

Editorial Board Member of *World Journal of Medical Genetics*, Béla Melegh, MD, PhD, Professor, Department of Medical Genetics, University of Pecs, Pecs 7624, Hungary

World Journal of Medical Genetics (*World J Med Genet*, *WJMG*, online ISSN 2220-3184, DOI: 10.4236/wjmg.2018.81001)

WJMG covers topics concerning genes and the pathology of human disease, molecular analysis of simple and complex genetic traits, cancer genetics, epigenetics, gene therapy, developmental genetics, regulation of gene expression, strategies and technologies for extracting function from genomic data, pharmacological genomics, genome editing, and other topics. *WJMG* include editorial, frontier, diagnostic advances, original articles, case report, clinical case conference (Clinicopathological conference), and review.

We encourage authors to submit their manuscripts to *WJMG*.

Abstract

We present a patient with a history of colonic polyposis and family history significant for colon polyps and colorectal cancer (CRC). The patient and the family also had a history of bone loss of the jaw and early tooth loss, consistent with oligodontia. Genetic testing revealed the patient to have a previously unpublished variant of unknown significance (VUS) in the *AXIN2* gene. These clinical findings have been demonstrated previously in only two other families, both of which exhibited oligodontia, colorectal neoplasia (polyps and cancer) and a heterozygous mutation in *AXIN2*. The *AXIN2* protein is component of the Wnt pathway, which is known to be vital for organism development and cellular homeostasis. Alterations of the Wnt pathway lead to cell proliferation and neoplasm, in addition to agenesis of physical structures (such as teeth). The analysis of our pedigree further supports an association between colonic neoplasm (polyposis and CRC), the *AXIN2* gene in general, and this particular VUS. It also highlights the importance of analyzing and disseminating information on pedigrees with less commonly encountered genomic abnormalities so that genotypic-phenotypic correlations can be solidified.

Core tip: Biochemical research, murine models, and 2 prior human families lend support to a genotypic-phenotypic correlation between alterations in the AXIN2 and polyposis/colorectal cancer. Our paper uses genetic testing and pedigree analysis to include a third family. This information would impact future genetic testing, the classification of identified variants, and screening in those with identified AXIN2 mutations and variants.

INTRODUCTION

Concern for familial colorectal cancer (CRC) syndromes results in germline genetic testing and DNA changes are often classified as variants of unknown significance (VUS) in approximately 30% of testing. The International Society for Gastrointestinal Hereditary Tumours Database (InSiGHT, www.insight-group.org) that collects variants to support research and clinical management lists greater than 2000 different variants, which are thought to be a minuscule representation of the actual number that exist^[1]. When a VUS is identified, it is difficult to determine if it is responsible for the patient's phenotype. As more genetic testing is completed, the additional collected data can lead to variant reclassification. This expanding information results in a more definitive link to specific clinical syndromes. In this report we present a case of a patient and her family that supports a link between alterations of a gene and a phenotypic result of oligodontia and colonic neoplasm.

CASE REPORT

A 55-year-old woman, the proband, underwent screening colonoscopy revealing 12 tubular and tubulovillous adenomas, 0.5-1.8 cm in size. Her family history was notable for gastrointestinal neoplasms. Multiple colon polyps were discovered after routine screening in the patient's brother (in his 50s) and her father (age unknown). CRC was diagnosed in one of the patient's sisters (in her 40s) and in her paternal grandfather (in his 80s). The patient has 3 other siblings that have not undergone colonoscopy. The patient's mother had bile duct cancer (in her 60s) and a maternal cousin received an unknown cancer diagnosis (in her 20s). The patient, her father and her siblings all have bone loss of the jaw and early tooth loss, consistent with oligodontia. A pedigree is attached (Figure 1).

As per guidelines, germline genetic testing was

Figure 1 Pedigree of family indicating history of cancer, colon polyps, and oligodontia.

performed given the patient's history of > 10 adenomas and family history of colon polyps and cancer^[2]. Results demonstrated a heterozygote VUS [c.265C>A (p.Gln89Lys)] in the AXIN2 gene. This previously unpublished variant occurs at a position that has been conserved across species, but the effects of the glutamine to lysine substitution upon the resultant protein's structure and function are unclear. APC, MUTYH, MLH1, MSH2, MSH6, PMS2, tp53 and EPCAM sequencing revealed no abnormalities.

DISCUSSION

Familial adenomatous polyposis (FAP) and Lynch syndrome (LS), are the most commonly encountered familial CRC syndromes. Both of these conditions have been well described at the genetic level. FAP involves the adenomatous polyposis coli (APC) gene, which is classified as a tumor suppressor gene^[3]. Mutations in the APC gene lead to the phenotype of numerous benign adenomatous polyps that are capable of malignant transformation. LS is an autosomal dominant genetic condition that increases the risk of colon and other cancers through inherited mutations that impair DNA mismatch repair^[4]. Several genes have been implicated in LS, most frequently MSH2, MLH1, MSH6, PMS2 and case reports of others^[5,6]. Despite our knowledge of these and other well-described CRC syndromes, such as MUTYH polyposis, there are still cases where no genetic etiology is found, even when suspected. Leading to speculation that other syndromes and genes remain to be described^[7].

The germline and somatic mutations within the AXIN2 gene are believed to affect the beta-catenin-dependent Wnt pathway (Figure 2), which regulates cell differentiation during development and cellular homeostasis^[8]. The signal cascade begins when the Wnt protein binds to the Frizzled family receptor, a distinct family of G-protein coupled receptors^[9]. This leads to an increase of β -catenin in the cytoplasm of a cell and an eventual translocation into the nucleus, where it acts as a transcriptional co-activator of transcription factors that belong to the TCF/LEF family. The APC, AXIN1 and AXIN2 proteins are involved in the assembly of a

Figure 2 Wnt cell signaling pathway. Wnt: Wnt protein; Dsh: Disheveled phosphoprotein; APC: Adenomatous polyposis coli; GSK3: Glycogen synthase kinase 3; TCF: T-cell factor.

destruction complex that degrades beta-catenin and provide negative feedback regulation^[10].

When a mutation in the *AXIN2* gene occurs, the resulting transcribed mRNA transcribed is truncated, lacks a C-terminal domain and is guided to the degradation pathway^[11]. This alteration prevents AXIN2 from interacting with the other necessary proteins and providing the scaffolding for the destruction complex^[12]. Disruption of the destruction complex allows escape of beta catenin, increased transcription of *Wnt* target genes, and the development of colon polyps and CRC^[13].

In terms of prior pedigree analyses, two published reports of heterozygous germline mutations of *AXIN2* associated with CRC described premature stop codons within exon 7, in families missing numerous permanent teeth^[13,14]. One report was in a four generation Finnish family in which 11 members exhibited full penetrance of oligodontia^[13]. Seventeen members of the family underwent molecular analysis. All 11 family members with oligodontia had the same Arg6565Stop nonsense mutation, which was not present in the other 6 family members without oligodontia or in > 200 unrelated control individuals. Ten family members were surveyed with colonoscopy or sigmoidoscopy. Three family members without oligodontia had normal endoscopic evaluation. Of the 7 with oligodontia that underwent endoscopy, 6 had colorectal neoplasms ranging from polyposis to CRC. The second documented family also demonstrated high penetrance oligodontia along with other ectodermal dysplastic findings including absent eyebrows and sparse hair in several family members^[14]. Of the 5 family members with oligodontia, 4 underwent endoscopic surveillance that revealed gastrointestinal polyps (unknown number of polyps, 5 colonic adenomas, > 100 adenomas, and multiple fundic gland polyps with normal colonoscopy). All family members with abnormal endoscopy were found to have the same c.1989G>A mutation in the *AXIN2* DNA sequence. One family member without oligodontia had a normal colonoscopy,

no malignancies and no alterations of the *AXIN2* gene.

As there are only 2 reported pedigrees linking *AXIN2* with polyposis and CRC, the relationship between this gene and colonic neoplasia has not been correlated in a widespread fashion. The analysis of our pedigree further supports an association between colonic neoplasm (polyposis and CRC), the *AXIN2* gene in general and with this particular previously unreported VUS. In our pedigree, the fact that oligodontia was present in the patient's father and that the patient's sister with CRC did not share the same mother supports that the *AXIN2* VUS was paternal in origin. This is an important distinction as there is also a strong history of cancer in the maternal family line.

This report highlights the importance of analyzing and disseminating information on pedigrees so that genotypic-phenotypic correlations can be solidified. This is of particular consequence given the increased rates of germline genetic testing in populations and resultant identification of VUSs^[15]. *AXIN 2* is not a commonly tested gene in patients or families suspected of harboring a CRC syndrome. Hence, the true prevalence of *AXIN 2* abnormalities in potential syndromic families is unknown and there may be other phenotypic associations with the *AXIN 2* gene that are as of yet undiscovered. Further research to better understand the relationship between *AXIN 2* and colorectal neoplasia is required. As genetic panel testing becomes more common, it may be beneficial to include *AXIN 2* analysis, particularly in those that test negative for more common CRC syndromes.

ARTICLE HIGHLIGHTS

Case characteristics

A 55-year-old woman with 12 tubular and tubulovillous adenomas and significant family history of colon polyps and gastrointestinal neoplasms, including colorectal cancer (CRC).

Clinical diagnosis

Support for a familial polyposis/CRC familial syndrome based on genetic mutation of *AXIN2*.

Differential diagnosis

Familial polyposis/CRC familial syndrome from another mutation.

Laboratory diagnosis

AXIN2 gene variant on genetic testing.

Imaging diagnosis

Multiple polyps found on colonoscopy.

Pathological diagnosis

Twelve tubular and tubulovillous adenomas.

Treatment

Increased frequency of screening colonoscopies for the patient, her family members and possible genetic testing and counseling.

Related reports

Two other families with significant polyposis/CRC findings with *AXIN2* mutations.

Term explanation

Polyposis: 10 or more colonic polyps; Oligodontia: Congenital absence of 6 or more adult teeth.

Experiences and lessons

It will be important to categorize all genetic abnormalities to better understand their clinical significance.
