*World J Radiol* 2014 June 28; 6(6): 223-391

## Editorial Board

2014-2017

The *World Journal of Radiology* Editorial Board consists of 365 members, representing a team of worldwide experts in radiology. They are from 36 countries, including Afghanistan (1), Argentina (2), Australia (5), Austria (7), Belgium (2), Brazil (8), Canada (6), Chile (1), China (43), Croatia (1), Denmark (4), Egypt (6), France (5), Germany (22), Greece (10), India (12), Iran (6), Ireland (2), Israel (3), Italy (47), Japan (13), Netherlands (1), New Zealand (1), Pakistan (1), Poland (2), Portugal (1), Serbia (1), Singapore (3), Slovakia (1), South Korea (18), Spain (4), Sweden (2), Switzerland (4), Thailand (1), Turkey (26), United Kingdom (11), and United States (82).

## Contents

*World Journal of Radiology*  
Volume 6 Number 6 June 28, 2014

**APPENDIX** I-V Instructions to authors

**ABOUT COVER** Editorial Board Member of *World Journal of Radiology*, Georgios Plataniotis, MD, PhD, Doctor, Department of Oncology, Sussex Cancer Centre, Royal Sussex County Hospital, Brighton BN2 5 BE, United Kingdom

**AIM AND SCOPE** *World Journal of Radiology* (*World J Radiol*, *WJR*, online ISSN 1949-8470, DOI: 10.4329) is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

*WJR* covers topics concerning diagnostic radiology, radiation oncology, radiologic physics, neuroradiology, nuclear radiology, pediatric radiology, vascular/interventional radiology, medical imaging achieved by various modalities and related methods analysis. The current columns of *WJR* include editorial, frontier, diagnostic advances, therapeutics advances, field of vision, mini-reviews, review, topic highlight, medical ethics, original articles, case report, clinical case conference (clinicopathological conference), and autobiography.

We encourage authors to submit their manuscripts to *WJR*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

**INDEXING/ABSTRACTING** *World Journal of Radiology* is now indexed in PubMed Central, PubMed, Digital Object Identifier, and Directory of Open Access Journals.

**Key words:** White matter hyperintensities; Major affective disorders; Suicidal behaviour; Neuroimaging; Outcome

**Core tip:** Understanding neural correlates underlying psychiatric morbidity over time is critical but, to date, structural magnetic resonance imaging studies identified only not stable risk predictors of unfavourable outcome in psychiatric populations. The presence of white matter hyperintensities (WMHs) has been commonly associated with a poor outcome in individuals with major affective disorders. Based on our studies, subjects with WMHs may be considered at higher suicidal risk than those without and the severity of WMHs as assessed by the Fazekas modified scale may serve as a trait marker of disease. WMHs may represent an interesting neurobiological marker between the underlying vulnerability and clinical presentation of major affective disorders.

Serafini G, Gonda X, Rihmer Z, Girardi P, Amore M. White matter abnormalities: Insights into the pathophysiology of major affective disorders. *World J Radiol* 2014; 6(6): 223-229 Available from: URL: <http://www.wjgnet.com/1949-8470/full/v6/i6/223.htm> DOI: <http://dx.doi.org/10.4329/wjr.v6.i6.223>

### Abstract

The presence of white matter hyperintensities (WMHs) has been commonly associated with poor outcome in subjects with major affective disorders. Unfortunately, WMHs may be frequently confounded by the use of psychoactive medications and duration of illness. Although findings from the current literature are quite conflicting, we proposed that subjects with WMHs may be at higher suicidal risk when compared to other subgroups without. Based on the Fazekas modified scale, the severity of WMHs may serve as a trait marker of disease. Interestingly, the presence of WMHs may represent a neurobiological marker between the underlying vulnerability and clinical presentation of major affective disorders.

### INTRODUCTION

Major affective disorders are chronic and disabling diseases that are associated with significant functional impairment. Patients with major affective disorders commonly experience long-term negative outcomes, frequent relapses, incomplete recovery between episodes, residual symptoms, persistent psychosocial impairment and high suicide risk<sup>[1,2]</sup>. Among all major affective disorders, bipolar disorder (BD), including both BD type I and type II, is a serious mental illness that affects approximately

1%-3% of the adult population. However, if subthreshold cases are also considered, the lifetime prevalence of bipolar disorders is around 6%<sup>[3]</sup>. White matter hyperintensities (WMHs) are, no doubt, the most common neuroimaging finding in patients with BD, regardless of age<sup>[4]</sup>. However, WMHs are also frequent in other major affective disorders (for details see Table 1 in the recent study of Serafini *et al*<sup>[5]</sup>).

WMHs are hyperintense signals on T2-weighted magnetic resonance images (MRI) identifying ependymal loss and altered brain myelination. According to their localization, WMHs may be classified in periventricular white matter hyperintensities (PWMHs) having a debated origin and deep white matter hyperintensities (DWMHs) with a predominant vascular aetiology<sup>[6]</sup>. WMHs are known to be commonly associated with older age and several risk factors such as arterial hypertension and diabetes mellitus (Figure 1).

WMHs are frequently associated with demyelinating disorders, in particular multiple sclerosis, an illness involving the presence of different causative mechanisms<sup>[7,8]</sup>. As suggested<sup>[7,8]</sup>, distinct patterns of demyelination have been documented over time and subcortical WMHs have been repeatedly recorded in patients with multiple sclerosis. MRI may be commonly used to monitor disease progress in the white matter of patients with multiple sclerosis<sup>[9]</sup>. However, MRI techniques may be considered as not sufficiently sensitive to detect purely cortical MS lesions<sup>[10]</sup> and their sensitivity can be improved using higher field strength or voxel-based morphometry.

Several studies suggested that WMHs are consistently associated with major affective disorders and suicidal behaviour in children as well as in young adults<sup>[11,12]</sup>. Overall, the association between WMHs and major affective disorders has been confirmed by several lines of evidence, not only in patients with major depressive disorder (MDD) but also in those with bipolar disorder (BD)<sup>[13]</sup>, respectively. This manuscript aimed to selectively review our research studies that have been published to date about the association between white matter hyperintensities assessed by MRI, major affective disorders, and suicidal behaviour.

A critical review of the eight studies that have been published by our research group about white matter abnormalities, major affective disorders, and suicidal behaviour has been conducted.

This is, in summary, an educational commentary reviewing the evidence derived by our research studies concerning the presence and significance of white matter abnormalities in subjects with major affective disorders.

## MAIN FINDINGS

Eight research articles have been performed by our research group about the association between WMHs, major affective disorders, and suicidal behaviour. The presence of WMHs was assessed by a neuroradiologist blind to all clinical information, using the modified Fazekas four-point rating scale describing MRI hyperintensities

on an ascending scale of intensity and frequency<sup>[14]</sup>. A second neuroradiologist, blind to all clinical information and previous ratings, usually reviewed all MRI films.

## STUDIES CONDUCTED ON SAMPLES OF SUBJECTS WITH BOTH UNIPOLAR AND BIPOLAR DISORDERS

Pompili *et al*<sup>[12]</sup> initially suggested that WMHs in patients with major affective disorders might be useful biological markers of suicidality. The authors investigated a sample of 65 subjects of which 44.6% had a history of at least one suicide attempt. After logistic regression analyses they reported that the prevalence of WMHs was significantly higher in subjects with past suicide attempts and elevated suicide risk.

Subsequently, Pompili *et al*<sup>[15]</sup> analyzed 99 patients of which 40.4% were diagnosed as BD-I, 21.2% were diagnosed as BD-II and 38.4% as unipolar MDD. They found that 27.3% of patients showed evidence of PWMHs, 36.4% presented DWMHs whereas 14.1% had hyperintensities in both periventricular and deep locations. Interestingly, the presence of PWMHs was the only variable significantly associated with attempted suicide even after controlling for age. Subjects with PWMHs were 8 times more likely to have attempted suicide when compared to individuals without PWMHs. Therefore, patients with major affective disorders and PWMHs are more likely to have a history of suicide attempts even after controlling for potential confounding variables such as cardiovascular risk factors and age.

In 2011, Serafini *et al*<sup>[16]</sup> reported that differences among temperament groups as measured by the Temperament Evaluation of Memphis, Pisa, Paris and San Diego-autoquestionnaire (TEMPS-A) are supported by differences at the MRI indicating that different temperament profiles are associated with differences in the subcortical brain structures of 247 patients with major affective disorders (specifically 143 with BD type I, 42 with BD type II, and 62 with MDD). TEMPS-A is a self-report questionnaire designed to measure temperamental variations in psychiatric patients and healthy volunteers and has been used by the authors on the basis of the diagnostic criteria for affective temperaments (cyclothymic, dysthymic, irritable, hyperthymic, and anxious). They found that 48% of patients had PWMHs (specifically, more than 15% had PWMHs of 2 or higher on the Fazekas modified scale), and 39% had DWMHs (in particular, more than 7% had DWMHs of 2 or higher on the Fazekas modified scale). Patients in the high- dysthymic, cyclothymic, irritability, and anxiety group were more likely to have higher Beck Hopelessness Scale (BHS), more DWMHs, higher Mini International Neuropsychiatric Interview (MINI) suicidal risk, and more recent suicide attempts when compared with patients in the hyperthymia group. BHS is a 20-item psychometric instrument designed to measure negative attitudes about the future whereas MINI is a short structured interview developed

Table 1 Salient publications of our research group about white matter hyperintensities in affective disorders

Ref.	Sample characteristics	Study type	Location of WMHs	Main findings	Limitations of the study	Conclusion
Serafini <i>et al</i> <sup>[6]</sup>	148 patients (77 men, 71 women) with BD-I having a mean age of 47.9 yr	Research article	Centrum semiovale (24.4%) and corona radiata (20.2%) regions, cortical and subcortical deep frontal (17.6%), parietal (15.1%), and temporal (8.4%) areas	A total of 73 subjects (49.3%) reported PWMHs and 59 (39.9%) had DWMHs. Overall, 41 (27.7%) subjects had both PWMHs and DWMHs. Patients with BD-I and lower insight for mania had significantly more PWMHs (54.6% <i>vs</i> 22.2%; <i>P</i> < 0.05), significantly higher scores on the HDRS-17 (27.05 <i>±</i> 6.54 <i>vs</i> 23.67 <i>±</i> 8.64; <i>t</i> <sub>46</sub> = -1.98; <i>P</i> < 0.05), and more frequent BHS score $\geq 9$ (66.2% <i>vs</i> 38.9%; <i>P</i> < 0.05) when compared to those with higher insight for mania	All participants were inpatients (a potential confounder). The present study did not include a formal measure of insight. The effects of psychoactive medications on insight ratings and image processing were not analyzed	Patients with PWMHs were more likely to have impaired insight than those without. Different insight levels reflected different MRI findings
Serafini <i>et al</i> <sup>[9]</sup>	85 adult outpatients (16 men and 69 women) with CH and having a mean age of 50.1	Research article	Not specified	Above 40% of patients had PWMHs and almost 98% had DWMHs. Patients with PWMHs differed from those without periventricular lesions on depression severity ( <i>t</i> 77.76 = 2.30; <i>P</i> < 0.05). Patients with PWMHs had lower CES-D scores (13.79 <i>±</i> 7.51 <i>vs</i> 18.19 <i>±</i> 9.68) than patients without PWMHs. Patients with more severe DWMHs were older (53.89 <i>±</i> 13.26 <i>vs</i> 47.40 <i>±</i> 11.91) and reported lower scores on the drive dimension (9.97 <i>±</i> 2.86 <i>vs</i> 11.14 <i>±</i> 2.52) than patients with mild lesions or without any deep lesion	Different mechanisms may be considered in the emergence of WMHs and it is possible that WMHs may represent only the 'tip of the iceberg' in terms of structural white matter lesions	Patients with PWMHs were 1.06 times more likely to have lower CES-D scores ( <i>P</i> < 0.05) than patients without PWMHs. Patients with more severe DWMHs were 1.04 times more likely to be older ( <i>P</i> < 0.05) than patients with mild or without any DWMHs
Serafini <i>et al</i> <sup>[6]</sup>	247 patients (118 men, 129 women) with major affective disorders, specifically 143 BD-I, 42 BD-II, and 62 with MDD	Research article	Centrum semiovale (24.4%) and corona radiata (20.2%) regions, cortical and subcortical deep frontal (17.6%), parietal (15.1%), and temporal (8.4%) areas	48% of patients had PWMHs (more than 15% had PWMHs of 2 or higher on the Fazekas modified scale), and 39% had DWMHs (more than 7% had DWMHs of 2 or higher on the Fazekas modified scale). Patients in the high dysthymic, cyclothymic, irritability, and anxiety group were more likely to have higher BHS $\geq 9$ = 77% <i>vs</i> 52%; <i>P</i> > 0.001), more DWMHs (46% <i>vs</i> 29%; $\chi^2_{(1)} = 3.90$ ; <i>P</i> < 0.05), higher MINI suicidal risk (54% <i>vs</i> 42%; <i>P</i> < 0.05), and more recent suicide attempts (24% <i>vs</i> 14%; <i>P</i> < 0.05), than patients in the hyperthymia group	The small sample size did not allow to generalize findings. The association between the lethality or number of suicide attempts and the presence, severity, or number of hyperintensities was not assessed. The study lacks of accounting for the cognitive effects of medications	Differences among temperament groups as measured by the TEMPS-A are supported by differences at the MRI indicating that different temperament profiles are associated with differences in subcortical brain structures
Serafini <i>et al</i> <sup>[20]</sup>	A 76-year-old woman with BD hospitalized for a mixed state	Case report with a 2-yr follow-up	Not specified	Patient had severe WMHs, she took lithium and haloperidol during the hospitalization. She was euthymic at discharge as well as after two-years of follow-up. Her nutrition had a high concentration of Vitamin-D	A second MRI was not performed	Although WM lesions were persistent, the patient improved in both mood and quality of life. Lithium and Vitamin-D may have exerted possible protective effects
Serafini <i>et al</i> <sup>[18]</sup>	54 patients (30 men and 24 women) with LOBD ( $\geq 60$ yr old) having a mean age of 68 yr. 76% had a diagnosis of BD-I, and 24% had a diagnosis of BD-II	Letter to the Editor including research data	Centrum semiovale (22%), corona radiata (15%), paratrigenal regions (6%), cortical, subcortical deep frontal (46%), parietal (24%) areas	Confluence of DWMH lesions were found in 17% of the patients (modified Fazekas scale $\geq 2$ ) whereas in 28% PWMH confluent lesions (modified Fazekas scale $\geq 2$ ) were reported. No significant association resulted between diagnosis and PWMHs or DWMHs. BD-II with DWMHs had a poorer quality of life than BD-I subjects	The link between clinical features of bipolar disorders and deep brain lesions on MRI remains quite unknown	MRI findings of DWMHs could be a useful biological predictor of severity in patients with BD-II
Pompili <i>et al</i> <sup>[17]</sup>	47 LOBD patients (55.3% men and 44.7% women)	Review article including research data	Frontal (26.1%) and centrum semiovale areas (26.1%), corona radiata (17.4%), parietal (17.4%), and paratrigenal regions (8.7%)	55.3% of these patients had periventricular WMHs, 46.4% had WMHs of mild severity, 50% WMHs of moderate severity, and only 3.6 WMHs of high severity. 34% of LOBD patients had both deep and periventricular WMHs. A significant relationship between older age with LOBD and WMHs was reported	Vascular-related mechanisms cannot be the only factors implicated in the pathophysiology of the WMHs in LOBD subjects. The study did not assess how cerebro-vascular risk factors are related to the type / intensity of medications, and the progression of WMHs	MRI findings of WMHs could be a useful biological predictor of severity in patients with LOBD

Pompili <i>et al</i> <sup>[5]</sup>	99 patients having a mean age of 46.5 yr. 40.4% were diagnosed as BD-I, 21.2% as BD-II, and 38.4% as unipolar MDD	Research article	Corona radiate (n = 10), centrum semiovale (n = 6), and frontal subcortical white matter (n = 18)	It has been suggested that 27.3% of patients showed evidence of PWMHs and 36.4% of DWMHs whereas 14.1% of patients had hyperintensities in both locations. The presence of PWMHs was the only variable significantly associated with attempted suicide even after controlling for age. Subjects with PWMHs were 8 times more likely to have attempted suicide than individuals without PWMHs [OR = 8.08 (95%CI: 2.67-24.51)]	The small sample size may affect the generalization of results. PWMHs were able to explain only a small part of the variability of suicide attempt risk, indicating that one single variable is not sufficient to predict suicidality	Patients with affective disorders and PWMHs are more likely to have a history of suicide attempts even after controlling for potential confounding variables such as cardiovascular risk factors and age
Pompili <i>et al</i> <sup>[23]</sup>	65 subjects, 29 (44.6%) with a history of at least one suicide attempt, and 36 (65.4%) without. Subjects had a mean age of 44.61 yr	Research article	Not specified	After logistic regression analyses, the prevalence of WMHs was significantly higher in subjects with past suicide attempts (P = 0.01) and other clinical indicators of elevated suicide risk	The association between WMHs and suicidality holds true for both unipolar and bipolar depressed patients	WMHs in patients with major affective disorders might be useful biological markers of suicidality

AD: Affective disorders; BD-I: Bipolar disorder type I; BD-II: Bipolar disorder type II; BHS: Beck Hopelessness Scale; CES-D: Center for Epidemiologic Studies Depression Scale; CH: Chronic headache; DWMHs: Deep WMHs; LO: Late-onset; LOBD: Late-onset bipolar disorder; Mini: Mini International Neuropsychiatric Interview; MDD: Major depressive disorder; MRI: Magnetic resonance imaging; PWMHs: Periventricular WMHs; SA: Suicide attempts; WMHs: White matter hyperintensities; TEMPS-A: Temperament Evaluation of Memphis, Pisa, Paris and San Diego-autoquestionnaire. WMHs that usually appear as hyperintense signals on T2-weighted MRI, are characterized by ependymal loss and differing degrees of myelination and can be related to several clinical conditions such as major depressive disorders (BDI, BD II, MDD), and CH. The mentioned Table reported the most relevant publications of our research group about WMHs and their significance in major affective disorders.

to explore psychiatric disorders according to DSM-III-R; importantly, one section of this instrument is developed to assess suicidal risk with questions about past and current suicidality.

STUDIES CONDUCTED ON SAMPLES OF PATIENTS WITH BIPOLAR AFFECTIVE DISORDERS

Pompili *et al*<sup>[17]</sup> conducted an overview of the literature (including research data) in which reported that 55.3% of patients had periventricular WMHs (46.4% of them of mild severity, 50% of moderate severity, and only 3.6 of high severity, respectively). They also found that 34% of late-onset bipolar disorder (LOBD) patients had both deep and periventricular WMHs and a significant relationship has been suggested between older age with LOBD and WMHs. The authors concluded that MRI findings of WMHs could be a useful biological predictor of severity in patients with LOBD.

Subsequently, Serafini *et al*<sup>[18]</sup> reported that in a sample of 54 patients (30 men and 24 women) with LOBD ( $\geq 60$  years old) 76% had a diagnosis of BD type I, 24% a diagnosis of BD type II whereas confluence of deep lesions (modified Fazekas scale  $\geq 2$ ) was found in 17% of the patients and in 28% periventricular confluent lesions (modified Fazekas scale  $\geq 2$ ). The authors suggested that no significant association between diagnosis and PWMHs/DWMHs emerged but, interestingly, subjects with BD type II and DWMHs had a poorer quality of life compared to patients with BD type I.

Finally, Serafini *et al*<sup>[5]</sup> suggested that in a sample of 148 patients with BD type I (having a mean age of 47.9 years) a total of 49.3% reported PWMHs and 39.9% had DWMHs. Overall, 27.7% of subjects had both PWMHs and DWMHs. They reported that patients with BD type I and lower insight for mania had significantly more PWMHs (54.6% vs 22.2%;  $P < 0.05$ ), significantly higher scores on the HDRS<sub>17</sub> ( $27.05 \pm 6.54$  vs  $23.67 \pm 8.64$ ;  $t_{146} = -1.98$ ;  $P < 0.05$ ), and more frequent BHS scores  $\geq 9$  (66.2% vs 38.9%;  $P < 0.05$ ) when compared to patients with BD type I and higher insight for mania. Importantly, different insight levels reflected different MRI findings. The authors concluded that patients with PWMHs were more likely to have impaired insight than those without.

STUDIES ON SAMPLES OF PATIENTS WITH CHRONIC MIGRAINE

Serafini *et al*<sup>[19]</sup> found that in a sample of 85 adult outpatients with a chronic headache above 40% of patients had PWMHs and almost 98% DWMHs, respectively. Patients

**Figure 1 White matter hyperintensities as assessed by magnetic resonance images.** White matter hyperintensities (WMHs) appear as hyperintense signals on T2-weighted magnetic resonance images and represent ependymal loss and differing degrees of myelination. These lesions can be related to a wide variety of clinical conditions and pathophysiological processes. WMHs, depending on the localization, are commonly classified as periventricular hyperintensities (PWMHs) or deep white matter hyperintensities (DWMHs). DWMHs were identified as having mainly a vascular aetiology whereas PWMHs could be due to ependymal loss, differing degrees of myelination and cerebral ischemia. WMHs are reported to be commonly associated with older age, and cardiovascular risk factors such as hypertension and diabetes.

with PWMHs significantly differed from those without periventricular lesions on depression severity. Patients with PWMHs had lower Center for Epidemiologic Studies Depression Scale (CES-D) scores ( $13.79 \pm 7.51$  *vs*  $18.19 \pm 9.68$ ) when compared with patients without PWMHs. Also, patients with more severe DWMHs were older ( $53.89 \pm 13.26$  *vs*  $47.40 \pm 11.91$ ) and reported lower scores on the drive dimension ( $9.97 \pm 2.86$  *vs*  $11.14 \pm 2.52$ ) than patients with mild or without any deep lesion.

Overall, patients with PWMHs were 1.06 times more likely to have lower CES-D scores compared to patients without PWMHs. Patients with more severe DWMHs were 1.04 times more likely to be older than patients with mild or without DWMHs.

## CASE REPORTS

Based on a case report study of a 76-year-old woman with BD hospitalized for a mixed state and having severe WMHs treated with lithium and haloperidol during the hospitalization, Serafini *et al.*<sup>[20]</sup> found that she was euthymic at discharge as well as after two-years of follow-up. The authors suggested that, although WM lesions were persistent, the patient improved in both mood and quality of life. Lithium and Vitamin-D (highly present in her nutrition) may have exerted possible neuroprotective effects.

## DISCUSSION AND CLINICAL IMPLICATIONS

Patients with WMHs, particularly those with abnormalities in the white matter of prefrontal cortex, amygdala-hippocampus complex, thalamus and basal ganglia whose integrity implicates adequate mood regulation may be at

higher risk for developing mood disorders because of possible alterations of neuroanatomic pathways<sup>[21]</sup>. Also, volumetric studies clearly indicated the possible involvement of the frontal cortex, temporal lobes, basal ganglia and cerebellum in BD and, recently, subgenual cingulate cortex in adolescents with BD type I<sup>[22]</sup>.

Understanding the nature and significance of white matter abnormalities in major affective disorders is critical as these lesions may represent neurobiological markers able to indicate the risk for subsequent development of more aggressive illness subtypes and the need of more targeted interventions<sup>[23]</sup>.

WMH location may be critical in the expression of certain affective dysfunctions (*e.g.*, cognitive/emotional impairments). Periventricular lesions seem to be more common in BD type I compared to BD-type II, and healthy controls<sup>[5,12,18]</sup>. This may indicate that these neuroimaging findings are sensitive and even subtype selective diagnostic tools in bipolar patients whereas DWMHs are predictors of a less favourable outcome being associated with a poorer response to treatment, and recurrent illness episodes<sup>[24]</sup>.

A relevant association between increased rates of WMHs and a history of suicide attempts has also been suggested in both unipolar and bipolar patients<sup>[12]</sup>. This finding has been replicated in a sample of 99 consecutively admitted inpatients with major affective disorders where neuroimaging measures were found to be markers of risk for suicidal attempts. Specifically, attempters and nonattempters differed only for the presence of PWMHs, with the former who were more likely to have PWMHs<sup>[15]</sup>. Moreover, a significant association between older age and WMHs<sup>[17]</sup>, and between DWMHs and poor prognosis was reported in a sample of patients with late-onset bipolar II disorder<sup>[18]</sup> demonstrating that WMHs could be useful biological predictors of illness severity.

Differences in MRI profiles were also found to be associated with differences among temperament groups measured by the TEMPS-A<sup>[16]</sup>. Specifically, patients with higher scores for dysthymic and lower scores for hyperthymic temperament were more likely to have higher BHS scores, more DWMHs, higher MINI suicidal risk, and more recent suicide attempts than patients with higher scores for hyperthymic and lower scores for dysthymic temperament. The presence of a dysthymic temperament profile together with DWMHs may presumably play a critical role in the emergence of hopelessness as assessed by BHS. These differential characteristics may be used for grouping subjects with mood disorders potentially helping in optimizing reliable treatment strategies.

It has also been found that in contrast to hyperthymic temperament the short allele of the serotonin transporter gene was significantly related to depressive, cyclothymic, irritable and anxious temperaments<sup>[25]</sup> and with violent suicidal behavior in nonclinical populations. A study on elderly depressed patients showed that individuals with the short allele of the serotonin transporter gene had more microstructural white matter abnormalities in the frontolimbic and other brain regions<sup>[26]</sup> compared to

those without. These findings indicate that the short allele of the serotonin transporter gene, DWMHs, affective temperaments containing more or less depressive component, and suicidal behaviour (in chronological order) are strongly related to each other and the presence of the first three in the same subject could serve as a powerful marker for predicting future suicidal behaviour.

However, also negative associations have been reported<sup>[5,19,20]</sup>. In particular, patients with chronic migraine and PWMHs reported fewer depressive symptoms as assessed by the Center for Epidemiologic Studies Depression Scale (CES-D) than those with chronic migraine without PWMHs<sup>[19]</sup>. In contrast with the generally poor outcome related to the presence of WMHs in patients with affective disorders, the possible protective effect of lithium and Vitamin-D in ameliorating mood and psychosocial functioning in a patient with BD has also been suggested<sup>[20]</sup>.

Additionally, our last study found that subjects with PWMHs were more likely to have impaired insight compared to those without, but any association between PWMHs and suicidal behaviour as assessed using BHS has been found<sup>[5]</sup>.

These latter findings<sup>[5]</sup> seem to contradict our previous results regarding the association between WMHs and poor outcome including suicidality in both unipolar and bipolar depressed individuals. However, in these studies we recruited a sample of subjects with chronic migraine and a sample of patients with BD type I respectively, whereas the previous results were reported in mixed samples (including both bipolar and unipolar depressed patients)<sup>[12,15]</sup> or other specific subgroups<sup>[5,16-20]</sup>. It's possible to speculate that the association between PWMHs and suicidal behaviour is significant only in some specific subgroups of patients with major affective disorders in which WMHs may serve as a marker of disease. WMHs could not be a risk factor for suicide among inpatients with other predominant conditions (*e.g.*, chronic migraine) or in those with certain specific illness subtypes.

Another consideration needs to be critically addressed. WMHs were in most cases able to explain only a small part of the variability related to suicide attempt risk, indicating that one single variable is not sufficient to predict a complex behaviour such as suicide<sup>[15]</sup>. Table 1 summarized the most relevant findings of our studies.

## LIMITATIONS

MRI studies investigating the presence of WMHs should be considered in the light of the following limitations. First, the small sample size of the studies did not allow for generalization of the present findings. In addition, samples are often mixed including inpatients admitted to a psychiatric hospital for more severe affective symptoms that were compared to outpatients usually exhibiting less severe/more stable illness episodes. Also, in most cases the absence of a direct comparison between patients with major depression and other subjects with different mood disorders limited the clinical relevance of the findings.

Not all studies evaluated the presence, severity, or number of hyperintense lesions and most of them used visual scales such as the Fazekas modified rating scale that is a less objective evaluation method than many volumetric methods available.

Moreover, most studies recruited patients treated with psychoactive medications or having a history of substance abuse, but not all analyzed the effects of these variables on insight ratings and image processing. The lack of accounting for the cognitive effects of medications may be considered an important limitation. In order to comprehensively examine the effect of different medications on the neurobiology of clinical symptoms, studies should investigate patients with early affective symptoms or first illness episodes. Also, not all studies include a healthy comparison group and this may limit conclusive statements about the specificity of results.

Other methodological issues concern the procedure. MRI studies were of quite low spatial resolution especially if performed using a 1.5 T scanner. Studies using 3 T scanner and/or higher resolution techniques would likely yield a much higher number and extent of WMHs than studies using a 1.5 T scanner. An analysis quantifying total white matter lesion volume would strengthen the findings of most studies. In addition, diffusion tensor imaging techniques may be more sensitive for detecting white matter abnormalities associated with mood disorders. Finally, although some studies reported that WMHs were predominant in some brain regions, not all analyzed WMHs using regional analyses.

## CONCLUSION

In summary, although it is possible that WMHs may represent only the 'tip of the iceberg' and an extreme consequence of underlying microstructural processes that affect brain connectivity, we believe that they may represent relevant biological markers of poor outcome in patients with major affective diseases. The presence of WMHs may be used for grouping subjects who will manifest more severe illness impairments from those who will present a better outcome, potentially helping clinicians in optimizing the best treatment strategy. WMHs may be considered as a proxy for identifying subgroups of patients with more severe illness subtypes requiring more targeted interventions. For example, the early identification of individuals at risk for highly lethal suicide attempts through the assessment of WMHs may help to closely monitor this clinical subgroup of subjects with poor outcome.

Based on our studies, it has been demonstrated that WMHs are a useful biological marker of poor outcome including suicidality in the specific subpopulations of patients which were investigated. However, as studies using MRI techniques are biased by several limitations, further prospective studies are needed in order to provide a better understanding of the biological processes involved in WMH progression as well as to elucidate the nature of the association between WMHs and major affective disorders.

## Abstract

Hydrostatic pulmonary edema is as an abnormal increase in extravascular water secondary to elevated pressure in the pulmonary circulation, due to congestive heart failure or intravascular volume overload. Diagnosis of hydrostatic pulmonary edema is usually based on clinical signs associated to conventional radiography findings. Interpretation of radiologic signs of cardiogenic pulmonary edema are often questionable and subject. For a bedside prompt evaluation, lung ultrasound (LUS) may assess pulmonary congestion through the evaluation of vertical reverberation artifacts, known as B-lines. These artifacts are related to multiple minimal acoustic interfaces between small water-rich structures and alveolar air, as it happens in case of thickened interlobular septa due to increase of

extravascular lung water. The number, diffusion and intensity of B lines correlates with both the radiologic and invasive estimate of extravascular lung water. The integration of conventional chest radiograph with LUS can be very helpful to obtain the correct diagnosis. Computed tomography (CT) is of limited use in the work up of cardiogenic pulmonary edema, due to its high cost, little use in the emergencies and radiation exposure. However, a deep knowledge of CT signs of pulmonary edema is crucial when other similar pulmonary conditions may occasionally be in the differential diagnosis.

**Core tip:** Acute decompensated heart failure (ADHF) is a frequent emergency condition that represents a diagnostic challenge for the emergency physicians. Imaging has a fundamental role in the diagnosis of heart failure, but the efficacy of the diagnostic process is highly dependent from the ability to integrate information drawn from lung ultrasound (LUS), chest radiography and computed tomography (CT). Chest radiography and LUS are the most used diagnostic tools: the first one combining relative low cost with the panoramic view that allows exclusion of many pulmonary conditions that comes into the differential diagnosis; otherwise the second one has higher sensitivity in the diagnosis of the early signs of pulmonary congestion and permit to perform the examination at bedside during the first clinical approach. CT scan is the best method to have a panoramic thoracic view and CT scan is a powerful method but it has many limitations due to costs, availability in emergency situations and relatively high

radiation exposure. The modern clinician and radiologist should be aware of the potential and limitations of these diagnostic tools and be prepared to integrate information derived from a correct use of ultrasound, conventional radiology and CT.

## INTRODUCTION

Acute decompensated heart failure (ADHF) is a frequent emergency condition that, often represents a diagnostic challenge for the emergency physicians. Accurate assessment of effectiveness of medical treatment on reducing pulmonary congestion, which is the consequence of elevated cardiac filling pressure, is a basic step for a correct management of patients with ADHF. Most patients hospitalized for ADHF are not submitted to invasive hemodynamic measurements, and clinical improvement relies on change in physical findings, radiologic imaging, and hormone levels. Physical findings of elevated filling pressure are often inadequate and rarely decisive to assess real clinical improvement when considered alone<sup>[1-3]</sup>.

Chest X-ray (CXR) is the traditional first line procedure to assess pulmonary congestion, but interpretation of radiologic signs, such as vascular opacity redistribution and interstitial edema, are often questionable and subjective, while different levels of expertise of the readers may cause high inter-observer variability.

In doubtful cases, lung ultrasound (LUS) has been shown to be of value in assessing pulmonary congestion by the evaluation of vertical comet tail artifacts, named B-lines. These artifacts represent easy-to-acquire and highly reproducible bedside signs of diffuse interstitial syndrome, but their limitation is the low specificity<sup>[4,5]</sup>.

B-lines are caused by a change of the normal balance between the air and fluid pulmonary content, when air is lost and fluid are increased. The multiple and small air-fluid interfaces due to small water-rich structures surrounded by air presenting in the lung periphery, create a reverberation phenomenon represented on the screen by multiple B-lines<sup>[6]</sup>. However, this phenomenon is irrespective of the cardiogenic or pulmonary origin of the condition.

Concerning thoracic computed tomography (CT) scan, it is rarely used for diagnosing pulmonary congestion, unless highly selected cases where other pulmonary interstitial conditions come into the differential. Signs of hydrostatic pulmonary edema on high-resolution CT should always be recognized, even if edema may sometimes be misdiagnosed and the differential diagnosis not always is easily read by the radiologist. Indeed, sometimes signs of pulmonary congestion on CT imaging represent

an unexpected condition on patients investigated for other diseases<sup>[7]</sup>.

This review describes the specific signs of cardiogenic pulmonary edema of these three main imaging techniques and discuss their role in the diagnostic process.

## CHEST X-RAY

In the acute phase of decompensated heart failure, the early pulmonary alteration is congestion of the vascular bed due to progressive increase of capillary hydrostatic pressure. When pressure increases further and the lymphatic vessels become congested, fluids begin to accumulate in the interstitium around arteries, veins, and airways, and particularly in the interlobular septa. In the early phase, this mechanism protects the lung against the final stage of congestion, that is leakage of fluids into the alveolar spaces, the alveolar edema. The radiologic findings at chest radiography reflect the anatomic-pathologic alterations.

As severity of congestion increases, the sequence of signs visible on chest radiographs are: (1) vascular opacity "redistribution" towards the upper lobes and distention of the upper pulmonary veins; (2) enlargement and loss of definition of hilar structures; (3) septal lines in the lower lung, indicated as Kerley A and B lines; (4) peribronchial and perivascular cuffing with widening and blurring of the margins; and (5) thickening of interlobar fissures with subpleural fluid accumulation (Figure 1)<sup>[8,9]</sup>.

Redistribution, known also as cephalization, occurs only in the setting of chronic pulmonary venous hypertension, very often encountered in mitral stenosis (Figure 2). Cardiomegaly and pleural effusions are adjunctive radiologic findings quite frequently detected in cardiogenic pulmonary congestion. When congestion increases and becomes alveolar edema, chest radiography shows bilateral and usually symmetric parenchymal opacities, with a central or basilar distribution, without air bronchogram<sup>[10]</sup> (Figure 3).

The distribution of alveolar edema may be influenced by gravity. In this case performing the examination in supine or orthostatic position and right or left decubitus, may consistently change the radiologic pattern. Moreover, a coexistent condition of chronic obstructive lung disease may influence irregular distribution of edema as fluids tend to leak in the area of the lung where the structure of the organ is less subverted.

In the emphysematous lung, edema of the alveolar spaces will not be imaged because of alveolar destruction in over-inflated areas, while accentuation of interstitial signs of congestion may still being detected at CXR.

In case of large, acute myocardial infarction (MI) that involves the function of the mitral valve, a regional asymmetric distribution of pulmonary edema may produce atypical radiologic patterns that mimic non-cardiogenic edema or, in some cases, even pneumonia (Figure 4).

This pattern is caused by the flow vector due to mitral regurgitation, which may be massively directed toward the right superior pulmonary vein<sup>[11]</sup>. However, opacities

**Figure 1** Posterior-anterior chest X-ray in a patient with congestive heart failure and interstitial pulmonary edema. In the figure are shown radiographic signs that suggest interstitial pulmonary edema including enlarged and loss of definition of large pulmonary vessels, both Kerley's A and Kerley's B lines associated with cardiomegaly.

**Figure 2** Posterior-anterior chest X-ray demonstrating enlargement of atrial and left ventricles, with redistribution of lung circulation from bases to apex suggestive to pulmonary congestion (A), note the blood vessels are more prominent in the upper lung fields compared to the lung bases, just the opposite of normal (B).

due to alveolar edema may rapidly change their dimension and even dissolve on the effect of treatment. Thus, radiologic follow-up may sometimes contribute to resolve the diagnostic dilemma.

Signs of pulmonary congestion at chest radiography may even precede clinical symptoms. Conversely, pulmonary edema may be still visible radiographically for hours or even days after hemodynamic recovery<sup>[12]</sup>.

To date, CXR represents the first line imaging exam in patients presenting to the emergency department (ED)

**Figure 3** Supine radiogram in a patient with cardiogenic alveolar edema. Note that the vascular perihilar structures are not defined because of the presence of confluent peripheral and gravitational consolidations, with large pleural effusion. Cardiomegaly is also present.

**Figure 4** Antero-posterior chest radiograph with asymmetric pulmonary edema with grade 3 mitral insufficiency shows pulmonary edema predominantly within the right upper lobe.

complaining of acute dyspnea. The possibility of correct diagnosis at CXR is greater the more severe and prolonged will be pulmonary congestion, because the radiologic signs are more accurate and clearly visible. Relating the diagnosis of cardiogenic pulmonary congestion, CXR is moderately specific (specificity 76%, 83%), but not very sensitive (50%-68%)<sup>[13]</sup>.

Therefore, CXR does not have a direct role in the pathway for the diagnosis of heart failure, where the standard of care is cardiac and LUS. The main reason of this limitation is that CXR is not sensitive enough, because heart failure cannot be ruled out with certainty in the presence of a normal radiologic pattern. However, our opinion is that CXR is highly useful to diagnose alternative diagnoses when they are, together with decompensated heart failure in the differential.

## LUNG ULTRASOUND

Quite recently, LUS opened new perspectives in the bedside evaluation of pulmonary congestion. Many authors produced a growing number of papers showing the power of LUS in diagnosing pulmonary diseases<sup>[14-20]</sup>.

Rather than from technologic progress, development

**Figure 5** Lung ultrasound scan showing multiple B-lines from a case of cardiogenic pulmonary oedema. When a similar pattern is visualised on multiple locations in the anterior and lateral chest, it is diagnostic of the interstitial syndrome.

of modern LUS is mainly based on discovering the significance of sonographic artifacts<sup>[21]</sup>. Particularly, some vertical echogenic linear artifacts, known as B-lines, are simple, noninvasive signs of pulmonary interstitial fluid that can be easily evaluated at bedside. B-lines originate from multiple small subpleural air/fluid acoustic interfaces, due to the fact that air and water are two elements with opposite values of acoustic impedance<sup>[22]</sup>. This phenomenon is related to the contrast between air-filled and water-rich structures, which generate multiple reverberation of the ultrasound beam that is visualized on the screen as linear vertical artifacts, the B-lines (Figure 5).

In the normally aerated lung, only a very few B-lines can be detected by sonography<sup>[23]</sup>.

When the water content increases and air decreases due to disease, the thickened interlobular septa and fluid into the alveolar spaces cause the appearance of multiple and diffuse B-lines (Figure 6)<sup>[4,5]</sup>.

Any condition of the lung where alveolar air is partially lost and interstitial fluids or cellularity are diffusely increased, causes the appearance of B-lines at LUS. B-lines underlines the so called interstitial syndrome.

The fundamental technique for diagnosing interstitial syndrome consists of examining the anterior and lateral chest using four intercostal scans per side, corresponding to the upper and inferior areas anteriorly and the upper and basal areas laterally. A positive scan is characterized by a minimum of three B-lines, whereas a positive examination is defined by at least two positive areas per side<sup>[5,17]</sup> (Figure 6).

Simple detection of B-lines does not allow differentiation of the disease involving the lung interstitium, but other organ ultrasound signs can be used to confirm the diagnosis of pulmonary congestion in decompensated heart failure. For convenience a focused cardiac sonography can be performed using the same probe used for lung examination, looking for global left ventricle function impairment, which will be detected in about 50% of cases with acute decompensated heart failure<sup>[24]</sup>.

Regarding LUS, other signs than B-lines may be evaluated for differentiating similar patterns of interstitial

syndrome from cardiogenic and non-cardiogenic causes. These includes evaluation of pleural sliding and irregularities, distribution of B-lines and sub-pleural consolidations. Some studies showed the reliability of these signs in differentiating signs of cardiogenic pulmonary edema from ARDS and pulmonary fibrosis<sup>[25]</sup>.

The primary diagnosis of pulmonary interstitial fluid in the emergency setting is crucial for the differential diagnosis between a cardiogenic and non-cardiogenic respiratory failure. Some studies showed the usefulness of B-lines as a primary diagnostic test in acute respiratory failure patients<sup>[20,26]</sup>. Lung ultrasound appears to be particularly useful in differentiating between exacerbation of chronic obstructive pulmonary disease (COPD), a condition that does not show B-lines, and decompensated heart failure. In a study performed in dyspneic patients in the emergency department, diffuse B-lines were detected in 100% of patients with cardiogenic pulmonary oedema but was absent in 92% of cases with exacerbation of COPD and 98.75% of those with normal lungs<sup>[26]</sup>. Conclusion of the study was that sonographic detection of B-lines might help distinguish pulmonary edema from exacerbation of COPD.

Other studies showed the correlation between B-lines and natriuretic peptides in the primary evaluation of acute decompensated heart failure in the Emergency department<sup>[27]</sup>. Pulmonary interstitial fluid, sonographically demonstrated by B-lines, was strictly correlated with natriuretic hormones level. Conclusions of these studies was that LUS can be used alone or can provide additional predictive power to natriuretic peptides in the immediate evaluation of dyspneic patients to diagnose the cardiac origin of the symptom.

Another great potential of LUS is that B-lines are highly sensitive to the resolution of lung congestion in patients admitted to the hospital for acute decompensated heart failure. Clearance of B-lines represents a direct sign of effective treatment, but also may be useful to specify the diagnosis in cases where the origin of B-lines cannot be differentiated at a first examination<sup>[28]</sup>.

Finally, LUS may be also useful to diagnose unsuspected conditions when it is performed in combination with other tools, showing similar performances as compared to other more panoramic chest diagnostic imaging tools<sup>[29-32]</sup>.

## COMPUTED TOMOGRAPHY

On high resolution computed tomography (HRCT), signs of hydrostatic edema generally results in a combination of septal thickening and ground-glass opacities. Incidence and predominance of these signs is individually variable<sup>[33-39]</sup> (Figure 7).

Crazy paving and consolidation are also frequently imaged. In some patients, ill-defined perivascular and centrilobular opacities may also be detected, or ground-glass opacity may appear lobular and patchy with a tendency to have a parahilar and gravitational distribution (Figure 8)<sup>[40]</sup>.

There is some evidence that a parahilar or bat wing

**Figure 6** A typical sonographic pattern of diffuse alveolar-interstitial syndrome (left side) and corresponding chest radiograph (right side) in a case of acute cardiogenic pulmonary oedema. In the sonographic images on either side of the radiogram, the presence of multiple adjacent comet-tail artefacts (at least three per scan and in all chest areas examined) can be easily distinguished. The images illustrate the sonographic B+ pattern corresponding to the radiological finding of pulmonary oedema.

distribution of edema is typically found in patients who have a rapid accumulation of fluid<sup>[40]</sup>. Occasionally edema may have unilateral distribution, as may happen in patients with a prolonged lateral decubitus, or asymmetric and even with bizarre distribution in patients with region-

al emphysema<sup>[29]</sup>. In studies on hydrostatic edema in dog lungs, high resolution CT patterns showed predominantly central, peribronchovascular, and posterior distribution of edema, associated with an apparent increased thickness of bronchial walls<sup>[30,31]</sup>.

**Figure 7** Computed tomography scan through lower lobes shows, limited areas of ground-glass opacity, with thickening of major fissures reflecting subpleural interstitial edema. Is also present interlobular septal and peribronchovascular interstitial thickening.

**Figure 8** Computed tomography scan through aortic arch and pulmonary arteries planes shows ground-glass opacity with geographic distribution and partial sparing of the lung periphery. Thickening of interlobular septa and sub-pleural edema and bilateral pleural effusion with passive atelectasis of lower lobes is also present.

## STRENGTHS AND WEAKNESSES OF INTEGRATED USE OF LUS, CHEST X-RAY AND CT FOR THE DIAGNOSIS OF CARIOGENIC PULMONARY EDEMA

Imaging has a fundamental role in the diagnosis of heart failure, but the efficacy of the diagnostic process is highly dependent from the ability to integrate information drawn from LUS, chest radiography and CT (Table 1).

Chest radiography has the great advantage of combining relative low cost with the panoramic view that allows exclusion of many pulmonary conditions that comes into the differential diagnosis. CT scan is the best method to

have a panoramic thoracic view, and much more sensitive than chest radiography for the first diagnosis of many conditions, like pulmonary embolism and early phase of cardiogenic pulmonary edema. However, it has many limitations due to costs, availability in emergency situations and relatively high radiation exposure. However, in recent years technological advances have made it possible to improve the modulation of dose exposure to follow the principles of radiological protection. Besides radiation exposure, low availability and feasibility are other fundamental limitations. CT scan cannot be performed as routine technique in heart failure because of the high prevalence of this disease and high costs of use.

However, while LUS and chest radiography are the first choice imaging technique in most cases, in selected cases where multiple conditions are in the differential, CT

scan may become the method of reference. This is the case in acutely dyspneic patients when the differential diagnosis with pulmonary embolism is a challenge. In other cases, when the differential diagnosis includes diffuse parenchymal lung diseases, the high-resolution CT of the chest may be useful to rule-out or confirm pulmonary congestion.

Lung ultrasound has the limitation of being a surface imaging technique far less panoramic than chest radiography and CT scan. However, the great advantages of LUS are a higher sensitivity than chest radiography in the diagnosis of the early signs of interstitial thickening due to pulmonary congestion, and the possibility to perform the examination at bedside during the first clinical approach (Table 2).

## CONCLUSION

In the diagnostic imaging of pulmonary congestion due to decompensated heart failure, LUS and CXR are the most used diagnostic tools. Lung ultrasound does not fully replace CXR but may be of great help in some specific situations, like in the emergency setting when a prompt diagnostic evaluation of dyspneic patients at bedside is needed and also for monitoring clinical evolution. Moreover, LUS outperforms conventional radiology for the diagnosis of early signs of pulmonary congestion and should always be considered when radiologic signs are not detected on CXR but heart failure is still considered a possibility. However, LUS standing alone has a limited specificity for cardiogenic pulmonary congestion. Indeed, the main ultrasound signs of the interstitial syndrome, the B lines, are also detected in other pulmonary conditions, even chronic, characterized by loss of aeration and increase in fluids. Moreover, CXR is superior to LUS as a panoramic imaging modality that allows an immediate and comprehensive evaluation of the thoracic structures. CT scan is a powerful method for the evaluation of the thorax and even more panoramic, but is of limited use in the first diagnosis of decompensated heart failure in comparison to CXR and LUS. However, in selected cases it may be of help in the differential diagnosis of interstitial lung diseases or other causes of respiratory failure. Very often, in cases when a CT study is performed to investigate other conditions, the diagnosis of pulmonary congestion is incidental.

Integration of information obtained by the correct use of these three thoracic imaging, may improve the accuracy of the diagnostic process for cardiogenic pulmonary edema. The modern clinician and radiologist should be aware of the potential and limitations of these diagnostic tools and be prepared to integrate information derived from a correct use of ultrasound, conventional radiology and CT.

### **Abstract**

The use of fluorodeoxyglucose positron emission tomography (FDG PET) scan technology in the management of head and neck cancers continues to increase. We discuss the biology of FDG uptake in malignant lesions and also discuss the physics of PET imaging. The various parameters described to quantify FDG uptake in cancers including standardized uptake value, metabolic tumor volume and total lesion glycolysis are presented. PET scans have found a significant role in the diagnosis and staging of head and neck cancers. They are also being increasingly used in radiation therapy treatment planning. Many groups have also used PET derived values to serve as prognostic indicators of outcomes including loco-regional control and overall survival. FDG PET scans are also proving very useful in assessing the efficacy of treatment and management and follow-up of head and neck cancer patients. This review article focuses on the role of FDG-PET computed tomography scans in these areas for squamous cell carcinoma of the head and neck. We present the current state of the art and speculate on the future applications of this technology including protocol development, newer imaging methods such as combined

magnetic resonance and PET imaging and novel radiopharmaceuticals that can be used to further study tumor biology.

**Key words:** Fluorodeoxyglucose; Positron emission tomography; Squamous cell carcinoma; Head and neck cancer; Radiation therapy planning

**Core tip:** Fluorodeoxyglucose positron emission tomography (FDG PET) computed tomography (CT) scans should be obtained for patients for squamous cell carcinoma of the head and neck whenever clinically indicated and feasible. Pre-treatment scans are helpful in detecting the sites of primary cancer, staging the tumor and ruling out the presence of distant metastases. For patients undergoing radiation therapy, PET/CT scans provide anatomic as well as functional information to aid in treatment planning. After completion of radiotherapy, PET scans should be obtained approximately 12 wk after treatment to assess treatment response and to determine if any salvage therapy is required for persistent, recurrent or metastatic disease.

### **INTRODUCTION**

Head and neck cancers (HNC) account for approximately 650000 new cancers each year across the world and result in about 350000 deaths, representing 6% of all cancer cases<sup>[1,2]</sup>. In the United States, approximately 52000 new

cases of oral cavity, pharyngeal and laryngeal cancers are diagnosed every year with approximately 11000 deaths<sup>[3]</sup>. Approximately 95% of these are squamous cell carcinomas (HNSCC) and they often present in locally advanced stages. The treatment of head and neck cancers involves a multi-disciplinary approach and includes surgery, radiation therapy and chemotherapy. Traditional staging approaches for head and neck cancers include clinical examination and surgical pathologic staging. The advent of concurrent radiation and chemotherapy for organ preservation in head and neck cancers has reduced the incidence of surgical resection especially in locally advanced larynx cancers and oropharynx cancers<sup>[4,5]</sup>. However, this has also brought forth the need to have detailed non-invasive imaging techniques to accurately identify tumor size and location, cervical lymph node involvement and presence or absence of distant metastases. The use of computed tomography (CT) scans and magnetic resonance imaging (MRI) scans allowed structural and anatomical information to be obtained and vastly improved the ability of oncologists to clinically stage these patients appropriately. However, the use of fluorine-18-fluorodeoxyglucose positron-emission tomography (FDG-PET) has added a new biologic and functional end-point to these imaging techniques and opened a whole new arena for research and development in management of head and neck cancers. Additionally, PET/CT and PET/MRI combinations are now able to provide both anatomic and functional information in co-registered images.

The review will focus on the current applications of FDG PET/CT scans in management of squamous cell cancers of the head and neck. The use of PET/MRI and FDG PET/CT for other head and neck cancers (*e.g.*, salivary gland, thyroid cancers *etc.*) is beyond the scope of this review.

## BIOLOGY OF FDG-UPTAKE

Rapidly proliferating cancers cells utilize glucose as a source of energy and metabolism. Glucose undergoes glycolysis after intracellular transportation. This transportation is mediated by a family of glucose transporter proteins (GLUTs)<sup>[6-8]</sup>. These trans-membrane proteins allow energy independent transport of glucose across the hydrophobic cell membrane. Thirteen GLUTs have been identified of which GLUT1, GLUT3, and GLUT4 have high affinity for glucose. The expression of GLUTs is induced by hypoxia-inducible factor, growth factors and various oncogenes<sup>[9]</sup>. Increased expression of GLUT1 has been found in many cancers, including head and neck cancer<sup>[9]</sup>. The degree of expression of GLUT1 has also been shown to be associated with aggressiveness of the cancer. Elevated glycolytic activity and increased expression of GLUT1 are found in advanced cancer stages and predict significantly poorer treatment outcomes<sup>[10-13]</sup>.

Fluorine<sup>18</sup>-FDG (<sup>18</sup>F-FDG) is an analog of glucose with <sup>18</sup>F occupying the position of oxygen on carbon-2. Similar to glucose, GLUTs facilitate the transport of <sup>18</sup>F-

FDG into the cell. In the next step, both glucose and FDG are phosphorylated by the hexokinase enzyme. Glucose, upon phosphorylation, enters the glycolytic pathway for energy production. FDG, on the other hand, cannot undergo glycolysis and is trapped as FDG-6-phosphate in the intracellular environment. This trapped FDG can then be imaged to spatially locate the metabolically active cancer cells. FDG uptake in cancer cells of HNSCC was shown to be significantly correlated with cell proliferation by flow cytometry<sup>[14,15]</sup>.

## PHYSICS OF PET IMAGING

A detailed description of the physics of FDG-PET scanning is beyond the scope of this review. However, in brief, at the heart of this imaging technique is the radioisotope <sup>18</sup>F. It is produced using a cyclotron and has a half-life of 110 min allowing it to be transported for use in PET scanner facilities.

<sup>18</sup>F decays by positron ( $\beta^+$ ) emission 97% of the time and is converted to oxygen-18. The emitted positron travels a short distance in soft tissue, decelerates rapidly and interacts with an electron near the end of its track. This interaction is called the annihilation reaction and mass is converted to energy with the release of two 0.511MeV photons which travel outwards at 180° to each other. These annihilation photons are detected by scintillators and a simultaneous or coincident detection of these photons makes it possible to spatially localize the point of origin. The information is collected on a multitude of such coincident events and processed to generate a PET image.

Nowadays, most PET scans are co-registered with simultaneously obtained CT scans to produce PET/CT images which give functional information along with anatomic co-localization. For areas like the head and neck a smaller area can be scanned with intravenous contrast administration to obtain further normal tissue anatomy and tumor extent.

## QUANTITATIVE IMAGE INTERPRETATION

In order to be used as a valid imaging biomarker, accurate and reproducible quantification of FDG uptake is necessary. A simplified measurement using standardized uptake value (SUV), given by the following formula, is now the most widely used method for the quantification of FDG uptake.

$$SUV = \frac{\text{Tissue activity } (\mu\text{Ci} / \text{ml})}{\text{Injected Dose } (m\text{Ci}) / \text{Body weight } (kg)}$$

In this formula, tissue activity is the radioactivity measured by the PET scanner within a region of interest (ROI) or the maximal value; injected dose is the dose of <sup>18</sup>F-FDG administered, corrected for physical decay. The SUV in this formula represents the activity of <sup>18</sup>F-FDG within the tumor measured over a certain interval after <sup>18</sup>F-FDG

injection and normalized to the dose of  $^{18}\text{F}$ -FDG administered and to the body weight<sup>[16]</sup>.

There are many different factors that can affect  $^{18}\text{F}$ -FDG uptake and its subsequent quantification. The biologic factors include blood glucose level, interval between injection and start of PET study, patient motion and breathing, patient comfort, and inflammatory process near or at the tumor. There are also many technical and physical factors such as attenuation correction, calibration, image reconstruction, data analysis, *etc.*, which are beyond the scope of this review and have been discussed by others<sup>[17-20]</sup>. Despite these, it has been shown that there is a good correlation between SUV and glucose utilization rate in various cancers including HNSCC<sup>[21]</sup>.

Various forms of SUV-based parameters have been described in literature. These include: (1) SUVmax- This measures the highest (maximal) SUV in a region of interest. This has been the most common used parameter in clinical practice as it is thought to be the most reproducible and independent of how the ROI is defined. However, it represents only a single point within the tumor/lesion and may not be representative of the entire tumor volume; (2) SUVmean or SUVaverage- This value may provide a more global picture of the tumor activity as it averages the intensity of uptake in a region of interest (ROI). This, however, suffers from the subjectivity and variability of the definition of this ROI which may differ between individuals and institutions; (3) Metabolic tumor volume (MTV)- This is measured in cubic centimeters and represents the tumor volume with active FDG uptake. There is no standard way for tumor segmentation from PET images (For further discussion, refer to Chapter 4 on PET in radiotherapy treatment planning). Threshold-based method is often used. Some authors used a threshold of SUV > 2.5. Others used 40% or 50% SUVmax as a threshold. The MTV is measured as the tumor volume with SUV above the threshold selected. However, the volumes vary significantly depending on the threshold selected; and (4) Total lesion glycolysis (TLG) - This is a product of the tumor volume, determined by CT - scan or MRI, and SUVmean.

## USE OF PET/CT IN THE DIAGNOSIS AND STAGING OF HEAD AND NECK CANCERS

Primary cancers of the head and neck are mainly diagnosed by clinical examination in the office and supplemented by imaging studies such as CT scans and MRI. Staging of the primary tumor, *i.e.*, T-stage in the American Joint Committee on Cancer (AJCC) staging system, mainly depends on the tumor size and invasion of the primary tumor, which is better assessed by CT and MRI imaging.

Occasionally, in about 2%-9% of cases, patients may present with a lymph node in the neck with no obvious primary site visible on clinical or routine diagnostic imag-

ing tests<sup>[22]</sup>. Such cases are labeled as unknown or occult primary head and neck cancers. Pathologic evaluation of the nodes, usually by fine needle aspiration, may reveal a diagnosis of squamous cell carcinoma or adenocarcinoma. Squamous cell histology indicates that the primary site is likely in the head and neck while adenocarcinomas mainly arise below the clavicle (*e.g.*, lung cancer, gastric cancer). The traditional method for detection of the primary site in cases of squamous cell histology involves examination under anesthesia and random biopsies from the nasopharynx, oropharynx, hypopharynx, larynx and any mucosal areas which appear abnormal. Tonsillectomy is often performed. These maneuvers are able to detect the primary site in about half of the cases initially labeled as unknown primary head and neck cancers<sup>[23]</sup>.

FDG-PET scans have been proven to be an invaluable tool in these cases. Rusthoven *et al.*<sup>[24]</sup> summarized the results of 16 published studies with a combined total of 302 patients to evaluate the role FDG-PET in unknown primary head and neck cancers. They reported that FDG-PET was able to detect primary tumors in 24.5% (range, 5% to 73% in various studies) cases where conventional methods were unsuccessful. The primary site was found at the base of tongue in 27 patients (24.3%), tonsils in 20 patients (18.0%) and below the clavicle in 27 patients (24.3%). The sensitivity, specificity, and accuracy of FDG-PET in the detection of primary tumors were 88.3%, 74.9%, and 78.8%, respectively. Interestingly, PET scans were able to identify an additional 16% regional nodal metastases and 11% distant metastases previously undiscovered. Several prospective studies have confirmed these findings<sup>[22,25]</sup>. Rudmik *et al.*<sup>[25]</sup> recently reported results of 30 patients who underwent PET/CT. PET/CT was performed after conventional workup and prior to operative panendoscopy. The surgeons were blinded to the results. Patients had routine examination under anesthesia and directed biopsies, and the PET/CT results were then revealed to the surgeon intraoperatively. Additional biopsies were taken if the PET/CT was positive. The traditional work-up identified tumors in 25% of patients, whereas PET/CT-directed biopsies revealed the primary lesion in 55% of patients. The sensitivity, specificity, positive predictive value, and negative predictive value of PET/CT in detection of primary tumor were 92%, 63%, 79%, and 83%, respectively.

Detection of the site of primary cancer allows directed therapy to the tumor (surgery or radiation therapy) while sparing or minimizing the toxicity to uninvolved mucosal areas or tissues. The current paradigm for diagnosis and staging work-up for unknown primary cancers involves obtaining a PET/CT and then obtaining directed biopsies from the suspicious areas. Figure 1 illustrates a patient who presented with multiple left neck nodes. Conventional workup failed to identify the primary tumor but PET showed the primary tumor in left base of tongue.

As noted above, PET scans have also helped in identification of previously unidentified involved cervical

**Figure 1 Computed tomography.** A: A patient presented with multiple left neck nodes (arrows); B: The conventional methods as well as the computed tomography (CT) imaging could not identify the primary tumor; C: A positron emission tomography/CT scan showed increased fluorodeoxyglucose uptake in the left base of tongue (arrow) and a directed biopsy of this area confirmed the primary site.

**Figure 2 Increased fluorodeoxyglucose positron-uptake in the low neck revealed a metastatic lymph node which would otherwise be difficult to detect because of the presence of muscular and vascular structures in this region of the neck.**

lymph nodes. Various CT and MRI based criteria have been developed to label lymph nodes are being involved by cancer or not<sup>[26]</sup>. However, this may still result in 20%-30% rate of false-positive and false-negative results. Various reports comparing FDG-PET with other imaging modalities including ultrasound, CT and MRI have consistently reported a much higher sensitivity and specificity for PET scans when compared with the gold-standard, surgical lymph node dissection<sup>[27,28]</sup>. This has specially been helpful in detecting lymph nodes which are at a distance from the primary or in the contralateral neck, especially when the lymph node has not reached size criteria by CT/MRI. PET is also very helpful in detecting involved lymph nodes in the lower neck where there are complex muscular and vascular structures (Figure 2). The average sensitivity and specificity for PET scan to detect

involved nodes are reported to be 90% or higher<sup>[27]</sup>.

Local-regionally advanced head and neck cancers metastasize to mediastinal lymph nodes, lungs, bone and liver. PET scans are also helpful in ruling out presence of distant metastases as PET images in head and neck cancer are often obtained from skull base to hips and PET are more sensitive in small metastasis than CT. Various reports have documented the incidence of distant metastases as detected by PET scans ranging from 6% to 25% for stage III/IV head and neck cancers<sup>[29-34]</sup>. The sensitivity and specificity of PET scans for the detection of metastases are 77% and 94%, respectively. Hearle *et al*<sup>[35]</sup> noted distant metastases in 10% of 299 patients evaluated with 97% sensitivity and 96% specificity. These PET findings resulted in a change in the management plan in 8% to 15% of cases<sup>[30,36]</sup>. Figure 3 shows a head and neck

**Figure 3** Small bone metastases detected in a patient with head and neck squamous cell carcinoma (arrow). These lesions were not visible on the computed tomography scan.

cancer patient with small bone metastases detected by PET scan but these lesions were missed in the CT scan.

The use of tobacco products (chewing and smoking) and alcohol have been associated with the development of head and neck cancers. This risk extends to other sites of the aero-digestive tract including lung and esophageal cancers. Synchronous primary cancers have been noted in approximately 10% of head and neck cancer patients. Strobel *et al.*<sup>[37]</sup> reported 69 synchronous primary cancers in 62 patients among 589 consecutive patients imaged with PET scans. Most (80%) of these were in the upper aero-digestive tract. A recent report from Japan noted a higher rate (18%) of second primary cancers among 230 head and neck cancer patients<sup>[38]</sup>. Evaluation of the diagnostic sensitivity showed that PET scans were most likely to detect second primaries in other head and neck sites and lungs while the sensitivity for finding gastric and esophageal cancers was much lower at 25% and 7.6%, respectively. Needless to say, the discovery of these second primary cancers resulted in a change in the management plan for these patients. Figure 4 shows a patient who presented with right oral tongue cancer and PET was obtained as part of the workup that revealed he also had a cancer in the soft palate as well in the upper esophagus. Figure 5 is an example of a patient with a synchronous laryngeal and lung squamous cell carcinomas.

## RADIATION THERAPY PLANNING

Radiation treatment plays an important role in the management of head and neck cancer. Radiotherapy is given as a definitive treatment when the tumor is not resectable or when organ preservation is preferable<sup>[5,39]</sup>. Radiotherapy is also given to patients who have high risk pathology features after surgery<sup>[40,41]</sup>. Chemotherapy is often administered concurrently with radiotherapy in locally advanced disease.

In the past decade, intensity-modulated radiotherapy (IMRT) has become a standard radiation technique in head and neck cancer<sup>[42,43]</sup>. IMRT is a highly conformal radiation technique which allows delivery of different

radiation dose to different adjacent structures, also called dose painting, thus enabling delivery of high dose to the tumor targets while sparing the normal tissues. The use of IMRT has led to a reduction in xerostomia and improvements in quality of life following treatment<sup>[44-46]</sup>. However, highly conformal treatments can lead to disease not being included in the high-dose radiation treatment volume, resulting in locoregional failures. On the other hand, over-drawing the target volumes can result in high-dose radiation being unnecessarily delivered to normal tissues that may lead to increased toxicities. Therefore, accurate delineation of the tumor volume and regions at risk are critical in order to achieve the best treatment outcomes.

Since FDG PET scan has a high sensitivity in detecting tumor, it plays an important role in radiation treatment planning especially in IMRT planning. FDG PET scan is routinely obtained and co-registered with treatment planning CT images for treatment planning. Currently there are following several practical applications of PET in radiation treatment planning: (1) Detecting small lymph nodes that are not size criteria in CT and including these nodes in high dose target. In general, lymph nodes less than 1.0 cm in CT or MRI are usually called benign. However, PET scan has higher resolution and can detect malignant node as small as 0.5 to 0.6 cm. As mentioned above, PET has a high sensitivity for malignant lymph node, reported being up to 90%. Therefore, PET avid nodes are included in the high dose radiation targets especially when biopsy confirmed to be malignant. Figure 6 shows a patient with nasopharyngeal cancer, initially staged as T1N0 after conventional workup. However, FDG PET revealed hypermetabolic foci in the primary tumor in the nasopharynx and in bilateral level II lymph nodes which were small and were not called as lymphadenopathy in the CT and MRI (Figure 6B). Fine needle biopsies of the right level II lymph node was obtained and confirmed to contain metastatic disease. Therefore, these lymph nodes were included in the high dose area in the IMRT plan (Figure 6C); (2) Detecting the primary tumor in patients who present with “unknown primary” and including the primary tumor in the high dose target. As mentioned above, in head and neck cancer with unknown primary, FDG PET can detect primary tumor in 25% of patients where conventional work up were unsuccessful. Most of these primary tumors are in the oropharynx, such as tonsil and the base of the tongue. When the primary tumor is detected, the patient is treated with radiation field tailored to the primary tumor, thus avoiding radiating the whole pharyngeal axis which is the standard radiation technique in patients with unknown primary. Figure 7 illustrates the IMRT plan for the patient with the primary tumor detected in PET. The left base of tongue tumor detected by PET was included in the high dose field while the larynx and nasopharynx were spared; (3) Accurate delineation of the edge of the primary tumor. Accurate delineation of the edge of tumor to generate gross tumor volume (GTV) is the first step in target de-

**Figure 4** A positron emission tomography scan was obtained in a patient with a diagnosis of right oral tongue cancer (anterior arrow in axial views). The positron emission tomography/computed tomography revealed two additional primary cancers, one in the soft palate and the other in the upper esophagus.

**Figure 5** A patient with a synchronous laryngeal and lung squamous cell carcinomas. A 70-year-old male with diagnosis of squamous cell carcinoma of the glottic larynx T3N0M0 (A and B; arrow). He underwent a positron emission tomography/computed tomography scan which revealed additional lesions in the right lung which were biopsied endobronchial and shown to be a second primary lung cancer with mediastinal lymphadenopathy (C and D; arrows).

lineation for IMRT planning. It is often difficult to separate the tumor from surrounding soft tissue and muscle in CT imaging which is the primary imaging modality in radiation treatment planning, especially for tumor in the

oral tongue and oropharynx. Figure 8 shows a patient with oral tongue cancer, comparing CT (Figure 8A) *vs* PET (Figure 8B). The border of the tumor in the CT was not very clear, difficult to separate from the tongue

**Figure 6** A patient with nasopharyngeal cancer. A: Initial stage was T1N0 when the patient was referred to our institution after conventional workup (arrow in axial image); B: Fluorodeoxyglucose positron emission tomography revealed hypermetabolic foci in the primary tumor in the nasopharynx and in bilateral level II lymph nodes which were small and were not called as lymphadenopathy in her computed tomography and magnetic resonance imaging. Fine needle biopsies of these lymph nodes were obtained. The right level II node (arrows) was confirmed to contain metastatic disease, while the left level II lymph node was not diagnostic; C: Intensity modulated radiotherapy plan for this patient. The right level II node was treated to a high dose of radiation. The lower neck was treated with an anterior-posterior field (From Woods C, Sohn J, Machtay M, Yao M. Radiation treatment planning for head and neck cancer with PET. *PET Clinics* 2012; 7: 396; with permission).

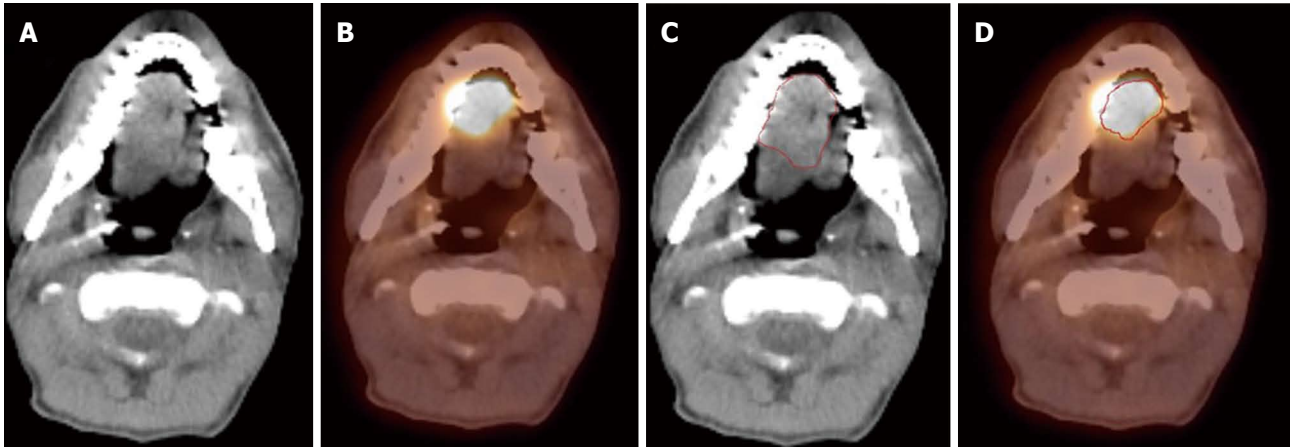

**Figure 7** Treatment plan for the patient described in Figure 1. The base of tongue was found to be the primary cancer site and this area was included in the high dose intensity-modulated radiotherapy plan while sparing uninvolved mucosal areas.

muscle. Yet, the PET showed sharp contrast between the tumor and surrounding tissue. The GTV based on CT (Figure 8C) is much larger than that based on PET (Figure 8D). Several studies have published comparing GTV generated by CT *vs* those when PET was incorporated, and noted a trend for decreasing GTVs when PET was used<sup>[47-52]</sup>. Some studies also showed that the interobserver variability decreased when PET was used for target delineation<sup>[47]</sup>; and (4) In postoperative radiation, detecting recurrent tumor even before radiation and including the recurrent tumor in high dose target. Patients with high risk pathology features are treated with adjuvant chemo-

radiation for better local regional control and survival. Postoperative radiotherapy is often given 4 to 6 wk after surgery when the surgical wound is fully healed. However, some patients may have local regional recurrences even before radiation. Because of the anatomical distortion and fibrotic changes after surgery, and flap reconstruction, these recurrences are difficult to be detected by physical examination and CT imaging. FDG PET is ideal imaging modality at this setting. Shintani *et al*<sup>[53]</sup> reported 91 consecutive patients referred to postoperative adjuvant radiation after complete surgical resection. These patients had FDG PET obtained at a median time of 28 d after surgery. They reported 27 patients with suspicious PET findings. Further biopsies led to changes in adjuvant treatment in 14 patients (15.4%), including increasing the radiation therapy dose in 6 patients, and extending the radiation therapy treatment volume and increasing the dose in 1 patient. Liao *et al*<sup>[54]</sup> also reported 29 patients who had a PET scan obtained before postoperative radiation. They found 7 patients with positive PET studies, 3 with distant metastases and 4 with local regional recurrences. For those who had local regional disease detected by the PET, the radiation volumes and radiation dose have to be changed, with higher dose delivered to the recurrent tumor. Thus, for patients with high risk features, especially for those who have a prolonged interval from surgery to radiation, a post-surgery and pre-radiation FDG PET will be valuable in treatment decision and radiation treatment planning.

Following are some active investigations in further ex-

**Figure 8** A patient with oral tongue cancer. The edge of the tumor was not very clear in the computed tomography (CT) image (A), but more obvious in the PET image (B). Gross tumor volume was outlined based on CT scan (C) vs with fluorodeoxyglucose positron emission tomography/CT (D). The volume included is larger with CT alone.

ploration how to use PET in radiation treatment in head and neck cancer: (1) Subvolume delineation and dose escalation. Tumors are not homogeneous. Since FDG uptake is correlated with tumor aggressiveness, the region of the tumor with higher FDG uptake may harbor more aggressive cancer cells and may require higher radiation dose to eradicate. Indeed, FDG-avid regions in the tumor have been shown to be correlated with hypoxia that is associated with tumor radioresistance<sup>[55,56]</sup>. With the dose painting capability of IMRT, a higher radiation dose can be delivered to these tumor subvolumes to achieve potentially better tumor control. Schwartz *et al.*<sup>[57]</sup> studied theoretical IMRT models using PET derived volumes in 20 patients with head and neck cancer. They found that a mean dose of 74.9 Gy (range, 71.53-80.98 Gy) could be delivered to the PET-avid volume without overdosing the adjacent critical structures. Madani *et al.*<sup>[58]</sup> conducted a Phase I study of dose escalation to FDG-avid subvolumes. They reported it was feasible to deliver a radiation boost of 30 Gy in 10 fractions to the PET tumor volume before standard IMRT treatment, and they are planning a randomized phase II trial comparing this treatment regimen with standard IMRT; and (2) Adaptive radiation therapy. During the course of radiation treatment, the patient can have significant physical/anatomical changes due to tumor response. A second CT simulation and re-planning are required in order to ensure the tumor is being dosed appropriately. Changes also occur in the FDG uptake of the tumor during the course of radiotherapy and some investigators have explored adaptive radiotherapy and planning techniques to alter the plan based on the changes in PET imaging<sup>[59,60]</sup>.

## ASSESSMENT OF TREATMENT EFFICACY, FURTHER MANAGEMENT AND FOLLOW-UP

FDG PET/CT scans have been proven to be a useful technology in assessing treatment response in patients

treated with definitive radiation and chemotherapy and for detecting residual and recurrent disease. PET/CT scans are usually performed 2 to 3 mo after treatment completion. The optimal timing of obtaining the scan has been debated in literature and based on many reports it has been determined that the 12-wk time point after completion of therapy may be the most appropriate<sup>[31,61,62]</sup>. Scans obtained at earlier time-points (< 8 wk) have a high rate of false-positive FDG uptake in the radiation treatment field due to inflammatory changes. Scans done too late (> 16 wk) may allow residual loco-regional disease to grow and metastasize. If increased FDG uptake is noted at the primary site, patients should undergo a biopsy followed by a surgical resection for residual disease. Figure 9 shows a serial PET/CT scans in a patient treated for oropharyngeal squamous cell carcinoma.

The role of FDG PET/CT in decision making for neck dissection after chemoradiation has also been extensively investigated. Yao *et al.*<sup>[63]</sup> reported a 100% negative predictive value (NPV) and 43% positive predictive value (PPV) for PET scans done 12 wk after radiation in 53 patients who were noted to have a complete response at the primary site. A prospective study in 112 consecutive patients reported by Porceddu *et al.*<sup>[64]</sup> also noted the utility of the 12-wk post radiochemotherapy PET scan in decision making for neck dissection. Patients who had equivocal PET results underwent another scan 4 to 6 wk later. Patients who had CT abnormalities but were PET-negative were observed and no subsequent neck node failures were noted in these patients. Nine patients continued to have PET-positive disease in the neck of which 8 underwent surgery. Residual disease was noted pathologically in 6 of these 8. Another prospective study from MD Anderson Cancer Center reported on 98 patients<sup>[65]</sup>. They stratified patients into low-risk and high-risk groups based on tumor stage, nodal stage, overall stage, tumor site, smoking history and HPV status. The most significant benefit of FDG PET/CT over CT scans was noted in detecting residual disease among high-risk patients. The NPV of PET/CT was 75% as compared to 37.5%

**Figure 9** Sixty-six year old male was diagnosed with squamous cell carcinoma of the left base of tongue T4aN1M0. He received external beam radiation therapy (70 Gy in 35 fractions) with concurrent cisplatin 100 mg/m<sup>2</sup> (3 cycles). Positron emission tomography/computed tomography scans were done pre-treatment (A) and at 3-mo (B) and 8 mo (C) post-radiation therapy. Follow-up images show good response to treatment with sustained response at least 8 mo from treatment.

for CT alone.

The role of FDG-PET scans for long term follow-up surveillance for detection of loco-regional and distant metastatic recurrence has also been extensively investigated. Gupta *et al*<sup>[66]</sup> conducted a meta-analysis of 51 studies involving 2,335 patients. They reported a NPV of approximately 95% for both primary and neck disease for response assessment and surveillance. A recent report analyzed the role of long-term surveillance PET/CT scans in 214 patients with negative scans after completion of therapy<sup>[67]</sup>. Nine percent of these patients recurred on follow-up. This suggested a NPV for surveillance PET/CT of 91%. Based on these data the authors recommended that radiologic surveillance can be stopped early in those patients who are noted to have two consecutive negative PET/CT scans within 6 mo of each other.

## PROGNOSIS

Many attempts have been made to establish PET/CT scan derived parameters as prognostic indicators. These studies have looked at pre-treatment, post-treatment and during treatment scans to obtain SUV and metabolic tumor volume (MTV) to serve as prognostic indices. Most of these studies have been retrospective. However, some prospective trials have also been reported. A recent review article summarizes these studies<sup>[68]</sup>.

Allal *et al*<sup>[69]</sup> conducted a prospective study in 120 patients with HNSCC to evaluate the role of pre-treatment SUV in predicting for local control and disease-free survival. Seventy-three patients underwent radiation therapy with or without concurrent chemotherapy and 47 had surgery with or without adjuvant radiation therapy. At a median follow-up of 48 mo, 46 patients had recurrent and/or distant metastatic disease. In these patients the SUV was noted to be 5.8 *vs* 3.6 for those with disease controlled ( $P = 0.002$ ). On the other hand, Vernon *et al*<sup>[70]</sup> reviewed 42 patients receiving PET/CT guided definitive radiotherapy and found that neither SUV of the primary tumor nor SUV of the lymph node was predictive of tumor recurrence.

In another prospective study, FDG PET was obtained 4 wk prior to chemoradiotherapy and 8 wk after completion of treatment in 98 patients<sup>[71]</sup>. Primary tumor and nodal SUVmax was calculated for both time points. The only prognostic factor for disease-specific survival was found to be the post-treatment primary tumor SUVmax. The mean SUVmax for those who failed was 7.2, compared to 4.2 for those who did not fail ( $P < 0.01$ ). Pre-treatment SUVmax of primary tumor and lymph node were not found to be significantly associated with treatment outcomes. The conclusions from these studies are not consistent, partly due to the inherent problems with SUV measurement as it represents only a single point within the tumor but not represent the entire tumor. Additionally, there is heterogeneity in the patient population, heterogeneity in treatment modalities, small patient samples and the use of different endpoints.

In recent years, PET-based tumor volumes, *i.e.*, metabolic tumor volume (MTV), are being explored. La *et al*<sup>[72]</sup> from Stanford University evaluated the prognostic value of MTV in 85 patients. A threshold of 50% maximal intensity was used to define the metabolic tumor volumes. They found that MTV had a significant relationship with disease-free survival ( $P < 0.001$ ) and with overall survival ( $P < 0.001$ ) on univariate analysis. An increase in MTV of 17.4 mL was significantly associated with an increased hazard of first event (recurrence or death). SUVmax did not show a significant relationship with either of these endpoints. Another report from the same group of investigators validated these findings in an additional 83 patients<sup>[73]</sup>. Recently the results of a sub-group of patients enrolled on the RTOG 0522 trial were presented<sup>[74]</sup>. Seventy-four patients underwent baseline and 8-wk post treatment PET scans. Baseline SUVmax or SUVpeak of the primary or nodal disease were not predictive for outcomes. However, patients having a primary tumor MTV above the cohort median had a significantly worse loco-regional control and progression free survival.

Some groups have also evaluated the utility of PET scans done during therapy. PET scans were done after neoadjuvant chemotherapy in 16 patients. These patients

then underwent surgical resection and histopathologic responses were correlated with SUVmax. Comparisons between pathologic responders and non-responders revealed that there was significant difference in post-chemotherapy SUVmax and percent decrease in SUVmax<sup>[75]</sup>.

The applicability of PET scans during the course of radiation therapy is harder to evaluate because of difficulty in image interpretation with inflammatory changes due to radiation and the cost of additional imaging. Such a study has, however, been done and reported on by Hentschel *et al*<sup>[76]</sup>. This prospective study evaluated the role of serial PET scans during early phase of radiation therapy and the ability of these scans to predict treatment outcomes. Patients were divided into two groups and all of them underwent 4 PET scans. In one group, PET scans were obtained before treatment, at 10 Gy, 30 Gy and 50 Gy. In the other group, PET scans were obtained before treatment, at 20 Gy, 40 Gy, and 60 Gy. Patients who had a rapid early response with > 50% decline in SUVmax at 10 Gy or 20 Gy as compared to the pre-treatment SUVmax had a significantly higher overall survival, loco-regional control and disease-free survival at 2 years. The 2-year overall survival was 88% for those who had more than 50% decline in SUVmax compared to 38% for those with less than 50% decline ( $P = 0.02$ ). The 2-year disease-free survival was 75% and 31%, respectively for those with > 50% decline as compared to < 50% decline in SUVmax. And the 2-year local-regional control rate was 88% *vs* 40% for those with > 50% decline *vs* to those < 50% decline in SUVmax ( $P = 0.06$ ).

There is currently no consensus on what time points to use for PET scan based prognostication and what parameters are the most useful. There may be value in combining traditional prognostic factors with PET based parameters. Yao *et al*<sup>[77]</sup> showed that T-stage, N-stage and pretreatment SUV of the lymph node were significantly associated with distant metastasis. However, the combination of these factors can better predict distant metastasis-free survival. The 3-year distant metastasis-free survival was 98.1% for no factors, 88.6% for one factor, 68.3% for two factors, and 41.7% for three factors. Similarly, Moeller *et al*<sup>[65]</sup> incorporated HPV status in their mortality risk assessment in addition to post-treatment tumor SUVmax. They noted FDG PET/CT was predictive for outcomes in HPV-negative and non-oro-pharyngeal primaries.

## FUTURE DIRECTIONS

FDG PET/CT scan has been proven to be a useful technology on many fronts in head and neck cancer and has significant impact on the management as discussed above. Currently, there are many exciting new areas of research and development that are being actively investigated and will continue to expand the role of this imaging modality in the future. These efforts can be broadly categorized as follows: (1) Protocol development and standardization: a: Head and neck cancer staging - There may be a possibil-

ity of combining anatomical information, which forms the basis of the current AJCC system, with functional information obtained from PET scans; b: Standardized uptake value (SUV) - Even though SUV is a widely used and reported parameter it suffers from some drawbacks that make it difficult to compare values between different institutions<sup>[19,78,79]</sup>. Further standardization in the way SUV is determined would allow inter-institutional collaboration and co-operative group clinical trials. Additional objectively measurable parameters which allow cross-platform and cross-hardware comparisons also need to be developed; c: PET/CT simulators - PET/CT scans are often co-registered with CT scans obtained for radiation therapy planning. PET/CT simulators are also available at some institutions which facilitate this. Consensus guidelines need to be developed for tumor and target volume delineation when using PET information for radiation treatment planning; d: PET as a prognostic indicator - The use of PET/CT scans as prognostic indicators in head and neck cancers and for follow-up and surveillance requires further research and investigation; and e: Economic analyses - Cost-benefit analyses suggest that PET/CT scans are cost-effective for diagnosis, staging and therapeutic decision making in head and neck cancers<sup>[80,81]</sup>. Common availability and decreasing costs of this technology will allow greater use and acceptance; (2) Newer imaging technology - Magnetic resonance imaging (MRI) offers superior imaging for soft-tissue delineation but offers little functional information unless MR spectroscopy is performed. MR spectroscopy can be performed in a limited volume. Recently MR/PET hybrid technologies have been developed for used in the clinic. This offers the advantages of high-quality soft tissue imaging from MR with whole-body and functional imaging from the PET component<sup>[82-84]</sup>. A recent review article highlights the potential for this new hybrid technology, the technical challenges and its use in clinical situations<sup>[85]</sup>; and (3) Newer radiopharmaceuticals - Many new radioisotopes and radiotracers are being developed to image further functional characteristics of tumors including hypoxia, tumor proliferation, amino acid metabolism and presence of EGFR on tumor cells. An excellent review on this topic has been provided by Wang *et al*<sup>[86]</sup>. As outlined in this review, a large number of efforts are being focused on hypoxia imaging. Hypoxia poses a major radiobiological disadvantage and confers radioresistance to the tumor. Hypoxic cells are not killed in response to radiation therapy and may be responsible for treatment failure, either locally or as distant metastasis. Some of the newer radiopharmaceuticals being used to image the hypoxic portion of the tumor include [<sup>18</sup>F]fluoromisonidazole (FMISO), copper-diacetyl-bis (N4-methylthiosamincarbazone) (Cu-ATSM) and [<sup>18</sup>F]fluoroazomycin arabinoside (FAZA). Once identified using PET scans, these hypoxic areas of the tumor can be preferentially targeted to receive a higher dose of radiation using IMRT technique.

The applications of FDG PET/CT scanning mentioned in this article highlight the extensive work done

by groups across the world to the study the usefulness and application of this technology in various scenarios. Future work will continue to highlight the importance of this imaging modality in head and neck cancers.

### Abstract

Congenital hyperinsulinism (CHI) is a rare but complex heterogeneous disorder caused by unregulated secretion of insulin from the  $\beta$ -cells of the pancreas leading to severe hypoglycaemia and neuroglycopenia. Swift diagnosis and institution of appropriate management is crucial to prevent or minimise adverse neurodevelopmental outcome in children with CHI. Histologically there are two major subtypes of CHI, diffuse and focal disease and the management approach will significantly differ depending on the type of the lesion. Patients with medically unresponsive diffuse disease require a near total pancreatectomy, which then leads on to the development of iatrogenic diabetes mellitus and pancreatic exocrine insufficiency. However patients with focal

disease only require a limited pancreatectomy to remove only the focal lesion thus providing complete cure to the patient. Hence the preoperative differentiation of the histological subtypes of CHI becomes paramount in the management of CHI. Fluorine-18L-3, 4-hydroxyphenylalanine positron emission tomography ( $^{18}\text{F}$ -DOPA-PET) is now the gold standard for pre-operative differentiation of focal from diffuse disease and localisation of the focal lesion. The aim of this review article is to give a clinical overview of CHI, then review the role of dopamine in  $\beta$ -cell physiology and finally discuss the role of  $^{18}\text{F}$ -DOPA-PET imaging in the management of CHI.

**Key words:** Congenital hyperinsulinism; Fluorine-18L-3, 4-hydroxyphenylalanine positron emission tomography; Focal congenital hyperinsulinism; Diffuse congenital hyperinsulinism; Ectopic congenital hyperinsulinism; Standardized uptake value

**Core tip:** This manuscript describes how the advent of fluorine-18L-3, 4-hydroxyphenylalanine positron emission tomography ( $^{18}\text{F}$ -DOPA-PET) scanning has revolutionised the management of patients with a very complex condition called congenital hyperinsulinism.  $^{18}\text{F}$ -DOPA-PET scanning allows the accurate pre-operative localisation of the focal lesion in these patients which can then be surgically removed allowing complete cure from the hypoglycaemia.

## INTRODUCTION

Congenital hyperinsulinism (CHI) is a heterogeneous condition due to the dysregulated and inappropriate secretion of insulin from the  $\beta$ -cells of the pancreas leading to severe hypoglycaemia in infants. The incidence of CHI is 1 in 50000 in the general population and 1 in 2500 in the consanguineous cohorts<sup>[1]</sup>. Based on the clinical presentation-CHI can be classified into two major subgroups, transient or persistent and based on histology into three forms such as focal (40%), diffuse (50%) or atypical (10%)<sup>[2]</sup>. Transient CHI is observed in children who are born small for gestational age, those with intrauterine growth restriction (IUGR), those subjected to birth asphyxia and those born to mothers with diabetes mellitus (pre or gestational diabetes) and can last up to a week<sup>[3]</sup>. However it can last longer up to a few months in some children with IUGR<sup>[4]</sup>.

The insulin secreting  $\beta$ -cells of the pancreas consists of a potassium channel ( $\text{K}_{\text{ATP}}$  channel) which plays a crucial role in insulin secretion and glucose homeostasis<sup>[5]</sup>. The  $\text{K}_{\text{ATP}}$  channel proteins are encoded by two genes. These are “sulphonylurea receptor subunit” (SUR1 encoded by *ABCC8*) and the “inward rectifying potassium channel subunit” (Kir6.2 encoded by *KCNJ11*) genes<sup>[6]</sup>. Both these genes are localised to chromosome 11p15.1<sup>[7]</sup>. Nearly 90% of medically unresponsive persistent CHI is caused by loss of function (recessive inactivating) mutations in these two subunits of the  $\text{K}_{\text{ATP}}$  channel involved in regulating insulin secretion<sup>[8]</sup>. They are predominantly autosomal recessive (AR) and rarely autosomal dominant (AD) in inheritance.

Mutations in genes encoding enzymes involved in insulin secretion are rare causes of CHI. They are (1) glutamate dehydrogenase (GDH) encoded by *GLUD1* gene (AD); (2) glucokinase (GCK) encoded by *GCK* gene (AD); (3) L-3-hydroxyacyl-coenzyme A dehydrogenase (HADH) encoded by *HADH* gene (AR); (4) hepatocyte nuclear factor 4-alpha (HNF4-a) encoded by *HNF4A* gene (AD); (5) monocarboxylate transporter (MCT1) encoded by *SLC16A1* gene (AD); and (6) uncoupling protein 2 encoded by *UCP2* gene (AD)<sup>[9]</sup>. No genetic aetiology has been identified in about 70%-80% of patients who are responsive to medical therapy with diazoxide.

Of the three histological forms of CHI, the typical diffuse form is characterised by the abundant distribution of enlarged and hyperchromatic nuclei throughout the islets<sup>[2]</sup>. It is predominantly caused by recessive loss of function mutations in the  $\text{K}_{\text{ATP}}$  channel (*ABCC8* and *KCNJ11* genes) and when unresponsive to medical therapy requires a near total ( $\geq 95\%$ ) pancreatectomy<sup>[2]</sup> (Figure 1). The focal form is characterised by an isolated cluster of abnormal insulin producing cells with ‘normal’ surrounding tissue within the pancreas (Figure 2). Histologically it involves focal adenomatous hyperplasia of the islet cells with ductuloinisular complexes and scattered giant  $\beta$ -cell nuclei surrounded by normal pancreatic parenchyma<sup>[2,10,11]</sup>. Focal CHI is always sporadic in inheritance and caused by the paternal heterozygous mutation

Diffuse:

Associated with a paternal mutation in *ABCC8*/*KCNJ11* and paternal UPD encompassing 11p5.1 to 11p15.5 in the focal area

**Figure 2** Focal lesion affecting only a single region of the pancreas. It is associated with a paternal mutation in the *ABCC8* or *KCNJ11* and paternal uniparental disomy encompassing 11p5.1 to 11p15.5 in the focal area.

in *ABCC8*/*KCNJ11* genes along with somatic loss of maternal allele in the focal hyperplastic tissue requiring a focal lesionectomy<sup>[12]</sup>.

Nearly 10% of CHI is of atypical form, the molecular mechanism and histopathological differentiation of which is yet to be completely understood<sup>[13]</sup>. Children with persistent CHI often require high glucose concentrations ( $> 8\text{mg/kg/min}$ ) to maintain euglycemia. The diagnosis of CHI is primarily made by biochemical investigations demonstrating detectable levels of insulin in relation to hypoglycaemia along with reduced/absent free fatty acids and ketone bodies<sup>[12]</sup>. Current medical management for CHI includes Diazoxide along with Chlorothiazide as the first line therapy and Octreotide as a second line drug<sup>[12]</sup>.

Children who are not responding to medical management, and in whom the genetic testing is inconclusive or in favour of a focal lesion, should undergo  $^{18}\text{F}$ -DOPA-PET scan to ascertain the type of lesion whether it is fo-

**Figure 3 Dopamine biochemistry.** Phenylalanine is converted into L-Tyrosine. L-Tyrosine is then converted into L-Dopa by Tyrosine Hydroxylase. L-Dopa is then converted into Dopamine by DOPA decarboxylase.

cal or diffuse and provide guidance towards surgery<sup>[1]</sup>.

Pre-operative delineation of the subtype of the lesion becomes extremely crucial as the management approach and the treatment modalities differ significantly based on the type of the lesion. Focal CHI typically does not respond to medical management and a focal lesionectomy provides a definite cure for the condition by avoiding further hypoglycaemic episodes and its neurological complications. A focal lesionectomy also minimises the risk of iatrogenic diabetes mellitus and exocrine pancreatic insufficiency. Children with diffuse CHI warrant a sub total or a near total pancreatectomy to prevent brain damage from neuroglycopenia, however the risk of developing diabetes mellitus and exocrine insufficiency in later life is quite high<sup>[14]</sup>.

## DOPAMINE METABOLISM

Dopamine is synthesised from a non-essential amino acid, tyrosine which is first converted to L-dopa by tyrosine hydroxylase. This is the rate limiting step in dopamine production. Then L-Dopa is decarboxylated to dopamine by DOPA decarboxylase. Dopamine is then oxidised to nor-adrenaline (Figure 3).

Dopamine plays different roles in various internal organs. In the brain, it acts as a neurotransmitter and plays

a major role in neuropsychiatric and movement disorders such as Schizophrenia and Parkinson's disease<sup>[15]</sup>. It also acts as a local chemical messenger in other organs such as blood vessels, kidney, gastrointestinal mucosa and including pancreas<sup>[16]</sup>.

Dopamine exerts its effects by binding to and activating receptors on the surface of cells. In humans five subtypes of dopamine receptors have been identified, labelled D1 through D5<sup>[16]</sup>. All of them exert their effects *via* a complex second messenger system [e.g., cyclic AMP]. Dopamine signalling is mediated by five cloned receptors, grouped into D1-like (D1 and D5 receptors) and D2-like (D2, D3 and D4 receptors) families. The presence of dopamine receptors from both families has been identified in human isolated islets<sup>[16]</sup>. D2 receptor expression was confirmed by immunodetection revealing localization on insulin secretory granules of human  $\beta$ -cells<sup>[16]</sup>.

Studies carried out in mouse pancreatic islets have shown pancreatic islets as the site for Dopamine synthesis and storage outside the central nervous system and both Dopamine and L-Dopa exerts a negative feedback action on insulin secretion in correlation with the reduction in intracellular  $[\text{Ca}^{2+}]$  influx<sup>[17,18]</sup>.

A study done recently has shown a negative feedback regulatory circuit for glucose-stimulated insulin secretion in purified human islets *in vitro*<sup>[19]</sup>. The release of dopamine and insulin together in response to the glucose load is demonstrated by the *in-vitro* infusion of dopamine into the insulin-containing secretory granules of human  $\beta$ -cells. Dopamine in turn exerts an antagonistic action on the D2 receptors that are also expressed on  $\beta$ -cells and thus inhibiting insulin secretion<sup>[19]</sup>.

Neuroendocrine cells and pancreatic islets take up L-DOPA and convert it into Dopamine by the enzyme DOPA decarboxylase, which is expressed in  $\beta$ -cells of the pancreatic islets<sup>[20-23]</sup>. Thus decarboxylation of the L-DOPA to dopamine in the  $\beta$ -cells of the pancreatic islets allows localization of the lesion by means of PET scanning, using radioactive isomer  $^{18}\text{F}$ -L-DOPA<sup>[24]</sup>.  $^{18}\text{F}$ -DOPA is a radiotracer analogue of DOPA and this radioactive tracer is taken up, decarboxylated and stored in cytoplasmic secretory granules by both the endocrine and exocrine cells of the pancreas<sup>[23,25]</sup>. This mechanism acts as the principle behind the use of this non-invasive  $^{18}\text{F}$ -DOPA-PET imaging technique as the diagnostic tool of choice in localising the focal lesion. Both focal and diffuse forms have high DOPA decarboxylase activity and in focal lesions there is excessive tracer uptake in the lesion when compared to the rest of the pancreas (Figure 4).

In diffuse CHI there is generalised increased tracer uptake with a relatively higher uptake in the head when compared to the rest of the pancreas<sup>[14,26,27]</sup>.  $^{18}\text{F}$ -DOPA is excreted by kidneys hence normal bio-distribution is seen in kidneys, ureter and urinary bladder. An excessive uptake is also seen in gall bladder and biliary tract and a low uptake is seen in liver, heart and basal ganglia<sup>[26]</sup>.

**Figure 4** Fluorine- $^{18}\text{L}$ -3, 4-hydroxyphenylalanine positron emission tomography scan showing the focal lesion in the tail of the pancreas.

## DIAGNOSTIC METHODS TO LOCALISE FOCAL LESION

Until recently the methods used to localise the focal lesion were (1) Hepatic portal venous sampling (PVS)<sup>[28,29]</sup>, (2) arterial calcium stimulation test<sup>[30,31]</sup>, and (3) tolbutamide response test<sup>[32]</sup>. PVS is invasive, time consuming, technically challenging and is associated with risk of severe hypoglycaemia and the accuracy is only about 70%<sup>[28,33]</sup>. Arterial calcium stimulation and tolbutamide response test are not found to be accurate in distinguishing between focal and diffuse CHI<sup>[30-32,34,35]</sup>. Imaging modalities such as computed tomography (CT) and magnetic resonance imaging (MRI) has not been found very useful in localising the focal lesion<sup>[14]</sup>.

$^{18}\text{F}$ -DOPA-PET/CT was first reported for the localisation of the focal lesion by Riberio *et al*<sup>[13]</sup> in 2005 and Otonkoski *et al*<sup>[36]</sup> in 2006. Since then several studies have shown that  $^{18}\text{F}$ -DOPA-PET/CT provides precise differentiation between focal and diffuse forms albeit exact localisation of the lesion may not be accurately attributed by the scan technique<sup>[13,21,37]</sup>. However,  $^{18}\text{F}$ -DOPA-PET/CT is non-invasive, relatively simple to use and more efficient than the invasive procedures such as PVS, and arterial calcium stimulation tests in differentiating and localising the pancreatic lesions<sup>[38]</sup>. The sensitivity and specificity of  $^{18}\text{F}$ -DOPA-PET/CT in detecting focal lesions measuring between 2 mm and 10 mm is approximately 90% and 100% respectively<sup>[39]</sup>. Thus the use of  $^{18}\text{F}$ -DOPA-PET/CT has revolutionised the surgical outcome in these children with CHI.

## USE OF $^{18}\text{F}$ -DOPA-PET/CT IN CHI

The use of  $^{18}\text{F}$ -DOPA-PET/CT in distinguishing between focal and diffuse CHI was first reported by Riberio *et al*<sup>[13]</sup>, where the authors subjected 15 neonates to  $^{18}\text{F}$ -DOPA-PET scan. Abnormal focal uptake was observed in 5 children and diffuse uptake in the rest. Histopathology findings of all 5 patients with focal lesion and 4 patients with diffuse uptake who underwent surgery matched with their PET scan findings.

Otonkoski *et al*<sup>[36]</sup> used  $^{18}\text{F}$ -DOPA-PET/CT in 14 patients (*ABCC8* mutation in 11/14 patients) and found focal uptake in 5 patients, diffuse uptake in the remaining 9 patients.  $^{18}\text{F}$ -DOPA-PET/CT findings were confirmed by histology in all 5 patients with focal uptake and 4 out of 9 in patients with diffuse uptake. This group also measured the standardized uptake value (SUV) of  $^{18}\text{F}$ -DOPA and found a SUV of  $> 50\%$  higher uptake than the maximum SUV of the unaffected part of the pancreas in the focal group which corresponded with the histology findings. The remaining 9 patients with a diffuse uptake on the  $^{18}\text{F}$ -DOPA-PET/CT scan had a SUV ratio of  $< 1.5$ . Histology findings confirmed diffuse disease in 4 patients and pancreatic venous sampling in 4 patients. The authors concluded by proposing  $^{18}\text{F}$ -DOPA-PET/CT as the best modality of choice in locating a focal lesion<sup>[36]</sup>.

Riberio *et al*<sup>[40]</sup> did a retrospective study in 2007 on forty nine children with CHI who had undergone  $^{18}\text{F}$ -DOPA-PET/CT scanning. They identified abnormal focal pancreatic uptake of  $^{18}\text{F}$ -DOPA in 15 children, where diffuse radio-tracer uptake was observed in the pancreatic area in the other 34 children. They also subjected 12 of the 49 children for pancreatic venous sampling (PVS) and 31 for MRI. In children who underwent both PET and PVS, the results were concordant in 11 out of 12. The authors concluded that PET scan with  $^{18}\text{F}$ -DOPA is an accurate non-invasive technique allowing differential diagnosis between focal and diffuse forms of CHI<sup>[40]</sup>.

Arbizu Lostao *et al*<sup>[41]</sup> reported their first patient from Spain in whom the diagnosis of focal CHI was made in a 13 month old child using combined genetic analysis [paternal heterozygous mutation (G111R) in the *ABCC8* gene] and  $^{18}\text{F}$ -DOPA-PET/CT imaging (focal uptake in the body of the pancreas) was successfully treated by surgery. This case report reiterates the importance of performing combined investigations towards the successful management of CHI.

Barthlen *et al*<sup>[22]</sup> in 2008 reported the correlation of  $^{18}\text{F}$ -DOPA-PET/CT scan findings with the intra-operative findings in 9 out of 10 children. A limited resection was found to be curative in 8 out of 9 children. They also reported their follow up data on these children with no evidence of diabetes or exocrine pancreatic insufficiency<sup>[22]</sup>.

Cherubini *et al*<sup>[42]</sup> have reported that  $^{18}\text{F}$ -DOPA-PET/CT imaging can distinguish between focal and diffuse lesions in majority of the cases and 100% accurate in locating the focal lesion. The authors also highlighted the potentiating effects of non-invasive imaging technique using  $^{18}\text{F}$ -DOPA-PET/CT imaging combined with laparoscopic pancreatic surgery in the prompt localisation and excision of the focal lesion, preventing iatrogenic diabetes mellitus in later life<sup>[42]</sup>.

Yorifuji *et al*<sup>[43]</sup> reported a boy with focal CHI whose disease activity was not consistent with the uptake of  $^{18}\text{F}$  DOPA. A diagnosis of CHI was made on day 2 of his life when he presented with hypoglycaemic seizures. A paternal heterozygous mutation c.4186G 1T (p.D1396Y)

in the *ABCC8* was identified followed by an uptake in the body of pancreas in the  $^{18}\text{F}$ -DOPA-PET/CT scan. A diagnosis of focal CHI was made and he was managed conservatively with frequent feeding regime. He achieved spontaneous remission at 1 year and 10 mo of age and a follow up  $^{18}\text{F}$ -DOPA-PET/CT scan revealed no difference in uptake between the two scans despite achieving clinical remission. Further to this an arterial stimulation venous sampling test was done which showed a low basal and stimulated insulin release illustrating that  $^{18}\text{F}$ -DOPA-PET/CT uptake may not always correlate with the insulin secreting capacity of the  $\beta$ -cells and the spontaneous remission of hypoglycaemia can be a functional process and not due to the apoptotic death of  $\beta$  abnormal cells<sup>[43]</sup>.

Zani *et al*<sup>[44]</sup> evaluated the accuracy of  $^{18}\text{F}$ -DOPA-PET/CT imaging technique in differentiating between focal and diffuse lesions and localisation of the focal lesion. The authors reviewed the results of  $^{18}\text{F}$ -DOPA-PET/CT scan performed in 19 patients. Five of them had diffuse uptake and the same was confirmed by histology. The remaining 14 patients showed a focal uptake which was confirmed by histology however the localisation was not accurate in 5 children leading to incorrect surgical resection. The authors concluded that  $^{18}\text{F}$ -DOPA-PET/CT scan can distinguish between focal and diffuse CHI and the exact localisation in only 2/3 of patients with focal lesions. The authors also suggested undertaking intraoperative histological confirmation of the focal lesion prior to complete excision<sup>[44]</sup>.

Masue *et al*<sup>[45]</sup> reported their experience of the use of  $^{18}\text{F}$ -DOPA-PET/CT in 17 Japanese children by assessing their results either by simple inspection or by calculating the pancreas percentage and compared those results with the genetic analysis and histology. Pancreas percentage is the expression of uptake of the head, body and tail of the pancreas as the total maximum SUV of the whole pancreas. They found the localisation and histology was consistent in all 17 children. However the overall results were consistent with the molecular diagnosis and histology in only 7/17 and 6/12 patients respectively. They also reported a substantial improvement in the accuracy of PET studies by using pancreatic percentage<sup>[45]</sup>.

Ismail *et al*<sup>[12]</sup> reported the marked variation in the clinical, genetic, radiological and histopathological features of focal CHI in 3 of their patients. All 3 of them had paternal heterozygous mutation in *ABCC8* gene (c.3992-9G  $\rightarrow$  A in the first 2 patients and c.4477G  $\rightarrow$  A in third patient). Of the 2 patients, first patient was responded to Diazoxide but not the second patient. The focal lesions in these 2 patients were accurately localised using  $^{18}\text{F}$ -DOPA-PET/CT imaging. Both of them underwent focal lesionectomy and were completely cured. Histology confirmed the presence of focal nodules with large nuclei along with the remaining normal pancreatic tissue in the first 2 patients. The authors proposed that unknown genetic or environmental factors may influence the phenotypic variation in response to treatment and some focal

lesions can respond to medical management. The authors have also highlighted that a paternally inherited c.3992-9G  $\rightarrow$  A mutation in the *ABCC8* gene is associated with a mild focal phenotype responding to medical management in some patients of Ashkenazi Jewish origin<sup>[12]</sup>. This finding is based on previous reports that nearly 90% of CHI in Ashkenazi Jewish population is associated with c.3992-9G  $\rightarrow$  A mutation and p.F1388del in the *ABCC8* gene<sup>[46]</sup>. The third patient had undergone two  $^{18}\text{F}$ -DOPA-PET/CT imaging, with an unusually large focal lesion involving the whole pancreas. The first scan showed the tracer uptake in the body and tail and the second scan performed post lesionectomy showed a tracer uptake in the head of the pancreas and the patient underwent 2 pancreatic surgeries. Macroscopically this patient had a normal looking pancreas but microscopically islet cell nodules with large nuclei were found along with some normal pancreatic tissue. Despite undergoing the second surgery this patient was reported to be dependent on continuous gastrostomy feeds to maintain euglycemia<sup>[12]</sup>.

Giurgea *et al*<sup>[47]</sup> reported that the size of the focal lesion is determined by the timing when the somatic loss of maternal allele occurs during the gestational age<sup>[47]</sup>. The earlier it occurs the larger the size of the focal lesion can be, as found in the 3 patient in this report. Also it has been suggested that an unknown mechanism might play a role in different rate of tracer uptake in different regions of pancreas in large focal lesions<sup>[47]</sup>.

Meintjes *et al*<sup>[26]</sup> recently evaluated and reported the accuracy of delineating the focal and diffuse CHI using  $^{18}\text{F}$  fluoro-L-DOPA/CT and contrast enhanced CT. They performed 22  $^{18}\text{F}$  fluoro-L-DOPA/CT and contrast enhanced CT studies on 18 patients and assessed those results using visual assessment followed by quantitative comparison of SUVs measured by calculating the uptake on head, body and tail of the pancreas. They derived an SUV ratio using the formula-highest SUV (max)/next highest SUV (max). The authors also proposed a time activity curve which showed the focal pancreatic islet uptake relatively constant over time suggesting performing imaging at 20 min and 50 min after the radio tracer injection. The use of intravenous contrast agents during CT provides invaluable information for the surgeons in delineating the anatomical landmarks while performing surgery.

Of the 18 patients 13 showed diffuse with an SUV ratio of  $< 1.3$  and five showed focal uptake with an SUV ratio of  $> 1.5$  with an SUV (max) 50% higher than that of the unaffected area of the pancreas. Out of these five patients four of them had paternal *ABCC8* mutation. All five patients were cured after limited focal resection with three of them requiring second  $^{18}\text{F}$ -L-DOPA/CT and contrast enhanced CT and surgery. Of the 13 patients who had diffuse disease, 9 of them were negative for *ABCC8/KCNJ11* mutations and 3 had positive paternal *ABCC8* mutation. Out of 13, 2 patients underwent surgery and 11 patients remain on high dose Diazoxide treatment one of them had 3 pancreatectomies without

cure. The authors concluded by highlighting the importance of per-operative  $^{18}\text{F}$ -L-DOPA/CT and contrast enhanced CT studies in not only distinguishing between the focal and the diffuse disease but also the precise localisation of the anatomical landmarks<sup>[26]</sup>.

Laje *et al*<sup>[48]</sup> did a retrospective review to determine the accuracy of  $^{18}\text{F}$ -DOPA-PET/CT scan in diagnosing focal CH on 105 children in whom a pre-operative  $^{18}\text{F}$ -DOPA-PET/CT scan was undertaken. Out of 105 patients, 53 patients had focal lesion and the remaining 52 patients had diffuse disease. Eight out of 53 patients with focal lesion were reported to have diffuse disease on their pre-operative  $^{18}\text{F}$ -DOPA-PET/CT scan. The location of the eight missed lesions was head (3), body (2) and tail (3) which showed a homo/heterogeneous tracer uptake throughout the pancreas. Thus the sensitivity of  $^{18}\text{F}$ -DOPA-PET/CT scan in diagnosing a focal lesion was 85% based on this study. Two out of 52 patients with diffuse disease were reported to have focal lesion on their pre-operative  $^{18}\text{F}$ -DOPA-PET/CT scan with a specificity of 96%. The positive predictive value of the study was 96% with 45 out of 47 patients having a true focal lesion. The authors concluded that the sensitivity and specificity of the  $^{18}\text{F}$ -DOPA-PET/CT scan varies based on the location of the lesion and the experience of the radiologists<sup>[48]</sup>.

A meta-analysis was performed and published recently by Yang J and his colleagues reviewing the diagnostic role of  $^{18}\text{F}$ -DOPA PET and  $^{18}\text{F}$ -DOPA PET/CT imaging in CHI in 10 studies involving 181 children. The pooled sensitivity and the specificity in detecting focal CHI using  $^{18}\text{F}$  DOPA PET and PET/CT was reported to be 88% (95%CI: 80%-94%) and 79% (95%CI: 69%-87%) respectively on a per-patient-based analysis in this systematic review. The area under the summary receiver operating characteristic curve (SROC) was estimated to be 0.92% suggesting that  $^{18}\text{F}$ -DOPA PET and PET/CT imaging are accurate tools for distinguishing focal diagnosing CHI, although there is a minimal risk of both false positive and false negative results. The authors concluded that  $^{18}\text{F}$ -DOPA PET is very helpful in differentiating between focal and diffuse lesions, and should be the first investigation of choice when the genetic test results are inconclusive and  $^{18}\text{F}$ -DOPA PET/CT is very helpful in localising the lesion and thereby improving the treatment outcome in focal CHI<sup>[27]</sup>.

Blomberg *et al*<sup>[38]</sup> conducted a systematic review and meta-analysis recently to quantify the diagnostic performance of pancreatic venous sampling (PVS), selective pancreatic arterial calcium stimulation with hepatic venous sampling (ASVS) and  $^{18}\text{F}$ -DOPA-PET/CT in diagnosing and localising focal CH. They reported that  $^{18}\text{F}$ -DOPA-PET/CT is superior in distinguishing focal from diffuse CH with a summary diagnostic odds ratio (DOR) of 73.2 when compared to PVS (summary DOR 23.5) and ASVS (summary DOR, 4.3). Also the pooled accuracy for localising a focal lesion by  $^{18}\text{F}$ -DOPA-PET/CT is higher (0.82) when compared to PVS (0.76) and ASVS

(0.64). Thus this review concluded that  $^{18}\text{F}$ -DOPA-PET/CT is superior in diagnosing and localising focal CHI lesion in patients requiring surgery albeit the limitation of the review is the inclusion of small sample sizes and high probability of bias leading to the overestimation of diagnostic accuracy<sup>[38]</sup>.

## ECTOPIC PANCREAS AND THE ROLE OF $^{18}\text{F}$ -DOPA-PET/CT

The pancreas begins to develop from the distal end of the foregut endoderm during the fourth week when both the dorsal and ventral pancreatic buds grow into the mesogastrium<sup>[49]</sup>. Thus the pancreatic acinar and the islet cells are derived from the endodermal cells lining the upper and duodenal region of the foregut<sup>[50]</sup>. During the course of this development an ectopic pancreatic tissue may occur in the stomach, duodenum, jejunum, ileum and rarely in Meckel's diverticulum, appendix, biliary tract or lungs<sup>[49]</sup>.

There have been reports of ectopic pancreatic tissue causing CHI in both adults and children. We reported a child with persistent and severe hyperinsulinaemic hypoglycaemia (HH) despite undergoing three pancreatectomies with a choledochoduodenostomy and a cholecystectomy. An  $^{18}\text{F}$ -DOPA-PET/CT scan localised the ectopic lesion in the vicinity of the former head of pancreas. The same lesion was found to be localized near the duodenum, either in the duodenal wall or cavity on the magnetic resonance scan (MRI). He is subsequently managed medically<sup>[33]</sup>.

Peranteau *et al*<sup>[51]</sup> in 2007 reported another patient with persistent hypoglycaemia despite undergoing a near-total pancreatectomy. A subsequent  $^{18}\text{F}$ -DOPA-PET/CT scan demonstrated one focus in the remnant pancreatic head and 3 in the abdomen. The lesion in the pancreatic remnant was removed completing a total pancreatectomy and further abdominal exploration revealed 4 pancreatic ectopic rests in the jejunum. The lesions were surgically removed and the histopathology confirmed focal islet cell hyperplasia in all the lesions. This patient required insulin therapy for a short term post operatively.

In both of these patients  $^{18}\text{F}$ -DOPA-PET/CT scan was performed post near total pancreatectomy with the persistence of hypoglycaemic symptoms. However a preoperative localisation of the focal lesions would have led to the removal of local and ectopic lesions and preservation of the rest of the pancreas. Thus the use of  $^{18}\text{F}$ -DOPA-PET/CT scan in the management of CHI is justified in identification of both focal lesions within the pancreas and ectopic pancreatic tissue<sup>[51]</sup>.

A standardised protocol for the use of  $^{18}\text{F}$ -DOPA-PET/CT was derived in 2005 and advocated to achieve maximum acquisition with minimum radiation. This guideline was derived based on the survey conducted in 2005 reviewing the experience of all the PET centres. The result of the survey showed that  $^{18}\text{F}$ -DOPA-PET/CT has 94% sensitivity and 100% specificity. Thus pre-

operative performance of  $^{18}\text{F}$ -DOPA-PET/CT has been proposed as the most accurate way of localising the focus enabling limited resection and thereby preventing the risk of iatrogenic diabetes<sup>[14]</sup>. Studies recommended performing  $^{18}\text{F}$ -DOPA/CT studies only in tertiary endocrine centre equipped with necessary expertise to perform and interpret the results<sup>[14]</sup>.

## CONCLUSION

We conclude that  $^{18}\text{F}$ -DOPA-PET/CT is a safe, non-invasive and the most preferred investigation of choice (1) to distinguish between the focal and diffuse forms of CHI; and (2) to enable accurate localisation and enucleation of the focal lesion preventing the risk of developing iatrogenic diabetes mellitus and pancreatic insufficiency. However a multi-disciplinary team (MDT) approach is essential and has to be undertaken in a tertiary centre built-in with necessary expertise for the successful interpretation and management of CHI patients.

### Abstract

To provide a systematic review of scientific literature on functional magnetic resonance imaging (fMRI) studies on sustained attention in psychosis. We searched PubMed to identify fMRI studies pertaining sustained attention in both affective and non-affective psychosis. Only studies conducted on adult patients using a sustained attention task during fMRI scanning were included in the final review. The search was conducted on September 10<sup>th</sup>, 2013. 15 fMRI studies met our inclusion criteria: 12 studies were focused on Schizophrenia and 3 on Bipolar Disorder Type I (BDI). Only half of the Schizophrenia studies and two of the BDI studies reported behavioral abnormalities, but all of them evidenced significant functional differences in brain regions related to the sustained attention system. Altered functioning of the insula was found in both Schizophrenia

and BDI, and therefore proposed as a candidate trait marker for psychosis in general. On the other hand, other brain regions were differently impaired in affective and non-affective psychosis: alterations of cingulate cortex and thalamus seemed to be more common in Schizophrenia and amygdala dysfunctions in BDI. Neural correlates of sustained attention seem to be of great interest in the study of psychosis, highlighting differences and similarities between Schizophrenia and BDI.

**Key words:** Sustained attention; Affective psychosis; Non-affective psychosis; Schizophrenia; Bipolar disorder; Functional magnetic resonance imaging; Insula

**Core tip:** In the present paper, we systematically reviewed functional magnetic resonance imaging studies investigating sustained attention in affective and non-affective psychosis. We found that differences between cases (patients, unaffected relatives of psychotic probands) and controls in terms of functional activation of sustained attention system structures were detectable even when the groups performed comparably. In particular, the insular cortex seems to be a trait marker for psychosis in general, whereas other regions (thalamus, cingulate cortex, amygdala) seem to be differently impaired in affective and non-affective psychosis.

### INTRODUCTION

Sustained attention can be defined as the ability to main-

tain a high vigilance level for prolonged periods of time, allowing the subjects to respond in an appropriate way to infrequent and unpredictable stimuli<sup>[1]</sup>.

Abnormalities in sustained attention have been reported in both schizophrenic<sup>[2-4]</sup> and Bipolar Disorder (BD) patients<sup>[5-8]</sup> and several studies suggested a correlation with a worse prognosis and a poorer quality of life<sup>[9-12]</sup>. Sustained attention deficits seem to be independent from medications<sup>[13,14]</sup> and illness states<sup>[15]</sup>. Studies comparing directly schizophrenic and BD patients found that the two groups were qualitatively similar in sustained attention deficits<sup>[16]</sup>, even though schizophrenic patients were usually quantitatively more impaired<sup>[17-20]</sup>. A reduced attentional performance has also been highlighted in non-affected relatives of schizophrenic<sup>[21,22]</sup> and bipolar patients<sup>[23]</sup>: it has been therefore proposed as a candidate endophenotype for both affective<sup>[24-26]</sup> and non-affective psychosis<sup>[27-30]</sup>. Candidate endophenotypes must be associated with illness, state independent, heritable, and found in unaffected relatives of probands at a higher rate than in general population<sup>[31]</sup>. By contrast, some behavioral studies failed to find any significant performance deficit in schizophrenic patients<sup>[32]</sup>, in bipolar patients<sup>[33]</sup> or in unaffected relatives of bipolar probands<sup>[34,35]</sup>, so the role of sustained attention as a trait-marker of psychosis is still controversial. The discordant results reported in scientific literature may be due to the differences in experimental paradigms and inclusion/exclusion criteria.

The most commonly used tasks to assess sustained attention are the “oddball paradigms”, where subjects are required to identify rare and unpredictable target stimuli presented among a stream of frequent non-target stimuli<sup>[36,37]</sup> or among both frequent and rare non-target stimuli, usually called “standards” and “novels” respectively<sup>[38,39]</sup>. A particular kind of oddball paradigm is the Continuous Performance Test (CPT), initially developed by Beck *et al.*<sup>[40]</sup> and nowadays considered a well validated instrument to measure sustained attention in both research and clinical settings<sup>[41]</sup>. There are numerous versions of CPT, differing from one another for the sensorial modalities (visual or auditory)<sup>[42,43]</sup> the perceptual complexity of the stimuli (CPT with degraded stimuli: DS-CPT)<sup>[44]</sup> and the response required: only on targets, on both targets and non-targets and only on non-targets (Conners’ CPT II)<sup>[45]</sup>. Other CPT versions increase the number of stimuli presented per minute to intensify the attentional load (*e.g.*, the Rapid Visual Information Processing task, RVIP)<sup>[46]</sup>. Some CPTs are designed to assess both sustained attention and working memory resources, *e.g.*, the CPT-AX (a character or number preceded by another character or number as a target)<sup>[47]</sup> or the CPI-IP (identical pairs of stimuli as a target)<sup>[48]</sup>. Several scores are used to measure the behavioral performance in oddball paradigms: the rate of correct targets (“hits”, “H”) and incorrect targets (“omission errors”); the rate of correct non-target (“correct rejections”) and incorrect non-target (“false alarms”, “FA”) “commission”) and the mean reaction times (RT) to the stimuli. Subjects who respond accurately and rap-

idly to both target and non-target are considered good performers, whereas a high number of omissions indicate a reduced attention and a high number of commissions indicate augmented impulsivity. Using the signal detection theory<sup>[49]</sup> other measures of accuracy may be calculated, such as the sensitivity index ( $d'$ ,  $d\text{-prime}$ ), its nonparametric analog ( $A'$ ,  $A\text{-prime}$ ) and the response criterion ( $B''$ , beta,  $\ln b$ ).  $d'$  is the standardized difference between hit rate and false alarm rate [ $d' = z(\text{Hits}) - z(\text{False alarms})$ ] and it is considered a good measure of discriminability.  $B''$  instead represents an index of response bias, the subject's tendency to under respond or over respond [ $B'' = (1-H) - FA(1-FA)/H(1-H)+FA(1-FA)$ ].

Functional neuroimaging studies increase the possibility to detect subtle differences in brain functioning even in behaviorally intact subjects. In healthy individuals, sustained attention tasks usually elicit a widespread cortical and subcortical network, including dorsal and medial prefrontal cortex, parietal, temporal and occipital areas, cingulate gyrus, insula, cerebellum, and basal ganglia<sup>[50-53]</sup>. Different components of sustained attention have their anatomical and functional correlates in different brain regions: subcortical structures have been associated with arousal control, dorsal frontal and temporoparietal cortex with attention maintenance over time, and anterior ventromedial regions, such as anterior cingulate cortex (ACC) and anterior insula, with conflict monitoring, target detection and error signaling<sup>[54]</sup>. Moreover, ACC and insula are reported to play a crucial role in emotional regulation, linking emotion to cognition<sup>[55,56]</sup>.

The aim of the present paper is to review fMRI correlates of sustained attention in affective and non-affective psychosis, discussing the literature findings and the role of sustained attention as a candidate endophenotype for psychotic disorders.

## SEARCH

We searched PubMed to identify functional magnetic resonance (fMRI) studies investigating sustained attention in affective and non-affective psychosis. The following search words were used, both alone and in combination: sustained attention, fMRI, affective psychosis, non-affective psychosis, Schizophrenia, Bipolar Disorder. The search was conducted on September 10<sup>th</sup>, 2013 and yielded 42 records. Moreover, we manually checked the reference lists of the identified articles and we found 9 further potential studies, for a total number of 51 records. Inclusion criteria were the following: articles written in English, patients' age  $\geq 18$  years, psychotic patients and/or subjects at augmented risk for psychosis, studies providing both behavioral and fMRI results during a sustained attention task. Structural MRI studies and fMRI studies reporting data acquired during paradigms other than sustained attention tasks or during resting state were excluded.

By reading titles and abstracts, we excluded 18 records. By reading the full texts of the 33 remaining arti-

Figure 1 Flow chart of the systematic review. fMRI: Functional magnetic resonance imaging.

cles, we identified 15 papers meeting our inclusion criteria and therefore included in the qualitative synthesis (Figure 1).

## RESEARCH

A total number of 578 subjects was tested by the 15 studies included in the qualitative synthesis: 272 normal comparisons (NC), 173 schizophrenic patients (SCZ), 17 unaffected relatives of schizophrenics (REL-SCZ), 10 subjects at ultra high risk for Schizophrenia (UHR-SCZ), 84 Bipolar Disorder type I patients (BDI) and 22 unaffected relatives of BDI patients (REL-BDI). The majority of SCZ were male (68.8%), conversely to what observed in BDI, where males represented only 30.9% of the total.

### Sustained attention in schizophrenia

A total number of 12 studies was selected<sup>[57-68]</sup>. The characteristic of the groups and the results of the studies are depicted in Table 1.

Right handedness was an inclusion criteria in 6 studies<sup>[57,59,60,63,66,68]</sup>. Nine studies enrolled only SCZ, one had both a SCZ group and an additional group of UHR-SCZ<sup>[61]</sup> and two had only REL-SCZ<sup>[66,68]</sup>. In the study by Morey *et al.*<sup>[61]</sup>, patients were divided into early SCZ (mean illness duration 1.7 years) and chronic SCZ (mean illness duration 15.3 years). In the study by Honey *et al.*<sup>[60]</sup>, patients were divided into SCZ with both negative and positive symptoms ( $n = 11$ ) and SCZ with predominantly positive symptoms ( $n = 11$ ). The SCZ ( $n = 173$ ) enrolled in the studies were clinically stable and in the majority of cases were medicated (range: 87.5%-100%). Only 2 of the 10 UHR-SCZ received medications at the moment of the scanning, whereas all the REL-SCZ ( $n = 17$ ) and the NC ( $n = 204$ ) were drug naïve. In seven of the 10 studies including a SCZ group, the mean illness duration was also reported<sup>[58-63,65]</sup> and it ranged from 1.7 to 33 years. The

UHR-SCZ group in the study by Morey *et al.*<sup>[61]</sup> met at least one of the following criteria: (1) reporting brief intermittent psychotic states; (2) reporting attenuated positive symptom states; and (3) being first-degree relatives of schizophrenic/schizotypal probands plus reporting a significant recent loss of social/work functioning. The 11 REL-SCZ enrolled by Sepede *et al.*<sup>[68]</sup> were all unaffected siblings of schizophrenic patients, whereas the 6 REL-SCZ enrolled by Filbey *et al.*<sup>[66]</sup> were presumed obligate carriers of schizophrenia (POCs): unaffected subjects having a first-degree relative (sibling or parent) plus a child affected by schizophrenia. Ten of the 12 studies used visual stimuli, whereas the other two<sup>[62,65]</sup> used auditory stimuli. The tasks administered were: oddball tasks ( $n = 4$ ), CPT-X ( $n = 1$ ), DS-CPT-X ( $n = 2$ ), CPT-IP ( $n = 2$ ), RVIP ( $n = 1$ ), and other attention tasks ( $n = 2$ ), with a total duration of the experiment ranging from 6 to 49 min.

fMRI images were acquired using a 1.5 T scanner in seven studies, a 3 T scanner in 2 studies and a 4 T scanner in three studies. A block design was used to present the tasks in six studies, whereas an event-related design was used in other five studies. Only one study<sup>[67]</sup> used a block/event-related mixed design. A whole brain approach was used in eight studies to analyze the BOLD fMRI signal whereas three studies<sup>[60,61,67]</sup> used a region of interest (ROI) approach and/or a masked brain analysis, limiting the analysis to areas known to be involved in sustained attention processing and/or to areas showing significant between-group or within-condition differences. Only one study<sup>[64]</sup> used the ROI analysis after the whole brain analysis. In the study by Honey *et al.*<sup>[60]</sup>, connectivity analyses were also performed.

### Behavioral results

In four of the ten studies involving SCZ ( $n = 57$ ), no significant behavioral differences were found with respect to NC<sup>[57,58,63,64]</sup>. In the other six studies, SCZ ( $n = 116$ ) performed worse than NC: a reduced accuracy was evi-

**Table 1 Functional magnetic resonance imaging studies of sustained attention in Schizophrenia**

Ref.	Participants	Task and behavioral results	fMRI methods and results
Volz <i>et al</i> <sup>[57]</sup> , 1999	SCZ ( <i>n</i> = 14), age 34.1 ± 12.3, males 78.6%, medicated 100%  NC ( <i>n</i> = 20), age 28.2 ± 5.7, males 60%	CPT-IP. Type of stimuli: letters TNS = 720, Target = 25%, SET = 600 ms, ISI = 1200 ms, TET = 30 min Required response: on targets. Behavioral measures: hit rate, mean RT, <i>d'</i> , <i>ln b</i> Results: no between group differences	1.5 T, block design (4 blocks). baseline: finger tapping Whole brain analysis. Imaging package: SPM96 Results: NC > SCZ in the R mesial PFC, ACC and L TH
Eyler <i>et al</i> <sup>[58]</sup> , 2004	SCZ ( <i>n</i> = 8)/SCA ( <i>n</i> = 1) age 58.9 ± 9.9, males 55.6%, illness duration: 33 yr, medicated 100% NC ( <i>n</i> = 10), age 59.8 ± 5.7, 12 males 60%	CPT-X. Type of stimuli: letters. TNS = 72 Target = 33.3% ISI = 500 ms, TET = 6 min 3 s  Required response: on targets Behavioral measures: mean RT, <i>d'</i> Results: no between group differences	1.5 T, block design. baseline: digit fixation 8 task blocks and 9 baseline blocks Whole brain analysis. Imaging package: AFNI Results: NC > SCZ in R IFG/insula (BA 47/45) SCZ > NC in R postcentral gyrus (BA 3) and L cerebellum
Salgado-Pineda <i>et al</i> <sup>[59]</sup> , 2004	SCZ ( <i>n</i> = 14), age 25.5 ± 4.1, males 50%, medicated 100%, illness duration: 1.9 yr NC ( <i>n</i> = 14), age 25.1 ± 3.3, males 50%	CPT-IP. Type of stimuli: numbers. TNS = 900 Target = 15% ISI = 1100 ms, TET = 14min  Required response: on targets Behavioral measures: omission errors, commission errors, mean RT, <i>d'</i> , <i>ln b</i> Results: Between group differences -omissions, commission and <i>d'</i> : NC > SCZ -mean RT: SCZ > NC	1.5 T, block design. baseline: digit response 2 task blocks and 2 baseline blocks. Whole brain analysis. Imaging package: SPM2 Results: NC > SCZ in R IFG (BA 44), R angular gyrus (BA 39), R STG (BA 37), R MTG (BA 21), R TH
Honey <i>et al</i> <sup>[60]</sup> , 2005	N-SCZ: SCZ with both negative and positive symptoms: ( <i>n</i> = 11), age 42.6 ± 9.2, males 90.9%, age of onset: 22.2 yr, medicated 100%  P-SCZ: SCZ with predominant positive symptoms: ( <i>n</i> = 11) age 41.1 ± 9.2, males 81.8%, age of onset: 24.7 yr, medicated 100%  NC ( <i>n</i> = 12), age 33.3 ± 11.8, 12 males 83.3%	CPT-X with 2 levels of difficulty: undegraded and degraded stimuli (0% and 40% pixel inverted). Type of stimuli: digits TNS = 280 Target = 25% SET = 42 ms, ISI = 958 ms TET = 6 min  Required response: on targets Behavioral measures: mean RT, <i>d'</i> Results: N-SCZ were less accurate than NC in target discrimination ( <i>d'</i> )	3T, block design, baseline: screen fixation 10 task blocks and 10 baseline blocks. Imaging package: SPM2 Masked brain analysis (ROIs involved in attention processing, differentiating the groups and showing a task related activity associated to attentional load). Connectivity analysis (seed ROIs: ACC and cerebellar vermis) Results Task <i>vs</i> baseline: NC > (P-SCZ = N-SCZ) in R and L angular gyrus, MFG, L putamen (P-SCZ = N-SCZ) > NC in R and L SFG, R and L IPL, R SPL, R post central gyrus, L precentral gyrus, R and L TH, ACC, PCC, R MiFG, R IFG, cerebellum; P-SCZ > N-SCZ in R STG, R MiFG and L SPL Connectivity with ACC: NC > (P-SCZ = N-SCZ) in R and L MSFG, R and L IFG; (P-SCZ = N-SCZ) > NC in R and L precentral gyrus, R postcentral gyrus, cerebellum; P-SCZ > N-SCZ in ACC; N-SCZ > P-SCZ in SMA Connectivity with cerebellum: NC > (P-SCZ = N-SCZ) in R and L MSFG, L MFG; (P-SCZ = N-SCZ) > NC in L MiFG; P-SCZ > N-SCZ in R and L IFG, ACC, L SPL, R precentral gyrus, L postcentral gyrus
Morey <i>et al</i> <sup>[61]</sup> , 2005	UHR ( <i>n</i> = 10), age 22.6 ± 4.4, male 50%, medicated 20%,  Early SCZ ( <i>n</i> = 15) age 24.1 ± 6.5, male 67%, age of onset 22.3 yr, illness duration 1.7 yr, medicated 86.7%	Visual oddball task Type of stimuli: circles ("targets"), squares (frequent non targets-"standards"), objects (rare non targets-"novels")  TNS = 1400 Target = 3% SET = 500 ms, ISI = 1500 ms, TET = 36 min 24 s Required response: on both targets and non-targets	1.5T, 7 runs. Event-related design. Imaging package: SPM99 ROI analysis: ACC, MiFG, IFG, BG, and TH. Conditions: -Targets -Novels -Standards (baseline) Results Targets <i>vs</i> novels activations -in ACC, MiFG and IFC: NC > UHR, Early SCZ and Chronic SCZ -in IFG: (1) NC > Early SCZ and Chronic SCZ; (2) only NC and UHR showed R > L activations, whereas Early SCZ and Chronic SCZ showed a reduced laterality

Liddle <i>et al</i> <sup>[62]</sup> , 2006	Chronic SCZ ( <i>n</i> = 11) age 38.1 ± 7.7, male 82%, age of onset 22.9 yr, illness duration 15.3 yr, medicated 100%	Behavioral measures: hit rate, <i>d'</i> , <i>B''</i>	Target <i>vs</i> baseline activations: -in ACC, MiFG and IFC: NC > Early SCZ and Chronic SCZ -in BG and TH: NC > Early SCZ and Chronic SCZ (results confirmed comparing Chronic SCZ with Older NC)
	NC ( <i>n</i> = 16) age 28.0 ± 11.6, male 59%	Results: Between group differences: -Hit rate: NC > Early SCZ and chronic SCZ - <i>d'</i> : NC > UHR, Early SCZ and Chronic SCZ	
	Older NC ( <i>n</i> = 10) age 34.0 ± 12.1, male 67%	Auditory oddball task Type of stimuli: 1500 Hz tones ("targets"), 1000 Hz tones (frequent non targets-"standards"), noises (rare non targets-"novels")	1.5 T, event related design, whole brain analysis Imaging package: SPM99. Conditions: -correct targets -correct novels -correct standards (baseline) -missed targets -standard false alarms
	SCZ ( <i>n</i> = 24)/SCA ( <i>n</i> = 4) age 31.6 ± 10.1, males 67.9%, illness duration 7 yr, medicated 96.4%	TNS = 488 Target = 10% SET = 200 ms, ISI = 2000 ms, TET = 16 min Required response: on targets Behavioral measures: RT, omissions, commissions Results: SCZ were significantly slower and less accurate than NC	Results Targets <i>vs</i> baseline activations: NC > SCZ: in L and R amygdala, R hippocampus, R and L STS, L and R insula, R and L orbitofrontal cortex (BA 47), ACC, PCC, L and R SPL, R and L IPL, L and R middle IFG, L and R superior MFG, L and R TH, L and R striatum, L and R cerebellum
Gur <i>et al</i> <sup>[63]</sup> , 2007	NC ( <i>n</i> = 28), age 28.2 ± 8.9, males 75 %	Visual oddball task. SCZ: Schizophrenic patients; NC: Normal comparisons; SCA: Schizoaffective patients; REL-SCZ: Unaffected first degree relatives of schizophrenic patients; POC-SCZ: Presumed Obligate carriers of schizophrenic patients; UHR: Ultra high risk subjects; SET: Stimulus exposure time; ISI: Interstimulus interval; TNS: Total number of stimuli; TNT: Total number of targets; TET: Total experiment time; RT: Response time; R: Right; L: Left; PFC: Prefrontal cortex; ACC: Anterior cingulate cortex; PCC: Posterior cingulate cortex; MFG: Medial frontal gyrus; MSFG: Medial superior frontal gyrus; IFG: Inferior frontal gyrus; SFG: Superior frontal gyrus; SMA: Supplementary motor area; IPL: Inferior parietal lobule; SPL: Superior parietal lobule; IPS: Intraparietal sulcus; MTG: Middle temporal gyrus; STG: Superior temporal gyrus; STS: Superior temporal sulcus; MOG: Middle occipital gyrus; IOG: Inferior occipital gyrus; TH: Thalamus; BG: Basal ganglia.

denced by Honey *et al*<sup>[60]</sup> and Morey *et al*<sup>[61]</sup>, whereas Wolf *et al*<sup>[65]</sup> reported an increased mean reaction time and Salgado *et al*<sup>[59]</sup>, Liddle *et al*<sup>[62]</sup> and Carter *et al*<sup>[67]</sup> reported both reduced accuracy and increased mean reaction times with respect to NC. In their 10 UHR subjects, Morey *et al*<sup>[61]</sup> reported a reduced accuracy. On the contrary, the 17 REL-SCZ enrolled by Filbey *et al*<sup>[66]</sup> and Sepede *et al*<sup>[68]</sup> performed similarly to controls.

## FMRI results

Significant between-group differences in several brain regions were found in all the selected studies, even when the groups performed comparably. The most reported

differences were observed in cingulate gyrus, thalamus (TH), inferior parietal lobule (IPL), inferior frontal gyrus (IFG) and insula. The anterior part of the cingulate cortex (ACC) significantly differentiated the groups in seven studies: SCZ showed a reduced activation with respect to NC in 4 SCZ groups<sup>[57,61-63]</sup>, and the same pattern was observed in the UHR subjects enrolled by Morey *et al*<sup>[61]</sup> and in the REL-SCZ enrolled by Sepede *et al*<sup>[68]</sup>. By contrast, two studies<sup>[60,65]</sup> reported an augmented activation in SCZ with respect to NC. Also the posterior part of the cingulate cortex (PCC) significantly differentiated the groups in six studies. Honey *et al*<sup>[60]</sup> reported an increased activation in the SCZ with respect to NC, whereas a decreased

activation was found by Gur *et al.*<sup>[63]</sup> and Liddle *et al.*<sup>[62]</sup> Interestingly, in three studies, the PCC was reported to be deactivated during attention task, with respect to the baseline/control task, and the amount of the deactivation was larger in SCZ<sup>[64]</sup> and REL-SCZ<sup>[66,68]</sup> with respect to NC. A significant hypoactivation of the IFG was found in five studies<sup>[58-62]</sup>. The medial regions of the prefrontal cortex, located dorso-rostrally with respect to the cingulate cortex, appeared to be hyperactivated in SCZ<sup>[57,60]</sup> or REL-SCZ<sup>[68]</sup>.

The insular cortex significantly differentiated the groups in five studies. A reduced activation in SCZ was reported bilaterally by Liddle *et al.*<sup>[62]</sup> and limited to the right hemisphere by Eyler *et al.*<sup>[58]</sup> By contrast, Gur *et al.*<sup>[63]</sup> found a reduced activation in the R insula, counterbalanced by an augmented activation in the L insula, and Wolf *et al.*<sup>[65]</sup> reported a bilateral augmented activation. In the event-related study by Sepede *et al.*<sup>[68]</sup>, REL-SCZ hyperactivated the bilateral insula during correct target responses and hyperactivated the L insula during wrong target responses. An altered functioning of the inferior parietal lobule (IPL) was detected in 4 studies, three showing a reduced activation in SCZ with respect to NC<sup>[60,62,66]</sup>, one an increased activation<sup>[63]</sup>. Other parietal regions were also reported to differentiate the groups. In the angular gyrus Salgado *et al.*<sup>[59]</sup> and Honey *et al.*<sup>[60]</sup> reported a reduced activation, Gur *et al.*<sup>[63]</sup> an increased activation; in the superior parietal lobule (SPL) Liddle *et al.*<sup>[62]</sup> and Filbey *et al.*<sup>[66]</sup> found a reduced activation, Honey *et al.*<sup>[60]</sup> an increased activation in SCZ with respect to NC.

When considering the subcortical regions, SCZ significantly hyperactivated the TH in six studies<sup>[57,59,61,62,63,67]</sup>, whereas Sepede *et al.*<sup>[68]</sup> found an increased activation during wrong target responses in REL-SCZ. Other subcortical structures, such as the basal ganglia, appeared to be less activated in SCZ with respect to NC in 4 studies<sup>[60,61,63]</sup>.

## SUSTAINED ATTENTION IN BIPOLAR DISORDER

Three studies enrolled BDI patients<sup>[69-71]</sup> and one of these studies had also a group of unaffected, drug-naïve, BDI-REL<sup>[71]</sup>. The characteristic of the groups and the results of the studies are depicted in Table 2. Right handedness was an inclusion criteria in two studies<sup>[69,71]</sup>. The BDI ( $n = 84$ ) enrolled in the three studies were euthymic ( $n = 34$ ) or affected by a manic/mixed episode ( $n = 50$ ). About 80% of the 74 patients in the studies by Fleck *et al.*<sup>[70]</sup> and Sepede *et al.*<sup>[71]</sup> were under medication at the moment of the fMRI scanning, whereas the 10 BDI in the study by Strakowski *et al.*<sup>[69]</sup> were drug free. All the NC ( $n = 68$ ) and the BDI-REL ( $n = 22$ ) were drug naïve. In two of the studies<sup>[69,71]</sup>, the mean illness duration was also reported and it was 2.2 and 4.7 years respectively. The presence of psychotic features during the acute phases of the illness (95.8%) was reported only by Sepede *et al.*<sup>[71]</sup> All the three selected studies used a visual CPT to assess sustained at-

tention (CPT-IP:  $n = 2$ ; DS-CPT-X:  $n = 1$ ), with a total duration of the experiment ranging from 6 to 15 min.

fMRI images were acquired using a 1.5 T ( $n = 1$ ), a 3 T ( $n = 1$ ) or a 4 T ( $n = 1$ ) scanner, presenting the tasks with an event-related design ( $n = 2$ ) or a block design ( $n = 1$ ). A whole brain approach was used in two studies to analyze the BOLD fMRI, whereas Fleck *et al.*<sup>[70]</sup> performed a whole brain analysis followed by a ROI analysis.

## Behavioral results

In their group of 10 euthymic and unmedicated BDI, Strakowski *et al.*<sup>[69]</sup> did not find any behavioral deficit with respect to NC. On the contrary, both Fleck *et al.*<sup>[70]</sup> and Sepede *et al.*<sup>[71]</sup> reported a reduced target accuracy in their manic/mixed ( $n = 50$ ) or euthymic ( $n = 24$ ) BDI patients. An impaired performance was also found in the group of 22 unaffected and unmedicated BDI-REL enrolled by Sepede *et al.*<sup>[71]</sup>.

## fMRI results

Significant between-group differences in several brain regions were found in all the three selected studies, even when the groups performed comparably. The regions more reported to differentiate the groups were: IFG, insula, amygdala and IPL.

The IFG/insula showed an altered pattern of activation in all the three selected studies: an augmented activation in BDI with respect to NC was found by Strakowski *et al.*<sup>[69]</sup>, whereas Fleck *et al.*<sup>[70]</sup> reported a reduced activation. In the study by Sepede *et al.*<sup>[71]</sup>, BDI showed a reduced activation during correct target responses and an augmented activation during wrong target responses, with REL-BDI showing an intermediate pattern of functioning between BDI and NC. The amygdala was found to be more activated with respect to NC in two studies, involving euthymic<sup>[69]</sup> or manic<sup>[70]</sup> BDI. The IPL seemed to be hyperactivated in the euthymic BDI enrolled by Strakowski *et al.*<sup>[69]</sup> and in the REL-BDI by Sepede *et al.*<sup>[71]</sup>.

## DISCUSSION

In this paper we systematically reviewed fMRI studies on sustained attention in affective and non-affective psychosis.

We found several studies on Schizophrenia that met our inclusion criteria, whereas the publications on BDI were very few. This result is quite surprising, considering the large amount of behavioral data that reported sustained attention deficits in both acute and euthymic phases of BDI.

Summarizing the literature findings on affective and non-affective psychosis, we highlighted that patients and at-risk subjects significantly differed from healthy comparisons in the functioning of several brain regions belonging to the sustained attention system, even when they were behaviorally intact. There were regions that seemed more impaired in Schizophrenia, other more impaired in Bipolar Disorder and other that appeared altered in both

**Table 2 Functional magnetic resonance imaging studies of sustained attention in bipolar disorder**

Ref.	Participants	Task and behavioral results	FMRI methods and results
Strakowski <i>et al</i> <sup>[69]</sup> , 2004	BDI ( <i>n</i> = 10), age 25.5 ± 8.1, males 40%, euthymic, age of onset 23 yr, illness duration 2.2 yr, medicated 0% (drug free)  NC ( <i>n</i> = 10), age 25.3 ± 7.3, males 40%	CPT-IP. Type of stimuli: digits TNS = 400 SET = 700 ms, ISI = 750, TET = 6 min  Required response: on targets. Behavioral measures: <i>d'</i> , percent correct, percent false positive Results: no between-group differences	3T, block design, 5 task blocks and 5 baseline blocks Baseline: digits fixation Whole brain analysis. Imaging package: CHIPS  Results: BDI > NC in: R IFG/insula (BA 13/47), R and L ventral PFC (BA 10/47), parahippocampus/amygdala (BA 34), MOG/MTG (BA 18/19/39), R IPL (BA 40), R SPL (BA 7/40), L postcentral gyrus (BA 43), hypothalamus; NC > BDI in: L fusiform gyrus (BA 20) and L MFG (BA 11)
Fleck <i>et al</i> <sup>[70]</sup> , 2012	BDI ( <i>n</i> = 50), age 30 ± 10, males 30%, manic, medicated 80%  NC ( <i>n</i> = 34), age 31 ± 9, males 41%	CPT-IP. Type of stimuli: digits TNS = 900, Target = 15%, SET = 750 ms, ISI = 1000 ms, TET = 15 min  Required response: on targets Behavioral measures: <i>A'</i> , <i>B''</i> , RT, correct rejection Results: patients performed worse in terms of correct rejections and showed a trend <i>vs</i> a reduced <i>A'</i>	4T, Event-related design, 3 runs (periods) Whole brain analysis. Imaging package: AFNI ROi based analysis: anterior-limbic network (IFG, BG, TH, amygdala, cerebellar vermis) + SFG Baseline: visual count down condition Task conditions: -hits, misses and false alarms -correct rejections on non-targets Results: In period 1: NC > BD in cerebellum; BD > NC in TH; NC > BD in deactivation of L PCC and R angular gyrus In period 2: NC > BD in bilateral IFG and L TH In period 3: NC > BD in activation of R IFG Over time: BD activated and NC deactivated L striatum and bilateral amygdala Unmedicated BD > medicated BD in activation of R IFG and cerebellum
Sepede <i>et al</i> <sup>[71]</sup> , 2012	BDI ( <i>n</i> = 24), age 34.8 ± 8.0, males 41.7%, euthymic, age of onset 29.9, illness duration 4.7 yr, psychotic features during acute phases 95.8%, medicated 83.3%  REL-BDI ( <i>n</i> = 22), age 31.5 ± 7.3, males 31.8% medicated 0% (drug naïve)  NC ( <i>n</i> = 24), age 32.5 ± 6.2, males 33.3%	CPT-X with 2 levels of difficulty: undegraded and degraded stimuli (0% and 40% pixel inverted) Type of stimuli: digits TNT = 80, Target = 20%, TNS = 408 ± 30 SET = 200 ms, ISI = 2000 ms, TET = 14 min  Required response: on targets and non-targets Behavioral measures: correct target, correct non-targets, incorrect target, incorrect non-target, mean RT  Results: both BDI and REL-BDI were less accurate than NC in target recognition (percent correct target)	1.5T, event-related design, 2 runs (0%, and 40% degraded). Whole brain analysis. Imaging package: BrainVoyager QX 1.9. Task conditions: -correct responses on target -incorrect responses on target -correct responses on non-targets (baseline)  Results Correct target <i>vs</i> baseline: (NC = REL-BDI) > BDI in R insula (BA13) REL-BDI > (NC = BDI) in deactivating PCC/retrosplenial cortex (BA 23/29) During the 40% degraded run, correct target condition: REL-BDI > (NC = BDI) in R and L IPL (BA 40), L insula/IFG (BA 13/45) Incorrect target <i>vs</i> baseline: (BDI = REL-BDI) > NC in middle PCC (BA 31) and R insula/IFG (BA 13/45) BDI > REL-BDI > NC in L insula (BA 13)

BDI: Bipolar disorder type 1 patients; REL-BDI: Unaffected relatives of bipolar disorder type 1 patients; NC: Normal comparisons; PFC: Prefrontal cortex; ACC: Anterior cingulate cortex; PCC: Posterior cingulate cortex; MFG: Medial frontal gyrus; SFG: Superior frontal gyrus; IFG: Inferior frontal gyrus; IPL: Inferior parietal lobule; SPL: Superior parietal lobule; MTG: Middle temporal gyrus; MOG: Middle occipital gyrus; TH: Thalamus; BG: Basal ganglia; R: Right; L: Left.

conditions.

In the studies on schizophrenic patients and subjects at augmented risk for schizophrenia, the most frequent dysfunctions were located in the cingulate gyrus and in the thalamus. The anterior part of the cingulate gyrus is a key region in sustained attention, cognitive control and

error processing<sup>[72-74]</sup>. An altered function of ACC has been consistently reported in both schizophrenic patients and unaffected relatives<sup>[75,76]</sup> during attentional control<sup>[77]</sup> conflict/error monitoring<sup>[78-81]</sup>, working memory<sup>[82-84]</sup> and semantic<sup>[85]</sup> tasks.

The posterior part of the cingulate gyrus is usu-

ally deactivated during active tasks with respect to rest conditions, and it is therefore considered a part of the Default Mode Network (DMN) of the brain<sup>[86]</sup>. It has a crucial role not only in internally focused tasks, but also in active regulation of the arousal state and in balancing between internally and externally oriented attention<sup>[87]</sup>. A lower volume of PCC/retrosplenial cortex has been associated to a poorer outcome in Schizophrenia<sup>[88]</sup>, and an altered function of this region has been evidenced during semantic<sup>[89]</sup>, self-evaluation<sup>[90,91]</sup> and fear-conditioning<sup>[92]</sup> tasks.

The thalamus is a subcortical structure whose integrity is needed to the correct functioning of cognitive processes. It is not a simple passive relay station, but a nodal link actively connecting top-down to bottom-up components of the attention/arousal system<sup>[1,93]</sup> and different cortical regions via cortico-thalamo-cortical pathways<sup>[94]</sup>. Both structural and functional MRI studies on Schizophrenia frequently reported significant abnormalities in schizophrenic patients, so a disruption of thalamocortical connections was suggested as one of the possible neural basis of cognitive and sensorial symptoms of Schizophrenia<sup>[95-98]</sup>.

With regard to Bipolar Disorder, amygdala was found to be altered in two of the three reviewed. In humans, the amygdala plays a key role in detecting dangers and other emotionally salient stimuli in the environment, in order to make the subject ready to react in an appropriate way<sup>[99]</sup>. During emotional tasks, an altered functioning of the amygdala in BD has been extensively reported, especially in manic patients<sup>[100-103]</sup>, but also during depressive<sup>[104]</sup> and euthymic states<sup>[105,106]</sup> of the illness. An important finding highlighted by the current review is that an augmented activation of the amygdala was observed also during attention tasks without any emotional components, this results suggesting that emotional limbic areas may interfere with cognition in BD<sup>[107]</sup>.

In our systematic review we reported that an altered functioning of the insula during sustained attention task was frequently found in both Schizophrenia and Bipolar Disorder.

The insular cortex, due to its location at the interface of frontal, parietal and temporal lobes, is involved in cognitive, emotional and somato-sensorial processes<sup>[56,108]</sup>, providing a hub that integrates salient stimuli with autonomic and sensorial data<sup>[109]</sup>. Many studies reported an insular dysfunction in Schizophrenia, Bipolar Disorder, and “at-risk subjects”, during both tasks<sup>[110-115]</sup> and resting state<sup>[116-119]</sup>, thus suggesting a key role of this region in vulnerability for psychosis, regardless of the affective or non-affective diagnostic distinction.

## CONCLUSION

In the present paper, we systematically reviewed fMRI studies pertaining sustained attention in affective and non-affective psychosis.

We found that differences between cases (patients,

unaffected relatives of psychotic probands) and controls in terms of functional activation in brain regions belonging to the sustained attention system were detectable even when the groups performed comparably. In particular, the insular cortex seems to be a trait marker for psychosis in general, whereas other regions seem to be differently impaired in affective and non-affective psychosis: alterations of the cingulate cortex and thalamus appear to be more common in Schizophrenia whereas amygdalar dysfunctions may be more frequently observed in Bipolar Disorder. Therefore, investigating neural correlates of sustained attention seem to be of great interest in the study of affective and non-affective psychosis as it may clarify differences and similarities between these two disabling psychiatric conditions.

## Limits of the study

An important limitation of the present paper is that we included in the qualitative synthesis only those studies conducted on selected versions of CPTs that were focused on sustained attention, excluding papers with CPT versions designed to measure other cognitive functions, such as working memory or emotional processing. Moreover, it's possible that our search strategy did not succeed in finding all the available literature on the topic and that adding other search words (*i.e.*, Continuous performance Test, oddball task) or other data bases would have improved the results. Due to the small number of published studies on Bipolar Disorder, our results should be interpreted with caution and further research are needed to clarify the role of sustained attention in affective psychosis.

## Abstract

Evaluation of rotator cuff is a common indication for magnetic resonance imaging (MRI) scanning of the shoulder. Conventional MRI is the most commonly used technique, while magnetic resonance (MR) arthrography is reserved for certain cases. Rotator cuff disorders are thought to be caused by a combination of internal and external mechanisms. A well-structured MRI report should comment on the relevant anatomic structures including the acromial type and orientation, the presence of os acromiale, acromio-clavicular degenerative spurs and fluid in the subacromial subdeltoid bursa. In addition, specific injuries of the rotator cuff tendons and the condition of the long head of biceps should be accurately reported. The size and extent of tendon tears, tendon retraction and fatty degeneration or atrophy of the muscles are all essential components of a surgically relevant MRI report.

## INTRODUCTION

Rotator cuff disorders are common in the middle and old age population. They are a major cause of chronic shoulder pain. In addition, rotator cuff disorders result in loss of strength and stability of the shoulder<sup>[1,2]</sup>.

The balanced combination between accurate clinical examination, clear view of the patient's needs and disabilities and precise radiological diagnostic modalities is invaluable in the correct formulation of the treatment plan of the patient whether surgically or conservatively. Magnetic resonance imaging (MRI), which is considered by many authors the modality of choice for diagnosing rotator cuff disorders<sup>[3,4]</sup>, has a very important role in achieving this balance.

In this article, we discuss the techniques of MRI of the shoulder; the relevant rotator cuff anatomy, mechanisms of injury, and the specific imaging findings of rotator cuff disorders that are important for formulating a well-structured and complete MRI report.

## MRI TECHNIQUE

MR imaging of the shoulder for evaluation of rotator cuff disorders may be carried out either conventionally (non-arthrographic), or with direct contrast distension of the joint (MR arthrography). Magnetic resonance arthrography was reported to be the most accurate imaging technique for diagnosis of both partial and full-thickness rotator cuff tears<sup>[5,6]</sup>, but is limited by invasiveness and necessity of fluoroscopic guidance for injection, and therefore not routinely used for rotator cuff disorders<sup>[7,8]</sup>. An alternative technique, indirect MR arthrography, is a non-invasive technique using intravenous rather than intra-articular contrast to provide the arthrographic effect<sup>[9,10]</sup>. Continuous advances in MRI field strength, gradients, and coil technology have allowed even more accuracy for conventional MRI than that reported in the early literature, and conventional MRI is still the most commonly used technique for diagnosis of rotator cuff tears<sup>[3,11,12]</sup>.

MR imaging is typically performed in the supine position with the arm by the side of the patient, in the neutral position. Images must be obtained in axial, coronal oblique and sagittal oblique planes<sup>[13]</sup>. The sequences used may vary but typically include T1-, proton density- and T2-weighted sequences and it is recommended to have both fat-suppressed and non-fat-suppressed sequences. Additional imaging in the abduction external rotation (ABER) position of the shoulder was reported to improve sensitivity and increase diagnostic confidence for partial-thickness tears of the supraspinatus tendon<sup>[10,14]</sup>. However, this technique is not widely spread due to difficult positioning and prolonged scan time.

## ROTATOR CUFF ANATOMY

The rotator cuff consists of four muscles; the supraspinatus, infraspinatus, subscapularis and teres minor muscles. The supraspinatus muscle originates from the supraspinous fossa of the scapula and passes on the superior aspect of the humeral head to be inserted in the greater tuberosity. The infraspinatus muscle originates from the infraspinous fossa and shares a common tendinous insertion with the supraspinatus tendon on the greater tuberosity; together with the tendon of teres minor muscle<sup>[15]</sup>. On the other hand, the subscapularis muscle originates from the subscapular fossa of the scapula and its wide tendon inserts in the lesser tuberosity, separated from the insertion of the other rotator muscles by the rotator interval.

The long head of biceps tendon is anatomically and functionally related to the rotator cuff. The tendon arises from the supraglenoid tubercle and its proximal segment (2-3 cm) is intra-articular. It exits the gleno-humeral joint and passes through the rotator interval between the subscapularis and supraspinatus tendons into the bicipital (intertubercular) groove of the proximal humerus<sup>[16]</sup>.

## MECHANISMS OF ROTATOR CUFF INJURY

The exact pathophysiology of rotator cuff injury, after exclusion of acute trauma, is still not fully understood. The current understanding is that rotator cuff degeneration is caused by a multifactorial pathogenesis, including both internal and external mechanisms<sup>[17,18]</sup>.

### Internal mechanisms

Those are mechanisms that originate from within the tendons in the form of degenerative processes, possibly age-related, that result in alterations in the tendon biology, morphology, vascularity and mechanical properties<sup>[18,19]</sup>.

### External mechanisms

External mechanisms include the well-known impingement syndromes, of which the subacromial impingement is the commonest. Subacromial impingement is defined as entrapment of the subacromial subdeltoid bursa and the supraspinatus tendon between the coraco-acromial arch and the greater tuberosity of the humerus. The main causes of this type of impingement include abnormal acromion configuration<sup>[20]</sup>, osteoarthritis of the acromioclavicular (AC) joint and narrowed subacromial space<sup>[21]</sup>.

Another type of impingement syndromes is subcoracoid impingement; defined as entrapment of the subscapularis tendon in the coracohumeral interval (the space between the coracoid process and the anterior humerus). It is usually caused by abnormal coracoid configuration that may be congenital, traumatic or iatrogenic<sup>[17,21]</sup>.

Less common types of impingement include secondary external impingement due to glenohumeral instability in the absence of outlet stenosis of the rotator cuff tendons<sup>[22]</sup>, as well as internal impingement (intra-articular) due to compression of the articular surface of the tendons between the humeral head and glenoid<sup>[23]</sup>.

## MRI FINDINGS

### Acromion type

The acromion was classified according to its shape into three types (Figure 1). Type I has a flat under surface, type II a concave under surface and type three a concave under surface with anterior hook. Some authors added a further type IV to the original classification describing a convex under surface<sup>[24,25]</sup>. The shape of acromion is best depicted on sagittal oblique MR images lateral to the AC joint plane. The most common type is type II, while type III is the one most commonly associated with rotator cuff tears where its anterior hook causes injury of the anterior fibres of the supraspinatus tendon<sup>[26]</sup>.

### Acromion orientation

Normally, the acromion has no slope either anteriorly,

**Figure 1 Acromion types.** Sagittal oblique T2-weighted images of different patients showing type I flat acromion (A), type II concave under surface (B) and type III concave under surface with anterior hook (C).

**Figure 2 Acromion orientation.** A: Coronal oblique T1-weighted image shows low lying acromion (a) in relation to the clavicle (c) at the Acromio-clavicular joint level; B: Coronal oblique T1-weighted image in another patient shows infero-lateral slope of the acromion. The angle between the acromion and the clavicle is tilted by 20 degrees.

laterally or inferiorly. A lateral or anterior down-sloping acromion and a low-lying acromion are thought to play a role in the development of subacromial impingement<sup>[21]</sup>.

A low-lying acromion is diagnosed when the lower acromial surface is below the lower surface of the clavicle at the AC joint level on the anterior coronal oblique MR image (Figure 2A). On the same image showing the AC joint, an infero-lateral slope is detected by measuring the angle between the acromion axis and the clavicle (Figure 2B); an angle more than 10 degrees is abnormal<sup>[27]</sup>. An anterior slope is diagnosed on sagittal oblique images when the anterior part of the acromion is closer to the

**Figure 3 Os acromiale.** Axial T1-weighted image showing the os acromiale.

**Figure 4 Acromio-clavicular joint osteoarthritis.** Coronal oblique fat-sat proton-density-weighted image shows degenerative changes of the acromio-clavicular joint (arrow) in a patient with rotator cuff tear.

related part of the humeral convexity than its posterior part.

### Os acromiale

The acromion is formed from multiple ossification centres with complete fusion between the ages of 22 and 25 years. If one of the ossification centres fails to fuse, an accessory ossicle is formed; the os acromiale<sup>[28]</sup>. The os acromiale is mobile and is thought to contribute to impingement, but the reported incidence in normal population is between 1% and 15%<sup>[28]</sup>. It is best assessed in the upper axial images (Figure 3) where a low signal space is detected between the high signal marrow of the distal acromion and the non-fused ossicle<sup>[25]</sup>. On coronal oblique images it can be suspected by the presence of the so called “double AC joint”; the normal AC joint appears on the anterior image and the pseudo-articulation of the os acromiale appears on the posterior one<sup>[27]</sup>.

### AC joint

Osteoarthritis of the AC joint (Figure 4) is a common finding in patients with rotator cuff disorders. However, its role in impingement remains unclear and could either be a risk factor for impingement or a result of rotator cuff injury and disturbed shoulder biomechanics. A large osteophyte arising from the inferior surface of

**Figure 5 Supraspinatus tendinosis.** A: Coronal oblique T1-weighted image. B: Coronal oblique fat-sat proton-density image. Images (A) and (B) show focal high signal intensity within the distal supraspinatus tendon (arrow); C: Coronal oblique fat-sat T2-weighted image shows focal high signal at the same site within supraspinatus tendon (arrow). Final diagnosis was tendinosis.

**Figure 6 Partial interstitial supraspinatus tendon tear.** Coronal oblique fat-sat proton-density-weighted image showing focal high signal within the supraspinatus tendon fibres (arrow). Also note the associated high signal intensity fluid in the subacromial subdeltoid bursa.

the joint is thought to be a cause of tendon tear<sup>[29]</sup>. MRI is more sensitive than radiography for detection of AC joint degenerative disease. MRI can differentiate joint enlargement due to capsular hypertrophy (intermediate signal intensity) from joint effusion (bright signal on T2-weighted images). Osteophytes appear in late stages of the disease<sup>[30]</sup>.

#### **Subacromial subdeltoid bursa**

The subacromial subdeltoid bursa is a synovial lined structure between the acromion and deltoid muscle externally and the rotator cuff tendons internally. The subacromial and subdeltoid components are connected in 95% of individuals. Normally it is not connected with the joint space but communication occurs in association with full thickness supraspinatus tears<sup>[31,32]</sup>.

The normal bursa usually does not exceed 2 mm in thickness and is usually located posteriorly. On coronal MRI, features suggesting abnormal amount of fluid include thickness of fluid signal more than 3 mm, fluid signal medial to the level of the AC joint, and fluid in the anterior part of the bursa<sup>[33]</sup>.

#### **Rotator cuff tendons and specific injuries**

**Tendinitis and tendinosis:** Tendinitis and tendinosis typically appear as focal areas of increased signal intensity on proton density weighted images, that is less than that of fluid on T2-weighted images (Figure 5). Chronic forms are associated with thickening (tendinosis)<sup>[34]</sup>.

**Partial thickness tear:** A partial thickness tear appears on fat-suppressed T2-weighted MR images as fluid signal intensity with thinning, or an incomplete gap, in the tendon<sup>[3]</sup>. The supraspinatus tendon is usually about 12 mm in average cranio-caudal thickness. Partial thickness tears are classified according to their depth into either grade I, in which less than one fourth of the fibres is torn; grade II, when more than one fourth and less than half of the tendon thickness is torn and grade III, when more than half of the tendon thickness is torn<sup>[24,35]</sup>.

According to the tear site, partial thickness tears of the supraspinatus tendon are classified into bursal; articular surface or intra-tendinous tears (Figure 6). Articular surface tears are more common<sup>[35]</sup>.

**Full thickness tear:** A full-thickness tendon tear appears as a focal, well-defined area of increased signal intensity on both T1- and T2-weighted images (Figure 7), that traverses the whole thickness of the tendon from the bursal to the articular surface<sup>[7,36]</sup>.

Full-thickness tendon tears are classified according to the tear dimensions as small (less than 1 cm), medium (between 1 and 3 cm), large (between 3 and 5 cm) or massive (exceeding 5 cm)<sup>[24]</sup>. The dimensions are measured on coronal and sagittal T2 fat-suppressed images<sup>[37]</sup>.

The degree of retraction of the torn supraspinatus tendon is typically assessed on coronal oblique images. When the tendon stump is still close to the insertion site, it is classified as stage 1. A stump retracted to the level of the humeral head is classified as stage 2, while stage 3 denotes retraction of the stump to the level of the glenoid<sup>[38,39]</sup>.

**Figure 7 Full-thickness supraspinatus tendon tears in two different patients.** A: Coronal oblique fat-sat T2-weighted image shows full-thickness supraspinatus tendon tear without significant tendinous retraction (arrow); B: Coronal oblique fat-sat T2-weighted image in another patient shows torn retracted supraspinatus tendon (arrow).

**Figure 8 Subacromial impingement.** A: Coronal oblique fat-sat T2-weighted image; B: Coronal oblique fat-sat proton-density-weighted image. Both images show findings associated with subacromial impingement in the form of osteoarthritis of the acromio-clavicular joint, distended subacromial subdeltoid bursa by fluid signal (arrowhead) and focal thickening of the distal supraspinatus tendon with partial irregularity of the bursal surface reported as partial tear (arrow).

**Figure 9 Magic angle artifact.** A: Coronal oblique T1-weighted image. B: Coronal oblique fat-sat proton-density image. Images (A) and (B) show focal high signal intensity within the distal supraspinatus tendon (arrow); C: Coronal oblique fat-sat T2-weighted image shows normal signal of the supraspinatus tendon (arrow). Final diagnosis was magic angle artifact with normal tendon.

**Supraspinatus tendon:** The most common site for rotator cuff tears is the supraspinatus tendon, especially at its distal part 1 to 2 cm from its insertion, the so called “critical zone”, where the vascularity is low and the effect of subacromial space narrowing or subacromial impingement is maximized (Figure 8)<sup>[26]</sup>.

The supraspinatus tendon is best evaluated on the

coronal oblique images. A potential pitfall is the magic angle artefact (Figure 9); that may occur whenever parallel collagen fibres are oriented at 55 degrees relative to the magnetic field. This effect is common at the distal end of the supraspinatus tendon and appears as high signal mimicking tendinitis or partial tear on short time of echo (TE) MR sequences. However, the high signal intensity

**Figure 10** **Infraspinatus tendinosis.** Posterior coronal oblique fat-sat proton-density-weighted image showing focal thickening of the infraspinatus tendon fibres with abnormal high signal diagnosed as tendinosis (arrow). Also note fluid signal within the subacromial subdeltoid bursa.

**Figure 11** **Subscapularis tendinosis.** A: Axial gradient-recalled echo image showing focal high signal within the subscapularis tendon with fibres thickening (arrow); B: Anterior coronal oblique fat-sat T2-weighted image of the same patient showing high signal within the lower fibres of the subscapularis tendon (arrow).

disappears on using long TE sequences; for example T2 fat-suppressed sequence<sup>[25]</sup>.

**Infraspinatus tendon:** The infraspinatus tendon is most commonly torn as an extension from supraspinatus tear (postero-superior cuff tear)<sup>[39]</sup>. The infraspinatus tendon is best evaluated on posterior coronal oblique fat-suppressed T2-weighted or STIR images (Figure 10). A second look may also be carried out on the upper axial images as well as on sagittal images<sup>[13]</sup>.

**Figure 12** **Sub-coracoid impingement.** A and C: Axial gradient-recalled echo images; B: Axial T1-weighted image showing narrowed coraco-humeral distance (arrows in A) with tapered coracoid process, thickening and abnormal high signal of the subscapularis tendon (asterisk in C).

**Subscapularis tendon:** Subscapularis tendon tears may occur as a component of massive rotator cuff tears<sup>[40,41]</sup>. The tendinous part of the subscapularis tendon is the broadest tendon among the rotator cuff and therefore commonly affected by tears and tendinitis (Figure 11).

The subscapularis tendon may be affected in isolation in traumatic injury<sup>[41]</sup>. Subcoracoid impingement, which is a cause of subscapularis degenerative tears (Figure 12), is suspected when the distance between the coracoid process and the lesser tuberosity of the humerus is less than 6 mm on axial MR images<sup>[21,42]</sup>. Other reported associated MRI signs include subcortical bone marrow edema of the coracoid process and lesser tuberosity of the humerus.

**Teres minor tendon:** The teres minor tendon is the least injured among rotator cuff tendons<sup>[43]</sup>. The teres minor

**Figure 13 Supraspinatus muscle atrophy, tangent sign.** Sagittal oblique T1-weighted image showing the upper border of supraspinatus muscle below the line extending between the scapular plate and spine.

tendon is best evaluated on posterior coronal oblique and axial MR images and to less extent on sagittal images.

### Muscle atrophy and fatty degeneration

Atrophy of the supraspinatus muscle could be assessed by calculating the occupation ratio of the supraspinatus fossa. On the most lateral oblique sagittal image, atrophy of the supraspinatus muscle is diagnosed if the supraspinatus muscle occupies less than half the area of the fossa<sup>[44,45]</sup>.

The tangent sign (Figure 13) describes an additional straight line drawn from the top of the coracoid process to the top of the spine of the scapula on the same oblique sagittal image as above. Atrophy is diagnosed when the superior border of the muscle lies below the tangent line<sup>[24,45,46]</sup>.

Fatty degeneration of the supraspinatus muscles could be assessed on the T1-weighted oblique sagittal image in which the spine and body of the scapula appear. Fatty degeneration could be classified as either low (grade 0; no fat or grade 1; some fatty streaks) or moderate (grade 2; muscle > fat) or advanced (grade 3; muscle = fat and grade 4; muscle < fat)<sup>[47-49]</sup>.

### Long head biceps tendon

MR evaluation of the intra-articular segment of the long head biceps tendon (LHBT) is best carried out on both oblique sagittal and oblique coronal images, while the extra-articular segment is best evaluated on axial images. The LHBT tendon is covered with a synovial sheath connected with the joint space along its course within the bicipital groove<sup>[30,50]</sup>. Therefore, fluid signal around the tendon may be seen in cases of joint effusion, nevertheless in proportionate amount, and should not be mistaken for tenosynovitis. Tenosynovitis of the LHBT is diagnosed if fluid is detected around the tendon only or if the amount of fluid around the tendon is clearly out of proportion to that in the glenohumeral joint<sup>[51]</sup>. Tendinosis of the LHBT is suspected when focal thickening and high signal (but less than that of fluid) of the tendon

**Figure 14 Subscapularis tendon avulsion with long head of biceps tendon dislocation.** A: Axial T1-weighted image; B: Axial gradient-recalled echo image; C: Coronal oblique T1-weighted images showing avulsion of the subscapularis tendon (asterisk in B) with muscular atrophy and long head biceps tendon dislocation (arrows) with diffuse tendinous thickening and high signal.

or part of it is noted, usually associated with fluid signal within the synovial covering<sup>[52]</sup>. The most commonly affected part is the supra-humeral portion or the horizontal part and it may be a result of impingement. Tears of the LHBT vary from partial to complete tear to tendon avulsion. Tears appear as focal areas of high signal intensity, similar to that of fluid on T2-weighted images. Avulsion is diagnosed by noting the absence of the intra-articular segment of the tendon with no signs of dislocation. A dislocated LHBT (Figure 14) is often medially displaced, and is commonly associated with subscapularis tendon tear<sup>[50-52]</sup>.

**Figure 15 Calcific tendinopathy.** Coronal oblique fat-sat proton-density-weighted image showing focal area of signal void (calcifications) within the distal supraspinatus tendon fibres (arrows). Diagnosis was confirmed by ultrasonography.

**Figure 16 Bony degenerative changes.** Coronal oblique fat-sat T2-weighted image showing focal fluid-like high signal within the distal supraspinatus tendon fibres reported as partial capsular surface tear with subcortical cystic erosion of the greater tuberosity at the rotator cuff insertion (thin arrow). Also note fluid signal within the subacromial subdeltoid bursa reported as bursitis (thick arrow).

### Other findings

**Bony changes:** Erosions and degenerative changes of the lateral aspect of the greater tuberosity of the humerus (Figure 15) are common associated findings in rotator cuff disorders<sup>[30]</sup>. This finding is important for surgical planning as it significantly decreases the hold of anchors used during repair of torn rotator cuff tendons.

**Calcific tendinopathy:** Calcific tendinopathy most commonly affects the supraspinatus tendon, less commonly the infraspinatus and other tendons. On MRI, calcifications typically appear as focal areas of signal void on all spin echo sequences (Figure 16), and is usually difficult to detect within the natively low signal tendon<sup>[7,53]</sup>. The area of signal void increases on gradient-recalled echo sequence due to susceptibility effects<sup>[30]</sup>.

## CONCLUSION

Evaluation of rotator cuff disorders is one of the commonest indications for magnetic resonance (MR) imaging of the shoulder. Complete and accurate interpretation of MR images is essential to provide the treating clinician with adequate information for choosing the best therapy and avoiding unnecessary interventions. Radiologists should be familiar with the technique of MRI of the shoulder, the anatomy of the rotator cuff and the mechanisms of rotator cuff injury. A well-structured MRI report should include full comment on the rotator cuff tendons and all other relevant structures.

**Key words:** Carpal tunnel syndrome; Anatomy; Ultrasonography; Magnetic resonance imaging; Computed tomography; Ultrasonography; Diagnosis; Nerve conduction study; Treatment

**Core tip:** A review of the carpal tunnel syndrome (CTS) highlighting anatomy, diagnosis and eventual treatment. This paper synthesizes all the aspects necessary to properly and successfully treat CTS, unlike past reviews which have focused on simply just one or a few factors. This review contains all the necessary material to fully understand CTS.

## INTRODUCTION

In the United States, about 2.7 million doctors' office visits/year are related to patients complaining about finger, hand or wrist symptoms<sup>[1]</sup>. The diagnosis of these symp-

## Abstract

Carpal tunnel syndrome (CTS) is the most commonly

toms can include various types of nerve entrapments, tendon disorders, overuse of muscles or nonspecific pain syndromes<sup>[1]</sup>. The most common type among them is carpal tunnel syndrome (CTS), which accounts for 90% of all entrapment neuropathies<sup>[2,3]</sup> and is one of the most commonly diagnosed disorders of the upper extremities<sup>[3,4]</sup>. It is expected that 1 in 5 patients who complain of symptoms of pain, numbness and a tingling sensation in the hands will be diagnosed with CTS based on clinical examination and electrophysiological testing<sup>[3]</sup>. CTS is estimated to occur in 3.8% of the general population<sup>[3,5]</sup>, with an incidence rate of 276:100000 per year<sup>[6]</sup>, and happens more frequently in women than in men, with a prevalence rate of 9.2% in women and 6% in men<sup>[3,7]</sup>. It is most often seen bilaterally at a peak age range of 40 to 60 years old; however, it has been seen in patients as young as twenty and as old as eighty-seven years old<sup>[3,8]</sup>.

The carpal tunnel (CT) is found at the base of the palm. It is bounded partly by the eight carpal bones and partly by a tough fibrous roof called the transverse carpal ligament (TCL). The tunnel gives passage to: (1) eight digital flexor tendons (two for each of the medial four fingers); (2) flexor pollicis longus (FPL) tendon for the thumb; (3) their flexor synovial sheaths; and (4) the median nerve (MN)<sup>[1]</sup>. CT is therefore quite tightly packed and any condition that might increase the volume of the structures inside it can cause compression of the MN. This in turn might lead to ischemia of the nerve which presents as pain and paresthesia<sup>[1,8]</sup>.

The American Academy of Orthopedic Surgeons (AAOS) defines CTS as “a symptomatic compression neuropathy of the median nerve at the level of the wrist”<sup>[3,9]</sup>. MN gives sensory branches to the lateral three fingers and the lateral half of the ring finger so that when it is compressed, symptoms of CTS are manifested in those fingers<sup>[3]</sup>. The palm of the hand, however, remains unaffected by CTS as it is supplied by the sensory cutaneous branch of median nerve (PCBMN). This branch arises about 6 cm proximally to the TCL, then passes superficially to the ligament so it is not affected by the pressure changes within the CT<sup>[3]</sup>.

Furthermore, the most common diagnosis in patients with symptoms of pain and numbness is idiopathic CTS with a tingling sensation along the MN distribution in the hands<sup>[10]</sup>. Although this syndrome is widely recognized, its etiology remains largely unclear. Recent biomechanical, MRI and histological studies have strongly suggested the close relationship of the dysfunction of neuronal vasculature, synovial tissue and flexor tendons within the CT and the development of idiopathic CTS<sup>[11,12]</sup>.

CT is the fibro-osseous pathway on the palmar aspect of the wrist which connects the anterior compartment of the distal forearm with the mid-palmar space of the hand. On its bottom, the CT is made up of the carpal bones articulating together to form a backward convex bony arch, resulting in formation on the dorsal side and concave on the palmar side, forming a tunnel-like groove called the *sulcus carpi*. This osseous groove is topped volar by the tough flexor retinaculum (FR), which arches over

the carpus, thus converting the sulcus carpi into the CT.

FR can be differentiated into three continuous segments: (1) a proximal thin segment called the volar carpal ligament. It is the thickened deep antebrachial fascia of the forearm; (2) the middle tough segment is the TCL; and (3) the distal segment is formed from an aponeurosis which extends distally between the thenar and hypothenar muscles. Therefore, it is recommended to have a more extensive surgical release instead of only resection of the middle segment of the FR<sup>[13]</sup>.

The width of the CT is about 20 mm at the level of the hook of hamate, which is narrower compared to its proximal (24 mm) or distal (25 mm) end<sup>[13,14]</sup> counterparts. Moreover, the narrowest sectional area of the tunnel is located 1 cm beyond the midline of the distal row of the carpal bones where its sectional area is about 1.6 cm<sup>2</sup><sup>[15]</sup>.

In healthy individuals, the intra-CT pressure is about 3-5 mmHg when the wrist is in a neutral position<sup>[16,17]</sup>. MN blood flow was found to be impaired when the CT pressure approached or exceeded 20-30 mmHg. Common functional positions of the wrist, *e.g.*, flexion, extension or even using a computer mouse, might result in an increase of tunnel compression pressures to levels high enough to impair MN blood flow<sup>[18]</sup>. For example, placing the hand on a computer mouse increase the CT pressure to 16-21 mmHg, while using the mouse to point and click increased the CT pressure up to 28 to 33 mmHg<sup>[19]</sup>. Interestingly, CT pressure was shown to increase to 63 mmHg with 40 degrees of wrist extension and 0 degrees of metacarpophalangeal flexion<sup>[20]</sup>.

The position of adjacent muscular structures is thought to play a significant role in these positional increases in CT pressure<sup>[20]</sup>. In a study of the MN in fresh human cadavers, a significant distal bulk of the flexor digitorum superficialis (FDS) muscle was found to enter the proximal aspect of the tunnel during wrist extension<sup>[21]</sup>. Similarly, the lumbrical muscles were shown to enter the distal aspect of the tunnel during metacarpophalangeal flexion. Computer modeling suggests that when the metacarpophalangeal joints are flexed to 90 degrees, the lumbrical muscles remain in the CT, even if the wrist is kept extended<sup>[22]</sup>.

A thorough knowledge of the complex anatomy of the CT and its surrounding structures in addition to an emphasis on its clinical applications is essential for a better understanding of the pathophysiology of CTS, along with its symptoms and signs. Such knowledge will enable surgeons to take the most appropriate and safest approach during open or endoscopic carpal tunnel release (ECTR) surgeries by accurately identifying structures at or near the CT in order to avoid or reduce its surgical complications and ensure optimal patient outcome. It is also important to be aware of the likely possible anatomical variations that might be the cause of MN compression or may be anticipated and more readily recognized by hand surgeons. This review aims to provide an overview of CTS by considering anatomy, pathophysiology, clinical manifestation, diagnostic modalities and manage-

ment of this common condition, with an emphasis on its diagnostic imaging evaluation.

## CLINICAL AND SURGICAL ANATOMY OF CT

Movements of the wrist joint have an effect on the shape and width of the CT. The width of the tunnel decreases considerably during the normal range of wrist motion and since the bony walls of the tunnel are not rigid, the carpal bones move relative to each other with every wrist movement. Both flexion and extension increase the CT pressure. The cross section of the proximal opening of the CT was found to be significantly decreased with a flexing wrist joint. This is likely due to the radial shifting of the TCL and the movement of the distal end of the capitate bone. In extreme extension, the lunate bone compresses the passage as it is pushed towards the interior of the tunnel<sup>[15]</sup>.

TCL is the thick (2-4 mm) central segment of the FR. It is a strong fibrous band formed from interwoven bundles of fibrous connective tissues<sup>[13]</sup> and is short and broad (average width is 25 mm and length is 31 mm)<sup>[23,24]</sup>. It extends from the distal part of the radius to the distal segment of the base of the third metacarpal. The mean proximal limit of its central portion is 11 mm distal to the capitate-lunate joint and the mean distal limit of its distal portion is 10 mm distal to the carpometacarpal joint of the third metacarpal<sup>[13]</sup>.

Regarding laminar configuration of the TCL, four basic laminae were identified: (1) strong distal transverse; (2) proximal transverse; (3) ulnar oblique; and (4) radial oblique. The most common pattern showed predominance of the distal transverse and the ulnar oblique laminae in every layer of the FCL. In half of the dissected hand samples, the distal transverse and ulnar oblique laminae dominated in the superficial layer, while the proximal transverse and the radial oblique laminae dominated in the deep layer. So, the strong distal transverse lamina is likely to be excised during the final step of ECTR because of its superficial localization. This could be a major cause for the frequent occurrence of incomplete release. Moreover, the almost universal superficial ulnar oblique lamina predisposes to scarring, which may cause radial shifting of the ulnar neurovascular bundle and may affect the PCBMN. It is concluded that the minor complications of ECTR depend partly on the variations in the laminar arrangement of the TCL<sup>[25]</sup>. In another study performed on eight dissected TCLs, the transverse fibers were the most prominent (> 60%), followed by the oblique fibers in the pisiform-trapezium direction (18%), the oblique fibers in the scaphoid-hamate direction (13%) and finally the longitudinal fibers (8%)<sup>[26]</sup>.

### Borders of the TCL

The TCL is attached medially to the pisiform bone and hook of the hamate, while laterally it splits into superficial and deep laminae. The superficial lamina is attached

to the tubercle of the scaphoid and trapezium and the deep lamina is attached to the medial lip of the groove on the trapezium. Together with this groove, the two laminae form a tunnel, lined by a synovial sheath containing the tendon of flexor carpi radialis (FCR)<sup>[24]</sup>.

### Proximal border of the TCL

Proximally, the TCL is attached to the volar carpal ligament which extends from the radius to the ulna over the flexor tendons as they enter the wrist<sup>[24]</sup>. This border corresponds to the distal flexion wrist crease, which also crosses the proximal end of scaphoid and pisiform bones.

### Distal border of the TCL

This border is attached to the central portion of the palmar aponeurosis (PA). As measured along the axis of the radial border of the ring finger, the average distance between this border and the superficial palmar arch ranges from 5.5-19 mm<sup>[27-31]</sup>. The mean distance from this distal border to the nearest aspect of the motor branch of MN is about 2.7-6.5 mm<sup>[23,32]</sup>.

Immediately proximal to the distal end of the TCL and in line with the axis of ring finger, a palmar fat pad (fat drop sign) is visualized overlapping this border. It is a reliable anatomic landmark during CT release which must be retracted in order to visualize the distal end of the TCL<sup>[14]</sup>. Its proximal aspect lies at about 2 mm proximally to the distal edge of the TCL. The distance between the distal end of the TCL and the palmar fat pad decreases by flexing the fingers, but the distance between the TCL and the palmar arch or the PCBMN is not markedly affected. When dividing the TCL from proximal to distal, visualization of the proximal part of the fat pad is a useful indication that the distal edge of the TCL is within approximately 2 mm and indicates that distal dissection beyond this level is unnecessary in order to avoid injury of the superficial palmar arch or the PCBMN<sup>[32]</sup>.

### Surfaces of the TCL

**Palmar (volar) surface:** This surface gives partial origin to all the thenar and hypothenar muscles except the abductor digiti minimi muscle and it also receives partial insertion from the flexor carpi ulnaris (FCU) and palmaris longus (PL).

This surface is entirely hidden by the muscular attachments, which makes it appear much deeper than surgeons think. This might urge surgeons to make a longer incision for good exposure of the TCL and to complete its division<sup>[33]</sup>. The middle part of this surface is crossed by the PL tendon (if present), with a nerve on each of its sides; palmar cutaneous branch of ulnar nerve (medially) and PCBMN (laterally). The ulnar nerve and vessels cross the medial part of this surface through a special fascial tunnel called the Guyon tunnel<sup>[33]</sup>.

The superficial branch of the radial artery arises from the radial artery just before the latter curves round the carpus. It passes through and occasionally over the the-

nar muscles, which it supplies. It sometimes anastomoses with the end of ulnar artery to complete the superficial palmar arch<sup>[24]</sup>.

When present, it is a slender and flattened tendon, which passes superficially to the TCL and lies medially to the tendon of FCR. It is partially inserted into its central part of the TCL and extends distally to attach to the proximal part of PA. Frequently, it sends a tendinous slip to the thenar muscles. The MN lies deep to this tendon but when absent, the nerve becomes separated from the skin only by a thin subcutaneous fat and deep fascia<sup>[24]</sup>.

PCBMN arises from the MN proximal to the TCL. It pierces the deep fascia and runs superficially to the TCL, just laterally to the PL tendon. It then divides into lateral branches supplying the thenar skin, communicating with the lateral cutaneous nerve of forearm. The medial branches supply the central palmar skin and communicate with the palmar cutaneous branch of ulnar nerve<sup>[24]</sup>.

Injury to the PCBMN is the most common complication of CT surgery<sup>[34]</sup> and it has been suggested that the mini incision done between the superficial palmar arch and the most distal part of the PCBMN in the palmar region is the safe zone for CT surgery<sup>[34]</sup>. Decreased levels of discomfort in patients undergoing endoscopic and subcutaneous types of CT release may be in part due to the preservation of the crossing cutaneous nerves during these procedures<sup>[35]</sup>.

Communicating sensory branches may be multiple and often arise in the proximal forearm and sometimes from the anterior interosseous branch. They pass medially between FDS and FDP and behind the ulnar artery to join the ulnar nerve. This communication is a factor in explaining anomalous muscular innervations in the hand<sup>[24]</sup>. In relation to an incision for CT release, PCBMB was found to cross the incision only in one specimen (of 25 fresh frozen cadaveric hands), while its terminal branches were identified at the margin of the incision in another two specimens<sup>[35]</sup>.

It arises from the ulnar nerve near the middle of the forearm at about 4.9 cm proximally to the pisiform bone. It then runs distally just medially and parallel to the PL tendon. It enters the palm of hand superficially to the TCL. In 24 specimens, at least one, usually multiple, transverse palmar cutaneous branch was identified originating at about 3 mm distally to the pisiform within Guyon's canal. In another 10 specimens (of 25 hands), a nerve of Henle arose at about 14.0 cm proximally to the pisiform, travelling with the ulnar neurovascular bundle to the wrist flexion crease<sup>[35]</sup>.

They pass superficially to the FR and enter the hand by passing through a groove between the pisiform (medially) and the hook of hamate (laterally and more distally). The ulnar artery is radial to the nerve and can be easily felt on the ulnar side of the front of the wrist. They usually pass just over the ulnar to the superior portion of the hook of the hamate. Over the FR, they are kept in place by a fascial extension from the volar carpal ligament, forming the ulnar canal (Guyon's canal). This

extension is attached medially to the pisiform bone and blends laterally with the TCL<sup>[33]</sup>. They lie in the shelter of the lateral edge of the tendon of FCU<sup>[24]</sup>. Pisiform bone is palpated at the base of the hypothenar eminence and serves to mark the entry on its lateral side of the ulnar nerve and artery into the hand. The mean distance from the radial aspect of the pisiform to the radial border of Guyon's canal and the ulnar edge of the PL tendon is about 10.3 mm and 16.1 mm respectively<sup>[23]</sup>. As the ulnar nerve passes between the pisiform and hook of hamate, it terminates by dividing into superficial and deep branches.

With the wrist in neutral position, a looped ulnar artery runs from 2-7 mm medially<sup>[27]</sup> to 1-4 mm laterally to the hook of the hamate<sup>[36]</sup>. It then continues to form the superficial palmar arch. With the wrist in radial deviation, the looped ulnar artery migrates to the ulnar side of Guyon's canal (-2-2 mm radially to the hook of the hamate). During ulnar deviation of the wrist, the ulnar artery shifts more laterally beyond the hook of the hamate (2-7 mm). So, in order to minimize postoperative bleeding and avoid iatrogenic ulnar vascular and neural injury, it is recommended to: (1) transect the TCL over 4-5 mm apart from the lateral margin of the hook of the hamate without placing the edge of the scalpel toward the ulnar side; (2) not to transect the TCL in the ulnar deviation wrist position<sup>[27]</sup>; and (3) make the proximal portal just medial to the PL tendon in order to spare the ulnar neurovascular structures<sup>[36]</sup>. However, injury to the ulnar artery within Guyon's canal has not been a problem during ECTR surgery<sup>[14]</sup>.

Variations: (1) An anomaly of the ulnar nerve with an aberrant branch was observed to cross the CT incision<sup>[37]</sup>; and (2) A small arterial branch (average diameter, 0.7 mm) arising from the ulnar artery ran transversely just over the TCL in 6 (of the 24 specimens). This branch was consistently located within 15 mm proximally to the TCL distal margin<sup>[27]</sup>.

**The deep surface of the TCL:** With the carpal bones, this surface forms the CT which is traversed by nine flexor tendons of the fingers, their flexor synovial sheaths and the median nerve.

The median nerve is the softest and most volar structure in the CT. Its average cross-sectional area is 6.19 mm<sup>2</sup><sup>[38]</sup>. It lies directly beneath the TCL and is superficial to the nine digital flexor tendons (Figure 1). Proximally to the TCL, the MN lies just laterally to the tendons of FDS and between the tendons of FCR and PL (Figure 2). Its location extends an average of 11 mm radially to the hook of hamate<sup>[27]</sup>. Distally to the TCL, it enlarges and flattens and usually divides into five or six branches: (1) the recurrent motor branch; (2) three proper digital nerves (two to the thumb and one to the radial side of index finger); and (3) two common digital nerves (one to index/ middle and one to middle/ ring)<sup>[24]</sup>. Trapped or pinched nerves have a useful electrical property for the diagnosis in that the speed of its conduction slows at the

**Figure 1** Sketch of the palm, showing specific details of the inner structures of the carpal tunnel (inside the wrist). The median nerve and its branches after the wrist are marked in yellow.

**Figure 2** Sketch of the cross-section of the carpal tunnel on a hand. Median nerve is shown in yellow and the nine flexor tendons are marked in blue.

site of trouble due to demyelination.

**Anomalies of the median nerve:** Variations of the MN at the wrist were reported in about 11% of the examined specimens. Neural variations arising from the medial aspect of the MN were common and could be a cause of iatrogenic injury during endoscopic or open release<sup>[39]</sup>.

In a study performed on 246 carpal tunnels at operation, four groups of variations were described: (1) variations in the course of MN were found in 12%; (2) accessory branches at the distal portion of the CT in 7%; (3) high divisions of the MN in 3%; and (4) accessory branches proximal to the carpal canal in 1.5%. These findings emphasize the importance of approaching the MN from the ulnar side when opening the CT<sup>[40]</sup>.

### High bifurcation of the MN

**Persistent median artery:** the median artery is a transitory vessel that represents the embryological axial artery of the forearm. It normally regresses in the second fetal month<sup>[41,42]</sup>. Its persistence in the human adult has been documented as two different types: as a large, long vessel which reaches the hand (palmar type); or as a small and short vessel which ends before reaching the wrist joint (antebrachial type)<sup>[43,44]</sup>. It occurred in about 3.4%-20% of a 646 population sample of hands<sup>[37,45]</sup>. It is more frequent in females than in males, occurring unilaterally more often than bilaterally and slightly more frequently on the right than on the left. Most frequently, it arises from the caudal angle between the ulnar artery and its common interosseous trunk (59%). Other origins may be from the ulnar artery or from the common interosseous trunk. It ends as the 1<sup>st</sup>, 2<sup>nd</sup> or 1<sup>st</sup> and 2<sup>nd</sup> common digital arteries (65%) or joins the superficial palmar arch (35%). It pierces the MN in the upper third of the forearm in 41% of cases with the palmar type<sup>[45]</sup>. The median artery in its palmar type passes under the FR, running in the CT together with the MN and flexor tendons. This relationship has been considered an etiological factor in CTS<sup>[46]</sup>.

An aberrant sensory branch arising from the ulnar side of the MN and piercing the ulnar margin of the

TCL was found in 3% of hands (of 110 in operations)<sup>[39]</sup>.

Martin-Gruber anastomosis is a motor communicating nerve, which may cross over from the median to ulnar nerve in the forearm (motor not sensory connections). It occurs in two patterns: either from the MN in the proximal forearm to the ulnar nerve in the middle to distal third of the forearm; or from the anterior interosseous nerve to the ulnar nerve<sup>[47]</sup>.

Other motor anastomoses between the MN and ulnar nerve include: (1) motor branch of the MN to superficial head of flexor pollicis brevis (FPB) and ulnar nerve to the deep head of the FPB; (2) anastomosis, of the MN and ulnar motor branches through first lumbrical or through innervation of the adductor pollicis muscle; (3) branch of the MN to third lumbrical joining neural branch to this muscle from deep branch of ulnar nerve; (4) the MN may also form anastomoses with branch of radial nerve close to abductor pollicis brevis which has the radial nerve innervating this muscle; and (5) first dorsal interosseous, adductor pollicis or even abductor digiti minimi may be innervated by the MN<sup>[47]</sup>.

### Motor branch (recurrent or thenar branch)

It is a short and thick branch commonly arising from the radial side of the MN. It may however, arise from the volar or the ulnar side of the MN<sup>[14]</sup>. It may be the first palmar branch or a terminal branch which arises level with the digital branches of MN. It runs laterally, just distal to the TCL, with a slight recurrent curve beneath the part of the PA covering the thenar muscles. It runs around the distal border of the TCL to lie superficially to the FPB, which it usually supplies, and continues either superficially to the muscle or through it. It gives a branch to the abductor pollicis brevis, which enters the medial edge of the muscle and then passes deep to it to supply the opponens pollicis, piercing its medial edge. Its terminal part occasionally gives a branch to the 1<sup>st</sup> dorsal interosseous, which may be its sole or partial innervation. It may arise in the CT and pierces the TCL, a point of surgical importance<sup>[24]</sup>. The position of the motor branch (in 30 hands) was extraligamentous in 46%-60%, subligamentous in 31%-34% and transligamentous in 6%-23% of

116 fresh frozen cadaveric hands<sup>[34,40]</sup>. So, the most common pattern of the motor branch is extraligamentous and recurrent. The mean distance between the distal edge of the TCL and this branch is about 2.7-6.5 mm<sup>[23,32]</sup>.

### The flexor tendons

The flexor tendons are the four tendons of the FDS, four tendons of the FDP and the tendon of the FPL. The superficialis tendons are all separate and the tendons for the middle and ring fingers lie superficially to those for the index and little fingers. The MN lies superficially to the tendons of FDS. The profundus tendons are still deeper to the FDS tendons. Only the slip to the index finger is separate; the other three are still fused and lie medially to the index slip<sup>[33]</sup>. The FPL tendon passes radially through a special canal between the two laminae of the TCL and the groove of trapezium. It is surrounded by a separate synovial sheath called the "radial bursa" which extends along the thumb as far as the insertion of the tendon at the base of the distal phalanx. Proximally, the radial bursa extends to a point 2.5 cm above the wrist joint/TC. It is sometimes connected to the base of the second metacarpal or may be absent<sup>[24]</sup>.

## MECHANICS OF FLEXOR TENDONS AND THE MN WITH FINGER AND WRIST MOVEMENTS

Along their course, the long flexor tendons pass through a flexor pulley system which includes the TCL, PA and the digital pulleys, where the lubricant effect of synovial fluid maintains low friction between these tendon and the pulleys. *In vivo* and during active flexion and extension of the wrist and fingers, measurements revealed that longitudinal tendon excursion is about 24-50 mm<sup>[48,49]</sup>, while MN excursion was found to range from 11-28 mm during wrist and elbow movement<sup>[50,51]</sup>.

It is highly suggested that non-inflammatory fibrosis and thickening of the synovium is a leading cause for MN compression<sup>[52]</sup>. These synovial changes also alter the gliding characteristic of the subsynovial connective tissue (SSCT), where it moves en bloc with the tendons and MN, which may play a role in the etiology of CTS<sup>[53,54]</sup>. About 90% of the synovial specimens resected from patients with idiopathic CTS did not exhibit inflammatory changes, but mostly edema or fibrosis<sup>[55,56]</sup>. Other findings of chronic synovial degeneration were reported as indicated by the increase in fibroblast density, collagen fiber size and vascular proliferation<sup>[57]</sup>.

Additionally, the flexor tendons move upwards (volar displacement) from the floor of the CT during active finger movement<sup>[58-60]</sup>. This movement causes a force of compression/ reaction between the tendons and the TCL. Almost the same amount of force of the flexor tendon could be applied to the TCL during finger movement<sup>[61]</sup>.

Because the SSCT and tendon are physically connect-

ed, a decrease in SSCT motion (due to fibrosis) relative to the tendon would increase the shear strain on the SSCT with tendon motion. Thus, this result suggests that the SSCT may be predisposed to maximum shear injury from activity done in 60 degrees of wrist flexion more than the motion in all other wrist positions<sup>[62]</sup>. During hand and finger motions, friction between the FDS tendon and the MN is thought to play a role in the development of cumulative trauma disorders<sup>[62]</sup>. Also, the ratio of MN excursion to tendon excursion was much lower in finger-only motions compared to wrist motions with or without finger motion<sup>[63]</sup>. High velocity tendon motion was reported to predispose to SSCT shear injury<sup>[64]</sup>.

A step forward damage in the SSCT in the CT was observed to follow repeated stretch tests within the physiological range of tendon excursion<sup>[12,62]</sup>. Similarly, repetitive hand activities caused thickening of the synovial lining of the tendons that share the CT with the MN<sup>[20,65]</sup>.

Furthermore, shear tension and injury of the SSCT in CTS patients is significantly higher than that in normal subjects<sup>[66]</sup> and the excursion of the MN is markedly reduced<sup>[50,51]</sup>. This finding may be consistent with the fact that fibrosis of the synovial tissue within the CT is often observed in CTS patients.

## PALMAR APPONEUROSIS (STRUCTURE AND FUNCTION)

The deep fascia of the palm of hand (palmar fascia) is thin over the thenar and hypothenar eminences, but its central portion, the PA, is triangular in shape. It has great strength and thickness. Its apex is continuous proximally with the distal border of TCL and receives the expanded tendon of the PL. Its base divides below into four slips, one for each finger<sup>[33]</sup>.

The PA covers the central compartment of the hand which contains the long flexor tendons and their synovial sheaths, the lumbricals, the superficial palmar arch and branches of the median and ulnar nerves with their digital nerves and vessels. Between the flexor tendons and the fascia covering the deep palmar muscles lies the medial central palmar (mid-palmar) space which is continuous with the space of at distal forearm in front of pronator quadratus (Space of Parona) via the CT<sup>[24]</sup>.

The deeper part of each slip subdivides into two processes, which are inserted into the fibrous sheaths of the flexor tendons. At the points of division into the slips, numerous strong transverse fascicular fibers of the PA are positioned at the proximal margin of the flexor tendon sheath. They bind the separate processes together and are attached by vertical septa to the underlying transverse metacarpal ligament, thus forming a tunnel around the flexor tendon and a PA pulley for the flexor tendons in conjunction with the first and second annular pulleys of the digital flexor mechanism<sup>[67,68]</sup>.

The PA pulley might be considered as important as the annular and cruciate flexor tendon pulleys. The PA decreases the tendency to bowstring around the metacar-

pophalangeal joint with a combination of proximal annular pulleys<sup>[69]</sup>.

The PA forms a fibrotendinous complex that functions as the tendinous extension of the PL when present and as a strong stabilizing structure for the palmar skin of the hand. It has a deeper transverse portion that crosses the palm at the proximal end of the metacarpal bones.

Aponeurosis provides firm attachment to overlying skin, helps to form the ridges in the palm, which in turn help to increase friction so that we can grasp objects firmly, protects underlying structures and provides attachment to muscles. The transverse fascicular fibers of the PA at the proximal margin of the flexor tendon sheath appear to function as a pulley<sup>[67]</sup>.

## CLINICAL DIAGNOSIS OF CTS

The stages of CTS symptoms and signs can be categorized into three stages. In the first stage, the patient will awaken from sleep with a feeling of a numb or swollen hand, with no actual swelling visible. They may feel severe pain coming from their wrist emanating to their shoulder, with a tingling in their hand and fingers known as brachialgia paresthetica nocturna. Patients will note that shaking or flicking of their hand will stop the pain and that their hand may feel stiff in the morning. The second stage involves the symptoms being felt during the day. These may be felt especially when the patient performs repeated hand or wrist movements or if they remain in the same position for a long time. Patients may also notice clumsiness when using their hands to grip objects, resulting in the objects falling. The third and final stage occurs when there is hypotrophy or atrophy of the thenar eminence. When this stage is reached, sensory symptoms may no longer be felt at all<sup>[70]</sup>.

When diagnosing a patient with CTS, it is important to create a case history relevant to the characteristic signs of CTS. The patient must be questioned about whether their symptoms occur mainly at night or during the day, whether certain positions or repeated movements provoke their symptoms, if they use any vibratory instruments for work, whether their symptoms are felt in the hand, wrist or shoulder (and where in the areas symptoms are felt), what patients may do to alleviate symptoms (shaking, flicking, *etc.*), or if the patient may have a predisposing factor<sup>[70]</sup>. Many factors may in fact be connected to CTS. They can include inflammatory arthritis, diabetes mellitus, pregnancy, hypothyroidism, Colles' fracture, acromegaly, amyloidosis, adiposity, myxedema, chronic polyarthritis or the use of corticosteroids and estrogens<sup>[1,70]</sup>.

A proper physical examination of the patient's hand and wrist is an important first step towards the diagnosis of CTS as certain physical findings may suggest the presence of other conditions. Abrasions or ecchymosis on the wrist and hands may indicate that there has been injury to the tissue, which could also include injury to the

median nerve. If bony abnormalities like the boutonniere deformity, the swan neck deformity or the ulnar deviation of the wrist are found, it could be concluded that the patient suffers from rheumatoid arthritis. If bossing on the carpal or distal phalanx is observed, osteoarthritis may be the cause. Other neuropathy syndromes or carpo-metacarpal arthritis may be suspected if thenar atrophy is seen as this condition usually happens only with severe and chronic CTS, which is not as common<sup>[71]</sup>.

Since patient history and physical examination have only limited diagnostic value and do not reveal the specific areas of symptom occurrence, patients can additionally be asked to fill out a self-diagnosis questionnaire known as the Katz Hand Diagram. A Katz Hand Diagram allows the patient to specify where they are experiencing symptoms and to classify the symptoms as numbness, pain, tingling or hypoesthesia. The completed symptom diagram can then be classified into one of three patterns of CTS.

Classical pattern: symptoms experienced by at least two of either the first, second or third fingers. Symptoms may also involve the fourth and fifth fingers, as well as wrist pain and radiation of pain proximally to the wrist however should not involve the palm or dorsum of the hand is not allowed. Probable/possible pattern: includes the same symptoms as in the classical pattern, however the palmar symptoms should only be limited to the median side. Possible pattern: symptoms involving only one of the first, second or third finger. Unlikely pattern: no symptoms are present at all in the first, second or third finger<sup>[70]</sup>.

A classical or probable diagram indicates the presence of CTS (sensitivity = 64%; specificity = 73%)<sup>[70-73]</sup>. An additional subjective test is referred to as the flick sign (sensitivity = 93%; specificity = 96%)<sup>[71,73]</sup> where the patient is simply asked whether or not they relieve the symptoms which awaken them at night with flicking or shaking of their hands. If the patient reports that this does happen to them, this may be indicative of CTS<sup>[74]</sup>.

Additionally, traditional tests known as provocative tests can be easily conducted by the physician on the patient to determine the possibility of CTS. One such test is a wrist flexion test known as Phalen's test (sensitivity = 57%-91%; specificity = 33%-86%)<sup>[71,73,74]</sup> that involves the patient placing their elbows on a flat surface, maintaining their forearms vertically and allowing their wrists to fall into flexion for up to one minute.

The "reverse Phalen's test" (sensitivity = 57%; specificity = 78%)<sup>[74]</sup>, also known as the wrist extension test or "Wormser's test"<sup>[75]</sup>, is also possible and involves the patient actively extending their fingers and wrist for two minutes. Another well known test is Tinel's sign (sensitivity = 23%-60%; specificity = 64%-87%)<sup>[71,73,74]</sup>, where the physician taps along the patient's median nerve near the carpal tunnel. Durkan's test (sensitivity = 64%; specificity = 83%)<sup>[74]</sup>, or carpal compression, is a test where the physician presses on the proximal edge of the carpal ligament with their thumb, compressing the median nerve.

The hand elevation test (sensitivity = 75.5%; specificity = 98.5%)<sup>[76]</sup> is done by asking the patient to raise both of their arms, along with their elbows and shoulders, and holding the position for up to two minutes. The tourniquet test (sensitivity = 21%-59%; specificity = 36%-87%)<sup>[73,74]</sup>, or Gillet test, is performed by having the physician raise a blood pressure cuff placed on the patient's arm to the level of their systolic blood pressure. For all of the above noted tests, if paresthesia develops or increases in the median nerve distribution within one minute or less, then the test is deemed to have a positive result and CTS in the patient may be suspected<sup>[1,74]</sup>.

It is important to note that, although provocative tests and physical examination are simple and low cost methods to test for reproduction of the patient's symptoms and to determine if CTS should be suspected, provocative tests have scarce or no diagnostic value<sup>[1,70,71]</sup> and physical examination has inadequate predictive value if the likelihood of CTS is low<sup>[77]</sup>. There have been no trends identified between testing positive for various provocative tests and the severity of CTS<sup>[78]</sup> and therefore proper diagnostic conclusions based on these tests cannot be made.

### Nerve conduction studies

Due to this lack of diagnostic value in the mentioned tests, if CTS is suspected in a patient, adjunctive electrodiagnostic tests can be performed for a better diagnosis as they quantify and stratify the severity of CTS<sup>[71]</sup>. These tests include nerve conduction studies and electromyography which may help with the future decision of treatment options and they have a sensitivity of 56% to 85% and a specificity of at least 94%<sup>[71]</sup>. Because of their high specificity and sensitivity percentages, nerve conduction studies are considered to be the gold standard for CTS diagnosis<sup>[3,72]</sup>. Nerve conduction studies provide insight on the median nerve's true physiological health on a quantitative basis by comparing the latency and the amplitude of the nerve across the carpal tunnel to another nerve segment not passing through the carpal tunnel (*e.g.*, the radial or ulnar nerve)<sup>[5]</sup>. This is done by transcutaneously stimulating the nerve to create an action potential through an electrical pulse and having the depolarization wave detected by a recording electrode, that has been placed proximally or distally, and defining the response time of the median nerve as the "sensory conduction velocity" (SCV)<sup>[3,70,79]</sup>.

It is necessary to compare the response of the median nerve to another nerve not within the carpal tunnel due to the fact that there are different factors like gender, age, obesity, temperature, finger diameter or concurrent systemic disease that can influence the latency or amplitude of the median nerve<sup>[3,80,81]</sup>. Using these controls increases the accuracy and sensitivity of diagnosis, with a sensitivity of 80%-92% and a specificity of 80%-99%<sup>[3,79]</sup>. Additional data may also be obtained by studying the distal motor latency (DML) in the median and ulnar nerves in the same hand<sup>[3]</sup>.

Diagnostic criteria for CTS in nerve conduction studies include the median nerve showing extended amounts of sensory and motor latencies as well as delayed or diminished sensory and motor conduction velocities<sup>[3]</sup>. Nerve conduction studies focus on defining whether there has been damage to the median nerve inside the carpal tunnel to quantify the severity of this nerve damage using a scale and to define the physiology of this injury as a conduction block, demyelination or axonal degeneration<sup>[3,9,70]</sup>. The electrophysiological classification of the severity of CTS has been defined by the American Association of Electrodiagnostic Medicine (AAEM) and is as follows: (1) Negative CTS: normal findings on all tests (including comparative and segmental studies); (2) Minimal CTS: abnormal findings only on comparative or segmental tests; (3) Mild CTS: SCV is slowed in the finger-wrist tract with normal DML; (4) Moderate CTS: SCV is slowed in the finger-wrist tract with increased DML; (5) Severe CTS: absence of sensory response is seen in the finger-wrist tract with increased DML; and (6) Extreme CTS: complete absence of a thenar motor response<sup>[3,70,82]</sup>.

Nerve conduction studies can be paired with electromyography in order to tell the difference between muscle weakness that has been created by neurological disorders and primary muscle conditions<sup>[71]</sup>. Adjunctive tests are, however, best used for patients who present with untypical symptoms and examination or if they possess an intermediate probability of having CTS. Although nerve conduction studies are a more accurate way of diagnosing CTS, they cannot be used for every patient showing symptoms of CTS as this would be expensive and inefficient<sup>[3,72]</sup>. Although nerve conduction studies are the most sensitive and accurate way to diagnose CTS, false positives and false negatives are still possible and account for 16%-34% of "clinically defined CTS" going undiagnosed<sup>[3,83]</sup>.

When diagnosing CTS, it is important to remember that many other conditions can produce similar symptoms to CTS<sup>[71]</sup>. A thorough physical examination along with an accurate patient history is an important first step for a correct diagnosis and the following list include some of the conditions that CTS must be differentiated from, along with the physical findings they are associated with: Wrist arthritis: seen in patients experiencing limited motion at the wrist or if there are radiological findings of arthritis; Carpometacarpal arthritis of thumb: characterized by joint line pain, pain experienced during motion or arthritis in radiological findings; Cervical radiculopathy (C6-C7): symptoms can include neck pain and numbness in the thumb and index finger only; Flexor carpi radialis tenosynovitis: can be suspected if there is tenderness near the base of the thumb; Ulnar or cubital tunnel syndrome: signs can include first dorsal interosseous weakness or tingling in the fourth and fifth digit; Median nerve compression at elbow: if there is tenderness at the proximal forearm; Raynaud's phenomenon: if the patient has a history of symptoms related to cold exposure; Vibration

white finger: seen in patients who use vibrating hand tools at work; Volar radial ganglion: if a mass near the base of thumb is found above the wrist flexion crease; Brachial plexopathy (in particular of the upper trunk); Thoracic outlet syndrome and CNS disorders (multiple sclerosis, small cerebral infarction)<sup>[3,70,71]</sup>.

Electrodiagnostic testing can be helpful with a differential diagnosis by being able to identify other hand dysesthesia conditions like cervical radiculopathy, polyneuropathy or median nerve entrapment syndromes<sup>[73,84]</sup>. Additionally, needle electromyography specifically may be helpful with disorders that are proximal to the median nerve as well as to rule out a radiculopathy<sup>[70]</sup>.

Quantitative sensory testing is also used for sensory or motor tests to give quantitative results when diagnosing CTS. These tests include testing for touch threshold using Semmes-Weinstein Monofilaments (SWMF) (sensitivity = 59%-72%; specificity = 59%-62%)<sup>[73,74]</sup>, also referred to as Weinstein Enhances Sensory Test (WEST), where a five piece SWMF/WEST set is used and the filaments are applied onto digit pulps. Positive results of this test are deemed as a threshold greater than 2.83 in digits D1-D3 (an abnormal result); usually D2 or D3 are also assessed and comparison with D5 can improve the specificity as it eliminates thresholds that are larger than 2.83 due to aged or calloused skin. Another quantitative test is the two-point discrimination test (sensitivity = 6%-32%; specificity = 64%-99%)<sup>[73,74]</sup> where the patient is asked to differentiate between the touch of prongs as they are applied until the skin blanches. Positive results (an abnormal finding) of this test are > 5 mm on pulps. Testing for the vibration threshold, measuring with either a tuning fork (sensitivity = 55%; specificity = 81%)<sup>[74]</sup> or vibrometer (sensitivity = 50%; specificity = 73%)<sup>[74]</sup>, is also possible. These tests include applying a tuning fork (at 256 cps) tangentially to the fingertip pulp D1-D3 after hitting it to the affected side and comparative site or by applying a vibration stimulus to the digital pulp with a vibrometer and observing if the patient's feeling is different compared with the normal site (D5) or alternate site or, in the case of the vibrometer, if the thresholds are greater than norms for positive results. Current perception threshold (sensitivity = 80%; specificity = 61%)<sup>[74]</sup> is tested for by delivering different frequencies of current and touching the patient with the equipment delivering this current. This stimulates the sensory nerves and positive results can be identified by comparing the patient's thresholds and frequency ratios with established norms in a computer software analysis. Thenar weakness or thenar atrophy (sensitivity = 4%-28%; specificity = 82%-99%)<sup>[71,73]</sup> can also be tested for by visually inspecting the abductor pollicis brevis to look for loss of muscle bulk (positive result for thenar atrophy) or to use Oxford grading for the abductor pollicis brevis and observing a grade less than 5 (for thenar weakness). Thenar muscles are innervated by the median nerve, so the impairment of these muscles is indicative of the compromise of the motor fibers<sup>[74]</sup>.

All in all, debate and disagreement still exist on the

**Figure 3** Axial computed tomography scan shows bony part of carpal tunnel at the level of outlet. Bony structures from left to right are HAMATE, CAPITATE, TRAPEZOID, TRAPEZIUM. FR (arrow) b and flexor tendons can be detected by computed tomography scan.

proper and accurate diagnosis of CTS. However, most experts can agree that the combination of nerve conduction studies (currently deemed the gold standard for diagnosis) and subjective symptoms allow for the most accurate way of diagnosing CTS<sup>[78]</sup>.

### Computed tomography and conventional X-ray

Plain radiography has a limited role in diagnosing primary CTS as it cannot reveal the soft tissue part of the carpal tunnel. However, it might be useful in cases associated with bony stenosis, fracture and soft tissue calcification<sup>[85]</sup>. Therefore, it should not be indicated unless there is a history of trauma to the hand or limitation in the range of wrist movement. CT scanning might provide a better alternative than plain radiography to clearly visualize the bony part of the carpal tunnel (Figure 3).

It can easily reveal the unusual bony structures and the structure occupying the space within the carpal tunnel that are not discovered by external examination<sup>[86]</sup>. However, compression of the nerve cannot be clearly visualized unless it is due to the bony condition. In addition, several other reports have demonstrated the minor contribution of this approach in cases of primary CTS<sup>[87,88]</sup>. In summary, plain radiograph and CT scan play minor roles in CTS diagnosis and they are difficult to standardize due to their inherent limitations in evaluating soft tissue changes<sup>[85]</sup>. Therefore, CT scans and plain radiography should not be used as routine CTS diagnostic tools unless hard tissue related changes such as bone fracture, osseous carpal stenosis and calcifying of soft tissue are suspected<sup>[85]</sup>.

### Ultrasonography

Due to recent advances at increasing resolution of sonographic pictures, it is possible to acquire a high quality image of peripheral nerves and fascia. Ultrasonography (US) is also able to identify changes in the flexor retinaculum, perineural and intraneural vascularization of the median nerve in idiopathic carpal tunnel syndrome (Figures 4-7). It can also identify the causes for secondary CTS. A study

**Figure 4** Axial ultrasound image shows flexor retinaculum bowing as an echogenic line (arrow) in carpal tunnel and cross sectional area of median nerve (stellate) in a patient with carpal tunnel syndrome.

**Figure 5** Longitudinal color Doppler sonogram in a 40-year-old woman with severe carpal tunnel syndrome shows intraneural hypervascularity in the median nerve.

**Figure 6** Spectral Doppler waveform of the median nerve shows low resistance hypervascularity of affected median nerve in a 40-year-old woman with severe carpal tunnel syndrome.

**Figure 7** Axial ultrasound image shows hypoechoic cable like neural fascicle (arrows) separated by substratum hyperechoic fat in a patient with secondary carpal tunnel syndrome due to lipofibromatous hamartoma of the median nerve.

by Nakamichi and Tachibana included 414 symptomatic wrists and 408 control wrists<sup>[89]</sup>. Both sonography and nerve conduction studies were performed and the results were compared. The cross-sectional area of the median nerve was measured at the distal edge of the flexor retinaculum, the hook of hamate and the pisiform. Clear differences between the symptomatic patients and control patients were observed at all three levels. Nakamichi and Tachibana proposed cut off values of the CSA for each level ranging from an average of 12 mm<sup>2</sup> to 13, 11 and 14 mm<sup>2</sup> at all three levels. Specificity was found to be greater than 95% with sensitivity ranging from 43%-57%<sup>[89]</sup>.

Along the same lines, in a study carried out by El Miedany *et al.*<sup>[90]</sup>, sensitivity and specificity were determined by measuring the CSA at the carpal tunnel inlet. Sensitivity and specificity measurements were found to be much higher than those presented by Nakamichi and Tachibana<sup>[89]</sup>. The study included 96 symptomatic wrists and 156 control wrists, all of which were analyzed using both ultrasound and nerve conduction studies. Cut off for mild disease was 10 mm<sup>2</sup>, moderate at 13 mm<sup>2</sup> and severe at 15 mm<sup>2</sup>. Sensitivities and specifics for mild, moderate and severe disease were measured to be 98% and 100%, 98% and 97%, and 97% and 99%.

Theoretically, nerve enlargement results from a series of factors including inflammation, fibrosis, new axonal growth, endoneurial edema, demyelination, remyelination, *etc.* These indicators of increased CSA are all visible on US. Recent studies have shown that US is effective in confirming the diagnosis of CTS. One advantage that US has over NCS is that other lesions which display symptoms similar to CTS can be excluded from examination; these include tenosynovitis, mass lesions and anatomic defects. Moreover, US is low cost, readily available, noninvasive and total examination time is short. It can be recommended to use US as a replacement for clinical findings and first-line therapy in the diagnosis of CTS. However, in more complicated cases where diagnosis of CTS may require some confirmation, US would be a great tool as it is more sensitive and less invasive than nerve conduction studies.

It remains the case that there is not yet a reliable diagnostic standard for CTS. However, many of the studies in this review were able to rule out CTS if the CSA of the median nerve in the carpal tunnel inlet was below 10 mm<sup>2</sup>. Flexor retinaculum bowing, flattening of the median nerve and decreased longitudinal excursion on

**Figure 8** Axial T1W image of carpal tunnel at the level of tunnel outlet shows bony part of carpal tunnel as intermediate signal intensity composed from left to right hamate, capitate, trapezoid, trapezium. dynamic assessment are other measurements offered in addition to the CSA of the median nerve in the US assessment of CTS but are not as reliable. Limitations of US include axial and lateral resolution of the transducer that restrict the sonographic measurements as well as the challenge in differentiating the MN from the surrounding structures, especially in the distal CT. Ultrasonography can be implemented universally when a standardized protocol is used because the measurements are found to be reproducible.

### Magnetic resonance imaging

Magnetic resonance (MR) imaging allows for good imaging of soft tissue. This makes MR imaging the optimal choice when studying CT in detail (Figure 8).

The drawbacks to MR imaging are that it is very costly, time consuming and not readily available. For these reasons, it is not advisable for MR imaging to be used in the diagnosis of CTS. The use of MR imaging is advisable in cases where the patient is resistant to therapy and/or for research. MR imaging does not add enough information of value to justify its use in the routine diagnosis of CTS in place of clinical and electrophysiological evaluation. Use of MR imaging can be justified in various circumstances, such as acute severe CTS following blunt trauma, arthritis, lack of evidence of nerve compression, surgical failure, long lasting CTS, detection of fibrous tissue and scars surrounding the MN and other anomalies of CT<sup>[91]</sup>. MRI can be used to determine the exact point of nerve entrapment, for diagnosis in the case of ambiguous symptoms and to identify space-occupying lesions<sup>[92]</sup>.

MR imaging is useful for revealing the cause of nerve compression or elongation. Studies of MRI on CTS have shed tremendous light on the pathophysiology of idiopathic CTS. Typical indicators of idiopathic CTS are proximal enlargement of the cross-sectional area (CSA) of the median nerve of the carpal tunnel, greater signal intensity over the MN and palmar bowing of the TCL<sup>[93]</sup>.

The degree to which these findings are evident depends on the stage of the disease as enlargement of the CSA and increased signal intensity become more pronounced as the disease progresses. On T2-weighted MRI scans, high-signal intensity over the median nerve can indicate any of the following: accumulation of the axonal transportation, myelin sheath degeneration or edema<sup>[94]</sup>. Enlargement of the structures within the carpal tunnel may be indicated by palmar bowing of the TCL. The severity of nerve compression can be determined accurately by sagittal images<sup>[95]</sup>. It must be noted that no parameter has been developed that is able to be used to define CTS clearly. However, MRI provides the greatest diagnostic sensitivity for idiopathic CTS<sup>[96]</sup>. MRI can be used to predict surgical outcomes in patients with CTS irrespective of NCSs. Moreover, patients prefer MRI to NCSs<sup>[96]</sup>. MRI studies have indicated that increased T2-signal intensity in the median nerve and bowing of the flexor retinaculum seem to be the most sensitive MR signs of CTS. Increases in CSA area, flattening of the MN and peritendon pathology are other potential indicators of CTS on MRI<sup>[97]</sup>.

Previous reviews on MRI have pointed to the complications also encountered in this review. Original studies provide unsatisfactory descriptions of the reference diagnosis and only recruit asymptomatic referents<sup>[93]</sup>. Consensus criteria of CTS include symptoms, clinical findings and electrophysiological criteria<sup>[16,98]</sup>. The lack of consistency in diagnostic criteria provides for variations in patient spectra which takes a toll on the test accuracy<sup>[99]</sup>. A possible remedy for this in the future would be to include more detailed descriptions of the symptoms of the referents before the original studies.

Bak *et al*<sup>[100]</sup> studied twenty patients with CTS to determine if various MRI parameters correlated with nerve conduction test results. Results of the nerve conduction tests did not affect inclusion in the study. While no correlation was found, it should be noted that the patients did not show enlargement of the cross sectional area of the MN. The nerves seemed round rather than flat. Such a finding begs the question of diverse pathophysiological mechanisms behind CTS and how the diverse stages of chronicity of the disease affect the imaging outcome.

Unsatisfactory documentation of clinical characteristics has been shown to lead to overestimation of test accuracy. On the other hand, unsatisfactory documentation of reference diagnosis leads to underestimating test accuracy<sup>[99]</sup>. Additionally, insufficient blinding and a poor description of results may also lead to the overestimation of test accuracy.

Two studies that used referents with contralateral symptom-free hands did not find the cross sectional area of the median nerve to be enlarged<sup>[100,101]</sup>, which is an observation made in other studies in which healthy volunteers were the referents. This finding can be attributed to other factors besides CTS. So long as there is a gold standard for the diagnosis of CTS, any other disease that causes similar symptoms may prove to hinder future studies.

## TREATMENT OF CARPAL TUNNEL SYNDROME

Treatment of CTS can be classified as surgical and non-surgical. Surgical treatments include standard open carpal tunnel release, endoscopic carpal tunnel release, open carpal tunnel release combined with procedures and open carpal tunnel release using various incision techniques<sup>[102]</sup>. Non-surgical treatments, also referred to as conservative treatments, include a wider range of options such as splinting, cortical steroid injections, non-steroidal anti-inflammatory drugs, B6 vitamin, diuretics, ultrasound therapy, ergonomic positioning, manual therapy intervention, lidocaine patches and acupuncture<sup>[103-105]</sup>. Treatment decisions on carpal tunnel syndrome are based on the severity of the symptoms. Non-surgical treatments are recommended for patients with mild symptoms of CTS. Patients with moderate to severe symptoms are recommended for surgical evaluation.

### Non-surgical treatment

Non-surgical treatment of CTS is recommended for patients that show mild to moderate symptoms of CTS. There is a variety of treatments that do not involve surgical procedures; however, splinting and steroids are most commonly used and supported by evidence<sup>[102]</sup>. The most common splinting method is the neutral splint, which involves the immobilization of the wrist in a neutral position. This neutralizes flexion and extension of the wrist, thus increasing carpal tunnel pressure<sup>[106]</sup> (Gerritsen, 2001 #73). Neutral splinting is generally recommended for use for a period of 6 wk during night time, however studies have shown better improvement in the full time use of the splints<sup>[107]</sup>. Long term studies have shown considerable results of treatment success of night wrist splints at 3 mo of treatment<sup>[108]</sup> and after 12 mo of additional treatment after 6 wk treatment with night splints<sup>[109]</sup>. Other splinting methods include soft hand splints<sup>[106,110]</sup>, volar wrist cock-up and modified ulnar gutter splints<sup>[111]</sup>. Soft hand splinting and neutral wrist splinting have been seen to show no significant differences within 3 mo of treatment<sup>[112]</sup>; however, soft hand splinting can be considered an alternative to neutral wrist splinting<sup>[113]</sup>. Treatment using steroids is done by local injection of corticosteroids directly into the patient's carpal tunnel. There is a risk associated with the injections and the possible decompression of the median nerve<sup>[114]</sup>, thus different approaches have been used regarding the injection site of the steroid. Injection through the wrist crease has been done using a distal or proximal approach to the wrist crease, with the distal approach resulting in a more comfortable and alternative approach<sup>[115]</sup>. Other methods include intercarpal injections of steroids, shown to be a safe approach. Several studies have been conducted using an ulnar approach to the palmaris longus tendon<sup>[114,116]</sup> and have shown the treatment to be effective and risk free. Overall, treatments involving local steroid injections are effective in relieving symptoms associated with CTS for a short time, thus they are considered an effective short-term treat-

ment<sup>[110,117,118]</sup>. Local anesthetic injections such as procaine hydrochloride have been shown to be effective additions to steroid injections; however, studies have shown that procaine hydrochloride injections are as effective as steroid injections in short term treatment of CTS<sup>[119,120]</sup>.

A different approach to steroidal treatments is oral steroids such as prednisolone, proven effective for short-term treatment<sup>[121]</sup>. Studies involving several types of nonsteroidal anti-inflammatory drugs have concluded that NSAIDs have no effect in pain relief and treatment of CTS and their effect has been compared to that of a placebo<sup>[71,122]</sup>. However, other studies have shown effectiveness of NSAIDs drugs such as Naproxen in short term pain relief for CTS<sup>[123]</sup>. Several studies have concluded that pyridoxine and diuretics, such as trichlor-methiazide, have no more effect than a placebo in the treatment of CTS<sup>[71,122]</sup>. Ergonomic positioning has been tested for possible effects on CTS and, despite the presence of pain relief after a period of 12 wk under treatment, the evidence was not enough to prove the effect of ergonomic positioning on CTS<sup>[124]</sup>. Heated lidocaine patches have also been identified as possible alternative short-term treatments for CTS, showing significant pain reduction following a two week study<sup>[105]</sup>. Acupuncture is another treatment approach for CTS. Studies have shown significant pain reduction in patients with CTS using proximal and distal acupoints, as well as improvement of overall subjective symptoms using sham acupoints<sup>[125,126]</sup>. Acupuncture has been shown to be as effective as night splints in the treatment of CTS<sup>[105]</sup>. Ultrasound therapy is another alternative conservative treatment that has been shown to have positive effects in short term treatments of CTS in patients showing mild to moderate symptoms<sup>[127,128]</sup>. Manual therapy intervention studies have concluded improved signs and symptoms for CTS<sup>[104]</sup>. It is important to note the role of sonography in assessing the possible effects on different types of treatments for CTS, including corticosteroid injection and splinting treatments<sup>[106]</sup>.

### Surgical treatment

Surgical treatment of CTS consists of the division of the transverse carpal ligament which reduces the pressure on the median nerve by increasing the space in the carpal tunnel<sup>[2]</sup>. Surgery is recommended for most patients with moderate to severe CTS. There are two different categories of methods used for surgical treatment of CTS: open release and endoscopic release. Open carpal tunnel release consists of the standard method of open release, as well as several modified methods. Modifications to the standard open carpal tunnel release (OCTR) include new incision techniques, such as the mini-open release, and addition of other procedures such as epineurotomy<sup>[102,129]</sup>. The standard open carpal tunnel release consists of a longitudinal incision at the base of the hand and in line with this incision, the incision of the subcutaneous tissue, the superficial palmar fascia and the muscle of the palmaris brevis<sup>[129]</sup>. The mini-open carpal tunnel release is a relatively new technique that consists of a longitudinal

incision that varies from 1.5-3.0 cm, placed in line with the radial border of the ring finger<sup>[129]</sup>. Different tools have been used for the mini-open carpal tunnel release, such as the Indiana Tome, the Knifelight, the Safeguard System and PSU retractor<sup>[129]</sup>. Epineurotomy has been used as an additional procedure to the OCTR, with the prospective of minimizing median nerve compression occurring after standard OCTR<sup>[72]</sup>. Endoscopic carpal tunnel release (ECTR) is another new technique that was developed by Okutsu and colleagues since 1986<sup>[131]</sup>. The two most commonly used methods of endoscopic carpal tunnel release are the single-portal and dual-portal technique; techniques that differ based on the number of ports used to access the carpal tunnel<sup>[130]</sup>. The single portal technique consists of the release of the transverse carpal ligament by using a single incision at the wrist. The double-portal technique consists of two incisions, one at the wrist and one at the palm of the hand. Several studies have tried to compare the efficiency and outcomes of the techniques involving carpal tunnel release procedures. Open carpal tunnel release and endoscopic carpal tunnel release have been shown to have no significant differences in outcomes within 12 wk of surgery<sup>[132]</sup> and within 1 and up to 5 years of surgery<sup>[129]</sup>. Mini-open carpal tunnel release and standard open carpal tunnel release have shown no significant differences within 4 mo of surgery<sup>[133]</sup> and within 6 mo of surgery<sup>[134]</sup>; however, mini-open carpal tunnel release has been shown to have better outcomes in earlier stages after surgery<sup>[134]</sup>. ECTR release is sometimes favored over OCTR as dividing the skin from below preserves the muscle and overlying skin, thus facilitating return to work; however, it has an increased risk of nerve or artery injury because of limitations in visualization<sup>[129]</sup>. ECTR has been shown to have better outcomes in muscle strength within 12 wk of surgery<sup>[132]</sup> and better outcomes compared to both standard open and mini-open release within 4 wk of surgery<sup>[133]</sup>. Additional epineurotomy procedures have been shown to have no significant difference in electrophysiological effects or nerve volume compared to the standard OCTR within 180 d after surgery<sup>[135]</sup>.

## CONCLUSION

This review has explored and emphasized one of the most common entrapment neuropathies. There are several imaging modalities for assessing this condition but after analyzing the various options, it seems as if ultrasound examination with high-frequency probes and improved power Doppler technology should be used as the primary imaging investigation in the initial evaluation of CTS as it is the most beneficial and accurate. ECTR has been shown to have better outcomes than both standard open and mini-open release.

### Abstract

Huntington's disease (HD) is a progressive and fatal neurodegenerative disorder caused by an expanded trinucleotide CAG sequence in huntingtin gene (HTT) on chromosome 4. HD manifests with chorea, cognitive and psychiatric symptoms. Although advances in genetics allow identification of individuals carrying the HD gene, much is still unknown about the mechanisms underlying the development of overt clinical symptoms and the transitional period between premanifestation and manifestation of the disease. HD has no cure and patients rely only in symptomatic treatment. There is an urgent need to identify biomarkers that are able to monitor disease progression and assess the development and efficacy of novel disease modifying drugs. Over the past years, neuroimaging techniques such as magnetic resonance imaging (MRI) and positron emission tomography (PET) have provided important advances in our understanding of HD. MRI provides information about structural and functional organization of the brain, while PET can detect molecular changes in the brain. MRI and PET are able to detect changes in the brains of HD gene carriers years ahead of the manifestation of the dis-

ease and have also proved to be powerful in assessing disease progression. However, no single technique has been validated as an optimal biomarker. An integrative multimodal imaging approach, which combines different MRI and PET techniques, could be recommended for monitoring potential neuroprotective and preventive therapies in HD. In this article we review the current neuroimaging literature in HD.

**Key words:** Huntington's disease; Premanifest Huntington's disease gene carriers; Functional magnetic resonance imaging; Magnetic resonance imaging; Positron emission tomography

**Core tip:** Huntington's disease (HD) is a hereditary and fatal neurodegenerative disorder. Although advances in genetics allow identification of individuals carrying the HD gene, much is still unknown about the mechanisms underlying the development of overt clinical symptoms and the transitional period between premanifestation and manifestation of the disease. Neuroimaging techniques such as magnetic resonance imaging and positron emission tomography may be a suitable biomarker for monitoring disease progression in HD and for assessing the efficacy of future disease modifying therapies. In this article, we provide an overview of the findings from neuroimaging techniques in HD.

### INTRODUCTION

Huntington's disease (HD) is an inherited neurodegenerative disorder characterised by chorea, cognitive dysfunction and psychiatric symptoms caused by an expanded

trinucleotide CAG sequence in huntingtin gene (HTT), which is on chromosome 4<sup>[1]</sup>. HD prevalence varies by ethnic origin and different genetic profiles, in Caucasian populations of North America and Western Europe is 5.70 per 100000 whereas in Asian population is lower (0.40 per 100000)<sup>[2]</sup>. Although juvenile onset and late onset of HD are not uncommon, the disease usually appears at mid-40s, and there is an inverse correlation between age of onset and the size of the CAG repeat expansion<sup>[3]</sup>. However, subclinical changes and pathological processes are thought to precede the initiation of symptoms by several years<sup>[4,5]</sup>.

HD pathology is characterised by the formation of intranuclear inclusions of mutated huntingtin in the brain. These aggregates have been shown to interact and impair the function of a number of transcription factors leading to the loss of GABAergic medium spiny neurons (MSNs) in the striatum but also in cortical areas<sup>[6,7]</sup>. Currently there is no proven biomarker for HD, no effective treatment, and the disease will eventually lead to death, typically 15-20 years following symptomatic onset<sup>[8]</sup>. Much is still unknown about the mechanisms that underlie the clinical symptoms and the rate of progression from pre-clinical signs to development of overt symptoms.

Neuroimaging techniques such as magnetic resonance imaging (MRI) and functional MRI (fMRI) have played a critical role in characterizing structural and functional changes in the brain during the asymptomatic and symptomatic stage of the disease. PET imaging, by measuring the distribution of a radionuclide (radioligand) that is introduced into the body on a biologically active molecule, is a powerful technique for investigating *in vivo* abnormalities in brain metabolism and receptor distributions<sup>[9]</sup>. This analytical imaging method has the potential to give both structural and kinetic information and in comparison with other imaging techniques, provides high sensitivity, and high spatial and temporal resolution<sup>[10]</sup>. PET with the application of different radioligands has been used to measure metabolic changes in the brain of HD several years before disease onset (Table 1). In this article, we provide an overview of the findings from neuroimaging techniques in HD.

## LITERATURE RESEARCH

PubMed was searched for papers that were published before December 2013. The following key words were used in the search: "Huntington's disease", "positron emission tomography", "magnetic resonance imaging", "functional magnetic imaging". Additional papers were identified from citations in the articles found in PubMed. Only articles published in English were considered. A total number of 37 MRI and 49 PET studies were reviewed.

## MRI

### Structural MRI studies

The most consistent change in the HD brain is a significant progressive volumetric loss of the striatum<sup>[4,11-20]</sup>. A

reduction of 50%-54% in mean putamen volume and 28%-29% in mean caudate volume has been reported in patients with mild to moderate HD<sup>[11,12]</sup>. Striatal atrophy has been also documented in early HD patients with Total Functional Capacity (TFC) scores between I-II<sup>[14,15]</sup> and in premanifest HD gene carriers who were even 15-20 years before predicted disease onset<sup>[4,13,16-20]</sup>. The amount of volume loss in the striatum correlates with the age of onset, the disease duration and the CAG repeat length<sup>[14,15,21]</sup>. While motor impairment correlates with increased putamen atrophy, Mini-Mental Status Examination scores (MMSE) and cognitive assessments are inversely correlated with the amount of caudate volume loss<sup>[11,12]</sup>.

Cortical volume loss has been also reported in HD patients<sup>[17-20,22,23]</sup>. Cortical thinning occurs early during the course of the disease and seems to be topographically selective proceeding from posterior to anterior cortical regions as the disease progresses<sup>[22,23]</sup>. Individual variability in regional cortical thinning may also have a role in explaining phenotypic variability. For example, HD patients with more prominent bradykinesia showed significant cortical volume loss in frontal regions including the pre-motor and supplementary motor areas compared to HD patients with chorea<sup>[23]</sup>. Additionally, regional cortical atrophy correlates with clinical measures such as TFC, Unified HD rating scale (UHDRS) and cognitive tests enhancing the role of this measurement as potential biomarker for assessing neuroprotective therapies<sup>[23]</sup>. Widespread white matter (WM) atrophy has been identified in HD patients and has been associated with longer CAG length and decline in cognitive and motor performance<sup>[24]</sup>. Changes in WM volume are detectable up to 12-15 years before the predicted onset and correlate with cognitive functions underlining the role of structural connectivity degeneration in the pathogenesis of HD<sup>[25]</sup>. Diffusion tensor imaging (DTI) studies have also reported WM tract abnormalities in premanifest HD gene carriers and alterations in diffusion indices were correlated with cognitive performance<sup>[26-28]</sup>. Dumas and coworkers<sup>[28]</sup> have found abnormal WM connections of the sensori-motor cortex, which correlated with the 5-year probability for symptomatic conversion.

TRACK-HD is a multicentre longitudinal study, which focused in identifying sensitive and reliable biomarkers in premanifest HD gene carriers and early HD patients<sup>[17-20]</sup>. Four groups were enrolled in TRACK-HD: 120 premanifest HD gene carriers which were subdivided in pre-HD A and pre-HD B according to the proximity to predicted disease onset (pre-HD A > 10.8 years; pre-HD B < 10.8 years), and 123 early HD patients subdivided in two groups according to the TFC scores (HD stage I, HD stage II). At 12 months follow-up significantly increased total brain volume atrophy rates were reported in both premanifest HD gene carriers and early HD patients. Caudate and putamen volume was reported reduced by 1.4% to 4.5% compared with baseline in premanifest and early HD group. Atrophy of WM was also increased in all groups<sup>[18]</sup>. Over 24 mo, greater increases

PET: Positron emission tomography; *HD*: Huntington's disease.

in caudate and putamen atrophy were observed in all four subgroups. Higher rates of whole brain and grey matter (GM) loss were reported in pre-*HD* B, *HD*-I and *HD*-II; whereas in the pre-*HD* A GM atrophy was confined to the striatum. Interestingly, WM atrophy around the striatum and within the corpus callosum and posterior WM tract was observed even in the earliest premanifest stage<sup>[19]</sup>. At 36 mo, early *HD* patients showed further significant increases in whole brain, caudate, putamen and GM atrophy and these measures were strongly associated to TFC decline. Although in pre-*HD* A group increased rates of whole brain, striatal and WM atrophy were observed, these were not accompanied by progressive worsening of motor and cognitive performance. On the contrary, pre-*HD* B showed higher rates of brain structural loss compared to pre-*HD* A group and these were associated with significant decline in several motor and cognitive tests. Furthermore, striatal and GM volume measures were sensitive predictors of subsequent clinical diagnosis of *HD* in the pre-*HD* B group<sup>[20]</sup>. Taken together, these findings suggest that MRI measures are able to track pathology in premanifest and manifest *HD* gene carriers and could be useful for the designing of future clinical trials.

### Functional MRI studies

There is growing evidence that the severity of clinical manifestations in *HD* does not depend only on neuronal loss but also on neuronal dysfunction and circuitry reorganization, and these processes may occur at an early stage of the disease, possibly prior to neurodegeneration. Functional neuroimaging approaches such as functional MRI (fMRI) provide a dynamic images of the brain aiding to elucidate neural activity by measuring haemodynamic response (blood flow) of neural activation. Data from manifest *HD* patients have shown reduced task-activation in several subcortical and cortical regions as well as increased activation in different cortical areas, which were interpreted as a compensatory mechanism for task performances<sup>[29-34]</sup>. Interestingly, in premanifest *HD* gene carriers further from disease onset increased activation in several brain regions was observed, whereas premanifest *HD* gene carriers closer to disease onset showed reduced activation in the striatum<sup>[35-38]</sup>. Using fMRI and

a group independent component analysis, Unschuld and colleagues<sup>[39]</sup> investigated networks of functional connectivity while performing a Stroop colour-naming task in both healthy controls and premanifest *HD* gene carriers and correlated with depressive symptoms. Stroop related activity of the ventromedial prefrontal cortex was more significantly correlated with depressive symptoms in premanifest *HD* gene carriers than healthy controls. This correlation was stronger in the premanifest *HD* subgroup with CAG repeat length greater than 42<sup>[39]</sup>. Using a Tower of London fMRI task, the same group found significantly reduced functional coupling between the medial prefrontal cortex area and the left premotor cortex in a group of premanifest *HD* gene carriers and early manifest *HD* subjects<sup>[40]</sup>. These findings suggest that impaired brain network connectivity reflects cognitive and mood dysfunction in *HD* subject even at the earlier stage of the disease. Recently, studies have been focused in investigating functional brain connectivity patterns at rest with fMRI (resting state fMRI). This approach has the potential to give insight into functional changes without the interference of cognitive ability to perform a given task<sup>[41,42]</sup>. Resting state fMRI data have shown intrinsic reductions in functional connectivity in both premanifest and manifest *HD* gene carriers<sup>[43-45]</sup>. In premanifest *HD* gene carriers reduced blood-oxygen-level-dependent (BOLD) synchrony was observed between the caudate and premotor cortex<sup>[46]</sup>. Using a method that measures changes in synchrony in BOLD signal amplitude and across space, Poudel and coworkers<sup>[44]</sup> have found several abnormal networks in both premanifest and manifest *HD* subjects. For example, they have reported a decreased resting state synchronization in the sensori-motor network of premanifest *HD* gene carriers, and interestingly, the level of synchrony was associated with motor performance as measured by speeded self-paced tapping<sup>[44]</sup>. Overall these findings show abnormal functional network connectivity in both premanifest and manifest *HD*, suggesting that resting state fMRI may be useful in measuring early neuronal dysfunction and for monitoring progression of the disease.

Neurovascular alterations have been also found in premanifest *HD* gene carriers. Cortical arteriolar cerebral blood volume (CBV<sub>a</sub>) was significantly elevated in pre-

manifest *HD* gene carriers compared to normal controls and correlated with genetic measures such as the CAG-age product score and the estimated years to onset<sup>[47]</sup>. Metabolic brain changes may also occur in premanifest *HD* gene carriers and they may precede structural brain changes<sup>[48]</sup>. N-acetylaspartate (NAA) and glutamate levels were decreased in the posterior cingulate cortex of 12 premanifest *HD* gene carriers and they correlated with cognitive decline as measured with the Montreal Cognitive Assessment<sup>[47]</sup>. Neurovascular alterations and metabolic brain changes occurs before substantial brain atrophy suggesting that they may be used as potential biomarker for clinical and therapeutic future studies.

## PET

### Dopaminergic system

Altered dopamine signalling may play a key role in the pathogenesis of *HD*<sup>[49,50]</sup>. In particular, striatal MSNs expressing dopamine receptors are primarily affected in *HD*, whereas presynaptic dopaminergic nerve terminals are relatively spared<sup>[51]</sup>. PET studies in premanifest and manifest *HD* gene carriers have shown severe involvement of the postsynaptic dopaminergic system, whereas the dopaminergic nerve terminals seem to be less affected<sup>[52-55]</sup>. An <sup>18</sup>F-fluorodopa case-study did not demonstrate diminished striatal dopamine synthesis capacity suggesting an intact nigrostriatal pathway<sup>[52]</sup>. However, Ginovart and coworker<sup>[56]</sup>, using PET with <sup>11</sup>C-b-CIT, have found a 50% decrease in striatal dopamine transporter (DAT) binding. In line with this finding, nigrostriatal density of the type-2 vesicular monoamine transporter (VMAT2) was found reduced in *HD* patients<sup>[57]</sup>. It still remains unclear whether degeneration of nigrostriatal dopaminergic neurons or presynaptic terminal dysfunction takes place in *HD*.

Investigations of postsynaptic dopaminergic systems, specifically the role of D1 and D2 receptors, which are highly expressed in MSNs, have shown reduced receptor densities and activity in the striatum of *HD* patients even at the early stage of the disease. The radioligand <sup>11</sup>C-SCH23390 is a selective antagonist of D1 receptors while <sup>11</sup>C-raclopride is a selective reversible antagonist of D2 receptors. Striatal D1-dopamine receptor density was found reduced by 75% in five *HD* patients with mild to moderate disease compared to a group of healthy controls<sup>[58]</sup>. Additionally, one premanifest *HD* gene carrier showed D1 binding in the lower range of the control subjects<sup>[58]</sup>. Turjanski and colleagues<sup>[55]</sup> have studied 10 non-neuroleptic treated patients with *HD* with either the choreic or the akinetic-rigid predominant phenotypes of the disease. They found severe parallel reduction of striatal D1 and D2 receptor binding with greater loss of mean striatal D1 and D2 binding in the akinetic-rigid patients than those choreic patients without rigidity<sup>[55]</sup>. However, there were no significant correlations between D1 and D2 striatal receptor binding and the duration of symptoms. Mean <sup>11</sup>C-SCH23390 and <sup>11</sup>C-raclopride bind-

ing was found to be reduced by 40% in the striatum of five patients with *HD*<sup>[56]</sup>. The degree of the decrease in D1 and D2 binding in the striatum was significantly associated with the duration of symptoms indicating that these two receptors may be reliable quantitative markers for monitoring disease progression<sup>[56]</sup>. Moreover, a reduction in D1 receptor binding was found also in the temporal cortex suggesting that dopaminergic abnormalities occur in cortical areas and may play a role in the development of cognitive dysfunction observed in *HD*<sup>[56]</sup>. Specifically, striatal D1 and D2 receptor density showed strong relationships with performance in several tasks assessing executive function, visuospatial ability, episodic memory, verbal fluency, perceptual speed and reasoning in a group of five *HD* patients<sup>[59]</sup>. Thus, cortico-striatal and/or thalamo-cortical circuitry may be associated with cognitive impairment in *HD*<sup>[59]</sup>. A correlation between striatal D1 and D2 receptors binding, but mainly D2, and cognitive performance was found also in 17 premanifest *HD* gene carriers, in whom both striatal dopamine receptor levels and cognitive performance were lower in the subjects closer to the predicted disease onset<sup>[60]</sup>. Using <sup>11</sup>C-raclopride PET and statistical parametric mapping, Pavese and coworkers<sup>[61]</sup> have found a reduction in D2 receptor density in cortical regions of symptomatic *HD* patients, which were also evident in frontal and/or temporal regions in 55% of premanifest *HD* gene carriers<sup>[62]</sup>, suggesting that changes in cortical D2 receptor availability might be an early event in *HD* pathophysiology. Van Oostrom and colleagues<sup>[63]</sup> have also reported a reduction in striatal D2 receptor availability in 50% of premanifest *HD* gene carriers and these reductions correlated with increases in cumulative disease load as measured by disease burden (CAG index).

Clinically manifested *HD* patients have been shown to have constant loss of D2 receptor availability at around 5% per year in striatal and extrastriatal regions including frontal and temporal cortex, though no correlation between changes in UHDRS motor scores and reductions in striatal binding were observed<sup>[61]</sup>. Longitudinal <sup>11</sup>C-raclopride PET studies in premanifest *HD* gene carriers have reported rates of decline from 4%<sup>[64]</sup> up to 6.3%<sup>[65]</sup>. Andrews and coworkers<sup>[64]</sup> investigated striatal dopamine D1 and D2 receptor binding over a follow-up period of 40 mo in nine premanifest *HD* gene carriers and four symptomatic *HD* patients. They reported a mean annual loss of D1 and D2 binding of 2% and 4% respectively in the group of premanifest *HD* gene carriers and a mean annual loss of D1 binding of 5% and D2 binding of 3% in symptomatic *HD* patients<sup>[64]</sup>. Additionally, UHDRS motor scores and TFC correlated with PET measures of striatal dopamine receptor in both groups. Interestingly, premanifest *HD* gene carriers who demonstrated active progression had an increased mean annual loss of D1 and D2 receptor binding (5% and 6.5% respectively). Thus, the authors conclude that PET measures of striatal D1 and D2 dopamine binding may be used to identify asymptomatic *HD* gene carriers who are actively

progressive<sup>[64]</sup>. A reduction in the striatal dopamine D2 binding, in particular in the putamen, correlates weakly with the increasing probability of symptomatic conversion within 5 years, as calculated by an age and CAG repeat based model<sup>[51]</sup>. Although, putaminal D2 binding correlated with predicted time to disease onset, the rate of change of D2 receptor changes were not increased around the onset of HD symptoms<sup>[51]</sup>. A cross-sectional study by Antonini and colleagues<sup>[66]</sup> indicated that striatal degeneration in HD patients might proceed in a non-linear fashion. They found a correlation between CAG repeat length and the estimated percentage loss of striatal D2 binding after age correction in premanifest HD gene carriers and symptomatic HD patients. While CAG repeat length influenced the rate of disease progression, the slopes of the correlation for asymptomatic mutation carriers and patients were significantly different, implying that the rate of disease progression is faster during the earlier asymptomatic stages of the disease<sup>[66]</sup>. These data suggest that striatal D2 measures are more sensitive in premanifest HD than later in the disease.

While the loss of striatal dopamine D2 receptors is well known, few studies have addressed the extrastriatal D2 receptor distribution in patients with HD. Statistical parametric mapping of <sup>11</sup>C-raclopride binding in patients with HD suggest a loss of cortical dopamine D2 receptors in symptomatic HD patients<sup>[61,62]</sup>. A significant reduction in postsynaptic dopamine D2 receptor binding was also found in the hypothalamus of nine premanifest HD patients and in 10 asymptomatic HD gene carriers<sup>[67]</sup>. These findings suggest that hypothalamic dysfunction occurs early during the course of the disease and may be responsible for the development of commonly reported nonmotor symptoms in HD including progressive weight loss, alterations in sexual behaviour and disturbances in the wake-sleep cycle<sup>[67]</sup>.

Using PET with <sup>11</sup>C-FLB457, a radioligand with high affinity for dopamine D2 receptor, Esmaeilzadeh and coworkers<sup>[68]</sup> have investigated density of dopamine D2 receptors in extrastriatal brain regions in patients with mild to moderate HD. They found that unlike from striatum, D2 receptors seem to be relatively spared in the brain extrastriatal regions in HD patients suggesting that D2 receptor binding in brain regions outside the striatum may not be a reliable biomarker in HD<sup>[68]</sup>.

Moreover, PET with D1 and D2 receptor radioligands has been used to assess the efficacy of restorative therapy. In 1998, a multicentre open label pilot study was designed to evaluate the safety and efficacy of bilateral fetal striatal transplantation in HD<sup>[69]</sup>. Five HD patients were transplanted and followed up clinically and with PET over a 3-10 year postoperative period<sup>[70,71]</sup>. No significant differences were found over time between patients, grafted and non-grafted on the UHDRS and striatal D1 and D2 binding suggesting that there was no obvious surviving striatal graft tissue<sup>[70,71]</sup>.

### Brain activation and metabolism

Measurements of cerebral blood flow and glucose me-

tabolism could serve as an index of neuronal integrity and functional state of the synapse<sup>[72,73]</sup>. Striatal glucose hypometabolism and regional reductions in cortical glucose have been identified in HD patients and have been found to correlate with motor and cognitive symptoms<sup>[65,74,75]</sup>. Specifically, decreases of caudate and regional cortical metabolism correlated with cognitive decline<sup>[75,76]</sup>, whereas striatal hypometabolism was associated with motor deficits and reduced TFC<sup>[77]</sup>. Striatal and cortical hypometabolism has been also found in premanifest HD gene carriers to precede neuronal loss<sup>[78-80]</sup>. A recent <sup>18</sup>F-FDG PET study has shown that premanifest HD gene carriers who became symptomatic after five years from the PET scan had a mean glucose uptake in the caudate significantly lower than those who did not convert, and this difference was independent of mutation size<sup>[80]</sup>. These findings suggest that reduced glucose levels may be contribute to the time of HD onset. In a combined <sup>18</sup>F-FDG and <sup>11</sup>C-raclopride longitudinal study, premanifest HD gene carriers showed an annual loss of 2.3% in striatal glucose metabolism and 6.3% annual decline in D2 receptor binding<sup>[65]</sup>. These findings suggest that glucose metabolism is a less sensitive marker of disease progression compared to <sup>11</sup>C-raclopride<sup>[65]</sup>. On the other hand, decreased cortical metabolism in the early stage of HD is indicative of rapid progression<sup>[81]</sup>. Indeed, cortical metabolism in the frontotemporal and parietal cortices was significantly lower in early HD subjects with faster progression of the disease as measured with the UHDRS and Independence Scale<sup>[81]</sup>.

PET with H<sub>2</sub><sup>15</sup>O has been used to investigate changes of motor-associated cortical activation in HD<sup>[82,83]</sup>. During motor tasks such as paced joystick movements or sequential finger-to thumb opposition, HD patients showed impaired activation of the striatum and its frontal motor projection areas<sup>[82,83]</sup> along with enhanced activity of the parietal areas<sup>[82]</sup> and insular areas<sup>[83]</sup>. These findings suggest that the loss of MSNs in the striatum leads to impairment of the basal ganglia-thalamo-cortical motor output and may induce a compensatory recruitment of additional accessory motor pathways<sup>[82,83]</sup>. Moreover, different patterns of brain activation have been showed in HD patients during word generation task<sup>[84]</sup>. HD patients showed decreased cerebral blood flows in the anterior cingulate and the inferior frontal gyri, which are important in lexical selection and a compensatory activation of the left supramarginal gyrus and the right inferior frontal gyrus, suggesting that compensatory language strategies are present in HD<sup>[84]</sup>.

<sup>18</sup>F-FDG PET imaging and network approaches have been used to identify spatial covariance patterns in premanifest HD<sup>[85-87]</sup>. A cross-sectional analysis of metabolic changes from premanifest HD gene carriers and healthy controls, has reported a reproducible disease related pattern, characterized by relative bilateral increases in thalamic, occipital, and cerebellar glucose metabolism associated with bilateral decreases in striatal metabolism, which discriminated between the HD and healthy control groups<sup>[86]</sup>. However, this pattern in HD gene carriers

did not show consistent changes over time, thus limiting its utility as a network biomarker of preclinical disease progression<sup>[86]</sup>. Recently, Tang and coworkers<sup>[87]</sup> demonstrated the feasibility of network-based approach by using longitudinal metabolic imaging data from premanifest HD carriers to identify a distinct spatial covariance pattern associated with disease progression. Changes in pattern expression over a seven years period were used to quantify the rate of progression in the preclinical period<sup>[87]</sup>. They found a significant spatial covariance pattern characterized by progressive changes in striato-thalamic and cortical metabolic activity which increased linearly over 7 years and was not influenced by symptomatic conversion<sup>[87]</sup>. Additionally, premanifest HD gene carriers which showed further increases in metabolic network activity at baseline (> 2 SD above the normal mean) had a greater risk of symptomatic conversion in the following 5-year period<sup>[87]</sup>. These findings suggest that metabolic network measurements may provide a sensitive tool for evaluating disease progression prior to clinical diagnosis.

Measures of glucose brain metabolism have been used to assess the restoration of striato-cortical function in five HD patients who underwent bilateral striatal transplantation<sup>[88,89]</sup>. In 2-year follow-up of these five patients, Gaura and colleagues<sup>[89]</sup> reported that the three patients, who showed clinical improvement or stabilization, had increased in striatal/cortical glucose metabolic rate, which is suggestive of restoration of function of striatal-cortical connections. Conversely, findings from NEST-UK multicentre study failed to show significant change in <sup>18</sup>F-FDG uptake over 2 years of follow-up<sup>[70]</sup>. Thus, the ability of bilateral striatal transplantation to restore striato-cortical pathways remains to be elucidated.

### Neuroinflammation and activated microglia

Recent evidence suggests that microglial activation plays a role in the pathogenesis of HD<sup>[90,91]</sup>. Microglia constitute about 10% of the total brain cell population, and represent the main immunocompetent phagocytic cells in the central nervous system<sup>[92]</sup>. Although microglial activation is unlikely to initiate neuronal death, it could contribute to the neurodegenerative processes<sup>[93,94]</sup>. Indeed, upon exposure to neuronal insults such the presence of abnormal huntingtin protein aggregations, microglia become activated and release pro-inflammatory cytokines (*e.g.*, TNF- $\alpha$  and IL-1 $\beta$ ). These cytokines in turn cause further activation of microglia, resulting in a self-propagating inflammatory cascade, which may lead to neuronal death. Microglial activation upregulates the expression of the 18 kDa translocator protein (TSPO) which is involved in the release of proinflammatory cytokines during inflammation and is present at very low levels in the normal healthy CNS<sup>[95,96]</sup>. The upregulation of TSPO expression can be detected *in vivo* with PET and selective radioligands such as <sup>11</sup>C-PK11195<sup>[97,98]</sup>. Using PET with <sup>11</sup>C-PK11195, Pavese and coworkers<sup>[99]</sup> have found significant microglial activation in the striatum and cortical regions of symptomatic HD patients, and reported that striatal PK binding correlates with loss of striatal dopa-

mine D2 binding as measured with <sup>11</sup>C-raclopride PET. Additionally, striatal <sup>11</sup>C-PK11195 binding correlated with clinical severity as measured with the UHDRS<sup>[99]</sup>. In premanifest HD gene carriers <sup>11</sup>C-PK11195 binding was found to be also increased in striatum and cortical regions compared to a group of normal controls, and higher striatal <sup>11</sup>C-PK11195 binding correlated with lower striatal D2 binding<sup>[100]</sup>. These findings suggest that early and widespread microglial activation occurs in premanifest HD gene carriers and it is associated with subclinical striatal neuronal loss of dopamine D2 receptor binding, indicating a potential role of activated microglia in HD pathogenesis.

A more recent multimodal imaging study using MRI, <sup>11</sup>C-PK11195 and <sup>11</sup>C-raclopride PET, has showed increased levels of activated microglia in several brain areas across HD gene carriers who were either premanifest or manifested patients<sup>[101]</sup>. Of particular interest, high levels of activated microglia were observed in the associative part of the striatum, which is involved in cognitive function. High levels of microglial activation in the associative striatum and in the brain regions related to cognitive function correlated with a higher probability of symptomatic HD onset over the next 5 years in the group of premanifest HD gene carriers<sup>[101]</sup>. These findings highlighted the role of immune response in the pathophysiology and clinical expression of HD.

### Cannabinoid system

Dysregulation of the endocannabinoid system may play a critical role in the pathogenesis of HD. The type 1 cannabinoid receptors (CB1R) are expressed in the basal ganglia, mainly in the GABA-ergic striatal MSNs expressing D1 and D2 receptors and are a key modulator of synaptic transmission in the brain<sup>[102-104]</sup>. Evidences from animal models of HD and postmortem tissue of HD brain have shown that decreased levels of CB1R and CB1 messenger RNA<sup>[105-107]</sup>. Recently, *in vivo* imaging of CB1R has become feasible using PET with <sup>18</sup>FMK-9470<sup>[108]</sup> and <sup>11</sup>C-MePPEP<sup>[109,110]</sup>. Using PET with <sup>18</sup>FMK-9470, Van Laere and coworkers<sup>[111]</sup> have investigated the levels of CB1R in the brain of 20 symptomatic HD patients. They found decreased CB1R availability throughout the grey matter of the cerebrum, cerebellum, and brain stem in HD patients. Further studies of CB1R system in premanifest HD gene carriers are expected in order to further understand the role of this system in the pathophysiology of HD.

## CONCLUSION

Currently, there are no therapies able to slow down progression in HD and symptomatic treatments such as acetylcholinesterase inhibitors have provided limited evidence of their efficacy in HD<sup>[112]</sup>. Identification of reliable biomarkers of HD progression will be important for the development and evaluation of disease-modifying treatments. Neuroimaging techniques may be a suitable biomarker for monitoring disease progression in HD

and for assessing the efficacy of future disease modifying therapies. Although MRI techniques have shown to be useful for monitoring disease progression, PET imaging is able to detect changes and specific targets early in pre-manifest HD stages. However, at this stage an integrative multimodal imaging approach, which combines different MRI and PET techniques, could be recommended.

Imaging of the small bowel: Crohn's disease in paediatric patients. *World J Radiol* 2014; 6(6): 313-328 Available from: URL: <http://www.wjgnet.com/1949-8470/full/v6/i6/313.htm> DOI: <http://dx.doi.org/10.4329/wjr.v6.i6.313>

### Abstract

In more than 20% of all patients, the Crohn's disease presents before the age of 18 years. The diagnosis and management of Crohn's disease in children has changed dramatically over the last decade, mainly due to increased awareness, availability of newer diagnostic modalities such as magnetic resonance imaging (MRI) and newer, more powerful treatments such as biologics. Imaging of the small bowel is needed for diagnosis, management, follow-up and also evaluation of the disease in terms of location, extent, activity and complications. We review all the methods (barium examinations, ultrasonography, computed tomography, MR, and computed tomography- positron emission tomography) commonly used for imaging the small bowel in paediatric patients with Crohn's disease analyzing the advantages and disadvantages of each modality, with particular emphasis on MR imaging.

### INTRODUCTION

Crohn's disease (CD) begins in childhood, below 20 years of age, in 20% of cases and may involve characteristically any part of the gastrointestinal (GI) tract. The Paris classification has recently revised the Montreal classification, that had several weakness points relating children's classification<sup>[1]</sup>. Important modifications developed regarding CD include classifying age at diagnosis as A1a (0 to < 10 years), A1b (10 to < 17 years), A2 (17 to 40 years), and A3 (> 40 years), distinguishing disease above the distal ileum as L4a (proximal to ligament of Treitz) and L4b (ligament of Treitz to above distal ileum), allowing both stricturing and penetrating disease to be classified in the same patient (B2B3), and denoting, at any time, the presence of growth failure in the patient as G1 versus G0 (never growth failure)<sup>[2]</sup>.

Although the exact frequency of the small bowel (SB)

CD is unknown, most gastroenterologists believe that its prevalence has been underestimated and that it may have an increased incidence among children and young adolescents<sup>[2]</sup>. A recent study performed in pediatric patients with magnetic resonance (MR) enterography<sup>[3]</sup>, according to previous studies<sup>[4]</sup>, confirmed that the involvement of the terminal ileum is common to more than three times compared to that of the jejunum and the rest of the ileum. Moreover, the involvement of the jejunum alone is uncommon and it is more difficult to investigate because of its tendency to stay non distended<sup>[3]</sup>.

The clinical importance of the SB CD phenotype is the impact that a diffuse SB disease is expected to have on a child's growth and development. Moreover, patients with SB CD are more likely to experience complications, including intestinal obstruction and less commonly fistulization<sup>[4,5]</sup>.

Thus, objective evaluation of the SB is essential in differentiating CD from other enteropathies and in directing the management of the patients with inflammatory bowel disease (IBD)<sup>[6,7]</sup>. The morphological evaluation of the SB, useful in the diagnosis and management of CD, has long been made only with conventional radiology. In the last decade there has been a progressive improvement of cross-sectional imaging [ultrasonography (US), computed tomography (CT), and magnetic resonance (MR)] that has significantly changed the way to diagnose and treat the patients<sup>[8,9]</sup>. Indeed, their accuracy in detecting mucosal alterations and transmural and perienteric inflammations, has led to a new disease staging, a detection of asymptomatic disease and a better assessment of response to therapy<sup>[10]</sup>. For these reasons modern cross-sectional imaging have replaced the traditional fluoroscopy-based for visualization of the SB. In the "Porto criteria" small-bowel follow-through (SBFT) was the recommended imaging modality in children<sup>[11]</sup>. However, concerns about the proven increased risk of high radiation exposure in pediatric patients mandates the use of alternative techniques when possible<sup>[12-14]</sup>. In the European Crohn's and Colitis Organization (ECCO) guidelines<sup>[14]</sup> it is stated that MR and CT enterography or enteroclysis are the imaging modalities with the highest diagnostic accuracy. Moreover in the pediatric section of the ECCO guidelines<sup>[15,16]</sup> dynamic contrast-enhanced MRI is considered the best imaging to show most of the CD's lesions without exposure to ionizing radiation. In the same way the Appropriateness Criteria of the American College of Radiology<sup>[17]</sup> point out that, in the pediatric patients, MR enterography may have sensitivity and specificity similar to CT enterography and avoids radiation risks. Ultimately the same accuracy, the choice of examination depends on several variables, such as institutional preferences and resources (US, CT, or MR scan), age and compliance of the patient, the eventually acute presentation, and finally radiologist expertise.

In this article we discuss all the methods commonly used for imaging the small bowel in paediatric patients with Crohn's disease analyzing the advantages and disad-

vantages of each modality, with particular emphasis on MR imaging.

## BARIUM STUDIES

Traditionally in children with suspected CD has been studied with barium studies, enteroclysis (SBE) or SB follow-through (SBFT), considered to be the gold standard examination for the SB<sup>[18,19]</sup>. SBE was considered the best exam for SB disease, however children poorly tolerate the required insertion of a naso-jejunal tube. SBFT has long been considered as the most common, non-invasive, inexpensive and easily accessible radiological method<sup>[14]</sup>, but, currently, it has only a secondary role in small bowel imaging. US and MR enterography are methods of choice for imaging SB diseases in pediatric populations.

Early mucosal changes, such as aphthous ulceration, can be detected by SBFT. This technique can also assess bowel motility that help to differentiate strictures from mural thickening and allows a functional evaluation of the pathological segment studying the SB transit time<sup>[14-16]</sup>.

Although SBE and SBFT can effectively depict the presence of mucosal abnormalities effectively, including fissures, cobblestone mucosa, pseudo-polyps, and skip lesions, they are imprecise for the diagnosis of transmural and extramural disease<sup>[14,20,21]</sup>, except in the overt forms (Figure 1).

A retrospective analysis of 164 children revealed a diagnostic sensitivity of only 45% for SB radiography compared with ileo-colonoscopy<sup>[22]</sup>. Moreover, SBFT is not accurate for the detection of active CD in the SB<sup>[20-23]</sup>. In fact, it can directly examine the mucosa demonstrating early active mucosal disease such as aphthous and linear ulcers, but it does not allow to evaluate the small bowel wall and the mesentery, except with indirect signs. Moreover, superimposed bowel loops or non-palpable bowel loops deep in the pelvis can hide active disease or its complications<sup>[20]</sup>.

Concerns regarding the risks of radiation exposure in the pediatric population has increased with the spread use of these imaging studies. Children especially are at risk because they are inherently more radiosensitive and because they have more remaining years of life during which a radiation-induced cancer could develop<sup>[24]</sup>.

A major disadvantage of barium studies, especially in children, is the radiation exposure, particularly if fluoroscopy time is not kept to a minimum<sup>[13]</sup>. Gaca *et al*<sup>[13]</sup> studied a total of 176 children with CD who underwent averaging 1.2 SBFTs. On average SBFT took 5.1 min with 3.3 abdominal radiographs. The effective doses (mSv) for a 5-min fluoroscopy were 0.15 for the central abdomen, 0.35 for the right lower quadrant, and 0.56 for the pelvis, yielding an average effective dose for SBFT (5-min fluoroscopy, 3.3 abdominal radiographs) of 1.8-2.2 mSv. Although 5 min of fluoroscopy time for an SBFT might seem excessive, this was calculated based on the average of 30 examinations performed by five experienced pediatric radiologists<sup>[13]</sup>. In the young population of CD

**Figure 1** Barium studies in patients with Crohn's disease. Double-contrast barium enema examination (A and B) demonstrate longitudinal (arrows) and perpendicular (arrowheads) ulcerations in the terminal ileum. Small-bowel follow-through (C) demonstrates an abscess cavity (white arrow) with fistulae connecting the cavity to the adjacent small bowel (black arrows).

**Figure 2** Thickening of the bowel wall, 5 mm, (arrow) with wall layers preserved. The hyperechoic band corresponds to thickened submucosa.

patients, the ionizing radiation required for SBE limits the use of this technique for the follow-up of the disease. Moreover, SBFT and SBE examinations can often result in incomplete studies. In fact they cause more patient discomfort compared with CT<sup>[25]</sup> and MRI<sup>[26]</sup>, barium contrast can be poorly tolerated by children especially in severe and advanced disease and abdominal pain can limit compression preventing the adequate visualization of overlapping loops.

## ULTRASONOGRAPHY

US has the distinct advantage of being widely available, inexpensive, non-invasive, radiation-free and relatively easy to perform<sup>[7,27]</sup>. Over the past few years, improvements in US equipment such as high-frequency transducers (7-12 MHz), combined with oral and intravenous (CE-US) contrast agents<sup>[28,29]</sup>, have overcome some of the obstacles in bowel US that existed in the past, thus raising a great enthusiasm for its use in IBD children.

US can be considered a valuable tool in the preliminary diagnostic process of paediatric patients with suspected IBD, prior to further invasive tests<sup>[30,31]</sup>.

Inflamed bowel can show both mural and extramural pathological changes. Bowel wall thickness is the most important US sign of IBD (Figure 2), with different thickness values used as a threshold for a positive diagnosis in the various reports (from 1.5 mm to 3 mm in the terminal ileum and < 2 mm in the colon)<sup>[27,32-35]</sup>.

The other US signs are altered echogenicity, loss of

**Figure 3** Transversal (A) and longitudinal (B) section of a thickened ileal loop due to Crohn's disease. The "target" sign, corresponding to remarkable bowel wall thickness, is visible as a strong echogenic centre surrounded by a hypoechoic border (A). The adjacent mesentery is thickened and hyperechoic, due to the transmural nature of inflammation in Crohn's disease (A and B).

the normally visible stratification (Figure 3), increased Colour-Doppler signal denoting hyperaemia (Figure 4) and relative decrease or lack in peristalsis signifying some degree of stiffness<sup>[31]</sup>. Extra-mural findings include changes involving the surrounding mesentery, that appears thickened and hyperechoic and generally shows enlarged mesenteric lymph-nodes (Figure 4)<sup>[30,36]</sup>.

Bowel US and ileocolonoscopy with histology have demonstrated an overall sensitivity of 74 and 88% and a specificity of 78 and 93%, respectively, in the detection of SB CD lesions<sup>[35,37]</sup>. The sensitivity of US in the detection of SB lesions is greater for those of the terminal ileum (approximately 90%-95%) than for those of the proximal SB (75%)<sup>[38]</sup>. US is useful for the follow-up

**Figure 4** Longitudinal view of the terminal ileum in a 13-year-old boy with active Crohn's disease. The bowel wall is thickened and shows increase in Color Doppler signals denoting inflammatory hyperemia (A). Note in (B) the fibrofatty proliferation of the surrounding mesentery which appears hyperechoic and the enlarged mesenteric lymph-nodes.

**Figure 5** Longitudinal section of a distal ileal loop showing stiffness, mural thickening (arrowhead), lumen narrowing (arrow) and mild dilatation of the pre-stenotic segment (asterisk), suggesting a fibrotic nature of the stenosis.

of patients with CD<sup>[39,40]</sup> and in early identifying intra-abdominal complications, such as abscesses, fistulae and strictures<sup>[41-44]</sup>. The reported sensitivity of US in detecting CD strictures approximately is 74%-80%<sup>[41]</sup>. US can also aid differentiate between fibrotic and inflammatory strictures. An increased Colour-Doppler signal in the stenosis is suggestive of activity, while poor vascularity of the bowel wall, an adjacent loops' retraction and a pre-stenotic bowel segment distension are suggestive of fibrotic stenosis (Figure 5)<sup>[31]</sup>.

Some challenges about US still remain: US strongly relies on the operator's experience and skill more than other imaging modalities, and it requires an high resolution equipment. Moreover, even in expert hands, US may result in false positive findings<sup>[34]</sup>: thickening of the intestinal wall is not specific for CD, also being present in infectious, neoplastic and other inflammatory conditions. US may also provide false negative results<sup>[38,42]</sup>, for example in obese patients or when CD is characterized by only superficial lesions, like isolated aphthous ulcers and mucosal erosions, or in presence of intestinal gas that make hardly visible the bowel wall, particularly the proximal ones.

Small Intestine Contrast US (SICUS). Some studies

in adults have demonstrated that the so called SICUS, enables to overcome limits of standard US. Dissociation of intestinal overlapping loops and visualization of the entire SB, from the Treitz angle to the ileo-cecal valve, are obtained by distending the SB with an oral anechoic non-absorbable contrast solution (iso-osmolar polyethylene glycol)<sup>[36]</sup>. Briefly, US examination is performed after the ingestion of the oral contrast solution, that fill in the loops, and the administration of the intravenous (*iv*) contrast. Unfortunately the procedure is time consuming, requiring in some cases more than 2 hours. Pallotta *et al*<sup>[28]</sup> studied 148 patients, 57 with a known diagnosis of CD, showing SICUS to be more sensitive and specific (94% and 98%, respectively) than conventional US (57% and 100% respectively) in assessing SB lesions. The use of an oral contrast agent can significantly improve US sensitivity, approximately of 90% (Figure 6) and of over 75% for a single and multiple SB stenosis, respectively<sup>[42]</sup>.

SICUS can make a dynamic evaluation of the affected segment differentiating between inflammatory and fibrotic stenosis. In fact, it can assess lumen stenosis and dilatation of the prestenotic segment, mural thickness with bowel wall stratification pattern and peristalsis of the affected segment differentiating between. SICUS is a very promising technique in children with CD, but its use in pediatric patients has still to be investigated.

## CROSS SECTIONAL IMAGING

Good distension of SB loops during the CT and MRI examination is crucial for the correct evaluation of bowel wall abnormalities since collapsed SB loops are difficult to evaluate for bowel wall thickening or hyper-enhancement. Distension of the SB can be achieved by fluid administration after naso-jejunal intubation (CT/MR enteroclysis)<sup>[45,46]</sup> or per Os (CT/MR enterography)<sup>[47,48]</sup>. Although better distension of the loops is obtained with the MR/CT enteroclysis, there are various studies that show comparable accuracy between the two techniques<sup>[20,45,47,48]</sup>. The placement of the nasojejunal tube, necessary for the enteroclysis, is invasive, requires the use of ionizing

**Figure 6** The oral anechoic contrast solution, (polyethylene glycol), allows a better definition of lumen narrowing (arrow) and pre-stenotic dilatation (asterisk) as well as a more accurate measurement of the length of the stenosis. Small intestine contrast ultrasonography also provides a dynamic assessment of the stenotic bowel loop: poor distensibility and presence of pre-stenotic dilatation suggest fibrosis, whereas normal distensibility and preserved peristalsis are features of inflammatory stenosis.

**Figure 7** Magnetic resonance enteroclysis under anesthesia in one-year old male with Crohn's disease at colonoscopy. Coronal thick-slab HASTE image (A) shows good opacification of proximal and distal small bowel. The coronal T2-weighted (T2-w) image (B) and coronal fat-suppressed (FS) three-dimensional (3D) T1-weighted (T1-w) breath-hold gradient-echo (GE) image (C) are performed in free breathing.

radiations, which also entails the need for coordination between MR/CT suites and fluoroscopy units, and it can be very anxiety provoking resulting in poor patient tolerance. Moreover, the increased time and costs compared to enterography, make CT/MR enterography the preferred imaging method, respect to CT/MR enteroclysis, in pediatric patients.

An important limitation of CT/MR enterography is the need to drink an important amount of fluid in a short time, particularly uncomfortable in young patients. The assessment of mucosal abnormalities requires a correct distension of the loops obtained only with a proper timing of the study both in scanning or fluid ingestion. The collapsed bowel loops may mimic wall thickening and hyper-enhancement, leading to false-positive results.

The younger patients and the parents have to be motivated and aware of the importance of performing an adequate SB distension, which is fundamental for obtaining an optimal MR examination. The presence of a parent in the MR room is reassuring for younger children.

Most children diagnosed with IBD are of school age or adolescence. In a study from uniform data collected from a cohort of pediatric patients with IBD (1370 children), the mean age at diagnosis was 10.3 years with 47.7% diagnosed at 6 to 12 years of age and 36.9% at 13 to 17 years of age<sup>[49]</sup>. In our experience, children of this age are generally able to undergo the exam without seda-

tion.

In the event a child refuses to drink the contrast agent, we will offer placement of a temporary nasogastric tube for contrast agent delivery. The enteric tube will be removed right after all of the contrast material is given and before the MR examination begins.

Patients under the age of 6 years, who require anesthesia do not undergo MR enterography and are usually imaged by using high-resolution bowel US or MR enteroclysis under anesthesia. The positioning of the tube takes place after the anesthesia. Children between 6 mo and 6 years of age are usually sedated with the intravenous injection of midazolam (Versed; Hoffman-La Roche, Basel, Switzerland) (0.05 mg per kilogram of body weight) or pentobarbital (Nembutal; Ovation Pharmaceuticals, Deerfield, Ill) (5 mg per kilogram of body weight). The sequences are performed in free breathing, making them as short as possible (Figure 7).

### Computed Tomography

The relatively high radiation exposure is a limitation to the use of multi-detector CT (MDCT) enterography in children, and, in fact, most data regarding this method come from studies in adults<sup>[50]</sup>. The only recent pediatric IBD population's study<sup>[51]</sup> concluded that MDCT can be used as an alternative to barium studies for the evaluation

**Figure 8** Transverse (A) and coronal (B) computed tomography show bowel wall thickening and mucosal hyper-enhancement with pseudo polyps (white arrows) as well as mesenteric lymph nodes, that are irregular in size and shape (black arrowhead) and increased mesenteric vascularity (asterisk). These features may be detected in case of acute exacerbation on a background of longstanding disease.

**Figure 9** Transverse (A) and MRP sagittal (B) computed tomography show stratified enhancement of terminal ileum (arrows), and hyperemic mesentery with the "comb sign" (asterisk).

**Figure 10** Transverse computed tomography (A) and post contrast T1-fat sat magnetic resonance imaging (B) images show a complex network between closely adherent small bowel loops appearing as a stellate configuration (arrows) due to entero-enteric fistulas.

of the SB and that most of the children prefer CT rather than barium studies. Several studies on adult population showed that is an excellent non-invasive tool for diagnosing CD, and for the follow-up of the disease during therapy<sup>[19,20,52-54]</sup>. CT enterography can establish disease extension and activity on the basis of wall thickness and increased *in vivo* contrast enhancement. In recent studies bowel wall thickness is considered pathological when exceeds 3 mm<sup>[55,56]</sup> (Figure 8). A sign of active disease is an

increased bowel wall enhancement after administration of *in vivo* contrast medium<sup>[57,58]</sup>. The post-contrast wall pattern depends on the different enhancement of the mucosa and/or serosa and the submucosa, usually hypodense for the presence of edema, and can be seen as mural stratification or target sign (Figure 9), with two or three different layers of density respectively. In chronic CD, the affected segments may present a non-enhancement pattern after contrast medium, with the loss of mural stratifica-

**Figure 11** Eighteen-years-old female with active Crohn's disease and abscess. Transverse T2-w (A), DWI (B), transverse (C) and coronal (D) post-contrast FS-T1-w image (C) show inflamed segments of the terminal ileum (arrowhead) with pericecal fluid-collection around thickened and hyper-vascular walls (arrow), according to abscess. A small air bubble in the antideclive portion of the fluid collection is visible in the transverse T2-w (A) and transverse post-contrast FS-T1-w image (C).

tion, suggestive of fibrosis. Another typical extramural lesion in CD is the comb sign due to an increased vascularity of the mesentery seen in the images as tortuous dilated vessels associated with a wide spacing of the vasa recta (Figure 8).

The most reliable criterion to define a stricture is a localized, persistent narrowing, whose functional effects may be judged from pre-stenotic dilatation<sup>[59]</sup>. CT, together with MRI, is the most accurate technique to detect the presence of extraluminal complications, such as abscesses, fistulae (Figure 10) and inflammatory conglomerates in CD<sup>[20,46,53,54,60-62]</sup>.

CT has a high accuracy in the imaging of CD but it is limited by the use of ionizing radiations especially in children particularly in these type of chronic diseases that require a close follow up<sup>[13,63]</sup>.

The radiation dose can be significantly reduced by the use of last generation MDCT scan with specific pediatric protocols<sup>[64,65]</sup> which include the introduction of noise to simulate low-dose exams<sup>[66]</sup>.

Still, in pediatric patients MR must be preferred to MDCT, since it does not use ionizing radiation to which children are more vulnerable than adults for their longer life expectancy. Moreover, despite new formulations and improved safety, iodinated contrast media for CT are not without risk and the risks must be balanced against the possible benefits. However, in the hospitals without MR scan, or where it is difficult to schedule an emergent MRI, or in emergency situations, such as high-grade SB occlusion, MDCT remains the best technique in pediatric

patients, too. In fact CT has greater availability and it is less time-consuming than MR (20-30 min for MR, respect to 10 s for MDCT).

### Magnetic Resonance

The main advantages of MRI are, in addition to the lack of ionizing radiations, a superior soft tissue contrast with a better assessment of trans and extramural disease, its noninvasiveness and the multiplanar capability. Additionally, some MRI sequences (diffusion, perfusion, motility) can provide functional and quantitative information of the bowel wall (diffusion, perfusion, motility) that CT cannot obtain. Especially, diffusion-weighted sequence does not significantly increase the time of the examination and may provide helpful clues for the identification of areas of active inflammation and of abscesses (Figure 11) without *in* contrast agent. Moreover, the use of cine MRI in patients suffering from CD proves the association of motility changes of the SB wall and extraluminal alterations, which can help in the differential diagnosis between fibrotic and inflammatory stenosis<sup>[67]</sup>.

In relation to imaging features, CD may present as active inflammation (without strictures or fistulas), penetrating lesions, or fibrostenotic disease<sup>[68]</sup>. Patients may present characteristics of more than one disease subtypes.

Active disease. Various MR imaging findings have been proposed as correlating with CD activity. Increased wall thickening and mural contrast enhancement (CE) on MRI were found to be sensitive and specific for active CD in pediatric population<sup>[69]</sup>. Laghi *et al.*<sup>[69]</sup> found a strong

**Figure 12** Thirteen years old male with active Crohn's disease. Coronal T2-weighted image (A), and transverse fat saturation T2-weighted images (B and C), show mural thickness and increased mural signal (arrowhead in B, C, and D) in the terminal ileum due to edema. Coronal post-contrast T1-weighted fat-suppressed image (D) at the same level shows mural stratification (asterisk).

**Figure 13** Thirteen years old female with active Crohn's disease. Coronal (A), transverse (B) T2-weighted images show thickened, inflamed segments of ileum and fat proliferating in the mesentery. The thin layer of high signal on T2 in b represents edema. The mass of the fat will displace adjacent small bowel. Coronal post-contrast T1-weighted fat-suppressed image (C) shows increased vascularity (asterisks), named "comb sign", adjacent to a hyper-enhancing thickened segment of ileum.

correlation between a semi-quantitative score (reflecting bowel-wall CE and thickening) and Pediatric Crohn's Disease Activity Index (PCDAI) in CD patients. In a recent study on pediatric population, Alexopoulou *et al*<sup>[70]</sup> showed that the MR percentage of CE (%CE) of the bowel wall do not correlate with PCDAI values. Other studies have reported similar results in the past<sup>[71,72]</sup>, while a correlation with C-reactive protein (CRP) was already demonstrated in pediatric<sup>[70]</sup> and adult<sup>[71]</sup> population. In children, clinical evaluation of disease activity may be even more subjective due to incomplete cooperation, and this explains the observed lack of correlation between PCDAI and %CE values, while in contrast, %CE values were correlated with CRP, which is a more objective

marker of inflammation<sup>[70]</sup>.

The wall thickening, its high mural signal intensity on T2-weighted fat-saturated (FS-T2-w) images, and the presence of mural stratification on post-contrast T1-weighted fat-saturated (FS-T1-w) images reflect histologic features of acute SB inflammation in CD<sup>[69,71,72]</sup> (Figure 12). A purely quantitative approach would be desirable for MRI evaluation of active disease. However, in patients with CD, measurements of the bowel wall MR signal intensity are subjected to wide limits of both inter- and intra-reader agreement, which may substantially limit their utility when applied to the development of quantitative measures of inflammatory activity in the affected bowel segments<sup>[73,74]</sup>.

**Figure 14** Coronal (A), transverse (B) T2-weighted images show thickened, inflamed segments of the terminal ileum with deep ulcers seen as high-contrast protrusions within bowel wall (arrows).

**Figure 15** Twelve years old female with active disease and follow-up. Transverse T2-weighted image (A) shows mural thickening (arrows) and increased mural signal (arrow) in the terminal ileum and coronal T1-weighted image (B) shows mural stratification (arrow), increased mesenteric vascularity adjacent to the inflamed bowel loop (the comb sign), and enlargement and hyper-enhancement of lymph-nodes (asterisk). In the same patient and at the same level, six months later after therapy, transverse T2-weighted image (C) shows the loss of increased mural signal (arrow) and coronal T1-weighted image (D) shows homogeneous enhancement without mural stratification (arrow), reduction of increased mesenteric vascularity adjacent to the inflamed bowel loop, and disappearance of lymph-nodes (asterisk).

Acute inflammation can also present with the comb sign (Figure 13), due to an increased vascularity of the mesentery, ulcers (Figure 14) and enlarged and high enhancing lymph-nodes<sup>[74-77]</sup>.

A proper luminal distension is essential to assess ulcers on MRI, especially if superficial<sup>[74]</sup>. In a systematic review of seven studies<sup>[52]</sup>, MRI showed an accuracy of 91%, 62% and 62% in correctly staging a frank, mild and in remission disease, respectively. MRI more often overstaged than understaged disease activity in CD, but in most of these patients radiological staging and disease staging by the reference standard differed one grade. However, this review has the limit of including old studies without considering the new state-of-the-art tech-

niques.

Actually radiologist use different protocols and features for grading CD, as recently showed by Ziech *et al.*<sup>[78]</sup>. The authors show that the most frequently used MR protocols include T2-w (79%) and CE FS-T1-w (83%) sequences and that the features most frequently seen as important for grading are the presence of bowel wall thickening (79% of radiologists), abscesses (75%) and CE (75%) and stratification (46%) at T1-w images.

Currently, the most important applications of MR care the confirmation of the disease and the follow-up of patients with an already established diagnosis of CD, both by monitoring the response to medical treatment by assessing disease activity (Figure 15) and by early identify-

Figure 16 Transverse T2-w image (A) and coronal post-contrast FS-T1-w image (B) show cluster of bowel loops (arrow) interconnected by fistulas and adhesions.

Figure 17 Coronal (A) and transverse (B and C) CE FS-T1-w 3D gradient-echo image show a small abscess close to the terminal ileum (arrows). Mural stratification and "comb sign" of the right colon flexure (black arrow), cecum (curved arrow), and appendix (white arrow) and homogeneous avid enhance of the terminal ileum (arrowhead). Enlargement and hyper-enhancement lymph-nodes (asterisk) are also visible.

ing of abscesses, fistulae and strictures.

### Penetrating disease

Transmural inflammation can result from ulcers that deeply penetrate the bowel wall forming serpiginous tracts and fistulas.

MR enterography is accurate in identifying extraluminal complications of CD. In young adults MR enterography showed a diagnostic value similar to MDCT enterography at least for acute complications of CD, such as fistulas and abscesses<sup>[79]</sup>. The abscesses can be treated by percutaneous interventions. Whereas penetrating disease may benefit from antibiotics or biologic therapies, while the use of steroids is usually avoided. Because of the exquisite sensitivity to detect fluid as well as its superior soft tissue contrast, MR easily depicts entero-entero (Figure 16), entero-vesicular, entero-cutaneous, perianal fistulae and abscesses (Figure 17). MR imaging may also detect small volumes of gas within an abscess (Figure 11). MR enterography can assess fistulizations, sinus tracts, and abscesses, especially with the use of post-contrast FS-

T1-w images (Figure 10) because of their avidly enhancing walls<sup>[80]</sup>. Entero-enteric fistulas often form a complex network between closely adherent SB loops that may appear as a stellate configuration on CE MR images.

### Fibrotensosing disease

Over the time, chronic inflammation of the bowel wall may evolve in mural fibrosis that can lead to intestinal occlusion if it causes strictures. The identification of fibrotic stenosis is fundamental for they are not responsive to medical therapy and need surgical resection. In general MR enterography has a good accuracy in assessing SB strictures that are considered significant if the dilatation of the upstream bowel exceeds 3 cm<sup>[77]</sup> (Figure 18). When there is mural fibrosis with permanent strictures, the thickened bowel wall of the pathological segment does not show a hyperintensity on T2-w images or a stratified post-contrast pattern on T1-w images typical of acute inflammation<sup>[74]</sup>. These items may be useful to distinguish between transient strictures supported by acute inflammation or fibrotensosing disease (Figure 19).

**Figure 18** Fifteen years old male with small bowel obstruction caused by fibrotic stricture. Thick-slab T2-w sequence (A) shows bowel dilatation greater than 3 cm (double arrows), according to functionally significant stricture. Coronal T2-w sequence (B) shows mural thickening of the terminal ileum without increased wall signal (asterisks). Transverse (C and D) CE FS-T1-w 3D GE show a homogeneous avidly enhancing of the cecum (arrow in C and D), terminal ileum (asterisks in C) and appendix (arrows in D). These findings can be finding in the small bowel obstruction due to fibrotic stricture.

**Figure 19** Eighteen-years-old female with long standing Crohn's disease. Coronal (A), transverse (B) T2-w images and coronal (C), transverse (D) post-contrast FS-T1-w images show thickening and hyper-enhancement of the ileocecal valve causing stricture.

Cine MRI sequences, allowing the evaluation of bowel motility, can further help this differential diagnosis. Inflammation along the mesenteric border often result in pseudosacculations along the antimesenteric border and can be thought of as the MR equivalent of the mesenteric border linear ulcer seen at SBF<sup>2</sup>T examination (Figure 20). In general, the affected segments are characterized by increased rigidity, loss of distensibility and diminished peristalsis.

**Suspected CD:** In young patients with suspected CD, MR enterography is a valid method to diagnose or ex-

clude the disease. Particularly, it can be used as the first radiological modality in pediatric patients in which the results of endoscopy examinations are normal but a high suspicion of CD is still present<sup>[81]</sup>. However, there is much debate about the best modality to use to examine the SB, because wireless endoscopic examinations, like radiological studies, have their advantages, such as the non-invasiveness and the high diagnostic accuracy in evaluating the small intestine, especially in patients who cannot undergo MR, whose bowel loops are not optimally distended or who are uncooperative, and disadvantages, such as capsule retention due to ileal strictures and

**Figure 20** Coronal thick-slab HASTE (A) and coronal T2-weighted (B) images show pseudosacculations produced by asymmetric thickening of the ileal mesenteric border.

delayed capsule transit due to inflammatory lesions<sup>[82,83]</sup>. If a bowel obstruction is suspected, MR enterography is preferred to capsule endoscopy for the risk of capsule retention<sup>[84]</sup>. Moreover, MR enterography can help the diagnosis of terminal ileitis in symptomatic patients when endoscopy is unsuccessful.

**Additional MRI findings:** Extra-intestinal lesions are detected with MRI in 24%-58% of patients<sup>[84-86]</sup>. Herfarth *et al*<sup>[86]</sup> performed MR enteroclysis in 710 patients with a suspicion or a diagnosis of IBD finding extra-intestinal lesions in 57% of patients of which the 12% of great clinical importance. The colonic features of CD at MR enterography can reliably be diagnosed only in severe inflammation (Figure 21).

The detection of colonic mild disease can be very difficult even if the colon is well distended with the help of a rectal enema (MR colonography); moreover the main weaknesses of MR colonography is the impossibility of obtaining tissue sampling. However, Rimola *et al*<sup>[87]</sup> demonstrated good correlations between the presence and the severity of CD lesions depicted with endoscopy and MR Colonography.

MR is an effective imaging technique for the evaluation of patients with perianal CD. During MR enterography, it is possible to perform specific pelvic sequences, such as FS-T2-w, to evaluate perianal CD, increasing only few minutes of exam time (Figure 22).

MR has an accuracy of 76%-100% compared to examination under anesthesia for fistulae and may provide additional information<sup>[88]</sup>. This technique is an important tool because it can accurately reveal the location and extent of disease, including a clinically undetected fistula or abscess, and it can guide surgery<sup>[89]</sup>.

**3T MRI:** There has been little experience of the use of 3 Tesla (T) MR imaging in children with CD, but it seems to have the advantage of increasing the signal-to-noise ratio (SNR) of approximately 1.7-1.8 times compared to 1.5T MR. This increases the spatial and/or temporal resolution, improving the detection of early, superficial or subtle abnormalities. However, the 3T advantages are

**Figure 21** Colonic distention is optimized with a rectal enema. Coronal T2-w (A) and post-contrast FS-T1-w (B) images show bowel wall thickening, and mural stratification of terminal ileum (arrow) and sigma (arrows) walls.

potentially offset by other issues such as greater chemical shift, susceptibility artifact, B1 inhomogeneity and specific absorption rate<sup>[90,91]</sup>.

## PET-CT ENTEROGRAPHY

Combining the morphologic patterns obtained by CT enterography with the <sup>18</sup>F-FDG metabolic activity obtained by PET, PET-CT enterography as a single test may provide accurately fused morphologic, physiologic, and metabolic imaging, useful in the diagnosis, evaluation of activity, follow-up, and objective assessment of CD<sup>[92]</sup>. Groshar *et al*<sup>[93]</sup> showed a statistically significant difference in mean SUV max among the different mural patterns revealed on CT enterography: intramural edema (active inflammation), intramural soft tissue attenuation (inflammatory infiltrate), and intramural fat (chronic inflamma-

**Figure 22** Twelve years old male with terminal ileum Crohn's disease and perianal fistula. Transverse T2-w (A) and post-contrast FS-T1-w (B) shows terminal ileum submucosa edema (black arrow) and mural stratification (arrows), respectively. Transverse FS-T2-w (C) image shows perianal fistula (arrowhead) in the same patient.

tion). Therefore, PET-CT data could help to distinguish between acute inflammation and fibrotic strictures. However, physiologic uptake of FDG by the intestine can lead to false positive results<sup>[94,95]</sup>. Moreover, the effective dose from PET-CT is actually too high for pediatric patients<sup>[92]</sup>.

## CONCLUSION

The diagnosis and management of CD in children has changed dramatically over the last decade, mainly due to the increased awareness of the risk of the ionizing radiations, the availability of improved diagnostic modalities, and newer, more powerful treatments such as biologics. Techniques without ionizing radiation (US and MRI) are the preferred modalities for the evaluation of the SB in pediatric patients. The goals of the proximal future studies will be the development of a MR validated score system capable of measuring intestinal damage and inflammatory disease activity in children with CD. In future, a potential new imaging technique could be the PET-MR, which combines the morphological MR images with the functional PET information. Several radiopharmaceuticals are now available for imaging CD, but new tracers could change the future of the diagnostic imaging.

**Key words:** Vertebroplasty; Kyphoplasty; Osteoporosis; Vertebral fracture; spine metastasis

**Core tip:** This extended review of current literature on vertebral augmentation is supported by our wide experience in the treatment of vertebral fractures. The most innovative topics are the possibility of treating multilevel vertebral fractures in the same session and the failure of vertebral augmentation due to mechanical disruption of the cement. This is intended to present a thorough review to physicians interested in osteoporosis and vertebral fractures.

Comparative review of vertebroplasty and kyphoplasty. *World J Radiol* 2014; 6(6): 329-343 Available from: URL: <http://www.wjgnet.com/1949-8470/full/v6/i6/329.htm> DOI: <http://dx.doi.org/10.4329/wjr.v6.i6.329>

### Abstract

The aim of this review is to compare the effectiveness of percutaneous vertebroplasty and kyphoplasty to treat pain and improve functional outcome from vertebral fractures secondary to osteoporosis and tumor conditions. In 2009, two open randomized controlled trials published in the New England Journal of Medicine questioned the value of vertebroplasty in treating vertebral compression fractures. Nevertheless, the practice of physicians treating these conditions has barely changed. The objective of this review is to try to clarify the most important issues, based on our own experience and the reported evidence about both techniques, and to guide towards the most appropriate choice of treatment of vertebral fractures, although many questions still remain unanswered.

### INTRODUCTION

The treatment of pain related to vertebral body fractures by vertebroplasty or kyphoplasty has become a widespread practice. The main reported advantages of Kyphoplasty *vs* vertebroplasty are restoration of vertebral body height and a lower rate of cement extravasation. Although both techniques would appear effective in achieving pain relief, the impact on functional outcome is not sufficiently proved.

The choice of vertebroplasty or kyphoplasty and the selection of patients for one or other procedure remain unresolved questions. These issues are complicated by the considerable competition between the procedures and the conflicting claims made for each<sup>[1]</sup>. The degree of pain relief and functional improvement obtained must play an important role in the choice between these techniques. Previous studies reported good outcomes that remained stable during long follow-up periods for both vertebro-

plasty and kyphoplasty<sup>[2,3]</sup>. However, comparative studies are scarce. At present, different devices claiming advantages over more traditional methods are being developed.

Due to the existing controversies regarding the treatment of vertebral fractures, the objective of this review is to analyze the evidence of current literature supported by our own experience.

## EPIDEMIOLOGY AND TYPES OF VERTEBRAL FRACTURES

Vertebral fractures can be secondary to high or low energy trauma. With population ageing most of the fractures (85%) are due to low energy trauma. These are more frequent in women and its prevalence increase with age in both sexes. High energy fractures are more frequent in men and are not related with older age. The incidence of clinically diagnosed vertebral fractures was assessed in a population-based study in Rochester, Minnesota, 1985-1989. The overall age- and sex-adjusted incidence rate was 117 per 100000 person-years (95%CI: 105 to 130). The age-adjusted rate in women (145 per 100000 person-years) was almost twice that in men (73 per 100000 person-years). Of all fractures, 47 (14%) followed severe trauma, 282 (83%) followed moderate or no trauma, and 12 (3%) were pathologic<sup>[4]</sup>.

Vertebral compression fractures (VCF) are the most common fracture in osteoporotic patients, followed by hip, wrist or ankle fractures. These are known as low energy fractures or insufficiency fractures because the main cause is the fragility of bone that make it prone to injury with minimal or not trauma. After suffering the first vertebral fracture, the risk of developing new vertebral fractures increases 5-10 times<sup>[5]</sup>.

Pathologic vertebral fractures are secondary to osseous involvement by a localized debilitating condition, mainly tumors. Most are due to malignancies such as metastases, myeloma and primary bone tumors, although benign tumors like haemangioma can also lead to a vertebral fracture. The spine is the musculoskeletal target most affected by metastases, mainly secondary to breast, lung, prostate, kidney and thyroid tumors<sup>[6]</sup>. Nevertheless, even in oncologic patients, a third of the vertebral fractures are due to coexisting osteoporosis<sup>[7]</sup>. Imaging techniques and biopsy help to differentiate the underlying cause.

Vertebral fractures happen in 50%-70% of patients with multiple myeloma. It may lead to spinal cord compression until 15% of the patients. On imaging its appearance may be misleading, simulating an osteoporotic vertebral compression fracture<sup>[8]</sup>.

## IMAGING OF VERTEBRAL FRACTURES

Conventional Radiographs are usually the first technique used to study patients with suspected vertebral fracture. While its ability to diagnose high energy posttraumatic fractures is high, its findings may be misleading diagnos-

ing pathologic or insufficiency fractures.

When a high energy fracture is detected radiographically, many authors suggest the addition of computed tomography (CT) to the study, as it allows for better definition of fracture anatomy. When the clinical presentation suggests a fracture and conventional radiography is not diagnostic, a multi-slice CT or magnetic resonance imaging (MRI) help to clear out traumatism of spine. A prospective study found a CT sensitivity of 99% in detecting fractures compared to 87% with plain-film radiography<sup>[9]</sup>.

Osteoporotic vertebral fractures deformity usually is presented in two ways, wedge and biconcave (fish vertebra or diabolo-shaped vertebra) types, while pathological fractures often demonstrate predominately osteolytic changes. The presence of air collections within a vertebral body is considered a sign of vertebral cleft that may be due to fracture instability and/or necrosis (Kummel's disease) and is more frequently associated to benign osteoporotic fractures<sup>[10]</sup>. Nevertheless cases associated to metastasis and myeloma has been described<sup>[11]</sup> (Figure 1).

A 15% vertebral body height loss constitutes a vertebral compression fracture. The leading cause of vertebral compression fractures is osteoporosis. Morphologic changes that allow for the diagnosis of an osteoporotic fracture may require time for their development. Therefore, the absence of a fracture on plain-film radiography in an osteoporotic patient does not rule it out, and when symptoms persist, a MRI should be performed. MRI can detect fractures without vertebral deformities and can better discriminate between benign and malignant fractures<sup>[12]</sup>. Additionally, MRI provides valuable information on factors such as the degree of edema, vertebral deformities, and invasion of the spinal canal, all of which are useful data for planning medical, percutaneous (kyphoplasty, vertebroplasty) or surgical treatment<sup>[13]</sup>.

Plain-film radiography is somewhat insensitive when it comes to the visualization of the bone destruction or marrow replacement, requiring, depending on the size of the lesion, between 30%-50% of bone density loss before the lesions become visible<sup>[14]</sup>. The detection of blastic lesions may also be delayed with conventional radiography. One study reported that in the case of breast cancer, plain film detection of blastic lesion may be delayed by 3-6 mo<sup>[15]</sup>.

Based on vertebral morphology and bone marrow signal, MRI can differentiate between osteoporotic and pathologic fractures with high confidence. Pathologic fractures may show complete substitution of normal bone marrow or, when incomplete, tend to show and nodular or patchy pattern. Morphologic signs are a convex vertebral border, due to expansion by growing tumor, and the presence of asymmetric paravertebral mass. Acute osteoporotic vertebral fractures tend to show a band-like pattern of subchondral edema and, quite often, the lineal pattern of the vertebral fracture can be depicted inside the edema<sup>[13]</sup>. A retropulsed bone fragment and the presence of intra vertebral cleft are characteristic

**Figure 1** Sagittal T2 weighted (A) image shows meta-static compression fracture with intravertebral cleft (arrow) and epidural cyst (arrowhead), computed tomography guided biopsy (B), Sagittal computed tomography before (C) and after (D) vertebroplasty showing air filling of the cyst (arrowhead).

of benign compression fractures<sup>[11]</sup>. Chronic vertebral compression fractures are characterized by morphologic changes with recovery of normal signal of the bone marrow (Figure 2).

## MEDICAL TREATMENT OF VERTEBRAL FRACTURES

Non-operative treatment of traumatic vertebral com-

pression fractures is usually appropriate for patients with normal neurological status without suspected radiological instability, with an anterior vertebral body height > 50% of the posterior height and a Kyphotic angulation < 25°; or incomplete injury of the posterior column of the vertebral body<sup>[16,17]</sup>. Although in some cases early closed reduction and casting can be performed, bracing alone and physiotherapy in younger patients (< 65 years) is usually the best treatment option. A short period of bed rest (less

**Figure 3 Segmental kyphotic deformity.** A: Wedge fracture of T12; B: Local vertebral kyphosis angle; C: Regional kyphosis; D: Segmental kyphosis (SK). One vertebra, one disc=one segment. Sagittal index (SI):  $SI = SK - X$  ( $X = +5$  in the thoracic spine,  $X = -10$  in the lumbar spine,  $X = 0$  in T12-L1).

than 1 wk) avoids complications caused by immobilization. In older patients, percutaneous vertebral augmentation may promote early mobilization and reduce analgesic intake<sup>[17]</sup>.

Traditional treatment for osteoporotic fractures has been medical, including lifestyle changes (diet, smoking and exercise), pain management with rest, analgesic and anti-inflammatory drugs and external brace. Medical treatment for osteoporosis includes calcium supplements, vitamin D, hormone replacement and bisphosphonates. These treatments have strong effects on pain, but minimal effect on vertebral stability, vertebral height restoration or reduction of kyphotic deformity. Side effects of chronic medication and rest are increased demineralization of bone and greater risk of developing new fractures. Surgery is left for fractures with vertebral instability or neurological compression.

Traditional treatment for painful vertebral metastases is based on rest, braces, analgesic drugs, radiotherapy and chemotherapy. External beam radiation therapy is the current gold standard treatment for cancer patients with localized bone pain. Nevertheless, 20%-30% of patients do not experience pain relief with this approach. Radiation treatment can also result in additional early bone loss due to inflammation, and limited weight-bearing should be recommended during radiation to prevent pathological fractures. Radiotherapy control of pain is achieved in approximately 70%-80% of the cases, but its maximum effects usually takes place 1 mo after the beginning of treatment and osseous reinforcement up to 2 to 4 mo after, increasing the risk of vertebral collapse with its biomechanical consequences<sup>[18]</sup>.

## PERCUTANEOUS AND SURGICAL TREATMENT OF VERTEBRAL FRACTURES

Criteria for surgical indication of high-energy fractures are variable<sup>[19]</sup>. In our center, surgery is mainly indicated when the body fracture is associated to injury of the posterior column or in cases with neurologic deficit (deterioration of the initial neurologic status constitutes an emergency. It can also be indicated in cases without neurological deficit when there are other radiological signs of instability: central canal narrowing  $> 50\%$ , vertebral height loss  $> 50\%$ , fracture-dislocation, local vertebral kyphosis  $> 25^\circ$ - $30^\circ$ , regional traumatic angle of kyphosis  $> 20^\circ$  and sagittal index (SI)  $> 15^\circ$ .

Local vertebral kyphosis angle is measured between the tangent to the upper endplate and the lower endplate of the injured vertebra. Regional kyphosis is the angle defined by the tangent to the upper endplate of the vertebra overlying the fracture and the tangent to the lower endplate of the vertebra underlying the injured vertebra. The SI is defined as segmental kyphotic deformity minus baseline sagittal contour in the segment with the fractured vertebral body. The segmental kyphotic deformity is the angle between the inferior endplate of the injured vertebra and the inferior endplate of the overlying vertebra. The baseline sagittal contour in each vertebral segment arbitrarily amounts to  $+5^\circ$  for the thoracic region,  $0^\circ$  T12-L1 and  $-10^\circ$  for the lumbar spine segments (Figure 3). The normal index is  $0^{[20]}$ .

Accepted methods for surgical decompression and stabilization include anterior or posterior approaches and

**Figure 4** Forty-five years old man with acute Wedge impaction fracture of L1 (A) treated by posterior instrumentation and vertebral body kyphoplasty using biological cement (B).

a combination of both procedures. Instrumented fusion is better than laminectomy alone because it does not restore neurological function and it's associated with significant complications, such as persistent spinal instability and progressive kyphosis, mechanical pain and worsening of neurological injury<sup>[19]</sup>.

Sometimes, instrumentation is complemented with VT or KP. Transpedicular vertebral augmentation for the direct restoration of burst fractures in combination with posterior instrumentation may avoid the surgical anterior reconstruction. The aim is to reinforce the anterior column and prevent anterior vertebral body height loss<sup>[21]</sup> (Figure 4).

The role of vertebroplasty and kyphoplasty in the treatment of high energy vertebral fractures is not still well defined, although good results with regard pain relief and quality of life have been reported using both procedures<sup>[22,23]</sup>. In young patients it has been suggested the use of biological cement, instead of PMMA, due to its capacity of integrating with bone<sup>[24]</sup>. Nevertheless, it has been reported that low resistance against flexural, tractive, and shear forces compared to PMMA, may lead to a higher risk of cement failure and subsequent loss of correction, mainly when fracture of the posterior wall of the vertebra is present<sup>[25]</sup>. The aim of treating percutaneously these fractures is to recovery vertebral height and to obtain early relieving of pain in order to reducing recovery time in young active population.

The principal surgical options for treatment of osteoporotic VCFs are decompression and fusion. The success of surgical instrumentation is compromised by poor bone quality<sup>[26]</sup>. As a result, interest in new and quick methods for pain relief and early functional restoration has increased. Percutaneous treatment of osteoporotic fractures is mainly indicated after failure of medical treatment, when the patient has a disabling pain or when there are severe side effects due to analgesic medication. In order to minimize these effects in patients with VCFs and reduce prolonged hospital resource utilization, VP and KP have been increasingly used with the expectation of a more rapid pain relief and earlier mobilization than that achieved with medical pain management<sup>[27]</sup>. Recently a randomized non-blinded trial appeared, strongly indicating that vertebroplasty is dramatically superior to conservative therapy<sup>[28]</sup>.

Surgery in vertebral metastases is left for lesions affecting a unique vertebra or for treating neurological deficit secondary to compression or instability. Inconveniences of surgery are long recovery times and high morbidity and mortality<sup>[29]</sup>.

Although external beam radiation therapy is the current gold standard treatment for cancer patients with localized bone pain we have to take into consideration that the life expectancy of most patients with bone metastases is limited, and that around 12-20 wk are usually required before maximum benefits are obtained from post-radiation therapy. In these cases vertebral augmentation techniques in isolation or combined with thermal ablation provide the earliest possible pain relief<sup>[30]</sup>.

## HISTORICAL NOTES

Deramon and Galibert performed the first vertebroplasty in France in 1984. It was performed in a patient with an aggressive haemangioma at the C2 level with resolution of pain. The results were so gratifying that cement injections were soon used in more patients with symptomatic hemangiomas and fractures due to tumors. The application of vertebroplasty in osteoporotic VCF was first published in 1989<sup>[31]</sup>. The hopeful analgesic effect led to the widespread use of augmentation for treating osteoporotic VCF<sup>[32]</sup>. Over the last years, osteoporotic fractures have become the main indication for vertebroplasty<sup>[33]</sup>.

Kyphoplasty is the most widely used modification of vertebroplasty and was developed specifically for use in the osteoporotic vertebra. The basic idea behind this procedure was to raise the end plate of fractured vertebral body with an orthopedic balloon to achieve a more favorable angle of kyphosis before the cement augmentation. Therefore, a cavity is first created within the vertebral body before injecting the cement. The first kyphoplasty was performed by the orthopedic specialist Mark Reiley in California in 1998 with good results<sup>[34]</sup>.

## TECHNICAL ISSUES

Vertebroplasty involves the injection of polymethyl-metacrilate (PMMA) cement into an injured vertebral body *via* a needle that is placed percutaneously either using a transpedicular or extrapedicular approach. The

**Figure 5** Sagittal STIR image (A) in a patient with multiple thoracolumbar compression fractures, eight vertebrae were treated in the same procedure (B and C).

injection has to be forced to surpass the local pressure of the trabecular bone of treated vertebra increasing the risk of leakage through the cracks of the fractured vertebra. It may be performed under general anesthesia, although more commonly the patient is given a local anesthetic at the injection site and conscious sedation<sup>[35]</sup>.

Kyphoplasty, a modification of vertebroplasty, involves the percutaneous insertion of an inflatable high-pressure bone tamp into the fractured vertebral body with the aim of elevate the end-plates by creating a cavity inside the vertebral body that filled with cement help to restore and stabilize the vertebral height. The cavity allows low pressure injection of more viscous cement, lowering the risk of extravasation<sup>[33]</sup>.

PMMA is the most frequent cement used in these procedures. It is the result of the polymerization of methyl methacrylate monomers to PMMA polymers. It is cheap, easy to manipulate, allows combination with radiopaque materials and gives the appropriate stiffness and strength to the vertebral body. However, it does not have osteoinductive or osteoconductive properties and, therefore, it will not integrate itself to host bone over time. Its stiffness may promote mechanical overload to adjacent vertebral bodies<sup>[25]</sup>.

New biological materials have been introduced as alternatives to PMMA, such as calcium phosphate and hydroxyapatite. These are not exothermic, allowing the deposition of new bone that, eventually, could replace the cement. These cements would in time become incorporated into the patient's bone, therefore functioning in a more physiological and biomechanically compatible fashion. This requires the presence of trabecular bone and the haversian canal system, thus cavity creation with a balloon will probably never be a part of the future of biological cements and prophylactic vertebroplasty<sup>[33]</sup>. Nevertheless, biological cements are expensive; their manipulation is not easy due to their high viscosity that makes difficult the interstitial diffusion inside the vertebral body<sup>[36]</sup>. These materials have been recommended in high-energy fractures of young patients<sup>[37]</sup>, although other

authors find a high rate of mechanical failure with these materials, due to its lower resistance to shear, flexion and distraction forces<sup>[25]</sup>.

The number of vertebrae augmentable per session also remains unclear, although extensive augmentation to more than three vertebral levels per session has been shown as feasible<sup>[38]</sup>. However, it may lead to an increase of the amount of bone marrow floating to the pulmonary capillary system, increasing the risk of pulmonary fat embolism. Also, with PMMA there is some risk of incomplete polymerization, leading to increased residual toxic monomers that may result in adverse systemic effects, such as hypotension, bradycardia, asystole and bronchospasm. If the amount of cement injected in each vertebral body due to these reasons is reduced, it might result in incomplete stabilization of some vertebral body fractures leading to residual instability and pain. Notwithstanding, we have treated some cases of multilevel fractures in one single operative session with quite good results<sup>[35]</sup> (Figure 5). We recommend carefully planning the positioning of the needles and the amount of cement to be injected; taking into account the anatomical characteristics of each vertebral fracture, such as location of the fracture lines, integrity of vertebral walls and the presence of vertebral clefts.

## CLINICAL SUCCESS OF

## VERTEBROPLASTY AND KYPHOPLASTY

Analgesic effect effects of these techniques can rely in many factors, such as ablation of C-nociceptive fibers by the thermal effect of the cement, mechanical stabilization of the fracture, height restoration of the vertebral body. The thermal effect also leads to tumor necrosis in patients with metastases<sup>[39]</sup>.

Mechanical stabilization of the vertebral body relies on basal bone density, volume and localization of the injected cement. The filling of 14% to 30% of the volume is able to recover vertebral stiffness, although partial recovery of the stiffness, below the pre-fracture state, would be enough to obtain clinical healing<sup>[40]</sup>.

Cadaveric studies have shown greater recovery of vertebral height with kyphoplasty (5.1 mm) than with vertebroplasty (2.3 mm)<sup>[41]</sup>. Yet, clinical studies are contradictory. While some authors found greater height restoration with kyphoplasty<sup>[42]</sup>, others didn't find differences between both techniques<sup>[43]</sup>. In comparison with cadaver studies, the disk and paravertebral soft tissues may hinder augmentation with more aggressive techniques in living patients.

Vertebroplasty can mainly restore vertebral height when there is fragment instability with intravertebral clefts, indicating non-union of the fracture fragments. The cleft may be filled with greater amount of cement, mainly when there is integrity of the walls of the vertebral body, without extravasations leading loss of intravertebral pressure<sup>[41,44]</sup> (Figure 6).

Relationship between vertebral height restoration and

**Figure 6** Sagittal T2 weighted image (A) and lateral X-ray film (B) of a vertebral fracture with intravertebral cleft, AP (C) and lateral (D) view after vertebroplasty.

clinical evolution is not well established. Some studies found no better pain resolution with height restoration and don't consider this factor mandatory in order to achieve pain control<sup>[45]</sup>.

Another issue to consider is the stability over time of the height restoration. A follow up of height loss after performing these techniques shows the loss to be greater in kyphoplasty, due to less homogeneous distribution of cement, than in vertebroplasty, where the cement intermingles with host bone. Therefore, height recovery differences tend to vanish with time<sup>[46]</sup>.

Short-term pain relief has been demonstrated in osteoporotic and tumor fractures treated with vertebroplasty and kyphoplasty<sup>[47,48]</sup>. Long-term outcomes have not been so well established, although some reports state that the beneficial effects of vertebroplasty remain after a follow-up period of several years<sup>[49,50]</sup>.

Compared with medical treatments, pain relief after VP seems on the whole significantly superior. The follow-up point at which the difference becomes insignificant varies between studies at 3 mo<sup>[51]</sup>, 6 mo<sup>[52]</sup> or 1 year<sup>[53]</sup>. Regarding Kyphoplasty, two prospective controlled studies evaluated and compared the efficacy and safety of this technique *vs* medical management and found better long-term pain relief and superior functional outcome with kyphoplasty, up to 3 years<sup>[54,55]</sup>.

## CLINICAL EVIDENCE OF AUGMENTATION EFFECTIVENESS

Two recent randomized works<sup>[56,57]</sup> stated that there is not better results between vertebroplasty and a sham treatment that only inject local anesthetic in the fractured area.

Nevertheless, bias in both studies may invalidate their conclusions<sup>[58]</sup>. First of all, the small sample size avoid that a better evolution in the vertebroplastic group reaches statistical significance. Second at all, the percentage of control patients that chose to pass to the vertebroplasty group was high enough to invalidate the randomization of the studies. With regard selection of the patients, those with high pain scores were not included. These patients tend to show better results after vertebroplasty<sup>[59]</sup>. Another important factor was the inclusion of a high percentage of non-acute fractures; therefore, it is unclear if the origin of the back pain was the osteoporotic VCF or other common reasons for back pain in the elderly, such as arthritis of facet joint or disc pain. By nature of the patient population studied, "sham" facet injections may have led to decreased facet pain. Local anesthetic infiltration of the posterior longitudinal ligament is an established treatment for osteoarthritis back pain. Perhaps a sham procedure in which a dry needle was inserted might have been a more appropriate control. Other differences with previous studies are lower amount of injected PMMA, non-confirmation by imaging of vertebral fractures previous to procedure in patients with known fractures of less than 1 year and a lack of standardization of the medical treatment. The interpretation of the data is even more difficult due to the absence of a medical treatment group<sup>[60]</sup>.

It has been stated that a percentage of patients with pain following VCF do not have pain arising from the fracture itself, but due to instability or overload on the facet joints produced by adjacent vertebral body deformity<sup>[61]</sup>. Since both causes of pain, VCF and osteoarthritis, may concur at the same time, we often combine

**Figure 7** Sagittal T1 weighted image (A) showing vertebral compression fracture of L2 (arrow) and degenerative spondylolisthesis of L4 (arrowhead), computed tomography guided transforaminal epidural injection (B), Sagittal computed tomography after vertebroplasty (arrow) and epidural injection (arrowhead) (C).

vertebroplasty and spinal injection in the same session, mainly in older patients, relying on edema detected at the facet joints or on degenerative vertebral endplates changes, at the same or at a different level of the fractured vertebrae (Figure 7). This is supported by previous studies that found overall facet joint signal-change scores significantly higher at vertebral body levels affected by an acute/subacute compression fracture than in control levels with either normal bodies or chronic compression fractures<sup>[62]</sup>. This practice does not add too much time to vertebroplasty procedures, avoiding multiple scheduling of patients.

It is highly recommended to perform a spine MRI close before any of these percutaneous procedures<sup>[63]</sup>. The presence of a pattern of bone marrow edema is associated with a good clinical short term success relieving pain<sup>[54]</sup>. Nevertheless, improvement has been also demonstrated in patients with vertebral fractures without bone marrow edema<sup>[64]</sup>.

Grades of recommendation of these techniques are based on the clinical evidence of published papers as follow<sup>[65]</sup>: Good evidence [level I studies with consistent findings; *e.g.*, high quality randomized controlled trials (RCT)], Fair evidence (level II or III studies with consistent findings; *e.g.*, low quality RCT, case/control and cohorts studies), Poor quality evidence (level IV or V studies with consistent findings; *e.g.*, case series and expert opinions), or Insufficient evidence (inconsistent findings or lack of investigation for or against recommending intervention).

Meta-Analysis of published papers show fair to good evidence that in patients with osteoporotic VCF outcomes on physical disability, general health and pain relief are better with VP and KP than with medical management within the first 3 to 6 mo after intervention. Nevertheless, there is fair evidence that by the first or second year after intervention, VP provides a similar degree of pain control and physical function as that attained with optimal medical management. There is insufficient evidence whether KP results in greater pain relief one and 2 years after intervention<sup>[27]</sup>.

Although not assessed in comparative studies, the reported degree of acute pain improvement in tumor-associated vertebral compression fractures is far better than that typically reported with radiation and medical management. Nevertheless, studies yield poor-quality evidence<sup>[27]</sup>.

## COMPLICATION OF TREATMENT OF VERTEBRAL FRACTURES

The aggregate rates of complications of vertebroplasty and kyphoplasty are small; ranging from 2%, when treating osteoporotic compression fractures, to 10% in cases related to malignant tumors<sup>[46]</sup>.

The main risk of these percutaneous procedures is the extravasation of PMMA. Investigations on cement leakage in vertebroplasty report a rate of 11%-76%. In investigations on kyphoplasty, cement leakage data ranges from 4.8% to 39%. Cement leakage is reported at a higher rate if CT scans are used<sup>[45]</sup>. There are many routes by which cement may leak from a vertebra: paravertebral leakage, venous leakage or leakage into the spinal canal and intervertebral foramen (Figure 8). Injury of the surrounding soft tissues is mainly due to the high temperature of polymerization of PMMA. The most sensitive structures are neural tissues, spinal cord and nerve roots. Fortunately, most of the extravasations are to the disk or paravertebral tissues, hence asymptomatic. Transient radicular symptoms have been described in up to 3%-4% of the patients<sup>[66]</sup> and only isolated cases of paraplegia after these procedures have been reported, most of them due to failure of technical issues<sup>[48]</sup>.

The monomers that don't contribute to the polymerization have systemic cardio-pulmonary effects. Pulmonary embolism can be due not only to the cement but also to the fat from the bone marrow extruded into the venous system by the high pressure injected cement or by inflating the balloons<sup>[67]</sup>.

The relationship between percutaneous vertebral augmentation and the development of new fractures it is not well stated. Previous studies have found a greater rate of

**Figure 8** Axial computed tomography shows extravasations to epidural space and paravertebral area (arrows) (A), leakage to the intervertebral disc (arrow) (B), venous leakage (arrow) (C), tail of cement in the path of the needle (arrow) (D).

**Figure 9** Sagittal STIR magnetic resonance image (A) shows fractures with edema of L1 to L3. Kyphoplasty was performed in these vertebrae (B), 3 wk later back pain returned and magnetic resonance imaging showed development of new fractures in L4 and L5 (C), vertebroplasty was performed at these levels (D).

new fractures in these patients than in the osteoporotic population, but the same as in those osteoporotic patients that have already developed a fracture<sup>[68]</sup>. Another article found fewer incidences of new fractures in patients treated with kyphoplasty than in patients managed with medical therapy. This was attributed to improvement of mechanical conditions due to vertebral height restoration and kyphotic correction<sup>[36]</sup>. The higher incidence of fractures in the early postoperative period could potentially be explained by increased patient activity and higher stress secondary to a diminished level of pain (Figure 9).

The possibility of treating adjacent vertebrae to the fractured vertebra is not supported by evidence studies<sup>[69]</sup>, but we think that it is highly recommended treating a

non-fractured vertebra when both, the upper and lower adjacent vertebrae, have been cemented.

Another complication is incomplete stabilization or residual instability of treated vertebral bodies. Due to the lack of data in spine literature regarding this issue as a cause of procedural failure, there are no figures. Relapse of vertebral instability may be due to mechanical failure of the cement, mainly when biological substitutes are used in fractures with loss of integrity of the posterior vertebral wall<sup>[25]</sup>. Incomplete filling of vertebral fracture lines may be followed by persistent instability with residual edema. When a vertebral cleft or cyst exists, kyphoplasty might be more prone to cause instability than vertebroplasty because the cement ball does not intermingle

**Figure 10** Sagittal computed tomography (A) a lateral radiography (B) showing fracture of L3 with intravertebral cyst (arrow), after Kyphoplasty (C) the ball of cement is not incorporated to the instable vertebral fracture, sagittal STIR image showing multiple thoracolumbar fractures with edema (D), treated with vertebroplasty, the cement do not stabilized the fracture of T10 and T12 (arrows) with persistent edema 6 mo after the procedure (E, F).

with vertebral trabeculae (Figure 10).

## WHAT TREATMENT DO I CHOOSE?

Percutaneous vertebral augmentation has been shown to be more effective than prolonged non-operative medical treatment in patients with painful VCFs when adequate analgesia and improved functional status has not been achieved by nonoperative therapy<sup>[70]</sup>. The choice of vertebroplasty or kyphoplasty and the selection of patients for one or other procedure remain unresolved questions. These issues are complicated by the considerable competition between the procedures and the conflicting claims made for each<sup>[1]</sup>. Choice may well be influenced by degree of pain relief, functional improvement and anatomic and technical factors; including operator's experience or preference. Previous studies reported good outcomes that remained stable during long follow-up periods for both vertebroplasty<sup>[71,72]</sup> and kyphoplasty<sup>[73,74]</sup>. However, comparative studies are scarce and acknowledge the need of more high quality randomized controlled trials<sup>[75]</sup>. A recent meta-analysis found significant differences regarding anatomical restoration by kyphoplasty versus vertebroplasty, such as a mean long term kyphotic correction of 2.64°, mean anterior vertebral height recovery of 3.67 mm and lower risk of cement extravasation (risk ratio of 0.7)<sup>[76]</sup>. Nevertheless, these anatomic differences were not clinically relevant because most of the studies comparing both techniques found no differences in clinical outcome

in osteoporotic patients<sup>[77-79]</sup>. Although a systematic review found greater quality of life and disability improvement in kyphoplasty over vertebroplasty, the need to define confounding variables was pointed out, because the selection of patients may depend on different indications for KP or VP in non-randomized studies, thus leading to misleading conclusions<sup>[80]</sup>. An example could be a recent prospective study, included in this systematic review, that found better results in kyphoplasty patients but that was clearly biased because two of the oldest patients were arbitrarily reallocated in the vertebroplasty group<sup>[81]</sup>.

Based on these data, we recommend vertebroplasty as the primary treatment for osteoporotic VCF that do not respond to medical treatment. Kyphoplasty, which is a much more costly procedure, should only be used as an alternative approach in selected patients, such as those with a recent fracture affecting one or two vertebrae.

## FUTURE DEVELOPMENTS

A variety of modifications of these techniques with variable success is being used. The commercial success of Kyphoplasty led to the development of several similar devices, but none have shown any benefit over vertebroplasty in an independent head-to-head trial<sup>[33]</sup>.

Now that the Kyphon device is off patent, there are legions of copycat devices available from most manufacturers. A modified procedure employs reusable hinged-tip curet to manually create a cavity in fractured vertebral

**Figure 11** Sagittal T2 magnetic resonance weighted image (A) and lateral X-ray film (B) showing a severe collapse of L1, AP (C) and lateral (D) view after vessel-plasty.

**Figure 12** Sagittal magnetic resonance imaging T1 weighted image of a patient with vertebral metastases (A), radiofrequency thermal ablation was performed before cementation (B, C), post procedure computed tomography (D).

bodies under fluoroscopy guidance, allowing low resistance injection of more viscous cement<sup>[82]</sup>. We have often used a similar curet to create space for the balloon when the hardness of the vertebral body prevented the balloon from creating a cavity of the appropriate size.

Vesselplasty has been introduced as a new alternative to vertebroplasty and kyphoplasty. It has been devised to obtain control of the volume of injected cement and restoration of the vertebral body height. It was first performed in 2004 by Darwono. Instead of using a balloon to create a cavity, vesselplasty uses a polyethylene terephthalate balloon container (vessel) that serves as both, a vertebral body expander and a bone cement container. Introduced into the collapsed vertebral body, it is expanded by the injection of PMMA. Due to the porous structure of the vessel, a small amount of bone cement interdigitates with the trabecular bone around the ves-

sel increasing its stability<sup>[83]</sup>. We are now introducing this technique in our hospital and we have found it very useful in cases of severe vertebral collapse, where the vessel acts as a prosthetic material that minimally restores the crushed vertebral body (Figure 11).

Another issue is the combination of percutaneous cementoplasty using polymethyl methacrylate with other techniques, such as radiofrequency thermal ablation (RFTA). It is sometimes indicated to reinforce bone structures and stabilize bones with high risk of pathologic fractures resulting from metastatic disease, and it is especially indicated for weight bearing bones. The combined use of RF ablation and cementoplasty appears to be useful in order to achieve tumor necrosis and stabilize the fractured vertebrae. The coagulation necrosis produced by RFTA may promote the homogenous distribution of the bone cement within the ablated lesion. The

clinical use of this combined therapy has been reported in several studies, but experience with this approach in vertebral fractures is still limited. Bone cement heats up to 80 °C, which may help to strengthen the anticancer effects of RFTA<sup>[84]</sup> (Figure 12). Radiofrequency assistance and heating the needle tip constantly can also be used to increase cement viscosity, lowering the extravasation.

## CONCLUSION

This extended review try to update the knowledge about vertebral augmentation based in current literature and our own experience. However, operator's experience or preference is also important clues in deciding appropriate treatment of vertebral fracture. Nevertheless, we hope this review will be helpful to clinician dealing with spinal diseases.

differences in the motion of water molecules among tissues and this information is useful in assessing the biological behavior of cancers. Promising results in predicting and monitoring the response to CRT have been reported in several types of cancers. Recently, growing evidence has emerged showing that DW-MRI can serve as an imaging biomarker in the management of bladder cancer. The qualitative analysis of DW-MRI can be applied to detecting cancerous lesion and monitoring the response to CRT. Furthermore, the potential role of quantitative analysis by evaluating apparent diffusion coefficient values has been shown in characterizing bladder cancer for biological aggressiveness and sensitivity to CRT. DW-MRI is a potentially useful tool for the management of bladder cancer, particularly in multimodal bladder-sparing approaches for MIBC.

### Abstract

Bladder-sparing strategy for muscle-invasive bladder cancer (MIBC) is increasingly demanded instead of radical cystectomy plus urinary diversion. Multimodal therapeutic approaches consisting of transurethral resection, chemotherapy, radiotherapy and/or partial cystectomy improve patients' quality of life by preserving their native bladder and sexual function without compromising oncological outcomes. Because a favorable response to chemoradiotherapy (CRT) is a prerequisite for successful bladder preservation, predicting and monitoring therapeutic response is an essential part of this approach. Diffusion-weighted magnetic resonance imaging (DW-MRI) is a functional imaging technique increasingly applied to various types of cancers. Contrast in this imaging technique derives from

**Core tip:** Diffusion-weighted magnetic resonance imaging (DW-MRI) is a functional imaging increasingly applied in the management of bladder cancer. This imaging offers unique information reflecting physiological character of the tissues by quantifying the diffusion of water molecules. DW-MRI provides accurate information for the diagnosis of bladder cancer in a noninvasive manner. Furthermore, growing evidence has emerged showing that DW-MRI can serve as an imaging biomarker of bladder cancer for assessing biologic aggressiveness and therapeutic sensitivity and for monitoring the therapeutic response. This review focuses on the potential role of DW-MRI in multimodal organ-preservation strategies for bladder cancer.

Diffusion-weighted magnetic resonance imaging in management of bladder cancer, particularly with multimodal bladder-sparing strategy. *World J Radiol* 2014; 6(6): 344-354 Available from: URL: <http://www.wjgnet.com/1949-8470/full/v6/i6/344.htm> DOI: <http://dx.doi.org/10.4329/wjr.v6.i6.344>

## INTRODUCTION

Bladder cancer is the second most common genitourinary cancer in the United States and some 55600 new cases and 15100 deaths from bladder cancer are estimated to have occurred in 2012<sup>[1]</sup>. At the initial diagnosis, a third of all cases are diagnosed as muscle-invasive bladder cancer (MIBC)<sup>[2]</sup>, and radical cystectomy has long been the treatment of choice for the treatment of localized MIBC. However, concern for patients' quality of life has strengthened the trend toward bladder-sparing approaches with various treatment modalities<sup>[3]</sup>. In this treatment approach, meticulous evaluation of the bladder cancer is essential. Diffusion-weighted magnetic resonance imaging (DW-MRI) is a functional imaging technique increasingly applied to various types of cancer. Recently, growing evidence has emerged showing that DW-MRI can serve as an imaging technique that is useful for characterizing the pathophysiology of cancer. The biological behavior assessed with this imaging technique will play an important role in multimodal organ-preserving strategies for MIBC. Thus, this review focuses on the potential role of DW-MRI in multimodal organ-preservation strategies for MIBC.

### Trimodality bladder-sparing strategy for MIBC

Favorable oncological and functional outcomes using bladder-sparing trimodality therapy combined with transurethral resection of bladder tumor (TURBT), chemotherapy and radiotherapy have been reported by several groups including Harvard University, the University of Paris and the University of Erlangen in Germany<sup>[4-6]</sup>. In most trimodality bladder-sparing approaches, patients who achieve complete response (CR) after the trimodal treatment are selectively subjected to consolidative therapies for bladder preservation, whereas those who do not achieve CR are advised to undergo early radical cystectomy. The 5-year survival rates after trimodality bladder-preserving trials were reported to be 50%-60%, which is comparable to those of radical cystectomy series<sup>[7,8]</sup>.

In the trimodality bladder preservation strategies, clinically tumor-free status after TURBT followed by chemoradiotherapy (CRT), as well as lower T stage and completeness of the TURBT, are important prognostic factors<sup>[6,9-11]</sup>. However, even the patients who clinically achieved CR after TURBT followed by CRT still may develop local tumor recurrence and lymph node metastases. Zietman *et al*<sup>[12]</sup> reported that two-thirds of non-MIBC (NMIBC) recurrences developed in the original MIBC sites. Tunio *et al*<sup>[13]</sup> also showed that 21% of the MIBC

patients who achieved CR after trimodality therapy developed MIBC recurrence, and 69% of the recurrences arose from the original MIBC site. This problem could be due, in part, to subclinical viable bladder cancer cells remaining in the original MIBC site, which were missed by conventional imaging studies and biopsy-based evaluation<sup>[14]</sup>.

### Limitations of conventional radiological evaluations in bladder-sparing strategy for MIBC

Contrast-enhanced CT and conventional MRI are the standard techniques that have been used for the radiological evaluation of urinary system tumors. While CT is generally used to screen for metastasis, MRI plays a pivotal role in the staging of bladder cancer because of its superior soft tissue delineation, especially in the context of muscle-invasion. The diagnostic accuracy of MRI in differentiating MIBC from NMIBC is reported to be 75%-92%<sup>[15,16]</sup>. However, these anatomical imaging techniques are not ideal for tissue characterization and assessing tumor aggressiveness. Furthermore, these anatomical imaging techniques often overestimate the extent of tumor after TURBT and CRT due to the post-treatment changes. In multimodal organ-preserving strategies, generally, prior to CRT, TURBT is performed for debulking of the tumor. Both TURBT and CRT can induce local fibrotic and inflammatory changes, both of which manifest as bladder wall thickening<sup>[17]</sup>. Additionally, after the combined therapy, bladder cancer may regress and present as a flat lesion. Therefore, anatomical assessment of therapeutic response based on the response evaluation criteria in solid tumors on T2WI is not appropriate for discriminating small remnants of cancerous tissue from these secondary changes. Dobson *et al*<sup>[18]</sup> showed the utility of dynamic contrast-enhanced (DCE) MRI for discriminating cancerous tissue from radiation-induced fibrosis in thickened bladder walls. However, inflammatory changes secondary to treatments may persist for many years<sup>[19]</sup>. These false-positive results on DCE are often problematic, and they lower its specificity for detecting residual bladder cancer<sup>[19]</sup>. Thus, the utility of T2WI and DCE is still limited in monitoring the therapeutic response after TURBT and CRT<sup>[20]</sup>.

## DIFFUSION-WEIGHTED MRI IN CANCER

### Biophysical basis and clinical application

The DW-MRI technique was initially devised by Stejskal and Tanner in 1965. Since 1985, DW-MRI has been mainly used for neuroimaging, especially for diagnosis of acute cerebral infarction and intracranial tumors<sup>[21]</sup>. With the recent advent of echo planar imaging, high gradient amplitudes, multichannel coils, and parallel imaging, DW-MRI of the abdomen and pelvis has become possible, and a growing number of studies have demonstrated the usefulness of this imaging technique in the diagnosis of malignant tumors of the abdomen<sup>[22,23]</sup>. Because the signal of DW-MRI is derived from the inherent tissue contrast,

**Figure 1** Magnetic resonance images of a 79-year-old man with non-muscle invasive bladder cancer (urothelial cancer, stage pTa, grade 2 > 3). A: T2WI shows a hypointense tumor at the trigone; B: The signal intensity of diffusion-weighted magnetic resonance imaging depends on both water diffusion and the T2 relaxation time; C: Due to the very long T2 relaxation time of urine, the signal of the urine in the bladder remains high on the diffusion-weighted magnetic resonance imaging with a  $b$ -value of 500 s/mm<sup>2</sup>. This is known as the “T2 shine-through effect”; D: Using a  $b$ -value of 1000 s/mm<sup>2</sup> decreases the signal of the urine, as well as those of the seminal vesicles, while the bladder cancer (arrow head) shows little signal attenuation with the increased  $b$ -value.

this imaging technique requires no contrast agent and is applicable to patients with allergies to contrast agents or those with renal insufficiency. Furthermore, the addition of DW-MRI to a routine MRI examination requires only a few additional minutes and can be adopted for most current clinical MRI scanners.

DW-MRI is a functional imaging technique, the contrast of which results from quantifying the microscopic mobility of water molecules in tissue<sup>[22,23]</sup>. In biological tissues, the diffusion of water molecule is inversely correlated to the tissue cellularity and the integrity of cell membranes. In the area of tumor tissues, which have a high cellular density with intact cell membranes, water molecule diffusion is restricted, while the diffusion of water molecule is less restricted in areas of low cellular density. Areas where the diffusion is restricted generally show high signal intensity on DW-MRI, and malignant lesions typically show high signal intensity because of their higher cellularity, tissue disorganization, and decreased extracellular space, all of which restrict water diffusion. In recent years, an increasing number of studies have shown the usefulness of visual assessment of DW-MRI for detecting malignant tumors, and DW-MRI has quickly become a useful adjunct for assessing various types of tumors including bladder cancer<sup>[24-27]</sup>.

### Quantifying the degree of diffusion

The sensitivity of the diffusion is varied by changing the

“ $b$ -value” which is proportional to the gradient amplitude, the duration of the applied gradient, and the time interval between the paired gradients<sup>[22,23]</sup>. Small  $b$ -values attenuate the signals of water molecules with a large degree of motion or a great diffusion distance. By using higher  $b$ -values, the perfusion in the intra-vascular space is restricted and slow-moving water molecules or small diffusion distances can be distinguished (Figure 1). Therefore, DW-MRI should be performed using three or more  $b$ -values including  $b = 0$  s/mm<sup>2</sup>,  $b \geq 100$  s/mm<sup>2</sup>, and  $b \geq 500$  s/mm<sup>2</sup>. Comparing the images obtained at different  $b$ -values is useful for characterizing the lesion. The apparent diffusion coefficient (ADC) value is assessed for quantitative evaluation of DW-MRI by evaluating the signal attenuation of tissue on DW-MRI with increasing  $b$ -values. Generally, the software automatically calculates the ADC values, and the calculated ADC values for each pixel of the image are displayed as a parametric map. By drawing regions of interests (ROI) on this ADC map, the ADC value of the delineated region can be easily obtained. However, because of their poor anatomical details, DW-MRI and ADC maps should be evaluated in combination with T1WI and T2WI, and the correlation with anatomical images is important to accurately set the ROI for the target lesion. Quantitative evaluation of DW-MRI by assessing the ADC value is potentially useful for tissue characterization based on the differences in water diffusion. The correlation of tumor ADC values with their

biological aggressiveness has been reported for various types of malignancies<sup>[28-30]</sup>. However, the reproducibility of the ADC value is an intrinsic limitation in ADC measurement because the ADC value depends on the MRI system and imaging protocol used. To standardize the ADC assessment, some trials using ADC ratio, calculated with respect to surrounding normal tissues, have been performed recently.

### Predicting treatment sensitivity

The important clinical implication of DW-MRI in multimodal organ preservation strategies for MIBC is the ability to predict therapeutic response prior to treatment. In a number of prospective studies in various types of cancers including brain tumors and cervical and rectal cancers<sup>[31-35]</sup>, the potential of DW-MRI to predict the sensitivity to radiotherapy has been shown. The tumors with higher ADC values are less likely to respond to the treatment. The hypothesized mechanism underlying this relationship is the presence of necrosis reflected in a higher ADC value, which predicts a poor outcome related to hypoxia-mediated radioresistance. Meanwhile, soon after the initiation of chemotherapy and/or radiotherapy, immediate cell death can be observed after the commencement of the treatment, which is reflected as an early increase in the ADC value. In cervical cancer and rectal cancer, this early increase in ADC value is observed in patients who show good response to CRT, and can be a potential early biomarker for treatment outcomes<sup>[35-38]</sup>. Following this early ADC increase, edema and fibrosis cause a subsequent ADC decrease<sup>[35-37]</sup>.

### Monitoring treatment response

Importantly, the DW-MRI can be an imaging biomarker in monitoring treatment effect. In response to successful treatment, cell necrosis and loss of cell membrane integrity are induced, leading to increased water diffusion. Furthermore, tumor apoptosis induced by treatment results in cell shrinkage. These changes are reflected by increases in ADC value<sup>[22]</sup>. Clinical studies in many types of malignancies, including liver cancer, cerebral gliomas, and soft-tissue sarcoma, have demonstrated the correlation between therapeutic effect and changes in water diffusion in tumors<sup>[39-41]</sup>.

## CLINICAL APPLICATION OF DW-MRI IN BLADDER CANCER

### Detecting bladder cancer

Since the first report by Matsuki *et al.*<sup>[26]</sup> showing the utility of DW-MRI for detecting bladder cancer, a number of studies have shown the usefulness of DW-MRI for the diagnosis of bladder cancer<sup>[24-27]</sup>. On DW-MRI with a high *b*-value, bladder cancers generally show a hyperintense signal, while the signals of the surrounding tissues, including urine, are much less intense<sup>[26,42]</sup> (Figure 1). This good signal contrast is obtained between bladder cancer

and the surrounding tissue. The sensitivity, specificity and accuracy for detecting bladder cancer were reported to be 90%-98%, 92%-93% and 91%-97%, respectively<sup>[24,25,27]</sup>. In several studies, quantitative analysis consistently showed restricted diffusion and lower ADC values in bladder cancer compared with the surrounding structures<sup>[26,42]</sup>.

### Detecting lymph node metastasis

MIBC has the potential to metastasize to lymph nodes and distant organs, and detecting metastatic lesion is another problem in managing MIBC. At the time of surgery, 25% of the patients who undergo radical cystectomy have a lymph node metastasis. Lymph node staging has been generally performed by CT or conventional MRI based on size criteria and morphological appearance, and the accuracy for staging nodal disease ranges from 73% to 90%<sup>[43]</sup>. On DW-MRI, benign lymph nodes show high signal intensity due to their highly cellular structures composed of lymphoid elements (Figure 2). The utility of DW-MRI has been shown in lymph node staging in various cancers<sup>[44-48]</sup>. Papalia *et al.*<sup>[49]</sup> showed that malignant lymph nodes have a significantly lower ADC value than benign lymph nodes with sensitivity of 76.4% and specificity of 89.4% in a study that included 36 patients with bladder cancer undergoing radical cystectomy. However, there is a substantial overlap in ADC values between malignant and benign lymph nodes, and discriminating malignant nodes from benign nodes on DW-MRI is still challenging<sup>[50]</sup>. Recently, Thoeny *et al.*<sup>[51]</sup> reported an excellent diagnostic accuracy of 90% in detecting pelvic lymph nodal involvement by the combined use of ultra-small super paramagnetic iron oxide (USPIO) and DW-MRI. This agent is taken up by macrophages resulting signal loss in normal lymph nodes, while the signal of metastatic lymph nodes is not influenced<sup>[51-55]</sup>. Further studies are needed to confirm this encouraging result.

### Detecting bone metastasis

DW-MRI for evaluating primary bladder cancer occasionally shows abnormal signals of pelvic bones or femur heads. Bone metastasis typically shows clear high signal intensity on DW-MRI<sup>[56,57]</sup>. However, as well as benign bone tumors, hematopoietic bone marrow also appears as a hyperintense lesion on DW-MRI because of rich hematopoietic cells<sup>[58,59]</sup>. These false-positive findings in detecting metastasis should be kept in mind for staging bladder cancer<sup>[60]</sup>. Furthermore, identifying microscopic metastases or developing metastases remains a challenge, and a third of MIBC patients have undetected metastases at the initial diagnosis<sup>[61]</sup>.

### Characterizing histopathological features

Because the contrast of DW-MRI is based on difference in the degree of water diffusion between tissues, the spatial resolution of DW-MRI is generally low. However, using the clear contrast between bladder cancer and the surrounding tissues, the utility of DW-MRI for staging of

**Figure 2** Magnetic resonance images of a 45-year-old man with muscle-invasive bladder cancer (urothelial cancer, stage cT3N1) before and after chemoradiotherapy. A: Before CRT, an enlarged right external iliac lymph node (arrow head) is visible on T2WI; B: The lymph node on the corresponding DW-MRI shows a hyperintense signal; C and D: After CRT, size reduction on T2WI (C) and signal attenuation on DW-MRI (D) in lymph node is evident, consistent with the expected treatment response. CRT: Chemoradiotherapy; DW-MRI: Diffusion-weighted magnetic resonance imaging.

**Figure 3** Magnetic resonance images of a 63-year-old man with non-muscle-invasive bladder cancer (urothelial cancer, stage pT1, grade 2 > 3). A: T2WI shows a large papillary tumor on the left bladder wall; B: DW-MRI displays a C-shaped high-signal tumor with a low-signal-intensity stalk connecting to the bladder wall. This C-shaped high signal is known as an "inchworm sign", which is a criterion for T staging in non-muscle-invasive bladder cancer (stage cT1 or less). DW-MRI: Diffusion-weighted magnetic resonance imaging.

bladder cancer based on the signal shape and contrast has been shown (Figure 3). On DW-MRI, bladder cancers generally show a hyperintense signal in distinct contrast to the hypointense signal of the submucosal layer and the intermediate signal of the intact bladder wall. On the basis of these findings, El-Assmy *et al.*<sup>[62]</sup> reported the ability to discriminate MIBC from NMIBC with an accuracy of 63.6% in a study that included 106 patients. Takeuchi *et al.*<sup>[63]</sup> reported that bladder cancer staging accuracy improved from 67 to 88% when DW-MRI was added to T2WI.

Furthermore, the utility of DW-MRI in characterizing bladder cancer has been consistently shown in multiple studies using quantitative analysis (Figures 4 and 5). Takeuchi *et al.*<sup>[63]</sup> reported that the ADC value of grade 3 tumors was significantly lower than that of grade 1 and 2 tumors in a prospective study that included 40 patients. Avcu *et al.*<sup>[64]</sup> also reported similar results showing an inverse correlation between the ADC value and the histological grade. The existence of a substantial overlap between the histological grades or stages poses a limit to qualitative analysis and the clinical application

**Figure 4** Magnetic resonance images of a 52-year-old woman with non-muscle-invasive bladder cancer (urothelial cancer, pTa, grade 2). A: T2WI shows a hypointense tumor at the posterior wall; B: DW-MRI displays the tumor as a high-signal mass; C: The corresponding ADC map demonstrates a lesser degree of restricted diffusion. The mean ADC value with the ROI positioned not extending over the tumor is  $1.21 \times 10^{-3}$  s/mm<sup>2</sup>. DW-MRI: Diffusion-weighted magnetic resonance imaging; ADC: Apparent diffusion coefficient.

**Figure 5** Magnetic resonance images of a 75-year-old man with muscle-invasive bladder cancer (urothelial cancer, stage cT4, grade 3). A and B: T2WI shows a large hypointense tumor at the bladder neck, invading the prostate; C: DW-MRI displays the tumor as a high-signal mass; D: The corresponding ADC map demonstrates restricted diffusion. The mean ADC value of the tumor is  $0.63 \times 10^{-3}$  mm<sup>2</sup>/s. DW-MRI: Diffusion-weighted magnetic resonance imaging; ADC: Apparent diffusion coefficient.

of this technique. However, these studies indicated that advanced and aggressive bladder cancers tend to have a low ADC values. Actually, Kobayashi *et al.*<sup>[27]</sup> found that clinically aggressive tumors, including MIBC and high-grade T1 tumors, had a significantly lower ADC value than the other less aggressive tumors. A threshold ADC value differentiated these two entities with 87% accuracy in a series of 121 patients. The underlying mechanisms whereby the ADC value reflects these tumor characters are thought to be the tumor cell morphological characters such as dense cellularity and large cellular size<sup>[22,23]</sup>. Recent studies have shown an inverse correlation between ADC value and the Ki-67 labeling index, a marker of cell

proliferation, in bladder cancer<sup>[65-67]</sup>. These data suggest the potential of ADC value to serve as a quantitative bio-marker characterizing the biological features of bladder cancer.

### Predicting metastatic potential

The potential role of ADC values in predicting the metastatic potential of localized high-grade bladder cancers was shown in a small study that included 17 patients. This study showed that invasive high-grade bladder cancers with metastasis had lower ADC values than those without metastasis<sup>[68]</sup>. ADC value can be a supplemental parameter for predicting the presence of metastasis, which

**Figure 6** Magnetic resonance images of a 61-year-old man with muscle-invasive bladder cancer (urothelial cancer, stage cT3, grade 3) treated with the Tokyo Medical and Dental University protocol consisting of transurethral resection of bladder tumor and induction chemoradiotherapy (CRT) followed by radical or partial cystectomy. T2WI shows a large hypointense tumor at the bladder neck, invading the prostate. At the diagnosis, DW-MRI with a  $b$ -value of 1000  $\text{s/mm}^2$  displays a hyperintense lobulated mass. After TURBT and CRT, this lesion shows wall thickening (arrow head) on T2WI and enhancement on DCE, while the abnormal signal on DW-MRI is diminished to normal signal intensity. Histopathologic examination of the cystectomized sample reveals no remaining bladder cancer, revealing the findings of post-CRT T2WI and DCE to be false-positive findings reflecting post-treatment changes in bladder tissues. TURBT: Transurethral resection of bladder tumor; CRT: Chemoradiotherapy; DW-MRI: Diffusion-weighted magnetic resonance imaging; DCE: Dynamic contrast-enhanced.

has a great impact on treatment decisions.

## POTENTIAL ROLES OF DW-MRI IN MULTIMODALITY BLADDER-SPARING STRATEGIES

### **Novel bladder-sparing approach incorporating consolidative partial cystectomy with pelvic lymph node dissection**

We started a pilot study of a selective bladder-sparing protocol incorporating consolidative partial cystectomy with pelvic lymph node dissection after induction low-dose chemoradiotherapy (LCRT) in 1997 at Tokyo Medical and Dental University (TMDU)<sup>[10,11,14,69-71]</sup>. Consolidative partial cystectomy with pelvic lymph node dissection is intended to eradicate possible remaining subclinical residual tumor tissue in the original MIBC sites and micrometastases in the pelvic lymph nodes. Candidates for bladder preservation are selected based on the extent, location, and post-LCRT status of the tumor. More than one-third of MIBC patients without any metastasis meet our criteria for partial cystectomy. Partial cystectomy with pelvic lymph node dissection was performed in 70 patients following LCRT. A functional native bladder was

preserved in 91% of patients, and none has developed MIBC or lymph node recurrence<sup>[10,14]</sup>.

### **Predicting sensitivity to CRT**

In the majority of CRT-based bladder-sparing protocols for localized MIBC, patients who achieve a clinical CR are subjected to consolidative treatment with CRT for bladder preservation. In these protocols, treatment effect cannot be histologically evaluated. In the above-mentioned bladder-sparing protocol incorporating partial cystectomy, histopathological therapeutic effects of LCRT can be assessed, which is one of advantages of the TMDU protocol. By comparing DW-MRIs taken before and after LCRT with this therapeutic effect, the utility of DW-MRI for predicting treatment sensitivity and in monitoring therapeutic response can be evaluated<sup>[20,67]</sup>.

We found a significant inverse correlation between LCRT sensitivity and ADC value of the tumor<sup>[67]</sup>. LCRT-sensitive MIBCs had significantly lower ADC values than LCRT-resistant MIBCs. With a defined cut-off ADC value, the sensitivity, specificity and accuracy in predicting LCRT sensitivity were 92%, 90%, and 91%, respectively. These findings are consistent with previous reports on other tumors including brain, cervix and rectum<sup>[31-35]</sup>. However, the presence of necrosis is not common in

MIBC, which is understood to be the background of the correlation between lower ADC values and favorable CRT response. One possible explanation of this correlation found in MIBC is that the relationship between the proliferative activity and the ADC value of MIBC; highly proliferating MIBCs show low ADC values<sup>[65,67]</sup>. Because favorable CRT response in highly proliferating MIBC has been reported<sup>[72,73]</sup>, a low ADC value would be predictive of a better CRT sensitivity of MIBC.

### Monitoring response to CRT

We also showed the utility of DW-MRI in monitoring the therapeutic response of MIBC treated with LCRT, as has been reported for other cancers. The sensitivity/specificity/accuracy of T2WI, DCE, and DW-MRI in predicting pathologic CR were 43%/45%/44%, 57%/18%/33%, and 57%/92%/80%, respectively<sup>[20]</sup>. DW-MRI improved the accuracy for detecting the remaining cancer after LCRT, primarily due to its increased specificity (Figure 6). However, the low sensitivity in detecting small lesions is a notable limitation, which makes it difficult to detect microscopic residual cancers, as is the case with the other imaging techniques. Further studies are necessary to evaluate the potential of DW-MRI as an imaging technique in the context of bladder-sparing approaches. Multiple approaches, including DW-MRI and biopsies to monitor the therapeutic response, may improve the accuracy of these techniques. However, the limits discussed here in detecting remaining cancers justify partial cystectomies to eliminate the possibly of remaining microscopic tumors in the original invasive cancer site, even in the patients who achieve clinical CR after CRT.

## CONCLUSION

Recent studies have shown that the DW-MRI is a unique imaging technique that provides qualitative and quantitative information on biological features of bladder cancer, and is potentially useful as an imaging technique in the management of bladder cancer, particularly in multimodal bladder-sparing strategies for MIBC. Further large prospective studies are needed to clarify the practical roles of DW-MRI in the management of bladder cancer.

### Abstract

Acute aortic syndrome (AAS) is a spectrum of conditions, which may ultimately progress to potentially life-threatening aortic rupture. This syndrome encompasses aortic dissection (AD), intramural haematoma, penetrating atherosclerotic ulcer and unstable thoracic aortic aneurysms. Multi-detector CT (MDCT) is crucial for the diagnosis of AAS, especially in the emergency setting due to its speed, accuracy and ready availability. This review attends to the value of appropriate imaging protocols in obtaining good quality images that can permit a confident diagnosis of AAS. AD is the most commonly encountered AAS and also the one with maximum potential to cause catastrophic outcome if not diagnosed and managed promptly. Hence, this review briefly addresses certain relevant clinical perspectives on this condition. Differentiating the false from the true lumen in AD is often essential; a spectrum of CT findings, *e.g.*, "beak sign", aortic "cobwebs" that allows such differentiation have been described with explicit illustrations. The value of non enhanced CT scans, especially useful in the diagnosis of an intramural hematoma has also been illustrated. Overlap in the clinical and imaging features of the various conditions presenting as AAS is not unusual. However, on most instances MDCT enables the right

diagnosis. On select occasions MRI or trans-esophageal echocardiography may be required as a problem solving tool.

### INTRODUCTION

Acute aortic syndrome (AAS) is a term used to describe a constellation of emergency aortic conditions requiring prompt diagnosis and treatment. These inter-related conditions include aortic dissection (AD), intramural haematoma (IMH) and penetrating atherosclerotic ulcer (PAU)<sup>[1]</sup>. In addition, unstable thoracic aortic aneurysm

at high risk for rupture may also be considered an AAS. This syndrome has an estimated incidence of (2-3.5)/100000 per year<sup>[2]</sup>. The most common risk factors are hypertension and genetic conditions of the connective tissue such as Marfan's syndrome. The clinical presentations of the various entities of AAS are essentially indistinguishable from each other with severe chest or abdominal pain being the most common symptom. Clinical suspicion of AAS should herald prompt diagnostic imaging as mortality from AAS increases by approximately 1%-2% per hour<sup>[3]</sup>. MDCT typically with electrocardiographic gating (ECG-gated MDCT) is the technique of choice for diagnosis of AAS due to the rapid acquisition times and ready availability in the emergency department<sup>[4]</sup>. Other diagnostic imaging modalities include conventional and transoesophageal echocardiography and magnetic resonance imaging (MRI), that are usually reserved for problem solving or if there is contraindication to the use of iodinated contrast<sup>[1,2,5]</sup>. This review will focus on MDCT in the diagnosis of AAS. MDCT protocols will be discussed along with the discriminating and overlapping radiological diagnostic features of AAS.

### MDCT PROTOCOL FOR AAS

MDCT angiography with electrocardiographic (ECG) gating enables the evaluation of AAS with reduced pulsation artefacts (Figure 1) in the ascending aorta compared to non-gated MDCT angiography<sup>[6]</sup>. The ECG-gating can either be performed prospectively (scanning performed at a specified segment of the cardiac cycle), or retrospectively (scanning performed throughout the cardiac cycle but data gathered in a specified segment of the cardiac cycle is selected retrospectively for generating images). A retrospective acquisition allows increased scope for correction of artefacts from dysrhythmias or motion, but comes at the cost of increased radiation exposure<sup>[1,6]</sup>. ECG-gating with motion-free images allows for improved assessment of the ascending aorta, aortic annulus, sinuses of Valsalva and coronary arteries<sup>[6,7]</sup>. There is also improved depiction of the site of primary intimal tear, extent of the intimomedial flap and involvement of the aortic branches. Studies have also shown a reduction in radiation dose of as much as 45%-50% using ECG-gated high pitch CT compared to non-ECG-synchronised standard-pitch CT<sup>[8,9]</sup>. Although ECG-gating is preferred, its absence rarely precludes the diagnosis of clinically significant acute aortic conditions if an experienced reader is interpreting the non-gated CT aortogram.

The details of the scan protocol vary according to the scanner system being used. As an illustration we have described here the protocol of ECG-gated CT angiography on a 64-section helical CT system (Somatom Sensation, Siemens, Erlangen, Germany) performed in our department. Z-axis coverage is determined on a planning topogram from the root of the neck to the common femoral artery bifurcation. A 100 mL bolus injection of intrave-

**Figure 1** Cardiac-gated computed tomography aortogram in a 55-year-old with chest pain and suspected acute aortic syndrome. A: Axial oblique; B: Coronal reconstructions. No dissection or aneurysm was detected. Retrospective reconstruction at 78% of the cardiac cycle allowed for accurate evaluation of the aortic root and valve cusps in both axial oblique and coronal reconstructions with no pulsation artefacts.

nous contrast (Iohexol 300 mg/mL, Nycomed) is injected at a rate of 3-4 mL a second. Bolus tracking is used to trigger scanning when the attenuation of the descending aorta reaches 150 HU. Retrospective gating is typically used with images reconstructed at 78% of the R-R interval. The section thickness is 0.6 mm with 3 mm reconstructions in the axial, coronal and sagittal oblique planes sent to the PACS for reporting. Additional post processing is performed by the reporting radiologist when clinically indicated for three-dimensional reconstructions to obtain volume rendered images, maximum intensity projections and shaded surface display. Delayed phase images are useful in selected cases of suspected aortic rupture or in cases of dissection to determine the opacification of both the lumina. Although a contrast enhanced CT angiogram is the standard of care, a non-enhanced CT that precedes the angiogram is useful in AAS to evaluate for IMH, which can progress to frank dissection. NECT can also be useful to assess for secondary signs of aortic rupture such as hyperdense, haemorrhagic pericardial, pleural or mediastinal fluid collections. In patients with known allergy to iodinated contrast medium or at high risk of contrast induced nephropathy, the preliminary information obtained through a non-enhanced CT scan may sometimes suffice to make the further clinical decision.

### AD

The most common pathology in AAS is AD that begins as a tear or ulcer in the aortic intima allowing blood to penetrate and disrupt the aortic media<sup>[2]</sup>. Haemorrhage may also occur *de novo* within the media due to rupture of the vasa vasorum leading to dissection. Irrespective of the initiating cause AD involves separation of the aortic layers and formation of a false lumen<sup>[10]</sup>. The false lumen is separated from the true lumen by an intimomedial flap (Figures 2-7). The dissection may then propagate in an antegrade and/or less likely retrograde fashion with a po-

**Figure 2** A 47-year-old gentleman with Stanford type B aortic dissection. The dissection flap is flat in all the computed tomography angiographic images. The ascending aorta is not involved and the true lumen is smaller in calibre and shows early and more intense enhancement than the false lumen at the level of the right pulmonary artery (A). The small calibre true lumen gives rise to the coeliac axis (B) and is outlined by atherosclerotic calcifications (C).

**Figure 3** Axial contrast enhanced magnetic resonance aortogram of the same patient as in Figure 2 with type B aortic dissection. In the arterial phase image (A: Axial; B: Coronal 3D reconstruction; 30 s post injection) the true lumen is of small calibre and shows early intense contrast enhancement compared to the larger false lumen. In the second delayed phase (70 s post injection) the enhancement between the lumens becomes more similar (C: Axial; D: Coronal 3D reconstruction).

**Figure 4** A 35-year-old gentleman with Marfan's syndrome and a type B aortic dissection. Axial images (A and B) from a computed tomography aortogram reveals an intimal flap (arrows) with strands of incompletely sheared aortic media or "cobwebs" seen in the descending thoracic aorta (dashed arrows).

tential to fenestrate back into the aortic lumen or rupture out through the adventitia with life threatening consequences<sup>[11]</sup>. Dissection can extend into aortic branches and when it involves major visceral arteries, it can lead to cata-

strophic consequences such as a cerebrovascular event, bowel ischemia, acute renal failure, limb gangrene *etc.*

Risk factors for dissection include hypertension, smoking, trauma (typically road traffic accidents), vas-

**Figure 5** A 59-year-old lady with a type B aortic dissection. Axial images from a computed tomography aortogram show atherosclerotic calcifications outlining the true lumen at the lower thoracic aorta (A). The true lumen is of smaller calibre and shows early and more intense enhancement than the false lumen at this level. More inferiorly at the level of the left renal vein (B), eccentric intimal flap calcification (note the calcification along the true luminal aspect of the flap) is exquisitely demonstrated.

**Figure 6** A 45-year-old with a type B aortic dissection. An axial image from a computed tomography aortogram at the upper abdominal aorta shows the "beak" sign (arrow): note the acute angle between the dissection flap and the outer wall of the larger calibre false lumen. The "beak" or space formed by the acute angle is filled with high-attenuation contrast-enhanced blood in this case but it may stay unopacified when filled with clots.

cular inflammation (*e.g.*, Takayasu's arteritis) or infection (*e.g.*, syphilis) and genetic connective tissue disorders (*e.g.*, Marfan's and Ehlers-Danlos syndromes). Propagation of the blood within the media to form a dissection requires pre-existing medial degeneration or cystic medial necrosis, which leads to a weakened aortic wall and represents the end point of many of the risk factors listed above<sup>[2,10]</sup>.

Two anatomical classification systems exist for AD: De Bakey and Stanford. The Stanford classification is most commonly used as it has a direct bearing on the subsequent therapy. Stanford type A dissections involve the ascending aorta (proximal to the origin of the brachiocephalic artery origin) with or without aortic arch or descending aorta (distal to the left subclavian artery origin) involvement<sup>[2]</sup>. Type A dissections are typically treated as a surgical emergency. Mortality is estimated at 20% in the first 24 h without immediate surgical management and approximately 40% in the first week<sup>[12,13]</sup>. Complications of type A dissection include aortic regurgitation, aortic rupture, tamponade and compromise of the arch branches or coronary arteries leading to myo-

cardial infarction. Type B constitutes all those dissections that do not involve the ascending aorta. It more often involves the descending aorta and is typically treated medically with anti-hypertensive medications. Without adequate management, uncomplicated type B dissections have an estimated 10% mortality at 1 mo in comparison to 50% for type A dissections<sup>[2,12]</sup>. Type B dissections can be complicated by branch disruption and end organ malperfusion, progression to type A dissection and rupture. The role of endovascular repair is well established in Stanford type B lesions while in select situations it may be performed even in type A lesions<sup>[14]</sup>. The aim of endovascular intervention is to occlude the intimal tear allowing for false lumen thrombosis and regression, typically by placing an aortic endograft. End-organ ischaemia and malperfusion may also be improved by placement of branch stents and the use of aortic fenestrations to relieve compression of the true by a distended false lumen<sup>[1,14,15]</sup>.

MDCT angiography has a sensitivity and specificity of close to 100% for diagnosis of acute AD<sup>[16,17]</sup>. Cardiac synchronisation should be performed to limit pulsation artefacts in the ascending aorta, which on non-gated MDCT are often the cause of false-positive findings of a thoracic dissection. In AD, the role of MDCT angiography can be summarized as to identify<sup>[1,14,18]</sup>: (1) Sites of primary entry and re-entry; (2) Intimal flap, false and true lumen morphology along with the presence of calcifications and thrombus; (3) Extent of the dissection and involvement of the ascending and descending aorta; (4) Evidence of rupture; (5) Involvement of the aortic valve, coronary and aortic arch branches; (6) Abdominal aortic branch patency and evidence of end-organ malperfusion; and (7) Morphology and diameter of the aorta along with the patency, size and tortuosity of the iliac and femoral arteries (useful for endovascular treatment planning).

The intimal flap forms a double-barrelled aorta and separates the true from the false lumen<sup>[4]</sup>. This is seen in approximately 70% of cases on MDCT angiography and with three dimensional reconstructs the complex,

**Figure 7** A 37-year-old gentleman with Marfan's syndrome and a type A aortic dissection. The axial image at the level of the left atrium shows an intimal intussusception type dissection in the descending thoracic aorta with the true lumen surrounded by the false lumen (A and B; intimal flap highlighted by the arrows).

often spiralling nature of the dissection can be seen in better detail<sup>[19]</sup>. Other appearances include a circumferential intimal flap due to complete dissection of the intima. The true lumen takes on a cylindrical or filiform shape and this may result in an intimal intussusception producing a “windsock” appearance (Figure 7). Differentiation between the false and true lumen is useful for endovascular treatment planning as an endograft should be placed within the true lumen<sup>[1,15]</sup>.

The true lumen can usually be identified by tracing back or forth from an uninvolved portion of the aorta; this may be difficult if the aortic root is involved proximally or the dissection extends into the iliac vessels distally<sup>[1,20]</sup>. In these cases the most useful imaging signs include a false lumen that is larger in calibre than the true lumen and the “beak” sign<sup>[20]</sup>. In most cases of acute dissections the false lumen is larger in calibre than the true lumen. This is likely due to sustained systolic pressure in the false lumen exceeding that of the true lumen leading to compression. The “beak” sign (Figure 6) is only seen in the false lumen and is often present in most patients with dissection. It is usually noted both in acute and chronic dissection and is defined as the presence of an acute angle between the dissection flap and the outer wall of the false lumen; the space formed by the acute angle could be filled with high-attenuation material (contrast-enhanced blood) or low-attenuation material (hematoma)<sup>[21,22]</sup>. Other less common and less reliable signs for differentiation between the true and false lumen have been documented in the literature. The false lumen may contain thrombus and fine ribbons of low attenuation (“cobwebs”), which likely represent strands of incompletely sheared aortic media (Figure 4)<sup>[22]</sup>. Differential contrast enhancement between the true and false lumen is not unusual with the true lumen often showing early opacification with contrast in the arterial phase, while the false lumen starts opacifying later in the portovenous and delayed phase (Figure 3)<sup>[23]</sup>. The surface of the dissection flap that is calcified generally involves the intimal surface of the true lumen; this is described as eccentric flap calcification. The side of the flap subtending the false lumen

will have soft tissue attenuation (Figure 5). In acute dissections the lumen with outer wall calcification tends to be the true lumen. Along with eccentric flap calcification this is due to the presence of atherosclerotic calcified plaque in the aortic intima of the true lumen (Figures 2 and 5). A less useful sign is the curvature of the intimal dissection flap. Researchers have found equal incidence of curvature of the flap towards or away from the false lumen. However, in chronic dissections the dissection flap is more likely to be flat. This is likely due to interval healing and development of fibrosis and thickening leading to reduced flap mobility<sup>[19,24]</sup>.

A thrombosed dissection and an aneurysm with mural thrombus may have a similar appearance. The following features will aid the differentiation: (1) Mural thrombus would not have a spiralling pattern like a dissection; (2) Mural thrombus tends to have an irregular surface rather than the smooth surface of the dissection flap; and (3) in an aneurysm with mural thrombus, the calcium will be along the outer wall while in the thrombosed false lumen it would be along the flap. A thrombosed dissection can be indistinguishable from intramural hematoma; however the differentiation is of only academic interest since management stays the same in both conditions.

## AORTIC IMH

Aortic IMH is considered a variant of dissection and is characterised by bleeding of the vasa vasorum in the aortic media without intimal tear (Figure 8). It accounted for 5.7% of AAS in the International Registry of Acute Aortic Dissection (IRAD)<sup>[12,25]</sup>. The vasa vasorum may spontaneously rupture or haemorrhage may occur due to an intimal defect/PAU<sup>[1]</sup>. IMH may progress to aneurysmal dilatation and rupture (20%-45%), provoke a secondary intimal tear that can progress to dissection (28%-47%), or may regress (10%)<sup>[26]</sup>. The most common site of IMH is in the descending aorta (approximately 2/3rds) and risk factors are similar to those for dissection with hypertension being the most prevalent one<sup>[2,25]</sup>. The clinical presentation of IMH is also similar to aortic dissection;

**Figure 8** A 61-year-old lady with severe chest pain, breathlessness and a prior history of atrial flutter. Computed tomography aortogram in the emergency department shows hyperdense, eccentric wall thickening of the aortic wall consistent with an intramural haematoma (A, white arrow). A concurrent contrast enhanced axial image at the same level shows no leakage of contrast into this thickened aortic wall (B). The intramural haematoma shows partial resolution at 1 mo (C) and complete resolution at 6 mo (D).

**Figure 9** Computed tomography aortogram in a 75-year-old man shows an intramural hematoma (note the eccentric wall thickening in the descending aorta) with intimal surface defect (A: arrow). At one year follow up it has progressed into a frank penetrating ulcer (B: arrow).

chest pain is the usual symptom in ascending aortic IMH while back pain accompanies descending aortic IMH<sup>[27]</sup>. IMH is classified along the lines of dissection into Stanford type A and B categories<sup>[1]</sup>. Stanford type A IMH is typically treated surgically, with 30 d mortality of 14% *vs* 36% for those treated medically<sup>[28]</sup>. In contrast, type B IMH is initially treated medically with antihypertensive medications with a 30-d mortality of 8%<sup>[27]</sup>. However, close CT follow-up is recommended in these patients as aneurysmal dilatation or progression to frank dissection of the aorta will require emergency open surgical or endovascular repair<sup>[1,27]</sup>.

On MDCT, IMH is seen as a hyperdense, crescent shaped region within the aortic wall on non-enhanced CT<sup>[1,4,29]</sup>. No enhancement is seen and by definition no intimomedial flap or tear should be visualized<sup>[30]</sup>. Unlike a dissection that spirals down, IMH tends to have constant circumferential relationship with the aortic lumen. With the higher resolution of modern imaging technologies, small projections or ulcerations can sometimes be seen communicating between the aortic lumen and the IMH<sup>[4,31]</sup>. Studies based on non-cardiac gated CT showed a sensitivity of greater than 96% for the detection of IMH using both unenhanced and contrast enhanced CT<sup>[1,32]</sup>.

**Figure 10** A 62-year-old with acute chest pain. A computed tomography aortogram (A-coronal) shows a penetrating atherosclerotic ulcer at the proximal descending aorta with contrast seen within the aortic media (black arrows) and non-opacifying hyperdensity throughout the rest of the descending thoracic aortic wall compatible with intramural haematoma (white arrow). The axial image (B) shows the contrast extending within the aortic wall and splitting the same. The sagittal oblique reconstruction (C) gives a better demonstration of the penetrating atherosclerotic ulcer at the distal aortic arch (black arrow) with intramural hematoma and progressing into an aortic dissection (white arrow).

## PAU

This entity is a manifestation of advanced, severe atherosclerotic disease that leads to disruption of the aortic intima with extension of blood into the aortic media (Figure 9)<sup>[1,2,4]</sup>. This is in contrast to the underlying pathological process in AD, which usually results from disease of the media without any underlying atherosclerotic intimal plaque<sup>[33,34]</sup>. Disruption of the media by the deep ulceration may lead to vasa vasorum haemorrhage and IMH producing acute chest or back pain with risk of progression to aortic dissection<sup>[25,35]</sup>. PAU can also penetrate beyond the aortic media leading to focal outpouching of the adventitia, producing a pseudoaneurysm with risk of frank rupture<sup>[4,29]</sup>. Saccular aortic aneurysms may represent the end point of such PAU<sup>[36]</sup>.

PAU most commonly occurs in the descending thoracic aorta (90%) and is associated with type B IMH in the majority of cases. It is seen as a focal contrast-filled outpouching into the aortic wall on MDCT (Figure 10)<sup>[37,38]</sup>. Other MDCT features include overhanging edges with a focal bulge of the external aortic contour. It can be differentiated from a benign atherosclerotic ulcer as the latter would not have contrast extending into the aortic media and would not be associated with an IMH<sup>[39]</sup>. Given the relationship with IMH the use of unenhanced images can improve visualisation of crescentic high attenuation haemorrhage in the aortic wall along with displacement of intimal calcifications<sup>[1,22]</sup>.

The natural history and management of patients with PAU remains controversial. PAU tends to have a worse prognosis than dissection with increased incidence of rupture even if the ulcer is limited to the descending thoracic or abdominal aorta<sup>[25]</sup>. Most patients are symptomatic although in approximately a quarter of cases PAU may present incidentally<sup>[1,40]</sup>. The condition typically occurs in elderly patients with multiple co-morbidities and risk factors for atherosclerosis<sup>[41]</sup>. These factors, especially underlying coronary and peripheral arterial atherosclerosis, may preclude open surgical repair in this group of

patients<sup>[42]</sup>. Open surgical repair, typically with a synthetic graft is performed in patients with ascending aortic PAU (these are rare) and in patients with haemodynamic instability and high risk of rupture, *e.g.*, rapid enlargement of the lesion<sup>[1,18]</sup>. Endovascular graft placement in patients with symptomatic PAU is an alternative with potentially lower morbidity and mortality<sup>[43-45]</sup>. Sometimes, conservative management with antihypertensive therapy may be adequate or may be the best option in PAU especially in asymptomatic patients with involvement of the descending aorta and in those who are poor candidates for any form of invasive treatment. The medically treated patients need at least an annual follow-up to assess for disease progression, which has a strong likelihood in initially symptomatic patients<sup>[19,44,46,47]</sup>.

## UNSTABLE THORACIC AORTIC ANEURYSM

Thoracic aortic aneurysms are relatively uncommon and defined as the permanent dilatation of the aorta to more than 150% of its usual diameter or greater than 5 cm. True aneurysms tend to be fusiform and involve all three layers of the aortic wall<sup>[48]</sup>. False or pseudoaneurysms are typically saccular and often limited by the adventitia alone (Figure 11). The most common cause for both types is atherosclerosis (approximately 70%), although false saccular aneurysms often arise following surgery, trauma or due to an infective/inflammatory aetiology<sup>[1,19,49]</sup>.

Thoracic aortic aneurysms are often clinically asymptomatic but they are considered unstable when showing rapid increase in size or evidence of contained or impending rupture on MDCT. Unstable thoracic aortic aneurysms may be considered an AAS, especially when symptomatic as they are clinically indistinguishable from dissection, IMH or PAU<sup>[4]</sup>. The risk of rupture is related to the diameter of the aneurysm sac, with a significantly higher risk for those in the ascending aorta measuring greater than 6 cm, and 7.2 cm in the descending aorta<sup>[50]</sup>.

**Figure 11** A 68-year-old with chest pain and long standing hypertension. A saccular aneurysm is seen arising from the lateral aortic arch just distal to the origin of the left subclavian artery on this computed tomography aortogram. Atherosclerotic calcifications are seen at the periphery of the aneurysm (A) and there is heterogeneous contrast opacification secondary to turbulent flow on the arterial phase (B). No evidence of rupture is apparent. The aneurysm was excluded using an aortic stent graft as seen in the sagittal plane (C). The excluded sac has completely thrombosed with no endoleak as seen on an axial image (D).

On serial CT scans an annual increase in diameter of the thoracic aortic aneurysm of at least 1 cm is also considered a sign of increased likelihood of rupture<sup>[19,51]</sup>. Other morphological MDCT signs of impending rupture should also be taken into account for therapeutic decision making. These include associated IMH with a high attenuating crescent in the aortic wall, discontinuity of circumferential intimal atherosclerotic calcifications within a fusiform aneurysm, a “draped” aortic appearance conforming to the anterolateral contour of an adjacent vertebral body, eccentric or nipple like contour to the aorta, and poor visualisation of the posterior aortic wall<sup>[1,19,52,53]</sup>. Frank rupture of a thoracic aortic aneurysm on MDCT is suggested by peri aneurysmal fat stranding, mediastinal haematoma, haemothorax most commonly on the left, hemopericardium or pericardial effusion and evidence of haemodynamic compromise, *e.g.*, collapsed IVC<sup>[1,19]</sup>.

Therapy should be considered for all symptomatic aneurysms regardless of size due to the high risk of rupture. Otherwise surgical or endovascular therapy should be considered for ascending thoracic aortic aneurysms measuring greater than 5.5 cm, and those in the descending thoracic aorta measuring greater than 6 cm. Similar to dissection open surgical or hybrid surgical and endovascular techniques are the mainstay of ascending thoracic aortic aneurysm therapy<sup>[13]</sup>. Smaller aneurysms, typically less than 5.5 cm in diameter can be followed up with serial CT or MRI on an annual basis. However those with underlying genetic connective tissue predispositions to

aneurysm formation such as Marfan’s syndrome should be considered for therapy at smaller diameters. Overall decision on when to intervene should be tailored to the individual clinical scenario and involve an experienced multidisciplinary team<sup>[1,19,54,55]</sup>.

## OTHER IMAGING MODALITIES AND TECHNIQUES

This article has focused on the use of MDCT in the diagnosis and management of AASs while other imaging modalities including conventional angiography, transoesophageal or transthoracic echocardiography and MRI have a complimentary/alternative role in dealing with this clinical problem. MDCT also has some disadvantages including radiation exposure and potential risk of contrast induced nephropathy, which can be overcome by using alternative methods. Conventional angiography is historically the gold standard for evaluation of AASs. However it is invasive, unable to assess for IMH, and can lead to false negative exclusion of dissection. Transthoracic echocardiography can be used in the initial evaluation of suspected AASs in the emergency department. The technique can sometimes visualise the proximal extent of an aortic dissection but can provide vital secondary evidence of aortic root/valve dysfunction and pericardial effusions or tamponade. Invasive transoesophageal echocardiography can then be considered for further detailed

evaluation, and is especially valuable in unstable patients as it can be performed at the bedside. In experienced hands the technique has high sensitivity and specificity for ascending aortic dissection. It has the ability to detect the entry and re-entry site of dissection and can evaluate for the direction of flow within the false lumen. Additional evaluation of the aortic valvular and left ventricular function is useful to exclude proximal extension of the dissection into the aortic root and left coronary artery respectively. Transoesophageal echocardiography is of limited use at the proximal aortic arch since artefacts from air in the adjacent right main bronchus interferes with echocardiographic imaging. Other limitations of the technique include inability to visualise surrounding structures in the mediastinum, and inadequate assessment of anatomical detail required for planning endovascular or hybrid therapy<sup>[1-3]</sup>.

MRI is a useful modality in the assessment of AASs but has limited scope in the emergency setting due to the longer acquisition times and potentially limited availability<sup>[1,2]</sup>. In stable patients it has a role in confirming IMH, when CT is indeterminate. It can provide high resolution multiphasic images of the aorta without the use of ionising radiation<sup>[56]</sup>. Real time examination of the aortic root and valve function can also be performed with MRI. This modality is likely to play an increasing role in the follow-up of patients with AASs allowing for a comprehensive assessment. MRI is also the modality of choice for patients with contraindications to CT and iodinated contrast<sup>[57]</sup>.

## CONCLUSION

MDCT is the modality of choice for the evaluation of suspected AAS in the emergency setting. High sensitivity, rapid acquisitions and easy access to the technique are its major advantages over transoesophageal echocardiography and MRI. There is a wide base of expertise available in interpreting MDCT with limited interpersonal variability in the inference. Most radiologists and vascular surgeons are comfortable and confident of using this modality in diagnosing and treating AAS. Detailed assessment of the morphology of the aorta using MDCT allows for the classification of the interlinked AASs and helps in determining the treatment. It permits assessment of life-threatening complications associated with acute aortic conditions. It is also useful in identifying some of the other conditions such as acute pulmonary embolism and pneumothorax that can mimic AAS.

### Abstract

Recent retrospective studies have reported the use of stereotactic radiosurgery (SRS) in the treatment of gynecologic cancers. SRS uses real-time imaging and high dose radiation beams attached to precise robotic arms to target malignant lesions while sparing normal tissue. The purpose of this review is to examine the indications for SRS in gynecologic oncology, review the current literature regarding the use of SRS in gynecologic cancers, and identify future directions for research in this area. Literature on stereotactic radiosurgery was reviewed using the PubMed search engine. Articles written in English from 1993-2013 were reviewed, and 20 case series and clinical trials were included. The safety and efficacy SRS has been demonstrated in all gynecologic disease sites including cervical, endometrial, vulvar, vaginal, and ovarian cancers. Indications for its use include non-central pelvic recurrences in previously irradiated patients, complex or non-resectable disease recurrence, and solitary brain metastases. Toxicities

are usually mild, though grade 3-4 toxicities have been reported. SRS is a promising second line treatment modality for patients with primary or recurrent disease who cannot undergo standard surgical or radiation therapy. Further research is required to determine optimal dosing and fractionation schedules, delineate appropriate patient populations, and assess longterm morbidity and survival.

**Key words:** Stereotactic radiosurgery; Stereotactic body radiotherapy; Gynecologic oncology

**Core tip:** Stereotactic radiosurgery is a novel treatment modality in gynecologic oncology. Its use has been reported for inoperable primary tumors, recurrent tumors in or near irradiated fields, and isolated pelvic nodal metastases. Associated toxicities are usually mild. Though further research is needed to establish the role of SRS in gynecologic oncology, it represents an important second line therapy in appropriately selected patients.

### INTRODUCTION

Stereotactic radiosurgery (SRS) is an emerging technology in the treatment of gynecologic cancers. It targets malignant lesions using real-time imaging in combination with high dose radiation beams attached to precise robotic arms. First used in the treatment of intracranial lesions, technological advancements in radiation and

image-guidance have allowed for its use in a variety of extracranial locations. Because SRS can focus on targets with sub-millimeter accuracy, it has been used for inoperable primary tumors near radiosensitive tissues, recurrent tumors in or near irradiated fields, and isolated pelvic nodal metastases. Its precise beams spare normal tissues and result in decreased toxicity when compared to conventional radiotherapy.

SRS is of particular interest in women with gynecologic malignancies, since many of these patients will recur in or near previously irradiated tissues, inoperable anatomic regions, or sites inaccessible to traditional radiation therapy<sup>[1]</sup>. Recent retrospective studies have reported on the safety and efficacy of SRS in the treatment of gynecologic cancers. The purpose of this review is to examine the indications for SRS in gynecologic oncology, review the current literature regarding the use of SRS in gynecologic cancers, and identify future directions for research in this area.

## STEREOTACTIC RADIOSURGERY

Stereotactic radiosurgery combines the complex dose distributions of intensity modulated radiation therapy (IMRT), the accuracy, reproducibility, and high doses of radiosurgery, and the fractionation of external beam radiation therapy to build a technique capable of treating complex abdominal-pelvic tumors. In this method, linear accelerators generate multiple X-ray beams, which can precisely target malignant tissues using advanced treatment planning, real-time imaging, and/or fiducial marker localization. The precision of these X-ray beams allows delivery of high doses to the tumor while sparing normal tissues. Doses are usually divided into 1-5 fractions given over 1-2 wk. Body immobilizers may be used to maintain spatial relationships during treatment sessions. Real-time image guidance ensures accurate tumor location, as abdominal and pelvic structures can exhibit substantial inter- and intra-fraction movement.

SRS has been utilized for lung, liver, pancreatic, renal, prostate, spinal, and pelvic tumors. It was first described for use in liver and lung lesions in the 1980s and has been used for gynecologic cancers since 2006. Twelve, small retrospective case series and one phase II clinical trial have described single institution experiences with SRS in the treatment of uterine, cervical, vaginal, vulvar, and ovarian cancers (Table 1). These series include a combined 291 patients who have undergone SRS for distant, local, lateral pelvic, or isolated pelvic node recurrences or as a substitute for brachytherapy in primary disease. One study specifically reported hematologic toxicities associated with SRS. Populations in these studies were heterogeneous, and varying doses and fractionation schedules have been described. Differences in reporting these results make it difficult to calculate a composite rate of survival, loco-regional control, or disease response.

The largest population was described by Kunos *et al.*<sup>[1]</sup>, in a phase II clinical trial evaluating the safety and

efficacy of SRS in 50 patients with recurrent cervical, endometrial, ovarian, and vulvar cancer. SRS was used to deliver 24 Gy in 3 fractions to a clinical target volume (CTV) that included the gross tumor volume (GTV) as well as surrounding fluorodeoxyglucose (FDG)-avid areas. The positron emission tomography (PET) images were overlaid and co-registered with computed tomography (CT) scans in order to accurately target the entire tumor site. One patient had a complete response, and the overall response rate (defined as complete response, partial response, or stable disease without progression) was 96%. Sixty-two percent of patients showed clinical benefit at 6 mo. Most toxicity was mild, though one patient did experience grade 4 hyperbilirubinemia and another developed an enterovaginal fistula. The study authors concluded that SRS was safe and efficacious for patients with recurrent gynecologic malignancies<sup>[1]</sup>. All other data are derived from case series, and no controlled trials have been published. While studies mostly describe patients with endometrial or cervical primaries, SRS has been utilized for all gynecologic disease sites.

## CERVICAL CANCER

Since radiation therapy is commonly used in cervical cancer, SRS is an attractive option for inoperable patients with primary or recurrent disease. Overall, 76 cases describing the use of SRS in cervical cancer have been published in 9 series. Four papers describe its use in the primary setting (usually as a substitute for brachytherapy), while others report its use for loco-regional, para-aortic node, or pelvic side-wall recurrences. All series included only patients who were unsuitable or unwilling to undergo other treatment modalities such as brachytherapy or surgical resection.

The largest series of patients treated with SRS for primary disease was published by Hsieh *et al.*<sup>[2]</sup> in 2013. They described 9 patients with locally advanced cervical cancer who were treated with SRS (*via* helical tomotherapy) as a replacement for brachytherapy boost after the standard dose of EBRT and concurrent cisplatin. These patients were unable to undergo the recommended brachytherapy due to anatomic factors or medical comorbidities. Though three-year actuarial loco-regional control was 77.8%, three-year disease free survival was only 28.6%. Distant metastases were the most common pattern of failure, suggesting efficacy of SRS in controlling central pelvic disease<sup>[2]</sup>. Mollà *et al.*<sup>[3]</sup> reported similar results when treating primary disease. Their population included seven cervical cancer patients who underwent EBRT with SRS boost due to high-risk disease after initial surgical management. Only one patient recurred within the 12-month follow up period; however, actuarial values were not calculated. Toxicities were low in both series, consisting mostly of grade 1 or 2 sexual and GI symptoms. However, one patient did have grade 3 diarrhea, and another had grade 3 thrombocytopenia. One patient with stage 4A disease developed a rectovaginal fistula. Four patients

EBRT: External beam radiation therapy; SRS: Stereotactic radiosurgery; NED: No evidence of disease; BT: Brachytherapy; OS: Overall survival; HT: Helical tomotherapy; IMRT: Intensity modulated radiation therapy; PFS: Progression free survival.

had rectal bleeding following treatment<sup>[3]</sup>. Two other papers by Hsieh *et al*<sup>[4,5]</sup> report similar findings in this patient population, and Haas *et al*<sup>[6]</sup> described 100% disease free survival at 14 mo in a series of six patients treated with SRS boost for primary disease.

These rates of local control exceed that of brachytherapy in many studies; however, the small sample sizes,

short duration of follow-up, and lack of a brachytherapy control group make it impossible to compare the two treatments. Still, the authors of these papers suggest that SRS could be considered as an alternative to brachytherapy boost, especially in patients unsuited for brachytherapy.

SRS has been more frequently described for recur-

**Figure 1 CyberKnife (left) and GammaKnife (right).** The CyberKnife device employs a mobile frame to radiate tumors in complex locations. The GammaKnife provides head immobilization for more accurate radiation delivery.

rent disease. Guckenberger *et al*<sup>[7]</sup> describe its use in 12 patients with local recurrences of cervical cancer. Six patients in this study (which included patients with endometrial and cervical cancer) had undergone previous radiation, though most had received only vaginal brachytherapy. The majority of patients had been surgically treated for their primary disease. Those who had not had previous EBRT underwent standard external radiation at a dose of 45 Gy followed by a SRS boost using 14-20 Gy in 3 fractions. Patients previously treated with external beam radiation underwent only SRS. Loco-regional control was again excellent, with 81% loco-regional control at 3 years. Overall 3-year survival was 34%, and systemic disease progression remained the most common pattern of failure<sup>[7]</sup>. This survival rate is similar to that of patients who undergo brachytherapy boost after EBRT for recurrent disease.

Interestingly, while pelvic sidewall recurrences carry a poor prognosis in patients treated with brachytherapy boost, location was not found to be a prognostic factor for patients treated with SRS<sup>[8]</sup>. Dewas *et al*<sup>[9]</sup> included four cervical cancer patients in their series describing SRS for lateral pelvic recurrences of cervical, uterine, anal, rectal, and bladder cancers. In this study, previously irradiated patients were treated with CyberKnife SRS (36 Gy in 6 fractions) for lateral pelvic masses (Figure 1). While disease free survival remained relatively low (8.3 mo), the authors argued that this treatment delayed local progression, as these recurrences would usually progress much more rapidly, improving quality of life. No grade 3 or higher toxicities were noted, and self-reported pain scores were improved after treatment. However, results should be interpreted with caution, as none of these patients exhibited unequivocal response. Favorable response was reported based on decreased uptake of contrast material on follow up PET studies<sup>[9]</sup>. Further research is needed to determine whether SRS is superior to alternate radiation modalities in patients with lateral pelvic recurrences.

Another clinical challenge in recurrent cervical cancer occurs in patients with isolated, unresectable, para-aortic nodal recurrence. Though this type of recurrence is rare, it is associated with a poor prognosis and high post-treatment morbidity due to the radiosensitivity of surrounding organs, particularly the small bowel. Because of the precision of its radiation beams, SRS could be an excellent treatment modality for this type of recurrence. Choi *et al*<sup>[10]</sup> described their experience in 28 patients with cervical cancer recurrence confined to para-aortic nodes. These patients received EBRT followed by SRS boost with 33-45 Gy in 3 daily fractions. Twenty-five patients received cisplatin before, during, or immediately after their radiation courses. Four year overall survival was 50.1%, and 96.5% of patients had at least partial response. Median time to disease progression was 32 mo. Though this population is small, SRS appears to be associated with improved overall survival, fewer toxicities, and shorter treatment times when compared for EBRT for nodal para-aortic recurrence<sup>[11,12]</sup>.

In combination, these reports indicate that SRS may be a promising therapeutic modality for primary and recurrent cervical cancer, especially in patients who have undergone previous radiation and/or are not candidates for surgical resection. Further studies are needed to clarify patient populations most likely to benefit from SRS. The role of concurrent chemotherapy with SRS is also an important area of research, as distant metastases are the most common sites of failure.

## ENDOMETRIAL CANCER

SRS has been similarly studied in endometrial cancer. Seventy cases of SRS use for primary or recurrent endometrial cancer have been described in nine unique series. However, dosing regimens are not uniform, and study populations are heterogeneous. SRS has been used as a substitute for both EBRT and brachytherapy boost after

surgical therapy for high-risk disease, as well as in the treatment of recurrent endometrial cancer. It has also been used as a substitute for IMRT, due to its improved accuracy and ability to target higher doses of radiation to precise areas of tissue.

The largest series of SRS in the primary setting was published by Hsieh *et al*<sup>[2]</sup>. They reported 31 cases of FIGO stage I B to III C uterine cancer, in which either SRS or IMRT was used as a substitute for EBRT after surgical staging for primary disease. IMRT or SRS was followed by vaginal brachytherapy in all patients. Two patients received concurrent cisplatin. This study is unique in that it is the only study that has compared SRS to another treatment modality. However, the study was not powered to detect statistical differences between the groups. While the study found no differences in overall survival or toxicity in SRS when compared to IMRT, SRS did provide significantly better critical organ sparing for the rectum, bladder, femoral heads, and intestines when compared to IMRT using dose-volume histograms. One cervical stump failure occurred in each group, and no grade 3 or 4 toxicities were noted<sup>[2]</sup>.

SRS has also been studied as a substitute for brachytherapy in patients with primary endometrial cancer. Mollà *et al*<sup>[3]</sup> included nine patients with FIGO stage I - III uterine cancer in their series describing SRS boost after primary or post-operative EBRT. As described above, patients received 45 Gy EBRT or IMRT followed by 14-20 Gy SRS, usually following surgical treatment for either endometrial or cervical cancer. While most subjects had primary disease, two patients were enrolled due to local relapse. Patients underwent therapy at varying doses and fractionations. At 12-month median follow up, no recurrences were reported for the endometrial cancer group. Mostly grade 1 or 2 toxicities were noted, though one of the patients with recurrent endometrial cancer experienced persistent (grade 3) rectal bleeding 18 mo after re-irradiation at the vaginal vault<sup>[3]</sup>.

SRS is more commonly used in the setting of recurrent endometrial cancer, especially in previously irradiated patients. Both Guckenberger *et al*<sup>[7]</sup> and Deodato *et al*<sup>[13]</sup> have published separate series describing the use of SRS for distant or local recurrences of endometrial and cervical cancers. Favorable rates of local control were demonstrated, though statistics for cervical vs. uterine cancers were not separately reported. Both series were small, including only seven and three endometrial cancer patients, respectively<sup>[7,13]</sup>. Two patients with isolated para-aortic nodal recurrences of endometrial cancer were also included in the above-mentioned study by Choi *et al*<sup>[10]</sup> with results as described above. While it is likely that results from cervical cancer patients could be extrapolated to those with endometrial cancers, it is difficult to draw conclusions with these small patient populations. Study authors have suggested that SRS could benefit patients with pelvic or para-aortic node recurrences who are not candidates for exenteration or salvage radiotherapy; however, further studies are needed to confirm these results

and delineate optimal SRS dosing and fractionation.

## OVARIAN CANCER

While the use of radiation therapy is much more common in endometrial and cervical cancers, SRS has also been used in the treatment of recurrent or non-operative ovarian cancers. Higginson *et al*<sup>[14]</sup> describe the use of SRS for patients with isolated lung metastasis, para-aortic nodes, or vaginal cuff recurrences after primary surgery and adjuvant therapy.

Kunos *et al*<sup>[15]</sup> included three cases of ovarian cancer in a 2009 report of their single-institution experience with SRS. These cases involved patients with multiple local and distant recurrences treated with multiple courses of chemotherapy, prior radiation, and/or surgeries. One patient with FIGO stage III C papillary serous cancer received primary surgery followed by two differing chemotherapy courses, as well as a repeat operation with intra-operative radiation before opting for SRS in the place of pelvic exenteration for a third relapse of her cancer. Stable disease remained after radiotherapy and the patient was without evidence of progression for 9 mo, treated with concurrent bevacizumab and cyclophosphamide. Another patient was free of disease at 10 mo after SRS was used to treat a persistent vaginal lesion following primary debulking, several chemotherapy courses, and external pelvic radiation. A third patient who underwent SRS after multiple surgeries, one dose of intra-operative radiation, and 3 mo of single-agent chemotherapy had stable disease at six month follow up with no more than grade 2 acute toxicities<sup>[15]</sup>.

Deodato *et al*<sup>[13]</sup> described four other cases of SRS use in ovarian cancer. Three patients were without evidence of disease at 37, 31, and 19 mo after undergoing SRS to presacral lymph nodes, hepatic lesions, and supraclavicular nodes, respectively. One patient was alive with disease at 18 mo after SRS dosing to anterior mediastinal and left internal mammary nodes<sup>[13]</sup>. Further studies are needed to define the appropriate patient population for SRS use in ovarian cancer. Currently, SRS is only used as a palliative measure for patients with localized, recurrent disease.

## TOXICITIES

Most toxicities associated with SRS are mild and self-limiting. They include grade 1-2 fatigue, diarrhea, dysuria, nausea, and sexual side effects. However, rare grade 3 toxicities have been reported in almost every series. Rectal bleeding was reported in 4 patients in two different series of patients receiving EBRT followed by SRS boost. One of these events occurred in a patient with a history of prior radiation; however, the other patients with rectal bleeding had not undergone previous radiation therapy. Four patients in three series reported enterovaginal fistulas; all of these occurred in the recurrent setting<sup>[1,2,7]</sup>.

The largest study of toxicities associated with SRS was published by Kunos *et al*<sup>[16]</sup> in 2012. This retrospec-

tive series analyzed hematologic toxicity in 61 women treated with SRS for stage 4 gynecologic malignancies. Ninety-three percent of these patients had received chemotherapy prior to SRS. Twenty-five percent had grade 2 fatigue, but the incidence of grade 3 fatigue was only 3%. All symptoms resolved by 30 d post-radiation. No neutropenia was reported; however, 5% of women had grade 1 anemia (Hb < 10.0 g/dL), and there were single incidences of grade 1, 2, and 3 thrombocytopenia. Further studies are required to better estimate the rates of non-hematologic toxicities, though it is difficult to isolate SRS as the cause of morbidity, since many patients receive surgery, chemotherapy, and other methods of radiation prior to receiving SRS<sup>[16]</sup>.

## SRS IN GYNECOLOGIC CANCER

For now, the indications for SRS in gynecologic oncology remain undefined. Our review found three clinical scenarios for which SRS could provide benefit. These include non-central pelvic recurrences in previously irradiated patients, complex or unresectable disease recurrence, and solitary brain metastases (Table 2). This is an especially promising area of research, as few treatment options are available for these patients.

## RECURRENT CERVICAL CANCER

Patients with locally advanced primary cervical cancer are usually treated with curative chemoradiation. Others may undergo primary surgery but require adjuvant chemoradiation due to high-risk pathologic features, positive margins, positive parametria or positive pelvic lymph nodes. In this population, utilization of traditional radiotherapy in a previously radiated field is associated with prohibitive toxicity, and thus, SRS may represent a suitable alternative. While central pelvic recurrences can be treated with surgical exenteration, many patients have non-central recurrences or comorbid conditions that make them unsuitable for aggressive surgical resection with significant quality of life implications. Currently, the majority of these patients are treated with systemic chemotherapy using cisplatin, paclitaxel, and bevacizumab (following presentation of GOG 240)<sup>[17]</sup> or are enrolled in clinical trials. Cyberknife SRS represents another therapeutic alternative and has decreased morbidity compared to exenteration. Series by Guckenberger, Dewas, and Deodata report mostly grade 1-2 toxicity, even in previously irradiated patients<sup>[7,9,13]</sup>. In one series, two out of the three patients with grade 3-4 toxicities had received prior radiation; however, most previously irradiated patients did not suffer significant morbidity<sup>[7]</sup>.

## COMPLEX OLIGOMETASTASES

Although the location of gynecologic cancer recurrence is unpredictable, patients with cervical and endometrial cancer commonly recur in the pelvis. A proportion, how-

**Table 2 Indications for SRS in recurrent and metastatic gynecologic malignancy**

Recurrent cervical cancer	Recurrence in a previously radiated fields
	Recurrence in patients who are not candidates for pelvic exenteration
Complex oligometastases	Unresectable oligometastases
	Oligometastases in abdominal retroperitoneum
Central nervous system and brain metastases	Intracranial lesions not accessible to Gamma Knife

ever, will have distant disease recurrence in complex locations involving the abdominal retro-peritoneum. Clinical options in this setting are limited, as access for adequate surgical resection is difficult to achieve. Treatment using chemotherapeutics or biologic agents is encouraged, and a combined approach utilizing systemic chemotherapy in conjunction with SRS is promising. Research regarding the above is limited, and given the unmet clinical need, warrants further investigation. There are well-defined selection criteria for utilization of SRS in the treatment of oligometastases for other primary disease sites such as lung, prostate and liver, and this data can may be extrapolated to gynecologic cancer patients.

## CENTRAL NERVOUS SYSTEM AND BRAIN METASTASES

Central nervous system (CNS) and brain metastases are rare in gynecologic malignancies. Between 0.4%-1.2% of cervical cancers involve intracranial metastases, and percentages are similar for other pelvic disease sites. These lesions are usually treated with whole brain radiation or Gamma Knife stereotactic radiosurgery (Figure 1). A series by Menedez *et al.*<sup>[18]</sup> included 14 patients with brain metastases from primary endometrial, ovarian, or cervical cancer. Patients received 16-20 Gy and experienced median survival of 5-13 mo. While the CyberKnife system is not well studied in gynecologic malignancies, its use is described for brain metastases in primary lung, breast, colon, and other cancers. CyberKnife eliminates the need for target fixation and allows for expanded treatment freedom for large or complex lesions.

The preference for Gamma Knife in the treatment of brain and spinal cord metastasis stems from the theoretical improvement in accuracy, 0.5 mm or less, over CyberKnife (1 mm or less), although these measurements have been disputed (Figure 1). Additionally, the smaller size of the Gamma Knife collimators reduce the potential injury to neighboring normal brain tissue, improving long term morbidity. The Gamma Knife also improves precision using a rigid immobilization device to prevent head movement during treatment. Conversely, utilization of CyberKnife SRS, allows for improved therapeutic versatility given the dynamic nature of the robotic arms, compensating for target organ motion, and allowing access to portions of the CNS that are difficult to treat using

Gamma Knife therapy.

## FUTURE RESEARCH

While SRS is a promising treatment modality for inoperable or recurrent gynecologic cancers, many aspects of treatment remain uncertain. The available series describing SRS use heterogeneous dosing and fractionation schedules, and the optimal regimen has not been delineated. Controlled trials comparing SRS to brachytherapy or IMRT are also needed. Studies of SRS use for adjuvant therapy in high risk disease could further define the role of SRS in gynecologic malignancies. Today, SRS remains a second line treatment, reserved for patients with primary disease who are unsuitable for standard surgical or radiation therapy or for recurrent disease in a previously irradiated field.

Because most patients in the above-mentioned series suffered disease recurrence or progression outside the treatment area, many researchers have proposed concurrent chemotherapy with SRS to prevent progression of occult disease. Twenty five patients reported in the literature have received concurrent cisplatin during SRS, and four patients have received other chemotherapy regimens within 4 mo of SRS<sup>[1,2,3,7,10]</sup>. However, this patient population is too small for any comparisons to be made regarding the benefits of concurrent chemotherapy. A phase I clinical trial of palliative SRS with gemcitabine and carboplatin is currently enrolling patients with recurrent or persistent cervical, endometrial, ovarian, vulvar, and vaginal cancers (NCT01652794).

## CONCLUSION

SRS is an emerging area of radiation oncology, which has been successfully used in high risk gynecologic malignancies. Because of its unique ability to precisely target malignant lesions while sparing surrounding normal tissues, SRS can safely radiate tumors that may be difficult or impossible to treat with surgery or conventional radiotherapy. SRS has been described for all gynecologic malignancies and appears to have an excellent safety profile. Further research is necessary to determine optimal dosing and fractionation schedules, delineate appropriate patient populations, and evaluate long term survival and morbidity.

### Abstract

**AIM:** To evaluate the impact of computed  $b = 1400 \text{ s/mm}^2$  (C-b1400) *vs* measured  $b = 1400 \text{ s/mm}^2$  (M-b1400) diffusion-weighted images (DWI) on lesion detection rate, image quality and quality of lesion demarcation using a modern 3T-MR system based on a small-field-of-view sequence (sFOV).

**METHODS:** Thirty patients (PSA:  $9.5 \pm 8.7 \text{ ng/mL}$ ;  $68 \pm 12$  years) referred for magnetic resonance imaging (MRI) of the prostate were enrolled in this study. All measurements were performed on a 3T MR system.

For DWI, a single-shot EPI diffusion sequence ( $b = 0, 100, 400, 800 \text{ s/mm}^2$ ) was utilized. C-b1400 was calculated voxelwise from the ADC and diffusion images. Additionally, M-b1400 was acquired for evaluation and comparison. Lesion detection rate and maximum lesion diameters were obtained and compared. Image quality and quality of lesion demarcation were rated according to a 5-point Likert-type scale. Ratios of lesion-to-bladder as well as prostate-to-bladder signal intensity (SI) were calculated to estimate the signal-to-noise-ratio (SNR).

**RESULTS:** Twenty-four lesions were detected on M-b1400 images and compared to C-b1400 images. C-b1400 detected three additional cancer suspicious lesions. Overall image quality was rated significantly better and SI ratios were significantly higher on C-b1400 ( $2.3 \pm 0.8 \text{ vs } 3.1 \pm 1.0$ ,  $P < 0.001$ ;  $5.6 \pm 1.8 \text{ vs } 2.8 \pm 0.9$ ,  $P < 0.001$ ). Comparison of lesion size showed no significant differences between C- and M-b1400 ( $P = 0.22$ ).

**CONCLUSION:** Combination of a high b-value extrapolation and sFOV may contribute to increase diagnostic accuracy of DWI without an increase of acquisition time, which may be useful to guide targeted prostate biopsies and to improve quality of multiparametric MRI (mMRI) especially under economical aspects in a private practice setting.

Feasibility study of computed vs measured high b-value (1400 s/mm<sup>2</sup>) diffusion-weighted MR images of the prostate. *World J Radiol* 2014; 6(6): 374-380 Available from: URL: <http://www.wjgnet.com/1949-8470/full/v6/i6/374.htm> DOI: <http://dx.doi.org/10.4329/wjr.v6.i6.374>

## INTRODUCTION

Prostate cancer (PCa) is currently the most commonly diagnosed non-skin cancer and the second leading cause of cancer related death in the United States<sup>[1]</sup>. Recent technical improvements such as the beneficiary SNR gains of higher field strength made MRI a valuable diagnostic measure that allows to detect prostate cancer with a high diagnostic accuracy even at earlier disease stages<sup>[2]</sup>. Multi-parametric MR (mMRI) imaging is the mainstay of prostate cancer imaging<sup>[3-6]</sup>, most commonly consisting of T2-weighted imaging (T2w), diffusion-weighted-imaging (DWI), dynamic contrast-enhanced imaging (DCE) and proton MR spectroscopy imaging (MRSI)<sup>[7-10]</sup>. Among those, DWI is probably the most promising technique, especially for detection of peripheral zone (pz) tumors and estimation of Pca aggressiveness<sup>[11-13]</sup>, but also for monitoring therapy<sup>[14]</sup>. Recent studies indicate that the measurement of high b-values (2000 s/mm<sup>2</sup>) increases the lesion detection rate<sup>[15]</sup>, even though the ability to discriminate malignant from benign tissue in the pz is limited due to a significant overlap of ADC-values<sup>[16]</sup>. In clinical routine, the standard protocol commonly involves b-values from 0 to 800 s/mm<sup>2</sup>. The use of higher b-values is currently limited by the two following factors: reduction of SNR at b-values > 1000 s/mm<sup>2</sup> due to T2 signal decay as a consequence of a prolonged TE<sup>[17]</sup> and cost effectiveness considerations due to a prolonged acquisition time, especially in a private practice setting. Due to these shortcomings, techniques that allow for the calculation of a high b-value DWI based on routinely measured lower b-values<sup>[18]</sup> seem to be appealing. In this context, recent studies indicate that computed DWI (cDWI) is feasible with good SNR and without additional scan time, which may improve disease detection<sup>[18]</sup>.

On the one hand high field strength imaging at 3 Tesla (T) with higher intrinsic SNR is superior to 1.5 T for the detection of prostate cancer<sup>[19]</sup>, on the other hand susceptibility artifacts related to the proximity of the pz to the air-filled rectum are more relevant. Recently, small FOV (sFOV) imaging strategies for DWI based on<sup>[20]</sup> the use of 2d radiofrequency (RF) excitation pulses for the excitation of a small volume spanning of the prostate region

only were developed to overcome these shortcomings of 3T MRI<sup>[21]</sup> and allow for a reduction of artifacts and a smooth fusion with morphologic T2w images. For this study a b1400 sequence was extrapolated from a sFOV and low (< 1000 s/mm<sup>2</sup>) b-value protocol to combine the advantages of reduced distortion artifacts and higher SNR of computed images. The purpose of this study is to compare lesion detection rate, image quality and quality of lesion demarcation of a computed (C-b1400) and a measured b = 1400 s/mm<sup>2</sup> (M-b1400) sequence based on a sFOV image set utilizing a modern 3T MR-system.

## MATERIALS AND METHODS

### Study population

Thirty consecutive patients (median PSA: 9.5 ± 8.7 ng/mL; mean age: 68 ± 12 years) who underwent functional prostate MR at our institution were enrolled in this study.

Among the indications for the study, 21 patients were referred due to elevated PSA levels, 4 for PCa staging, 4 for surveillance of post-treatment recurrence and one for suspected prostatitis.

### MR Imaging

All measurements were performed on a 3 T clinical whole-body MR scanner (Verio, Siemens Healthcare, Erlangen, Germany) and state-of-the-art mMRI parameters were applied<sup>[19]</sup>. One hundred mL endorectal gel was administered prior to the examination, in order to reduce artifacts due to heterogeneous rectal content. For DWI, a single-shot EPI diffusion sequence with the following parameters was utilized: TE/TR= 63/4200 ms, 8 averages, FOV 300 mm × 93 mm, matrix 192 × 60, slice thickness 3.6 mm, no gap, SPAIR fat saturation, b-values = 0, 100, 400, 800 s/mm<sup>2</sup>. An outer volume suppression by two sharp defined coronal saturation bands was applied which allowed to reduce the acquisition to a small rectangular FOV with an inplane resolution of 1.5 mm × 1.5 mm to gain SNR and to reduce distortion artifacts. The conventional full excitation was used in the sequence, followed by a short EPI readout covering only the sFOV in anterior-posterior direction. Total scan time for this sequence was 5 min 49 s. The ADC was calculated from diffusion images with all the measured b-values. C-b1400 was calculated voxelwise from the ADC and diffusion images according to:

$S(b_{1400}) = S_0 \cdot \exp(-ADC \cdot b_{1400})$  with the pixel intensity  $S_0$  in  $b = 0$  s/mm<sup>2</sup>.

A b-value of 1400 s/mm<sup>2</sup> was chosen to keep sequence parameters similar. Additionally, the M-b1400 sequence (b = 1400 s/mm<sup>2</sup>, TE/TR = 73/4400 ms, all other parameters identical, duration: 1min45s) was acquired immediately after the original DWI sequence for evaluation and comparison (Figure 1).

### Image analysis

Data sets of every patient were analyzed by two radiologists (DH, 3 years of experience in prostate imaging) and (LKB, 6 years of experience in prostate imaging) in con-

**Figure 1** Axial T2-weighted image of an 88 years old patient with a PSA level of 8.2 ng/mL and negative findings upon digital rectal examination. T2w shows a focal hypointense lesion in the posterolateral left midgland pz (arrowhead in A). Measured b-values of 0, 100, 400 and 800 s/mm<sup>2</sup> (arrowheads in B, C, D and E, respectively) do not depict the suspected lesion with sufficient contrast to background prostate. M-b1400 shows good lesion-to-prostate contrast (arrowhead in F). C-b1400 depicts the lesion with the same lesion-to-prostate contrast and a slightly improved demarcation (arrowhead in G). The ADC value of the suspicious lesion was as low as  $648 \times 10^{-3} \text{ mm}^2/\text{s}$  [ADC map (H)].

**Figure 2** M-b1400 (left) and C-b1400 (right) images of a 63 years old patient with elevated PSA levels, at corresponding axial slice position. Region-of-interests were placed in the prostate and in the bladder content to obtain signal intensity-ratios to estimate signal-to-noise-ratio. Calculated b-value images show higher SI-ratios and more anatomical image details (*i.e.*, bladder contour).

sensus, For the measurement of prostate signal intensity, a region-of-interest (ROI) was placed overlying the visualized portion of the prostate at the level of the bladder. Another ROI which was placed in the bladder content served as reference. The size and the localization of these ROIs were chosen identical on both the C-b1400 and M-b1400, to allow for an adequate comparison (Figure 2).

Lesion detection rate (cancer suspicious lesions) as well as lesion diameters were obtained and compared. Image quality, quality of lesion demarcation and diagnostic confidence of the observers were rated according to a 5-point Likert-type scale from “1” (“excellent”) to “5” (“poor”). Lesion-to-bladder and prostate-to-bladder signal-intensity (SI) ratios were obtained and compared to estimate signal-to-noise-ratio (SNR).

### Statistical analysis

SPSS (Version 20; IBM SPSS Statistics, United States) was

used for statistical analysis. Measured values did not show Gaussian distribution so Wilcoxon-tests were performed for comparison of C-b1400 and M-b1400.

## RESULTS

### Patients and lesions

In 30 consecutive patients, a total of 27 lesions were evaluated. Lesions were rated as prostate cancer ( $n = 15$ ), nodules of benign prostate hyperplasia (BPH) ( $n = 8$ ) and cancer recurrence ( $n = 4$ ). Two patients presented with locally recurrent cancer after prostatectomy.

### Image quality, lesion detection rate, lesion demarcation and diagnostic confidence

Image quality was rated significantly better in C-b1400 (mean =  $2.3 \pm 0.8$ ) compared to M-b1400 (mean =  $3.1 \pm 1.0$ ;  $P < 0.001$ ). Moreover, the computed images sub-

**Figure 3** M-b1400 (left column) and C-b1400 (right column) images of the same patient. Demarcation of two oval hyperintense suspicious lesions is very good on both images (arrows).

**Figure 4** Images of a 68 years old patient with elevated PSA levels and signs of benign prostate hyperplasia. M-b1400 (upper image on the left) was acquired with reduced image quality due to distortion artifacts. The C-b1400 (below) in corresponding slice position and identical window level shows an improved image quality with demarcation of several lesions that were rated as benign prostate hyperplasia-nodules taking into account T2w (right image) and dynamic contrast-enhanced imaging.

jectively showed more anatomical detail. We did not find significant differences regarding the quality of lesion demarcation with a trend to better results of C-b1400 (mean =  $2.6 \pm 1.0$  vs  $2.8 \pm 0.9$ , respectively;  $P = 0.29$ ) (Figures 3 and 4).

C-b1400 detected 3 additional cancer suspicious lesions compared to M-b1400 images, which were confirmed by ADC maps, T2w and DCE evaluation. Overall diagnostic confidence was rated slightly better on C-b1400, even though results were not significantly different ( $2.2 \pm 0.9$  vs  $2.1 \pm 0.8$ ,  $P = 0.48$ , respectively) (Table 1).

#### SI-ratios and lesion size

Significantly higher SI-ratio of prostate-to-bladder and

lesion-to-bladder were obtained for C-b1400 compared to M-b1400 ( $P < 0.001$  and  $P < 0.001$ , respectively).

Comparison of lesion size showed no significant differences between calculated and measured images ( $P < 0.22$ ) (Table 2). All statistical data are given as means and standard deviations.

## DISCUSSION

The study compared lesion detection rate, image quality and quality of lesion demarcation of a C-b1400 derived from a standard DWI protocol with M-b1400 images. A significantly better image quality of the C-b1400 was observed. Moreover, C-b1400 revealed more additional sus-

**Table 1 Comparison of C-b1400 and M-b1400 images; image quality, quality of lesion demarcation and level of confidence were rated according to a 5-point Likert-type scale**

<b>b = 1400 s/mm<sup>2</sup></b>	<b>Image quality (n = 30)</b>	<b>Lesion demarcation (n = 24)</b>	<b>Diagnostic confidence (n = 30)</b>
M-b1400	3.1 ± 1.0	2.8 ± 0.9	2.2 ± 0.9
C-b1400	2.3 ± 0.8	2.6 ± 1.0	2.1 ± 0.8
P-value	< 0.001	0.29	0.48

**Table 2 Objective parameters: Prostate-to-bladder and lesion-to-bladder signal intensity ratios were obtained to estimate signal-to-noise-ratio and contrast-to-noise ratio**

<b>b = 1400 s/mm<sup>2</sup></b>	<b>SI prostate/bladder (n = 28)</b>	<b>SI lesion/bladder (n = 24)</b>	<b>Lesion diameter (mm) (n = 24)</b>
M-b1400	1.9 ± 0.5	2.8 ± 0.9	16.9 ± 10.0
C-b1400	3.7 ± 1.0	5.6 ± 1.8	17.7 ± 10.0
P-value	< 0.001	< 0.001	0.22

Lesion diameters are presented in units of mm. SI: Signal intensity.

picious lesions that were confirmed by comparison with ADC maps and T2w. C-b1400 exhibited higher prostate-to-bladder and lesion-to-bladder SI ratios than M-b1400, which could indicate better SNR.

Multiple studies have tried to determine an optimal b-value to visualize prostate cancer using DWI at 3 T. A study by Metens *et al*<sup>[22]</sup> assessed examinations of forty-one patients with biopsy proven prostate cancer who underwent 3 T DWI performed with 5 b-values (1000, 1500, 2000 and 2500 s/mm<sup>2</sup>) using a 16-channel coil. Best lesion visibility, the central gland-to-lesion (CG-L) and the peripheral zone-to-lesion (PZ-L) contrast-to-noise ratio (CNR) were compared between different b-value images. In a subset of 29 patients a high resolution b = 1500 s/mm<sup>2</sup> DWI sequence was additionally assessed. The b = 1500 s/mm<sup>2</sup> and b = 2000 s/mm<sup>2</sup> images provided the best lesion visibility. The highest CG-L and PZ-L CNR were obtained with b = 1500 s/mm<sup>2</sup> ( $P < 0.01$ ).

Another recent study assessed the diagnostic accuracy of 3T DWI for detection of prostate cancer by using different b-values. Seventy-three patients underwent MRI at 3 T. Three MRI sets were reviewed by two radiologists: MRI and DWI (b = 500 s/mm<sup>2</sup>) (protocol A), MRI and DWI (b = 1000 s/mm<sup>2</sup>) (protocol B), and MRI and DWI (b = 2000 s/mm<sup>2</sup>) (protocol C). Areas under the receiver operating characteristic curve (AUCs) were calculated. The mean of the AUCs in protocol C was larger than those in protocol A and in protocol B ( $P < 0.05$ ). The authors concluded that a b-value = 2000 s/mm<sup>2</sup> at 3 T can improve the diagnostic accuracy for detection of prostate cancer<sup>[15]</sup>. On the other hand, a study to determine whether the ADC obtained from a high b-value (2000 s/mm<sup>2</sup>) is superior to that obtained from a standard b-value (1000 s/mm<sup>2</sup>) in a monoexponential model to discriminate malignant from benign pz tissue found little diagnostic advantage of the high b-value due to significant ADC overlap<sup>[16]</sup>.

Blackledge *et al*<sup>[18]</sup> described a method to extrapolate high-b-value images from DWI performed at lower b-values which allowed for an improved lesion conspicuity. Computation of DWI resulted in a higher SNR compared with measured DWI, especially at b-values > 840 s/mm<sup>2</sup>. Moreover, in oncologic patients, a computed b-value of 2000 s/mm<sup>2</sup> showed good image quality and high background suppression. Evaluation of images with a computed b-value of 2000 s/mm<sup>2</sup> resulted in higher overall diagnostic sensitivity (96.0%) and specificity (96.6%), compared with a measured b-value of 900 s/mm<sup>2</sup> (sensitivity, 89.4%; specificity, 87.5%;  $P < 0.01$ ).

In concordance with this study, our results suggest that computed b1400-images can be obtained with a better image quality due to lesser artifacts and more anatomical detail than measured b1400-images, probably as a benefit of the high SNR of the original lower b-value image sets. Nevertheless, there was no significant difference of the overall diagnostic confidence between the two image sets with a trend to better results for C-b1400 indicating a similar diagnostic performance of both, even though objectively three additional cancer suspicious lesions could be detected on C-b1400. Moreover, the comparison of the diameters of the largest lesions on measured and computed b1400 images did not reveal a significant difference between the techniques (Table 2).

Our study had a number of limitations. First of all, due to the private practice setting, there was no histopathologic confirmation of the assigned lesions. Then again, the study predominantly focused on image quality, lesion detection rate and lesion conspicuity. With regards to the reported ADC overlap of lesions, we believe that the primary value of the presented technique is to detect and draw attention to any lesion. The dignity of these lesions should be evaluated taking into account the clinical context of the patients and additional sequences such as T2w, DCE and MRSI. Moreover, we applied a monoexponential model for the computation of C-b1400 images. Several recent publications report that there is a significant deviation from a pure Gaussian probabilistic model when applying high b-values  $\geq 1000$  s/mm<sup>2</sup>. It was confirmed that the deviation quantified by kurtosis has a greater sensitivity than ADC or the diffusion constant D for the differentiation between PCa and benign lesions of the pz (93.3% vs 78.5% and 83.5%)<sup>[23]</sup>. A more recently published study shows that kurtosis has the best performance in differentiating PCa from benign prostate, using different sets of b-values<sup>[24]</sup>. In both studies, high b-values up to 2000-2300 s/mm<sup>2</sup> were applied for acquisition which results in a relevant deviation from a pure Gaussian probabilistic model. On the other hand, the impact of kurtosis in ADC calculation using lower b-values up to 800 is small and can be neglected, which falls in the range of the b-values acquired in the present study<sup>[25]</sup>. Furthermore, in this preliminary feasibility study, patients were included consecutively, and the indications and clinical contexts for the examinations were not homogeneous. In addition, a major concern of b-values above 1000 s/mm<sup>2</sup> in DWI acquisition is their intrinsically lower SNR

and the consecutive compromise of the calculation of the ADC. In clinical practice, stronger diffusion encodings are usually achieved by the prolongation of the motion probing gradients, which leads to a longer TE and an increased T2 decay of the signal. As a result, the highest chosen b-value ultimately determines the TE of the whole diffusion scan and may thus affect the SNR of the whole image set. It is therefore appealing to avoid signal loss by maintaining a shorter TE for conventional diffusion acquisition protocol, while associating the computation of high b-value image sets (*i.e.*, above  $b = 1200 \text{ s/mm}^2$ ), in order to benefit from the better SNR of the calculated ADC. In this study, only the readout was reduced to a sFOV, whereas more sophisticated techniques combine a sFOV readout with a sFOV excitation pulse<sup>[20]</sup>. Finally, a direct measurement of SNR was not feasible due to the sFOV which did not allow for inclusion of surrounding air for precise calculations. Nevertheless, the prostate-to-bladder and lesion-to-bladder SI ratios were calculated as a potential surrogate for the actual SNR.

In conclusion, computed high b-value images derived from a sFOV DWI protocol is clinically feasible and may increase accuracy in comparison to measured  $b = 1400 \text{ s/mm}^2$  images, without an increase of examination time, which is especially important regarding further application in clinical routine in a time and cost-efficient manner. Additionally, this approach allows for the calculation of virtually any given b-value from the originally measured DWI sequence, which can be further fine-tuned for different clinical settings and applications.

Combination of a high b-value extrapolation and sFOV readout may contribute to increase diagnostic accuracy of DWI without an increase of acquisition time, which may be useful to guide targeted prostate biopsies and to improve quality of mMRI especially under economical aspects in a private practice setting. However, further studies are needed to proof the preliminary results of this study in larger cohorts of clinical patients.

## COMMENTS

### COMMENTS

Prostate cancer is the most common malignant tumor entity in males. Differentiation between benign and malignant prostatic disease is hindered by a similar appearance on morphologic images. Multiparametric magnetic resonance imaging (mMRI), mostly consisting of high-resolution T2-weighted sequences, Dynamic Contrast Enhanced Imaging (DCE) and Diffusion-Weighted Imaging (DWI) has extensively improved sensitivity and specificity of the examination. It has been demonstrated that high b-values of DWI contribute to improve lesion detection rate which helps to guide targeted prostate biopsies. These high b-values can either be measured directly or extrapolated based on a standard low b-value DWI sequence.

### Research frontiers

The use of higher b-values is currently limited by the two following factors: reduction of SNR at b-values  $> 1000 \text{ s/mm}^2$  due to T2 signal decay as a consequence of a prolonged TE and cost effectiveness considerations due to a prolonged acquisition time, especially in a private practice setting. Due to these shortcomings, techniques that allow for the calculation of a high b-value DWI based on routinely measured lower b-values seem to be appealing. On the one hand high field strength imaging at 3 Tesla with higher intrinsic SNR is superior to 1.5 T for the detection of prostate cancer, on the other hand susceptibility artifacts related to the proximity of the peripheral zone to the air-filled rectum are

more relevant. Recently, small FOV (sFOV) imaging strategies for DWI based on the use of 2d radiofrequency excitation pulses for the excitation of a small volume spanning of the prostate region only were developed to overcome these shortcomings of 3T MRI and allow for a reduction of artifacts and a smooth fusion with morphologic T2w images

### Innovations and breakthroughs

For this study a b1400 sequence was extrapolated from a sFOV and low ( $< 1000 \text{ s/mm}^2$ ) b-value protocol to combine the advantages of reduced distortion artifacts and higher SNR of computed images. The purpose of this study is to compare lesion detection rate, image quality and quality of lesion demarcation of a computed (C-b1400) and a measured  $b = 1400 \text{ s/mm}^2$  (M-b1400) sequence based on a sFOV image set utilizing a modern 3T MR-system.

### Applications

The study results suggest that extrapolated high b-value images may contribute to increase lesions detection rate in a cost- and time efficient manner, which may help to guide targeted prostate biopsies.

### Terminology

Prostate cancer: Early prostate cancer usually causes no symptoms. Sometimes, however, prostate cancer does cause symptoms, often similar to those of diseases such as benign prostatic hyperplasia; Diffusion-weighted Imaging (DWI): DWI measures the movement of protons in between cells and is related to cell density. Low b-value images are rather T2-weighted and are sensitive to "T2-shine-through"-effects whereas high b-values are more useful to evaluate the properties of tissue diffusability.

### Peer review

The authors compared the utility of computed vs measured high b-value DWI for the assessment of prostate lesions. It is well written.

**METHODS:** Sixty consecutive individuals (30 males;  $73 \pm 7$  years) scheduled for risk stratification by means of unenhanced ECG-triggered cardiac computed tomography (gCCT) underwent additional unenhanced ngCCT. All CT scans were performed on a 64-slice CT scanner (Somatom Sensation 64 Cardiac, Siemens, Germany). CACS was calculated using conventional methods/scores (Volume, Mass, Agatston) as previously described in literature. The CACS value obtained were compared. The Mayo Clinic classification was used to stratify cardiovascular risk based on Agatston CACS. Differences and correlations between the two methods were compared. A  $P$ -value  $< 0.05$  was considered significant.

**RESULTS:** Mean CACS values were significantly higher for gCCT as compared to ngCCT (Volume:  $418 \pm 747$  vs  $332 \pm 597$ ; Mass:  $89 \pm 151$  vs  $78 \pm 141$ ; Agatston:  $481 \pm 854$  vs  $428 \pm 776$ ;  $P < 0.05$ ). The correlation between the two values was always very high (Volume:  $r = 0.95$ ; Mass:  $r = 0.97$ ; Agatston:  $r = 0.98$ ). Of the 6 patients with 0 Agatston score on gCCT, 2 (33%) showed an Agatston score  $> 0$  in the ngCCT. Of the 3 patients with 1-10 Agatston score on gCCT, 1 (33%) showed an Agatston score of 0 in the ngCCT. Overall, 23 (38%) patients were reclassified in a different cardiovascular risk category, mostly (18/23; 78%) shifting to a lower risk in the ngCCT. The estimated radiation dose was significantly higher for gCCT (DLP  $115.8 \pm 50.7$  vs  $83.8 \pm 16.3$ ; Effective dose  $1.6 \pm 0.7$  mSv vs  $1.2 \pm 0.2$  mSv;  $P < 0.01$ ).

**CONCLUSION:** CACS assessment is feasible on ngCCT; the variability of CACS values and the associated re-stratification of patients in cardiovascular risk groups should be taken into account.

**Key words:** Coronary artery calcium score; Lung cancer

### Abstract

**AIM:** To evaluate the feasibility of coronary artery calcium score (CACS) on low-dose non-gated chest CT (ngCCT).

screening; High-resolution computed tomography; Un-enhanced chest computed tomography; Cardiovascular risk stratification

**Core tip:** Low dose chest computed tomography (CT)/high-resolution CT (HRCT) is entering the clinical practice for the screening of individuals at high risk of lung cancer. This study provides evidence that a surrogate stratification of cardiovascular risk can be performed on low-dose chest CT performed in the settings of lung cancer screening. This finding has some relevant consequences since lung cancer and atherosclerosis share some similarities concerning risk factors (smoking), patients' population (age decade and gender prevalence).

## INTRODUCTION

Coronary artery calcium score (CACS) has been regarded as an independent predictor for cardiovascular risk stratification<sup>[1,2]</sup>. CACS has been performed in asymptomatic individuals for at least two decades using Electron-Beam Computed Tomography (EBCT) and more recently using Multi-Slice Computed Tomography (MSCT), however it has not entered guidelines for cardiovascular risk stratification until recently. In several countries it is applied as a part of primary prevention mostly based on self-referral.

With the introduction of MSCT the potential for anatomical screening has become a clinical reality<sup>[3,4]</sup>. Besides Coronary Artery Disease (*i.e.*, CACS), also colon cancer (*i.e.*, Virtual Colonoscopy) and lung cancer (*i.e.*, low-dose chest CT) have been proposed as topics for screening<sup>[5]</sup>. While CACS has already showed a potential for screening asymptomatic individuals, colon cancer screening and lung cancer screening are undergoing large multicenter studies to test whether CT is viable tool for this purpose<sup>[6-8]</sup>.

A very basic observation relies on the fact that in the context of lung cancer screening, the data collected (*i.e.*, low-dose chest CT) are somehow similar to the ones collected for CACS assessment. The main difference relies on the fact that low-dose chest CT is not performed with ECG synchronization protocols (*i.e.*, retrospective ECG gating or prospective ECG triggering), however the increasing speed of MSCT equipment may reduce the discrepancy between the two protocols. The hypothesis is that in principle it is possible to assess CACS on low-dose chest CT (ngCCT: non-gated low-dose chest CT). Therefore, we wanted to test the differences between the CACS values obtained with ngCCT and conventional ECG-gated CT protocol (gCCT: gated Cardiac CT) in

the same population of asymptomatic individuals. The aim of the study was compare the CACS values obtained with gCCT (as the reference standard) to ngCCT, and to verify the feasibility and variability of cardiovascular risk stratification using the two protocols.

A novelty of our paper is the comparison of gCCT CACS values with ngCCT ones obtained analyzing dataset reconstructed with 5 mm slice thickness and 5.0mm increment unlike other previously published studies based on dataset with 3 mm, 2.5mm, 1.5 mm or 1mm slice thickness<sup>[3,4,9,10]</sup>. The feasibility of cardiovascular risk stratification using non gated CACS values obtained with the same standard dataset routinely reconstructed (5mm slice thickness) would allow a wide and fast use in daily clinical practice. The description of the degree of cardiovascular risk reclassification using ngCCT *vs* gCCT values is another innovative aspect of our study.

## MATERIALS AND METHODS

### Patients

During a period of 6 mo we prospectively enrolled 60 consecutive asymptomatic individuals (30 males; 72 ± 10 years) who were referred for the assessment of CACS (Table 1). The individuals were excluded based on conventional contra-indications to Radiation Exposure (*i.e.*, potential or actual pregnancy, age < 50 years). All patients underwent two CT scans: the first (gCCT) for CACS purposes and the second for lung parenchyma (ngCCT) assessment, using conventional parameters.

We collected demographics (age, gender, height, weight), heart rate during the scans, and radiation dose for both scans in all patients.

Informed consent was obtained from all patients and the local Medical Ethical Committee approved the study.

### CT scan

All individuals underwent two un-enhanced CT scans (Table 2). For gCCT, scanning was performed by using 64-slice CT system (Sensation 64 Cardiac, Siemens Medical Solutions, Forchheim, Germany) and spiral retrospective ECG gating technique. All CT scans of the heart (from the carina to the apex of the heart) were acquired during one inspiratory breath-hold without the use of the contrast medium and without the additional administration of chronotropic drugs. Scan parameters were: detector collimation: 32 mm × 0.6 mm, Z-axis focal spot alternation resulting in simultaneous acquisition of 64 slices; gantry rotation time: 330 ms; effective temporal resolution 165 ms; table feed per rotation: 3.84 mm; pitch 0.2; tube voltage 120 kV; tube power 150 mAs; direction in which data acquisition proceeded: cranio-caudal.

Image were reconstructed with the following parameters: slice thickness 3 mm, slice increment 1.5 mm, field of view (FOV) 150-180 mm, convolution kernel filtering for CACS (b35f). Temporal windows were set at -350ms prior to the next R wave.

For ngCCT, scanning was performed by using 64-slice

**Table 1** Demographics *n* (%)

Clinical characteristics	Population ( <i>n</i> = 60)
Age (yr, mean $\pm$ SD)	73.4 $\pm$ 7.1
Male gender	30 (50)
BMI (kg/m <sup>2</sup> , mean $\pm$ SD)	25.9 $\pm$ 4.5
BSA (m <sup>2</sup> , mean $\pm$ SD)	1.8 $\pm$ 0.2
Mean heart rate (bpm, mean $\pm$ SD)	73.0 $\pm$ 15.7
Additional negative chronotropic drugs	None

Baseline characteristics of study population. BMI: Body mass index; BSA: Body surface area.

**Table 2** scan and reconstruction parameters

Parameters	gCCT	ngCCT
Scan parameters		
Technique	Spiral	Spiral
kV	120	120
mAs	150	30
Gantry rotation time (ms)	330	330
Individual detector width (mm)	1.2	0.6
Number of detectors	20 $\times$ 2	32 $\times$ 2
ECG gating	Yes	No
Prospective ECG modulation of tube current	Yes	No
Table feed/s (mm)	14.4	86.4
Pitch	0.2	1.5
Scan range	Carina-Apex	Chest
DLP (mGy; mean $\pm$ SD)	116 $\pm$ 51	84 $\pm$ 16 <sup>a</sup>
Effective dose (mSv; factor = 0.014; mean $\pm$ SD)	2.0 $\pm$ 0.9	1.2 $\pm$ 0.5 <sup>a</sup>
Effective dose (mSv; factor = 0.014; median, IQR)	1.61; 1.15-2.0	1.13; 1.05-1.20 <sup>a</sup>
Reconstruction parameters		
Effective slice width (mm)	3.0	5.0
Reconstruction increment (mm)	1.5	5.0
FOV (mm)	140-160	250-300
Kernel filtering	B35f <sup>1</sup>	B30f (medium-smooth)

The Table shows the scan parameters for gCCT and ngCCT. gCCT *vs* ngCCT, <sup>a</sup>*P* < 0.05; <sup>1</sup>Dedicated filter for calcium scoring. gCCT: ECG gated cardiac computed tomography; ngCCT: Non-gated chest computed tomography; FOV: Field of view; ECG: Electrocardiogram; DLP: Dose length product.

CT system (Sensation 64 Cardiac, Siemens Medical Solutions, Forchheim, Germany) and spiral non ECG gated technique. All CT scans of the whole lung were acquired during one deep inspiratory breath-hold without the use of IV contrast medium. Neither electrocardiographic triggering, nor any dose-modulation system were used. The scanner was regularly calibrated to allow reliable measurements and comparison between examinations. Standard low dose chest CT parameters were: detector collimation 0.6 mm, slices per rotation 32  $\times$  2, gantry rotation time 330 ms, pitch 1.5, tube voltage 120 kV, tube power 30 mAs.

Image were reconstructed with the following parameters: slice thickness 5 mm, slice increment 5mm, field of view (FOV) 250-300 mm, convolution kernel filtering medium-smooth (b30f).

## CT data analysis

The images of the study population were transferred to a dedicated CT workstation (MMWP, Siemens Medical Solutions, Forchheim, Germany) and analyzed by one operator with more than five years of experience in cardiac imaging, who was blinded to participants' data and scan protocol. CACS assessment was performed using a dedicated software (CaScore, Siemens, Forchheim, Germany). For the purpose of intra- and inter-observer variability assessment the main observer re-read all scans and a second operator with three years of experience in cardiac imaging read the entire CT dataset. There was a time of 2 months between the two additional readings (one of the main operator for intra-observer variability and one for the additional reader for the inter-observer variability).

## Statistical analysis

Continuous variables are expressed as mean  $\pm$  SD and/or median, where appropriate. Differences between groups were compared using the Student's *t* and Wilcoxon tests, as appropriate. Correlation was assessed using the Pearson's *r* test while the bias was assessed using the Bland-Altman method. Intra- and inter-observer variability were assessed for all CACS measurements and compared using the Bland-Altman method.

Radiation dose (Dose Length Product: DLP) was estimated using the CT DIvol multiplied for the scan length. For the estimation of the effective dose a factor of 0.014 was applied<sup>[11]</sup>.

Statistical analysis was performed with SPSS (version 12.0, SPSS Inc., Chicago, IL, United States) and MedCalc (version 9.3.0.0., MedCalc Software, Mariakerke, Belgium) software. Significance was set at *P* < 0.05.

## RESULTS

The scans were successful in all patients. Mean heart rate during the scans was 73  $\pm$  16 bpm.

## CACS assessment

The time required to perform CACS was 3  $\pm$  1 min.

Mean CACS values were significantly higher for gCCT as compared to ngCCT (Volume: 418  $\pm$  747 *vs* 332  $\pm$  597; Mass: 89  $\pm$  151 *vs* 78  $\pm$  141; Agatston: 481  $\pm$  854 *vs* 428  $\pm$  776; *P* < 0.05). The mean difference (Delta) between gCCT and ngCCT was 86  $\pm$  267 for Volume, 11  $\pm$  36 for Mass and 53  $\pm$  188 for Agatston score, showing a sharp tendency for global underestimation of CACS in ngCCT (Table 3, Figures 1-3).

The correlation between values was always high (*r* = Volume: 0.95; Mass: 0.97; Agatston: 0.98) between the two scans. The correlation between heart rate and the difference between the two scans was very low (*r* = -0.09), suggesting that the variability was not related to heart rate. Instead there was a moderate correlation (*r* = 0.50) between the differences (delta) between the two scans and the Agatston score in gCCT, suggesting that the higher the CACS value, the higher the variability.

Intra- and Inter-observer variability was very limited

**Table 3** coronary artery calcium score values

Parameters (mean $\pm$ SD)	gCCT	ngCCT	Delta (absolute)	Delta	P	r	R <sup>2</sup>
Volume	418.1 $\pm$ 746.5	332.0 $\pm$ 596.9	-86.1 $\pm$ 263.8	-21%	< 0.05	0.947	0.896
Mass	88.9 $\pm$ 151.2	77.9 $\pm$ 140.5	-11.1 $\pm$ 35.5	-12%	< 0.05	0.973	0.946
Agatston	480.8 $\pm$ 853.7	427.7 $\pm$ 776.3	-53.1 $\pm$ 188.4	-11%	< 0.05	0.978	0.956

The Table shows the mean values of CACS Volume, Mass, and Agatston score for the study population. On average gCCT shows CACS values significantly higher with a high correlation to ngCCT. The percentage underestimation (delta) of ngCCT of Agatston score is -11%. CACS: Coronary artery calcium score; gCCT: ECG gated cardiac computed tomography; ngCCT: Non-gated chest computed tomography.

**Figure 1** Coronary artery calcium score values. The Figure shows the mean and median values of Volume, Mass, and Agatston Score for gCCT and ngCCT in the total population. There is a sharp tendency to underestimate of ngCCT for all types of CACS score. gCCT: ECG gated cardiac computed tomography; ngCCT: Non-gated chest computed tomography; CACS: Coronary artery calcium score.

for both gCCT and ngCCT ( $P > 0.05$ ). Intra-observer variability of Agatston score showed a bias of -0.148 for ngCCT and 0.057 for gCCT. Inter-observer of Agatston score showed a bias of -0.259 for ngCCT and 0.178 for gCCT.

### Reclassification

With the tendency of ngCCT to underestimate CACS values we observed a relevant degree of reclassification (Table 4, Figure 4).

Overall, 23 (38%) patients were reclassified in a different cardiovascular risk category, mostly (18/23; 78%) shifting to a lower risk in the ngCCT; in 5/23 (22%) cases the CACS score shifted to a higher cardiovascular risk category.

Of the 6 patients with 0 Agatston score on gCCT, 2 (33%) showed an Agatston score  $> 0$  in the ngCCT. Of the 3 patients with 1-10 Agatston score on gCCT, 1 (33%) showed an Agatston score of 0 in the ngCCT.

Two patients showed very different values of CACS between the two scans; they correspond both the very high values of Agatston score ( $> 1000$ ); therefore, the difference is not relevant for stratification of risk. The main reason for such a difference (beside the lack of cardiac synchronization in ngCCT) was related to higher heart rates ( $> 80$  bpm).

### Radiation dose

The estimated radiation dose was significantly higher for gCCT (DLP  $115.8 \pm 50.7$  vs  $83.8 \pm 16.3$ ; Effective dose  $1.6 \pm 0.7$  mSv vs  $1.2 \pm 0.2$  mSv;  $P < 0.01$ ).

### DISCUSSION

A number of randomized lung cancer screening trials are currently undergoing with the aim of reducing mortality related to this life-threatening condition<sup>[12]</sup>. Although atherosclerotic vascular disease accounts for more death and disability than all types of cancer, the importance of detecting subclinical atherosclerosis and targeting prevention of future cardiovascular events is only now starting to be highlighted in the lung cancer screening setting<sup>[3,4,13-15]</sup>. Preliminary experiences shows a very high correlation between CACS assessed on low dose HRCT and cardiovascular events<sup>[4]</sup>.

These findings are also suggesting that cardiovascular mortality as predicted by CACS is higher as compared to lung cancer mortality in a population of high risk smokers<sup>[4]</sup>. This finding can be expected from epidemiological data on all-cause mortality<sup>[8]</sup>, however for the first time we have a tool that can stratify risk for both diseases. This is the first study that addressed the issue of CACS assessment in lung cancer screening context in a prospective cross-over fashion.

Our study is focused on showing the correlation between CACS obtained in conventional gCCT scans and in low-dose CT (ngCCT). The correlation we found is very high with a tendency of ngCCT to underestimate total calcium burden. The cardiovascular reclassification occurring in individuals undergoing HRCT, following the Mayo Clinic classification is important (about 38% of the individuals). Nevertheless, the predictive value on mortality has been shown to remain preserved<sup>[3,4]</sup>.

The most important findings of our study are related to the classification of individuals with none or very low CACS values. In general one third of the individuals with CACS 0 (which means no evidence of CAD) are reclassified in higher category, while one third of the individuals with very low CACS (CACS 1-10) are reclassified as CACS 0. This is particularly important for the negative predictive value of CACS concerning obstructive CAD and cardiovascular events.

The technique applied to ngCCT in this study is the standard one (dataset reconstructed with 5 mm slice thickness and 5 mm slice increment) and does not re-

**Figure 2 Scatter plots coronary artery calcium score values.** The scatter plots show the high correlation of Volume (A), Mass (B), and Agatston (C) scores obtained with gCCT and ngCCT. gCCT: ECG gated cardiac computed tomography; ngCCT: Non-gated chest computed tomography.

quire any additional reconstruction as suggested by other studies previously published (from 1 mm to 3 mm slice thickness)<sup>[3,4,9,10]</sup>. CACS assessment can be done using the same data routinely reconstructed for the purpose of lung cancer screening, resulting easily applicable in daily clinical practice.

### Clinical implications

From our observation and the observation of Jacobs *et*

**Figure 3 Bland-Altman plots of coronary artery calcium score values.** The Bland-Altman plots show the slight but significant tendency to overestimate Volume (A), Mass (B), and Agatston (C) scores of ngCCT as compared to gCCT. There are 2 patients with values far off in ngCCT vs gCCT. However, they are both with very high values and this does not affect significantly further reclassification. gCCT: ECG gated cardiac computed tomography; ngCCT: Non-gated chest computed tomography.

*al.*<sup>[3,4]</sup> we can suggest that individuals undergoing HRCT for lung cancer screening should be assessed for CACS. CACS assessment is a relatively simple procedure that requires a dedicated software application (currently available on all CT scanners able to perform Cardiac Imaging) and a basic training. It is not time consuming (it requires few minutes) but it has a very important prognostic value

**Table 4 Cardio vascular risk stratification based on absolute coronary artery calcium score classes *n* (%)**

CACS class	gCCT	ngCCT
0	6 (10)	10 (16.7)
1-10	6 (10)	7 (11.7)
11-100	14 (23.3)	10 (16.7)
101-400	14 (23.3)	17 (28.3)
400-1000	14 (23.3)	10 (16.7)
> 1000	6 (10)	6 (10)

The Table shows how the total Agatston score distributed using the Mayo Clinic Classification (Rumberger *et al*<sup>[17]</sup>) with gCCT and ngCCT within the same population. In total 23 (38.3%) patients shifted to a different cardiovascular risk group. gCCT: ECG gated cardiac computed tomography; ngCCT: Non-gated chest computed tomography.

which is independent from conventional cardiovascular risk factors<sup>[1,2,15]</sup>.

### Limitations

**Study has several limitations:** The first is the relatively low number of patients. This also limits the sub-analysis of the CACS groups. However, this is the first study that prospectively tests in a cross-over design the hypothesis that ngCCT could be used for CACS purposes. Enrolling more patients would have exposed more individuals to un-necessary additional radiation.

The second limitation is the additional radiation dose delivered to the patients which is consistent with the design of the study and has been minimized by using available hardware and software solutions.

The third limitation is related to the absence of prospective ECG triggering protocol for gCCT. This feature was available but we decided not to use it due to the higher reproducibility of spiral CT scanning for CACS<sup>[16]</sup>. The use of prospective ECG triggering would have further reduced the radiation dose of gCCT. The fourth limitation is the lack of outcome data. However, this was beyond the aim of the study and the number of patients enrolled is not adequate for this purpose anyway. This aspect has been showed in other studies<sup>[4]</sup>. Recently another substudy of the MILD trial provided insight into this aspect and showed that individuals with > 400 modified Agatston score performed on non-gated chest CT scans have a worse prognosis in terms of mortality and cardiovascular events<sup>[8]</sup>. Actually, with this study we wanted to demonstrate the feasibility of CACS in ngCCT scans.

CACS assessment is feasible on unenhanced chest CT, however the variability of CACS values and the associated re-stratification of patients in cardiovascular risk groups should be taken into account.

## COMMENTS

### Background

Lung cancer screening is a long standing topic. Low dose high resolution computed tomography (CT) is becoming the preferred mean for this purpose in high risk smoker population. Meanwhile, coronary artery calcium score by means of CT has become a strong and reliable method for cardiovascular risk stratification in asymptomatic individuals.

**Figure 4 Restrification.** The Figure shows the pattern of reclassification of cardiovascular risk categories using the Mayo Clinic Classification (Rumberger *et al*) with gCCT and ngCCT within the same population (CACS score according to Agatston). ngCCT determines a shift in the ranges between 1 and 400 Agatston score. Some of these patients shift to a lower category (in particular the ones with Agatston score between 1 and 10), while some of the patients shifts towards higher risk categories (in particular the ones with Agatston score between 11 and 100). In total 23 patients shifted to another cardiovascular risk category in ngCCT. gCCT: ECG gated cardiac computed tomography; ngCCT: Non-gated chest computed tomography; CACS: Coronary artery calcium score.

### Research frontiers

This study demonstrates that coronary artery calcium score for cardiovascular risk stratification can be performed in the context of lung cancer screening by means of low dose CT.

### Innovations and breakthroughs

There are no studies in literature performed as cross-over and prospective in such a population.

### Applications

This study provides the clue on the feasibility of coronary calcium score in individuals undergoing low dose CT for lung cancer screening.

### Terminology

Low dose computed tomography: it is a diagnostic method by which it is possible to detect small pulmonary nodules before they become larger tumors. Coronary artery calcium score: it is a test performed with CT that allows the quantification of coronary artery calcium as a surrogate and independent marker of cardiovascular risk.

### Peer review

This is a well written manuscript that compares quantification of coronary artery calcium scoring by non-gated techniques with traditional thick slice reconstructions as used in lung screening exams with calcium scoring by traditional gated techniques with thin slice reconstructions.

**Key words:** Seizure; Rupture; Temporalis; Muscle; Pediatric

**Core tip:** We report the unique case of a unilateral temporalis muscle rupture following new onset tonic-clonic seizures in a 16-year-old boy. The favored mechanism in our patient is a pull on the temporalis myotendinous insertion on the mandible following vigorous and brisk deviation of the head and neck during seizure. Although this is a rare entity, it is important to be familiar with such type of injury in a patient who develops unilateral facial swelling and pain following tonic-clonic seizures in order to prevent misdiagnosis and mistreatment.

Naffaa LN, Tandon YK, Rubin M. Myotendinous rupture of temporalis muscle: A rare injury following seizure. *World J Radiol* 2014; 6(6): 388-391 Available from: URL: <http://www.wjgnet.com/1949-8470/full/v6/i6/388.htm> DOI: <http://dx.doi.org/10.4329/wjr.v6.i6.388>

### Abstract

Seizures are one of the most common pediatric neurologic disorders. Many complications secondary to seizures have been described in the literature including head trauma, fractures, drowning and burns. However, to the best of our knowledge, rupture of the myotendinous insertion of the temporalis muscle on the mandible secondary to a seizure has never been described in the literature. We report the case of a unilateral temporalis muscle rupture in a 16-year-old boy who developed unilateral facial swelling following new onset tonic-clonic seizures. We emphasize on the computed tomography and magnetic resonance imaging findings in this case report. Two mechanisms have been proposed to explain such an injury. The favored mechanism in our patient is a pull on the temporalis myotendinous insertion on the mandible following vigorous and brisk deviation of the head and neck during seizure. Radiologists should be familiar with this type of injury following seizures in order to prevent misdiagnosis and subsequently mistreatment.

### INTRODUCTION

Seizures are one of the most common pediatric neurologic disorders. It is estimated that 4% to 10% of children will have at least one seizure in the first 16 years of life<sup>[1]</sup>. Many complications have been described in the literature secondary to seizures, such as head trauma, fractures, drowning and burns<sup>[2-4]</sup>. However, to the best of our knowledge, this is the first reported case of myotendinous rupture of the temporalis muscle after seizures. We report the computed tomography (CT) and magnetic resonance imaging (MRI) findings of rupture of the myotendinous insertion of the right temporalis muscle on the coronoid process of the mandible following generalized tonic-clonic seizures. Two mechanisms have been proposed to explain such an injury: significant pull on the

myotendinous insertion following brisk and forceful deviation of the head and neck toward the contralateral side during seizures or direct fall on the face. In our patient, the first mechanism is favored as there was no witnessed fall nor signs of facial trauma on physical exam.

## CASE REPORT

Patient is a 16-year-old male with a past medical history of Attention Deficit Hyperactivity Disorder (ADHD) who was admitted for new onset seizures. Approximately 12 h prior to his presentation to our institution, he had a sudden witnessed episode of violent bilateral shaking of his arms and legs that lasted approximately 2 min associated with foaming at the mouth. He was taken to an outside hospital emergency department (ED) where a basic metabolic panel including glucose and calcium levels was normal. His urine toxicology was negative and urine analysis was also within normal limits. Head CT was performed and was reportedly normal. Just prior to discharge from the ED, his mother noticed a small bump that had developed over his right temple.

He was discharged home after he returned to his neurological baseline. At home, the patient continued to have increasing facial swelling that was spreading down to his cheek. Patient also began to complain of pain and noted difficulty opening his mouth secondary to pain. At home, a few hours after returning from the ED, the patient's mother again witnessed him having another seizure that lasted approximately 2 min where he was noted to have bilateral arm and leg shaking with foaming at the mouth. He was taken back to the outside hospital ED. He returned to his neurological baseline and was transferred to our institution for further management.

Shortly after arrival to our institution, he had another seizure witnessed by nursing staff where he had full body stiffening followed by bilateral jerking of his arms and legs with his eyes and head deviated to the left. This episode lasted 1.5 min. The patient's mother and the providing physicians noted that the right sided facial swelling continued to worsen and the patient continued to experience worsening right sided facial pain. On physical exam, there was diffuse swelling over the right temporal region extending all the way down to reach the right ear and right jaw. This region was extremely tender to palpation. There were no external signs of trauma such as bruising or laceration. Laboratory tests including CBC demonstrates a high WBC of 17.8 (Normal range: 4.5-13.0  $10^9/L$ ), elevated CPK of 762 (Normal range: 24-195 U/L), normal blood amylase, negative blood culture at 24 h and normal coagulation profile. The initial differential diagnosis for the facial swelling included a dental abscess, parotitis, or non specific myositis. Patient was empirically started on Clindamycin to treat any potential underlying infectious etiology.

A CT scan of the face with intravenous contrast was performed in our institution for further evaluation using the following technique: GE Medical Systems,

**Figure 1** Axial contrast enhanced computed tomography images of the face with soft tissue settings demonstrate swelling (A) and subtle hypoattenuation (B) of myotendinous portion of right Temporalis muscle (straight arrows) as it passes medial to the zygomatic bone just prior to its insertion to the coronoid process and anterior ramus of the right mandible. It contains a small high density material which may represent hemorrhage (arrowhead). Note the normal appearance of contralateral temporalis muscle (curved arrows).

Pitch:0.562:1, Pixel spacing: 0.361 mm/0.361 mm, Kvp 120, mA 129, rotate time: 0.8, ST 2.5 mm, FOV 18 cm, Tilt 0, W:342, L:56, Contrast: 98 cc of Iovue 300. The CT images (Figures 1 and 2) demonstrate swelling and diminished attenuation of right temporalis muscle most prominent near its myotendinous portion as it passes medial to the zygomatic bone just prior to its insertion to the coronoid process and anterior ramus of the right mandible. A small high density is identified just prior to its insertion to the mandible which may represent hemorrhage. The CT findings were in favor of a non specific myositis, possibly infectious in nature. The subtle hypoattenuation near the insertion to the mandible was felt to represent a possible phlegmon without a mature abscess seen.

An MRI of the face prior and following intravenous contrast administration was performed the next day for better characterization. The following pulse sequences were obtained on a 3 Tesla magnet (Siemens/Skysa): T2 coronal SPIR (repetition time/echo time = 6580/91, Number of excitations (NEX) = 2, matrix =  $320 \times 240$ , slice thickness = 2.5 mm), T2 axial fat sat (6070/98, NEX = 2, 4 mm,  $256 \times 256$ , 2 mm), T1 coronal (600/8.4, NEX = 1,  $256 \times 205$ , 2.5 mm), T2 axial GRE (627/19.9, NEX = 1,  $320 \times 240$ , 4 mm), T1 axial fat sat pre and post intravenous administration of 5.7 mL of Gadavist

**Figure 2** Three millimeter reconstructed contrast enhanced coronal computed tomography images of the face with soft tissue settings demonstrate swelling of the entire right temporalis muscle more prominent at its myotendinous insertion to the mandible (straight arrow). There is also swelling of right masseter muscle (curved arrow). Small high density material is again seen in region of myotendinous insertion of right temporalis muscle suggesting hemorrhage (arrowhead).

**Figure 3** T2 Coronal SPIR (A) and T1 Coronal SPIR post contrast images (B) through the face demonstrate rupture of myotendinous insertion of right temporalis muscle with a 2.5 cm × 1.5 cm collection surrounding the coronoid region of right mandible at the site of temporalis muscle insertion (straight arrows), the collection demonstrates low signal on T2 weighted imaging (A) and susceptibility artifact/blooming on the T2 axial GRE image (C) consistent with hematoma. Additionally, there is mild swelling, increased T2 signal and mild enhancement in the right masseter muscle notably near its insertion to the anterior mandible as demonstrated on figures A and B suggesting a sprain (curved arrow). Swelling and edema of overlying subcutaneous soft tissues is noted as well.

(661/8.4, NEX = 1, 256 × 205, 4 mm), T1 coronal fat sat post contrast (899/8.4, NEX = 1, 256 × 205, 2.5 mm). The MRI findings (Figure 3) are consistent with rupture of the right temporalis myotendinous junction with a small hematoma formation at its insertion onto the coronoid process of the mandible. There was swelling and mild inflammatory changes in the entire right temporalis muscle over the temporal calvarium. Swelling and mild inflammatory changes were also seen in the right masseter muscle especially at its attachment to the anterior ramus and angle of the mandible consistent with sprain.

Plastic surgery was consulted and after examining the patient decided to treat conservatively with pain medication and physical therapy.

## DISCUSSION

The temporalis muscle is a broad, fan shaped muscle that fills the temporal fossa, superior to the zygomatic arch. The muscle originates from the temporal fossa and the deep surface of the temporal fascia. As the muscle fibers descend, they form a tendon which passes medial to the zygomatic arch and inserts into the medial surface, apex, and anterior border of the coronoid process, and the anterior border of the mandibular ramus<sup>[5,6]</sup>. Its function is to elevate and retract the mandible<sup>[5,6]</sup>.

Thorough review of the literature reveals that not

much has been written about rupture of the temporalis muscle insertion. Etiologies that have been described as a potential cause for injury include direct injury to the muscle fibers caused by inappropriate intra operative dissection or retraction<sup>[7-10]</sup>. Direct trauma such as a blow to the side of the head or a motor vehicle accident can also cause injury to the temporalis muscle. Sleep bruxism is a common sleep-related motor disorder characterized by tooth grinding and clenching in which there can be strain of the temporalis muscle<sup>[11]</sup>. However, frank rupture of the myotendinous insertion of the temporalis muscle has not been reported especially in the context of seizure related injuries.

We describe the CT and MRI findings of rupture of myotendinous insertion of right temporalis muscle on the mandible in a 16-year-old male following multiple witnessed generalized tonic-clonic seizures. Two mechanisms have been proposed to explain such an injury: significant pull on the myotendinous insertion following violent jerking of his head and neck to the contralateral side during seizures or a direct fall on the face. In our patient, the first mechanism is favored as no facial bruising or laceration were identified on physical exam and no direct trauma or fall to the head or face was witnessed by parents or medical staff.

Rupture of the myotendinous junction of temporalis muscle is extremely rare. It is important to be familiar

with such type of injury in a patient who developed unilateral facial swelling and pain following tonic-clonic seizures in order to prevent misdiagnosis and mistreatment.

## COMMENTS

### Case characteristics

Sixty-year-old boy who developed unilateral facial swelling and pain following new onset tonic-clonic seizures.

### Clinical diagnosis

Diffuse swelling over the right temporal region extending all the way down to reach the right ear and right jaw which was tender to palpation.

### Differential diagnosis

Dental abscess, parotitis, non specific myositis, rupture of the myotendinous junction of temporalis muscle.

### Laboratory diagnosis

WBC 17.8; CPK of 762; normal blood amylase; negative blood culture at 24 h; negative urine toxicology; normal coagulation profile; normal basic metabolic panel and urine analysis.

### Imaging diagnosis

Computed tomography finding: Swelling and diminished attenuation of right temporalis muscle most prominent near its myotendinous portion as it passes medial to the zygomatic bone just prior to its insertion to the coronoid process and anterior ramus of the right mandible. A small high density is identified just prior to its insertion to the mandible which may represent hemorrhage; Magnetic resonance findings: Rupture of the right temporalis myotendinous junction with a small hematoma formation at its insertion onto the coronoid process of the mandible. Swelling and sprain of the right masseter muscle especially at its attachment to the anterior ramus and angle of the mandible.

### Treatment

Conservative treatment with pain medication and physical therapy.

### Related reports

The literature regarding rupture of the temporalis muscle insertion is sparse. Potential etiologies described in the literature include direct injury to the muscle fibers caused by inappropriate intra operative dissection or retraction or direct trauma such as a blow to the side of the head or a motor vehicle accident.

### Experiences and lessons

This case reports a rare case of temporalis muscle rupture following seizure. Although this is a rare entity, it is important to be familiar with such type of injury in a patient who develops unilateral facial swelling and pain following a tonic-clonic seizure in order to prevent misdiagnosis and mistreatment.

### Peer review

The authors present an interesting and well done clinical note and describe the neuroimaging findings of rupture of myotendinous insertion of right temporalis

muscle of the mandible in a 16-year-old male following multiple witnessed generalized tonic-clonic seizures. This is the first reported case of myotendinous rupture of the temporalis muscle after seizure. This information is interesting from a clinical point of view.

## GENERAL INFORMATION

*World Journal of Radiology* (*World J Radiol*, *WJR*, online ISSN 1949-8470, DOI: 10.4329) is a peer-reviewed open access (OA) academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

### Aim and scope

*WJR* covers topics concerning diagnostic radiology, radiation oncology, radiologic physics, neuroradiology, nuclear radiology, pediatric radiology, vascular/interventional radiology, medical imaging achieved by various modalities and related methods analysis. The current columns of *WJR* include editorial, frontier, diagnostic advances, therapeutics advances, field of vision, mini-reviews, review, topic highlight, medical ethics, original articles, case report, clinical case conference (clinicopathological conference), and autobiography.

We encourage authors to submit their manuscripts to *WJR*. We will give priority to manuscripts that are supported by major national and international foundations and those that are of great basic and clinical significance.

*WJR* is edited and published by Baishideng Publishing Group (BPG). BPG has a strong professional editorial team composed of science editors, language editors and electronic editors. BPG currently publishes 43 OA clinical medical journals, including 42 in English, has a total of 15471 editorial board members or peer reviewers, and is a world first-class publisher.

### Columns

The columns in the issues of *WJR* will include: (1) Editorial: The editorial board members are invited to make comments on an important topic in their field in terms of its current research status and future directions to lead the development of this discipline; (2) Frontier: The editorial board members are invited to select a highly cited cutting-edge original paper of his/her own to summarize major findings, the problems that have been resolved and remain to be resolved, and future research directions to help readers understand his/her important academic point of view and future research directions in the field; (3) Diagnostic Advances: The editorial board members are invited to write high-quality diagnostic advances in their field to improve the diagnostic skills of readers. The topic covers general clinical diagnosis, differential diagnosis, pathological diagnosis, laboratory diagnosis, imaging diagnosis, endoscopic diagnosis, biotechnological diagnosis, functional diagnosis, and physical diagnosis; (4) Therapeutics Advances: The editorial board members are invited to write high-quality therapeutic advances in their field to help improve the therapeutic skills of readers. The topic covers medication therapy, psychotherapy, physical therapy, replacement therapy, interventional therapy, minimally invasive therapy, endoscopic therapy, transplantation therapy, and surgical therapy; (5) Field of Vision: The editorial board members are invited to write commentaries on classic articles, hot topic articles, or latest articles to keep readers at the forefront of research and increase their levels of clinical research. Classic articles refer to papers that are included in Web of Knowledge and have received a large number of citations (ranking in the top 1%) after being published for more than years, reflecting the quality and impact of papers. Hot topic articles refer to papers that are included in Web of Knowledge and have received a large number of citations after being published for no more than 2 years, reflecting cutting-edge trends in scientific research. Latest articles refer to the latest

published high-quality papers that are included in PubMed, reflecting the latest research trends. These commentary articles should focus on the status quo of research, the most important research topics, the problems that have now been resolved and remain to be resolved, and future research directions. Basic information about the article to be commented (including authors, article title, journal name, year, volume, and inclusive page numbers); (6) Minireviews: The editorial board members are invited to write short reviews on recent advances and trends in research of molecular biology, genomics, and related cutting-edge technologies to provide readers with the latest knowledge and help improve their diagnostic and therapeutic skills; (7) Review: To make a systematic review to focus on the status quo of research, the most important research topics, the problems that have now been resolved and remain to be resolved, and future research directions; (8) Topic Highlight: The editorial board members are invited to write a series of articles (7-10 articles) to comment and discuss a hot topic to help improve the diagnostic and therapeutic skills of readers; (9) Medical Ethics: The editorial board members are invited to write articles about medical ethics to increase readers' knowledge of medical ethics. The topic covers international ethics guidelines, animal studies, clinical trials, organ transplantation, etc.; (10) Clinical Case Conference or Clinicopathological Conference: The editorial board members are invited to contribute high-quality clinical case conference; (11) Original Articles: To report innovative and original findings in radiology; (12) Brief Articles: To briefly report the novel and innovative findings in radiology; (13) Meta-Analysis: Covers the systematic review, mixed treatment comparison, meta-regression, and overview of reviews, in order to summarize a given quantitative effect, e.g., the clinical effectiveness and safety of clinical treatments by combining data from two or more randomized controlled trials, thereby providing more precise and externally valid estimates than those which would stem from each individual dataset if analyzed separately from the others; (15) Letters to the Editor: To discuss and make reply to the contributions published in *WJR*, or to introduce and comment on a controversial issue of general interest; (16) Book Reviews: To introduce and comment on quality monographs of radiology; and (17) Autobiography: The editorial board members are invited to write their autobiography to provide readers with stories of success or failure in their scientific research career. The topic covers their basic personal information and information about when they started doing research work, where and how they did research work, what they have achieved, and their lessons from success or failure.

## SPECIAL STATEMENT

All articles published in journals owned by the BPG represent the views and opinions of their authors, and not the views, opinions or policies of the BPG, except where otherwise explicitly indicated.

### Biostatistical editing

Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Redit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc.* The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

### Conflict-of-interest statement

In the interests of transparency and to help reviewers assess any potential bias, *WJR* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indi-

cate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: [http://www.icmje.org/ethical\\_4conflicts.html](http://www.icmje.org/ethical_4conflicts.html).

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

### Statement of informed consent

Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

### Statement of human and animal rights

When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case

that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/esps/>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS ([http://www.wjgnet.com/1948-5204/g\\_info\\_20100312180518.htm](http://www.wjgnet.com/1948-5204/g_info_20100312180518.htm)) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [bpgooffice@wjgnet.com](mailto:bpgooffice@wjgnet.com), or by telephone: +86-10-85381891. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medi-

cine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-85381891 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

### Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/..."), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ), and CONCLUSION (no more than 26 words).

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Core tip

Please write a summary of less than 100 words to outline the most innovative and important arguments and core contents in your paper to attract readers.

### Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: [http://www.wjgnet.com/1948-5204/g\\_info\\_list.htm](http://www.wjgnet.com/1948-5204/g_info_list.htm).

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

# Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

# Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

# REFERENCES

## Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

## PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

## Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

## Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h; blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantities can be found at: [http://www.wjgnet.com/1948-5204/g\\_info\\_20100312183048.htm](http://www.wjgnet.com/1948-5204/g_info_20100312183048.htm).

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gylA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kbo I*, *Kpn I*, *etc.*

Biology: *H. pylori*, *E. coli*, *etc.*

**Examples for paper writing**

All types of articles' writing style and requirement will be found in the link: <http://www.wjgnet.com/esps/NavigationInfo.aspx?id=15>

**SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED**

Authors must revise their manuscript carefully according to the

revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system via the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to [esps@wjgnet.com](mailto:esps@wjgnet.com).

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from [http://www.wjgnet.com/1948-5204/g\\_info\\_20100312182928.htm](http://www.wjgnet.com/1948-5204/g_info_20100312182928.htm).

**Responses to reviewers**

Papers revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: [http://www.wjgnet.com/1948-5204/g\\_info\\_20100312182841.htm](http://www.wjgnet.com/1948-5204/g_info_20100312182841.htm).

**Proof of financial support**

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

**STATEMENT ABOUT ANONYMOUS PUBLICATION OF THE PEER REVIEWERS' COMMENTS**

In order to increase the quality of peer review, push authors to carefully revise their manuscripts based on the peer reviewers' comments, and promote academic interactions among peer reviewers, authors and readers, we decide to anonymously publish the reviewers' comments and author's responses at the same time the manuscript is published online.

**PUBLICATION FEE**

WJR is an international, peer-reviewed, OA online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium and format, provided the original work is properly cited. The use is non-commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. Publication fee: 698 USD per article. All invited articles are published free of charge.
