\kappa$ B expression in HepG2 or HepG2/ADM cells were determined by Western blot. The number indicates the ratio of HepG2/ADM cells to HepG2 cells ( $n = 3$ , mean  $\pm$  SD); B and D: The gray intensity images of Figure 1A and Figure 1C, respectively; E: The levels of mdr1 and NF- $\kappa$ B mRNA expression were determined by qRT-PCR. <sup>b</sup> $P < 0.01$  ( $n = 3$ , mean  $\pm$  SD), compared with hepG2 or LO<sub>2</sub> cell line. P-gp: P-glycoprotein; NF- $\kappa$ B: Nuclear factor- $\kappa$ B; ADM: Adriamycin.

the increasing dose of metformin, and the phosphorylated p65 expression in the nucleus was also decreased. Metformin could down-regulate P-gp expression by inhibiting NF- $\kappa$ B activation in a dose- and time-dependent manner.

#### Synergistic effect of metformin plus NF- $\kappa$ B-siRNA

The synergistic effects of metformin combined with NF- $\kappa$ B siRNA in reversing MDR are shown in Figure 4. HepG2/ADM cells were divided into three groups: Untreated cells, cells treated with metformin alone and those treated with metformin combined with NF- $\kappa$ B-siRNA. In the NF- $\kappa$ B-siRNA group, NF- $\kappa$ B-siRNA was transfected into HepG2/ADM cells for 24 h, and then cells were treated with 1 mmol/L metformin for 48 h. The levels of P-gp expression were  $0.91 \pm 0.24$ ,  $0.63 \pm 0.13$  and  $0.22 \pm 0.02$  ( $F = 14.47$ ,  $P = 0.005$ ) in untreated, metformin and the metformin combined with NF- $\kappa$ B-siRNA groups, respectively. The expression of P-gp was significantly

reduced in cells treated with metformin plus NF- $\kappa$ B-siRNA compared with that in cells only treated with metformin ( $t = 5.39$ ,  $P = 0.006$ ).

## DISCUSSION

Recent advances in surgical techniques and interventional therapy have improved survival of HCC patients<sup>[6,7,29]</sup>. However, the emergence of MDR to a series of clinical chemotherapeutics with different structures or target sites severely blocks the successful management of HCC and still is a difficult problem to be solved in clinical practice<sup>[30,31]</sup>. MDR in HCC could result from several biochemical mechanisms including decreased drug influx, increased drug efflux, altered cell cycle checkpoints, altered drug targets, increased drug metabolism and/or resistance to drug-induced apoptosis. Therefore, it is very important to find safe and effective MDR reversal agents for HCC<sup>[32]</sup>. In the present study, metformin with

**Figure 2** Metformin enhances adriamycin-induced apoptosis of HepG2/adriamycin cells. Cell early apoptosis was measured by Annexin-V-PE/7-AAD double staining assay in triplicate. A: The blank group (untreated); B: The control group (only treated with adriamycin); C: The experiment group (treated with metformin plus adriamycin). AAD: AnnexinV apoptosis detection.

**Figure 3** Metformin down-regulates P-glycoprotein expression via the nuclear factor- $\kappa$ B signaling pathway. A: After HepG2/ADM cells were treated with different doses of metformin for 24 h, the levels of P-gp and p-p65 expression analyzed by Western blot were decreased in a dose-dependent manner, and the cytoplasmic p65 increased in a dose-dependent manner; B: The gray intensity images of Figure 3A. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs the blank group ( $n = 3$ , mean  $\pm$  SD); C: After HepG2/ADM cells were treated with 1 mmol/L metformin for different time periods, the levels of P-gp and p-p65 expression analyzed by Western blot were decreased in a time-dependent manner, and the cytoplasmic p65 increased in a time-dependent manner; D: The gray intensity images of Figure 3C. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs the blank group ( $n = 3$ , mean  $\pm$  SD). P-gp: P-glycoprotein; NF- $\kappa$ B: Nuclear factor- $\kappa$ B; ADM: Adriamycin.

silencing NF- $\kappa$ B gene transcription was used to reverse MDR of HepG2/ADM cells with high NF- $\kappa$ B expression.

Anti-cancer drug efflux is one of the most common mechanisms of MDR of HCC cells, and it is mediated by ATP-binding cassette transporters<sup>[33,34]</sup>, such as P-gp encoded by *MDR1* gene, which is located downstream of the NF- $\kappa$ B signaling pathway. P-gp expression regulated by *MDR1* is the most important and common cause of MDR, and weakened the apoptosis of cancer cells induced by chemotherapeutic drugs. Both P-gp expression and NF- $\kappa$ B activation are linked closely with HCC progression<sup>[35]</sup>. Usually NF- $\kappa$ B takes part in gene transcription by means of homodimers or heterodimers,

such as p50/p65, p65/p65, and p65/Rel. In quiescent cells, they are predominantly cytoplasmic, associating with members of inhibitory I $\kappa$ B family and forming NF- $\kappa$ B/I $\kappa$ B complexes without activity. Both P-gp and NF- $\kappa$ B at the protein or transcriptional level were significantly higher (Figure 1), with p65 expression decreasing in HepG2/ADM cells, indicating that abnormal P-gp and NF- $\kappa$ B expression could associate with the MDR formation of HCC cells<sup>[20]</sup>.

Metformin is a safe, low-cost drug, and therefore remains one of the most commonly prescribed drugs worldwide<sup>[16,36]</sup>. The anticancer effects of metformin indicate the possibility that certain diabetes-associated types of

**Figure 4** Alteration of P-glycoprotein expression in cells treated with metformin plus nuclear factor- $\kappa$ B-small interference RNA. A: Alteration of P-gp expression in different groups of cells. A significant decrease of P-gp expression analyzed by Western blot was found in HepG2/ADM cells treated with the metformin plus NF- $\kappa$ B-siRNA; B: The gray intensity images of Figure 4A. <sup>b</sup> $P < 0.01$  vs the blank group ( $n = 3$ , mean  $\pm$  SD). P-gp: P-glycoprotein; NF- $\kappa$ B: Nuclear factor- $\kappa$ B; ADM: Adriamycin; siRNA: Small interference RNA.

cancer<sup>[37,38]</sup> may be circumvented, and metformin has anti-proliferative potential against cancer cells or reversing MDR *in vitro* and *in vivo*<sup>[39,40]</sup>. However, the precise molecular mechanisms whereby metformin works in cancer prevention remain multi-factorial and ill-defined. Metformin affected HepG2/ADM cell proliferation in a dose- and time-dependent manner (Table 1). Metformin at  $< 3$  mmol/L had no significant impact on HepG2/ADM cells, but the cells treated with metformin between 3-10 mmol/L were more sensitive to adriamycin with regard to promoting cell apoptosis (Figure 2) and inhibiting cell proliferation (Table 2), suggesting that metformin could increase the sensitivity of HepG2/ADM cells to anti-cancer drugs.

There are few studies on the effect of metformin on MDR of HCC cells. siRNA strategy is a powerful technique to inhibit specific gene expression, which has highlighted the potential use of siRNA molecules to study gene function or explore new HCC therapeutic agents<sup>[41,42]</sup>. The expression of NF- $\kappa$ B gene transcription was inhibited by specific siRNA, which significantly down-regulated P-gp and enhanced the chemosensitivity of HCC cells to doxorubicin, confirming the mechanism of decreasing P-gp *via* the NF- $\kappa$ B signaling pathway. The synergistic effects of metformin and NF- $\kappa$ B siRNA were found in HepG2/ADM cells with regard to cell proliferation inhibition, cell cycle arrest, and inducing cell apoptosis. These data confirm that the metformin could enhance the HepG2/ADM cells sensitivity to adriamycin and reverse MDR *via* the NF- $\kappa$ B signaling pathway (Figure 4).

In conclusion, the development of MDR still is one of major causes of HCC chemotherapy failure<sup>[43,44]</sup>. Although specific NF- $\kappa$ B siRNA is a powerful small molecule reagent designed to silence expression of NF- $\kappa$ B and MDR1/P-gp related to MDR to increase tumor cell sensitivity to anti-cancer drugs, how to apply metformin plus interfering NF- $\kappa$ B activation for effective reversal of MDR of HCC cells still needs to be further explored.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) multidrug resistance (MDR) to a series of clinical chemotherapeutics with different structures or different target sites severely blocks the successful management of HCC. The mechanism of classical MDR is the significant overexpression of MDR1/P-glycoprotein (P-gp) that acts as an efflux pump on cell surface. Intracellular anti-cancer drugs increasingly flow from cells through the efflux pump, thus drug concentrations become lower and cancer cells become resistant to chemotherapeutic drugs such as doxorubicin.

### Research frontiers

Metformin could target AMP-activated protein kinase mammalian target of rapamycin pathway, suppress hypoxia-inducible factor-1 $\alpha$  (HIF-1 $\alpha$ ) and transcriptionally down-regulate P-gp and MDR-associated protein 1, suggesting that metformin may reverse MDR by targeting the AMP-activated protein kinase/mammalian target of rapamycin/HIF-1 $\alpha$ /P-gp and MDR-associated protein 1 pathways. However, whether metformin plus nuclear factor- $\kappa$ B (NF- $\kappa$ B) inhibition might effectively reverse MDR of HCC cells remains to be explored.

### Innovations and breakthroughs

Recently, there are few studies on the effects of metformin on MDR of HCC cells. In this study, the data suggested that the abnormal expression of MDR1/P-gp and NF- $\kappa$ B activation during HCC development were related to MDR formation, which might be down-regulated through inhibiting activation of the NF- $\kappa$ B signaling pathway with specific small interference RNA (siRNA). The combination of metformin with interfering NF- $\kappa$ B gene transcription could effectively reverse the MDR of HCC cells.

### Applications

The abnormal expression of MDR1/P-gp in HCC was related to MDR formation, which could be down-regulated through inhibiting activation of the NF- $\kappa$ B signaling pathway with specific siRNA and increasing sensitivity of HCC cells to chemotherapy drugs. Interfering NF- $\kappa$ B activation with metformin is effective to reverse MDR of HCC cells. However, how to apply metformin plus interfering NF- $\kappa$ B activation for effective reversal of MDR of HCC cells still needs to be explored.

### Terminology

Metformin is a safe, low-cost drug. The anticancer effects of metformin indicate the possibility that certain diabetes-associated types of cancer may be circumvented. Indeed, many retrospective meta-analyses have shown that metformin possesses anti-cancer activities and decreases the incidence of primary cancer development in those taking metformin routinely, and a multitude of clinical cancer trials are actively assessing its benefits in non-diabetic population who have already developed cancer. However, the precise molecular

mechanisms whereby metformin works in cancer prevention remain multi-factorial and ill-defined.

### Peer-review

Authors have done excellent work in this present study. They have explored the effect of metformin and interfering *NF-κB* gene transcription with specific siRNA, alone or in combination, on *MDR1* gene regulation. The application of interfering *NF-κB* activation with metformin was more effective to reverse MDR of HCC cells.

### Abstract

This report describes a patient that developed recurrent metastatic hepatocellular carcinoma (HCC) to a supra-pancreatic lymph node four years after being treated for primary HCC *via* complete left hepatectomy. Metastatic HCC was proven by pathologic confirmation. The report addresses the role of surgical resection as a treatment modality for recurrent HCC to solitary lymph nodes. The role of biological chemotherapy as adjuvant treatment is also addressed.

**Key words:** Hepatocellular carcinoma; Lymph node; Recurrence; Metastatic; Extrahepatic

© **The Author(s) 2016.** Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Recurrence of primary hepatocellular carcinoma to a solitary extracellular site is a rare occurrence, especially after complete hepatic lobectomy for the

primary tumor. In this report we describe a case of recurrence to a solitary suprapancreatic lymph node four years after initial resection. This is the only report to describe such a recurrence this long after the primary resection.

Metastatic recurrence to a solitary lymph node four years after hepatic lobectomy for primary hepatocellular carcinoma. *World J Hepatol* 2016; 8(23): 994-998 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i23/994.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i23.994>

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world, with the highest prevalence rates occurring in the eastern hemisphere. However, there has been a rise in prevalence in the Western hemisphere. It has been postulated that this pattern is due to higher incidence of hepatitis B and C virus seen outside of the United States<sup>[1]</sup>. Tumor staging and strategies for treatment of HCC have been well described with current guidelines following the recommendations of the 2010 AHPBA/SSO/SSAT consensus conference on HCC<sup>[2]</sup>. Current guidelines are primarily geared toward patients with primary resectable and non-resectable HCC. However, data is lacking with regard to the treatment of recurrent extrahepatic HCC. Systemic chemotherapy has proven to be of minimal benefit for patients with advanced, and recurrent extrahepatic HCC. There are current studies being conducted that support the use of multikinase inhibitors, including Sorafenib, as a viable option for patients with advanced and extrahepatic HCC<sup>[3]</sup>.

It is well known that the most common type of recurrence of HCC is intrahepatic. The most common sites for hematogenous spread are the lung, followed by the adrenal gland, and bone<sup>[4]</sup>. Metastases of HCC to lymph nodes (LN) are quite rare. In one report that included a subset of Japanese patients who underwent hepatic resection, the prevalence of lymphatic involvement was as low as 2.2%<sup>[5]</sup>. Another study showed that the 5-year survival rate for patients with lymph node metastasis is approximately 20%<sup>[6]</sup>. There have been few reports describing metastasis to LN that have been treated with surgical resection, and their results have been varied<sup>[7-11]</sup>. With this in mind, the importance of surgical resection of extrahepatic HCC recurrent to lymph nodes cannot be understated as a viable treatment modality. Interestingly, this is the first reported case where isolated lymph node metastasis has occurred greater than 3 years after initial hepatic resection. We describe a case of HCC recurrent to a solitary suprapancreatic lymph node treated by complete surgical resection.

## CASE REPORT

The patient is a 67-year-old woman who presented with a suprapancreatic mass on magnetic resonance imaging (MRI). She initially presented 4 years prior with HCC of the left lobe of the liver measuring 10.8 cm × 7.4 cm × 9.5 cm. She was asymptomatic at the time of the discovery and the tumor was found due to imaging studies prior to a recent thoracic aortic aneurysm repair. Interestingly she did not have known risk factors for developing HCC such as cirrhosis, chronic hepatitis, tobacco use, diabetes, nonalcoholic fatty liver disease, hemochromatosis, or alpha-1 antitrypsin deficiency. Laboratory findings at that time showed a alpha fetoprotein (AFP) level of 119000 ng/mL. She subsequently underwent complete left hepatic lobectomy and had no complications post procedure. The patient was in remission for almost 4 years, but had a steady increase in AFP, 177-883 ng/mL, from year 3 to 4. Serial computed tomography (CT) imaging showed no evidence of recurrence over that time period. Subsequent MRI showed a soft tissue mass medial to the right hepatic lobe/porta hepatis measuring 4.6 cm × 5.6 cm (Figure 1). CT guided biopsy of the mass revealed a poorly differentiated malignant neoplasm, favoring HCC. The patient had no history of viral hepatitis, alcoholic liver disease, jaundice, abdominal pain, weight loss, chronic cough, bloody stools, bone pain, or any other signs to suggest metastatic disease. She was subsequently taken to the operating room for *en bloc* resection of a large suprapancreatic retroperitoneal mass, celiac and portal lymphadenectomy. Pathology showed the suprapancreatic mass to be consistent with HCC, high grade within a lymph node structure. Portal and celiac axis lymph nodes were negative for metastasis. Interestingly, immunohistochemical stains for the recurrent carcinoma showed not only tumor markers that confirm hepatocellular origin, but might suggest a more aggressive tumor - staining positive for cytokeratin 19 (CK19), glypican 3 (G3) and hepatocyte paraffin 1 (HP1). Microscopic pathologic figures are shown in Figures 2 and 3. The patient's post-operative course has been uncomplicated and at eight months post op she is disease free. Current AFP level is 2.2 ng/mL.

## DISCUSSION

The recurrence of HCC can be classified as early or late phase<sup>[12]</sup>. Early phase recurrence typically occurs within the first two years post-resection, and is related to aggressive features of the primary tumor such as high tumor grade, local invasion, and multifocal tumors. Late recurrence occurs more than two years after resection and is related to *de novo* tumor formation, typically in patients with cirrhotic liver disease. The fact that our patient recurred to an extrahepatic LN nearly four years post-surgery is remarkable, and of the first to be reported this late, post-resection. The initial tumor was without aggressive characteristics, as it was moderately

**Figure 1 Suprapancreatic mass.** The left panel (A) shows an axial post contrast T1 fat suppressed sequence that demonstrates an arterial phase enhancing mass medial to the liver; the right panel (B) shows an axial T2 HASTE sequence demonstrating a mass with increased T2 signal medial to the liver. T: Tumor.

**Figure 2 Initial hepatic lobectomy.** On the left-hand set of H and E-stained quarter panel images, the upper left two-image combination quarter panel (A) shows the trabecular architecture, the trabeculae as "T"; the upper right H and E quarter panel (B) shows L-V; the lower H and E quarter panels show high power views of solid pattern tumor with focal geographic necrosis [lower left (F) as "N"] and numerous mitoses [lower right (G) with "M" times 4]; on the right-hand set of IHC-stained split full-height images, the mass, along the bottom (H-J) show negative G3 (H), CK19 (I), HP1 (J); the L-V, along the top (C-E) with a similar pattern, but with weak but convincing HP1 positivity. Both HP1 stains are inset with 100 × high power images (100 ×). Arrows on the L-V IHC (C and D) stains indicate the tumor (opposite vessel wall). L-V: Lymph-vascular tumor; Mass: Main mass; LN: Lymph node; G3: Glypican 3; CK19: Cytokeratin 19; HP1: Hepatocyte paraffin 1; T: Tumor.

**Figure 3 Resected recurrence.** A: The H and E-stained shows a tiny area of likely LN at one end; B: Shows obvious tumor cells nests; On the right-hand set of IHC stained split full-height images, both the main mass (F-H); and obvious nodal tumor (LN2) (C-E), are strongly positive on G3 (C), CK19 (D), and HP1 (E) stains. Mass: Main mass; LN: Lymph node; G3: Glypican 3; CK19: Cytokeratin 19; HP1: Hepatocyte paraffin 1.

differentiated and without local invasion. Additionally, the initial tumor stained negative for CK19, G3 and was only weakly positive for HP1 in the lympho-vascular invasive sample as seen in Figure 1. Interestingly, the recurrent tumor was positive for these three biomarkers, suggesting hepatocellular origin and a more aggressive tumor<sup>[13]</sup>. Clonal selection, therapeutic selection, or possibly both may explain this finding.

LN status is essential to the staging of cancers, including HCC. The presence of LN metastasis is associated with poorer survival and higher risk of tumor recurrence<sup>[4]</sup>. Although the most common intra- and extra-hepatic recurrence is to liver and lung respectively, metastases to LNs are not that uncommon. There have been two reports that showed LN metastases in 28% and 25% of autopsied cases of HCC, respectively<sup>[14,15]</sup>. However, a more recent study of surgical patients in Japan showed only 2.2% LN involvement in patients that underwent hepatic resection<sup>[5]</sup>. This discrepancy may be due to the fact that more advanced HCC cases that are more likely to have extrahepatic metastases are less likely to undergo resection. This finding illuminates the importance LN dissection in hepatic surgery. LN dissection is not the current standard when performing hepatic resection for HCC. In a study by Ercolani *et al.*<sup>[16]</sup> the role of lymphadenectomy was addressed. In 40 patients with HCC the incidence of LN metastases was 7.5%. It was also found that the most common site of LN metastases from HCC is the hepatic pedicle node, followed by the retropancreatic space, and common hepatic artery station. The authors concluded that regional lymphadenectomy is a safe procedure after liver resection; however, this is yet to become common practice.

Several case reports have been published on the findings of metastatic HCC to LNs<sup>[7-11]</sup>. Patients in these reports often had cirrhosis, and all but one of these patients underwent resection with varied short-term survival results. One report described a patient with a solitary suprapancreatic LN metastasis that underwent pancreaticoduodenectomy and had reported disease free survival for 27 mo. Another patient with LN metastases to two paraaortic mediastinal LNs underwent complete resection, but had recurrence and died 13 mo later<sup>[10]</sup>. It is reasonable to argue liver disease, and multiple LN involvement may be factors for worse prognosis post LN resection.

Our patient appears to be an excellent candidate for resection, as she had a solitary LN, and is without cirrhotic, viral or alcoholic liver disease. In addition, adjuvant treatment with sorafenib - an oral multikinase inhibitor that has been shown to suppress tumor growth and angiogenesis by inhibiting the Raf/MEK/ERK signaling pathway and receptor kinases, such as VEGFR-1, VEGFR-2, VEGFR-3, and PDGFR $\beta$  - should be considered<sup>[3]</sup>. Sorafenib was shown to increase survival in patients with advanced HCC in the SHARP (Sorafenib HCC Assessment Randomized Protocol) trial. However, data is lacking on whether this multikinase inhibitor is useful in the

treatment of recurrent extrahepatic HCC. One recent study showed that the therapeutic effect of sorafenib was comparable in advanced HCC with or without extra-hepatic metastasis<sup>[3]</sup>. It may be beneficial to initiate adjuvant treatment in patients with recurrent LN involvement, but further studies need to be performed prior to this becoming standard.

## COMMENTS

### Case characteristic

A 67-year-old woman who presented with a suprapancreatic mass on magnetic resonance imaging (MRI). The patient was asymptomatic at the time of presentation. Imaging studies were performed because of increased serum alpha fetoprotein levels led to increase suspicion for recurrence of primary hepatocellular carcinoma (HCC) resected four years prior.

### Clinical diagnosis

The patient was asymptomatic at the time of presentation.

### Differential diagnosis

Recurrent primary HCC, metastatic cancer, reactive lymphadenopathy, primary tumor of unknown origin, lymphoma.

### Laboratory diagnosis

Elevated alpha fetoprotein level of 883 ng/mL.

### Imaging diagnosis

MRI showed a soft tissue mass medial to the right hepatic lobe/porta hepatis measuring 4.6 cm  $\times$  5.6 cm.

### Pathological diagnosis

HCC, high grade within a lymph node structure.

### Treatment

Surgical resection of lesion.

### Related reports

HCC is a primary liver cancer. HCC typically does not recur to an extrahepatic solitary lymph node after primary resection.

### Term explanation

HCC is a primary liver cancer. It is the fifth most common human cancer worldwide.

### Experiences and lessons

Surgical resection of HCC recurrence to a solitary lymph node is a viable option and may also be curative. Long term follow-up of this patient will further illuminate the possibility of cure.

### Peer-review

An interesting case presentation with a long period disease-free up to 4 years. It should be benefit to the knowledge of the hepatologists and keep in mind for the importance of clinical follow-up after extensive hepatectomy.

### ABOUT COVER

Editorial Board Member of *World Journal of Hepatology*, Christoph A Maurer, MD, FACS, FRCS(Hon), FEBS, Professor of Surgery, Department of Surgery, Hirslanden-Clinic Beau-Site, 3013 Bern, Switzerland

### AIM AND SCOPE

*World Journal of Hepatology* (*World J Hepatol*, *WJH*, online ISSN 1948-5182, DOI: 10.4254), is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJH* covers topics concerning liver biology/pathology, cirrhosis and its complications, liver fibrosis, liver failure, portal hypertension, hepatitis B and C and inflammatory disorders, steatohepatitis and metabolic liver disease, hepatocellular carcinoma, biliary tract disease, autoimmune disease, cholestatic and biliary disease, transplantation, genetics, epidemiology, microbiology, molecular and cell biology, nutrition, geriatric and pediatric hepatology, diagnosis and screening, endoscopy, imaging, and advanced technology. Priority publication will be given to articles concerning diagnosis and treatment of hepatology diseases. The following aspects are covered: Clinical diagnosis, laboratory diagnosis, differential diagnosis, imaging tests, pathological diagnosis, molecular biological diagnosis, immunological diagnosis, genetic diagnosis, functional diagnostics, and physical diagnosis; and comprehensive therapy, drug therapy, surgical therapy, interventional treatment, minimally invasive therapy, and robot-assisted therapy.

We encourage authors to submit their manuscripts to *WJH*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

### INDEXING/ ABSTRACTING

*World Journal of Hepatology* is now indexed in PubMed, PubMed Central, and Scopus.

### Abstract

Hepatorenal syndrome (HRS) plays an important role in patients with liver cirrhosis on the wait list for liver transplantation (LT). The 1 and 5-year probability of developing HRS in cirrhotic with ascites is 20% and 40%, respectively. In this article, we reviewed current concepts in HRS pathophysiology, guidelines for HRS diagnosis, effective treatment options presently available, and controversies surrounding liver alone *vs* simultaneous liver kidney transplant (SLKT) in transplant candidates. Many treatment options including albumin, vasoconstrictors, renal replacement therapy, and eventual LT have remained a mainstay in the treatment of HRS. Unfortunately, even after aggressive measures such as terlipressin use, the rate of recovery is less than 50% of patients. Moreover, current SLKT guidelines include: (1) estimation of glomerular filtration rate of 30 mL/min or less for 4-8 wk; (2) proteinuria > 2 g/d; or (3) biopsy proven interstitial fibrosis or glomerulosclerosis. Even with these updated criteria there is a lack of consistency regarding long-term benefits for SLKT *vs* LT alone. Finally, in regards to kidney dysfunction in the post-transplant setting, an estimation of glomerular filtration rate < 60 mL/min per 1.73 m<sup>2</sup> may be associated with an increased risk of patients having long-term end stage renal disease. HRS is common in patients with cirrhosis and those on liver transplant waitlist. Prompt identification and therapy initiation in transplant candidates with HRS may improve post-transplantation outcomes. Future studies identifying optimal vasoconstrictor regimens, alternative therapies, and factors predictive of response to therapy are needed. The appropriate use of SLKT in patients with HRS remains controversial and requires further evidence by the transplant community.

**Key words:** Liver transplantation; Simultaneous liver kidney transplantation; Vasopressors; Dialysis; Post-transplant outcomes; Hepatorenal syndrome

**Core tip:** We aim to review the literature on hepatorenal syndrome (HRS) in the setting of liver transplantation (LT) and address critical issues that are barriers to improved outcomes. Many consistencies have remained as treatment options including albumin, vasoconstrictors, renal replacement therapy, and eventual LT. Moreover, the utility of simultaneous liver kidney transplantation in HRS patients still requires further evidence by the transplant community.

Modi RM, Patel N, Metwally SN, Mumtaz K. Outcomes of liver transplantation in patients with hepatorenal syndrome. *World J Hepatol* 2016; 8(24): 999-1011 Available from: URL: <http://www.wjgnet.com/1948-5182/full/v8/i24/999.htm> DOI: <http://dx.doi.org/10.4254/wjh.v8.i24.999>

## INTRODUCTION

Prior to diagnosing a patient with hepatorenal syndrome (HRS) in the setting of liver transplantation (LT), it is important to rule out other etiologies of renal dysfunction. A broad differential should include reversible causes such as acute kidney injury (AKI) or acute tubular necrosis (ATN) and irreversible cause like chronic kidney disease (CKD) or parenchymal kidney disease.

Traditionally there are three types of AKI (pre-renal azotemia, intrinsic kidney disease, and post-obstructive causes) that are still common in patients with liver disease in addition to HRS<sup>[1]</sup>. Common causes of pre-renal injury independent of HRS include infection, intravascular fluid depletion, GI fluid losses, surgery or bleeding, and renal artery occlusion<sup>[2]</sup>, all of which should appropriately respond to volume expansion with albumin within 48 h. If there is any recent contrast media or nephrotoxic agent with granular casts and proteinuria > 500 mg, it is important to consider ATN as a likely diagnosis<sup>[3]</sup>. A recent study evaluating patients with AKI [pre-renal azotemia ( $n = 35$ ), HRS ( $n = 35$ ), ATN ( $n = 36$ )] revealed that pre-renal azotemia has a lower mortality when compared to both HRS ( $P = 0.05$ ) and ATN ( $P = 0.04$ )<sup>[4]</sup>.

Intrinsic kidney disease is more common than previously believed in the cirrhotic population, and is thought to be related to the underlying etiology of cirrhosis<sup>[2]</sup>. Kidney biopsy is most useful in intrinsic kidney disease with hematuria (50 red blood cells per high power field), proteinuria (> 500 mg/d), renal insufficiency of unknown origin, or HRS for a prolonged period of time. Histologically, IgA nephropathy, membranoproliferative glomerulonephritis, focal global glomerulosclerosis, and diabetic nephropathy<sup>[5]</sup> are the most common biopsy findings. The importance of diagnosing parenchymal disease is especially important if a patient is being considered for combined liver-kidney transplantation<sup>[6]</sup>. Additionally, obstructive causes of renal dysfunction

including nephrolithiasis, bladder outlet obstruction and other intra-abdominal etiologies should be assessed.

If the aforementioned workup returns negative, HRS should be considered as a potential cause of renal dysfunction. The 1-year and 5-year probability of developing HRS in patients with ascites is 20% and 40%, respectively<sup>[7]</sup>. The most recent diagnostic criteria for HRS from the International Ascites Club (IAC) in 2007 include creatinine (Cr) > 1.5 mg/dL, no improvement of Cr after volume expansion with albumin after 48 h, no current or recent exposure to nephrotoxic drugs, absence of parenchymal disease (proteinuria > 500 mg/d), microscopic hematuria (50 red blood cells per high power field), and abnormal renal ultrasonography<sup>[8]</sup>.

In this review, we will focus on various aspects of HRS and its impact on various phases of LT. Literature was searched for this review from various search engines including PubMed, Cochrane, and Scopus. Each of the citations for the papers originally pulled was then reviewed for additional articles for inclusion.

## ROLE OF CR AND OTHER MARKERS OF RENAL IMPAIRMENT IN CIRRHOTICS

There is concern that serum Cr may not reflect accurate kidney function in the setting of HRS with significant liver dysfunction<sup>[8,9]</sup>. Cr is an indirect measure of renal function as it is derived from non-enzymatic conversion of creatine, which is stored in muscle and being produced within the liver. As patients develop cirrhosis there is increased muscle wasting, decreased protein intake, and diminished creatine synthesis resulting in overestimation of renal function<sup>[9,10]</sup>. Moreover, two individuals with similar glomerular filtration rates may have varying Cr levels due to variation associated with age, sex, race, body mass index, and bilirubin concentrations<sup>[11]</sup>. For example, women generally have lower serum Cr levels compared to men resulting in lower median MELD scores (14 vs 15,  $P < 0.001$ ) and a higher likelihood to die on the transplant list when compared to the pre-MELD era<sup>[12]</sup>.

Multiple mathematical formulas have been developed to utilize serum Cr to calculate an estimation of glomerular filtration rate (eGFR). These include Cockcroft-Gault (C-G) and Modification of Diet in Renal Disease (MDRD) which incorporate different variables. C-G requires age, gender, weight, and serum Cr, while MDRD-4 utilizes age, gender, ethnicity, and serum Cr and MDRD-6 also involves albumin and urea<sup>[13,14]</sup>. In our cirrhotic population, MDRD-6 is used more widely when compared to C-G given inclusion of albumin and urea. Moreover, exogenous markers such as inulin have been previously documented to improve accuracy when determining renal function. Unfortunately the "gold standard" inulin infusion technique is time consuming, expensive, and potentially invasive making it a less viable option<sup>[15]</sup>.

Multiple AKI biomarkers including NGAL, Cystatin C, IL-18, NAG, and KIM-1 have been well characterized

and may delineate patients who have the risk of progression of disease and will require renal replacement therapy (RRT)<sup>[2,16,17]</sup>. For example, Aberg *et al.*<sup>[18]</sup> looked specifically at the urinary marker neutrophil gelatinase-associated lipocalin (NGAL) in 203 LT patients and demonstrated that raised urinary levels of NGAL independently predicted pre-LT kidney dysfunction in the setting of HRS and could have the potential to help decide the need to performed combined liver-kidney transplantation. Additionally, urinary NGAL levels to be a strong predictor for short-term mortality, with HRS patients having intermediate levels between prerenal azotemia and intrinsic AKI<sup>[19]</sup>. Furthermore, certain studies have also shown cystatin C level may be an important marker for predicting mortality in HRS<sup>[20,21]</sup>. However, it is important to note that at this time current IAC or Acute Dialysis Quality Initiative do not recommend evaluating for these biomarkers.

## BRIEF PATHOPHYSIOLOGY AND TYPES OF HRS

The pathophysiology of HRS has been well documented previously with portal hypertension leading to splanchnic artery dilatation<sup>[22,23]</sup>. This phenomenon results in a number of downstream effects including arterial under-filling, increased cardiac output, and vasoconstriction of renal arteries<sup>[8]</sup>. Ultimately the kidneys respond with increased activity of renin-angiotensin-aldosterone system as well as non-osmotic release of vasopressin, both of which result in worsening GFR, ascites, and hemodynamic instability<sup>[24,25]</sup>.

HRS is typically divided into two subtypes, type 1 and type 2, based on the rate of progression of renal disease and prognosis. Diagnostic criteria for type 1 HRS (in addition to criteria for HRS according to IAC mentioned above) include serum Cr > 2.5 mg/dL, doubling of serum Cr in less than 2 wk, no history of diuretic resistant ascites, and generally a precipitating event. On the other hand, type 2 HRS is a gradually progressive renal impairment without any precipitating events and usually associated with diuretic resistant ascites. Additionally, patient outcomes in terms of survival were reported to be better with type 2 HRS vs type 1<sup>[26]</sup>.

## CLASSIFICATIONS OF RENAL DYSFUNCTION IN PATIENTS WITH CIRRHOSIS

Various criteria are used for classification of renal dysfunction in patients with liver cirrhosis. Two of the most commonly used criteria include the Risk, Injury, Failure, Loss, and End-Stage Kidney Disease (RIFLE) and AKI network (AKIN). The RIFLE criteria utilize both serum Cr level and urine output to assess what stage of renal injury has occurred. For example, acute renal injury is Cr doubled from baseline and urine output <

0.5 mL/kg per hour over 12 h while acute renal failure is Cr tripled from baseline and urine output < 0.3 mL/kg per hour over 24 h. A major limitation of the RIFLE classification is that per these criteria a large number of cirrhotic patients would already present with some degree of AKI. In 2007 the AKIN has proposed a new definition of AKI that condenses RIFLE into 3 stages to increase sensitivity and specificity of diagnosing AKI. Moreover, the Kidney Disease Improving Global Outcomes recently defined AKI as diminished kidney function resulting in 0.3 mg/dL increase in serum Cr in 48 h, or a 50% increase in baseline Cr (within 7 d), or a urine volume of < 0.5 mL/kg per hour for 6 h<sup>[8,27]</sup>. It has been well documented that approximately 20% of patients hospitalized for decompensated cirrhosis present with a concomitant AKI<sup>[28]</sup>. This phenomenon is related to the progressive vasodilatory state of cirrhosis causing a decrease in arterial volume and resultant vasoconstriction of renal vessels. Interestingly, two prospective studies assessing AKI criteria in patients with cirrhosis found that AKI with serum Cr values < 1.5 mg/dL is a relatively benign and potentially reversible condition, while significant increase in Cr (> 1.5 mg/dL) is associated with a worse prognosis<sup>[29,30]</sup>.

A retrospective study utilized the RIFLE classification to look at 283 patients who underwent LT and stratified them into three cohorts: Risk, injury, and failure. Moreover, the failure group was further subdivided by etiology (HRS vs ATN) and the clinical course was followed for 5 years. Comparing these groups, the ATN group had significantly worse 1- and 5-year survival and renal outcomes, with an increased incidence of stage 4 and 5 CKD<sup>[31]</sup>. While only a single-center retrospective study, it is instrumental in demonstrating that the etiology of AKI may be more important than initially thought in predicting renal recovery<sup>[32]</sup>.

Prerenal injury, ATN, and HRS encompass close to 80% of AKI etiology in the in the pre-transplantation setting<sup>[33]</sup>. A United Network for Organ Sharing (UNOS) based study in 2002 found that 40% of LT candidates have kidney dysfunction, best defined as a GFR < 60 cm<sup>3</sup>/min per square meter<sup>[34]</sup>. More recently, a prospective study following 463 patients classified renal failure into four main categories: Infections (*n* = 213, 46%), hypovolemia associated renal failure (*n* = 149, 32%), HRS (*n* = 60, 13%), parenchymal nephropathy (*n* = 41, 9%)<sup>[35]</sup>. While this is a simple classification, it is useful to assess prognosis and decisions regarding LT.

## PREVALENCE AND PRECIPITANTS OF HRS IN WAIT-LIST AND TRANSPLANT PATIENTS

The prevalence of HRS has been reported to increase with severity and duration of cirrhosis. Ginès *et al.*<sup>[36]</sup> studied 229 patients with cirrhosis and found an 18% incidence of HRS at one year, with an increase to 39% within five years. Additionally, Wong *et al.*<sup>[37]</sup> reported

HRS in 48% of patients on the LT waiting list, indicating an increased prevalence with disease progression. Various precipitants of HRS include spontaneous bacterial peritonitis, large volume paracentesis with inadequate albumin replacement, use of nephrotoxic drugs and hypovolemia due to bleeding and or dehydration. With the help of early diagnosis and aggressive management with vasopressors the incidence of HRS may decrease with an improvement in overall outcomes<sup>[38]</sup>.

## MANAGEMENT OF HRS

Medical management of HRS has been shown to improve short-term outcomes; however, long term outcomes are dismal without LT. Current medical treatment includes avoidance of HRS precipitants and pharmacological management prior to considering transjugular intrahepatic portosystemic shunt (TIPS) and RRT. Pharmacological treatment serves as a bridge to transplantation to improve the patient's prognosis. There is a consensus on general measures in treating HRS including suspension of diuretic therapy, avoidance of nephrotoxic drugs and adjustment in doses of drugs. Moreover, per AASLD guidelines the role of albumin after large volume paracentesis (8 g of albumin for each liter of ascites removed) has been the standard of care.

### Role of terlipressin in HRS

Given the significance of arterial vasodilatation in the pathophysiology of HRS, vasoconstrictors along with albumin have improved renal function in approximately 40%-60% of patients with type 1 HRS (Table 1)<sup>[39]</sup>. Terlipressin plus albumin has been shown to improve renal function in 35%-40% of patients with type 1 HRS, with initial IV boluses of 0.5-1 mg every 4 h that can be titrated to 3 mg every 4 h if there is limited response<sup>[40-42]</sup>. A study comparing terlipressin bolus vs continuous infusion found that while the rate of response was not statistically significant, the rate of adverse of events was lower in the infusion group with lower associated dosing<sup>[43]</sup>.

While many studies demonstrate the use of terlipressin as a bridge to transplantation, it is important to note that fewer than 50% of patients who used terlipressin in the setting of HRS recover from a renal standpoint. One study assessed the efficacy of terlipressin plus albumin vs albumin alone for treatment of HRS-1 in the setting of LT. The 6-mo survival rate for those in the terlipressin group was 100% for transplanted patients and 34% for non-transplanted patients, while in the control group survival was 94% for transplanted patients and 17% for non-transplanted patients<sup>[44]</sup>. This study was able to show that terlipressin likely improved pre-transplant renal function while having no significant impact on post-transplant survival. On the other hand, Sagi *et al*<sup>[45]</sup> concluded improved transplant-free survival at 90 d (RR = 1.86, 95%CI: 1.0-3.4,  $P = 0.05$ ) in those in the terlipressin arm when studying 223 patients in 4 separate trials. A prospective, randomized, double-blind, placebo-controlled clinical trial showed that terli-

pressin group showed Cr improvement from baseline to day 14 while on the treatment<sup>[46]</sup>. It appears that terlipressin treatment beyond one week and up to 20 d has the potential for further improvement<sup>[47]</sup>. Moreover, a recent meta-analysis of randomized trials (5 trials,  $n = 243$  patients), showed the overall rate of patients on terlipressin with HRS who recovered renal function was 8.09 (95%CI: 3.52-18.59,  $P < 0.001$ )<sup>[48]</sup>.

One study found a better response to terlipressin in the setting of higher serum sodium concentrations and lower serum bilirubin at the beginning of treatment<sup>[49]</sup>, which would indicate that the early identification and treatment of HRS-1 may improve outcomes. A larger study was able to identify independent predictors of survival in the setting of terlipressin including age, duration of treatment, MELD score, and alcoholic cirrhosis<sup>[50]</sup>, while an additional study was able to identify low urinary sodium prior to treatment being associated with poor survival<sup>[51]</sup>.

Similar to the type 1 HRS patient population, terlipressin has been shown to improve renal function in type 2 HRS (Cr improvement in 8 out of 11 patients) when compared to organic renal disease<sup>[52]</sup>. Interestingly, a recent study examined 56 patients awaiting LT who were diagnosed with type 2 HRS. A subset of patients were being treated with terlipressin and albumin, but no differences were found in mortality in peri-operative setting or in post-transplantation outcomes (AKI, need for RRT, or development of CKD) when compared to the control group<sup>[53]</sup>. Moreover, another study also showed no benefit in using terlipressin in the setting of type 2 HRS<sup>[54]</sup>. Furthermore, while LT helps reverse type 2 HRS, there may be an association with longer intensive care stays and early-post-transplant CKD stage 3<sup>[55]</sup>.

### Role of other vasoconstrictors in HRS

Terlipressin is not available in United States; therefore midodrine, octreotide, omipressin and noradrenaline with albumin have been used in uncontrolled studies to treat HRS. It was found that HRS patients were more likely to improve while treated with AVP when compared to octreotide alone<sup>[56]</sup>. Another study assessed the effect of octreotide, midodrine, and albumin on survival compared to control populations and found improved renal function and short-term survival in the setting of both HRS-1 and HRS-2<sup>[57]</sup>. With use of a combo of octreotide, midodrine and albumin, reversal of HRS has been reported to be as high as 40%<sup>[58]</sup>.

Ornipressin is another potent splanchnic vasoconstrictor, but has been shown to have a higher incidence of vascular complications when compared to terlipressin<sup>[59]</sup>. In regards to noradrenaline, an unblinded study in 2007 was able to show that noradrenaline is an effective alternative to terlipressin in the setting of HRS type 1<sup>[60]</sup>. A more recent meta-analysis looked at 4 smaller studies where 154 patients were included and found that there was no difference between noradrenaline and terlipressin in regards to mortality at 30 d (RR = 0.89, 95%CI: 0.68 to 1.17) and reversal of HRS (RR = 0.97, 95%CI: 0.76 to 1.23)<sup>[61]</sup>.

Table 1 The role of terlipressin and albumin in hepatorenal syndrome-1

Ref.	Terlipressin dose	Albumin	Length	Terlipressin group: Cr (mg/dL) or Cr Cl (mL/min)	Control group: Cr (mg/dL) or Cr Cl (mL/min)	30 d survival (terlipressin <i>vs</i> control)	Transplant free outcome

Cr: Creatinine; Cr Cl: Creatinine clearance; HRS: Hepatorenal syndrome; N/A: Not available.

A recently published randomized study directly compared terlipressin with albumin to midodrine plus octreotide with albumin<sup>[62]</sup>. Terlipressin group was found to be significantly more effective in improving kidney function in HRS patients (70% *vs* 28%)<sup>[62]</sup>. Additionally, a small study that looked at three patients who were initially on terlipressin and attempted to switch treatment to midodrine plus octreotide on multiple attempts were found to have serum Cr elevation as well as diminished urine output<sup>[63]</sup>.

### Other treatment options for HRS

Among other options available for HRS management, TIPS has been increasingly utilized. While it is well documented that TIPS is effective treatment for refractory variceal bleeding and ascites, its role in patients with renal dysfunction is unclear. Few small studies on HRS indicate some clear benefit after TIPS<sup>[64,65]</sup>. A study examining non-

transplantable cirrhotic (14 type 1 HRS and 17 type 2 HRS) patients showed renal function improved within two weeks after TIPS with improved mortality over the course of 18 mo<sup>[66]</sup>. A recent study utilizing UNOS demonstrated that patients on the LT list status-post TIPS procedure had a lower mortality rate compared to patients without TIPS<sup>[67]</sup>. This study hypothesized that the TIPS plays a role in promoting survival by improving nutritional status and preventing variceal bleeding, refractory ascites, and HRS. It is important to remember that TIPS can increase the risk of hepatic encephalopathy as well as liver failure in rare occasions<sup>[68]</sup>.

Molecular absorbent recycling system (MARS) has the ability to remove both small- and medium-sized lipophilic toxins and may have a role in improving complications of liver disease such as hepatic encephalopathy and HRS. Multiple studies have shown MARS having the ability to reduce cholestatic parameters, improve mentation, as well as renal function especially in patients with a Model for End-Stage Liver Disease (MELD) between 20-29<sup>[69,70]</sup>. In 2002 a study showed when MARS was used there was improvement in mentation and hepatic encephalopathy in 14 out of 19 centers<sup>[71]</sup>. Interestingly, when MARS was directly compared to hemodiafiltration there was a decrease in Cr and bilirubin as well as a decrease in mortality at day 7<sup>[72]</sup>. Furthermore, a study looking at MARS use in the post-transplantation setting with HRS, HE, or intractable pruritis showed improvement in symptoms and laboratory findings<sup>[73]</sup>. However, none of these studies showed long term benefit in HRS patients including transplant free survival.

## PREDICTORS OF MORTALITY IN PATIENTS WITH HRS

Yang *et al.*<sup>[74]</sup> studied the predictors of mortality in type 1 HRS in a tertiary care center and formulated a time-dependent proportional hazards model. Contrary to other studies reporting on MELD score as predictor mortality, they found increased Cr by each point and total bilirubin levels during the admission increased mortality risk by 29% and 4%, respectively. Increasing albumin level during the admission showed its protective value<sup>[74]</sup>.

Sanchez *et al.*<sup>[75]</sup> looked at pre and peri-transplant predictors of renal dysfunction requiring either RRT or HD. This study looked at 724 LT patients where a clinical prediction model was constructed to assess the probability of requiring dialysis post-transplantation in a prospective manner. Pre-LT Cr > 1.9 mg/dL (OR = 3.57), pre-LT BUN > 27 mg/dL (OR = 2.68), ICU stay > 3 d (OR = 10.23), and MELD score > 21 (OR = 2.5) were significant<sup>[75]</sup>. Furthermore, changes in MELD scores (influenced by Cr and bilirubin) during the admission predict prognosis more so than the initial MELD<sup>[74]</sup>. A recent study was performed in attempts to assess renal impairment prior to overt HRS development by measuring renal arterial resistance indices (RI)<sup>[76]</sup>. Interestingly, RI was significantly higher in patients with ascites than those without ascites and may be an

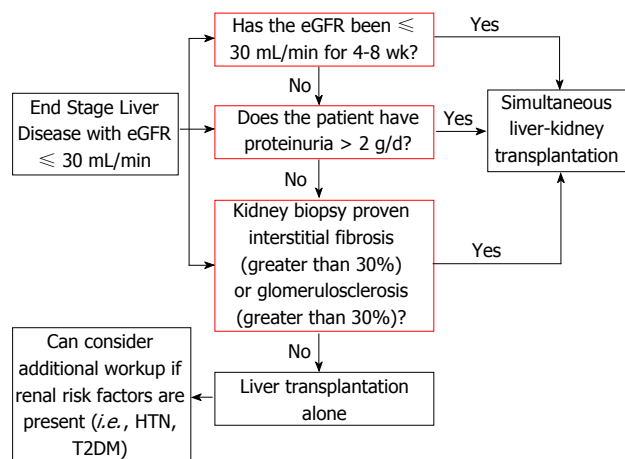

independent predictor of subsequent HRS development. Another study was able to show that "MAP responders" had improved response with better transplant-free survival in both the short-term and long-term settings<sup>[77]</sup>. However, these innovative modalities need further studies before being used in daily practice.

## LT ALONE VS SIMULTANEOUS LIVER KIDNEY TRANSPLANT FOR HRS

Since the introduction of the MELD scoring system there has been an increase in the number of simultaneous liver-kidney transplants (SLKT). From 2002 to 2013, the percentage of SLKT has increased from 4.2% to 8.1%, respectively. The most recent recommendations for SLKT include: (1) eGFR of 30 mL/min or less for 4-8 wk; (2) proteinuria > 2 g/d; and (3) biopsy proven interstitial fibrosis or glomerulosclerosis (Figure 1)<sup>[78]</sup>. An unintentional by product of SLKT has been a decrease number of kidney donors available for end stage renal disease (ESRD) patients. There are numerous studies indicating we should have stricter criteria for allocating two grafts to one patient as well as a debate on duration of renal dysfunction and duration of RRT in the setting of SLKT. A recent study proposed raising the dialysis requirement to greater than 12 wk (rather than current recommendations of 4-8 wk) to increase the number of kidney transplantations available for ESRD patients<sup>[79]</sup>. Table 2 outlines the outcomes of studies comparing liver transplantation alone (LTA) alone vs SLKT in the setting of HRS. One study retrospectively looked at 69 LT patients with a pre-transplantation Cr  $\geq$  1.5 and found that duration of pre-transplantation RRT rather than cause of renal dysfunction was a predictor of 6- and 12-mo kidney function post-LTA<sup>[80]</sup>. Interestingly, earlier studies have shown mixed data in regards to the utility of SLKT in the setting of HRS. A 1997 UNOS study looked at 414 SLKT vs 2442 LTA with a Cr > 2.0 and found a 5 year survival of 62.2% for SLKT patients and 50.4% for LTA recipients, suggesting SLKT may be beneficial for HRS patients<sup>[81]</sup>. Furthermore, another study including local center and UNOS database (2002-2008) compared LTA vs SLKT in the setting of renal impairment. Diagnosis of HRS was presumptive in UNOS database and confirmed on the local data. UNOS data showed a survival benefit of SLKT over LTA for those patients with poor renal function, specifically those with HRS, whereas results of local center suggest otherwise<sup>[82]</sup>.

On the other hand, a small study showed that in patients with HRS, SLKT did not confer a survival advantage over LTA (1-year patient survival was 72% vs 66%, *P*-value = 0.88)<sup>[83]</sup>. A much larger 2006 UNOS study that compared 1032 SLKT to 19137 LTA patients showed no mortality difference for patients with HRS (1 year survival was 72% vs 66%) unless the patient was receiving HD for longer than 8 wk, with a dialysis duration of > 12 wk that was a significant predictor for long-term outcomes<sup>[84]</sup>. Furthermore, one meta-analysis looked at 3536 SLKT

**Figure 1** Algorithm for evaluating for simultaneous liver-kidney transplantation in a liver transplant candidate with renal dysfunction. Modified from Saxena *et al.*<sup>[76]</sup>. eGFR: Estimation of glomerular filtration rate; T2DM: Type 2 diabetes mellitus; HTN: Hypertension.

(between 1984 to 2008) and found that the cumulative 1, 2, 3 and 5-year patient survival were 84.9%, 52.8%, 45.4% and 42.6%. It was concluded that there was no definitive evidence of better graft or patient survival in the SLKT population when compared to the LTA given the difficulty discerning irreversible kidney function in liver transplant candidates<sup>[85]</sup>. Additionally, one study found the rate of renal non-recovery within 6 mo of LTA for 2112 patients who underwent RRT within 90 d of their transplantation was only 8.9%, with risk factors for non-recovery including age, T2DM, and duration of RRT<sup>[86]</sup>. Because of this limitation as well as selection biases, the true survival benefit of SLKT in candidates without ESRD remains unproved<sup>[87]</sup>.

It appears that UNOS database studies have heterogeneous groups, including patients with renal impairment due to multiple reasons and hence a selection bias for patients with HRS. Single center studies have issue of small sample size. Nevertheless, chances of misclassification bias in small studies are less. These studies do not report added benefit of SLKT over LTA in patients with HRS, not on HD and duration of renal dysfunction < 8 wk.

Interestingly some studies address benefit of SKLT over LTA alone with respect to immune safety liver graft on kidney graft function due to immunogenic effect of liver. These studies justified SLKT over LTA for two additional reasons: (1) it is well documented there is significant decrease in graft rejection when a patient has a SLKT over an LTA (15% decreased reduction in graft loss); and (2) there is superior recipient and graft survival when compared to Kidney After LT or Liver After Kidney Transplantation<sup>[88,89]</sup>. Priority for allocation of kidneys to kidney-liver candidates follows the allocation priority for the non-renal organ. However, due to shortage of organ and justification of an equitable distribution of organ it is not possible to perform SLKT for this indication.

## HRS AND POST-TRANSPLANT MANAGEMENT/OUTCOMES

### Impact of HRS on outcomes of LT

The impact of LT on overall renal function has been well documented. Lafayette *et al.*<sup>[90]</sup> looked at renal function in the pre-transplantation setting and studied 115 liver transplant recipients by arbitrarily dividing them based on serum Cr into two groups (group 1 with Cr > 1.0, group 2 with < 1.0); they showed that group 1 patients had significantly longer ICU stays, higher hospital charges, and a greatly increased mortality rate<sup>[90]</sup>. Patients with HRS tend to require longer hospitalizations, increased intensive care duration, and further dialysis in the post-op setting<sup>[91]</sup>. Interestingly, when comparing HRS vs ATN post-transplant outcomes it was found that ATN was associated with higher mortality at 1 year post-LT along with increased incidence of CKD (stage 4 or 5) when compared to HRS<sup>[31]</sup>.

One of the first studies to address HRS in the post-operative setting was in reported in 1991 where Gonwa *et al.*<sup>[92]</sup> found close to 10% of HRS patients developed ESRD post-transplant when compared to 0.8% of non-HRS patients ( $P < 0.005$ ). However, a similar study revealed that while HRS patients were more likely to be dialyzed post-operatively, there was no difference between Cr levels at 24 wk between non-HRS vs HRS groups<sup>[93]</sup>. Park *et al.*<sup>[94]</sup> also confirmed this concept in a study that yielded similar results in 1-year patient survival after LT in the HRS patients vs those without HRS ( $P = 0.37$ ).

In regards to AKI in the post-LT setting, a large study looking at 1352 LT recipients found that 162 (12%) patients developed acute renal failure (ARF) within the first week. Type 2 HRS with GFR < 50 mL/min was reported to be one of major risk factor<sup>[95]</sup>. However, López Lago *et al.*<sup>[96]</sup> also looked at HRS vs non-HRS patients who developed ARF in the post-LT setting but found no differences in 1 year mortality, need for RRT, or rejection.

Many studies have aimed to identify the role of GFR following transplantation in stratifying risk of kidney impairment. Sato *et al.*<sup>[97]</sup> showed that an eGFR < 60 mL/min per 1.73 m<sup>2</sup> during the first month post LT can be associated with increased rate of development of CKD, 2 years post-OLT. Interestingly, a recent study assessed 191 LT patients who underwent intense post LT GFR measurements (especially at 1 and 3 years). The study concluded that a low GFR (< 40 mL/min per 1.73 m<sup>2</sup>) at 1 year was associated with higher risk for late renal dysfunction<sup>[98]</sup>. Moreover, Longenecker *et al.*<sup>[99]</sup> looked at the progression of GFR over 15 years post transplantation and found that eGFR < 60 mL/min per 1.73 m<sup>2</sup> and type 2 diabetes at the time of transplantation were associated with increased rates of progression to ESRD. When discussing long-term requirement of RRT post-transplantation, one study assessed 208 LT recipients and found 5.8% of surviving

LTA: Liver transplantation alone; SLKT: Simultaneous liver kidney transplantation; RRT: Renal replacement therapy; HRS: Hepatorenal syndrome; KALT: Kidney after liver transplantation; LAKT: Liver after kidney transplantation; N/A: Not available.

patients required RRT at 3 mo. While there was no significant difference between underlying liver disease and immunosuppressive agents, patients who were on RRT at 3 mo were also on HD 2 years post-LT as well<sup>[1100]</sup>.

While the majority of studies seem to indicate HRS increases the risk for worse post-transplantation kidney function, there are certain exceptions found in the literature. One study looked at 419 LTA performed between 1995 to 2009 and found that MELD scoring system did not impact all-cause mortality in the post-transplantation setting; however, there was a 2-fold greater mortality risk if patients required the need for pre-transplant RRT and post-transplant kidney dysfunction<sup>[1101]</sup>.

Duration of pre-transplantation RRT and vasopressors for reversal of HRS

In regards to post-LT outcomes in patients with HRS who required vasopressor treatment one study compared 27 cases (triple therapy of octreotide, midodrine, and albumin)

vs 16 controls (no vasopressor treatment) and found the GFR was similar at 1 mo ( $P = 0.61$ ) and 1 year ( $P = 0.13$ )<sup>[58]</sup>. Moreover, 11 out of the 27 cases responded to triple therapy but there was no difference in GFR at 1 mo ( $P = 0.96$ ) and 1 year ( $P = 0.48$ ) between responders vs non-responders. A smaller study looked at 9 HRS patients on vasopressin vs 27 non-HRS patients and found there was no significant renal impairment between the two groups in regards to duration of hospitalizations, infections, or renal impairment post-transplantation<sup>[102]</sup>. These two studies are much different than the findings from Wong *et al.*<sup>[103]</sup>; they found that patients without HRS reversal from triple therapy were found to have longer duration of pre-transplant dialysis and increase in post-transplant mortality<sup>[103]</sup>.

One study assessed 253 living donor LT patients and compared survival between starting RRT in the pre-transplant setting vs post-transplant setting. It was found that the duration of RRT was significantly shorter in the RRT-pre group compared to the RRT-post group ( $5.3 \pm 2.1$  d vs  $17.8 \pm 14.1$  d,  $P = 0.02$ ) as well as higher graft survival ( $100\%$  vs  $51.9\%$ ,  $P < 0.01$ )<sup>[104]</sup>.

#### How to manage immunosuppression in immediate post-LT period with HRS

Acute or chronic rejection has become more of a rarity with the current immunosuppression therapies<sup>[105]</sup>. However, calcineurin inhibitors (CNI) have significant nephrotoxic effects by inducing interstitial fibrosis, chronic microangiopathy, and tubular atrophy *via* increased extracellular matrix production, vasoconstriction, and cyclosporine induced apoptosis<sup>[11,106]</sup>. The landmark study in 1994 comparing tacrolimus vs cyclosporine showed that both were comparable in patient and graft survival; however, tacrolimus had substantially more adverse events, including nephrotoxicity, requiring discontinuation of the drug<sup>[107]</sup>.

It is standard practice in majority of transplant centers to use different types of T-cell specific antibody induction in patients with post LT renal dysfunction. Commonly used agents are interleukin-2 receptor antagonists (daclizumab, or basiliximab) and polyclonal antibodies (rabbit anti-thymocyte globulin) based on center preference. Also it is practiced to use mycophenolate mofetil (MMF) and wait for improvement in kidney function post LT and introduce CNI.

Unfortunately, currently there is still no treatment for nephrotoxicity outside of dose reduction of current immunosuppressive regimen<sup>[108]</sup>. Patients who are more than 10 years post-transplant have a higher incidence of ESRD and chronic renal failure, which is related to increase in serum Cr at various stages post-operatively<sup>[109]</sup>. MMF has been used in situations where CNIs are held to improve renal function<sup>[110]</sup> but there exists greater risk for rejection when using MMF<sup>[111]</sup>. Cincinatti *et al.*<sup>[112]</sup> show that combined MMF and low dose CNI therapy may actually promote tolerance, as this combination seems to be nephroprotective.

## FURTHER RESEARCH AND CONCLUDING REMARKS

We aimed to review the literature on HRS in the setting of LT and focused on the critical issues that are barriers to improved outcomes. Many consistencies have remained as treatment options including albumin, vasoconstrictors, RRT, and eventual LT. One area that was not well addressed in our literature search was the utility of norepinephrine in the setting of type 1 HRS not responding to currently approved octreotide and terlipressin based pharmacotherapy.

While current guidelines for SLKT have been recently updated, there is still much debate regarding the utility of SLKT over LTA. Certain studies have shown improved graft and patient survival in the SLKT patient population, but the literature has not been consistent regarding long-term kidney benefit. This is a topic that we anticipate will need to be further explored given variable results seen at this time. Equity in organ allocation must be taken into consideration as SLKT unavoidably allocates multiple grafts to a single recipient and removes donor kidneys from the transplant pool otherwise meant for patients with primary renal disease.

Finally, in regards to post-transplantation kidney dysfunction an eGFR  $< 60$  mL/min per  $1.73$  m<sup>2</sup> seems to be associated with an increased risk of patients having long-term ESRD. While patients continue to have increased patient and graft survival rates, future studies may benefit from continuing to delineate risk factors that may result in post-transplant RRT.

## ACKNOWLEDGMENTS

We would like to acknowledge Sarah E Ginier (Master of Library and Information Science Candidate May 2016) and Stephanie Schulte, MLIS (Associate Professor, Head, Research and Education Services) for their help in formulating the literature search for this review.

### Abstract

Non-selective beta blockers (NSBB) are commonly used to prevent portal hypertensive bleeding in cirrhotics.

Nevertheless, in the last years, the use of NSBB in critically decompensated patients, especially in those with refractory ascites, has been questioned, mainly for an increased risk of mortality and worsening of systemic hemodynamics. Moreover, even if NSBB have been reported to correlate with a higher risk of renal failure and severe infection in patients with advanced liver disease and hypotension, their use has been associated with a reduction of risk of spontaneous bacterial peritonitis, modification of gut permeability and reduction of bacterial translocation. This manuscript systematically reviews the published evidences about harms and benefits of the use of NSBB in patients with decompensated cirrhosis.

**Key words:** Beta blockers; Ascites; Cirrhosis; Portal hypertension
