Abstract

The justification for the use of statins in prevention: an intervention trial evaluating rosuvastatin (JUPITER) study was a real breakthrough in primary cardiovascular disease prevention with statins, since it was conducted in apparently healthy individuals with normal levels of low-density lipoprotein cholesterol (LDL-C < 130 mg/dL) and increased inflammatory state, reflected by a high concentration of high-sensitivity C-reactive protein (hs-CRP ⩾ 2 mg/L). These individuals would not have qualified for statin treatment according to current treatment guidelines. In JUPITER, rosuvastatin was associated with significant reductions in cardiovascular outcomes as well as in overall mortality compared with placebo. In this paper the most important secondary analyses of the JUPITER trial are discussed, by focusing on their novel findings regarding the role of statins in primary prevention. Also, the characteristics of otherwise healthy normocholesterolemic subjects who are anticipated to benefit more from statin treatment in the clinical setting are discussed. Subjects at "intermediate" or "high" 10-year risk according to the Framingham score, those who exhibit low post-treatment levels of both LDL-C (< 70 mg/dL) and hs-CRP (< 1 mg/L), who are 70 years of age or older, as well as those with moderate chronic kidney disease (estimated glomerular filtration rate < 60 mL/min every 1.73 m^2) are anticipated to benefit more from statin treatment. Unlikely other statin primary prevention trials, JUPITER added to our knowledge that statins may be effective drugs in the primary prevention of cardiovascular disease in normocholesterolemic individuals at moderate-to-high risk. Also, statin treatment may reduce the risk of venous thromboembolism and preserve renal function. An increase in physician-reported diabetes represents a major safety concern associated with the use of the most potent statins.

Key words: Rosuvastatin; Primary prevention; Justification for the use of statins in prevention: An intervention trial evaluating rosuvastatin; Cardiovascular events; Mortality

INTRODUCTION

Statins are still the cornerstone in the management of

dyslipidemia. Clinical trials demonstrated that statin therapy is associated with a significant reduction in cardiovascular morbidity and mortality when used for either primary or secondary prevention of cardiovascular events[1-3]. Interestingly, this benefit was so firmly confirmed in primary prevention studies involving patients with hypercholesterolemia, hypertension or diabetes mellitus, that the use of placebo in forthcoming statin trials has been considered as unethical[3].

The justification for the use of statins in prevention: an intervention trial evaluating rosuvastatin (JUPITER) study made a step forward. This trial involved 17 802 apparently healthy individuals with normal low-density lipoprotein cholesterol (LDL-C) (< 130 mg/dL) and increased levels of high-sensitivity C-reactive protein (hs-CRP ⩾ 2 mg/L). The hypothesis whether rosuvastatin may decrease cardiovascular morbidity and mortality as compared with placebo in these subjects was tested[4]. JUPITER participants would not have qualified for statin therapy according to the existing guidelines for the management of dyslipidemia[5].

JUPITER revealed that rosuvastatin 20 mg/d decreased LDL-C levels by 50% and hs-CRP levels by 37%[4]. Also, rosuvastatin was associated with a significant decrease in the combined primary endpoint of myocardial infarction, stroke, arterial revascularization, hospitalization for unstable angina, or death from cardiovascular causes by 44% compared with placebo, after a median follow-up of 1.9 years[4]. Apart from this benefit in the primary endpoint, impressive reductions in the incidence of separate cardiovascular outcomes, including myocardial infarction (by 54%), stroke (by 48%) and revascularization for unstable angina (by 47%) compared with placebo were noted in the rosuvastatin-treated arm[4]. A reduction by 47% was also observed in the secondary combined endpoint of myocardial infarction, stroke, or death from cardiovascular causes[4].

Since the first release of JUPITER, many secondary analyses of this study have come to the light with regard to the results of the study into separate subgroups of the study population. Also, the effect of rosuvastatin treatment on outcomes not assessed in the initial part of the study was examined. In this paper, the most important *post hoc* analyses of the JUPITER study are reviewed by discussing major clinical implications derived from their results.

JUPITER IN SUBPOPULATIONS

Unlike other statin trials of primary prevention, JUPITER involved a quite different population, especially in terms of lipid profile and inflammation. Indeed, the population of JUPITER consisted of normocholesterolemic (LDL-C levels < 130 mg/dL), middle-aged (⩾ 50 years for men and ⩾ 60 years for women) subjects who exhibited increased hs-CRP levels (⩾ 2 mg/L)[4]. All individuals were statin-naïve and suitable for statin use in terms of safety parameters, while none had a history of serious medical conditions that could affect morbidity and mortality rates in the study period, including diabetes, uncontrolled hypertension or cancer[4].

From a total of 89 890 people screened, only 17 802 (19.8%) were eligible and finally enrolled in this study. Of the screening failures, more than half (i.e. 52.2%) were due to increased LDL-C levels > 130 mg/dL, while approximately one third (i.e. 36.1%) were due to low hs-CRP levels < 2 mg/L[4]. After 12 mo of treatment with rosuvastatin, LDL-C levels were decreased to the lowest level ever achieved in a primary prevention trial with the use of statins (i.e. 55 mg/dL).

JUPITER results according to cardiovascular risk classification

Several subanalyses explored the efficacy of rosuvastatin in reducing cardiovascular outcomes in different risk groups according to the Framingham or the Reynolds 10-year risk scores or the European systematic coronary risk (SCORE). In contrast to JUPITER participants who exhibited a 10-year risk of < 5%, those with a 10-year risk of ⩾ 5% experienced significant decreases in the relative risk for the primary endpoint associated with rosuvastatin treatment[6]. Rosuvastatin-associated benefits in all subgroups according to the Framingham or Reynolds 10-year risk classification (5%-10%, 11%-20% or > 20%) were comparable with the overall treatment effect observed in this study[6].

Among JUPITER participants, 6091 and 7340 subjects had a baseline estimated 10-year Framingham risk of 5%-10% and 11%-20%, respectively[6]. According to current guidelines these subjects are considered as a population of "intermediate" risk. JUPITER participants with a 10-year risk of 5%-10% or 11%-20% experienced significant absolute risk reductions[6]. Interestingly, absolute risk reductions increased with increasing level of global risk as assessed by either Framingham or the Reynolds risk scores[6]. For example, the estimated 5-year number needed to treat (NNT) of participants with a 5%-10% Framingham risk score was 40 (95% CI: 22-206), whereas in subjects with a Framingham risk score of 11%-20%, NNT was 18 (95% CI: 12-32)[6].

In another subanalysis, the results of JUPITER were evaluated in groups of participants who exhibited high global risk as defined by a 10-year Framingham risk score > 20% or SCORE ⩾ 5%[7]. Rosuvastatin treatment was associated with a relative risk reduction for the combined endpoint of myocardial infarction, stroke and cardiovascular death as compared with placebo in "high" risk subjects defined by either a Framingham score > 20% [hazard ratio (HR), 0.50; 95% CI: 0.27-0.93] or SCORE ⩾ 5% (HR, 0.57; 95% CI: 0.43-0.78)[7]. No differential change in the same endpoint was detected between subjects with a Framingham score above or below 20% as well as between individuals with a SCORE above or below 5%[7]. This benefit of rosuvastatin was also evident for the

primary endpoint among subjects with SCORE ≥ 5%[7]. In high-risk subjects, no heterogeneity for the combined endpoint of myocardial infarction, stroke and cardiovascular death was noted in subgroups by gender, age, race/ethnicity, the presence of hypertension or family history of cardiovascular disease, smoking status, baseline levels of high-density lipoprotein cholesterol (HDL-C) and hs-CRP[7]. Of interest, among high-risk patients, those who were obese at baseline, as defined by body mass index ≥ 30 kg/m^2, had less benefit from rosuvastatin treatment[7].

JUPITER results according to the lowering of lipids and hs-CRP

In another subanalysis, the effect of reductions in LDL-C and hs-CRP levels on trial event rates was assessed, by using pre-defined study cut-offs for both parameters[8]. No significant interaction between the overall efficacy of rosuvastatin and baseline concentrations of hs-CRP above or below 5 mg/dL and LDL-C above or below 100 mg/dL was noted in the JUPITER study[8]. Rosuvastatin-treated subjects who did not reach post-treatment levels of LDL-C < 70 mg/dL experienced no significant benefits as compared with placebo. In contrast, in individuals who attained LDL-C levels < 70 mg/dL a significant reduction in vascular event rates of 55% was noted[8]. A reduction in hs-CRP levels was also associated with clinical benefit. Thus, in patients with hs-CRP levels < 2 mg/L at the end of the study a significant decrease of 62% in cardiovascular events was observed[8]. This decrease was also significant, but modest (i.e. 31%) among individuals who did not achieve hs-CRP levels < 2 mg/L. All of the above variations were independent of the baseline levels of both LDL-C and hs-CRP[8]. Interestingly, subjects who achieved low concentrations of both LDL-C and hs-CRP (< 1 mg/L) after rosuvastatin treatment were at the lowest risk of cardiovascular events, shown by a decrease of 79% in risk[8].

There were similar findings in analogous assessments when other lipid parameters related to residual cardiovascular risk, including non-HDL-C levels above or below 100 mg/dL, apolipoprotein (apo)B target level above or below 80 mg/dL, or apoB to apoA1 ratio above or below 0.5, were put in the analysis as a substitute for LDL-C levels[8]. In all these analyses, participants achieving low concentrations of hs-CRP and low values of each lipid variable had a better clinical outcome compared with those who did not achieve the respective target[8].

To assess whether the rosuvastatin-associated clinical benefit for the primary endpoint was associated with HDL-C and apoA1 levels, study participants were divided into quartiles according to these parameters[9]. In the placebo group, LDL-C levels remained high and there was an inverse association of vascular risk with HDL-C and apoA1 levels. In contrast, this was not the case in the rosuvastatin-treated group in which LDL-C levels were decreased up to 55 mg/dL[9]. Therefore, HDL-C concentrations may not be predictive of residual cardiovascular risk among patients treated with potent statins who attain very low concentrations of LDL-C.

JUPITER results according to age

Compared with other statin trials, the JUPITER study involved a relatively older population (mean age, 66 years)[4]. In older populations there is a weaker association between total cholesterol levels and cardiovascular outcomes, possibly due to the existence of age-related comorbid conditions[10]. To date, there are limited data from randomized clinical trials regarding the efficacy of statins in the primary prevention of cardiovascular disease in the elderly[11]. A *post hoc* analysis of the JUPITER study focused on the efficacy of rosuvastatin to prevent cardiovascular events in study participants who were 70 years or older at recruitment[12]. Of 17 802 participants in the study, 5695 belonged to this age group. Despite being in a minority, older subjects accounted for 49% of the 393 confirmed primary endpoints in the trial[12]. Compared with younger participants, the older subjects exhibited a quite different risk profile, with female gender and hypertension being more prevalent among older persons than in younger ones. On the other hand, a lower percentage of subjects 70 years or older were obese or current smokers compared with younger subjects[12].

No differential effect between older and younger participants was detected with regard to post-treatment reductions of LDL-C and hs-CRP levels[12]. The analysis revealed that subjects 70 years or older may benefit more from rosuvastatin treatment, since the absolute risk reduction of the primary endpoint in this subpopulation was 48% greater than that observed in younger subjects[12]. Likewise, the NNT to prevent one primary endpoint was 24 for older individuals *vs* 36 for younger ones[12]. This difference was also evident for the composite endpoint of the primary endpoint, any death and venous thromboembolism (NNT 17 in older persons *vs* 27 in younger ones)[12]. No serious safety concerns from rosuvastatin use were raised in the older subpopulation compared with the younger one[12].

JUPITER results according to gender

Unlike secondary prevention trials, in primary prevention trials the reductions in coronary events associated with statin treatment were significant only in men, and not in women[13]. In the JUPITER study there was a predominance of the male gender over female (11 001 men *vs* 6801 women)[4]. Compared with male participants, female participants were older[14]. The different age-specific inclusion criterion (≥ 60 years in women and ≥ 50 years in men) could have accounted for this difference. Also, the prevalence of obesity, hypertension and metabolic syndrome was higher among women than men[14]. At baseline, women exhibited higher levels of hs-CRP than men (4.6 mg/dL *vs* 4.1 mg/dL), whereas no variation was observed in baseline LDL-C levels[14].

No gender-related variation with regard to post-treat-

ment changes in lipid parameters and hs-CRP levels was noted[14]. Also, the relative risk reduction for the primary endpoint with rosuvastatin was similar and statistically significant in both men and women[14]. Likewise, the reduction in overall mortality was quite similar between men and women (23% and 18%, respectively)[14]. Several differences were detected between men and women with regard to separate cardiovascular outcomes. For example, women experienced a greater risk reduction for revascularization/unstable angina than men (HR, 0.24; 95% CI: 0.11-0.51 for women *vs* HR, 0.63; 95% CI: 0.46-0.85 for men, $P = 0.01$ for heterogenicity)[14]. Nevertheless, unlike in men, no benefit for women was proved for several components of the primary endpoint, including myocardial infarction, stroke or death from cardiovascular causes. Of interest, in women a smaller reduction in nonfatal stroke was observed than in men ($P = 0.04$ for heterogeneity)[14].

Relative risk reductions in events were similar in women with either a Framingham risk score of 5%-10% or > 10% (HR, 0.44; 95% CI: 0.22-0.89 and HR, 0.57; 95% CI: 0.34-0.97, respectively)[14]. The results were also similar for men stratified by Framingham risk scores. However, event rates were low in women and men with a Framingham risk score < 5% as well as in those younger than 65 years[14]. Subgroup analysis revealed that women with a family history of premature coronary heart disease may benefit more from rosuvastatin treatment than those without. This variation was not evident for men[14].

From these findings, the JUPITER study was the first primary prevention study which demonstrated that men and women with elevated hs-CRP levels could experience similar benefits from statin treatment in the prevention of cardiovascular outcomes.

JUPITER results in patients with chronic kidney disease

Patients with chronic kidney disease (CKD) exhibit increased cardiovascular morbidity and mortality compared with individuals with more preserved renal function[15]. Evidence from randomized clinical trials failed to show any benefit of statin treatment in high-risk patients with severe renal failure undergoing maintenance hemodialysis[15]. In the primary prevention basis, the WOSCOPS (West of Scotland Coronary Prevention Study) reported no significant benefit from pravastatin treatment among subjects with moderate CKD[16]. Pravastatin-associated benefits were obvious only in individuals with estimated glomerular filtration rate (eGFR) ⩾ 60 mL/min every 1.73 m^2[16].

The JUPITER study included 3267 patients with CKD, as defined by eGFR < 60 mL/min every 1.73 m^2[17]. From those, the vast majority (3253 subjects) had stage 3 impairment (eGFR 30-59 mL/min every 1.73 m^2) while only 14 had stage 4 renal impairment (eGFR 15-29 mL/min every 1.73 m^2)[17]. Subjects with renal impairment were older, more likely to be female and have a family history of premature cardiovascular disease, and exhibited a worse lipid profile as well as increased hs-CRP levels compared with those with normal renal function[17]. Also, those subjects were at increased risk of developing the primary endpoint of the study (HR, 1.54; 95% CI: 1.23-1.92, $P = 0.0002$) as well as arterial revascularization (HR, 1.53; 95% CI: 1.13-2.08, $P = 0.008$) and the combined endpoint of myocardial, infarction, stroke and cardiovascular death (HR, 1.44; 95% CI: 1.08-1.92, $P = 0.02$) compared with subjects with preserved renal function[17]. The two groups did not differ with regard to all-cause mortality and rates of venous thromboembolism[17].

The reduction in the primary endpoint by rosuvastatin treatment compared with placebo was significant (HR, 0.55; 95% CI: 0.38-0.82, $P = 0.002$) in the group of individuals with moderate CKD and was comparable to that observed in subjects with preserved renal function[17]. Likewise, the efficacy of rosuvastatin to reduce the risk of all vascular events was similar between the two groups. All-cause mortality was the only exception, which was reduced more by rosuvastatin in moderate CKD subjects compared with subjects with normal renal function (44% *vs* 12%, P for interaction = 0.048)[17]. Of interest, patients with moderate CKD experienced a greater absolute risk reduction in the primary endpoint than subjects with preserved renal function (NNT 14 and 35, respectively)[17]. No differential effect of rosuvastatin was noted in the two groups with regard to decreases in LDL-C and hs-CRP levels. There was no difference between the two groups regarding safety[17].

JUPITER AND ALTERNATIVE OUTCOMES

Stroke

In primary prevention trials with the use of statins there were no significant decreases in the risk of stroke[18]. Therefore, this outcome was assessed separately in a secondary analysis of the JUPITER study[19]. Rosuvastatin was associated with a decrease in the risk of stroke by 48% compared with placebo, a rate which was similar also for nonfatal strokes[19]. A decrease by 51% associated with rosuvastatin treatment was noted for ischemic strokes, which accounted for the majority of all strokes[19]. Nevertheless, no effect of rosuvastatin treatment was noted with regard to the risk of hemorrhagic stroke or transient ischemic attacks[19].

Rosuvastatin-related benefits in the risk of stroke were similar in different groups according to age, sex, ethnicity, the presence of traditional risk factors for stroke, including age > 70 years, smoking, hypertension and a family history of premature stroke or a Framingham risk score > 10%[19]. As with other vascular outcomes, the greatest reduction in stroke risk was noted among those who achieved LDL-C levels < 70 mg/dL and hs-CRP < 2 mg/L[19].

Venous thromboembolism

There is still controversy with regard to the nature and

the shared pathways of venous and arterial thrombosis[20]. Also, it has not yet been defined whether treatment proven efficacious in the prevention of one condition may have consistent benefits for the other[20]. Statins exhibit many lipid-independent antithrombotic and anticoagulant effects[21]. To date, there are conflicting data from observational studies as to the effect of statin treatment on the risk of venous thrombosis[20]. In the JUPITER study, rosuvastatin treatment was associated with a significant decrease in the risk of pulmonary embolism or deep vein thrombosis by 43% compared with placebo[22]. Similar benefits of rosuvastatin were found when provoked (in patients with cancer, recent trauma, hospitalization or surgery) and unprovoked events of venous thromboembolism were examined separately[22]. Also, subjects at high risk for venous thromboembolism, including those aged > 70 years, body mass index > 30 kg/m^2 and increased waist circumference, exhibited a similar benefit associated with rosuvastatin treatment as in lower risk individuals[22]. No association between the risk of venous thromboembolism and baseline lipid levels was noticed[22].

Renal function

There is evidence that statins, through either their lipid-lowering properties or their pleiotropic effects, may preserve renal function and reduce proteinuria[15]. The effect of rosuvastatin on renal function was also assessed in the JUPITER study. After 12 mo of treatment with rosuvastatin, eGFR was marginally improved compared with placebo (66.8 mL/min every 1.73 m^2 *vs* 66.6 mL/min every 1.73 m^2, $P = 0.02$)[17]. This benefit was not evident in subjects with eGFR < 60 mL/min every 1.73 m^2, while it was more profound in individuals with eGFR ⩾ 60 mL/min every 1.73 m^2 at baseline[17].

Incidence of physician-reported diabetes

Increasing interest has been focussed on the effect that various statins may exert on glucose metabolism and the risk of diabetes[23]. In WOSCOPS pravastatin was associated with a decrease of 30% in the incidence of diabetes compared with placebo[24]. Nevertheless, JUPITER showed an increase in physician-reported diabetes in rosuvastatin-treated subjects compared with placebo-treated subjects (270 and 216 reports, respectively, $P = 0.01$)[4]. These events were not adjudicated by the endpoint committee of the trial. This result was documented despite no difference being observed between study groups for fasting glucose or newly diagnosed glycosuria[4]. However, a minimal increase in glycosylated hemoglobulin (Hb) was observed in the rosuvastatin group (5.9% *vs* 5.8%, $P < 0.001$)[4]. After this finding we have shown that rosuvastatin may be associated with a dose-dependent increase in insulin resistance among hyperlipidemic patients with impaired fasting glucose[25]. These findings were consistent with those of two recent meta-analyses of large-scale placebo-controlled and standard-care controlled trials, which, respectively, reported a 9% and 13% increased risk for incident diabetes associated with statin therapy[26].

Hb levels in patients with anemia

There is evidence suggesting that anemia of chronic disease may be associated with a functional iron deficiency mediated by immune mechanisms[27]. It has also been hypothesized that statins may contribute to an increase in Hb levels through immunomodulatory properties. In the JUPITER trial, Hb levels were determined at baseline and at the final visit in a secondary analysis which included study participants with anemia, as defined by Hb < 13 g/dL for men and < 12 g/dL for women[28]. A total of 369 women and 433 men met the inclusion criteria for this analysis. No difference between rosuvastatin and placebo was noted with regard to post-treatment changes in Hb levels[28]. Similar results were also found among patients with slightly worse anemia, as defined by Hb < 12.5 g/dL for men and < 11.5 g/dL for women[28].

CLINICAL IMPLICATIONS

Before JUPITER, studies showing a benefit of statins in primary prevention were limited to groups at high risk of cardiovascular disease, currently characterized as individuals with diabetes, hyperlipidemia, a family history of premature cardiovascular disease or those at high global cardiovascular risk. Since JUPITER, the potential efficacy of statins to prevent cardiovascular outcomes has been expanded to include normolipidemic individuals. The JUPITER population consisted of apparently healthy men and women with normal levels of LDL-C and an increased inflammatory state, indicated by high levels of hs-CRP. This disturbance was mainly attributed to obesity, smoking or metabolic syndrome, conditions which were frequent among the subjects. In this population there was no indication for statin treatment according to clinical practice guidelines. Interestingly, in JUPITER, rosuvastatin markedly decreased cardiovascular outcomes and moderately decreased mortality in this cohort.

Almost 20% of population screened in the JUPITER study fulfilled the criteria for inclusion in the study. When the eligibility criteria of JUPITER were analyzed in comparison with other community-based studies, such as the REGARDS (Reasons for Geographic and Racial Differences in Stroke) and the ARIC (Atherosclerosis Risk in Communities) studies, it was found that 21% and 18.2%, respectively, of each study could have been eligible for inclusion in the JUPITER study[29,30]. Another analysis suggested that approximately 6.5 million people in the United States could have been eligible for JUPITER[31]. Therefore, according to the JUPITER results a relatively high proportion of an age-matched population in the community could benefit from statin treatment in terms

of primary prevention. If these data are translated into practice, the current guidelines for statin use in primary prevention may dramatically change, leading to increased use of statin treatment. Furthermore, increasing interest will be applied in measuring hs-CRP in the screening of the normolipidemic population[32].

Secondary analyses of JUPITER highlighted those subjects who could benefit more from rosuvastatin treatment in terms of reduction in clinical outcomes. JUPITER suggested that no such benefit may be evident among individuals at low 10-year risk of < 5%. On the other hand, in subjects considered as of "intermediate risk", including those with a 10-year risk of 5%-10% or 11%-20%, a profound clinical benefit in the primary prevention of cardiovascular disease may be produced by statin treatment. This finding implies that this group of subjects, who were currently outside treatment guidelines according to their baseline LDL-C levels (i.e. < 104 mg/dL), might well be considered for statin therapy. Also, in such populations hs-CRP may comprise a useful tool for the reclassification of risk. In an analysis recently performed by Choudhry *et al*[33], it has been suggested that measuring hs-CRP levels may be valuable in order to identify patients in whom rosuvastatin treatment may be cost-effective in the primary prevention setting. Rosuvastatin treatment was proved cost-effective among JUPITER-eligible patients, especially in those with a Framingham risk score ⩾ 10%[33].

Finally, after the results of JUPITER were disseminated, the Canadian Cardiovascular Society changed its guidelines to include the measurement of hs-CRP, along with LDL-C and HDL-C levels, among otherwise healthy men and women at "intermediate risk"[34]. Of interest, the absolute risk reduction associated with statin treatment in intermediate risk subjects may be in parallel with their 10-year risk for cardiovascular disease. All patients at high risk as defined by a Framingham score of > 20% or SCORE ⩾ 5%, except obese subjects, may experience significant benefits from statin treatment in the reduction of cardiovascular outcomes.

Clinical benefit from statin use may also be associated with post-treatment decreases in LDL-C levels and hs-CRP levels among normocholesterolemic subjects with increased hs-CRP levels. The JUPITER study proposed LDL-C levels 70 mg/dL and hs-CRP 1 mg/L as the cut-off points below which major clinical benefit could be achieved. If alternative lipid parameters are to be assessed instead of LDL-C, the suggested cut-off points are < 100 mg/dL for non-HDL-C, < 80 mg/dL for apoB and < 0.5 for the ratio apoB to apoA1. In contrast, HDL-C levels may not predictive of residual vascular risk in patients treated with a potent statin who attain very low concentrations of LDL-C.

Despite similar reductions in LDL-C and hs-CRP levels, elderly normocholesterolemic individuals with increased inflammation may benefit more by statin treatment compared with younger subjects. Also, there may not be a gender-specific effect of statin treatment on the incidence of cardiovascular outcomes in normocholesterolemic subjects with increased hs-CRP concentrations. Statin-associated reductions in clinical outcomes in primary prevention of normocholesterolemic subjects with hs-CRP > 2 mg/L may be evident either in the clinical setting of moderate CKD. Of interest, mortality rates are more amenable to a reduction after statin treatment in those subjects compared with individuals with preserved renal function.

Furthermore, it has been hypothesized that the carriers of the KIF6 allele are preferentially affected by statin treatment compared with non-carrier subjects. This hypothesis was tested in a recent *post hoc* analysis of the JUPITER study. No significant association of KIF6 polymorphism and the efficacy of rosuvastatin treatment in primary prevention resulted from this study[35].

Stroke incidence may also be reduced by statin treatment in normocholesterolemic subjects with increased inflammation. Both lipid-lowering effects of statins and antiinflammatory properties of these drugs could contribute to this benefit. Furthermore, except for a reduction in the incidence of atherothrombotic events, antithrombotic effects of statins may also be associated with a decrease in the risk of venous thromboembolism. Also, statin treatment could contribute to an improvement in renal function of normocholesterolemic subjects with increased hs-CRP levels.

A potential increase in the incidence of diabetes should be a safety concern with statin treatment, especially when most potent drugs of the class are prescribed. However, this issue is currently under investigation. To this context, aggregation of clinical trials supports the notion that statins modestly increase the risk of diabetes. Because diabetes has been considered as a risk equivalent for vascular disease, these findings create a paradox whereby statin therapy may be withheld to avoid excess risk of diabetes, while representing the strongest cardiovascular risk reduction tool in diabetics[26]. A close monitoring of glucose homeostasis parameters in patients treated with statins is strongly recommended.

A future promising indication for statins, as effective antiinflammatory agents, is suggested by recent studies reporting a role of inflammation, and particularly of CRP, in enhanced atherogenicity among subjects with autoimmune inflammatory disorders, such as rheumatoid arthritis, systemic lupus erythematosus, familial Mediterranean fever and Behcet's disease[36].

Abstract

Iron overload can lead to iron deposits in many tissues, particularly in the heart. It has also been shown to be associated with elevated oxidative stress in tissues. Elevated cardiac iron deposits can lead to iron overload cardiomyopathy, a condition which provokes mortality due to heart failure in iron-overloaded patients. Currently, the mechanism of iron uptake into cardiomyocytes is still not clearly understood. Growing evidence suggests L-type Ca^{2+} channels (LTCCs) as a possible pathway for ferrous iron (Fe^{2+}) uptake into cardiomyocytes under iron overload conditions. Nevertheless, controversy still exists since some findings on pharmacological interventions and those using different cell types do not support LTCC's role as a portal for iron uptake in cardiac cells. Recently, T-type Ca^{2+} channels (TTCC) have been shown to play an important role in the diseased heart. Although TTCC and iron uptake in cardiomyocytes has not been investigated greatly, a recent finding indicated that TTCC could be an important portal in thalassemic hearts. In this review, comprehensive findings collected from previous studies as well as a discussion of the controversy regarding iron uptake mechanisms into cardiomyocytes *via* calcium channels are presented with the hope that understanding the cellular iron uptake mechanism in cardiomyocytes will lead to improved treatment and prevention strategies, particularly in iron-overloaded patients.

Key words: Cardiomyocytes; L-type calcium channel; T-type calcium channels; Iron overload; Thalassemia

INTRODUCTION

Iron (Fe) is an essential element for all living organisms and plays a central role in many Fe-containing proteins such as in iron storage proteins (ferritin and hemosiderin), energy metabolism (cytochromes, mitochondrial aconitase and Fe-S proteins of the electron transport chain), cellular respiration (hemoglobin and myoglobin), and DNA synthesis (ribonucleotide reductase)[1-3]. However, under iron overload conditions the regulatory mechanism which keeps the balance between iron uptake

and iron excretion could be disrupted, causing an elevation of non-transferrin bound iron (NTBI) in the plasma of iron-overloaded patients[4,5]. NTBI is toxic and participates in the production of harmful hydroxyl radicals, which could cause severe cellular damage and organ dysfunction[1,2,6,7].

An excess of plasma iron can lead to iron accumulation in many organs including the heart[5]. Excessive iron accumulation in the heart can cause cardiac cellular damage known as iron-overload cardiomyopathy. This cardiac complication causes 71% of all deaths in thalassemia major patients[8]. Although iron chelation therapy is widely used for treating iron overload patients, iron overload cardiomyopathy is still the most common cause of mortality in these patients[9,10]. Even though the fundamental mechanisms for excessive iron uptake in the heart have been investigated for decades, the precise mechanism underlying cardiomyocyte dysfunction induced by iron overload is not clearly understood. Although several NTBI transporters have been proposed and are responsible for cellular iron uptake, recent evidence suggests that calcium channels may play an important role as a portal for cardiac iron uptake[11].

In this review, the role of L-type Ca^{2+} channels (LTCC) as well as T-type Ca^{2+} channels (TTCC) as iron transporters into the heart are presented. The consistent findings as well as discrepancies of results among various studies on iron uptake into cardiomyocytes *via* these calcium channels under various conditions are comprehensively reviewed and discussed.

LTCCS AS A PORTAL FOR IRON UPTAKE INTO CARDIOMYOCYTES

The L-type Ca^{2+} channel is a voltage-gated ion channel that plays a central role in cardiac and smooth muscle contraction[12]. LTCCs are heterotetrameric polypeptide complexes that are composed of $\alpha1$, $\alpha2/\delta$, β, and, in some tissues, γ subunits[12]. The Ca^{2+} channel $\alpha1$ subunit (170-240 ku) is organized into four homologous motifs (I -IV), with six transmembrane segments (S1-S6)[12]. Recently, 10 $\alpha1$ subunit genes have been identified including $Ca_v1.1$ ($\alpha1S$), 1.2 ($\alpha1C$), 1.3 ($\alpha1D$), 1.4 ($\alpha1F$), $Ca_v2.1$ ($\alpha1A$), 2.2 ($\alpha1B$), 2.3 ($\alpha1E$), $Ca_v3.1$ ($\alpha1G$), 3.2 ($\alpha1H$), and 3.3 ($\alpha1I$). For LTCCs, these can be divided into 4 classes: $Ca_v1.1$ ($\alpha1S$), 1.2 ($\alpha1C$), 1.3 ($\alpha1D$), and 1.4 ($\alpha1F$). In cardiac muscles, only the $\alpha1C$ (dihydropyridine-sensitive) subunit is expressed in high levels and is also called a high-voltage-activated channel[12]. LTCCs can be found in the heart and are primarily used for Ca^{2+} transport as well as playing an important role in the electrical activity of the heart. However, previous studies have shown that LTCCs can also transport other divalent cations including Fe^{2+}[13-15].

Several findings have been shown to support the role of LTCC in myocardial iron transport[11,15]. A study in an iron loaded perfused rat heart showed that iron uptake was increased by the LTCC agonist, Bay K 8644 and iron uptake was inhibited by the LTCC blocker, nifedipine[15]. Oudit *et al*[16] demonstrated that treatments with LTCC blockers such as amlodipine and verapamil could lead to the inhibition of LTCC current in cardiomyocytes, reduced myocardial iron accumulation, decreased oxidative stress and improved survival in iron-loaded mice. In addition, iron overloaded transgenic mice with cardiac-specific overexpression of LTCC were shown to have increased myocardial iron accumulation and oxidative stress, resulting in impaired cardiac function in comparison with control mice[16]. Furthermore, since the LTCC does not contain iron responsive elements (IREs) in the LTCC mRNA, it is not regulated by cellular iron levels under an iron overload condition. As a result, L-type Ca^{2+} currents were not decreased in iron overload conditions[16], confirming that the expression of LTCC was not regulated by the IRE. Furthermore, it has been shown in iron overloaded rats that the LTCC blocker diazepam could reduce mortality from iron overload without inhibition of iron absorption or urinary iron excretion[17].

In addition to the heart, a previous study also demonstrated that LTCC blockers verapamil and amlodipine did not decrease iron accumulation in the liver of mice with iron overload, and hypothesized that this was due to the fact that hepatocytes express minimal levels of LTCC[16]. However, a recent study by Ludwiczek and colleagues demonstrated that the LTCC blocker nifedipine could reduce iron accumulation in the liver of wild-type mice, but had no effect in divalent metal transporter 1 (DMT1) deficient mice, suggesting that this effect of nifedipine-mediated modulation of iron transport is *via* DMT1[18]. Nevertheless, these findings suggest that nifedipine could possibly be beneficial in iron overload cardiomyopathy.

DISCREPANCIES IN FINDINGS ON IRON UPTAKE INTO CARDIOMYOCYTES *VIA* LTCC

It is important to realize that not all reports regarding the mechanisms of iron uptake *via* LTCC are consistent. Despite strong evidence supporting the role of LTCC as a route for NTBI transport in the heart, Parkes and colleagues demonstrated otherwise[19]. In cultured rat neonatal myocytes, they demonstrated that LTCC blockers (nifedipine, verapamil, and diltiazem) did not alter iron uptake in these cells[19]. Our recent findings also demonstrated that the LTCC blocker verapamil could not prevent iron uptake into cultured adult mouse cardiomyocytes[20].

Several reasons to explain these inconsistent results may be drawn from previous reports. Most studies that support the role of LTCC for iron uptake in cardiomyocytes used freshly prepared cardiomyocytes taken from isolated perfused hearts[15] or *in vivo*[16]. However, a report that failed to show the role of LTCC in iron uptake into cardiomyocytes used cultured cardiomyocytes[19,20].

In cultured cardiomyocytes, it is possible that LTCC

may not fully develop compared with isolated cardiomyocytes obtained from the heart. If fully developed, it is also possible that the LTCC in cultured cardiomyocytes may not function properly. Furthermore, the ages of cultured cardiomyocytes could have played a role in this discrepancy.

In the light of these inconsistent findings, it is possible that cardiomyocytes obtained from different methods may have different cellular characteristics and properties. All of these proposed hypotheses have not been tested and will need to be further investigated to elucidate the definite mechanism of iron uptake into the heart and resolve these existing discrepancies.

TTCC AS A PORTAL FOR IRON UPTAKE INTO CARDIOMYOCYTES

TTCC have three isoforms: $Ca_v3.1$ (α1G), 3.2 (α1H), and 3.3 (α1I) that are localized to the brain, kidney, and heart and are also called low-voltage-activated channels[21]. It has been shown that only $Ca_v3.1$ and $Ca_v3.2$ are expressed in the heart[21]. TTCCs have been reported to be functionally expressed only in embryonic hearts and disappear in adults[22]. TTCC can be found abundantly only in sinoatrial pacemaker cells and Purkinje fibers of many species in adult hearts and are important for the maintenance of pacemaker activity[21,23]. However, TTCC currents and expression have been demonstrated to reappear and play an important pathological role in diseased hearts with conditions such as ventricular hypertrophy[21,24,25] and post-myocardial infarction[26]. The increased TTCC expression has been shown to contribute to the progression of heart failure[21].

Growing evidence indicates that TTCC blockers could be beneficial in diseased hearts. Recently, Horiba and colleagues demonstrated that the blockade of Ca^{2+} entry into cardiomyocytes *via* TTCC using the TTCC blocker efonidipine could block signal transduction involved in cardiac hypertrophy[27]. In addition, a study in a mouse model of dilated cardiomyopathy has shown that a TTCC blocker could restore the resting membrane potential, and reduce the number of premature ventricular contractions and ventricular tachycardia, thus reducing the incidence of sudden death in these mice[28]. These findings suggest that TTCC blockade may be potentially useful for the prevention of sudden death in patients with heart failure[28]. It is known that iron overload conditions can lead to increased iron uptake into cardiomyocytes, resulting in cardiac hypertrophy and failure[29-32]. However, it is not known if TTCC blockers could be cardioprotective in this type of cardiomyopathy.

Recently, our study using cultured cardiomyocytes taken from the heart of thalassemic mice demonstrated that intracellular iron accumulation in cultured ventricular myocytes of thalassemic mice was significantly higher than in wild type (WT) cells[20]. These findings suggest that thalassemic cardiomyocytes could have pathways which can greatly uptake iron into the cells more than that in WT cells. In addition, under an iron overloaded condition, our results demonstrated that the TTCC blocker, efonidipine, could prevent iron uptake into cultured thalassemic cardiomyocytes[20]. Although efonidipine is not a selective TTCC blocker and could also block LTCC, its efficacy in blocking TTCC is greater than that of LTCC[21]. In that study, since verapamil could not prevent iron uptake when efonidipine could, these findings suggested that TTCC could play a significant role in iron uptake into cardiomyocytes in this thalassemic cardiomyocyte model[20]. Moreover, our microarray data demonstrated that the TTCC genes were up-regulated in thalassemic hearts, which is well correlated with the iron uptake results, suggesting that TTCCs could play an important role in iron uptake in thalassemic hearts, and that their re-expression could be due to the pathological state of a thalassemic heart itself or from the iron-overloaded condition, or both.

Since iron overload patients can develop cardiomyopathy and heart failure[33-35], it is important that the association between iron overload, TTCC expression/function and cardiac complications be determined. Future studies in both basic and clinical research are needed to warrant the clinical usefulness of TTCC blockers in the prevention and treatment of iron overload cardiomyopathy particularly in thalassemia patients.

CONCLUSION

Iron overload is a serious and fatal complication in many diseases including iron-overload cardiomyopathy in thalassemia patients. Although pathways for cellular iron uptake have been investigated for many decades, its mechanism is still not clearly understood. In the past few years, findings regarding new possible pathways for cellular iron uptake have been suspected, including LTCC and TTCC. However, their definite roles as iron transporters in cardiomyocytes are still debated. Understanding the mechanism by which iron enters cardiac cells is very important, since it will provide us with the knowledge to be used in developing better treatment and prevention strategies in iron overloaded patients.

Abstract

Critical coronary stenosis have been shown to contribute to only a minority of acute coronary syndromes and sudden cardiac death. Autopsy studies have identified a subgroup of high-risk patients with disrupted vulnerable plaque and modest stenosis. Consequently, a clinical need exists to develop methods to identify these plaques prospectively before disruption and clinical expression of disease. Recent advances in invasive and non-invasive imaging techniques have shown the potential to identify these high-risk plaques. Non-invasive imaging with magnetic resonance imaging, computed tomography and positron emission tomography holds the potential to differentiate between low- and high-risk plaques. There have been significant technological advances in non-invasive imaging modalities, and the aim is to achieve a diagnostic sensitivity for these technologies similar to that of the invasive modalities. Molecular imaging with the use of novel targeted nanoparticles may help in detecting high-risk plaques that will ultimately cause acute myocardial infarction. Moreover, nanoparticle-based imaging may even provide non-invasive treatments for these plaques. However, at present none of these imaging modalities are able to detect vulnerable plaque nor have they been shown to definitively predict outcome. Further trials are needed to provide more information regarding the natural history of high-risk but non-flow-limiting plaque to establish patient specific targeted therapy and to refine plaque stabilizing strategies in the future.

INTRODUCTION

Technological advances in cardiovascular imaging in parallel with significant development in biomedical science has changed the way we assess coronary atherosclerosis. Interestingly, two very separate but intermingled concepts have emerged. In the first concept, regardless of the extent of coronary atheroma and luminal stenosis (as observed by coronary angiography), coronary pressure measurement is used to evaluate functional ischemia of the myocardium supplied by the stenotic epicardial vessel. The decision to revascularize a stenotic epicardial vessel is based on the presence or absence of a flow-limiting trans-stenotic coronary pressure gradient. The usefulness of this concept has been clinically validated[1-3]. The sec-

ond concept evolved after reports that claimed that most acute coronary events and coronary thromboses form on angiographically non-obstructive atheroma[4-6]. Standard coronary angiography often fails to identify the culprit lesion of non trans-mural acute myocardial infarction (AMI)[7]. In addition, the plaque burden, its delineation and constituents cannot be assessed by coronary angiography. These potentially lethal but mechanically non-obstructive plaques were later labeled as high-risk plaques or vulnerable plaques[8].

The extent of underlying plaque burden causing plaque rupture is a contentious issue. Early, and in fact some recent studies, have shown that coronary thrombosis and AMI are directly proportional to the severity of the coronary stenosis[9]. However, in contrast to this notion, there is also substantial evidence in the literature to believe that coronary thrombosis can develop in as many as two-thirds of cases with non-obstructive, high-risk vulnerable coronary plaques[4-6]. Regardless of the extent of underlying coronary atheroma leading to acute coronary syndromes (ACS), it is well documented that high-risk vulnerable plaques exist and are prone to rupture[10]. These plaques are generally treated conservatively and the possibility of adaptive remodeling is routinely overlooked. Most currently available diagnostic tests are unable to predict the risk of thrombosis associated with any particular lesion in the coronary arteries. Consequently, a clinical need exists to develop new techniques that are capable of identifying vulnerable plaques before disruption occurs.

VULNERABLE PLAQUE

The composition of atherosclerotic plaque is heterogeneous by nature and contains: (1) fibrocellular components [extracellular matrix and smooth muscle cells (SMCs)]; (2) lipid-cellular components (crystalline cholesterol and cholesterol esters mixed with macrophages); (3) thrombotic components (platelets and fibrin); and (4) calcium[11-14]. Vulnerable plaques that result in rupture have been now well described as thin cap fibroatheroma (TCFA). The term vulnerable plaque was first instituted by Muller *et al*[10]. These plaques contain extensive necrotic lipid core and a thin fibrous cap (< 65 μm)[14,15]. The TCFA that is prone to rupture is deficient in SMCs but contains type 1 collagen and infiltrating active macrophages. These macrophages release matrix metalloproteinases (MMPs) 1, 8 and 13 that weaken the fibrous cap and consequently result in rupture[16]. About 65%-70% of all coronary thrombi result from plaque rupture. Although the term *thin* (< 65 μm) fibrous cap is generally accepted to define vulnerable plaques, some conflicting reports have used higher thresholds (> 200 μm) to describe vulnerable plaques[17,18]. It is important to realize that that the pathological description of vulnerable plaque lacks physiological data. The histological observations are made on static and inert tissue while plaque rupture is a more dynamic process as recently reported by Abela *et al*[19]. Cholesterol expands in volume when crystallizing from a liquid to a solid, potentially leading to rupture. In addition to plaque rupture, plaque erosion and calcified nodules can also result in thrombotic plaque disruption[20]. Erosive plaques usually have intimal thickening and are composed of fibrotic tissue with a thick fibrous cap. The thick fibrous cap in contrast to a thin cap contains an abundance of SMCs, proteoglycans and type Ⅲ collagen, but very few inflammatory cells[20]. Determination of plaque characteristics is important to appreciate the pathophysiological process of atherothrombosis, and may also provide us with a means to establish risk assessment for individual plaques in individual patients. Accordingly, imaging modalities are required to reliably evaluate plaque composition and thereby allow implementation of treatment strategies to prevent adverse coronary events.

INVASIVE IMAGING MODALITIES

Invasive techniques to determine the vulnerable plaques have received more attention. In particular three different aspects of vulnerable plaques have been investigated using different invasive technologies. The first technique focuses on imaging the microanatomy of the plaque to identify the plaque components, and includes high frequency intra-vascular ultrasound (IVUS), virtual histology-IVUS®, intravascular optical coherence tomography and intravascular magnetic resonance imaging (MRI). The second set of techniques is directed at measuring metabolic activity of the plaque to predict the risk of plaque disruption, and includes intravascular thermography and elastography. The third technique relies on measuring plaque chemical composition and detailed characterization by employing near infrared reflectance or Raman spectroscopy. Although it is likely that initial prospective identification of vulnerable plaque will first be achieved by one of these competing intra-coronary technologies, several drawbacks exist in the widespread use of these technologies. Most invasive imaging modalities are novel and therefore require specific training and highly skilled staff, they are expensive to run and consequently are not feasible for routine clinical application. Readers are directed to specific reviews on invasive imaging to detect plaque[21]. This article will focus on current non-invasive modalities available to detect vulnerable plaque with especial focus on computed tomography (CT), MRI and positron emission tomography (PET) imaging.

NON-INVASIVE IMAGING TECHNIQUES

By their very nature, invasive imaging techniques are undesirable, with a lower level of patient acceptability than non-invasive alternatives, and thus face significant hurdles if they are to be accepted into routine clinical practice[22-26]. Non-invasive imaging modalities, namely CT, MRI and scintigraphic nuclear imaging techniques may provide an alternative to invasive imaging, and have shown consider-

Table 1 Characteristics of the "ideal" non-invasive imaging modality

Patient-related factors	Technical factors
Absence of ionizing radiation	Rapid image acquisition
Spacious (minimize claustrophobia)	High spatial resolution
Suitable for all (not precluded by aneurysm clips/pacemaker leads)	High contrast resolution
Absence of breath-holding	High temporal resolution
Administration of extrinsic contrast agents unnecessary	Electrocardiogram and respiratory gating
Wide range of clinical indications	Not limited by cardiac arrhythmia
	Provides both anatomic and metabolic information
	Reproducible
	Accurate

able promise in recent studies[27-32]. Continued technological advances have bridged the gap between the accuracies of these non-invasive "modern" techniques and their "traditional" invasive counterparts, with the result that the former have been accepted into routine practice for an ever-increasing spectrum of clinical conditions and indications. One of the ways to achieve increased sensitivity is through the use of nanoparticle-based molecular imaging[27,33,34]. Nanoparticle-enhanced MRI or single photon emission CT (SPECT) can identify a thrombus by detecting fibrin, confirm the presence of an inflammatory process by detecting leukocyte and macrophage infiltration, and recognize plaque angiogenesis by detecting specific integrins involved in the formation of new blood vessels[35-38]. In addition, molecules can also be used to label specific cells both *in vivo* and *ex vivo* for imaging, for example, stem cells for cardiac regeneration and lymphocytes for specific tumors. Furthermore, and in contrast to invasive imaging, molecular imaging may also be used to provide local treatments by targeting with specific therapeutic molecules. Finally, nanoparticle-enhanced MRI and PET scanners may play an important role in the development of new drugs by providing an *in vivo* assessment of the desired molecular effect of the investigational drug. This information could be very useful when deciding whether expensive phase Ⅲ trials for new pharmaceutical agents are justified.

The "ideal" non-invasive imaging modality

In order to understand the relative strengths and weaknesses of modalities in current practice, it is important to first determine the characteristics of the "ideal" non-invasive imaging modality (Table 1). Such a non-invasive modality would combine patient acceptability, acceptable clinical indications, safety, speed and high technical specification to produce unequivocal objective data upon which future management could be confidently based. It is apparent that modern techniques, while far superior to their predecessors, fall considerably short of these model standards.

MRI

Rapid innovation and development in MR technology has allowed for widespread acceptance of cardiovascular MRI as a valuable non-invasive *in vivo* imaging modality for assessment of myocardial contractility, viability and valvular function. This is due in no small part to the commercial availability of increasingly more robust coil and gradient technology in combination with novel pulse sequence design. This technique exploits differences in proton density, proton mobility, water content, chemical composition, molecular motion and diffusion to allow for exquisite soft tissue depiction, a reflection of the high contrast resolution of MRI. Most versatile at field strengths of 1.5 Tesla, this modality fulfils several of the desirable characteristics outlined in Table 1, including absence of ionizing radiation and requirement for breath-holding or extrinsic contrast agents as well as facilitating electrocardiogram (ECG) gating with high spatial and contrast resolution.

Despite the technological advances referred to above, coronary imaging has until recent times been beyond the capabilities of MRI. This reflects the diminutive size of the coronary vessels and thus poor contrast/signal to noise ratios, a short-lived "rest period" during diastole during which coronary motion is minimized, temporal restrictions imposed by the patient's ability to suspend respiration and the resultant limited spatial resolution attainable during that time period. Several of these issues have been addressed with considerable success by the introduction of T2 preparation navigator-gated and -corrected 3-dimensional segmented techniques which, although time-consuming, allow for volumetric imaging of the coronary arteries in their entirety with subsequent multiplanar reconstruction. However, coronary MR angiographic techniques remain technically demanding and suboptimal to merit widespread acceptance into the clinical arena.

HIGH RESOLUTION MRI FOR CORONARY PLAQUE IMAGING

MR angiographic evaluation of coronary arterial luminal patency has traditionally proven challenging for the reasons outlined above. One can appreciate therefore why attempts at coronary plaque imaging add an additional level of complexity, further stressing the boundaries of MRI capability. High resolution imaging using T1, T2 and proton density weighting allows for identification of

Table 2 Selected molecular imaging agents in cardiovascular disease

Biological process	Agent	Target	Imaging platform
Plaque rupture/thrombosis	Gadolinium carrying perfluorocarbon and peptides (EP-2104R)	Fibrin	MRI
	Phage display nanoparticles generated by CEST ^{99m}Tc-apcitide	Glycoprotein Ⅱb/Ⅲa receptor	SPECT
Inflammation/apoptosis	MNP + specific antibodies	E-selectin	MRI
	Monocrystalline iron oxide	ICAM/VCAM	PET
	Cross-linked iron oxide ^{18}FDG	Macrophages glucose transporter-1, hexokinase	SPECT
	^{99m}Tc-annexin	Phosphatidylserine/caspases	SPECT
	^{99m}Tc-interleukin-2	Lymphocytes	
Angiogenesis	MNP + specific antibody ^{99m}NC100692	VCAM-1/integrin $\alpha_v\beta_3$	MRI
Myocardial infarction	MNP ^{111}Indium oxide	Stem cell labeling	MRI/SPECT

MNP: Paramagnetic nanoparticle; CEST: Chemical exchange saturation transfer; MRI: Magnetic resonance imaging; SPECT: Single photon emission computed tomography; PET: Positron emission tomography; ICAM: Intercellular adhesion molecule; VCAM: Vascular cell adhesion molecule; ^{18}FDG: Fluorine-18 fluorodeoxyglucose.

calcium which is hypointense on all imaging sequences, lipid which is T1- and PD-hyperintense and T2-hypointense, and fibrous tissue which produces increased signal intensity on PD-weighted imaging, while it is isointense on T1 and isointense-to-hyperintense on T2-weighted imaging. These multi-contrast signal intensity "signatures" allow for characterization of various plaque components and plaque morphology on high-resolution imaging and therefore assessment of plaque vulnerability. In order to have a null signal from blood within the adjacent coronary lumen and thereby maximize contrast resolution, real-time respiratory navigated black blood fast spin echo sequences are generally utilized. Real-time slice position correction has also been employed. The accuracy of this technique has been histologically confirmed *ex vivo*[39]. This technique has also been employed to assess coronary wall thickness, with validation in both animal models and humans[40-43]. Fayad *et al*[41] reported positive remodeling and significant coronary wall thickening in patients with coronary artery disease in comparison with control patients. Such approaches may prove useful for non-invasive coronary plaque burden measurement in the absence of ionizing radiation exposure.

MOLECULAR MR FOR PLAQUE IMAGING

Evaluation of coronary plaque at the molecular level requires the addition of targeted contrast agents (Table 2). Paramagnetic gadolinium chelates are the most commonly used extracellular contrast agent for MRI. Although in nature this metal has a short half-life, this has been compensated by novel gadolinium constructs with albumin, high-density lipoprotein and liposomes[27,33,44-47]. In addition to a longer half-life, these new generation gadolinium chelates have improved affinity for adjacent protons, allowing superior imaging of the adjoining tissue. This affinity for protons is referred to as relaxivity time, R1 for longitudinal relaxivity (adjacent tissue appears bright) and R2 for transverse relaxivity (adjacent tissue appears dark).

Magnetic iron oxide is another class of paramagnetic nanoparticle (MNP) that has been used as a molecular agent for detection of plaque characteristics. Newer generations of MNP [termed monodisperse iron oxide (MION)] are pretreated with polymer coatings that offer several advantages including better *in vivo* stability and the ability to target multiple molecules by allowing stable conjugation of a variety of ligands to the nanoparticle. In addition, a cross-linked derivative of MION (CLIO) can be conjugated to near infrared fluorochromes to allow dual modality imaging with fluorescence microscopy and MRI[48,49]. These magnetofluorescent nanoparticle have been used to target specific molecules *in vivo*[49-52]. Furthermore, a longer half-life, a high relaxivity time and a small diameter allow this nanoparticle to be a useful molecular agent for plaque and myocardial imaging[53-56]. In addition to imaging static cellular markers, MNPs can be used to identify dynamic cellular targets (specific enzymes, e.g. proteases, oxidases) by using novel magnetic relaxation switches[57,58]. These magnetic relaxation switches produce a change in relaxivity time (R2) of the nanoparticle by undergoing reversible modification in structure in the presence of a specific enzyme, which is then detected by T2-weighted MRI[57,58]. These magnetic relaxation switches hold significant potential for identifying a large set of proteins relevant to clinical cardiology including troponin, brain natriuretic peptide and C-reactive protein.

After administration, the molecule-targeting nanoparticles can approach the plaque either through the lumen of the coronary artery or through the vasa vasorum in the outer vessel wall. These molecular agents can detect cell surface markers and therefore identify cells of interest. The cell surface markers are detected by attaching a targeted ligand to the nanoparticle, while cells are identified after cellular uptake and internalization of treated nanoparticles. To target and identify specific peptides or proteins, phage display screening libraries are normally used. Molecular MR approaches to image vulnerable plaque has focused on plaque thrombosis, plaque lipid content, plaque inflammation and plaque angiogenesis. To date, these molecular agents have successfully targeted several plaque components, including fibrin, cellular markers, e.g. vascular cellular adhesion molecule (VCAM),

and angiogenesis markers, e.g. integrin $\alpha_v\beta_3$.

Imaging targets of plaque rupture

Fibrin deposition on the plaque surface is the first step after endothelial disruption following plaque rupture. Therefore targeting fibrin on the plaque surface can potentially identify high-risk plaques that are prone to disruption. The first fibrin-targeting agent was perfluorocarbon nanoparticles, which contained a liquid perfluorocarbon core and an encapsulating phospholipid monolayer. These nanoparticles have the advantage of carrying > 90 000 gadolinium atoms, hence allowing superior T1-weighted contrast enhancement[59]. Fibrin can also be targeted using phage display methods, whereby fibrin-targeted gadolinium-labeled peptides are used. These peptides (e.g. EP-1873) allow MR detection of fibrin deposits on the surface of ruptured plaques with good histological correlation in an animal model of coronary thrombosis[60,61]. The new generations of fibrin specific peptides (e.g. EP-2104R) are more selective for fibrin and have demonstrated superior targeting of a thrombus *in vivo*[62]. The main limitation of fibrin-specific peptides is the small number of gadolinium atoms (only 4 atoms) that can be attached at one time, hence requiring accumulation in sufficient quantities at the site of imaging. Nonetheless, more recent chemical exchange saturation transfer (CEST) technology is now applied to nanoparticles allowing generation of stronger MR signals. CEST contrast can originate from endogenous amide or hydroxyl protons or from exchangeable sites on exogenous CEST agents. In this technology, exchangeable protons transfer magnetization to the strong signal of bulk water after irradiation. CEST contrast agents include a liposome-based nanoparticle LIPOCEST, and other paramagnetic nanoparticles PARACEST[63-66]. *In vitro* fibrin clots are targeted with the use of anti-fibrin antibody formulated with perfluorocarbon nanoparticle PARACEST contrast agents[66].

Imaging cell surface markers

One of the foremost goals of molecular imaging is to detect the early stages of vulnerable plaque formation. Inflammation plays a critical role in the initiation and pathogenesis of atherosclerosis[67]. Exposure to inflammatory cytokines leads to over-expression of cell surface adhesion molecules especially E-selectin, intercellular adhesion molecule-1 and VCAM-1. These adhesion molecules mediate adhesion and migration of leukocytes along the endothelial surface to the inflammatory site. Therefore significant attention has been paid to develop probes that can detect these activated molecules on the surface of endothelial cells.

The expression of E-selectin has been targeted *in vivo* by generation of pegylated paramagnetic liposomes formulated with anti E-selectin antibody. E-selectin could be successfully imaged in the collared carotid arteries of apolipoprotein E-deficient apoE $^{-/-}$ mice as compared with controls[37]. Several generations of MNPs have been used to target VCAM-1. More recently, a MNP phage display with linear peptide based probe was used to successfully image *in vivo* VCAM-1 expression in the aortic roots of apoE $^{-/-}$ mice[52]. Furthermore, statin treatment of these mice blunted the imaging signal by reducing accumulation of the probe in the aortic root, thereby demonstrating sufficient dynamic range to detect a treatment effect. The specificity of the MNP VCAM-1 probe has also been evaluated in *ex vivo* human carotid endarterectomy samples. Incubation of the samples with this probe resulted in co-localization of VCAM-1-expressing cells and the MNP probe on immunohistochemistry, and resulted in a reduction T2 signal[68].

Imaging cellular targets in atherosclerotic plaque

Gadofluorine is a more lipophilic chelate of gadolinium and forms micelles due to their hydrophobic fluorinated side chain[69]. This probe has been shown to accumulate in lipid rich atherosclerotic plaques in hypercholesterolemic animal models[35,70]. High density lipoprotein (HDL) plays a key role in removing excess cholesterol from the plaques, and therefore may be a suitable candidate for transfer of nanoparticles into the plaque. HDL-like nanoparticles containing gadolinium have been developed to image the plaque *in vivo*. It has been shown that these HDL-like nanoparticles accumulate in atherosclerotic plaques after their intravenous injection[44]. The rate of this contrast uptake appears to be related to the lipid and macrophage content of the plaques in apoE $^{-/-}$ mice[27]. In addition to gadolinium chelates, CLIO-MNPs have been used to image macrophages in both animal and human atherosclerotic plaques with good histological correlation[54,55,71]. Molecular targeting of macrophages could identify the presence of inflammation in the vulnerable plaques[33,44,72]. MNP-enhanced MRI has been used in a clinical trial to assess the effect of statin dose on the level of macrophage accumulation in patients with carotid atheromatosis[73].

Imaging for angiogenesis

Growing atherosclerotic plaques initiate angiogenesis to meet their increased metabolic needs. The microvessels can cause intra-plaque hemorrhage, thereby converting these plaques to high risk and prone to rupture. New vessel formation starts from the vasa vasorum in the outer wall of the arteries and is related to the key mediator of new blood vessel formation, integrin $\alpha_v\beta_3$[36]. This integrins may represent an important molecular target for diagnosing and treating angiogenesis-related diseases. In this context, an antagonist of integrin $\alpha_v\beta_3$ has been used to induce tumor regression by targeting inhibition of neovascularization both in animals and humans[74,75]. A paramagnetic liposome containing anti-$\alpha_v\beta_3$ antibodies has been used to image this integrin in an animal model[38]. Moreover, the use of an $\alpha_v\beta_3$ integrin antagonist (fumagillin) in an animal model of atherosclerosis resulted in an anti-angiogenic effect without affecting pre-existing normal blood vessels[34,74]. Other potential investigative targets for angiogenesis include vascular en-

dothelial growth factors and integrin $\alpha_1\beta_5$.

MRI has several distinct advantages over other techniques including the absence of ionizing radiation, use of significantly less nephrotoxic contrast agent, and facilitation of high spatial resolution imaging with superb soft tissue characterization. These traits can be further enhanced by the use of specific and targeted contrast agents. Molecular imaging can help detect vulnerable plaques and may provide a risk assessment of these plaques. Furthermore, novel therapeutic nanoparticles are being developed to target these high risk plaques to provide local treatment.

CARDIAC CT

In contrast to MRI, cardiac CT incurs significant ionizing radiation exposure (10-20 mSv for retrospective gated techniques and 1-10 mSv for prospective "single phase" techniques). This modality allows for rapid data acquisition at high spatial resolution, invokes less patient anxiety given its spacious, short gantry, and has fewer contraindications than MRI. However, patient cooperation with breath-holding instructions and administration of potentially nephrotoxic contrast agents are pre-requisites for diagnostic imaging.

Electron beam CT (EBCT), which featured non-mechanical movement of the electron source and fixed detectors has been replaced in recent times by multidetector row CT (MDCT) during which both the radiation source and detectors rotate during patient motion through the CT gantry. More recently, the introduction of dual-source CT methodologies have allowed for coronary imaging without the need for β blockade. Retrospective ECG gating allows coupling of MDCT data with the corresponding phase of cardiac contraction, providing multiphasic data with superior temporal resolution when compared with EBCT. This initially incurred penalties by means of increased radiation exposure although many "low dose" protocols have since been developed and accepted into routine clinical practice.

MDCT systems allow for non-invasive characterization of different plaque components[76]. Calcium can be detected with high sensitivity and has become the established means for detection and quantification of coronary artery calcification[77]. MDCT can also be used to detect non-calcified plaque in both *ex-vivo*[78] and *in vivo*[79,80] studies. The assessment of calcification within the arterial wall may provide an independent risk factor for coronary artery disease, but it fails to identify high risk vulnerable plaques. Early studies using contrast enhanced 4-slice MDCT of coronary plaques demonstrated good correlation in differentiating between soft, intermediate and calcified plaques, as compared with IVUS[81]. In another study, 4-slice MDCT demonstrated that non-calcified plaque contributed more to total plaque burden in patients with AMI in comparison to patients with stable angina[28]. More recent studies have attempted to quantify the total volume of non-calcified atherosclerotic plaque using 64-slice MDCT. One such study evaluated 50 patients some 17 mo apart and documented a mean annualized increase of 22% in plaque volume[31]. Inter-observer variability for the quantification of non-calcified plaque volumes was found to be substantial. In a separate study the same investigators reported strong correlation between CT plaque attenuation, positive remodeling and lipid content of the plaque at contrast enhanced 64-slice CT[82]. The progression of atherosclerotic lesions resulting in focal change in luminal patency is referred to as vessel wall remodeling[83]. Positive arterial remodeling is an adaptive compensatory mechanism aiming to maintain luminal patency. In contrast, negative remodeling results in luminal narrowing irrespective of the plaque volume[84-86]. It has been shown in studies that both positive remodeling and plaque lipid content determine plaque vulnerability[84,87,88]. This hypothesis was further confirmed in another clinical study where 16/64-slice CT was performed in 38 patients with ACS and 33 patients with stable angina. The investigators reported high positive predictive value for plaque vulnerability in the presence of positive remodeling, non-calcified plaque < 30 HU, and spotty calcification[89]. Low CT attenuation, positive remodeling and spotty calcification were further shown to be associated with high risk plaque in 147 patients by 64-slice CT[90]. Other investigators have reported a 97% sensitivity for 64-slice CT when compared with IVUS in detecting plaque in 26 patients who underwent both investigations, although MDCT performed less optimally in differentiating between soft and fibrous plaque composition[32]. It has been reported that CT tends to overestimate the volume of atherosclerosis compared with IVUS[91]. In a more recent study, Pflederer *et al*[92] compared morphological features of plaque in patients with ACS and stable patients using contrast-enhanced coronary dual-source CT. The culprit lesions in patients with ACS were reported to have spotty calcification, low CT attenuation, large plaque volume and higher remodeling indices, as compared to control stable lesions.

There is little doubt that future generations of MDCT scanners will allow for improved coronary arterial plaque detection and characterization. Continuing improvements in spatial and temporal resolution, combined with innovative techniques such as dual-energy CT and the non-invasive nature of CT may pave the way to making this modality highly attractive for the identification of vulnerable plaque in the wider population. High definition detectors, multi-source tube-detector configurations and flat panel detectors are likely to feature prominently in the near future.

SCINTIGRAPHIC IMAGING

Scintigraphic techniques including SPECT and PET hold the potential for superior functional and molecular atherosclerotic imaging for prediction of the risk of plaque rupture. These techniques allow study of changes at a cellular and molecular level, and have been used for clini-

cal and research purposes to study myocardial perfusion, innervation, angiogenesis, gene expression and stem cell labeling. While such metabolic information is surplus to that provided by MRI and MDCT, scintigraphic imaging techniques are limited by relatively poor spatial and temporal resolution. Both SPECT and PET involve significant ionizing radiation exposures, and as a result, these techniques also fall considerably short of the "ideal" described earlier.

Imaging cellular targets in atherosclerotic plaque

Fluorine-18 fluorodeoxyglucose (^{18}FDG) is a glucose analog that becomes concentrated in metabolically active cells. It has been suggested that its uptake within the atherosclerotic plaque is proportional to the degree of inflammation and macrophage density[93]. Preclinical studies have suggested that PET scanning can detect ^{18}FDG accumulation within the atherosclerotic plaque[29]. Rudd *et al*[30] demonstrated that human carotid plaque inflammation can be imaged with ^{18}FDG-PET and that symptomatic plaques accumulate more ^{18}FDG than asymptomatic lesions. In addition, histological examination of the excised symptomatic plaques in this study revealed heavy macrophage infiltration. This finding confirms that inflammation is present to a greater degree in symptomatic plaques. In a separate study, Tawakol *et al*[94] also showed noticeable correlation between ^{18}FDG-PET *in vivo* signals and macrophage content on histological examination after carotid endarterectomy.

Imaging proteases

Matrix degrading MMPs present in the fibrous cap of the vulnerable plaque can also provide a surrogate marker of plaque instability. Activated MMPs cause proteolysis of the extracellular matrix of the fibrous cap causing plaque remodeling and rendering it susceptible to rupture. Specific radiotracers based on inhibitors of MMPs (^{123}I-HO-I-CGS 27023A) have been generated and tested successfully in animal models[95,96]. Increased levels of macrophage or leukocyte apoptosis in the atherosclerotic plaque may contribute to plaque instability.

Imaging apoptosis

Annexin V is an endogenous protein that binds to phosphatidylserine, a negatively charged membrane phospholipid externalized to the cell surface during early cell apoptosis. ^{99m}Tc radiolabeled annexin V uptake in animal plaque has shown a good correlation with apoptosis[97]. In another similar animal model, treatment with statins resulted in a reduction in ^{99m}Tc annexin V accumulation within the plaque signifying plaque stabilization[98]. Intracellular activation of enzyme caspases is responsible for initiation of apoptosis and progress is ongoing to develop intracellular radiotracers to target these enzymes.

Imaging vasoconstricting peptides

Endothelins are 21 amino acid vasoconstricting peptides produced primarily by the endothelial cells and play a critical role in vascular homeostasis. Endothelin has three isoforms (ET-1, ET-2, ET-3), that bind to two endothelin receptors ET_A and ET_B, the latter being present on vascular endothelial cells. Elevated levels of ET-1 have been implicated in several vascular pathological processes including atherosclerosis, stent restenosis, endothelial dysfunction and angiogenesis. Positron emitting ^{18}F-labeled ET-1 has shown good receptor affinity *in vitro*[99]. ^{99m}Tc-labeled ETs have been used *in vivo* with high uptake in atherosclerotic plaques in animal models[100]. In addition, specific radiolabeled antagonists of ET receptors have been demonstrated in animal studies[101].

SPECT or PET imaging could be used to identify unstable plaque and therefore may allow target treatment of high-risk plaques regardless of their angiographic appearances. The shortcomings of PET scanning are the need for ionizing radiation, substantial background uptake by the active myocardium and poor spatial resolution; however, this has been overcome with new technological advances combining CT with a PET scanner in new hybrid CT/PET devices. The combined molecular and anatomical imaging with SPECT or PET combined with CT, MRI or echocardiography may increase anatomical localization of the radiotracer signal. At present, imaging of moving coronary arteries with SPECT and PET represents a challenge.

WHY IS PLAQUE DETECTION IMPORTANT?

Detection of vulnerable plaque may help avert subsequent acute coronary syndrome by facilitating timely preventive regional and local therapies to the coronary arteries. Identification and aggressive medical treatment of these high-risk plaques can stabilize these plaques and potentially reduce the incidence of AMI and sudden cardiac death. To date there has been no prospective clinical data available upon which to develop treatment criteria for these plaques. There are several shortcomings in current vulnerable plaque detection techniques. Most invasive and non-invasive methods of vulnerable plaque detection lack sensitivity and specificity. In addition, the natural history of vulnerable plaque is unclear and until the dynamic progression of such lesions is defined, it will be difficult to implement any coherent proven treatment strategy. Furthermore, at present there are no data to prove that interventional treatment strategies with percutaneous coronary intervention for these high risk but asymptomatic plaques are superior to conventional medical treatment. In our opinion it is therefore essential to refine the available non-invasive techniques to assess the natural progression of vulnerable plaque. An established gold-standard may then be used in a longitudinal study in patients with established coronary artery disease to truly characterize this complex and dynamic process.

CONCLUSION

Significant progress has been made in the last decade to advance our understanding of the biology of atheroscle-

rosis. This has resulted in identification of vulnerable plaques that are prone to acute thrombotic complications, which can account for the suddenness of clinical presentation in the majority of patients with coronary artery disease. A number of different novel imaging modalities have been investigated to define the specific characteristics of vulnerable plaque. However, most of these techniques are still undergoing constant refinement and cannot reliably identify vulnerable plaque in the clinical setting. It is important to realize that plaque composition is not equal to plaque vulnerability. Most of the methodologies described in this review are able to detect particular components of plaque, for example lipids and calcium. However, at present there is no definitive evidence that *in vivo* plaque composition is directly related to plaque vulnerability nor that the observed characteristics of a plaque are related to outcome. Further research is required to increase the sensitivity and specificity of these modalities to more accurately predict adverse events in the context of high-risk plaque. In our investigation of vulnerable plaque, it is essential that we do not forget to treat cardiovascular risk factors that initiate endothelial dysfunction, which remains the earliest pathological signal of atherosclerosis. In addition, peripheral blood can contain unique cells and cytokines that may also help in identifying the general population at risk for new sudden cardiovascular events. Many unanswered questions remain, but there is a real clinical imperative to understand the natural history of these non-obstructive plaques in order to better implement preventive strategies in the future.

Abstract

Genome-wide association studies (GWAS) have identified several genetic variants associated with coronary heart disease (CHD), and variations in plasma lipoproteins and blood pressure (BP). Loci corresponding to *CDKN2A/CDKN2B/ANRIL*, *MTHFD1L*, *CELSR2*, *PSRC1* and *SORT1* genes have been associated with CHD, and *TMEM57*, *DOCK7*, *CELSR2*, *APOB*, *ABCG5*, *HMGCR*, *TRIB1*, *FADS2/S3*, *LDLR*, *NCAN* and *TOMM40-APOE* with total cholesterol. Similarly, *CELSR2-PSRC1-SORT1*, *PCSK9*, *APOB*, *HMGCR*, *NCAN-CILP2-PBX4*, *LDLR*, *TOMM40-APOE*, and *APOC1-APOE* are associated with variations in low-density lipoprotein cholesterol levels. Altogether, forty, forty three and twenty loci have been associated with high-density lipoprotein cholesterol, triglycerides and BP phenotypes, respectively. Some of these identified loci are common for all the traits, some do not map to functional genes, and some are located in genes that encode for proteins not previously known to be involved in the biological pathway of the trait. GWAS have been successful at identifying new and unexpected genetic loci common to diseases and traits, thus rapidly providing key novel insights into disease biology. Since genotype information is fixed, with minimum biological variability, it is useful in early life risk prediction. However, these variants explain only a small proportion of the observed variance of these traits. Therefore, the utility of genetic determinants in assessing risk at later stages of life has limited immediate clinical impact. The future application of genetic screening will be in identifying risk groups early in life to direct targeted preventive measures.

Key words: Genome-wide association studies; Cardiovascular disease; Lipids; Blood pressure

INTRODUCTION

Cardiovascular disease (CVD) is the leading cause of mor-

bidity and mortality globally[1,2]. There is a concerted effort to reduce this disease burden, particularly that of coronary heart disease (CHD) and cerebrovascular disease in developed countries[3-5]. These range from primary preventive strategies targeted at risk factors through acute management and secondary prevention strategies[6-8]. Kahn *et al*[9] estimated that aggressive application of nationally recommended prevention activities for CVD would potentially add approximately 224 million quality adjusted life-years to the US adult population over the next 30 years and improve the average lifespan by at least 1.3 years.

CHD is the result of a combination of genetic and environmental factors. More than 200 risk factors have been associated with CHD and, among these low-density lipoprotein cholesterol (LDL-c) and blood pressure (BP) have been shown through randomized controlled trials to be causally related to CHD. A key factor in reducing the global burden of CVD is early prediction of disease to target preventive interventions. More personalised approaches to CVD prevention are attracting increasing interest. Whilst biomarkers and quantitative traits have been extremely useful in targeting primary prevention, the recent advances in genomics offer a smart option for predicting future risk of disease very early in life using the invariant nature of a genotype throughout an individual's life-span. For example, Cohen *et al*[10] demonstrated that a genetic variant resulting in a modest 28% reduction in LDL-c from birth results in an 88% reduction in the risk of CHD. Over the last 5 years, genome-wide association studies (GWAS) have revolutionised the discovery of common genetic variants associated with a range of diseases and traits.

There are three key characteristics of a genetic variant that determine its impact on the phenotype studied - (1) the frequency of the variant; (2) the effect size of the variant on the phenotype; and (3) the number of genetic variants acting on the phenotype. The "common disease common variant" hypothesis (CD:CV) is the model invoked to explain how genes influence common traits such as lipids, coronary artery disease (CAD) and BP[11]. This model proposes, using an evolutionary paradigm, that common disease is due to allelic variants with a frequency greater than 5% in the general population and small individual effect size[12]. The CD:CV framework requires population-wide genotyping of very large numbers of common genetic variants (Single Nucleotide Polymorphisms/SNPs) to determine which variants show significant association with the phenotype studied. Technological advances now allow reliable and high-throughput genotyping of hundreds of thousands of SNPs on a genome-wide scale[13]. Such studies employ large scale association mapping using SNPs, making no assumptions about the genomic location or function of the causal variant, and test the hypothesis that allele frequency differs between individuals with differences in phenotype. In most GWAS, emphasis is given to the "*P* value" for the association of genotype with disease risk, to reduce the potential for false positive association that arises when the association of hundreds of thousands to millions of markers are tested across the whole genome. The current popular method for multiple-test correction is the frequentist approach of adjusting for a number of independent tests - based on this, a significance level of 5×10^{-8} is commonly used, in populations of European ancestry for an overall genome-wide significance threshold of 0.05, adjusted for an estimated 1 million independent SNPs in the genome by the Bonferroni method[14]. It should be noted that the Bonferroni method is a fairly conservative correction method that may increase false negative rate. Other corrections like the False Discovery Rate or permutation testing can be used to set a different threshold. In this context, it is pertinent to recognise that the *P*-value is an index of a true positive signal and does not in any way reflect the predictive potential of the associated variant. The current gold standard of validity is multiple replication in independent samples. We review the implications of positive GWAS findings in current cardiovascular practice.

GWAS AND CHD

We summarise the GWAS results of CHD from nine case-control studies and three cohort studies[15-26] (Figure 1 and Table 1). The effect sizes (OR) of susceptibility alleles were modest and ranged from 1.05-2.0. Common variants in chromosome 9p21 were implicated in nine independent case-control studies[16-23,25] and in two cohort studies[15,25]. The most replicated SNPs at chromosome 9p21 were rs0757278 and rs13333049. The loci corresponding to *MTHFD1L*, initially identified in the Wellcome Trust Case Control Consortium (WTCCC) study[17], were later replicated in the German Family MI study[18] with genome-wide statistical significance. However, it did not reach genome-wide statistical significance in the combined analysis of ten different data sets in the study by Kathiresan *et al*[21]. Genetic loci corresponding to *CELSR2*, *PSRC1* and *SORT1* on chromosome 1p13.3 are identified in three independent studies[18,20,21].

GWAS AND LIPIDS

Aulchenko *et al*[27] studied total cholesterol (TC)-associated genetic markers and identified 11 loci significantly associated with the trait (Figure 2 and Table 2): these corresponded to *TMEM57*, *DOCK7*, *CELSR2*, *APOB*, *ABCG5*, *HMGCR*, *TRIB1*, *FADS2/S3*, *LDLR*, *NCAN* and *TOMM40-APOE*. Many of these genes are also implicated in other lipid traits. After screening the genome for common variants associated with plasma lipids in > 100 000 individuals of European ancestry, Teslovich *et al*[28] identified 39 novel loci associated with TC and replicated several other loci found to be associated with lipid traits in the previous GWAS.

Table 1 Single nucleotide polymorphisms associated with coronary heart disease in genome-wide association studies

TMEM57: Transmembrane protein 57; DOCK7: Dedicator of cytokinesis 7; CELSR2: Cadherin, EGF LAG seven-pass G-type receptor 2; LDLRAP1: Low density lipoprotein receptor adaptor protein 1; EVI5: Ecotropic viral integration site 5; IRF2BP2: Interferon regulatory factor 2 binding protein 2; APOB: Apolipoprotein B; ABCG5: ATP-binding cassette sub-family G member 5; RAB3GAP1: RAB3 GTPase activating protein subunit 1 (catalytic); RAF1: v-raf-1 murine leukemia viral oncogene homolog 1; HMGCR: 3-hydroxy-3-methylglutaryl-CoA reductase; TIMD4: T-cell immunoglobulin and mucin domain containing 4; HLA: Human leukocyte antigen (HLA) complex; C6orf106: Chromosome 6 open reading frame 106; FRK: Fyn-related kinase; DNAH11: Dynein, axonemal, heavy chain 11; NPC1L1: NPC1 (Niemann-Pick disease, type C1, gene)-like 1; TRIB1: Tribbles Homolog-1 (*Trib1*); CYP7A1: Cytochrome P450, family 7, subfamily A, polypeptide 1; TRPS1: Trichorhinophalangeal syndrome 1; GPAM: Glycerol-3-phosphate acyltransferase; mitochondrial; FADS: Fatty acid desaturase; SPTY2D1: Suppressor of Ty, domain containing 1 (S. cerevisiae); UBASH3B: Ubiquitin associated and SH3 domain containing B; BRAP: BRCA1 associated protein; HNF1A: Hepatocyte nuclear factor-1 α; HPR: Haptoglobin-related protein; LDLR: Low density lipoprotein receptor; NCAN: Neurocan; TOMM40: Translocase of outer mitochondrial membrane 40 homolog; CILP2: Cartilage intermediate layer protein 2; ERGIC3: Endoplasmic reticulum-Golgi intermediate compartment protein 3; MAFB: V-maf musculoaponeurotic fibrosarcoma oncogene homolog B; SNP: Single nucleotide polymorphisms; MAF: Minor allele frequency.

Prior to the publication of the meta-analysis of blood lipids conducted by Teslovich *et al*[28], 29 loci had been found to be associated with variation in high-density lipoprotein cholesterol (HDL-c) levels[20,27-39]. Teslovich *et al*[28] identified 31 novel loci associated with HDL-c with genome-wide significance. The most commonly-replicated loci are *LPL*, *LIPC*, *CETP*, *ABCA1*, *LIPG*, *APOA1/C3/A4/A5* and *GALNT2* (Figure 3 and Table 3). The *LIPC* locus has a set of common variants nearly 50 kb upstream of the gene, strongly associated with HDL-c and appearing to be independent of previously described variants that overlap the transcribed sequence of the gene. SNPs close to the mevalonate kinase-methylmalonic aciduria cblB type (*MMAB*) locus were found to be associated with HDL-c initially by Willer *et al*[20] and later confirmed by Kathiresan *et al*[29].

GWAS have identified several genetic loci associated with LDL-c (Figure 4 and Table 4)[20,27-32,34,36,40], such as the study by Teslovich *et al*[28] which identified 22 novel and 25 previously implicated loci. *CELSR2-PSRC1-SORT1* and *PCSK9* loci on chromosome 1, *APOB*, *HMGCR*, *NCAN-CILP2-PBX4*, *LDLR*, *TOMM40-APOE*, and *APOC1-APOE* were the most commonly-replicated loci in LDL-c. Several of these loci were also associated with

CHD in the WTCCC study[17].

In total, 43 different loci have been found to be associated with triglycerides (TAG) in GWAS (Figure 5 and Table 5). SNPs in proximity to *ANGPTL3*, *APOB*, *GCKR*, *MLXIPL*, *LPL*, *TRIB1*, *APOA1/A4/A5/C3*, and *NCAN-CILP2-PBX4* have been associated with TAG in several GWAS.

GWAS AND BP

In 2007, the Framingham Heart Study[41] reported on 1327 individuals whose BP had been sampled longitudinally in the Framingham Community project. In the same year, the WTCCC[17] reported results from 2000 Northern European subjects with HTN. Although a few SNPs did reach a statistical significance of $P < 10^{-5}$, none of them achieved genome-wide significance ($P < 5 \times 10^{-8}$). The most significant GWAS findings in blood pressure are summarized in table 6 and figure 6[42-50].

The global BPgen consortium[42] studied 34433 subjects of European ancestry, subsequently followed up the findings with direct genotyping of 71225 individuals of European ancestry and 12889 individuals of Indian Asian ancestry and conducted a joint analysis. They identified an association between systolic or diastolic BP (SBP/DBP) and common variants in eight regions near the *CYP17A1* (intergenic *CNNM2/NT5C2*), *CYP1A2* (intron *CSK*), *FGF5*, *SH2B3* (intron *ATXN2*), *MTHFR*, c10orf107, *ZNF652* and intron *PLCD3*. Furthermore, three of these common variants (*MTHFR*, *CYP17A1* and *CYP17A2* or *CSK*) were associated with HTN ($P < 5 \times 10^{-8}$). The CHARGE consortium study ($n = 29136$)

identified 13, 20 and 10 SNPs for SBP, DBP and HTN respectively[43].

In a joint meta-analysis of CHARGE consortium data with BPgen consortium data (n = 34433)[43], four CHARGE loci attained genome-wide significance for SBP (*ATP2B1*, *CYP17A1*, *PLEKHA7*, *SH2B3*), six for DBP (*ATP2B1*, *CACNB2*, *CSK-ULK3*, *SH2B3*, *TBX3-TBX5*, *ULK4*) and one for HTN (*ATP2B1*). The KORA study by Org *et al*[48] in a South German Cohort identified a SNP upstream of T-cadherin adhesion molecule (*CDH13*) gene on chromosome 16 (rs11646213) as significantly associated with HTN at a genome-wide level. Finally, in a

Table 6 Single nucleotide polymorphisms associated with hypertension and blood pressure in genome-wide association studies

E: European; AA: African American; EA: East Asians; SBP: Systolic blood pressure; DBP: Diastolic blood pressure; HTN: Hypertension; ACBD4: Acyl-CoA binding domain containing 4; ADH7: Alcohol dehydrogenase 7 (class IV), mu or sigma polypeptide; AGTRAP: Angiotensin II receptor-associated protein; ALDH1A2: Aldehyde dehydrogenase 1 family, member A2; ARID5B: AT rich interactive domain 5B (MRF1-like); AS3MT: Arsenic (+3 oxidation state) methyltransferase; ATP2B1: ATPase; Ca^{++} transporting; plasma membrane 1; ATXN2: Ataxin 2; C10orf107: Chromosome 10 open reading frame 107; C4orf22: Chromosome 4 open reading frame 22; CACNB2: Calcium channel, voltage-dependent, β 2 subunit; CDH13: Cadherin 13, H-cadherin (heart); CLCN6: Chloride channel 6; CNNM2: Cyclin M2; CPLX3: Complexin 3; CSK: C-src tyrosine kinase; CYP17A1: Cytochrome P450, family 17, subfamily A, polypeptide 1; CYP1A1: Cytochrome P450; family 1, subfamily A, polypeptide 1; CYP1A2: Cytochrome P450, family 1, subfamily A, polypeptide 2; FGF5: Fibroblast growth factor 5; HEXIM1: Hexamethylene bis-acetamide inducible 1; HEXIM2: Hexamthylene bis-acetamide inducible 2; LMAN1L: Lectin, mannose-binding, 1 like; MTHFR: Methylenetetrahydrofolate reductase (NAD(P)H); NPPA: Natriuretic peptide A; NPPB: Natriuretic peptide B; NT5C2: 5'-nucleotidase, cytosolic II; PHB: Prohibitin; PLCD3: Phospholipase C, Δ 3; PLEKHA7: Pleckstrin homology domain containing, family A member 7; PRDM8: PR domain containing 8; RHOBTB1: Rho-related BTB domain containing 1; RTKN2: Rhotekin 2; SH2B3: SH2B adaptor protein 3; STK39: Serine threonine kinase 39; TBX3: T-box 3; TBX5: T-box 5; TMEM26: Transmembrane protein 26; ULK3: Unc-51-like kinase 3 (C. elegans); ULK4: Unc-51-like kinase 4 (C. elegans); UMOD: Uromodulin, ZNF652: Zinc finger protein 652; SNP: Single nucleotide polymorphisms; OR: Odds ratio.

population of African origin, Adeyemo *et al*[44] identified four common variants (*MYLIP*, chr 6; *YWHAZ*, chr 8; *IPO7*, chr 11 and *SLC24A4*, chr 14) associated with SBP with genome-wide significance.

Wang *et al*[47] identified *STK39*, *SPAK* (STE20/SPS1-related proline and alanine rich kinase; a serine/threonine kinase) with a *P* value of 1.6×10^{-7} in an Amish cohort. Several other studies also identified potentially important genetic loci associated with BP traits with borderline genome-wide significance. These include *ATP2B1*[43,51] (ATPase, Ca^{++} transporting, plasma membrane 1) on chromosome 12, *FOXD3*[41] (fork head box D3) on chromosome 1, *CCNG1* (cyclin G1)[48] on chromosome 5, *BCAT1* (branched chain aminotransferase 1, cytosolic)[17] on chromosome 12, *ATXN2* (ataxin 2)[42,43] on chromosome 12 and *TBX3* (T-box3)[43] on chromosome 12 (Figure 6

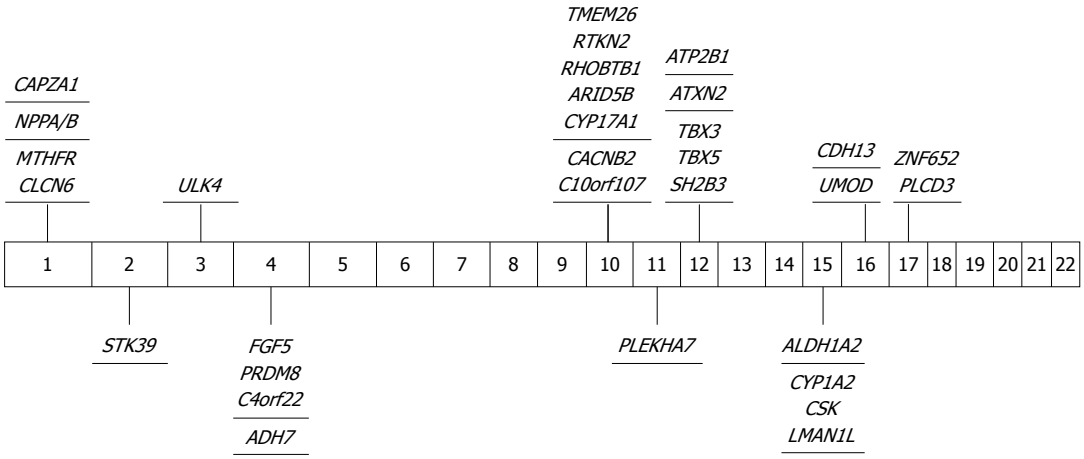

Figure 6 Significant genome-wide association study findings in blood pressure. and Table 6). However, none of these loci were replicated in other studies. Using an extreme case-control design, Padmanabhan *et al*[50] identified a novel HTN locus on chromosome 16 in the promoter region of uromodulin (UMOD; rs13333226, combined P value 3.6×10^{-11}). The minor G allele of this SNP is associated with a lower risk of HTN [OR (95% CI): 0.87 (0.84-0.91)], reduced urinary UMOD excretion and increased estimated glomerular filtration rate (3.6 mL/min per minor-allele, $P = 0.012$), and borderline association with renal sodium balance.

CLINICAL IMPLICATIONS

GWAS are a useful tool in the identification of new and unexpected genetic loci of common diseases and traits, thus providing key novel insights into disease biology. But the clinical utility of these discoveries is negligible at this stage. The comparatively small numbers of variants which have been successfully replicated in several independent studies explain only a small proportion of the observed variation of these traits and explain in aggregate less than 20% of disease heritability. For example, the loci underpinning LDL-C levels[28] and BP account for < 20% of the variance of these quantitative traits. The variants associated with CHD increase disease risk by up to 20% per allele[51,52]. Next generation sequencing is now used to study low-frequency and rare variants that may potentially explain some of the missing heritabilities; however it is likely that studies designed to test for gene-environment interactions and gene-gene interactions may hold the answer. There were attempts to develop genetic profiles using the results from GWAS studies, but these have very limited value in personalised risk prediction as the genotype-phenotype effect sizes are very small. In the few studies that have evaluated the ability of a panel of genetic markers to discriminate CHD cases, the area under the receiver operating characteristic curve has been small indicating that conventional risk factors and family history are better at predicting risk and the incremental advantage of adding genetic markers is negligible. A few studies have attempted reclassification based on incorporation of SNPs from GWAS of CAD, lipids, *etc*.[52-58], and while they showed some improvement in net reclassification, the interpretation of these are still controversial and not translatable into general use[59]. Many companies are providing direct-to-consumer genetic tests that provide a "genetic risk profile" for an individual using risk alleles of small-to-moderate effects despite the clinical utility of genetic screening not being established. None of the major healthcare providers in Europe and USA have adopted these tests for CHD risk prediction, and the FDA has advised that direct-to-consumer genetic tests should be considered to be medical devices requiring FDA approval for commercial use. The future application of genetic screening will be in identifying risk groups early in life to direct targeted preventive measures and potentially pharmacogenetic tests to identify those at higher risk for adverse events. While technology is not a barrier to achieving this, the discovery, evaluation and deployment of these tests will require the same standards as non-genetic tests[60].

Abstract

Cardiac rehabilitation protocols applied during the in-hospital phase (phase I) are subjective and their results are contested when evaluated considering what should be the three basic principles of exercise prescription: specificity, overload and reversibility. In this review, we focus on the problems associated with the models of exercise prescription applied at this early stage in-hospital and adopted today, especially the lack of clinical studies demonstrating its effectiveness. Moreover, we present the concept of "periodization" as a useful tool in the search for better results.

Key words: Cardiac rehabilitation; Exercise physiology; Physical therapy

INTRODUCTION

There are different levels of physical aptitude, and they are directly related to the functional capacity of each individual. The same person presents different levels of physical aptitude in different phases of one's life. Physical aptitude is determined by two different components: musculoskeletal and cardiopulmonary. The improvement of both is achieved with regular training (physical activity) and is associated with better exercise tolerance. On the other hand, physical aptitude can deteriorate due to disuse[1]. Bed rest significantly decreases the cardiovascular tolerance for exercise in normal subjects and contributes to physical debility[2-4].

The main components of physical aptitude include body composition, cardio-respiratory aptitude, muscle strength and flexibility[5]. All of them are directly compromised by bed restriction. The human body works like a fine-tuned gear system involving the respiratory, cardiovascular and musculoskeletal systems[6]. The first

is responsible for capturing atmospheric oxygen and distributing it into the blood stream through diffusion. The second is responsible for the systemic distribution of oxygenated blood which depends on the pumping function of the left heart. The third system (musculoskeletal) is responsible for capturing and extracting molecular oxygen from the blood stream and transforming it into energy through intracellular biochemical reactions, in order to generate movement[7].

The whole system improves as the individual exercises and the organism develops physiological adaptations[8]. In many individuals one or more of these gears can be pathologically compromised either by clinical disease, surgical intervention and/or by being bedridden. Patients with respiratory diseases tend to have difficulty in capturing and diffusing oxygen, as a result of alterations in their pulmonary volumes and capacities, interfering directly in their exercise tolerance[9]. Patients with decreased left ventricular function present a reduction in the ejection fraction and decrease in the amount of systemic oxygen, consequently reducing exercise tolerance[10,11].

When cardiopathies and pneumopathies coexist in the same patient, the results of such physiopathological alterations can be a reduction in muscle strength due to disuse induced by lower tolerance to exercise or due to the lower level of physical aptitude[12,13]. When such a population is submitted to an exercise program, psychopathological adaptations of the organism are observed[14], and specific methods of exercise prescription are necessary to fulfill the needs of these patients[15], taking into account each personal and functional adaptation[16].

CLINICAL EXERCISE PHYSIOLOGY IN HOSPITAL PHASE

Clinical exercise physiology is still an incipient science, as evidenced by the weakness of the exercise prescription models for the hospital phase. At this early phase, the focus of physical therapy is prescription to avoid inactivity, and to maintain or improve pulmonary capacities and muscular strength[1,17,18], especially in patients after cardiac surgery. Although it might seem simple, many authors question the efficacy of these physical therapy programs. Sivarajan *et al*[19] evaluated a type of in-hospital exercise prescription in patients who suffered a myocardial infarction and found no improvement in the treadmill performance. There is a low level of evidence to assess the efficacy of chest physical therapy in the hospital phase.

EFFICACY OF CHEST PHYSICAL THERAPY APPLIED IN POST CARDIAC SURGERY

A systematic review was carried out to determine the efficacy of the use of physiotherapy in the prevention of pulmonary complications in post-operative heart surgery patients and to assess the efficacy of chest physical therapy in the hospital phase[20]. Eighteen trials, involving 1457 patients were evaluated: 13 evaluated the use of respiratory physiotherapy in post-operative heart surgery patients; 8 evaluated respiratory boosters; 5 tested the efficacy of applying a continuous positive airway pressure system; and 3 tested the efficacy of applying intermittent positive pressure. Changes in the following variables were assessed: incidence of atelectasis and pneumonia; partial oxygen pressure in the arterial blood; forced vital capacity; and forced expiratory volume in the first second. No intervention showed superiority for any end point confirming findings from previous studies[21,22]. However, it is well accepted that patients submitted to cardiac or thoracic surgery need ventilatory special attention.

As a result of sternotomy and the insertion of thoracic and mediastinum drainage tubes, the majority of these patients tend to present a restrictive disturbance with reductions in the pulmonary volumes and capacities[23]. Thus ventilation tends to be compromised and the diffusion of systemic oxygen also tends to be reduced[24], as shown by the low oxygen levels found in the arterial blood in exams such as gasometry, up to 72 h after the surgical procedure. The exercise tolerance of these patients tends to be lower, demanding an exercise prescription that respects the balance between oxygen offer and consumption, avoiding an overload which, in this specific case, can lead to hemodynamic instability[25-27]. So there is a clear paradox: although it seems clearly reasonable to accept that respiratory interventions are needed in this population during phase I of cardiac rehabilitation, this is still not supported by strong evidence (Table 1).

THE SUBJECTIVITY OF PHASE I OF CARDIAC REHABILITATION

When evaluating current protocols for phase I of cardiac rehabilitation, subjectivity regarding exercise prescriptions can be noted. The intensity is still determined in a subjective way[34], both for patients after cardiac surgery and for patients after acute myocardial infarction (AMI), using a quantitative index, which is the perceived effort index scale, or even the rating of fixed increments in the values for increase in heart rate, such as +30 bpm for post-acute myocardium infarction patients, or even +20 bpm for post-heart surgery patients[35,36]. In addition there are no specific descriptions of models for respiratory exercise prescriptions (essential for patients after surgery), where the series and repetitions are defined in a random way according to the patient's tolerance. In general the intervals between series are also defined by the patients, which is also subjective in relation to the activity and recovery time or according to the training density[36].

Respiratory exercises still fail to present standardized prescriptions of series repetitions, and a difficulty in adjusting the overload was noted, since the rating of the values for the increment in heart rate could signify different levels of exercise intensity. For example, 130 bpm for a 70-year-old individual with a resting HR of 65 bpm

Table 1 Presentation of end-points of papers disclosed since 1992 about evidence based on cardiopulmonary physiotherapy

Study	Design of study	Study objective	Study conclusions
Dean *et al*[28], 1992	Review study involving 61 articles	Examines advances in cardiopulmonary physiology and clinical medicine since the development of classic chest physical therapy practice, and the discordance of current physical therapy practices with the physiologic advances	(1) Cardiopulmonary physiology, pathophysiology and clinical medicine have advanced exponentially compared with physical therapy; (2) Establishing the efficacy of conventional chest physical therapy has been confounded by the lack of specificity of the underlying pathophysiology; (3) Needed to define the parameters for prescribing, position and mobilization so that the efficacy of these noninvasive interventions can be maximally explored in patient care
Stiller *et al*[29], 1994	Randomized controlled trial, involving 127 patients	Investigate whether prophylactic chest physical therapy affected the incidence of postoperative pulmonary complications	The results suggest that the necessity for prophylactic chest physiotherapy after routine coronary artery surgery should be reviewed
Johnson *et al*[30], 1996	Randomized controlled trial involving 78 patients	To determinate whether higher personnel intensive chest physical therapy can prevent the atelectasis that routinely follows cardiac valve surgery	The routine prescription of high intensity physical therapy does not improve patient outcomes but does add significantly to patient costs
Stiller[31], 2000	Review study involving 82 articles	To evaluate actuation of physiotherapy in intensive care	Although recommendations can be made concerning evidence based practice for physiotherapy, in the intensive care unit (ICU) these are limited because of the lack of data evaluating the effectiveness of physiotherapy in these settings. There is an urgent need for further research to be conducted to justify the role of physiotherapy in ICU
Wynne *et al*[32], 2004	Metanalyses involving 159 articles	To evaluate postoperative pulmonary dysfunction in adults after cardiac surgery	No single method of pulmonary physiotherapy is superior to others in preventing pulmonary complications
van der Peijl *et al*[33], 2004	Randomized controlled trial involving 246 patients	Compare the effectiveness of a low frequency program with high frequency and to assess whether the latter would yield sufficient benefit for the patient to justify higher costs in material end personnel	High frequency exercise program leads to earlier performance of functional tasks but would allow a sensible redistribution of the physiotherapists activity towards complicated and, therefore, more demanding patients
Pasquina *et al*[20], 2003	Review study involving 18 trials (1457 patients)	To assess whether respiratory physiotherapy prevents pulmonary complications after cardiac surgery	The usefulness of respiratory physiotherapy for the prevention of pulmonary complications after cardiac surgery remains unproved

represents an effort of 83.5% of the reserve heart rate (RHR) according to Karnoven's formula, whereas for a 55-year-old individual with the same resting HR of 65 bpm, it represents 75% of the RHR, according to the same formula. Similarly, an increment of 20 bpm during an exercise for an individual with a resting heart rate of 100 bpm can represent a different effort than the same increment for an individual with a resting HR of 80 bpm. This subjectivity in relation to the principles of overload, reversibility and specificity in exercise prescription, explicit in the protocols for phase I of cardiac rehabilitation, warrants a prospective study that would assess current models of exercise prescription. The scientific community should be aware of the lower level of evidence to assess the efficacy of physical therapy. Moreover, exercise prescription during the hospital phase has to be redefined.

The subjectivity in relation to the basics principles of exercise prescription in phase I of cardiac rehabilitation.

In 1768, Herbeden observed that a patient with chest angina significantly improved after wood chopping for half an hour every day. This finding, described by White[37], was one of the first publications referring to the benefits of physical activity on cardiopathies. Nevertheless physical activity as a form of treatment was put aside until the beginning of the twentieth century mainly because of the seriousness that cardiopathy represented to the patient's health. During the sixties, as bed rest was mandatory as part of the treatment in any cardiopathy[38,39] a few studies started demonstrating the deleterious effects of bed restriction not only physically, but also psychologically[40-42].

A trend for early mobilization took a while to become routine in the larger centers, and in 1969 a 3-wk bed rest period was still common after AMI. For years authors like Miller[43] argued that the myocardium continued to take risk when the muscle was precociously mobilized, since the removal of necrotic areas of the myocardium was not complete before the end of the fourth week and collateral circulation could take longer to be recruited. Such publications led many specialists to discuss the subject as the I International Congress on Cardiac Rehabilitation in Hamburg, in 1977, when the need for early mobilization was affirmed[44]. In 1993 the World Health Organization defined cardiac rehabilitation as the sum of the activities required to favorably influence both the subjacent cause of the disease and the physical, mental and social conditions of the patient, allowing patients to preserve or reassume their role in the community as soon as possible. As the years went by, cardiac rehabilitation programs grew in importance as a result of their[45-47], great social relevance[48,49]. According to Charlson *et al*[50], the increase of risk factors towards cardiovascular diseases among the elderly population increase the number of CABG procedures, which is associated with a significant reduction in

Table 2 Presentation of the ACSM recommendations for the prescription of exercises in phase I of cardiac rehabilitation

Intensity
TPE below 13 (scale 6-20)
Post AMI: HR below 120 bpm or resting HR + 20 bpm (Arbitrary lower limit)
Post-surgery: resting HR + 30 bpm (Arbitrary upper limit)
Up to tolerance if non-symptomatic
Duration
Intermittent sessions lasting from 3 to 5 min
Resting periods
As the patient wishes
Lasting from 1 to 2 min
Shorter than the time of the exercise sessions
Total duration of 20 min
Frequency
Early mobilization: 3 to 4 times per day (1st to 3rd days)
Subsequent mobilization: twice per day (As from the 4th day)
Progression
Initially increase the duration by up to 10 to 15 min of exercise time and then increase the intensity

AMI: Acute myocardial infarction; TPE: Table of perceived effort; HR: Heart rate; ACSM: American college of sports medicine.

physical capacity[48,49]. Seventy to 80% of patients submitted to heart surgery tend to recover their complete work capacity 1 year after procedure. This delay could be attributed to post-operative complications such as atelectasis, and pneumonia[51-53], which, amongst others, contributed to a reduction of physical aptitude of the patients during their hospital stay, resulting in a slower recovery[54-57]. According to American college of sports medicine (ACSM), cardiac rehabilitation can be divided into 4 phases[30].

Phase I, known as the hospital phase, aims to minimize the effects of restriction to bed and ends with hospital discharge. Phase II (up to 12 wk) starts immediately after discharge and is known as the early out-patient phase[47,48]. The aim is to develop activities that simulate the metabolic expense of everyday activities. Phase III, known as the late out-patient phase (variable duration) aims to develop exercises with more intensity[47,48]. The fourth and final phase is known as the preventive phase and should have a starting date but not a finishing one, where the patient will choose a cyclical activity of greater affinity, carrying out the program at least 3 times a week throughout one's lifetime[18].

Despite the fact that phase I is considered to be most important in the rehabilitation program, it presents a subjective prescription of exercises. Nevertheless it is one of the most used protocols throughout the world and is used as a study tool by many professionals. ACSM recommendations for the prescription of exercises in phase I of cardiac rehabilitation (both for patients after AMI and for patients after surgery) are shown in Table 2. The subjectivity of the phase I protocol can be perceived from the definition of the intensity of the exercises, where this should be controlled from the table of perceived effort (TPE). This table was developed by Borg (1979) with the objective of allowing the individual who exercises to subjectively classify the sensations during exercise, taking into account the level of personal aptitude, the environmental conditions and the level of fatigue[58,59]. There are currently two TPE scales in use, one classifying the exercise intensity from 6 to 20, and the revised one classifying it from 0 to 10. In addition to control by TPE, exercise intensity can be defined from the variation in heart rate, where post-AMI patients should increase their HR by a maximum of 20 and 30 bpm from resting during the exercise[60]. The control of the exercise intensity by the HR with a pre-determined target does not individualize the prescription of the exercise. Thus individualization, one of the principle fundamentals for the success of the exercise prescription[61], is not respected. In addition, the control of the perceived effort defined by the patient himself, may not picture the true energy consumption with respect to the activity. The value representing the effort can be super-estimated by the more apprehensive patients, or even sub-estimated by more motivated patients.

The intra-hospital protocol, in agreement with ACSM, suggests that an exercise session should last approximately 20 min. The session should be composed of intermittent series of exercises, each lasting between 3 and 5 min, with intervals between the series defined according to the wishes of the patient, or lasting between 1 and 2 min or even shorter than the duration of the exercise sessions. The interval between series appears as the main tool for the principle of reversibility or recovery, being as important as the definition of the series of repetitions. The interval should be defined from the volume and intensity of the exercise carried out, based on metabolic recovery of the energy sources and in the composition of the muscle fibers involved in movement[61]. Thus leaving the definition of the interval time to the discretion of the patient could, for example, generate unnecessary overload, resulting in prejudice to the patient. Thus, it's clear that the criteria for the definition of progression of the series and control of the intensity are still subjective[62]. The individualization of exercise prescription is essential, especially for patients after cardiac surgery. At this moment (phase I), patients have reduced cardiopulmonary reserve in regard to their exercise tolerance[63], meaning it is necessary to provide a judicious prescription controlling its specificity, overload and reversibility. These three basic principles of exercise prescriptions, as described by Bompa[64], must be respected so that the prescription can provide some benefit to the individual independent of his level of physical aptitude, be the patient a recently operated cardiac patient or an athlete.

The principle of specificity defines the effects of training. Improvement and potentiation of the predominant energy substrate system relies on its proper identification. Then an individualized exercise plan that meets the specific needs of the patient can be carried out. Thus the non-inclusion of a well-defined program of respiratory exercises for post-operative heart surgery patients represents the lack of specificity of the present method of phase I cardiac rehabilitation. As a result of median

sternotomy and the insertion of thoracic drainage tubes, these patients tend to present with a reduction of up to 30% in their pulmonary volumes and capacities. According to Guizilini *et al*[27], a decrease in forced ventilatory capacity can determine a fall in the expiratory flow peak, which also decreases immediately after surgery. This fall is clinically important since it will compromise the ability to cough and remove respiratory secretions[5]. The precocious closing and obstruction of the small airways predisposes the individual to microatelectasis and consequently to a reduction in the partial oxygen pressure in the arterial blood (PaO_2)[64,65]. Thus if pulmonary re-expansion is not rapidly reestablished, exercise tolerance will be promptly reduced[66-68]. The overload principle establishes that a tissue or organ has to be exposed to a load to which it is not used in order to improve its function (McKirnan *et al*[66]). Repeated exposition is associated with an adaptation on the part of the tissue or organ, which results in an improvement in the functional capacity. An exercise prescription should determine the intensity, duration and frequency of the training session meaning the interaction of these three variables determines the cumulative overload to which the tissue or organ should adapt[64].

INDIVIDUALIZATION OF EXERCISE PRESCRIPTION DURING HOSPITAL PHASE: A NEED TO BE ACHIEVED

The exercises should follow an adequate progression for organ or tissue adaptation. The activity can progress by progressive load model, where it is necessary to plan exercise sessions with the same characteristics in a determined time period or microcycle[64]. An increase in the load of exercises causes a slight physiological imbalance, followed by an adaptation phase, resulting in an improvement in performance[65]. The specificity of the prescribed exercises can directly influence the total session time, depending, obviously, on the clinical situation of the patient and on one´s level of physical aptitude[63]. One example is the prescription of respiratory exercises for post-operative heart surgery patients. In order to tolerate peripheral active exercises, many patients require specific respiratory work in order to potentially increase pulmonary volumes and capacities and gaseous exchange, consequently improving the distribution and capture of systemic oxygen and improving exercise tolerance[66].

Thus it is very difficult to standardize the session time without defining the specificity of the exercises or the work to be carried out with each patient[61]. The third basic principle of exercise prescription is that of reversibility[64]. This can be passive or active, where continuous low intensity exercises can help the metabolic recovery of the individual. In addition, the anatomical-physiological modifications that allow the individual to gradually increase his/her load intensity depend on the overload principle and on the pauses for recovery. The training programs should show intensity, duration and recovery periods that allow the organism to adapt so as to try and recover functional homeostasis (Barbanti[5]). Quite apart from the general principles for the adjustment of exercise prescriptions, the components of a session should also be respected. An exercise session should include a warming-up period, a specific work period referring to the initial objective of the work, a period of recreational activity and a winding-down period[65].

These components arise within an exercise session according to the objective of the prescribed series and the level of physical aptitude of the individual. The need to supervise the longitudinal evolution of an exercise prescription, respecting the general principles and aiming at constantly improving performance, motivated competitive sports trainers to develop a structure that helped in the organization and planning of the activities. Thus models for sports training periods were developed (Gomes[65]). The overload principle, directly responsible for the improvement in physical aptitude, can be represented by the increment in volume or in the intensity of the activity. A random increase in the exercise time, associated with a random definition of the interval between exercises, makes it difficult to prescribe the progression of the series. Thus the problem defining the overload activities for hospitalized individuals makes it difficult to program the series or divide it into periods, including the program of activities to be performed after discharge.

The methods for exercise prescription are represented by the strategies used to obtain a better yield or adaptation to the exercise. There are two main patterns: continuous and intermittent. Continuous exercise is of a submaximal nature and medium to long term, with intervals not permitted. The moderate intensity makes it possible to maintain the effort for a longer period of time. Intermittent exercise is characterized by a series of repeated periods of exercise alternated with periods of active rest or recovery intervals. The repeated series of exercises can have previously defined numbers, duration, intensity and intervals (McArdle *et al*[8]). It is important to point out that Kirkeby-Garstad *et al*[61] questioned the efficacy of low intensity activities in this phase of cardiac rehabilitation. The correct combination of stimulus intensity and duration with adequate recovery intervals allows the individual to support more intense activities.

PERIODIZATION IN HOSPITAL PHASE OF CARDIAC REHABILITATION: A NEW IDEA FOR PHYSICAL THERAPY BASED ON EVIDENCE

The difficulty found in demonstrating the results of a subjective program of prescribed exercises in the hospital phase (phase I), has contributed to the lack of adhesion to rehabilitation programs. Currently, less than 25% of the patients eligible for rehabilitation are enrolled in training programs in specialized centers in developed countries (Carlson *et al*[69]). After CABG these values

reach 25%-50% of the cases. When the number of patients taking part in supervised rehabilitation programs in developed countries is considered, 25%-50% give up after 6 mo and more than 90% after 1 year. The pertinent protocols have been shown to be non-executable in daily practice. Thus the need has arisen to redefine the methodology for prescribing exercises for phase I so as to motivate participants to continue in the rehabilitation program, and primarily to demonstrate objectivity in their prescription, respecting the basic exercise prescription principles.

Over the years, medicine has based itself on personal experiences, on the authority of more titled academics and on the descriptions of physiopathological theories. According to Atallah *et al*[70], evidence based medicine has arisen to guide decisions about health care. In a way, this conception of medicine removes the emphasis on practice based on intuition and on non-systematized clinical experience. Thus, according to Sackett *et al*[71], clinical reasoning in the form of research gains special distinction. In addition to new followers, evidence based physiotherapy is currently gaining importance since the activities of the professionals do not simply limit themselves to the clinical or medical diagnosis, but also include an evaluation of the repercussions or impact the disease brings to the life of the individual. Thus descriptive epidemiology becomes fundamental for the knowledge of a certain disease and its repercussions, where the physiotherapist should establish his/her diagnosis, prognosis, activity or treatment program, also carrying out interventions or reevaluations. The professional should fall back on books and periodicals to find the theoretical foundation to define the treatment program and apply a certain technique or exercise prescription methodology. The evidence levels produced in scientific studies are used as classification criteria according to the quality of studies in the health area[70].

Thus Wright *et al*[34] questioned the benefit of low intensity exercise for heart surgery patients. For his part, Hulzebos *et al*[72] stated that the physiotherapeutic techniques applied to post-heart surgery patients in the hospital phase, presented controversy regarding their efficacy in reducing the incidence of pulmonary complications. Britto *et al*[73] showed a significant lack of evidence regarding the effectiveness of physiotherapeutic techniques applied in the treatment of pulmonary empyema in the hospital phase, and, according to the author, the clinical decision taken by the physiotherapist was based on studies, the majority of which presented rudimentary methods, on personal experiences and on information obtained from books and from the opinions of professors and experts. Crowe *et al*[22] questioned the effectiveness of using inspiratory boosters associated with respiratory physiotherapy in the pulmonary re-expansion of patients with a high risk for respiratory complications, already in the hospital phase of patients who suffered an AMI and submitted to CABG[74], Overend *et al*[75] evaluated the effect of incentive spirometry (IS) on postoperative pulmonary complications (PPC), and it follows that the evidence does not support the use of IS for decreasing the incidence of PPC following cardiac or upper abdominal surgery. Thus it is apparent that some of the results referring to the prescription of exercises in cardio-respiratory physiotherapy are being questioned.

PHYSIOTHERAPIC APPROACH AND NEEDS

The physiotherapic approach and needs are different. The methods of prescribing exercises during in hospital phases need an urgent review, especially the methods related to cardiac surgery. Currently different needs such as individualization and periodization of exercise prescription during the hospital phase of cardiac rehabilitation should be studied, aiming to improve outcomes and levels of evidence regarding the application of techniques of cardiopulmonary physiotherapy. From the subjective way that is done today, exercise prescription at this stage has little effectiveness. It´s not possible to argue in the 21st century the efficacy of physical therapy in this field. Maybe the starting point for reviewing methods of prescription in phase I is to take a look at subjective quality related to the basic principle of exercise prescription: specificity, overload and reversibility. Importing the periodization applied on sports training programs and respecting the different levels of physical aptitude during the hospital phase may help improve the quality of prescription.

CONCLUSION

Thus phase I of cardiac rehabilitation has become a challenge for evidence based physiotherapy, having the means for success with the adjustment of a new exercise prescription model as long as this model is based on the principles of the clinical physiology of exercise, in the individualizing of the prescription. There is a real necessity for prospective randomized clinical trials in the physical therapy field. Maybe the way of programming the activities, creating a pattern including periods with well defined micro-cycles and series based on the application of functional tests, could guarantee greater objectivity, greater adherence to the programs and, as a consequence, better results.

Abstract

We describe a patient with asymptomatic apical hypertrophic cardiomyopathy (AHCM) who later developed cardiac arrhythmias, and briefly discuss the diagnostic modalities, differential diagnosis and treatment option for this condition. AHCM is a rare form of hypertrophic cardiomyopathy which classically involves the apex of the left ventricle. AHCM can be an incidental finding, or patients may present with chest pain, palpitations, dyspnea, syncope, atrial fibrillation, myocardial infarction, embolic events, ventricular fibrillation and congestive heart failure. AHCM is frequently sporadic, but autosomal dominant inheritance has been reported in few families. The most frequent and classic electrocardiogram findings are giant negative T-waves in the precordial leads which are found in the majority of the patients followed by left ventricular (LV) hypertrophy. A transthoracic echocardiogram is the initial diagnostic tool in the evaluation of ACHM and shows hypertrophy of the LV apex. AHCM may mimic other conditions such as LV apical cardiac tumors, LV apical thrombus, isolated ventricular non-compaction, endomyocardial fibrosis and coronary artery disease. Other modalities, including left ventriculography, multislice spiral computed tomography, and cardiac magnetic resonance imagings are also valuable tools and are frequently used to differentiate AHCH from other conditions. Medications used to treat symptomatic patients with AHCM include verapamil, beta-blockers and antiarrhythmic agents such as amiodarone and procainamide. An implantable cardioverter defibrillator is recommended for high risk patients.

INTRODUCTION

Apical hypertrophic cardiomyopathy (AHCM) is a rare form of hypertrophic cardiomyopathy (HCM) which usually involves the apex of the left ventricle and rarely involves the right ventricular apex or both[1]. Historically, this condition was thought to be confined to the Japanese population but it is also found in other populations. Of all the HCM patients in Japan the prevalence of AHCM was 15%, whereas in USA the prevalence was only 3%[2].

CASE REPORT

A 57-year-old white male with a history of hypertension, coronary artery disease, paroxysmal atrial fibrillation and metastatic squamous cell carcinoma of the tongue was

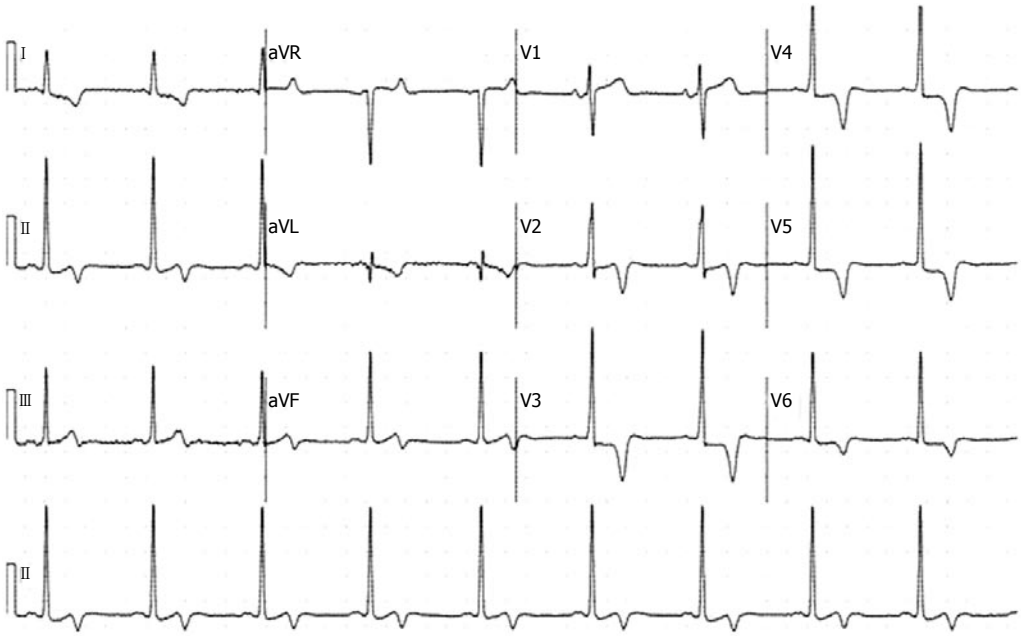

Figure 1 A 12-lead electrocardiogram showing left ventricular hypertrophy and inverted T-waves in the V2, V3, V4, V5 and V6 leads.

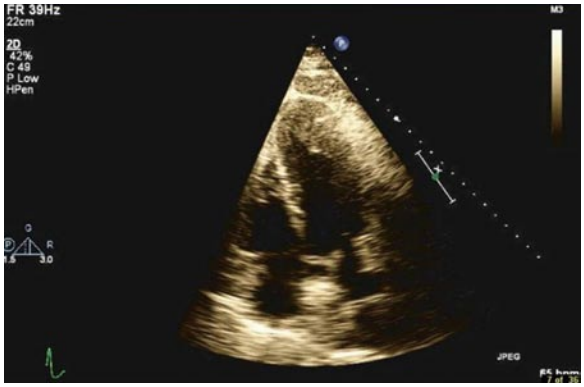

Figure 2 A 2D transthoracic echocardiogram showing left ventricular apical hypertrophy.

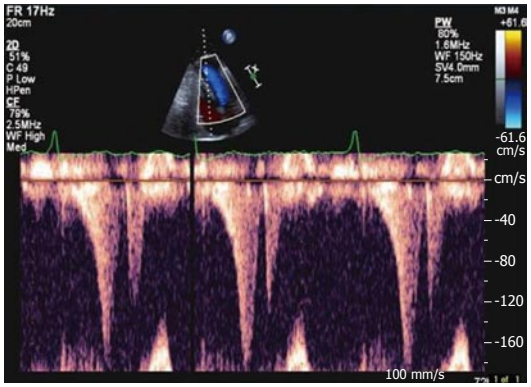

Figure 3 Doppler imaging showing a late peaking systolic gradient.

seen in March 2007 for preoperative evaluation. He had no complaints of chest pain, dyspnea or palpitations. There was no family history of sudden death, congestive heart failure or cardiomyopathy. On examination his blood pressure was 125/72 mmHg, heart rate 67 bpm with no heart murmur or any signs of congestive heart failure. The rest of the examination was normal. He was evaluated again in 2008 for altered mental status. His physical examination was unremarkable. A 12-lead electrocardiogram (ECG) showed left ventricular (LV) hypertrophy and inverted T-waves in V2 to V6 leads (Figure 1). All previous ECGs revealed similar findings. The cardiac enzymes and chest X-ray were normal. A transthoracic echocardiogram (TTE) showed apical hypertrophy with LV end diastolic diameter of 5.1 cm and normal systolic function (Figure 2). Doppler imaging showed a dagger-shaped late peaking systolic gradient, consistent with HCM (Figure 3). The ECG findings were attributed to AHCM. Since he was asymptomatic, no further investigations or particular treatment for this condition was carried out. One year later the patient developed episodes of atrial fibrillation and supraventricular tachycardia, for which he was treated with amiodarone. He had no other cardiovascular complications and was followed in the clinic, till he passed away in June 2009, due to widespread metastatic disease.

DISCUSSION

AHCM is frequently sporadic; however, a few families have been reported with autosomal dominant inheritance[3]. A sarcoma gene mutation (E101K mutation in the alpha-cardiac actin gene) has been identified in these families. A family history is more common in patients with asymmetric septal hypertrophy than with AHCM. Morphologically AHCM is divided into 3 types: pure focal, pure diffuse and mixed, of which pure focal is most common[4]. However in clinical practice this sub-classification is not widely accepted and its clinical relevance is

Table 1 Differential diagnosis of apical hypertrophic cardiomyopathy

Disease	Diagnostic tool to establish diagnosis of AHCM
Coronary artery disease	Echocardiogram/coronary angiogram and LVG
Left ventricular apical tumors	Echocardiogram with contrast/CCT/CMRI
Left ventricular apical thrombus	Echocardiogram with contrast/CCT/CMRI
Isolated ventricular non-compaction	CMRI/CCT
Endomyocardial fibrosis	LVG/CMRI

AHCM: Apical hypertrophic cardiomyopathy; CMRI: Cardiac magnetic resonance imaging; LVG: Left ventriculography; CCT: Cardiac computed tomography.

unknown. Others have divided AHCM into two groups, based on whether they had isolated asymmetric apical hypertrophy (pure AHCM) or had co-existent hypertrophy of the interventricular septum (mixed AHCM)[5]. The diagnostic criteria for AHCM included demonstration of asymmetric LV hypertrophy, confined predominantly to the LV apex, with an apical wall thickness ⩾ 15 mm and a ratio of maximal apical to posterior wall thickness ⩾ 1.5 mm, based on an echocardiogram or magnetic resonance imaging (MRI)[5].

The mean age of presentation of AHCM is 41.4 ± 14.5 years and is most commonly seen in males[5]. About 54% of patients with AHCM are symptomatic and the most common presenting symptom is chest pain, followed by palpitations, dyspnea and syncope[5]. AHCM may also manifest as morbid events such as atrial fibrillation, myocardial infarction, embolic events, ventricular fibrillation and congestive heart failure[5]. Other complications of AHCM include apical aneurysm and cardiac arrest. Physical findings of an audible/palpable fourth heart sound and a new murmur are common[5]. Our patient was asymptomatic, with no family history and had no physical findings.

The most frequent ECG findings are negative T-waves in the precordial leads which are found in 93% of patients, followed by LV hypertrophy in 65% of patients[5]. Negative T-waves with a depth > 10 mm are found in 47% of patients with AHCM[5]. The ECG in our patient showed LV hypertrophy and negative T-waves with a maximum depth of 7 mm. TTE shows hypertrophy of the LV apex and is the initial diagnostic tool for AHCM. When the baseline images are suboptimal, a contrast echocardiogram is useful in establishing the diagnosis[6]. On contrast ventriculography AHCM shows a distinctive LV "spade-like" configuration[5]. On single photon emission computed tomography (SPECT) myocardial perfusion imaging findings of resting "solar polar" map pattern and reduced flow reserve of the apex are the characteristics of AHCM[7]. Multislice spiral computed tomography can also be used to diagnose AHCM; besides diagnosis it provides information on cardiac anatomy, function and coronary arteries[8]. Cardiac MRI is also a valuable tool for diagnosing patients with inconclusive echocardiography and SPECT findings[9]. Although the initial diagnostic test for AHCM is most commonly TTE, the best diagnostic tool is considered to be cardiac MRI.

AHCM may mimic other conditions, including apical cardiac tumors[10], LV apical thrombus[11], isolated ventricular non-compaction[12], endomyocardial fibrosis (EMF)[13] and coronary artery disease[14] (Table 1). Chest pain in a patient with AHCM can be mistaken for ischemia from coronary artery disease[14]. Frequently these patients undergo a nuclear scan for abnormal ECG[15]. The majority of the patients with AHCM who suffer myocardial infarction have an apical infarct, and in these patients wall motion abnormalities varies from apical aneurysm to apical hypokinesis[5]. Some patients may have asymptomatic apical infarction[5]. Hence, in clinical practice, an apical aneurysm may sometimes be seen with AHCM in asymptomatic patients.

Isolated ventricular non-compaction may be differentiated from AHCM by high resolution images of the heart obtained by cardiac MRI[12]. An echocardiogram with contrast can be used to differentiate AHCM from a LV apical mass (thrombus or tumor)[11]. A LV angiogram shows apical obliteration during both systole and diastole in EMF, whereas in AHCM apical obliteration occurs only in systole and also there is an absence of significant ventricular hypertrophy in EMF patients[13].

In symptomatic patients with AHCM, verapamil, beta-blockers and antiarrhythmic agents are used[5]. Verapamil and beta-blockers are found to be beneficial in improving the symptoms in AHCM patients[16,17]. Amiodarone and procainamide are used in the treatment of atrial fibrillation and ventricular arrhythmias[18]. An implantable cardioverter defibrillator (ICD) is recommended for high risk HCM patients with (1) previous cardiac arrest or sustained episodes of ventricular tachycardia; (2) syncope; (3) a family history of sudden death; or (4) episodes of non-sustained ventricular tachycardia on serial Holter monitoring[19]. ICD has been was used in AHCM patients with cardiac arrest and non-sustained ventricular tachycardia[17].

Unlike other variants of HCM, the prognosis of AHCM is relatively benign. The overall mortality rate of AHCM patients was 10.5% and cardiovascular mortality was 1.9% after a follow-up of 13.6 ± 8.3 years[5]. Sudden death and cardiovascular events occur more commonly in patients with asymmetric septal hypertrophy than in those with AHCM[20]. A large LV end diastolic dimension may predict cardiac events in AHCM patients[21]. Some AHCM patients may develop sudden life-threatening complications, hence close follow-up of these patients is recommended[5].

Abstract

Acute myocardial infarction with normal coronary arteries is a well known condition, which is typically diagnosed in young patients. Coronary vasospasm, inherited, acquired or malignancy-induced hypercoagulable state, collagen vascular disease and coronary arterial embolism have been considered as underlying etiologic factors. An association between migraine with aura and increased risk of ischemic stroke, angina and myocardial infarction has been demonstrated in studies. Patients with migraine and especially with aura should be followed closely against cardiovascular events even if they are young and do not have traditional risk factors.

INTRODUCTION

Acute myocardial infarction (AMI) with normal coronary arteries is a well known condition, which has been described in the literature for many years. A number of hypotheses have been suggested to explain this condition. Coronary vasospasm, hypercoagulable state, collagen vascular disease and coronary arterial embolism have been considered as possible explanations. Migraine with aura (MWA) has been associated with an increased risk of ischemic stroke, angina and myocardial infarction. We report AMI with normal coronary arteries in a 50-year-old woman with a history of MWA who does not have traditional risk factors.

CASE REPORT

A 50-year-old woman was admitted to the hospital with complaints of retrosternal, squeezing chest pain lasting for 2 d. The patient had no known coronary artery risk factors. Her past medical history was significant for migraine headaches with nausea treated with a β-blocker for 5 years. Her electrocardiography (ECG) showed sinus rhythm without any ST-T wave abnormalities. Her blood chemistry was in the normal range except the troponin level, which was slightly elevated (0.65 ng/mL). Echocardiography showed normal left ventricular systolic function without any wall motion abnormality. Coronary angiography revealed normal coronary arteries (Figure 1A and B). The patient was discharged after 1 d with the diagnosis of Prinzmetal`s angina. The patient was subsequently admitted to hospital with complaints of aggravated chest pain

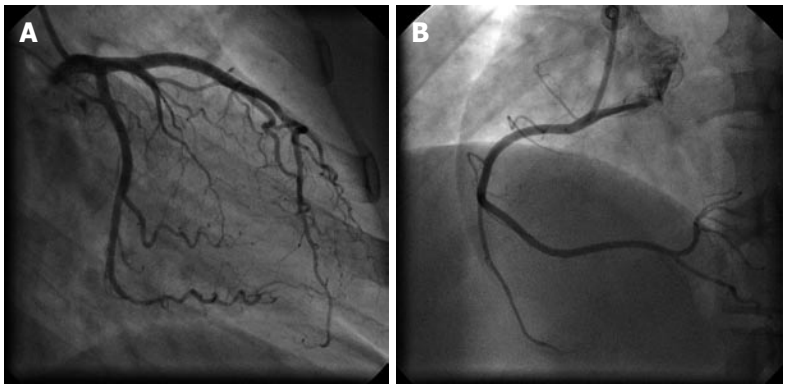

Figure 1 Coronary angiography. A: Normal left anterior descending artery and left circumflex artery; B: Normal right coronary artery.

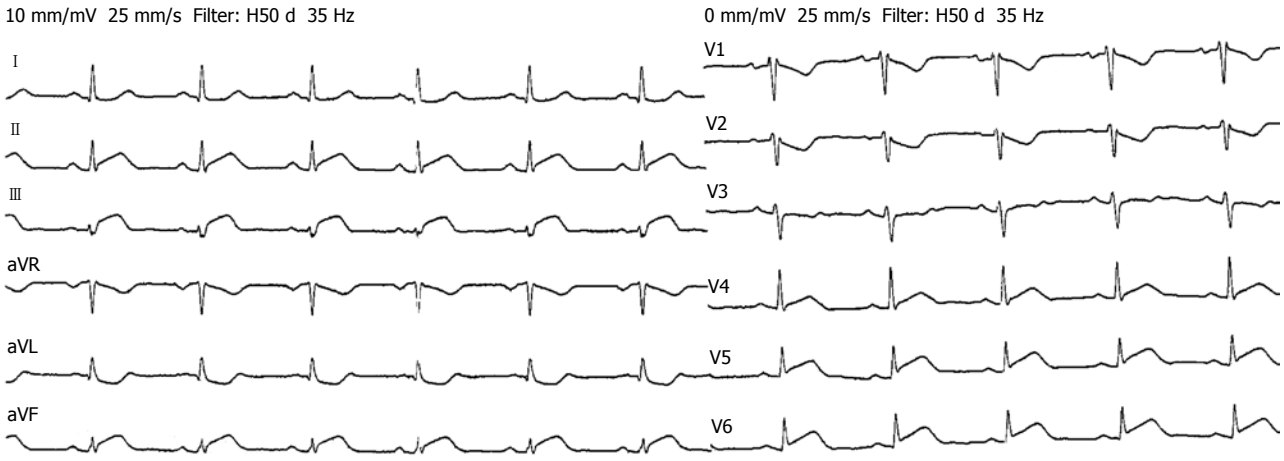

Figure 2 Electrocardiography showing acute inferolateral myocardial infarction.

compared to the first admission, accompanied by headache and nausea 20 h after the original discharge. ECG showed ST segment elevation in leads Ⅱ, Ⅲ, aVF and V4-6 with ST depression in leads Ⅰ, aVL and V1-2, which confirmed acute inferolateral myocardial infarction (Figure 2). There was no ST elevation in the right precordial leads. Thrombolytic therapy was not given as the coronary angiography 1 d before was normal and portable echocardiography revealed normal wall motion. Intravenous calcium channel blocker and nitrate treatment was started. 1 d after hospitalization troponin I level was 4.6 ng/mL. ECG revealed biphasic T waves in leads Ⅱ, Ⅲ and V4-6. Her control transthoracic echocardiography revealed mild hypokinesia in anterolateral and inferolateral walls with normal ejection fraction. The patient was discharged with calcium channel blocker and nitrate treatment.

DISCUSSION

AMI with normal coronary arteries is a well known condition, which is typically diagnosed in young patients. The prevalence of patients having AMI with normal coronary arteries has been reported as 2.8% in a recent study but there are differences in the prevalence between the published series[1,2]. This may relate to the various definitions of "normal" coronary arteries. Coronary vasospasm, inherited, acquired or malignancy-induced hypercoagulable state, collagen vascular disease and coronary arterial embolism were considered as the underlying etiologic factors[1,2]. However, an exact etiology could not be detected in a significant proportion of patients. There is no sex predilection and coronary artery risk factors are usually absent[1,3].

AMI with normal coronary arteries in young women who were under the hormonal influence of pregnancy or contraceptive pill usage has been reported in previous articles[4-6]. However, there was no pregnancy or history of contraceptive pill usage in our patient.

Migraine is a common neurologic disorder characterized by severe headache accompanied by autonomic dysfunction, nausea and vomiting. Transient neurologic symptoms before or during the headache attacks are known as migraine aura and they are most often visual[7]. An association between MWA and increased risk of ischemic stroke, angina and myocardial infarction has been demonstrated in a prospective cohort study. The age adjusted hazard ratios for ischemic stroke were 3.88 in the lowest risk score group and 1.00 for the highest. For myocardial infarction, these ratios were 1.29 and 3.34, respectively[7]. However the effects of migraine on the coronary arteries are still unknown.

Studies reported a high prevalence of patent foramen ovale (PFO) in patients with MWA[8,9]. Although PFO has been reported to be present in 40% to 60% of patients with MWA[10], there was no PFO in our patient.

A survey reported that migraine and coronary heart disease have a nonoverlapping age- and gender-specific prevalence[11]. Migraine is more prevalent in women than men throughout the lifespan and the peak prevalence of migraine occurs between ages of 30 and 49 years[11]. In a study, patients with migraine had lower blood pressure measured than those without migraine[12]. Antihypertensive drugs that are used in the treatment of migraine may control hypertension, which is a modifiable risk factor of coronary artery disease. The effects of antihypertensive drugs together with the nonoverlapping age- and gender-specific prevalence may result in a few patients with migraine experiencing myocardial ischemia.

Although the prognosis of patients with AMI and normal coronary arteries were reported as excellent in early reports, similar outcomes and prognosis in patients with normal coronary angiography and AMI compared with one- or two-vessel disease were reported in recent studies[1,13]. Also, similar mortality rates were reported in AMI patients with normal coronary arteries compared with patients with coronary artery stenosis[14].

Patients with migraine and especially with aura may have increased risk of myocardial infarction even with normal coronary arteries. They should be followed closely against cardiovascular events even if they are young and do not have traditional risk factors.

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Cardiology (*World J Cardiol*, *WJC*, online ISSN 1949-8462, DOI: 10.4330) is a monthly peer-reviewed, online, open-access (OA), journal supported by an editorial board consisting of 352 experts in cardiology from 41 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJC* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJC* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJC* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJC* is to rapidly report the most recent developments in the research by the cardiologists. *WJC* accepts papers on the following aspects related to cardiology: arrhythmias, heart failure, vascular disease, stroke, hypertension, prevention and epidemiology, dyslipidemia and metabolic disorders, cardiac imaging, paediatrics, nursing, and health promotion. We also encourage papers that cover all other areas of cardiology as well as basic research.

Columns

The columns in the issues of *WJC* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Articles: To report innovative and original findings in cardiology; (9) Brief Articles: To briefly report the novel and innovative findings in cardiology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJC*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of cardiology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on the research in cardiology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing

Statistical review is performed after peer review. We invite an expert

in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJC* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1949-8462office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1949-8462/g_info_20100316161927.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjc@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical

Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-85381892 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJC*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1949-8462/g_info_20100312194155.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1949-8462/g_info_20100312200347.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics
Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJC*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Cardiology
Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjc@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-8538-1892

Language evaluation
The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form
Please download a Copyright assignment form from http://www.wjgnet.com/1949-8462/g_info_20100312200118.htm.

Responses to reviewers
Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1949-8462/g_info_20100312195923.htm.

Proof of financial support
For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript
WJC will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases
Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee
WJC is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
