**ABOUT COVER**

Editorial Board Member of *World Journal of Clinical Cases*, Shu-Pin Huang, MD, Associate Professor, Attending Doctor, Director, Department of Urology, Kaohsiung Medical University, Kaohsiung 807, Taiwan

**AIMS AND SCOPE**

*World Journal of Clinical Cases* (*World J Clin Cases*, *WJCC*, online ISSN 2307-8960, DOI: 10.12998) is a peer-reviewed open access academic journal that aims to guide clinical practice and improve diagnostic and therapeutic skills of clinicians.

The primary task of *WJCC* is to rapidly publish high-quality Case Report, Clinical Management, Editorial, Field of Vision, Frontier, Medical Ethics, Original Articles, Meta-Analysis, Minireviews, and Review, in the fields of allergy, anesthesiology, cardiac medicine, clinical genetics, clinical neurology, critical care, dentistry, dermatology, emergency medicine, endocrinology, family medicine, gastroenterology and hepatology, etc.

**INDEXING/ABSTRACTING**

The *WJCC* is now indexed in PubMed, PubMed Central, Science Citation Index Expanded (also known as SciSearch®), and Journal Citation Reports/Science Edition. The 2019 Edition of Journal Citation Reports cites the 2018 impact factor for *WJCC* as 1.153 (5-year impact factor: N/A), ranking *WJCC* as 99 among 160 journals in Medicine, General and Internal (quartile in category Q3).

### Abstract

Inflammatory bowel diseases (IBDs) are characterized by a multifactorial partially unknown etiology that involves genetic, immunological and environmental factors. Up to 50% of IBD patients experience at least one extraintestinal manifestation; among them is the involvement of bone density which is referred to as metabolic bone disease (MBD), including osteopenia and osteoporosis. Bone alterations in IBDs population appear to have a multifactorial etiology: Decreased physical activity, inflammation-related bone resorption, multiple intestinal resections, dietary malabsorption of minerals and vitamin D deficiency, genetic factors, gut-bone immune signaling interaction, steroid treatment, microbiota and pathogenic micro-organisms interaction, and dietary malabsorption of minerals, that, all together or individually, may contribute to the alteration of bone mineral density. This review aims to summarize the prevalence and pathophysiology of metabolic bone alterations in IBD subjects outlining the main risk factors of bone fragility. We also want to underline the role of the screening and prophylaxis of bone alterations in Crohn's disease and ulcerative colitis patients and the importance of treating appropriately MBD.

## INTRODUCTION

Inflammatory bowel diseases (IBDs) are mainly represented by Crohn's disease (CD) and ulcerative colitis (UC), both characterized by a multifactorial, partially unknown etiology that involves genetic, immunological and environmental factors including intestinal microbiota<sup>[1]</sup>. A dysregulated immune response to an unknown trigger leading to a sustained pro-inflammatory response within the gastrointestinal (GI) tract seems to play a major pathogenic role. Also, 10%-40% of IBD patients may suffer from at least one extraintestinal manifestation (EIM)<sup>[2]</sup>, even before the occurrence of the intestinal disease<sup>[3]</sup>.

Among the most frequent EIMs, there are those affecting the musculoskeletal system and in particular the bone tissue, such as osteoporosis (OP)<sup>[4]</sup>.

OP is a systemic disease characterized by an increased risk of fractures even after a low energy trauma (fragility fracture). The reduction of bone strength is a consequence of a decrease in bone mineral density (BMD) and a deterioration in bone quality<sup>[5]</sup>. According to the World Health Organization the operational diagnosis of OP is based on BMD values equal or lower than 2.5 standard deviations (SD) from the average values for young healthy women (T-score < -2.5 SD) in post-menopausal women and men aged ≥ 50 years, while, osteopenia is defined by BMD values between -1 to -2.5 SD (T-score -1 < and > -2.5).

BMD is measured through dual-energy X-ray absorptiometry (DXA)<sup>[6,7]</sup>; T-score is a parameter comparing the BMD of a given patient with the average bone density of young healthy adults of the same sex, while, Z-score compares each BMD with the average BMD of a person with the same age and sex<sup>[8]</sup>.

OP is classified into two main groups: Primary (or idiopathic) and secondary. The first one is the most common and includes juvenile, postmenopausal and senile OP. Secondary OP might be caused by several conditions (*i.e.*, endocrine, hematological, GI, rheumatic or renal diseases) that negatively affect bone metabolism leading to poor bone strength. Other causes might be the chronic use of some medications, particularly glucocorticoids (GCs), anticoagulants, and anticonvulsants<sup>[9,10]</sup>. Therefore, the term "secondary OP" refers to all those clinical conditions in which the bone involvement is a consequence of the primary disease or results from the related treatments (*i.e.*, GCs). Secondary OP affects about 60% of males and more than 50% of premenopausal women<sup>[11,12]</sup>.

In IBD population, there are several pathological mechanisms that might result in low BMD and poor bone strength, thus leading to OP.

This review aims to summarize the prevalence and pathophysiology of metabolic bone alterations in IBD subjects outlining their main risk factors. We also underline the role of the screening and prophylaxis of BMD in CD and UC patients and the importance of early treatment.

## EPIDEMIOLOGY

OP is one of the most common noncommunicable diseases<sup>[13]</sup> and its incidence is increasing worldwide<sup>[14]</sup>. According to Svedbom *et al*<sup>[15]</sup>, 22 million women and 5.5 million men were estimated to have OP in Europe, with a reported incidence of 3.5 million new osteoporotic fractures in 2010, (620000 hip fractures, 520000 vertebral fractures, 560000 forearm fractures and 1800000 fractures in other skeletal sites). OP and its consequences (*i.e.*, fractures) carry a considerable economic burden on the health care systems<sup>[15]</sup> and, in particular, the socioeconomic costs of an osteoporotic hip fracture are equivalent to those of myocardial infarction and stroke<sup>[16]</sup>.

In IBD subjects, the prevalence of low BMD ranges from 22% to 77% and that of fragility fractures from 17% to 41%<sup>[17]</sup>. These wide ranges across different studies might be explained by the small number of samples and by the heterogeneity of the studies and of the populations.

Several studies have been performed to describe the relationship between IBD and bone alterations. Sheth *et al*<sup>[2]</sup> showed that both osteopenia and OP are frequently associated with IBD, ranging from 32% to 36% for osteopenia and from 7% to 15% for OP. The same study reported an increased relative risk of fragility fractures in CD patients and a prevalence of < 0.5% for osteonecrosis, a clinical condition characterized by the death of the bone tissue, commonly described as a complication of steroid therapy in IBD patients. A study of Boubaker *et al*<sup>[18]</sup> reported that in a Tunisian group of 67 patients, OP represented the most frequent EIM in CD patients with a prevalence of low BMD at hip and spine in 31.8% and 40.9% of cases, respectively. OP is strongly associated with CD in females, thus suggesting that female gender might be one of the risk factors for bone loss in IBD. A prospective study in Romania found osteopenia in 48.07% of UC patients and in 56.41% of CD patients, while OP was shown in 18.26% of UC patients and in 15.38% of CD patients<sup>[19]</sup>. A Swiss IBD cohort study performed on 877 patients showed a prevalence of bone density alteration in 20% of IBD patients and identified, by multivariate logistic regression analysis, corticosteroid usage, long disease duration and perianal disease as independent risk factors<sup>[4]</sup>. A Japanese study reported that two-thirds of IBD patients showed a loss of BMD, with a prevalence of OP of about 13% in their cohort of patients with mean age of 43 years. The prevalence of OP is more frequent in Western IBD population than in the Asiatic one<sup>[20]</sup> and, therefore, the prevalence of bone metabolism alterations generally varies depending on study population, location and design of the study performed.

Notably, the risk of fragility fractures seems to be increased in IBD population<sup>[21]</sup> although the literature shows controversial results. Recently, Komaki *et al*<sup>[22]</sup> showed that there was no increase in the risk of overall fractures in IBD patients, but they reported more fractures at the spine, associated with steroids therapy.

Pediatric IBDs seem to show a similar association with osteopenia and OP as in adults. In fact, it is known that children with IBD have a higher risk of low BMD<sup>[23]</sup>. The overall prevalence of osteopenia and OP in pediatric and young IBDs patients seems to vary from 20% to 50%<sup>[24]</sup>. A recent study suggested a positive association between BMD and physical activity and between low BMD and fractures in the childhood<sup>[25]</sup>. Incidence of fragility fractures is higher in the young IBD population and is likely to be associated to the use of GC<sup>[26,27]</sup>. Pediatric CD patients appear to be more severely compromised than those with UC, probably because CD inhibits linear growth more frequently than UC<sup>[28]</sup>.

CD and UC, while being both classified as IBDs, show considerable differences in the anatomic location and distribution of the intestinal lesions as well as in the underlying pathogenic mechanisms. This might have an influence on the incidence of bone alterations in each condition. Bjarnason *et al*<sup>[29]</sup> described no significant differences in T scores for spine or hip between patients with CD and those with UC. On the other side, in a study by Jahnsen *et al*<sup>[30]</sup>, BMD resulted significantly reduced in CD subjects at all measured sites compared with UC patients, and healthy subjects. Interestingly, the authors did not describe significant differences in BMD between UC and healthy subjects. Ardizzone *et al*<sup>[46]</sup>, in Italy, evaluated differences between CD and UC with respect to the pathogenic mechanisms underlying bone loss. Crohn's Disease Activity Index (CDAI)<sup>[31]</sup> and Truelove and Witts' Score<sup>[32]</sup> were used to grade disease activity of CD and UC, respectively. The distribution of normal, osteopenic and osteoporotic BMD values among CD and UC showed no significant differences also between patients with different disease activity. Also, in a study conducted in Sri-Lanka, there were no significant statistical differences in the frequency of OP between CD and UC, whereas the occurrence of OP among IBDs patients (13.5%) was higher than in healthy controls<sup>[33]</sup>. Recently, Vázquez *et al*<sup>[34]</sup> did not find any difference between patients with CD and those with UC regarding the prevalence of alterations of bone density.

The discrepancy between different studies may be due to variability in patient selection, differences in the methods used to evaluate bone density, and the body sites studied at DEXA (*i.e.*, radius *vs* lumbar spine or hip).

## PATHOPHYSIOLOGY

Both bone quality and quantity (BMD) depend on physiological mechanisms, such as bone modeling and remodeling that in turn are regulated by biochemical and mechanical factors, including osteoprotegerin (OPG), receptor activator of nuclear factor kappa-B ligand (RANKL), receptor activator of nuclear factor kappa-B (RANK), and weight bearing activities. In particular, the RANKL secreted by osteoblasts binds to the RANK receptor, located on pre-osteoclasts and mature osteoclasts, inducing osteoclast proliferation, activity and survival. OPG, a molecule secreted by osteoblasts, modulates bone turnover by inhibiting the binding of RANKL to RANK. The balance between OPG and RANKL release regulates osteoclast activity that in turn can be influenced by several hormones and cytokines, including vitamin D, estrogens, testosterone, GCs, parathormone (PTH), as well as pro-inflammatory mediators, such as interleukin-1 (IL-1) and tumor necrosis factor- $\alpha$  (TNF $\alpha$ ). In OP, an imbalance between the serum levels of OPG and RANKL occurs, with excessive bone resorption and impaired bone formation, with consequent overall reduction of bone mass<sup>[35]</sup>.

Other key modulators of bone turnover are the Wnt/ $\beta$ -catenin signaling and sclerostin, which acts mainly on osteoblasts and osteocytes. Sclerostin is a glycoprotein produced almost exclusively by osteocytes and its expression is influenced by many factors, including serum PTH and mechanical loading<sup>[36]</sup>. Animal studies have shown that the mechanical load reduces serum sclerostin, whereas unloading increases the transcription of *SOST*, the gene encoding for sclerostin. Once secreted, sclerostin through osteocyte canalicular system reaches the bone lining cells (capable of activation into mature osteoblasts), where it binds to specific co-receptors (LRP-5 and -6) to inhibit the Wnt pathway, with consequent reduction of osteoblastogenesis and bone formation. On the contrary, a reduction in sclerostin levels is associated with an activation of the Wnt/ $\beta$ -catenin pathway with subsequent enhancement of osteoblast activity and survival<sup>[37]</sup>. Moreover, there is a correlation between hypersclerostinemia and bone loss in subjects forced to prolonged immobilization, thus supporting the key role of sclerostin in the development of OP following reduced mechanical load<sup>[38]</sup>.

Among the most frequent secondary forms of OP, GCs use has been shown to decrease the number of osteoblast precursors and to increase the apoptosis of mature osteoblasts. The reduction in osteoblast differentiation is in partly mediated by the inhibition of the Wnt/ $\beta$ -catenin pathway along with increased expression of sclerostin, that antagonizes the Wnt signaling<sup>[39]</sup>. On the other hand, GCs decrease also osteoclast proliferation, although their activity tends to increase, through both the increase in RANKL and the reduction of OPG levels<sup>[40]</sup>. During GCs therapy, bone loss occurs rapidly with BMD reduction of 6%-12% within the first year, followed by a constant and gradual loss throughout the treatment period<sup>[41]</sup>. These two pathways are the basis of the most modern pharmacological approaches to OP: A human monoclonal antibody against the RANKL (denosumab) and a humanized monoclonal antibody that targets sclerostin (romosozumab).

Among the most frequent causes of secondary OP there are GI disorders, including IBDs. Chronic gut inflammation in IBD may contribute to OP through the activation of T lymphocytes resulting in enhanced release of inflammatory cytokines, such as TNF $\alpha$ , that modulates the OPG/RANKL/RANK pathway thus inducing bone loss<sup>[42]</sup> (Figure 1). Moreover, TNF $\alpha$  enhances sclerostin production that results in decreased bone formation. Interestingly, in patients affected by CD, bone loss occurs before GCs administration, supporting the detrimental role of systemic inflammation on bone health<sup>[43]</sup>.

There is a close relationship between bone and GI system that allows calcium absorption and bone mineralization; the GI tract may communicate with bone tissue through different mechanisms such as blood, nerves and immune cells, defining a characteristic gut-to-bone signaling axis that involves also incretins, serotonin and GI microbiota<sup>[44]</sup> (Figure 2).

Although in the general population female sex, early menopause, hormonal imbalance, smoke and old age are the main risk factors correlated with the onset of metabolic bone disease (MBD), in IBD patients the main risk factor seems to be the prolonged use of GCs<sup>[45,46]</sup>. Activity and severity of gut inflammation, intestinal malabsorption and calcium and vitamin D deficiency are also directly involved in the loss of BMD<sup>[47,48]</sup>. In particular, in CD the involvement of the terminal ileum may affect

**Figure 1** Modulation of osteoclast differentiation by serum TNF- $\alpha$  and anti-TNF- $\alpha$  treatment. A: TNF- $\alpha$  influences osteoclast precursor differentiation and bone resorption activity inducing RANKL expression on osteoblast cells and preventing the binding of OPG; B: Anti-TNF- $\alpha$  treatment reduces RANKL expression resulting in decrease of osteoclast differentiation and bone resorption.

the bile salt enterohepatic circulation thus leading to a reduced absorption of vitamin D. Chronic inflammation seems to have a key role in the reduction of BMD as suggested in some studies that show that rat models with colitis have a drastic loss of trabecular bone and a suppression of bone formation. At resolution of colitis with mucosal healing, the bone formation regresses to normal levels. During gut inflammation some mediators that alter the deposition of new bone matrix mediated by osteoblasts are produced, such as IL-6 and RANKL<sup>[49]</sup>.

Untreated inflammation may be the main determinant for the loss of BMD in IBDs. In fact, a study by Ghosh *et al*<sup>[43]</sup> showed that CD patients have very low T-scores at the diagnosis before any drug therapy. Several studies in last years have also demonstrated that the usage of anti-TNF agents seems to have a positive effect on BMD<sup>[50]</sup> (see below). Recent studies suggest a role for the inflammatory process in the alteration of bone metabolism through the involvement of immune system cells, however it is not clear whether the inflammation is directly involved in the loss of BMD or if other factors contribute to the decline of BMD in IBD patients.

Bone alterations in IBD population appear to have a multifactorial etiology: Genetic factors, gut-bone immune signaling interaction, inflammation-related bone resorption, multiple intestinal resections, microbiota and pathogenic micro-organisms interaction, and dietary malabsorption of minerals<sup>[51,52]</sup> (Figure 2).

However, the main factor that seems to directly affect bone metabolism, with consequent reduction in BMD values, is corticosteroid treatment. In the following paragraphs we will summarize the evidence linking these factors to BMD deterioration in IBD patients.

### Main risk factors

**Genetic factors:** The literature concerning the genetic predisposition to OP in IBD patients appears rather contradictory. A number of polymorphic sites apparently associated with the increased risk of bone loss in IBD patients such as *IL-6* and *IL-1ra* have already been described<sup>[53]</sup>. Todhunter *et al*<sup>[54]</sup> showed that the polymorphisms

**Figure 2** Gut-bone immune signaling: interplay between different factors which may affect bone metabolism in patients with inflammatory bowel diseases.

identified in some genes such as *COL1A1* and *IL-6* seems to influence BMD in IBD patients, particularly those with CD. Nemetz *et al*<sup>[55]</sup> showed also an increased risk of bone loss in patients with *IL1B* polymorphism (*IL1B*-511\*2) associated with hypersecretion of *IL1B*.

One of the latest genetic factors associated with OP development is OPG encoded by the gene *TNFRSF11B*, where the polymorphism c.-223C>T in 5' UTR region was identified as strongly related to OP in postmenopausal women. However, the genotyping analysis did not show unequivocal association between c.-223C>T of *TNFRSF11B* and a predisposition to OP in IBD patients, although this polymorphism is more frequent in IBD patients than in healthy controls<sup>[56]</sup>. Krela-Kaźmierczak *et al*<sup>[56]</sup> studied the relationship between different polymorphic variants of *TGFB1* and bone loss in IBD, finding no significant differences in BMD values or in the risk of fragility fractures between UC and CD patients and healthy controls with different polymorphic variants of the *TGFB1* gene. Moreover, no association between the 29T>C polymorphic variant of *TGFB1* and BMD of spongy bone and cortical bones was found<sup>[57]</sup>.

The gene encoding for bone morphogenetic protein 2 (BMP2) was analyzed using restriction fragments length polymorphisms (RFLPs) to determine the association among the incidence of 570 A>T polymorphism, BMD alterations, and the incidence of fractures in IBD patients. The analysis revealed no significant association between this polymorphism and changes in bone metabolism in both UC and CD patients<sup>[58]</sup>.

An interesting and recent theory correlates the presence of genetic alterations that might affect the ability to respond to endoplasmic reticulum (ER) stress and normal bone tissue physiology in IBD patients. A recent meta-analysis focused on the association between the genes involved in the response to unfolded proteins (UPR) and ER stress, which could directly correlate with the pathogenesis of IBDs<sup>[59]</sup>. It was suggested that the same defects in the Paneth cells inherent in UPR may also be present in bone cells, both osteoblasts and osteoclasts (although this has not yet been confirmed in IBD)<sup>[60]</sup>. Although its polymorphic variant seems to have no direct association with BMD, BMP2 activates the UPR during osteogenesis<sup>[61]</sup> allowing the production of RANKL<sup>[62]</sup>. In conclusion, during osteoblast differentiation ER stress is induced and activates also the PERK-eIF2 $\alpha$ -ATF4 pathway that appears as a potential target against bone diseases<sup>[61]</sup>. To date, the association between genetic factors and bone alterations in IBD patients is not clear and other risk factors must be taken into account, such as those related to nutrition and lifestyle, as well as the ethno-demographic characteristics.

**Gut-bone immune signaling:** Bone structure depends on the balance between osteoblasts activity, specialized in the deposition of new bone matrix and osteoclasts, responsible for the resorption of bone tissue. Mounting evidence suggests an immunological involvement in the alteration of bone metabolism<sup>[63]</sup>. Activated CD4+ cells appear to be important actors in the bone loss related to IBD. In fact, in mice models, bone marrow CD4+ cells producing IL-17 and TNF- $\alpha$  migrate into the bone marrow during the inflammation, promoting the recruitment of monocytes as osteoclast progenitors, thus contributing to the bone loss<sup>[64]</sup>. Ashcroft *et al*<sup>[65]</sup> reported that activated T cells, producing RANKL, are accumulated in the bone marrow during intestinal inflammation.

As already discussed, osteoclastogenesis is guided by the RANK-RANKL pathway and by the RANKL/OPG ratio. OPG produced by osteoblasts works as a decoy receptor for RANKL, thus interfering with osteoclast activation. Li *et al*<sup>[66]</sup> suggested that lymphocytes might work as key regulators of bone metabolism by interfering with this pathway. In particular, they found that over 60% of OPG is produced by B lymphocytes and that T lymphocytes stimulate OPG production by osteoblasts via CD40L/CD40 co-stimulation. Finally, they showed that B-cells as well as CD40 or CD40L knockout mice developed OP and OPG deficiency<sup>[66]</sup>.

Current knowledge strongly suggests a dynamic interplay between skeletal and immune system which is referred to as osteoimmunology. IL-17-producing helper T cells [T(H)17] induce RANKL, stimulating osteoclastogenesis through nuclear factor of activated T cells cytoplasmic 1 (NFATc1)<sup>[67]</sup>. There is evidence of activation of NFAT2 in lamina propria mononuclear cells of subjects with UC<sup>[68]</sup>.

All these studies seem to show, in IBD, a direct involvement of immune system in the bone loss, mainly due to CD4+ cells that appear osteoclastogenic during inflammation.

**Microbiota and pathogenic micro-organisms:** The human microbiota consists of a set of about 100 trillion of commensal micro-organisms belonging to different species, which express a genome of about a hundred times greater than that expressed by the host's cells. There is evidence that alterations of the microbiota composition influence the healthy state of the host<sup>[69]</sup>.

In particular, an immune response to an altered intestinal microbiota or an alteration of the immune response leading to its activation in the face of a normal intestinal microbiota both leading to a sustained inflammatory process, have been suggested as the main pathogenic mechanisms for the development of IBD<sup>[70]</sup>.

Several studies suggest a key role for microbiota in the alteration of BMD. Irwin *et al*<sup>[71]</sup> reported a close correlation between *H. hepaticus* infection and bone loss. McCabe *et al*<sup>[72]</sup> showed that treating healthy male mice with *Lactobacillus reuteri* enhanced bone density and suppressed basal TNF $\alpha$  mRNA levels in male mice, but not in females. They also showed that probiotics increased male trabecular bone parameters, as mineral density in the distal femur metaphyseal region as well as in the lumbar vertebrae and increased osteoblast serum markers in male mice, although no effect on bone parameters in females was found<sup>[72]</sup>. Furthermore, Schepper *et al*<sup>[73]</sup> investigated the effect of antibiotic treatment on gut and bone health in mice models. They found an increase in the Firmicutes/Bacteroidetes ratio, in the intestinal permeability, and a reduction of femoral trabecular bone volume. Treating the mice with *L. reuteri* reduced the post-antibiotic elevation of the Firmicutes/Bacteroidetes ratio and prevented bone loss. Antibiotic-induced dysbiosis was associated with decreased osteoblast and increased osteoclast activities<sup>[73]</sup>.

Recently, Naser *et al*<sup>[74]</sup> showed that the inflammation associated to *Mycobacterium avium subspecies paratuberculosis* (MAP) infection results in elevation of under-carboxylated osteocalcin (ucOC) and downregulation of active osteocalcin (OC) in CD patients. This suggest that MAP infection may serve as a trigger factor in the development of OP in CD patients.

**Nutrition and vitamin deficiency:** Nutritional alterations and vitamins or minerals deficiency due to inadequate diet intake and/or malabsorption correlate with a low BMD and may contribute to the development of osteopenia and OP both in UC and CD patients. Lim *et al*<sup>[75]</sup> assessed the nutritional status of 41 IBD patients with or without malnutrition and showed significantly higher serum C-reactive protein (CRP) and lower serum calcium in the malnourished group. No significant differences between malnourished and normal group were found as to BMD although lower bone density was more frequent in malnourished group. Also, Azzopardi *et al*<sup>[47]</sup> found a significant correlation between body mass index (BMI) and BMD of IBD patients<sup>[76]</sup>.

Many studies measured calcium daily intake in IBD patients. Silvennoinen *et al*<sup>[77]</sup> assessed calcium intake and measured BMD in IBD patients and controls. They found

that, although the daily intake of calcium was lower in IBD subjects than in controls, especially in male patients, there was no significant correlations between calcium deficiency and BMD<sup>[77]</sup>. Vernia *et al.*<sup>[78]</sup> analyzed by means of a questionnaire the dietary calcium intake in 187 IBD patients. They confirmed that calcium intake is frequently lower in IBD patients; moreover, most of the patients adopted some arbitrary dietary restrictions (*i.e.*, avoidance of milk or dairy products) which increased the risk of OP<sup>[78]</sup>. Calcium supplements as well as vitamin D administration showed an improvement of BMD at lumbar spine in osteoporotic patients with IBD. On the contrary, fluoride supplementation does not seem to provide any benefit to IBD patients<sup>[79]</sup>.

Vitamin D has systemic functions; it acts on regulation of the innate and adaptive immune responses and modulates calcium homeostasis involved in bone metabolism. In IBD patients a vitamin D deficiency negatively affects the immune system inducing dysregulation and inflammation-associated loss of BMD<sup>[80]</sup>. Vitamin D deficiency is more frequent in IBD patients than in the general population<sup>[81]</sup>. Del Pinto *et al.*<sup>[82]</sup>, in a meta-analysis involving 14 studies, with 938 IBD patients and 953 controls, showed that 64% of IBD patients had lower vitamin D serum levels than controls. Interestingly, UC appeared to be associated with more than double the odds of vitamin D deficiency compared to healthy controls. A recent study, aimed at evaluating the absorption of orally administered vitamin D in CD patients compared with healthy controls, showed a great variability in the bioavailability of vitamin D(2) in CD patients although no significant differences between patients with different location of disease or among those with or without previous surgery were found. Moreover, 24 h after an oral load of vitamin D(2), the authors reported that the ability of absorption in CD patients was on average 30% lower than in normal subjects ( $P < 0.001$ )<sup>[83]</sup>. Based on most of the studies, it seems reasonable that measurement of serum vitamin D levels should be included in the follow up of IBD patients both adults and children. In fact, in pediatric IBD patients a vitamin D deficiency may enhance the odds of developing osteopenia or OP<sup>[84]</sup>.

IBD patients might also have a reduced absorption of vitamin K, especially CD patients with an involvement of distal ileum. Besides playing a major role in coagulation processes vitamin K prevents bone resorption, inhibiting the production of prostaglandin E2 by osteoclasts, so its deficiency may affect BMD, as reported in both adults and pediatric patients<sup>[80]</sup>. However, the role of vitamin K in bone metabolism is controversial and the routine supplementation is not widely accepted yet<sup>[85]</sup>.

**Glucocorticoid therapy:** A major risk factor associated to bone metabolism alterations in IBD patients is GC therapy, which in several occasions is administered without additional vitamin D or calcium supplementation<sup>[4]</sup>. GCs are still largely used in IBD patients with moderate or severe disease<sup>[85]</sup>. GC therapy causes a biphasic bone loss, firstly with a rapid decrease of BMD of about 6% to 12% in the first year, and after, with an annual loss of about 3% for as long as the therapy is administered<sup>[87]</sup> associated with an increase of the fracture risk in the first 3 mo, which can reach a percentage as high as 75%. The fracture risk then decreases in the first 3 mo after GC withdrawal, before any significant improvement in BMD values<sup>[88]</sup>. GCs cause a reduction in the cortical thickness and an increased cortical porosity in mice models, associated with increased osteoclast number at the endocortical surface. Osteoclast formation in trabecular bone depends on the production of RANKL by osteocytes as well as by the increase in cortical bone resorption induced by mechanical unloading or by dietary calcium deficiency. *In vitro* models showed that GC therapy directly increases the production of RANKL and reduces OPG expression levels in stromal cells and osteoblasts<sup>[89]</sup>. Also, Hofbauer *et al.*<sup>[90]</sup> reported that RANKL inhibition prevented GC-induced bone loss.

Piemontese *et al.*<sup>[91]</sup> examined the effects of prednisolone on cortical bone in mice lacking RANKL production in osteocytes. Prednisolone increased osteoclast number at the endocortical surface, increased cortical porosity, and reduced cortical thickness in control mice, but none of these effects were found in mice lacking RANKL in osteocytes. Moreover, in cortical bone organ cultures and primary osteoblasts, dexamethasone suppressed OPG without any variation of RANKL levels. Therefore, based on these observations, OPG, rather than RANKL, seems to play a major role in the endocortical resorption.

OPG-mediated bone loss prevention acts through the inhibition of RANK-RANKL pathway and reduction of osteocytes apoptosis, induced by GCs. Weinstein *et al.*<sup>[41]</sup>, both *in vivo* and *in vitro*, studied the effect of OPG administration, with or without the fragment crystallizable region of Ig heavy chains (OPG-Fc), on the bone loss and on the apoptosis of osteocytes, with or without GCs administration. They showed that in mice treated with prednisolone combined with OPG-Fc or only with OPG-Fc there

was a decreased expression of both receptors of cathepsin K and OC, which are markers of osteoclast number. Moreover, OPG-Fc administration preserved the BMD at spine compared with animals who received only prednisolone. The authors also reported an increase of vertebral strength of about 29% in mice receiving OPG-Fc compared to those receiving OPG-Fc combined with prednisone. Finally, OPG-Fc administration, alone or combined with prednisolone, decreased the number of osteoclasts of about 7% and 5% respectively, compared with placebo group. Prednisolone also induced an increase of the osteocytes apoptosis of about 335%, which was prevented by OPG-Fc administration. This supports the concept that OPG administration may prevent the reduction of BMD, of vertebral cortical thickness, and of osteocytes viability induced by GCs<sup>[41]</sup>.

In conclusion, GC therapy is a major determinant of bone mass alteration in IBD patients. New generation GCs, such as budesonide or beclometasone, which show a very efficient hepatic first pass metabolism may represent a valid alternative to conventional GCs in order to try to minimize GC detrimental effect in general and on bone structure in particular<sup>[92,93]</sup>.

## DISEASE SEVERITY/ACTIVITY AND BONE MINERAL DENSITY

Calcium is an essential ion for bone formation and its only source is diet. The absorption of dietary calcium is a vitamin D-dependent process<sup>[94]</sup>. In the distal part of the intestine, 70%-80% of the ingested calcium is absorbed (mostly in the ileum)<sup>[95]</sup> through the action of Vitamin D receptor which is expressed in all segments of the small and large intestine with the highest levels reported in the cecum and colon. In patients with extensive intestinal resection, calcium absorption has been reported to be significantly higher when the colon is preserved<sup>[96]</sup>. In IBD, different segments of the intestine may be involved by the inflammatory process and the subsequent alterations of the absorptive processes have been suggested to be an important determinant of bone loss<sup>[97,98]</sup>. Several studies evaluated the correlation between disease extension or activity according to the Montreal classification for IBD<sup>[99]</sup> and BMD. In 1997, Bjarnason *et al.*<sup>[29]</sup> reported that there were no significant differences in T scores for spine or hip within the patient subgroups according to disease location. Also, Jahnsen *et al.*<sup>[30]</sup> assessed BMD in 60 patients with CD in 60 patients with UC and in 60 healthy subjects. Patients with CD had similar BMD, independently on whether the colon or the small intestine was involved. Furthermore, no differences were described between patients with CD with or without small bowel resection. In addition, no correlations between the length of small bowel resected and BMD were found. Finally, in the UC patients there was no influence of disease location and extension on BMD. More recently, the same results have been described by Vázquez *et al.*<sup>[34]</sup> on 107 patients with IBDs (53 with CD and 54 with UC) with different location of the disease. The extension and the location of the disease did not seem to influence BMD loss or vertebral fractures prevalence. In a study conducted in 99 consecutive CD outpatients, Cravo *et al.*<sup>[100]</sup> assessed disease activity by Harvey-Bradshaw Index (HBI). With a multivariate analysis, they described a direct and significant association between age (above 40 years), chronic active disease (HBI 4), previous colonic surgeries and the presence of OP. Both small bowel and colonic resection were similarly associated to OP. This might be explained by the major impact of inflammation due to disease severity in respect to the reduction of mineral absorption induced by short bowel syndrome, as initially hypothesized. Moreover, to support the role of chronic inflammation in the pathogenesis of bone loss, patients with active disease (HBI > 4) and those with a penetrating or structuring disease, which are usually more aggressive phenotypes, were also those with the highest rate of OP.

More recently, Lima *et al.*<sup>[101]</sup> evaluated the correlation between disease severity and BMD in 68 patients with UC and 60 with CD of 17-40 years of age. About half CD patients had an ileocolonic disease (53.3%) while 29 subjects (48.3%) had non-stricturing non-penetrating disease and 33.3% had perianal disease, according to Montreal classification. In the UC group, 29 patients (44.6%) had extensive UC according to the Montreal classification<sup>[99]</sup>. The authors described a higher incidence of osteopenia in UC and CD patients than controls (OR = 14.93/OR = 24.38, respectively). At multivariate analysis in CD group, low BMD was associated with sex (M > F), perianal disease, penetrating behavior and age at diagnosis > 40 years, while, no association was described between BMD and disease activity. In the UC group, low BMD was significantly associated to sex (M > F) and left colitis. Therefore, disease activity does not seem to be a major determinant of bone density alteration in CD and UC patients, while disease severity seems to be associated with osteopenia in IBD

patients. It must be emphasized that only 0.02% of UC patients and 0.26% of CD patients had active disease at the time DEXA was performed, and, therefore, the remission of the disease might have been associated with an increase in BMD.

## TNF-/ANTI-TNF- THERAPY AND BONE DENSITY ALTERATIONS

IBD is an immune-mediated inflammatory condition characterized by activation of different inflammatory pathways and abnormal secretion of different cytokines such as TNF- $\alpha$ <sup>[102]</sup>.

Anti-TNF- $\alpha$  is the first available biologic therapy for IBD and, currently, its effects on BMD are not known. Moreover, it is not clear whether the effects of anti-TNF $\alpha$  agents on bone health are the consequence of a direct interference with the process of bone modeling or if these effects are simply due to a decreased disease activity and subsequent improvement of mineral absorption.

As previously mentioned, two members of TNF superfamily, RANKL OPG, are the key regulators of bone remodeling. RANKL, derived by osteoblasts, stimulates formation of mature osteoclasts while OPG, produced by osteoblasts, is a competitor that inhibits the interaction between RANKL and its receptor<sup>[103]</sup>. TNF- $\alpha$  is a main actor of osteoclastogenesis by inducing activation of NF- $\kappa$  B transcription and, also, reducing bone formation through the inhibition of osteoblast differentiation<sup>[104]</sup>. Moreover, it increases the survival of osteoclasts by protecting them against apoptosis<sup>[105]</sup> while it induces apoptosis of osteoblasts to reduce bone formation<sup>[106]</sup>. Therefore, TNF- $\alpha$  not only plays a central role in the pathogenesis of IBD but is also involved in bone metabolism, promoting bone resorption through regulation of osteoclast activity (Figure 1). As described by Azuma *et al*<sup>[107]</sup>, TNF- $\alpha$  directly induces the differentiation of osteoclast progenitors into mature osteoclast playing an important role in local osteolysis in chronic inflammatory diseases. Based on this, many studies have evaluated the effect of infliximab, a chimeric (*i.e.*, half human and half murine) anti-TNF agent, on bone metabolism investigating serum bone marker, BMD or incidence of bone fractures. Only one study assessed the impact of adalimumab, another all human anti-TNF agent, on bone metabolism. In a Belgian study<sup>[108]</sup>, authors evaluated markers of bone formation and resorption at eight weeks from the beginning of infliximab therapy in comparison with healthy controls. In their cohort, regardless of patients' clinical response, anti-TNF- $\alpha$  increased bone formation and, in the majority of patients, strongly decreased bone resorption. In a one year follow up study<sup>[109]</sup>, after starting therapy, the mean BMD resulted to be increased significantly in CD patients without any correlation with concurrent corticosteroid therapy. So, the authors suggested that amongst the factors inducing bone loss in CD, the inflammatory disease process might be predominant over the effects of treatment with prednisone. This might be especially relevant in CD patients who need to continue steroid therapy despite concurrent immunomodulatory therapy.

In 24 patients with active CD treated with infliximab, Ryan *et al*<sup>[110]</sup> described a significant increase of bone alkaline phosphatase, a marker of bone formation, and OC, a bone specific calcium-binding protein produced by osteoblasts, which persisted up to 4 wk after the end of treatment. As underlined by other authors, the benefits occurred independently of the clinical response of CD to biological treatment. On the other side, Miheller *et al*<sup>[111]</sup> dosed serum OC and CrossLaps (bCL), a degradation product of collagen, in 27 patients with fistulizing CD treated with anti-TNF- $\alpha$ . In the group of patients who responded to therapy, but not in those who did not, serum bCL concentrations were significantly decreased from week 0 to week 6, while a statistically significant increase was described for OC, thus suggesting that the beneficial effect of anti-TNF therapy was related to the amelioration of the underlying inflammatory process.

More recently, a 7-year follow-up longitudinal prospective cohort study by Maldonado-Pérez *et al*<sup>[112]</sup> evaluated the role of anti-TNF- $\alpha$  in decreasing fracture risk or modifying BMD in IBD patients. The authors described no difference in the incidence of vertebral fracture and value of bone mass between the group of patients treated with anti-TNF- $\alpha$  and the control group which did not receive biological treatment. Despite the biological-treated patients had received GC therapy for a longer period of time compared to the control group, new fractures were more common and more severe in the control, nonbiological-treated group. After 7 years of follow-up, bone mass increased significantly in the spine and in the femoral neck in patients treated with anti-TNF- $\alpha$ , compared to subjects who did not receive biological therapy.

Only one study<sup>[113]</sup> evaluated the impact of adalimumab therapy on bone

metabolism. Parathyroid hormone, vitamin D, bone formation and resorption marker, pro- and anti-inflammatory OPG, and sRANKL were measured in healthy controls and in CD patients pre- and post-treatment with adalimumab. Moreover, viability and differentiation of human osteoblasts (hFOB 1.19) cells after exposure to sera from CD patients pre- and post-adalimumab treatment was also analyzed. Following adalimumab therapy, a rapid increase in bone formation markers (OC and procollagen type 1 N-terminal pro-peptide) and a not significant decrease of a bone resorption marker (C-telopeptide of type-1 collagen) were observed. In the *in vitro* study, osteoblasts exposed to sera of CD patients before adalimumab therapy showed consistently higher levels of viability and lower levels of ALP compared to control group suggesting a greater viability of osteoblasts associated to a lower osteoblast function likely due to an inflammatory-driven response. After treatment, serum of CD patients induced higher levels of ALP in hFOB cells probably due to an improvement of their functionality.

In conclusion, anti-TNF seems to improve BMD in IBD patients both through a direct beneficial effect on bone metabolism and through the improvement in the underlying intestinal inflammatory process. Whether other biologic agents now available for the treatment of IBD, such as vedolizumab or ustekinumab, have any effect on bone metabolism needs to be determined.

## DIAGNOSIS OF OSTEOPOROSIS

Diagnosis of OP should be based on patient clinical history, physical examination, BMD measurements, and laboratory investigations<sup>[17]</sup>. In particular, because changes in bone metabolism are frequently associated with the evolution of IBD and may have a negative impact on the patient's quality of life, assessment of BMD in all IBD patients is essential to prevent and treat appropriately MBDs. The gold standard for its assessment is DXA. Changes in BMD values are key determinants to evaluate treatment efficacy at follow-up. Moreover, FRAX algorithm by combining all the fracture risks with the hip BMD value can quantify the 10-year risk of experiencing a fragility fracture<sup>[114]</sup>. Laboratory tests are necessary not only to exclude secondary forms of OP but also for the bone metabolism assessment. They should include biochemical markers of bone turnover and vitamin D status that might provide additional information regarding the patient fracture risk.

Moreover, increase in the incidence of BMD loss supports the recommendation to screen patients with IBD at an early stage of the disease. Screening recommendation of European Crohn and Colitis Organization (ECCO)<sup>[115]</sup> does not differ from those for the general population. It considers risk factors such as postmenopausal state, ongoing corticosteroid treatment, cumulative corticosteroid use > 3 mo, history of low-trauma fracture and age. Moreover, annual DXA scans is recommended in patients receiving long-term steroid therapy (in particular when there are others risk factors) if the T-score approaches the threshold for treatment with bisphosphonates (BPs) (T-score < -1.5 SD)<sup>[116]</sup>.

## THE PHARMACOLOGICAL MANAGEMENT OF OP

The aim of the management of OP is to reduce the risk of fragility fractures in individuals at high-risk. Therefore, pharmacological intervention thresholds should be based on the assessment of this risk deriving from the integration of densitometric data with other important clinical factors as determined by the FRAX<sup>[116]</sup>. Approved pharmacological treatments for the management of OP can be classified into two categories: anti-resorption (or anti-catabolic) and anabolic drugs. Among anti-catabolic drugs, bisphosphonates (BPs) blocking the osteoclastic activity, manage to reduce the bone remodeling process with a consequent increase in bone density. Alendronate and risedronate are the most commonly used for the prevention of vertebral and non-vertebral fractures (including hip) based on strong scientific evidence of efficacy<sup>[117]</sup>. However, they have reduced compliance and persistence to prolonged therapy, due to daily or weekly administration regimens and possible gastro-intestinal adverse events. Zoledronic acid is a BP intravenously administered with documented efficacy in reducing the risk of vertebral, non-vertebral and hip fractures<sup>[117]</sup>. A meta-analysis of studies on BPs use in IBD patients showed that these drugs are effective in case of low BMD reducing the risk of vertebral but not of non-vertebral fracture<sup>[118]</sup>; so, the use of BPs should be recommended for fracture prevention in IBD patients taking always into account the possible adverse effects of treatment.

A powerful inhibitor of bone resorption is denosumab, a human monoclonal antibody capable of neutralizing RANKL, a cytokine that interacts with the RANK receptor on the membrane of preosteoclasts and mature osteoclasts, affecting their recruitment, maturation and survival. A dose of 60 mg subcutaneously every 6 months is sufficient to strongly inhibit osteoclastic activity and to reduce the risk of vertebral and non-vertebral fractures (including hip). Unlike BPs, discontinuation of denosumab is followed by a sharp increase in bone turnover and a rapid loss of BMD. Therefore, discontinuation of denosumab generally requires the patient to initiate BPs treatment at an appropriate dosage as soon as possible<sup>[19]</sup>.

Among anabolic drugs, teriparatide, the active fragment of PTH (1-34 PTH) is the most widely used. It can stimulate both bone formation and resorption, with a predominant effect on the neoformation (anabolic window) which is evident above all during the first 12 mo of treatment. It is generally used as a second line anti-osteoporotic drug in case of intolerance or resistance to other anti-resorption agents and as first choice in case of severe OP in patients with multiple fragility fractures<sup>[17]</sup>.

All clinical guidelines agree that the pharmacological therapy of OP, independently of the prescribed treatment, should always be supplemented by the administration of vitamin D and, in case of nutritional deficient intake, of calcium<sup>[20]</sup>.

ECCO guidelines<sup>[15]</sup> suggest, some recommendations concerning the management of bone alterations in IBD population (Table 1).

## CONCLUSION

The prevalence of OP and/or fragility fractures in IBD patients is controversial because of different factors, such as different study population and study design, and location of the disease. Moreover, some aspects still need to be clarified, particularly the correlation between the increased risk of fragility fractures in subjects affected by IBD.

Changes in bone metabolism are frequently associated with the evolution of IBD and may have a negative impact on the patient's quality of life.

In this context, even understanding the pathophysiological milieu seems to be quite challenging. For example, the genetic background predisposing to the development of osteopenia and OP, specific for IBD patients, since the strongly multifactorial nature of these diseases, does not allow to evaluate its pathogenic role without considering other factors, such as nutrition, lifestyle, or more simply, pharmacological therapy for IBD. On the other side, increasing evidence suggests a gut-bone signaling pathway, which is responsible for a close cross-talk between the musculoskeletal and the GI system, and whose alteration may potentially correlate with the evolution of this type of EIMs. Furthermore, because of the emerging role of intestinal microbiota in the pathogenesis of IBDs, a direct impact of dysbiotic commensal microflora on bone metabolism, as shown in the healthy population, seems to be possible. A schematic diagram summarizing the pathophysiologic mechanism, including molecular mechanisms, underlying BMD alteration in IBD patients is shown in Figure 3.

The nutritional aspects, always considered among the main factors capable of triggering bone alterations, appear once again crucial, especially regarding the intake of calcium and vitamin D, the lack of which, both in adults and children, shows a direct correlation with the increased probability of developing bone fragility, specifically linked to osteoporomalacic findings. For this reason, it is important to include the evaluation of serum vitamin D levels and of nutritional status in IBD patients, both in active phase and remission of disease, in order to avoid the establishment of malnutrition that may increase the onset of comorbidity.

Pharmacotherapy of IBD might play a major role in bone metabolism. GCs are the main determinants of bone alterations and their prolonged use is associated with OP, osteopenia and increased risk of fractures. Therefore, their use should be limited and, whenever possible, new generation corticosteroids with a safer profile should be used. Finally, anti-TNF agents seem to improve bone health in IBD patients both by directly interfering with the metabolic pathways involved in bone modeling and by decreasing the disease activity and severity. Whether new biologic agents exert any beneficial effect on bone tissue in IBD patients remains to be determined.

Finally, and more important, a thorough evaluation of bone metabolism including serological markers should be part of the follow-up of IBD patients in order to prevent and/or promptly treat any bone alteration which may alter their quality of life and increase the risk of fractures.

**Table 1 European Crohn and Colitis Organization guidelines for the management of bone alterations in inflammatory bowel diseases population**

ECCO guidelines for the management of bone alterations in IBD population	
Life style recommendations	Physical exercise; Stopping smoking; and adequate dietary calcium (1 g/daily)
Vitamin and mineral supplements	Calcium (500-1000 mg/daily); Vitamin D (dose of ~1000 IU daily, or higher dose if known vitamin D deficiency) supplement for prophylaxis in patients receiving systemic steroid therapy; Calcium and vitamin D supplement if the T score is lower than -1.5
Treatment recommendations	More intensive treatment in patients with a history of pre-existing fracture; Regular use of BPs and other therapies in subjects with underlying disease activity particularly in young and postmenopausal women or those with previous spontaneous fractures

ECCO: European Crohn and Colitis Organization; IBD: Inflammatory bowel diseases.

**Figure 3** Diagrammatic representation of the pathogenic mechanisms involved in alteration of bone mineral density in inflammatory bowel diseases.

### Abstract

Hepcidin is the hypsideremic hormone regulating iron metabolism. It is a defensin-like disulfide-bonded peptide with antimicrobial activity. The main site of hepcidin production is the liver where its synthesis is modulated by iron, inflammation and erythropoietic signaling. However, hepcidin locally produced in several peripheral organs seems to be an important actor for the maintenance of iron homeostasis in these organs. This review highlights the presence of peripheral hepcidin and its potential functions. Understanding the role of extrahepatic hepcidin could be of great physiological and therapeutic importance for several specific pathologies.

**Key words:** Hepcidin; Extrahepatic hepcidin; Iron metabolism; Bacterial infection; Inflammation

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Hepcidin is the key regulator of iron homeostasis and is involved in iron-related disorders, namely anemia of inflammation and primary and secondary hemochromatosis. Since the discovery of its hypsideremic role, considerable efforts were made to explore iron handling by hepcidin. Almost all these studies focused on the liver because this organ was shown to be the major source of systemic hepcidin. However, interesting pending data showed an extrahepatic production of hepcidin in several organs, but the involvement of this peripheral hepcidin in local and overall iron homeostasis remains unknown. Thus, we think that those in the field should: (1) Consider the presence of endogenous hepcidin in the peripheral organs; and (2) Be interested in the involvement of hepcidin in other physiological and pathological mechanisms, in particular antimicrobial activity, acid secretion regulation, immune inflammatory response, etc.

## INTRODUCTION

Iron is one of the most abundant metals in the planet with the potential of high toxicity to living cells. Highly active cells need iron for their metabolic activity because iron exhibits an optimal chemical property for electron transfer, facilitating biochemical reactions between different atoms and molecules. The toxicity of iron is due to induction of reactive oxygen species, which at high levels leads to cellular damage<sup>[1]</sup>.

In the body, 60% of iron is incorporated into hemoglobin, while 10% to 15% are found in muscle myoglobin and cytochromes. Circulating iron, related to transferrin, represents only 1%. Under physiological conditions, the liver and macrophages of the reticuloendothelial system are the main iron storage and recycling sites. One to two milligrams of iron are lost daily by sweating and desquamation of skin and intestinal cells, and in women by menstrual bleeding. This small amount is totally recovered by intestinal absorption of heme and non-heme iron, which takes place in the duodenal enterocytes<sup>[2]</sup>.

There is no effective mechanism for iron excretion. As a result, the exogenous iron supplied to the body is not eliminated and may accumulate in a toxic way in the tissues.

## BODY IRON METABOLISM

Dietary iron (Fe) III is reduced to FeII by duodenal cytochrome B reductase located in the brush borders of the enterocytes<sup>[3]</sup>. FeII is then transported through divalent metal transporter 1 (named DMT1 or SLC11A2)<sup>[4]</sup> and is exported to blood *via* ferroportin (FPN or SLC40A1), which shares no homology with DMT1 and is localized at the basolateral pole of the enterocytes<sup>[5]</sup>. The export of iron by FPN requires a ferroxidase activity provided by the enzymes hephaestin and/or ceruloplasmin allowing transferrin (Tf) to bind the circulating iron in the form of FeIII. Most cells in the body can assimilate Tf-bound iron through the ubiquitous transferrin receptor 1 (TfR1) that has a high affinity for the Tf-FeIII complex. After TfR1-mediated endocytosis, iron is released from Tf in the intracellular endosomes at acidic pH. The released FeIII is then reduced to FeII by a reductase, for example the six epithelial transmembrane antigen of the prostate 3 in erythroid cells. FeII is then transported to the cytosol through DMT1 localized in these endosomes. Erythroid cells of the bone marrow are the largest consumers of iron. About one billion iron atoms (20 to 30 mg) are used daily to form hemoglobin in newly produced erythrocytes. Macrophages of the spleen and liver recover heme iron from senescent erythrocytes after phagocytosis and catabolism of heme by the enzyme heme oxygenase<sup>[6]</sup>. The mobilizable iron is thus recycled to the plasma for redistribution to tissues. FPN is essential for the export of iron by macrophages<sup>[7]</sup>.

In all cells, unused iron is stored in a non-reactive form due to ferritin (Ft). FeII could be delivered to Ft by cytoplasmic chaperones, such as poly (rC)-binding protein 1<sup>[8]</sup>. Ft is a protein complex consisting of 24 subunits of two types called heavy and light ferritins. Each complex is capable of storing up to 4500 iron atoms, which are easily mobilized when needed. A secreted form of Ft, low in iron, is found in the plasma. This serum Ft, used clinically to evaluate iron stores, is composed mainly of light subunits, some of which are glycosylated. In the majority of cases, serum Ft concentrations correlate with tissue stores of iron except under certain conditions where the synthesis of Ft is mainly due to inflammation. Indeed, Ft stimulated by inflammatory cytokines<sup>[9]</sup> is widely recognized as a marker of acute and chronic inflammation.

## REGULATION OF IRON METABOLISM

### Intracellular regulation

Intracellular iron homeostasis is ensured by the iron response element (IRE)-iron regulatory protein (IRP) system that controls the post-transcriptional expression of several iron proteins (TfR1, DMT1, FPN, Ft, and ALAS2; the first enzyme involved in heme biosynthesis in erythroid cells)<sup>[10-13]</sup>. IREs are hairpin-like RNA motifs that serve as specific binding sites for IRPs. IRPs are soluble cytosolic proteins whose activity varies according to the intracellular iron concentration. There are two IRPs: IRP1 and IRP2 with a sequence identity of 56%<sup>[14]</sup>. The IRE-IRP interaction stabilizes the mRNA when the IRE motifs are located in the 3'-UTR region, such as for TfR1, and imposes a steric constraint on the translation of the protein when IRE motifs are located in the 5'-UTR region. This results in an increase in transferrin-related iron acquisition when intracellular iron levels are low. A decrease in FPN and ferritin expression also occurs because iron export and intracellular iron storage are not appropriate in this condition.

### Systemic regulation

Hepcidin was initially identified as an antimicrobial peptide<sup>[15]</sup> (see section below). Yet since 2001, it is considered to be the master regulator of iron balance in humans by decreasing iron absorption and increasing iron retention in macrophages and Kupffer cells<sup>[16,17]</sup>. The mechanism by which hepcidin inhibits these iron effluxes has been well studied in macrophages, where hepcidin binds to FPN and leads to its internalization and degradation in lysosomes<sup>[18,19]</sup>. In duodenal cells, studies have reported a different mechanism. Indeed, hepcidin was shown to decrease duodenal transepithelial iron transport without internalization of FPN from the plasma membrane<sup>[20-22]</sup>. In these cells, hepcidin leads to a decrease in the protein expression of DMT1 rather than that of FPN<sup>[21]</sup>. Recently, the non-internalization of FPN following hepcidin treatment was also shown in other cellular contexts<sup>[23,24]</sup>. Zhang *et al.*<sup>[23]</sup> first observed that FPN was highly expressed in mature red blood cells lacking the proteasomal degradation pathway. In these mature red blood cells, hepcidin was shown to inhibit iron export but did not change FPN abundance similarly to what we have previously observed in duodenal enterocytes<sup>[21]</sup>. Studies on hepcidin-FPN interactions in the transfected HEK293T cell line and *Xenopus* oocytes also confirmed that hepcidin binding is able to block iron export without causing FPN internalization<sup>[24]</sup>. Thus, it seems that depending on the cellular and membrane environment hepcidin binding may block iron efflux acting either on FPN activity and/or on its abundance at the cell membrane. Moreover, in the duodenum, a permanent increase in hepcidin, as in a transgenic mouse model for example, has been shown to ultimately reduce FPN abundance by mechanisms that remain to be explored<sup>[25]</sup>.

## HEPCIDIN PRODUCTION

Hepcidin is synthesized in the liver as a pre-propeptide of 84 amino acids (aa); it then undergoes successive proteolytic cleavage to produce the 25-aa bioactive form, which is secreted in plasma. Being a low-molecular-weight peptide, hepcidin is assumed to be rapidly excreted by the kidney<sup>[26,27]</sup>, where it is supposed to be taken up and degraded by the renal proximal tubule. Indeed, hepcidin was first isolated from human urine and named according to its synthetic site (hep-) and its antibacterial properties shown *in vitro* (-cidin). The mass spectroscopy studies have shown the presence of urinary 25-aa hepcidin as well as shorter forms (22 aa and 20 aa) that are supposed to be degradation products with still unknown functions<sup>[28]</sup>. Hepcidin exhibits a cysteine-rich structure reminiscent of four disulfide bridges defensins with *in vitro* antimicrobial activity<sup>[15,26,29]</sup>, suggesting ancestral innate defense properties against invasive bacteria. Hepcidin structure is characteristic of peptides able to disrupt bacterial membranes and is similar to other antimicrobial peptides such as defensins. Hepcidin may also limit bacterial proliferation by decreasing iron in plasma and extracellular fluids. With regards to this immune activity, hepcidin synthesis was shown to be highly induced by inflammatory signals such as IL-6, allowing it to play a major role in the anemia associated with chronic diseases and inflammation<sup>[30-33]</sup>. Hepcidin is also induced in the liver in response to lipopolysaccharide (LPS) through activin B and SMAD-signaling, but this pathway is still debatable<sup>[34-37]</sup>.

Hepcidin is mainly, but not exclusively, produced and secreted by the liver. Indeed, several studies have shown that hepcidin is locally synthesized by multiple other tissues including kidney<sup>[38]</sup>, macrophages<sup>[39,40]</sup>, stomach<sup>[41]</sup>, adipose tissue<sup>[42]</sup>, brain<sup>[43]</sup>, heart<sup>[44]</sup> and pancreas<sup>[45]</sup>. Iron is essential for the normal function of these organs. In addition, hepcidin was found in atypical biological fluids as bile, ascitic and pleural, and cerebrospinal liquid<sup>[46,47]</sup>. The functions carried out by this extrahepatic hepcidin

are not completely known but this concern has gained increased attention in recent years. Some related findings will be discussed below.

### Hepatic hepcidin

Serum levels of hepcidin are mostly correlated with the levels of liver hepcidin expression<sup>[48]</sup> demonstrating that hepatic hepcidin is the key regulator of systemic iron balance. This was obviously demonstrated in mouse models with either total or liver-specific ablation of the hepcidin gene<sup>[49,50]</sup>. Liver-specific knockout (KO) mice were shown to fully recapitulate the severe iron overload phenotype observed in the total KO mice with increased plasma iron and massive parenchymal iron accumulation.

The regulation of hepatic synthesis of hepcidin is extremely complex and responds to multiple signals, some of which are still unclear. Indeed, the synthesis of hepcidin is stimulated by the high intake of iron and by inflammation, while it is repressed by iron deficiency and by all the pathological situations that stimulate the erythropoietic activity (anemia, bleeding, hemolysis, dyserythropoiesis and erythropoietin injections).

Hepatic hepcidin is regulated by iron-mediated pathways through a complex of integral hemochromatosis proteins. Hemojuvelin (HJV) was first identified as the mutated protein in the majority of juvenile hemochromatosis<sup>[51]</sup>. The absence of HJV leads to a severe deficit in hepcidin production. HJV acts as a co-receptor with bone morphogenetic proteins (BMPs), enhancing activation of the SMAD pathway in response to binding of BMPs to their receptor (BMPR). BMP6 plays a major role in this pathway and in the stimulation of hepatic hepcidin by iron. In mice, the ablation of the *Bmp6* gene causes severe iron overload<sup>[52]</sup>. In humans, we and others<sup>[53-57]</sup> recently identified heterozygous mutations localized in the propeptide of the BMP6 protein leading to mild to moderate hemochromatosis. The BMP6 pathway is negatively controlled by matrilysin 2 that interrupts the binding of BMP6 on its BMPR in hepatocytes<sup>[58-61]</sup>. The BMP6 pathway also seems to be a target of erythroferrone, the erythroid factor that represses hepcidin when erythropoiesis is pathologically stimulated<sup>[62]</sup>.

The study of the different forms of genetic hemochromatosis has demonstrated the role of the human hemochromatosis protein (HFE) and transferrin receptor 2 (TfR2) in the regulation of hepcidin by iron. The forms of adult hemochromatosis are due to mutations of the *HFE* gene for the most common forms, or TfR2 for rarer forms and are characterized by a lack of activation of hepcidin in response to iron overload<sup>[63]</sup>. Mice deficient in *Hfe* or patients with *HFE* mutations have a low hepcidin mRNA level in the liver despite their iron overload. A model has been proposed in which HFE, TfR2 and HJV interact with each other at the hepatocyte membrane to form an "iron-sensing complex"<sup>[64]</sup>. When transferrin saturation in serum increases, holo-transferrin shifts HFE from its binding to TfR1, which allows its interaction with TfR2 and activates transcription of hepcidin-encoding gene. Thus, TfR2 acts as a sensor of the transferrin saturation (serum iron) and BMP6 as a tissue iron sensor activating hepcidin synthesis by interaction with HJV during excessive accumulation of iron in hepatocytes<sup>[65,66]</sup>.

### Extrahepatic hepcidin

**Hepcidin expression in the kidney:** In 2005, using immunocytochemistry assays, Kulaksiz *et al.*<sup>[38]</sup> observed for the first time that hepcidin was expressed in the kidney, namely in the cortical thick ascending limb (cTAL) and connecting tubules and to a lesser extent in the collecting ducts. Hepcidin was absent in the proximal tubule and descending and ascending thin limbs<sup>[38]</sup>. It was localized at the apical surface of the renal epithelial cells, which suggests that renal hepcidin is eliminated in the urine after an autocrine/paracrine action on renal tubules. Using microdissected and isolated renal tubules, we also confirmed that hepcidin is preferentially expressed throughout the distal nephron, particularly in the TAL<sup>[67]</sup>. Interestingly, the distal nephron expresses DMT1 and FPN transporters at the apical and the basolateral membrane, respectively and was described to be the site of the reabsorption of non-heme iron in kidney<sup>[68-71]</sup>. Using mouse models with defects in hepcidin production (hepcidin KO and HJV KO mice), our group had clearly shown that non-heme iron accumulated in this distal nephron particularly the TAL<sup>[71]</sup>. In the TAL cell line, we found that vectorial transport of iron was decreased following exogenous hepcidin treatment. In addition, similarly to what we observed in intestine<sup>[21]</sup>, hepcidin was able to decrease DMT1 both *in vivo* using kidney sections from hepc-/- mice and *in vitro* using TAL cells. All together, these reports highlight a new role of hepcidin in the control of renal iron transport and accumulation and suggest that local synthesis of hepcidin within renal tubules may play a crucial role in this effect. Hepcidin seems to specifically target the distal nephron rather than the proximal tubule. We investigated the importance of hepcidin in the protection of kidneys against urinary tract

infection<sup>[67]</sup>. We developed an experimental urinary tract infection model and showed that hepcidin KO mice inoculated with the gram-negative CFT073 strain exhibited higher renal bacterial load than infected wildtype mice as well as a significant attenuation of renal inflammatory profile. Hepcidin KO mice showed a marked alkalization of urine associated with repression of both Atp4a and Atp12a proton pumps. Pre-treatment of wildtype mice with hepcidin considerably reduced renal colonization by the CFT073 strain and restored the acidic pH of urine. *In vitro* experiments proved the bacteriostatic activity of hepcidin against UroPathogenic *Escherichia coli* because the bacterial growth was inhibited in the presence of this peptide. Interestingly, we found that CFT073 repressed renal hepcidin expression in infected mice through reduction of SMAD signaling. These results indicate that hepcidin plays a role in the fight against UroPathogenic *Escherichia coli* infection and that UroPathogenic *Escherichia coli* might target renal hepcidin to attenuate its global antibacterial activity in the early phase of a UTI<sup>[67]</sup>.

**Hepcidin expression in macrophages:** Macrophages play a central role in iron recycling and consequently in establishing iron balance. Initial studies from Liu *et al*<sup>[39]</sup> demonstrated that the reticuloendothelial system (RES, namely liver Kupffer and spleen macrophages) was able to produce hepcidin following LPS-induced inflammation in mice and upon treatment of mouse splenic adherent cells by LPS. This RES-produced hepcidin was independent of the iron pool of the cells because *in vivo* iron loading has been shown to induce hepcidin production in liver without increase in hepcidin mRNA in the spleen. In addition, when splenic cells were treated *in vitro* with ferric ammonium citrate, there was again no increase in splenic hepcidin mRNA expression. Peyssonnaud *et al*<sup>[40]</sup> also investigated the ability of macrophages to endogenously synthesize hepcidin *in vitro* and *in vivo* following bacterial infections. They found that intraperitoneal bacterial challenge was able to increase hepcidin expression in splenic macrophages *via* the LPS-mediated Toll-like receptor 4 pathway. In addition to RES, hepcidin was shown to be produced by alveolar macrophages at a low level when not stimulated but at a high level when exposed to LPS *in vitro* and *in vivo*<sup>[72,73]</sup>. In agreement with these previous data, Sow *et al*<sup>[74]</sup> also showed a strong induction of hepcidin mRNA expression in several macrophage cell lines infected with mycobacteria and/or treated with the inflammatory cytokine IFN- $\gamma$ .

The physiological significance of local hepcidin expression in macrophages is not yet fully determined but the hypothesis is that RES-produced hepcidin may contribute by greatly increasing the regulatory pool of hepcidin around liver Kupffer cells and spleen macrophages as well as other macrophages residing in tissues frequently confronted by infection. Increased local hepcidin might potentiate the retention of iron during conditions of inflammation and infection particularly since FPN is strongly expressed at the cell surface of these cells. These findings strongly suggested that macrophage hepcidin could play a role in host defense by acting on FPN expression and consequently limiting the availability of iron to invading bacteria.

Recently, we described the involvement of RES-produced hepcidin in iron metabolism dysregulation in Gaucher disease (GD), an inherited deficiency of the lysosomal enzyme glucocerebrosidase leading to accumulation of glucosylceramide in tissues including the spleen and the liver<sup>[75]</sup>. In order to understand the unexplained hyperferritinemia frequently reported in Gaucher disease patients, Perl's staining of spleen and bone marrow smears was performed. Analysis revealed iron accumulation in the lipid-laden macrophages also called Gaucher cells. Using an *in vitro* model of Gaucher cells, we have shown that hepcidin production was induced in these macrophages, and FPN protein was consequently internalized from the plasma membrane. Thus, hyperferritinemia in Gaucher disease could be related to the sequestration of iron in Gaucher cells due to local production and an autocrine action of hepcidin in these cells.

**Hepcidin expression in the stomach:** The gut is an additional organ that produces hepcidin<sup>[41]</sup>. In the stomach, hepcidin was found in the gastric fundus and corpus, more precisely, in parietal cells. *In vitro*, gastric hepcidin was upregulated upon treatment with IL6 and in response to bacterial infection. In humans, gastric hepcidin level was elevated during bacterial infection and then normalized after successful eradication. In addition, acid secretion in hepcidin KO mice was markedly reduced due to repression of Atp4a proton pump, and this was associated with gastric bacterial overgrowth. Thus, this original study was the first to show that hepcidin is a gastric factor essential for acid secretion and fight against *Helicobacter* bacterial invasion.

**Hepcidin expression in adipose tissue:** Hepcidin synthesis in adipose tissue was reported by Bekri *et al*<sup>[42]</sup> in severely obese patients with low-grade systemic

inflammatory disorder<sup>[42]</sup>. mRNA level of adipose tissue hepcidin was correlated with multiple indexes of inflammation (IL6, C-reactive protein). This observation was also confirmed by *in vitro* studies using cultured adipose tissue explants, where IL6 was shown to promote hepcidin expression. Thus, adipose tissue hepcidin is suggested to exacerbate the iron deficiency and iron deficiency anemia observed in the majority of obese patients. In this context, it is not clear whether adipose tissue hepcidin contributes to increased pool of systemic hepcidin, but one can suppose that adipose tissue may provide a high concentration of local hepcidin around intestinal cells and inhibit iron absorption *via* an autocrine/paracrine mechanism. Yet, numerous studies have been conducted to explore the role of hepcidin secreted by adipose tissue in obesity hypoferrremia. Several high-fat diet mouse models were developed for that purpose, but the results remained highly controversial<sup>[76-80]</sup>.

**Hepcidin expression in the brain:** Iron has a role in oxidative metabolism and is a cofactor in the synthesis of myelin and neurotransmitters. It is thus essential for normal neurological function. The presence of hepcidin in the brain was shown by Zechel *et al*<sup>[43]</sup>. Using different RNA and protein detection techniques, the cellular distribution of hepcidin in murine brain was investigated. Results showed a widespread distribution of this peptide in different brain areas. Many other reports described the presence of brain hepcidin production although to a lesser extent with protein levels higher than mRNA levels, suggesting that the liver is partially responsible in addition to locally produced hepcidin<sup>[81,82]</sup>.

Hepcidin expression in the brain is induced by inflammation. LPS and IL6 are known as major actors in inflammation-induced mechanisms. LPS was described as an indirect inducer of hepcidin expression in astrocytes *via* upregulated IL6 expression in microglia<sup>[83,84]</sup>. However, other experiments showed a direct upregulation of hepcidin by LPS in glial cells<sup>[85]</sup>.

Recently, we investigated iron metabolism in the brain of a mouse model of Sanfilippo syndrome (mucopolysaccharidosis type III) where the progressive accumulation of heparan sulfate oligosaccharides induced microglia and astrocytes to produce pro-inflammatory cytokines leading to severe neuroinflammation<sup>[86]</sup>. We found that iron accumulation in mucopolysaccharidosis type III mice mainly affected the cerebral cortex where hepcidin expression was higher than in wildtype mice. This increase was correlated with low expression of FPN and consequently brain iron retention. We showed *in vitro* that heparan sulfate oligosaccharides are directly responsible for the induction of hepcidin and a decrease in FPN level when added to microglia and to a lesser extent to astrocytes. Our results showed that microglia play a key role in brain hepcidin overexpression, and the regulation of brain hepcidin may be dependent on or independent of inflammation.

Because hepcidin may act as an antimicrobial peptide in the brain, we investigated hepcidin production in cerebrospinal fluid during infectious meningitis. Using a liquid chromatography tandem mass spectrometry method<sup>[48]</sup>, we compared hepcidin signal in cerebrospinal fluid of 5 patients diagnosed for viral meningitis *versus* 5 patients with bacterial meningitis. In viral infection, hepcidin signal was very low nearing the background level in the same range as healthy patients (Figure 1). By contrast, cerebrospinal fluid hepcidin was significantly increased in bacterial meningitis. These observations were different from what was observed in the liver where hepcidin was induced by both bacterial and viral infections, suggesting again that hepcidin plays tissue-specific roles<sup>[87]</sup>. The most frequent pathogens in community-acquired bacterial meningitis are pneumococcus and meningococcus, which are gram-negative germs and LPS producers<sup>[88]</sup>. Thus, like what was described in the kidney<sup>[67]</sup> and elsewhere<sup>[89]</sup>, brain hepcidin must be more sensitive to gram-negative bacteria and induced through the LPS/Toll-like receptor signal transduction pathway.

**Hepcidin expression in the heart:** Iron is essential for normal heart function; however, the dysregulation of cardiac iron homeostasis may be deleterious. Merle *et al*<sup>[44]</sup> performed the first analysis of hepcidin expression and its regulation in rat heart. They reported that hepcidin is expressed in cardiomyocytes, and it is regulated in response to hypoxia and inflammation, which strongly suggests that this peptide may play an important role in cardiac diseases. Quantification of hepcidin postulated the heart as the organ with the highest hepcidin level next to the liver<sup>[15,90]</sup>. Ge *et al*<sup>[91]</sup> studied the effect of hepcidin on FPN expression in cardiomyocytes. Using a cardiomyocyte cell line, they demonstrated that local hepcidin was able to reduce FPN level and iron export from these cells. Studies conducted by Lakhali-Littleton *et al*<sup>[92]</sup> strongly supported these data. Indeed, they first confirmed that FPN is expressed in cardiomyocytes and demonstrated that its cardiac-specific deletion leads to fatal cardiac iron overload. To go further, they generated mice with cardiomyocyte-specific

**Figure 1** Hepcidin signals measured by liquid chromatography tandem mass spectrometry in cerebrospinal fluid of patients with bacterial meningitis and viral meningitis ( $n = 5$  per group). Hepcidin signal is expressed in arbitrary unit, corresponding to the ratio of the area under the curve of hepcidin signal on the area under the curve of internal standard (heavy hepcidin). According to the Mann-Whitney test the difference was significant ( $P = 0.0076$ ).

hepcidin deletion or knock-in of hepcidin-resistant FPN. They found that both models maintained normal systemic iron homeostasis but developed fatal cardiac dysfunction as a consequence of cardiomyocyte iron deficiency<sup>[93]</sup>. Thus, they provided evidence for a cell-autonomous role of hepcidin in cardiac iron homeostasis.

**Hepcidin expression in the pancreas:** Data published by Kulaksiz *et al*<sup>[45]</sup> demonstrated that hepcidin is expressed in the pancreas of rat and human. Further analysis showed that it was localized in  $\beta$ -cells of the islets of Langerhans. In addition, the *in vitro* experiments performed in this study demonstrated that the expression of hepcidin in  $\beta$ -cells is directly regulated by iron.

Iron is important for normal insulin secretion. However, excess of iron have been shown to affect  $\beta$ -cell function in hemochromatosis models<sup>[94-96]</sup>, causing iron accumulation in the islets, decreased insulin secretion and increased apoptosis. In contrast, iron pool decrease was shown to protect from diabetes and loss of  $\beta$ -cell function in the obese (ob/ob) mouse model<sup>[97]</sup>. Both DMT1 and FPN are expressed in  $\beta$ -cells. In  $\beta$ -cell-specific DMT1 KO islets, glucose-stimulated insulin secretion was reduced<sup>[98]</sup>. These observations suggested that hepcidin produced by  $\beta$ -cells may be involved in an intrinsic regulation of pancreas iron and in their function in glucose homeostasis.

## CONCLUSION

Although only some organs have been addressed in this review, there is a number of studies describing the production of hepcidin in many others such as lungs<sup>[99,100]</sup>, prostate<sup>[101]</sup>, placenta<sup>[102,103]</sup> and retina<sup>[104]</sup>. Our hypothesis is that peripheral hepcidin is intended for an innate immune response including a defense against bacterial invasion. However, under local or systemic inflammatory conditions, the induction of this peripheral hepcidin may contribute to target tissue damage due to local accumulation of toxic iron and apoptosis. Nevertheless, despite considerable advances recently, further explorations deserve to be rapidly achieved to deeply investigate the cellular mechanisms and functions of peripheral hepcidin as well as its regulation in the different organs.

### Abstract

A potential strategy for patients with estrogen receptor (ER)-positive breast cancer is necessary to replace neoadjuvant chemotherapy which has limited benefit. Neoadjuvant endocrine therapy (NAE) has been indicated to be a favorable alternate approach to downstage large or locally advanced breast cancer in ER-positive, human epidermal growth factor receptor 2 (HER2)-negative (ER+/HER2-) patients, especially postmenopausal women. Previous studies have demonstrated the efficacy of various endocrine agents in NAE. Aromatase inhibitors (AIs) have proven superiority over tamoxifen as a suitable choice to optimize treatment efficacy. Fulvestrant was recently reported as an effective agent, similar to AIs. Furthermore, the addition of targeted agents exerts synergistic antiproliferative effects with endocrine agents and rapidly improves response rates in both endocrine sensitive and resistant tumors. The neoadjuvant platform provides a unique opportunity to define the appropriate strategy and address the mechanisms of endocrine resistance. In addition, the predictive value of biomarkers and genomic assays in NAE is under investigation to evaluate individual effects and validate biomarker-based strategies. In this review, we discuss the most relevant evidence on the potential of NAE for ER+ breast cancer. The current understanding also offers new insights into the identification of the optimal settings and valuable predictive tools of NAE to guide clinical treatment decisions and achieve beneficial therapeutic effects.

## INTRODUCTION

Neoadjuvant chemotherapy (NAC) has been defined as a standard treatment option for localized or locally advanced breast cancer. NAC is used to downgrade and downsize the tumor, which can decrease the extent of surgery and increase the likelihood of breast-conserving surgery (BCS). Moreover, it can improve the long-term prognosis for patients whose operative specimen showed a pathological complete response (pCR)<sup>[1,2]</sup>. Clinical evidence has demonstrated that the status of hormone receptor (HR) and human epidermal growth factor receptor 2 (HER2) leads to a corresponding response and efficacy of NAC<sup>[3]</sup>. However, patients with estrogen receptor (ER)-positive, HER2-negative (ER+/HER2-) breast cancer show limited results from NAC, with a lower pCR and poor objective response rate (ORR)<sup>[4]</sup>. Thus, an alternate neoadjuvant approach is required for breast cancer of this subtype. There is now increasing data that neoadjuvant endocrine therapy (NAE) may be a more appropriate treatment strategy than NAC<sup>[5]</sup>.

Traditionally, NAE has been reserved for locally advanced breast cancer in chemotherapy intolerant or feeble senior patients due to its indolent clinical response and difficulties in efficacy evaluation<sup>[6]</sup>. However, since the development of third-generation aromatase inhibitors (AIs), several studies were conducted to evaluate the effects of NAE on ER+ breast cancer<sup>[7,8]</sup>. Neoadjuvant AI has comparable efficacy to NAC in terms of pCR, ORR, and BCS, suggesting the feasibility of this well-tolerated strategy, mainly for postmenopausal patients<sup>[9]</sup>. The choice of chemotherapy or endocrine therapy (ET) as neoadjuvant treatment depends on disease characteristics and patient subtypes. We will discuss the most relevant clinical trials to illustrate whether NAE, either monotherapy or combination therapy, can serve as a potential option in patients with ER+/HER2- breast cancer.

Furthermore, optimal NAE settings can optimize treatment response and achieve the maximum therapeutic effect for ER+ breast cancer<sup>[10]</sup>. Emerging evidence has revealed the efficacy of different endocrine agents in presurgical application, including AIs, tamoxifen, and fulvestrant. The identification of optimal agents can result in tailored treatment for both postmenopausal and premenopausal patients. Combining targeted agents with AI or fulvestrant yields promising effects for postmenopausal patients with advanced or metastatic breast cancer<sup>[11,12]</sup>. The results are being translated to neoadjuvant settings and provide possibilities to fulfill the requirements of drug resistance mechanism exploration and new drug development<sup>[13]</sup>. Available neoadjuvant endocrine settings are generally favorable for ER+ breast cancer patients, but not all patients benefit equally. The neoadjuvant period can provide a usable platform for tumors to receive biopsy on treatment, leading to the exploration of predictive tools that can screen suitable individuals and select treatment options in breast cancer<sup>[14,15]</sup>. Current evidence suggested that compared with traditional tumor staging, biomarkers, especially Ki67, and genomic assays offered more accurate prediction information. This evidence provides novel insight into the development of biomarker-based strategies in NAE.

In this review, we will detail the most relevant evidence to verify the potential role of NAE. We identify optimal settings, including optimal duration, optimal endocrine agents, and optimal targeted agents, and then evaluate the prognostic role of biomarkers and genomic assays in NAE. NAE can act as a prospective strategy and scientific platform for optimizing treatment efficacy, screening suitable individuals, and investigating mechanisms of drug resistance in ER+/HER2- breast cancer.

## NAE AS A POTENTIAL APPROACH IN THE NEOADJUVANT SETTING

### NAE monotherapy

Several studies have already proved that NAE had a similar beneficial therapeutic effect to NAC for ER+ breast cancer (Table 1). A phase II clinical trial published by Semiglazov *et al*<sup>[16]</sup> suggested that there was no significant difference between the NAC arm (doxorubicin plus paclitaxel) and NAE arm (anastrozole or exemestane) in terms of clinical response (63.6% *vs* 64.5%), ultrasound response (46% *vs* 40%), or mammographic response (63% *vs* 60%). In comparison with the NAC arm, the NAE arm showed an improved BCS rate (24% *vs* 33%,  $P = 0.058$ ). Similar results were provided in the GEICAM/2006-03 trial between the NAC arm (epirubicin, cyclophosphamide, and docetaxel) and NAE arm (exemestane) in both clinical response rate (CRR 66% *vs* 48%,  $P = 0.075$ ) and BCS rate (47% *vs* 56%,  $P = 0.2369$ )<sup>[5]</sup>. Meanwhile, a subgroup analysis suggested that NAC had a clear advantage over NAE in premenopausal women (CRR, 75% and 44%,  $P = 0.027$ ), whereas in postmenopausal women, this advantage disappeared.

Regarding the safety of neoadjuvant settings, grade 3/4 toxicity was more common in NAC therapy than in NAE therapy (47% *vs* 9%,  $P < 0.001$ )<sup>[5]</sup>. The recent, multicenter NEOCENT trial also proposed that the NAC group had more serious adverse effects (AEs), such as alopecia, vomiting, stomatitis, and anemia, than the NAE group, affirming the safety and tolerability of NAE<sup>[17]</sup>. Furthermore, a meta-analysis including five randomized controlled trials with 538 patients, of whom 267 (49.6%) received NAE and 271 (50.4%) underwent NAC, can be considered the best evidence. This meta-analysis indicated that NAE was as efficacious as NAC in clinical response and increased the rates of BCS and wide local excision, with better tolerability<sup>[9]</sup>. Given the efficacy and low toxicity correlated with NAE, this treatment option as a potential alternative treatment strategy to NAC, especially in postmenopausal patients, was encouraged.

### NAE combination therapy

Based on this promising knowledge of NAE, neoadjuvant chemo-endocrine therapy (NCET), which combined NAE and NAC, was a potential treatment option for hormone-sensitive patients (Table 1). NCET has been explored in comparison with either NAE or NAC therapy. Nakayama *et al*<sup>[18]</sup> compared the efficacy between the single-agent anastrozole group and the anastrozole plus UFT (tegafur/uracil) group in the Neo-ACET BC trial. There was a greater tendency of tumor degeneration in the NCET group than in the NAE group, although the study was halted due to altered liver function. A recent trial enrolled 63 primary invasive breast cancer patients with initial exemestane treatment followed by response-dependent addition of cyclophosphamide. The results suggested that the clinical response of nonresponders was improved to be comparable to that of responders by the addition of cytotoxic agents to the endocrine agents (CRR for nonresponders and responders at weeks 24 and 36; 54% *vs* 85% and 71% *vs* 71%)<sup>[19]</sup>. NCET has a broad-range antitumor activity and favorable efficacy over NAE monotherapy.

In comparison with NAC and NECT, Mohammadianpanah *et al*<sup>[20]</sup> indicated that the addition of letrozole simultaneously with neoadjuvant FAC (5-fluorouracil, doxorubicin, and cyclophosphamide) therapy significantly increased clinical and pathologic response rates compared with chemotherapy alone. The CSCSG-036 trial confirmed that concurrent NAC and estrogen deprivation provided higher effectiveness in ER+ breast cancer (CRR, 84.8% *vs* 72.6%,  $P = 0.02$ ), especially for those with high Ki67 expression (91.2% *vs* 68.7%,  $P = 0.001$ )<sup>[21]</sup>. Similar toxicities were observed in the NCET and NAC arms, further supporting the role of NCET as a potential neoadjuvant treatment option. Owing to its promising clinical response and acceptable toxicity, NCET has shown great development prospects for ER+/HER2-breast cancer patients.

## OPTIMAL SETTING OF NAE

To understand the optimal settings for NAE, we will discuss clinical trials to identify the optimal duration, endocrine agents, and targeted agents (Tables 2 and 3).

### Optimal duration of NAE

The duration of NAE treatment in most clinical trials was approximately 4-6 mo, based on experience; however, some investigators noted that this common duration might not be sufficient to achieve the best results in tumor shrinkage<sup>[22-24]</sup>. Several

**Table 1** Neoadjuvant endocrine therapy and neoadjuvant chemo-endocrine therapy as potential approaches in the neoadjuvant settings

Clinical trial	Treatment arms (n)	Duration	Primary endpoint	ORR	BCS rate
Semiglazov <i>et al</i> <sup>[16]</sup> , 2007	(A) NAE: EXE 25 mg/d or ANA 1 mg/d (121); (B) NAC: doxorubicin 60 mg/m <sup>2</sup> plus paclitaxel 200 mg/m <sup>2</sup> (118)	3 mo	OR by clinical palpation	64% vs 64% ( <i>P</i> > 0.5)	33% vs 24 ( <i>P</i> = 0.58)
Alba <i>et al</i> <sup>[5]</sup> , 2012	(A) NAE: EXE 25 mg/d (41-47); (B) NAC: Epirubicin 90 mg/m <sup>2</sup> plus cyclophosphamide 600 mg/m <sup>2</sup> then docetaxel 100 mg/m <sup>2</sup> (EC-T) (41-48)	24 wk	OR by MRI	48% vs 66% ( <i>P</i> = 0.075)	56% vs 47 ( <i>P</i> = 0.2369)
Palmieri <i>et al</i> <sup>[17]</sup> , 2014 (NEOCENT)	(A) NAE: LET 2.5 mg/d (22); (B) NAC: 5-fluorouracil 500 mg/m <sup>2</sup> , epirubicin 100 mg/m <sup>2</sup> plus cyclophosphamide 500 mg/m <sup>2</sup> (FE100C) (22)	18-23 wk	OR by ultrasound and mammography	59.1% vs 54.5% ( <i>P</i> = 0.32)	
Nakayama <i>et al</i> <sup>[18]</sup> , 2018 (Neo-ACET BC)	(A) NAE: ANA 1mg/d (29); (B) NCET: ANA 1mg/d plus tegafur/uracil (UFT) 270 mg/m <sup>2</sup> (28)	24 wk	OR by MRI and CT	39.3% vs 14.3% ( <i>P</i> = 0.0683)	
Sato <i>et al</i> <sup>[19]</sup> , 2018	(A) NAE: EXE 25mg/d (14); (B) NCET: EXE 25 mg/d plus cyclophosphamide 50 mg/d (42)	24 wk	OR by clinical palpation	85% vs 54% (at weeks 24); 71% vs 71% (at weeks 36)	No increased rate shown
Mohammadianpanah <i>et al</i> <sup>[20]</sup> , 2012	(A) NCT: 5-fluorouracil 600 mg/m <sup>2</sup> , doxorubicin 60 mg/m <sup>2</sup> , and cyclophosphamide 600 mg/m <sup>2</sup> (FAC) (51); (B) NCET: letrozole 2.5 mg/d plus FAC (50)	9-13 wk	OR by clinical palpation	10.2% vs 25.5% ( <i>P</i> = 0.049)	
Yu <i>et al</i> <sup>[21]</sup> , 2019 (CSCSG-036)	(A) NCT: EC-T or FEC-T (124); (B) NCET: letrozole 2.5 mg/d plus EC-T or FEC-T (Tleuporelin) (125)	8-9 wk	OR by MRI	72.6% vs 84.8% ( <i>P</i> = 0.02)	

NAE: Neoadjuvant endocrine therapy; NAC: Neoadjuvant chemotherapy; NCET: Neoadjuvant chemo-endocrine therapy; EXE: Exemestane; ANA: Anastrozole; LET: Letrozole; OR: Objective response; BCS: Breast-conserving surgery.

clinical trials were established to assess the optimal duration of neoadjuvant AIs that would permit tumor regression and BCS eligibility for initially unsuitable patients<sup>[23]</sup>. A study comparing the tumor size of patients receiving exemestane treatment at 3 and 6 months revealed that extended exemestane therapy had a potential to significantly reduce tumor volume<sup>[25]</sup>. A phase IV clinical trial verified this conclusion with a slightly larger number of participants and suggested that 7.5-mo neoadjuvant letrozole therapy was optimal to achieve beneficial shrinkage in tumor volume and facilitate BCS, in comparison with 4-month conventional treatment<sup>[22]</sup>. Overall, long-term neoadjuvant treatment achieves further tumor reduction and increases the feasibility of the BCS rate, but the optimal treatment duration for NAE is still unknown and needs to be further investigated.

### **Optimal endocrine agents for NAE**

In the following paragraph, we will review clinical trials that were conducted to evaluate the efficacy of different endocrine agents and identify the optimal choice in both premenopausal and postmenopausal patients.

**Neoadjuvant AIs vs tamoxifen:** Clinical evidence favoring the three third-generation AIs, letrozole, anastrozole, and exemestane, rather than tamoxifen, in neoadjuvant treatment was established in several randomized clinical trials for ER+ breast cancer. For both the CRR and BCS, letrozole was superior to tamoxifen and had less toxicity, as shown in the P024 trial<sup>[7]</sup>. There was no statistically significant difference between

**Table 2** The optimal duration and optimal endocrine agents of neoadjuvant endocrine therapy

Clinical trial	Patient characteristics	Treatment arms (n)	Duration	Primary endpoint	ORR	BCS rate
Krainick-Strobel <i>et al</i> <sup>[23]</sup> , 2008	ER+ and/or PR+; Postmenopausal	LET 2.5 mg/d (33)	4-8 mo	OR by clinical palpation, mammography, ultrasound, and BCS	55% <i>vs</i> 24% at 4 and > 4 mo	71% <i>vs</i> 80% at 4 and > 4 mo

ER: Estrogen receptor; PR: Progesterone receptor; EXE: Exemestane; ANA: Anastrozole; LET: Letrozole; FUL: Fulvestrant; TAM: Tamoxifen; OR: Objective response; OFS: Ovarian function suppression; BCS: Breast-conserving surgery.

anastrozole and tamoxifen in ORR; however, anastrozole was more effective than tamoxifen in certain clinical subgroups of patients in the IMPACT and PROACT trials<sup>[26,27]</sup>. Semiglazov *et al*<sup>[16]</sup> proved that the exemestane group exhibited higher CRR and BCS rates than the tamoxifen group, but there was no difference in the effectiveness, as shown by ultrasound and mammography. A meta-analysis of seven randomized trials further demonstrated the efficacy of neoadjuvant AIs. There was significantly higher clinical and radiological response rates (OR = 1.69 and 1.49, respectively, *P* < 0.001) and BCS rate (OR = 1.62, *P* < 0.001) in the AI arm than in the tamoxifen arm<sup>[10]</sup>. As illustrated, neoadjuvant AIs treatment possessed better efficacy than tamoxifen.

**Neoadjuvant AIs *vs* fulvestrant:** Fulvestrant is a selective ER degrader that is recommended by NCCN guidelines as first-line ET for HR+ metastatic breast cancer after progression on TAM or AI<sup>[28]</sup>. Limited reports have appraised the appropriate

**Table 3** The optimal targeted agents

treatment dosing and clinical value of fulvestrant in NAE. The phase II NEWEST trial reported that 500 mg fulvestrant was significantly related to greater early reduction in the levels of ER (-25.0% vs -13.5%,  $P = 0.0002$ ) and Ki67 (-78.8% vs -47.4%,  $P < 0.0001$ ) than 250 mg. Meanwhile, individuals also had better responses at the recommended 500 mg dose (CRR at week 16, 22.9% vs 20.6%)<sup>[29]</sup>. A high-dose regimen of fulvestrant would improve clinical response and biological activity for ER+ breast cancer in NAE. Together with the same dose-dependent advantages in adjuvant settings, we support the application of 500 mg fulvestrant in future clinical practice.

To determine the efficacy of fulvestrant, a short-term neoadjuvant study first compared the biological activity of fulvestrant plus anastrozole treatment vs either agent alone. Quenel-Tueux *et al*<sup>[30]</sup> evaluated the utility of these two agents in 120 postmenopausal breast cancer patients who were not eligible for primary BCS, with different results. They demonstrated that the fulvestrant arm yielded equal effectiveness as the anastrozole arm in both objective response rate (53.8% vs 58.9%) and BCS rate (50.0% vs 58.9%)<sup>[30]</sup>. The CARMINA 02 trial also showed that the efficacy and tolerability of fulvestrant were similar to those of anastrozole<sup>[31]</sup>. These outcomes suggested the excellent therapeutic effects of fulvestrant and encouraged further exploration to verify whether it can serve as an ideal agent to replace well-recognized and valuable AIs in neoadjuvant therapy.

**Choice of different aromatase inhibitors:** To explore the choice of the beneficial AIs, the ACOSOG Z1031A trial involved 377 postmenopausal women with stage II/III ER+ (Allred score, 6 to 8) breast cancer. These patients were randomized to treatment with presurgical exemestane, letrozole, or anastrozole for 16 wk. The three AIs had clinically and biologically equivalent effects, as the CRR was 60%, 72%, and 68% and the geometric mean percentage change in Ki67 was 87.2%, 82.1%, and 78%, respectively<sup>[32]</sup>. Thus, the clinical and biological efficacy did not significantly differ among the three AIs in neoadjuvant settings.

**Optimal endocrine agents for premenopausal patients:** Current limited data encouraged the efficacy of AI plus ovarian function suppression (OFS) in neoadjuvant endocrine settings for premenopausal patients. Torrissi *et al*<sup>[33]</sup> confirmed the efficacy of NAE with letrozole plus gonadotropin-releasing hormone (GnRH) analogue in

premenopausal breast cancer patients. Over half of the patients achieved clinical response, and none of patients progressed during treatment<sup>[33]</sup>. The STAGE trial randomized 204 premenopausal patients into either the neoadjuvant anastrozole arm or tamoxifen arm, accompanied by goserelin, for 24 wk. They indicated the superiority of anastrozole over tamoxifen by assessing CRR (70.4 *vs* 50.5%,  $P = 0.004$ ) and BCS (86% *vs* 68%)<sup>[34]</sup>. Furthermore, the suitable selection of OFS has been discussed in premenopausal individuals. The TREND trial was conducted to evaluate the efficacy of degarelix (a GnRH antagonist) *vs* triptorelin (a GnRH agonist) in patients receiving neoadjuvant letrozole. Individuals treated with degarelix responded more quickly in inducing optimal OFS than those receiving triptorelin<sup>[35]</sup>. This finding supported the use of additional studies to assess whether degarelix optimizes treatment efficacy in neoadjuvant treatment and to screen for the optimal agents for OFS. In conclusion, AI plus OFS is a suitable selection in NAE for premenopausal patients, and it demands prospective validation in more clinical trials.

### Optimal targeted agents of NAE

The application of targeted agents was supported to promote endocrine response and reveal drug resistance mechanisms. We will review the promising antiproliferative effects of targeted agents, including cyclin-dependent kinase (CDK) 4/6 inhibitors and phosphatidylinositol 3-kinase (PI3K)/AKT/mammalian target of rapamycin (mTOR) pathway inhibitors.

**CDK 4/6 inhibitors:** CDK 4/6 inhibitors are suppressors of the cell cycle from G1 to S phase. By inducing retinoblastoma protein (Rb) hypophosphorylation, they effectively inhibit mitosis and thus subsequently prevent cell proliferation and tumor progression (Figure 1)<sup>[36]</sup>. CDK4/6 inhibitors in combination with endocrine therapies have yielded a good prognosis and clinical benefits for ER+ patients, and provoked thoughts about applying CDK4/6 inhibitors in NAE. The following several paragraphs will review clinical trials discussing the efficacy of CDK4/6 inhibitors, especially palbociclib, and addressing the mechanisms of drug resistance.

Newly published in 2018, PALLET, the largest phase II clinical study, has obtained worldwide focus for its concern with efficacy evaluation of a CDK4/6 inhibitor in NAE. In this trial, patients were randomized to letrozole monotherapy or letrozole plus palbociclib therapy for 14 weeks. The combination group showed remarkable superiority over letrozole monotherapy, with larger change in Ki67 (-4.1 *vs* -2.2), higher rate of complete cell-cycle arrest (CCCA, 90% *vs* 59%), and greater cleaved poly(ADP-ribose) polymerase (c-PARP, -0.80 *vs* -0.42), indicating that the combination of palbociclib and letrozole could induce the suppression of cell proliferation<sup>[37]</sup>. In NeoPalAna single arm trial, patients received neoadjuvant anastrozole, adding palbociclib on cycle 1 day 1 (C1D1) and leaving study if Ki67 was > 10% on C1D15. CCCA rate, as the primary endpoint, was significantly higher in C1D15 than C1D1 (87% *vs* 26%), and rebound of Ki67 expression occurred following withdrawal of palbociclib<sup>[38]</sup>. The significant improvement of CCCA rate and Ki67 suppression was observed in either luminal A or B subtype and with both PIK3CA mutant or wild type (WT) status, which is parallel to data from the PALOMA-3 trial<sup>[39]</sup>. Considering molecular remission, researchers pointed out that the antiproliferation effect corresponding to biomarkers was important to identify patients who might benefit and provide an effective endpoint for clinical research.

The POP trial investigated the antiproliferative action of palbociclib in the Rb phosphorylation process. Antiproliferative response, defined as  $\ln Ki67 < 1$  at day 5, was the primary endpoint, and it was improved in the palbociclib arm *vs* the placebo arm (58% *vs* 12%). Greater Ki67 and phospho-Rb decrease were observed in the palbociclib group<sup>[40,41]</sup>. Phospho-Rb was related to palbociclib activity, and changes in Rb phosphorylation might be an indicator for CDK4/6 inhibitors. In the MONALEESA-1 trial, patients randomly received either letrozole alone (A) or in combination with ribociclib at different dosages (B: 400 mg/d, C: 600 mg/d). The mean decreases in the Ki67-positive cell fraction from baseline were A, 69%; B, 96%; and C, 92%; this finding indicated the possible antiproliferative effect of combined letrozole and ribociclib<sup>[42]</sup>. Regarding abemaciclib, 224 postmenopausal patients were randomly assigned to undergo neoadjuvant abemaciclib monotherapy, anastrozole monotherapy, or combination therapy for 2 weeks in the neoMONARCH trial. Abemaciclib, alone or in combination with anastrozole, reduced Ki67 in more patients than anastrozole alone (59%, 66%, and 15%, respectively)<sup>[43]</sup>. Investigators concluded that CDK 4/6 inhibitors might serve as antiproliferative agents with manageable toxicities and may be predictive of improved disease-free survival. However, this conclusion is still uncertain due to small sample sizes and limited data, and continuous application should be guaranteed to maintain this effect.

**Figure 1 The crosstalk between estrogen receptor and growth factor receptor intracellular signaling pathways.**

Growth factor receptors (GFRs) activate the downstream PI3K/AKT/mTOR signaling pathway and the Cyclin D1/CDK4/6 complex, while the ER-E2 complex has the same effect<sup>[79]</sup>. The Cyclin D1/CDK4/6 complex drives cell proliferation by inducing Rb phosphorylation and promotes cell cycle from G1 phase to S phase in the nucleus<sup>[80]</sup>. Targeted agents against the CDK4/6 pathway and the PI3K/AKT/mTOR pathway can trigger cell cycle arrest and control tumor progression. ER: Estrogen receptor; GFR: Growth factor receptor; CDK4/6: Cyclin-dependent kinase; PI3K: Phosphatidylinositol 3-kinase; PIP2: Phosphatidylinositol 4,5-bisphosphate; PIP3: Phosphatidylinositol triphosphate; mTOR: Mammalian target of rapamycin; Rb: Retinoblastoma protein.

**PI3K/AKT/mTOR pathway inhibitors:** The PI3K/AKT/mTOR pathway was found to be a key survival mechanism responsible for endocrine resistance (Figure 1). Regarding PIK3CA inhibitors, the LORELEI trial randomized postmenopausal patients with ER+ HER2- operable breast cancer into two arms to investigate the effect of letrozole plus taselisib *vs* letrozole plus placebo for 16 wk<sup>[44]</sup>. The primary results showed that the improvement of ORR was significantly related to the addition of taselisib in the general patient population as well as PIK3CA mutant participants compared with letrozole monotherapy. The results encouraged the antitumor value of taselisib to be investigated in further research.

In preclinical studies, MK-2206 has been proved to be an allosteric pan-AKT inhibitor<sup>[45]</sup>. A clinical trial explored whether the addition of MK-2206 to anastrozole can lead to the pCR improvement of PIK3CA mutant ER+ breast cancer. This trial selected 22 PIK3CA mutant patients, of whom 16 received the experimental drug. The combination of anastrozole and MK-2206 had no further inhibitory effect on cell proliferation and did not promote apoptosis on C1D17 compared to anastrozole monotherapy<sup>[46]</sup>. The possibility of improving the efficacy of anastrozole by adding MK-2206 is low, and we disagree with the necessity to continue studying MK-2206 in the target population.

Everolimus, an analog of rapamycin, might competitively bind to the target protein of rapamycin and block downstream signal transduction to suppress tumor cell proliferation<sup>[47]</sup>. Everolimus utility in NAE was first discussed in a 2009 phase II randomized study carried out by Baselga *et al*<sup>[48]</sup>. Postmenopausal patients with ER+ breast cancer were treated with neoadjuvant letrozole plus everolimus or letrozole monotherapy. Investigators assessed CRR (68.1% *vs* 59.1%) and calculated the percentage of patients with Ki67 < 1% (57% *vs* 30%)<sup>[48]</sup>. The everolimus group was superior to the placebo group in both endpoints, indicating the better efficacy of everolimus in NAE. Clinical trials in this area were not adequate until Wu *et al*<sup>[49]</sup> compared neoadjuvant letrozole plus everolimus with neoadjuvant chemotherapy in ER+/HER2- nonmetastatic breast cancer, and a network meta-analysis by Wang *et al*<sup>[50]</sup> in 2016 concluded that letrozole in combination with everolimus was the most effective treatment in the neoadjuvant setting. Furthermore, we can expect outcomes in several ongoing neoadjuvant studies combining AI with everolimus, in an attempt to enhance the clinical response of NAE.

## BIOMARKERS AND GENOMIC ASSAYS FOR PREDICTION OF NAE BENEFIT

The molecular and genetic expression profiles measured in tumor specimens upon neoadjuvant treatment can provide a remarkable opportunity to explore predictive

tools. In the following paragraph, we will discuss the relevant research that elaborates the value of biomarkers and genomic assays and establish a potential biomarker-based strategy in neoadjuvant settings.

### **Ki67 and PEPI biomarkers**

Ki67, as a biomarker, can be commonly expressed in all stages of the cell cycle, except for G0, and it is of great significance in measuring tumor proliferation in breast specimens<sup>[51]</sup>. Current evidence showed that the decrease of Ki67 during NAE with endocrine or targeted agents can reveal anti-proliferation effects, and Ki67 level was inversely correlated with prognosis<sup>[52,53]</sup>. We encourage a broad development prospect for biomarker-based estimates of prognosis in the neoadjuvant therapy field.

Several clinical trials discussed the relationship between prognosis and Ki67 expression at baseline or after short-term treatment. DeCensi *et al*<sup>[54]</sup> assessed the levels of Ki67 at baseline and after 4 wk of presurgical tamoxifen treatment, and the multivariable hazard ratio for baseline and posttreatment Ki67 labeling index was 1.007 (95%CI: 0.975–1.041) *vs* 1.034 (95%CI: 1.001–1.068)<sup>[54]</sup>. A PerELISA study first indicated that patients with postmenopausal ER+ breast cancer who gained a reduction in Ki67 after 2-wk neoadjuvant letrozole treatment achieved a meaningful pCR rate without chemotherapy<sup>[55]</sup>. However, a recent study showed different results at baseline. The POETIC trial compared peri-surgical AI treatment (pre- and postsurgery) with no treatment in 4000 ER+ breast cancers<sup>[56]</sup>. The results announced at the SABCs 2017 conference suggested that Ki67 levels both at baseline and after short-term therapy were both predictive of efficacy. In conclusion, sufficient evidence has demonstrated that Ki67 levels measured after short-term neoadjuvant therapy were meaningfully related to survival. Whether Ki67 level at baseline can act as a predictive tool is controversial and needs further confirmation.

The preoperative endocrine prognostic index (PEPI) combines Ki67 level with ER status, pathological tumor size, and node status in the surgical specimen following NAE<sup>[57]</sup>. The predictive role of PEPI for relapse-free survival (RFS) was discovered by Ellis *et al*<sup>[32]</sup> in the P024 trial and validated in the independent IMPACT trial. Patients with a PEPI score equal to 0 (pT1 or pT2, pN0, Ki67  $\leq$  2.7%, Allred score  $<$  2) had an extremely low risk of relapse and can be exempt from adjuvant chemotherapy, while PEPI  $>$  0 recognizes a higher relapse risk. Recently, the predictive value of PEPI was verified in the ACOSOG Z1031B trial<sup>[32]</sup>. After a median follow-up period of 5.5 years, the incidence of recurrence in patients who completed the neoadjuvant AI period was significantly different. Kaplan-Meier analysis identified the relationship between RFS and PEPI, and the recurrence HR in patients with a PEPI score equal to 0 *vs* PEPI  $>$  0 patients was 0.27 ( $P = 0.014$ ). Moreover, the relapse risk was only 3.6% without chemotherapy in patients with a PEPI score equal to 0<sup>[58]</sup>. These results supported the use of the PEPI score to identify drug-sensitive or drug-resistant patients and guide tailored treatment decisions on avoiding chemotherapy.

### **Genomic assays**

Recent evidence indicated the predictive role of genomic assays including Oncotype DX, EndoPredict, MammaPrint, Blueprint assays, and a four-gene predictive tool (Table 4).

**Oncotype DX Recurrence Score assay:** The Oncotype DX® Breast Recurrence Score (RS) assay is a 21-gene validated genomic tool developed by Genomic Health to assess recurrence risk for patients who received adjuvant ET with ER+/HER2- early stage breast cancer, regardless of lymph node status<sup>[59,60]</sup>. The RS assay can predict the likelihood of benefit from adding chemotherapy to ET in the adjuvant settings. A low-risk RS tended to have a greater clinical response to ET<sup>[61]</sup>. Additionally, several studies have already incorporated the RS assay in the neoadjuvant setting and illustrated that the approach can be used to guide the decision of neoadjuvant systemic therapy.

We discuss the relevant trials considering the predictive role of RS assay in NAE. Ueno *et al*<sup>[62]</sup> indicated that the low-risk group (RS  $<$  18) was more likely to benefit from presurgical exemestane treatment than the high-risk group (RS  $\geq$  31) in CRR (54% *vs* 22%,  $P < 0.001$ ) and BCS (91% *vs* 47%,  $P = 0.003$ ). A 2017 multicenter study reported that the successful BCS rates of the low-intermediate risk group (RS 11–25) after NAE were 75% and 72%, respectively, which were higher than that of high-risk NAC<sup>[63]</sup>. NAE was found to be a scientific strategy for low-risk patients. Moreover, NAE was not inferior to NAE in midrange RS score, and this finding mirrored the results in similar adjuvant settings in the TAILORx trial<sup>[64]</sup>. Most recently, the larger, multicenter TransNEOS trial validated the feasibility of RS assay in predicting clinical response and successful BCS with neoadjuvant letrozole in 295 ER+/HER2-postmenopausal patients. The low RS-score group was considered to have an

**Table 4** Genomic assays to predict outcome in neoadjuvant endocrine therapy

Genomic assay	Gene number	Genomic information	Method	Current results in NAE	Ref.
Oncotype DX®	21 (16+5)	Proliferative-related genes: <i>Ki67 AURKA, BIRC5, CCNB1, MYBL2</i> Invasive-related genes: <i>MMP11, CTSL2</i> Estrogen-related genes: <i>ESR1, PGR, BCL2, SCUBE2</i> HER2-related genes: <i>ERBB2, GRB7</i> Other genes: <i>GSTM1, CD68, BAG1</i> Reference genes: <i>ACTB, GAPDH, RPLPO, GUS, TFRC</i>	QRT-PCR	Recurrence score; low RS results imply a greater likelihood of response to NAE	[62-63]
EndoPredict (EP)	12 (8+4)	Proliferative-related genes: <i>BIRC5, UBE2C, DHCR7</i> Estrogen-related genes: <i>RBBP8, IL6ST, AZGP1, MGP, STC2</i> Reference genes: <i>CALM1, OAZ1, RPL37A, HBB</i>	QRT-PCR	Lower genomic risk related to favorable response.	[69]
MammaPrint (and BluepPrint)	70	<i>AA555029_RC, ALDH4A1, AP2B1, AYTL2, BBC3, C16orf61, C20orf46, C9orf30, CCNE2, CDC42BPA, CDCA7, CENPA, COL4A2, DCK, DIAPH3, DTL, EBF4, ECT2, EGLN1, ESM1, EXT1, etc.</i>	Microarray analysis	Distinguish breast cancer subtypes; luminal-subtype patients have a promising prognosis	[73]
Four-gene predictive model	4	Proliferative-related genes: <i>ASPM and MCM4</i> Immune-related gene: <i>IL6ST</i> Apoptosis induction-related gene: <i>NGFRAP1</i>	QRT-PCR or IHC	Associated to RFS and BCS	[75]

NAE: Neoadjuvant endocrine therapy; QRT-PCR: Quantitative real time polymerase chain reaction; IHC: Immunohistochemistry.

improved BCS rate, implying a greater likelihood of response to NAE rather than NAC (CRR: 54% *vs* 22%,  $P < 0.001$ )<sup>[65]</sup>. In conclusion, the Oncotype DX assay would be a significant predictive tool for providing useful information to screen patients who would benefit from neoadjuvant systematic therapy, with NAE used for low-risk group and NAC for high-risk group.

**EndoPredict assay:** The EndoPredict® (EP) assay is a 12-gene signature test based on eight proliferation-related and differentiation-related cancer genes and four reference genes. EP score low-risk and high-risk categories were specified in previous studies, providing a score between 0 and 15 to assess recurrence risk<sup>[66]</sup>. EPclin is a diagnostic arithmetic genomic assay derived from the EP score by integrating clinical factors including nodal status and residual tumor size, which are also involved in PEPI<sup>[67]</sup>. EP and EPclin assays were shown to be prognostic for early and late distant recurrence<sup>[68]</sup>. Chow *et al*<sup>[69]</sup> enrolled 20 eligible patients with neoadjuvant letrozole plus palbociclib treatment in four repeated cycles. The EP score was significantly reduced after NAE, and patients in the high PEPI category had high EPclin scores, indicating that EPclin might be a better predictive marker than PEPI<sup>[69]</sup>. A retrospective analysis of ABCSG 34 reported at SABCS 2017 also examined the predictive role of EP score. The results after 6 months of neoadjuvant letrozole treatment showed that 27.3% of low-risk and

7.7% of high-risk patients achieved residual cancer burden<sup>[70]</sup>. The EP assay may help guide neoadjuvant therapy. Lower genomic risk is related to a favorable response to NAE and worse response to NAC. Further studies should be conducted to verify whether EP and EPclin scores can act as alternative parameters for prognosis in NAE settings in a wide range of population.

**MammaPrint and Blueprint assays:** The MammaPrint® assay, a 70-gene genomic assay, was of great significance in the accurate guidance of treatment decisions for breast cancer patients in adjuvant settings<sup>[71]</sup>. Blueprint®, a molecular profile that integrates the expression levels of 80 genes, can act as a complement with MammaPrint<sup>[72]</sup>. According to MammaPrint and Blueprint assays, patients were classified into four molecular subgroups: Luminal A, Luminal B, HER2, and Basal type. The identification of chemosensitivities or endocrine sensitivities in patients with different subtypes can provide insight into the response and prognosis of neoadjuvant therapy. The NBRST trial was designed to include patients with histologically proven breast cancer for selecting optimal therapy<sup>[73]</sup>. Approximately 68% of patients with Blueprint Luminal breast cancer who received AI therapy and 29% who received tamoxifen had a clinical response in NAE. Patients with MammaPrint Luminal A-subtype tumors had similar clinical efficacy to relatively high-risk Luminal B-subtype patients (CRR: 68.6% *vs* 66.7%)<sup>[74]</sup>. We discovered that luminal-subtype patients determined by these genomic assays could be valuable candidates for NAE and had a promising prognosis. Limited research focused on MammaPrint and Blueprint prognostic assays for the effective stratification of breast cancer patients in neoadjuvant therapy; therefore, further prospective development is needed to guide clinicians' decisions.

**Four-gene predictive model:** A clinical trial reported by Turnbull *et al*<sup>[75]</sup> provided a four-gene predictive model combining two pretreatment genes (immune-related *IL6ST* and apoptosis-related *NGFRAP1*) and two on-treatment genes (proliferation-related *ASPM* and *MCM4*) after 2 weeks of letrozole therapy to forecast clinical response with an accuracy of 96%<sup>[75]</sup>. Another blinded independent setting of patients receiving anastrozole yielded similar results, with an accuracy of 91%. The gene signature can be significantly associated with RFS and BCS, and accurately measured and performed by PCR and immunohistochemistry, which can give confidence to guide treatment decisions and facilitate further applications<sup>[76]</sup>. Although it is a viable result as a predictive biomarker based on one small, retrospective analysis, it needs to be confirmed in large, prospective clinical trials.

## DISCUSSION AND FUTURE OUTLOOK

NAE is a favorable alternate approach treatment to NAC for patients with ER+ breast cancer. Given efficacy and good tolerance associated with NAE, especially as NECT, consideration and identification of the optimal settings are of great significance for precision treatment. We consider that extended NAE therapy has a greater potential to result in tumor regression and BCS eligibility, but the optimal treatment duration remains to be further validated. The optimal endocrine agents have been widely discussed in neoadjuvant settings. For postmenopausal patients, AIs demonstrated superiority over TAM, and clinical efficacy is biologically and clinically equivalent among letrozole, anastrozole, and exemestane. For premenopausal patients, AI plus OFS is a beneficial strategy in both adjuvant and neoadjuvant settings despite limited data, as mentioned. The effective role of fulvestrant in NAE has also been indicated above. Additional relevant studies are demanded for the helpful knowledge of endocrine agents to define the most appropriate medication and investigate combination approaches in both postmenopausal and premenopausal patients in NAE.

Multiple trials have demonstrated that combination approaches with targeted agents are effective in inducing cell cycle arrest and preventing tumor progression. The potential antiproliferative effect of CDK4/6 inhibitors, especially palbociclib, has been confirmed to be broadly applicable to ER+ breast cancer patients in NAE. However, insufficient data have been published for PI3K/AKT/mTOR pathway inhibitors. Attempts to promote endocrine response and address mechanisms of both “*de novo*” and acquired endocrine resistance by application of targeted agents through specific intracellular signaling pathways are encouraged.

Apart from that, NAE will also provide a well-recognized scenario for biomarker research related to cell proliferation. The establishment of the Ki67 biomarker, which can replace the conventional clinical endpoint of tumor shrinkage, offered a feasible approach to reveal the antiproliferative effect of different drugs<sup>[77]</sup>. Moreover, Ki67

levels in postsurgical biopsies have been validated as an effective predictive tool for prognosis and facilitated the development of biomarker-based prognosis estimation. PEPI integrating four risk parameters associated with survival was further confirmed to predict RFS. The ongoing and highly anticipated ALTERNATE trial aimed to assess the validity of Ki67 level measurement following 4 wk treatment and a modification of the PEPI score prospectively responding to anastrozole, fulvestrant, or combination therapy<sup>[78]</sup>. If a biomarker-based strategy is ultimately determined, it will help guide the choice of treatment options and achieve the goal of individualized and precise treatment.

Compared with the molecular profiles, gene analysis provided more accurate information in predicting response, as the results remained the same during the treatment or washout period. The predictive role of genomic assays in NAE is in its infancy. The risk stratification through genetic analysis provided a unique opportunity to guide neoadjuvant systemic therapies. Different genomic assays could evaluate recurrence risks of individuals based on specific related genes and statistical algorithms and provided various risk stratification. Oncotype Dx has been widely recognized as the most useful potential assay in NAE to screen endocrine or chemosensitive individuals and divide individuals according to RS scores into low-risk, moderate-risk, and high-risk groups. Inconsistent with Oncotype Dx, Endopredict and MammaPrint assays have utility to classify candidates into high-risk and low-risk groups. Similarly, the low-risk group has a potential to benefit from NAE and exempt from adjuvant chemotherapy. Thus for, there are still insufficient retrospective and prospective studies to confirm the predictive role of genomic assays. We believe that with the publication of more clinical research results, genomic assays will become a useful predictive tool for clinicians to judge prognosis and guide clinical treatment.

## CONCLUSION

In conclusion, NAE can serve as a potential strategy for ER+ breast cancer. It allows the identification of suitable individuals with a good response and guides the decisions for clinical systemic treatment. We can meet our requirements of precise treatment through this platform. Although potential strategies have been proposed, the clinical practicability is lacking validity. Further explorations with large-range populations and long-term follow-up periods are demanded to verify the value of NAE.

## Abstract

### BACKGROUND

Vestigial like family member 3 (VGLL3) is associated with the prognosis of epithelial ovarian cancer and soft tissue sarcoma, but its role in gastric cancer (GC) is unclear.

### AIM

To explore the expression pattern and clinical significance of VGLL3 in GC.

### METHODS

Integrative analysis was performed on the GC transcriptome profiles and survival information deposited in the ONCOMINE, GEPIA, and ONCOLNC databases. The expression levels of VGLL3 mRNA and protein were analyzed in the freshly resected tumor and normal gastric tissues from GC patients by quantitative RT-PCR and Western blot, respectively. In addition, the *in situ* expression of VGLL3 in the GC tissues was determined by immunohistochemistry (IHC), and the patients were accordingly classified into the high and low expression groups. The correlation of VGLL3 expression status with patient prognosis was then determined by univariate and multivariate Cox

regression analyses.

## RESULTS

Analysis of the ONCOMINE and GEPIA databases showed that VGLL3 was significantly up-regulated in GC tissues ( $P = 0.003$ ), and associated with the tumor TNM stage ( $P = 0.0163$ ). The high VGLL3 expression group had a significantly worse prognosis compared to the low expression group, as per both GEPIA ( $P = 0.0057$ ) and ONCOLNC ( $P = 0.01$ ). The bioinformatics results were validated by the significantly higher VGLL3 mRNA and protein levels in the GC tissues compared to the adjacent normal tissues ( $P < 0.001$ ) in a cohort of 30 GC patients. Furthermore, high *in situ* expression of VGLL3 protein was associated with more advanced N and TNM stages and HER2 mutation ( $P < 0.05$ ) in a cohort of 172 patients. Kaplan-Meier analysis showed that the high VGLL3 expression group had a worse prognosis compared to the low expression group ( $P = 0.019$ ). Multivariate analysis showed that VGLL3 expression status was an independent risk factor for prognosis. In addition, the prognostic risk model nomogram showed that VGLL3 was the most important indicator, with an area under the receiver operating characteristic (ROC) curve (AUC) of 0.613 for 3-year survival and 0.706 for 5-year survival. Finally, the protein interaction network analysis revealed that VGLL3 is likely involved in the Hippo signaling pathway.

## CONCLUSION

VGLL3 is overexpressed in GC tissues and associated with a poor prognosis, indicating its potential as a novel prognosis biomarker and therapeutic target for GC.

**Key words:** Vestigial like family member 3; Stomach adenocarcinoma; HER2 mutation; Gastric cancer; Bioinformatics analysis

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** The present study for the first time revealed the expression of vestigial like family member 3 (VGLL3) in gastric cancer (GC) and its correlation with HER2 mutation. Overall, the findings of the present study suggest that VGLL3 is a novel prognostic biomarker for GC and highlight the significance of VGLL3 as a promising therapeutic target for GC.

## INTRODUCTION

Gastric cancer (GC) is a frequently occurring malignancy of the digestive tract<sup>[1]</sup>, and it was the fifth most commonly diagnosed and the third most common cause of cancer-related mortality worldwide in 2018<sup>[2]</sup>. Lack of early diagnosis and ineffective treatment options for the advanced stages are the primary reasons for the dismal 5-year survival rate of GC<sup>[3]</sup>. Therefore, it is imperative to identify novel biomarkers for early diagnosis and accurate prediction of prognosis. Vestigial like family member 3 (VGLL3) is a member of the vestigial like family of proteins<sup>[4]</sup>, and is associated with epithelial ovarian cancer<sup>[5]</sup> and soft tissue sarcoma<sup>[6]</sup>. The aim of this study was to determine the expression status and prognostic utility of VGLL3 in GC. To this end, we mined the transcriptomic data of GC from the ONCOMINE and GEPIA databases, and determined its correlation with the survival data from GEPIA and ONCOLINC. VGLL3 levels were upregulated in GC samples and associated with a poor prognosis. The bioinformatics data were successfully validated on the tumor and normal gastric tissues resected from GC patients. Based on the VGLL3 levels, the patients were stratified into the high and low expression groups, and a prognosis prediction model was established on the basis of VGLL3 status and clinical data. Our findings show a

strong prognostic role of VGLL3 in GC, which can potentially translate to clinical applications.

## MATERIALS AND METHODS

### *Patients and tissue samples*

A total of 172 tissue samples were obtained from gastric adenocarcinoma patients who underwent major surgery at the Affiliated Hospital of Jiangnan University between 2009 and 2012. The tissues were immediately fixed in formalin and embedded in paraffin for further analysis. In addition, fresh samples were dissected from 30 patients at the Affiliated Hospital of Jiangnan University in November 2018, and immediately stored in liquid nitrogen for molecular analysis. The mean follow-up duration was 43.1 mo and ranged from 0.2 to 86 mo. None of the patients received chemotherapy or radiotherapy before surgery<sup>[7]</sup>. The tumor stage classification was determined by three pathologists who were blinded to the patient data according to the guidelines of the American Joint Committee on Cancer (AJCC). Freshly resected tissues were obtained from 202 patients, and were fixed in formalin and embedded in paraffin. In addition, tissue specimens from 30 patients were flash frozen in liquid nitrogen. All participating clinicians and patients provided written informed consent.

### *Bioinformatics analysis*

The VGLL3 mRNA levels in the GC and normal gastric tissues were determined by integrated analysis of the Oncomine database ([www.oncomine.org](http://www.oncomine.org))<sup>[8]</sup> using Coexpedia ([www.coexpedia.org](http://www.coexpedia.org))<sup>[9]</sup>. ONCOLINC (<http://www.oncolnc.org/cancer/>) and Coexpedia were used to analyze the prognostic value of WISP1 in STAD. The STRING database (<http://www.string-db.org>) was utilized to construct the protein-protein interaction (PPI) network<sup>[10]</sup>.

### *RNA isolation and RT-qPCR*

Total RNA was extracted from frozen tissue samples using Trizol reagent (Invitrogen, Carlsbad, CA) according to the manufacturer's instructions, and reverse transcribed using the PrimeScript RT-PCR kit (Takara, Japan)<sup>[11]</sup>. RT-qPCR was performed on the ABI 7500 RealTime PCR System (Applied Biosystems, Inc. USA) using SYBR Green Master Mix (Takara, Japan), and the VGLL3 levels were normalized to  $\beta$ -actin. The following primers were used: Forward primer, 5'-CCAACTACAGTCACC-TCTGCTAC-3' and reverse primer, 5'-ACCACGGTGATTCCTTACTCTTG-3' for VGLL3; forward primer, 5'-CCTGTGGCATCCACGAAACT-3' and reverse primer, 5'-GAAGCATTTGCG GTGGACGAT-3' for  $\beta$ -actin. All reactions were performed in triplicates, and the  $2^{-\Delta\Delta Ct}$  method<sup>[12]</sup> was used to quantify the relative expression levels of VGLL3.

### *Western blot analysis*

Total protein was extracted from GC and para-cancerous tissues using the RIPA lysis buffer (Pierce, Thermo Scientific, Cramlington, United Kingdom)<sup>[13]</sup>, and quantified with the enhanced BCA protein assay kit (KeyGEN BioTECH, Jiangsu, China). Equal amount (40 mg) of proteins per sample were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SD-PAGE), and then transferred to polyvinylidene difluoride membranes (Bio-Rad, Hercules, CA, United States). After blocking with 5% non-fat milk for 1 h at room temperature (RT), the membranes were incubated overnight with anti-VGLL3 (ab83555, Abcam) and  $\beta$ -actin (ab8226, Abcam) primary antibodies at 4 °C. After washing thrice with TBST, the membranes were incubated with HRP-conjugated secondary antibody (1:1000) for 1 h at RT. The protein bands were visualized with an ECL chemiluminescence system after short exposure to X-ray films (Kodak, Japan). Densitometric analysis was performed with Image Pro-Plus software, and the relative expression levels of VGLL3 were normalized to tubulin.

### *Immunohistochemistry (IHC)*

The formalin-fixed tissues were dehydrated, embedded in paraffin, and cut into 5  $\mu$ m thick sections. IHC was performed according to the manufacturer's protocol<sup>[14]</sup>. Briefly, the sections were heated in citrate buffer in a microwave, cooled, and incubated overnight with anti-VGLL3 antibody (1:50, clone PA5-68441, Invitrogen) at 4 °C. After labeling with the secondary antibody for 1 hour at RT, color was developed using liquid DAB substrate. Three pathologists blinded to the patient identity observed and graded VGLL3 positivity as 0, 1 (1%–29% positively-stained cells), 2 (30%–69%), or 3 (70%–100%), and the staining intensity as 0 (negative), 1 (weak staining), 2 (moderate staining), or 3 (strong staining). The immunoreactive

score (IRS) was then calculated for each sample by multiplying the staining intensity and positivity scores, and graded as: 0-1, “-”; 2-3, “+”; 4-6, “++”; and 6-9, “+++”<sup>[15]</sup>. Based on the IRS, the samples were stratified into the high (4-9) and low (0-3) VGLL3 expression groups.

### Fluorescence in situ hybridization (FISH)

The tissue sections were treated with denaturing solution to denature the DNA into single strands, and hybridized with the PathVysion probes (No.36-161060, PathVysion HER-2DNA Probe Kit). After washing the unbound probe with DNA, the sections were counterstained with the nuclear dye DAPI (4', 6 diamidino-2-phenylindole). Positive LSI HER-2/neu and CEP 17 signals were counted under a fluorescence microscope, and the ratio of the copy number of HER-2/neu gene to that of chromosome 17 was calculated.

### Statistical analysis

Statistical analyses were performed with R\*64 version 3.5.2 software and Graphpad 6.01. HER2 status (positive or negative) was designated on the basis of the combined FISH and IHC results as per the American Society of Clinical Oncology/College of American Pathologists Clinical Practice Guidelines. VGLL3 expression levels in the tumor and normal samples were compared by the Student's *t*-test, and the association between VGLL3 and clinico-pathological features was assessed by the chi-square test. The overall survival (OS) curve was plotted by the Kaplan-Meier method and analyzed by the log-rank test. Univariate and multivariate analyses of the prognostic factors were performed using the Cox proportional hazard regression model. A nomogram was formulated based on the results of the multivariate analysis with the package of rms in R version 3.5.2 (<http://www.r-project.org/>)<sup>[16]</sup>. The receiver operating characteristic (ROC) curve was plotted to determine the sensitivity and specificity of the VGLL3-based prognostic score<sup>[17]</sup>, and the area under the curve (AUC) was calculated. All *P*-values were two-tailed and considered statistically significant when less than 0.05.

## RESULTS

### VGLL3 mRNA and protein levels are upregulated in GC samples

GEPIA database profiling showed that although VGLL3 was significantly overexpressed in GC samples of advanced TNM stages relative to those at the lower stages ( $P = 0.0163$ ), there was no significant difference between the GC and normal tissues ( $P > 0.05$ ). Integrated analysis of multiple VGLL3 transcriptome datasets from the ONCOMINE database, however, showed that VGLL3 was significantly overexpressed in GC ( $P = 0.003$ ), and notably associated with a poor prognosis according to the ONCOLINC database analysis ( $P = 0.01$ ,  $n = 378$ ) (Figure 1). In addition, GEPIA online survival analysis further confirmed that VGLL3 was a marker of poor prognosis in GC ( $P = 0.0062$ ,  $n = 384$ ). To validate the *in silico* data, we analyzed the expression levels of VGLL3 in the tumor and normal gastric tissues resected from 30 GC patients, and observed significantly higher levels of VGLL3 mRNA ( $P < 0.001$ ) and protein ( $P < 0.001$ ) in the GC tissues compared to normal tissues (Figure 2). Taken together, VGLL3 is upregulated in GC and possibly associated with a worse prognosis.

### VGLL3 is a potential prognostic factor for GC

The relationships between VGLL3 levels and the clinico-pathological characteristics of the patients are summarized in Table 1. High levels of VGLL3 were positively correlated with tumor lymph node metastasis ( $P = 0.028$ ) and TNM stage ( $P = 0.041$ ). In addition, the median survival time of the GC patients was significantly lower in the high VGLL3 expression group than in the low expression group (35 mo *vs* 49 mo,  $P = 0.019$ ; Figure 3C). Univariate analysis showed that the VGLL3 expression level ( $P = 0.019$ ) was the only significant prognostic factor of GC, whereas age, gender, differentiation, T stage, lymph node status, TNM stage, and HER2 status did not show any significant results ( $P > 0.05$ ). After including the significant factors in the Cox proportional hazards regression model for multivariate prognostic analysis, we found that VGLL3 expression ( $P = 0.019$ ) was an independent risk factor for GC. ROC curves were plotted to determine the power of the VGLL3 prognostic score in predicting the 3- and 5-year survival, and the AUCs were 0.613 and 0.706, respectively (Figure 3I). We constructed a PPI network of VGLL3 using the STRING database, and identified YAP1, TEAD1, WWTR1, and VGLL4 as upstream of VGLL3, and POU1F1, TEAD3, AKAP11, SYT17, CHMP28, TEAD4, and ERBBE2 (HER2) as downstream proteins (Table 2).

**Figure 1** Vestigial like family member 3 mRNA expression levels in gastric cancer tissues determined by integrated analysis of different databases. A and B: Vestigial like family member 3 (VGLL3) expression in gastric cancer and normal gastric tissues (A) and in different TNM stages (B) in the GEPIA database; C: VGLL3 expression reported in the five published studies in the ONCOMINE database; D and E: Kaplan-Meier survival analysis of patients in the GEPIA (D) and ONCOLNC (E) databases stratified by VGLL3 expression status.

**Figure 2** Vestigial like family member 3 mRNA and protein expression levels in gastric cancer. The expression of vestigial like family member 3 mRNA (A) and protein (B and C) in 30 pairs of gastric cancer and normal gastric tissues is shown.

## DISCUSSION

GC is the third most common cause of cancer-related deaths worldwide, mainly due to ineffective diagnostic and therapeutic options. It is often detected at the advanced stage, and is highly heterogeneous. Therefore, novel molecular biomarkers for the early diagnosis and treatment of GC are urgently needed. VGLL3 is a member of the vestigial-like family proteins that are related to sex and maturation<sup>[18-20]</sup>, and is reportedly associated with epithelial ovarian cancer and soft tissue sarcoma. Through bioinformatics data mining and integrated analysis, we found that VGLL3 mRNA was not only upregulated in the GC tissues relative to normal gastric tissues, but also significantly associated with advanced TNM stage GC and poor survival outcomes. To validate the *in silico* data, we analyzed the gastric tissues of GC patients, and found abnormally high levels of VGLL3 in the tumor relative to normal tissues. In addition, high *in situ* expression of VGLL3 was correlated with tumor lymph node metastasis, TNM stage, and HER2 mutation, but not with age, gender, differentiation, T stage, or M stage. The patients were stratified into the high and low VGLL3 expression groups, and the former showed a significantly poor survival. Univariate and multivariate analyses further indicated that VGLL3 expression and TNM stage were independent risk factors for the prognosis of GC. Finally, the respective AUCs of the 3- and 5-year survival of the VGLL3-based prognostic model were 0.613 and 0.706, indicating a somewhat imperfect predictive ability. This could be due to the insufficient number of samples and other confounding factors such as the patient's state of mind, economic status, and family environment. Taken together, we identified VGLL3 as a novel prognostic biomarker for GC.

To further elucidate the underlying molecular mechanisms, we analyzed the PPI network of VGLL3 through the STRING database, and found that the Hippo pathway was significantly enriched. In addition, the identified upstream molecules of VGLL3 are YAP1<sup>[6]</sup>, TEAD1, WWTR1, VGLL4, and the downstream molecules are POU1F1, TEAD3, AKAP11, SYT17, CHMP28, and TEAD4. Interestingly, the expression level of VGLL3 was related to ERBBE2 (HER2) mutation, although the relevant mechanistic connection is unclear.

To conclude, VGLL3 is highly expressed in GC and an independent risk factor, and further studies are needed to determine its underlying mechanism. Nevertheless, VGLL3 is a novel biomarker for GC prognosis and a potential therapeutic target for this malignancy.

**Table 1** Characteristics of gastric cancer patients according to vestigial like family member 3 expression status

Characteristic	Cases	High expression	Low expression	P-value
Age (yr)				
≤60	97	47	50	0.548
>60	75	32	43	
Gender				
Female	101	43	58	0.369

## ARTICLE HIGHLIGHTS

### Research background

Gastric cancer (GC) is the most prevalent gastrointestinal tract malignancy. The prognosis of GC patients remains relatively poor. It is urgent to explore prognostic markers for GC.

### Research motivation

There are insufficient reports about the correlation between VGLL3 and GC.

### Research objectives

The aim of the present study was to explore the expression pattern and clinical significance of VGLL3 in GC.

### Research methods

It was found that VGLL3 would be a potential prognostic marker by bioinformatics analysis. To validate the *in silico* data, the authors identified the expression of VGLL3 in GC patient samples by immunohistochemistry and evaluated clinical outcomes.

### Research results

Analysis of the ONCOMINE and GEPIA databases showed that VGLL3 was significantly up-regulated in GC tissues, and associated with the tumor TNM stage. In addition, the high VGLL3 expression group had a significantly worse prognosis compared to the low expression group, as per both GEPIA and ONCOLNC. The bioinformatics results were validated by the significantly higher VGLL3 mRNA and protein levels in the GC tissues compared to the adjacent normal tissues in a cohort of 30 GC patients. Furthermore, high *in situ* expression of VGLL3 protein was associated with more advanced N and TNM stages and HER2 mutation in a cohort of 172 patients. Kaplan-Meier analysis showed that the high VGLL3 expression group had a worse prognosis compared to the low VGLL3 expression group. Multivariate analysis showed that VGLL3 expression status was an independent risk factor for prognosis. In addition, the prognostic risk model nomogram showed that VGLL3 was the most important indicator, with an AUC of 0.613 for 3-year survival and 0.706 for 5-year survival. Finally, the protein interaction network analysis revealed that VGLL3 is likely involved in the Hippo signaling pathway.

### Research conclusions

VGLL3 is overexpressed in GC tissues and associated with a poor prognosis, indicating its potential as a novel prognosis biomarker and therapeutic target for GC.

### Research perspectives

The present study suggested that VGLL3 is a novel prognostic biomarker for GC, and the significance of VGLL3 as a promising therapeutic target for GC is highlighted.

## Abstract

## BACKGROUND

The clinical significance of intratumoral human epidermal growth factor receptor 2 (HER2) heterogeneity is unclear for HER2-positive gastric cancer, although it has been reported to be a significant prognosticator for HER2-positive breast cancer, which has received trastuzumab-based chemotherapy.

## AIM

To clarify the clinical significance of intratumoral HER2 heterogeneity for HER2-positive gastric cancer, which has received trastuzumab-based chemotherapy.

## METHODS

Patients with HER2-positive unresectable or metastatic gastric cancer who received trastuzumab-based chemotherapy as a first line treatment were included. The patients were classified into two groups according to their intratumoral HER2 heterogeneity status examined by immunohistochemistry (IHC) on endoscopic biopsy specimens before treatment, and their clinical

were deceased.

response to chemotherapy and survival were compared.

## RESULTS

A total of 88 patients were included in this study, and HER2 heterogeneity was observed in 23 (26%) patients (Hetero group). The overall response rate was significantly better in patients without HER2 heterogeneity (Homo group) (Homo *vs* Hetero: 79.5% *vs* 35.7%,  $P = 0.002$ ). Progression-free survival of trastuzumab-based chemotherapy was significantly better in the Hetero group (median, 7.9 *vs* 2.5 mo, HR: 1.905, 95% CI: 1.109-3.268). Overall survival was also significantly better in the Hetero group (median survival time, 25.7 *vs* 12.5 mo, HR: 2.430, 95% CI: 1.389-4.273). Multivariate analysis revealed IHC HER2 heterogeneity as one of the independent poor prognostic factors (HR: 3.115, 95% CI: 1.610-6.024).

## CONCLUSION

IHC of HER2 heterogeneity is the pivotal predictor for trastuzumab-based chemotherapy. Thus, HER2 heterogeneity should be considered during the assessment of HER2 expression.

**Core tip:** Although intratumoral human epidermal growth factor receptor 2 (HER2) heterogeneity has been reported as an important predictor of trastuzumab-based chemotherapy for HER2-positive breast cancer, the clinical significance of HER2 heterogeneity for gastric cancer had been unclear. We defined intratumoral HER2 heterogeneity as biopsy specimens were taken from two or more different portions of the tumor that showed different HER2 positivity by immunohistochemistry, and HER2 heterogeneity based on this definition was a pivotal poor predictor of tumor shrinkage and poor prognosticator. Thus, intratumoral HER2 heterogeneity should be included in the assessment of HER2 positivity.

## INTRODUCTION

Human epidermal growth factor receptor 2 (HER2) was introduced as a predictive biomarker for the treatment of gastric cancer along with trastuzumab<sup>[1]</sup>, and trastuzumab was subsequently recommended to be administered for HER2-positive gastric cancer as a molecular target drug<sup>[2,3]</sup>. Assessment of HER2 expression was performed by immunohistochemistry (IHC) and in-situ hybridization (ISH), where positive HER2 expression was defined as 3+ on IHC or 2+ on IHC with ISH positive<sup>[4]</sup>. The strong HER2 intensity of IHC 3+ was reported as a better prognostic factor for HER2-positive gastric cancer treated with trastuzumab-based chemotherapy<sup>[1]</sup>.

The frequency of intratumoral HER2 heterogeneity was reported as 45%-79% by IHC and 23%-54% by ISH for HER2-positive gastric cancers<sup>[5-8]</sup>, which were more frequent than that with HER2-positive breast cancers<sup>[9]</sup>. Although intratumoral HER2 heterogeneity was reported to be one of the poor predictors for treatment response and poor prognosticator for patients with HER2-positive breast cancer who received trastuzumab-based chemotherapy<sup>[10,11]</sup>, the clinical significance of intratumoral HER2 heterogeneity for HER2 positive gastric cancer treated with trastuzumab has not been well investigated. Recently, Wakatsuki *et al*<sup>[12]</sup> reported that intratumoral HER2 heterogeneity had a negative survival benefit for patients with surgically resected HER2-positive gastric cancer. However, HER2 assessment before treatment is usually based on the endoscopic biopsy specimen for metastatic gastric cancer, and the

clinical significance of intratumoral HER2 heterogeneity for biopsy specimen is still unknown.

The aim of this study was to clarify the clinical significance of intratumoral HER2 heterogeneity for HER2 positive gastric cancer treated with trastuzumab-based chemotherapy by evaluation of biopsy specimens.

## MATERIALS AND METHODS

### *Patients and data collection*

Patients with histologically confirmed HER2-positive metastatic or unresectable adenocarcinoma of the stomach or gastroesophageal junction cancer who received trastuzumab-based chemotherapy as first-line treatment at our hospital between July 2011 and December 2017 were included in this study. The patients were classified into two groups according to intratumoral HER2 heterogeneity, and their clinicopathological findings, clinical responses, progression-free survival (PFS) and overall survival (OS) were compared. Furthermore, the predictive factor for clinical response and prognostic factor were analyzed using multivariable analyses. We extracted clinicopathological findings such as age, sex, tumor diameter, tumor location, macroscopic tumor type, tumor markers, Eastern Cooperative Oncology Group performance score, TNM stage, metastatic site, chemotherapy regimen, histological type of endoscopic biopsy specimen, HER2 positivity, survival outcomes from our prospectively collected database and medical records. Biopsied specimens stained by IHC were reviewed and assessed for their intratumoral HER2 heterogeneity by two pathologists (A.K. and T.K.).

Patients who received gastrectomy prior to chemotherapy and patients who received chemotherapy without trastuzumab were excluded. Clinical response was evaluated according to new response evaluation criteria in solid tumors (RECIST guideline ver. 1.1) for patients with measurable metastatic lesions<sup>[13]</sup>. The onset of PFS was defined as the start of chemotherapy, and tumor progression was evaluated by imaging techniques and physical examination. Tumor progression dates for patients who received radical gastrectomy after good clinical response to chemotherapy were defined as the date of first recurrence after surgery. Tumor staging of gastric and EGJ type III tumor followed the Union for International Cancer Control TNM classification of 7<sup>th</sup> edition for gastric cancer, and tumor staging of EGJ type II tumor followed that for esophageal cancer<sup>[14]</sup>. Tumor histology was assessed according to the Japanese Classification of Gastric Carcinoma<sup>[15]</sup>, with well and moderately differentiated adenocarcinoma and papillary adenocarcinoma classified as differentiated type, and poorly differentiated adenocarcinoma, signet ring cell carcinoma, and mucinous carcinoma classified as undifferentiated type.

### *Treatment schedules*

Chemotherapy regimens were capecitabine or 5-fluorouracil plus cisplatin with trastuzumab (XPT/FPT) before September 2015 and S-1 plus oxaliplatin with trastuzumab (SOXT) after October 2015. XPT or FPT regimens were followed a ToGA study regimen<sup>[1]</sup>. SOXT regimen was followed according to the G-SOX study regimen in combination with trastuzumab; oxaliplatin was administered intravenously 100 mg/m<sup>2</sup> on day 1, while S-1 was administered orally 80 mg/m<sup>2</sup> for 14 d followed by a 7-d rest. This schedule was repeated every 3 wk. Trastuzumab was given by intravenous infusion at a dose of 8 mg/kg on day 1 of the first cycle, followed by 6 mg/kg every 3 wk until disease progression<sup>[16]</sup>.

### *HER2 immunohistochemistry and fluorescence in situ hybridization*

All endoscopic biopsy samples were fixed in neutral buffered 10% formalin. Formalin-fixed paraffin-embedded tumor samples were examined for HER2 using IHC and fluorescence in situ hybridization (FISH) when the HER2 score was 2+.

HER2 IHC analyses were performed using the PATHWAY anti-HER-2/neu (4B5) rabbit monoclonal primary antibody (Ventana Medical Systems, Tucson, AZ, United States). IHC HER2 scoring by biopsy specimen was performed as described in the ToGA study<sup>[1]</sup>. In brief, tumor cell clusters of at least five positive cells with complete basolateral or lateral membranous reactivity was considered HER2-positive for endoscopic biopsy samples irrespective of percentage of tumor cells stained. Tumor cells with strong membranous reactivity were scored 3+, and those with moderate reactivity were scored 2+. HER2 FISH analyses were performed at SRL (Tokyo, Japan) using the Path Vysion HER2 DNA Probe kit (Vysis, Downers Grove, IL, United States). When the ratio of HER2 signals to chromosome 17 centromere signals was 2.0 or greater, the gene was considered amplified (*i.e.*, FISH-positive). HER2 positivity

was defined as IHC score 3+ or IHC score 2+ and FISH positivity, because these criteria were considered to be indications for using trastuzumab by a subset analysis of the ToGA trial<sup>[1,3]</sup>.

### Assessment of intratumoral HER2 heterogeneity

Assessment of intratumoral HER2 heterogeneity was conducted on patients who underwent assessment of HER2 positivity from two or more different portions of the same tumor, and three or more biopsy specimens were obtained from each portion. Those patients whose HER2 assessment was performed from only one portion were excluded for further examination. Intratumoral HER2 homogeneity was defined as every portion being HER2-positive by IHC, and if any portion of the tumor was HER2-negative, the tumor was defined as intratumoral HER2 heterogeneity (Figure 1).

### Statistical analysis

The baseline characteristics of each group were compared using the  $\chi^2$  test or the Fisher's exact test for categorical data, and  $P < 0.05$  was considered statistically significant. The median OS rate and PFS rate were estimated by the Kaplan-Meier method. Independent prognostic factors for OS and PFS were evaluated by univariate and multivariable analysis of Cox proportional hazard model and presented as hazard ratio and 95% confidence interval (CI). Evaluated factors in multivariable analysis were those that were significant by univariate analysis. Data were censored on May 31, 2019. All statistical analyses were performed using SPSS Statistics 20 (SPSS Inc., Chicago, IL, United States).

This study was approved by the Institutional Review Board of the National Cancer Center, Japan (IRB file No. 2017-164, approval date: Oct. 11, 2017).

## RESULTS

A total of 776 patients with metastatic or unresectable adenocarcinoma of the stomach or gastroesophageal junction were treated in this study period, and HER2 positivity was observed in 127 cases (16.3%). Of these, patients who received upfront gastrectomy before chemotherapy ( $n = 5$ ) or chemotherapy without trastuzumab ( $n = 21$ ), and patients who underwent HER2 assessment from only one portion of the tumor ( $n = 13$ ) were excluded (Figure 2). Finally, a group of 88 patients were evaluated for intratumoral HER2 heterogeneity, in which HER2 homogeneity was observed in 65 (Homo group) and HER2 heterogeneity was observed in 23 (Hetero group) patients.

Patients' backgrounds are shown in Table 1. Intratumoral HER2 heterogeneity was significantly more frequently observed in macroscopically type 3 and type 4 patients than other types, and in patients with IHC 2+ compared to IHC 3+. Other background characteristics such as age, sex, performance status, TNM stage, metastatic site and chemotherapeutic regimens were not significantly different between the groups. Besides, the number of biopsy sites for HER2 assessment was not significantly different, *i.e.*, those numbers more than three was 46% for Homo group and 57% for Hetero group ( $P = 0.393$ ). Waterfall plot for tumor shrinkage and clinical responses for the patients with measurable metastatic lesions ( $n = 58$ ) of both groups are shown in Figure 3. Overall response rate (complete response and partial response) was 79.5% in the Homo group, which was considerably better than that in the Hetero group (35.7%,  $P = 0.002$ ). Kaplan-Meier curves of OS and PFS in both groups are shown in Figure 4. At the time of the analysis, the median follow-up was 18.5 mo (range, 4.7-88.0 mo). The median survival time (MST) in the Hetero group was 12.5 mo, which was considerably worse than that in the Homo group (25.7 mo, HR: 2.430, 95%CI: 1.389-4.273). Median PFS time in the Hetero group was 2.9 mo, which was also significantly worse than that in the Homo group (7.9 mo, HR: 2.000, 95%CI: 1.203-3.333). Multivariate analysis revealed IHC HER2 heterogeneity as one of the independent poor prognostic factors for OS (HR: 3.115, 95%CI: 1.610-6.024) and PFS (HR: 2.123, 95%CI: 1.225-3.676) (Table 2). Undifferentiated histological type (HR: 2.612, 95%CI: 1.388-4.916), number of non-curative factors (HR: 2.252, 95%CI: 1.113-4.553), clinical nodal status (HR: 2.119, 95%CI: 1.165-3.855), hepatic metastasis (HR: 2.084, 95%CI: 1.076-4.036) and HER2 score (2+) (HR: 2.008, 95%CI: 1.094-3.690) were also extracted as independent poor prognostic factors for OS. We compared survival results by the combination of each HER2 score (2+ or 3+) and HER2 heterogeneity (homogeneity or heterogeneity). MST for the Homo group with HER2 3+ was longest (28.2 mo), followed by Hetero group with 3+ (14.6 mo) and Homo group with 2+ (12.9 mo). Hetero group with 2+ had the worst prognosis (MST: 7.2 mo) (Figure 5).

**Figure 1 Assessment of intratumoral HER2 heterogeneity.** Assessment of intratumoral HER2 heterogeneity was conducted from at least two different portions of the same tumor, and more than three biopsy specimens were obtained from each portion. Homogeneity was defined by all assessed portions showing HER2 positivity, and heterogeneity was defined as a tumor with any portions that did not show HER2 positivity. HER2: Human epidermal growth factor receptor 2.

## DISCUSSION

In this study, we examined the effect of intratumoral HER2 heterogeneity by IHC for HER2-positive advanced gastric cancer treated with trastuzumab-based chemotherapy on their therapeutic responses and survival. Intratumoral HER2 heterogeneity by IHC evaluated by biopsy specimen before treatment was one of the independent poor predictive factors for tumor shrinkage and a poor prognosticator.

The definition of intratumoral HER2 heterogeneity for HER2-positive gastric cancer has not been well established. The cut-off value between HER2 homogeneity and heterogeneity of HER2 positive tumor cells varies from 50% to 100% for surgically resected specimens<sup>[5,6,12,17]</sup> and 30% to 100% for endoscopic biopsy specimens<sup>[7,8,18]</sup>. The clinical significance of intratumoral HER2 heterogeneity for HER2-positive gastric cancer treated with trastuzumab has not been well investigated, and there have been only a few studies conducted to date. Wakatsuki *et al*<sup>[12]</sup> defined the cut-off value of HER2 heterogeneity as 100% and reported that HER2 homogeneity group had significantly longer PFS (HR: 0.11, 95%CI: 0.03-0.41) and OS (HR: 0.18, 95%CI: 0.06-0.72). However, their study included only 28 patients who received trastuzumab-based chemotherapy after upfront gastrectomy for resectable gastric cancer, not metastatic cancer.

In post hoc exploratory analyses of the ToGA trial, the proportion of HER2-positive tumor cells in more than 30% of biopsy specimens could not be extracted as a predictive factor for good response to trastuzumab-based chemotherapy<sup>[18]</sup>. Yagi *et al*<sup>[8]</sup> recently reported that intratumoral HER2 heterogeneity was a poor predictor for trastuzumab-based chemotherapy and a poor prognosticator with the cut-off value of 100% from the median number of four biopsy specimens. Our current study selected patients in whom HER2 positivity could be assessed from more than two different portions of the tumor, and we defined HER2 heterogeneity as any of those tumor portions being negative for HER2. The number of biopsy specimens examined for each patient in our current study was more than six (*i.e.*, each of the three fragments were obtained from two or more different portions). Although Yagi *et al*<sup>[8]</sup> adopted the overall proportion of HER2-positive tumor cells to evaluate intratumoral HER2 heterogeneity, we employed the standard criteria of HER2 positivity generally performed in clinical diagnosis, *i.e.*, tumor cell cluster of at least five positive cells with complete basolateral or lateral membranous reactivity. According to our simple definition of intratumoral HER2 heterogeneity, the treatment outcomes were definitively different between the HER2 homogeneity group and heterogeneity group.

The stain intensity for IHC was reported as a significant prognostic factor for HER2-positive gastric cancer in the ToGA trial. The OS was significantly longer in IHC 3+ patients than IHC 2+ patients (MST: 17.9 and 12.3 mo)<sup>[1]</sup>. Assessment of HER2 positivity for endoscopic biopsy specimen in the ToGA trial was established without consideration of intratumor HER2 heterogeneity, which is now commonly adopted worldwide<sup>[4]</sup>. Prognostic significance of stain intensity for IHC was also explored in combination with heterogeneity for IHC in our current study. MST of Homo-IHC 3+ patients was 28.2 mo, which was much better than MST of IHC 3+ patients (17.9 mo) in the ToGA trial. Hetero-IHC 3+ and Homo-IHC 2+ patients had comparable

**Figure 2 Patient flow chart.** HER2 positivity was observed in 127 (16.3%) of 776 patients with metastatic or unresectable adenocarcinoma. After exclusion of 39 patients for the listed reasons, HER2 homogeneity was observed in 65 (Homo group) and HER2 heterogeneity was observed in 23 (Hetero group). HER2: Human epidermal growth factor receptor 2.

survival (14.6 and 12.9 mo), while Hetero-IHC 2+ patients had poorer survival (7.2 mo) compared to IHC 2+ patients (12.3 mo) in the ToGA trial. These results suggest that intratumoral HER2 heterogeneity should be included in the assessment of HER2 positivity in addition to the stain intensity for IHC, and patients with Homo-IHC 3+ might be the most responsive to further anti-HER2 agents. The survival benefits for anti-HER2 drugs such as lapatinib or pertuzumab in combination with trastuzumab and adjuvant therapy of trastuzumab or trastuzumab beyond progression have been demonstrated for breast cancers<sup>[19-22]</sup>. However, the efficacy of those anti-HER2 agents has not been shown for gastric cancers, and intratumoral HER2 heterogeneity may be one of the reasons for the difference of these results between breast and gastric cancers<sup>[23,24]</sup>.

Although the intrinsic mechanism underlying the correlation between HER2 heterogeneity and poor efficacy of trastuzumab-based chemotherapy is still unclear, chemo-resistance can be one of the main reasons for the treatment failure. Fabi *et al*<sup>[25]</sup> reported that the discordances of HER2 positivity between primary and metastatic lesions may be a possible cause of chemo-resistance of trastuzumab for metastatic breast cancers. Park *et al*<sup>[26]</sup> reported these discordances between primary and metastatic lesions could also be observed in HER2-positive gastric cancers, and HER2 heterogeneity of primary lesions existed in such cases with discordances of HER2 positivity. Another explanation for the poor efficacy of trastuzumab might be genomic alterations. Pietrantonio *et al*<sup>[27]</sup> reported that chemo-resistance against trastuzumab was more frequently observed in patients with genomic alterations including *EGFR/MET/KRAS/PI3K/PTEN* mutations than those without. They stated such genomic mutations were correlated with IHC 2+, *i.e.*, the existence of HER2 heterogeneity.

Our study has several limitations. First, concordance of intratumoral HER2 heterogeneity between endoscopic biopsy specimen and whole tumor tissues was not investigated in the current study. The concordance of HER2 positivity between biopsy specimens and surgically resected specimens was reported to be 80%-91% for IHC 3+ and 25%-57% for IHC 2+ patients<sup>[28-30]</sup>, thus the interpretation of HER2 heterogeneity for IHC 2+ patients must be made with care. In breast cancer, similar results have been reported comparing core needle biopsy specimens and surgically resected specimens<sup>[31]</sup>, and repeat testing or reflex testing using an alternative assay (IHC or ISH) are recommended for IHC equivocal cases<sup>[32]</sup>. Secondly, there was no common standard of adequate numbers and portions for the assessment of intratumoral HER2 heterogeneity. In this study, the assessment of intratumoral HER2 heterogeneity was performed from at least two portions of the tumor. Ohno *et al*<sup>[33]</sup> reported that HER2 positivity was different in different tumor regions, *i.e.*, the frequency of HER2 positivity in the biopsy specimen from the superficial spreading portion, ulcer mound, and mass portion was as high as 90% to 100%, while these from ulcer bed was only 45% due to the presence of concomitant necrotic tissues and associated

inflammation<sup>[34]</sup>. These results suggest that the assessment of HER2 heterogeneity should be based on biopsy specimens taken from the appropriate portion of the tumor. Thirdly, this study did not include the intratumoral heterogeneity of *HER2* gene amplification. Intratumoral heterogeneity of *HER2* gene amplification has been reported to be a significant prognostic factors for metastatic or resectable advanced breast cancers<sup>[9,11]</sup>. The significance of intratumoral heterogeneity of *HER2* gene amplification should also be clarified in further investigations.

In conclusion, intratumoral HER2 heterogeneity by IHC was a significant predictor of clinical response and a poor prognosticator for trastuzumab-based chemotherapy. Thus, intratumoral HER2 heterogeneity would be useful to further stratify patients with HER2-positive gastric cancer, and thus should be taken into account in future clinical trials.

**Table 2** Prognostic factors for overall survival and progression-free survival

## ARTICLE HIGHLIGHTS

### Research background

Human epidermal growth factor receptor 2 (HER2) was introduced as a predictive biomarker for the treatment of gastric cancer along with trastuzumab, and the strong HER2 intensity of immunohistochemistry (IHC) 3+ was reported as a better prognostic factor for HER2-positive gastric cancer treated with trastuzumab-based chemotherapy. Intratumoral HER2 heterogeneity for HER2-positive gastric cancers was reported to be more frequent than in HER2-positive breast cancers. Although intratumoral HER2 heterogeneity was reported to be one of the poor predictors for the treatment response and poor prognosticator for patients with HER2-positive breast cancer who received trastuzumab-based chemotherapy, the clinical significance of intratumoral HER2 heterogeneity for HER2-positive gastric cancer treated with trastuzumab has not been well investigated. Furthermore, even the definitions of HER2 heterogeneity for HER2-positive gastric cancer have not been established. In this study, we established the definition of intratumoral HER2 heterogeneity and clarified the clinical significance of HER2 heterogeneity for HER2-positive gastric cancer.

### Research motivation

HER2 heterogeneity may be a pivotal predictor for the efficacy of trastuzumab-based chemotherapy. Authors have previously reported that intratumoral HER2 heterogeneity had a negative survival benefit for patients with surgically resected HER2-positive gastric cancer. However, HER2 assessment before treatment is usually based on endoscopic biopsy specimen for metastatic gastric cancer, and the clinical significance of intratumoral HER2 heterogeneity for biopsy specimen is still unknown. If these clinical significances are clarified, HER2 heterogeneity might be introduced to the assessment of HER2 positivity for gastric cancer in the future.

### Research objectives

The aim of this study was to clarify the clinical significance of intratumoral HER2 heterogeneity for HER2-positive gastric cancer treated with trastuzumab-based chemotherapy by evaluation of biopsy specimens.

### Research methods

Patients with HER2-positive metastatic or unresectable adenocarcinoma of the stomach or gastroesophageal junction who received trastuzumab-based chemotherapy as first-line treatment at our hospital were included. The patients were classified into two groups (Homo- and Hetero-group) according to intratumoral HER2 heterogeneity, and their clinicopathological findings, clinical responses, progression-free survival (PFS) and overall survival (OS) were compared. Furthermore, the predictive factor for clinical response and prognostic factor were analyzed using multivariable analyses. Assessment of intratumoral HER2 heterogeneity was conducted on patients who underwent assessment of HER2 positivity from two or more different portions of the same tumor, and three or more biopsy specimens were obtained from each portion. Those patients whose HER2 assessment was performed from only one portion were excluded. We defined intratumoral HER2 homogeneity as every portion of the tumor being HER2-positive by IHC, and any portion of the tumor staining negative for HER2 was defined as intratumoral HER2 heterogeneity.

### Research results

A total of 776 patients with metastatic or unresectable adenocarcinoma of the stomach or gastroesophageal junction were treated in the study period, and HER2 positivity was observed in 127 patients (16.3%). Intratumoral HER2 heterogeneity was significantly more frequently observed in macroscopically type 3 and type 4 patients than other types, and patients with IHC 2+ than IHC 3+. Tumor shrinkage and clinical responses for the patients with measurable metastatic lesions were evaluated, and overall response rate (complete response and partial response) was considerably better in the Homo group than in the Hetero group. Median survival time in the Hetero group was 12.5 mo, which was considerably worse than that in the Homo group (25.7 mo, HR; 2.430, 95%CI: 1.389-4.273). Median PFS time in the Hetero group was 2.9 mo, which was also significantly worse than that in the Homo group (7.9 mo, HR: 2.000, 95%CI: 1.203-3.333). Multivariate analysis revealed IHC HER2 heterogeneity as one of the independent poor prognostic factors for OS (HR: 3.115, 95%CI: 1.610-6.024) and PFS (HR: 2.123, 95%CI: 1.225-3.676).

### Research conclusions

In this study, we examined the effect of intratumoral HER2 heterogeneity by IHC for HER2-positive advanced gastric cancer treated with trastuzumab-based chemotherapy on their therapeutic responses and survival. Intratumoral HER2 heterogeneity by IHC evaluated by biopsy specimen before treatment was one of the independent poor predictive factors for tumor shrinkage and a poor prognosticator. Our current study selected patients in whom HER2 positivity could be assessed from more than two different portions of the tumor, and we newly defined HER2 heterogeneity as any of those portions of the tumor that did not show HER2 positivity. We employed the standard criteria of HER2 positivity generally performed in clinical diagnosis, *i.e.*, tumor cell cluster of at least five positive cells with complete basolateral or lateral membranous reactivity. According to our simple definition of intratumoral HER2 heterogeneity, the treatment outcomes were definitively different between the HER2 homogeneity group and heterogeneity group. Assessment of HER2 positivity for endoscopic biopsy specimen in the ToGA trial was established without consideration of intratumor HER2 heterogeneity. Our

current study suggests that the combination of heterogeneity and IHC might be beneficial to predict the efficacy of trastuzumab-based chemotherapy.

### Research perspectives

HER2 heterogeneity is a pivotal predictor for the efficacy of HER2-positive gastric cancers. However, there are still some problems that need to be solved in the future. First, concordance of intratumoral HER2 heterogeneity between endoscopic biopsy specimen and whole tumor tissues has not been investigated in the current study. Secondly, there was no common standard of adequate numbers and portions for the assessment of intratumoral HER2 heterogeneity. Thirdly, this study did not include the intratumoral heterogeneity of HER2 gene amplification. Intratumoral heterogeneity of *HER2* gene amplification has been reported to be one of the significant prognostic factors for metastatic or resectable advanced breast cancers. The significance of intratumoral heterogeneity of *HER2* gene amplification should also be clarified by further investigations. The survival benefits for anti-HER2 drugs such as lapatinib or pertuzumab in combination with trastuzumab and adjuvant therapy of trastuzumab or trastuzumab beyond progression were demonstrated for breast cancers. However, the efficacy of those anti-HER2 agents had not been proven for gastric cancers, and intratumoral HER2 heterogeneity may be considered as one of the reasons for the difference of these results between breast and gastric cancers. If more detailed clinical significance of intratumoral HER2 heterogeneity is solved in the future, anti-HER2 drugs other than trastuzumab can be adopted, and treatment outcomes of HER2-positive gastric cancers would be improved.

## Abstract

## BACKGROUND

Glaucoma is a group of diseases characterized by a specific pattern of optic nerve neuropathy and retinopathy. Increasing evidence demonstrates glaucoma associated corneal endothelium loss. Direct-compression mechanism due to elevated intraocular pressure (IOP), cell toxicity after long term exposure to preservatives and glaucoma surgery have been reported to be the possible mechanism. Herein, we compare the specular endothelial microscopy in primary open-angle glaucoma (POAG) patients and healthy controls of the same age group to observe the corneal endothelium changes and the correlations to the mean IOP in a Chinese case control study.

## AIM

To investigate corneal endothelial cell density in Chinese patients with POAG.

## METHODS

A case control study was performed on 60 eyes of 60 patients with POAG. Exclusion criteria included history of corneal diseases, intraocular diseases, contact lens use, ocular trauma or surgery (including intraocular surgery and laser treatment), congenital abnormalities or systemic diseases such as diabetes. Intraocular pressure was measured using Goldmann tonometry. Indirect specular microscopy (TOPCON SP-2000P) was performed on central corneas and endothelial images were acquired. Endothelial cell density, area and cell counts were analyzed.

Endothelial cell density was  $2959 \pm 236$  cells/mm<sup>2</sup> in healthy controls and  $2757 \pm 262$  cells/mm<sup>2</sup> in patients with POAG. The POAG eyes had significantly lower endothelial cell density compared to healthy control eyes ( $P < 0.001$ ). In the POAG group, endothelial cell density was  $2686 \pm 233$  cells/mm<sup>2</sup> in the patients receiving medication and  $2856 \pm 272$  cells/mm<sup>2</sup> in the untreated subgroup. The eyes receiving medication had significantly lower endothelial cell density compared to untreated eyes. There was a negative correlation between cell density and mean IOP ( $r = -0.286$ ,  $P = 0.004$ ), positive correlation between the average cell area and mean IOP ( $r = 0.228$ ,  $P = 0.022$ ), maximum cell area and mean IOP ( $r = 0.218$ ,  $P = 0.029$ ) and minimum cell area and mean IOP ( $r = 0.290$ ,  $P = 0.003$ ). The percentage of hexagonal cells was not correlated with mean IOP.

### CONCLUSION

Patients with POAG have lower corneal endothelial cell density than healthy controls of the same age. This may be attributed to mechanical damage from elevated IOP and toxicity of glaucoma medications.

**Key words:** Corneal endothelium; Primary open angle glaucoma; Intraocular pressure

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Loss of corneal endothelial cells have been reported in primary open-angle glaucoma (POAG) patients. Elevated intraocular pressure, cell toxicity after long-term exposure to preservatives and glaucoma surgery have been reported to be possible mechanisms for endothelial damage. In this study, we aimed to document the corneal endothelial changes and their correlations with mean intraocular pressure between POAG patients and normal controls. We found that the corneal endothelial cell density in POAG patients is decreased and the average endothelial cell area is increased compared with those in healthy controls. High intraocular pressure and anti-glaucoma medication in POAG may be the main causes of corneal endothelial cell damage.

## INTRODUCTION

The corneal endothelial monolayer maintains corneal clarity by actively regulating stromal hydration through its barrier and pump functions. Corneal endothelial cells (CECs) have limited proliferative capacity *in vivo*<sup>[1,2]</sup>, thus damage to the corneal endothelium is irreversible. Loss of CECs occurs as a consequence of intraocular surgery, trauma or diseases such as diabetes and glaucoma<sup>[3-8]</sup>. At the early stage of endothelial damage, neighboring cells spread and/or migrate to compensate for the cell loss, which results in an increase in cell size and/or alteration of cell shape. Progression of cell loss further compromises corneal transparency and causes corneal edema, bullous keratopathy and impaired visual acuity.

Glaucoma is a group of diseases characterized by a specific pattern of optic nerve neuropathy and retinopathy<sup>[6,7,9]</sup>. There is increasing evidence of glaucoma-associated corneal endothelial changes. Loss of CECs has been reported in various types of glaucoma such as primary angle-closure glaucoma, primary open-angle glaucoma (POAG) and some types of secondary glaucoma<sup>[7,9-15]</sup>. Endothelial cell loss is attributed to both glaucoma itself and treatment that lowers intraocular pressure (IOP). A direct-compression mechanism due to elevated IOP has been proposed in CEC loss in acute angle-closure glaucoma<sup>[11,16]</sup>. In addition, cell toxicity after long-term exposure to preservatives in ocular hypotensive drugs is considered another possible mechanism for endothelial damage<sup>[13,17]</sup>. Moreover, endothelial cell loss caused by glaucoma surgery has been reported in patients after application of antiproliferative medications in filtration surgery and aqueous shunt implantation<sup>[18-21]</sup>.

In this study, we aimed to document the corneal endothelial changes and their correlations with mean IOP by comparing specular endothelial microscopy in patients

of similar age with and without glaucoma.

## MATERIALS AND METHODS

### Study subjects

Case control study. We recruited 60 POAG patients (32 male, 28 female; mean age  $63 \pm 13$  years, age range 50–80 years) who visited the Glaucoma Division at the Fourth Affiliated Hospital, China Medical University between February and March 2019 and 60 age-matched healthy controls (28 male, 32 female; mean age  $61 \pm 12$  years, age range 50–80 years). We retrospectively analyzed with regard to their pre-treatment characteristics. There was no significant difference of age between the two groups. Only one eye from each patient or healthy control was analyzed. All study procedures adhered to the Declaration of Helsinki for research involving human participants. The exclusion criteria included: previous ocular (including laser peripheral iridotomy), orbital or palpebral surgery; previous ocular trauma; previous or present contact lens use; other ocular diseases (such as corneal endothelial dystrophy, intraocular inflammation and infection) that could affect the corneal endothelium; and systemic diseases (such as diabetes and congenital abnormalities) that could affect the corneal endothelium.

### Specular microscopy

Indirect specular microscopy (SP-2000P; TOPCON, Tokyo, Japan) was performed on each subject. Images were captured from the central cornea and analyzed using IMAGENet 2000 software (TOPCON). Endothelial cell density (ECD), percentage of hexagonal cells, average cell area, maximum cell area, minimum cell area, standard deviation of cell area (SD) and coefficient of variation in cell area were determined. All examinations were performed by the same examiner.

### IOP evaluation

The IOP of all subjects was measured using Goldmann tonometry every 2 h from 08:00 to 18:00 h. The average of all measurements was determined and used for analysis.

### Statistical analysis

Statistical analysis was performed using SPSS version 19.0 (SPSS, Chicago, IL, United States). The unpaired Student's *t* test was used to compare the means between normal subjects and patients with POAG. The Chi-square test was applied to the comparison between untreated patients and patients receiving ophthalmic medication. Correlation between IOP and each characteristic of CECs was assessed by Pearson's correlation coefficient. Data are presented as mean  $\pm$  SD and the significance level was set at 0.05.

## RESULTS

### Endothelial cell characteristics of healthy eyes and POAG eyes

ECD was significantly lower in patients with POAG ( $2757 \pm 262$  cells/mm<sup>2</sup>) compared to the control group ( $2959 \pm 236$  cells/mm<sup>2</sup>). The average cell area was significantly increased in glaucoma patients ( $364.37 \pm 34.05$   $\mu$ m<sup>2</sup>) compared with the control group ( $322.23 \pm 54.69$   $\mu$ m<sup>2</sup>). Consistently, glaucoma patients exhibited increased maximum, minimum and SD of cell area. There were no significant differences in the coefficient of variation of cell area and percentage of hexagonal cells between the two groups (Table 1, Figure 1).

The 60 POAG patients were further divided into two subgroups, untreated patients ( $n = 25$ ) and patients receiving ophthalmic medications ( $n = 35$ ) at the time of the study. No significant difference in age and gender was found between the subgroups. The patients receiving medication had significantly lower ECD ( $2686 \pm 233$  cells/mm<sup>2</sup>) compared to the untreated subgroup ( $2856 \pm 272$  cells/mm<sup>2</sup>). Both subgroups had lower cell densities compared to the controls; however, only the difference between patients receiving medication and healthy controls was significant. The maximum, minimum and SD of cell area and percentage of hexagonal cells did not differ between the subgroups (Table 2).

### Correlations between endothelial cell characteristics and IOP

The mean IOP in POAG patients ( $24 \pm 5$  mmHg) was significantly higher than that in healthy controls ( $15 \pm 2$  mmHg). There was a negative correlation between ECD and mean IOP ( $r = -0.286$ ,  $P = 0.004$ ). Positive correlations were found between the

average cell area and mean IOP ( $r = 0.228$ ,  $P = 0.022$ ), maximum cell area and mean IOP ( $r = 0.218$ ,  $P = 0.029$ ) and minimum cell area and mean IOP ( $r = 0.290$ ,  $P = 0.003$ ). The percentage of hexagonal cells was not correlated with mean IOP (Figure 2).

## DISCUSSION

In Asian populations, primary angle-closure glaucoma is the major type of glaucoma<sup>[22,23]</sup>. However, a higher prevalence of POAG than primary angle-closure glaucoma has been reported in recent studies in Chinese populations<sup>[24,25]</sup>. Our data demonstrate that, in a Chinese case control study, patients with POAG had a reduction in corneal ECD and an increase in average endothelial cell area compared to age-matched healthy controls. To our knowledge, this is the first report on CEC loss in Chinese patients with POAG. Our data show a 5.47% reduction in ECD in POAG patients compared to healthy controls. Possible explanations include direct mechanical damage, elevated IOP, cytotoxic effects of ocular hypotensive eye drops, impaired endothelial metabolism due to disruptive aqueous humor circulation and congenital endothelial abnormalities.

Correlation between ECD loss and elevated IOP has been investigated<sup>[10]</sup>. High IOP directly damages the physical barrier function of CECs and affects the function of the endothelial pump leading to changes in aqueous humor dynamics, which cause corneal stromal edema<sup>[13]</sup>. Gagnon *et al*<sup>[13]</sup> hypothesized that the mechanism of IOP damage to CECs is as pressure dependent as damage to the optic nerve. Gagnon *et al*<sup>[13]</sup> showed that corneal ECD is inversely proportional to mean IOP. Some researchers hypothesized that CEC changes are not associated with high IOP<sup>[26-27]</sup>. Our data showed that the glaucoma and normal control groups had significant differences in corneal ECD, consistent with Gagnon *et al*'s<sup>[13]</sup> research.

Our results indicated the negative correlation between mean IOP and corneal ECD and the positive correlation between mean IOP and CEC area (Figure 2). High IOP may be an important factor in corneal endothelial injury. In a high IOP animal model, CEC density decreased by an average 5.8% compared with the normal control eyes<sup>[13]</sup>. CEC ultrastructure was observed by transmission electron microscopy, and mitochondrial swelling and vacuolar degeneration were observed after 3 d of high IOP, indicating that IOP damaged the physical barrier of endothelial cells. CEC dysfunction allows large amounts of water to enter the cells without any damage and cause endothelial cell edema. However, there was no significant change in intracellular nuclei compared to normal cells. However, if high IOP lasted for 2 wk, the mitochondrial vacuolization and dilated endoplasmic reticulum of CECs indicated aggravation of cell edema. Mild or moderate cell damage can return to normal after the cause of the damage is eliminated, or irreversible damage by cell necrosis may occur. Electron microscopic observation of CECs in a model with high IOP for 4 wk showed irreversible loss of heterochromatin edge, multiple nuclear membrane rupture, and nuclear efflux, showing signs of cell necrosis.

The above observations show that the longer the duration of high IOP, the more severe the ultrastructural destruction of CECs, which have some tolerance to high IOP. Within a certain range, if high IOP is controlled and the damage factor is removed, CECs can recover their structure and function and transparency. The longer high IOP persists, the less the healing capacity of CECs. When the damage exceeds its limit, irreversible damage occurs leading to moderate corneal edema and visual

**Figure 1** Indirect specular microscopy images of corneal endothelium in normal eyes and eyes with primary open-angle glaucoma. A: Corneal endothelial cells showed regular hexagonal monolayer with clear cell borders in normal eyes; B: Endothelial cells showed irregular and indistinct cell borders with guttae like dark cells in patients with glaucoma.

dysfunction.

It has been shown that damage to CECs can be caused by toxicity of anti-glaucoma medicine<sup>[28,29]</sup>. The preservative commonly used in anti-glaucoma medication, benzalkonium chloride, plays an important role in ocular surface damage. Its toxic and adverse effects are dose and time dependent and increase in combination and may damage corneal epithelial cells, CECs and central thickness of the cornea<sup>[30]</sup>. In this study, the corneal ECD of the glaucoma sub groups was compared, and covariance analysis was used to exclude the interference factor of average IOP on CECs. The ECD in the glaucoma treated group was significantly reduced compared with that of the untreated groups, which may have been caused by the benzalkonium chloride preservative in the anti-glaucoma medication. However, the difference in CEC area between the treated and untreated groups was not significant, and further large-scale studies are needed.

Aqueous circulation block may affect metabolism of the corneal endothelium and cause hypoxia in the aqueous humor<sup>[31]</sup>. That study reported that 30 patients with acute angle-closure glaucoma had significant changes in CEC density compared to normal subjects. The longer the duration of high IOP, the more severe the damage to the corneal endothelium was. The decrease in ECD and the increase in CEC area were related to the length of acute attack and high IOP. Meanwhile, patients with a history of acute attacks showed significantly increased cell area and various changes in shape. Even if the morphologically abnormal CECs show normal density, complications such as loss of corneal endothelial function are more likely to occur after surgery. CEC function requires a certain cell density, but more importantly, it depends on cell morphology, which is a more sensitive indicator of functional changes in the CEC membrane.

The normal corneal endothelium is composed of uniform regular hexagonal cells. Once this structure is destroyed, the corneal endothelium is in an unstable state, and the cells are easily damaged, which causes further deformation and loss<sup>[32]</sup>. High IOP and aqueous humor blockade can affect the metabolism of the corneal endothelium and cause pathological changes. Glaucoma patients may have congenital abnormal development of corneal endothelial cell layer and trabecular meshwork. In the diagnosis and treatment of glaucoma, the function of CECs directly affects visual acuity and tolerance of intraocular surgery as well as the treatment options. In patients with a history of elevated IOP, the risk of decompensation is greater, corneal edema is more likely and irreversible corneal opacity can be a perioperative or postoperative complication during or after intraocular surgery<sup>[33]</sup>.

The corneal ECD in POAG patients is decreased and the average endothelial cell area is increased compared with those in healthy controls. High IOP and anti-glaucoma medication in POAG may be the main causes of CEC damage. Therefore, for glaucoma patients, quantitative analysis of CEC morphology is necessary, and high IOP should be controlled as soon as possible to prevent corneal endothelial damage.

## ARTICLE HIGHLIGHTS

### Research background

The corneal endothelial monolayer maintains corneal clarity, and its damage is irreversible. Cornea endothelial cell loss is attributed to open-angle glaucoma, medicine and surgery treatments.

### Research motivation

The main topic is the changes in corneal endothelial cell density in primary open-angle glaucoma (POAG) patients.

### Research objectives

To investigate the corneal endothelium changes and the correlations to the mean intraocular pressure (IOP) in POAG patients.

### Research methods

Sixty POAG patients were selected as the patient group (32 male, 28 females; mean age  $63 \pm 13$  years, age range 50-80 years). Meanwhile, 60 age-matched healthy controls who underwent physical examination were selected. IOP was measured by Goldmann tonometry. Corneal endothelial cell density, percentage of hexagonal cells, average cell area, maximum cell area, minimum cell area, standard deviation of cell area and coefficient of variation in cell area were measured by specular microscopy.

### Research results

Endothelial cell density was  $2959 \pm 236$  cells/mm<sup>2</sup> in healthy controls and  $2757 \pm 262$  cells/mm<sup>2</sup> in patients with POAG. The POAG eyes had significantly lower endothelial cell density compared to healthy control eyes ( $P < 0.001$ ). In the POAG group, endothelial cell density was  $2686 \pm 233$  cells/mm<sup>2</sup> in the patients receiving medication and  $2856 \pm 272$  cells/mm<sup>2</sup> in the untreated subgroup. The eyes receiving medication had significantly lower endothelial cell density compared to untreated eyes. There was a negative correlation between cell density and mean IOP ( $r = -0.286$ ,  $P = 0.004$ ) and positive correlation between the average cell area and mean IOP ( $r = 0.228$ ,  $P = 0.022$ ), maximum cell area and mean IOP ( $r = 0.218$ ,  $P = 0.029$ ) and minimum cell area and mean IOP ( $r = 0.290$ ,  $P = 0.003$ ). The percentage of hexagonal cells was not correlated with mean IOP.

### Research conclusions

For glaucoma patients, quantitative analysis of CEC morphology is necessary, and high IOP should be controlled as soon as possible to prevent corneal endothelial damage.

### Research perspectives

Patients with POAG have lower corneal endothelial cell density than healthy controls of the same age. This may be attributed to mechanical damage from elevated IOP and toxicity of glaucoma medications.

## Abstract

## BACKGROUND

Myocardial bridge (MB) will compress the mural coronary artery (MCA) during the systole and cause myocardial ischemia. In the diagnosis of coronary heart disease (CHD), because the structure of MB is difficult to be observed by coronary angiography (CAG), the clinical study of the influence of MB on CHD is lacking. With the advancement of computed tomography coronary angiography technology, detailed observations of the MB anatomy have realized.

## AIM

To explore the main influencing factors of MB-related CHD and to find potential indicators for predicting MB-related CHD.

## METHODS

A total of 1718 patients with suspected CHD due to the symptoms of myocardial ischemia were enrolled as subjects. Patients diagnosed with CHD were included in a CHD group, and patients with no significant abnormalities were included in a control group. In the CHD group, patients were divided into an MB-CHD subgroup if MB-related CHD was found. In the control group, patients were divided into a simple MB subgroup if MB was found. The patient's clinical data and MB-related indicators, including the branch of MB, MB type (superficial/deep type), MB length, MB thickness, systolic and diastolic compression of the MCA, and MCA systolic stenosis rate were recorded and compared. Logistic regression analysis was used to explore the independent influencing factors of MD-related CHD. ROC curve was used to analyze the diagnostic efficacy of potential indicators for MB-related CHD.

## RESULTS

There were 1060 cases in the CHD group and 658 cases in the control group, and

there were 236 cases in the MB-CHD subgroup and 52 cases in the simple MB subgroup. Multivariate logistic regression analysis showed that the combined MB had a significant effect on the occurrence of CHD ( $P < 0.05$ ). MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis rate had significant effects on the occurrence of MB-related CHD ( $P < 0.05$ ). The area under the curve (AUC) of the combination of these influencing factors for the diagnosis of MB-related CHD was 0.959, which was significantly higher than the AUCs of the four indicators separately ( $P < 0.05$ ). The sensitivity was 97.06% and the specificity was 87.63%.

## CONCLUSION

MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis are independent influencing factors for MB-related CHD. The combination of these factors has potential diagnostic value for MB-related CHD.

**Key words:** Myocardial bridge; Coronary heart disease; Mural coronary artery; Computed tomography coronary angiography; Independent influencing factor

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** With the deep understanding of myocardial bridge (MB), it is considered to be the reason of such complications as acute myocardial infarction, ventricular tachycardia, syncope, and sudden cardiac death. Currently, how MB affects coronary heart disease remains unclear. Computed tomography coronary angiography can directly measure MB-related coronary heart disease (CHD), which was used to explore the relationship between MB and CHD. In this study, MB thickness, systolic compression, diastolic compression, and mural coronary artery systolic stenosis were proved to be the independent influencing factors for MB-related CHD. The combination of these factors has potential diagnostic value for MB-related CHD.

## INTRODUCTION

Myocardial fiber bundle covering the mural coronary artery (MCA) is called myocardial bridge (MB)<sup>[1-3]</sup>. With the development of computed tomography coronary angiography (CTA), studies have reported that MB can compress the MCA during systole, causing myocardial ischemia such as angina pectoris and myocardial infarction<sup>[4-7]</sup>. It is called MB-related coronary heart disease (CHD)<sup>[8]</sup>. Because the low detection rate of MB and the inconspicuous myocardial ischemia symptoms in most patients with MB, and common risk factors for CHD including age, dyslipidemia, hypertension, smoking, diabetes, obesity, and family history are numerous<sup>[9-12]</sup>, clinicians pay insufficient attention to MB and the studies on MB-related CHD are few. Currently, although coronary angiography (CAG) cannot specifically observe the detailed anatomical structure of MB, CTA has been developed to directly measure MB-related indicators in detail<sup>[13-16]</sup>. Therefore, the present study utilized CTA to assess the association between MB and CHD, in order to explore the main influencing factors of MB-related CHD and to find potential indicators for predicting MB-related CHD.

## MATERIALS AND METHODS

### Study participants

This study was approved by the Ethics Committee of the Capital Medical University Affiliated to Beijing Anzhen Hospital, and written informed consent was obtained

from all patients. Study participants were recruited from the department of cardiology, Beijing Anzhen Hospital, Capital Medical University due to the symptoms of myocardial ischemia from December 2016 to June 2018. All patients were diagnosed utilizing CAG or CTA. The inclusion criteria were: (1) Patients with myocardial ischemia symptoms such as angina pectoris and ST-T segment changes; and (2) Glomerular filtration rate (GFR) between 30 and 60 mL/min. The exclusion criteria were: (1) Patients with other heart diseases besides CHD; (2) Patients with poor physical condition and multiple organ failure; (3) Patients allergic to contrast agent; and (4) Patients with coagulopathy. Of all the subjects, if the MCA was found in the CAG, CTA would be performed to observe MB. Patients diagnosed with CHD were divided into a CHD group, and patients with no significant abnormalities were divided into a control group. In the CHD group, patients were divided into an MB-CHD subgroup if MB-related CHD was found. In the control group, patients were divided into a simple MB subgroup if MB was found.

### **Clinical data recording**

The family history of CHD, hypertension, diabetes, hyperlipidemia, smoking, ECG ST-segment changes, lipoprotein(a) [Lp(a)], homocysteine (HCY), plasminogen activator inhibitor-1 (PAI-1), and fibrinogen conditions of subjects were recorded in this study. The diagnosis of hypertension was based on the 2017 American Diabetes Diagnostic Criteria<sup>[17]</sup>: Grade 1 hypertension: systolic blood pressure 130-139 mmHg, diastolic blood pressure 80-89 mmHg; Grade 2 hypertension:  $\geq 140/90$  mmHg. The diagnosis of diabetes was based on the 2017 American Diabetes Association diagnostic criteria<sup>[18]</sup>: Fasting blood glucose  $\geq 7.0$  mmol/L; random blood glucose  $\geq 11.1$  mmol/L and patients with diabetic symptoms; 2 h postprandial blood glucose  $\geq 11.1$  mmol/L in the glucose tolerance test. Patients with atypical symptoms needed to repeat the test to determine the presence of diabetes according to the above criteria. The diagnosis of hyperlipidemia was based on: serum total cholesterol (TC)  $> 5.2$  mmol/L; triglyceride (TG)  $> 1.7$  mmol/L; serum low-density lipoprotein cholesterol (LDL-C)  $> 3.64$  mmol/L<sup>[19]</sup>.

### **CAG examination**

Selective CAG (Siemens Artis Zee floor) was performed in this study. The left coronary angiography was routinely performed in a spider position (left front oblique  $45^\circ$  + foot position  $30^\circ$ ), left shoulder position (left front oblique  $45^\circ$  + head position  $30^\circ$ ), head position (positive head position  $30^\circ$ ), right shoulder position (right front oblique  $30^\circ$  + head position  $30^\circ$ ), and liver position (right front oblique  $30^\circ$  + foot position  $30^\circ$ ). The right CAG was performed with left front oblique  $45^\circ$  and right front oblique  $30^\circ$ <sup>[20]</sup>.

### **CTA examination**

The scanning was performed using TOSHIBA AQUILION ONE TSX-301A. The ECG was placed on the patient's chest before scanning. ECG-gated scanning was used to scan from the bottom of the heart (marked by tracheal carina) to the whole heart. For enhanced scanning, a double-tube high-pressure syringe was used and the bolus tracking technique was adopted. The contrast agent iohexol 350 was injected through the middle of the elbow vein. The injection speed was 5 mL/s, and the total amount was 60-80 mL. Subsequently, 50 mL of physiological saline was injected at the same rate. After the images were acquired, the resulting data were delivered to the workstation for further analysis. In the section along the longitudinal axis of the coronary artery, if a certain coronary artery was distributed in a certain myocardium, it can be diagnosed as an MB. The branch of the MB was observed and recorded. MB type (superficial/deep type), MB length, MB thickness, MCA end-systolic diameter, and end-diastolic diameter were measured. The MCA systolic stenosis rate was calculated as (MCA end-diastolic diameter - MCA end-systolic diameter)/MCA end-diastolic diameter. The diameter method was used to estimate the systolic and diastolic compression of the MCA.

### **Statistical analysis**

Statistical analyses were performed using SPSS software (version 19.0; Chicago, IL, USA). The numerical data are expressed as the mean  $\pm$  SD and the comparison between the two groups was compared using the *t*-test. The categorical variables are expressed as number and percentage and the comparison between the two groups was performed by the chi-square test. Logistic regression was used for multivariate analysis to screen out the potential independent influencing factors of MB-related CHD. ROC curve was used to analyze the diagnostic efficacy of potential indicators for MB-related CHD. Statistical significance was defined as 2-tailed  $P < 0.05$  for all tests.

## RESULTS

Totally 1718 patients who underwent CTA or CAG were enrolled. Of all the participants, 1060 patients diagnosed with CHD were included in the CHD group, and the remaining 658 patients were included in the control group. There were 288 MB patients found in the present study. Totally 236 patients diagnosed with MB-related CHD were divided in the MB-CHD subgroup. It included 121 males and 115 females, and the average age was  $60.25 \pm 15.34$  years. The remaining 52 patients diagnosed with simple MB were divided into the simple MB subgroup. It included 32 males and 20 females, and the average age was  $52.65 \pm 12.86$  years. The lesions of 288 MB were all located in the left anterior descending wall coronary artery, as shown in [Figure 1](#).

### **Analysis of risk factors for CHD**

Clinical characteristics of the CHD group and the control group are shown in [Table 1](#). The ratio of gender, family history of CHD, abnormal TC, HDL-C, TG, Lp(a), HCY, PAI-1, and fibrinogen were comparable in the two groups ( $P > 0.05$ ). The average age, percentage of patients with abnormal hypertension, diabetes, smoking, ECG ST-segment changes, LDL-C, and combined MB in the CHD group were significantly higher than those in the control group ( $P < 0.05$ ). Multivariate logistic regression analysis indicated that the occurrence of CHD was influenced remarkably by hypertension, ECG ST-segment changes, diabetes, LDL-C, and combined MB ( $P < 0.05$ ) except for age and smoking ( $P > 0.05$ ). The further analysis revealed that factors affecting CHD ranked based on OR values as follows: hypertension, diabetes, MB, LDL-C, and ECG ST-segment changes ([Table 2](#)).

### **Comparison of MB-related parameters between the MB-CHD subgroup and simple MB subgroup**

The results of the comparisons between the MB-CHD subgroup and the simple MB subgroup showed that the difference of the MB length between the two groups was similar ( $P > 0.05$ ). The proportion of deep MB type, MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis rate in the MB-CHD subgroup were significantly higher than those in the simple MB subgroup ( $P < 0.05$ , [Table 3](#)).

### **Multivariate analysis of independent influencing factors of MB-related CHD**

MB type, thickness, systolic compression, diastolic compression, and MCA systolic stenosis rate were included in the logistic regression analysis. The results showed that MB type had no effect on the occurrence of MB-related CHD ( $P > 0.05$ ). MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis rate had obvious effects on the occurrence of MB-related CHD ( $P < 0.05$ ). The further study revealed that the factors influencing the occurrence of MB-related CHD were as follows in descending order: diastolic compression, MB thickness, MCA systolic stenosis rate, and systolic compression ([Table 4](#)).

### **Effectiveness analysis of MB-related parameters in diagnosing MB-related CHD**

The results of ROC curve analysis for the diagnosis of MB-related CHD by MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis rate are shown in [Table 5](#) and [Figure 2](#). The area under the curve (AUC) of diastolic compression was the highest, and its sensitivity reached 95.10%, followed by MB thickness, MCA systolic stenosis rate, and systolic compression. However, the AUC of each indicator did not exceed 0.9. Based on the logistic regression model, we established a combined diagnosis of four indicators, and found that the AUC of the combined diagnosis was 0.959, which was significantly higher than the AUCs of the four indicators separately ( $P < 0.05$ ). The sensitivity was 97.06% and the specificity was 87.63%.

### **Logistic regression analysis of the effect of the combination of four factors on MB-related CHD**

Since the combination of four indicators was the best indicator for the diagnosis of MB-related CHD in this study. We used logistic regression to analyze its effect on MB-related CHD using its optimal diagnostic point. The results showed that when the combination was  $> 0.275$ , the risk of the occurrence of MB-related CHD was 15.963 times higher than that when the combination was  $\leq 0.275$  ([Table 6](#)).

## DISCUSSION

**Figure 1** Computed tomography coronary angiography images of myocardial bridge lesions. Myocardial bridge (MB) was marked by the arrow in figures. A and B: MB in the left anterior descending coronary artery; C: MB in the anterior descending coronary artery; D: MB in the right anterior descending coronary artery.

Studies have reported that some patients with sudden cardiac death did not die from myocardial infarction caused by coronary atherosclerosis, but related to MB<sup>[8,21-24]</sup>. MB may compress coronary arteries during the systolic period, which can cause angina pectoris, myocardial infarction, left ventricular dysfunction, paroxysmal atrioventricular block, myocardial ischemia during exertion, sudden cardiac death, *etc*<sup>[25]</sup>. With the rapid development of imaging diagnostic technology, the detection rate of myocardial ischemia caused by MB has increased recently<sup>[26,27]</sup>. CTA has been widely used in MB detection, and it has been proved to non-invasively measure the length and thickness of MB, the systolic and diastolic pressure on MCA, and other MB anatomical features<sup>[28,29]</sup>. Therefore, in the present study, 288 patients with MB were screened from 1718 patients with suspected CHD. The detailed analyses of MB were performed by CTA in order to explore the effect of MB on CHD.

This study first compared the general data of CHD patients and patients without CHD. In addition to age, hypertension, diabetes, smoking, ECG ST segment changes, and LDL-C, which known as CHD influencing factors, the number of patients with combined MB in the CHD group was significantly higher than that in the control group. Further multivariate analysis showed that combined MB was an independent factor affecting CHD. Furthermore, its influencing effect was second only to the effect of diabetes on CHD. This finding indicates that patients with MB are more likely to suffer with CHD. It is indeed necessary to observe MB in detail and take action to prevent CHD.

In order to fully analyze the MB using CTA, we analyzed various anatomical features of MB including MB type (superficial/depth), MB length, thickness, systolic compression, and diastolic compression. The results showed that the proportion of deep MB, MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis rate in the MB-CHD subgroup were significantly greater than those in the simple MB subgroup. To further explore the effects of MB anatomical features on CHD, we performed a multivariate regression analysis using a logistic regression model. The results showed that MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis were four independent influencing factors on the occurrence of MB-related CHD. The diastolic compression and MB thickness had the greatest influence on MB-related CHD, suggesting that thicker MB will compress MCA during the diastolic phase, affecting MCA perfusion and leading to coronary ischemia.

To better analyze the clinical value of the above four MB anatomical features in the

Smoking	286 (27.0)	122 (18.5)	15.970	0.000
ST-segment changes	456 (43.0)	72 (10.9)	196.224	0.000
Abnormal TC	445 (42.0)	264 (40.1)	0.579	0.447
Abnormal LDL-C	583 (55.0)	260 (39.5)	38.960	0.000
Abnormal HDL-C	456 (43.0)	270 (41.0)	0.656	0.418
Abnormal TG	472 (44.5)	289 (43.9)	0.061	0.805
Abnormal Lp(a)	311 (29.3)	182 (27.7)	0.560	0.454
Abnormal HCY	225 (21.2)	115 (17.5)	3.595	0.058
Abnormal PAI-1	178 (16.8)	99 (15.0)	0.916	0.339
Abnormal fibrinogen	157 (14.8)	87 (13.2)	0.842	0.359
Combined MB	235 (22.2)	53 (8.1)	57.969	0.000

CHD: Coronary heart disease; MB: Myocardial bridge; TC: Total cholesterol; TG: Triglyceride; LDL-C: Low-density lipoprotein cholesterol; Lp(a): Lipoprotein(a); HCY: Homocysteine; PAI-1: Plasminogen activator inhibitor-1.

diagnosis of MB-related CHD. The MB thickness, systolic compression, diastolic compression, MCA systolic stenosis rate, and their combination were included in the ROC curve analysis. The results showed that the AUC of the diastolic compression was the largest when the four indicators were used for diagnosis separately, which was 0.870. The AUC of the other three anatomical features were not high. Although the specificity of the systolic compression was close to 100%, the sensitivity was only 37.25%. It cannot be used as a reliable indicator for the diagnosis of CHD. Similarly, although the sensitivity of diastolic compression was very high, reaching 95.1%, the specificity was only 68.28%. The AUC of combined diagnosis increased to 0.959, suggesting that the accuracy of the combination of the four features for diagnosing MB-related CHD was the best. Logistic regression showed that when the probability distribution of the combination of the four MB anatomical features was  $> 0.275$ , the risk of occurrence of MB-related CHD was 15.963 times higher than that when the value was  $\leq 0.275$ . It is suggested that the combination of the four MB anatomical features has potential diagnostic value for MB-related CHD.

The results of this study are unable to be used as clinical criteria currently due to its limited sample size and single-center research. We suggest that a multi-center and large-scale study should be performed to obtain effective indicators for MB-related CHD, in order to improve patients' life quality.

In conclusion, this study found that MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis were independent risk factors for MB-related CHD. The combination of the four MB anatomical features has potential diagnostic value for MB-related CHD. Clinical attention should be paid to MB, and the diagnostic value of MB anatomical features for MB-related CHD should be further explored.

## ARTICLE HIGHLIGHTS

### Research background

More and more reports indicate that myocardial bridge (MB) can compress the mural coronary artery during cardiac contraction, causing myocardial ischemia such as angina pectoris and myocardial infarction. It is clinically called MB-related coronary heart disease (CHD). Therefore, the relationship between MB and CHD has an important influence on the diagnosis of MB-related CHD. Currently, only when the MB reaches a certain thickness, it can be found in coronary angiography (CAG), which results in a high missing diagnosis rate.

### Research motivation

Currently, CAG cannot specifically observe MB-related details. Computed tomography coronary artery (CTA) has become an important means of non-invasive diagnosis of CHD. Studies have shown that CTA can directly show the anatomical relationship between the coronary artery and myocardium. Therefore, this study used CTA to assess the association between MB and coronary atherosclerosis, in order to explore the effect of MB on patients with CHD and improve the detection rate of MB-related CHD.

### Research objectives

In this study, CTA was used to observe the anatomy of MB and analyzed the effects of MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis rate on CHD. The purpose of this study was to evaluate the relationship between MB and coronary atherosclerosis by CTA.

### Research methods

CHD patients who underwent CTA or CAG were defined as the CHD group and the control group, respectively. CHD patients with combined MB were defined as the MB-CHD subgroup. Patients with simple MB were defined as the simple MB subgroup. The anatomical features of patients with MB were analyzed by multi-factor logistic regression. The ROC curve was used to analyze the diagnostic efficacy of the potential indicators for MB-related CHD.

### Research results

MB thickness, systolic compression, diastolic compression, and MCA systolic stenosis had significant effects on the incidence of MB-related CHD ( $P < 0.05$ ). The areas under the ROC curves for the four indicators in diagnosing CHD were 0.814, 0.755, 0.870, and 0.795, respectively. The efficacy of diastolic compression in the diagnosis of CHD was the highest. When the degree

of MB diastolic compression was > 48.68%, the risk of CHD was 15.953 times than that when the value was ≤ 48.68% ( $P < 0.05$ ).

### Research conclusions

MB length, MB thickness, systolic and diastolic compression of MCA have significant effects on the occurrence of MB-related CHD.

### Research perspectives

CTA is a non-invasive economic examination that can directly display the anatomical relationship between the coronary arteries and myocardium. The combination of the four MB anatomical features has potential diagnostic value for MB-related CHD. However, the results of this study cannot be regarded as the clinical criteria because of the limited sample size. We suggest that further multi-center study should be performed to obtain the effective indicators for MB-related CHD, in order to provide a reference for early diagnosis of MB.

## Abstract

## BACKGROUND

Serpin peptidase inhibitor, clade A member 3 (SERPINA3) belongs to the serpin family with an inhibitory activity against proteases. Its aberrant expression has been observed in a wide range of tumor cells. However, its clinical significance and biological function in endometrial cancer have been rarely studied. We designed a study to determine the levels of SERPINA3 and its significance in patients with endometrial cancer.

## AIM

To investigate the clinical significance and role of SERPINA3 expression in endometrial cancer cells.

## METHODS

Eighty endometrial tissue samples collected from patients with endometrial cancer were included in an observation group and 80 paraffin-embedded tissues samples collected from patients with normal endometrial tissues undergoing myomectomy were employed as a control group between January 2014 and December 2018. The expression of SERPINA3 mRNA was detected by quantitative polymerase chain reaction (PCR) for all endometrial tissues included in the study.

## RESULTS

The positive expression rate of SERPINA3 protein in endometrial cancer cells was 71.25% in the observation group, which was significantly higher than that in the control group (31.25%;  $P < 0.05$ ). There was no correlation between SERPINA3 protein in endometrial cancer cells and the age range at which women experienced menopause ( $P > 0.05$ ). However, it was associated with pathological

grade, clinical stage, vascular invasion, and lymph node metastasis ( $P < 0.05$ ). Pathological grade, clinical stage, vascular invasion, and lymph node metastasis were independent prognostic factors for endometrial cancer.

## CONCLUSION

The follow-up study of SERPINA3 can be used as a prognostic biomarker for endometrial cancer and as one of the targets for bio-targeted therapy for endometrial cancer.

**Key words:** Serpin peptidase inhibitor, clade A member 3; Endometrial cancer; Quantitative polymerase chain reaction; Expression

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Serpin peptidase inhibitor, clade A member 3 (SERPINA3) is considered to be associated with several cancers. In this study, the clinical significance and role of SERPINA3 expression in endometrial cancer were investigated. It was found that the expression of SERPINA3 was up-regulated in endometrial cancer and expression of SERPINA3 in endometrial cancer was correlated with pathological grade, clinical stage, vascular invasion, and lymph node metastasis. SERPINA3 has the potential to be used as a biomarker for prognosis and a specific target for targeted therapy in patients with endometrial carcinoma.

## INTRODUCTION

Endometrial cancer is a common malignancy which affects women in China. The incidence of endometrial cancer is just behind that of cervical cancer. It is also the representative malignant cancer of the female reproductive system with an elevated incidence rate in the United States<sup>[1]</sup>. Many patients are unaware of its onset and development due to the hidden cause and non-specific signs and symptoms in the early stages of the disease. As a result, a great proportion of women are diagnosed with endometrial cancer at an advanced stage, which causes them to miss the important opportunities for appropriate and effective interventions. In most cases, endometrial cancer presents as vaginal bleeding in postmenopausal women; and in non-menopausal women, it is characterized by increased menstrual loss and longer or irregular periods.

Therefore, cancer detection should be carefully used to effectively control the development of cancer, promote the early management intervention, and improve the prognosis accordingly. Currently, the most basic methods for detection of endometrial cancer include diagnostic curettage, adjuvant detection by B-mode ultrasonography, hysteroscopy, and nuclear resonance imaging<sup>[2,3]</sup>. Surgical therapy is the main intervention for most women with endometrial cancer. The follow-up intervention should focus on the non-invasive, accurate strategies for detecting the above mentioned therapies. Recently, more studies increased their interest in targeted therapy targeting cancer specific genes. Serpin peptidase inhibitor clade A member 3 (SERPINA3) is one of them. The related studies<sup>[4,5]</sup> revealed that SERPINA3 and its ectopic expression were identified in several cancers, *e.g.*, liver, prostate, lung, and breast cancers. However, few studies investigated SERPINA3 in patients with endometrial cancer. The present study examined the gene expression of SERPINA3 and its clinical significance in endometrial cancer.

## MATERIALS AND METHODS

### Sample collection

Eighty endometrial tissue samples collected from patients (aged 54-68 years, mean

age  $61.5 \pm 3.1$  years) with endometrial cancer were included in an observation group and 80 paraffin-embedded tissues samples collected from patients (aged 52-69 years, mean age  $60.2 \pm 2.9$  years) with normal endometrial tissues undergoing myomectomy were employed as a control group between January 2014 and December 2018. The tissue samples ( $6 \text{ cm} \times 4 \text{ cm} \times 2 \text{ cm}$  for both groups) were collected with the informed consent of the donors and relatives and with complete follow-up information and clinical data. All the patients were chemoradiotherapy, hormone therapy, and antitumor therapy naïve.

### **Tissue microarray construction**

Tissue microarrays were constructed and exposed to the dye. The most representative tumor regions were marked on haematoxylin and eosin stained section slides. This step was also applicable for normal endometrial tissues. Two focus points were selected per tissue block. Targeted tissue samples were extracted from the donor blocks by a fine hollow needle of 1.0 mm in diameter and then injected into the recipient paraffin blocks. The placement of each tissue sample on the coordinate grid of the recipient block was done according to the research aim and the requirements for the study. Once the recipient block was filled, it was cut to generate 4  $\mu\text{m}$  thick slices for analysis.

### **Immunohistochemical staining**

The slices were baked at  $70^\circ\text{C}$  for a total of 1 h. Xylene was used to remove paraffin wax. Then, hydration was performed in graded ethanol. For antigen retrieval, 0.01 mmol/L of sodium citrate buffer (pH = 6) was added and incubated at  $100^\circ\text{C}$  for 10 min. The sections were then incubated with rabbit anti-human polyclonal antibody (dilution, 1:50) at  $4^\circ\text{C}$  overnight, followed by incubation with goat anti-rabbit (IgG) secondary antibody (1:200) at room temperature for 1 h. Diaminobenzidine was used for staining. Hematoxylin stain was applied in the secondary staining step. At last, proper neutral balsam was added to seal the tissue. The scoring criteria were: a score of 0 was considered to reflect the positive expression rate of 0 to 10%, score of 1 reflect 10% to 30%, score of 2 reflect 30% to 60%, and score of 3 reflect  $>60\%$ . If the staining results were not consistent between the two tissue cores, the higher score was considered only. The expression was scored by two pathologists double-blindly. The consistent scores between the two pathologists were involved in the final analysis. Scores of 0 to 1 were defined as low expression and scores of 2 to 3 were defined as high expression.

### **Real-time quantitative polymerase chain reaction**

Total RNA was extracted using TRIZOL reagent. This step was done by strictly following standard instructions (PrimeScript RT, USA). A Rim eScriptRT kit was used for reverse transcription to obtain cDNA. The reaction condition was  $37^\circ\text{C}$  for 30 min and  $85^\circ\text{C}$  for 5 s. The ABI 7300 real-time PCR system was used for amplification. The primers used are as follows: SERPINA3 upstream primer, 5'-TGC CAG CGC ACT CTT CAT C-3' and SERPINA3 downstream primer, 5'-TGT CGT TCA GGT TAT AGT CCC; GAPDH upstream primer, 5'-TGC GAG TAC TCA ACA CCA ACA-3' and GAPDH downstream primer, 5'-GCA TAT CTT CGG CCC ACA-3'. The overall reaction system consisted of 0.8  $\mu\text{L}$  of GAPDH or AERPINA3 upstream and downstream primers, 7.6  $\mu\text{L}$  of cDNA, 10  $\mu\text{L}$  of SYBR Prem ixEx TaqTM, 0.4  $\mu\text{L}$  of Rox Reference Dye (50 $\times$ ), and 0.4  $\mu\text{L}$  of Rox Reference Dye II (50 $\times$ ). PCR reaction conditions were predenaturation at  $95^\circ\text{C}$  for 30 s and 40 cycles of denaturation at  $95^\circ\text{C}$  for 5 s and annealing at  $60^\circ\text{C}$  for 31 s. The obtained data were input into Excel for calculation and analysis.

### **Statistical analysis**

Statistical analyses were performed with SPSS19.0 software using " $\chi^2$ " and " $t$ " reflecting results of the test. The count data are presented using percentages and the measured data are presented as the mean  $\pm$  standard deviation. Significance level was considered at  $P < 0.05$ .

## **RESULTS**

### **Expression of SERPINA3 protein**

A comparison of SERPINA3 protein expression between the observation group and the control group showed that the positive expression rate of SERPINA3 protein in endometrial cancer cells was 71.25% (57/80) in the observation group, which was significantly higher than that in the control group (31.25%, 25/80;  $P < 0.05$ ).

### Relationship between SERPINA3 expression and pathologic features of endometrial cancer

SERPINA3 protein expression in endometrial cancer cells was associated with pathological grade, clinical stage, vascular invasion, and lymph node metastasis ( $P < 0.05$ ), rather than with the age range at which women experienced menopause ( $P > 0.05$ , Table 1).

### Factors influencing the prognosis of patients with endometrial cancer

Pathological grade, clinical stage, vascular invasion, and lymph node metastasis were independent prognostic factors for endometrial cancer (Table 2).

## DISCUSSION

Rising prevalence of endometrial cancer has been reported in China over the last decades, and accordingly the research work on endometrial cancer went further and more detailed. However, the exact cause of endometrial cancer is still unknown<sup>[6-8]</sup>. Currently, the research of endometrial cancer shows increasing interest in how prognosis can be improved by early diagnosis and effective treatment. The assessment of biomarkers may predict the prognosis of endometrial cancer, and should be further studied and interpreted, and studies of biomarkers and bio-targeted therapy for endometrial cancer should be warranted. SERPINA3, an important member of the serine peptidase inhibitors family, has been identified and validated in several cancer cells. However, very few studies have examined SERPINA3 in endometrial cancer cells<sup>[9]</sup>. As a typical acute-phase protein, SERPINA3 is regulated by inflammatory cytokines so that its expression is increased in the inflammatory response. The promoter of SERPINA3 is transcriptionally activated by three transcription factors and the transcriptional level of SERPINA3 is influenced by single nucleotide polymorphisms within the promoter<sup>[10-12]</sup>. Single nucleotide polymorphisms are expressed by regulating the components of genetic sequence when the inflammatory response occurs. Once the inflammatory response occurs, it is benefit for the synthesis of SERPINA3. Nowadays, studies have produced inconsistent and even contradictory results on the expression of SERPINA3. The relevant studies<sup>[13-15]</sup> showed that overexpression of SERPINA3 predicts that damage tends to occur in the body contributing to decreased cell adhesion ability and inhibition of apoptosis. It is revealed that the up-regulation of SERPINA3 is positively associated with malignant tumors.

Few studies have reported the relationship between SERPINA3 protein expression and the incidence of endometrial cancer in China. The current study revealed that pathological grade, clinical stage, vascular invasion, and lymph node metastasis of endometrial cancer were strongly associated with the expression of SERPINA3 ( $P < 0.05$ ). Recently, many studies demonstrated that SERPINA3 could be used as one of the biomarkers in predicting prognosis of several cancers. For instance, SERPINA3 is one of the proteins in signal transduction pathways of the inflammatory response. A study of clinical relapsed ovarian tumors showed that the up-regulation of SERPINA3 was associated with disease progression and chemical resistance<sup>[16]</sup>. Moreover, another study showed that methylation of the 5' region may account for up-regulation of SERPINA3 in placental disease. Researchers also found that overexpression of SERPINA3 in JEG-3 human choriocarcinoma cells could prevent apoptosis<sup>[17]</sup>. Furthermore, one study established that SERPINA3 levels were increased in patients with liver, pancreatic, and prostate cancers. Research studies on endometrial cancer have increased in recent years<sup>[18]</sup>. What is certain is that p53 mutations and subsequent overexpression of human epidermal growth factor receptor 2 (HER2) were common molecular events in endometrial cancer. According to Villalba *et al*<sup>[19]</sup>, an analysis of SERPINA3 expression in normal tissues and endometrial cancer tissues and in different surgical/pathological stages through immunohistochemistry and fluorescence quantitative real-time polymerase chain reaction (FQ-PCR) suggested that the up-regulation of SERPINA3 was strongly associated with factors such as poor differentiation and high surgical/pathological stage. In addition, it predicted a poor prognosis of endometrial cancer.

Endometrial cancer is a malignant tumor that lacks clear diagnosis and optimal treatment. There is currently no conclusive evidence available for the postoperative healing, and the overall survival rate has not been improved fundamentally, although hysterectomy is performed as the main treatment for most women with this cancer. Alternatively, effective postoperative bio-targeted therapy should be given to improve survival and delay recurrence subsequent to surgery in patients who experienced hysterectomy for endometrial cancer<sup>[1,20]</sup>. Based on the present study,

Table 1 Relationship between SERPINA3 expression and pathologic features of endometrial cancer

Variable		N	SERPINA3 protein		$\chi^2$	P-value
			-	+		
Pathological grade	I	45	19	26	9.774	< 0.05
	II	27	4	23		
	III/IV	8	0	8		
Clinical stage	G1	21	10	11	6.351	< 0.05
	G3	32	5	27		
	G2/G3	27	8	19		
Menopause	Yes	41	20	21	0.864	> 0.05
	No	39	15	24		
Vascular invasion	≤ 50%	52	7	45	16.953	< 0.05
	> 50%	28	16	12		
Lymph node metastasis	Positive	24	1	23	10.115	< 0.05
	Negative	56	22	34		

“-” indicates the negative expression of SERPINA3; “+” indicates the positive expression of SERPINA3.

lymph node metastasis and vascular invasion were independent prognostic factors influencing prognosis of endometrial cancer, and SERPINA3 played an important role in the prognosis of endometrial cancer. This further strengthens that SERPINA3 is one of biomarkers for predicting poor prognosis of endometrial cancer. Estrogen-independent type II carcinoma is the more common type of endometrial cancer. Activity of HER2 is increased and cell growth and apoptosis are regulated through the PI3K/ AKT pathway in this population. Whether a synergistic interplay exists between SERPINA3 and HER2 in the development of type II endometrial carcinomas should be further investigated<sup>[21,22]</sup>.  
In conclusion, SERPINA3 has the potential to be used as a biomarker for prognosis and a specific target for targeted therapy in patients with endometrial carcinomas based on a deepening understanding of endometrial carcinoma through research.

**Table 2** Factors influencing the prognosis of patients with endometrial cancer

Factor	B	SE	df	P	95%CI for Exp (B)

## ARTICLE HIGHLIGHTS

### Research background

The expression profile of serpin peptidase inhibitor clade A member 3 (SERPINA3) in patients with endometrial cancer has rarely been studied. In the present study, we detected the protein levels of SERPINA3 in patients with endometrial cancer and the correlation between the expression of SERPINA3 and the prognosis for endometrial cancer. The result revealed that SERPINA3 expression was significantly up-regulated in endometrial cancer and was closely correlated with pathological grade, clinical stage, vascular invasion, and lymph node metastasis. These findings indicated that SERPINA3 can be used as a prognostic biomarker for endometrial cancer and as one of the targets for bio-targeted therapy for endometrial cancer.

### Research motivation

The results of the present study may provide insight into the application of SERPINA3 as a predictor of clinical outcomes and a potential therapeutic target for endometrial cancer.

### Research objectives

The present study aimed to assess the significance of SERPINA3 levels in patients with endometrial cancer.

### Research methods

The present study examined tissue samples which were available from patients with endometrial cancer and patients with normal endometrial tissues. Tissue microarrays were constructed and immunohistochemical staining was performed. The expression of SERPINA3 mRNA was detected by quantitative PCR. The data were analyzed with SPSS19.0 software.

### Research results

We found that SERPINA3 expression was higher in endometrial cancer compared to normal tissues and up-regulated SERPINA3 was closely correlated with pathological grade, clinical stage, vascular invasion, and lymph node metastasis in endometrial cancer.

### Research conclusions

Assessment of tumor *vs* normal tissues showed that the expression of SERPINA3 was up-regulated in endometrial cancer. The SERPINA3 protein level in endometrial cancer cells was associated with pathological grade, clinical stage, vascular invasion, and lymph node metastasis, rather than with the age range at which women experienced menopause. SERPINA3 has the potential to be used as a biomarker for prognosis and a specific target for targeted therapy in patients with endometrial carcinomas.

### Research perspectives

Further studies are warranted to improve our understanding of the role of SERPINA3 in endometrial cancer.

## Abstract

## BACKGROUND

Heart defects are the most common congenital malformations in fetuses. Fetal cardiac structure and function abnormalities lead to changes in ventricular volume. As ventricular volume is an important index for evaluating fetal cardiovascular development, an effective and reliable method for measuring fetal ventricular volume and cardiac function is necessary for accurate ultrasonic diagnosis and effective clinical treatment. The new intelligent spatiotemporal image correlation (iSTIC) technology acquires high-resolution volumetric images. In this study, the iSTIC technique was used to measure right ventricular volume and to evaluate right ventricular systolic function to provide a more accurate and convenient evaluation of fetal heart function.

## AIM

To investigate the value of iSTIC in evaluating right ventricular volume and systolic function in normal fetuses.

## METHODS

Between October 2014 and September 2015, a total of 123 pregnant women received prenatal ultrasound examinations in our hospital. iSTIC technology was used to acquire the entire fetal cardiac volume with off-line analysis using QLAB software. Cardiac systolic and diastolic phases were defined by opening of the atrioventricular valve and the subsequent closure of the atrioventricular valve. The volumetric data of the two phases were measured by manual tracking and summation of multiple slices and recording of the right ventricular end-systolic volume and the right ventricular end-diastolic volume. The data were used to calculate the right stroke volume, the right cardiac output, and the right ejection fraction. The correlations of changes between the above-mentioned indices and

gestational age were analyzed. The right ventricular volumes of 30 randomly selected cases were measured twice by the same sonographer, and the intra-observer agreement measurements were calculated.

## RESULTS

Among the 123 normal fetuses, the mean right ventricular end-diastolic volume increased from  $0.99 \pm 0.34$  mL at 22 wk gestation to  $3.69 \pm 0.36$  mL at 35<sup>±6</sup> wk gestation. The mean right ventricular end-systolic volume increased from  $0.43 \pm 0.18$  mL at 22 wk gestation to  $1.36 \pm 0.22$  mL at 35<sup>±6</sup> wk gestation. The mean right stroke volume increased from  $0.62 \pm 0.29$  mL at 22 wk gestation to  $2.33 \pm 0.18$  mL at 35<sup>±6</sup> wk gestation. The mean right cardiac output increased from  $92.23 \pm 40.67$  mL/min at 22 wk gestation to  $335.83 \pm 32.75$  mL/min at 35<sup>±6</sup> wk gestation. Right ventricular end-diastolic volume, right ventricular end-systolic volume, right stroke volume, and right cardiac output all increased with gestational age and the correlations were linear ( $P < 0.01$ ). Right ejection fraction had no apparent correlation with gestational age ( $P > 0.05$ ).

## CONCLUSION

Fetal right ventricular volume can be quantitatively measured using iSTIC technology with relative ease and high repeatability. iSTIC technology is expected to provide a new method for clinical evaluation of fetal cardiac function.

## INTRODUCTION

Heart defects are the most common congenital malformations in fetuses with an incidence six times greater than chromosome abnormalities and four times greater than neural tube defects<sup>[1,2]</sup>. The diagnosis of congenital heart disease is a challenge using prenatal ultrasound and is the focus of perinatal medical research. Congenital heart disease can be divided into structural and functional abnormalities. Indeed, fetal cardiac structure and function abnormalities often lead to changes in ventricular volume. As ventricular volume is an important index for evaluating fetal cardiovascular development, an effective and reliable method for measuring fetal ventricular volume and cardiac function is necessary for accurate ultrasonic diagnosis and effective clinical treatment of congenital heart disease.

Numerous studies have focused on fetal heart function in an effort to evaluate cardiac function in the healthy fetus and in those in states of cardiac decompensation<sup>[3]</sup>. The accuracy of traditional two-dimensional (2D) ultrasound in the quantitative evaluation of fetal heart function has not been widely accepted<sup>[4-15]</sup>. Spatiotemporal image correlation (STIC) technology overcomes many of the shortcomings of conventional 2D ultrasound in the measurement of fetal ventricular volume and evaluation of fetal cardiac function. Recently, a number of studies have used STIC technology in combination with organ computer-aided analysis software to

measure fetal ventricular volume and evaluate heart function with proven accuracy and feasibility<sup>[4-7,16-27]</sup>. However, STIC still has some limitations and the imaging principle determines that STIC is not a real-time three-dimensional (3D) imaging technology. One-way scanning using the sensors during the scanning process execution is slow, which leads to relatively long image acquisition time. Therefore, STIC is vulnerable to the effects of fetal and maternal respiration, resulting in degradation of image quality<sup>[21,23]</sup>.

The new intelligent STIC (iSTIC) technology adopts an electronic matrix type of probe, which is composed of thousands of vibrating bits, thus generating real-time 3D images with acquired data. The new iSTIC technology acquires high-resolution volumetric images of one cardiac cycle in only 2 s, thus reducing the effects of fetal movement on the image. iSTIC realizes real-time 3D visualization of the fetal heart, which has been shown to have many advantages<sup>[24,25,27-29]</sup>. In the present study, the iSTIC technique was used to measure right ventricular volume in normal fetuses and to evaluate right ventricular systolic function to provide a new method for more accurate and convenient evaluation of fetal heart function.

## MATERIALS AND METHODS

### General information

One hundred twenty-three healthy gravidas with singleton gestations who visited our hospital for prenatal ultrasonography between October 2014 and September 2015 were included in the study. The maternal age range was 22–36 years (average,  $26.60 \pm 3.54$  years). The gestational age range was 22–35<sup>+</sup>6 wk (mean,  $28 \pm 3.79$  wk), including 20 cases at 22–23<sup>+</sup>6 wk, 24 cases at 24–25<sup>+</sup>6 wk, 20 cases at 26–27<sup>+</sup>6 wk, 16 cases at 28–29<sup>+</sup>6 wk, 18 cases at 30–31<sup>+</sup>6 wk, 15 cases at 32–33<sup>+</sup>6 wk, and 10 cases at 34–35<sup>+</sup>6 wk. The inclusion criteria were as follows: (1) singleton pregnancy; (2) fetal biological measurement indicators consistent with the corresponding gestational age; (3) no obvious fetal anatomic abnormalities shown on 2D ultrasound examination; (4) pregnant women were informed of the purpose of the evaluation, and informed consent was obtained before image acquisition; and (5) fetal heart image acquired using real-time 3D iSTIC technology was free of artifacts.

### Instruments

An IU22 3D color Doppler ultrasound diagnostic instrument from Philips Company (Bothell, WA, USA) was used with a 2–4 MHz electronic matrix probe. QLAB software was used for image analysis and post-processing.

### Data acquisition

The information of the last menstrual period and the gestational age in the pregnant women was obtained and recorded. The women were asked to lie flat, and a fetal echo program was begun with transabdominal scanning using an X6-1 probe. They were advised to hold their breath during the acquisition process to avoid interference of motion artifacts. Using a 3D/4D iSTIC technology model for a 4-chamber view of the fetal heart, the 3D/4D sampling frame location was adjusted and the sampling range assured 3D/4D volume data acquisition. The sampling frame included the entire fetal heart. The fetal heart rate was measured and recorded after completion of data acquisition. All images were stored in a built-in hard disk in the machine for later offline analysis.

### Data analysis

(1) Post-processing of 3D image. The image stored in the built-in hard disk in the machine was extracted for analysis using QLAB software. The atrioventricular valve opening and closing framing at end systole and diastole in the entire cardiac cycle were observed to measure the fetal right ventricular volume. End systole was defined as the moment before atrioventricular valve opening, and end diastole was defined as the moment immediately after the atrioventricular valve closed. The center point of the central position of the right ventricle was adjusted using stacked contours to draw a line along the endocardium of the right ventricular apex to the edge of the tricuspid valve, the software was then automatically stratified followed by manual outlining of the contour of each layer of the lining of the heart at the short axis view of the heart including the trabecular muscle and regulating bundle. Computer software automatically calculated the volume of the right ventricle (Figure 1). The right ventricular end-diastolic volume (REDV) and the right ventricular end-systolic volume (RESV) were measured by the same observer three times to obtain the average value.

(2) The heart function index was calculated as follows: The right stroke volume

Figure 1 Fetal right ventricular end diastolic volume obtained by intelligent spatiotemporal image correlation technique.

(RSV) = REDV - RESV; the right cardiac output (RCO) = RSV  $\times$  fetal heart rate; the right ejection fraction = RSV/REDV.

(3) The paired Student's *t* test was performed by randomly retrieved images from 30 cases with the fetal right ventricular volume independently measured by two observers (twice for each observer or twice by the same observer) to evaluate the consistency of the measurement. The average value by each observer was compared.

### Statistical analysis

Data input and processing were carried out using SPSS 23.0 statistical software. The quantitative data conforming to normal distribution were presented as  $\bar{x} \pm s$ . Spearman rank correlation analysis was used to determine the relationship between fetal right ventricular volume and cardiac function parameter changes with gestational age. In addition, the paired Student's *t* test was used to evaluate the consistency of the measurement by the same observer and between different observers. Differences with  $P < 0.05$  were considered statistically significant.

## RESULTS

### Spearman rank correlation analysis

The changes in normal fetal REDV, RESV, RSV, and RCO with gestational age showed significant linear correlations, and the correlation coefficients were 0.903, 0.874, 0.866 and 0.865, respectively ( $P < 0.01$ , Figure 2, Table 1). Right ejection fraction did not change as gestational age increased, was relatively constant throughout the entire pregnancy, and was not significantly correlated with gestational age ( $P > 0.05$ , Table 1). Measurement of fetal right ventricular volume and cardiac function was carried out using the iSTIC technique (Table 2).

### Paired Student's *t* test

The intraclass correlation coefficients (ICC) of REDV measured by the same observer was 0.989 with a 95% confidence interval (CI) of 0.978–0.995. The ICC of RESV was 0.978 with a 95%CI of 0.955–0.989. The ICC of REDV measured by different observers was 0.988 with a 95%CI of 0.975–0.994. The ICC of RESV was 0.988 with a 95%CI of 0.900–0.977. There was no statistical difference between the same observer and different observers when applying the iSTIC technique to measure RESV and REDV using the consistency test, and the correlation coefficients were 0.989, 0.951, 0.990, and 0.980, respectively. The results showed that there was particularly good consistency between the same observer and different observers ( $P < 0.001$ , Table 3).

## DISCUSSION

Fetal cardiac function can be affected by a variety of conditions and prenatal interventions. Accurate assessment of fetal cardiac function could help to understand the process of fetal heart disease, improve the accuracy of diagnosis, and determine prenatal interventions<sup>[2,5,6,16,19,20,22,23,26,30-39]</sup>. Two-dimensional ultrasound is still the

<i>P</i>	< 0.001	< 0.001	< 0.001	< 0.001	0.187

REDV: Right ventricular end-diastolic volume; RESV: Right ventricular end-systolic volume; RSV: Right stroke volume; RCO: Right cardiac output; REF: Right ejection fraction.

traditional gold standard for diagnosis of fetal congenital heart diseases<sup>[17,20,21]</sup> but has a number of limitations in the quantitative evaluation of fetal ventricular volume and cardiac function. When abnormal fetal heart structure causes significant cardiac geometric morphology changes, accurate quantitative assessment of fetal ventricular volume and cardiac function by 2D ultrasound is difficult<sup>[3,34]</sup>.

Application of the STIC imaging technique in fetal heart disorders has been studied extensively, which adds the time factor into the process of 3D data acquisition with continuous unidirectional scanning of the target area by the sensor to obtain the 3D volume data composed of each 2D slice. After completion of volume data acquisition, the software can automatically group 2D sections at the same time to reorganize the image of the entire fetal cardiac cycle, with end-systolic and end-diastolic phases of the cardiac cycle image defined according to opening and closing of the atrioventricular valve in post-processing<sup>[3,16,17,20-23,29,36,38-42]</sup>. Such technology overcomes the imaginary heart geometry by 2D ultrasound along with a relatively simple image acquisition process and fewer requirements for operator experience. The imaging principle determines that STIC is not a real-time imaging technology but a delayed signal. Therefore, when an abnormality of the fetal heart leads to ventricular desynchrony, the maximum and minimum volume of the fetal ventricle cannot be accurately estimated using this method.

In contrast, iSTIC can generate real-time 3D images with an electronic matrix probe used vertically, and a horizontally-arranged 2D probe to conduct matrix volume imaging. The acoustic beam can automatically rotate for large-range scanning, which can significantly reduce the acquisition time of 3D image data and improve work efficiency. The acquisition time of one image by STIC is usually 8–12 s, but iSTIC only requires 2 s. With the imaging time significantly shortened, iSTIC has solved the contradiction between slow STIC imaging and a rapid fetal heart rate and reduced the effects of fetal and maternal respiration and other factors on the quality of the image. The image resolution is thus increased<sup>[29,43,44]</sup>. In theory, accuracy of the iSTIC technique in the measurement of fetal ventricular volume is higher than STIC, which also reduces the exposure time of the fetus to ultrasound.

In this study, iSTIC technology was used to evaluate the heart function of 123 normal fetuses. The results showed that the fetal right ventricular volume, right ventricular stroke output, and RCO increased as gestational age increased, thus showing a good correlation with gestational age. Right ejection fraction did not change as the gestational age increased, which was relatively constant throughout the pregnancy and consistent with a previous report<sup>[23]</sup>. During the entire process of fetal growth and development, the circulatory system plays a critical role. Unlike adults, the fetal right ventricle has the main circulating function. As the right ventricular volume continues to increase, the increased RCO with gestational age can meet the oxygen and nutrient demands for fetal development. In contrast, due to the anatomic and structural characteristics of the right ventricle, which has an irregular shape with the regulation bundle at the apex as well as a rougher endocardial surface compared with the left ventricle, it is particularly important to find an accurate and reliable method to measure fetal right ventricular volume and cardiac function indices.

This study had some shortcomings, such as small sample size and the manual delineation of the lining of the heart in post-processing, which requires clear endocardial imaging and multiple measurements to obtain an average value and reduce measurement errors as far as possible. Due to the rough endocardium surface of the right ventricle, measurement error is inevitable. In addition, there is currently no gold standard for the assessment of fetal heart function to compare the data obtained by iSTIC technology.

In summary, iSTIC technology can be used for the quantitative measurement of fetal right ventricular volume and the evaluation of right ventricular systolic function, which has shown a number of advantages, and the application of iSTIC technology in

**Table 2 Measured normal fetal right ventricular end-diastolic volume, right ventricular end-systolic volume, right stroke volume, right cardiac output, and right ejection fraction values with gestational ages between 22 and 35<sup>+</sup>6 wk**

Gestational age, wk	Case	REDV, mL	RESV, mL	RSV, mL	RCO, mL/min	REF
22–23 <sup>+</sup> 6	20	0.99 ± 0.34	0.43 ± 0.18	0.62 ± 0.29	92.23 ± 40.67	0.58 ± 0.12
24–25 <sup>+</sup> 6	24	1.43 ± 0.28	0.55 ± 0.15	0.90 ± 0.18	132.10 ± 26.61	0.62 ± 0.58
26–27 <sup>+</sup> 6	20	1.66 ± 0.39	0.69 ± 0.20	0.98 ± 0.22	149.25 ± 34.68	0.59 ± 0.06
28–29 <sup>+</sup> 6	16	2.06 ± 0.53	0.77 ± 0.15	1.29 ± 0.44	181.12 ± 57.03	0.61 ± 0.06
30–31 <sup>+</sup> 6	18	2.61 ± 0.33	1.00 ± 0.14	1.60 ± 0.26	232.58 ± 45.60	0.61 ± 0.05
32–33 <sup>+</sup> 6	15	2.98 ± 0.49	1.10 ± 0.17	1.88 ± 0.39	275.86 ± 55.43	0.63 ± 0.04
34–35 <sup>+</sup> 6	10	3.69 ± 0.36	1.36 ± 0.22	2.33 ± 0.18	335.83 ± 32.75	0.63 ± 0.03

REDV: Right ventricular end-diastolic volume; RESV: Right ventricular end-systolic volume; RSV: Right stroke volume; RCO: Right cardiac output; REF: Right ejection fraction.  $RSV = REDV - RESV$ ;  $RCO = RSV \times$  fetal heart rate;  $REF = RSV / REDV$ .

prenatal diagnosis is worthy of further study and discussion.

**Table 3** Consistency between the same observer and different observers

	<i>n</i>	Observer A	Observer B	<i>t</i>	<i>P</i>	<i>r</i>	<i>P</i>	ICC	95%CI
REDV	30	1.54 ± 0.82	1.51 ± 0.79	1.417	0.167	0.989	< 0.001	0.988	0.975-0.994
RESV	30	0.62 ± 0.36	0.61 ± 0.37	0.384	0.704	0.951	< 0.001	0.951	0.900-0.977
		First measurement	Second measurement						
REDV	30	1.54 ± 0.81	1.54 ± 0.84	0.196	0.846	0.990	< 0.001	0.989	0.978-0.995
RESV	30	0.63 ± 0.36	0.61 ± 0.37	1.731	0.094	0.980	< 0.001	0.978	0.955-0.989

REDV: Right ventricular end-diastolic volume; RESV: Right ventricular end-systolic volume; ICC: Intraclass correlation coefficients.

**Figure 2 Correlations.** A: Correlation between right ventricular end diastolic volume and gestational age (wk); B: Correlation between right ventricular end systolic volume and gestational age (wk); C: Correlation between right ventricular stroke volume and gestational age (wk); D: Correlation between right ventricular cardiac output and gestational age (wk). REDV: Right ventricular end-diastolic volume; RESV: Right ventricular end-systolic volume; RSV: Right stroke volume; RCO: Right cardiac output.

## ARTICLE HIGHLIGHTS

### Research background

Heart defects are the most common congenital malformations in fetuses. Fetal cardiac structure and function abnormalities lead to changes in ventricular volume. As ventricular volume is an important index for evaluating fetal cardiovascular development, an effective and reliable method for measuring fetal ventricular volume and cardiac function is necessary for accurate ultrasonic diagnosis and effective clinical treatment. The new intelligent spatiotemporal image correlation (iSTIC) technology acquires high-resolution volumetric images. Numerous studies have focused on fetal heart function which have not been widely accepted. The iSTIC technique was used to measure right ventricular volume in 123 normal fetuses, and to evaluate right ventricular systolic function to provide a new method for more accurate and convenient evaluation of fetal heart function.

### Research motivation

The iSTIC technique was used to provide a new method for more accurate and convenient evaluation of fetal heart function.

### Research objectives

One hundred twenty-three healthy gravidas with singleton gestations who visited our hospital for prenatal ultrasonography between October 2014 and September 2015 were included in the study.

### Research methods

The women were asked to lie flat, and a fetal echo program was begun with transabdominal scanning using an X6-1 probe. Using a 3D/4D iSTIC technology model for a 4-chamber view of the fetal heart, the 3D/4D sampling frame location was adjusted and the sampling range assured 3D/4D volume data acquisition and the sampling frame included the entire fetal heart. The fetal heart rate was measured and recorded after completion of data acquisition.

### Research results

The changes in normal fetal right ventricular end-diastolic volume, right ventricular end-systolic volume, right stroke volume, and right cardiac output with gestational age showed significant linear correlations. Right ejection fraction did not change as gestational age increased, was relatively constant throughout the entire pregnancy, and was not significantly correlated with gestational age.

### Research conclusions

iSTIC technology can be used for the quantitative measurement of fetal right ventricular volume and the evaluation of right ventricular systolic function.

### Research perspectives

iSTIC can generate real-time 3D images, only requires 2 s, and is the best method now. The direction of the future research is to improve the scanning time.

**Abstract****BACKGROUND**

Acute myocardial infarction (AMI) is a leading cause of mortality. Early reperfusion to restore blood flow is crucial to successful treatment. In the current reperfusion regimen, an increasing number of patients have benefited from direct percutaneous coronary intervention (PCI). In order to understand whether there is a correlation between the components of coronary thrombosis and the absence of reflow or slow blood flow after coronary stent implantation in direct PCI, we collected data on direct PCI cases in our hospital between January 2016 and November 2018.

**AIM**

To investigate the correlation between intracoronary thrombus components and coronary blood flow after stent implantation in direct PCI in AMI.

**METHODS**

We enrolled 154 patients (85 male and 69 female, aged 36–81 years) with direct PCI who underwent thrombus catheter aspiration within < 3, 3–6 or 6–12 h of onset of AMI between January 2016 and November 2018. The thrombus was removed for pathological examination under a microscope. The patients of the three groups according to the onset time of AMI were further divided into those with a white or red thrombus. The thrombolysis in myocardial infarction (TIMI) blood flow after stent implantation was recorded based on digital subtraction angiography during PCI. The number of patients with no-reflow and slow blood flow in each group was counted. Statistical analysis was performed based on data such as onset time, TIMI blood flow.

manuscript was prepared and revised according to STROBE the Statement-checklist of items.

## RESULTS

There were significant differences in thrombus components between the patients with acute ST-segment elevation myocardial infarction and non-ST-segment elevation myocardial infarction ( $P < 0.01$ ). In the group with PCI  $< 3$  h after onset of AMI, there was no significant difference in the incidence of no-reflow and slow-flow between the white and red thrombus groups. In the groups with PCI 3-6 and 6-12 h after onset of AMI, there was a significant difference in the incidence of no-reflow and slow-flow between the white and red thrombus groups ( $P < 0.01$ ). There was a significant correlation between the onset time of AMI and the occurrences of no-reflow and slow blood flow during PCI ( $P < 0.01$ ).

## CONCLUSION

In direct PCI, the onset time of AMI and color of coronary thrombus are often used to predict whether there will be no reflow or slow blood flow after stent implantation.

## INTRODUCTION

Acute myocardial infarction (AMI) is a critical illness with high mortality. Early reperfusion to restore blood flow is the key to successful treatment<sup>[1]</sup>. In the current reperfusion regimen, an increasing number of patients have benefited from direct percutaneous coronary intervention (PCI). However, as well as some coronary revascularization, there have been some cases of coronary artery no-reflow or slow blood flow after stent implantation in direct PCI<sup>[2-6]</sup>. In order to understand whether there is a correlation between the components of coronary thrombosis and the absence of reflow or slow blood flow after coronary stent implantation in direct PCI, we collected data on direct PCI cases in our hospital between January 2016 and November 2018.

## MATERIALS AND METHODS

### Patients

We enrolled 154 patients with AMI who were admitted to our hospital between January 2016 and November 2018. Patients underwent direct PCI within 12 hours of onset of AMI with aspiration catheterization and stent implantation. There were 85 men and 69 women, aged 36-81 years (mean age 59.8 years). There were 116 patients with acute ST-segment elevation myocardial infarction (STEMI), 38 with acute non-ST-segment elevation myocardial infarction (NSTEMI), 85 with right coronary artery

infarction, 47 with left anterior descending artery infarction and 22 with left circumflex artery infarction.

### Methods

**Grouping:** All patients were divided into 3 groups according to the time of AMI onset: < 3, 3-6 and 6-12 h. According to electrocardiography and coronary angiography, the patients were further divided into acute STEMI and acute NSTEMI groups.

**Coronary angiography:** The coronary condition and thrombolysis in myocardial infarction (TIMI) blood flow were recorded using the JUDKINS method. TIMI blood flow was graded as follows: Level 0, complete occlusion of the diseased blood vessels, no contrast agent was passed, and the distal myocardium was completely non-perfused; Level 1, the diseased blood vessels had a small amount of contrast agent and blood flow, but the distal arterial vascular bed was not fully developed; Level 2, the contrast agent slowly passed through the stenosis or was delayed at the distal end of the stenosis, the distal segment was developed, and the distal myocardium was perfused, that is, the distal vascular bed was fully developed after 3 cardiac cycles; Level 3, the contrast agent rapidly filled the blood vessel and was rapidly emptied, and all distal myocardial perfusion was complete, that is, the distal vascular bed was fully developed within 3 cardiac cycles. Patients with TIMI blood flow Level 0-2 had no reflow and slow blood flow<sup>[7]</sup>. The severity of coronary thrombosis load was assessed according to the following 6 points: (1) A long thrombus > 3 times the inner diameter of the reference vessel; (2) A strip-shaped thrombus with a length of > 5 mm at the proximal end of the occlusion; (3) A floating thrombus at the proximal end of the occlusion; (4) Inner luminal diameter > 4.0 mm; (5) Occlusion of the proximal vessel without abrupt blunt occlusion; and (6) Contrast agent retention in the distal end of the occluded vessel<sup>[8]</sup>.

**PCI:** Signed informed consent was obtained from each patient before surgery, and the double-resistance load was given (aspirin 300 mg and ticagrelor 180 mg orally). For patients older than 75 years, aspirin 300 mg and clopidogrel 300 mg were given orally. The appropriate guiding catheter was inserted into the coronary artery associated with the lesion of the offender and guide the wire to the distal end of the coronary artery through the lesion, and the Export AP thrombus aspiration catheter was passed to the lesion through the guiding wire, and pumping was repeated 3 to 5 times from the proximal end to the distal end of the lesion. According to angiography after aspiration of the thrombus, stent implantation was performed in patients with residual stenosis > 75%. The intraoperative TIMI myocardial perfusion grade was recorded and the number of cases without reflow or slow blood flow was recorded. In patients with no reflow or slow blood flow, tirofiban and sodium nitroprusside were given intracoronally through the aspiration catheter to improve blood flow. Typical cases are shown in [Figure 1](#) and [Figure 2](#).

**Observation of thrombus components:** The thrombus was extracted from the coronary artery and initially observed with the naked eye. The thrombi were classified as white or red, which was confirmed by fixed section microscopy ([Figure 3](#) and [Figure 4](#)).

### Statistical analysis

Statistical analysis was performed using SPSS version 19.0 software. Normal distribution measurement data are expressed as mean  $\pm$  SD. The Chi-square test was used to compare the data between the groups.  $P < 0.01$  was considered statistically significant.

## RESULTS

In the NSTEMI group, 28 cases of white thrombus and 10 of red thrombus were extracted. In the STEMI group, 4 cases of white thrombus and 112 of red thrombus were extracted. There was a significant difference in the thrombus components between the two groups ( $P < 0.01$ ), as shown in [Table 1](#). In the group with PCI at < 3 h after onset of AMI, there were 4 cases of white thrombus (1 had no reflow and slow blood flow), and 27 cases of red thrombus (none had no reflow and slow blood flow). There was no significant difference in the incidence of no reflow and slow blood flow after stent implantation between the two subgroups ( $P > 0.05$ ). In the PCI at 3-6 and 6-12 h after onset of AMI, there were 28 cases of white thrombus (20 patients had no reflow and slow blood flow), and 95 cases of red thrombus (15 patients had no reflow

**Figure 1** Thrombus aspiration and stent implantation with complete occlusion of the right coronary artery.

and slow blood flow). There was a significant difference in the incidence of no reflow and slow blood flow after stent implantation between these two subgroups ( $P < 0.01$ ), as shown in [Table 2](#). There was a significant correlation between the time of PCI after onset of AMI and the occurrence of no reflow and slow blood flow ( $P < 0.01$ ), as shown in [Table 3](#).

## DISCUSSION

The main cause of AMI is acute or secondary occlusion of the coronary artery. Early, effective and continuous opening of infarct-related blood vessels and restoration of effective blood perfusion can reduce the area of necrotic myocardium and reduce mortality<sup>[9]</sup>. Reperfusion of the myocardium by primary PCI is currently the preferred treatment for AMI. However, with the increasing use of primary PCI, some patients have no reflow or slow blood flow in infarct-related blood vessels after emergency stent implantation<sup>[10,11]</sup>. No reflow or slow blood flow refers to the phenomenon of no blood flow or slow blood flow after infarction-related coronary artery treatment by stent or balloon, resulting in no perfusion or hypoperfusion of myocardial tissue. The exact mechanism of no reflow or slow blood flow is not fully understood at present. It is not the result of simple mechanical microcirculation embolism, but the comprehensive consequences caused by the interaction of various pathophysiological mechanisms. The main mechanisms are currently considered to include: Myocardial ischemic injury, myocardial reperfusion injury, distal coronary artery embolization and microcirculatory injury. Myocardial ischemia can cause damage to vascular endothelial cells and trigger a cascade of cytokines. Ischemia causes damage to the vascular endothelium, adhesion of neutrophils and platelets, and causes stenosis or occlusion of the lumen, further aggravating microcirculatory disorders. During myocardial reperfusion, a series of changes have occurred, such as calcium overload, increased oxygen free radical production, inflammatory cell infiltration, and activation of apoptotic signaling pathways; these changes aggravate ischemia and form a vicious circle. In patients with AMI undergoing direct PCI, due to balloon pre-expansion or stent implantation, unstable intracoronary plaque rupture or microparticles (such as microthrombus of platelets) decrease, leading to vascular obstruction in the distal coronary artery. When the number of particles is  $< 25$  or the diameter of the particles is  $< 200 \mu\text{m}$ , it generally does not cause microvascular obstruction. When the number of particles is 25-200 or the particle diameter is  $> 200$

**Figure 2** Thrombus aspiration and stent implantation for complete occlusion of the left anterior descending coronary artery.

$\mu\text{m}$ , it can cause severe microvascular obstruction. At the same time, thromboxane or angiotensin released by the plaque substance may further lead to microcirculatory disorders<sup>[12-15]</sup>. Different patients have different mechanisms at different pathological stages. Patients with myocardial no reflow after emergency PCI have individual differences, which may be related to genetic susceptibility, and smoking, hypertension, hyperlipidemia and diabetes may also be unfavorable factors for the no-reflow phenomenon<sup>[16,17]</sup>. The same patient may have multiple different mechanisms at the same time. TIMI blood flow grading is commonly used in clinical evaluation. Coronary artery angiography TIMI blood flow Level 0 is no reflow, while Levels 1 and 2 are slow blood flow. A large number of clinical studies have found that the incidence of no reflow or slow blood flow in primary PCI is estimated to be 20%-30% with TIMI blood flow grading<sup>[18]</sup>. The rate of no reflow or slow blood flow estimated by microperfusion such as myocardial contrast echo is as high as 34%-39%<sup>[19,20]</sup>, which can cause an increase in myocardial infarct size, continuous reduction of ventricular function, and further increase mortality<sup>[21-23]</sup>. The incidence is higher in patients with high thromboembolic lesions<sup>[24,25]</sup>.

In conclusion, we found that there was a significant correlation between the onset time of AMI and no reflow and slow blood flow during surgery. The longer onset time of AMI, the higher the incidence of no reflow or slow blood flow. There was a significant difference in the thrombus components between acute STEMI and acute NSTEMI. Patients with acute STEMI had mainly red thrombus, while those with acute NSTEMI had mainly white thrombus, which was closely related to the mechanism of different types of AMI. In patients with PCI at > 3 h after onset of AMI, those with white thrombus were more likely to have no reflow and slower blood flow after stent implantation than patients with red thrombosis. This can predict whether there is no reflow or slow blood flow after stent implantation. At present, the prevention and treatment of microcirculatory disorders and coronary no reflow are limited<sup>[26-32]</sup>. Therefore, in patients with hyperthrombotic lesions that achieve complete recanalization of infarcted coronary arteries, pre-coronary administration of drugs, such as glycoprotein IIb/IIIa receptor antagonists or sodium nitroprusside, should be fully evaluated based on the nature of the thrombus extracted from the coronary arteries. Calcium antagonists<sup>[33,34]</sup> are important to reduce the occurrence of slow blood flow or no reflow.

## ARTICLE HIGHLIGHTS

### Research background

Acute myocardial infarction (AMI) is a leading cause of mortality. Early reperfusion to restore blood flow is crucial to successful treatment. An increasing number of patients have benefited from direct percutaneous coronary intervention (PCI). However, coronary artery no-reflow or slow blood flow after stent implantation and coronary revascularization occurred in direct PCI in some cases. The exact mechanism of no reflow or slow blood flow remains unclear.

### Research motivation

Although in the current reperfusion regimen, an increasing number of patients have benefited from direct PCI, there have been some cases of coronary artery no-reflow or slow blood flow after stent implantation in direct PCI as well as coronary revascularization. The exact mechanism of no reflow or slow blood flow is still unclear. In order to understand whether there is a correlation between the components of coronary thrombosis and the absence of reflow or slow blood flow after coronary stent implantation in direct PCI, we collected data on direct PCI cases in our hospital between January 2016 and November 2018.

### Research objectives

This study aims to investigate the correlation between intracoronary thrombus components and coronary blood flow after stent implantation in direct PCI in AMI.

### Research methods

A total of 154 patients with direct PCI who underwent thrombus catheter aspiration within < 3, 3–6 or 6–12 h of onset of AMI between January 2016 and November 2018 were included. The thrombus was removed for pathological examination. The patients of three groups according to the onset time of AMI were further divided into those with a white or red thrombus. The thrombolysis in myocardial infarction (TIMI) blood flow after stent implantation was recorded based on digital subtraction angiography during PCI. The number of patients with no-reflow and slow blood flow in each group was counted. Statistical analysis was performed on the onset time, thrombus component, and TIMI blood flow.

### Research results

There were significant differences in thrombus components between the patients with acute ST-segment elevation myocardial infarction and non-ST-segment elevation myocardial infarction ( $P < 0.01$ ). In the group with PCI < 3 h after onset of AMI, there was no significant difference in the incidence of no-reflow and slow-flow between the white and red thrombus groups. In the groups with PCI 3–6 and 6–12 h after onset of AMI, there was a significant difference in the incidence of no-reflow and slow-flow between the white and red thrombus groups ( $P < 0.01$ ). There was a significant correlation between the onset time of AMI and the occurrence of no-reflow and slow blood flow during PCI ( $P < 0.01$ ).

### Research conclusions

There was a significant correlation between the onset time of AMI and no reflow and slow blood flow during surgery. There was a significant difference in the thrombus components between acute ST-segment elevation myocardial infarction (STEMI) and acute non-ST-segment elevation myocardial infarction (NSTEMI). Patients with acute STEMI had mainly red thrombus, while those with acute NSTEMI had mainly white thrombus, which was closely related to the mechanism of different types of AMI. In patients with PCI at > 3 h after onset of AMI, those with white thrombus were more likely to have no reflow and slower blood flow after stent implantation than patients with red thrombosis. This can predict whether there is no reflow or slow blood flow after stent implantation. In patients with hyperthrombotic lesions that achieve complete recanalization of infarcted coronary arteries, pre-coronary administration of drugs, such as glycoprotein IIb/IIIa receptor antagonists or sodium nitroprusside, should be fully

evaluated based on the nature of the thrombus extracted from the coronary arteries. Calcium antagonists can help reduce the occurrence of slow blood flow or no reflow.

### Research perspectives

In direct PCI, the onset time of AMI and color of coronary thrombus are often used to predict whether there will be no reflow or slow blood flow after stent implantation. However, the exact mechanism of no reflow or slow blood flow is not fully understood. Multiple pathophysiological mechanisms might be involved, including myocardial ischemia, myocardial reperfusion injury, distal coronary artery embolization and microcirculatory injury. More prospective studies are needed to be carried out in the future in AMI patients with direct PCI after stent implantation.

## Abstract

### BACKGROUND

Noninvasive biomarkers have been developed to predict hepatitis B virus (HBV) related fibrosis owing to the significant limitations of liver biopsy. Both serum biomarkers and imaging techniques have shown promising results and may improve the evaluation of liver fibrosis. However, most of the previous studies focused on the diagnostic effects of various imaging techniques on fibrosis in all chronic liver diseases.

### AIM

To compare the performance of common imaging methods and serum biomarkers for prediction of significant fibrosis caused only by HBV infection.

### METHODS

A systematic review was conducted on the records available in PubMed, EMBASE, and the Cochrane Library electronic databases until December 2018. We systematically assessed the effectiveness of two serum biomarkers and three imaging techniques in predicting significant fibrosis solely caused by HBV infection. The serum biomarkers included aspartate aminotransferase-to-platelet ratio index (APRI) and fibrosis index based on the 4 factors (FIB-4). The three imaging techniques included acoustic radiation force impulse (ARFI), FibroScan, and magnetic resonance elastography (MRE). Three parameters, the area under the summary receiver operating characteristic curve (AUSROC), the summary diagnostic odds ratio, and the summary sensitivity and specificity, were used to examine the accuracy of all tests for liver fibrosis.

### RESULTS

Out of 2831 articles evaluated for eligibility, 204 satisfied the predetermined inclusion criteria for this current meta-analysis. Eventually, our final data

**E-Editor:** Wang J

contained 81 studies. The AUSROCs of serum biomarkers of APRI and FIB-4 were both 0.75. For imaging techniques (ARFI, FibroScan, and MRE), the areas were 0.89, 0.83, and 0.97, respectively. The heterogeneities of ARFI and FibroScan were statistically significant ( $I^2 > 50\%$ ). The publication bias was not observed in any of the serum biomarkers or imaging methods.

## CONCLUSION

These five methods have attained an acceptable level of diagnostic accuracy. Imaging techniques, MRE in particular, demonstrate significant advantages in accurately predicting HBV-related significant fibrosis, while serum biomarkers are admissible methods.

**Key words:** Hepatitis B virus; Diagnostic test; Imaging technology; Liver fibrosis; Meta-analysis

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Many researchers compared the diagnostic effects for liver fibrosis by new techniques within the domain of imaging techniques separately or focused on fibrosis in all chronic liver diseases. We perform a meta-analysis to compare the effectiveness of both some common imaging methods and serum biomarkers for prediction of significant fibrosis among hepatitis B virus (HBV)-monoinfected patients. The results reveal that imaging techniques have significant advantages in prediction of HBV-related significant fibrosis.

## INTRODUCTION

Liver fibrosis is a consequence of the accumulation of extracellular matrix components, caused by persistent liver damage and consequent wound healing reaction<sup>[1,2]</sup>. It can develop to cirrhosis, even hepatic failure and hepatocellular carcinoma<sup>[3]</sup>. Approximately one-third of cirrhosis cases worldwide are caused by hepatitis B virus (HBV) infection<sup>[2]</sup>. It is estimated that about 450 million people are chronically infected with HBV around the world<sup>[1]</sup>, resulting in 600000 to 1000000 deaths annually<sup>[4]</sup>. Therefore, the accurate diagnosis of the degree of liver fibrosis is essential for the management of chronic hepatitis B (CHB) patients and making clinical decision for doctors.

Liver biopsy is the current reference standard for the evaluation and staging of fibrosis, which is an invasive technique. However, it has several disadvantages, such as patients' reluctance, pain, hemoperitoneum<sup>[5]</sup>, intra- and interobserver variations, and sampling errors<sup>[6]</sup>. Therefore, several noninvasive methods, including serum biomarkers combining indices/scores and imaging techniques like magnetic resonance imaging (MRI), have been investigated for their potential in assessment of liver fibrosis.

There has been a dramatic increase in developing various noninvasive tests since 1991<sup>[7]</sup>. There are direct serum noninvasive tests such as hepacore and hyaluronic acid, indirect serum markers which consist of the combination of routine biochemical or haematological tests such as fibrosis index based on the 4 factors (FIB-4), aspartate aminotransferase-to-platelet ratio index (APRI), or Forns index and Fibrotest combined direct and indirect tests<sup>[8]</sup>. Among all of these tests, APRI and FIB-4, being extensively investigated in numerous studies, demonstrated the greatest potential.

On the other side, with the development of imaging technology, several imaging devices have been developed for the diagnosis and staging of liver fibrosis, which are truly noninvasive methods when compared with serum biomarkers. Historically, radiologists and clinicians have relied on the assessment of morphological changes

associated with liver fibrosis. Other imaging methods depend on changes in physical properties that can be assessed by quantification techniques. These include mechanical properties, texture,  $T_1\rho$  lengthening, perfusion, diffusion, and hepatocellular function<sup>[9]</sup>. Ultrasound (US)-based elastography techniques are portable, relatively inexpensive, fast to acquire, and do not require postprocessing<sup>[10]</sup>. In particular, 1D transient elastography, commercialized as FibroScan (Echosens, Paris, France), has been widely validated in clinical trials, adopted clinically, and used by clinicians at point of service<sup>[9]</sup>. Moreover, focal point shear-wave elastography, commercialized as acoustic radiation force impulse (ARFI) (Siemens Medical Solutions, Mountain View, CA), is mapped in 2D using US tracking pulses, and the resulting tissue displacement is measured<sup>[11]</sup>. It is integrated in a conventional US machine that can be performed with conventional US probes during an abdominal US scan<sup>[12,13]</sup>. In addition, many MRI techniques for imaging of liver fibrosis are being developed. They typically cover a larger liver volume than US elastography techniques, which may reduce sampling variability and technical failure rate.

These methods have exhibited promising results and may improve the management of liver fibrosis. However, most previous studies compared the diagnostic effects of these new imaging techniques alone and focused on fibrosis in all chronic liver diseases, which might underestimate or overestimate the role of the biomarkers. Therefore, we performed a meta-analysis to compare the pooled performance of some common imaging methods and serum biomarkers for prediction of significant fibrosis among HBV-monoinfected patients.

## MATERIALS AND METHODS

### Search strategy and selection criteria

Online database search was performed on EMBASE, PubMed, and the Cochrane Library (01/2008-12/2018) for the following terms: Diagnosis test, liver stiffness measurement, LSM, transient elastography, FibroScan, MR elastography, MRE, ARFI, acoustic radiation force impulse, point shear-wave elastography, imaging techniques, hepatitis B virus, HBV, chronic hepatitis B, CHB, and fibrosis. Other studies were identified by a manual search for referenced studies or review articles. EndNote X9 software was used to manage the references.

Studies should be included if they conformed all of the following five criteria: (a) The study evaluated the performance of the APRI and/or ARFI and/or FIB-4 and/or FibroScan and/or MRE for the prediction of fibrosis in HBV infected patients. Studies on patients with other etiologies of liver diseases were also included if data for HBV-infected patients could be independently extracted. Special populations of HBV-infected patients [e.g., HBV/HIV, HBV/ hepatitis C virus (HCV), or HBV/ hepatitis D virus (HDV) coinfection] were excluded; (b) Liver biopsy was used to diagnose liver fibrosis as a golden standard; (c) Data could be extracted to construct at least one  $2 \times 2$  table of test performance, based on some cutoff points of the five biomarkers for the significant fibrosis stage; (d) The study assessed the diagnostic accuracy for fibrosis stage  $F \geq 2$  according to METAVIR or a comparable staging system; and (e) The study included at least 50 patients. Studies of smaller sample sizes were excluded due to concerns on their applicability.

### Data extraction and quality assessment

Two reviewers (WWS and XYX) evaluated study eligibility, extracted data from the study, and graded the study quality independently. Any disagreements between the reviewers were resolved by detailed discussions together with a third reviewer (LHB). The parameters in our literature search included author, year of publication, region, age, patient gender, body mass index (BMI), histological scoring system, number of patients, average length of liver specimen, time interval between biopsy and other diagnostic tests, diagnostic method, prevalence of the fibrosis stage, as well as cutoff values to identify the fibrosis stage<sup>[14]</sup>.

XYX and ZQM independently appraised the quality of included studies using the quality assessment of diagnostic accuracy studies questionnaire (QUADAS-2)<sup>[15]</sup>. It could estimate the internal and external validity of diagnostic accuracy of studies used in systematic reviews.

### Statistical analysis and data synthesis

We extracted and tabulated the data in a series of  $2 \times 2$  tables that included sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) at each threshold value. The primary target was to identify significant fibrosis, defined by METAVIR<sup>[16]</sup>, Batts and Ludwig<sup>[17]</sup>, Scheuer<sup>[18]</sup>, and Chinese Hospital system<sup>[19]</sup>, for

stages F2 to F4, and Ishak<sup>[20]</sup> for stages F3 to F6. This gauge was chosen because significant fibrosis is often considered a threshold for the initiation of antiviral therapy<sup>[21]</sup>. The method of diagnostic test accuracy was examined in order to provide clinically meaningful results. We examined the area under the summary receiver operating characteristic curve (AUSROC) curve, the summary diagnostic odds ratio (DOR), and the summary sensitivity and specificity to further examine the accuracy of all tests for liver fibrosis.

The heterogeneity of the results between studies was assessed statistically using the Cochran-Q and the quantity  $I^2$ .  $I^2$  value can describe the percentage of total variation across studies that is attributable to heterogeneity rather than chance<sup>[22]</sup>. If there was significant heterogeneity, a meta-regression was conducted to explore the covariates that may induce heterogeneity, according to the following predefined characteristics: (1) Study design (prospective or retrospective); (2) Length of liver specimen ( $\geq 10$  mm,  $\geq 15$  mm,  $\geq 20$  mm, or not); (3) Liver biopsy scoring system; (4) Number of centers (single or multicenter); (5) Sample size; (6) Publication year (2014-2018 or 2008-2013); (7) Time interval between biopsy and tests (same day or not); (8) Prevalence of significant fibrosis; (9) BMI; and (10) Location of study.

The potential publication bias was assessed using the Deeks funnel plots<sup>[23]</sup>. All analyses were performed with Meta-Disc software (v. 1.4) and Stata15.0.

## RESULT

### Search results

The study selection process is shown in Figure 1. A total of 2831 studies were searched by the described search strategies, of which 2627 were excluded following title and abstract screening. Of those, 81 papers were included in the review following full-text screening (Text S5); 47 studies were related to the APRI<sup>[24-70]</sup>, 11 to the ARFI<sup>[29,42,69-77]</sup>, 32 to the FIB-4<sup>[24,25,27,30,35,36,39,40,43-46,48-55,57,58,60,62,63,65-69,78-79]</sup>, 29 to the FibroScan<sup>[28,38,42,52,53,58,60,61,71,73,80-98]</sup>, and 6 to the MRE<sup>[99-104]</sup>.

### Characteristics of the included studies

In the 47 studies of APRI, there were 13725 patients (median age, 37 years; 68.9% of males). The total prevalence of significant fibrosis was 55.9% (range: 16.7%-83.7%). Most studies were conducted in Asia (42 studies). Three studies were from Europe, one from North America, and another from Africa. We did not restrict study participants to any age, but only one study was conducted on children and adolescents exclusively<sup>[59]</sup>. Twenty-nine studies used the METAVIR score, ten used the Scheuer score, six utilized the Ishak score, and two used the Chinese Hospital System. There were 11179 patients (median age, 37 years; 68.7% of males) in 32 studies evaluating the performance of FIB-4. The total prevalence of significant fibrosis was 57.5% (range: 16.7%-83.7%). Twenty-nine studies were conducted in Asia, two in Europe, and one in North America. All studies included adults only. Seventeen studies used the METAVIR score, nine used the Scheuer score, four utilized the Ishak score, and two used the Chinese Hospital System.

A total of 1527 patients (median age, 36 years; 67.5% of males) were contained in 11 studies on ARFI. The total prevalence of F2 was 54.2% (range: 23.9%-74.3%). Ten studies were conducted in Asia and one in Germany. All the subjects were adults. Six studies used the METAVIR score, two used the Chinese Hospital System, and one used each of the Scheuer score, the Ishak score, and the Batts and Ludwig score.

In the 29 FibroScan studies, a total of 5035 patients (median age, 39 years; 71.4% of males) were included. The overall prevalence of significant fibrosis was 49.4% (range: 14.8%-85%). Twenty-one studies were from Asia, six from Europe, one from Africa, and another from North America. Twenty studies used the METAVIR score, five utilized the Batts and Ludwig score, three utilized the Scheuer score, and one used the Chinese Hospital System.

There were 1228 patients (median age, 49 years; 71.0% of males) used to evaluate the performance of MRE in six studies. The total prevalence of significant fibrosis was 61.4% (range: 45.2%-77.4%). One MRE study was from America and the other five were conducted in Asia. The results of methodological quality assessment according to the QUADAS-2 scale are described for all studies (Figure 2, Text S5).

### Performance of serum biomarkers for prediction of significant liver fibrosis

In the 47 studies evaluating the APRI, the area under the ROC curve (AUROC) ranged from 0.54 to 0.87. The AUSROC and the pooled sensitivity, specificity, and DOR are presented in Table 1 and Figure 3. The Cochran-Q was 1199.4 and  $I^2 > 50\%$ , which indicated significant heterogeneity across the included studies ( $P < 0.001$ ). Meta-

Figure 1 Flow diagram of article selection.

regression analysis was used to explore the heterogeneity of the APRI accuracy for predicting significant fibrosis, which was affected by BMI and prevalence of significant fibrosis with regard to sensitivity and only prevalence of significant fibrosis with regard to specificity (Figure S1). In the 32 studies evaluating the FIB-4 for the prediction of fibrosis stage of F2, the AUROC ranged from 0.56 to 0.85. The AUSROC was 0.75 (0.71-0.78) (Figure 3). The summary sensitivity, specificity, and DOR are shown in Table 1. The score of Cochran-Q was 488.9 ( $P < 0.05$ ) and heterogeneity was statistically significant. The heterogeneity of FIB-4 accuracy was mainly affected by prevalence of significant fibrosis with regard to sensitivity, and prevalence of significant fibrosis and study design with regard to specificity according to the meta-regression analysis (Figure S2). The summary sensitivity and specificity of serum indicators by BMI and prevalence of significant fibrosis are listed in Tables 2 and 3.

### Performance of imaging techniques for prediction of liver significant fibrosis

The AUROC ranged from 0.72 to 0.96 in 11 studies evaluating the ARFI. When combined, the AUSROC was 0.89 (0.86-0.91). The summary DOR was 23 (95%CI: 15-38), and the score of Cochran-Q was 27.8 and  $I^2 > 50\%$ , indicating significant heterogeneity across the included studies ( $P < 0.05$ ). In meta-regression analysis, we found that the causes of the heterogeneity were publishing year and sample size for sensitivity, and prevalence of significant fibrosis and BMI for specificity (Figure S3). In the 29 studies evaluating the FibroScan, the AUROC ranged from 0.61 to 0.94. The AUSROC and the pooled sensitivity, specificity, and DOR are also shown in Table 1 and Figure 3. There was significant heterogeneity across the included studies ( $I^2 > 50\%$ ,  $P < 0.001$ ). The heterogeneity of the FibroScan was mainly affected by prevalence of significant fibrosis and BMI with regard to sensitivity or specificity (Figure S4). In the six studies evaluating the MRE for the prediction of significant fibrosis, the AUROC ranged from 0.98 to 0.99. The AUSROC was 0.97 (0.96-0.98) (Figure 3). The summary sensitivity, specificity, and DOR are listed in Table 1, and the Cochran-Q and  $I^2$  of this measure were 0.44 ( $P > 0.05$ ) and 0, respectively. The result of the heterogeneity was statistically insignificant. The subgroup analysis of imaging methods by BMI and prevalence of significant fibrosis are listed in Tables 2 and 3, respectively.

### Publication bias

Funnel plots of these markers are illustrated in Figure S5. Symmetry was noted in the funnel plots and publication bias was not observed in any of the serum biomarkers or the imaging methods.

## DISCUSSION

Liver fibrosis progression is common in people infected with HBV. Patients with

**Figure 2** Summary of methodological quality of studies according to QUADAS-2.

significant fibrosis should be considered for clinical therapy, which can potentially reduce and even reverse complications<sup>[105]</sup>. Considering the risks and limitations of biopsy, researchers should make persistent efforts in researching some noninvasive methods to more conveniently and securely identify patients with significant fibrosis. FIB-4 and APRI are such noninvasive serum biomarkers that they have been gaining increasing acceptance in clinical practice. FibroScan, ARFI, and MRE gradually reveal an advantage with the development of US-based or MRI elastography techniques. These methods may reduce the demand for liver biopsy and also help to monitor the efficacy of treatments<sup>[62]</sup>.

Many scholars have researched the diagnostic effect of APRI and FIB-4 and usually compared them with other new methods. In addition, the World Health Organization (WHO) recommends APRI as the preferred noninvasive test to assess significant fibrosis or cirrhosis and FIB-4 to detect fibrosis stages  $\geq$  F3, considering lower cost, routinely available methods, and untrained staff<sup>[106]</sup>. Therefore, among all serum biomarkers, only APRI and FIB-4 were singled out in our analysis. Based on the results from an increasing number of studies, the difference between APRI and FIB-4 is not significant in relative diagnostic outcomes, although some articles described that FIB-4 had a higher diagnostic accuracy for cirrhosis when compared with APRI<sup>[107]</sup>. If only APRI and FIB-4 are available, APRI based on AST, ULN, and platelet count is suggested to diagnose liver significant fibrosis considering resource-limited settings.

With the development of imaging technology, US imaging and MRI devices have been explored to diagnose and stage liver fibrosis, which are truly noninvasive methods. In our meta-analysis, the AUSROCs of imaging techniques are generally bigger than those of APRI and FIB-4. Of these tests, transient elastography performed with FibroScan (Echosens, Paris) has been evaluated widely and has a good performance in predicting cirrhosis, which is corroborated by the Guidelines Development Group. They considered it the most useful test for the assessment of

cirrhosis in middle-income countries<sup>[106]</sup>. In addition, FibroScan acquires information from a much larger portion of the liver tissue compared to biopsy, and therefore, the risk of sampling error is significantly lowered. However, its performance is mediocre for diagnosing moderate liver fibrosis, and the AUSROC ranked in the middle of the five methods. Morbid obesity (BMI > 30), narrow intercostal spaces, and food intake may diminish the accuracy of FibroScan<sup>[107]</sup>. Because of the limitation of US technology, some researchers advocated that the accuracy of ARFI is similar if not superior to FibroScan for the diagnosis of liver fibrosis<sup>[108,109]</sup>. Our meta-analysis reveals that ARFI has a higher diagnostic accuracy than FibroScan in identifying HBV-related significant fibrosis. In contrast to FibroScan that has a fixed region of interest box at a fixed insertion depth, ARFI could be performed at variable depths. Furthermore, it can also be performed in obese patients and patients with ascites and integrated in a conventional US system<sup>[13]</sup>. MRE, the only MRI index, had the best result in prediction of significant fibrosis. The AUSROC of MRE reaches the standard of “best” and even closes to “1”<sup>[110]</sup>. And the summary sensitivity and specificity have reached 94% and 96%, respectively. It typically covers larger liver tissue than US elastography techniques, which may reduce sampling variability. While MRE has been incorporated into MRI devices, it might be more expensive and require more operator training and expertise. Therefore, it is not widely applied at present, and the number of research articles is limited.

Meta-regression method is a convenient and reliable way for heterogeneity screening. In our study, BMI, prevalence of significant fibrosis, sample size, publishing year, and study design provide heterogeneity in summarizing test results. This is consistent with a range of previous studies<sup>[38,111,112]</sup>. Some researchers suggested that BMI may reduce the accuracy of ultrasonic technique for detecting significant fibrosis<sup>[9,38]</sup>. Our results reveal that BMI may affect predicting outcomes of either serum biomarkers or imaging techniques. Imaging technology shows a better predictive effect in the normal weight group, while serum indicators reflect their superiorities in overweight HBV patients (Table 2). The high proportion of fibrosis stage  $\geq 2$  will reduce the accuracy of evaluating fibrosis by all methods (Table 3). Furthermore, publishing year and sample size are the main contributors to the heterogeneity of ARFI. The AUSROC of ARFI was 0.89 when we excluded the only one article before 2014, the AUSROC of which was 0.75. Therefore, the technology of ARFI, a new diagnostic method, is progressing gradually, and the evaluation effect is increasingly improved. Besides, the AUSROCs in subgroups of sample size between 100 and 300 were much more than others in most cases (Text S6). Although other methods showed no significant differences in the AUSROC among subgroups of sample size, there was a general pattern that the areas were larger in the middle while smaller on both sides (Text S6). This phenomenon is more prominent if the group was changed into three subgroups ( $n < 100$ ,  $100 \leq n \leq 300$ , and  $n > 300$ ) (Table 4). A few years ago, our team observed that when the sample size was larger than 150, the diagnostic accuracy of predicting fibrosis was noticeably enhanced<sup>[111]</sup>. Therefore, the sample size of 150-300 will be beneficial to the accuracy of diagnostic tests.

However, there are several limitations in our systematic review. First of all, the cut-off value was not considered due to the absence of threshold effect in all tests (Text S7). Second, the ALT levels were not considered because only a limited number of studies calculated the results by the subgroup of ALT. Third, only the studies published in English and Chinese languages were included. Lastly, other methods, though we have retrieved them, were not considered in this meta-analysis, because the number of articles was not adequate.

In conclusion, these five methods have attained an acceptable level of diagnostic accuracy in our meta-analysis. Imaging techniques are generally better than serum

biomarkers in prediction of HBV-related liver significant fibrosis. MRE is a promising indicator and will surprise us with the development of global economy and popularization of technology. If condition allows, ARFI could be a better choice, than FibroScan, for assessment of liver fibrosis in HBV-monoinfected patients with obesity or ascites. The prediction effects of serum markers are generally admissible. Their low cost and easiness in operation make them attractive especially in areas with limited resources and access to imaging technology.

## ARTICLE HIGHLIGHTS

### Research background

Liver fibrosis can develop to cirrhosis and even hepatic failure and hepatocellular carcinoma. Approximately one-third of cirrhosis cases worldwide are caused by HBV infection. Therefore, the accurate diagnosis of the extent of liver fibrosis for chronic hepatitis B patients is essential. Many serum biomarkers combining indices/scores and imaging or magnetic resonance imaging techniques have been undergoing dramatic development because of several drawbacks of liver biopsy. These methods have promising results and may improve the management of liver fibrosis. However, most of the previous studies compared the diagnostic effects of these new techniques within the domain of imaging techniques or focused on fibrosis in all chronic liver diseases, which might misestimate the role of these biomarkers. Therefore, we performed a meta-analysis to compare the pooled performance of some common imaging methods with serum biomarkers for prediction of significant fibrosis among HBV-monoinfected patients.

### Research motivation

We aimed to assess the accuracy of diagnostic tests for predicting significant fibrosis among patients monoinfected with HBV. Most studies are centered on the domain of imaging techniques and serum biomarkers separately or focused on fibrosis in all chronic liver diseases. Therefore, the key points are that data for HBV infected patients could be extracted independently and we want to integrate and compare the performance of methods of different fields. With the development of medicine and technology, more innovative methods could be invented in the near future. It will provide a boost to precision medicine that chooses a more appropriate and effective method to evaluate liver fibrosis for different populations of patients.

### Research objectives

We aimed to compare the pooled performance of some common imaging methods with serum biomarkers for prediction of significant fibrosis among HBV-monoinfected patients. Some serum biomarkers have been calculated and imaging techniques have been developed for the diagnosis of liver fibrosis, respectively. Integrating and comparing the performance of methods of different fields could provide a basis for future research and clinical application and a boost to precision medicine.

### Research methods

We examined the areas under the summary receiver operating characteristic curves, the summary diagnostic odds ratios, as well as the summary sensitivities and specificities to further examine the accuracy of all tests for liver fibrosis. Then, we assessed the heterogeneity between studies using the Cochran-Q and  $I^2$ . And the Deeks funnel plots were used to assess publication bias. Meta-regression was conducted to further accurately explore the covariates that may induce heterogeneity.

### Research results

Our meta-analysis revealed that ARFI showed a higher diagnostic accuracy than FibroScan in identifying HBV-related significant fibrosis. Furthermore, it can also be performed in obese patients and in patients with ascites and be integrated in a conventional ultrasound system. MRE, the only MRI index, had the best result in prediction of significant fibrosis. The area under the SROC curve of MRE reaches the standard of "best" and even closes to "1". The performances of APRI and FIB-4 are poorer than imaging techniques. However, the cut-off value should be considered in future studies.

### Research perspectives

Imaging techniques are better than serum biomarkers in prediction of HBV-related liver significant fibrosis in general. MRE is a promising indicator and other serum biomarkers are general.

## ACKNOWLEDGEMENTS

We thank Prof. Li-Jin Xu for comments that greatly improved the manuscript. And we also thank all participants for their contribution of time to this study.

### Abstract

#### BACKGROUND

Roux-en-Y gastric bypass (RYGB) is the most commonly performed surgical procedure used to treat obesity worldwide. Despite satisfactory results in terms of weight loss, over time many patients experience weight regain. There are many factors that contribute to weight regain after RYGB, including the diameter of the gastric-jejunal anastomosis (GJA). One of the most commonly performed endoscopic procedures for weight regain after RYGB is argon plasma coagulation (APC). We report a case of hematemesis after outlet revision with APC. We highlight several treatment modalities that can be used to treat this complication.

#### CASE SUMMARY

A 45-year-old female with a history of weight regain after RYGB was referred for possible endoscopic treatment for weight regain. On endoscopic evaluation, the diameter of the GJA was 22 mm. Due to the dilated GJA, treatment with APC was performed. Several months later she reported a return of poor satiety and an increased appetite. A repeat endoscopy was then performed. The GJA was approximately 15 mm and was incompetent. APC was performed. One day post procedure she had four episodes of hematemesis. An endoscopy was performed and a large ulcer with a visible arterial vessel was visualized at the GJA. Coagulation was attempted using a Coagrasper and after initial contact with the vessel, the vessel started oozing. Due to fibrosis and the depth of ulceration in the area, clips and repeat APC could not be used. Therefore, an attempt to inject

epinephrine injection was made. However, persistent oozing was noted. As a result, hemostatic powder was applied to the region of the bleeding vessel. Subsequently, no more bleeding was observed. On follow-up, the patient remained hemodynamically stable and a second look endoscopy was not performed. The patient was discharged three days later.

### CONCLUSION

APC revision of the GJA is known to be a relatively safe and effective strategy to manage weight regain post RYGB. Anastomotic site bleeding is an infrequent and potentially life-threatening complication associated with this therapy. Endoscopic management is the first line therapy used to achieve hemostasis in these cases.

## INTRODUCTION

Roux-en-Y gastric bypass (RYGB) is one of the most commonly performed surgical procedure used to treat obesity worldwide<sup>[1]</sup>. Despite satisfactory results in terms of weight loss, over time many patients experience weight regain<sup>[2]</sup>. There are many factors that contribute to weight regain after RYGB, including lack of exercise, medical conditions, psychiatric problems, overeating, medicines known to cause weight gain, poor family support, and dilation of the gastric-jejunal anastomosis (GJA)<sup>[2,3]</sup>.

Among these factors, the diameter of the GJA plays an important role in controlling weight regain post RYGB. Though effective, traditional surgical revision is used in less than 15% of patients because it is associated with relatively high complication rates (between 15% to 50%), longer operative time, increased intraoperative blood loss, and a non-negligible mortality rate (of more than twice that of the original procedure)<sup>[4-8]</sup>.

As a result, endoscopic revision of a dilated GJA was first reported in 2004 and has gained wide acceptance since that time<sup>[9]</sup>. One of the most commonly performed endoscopic procedures post RYGB is argon plasma coagulation (APC). It is safe, efficient, and easy to learn, and is associated with a low complication rate<sup>[10,11]</sup>. One associated complication is post APC bleeding.

We report a case of a patient with RYGB presenting with gastrointestinal bleeding after recent outlet revision with APC for weight loss. We highlight several treatment modalities that can be used to treat this complication.

## CASE PRESENTATION

### Chief complaints

We present a case of a 45-year-old female with obesity and a history of type 2 diabetes mellitus, gastroesophageal reflux disease, hypercholesterolemia, hypertension, and nonalcoholic fatty liver disease who underwent RYGB in 2005.

Her pre-procedure weight was 108 kg [Body Mass Index (BMI): 37.4 kg/m<sup>2</sup>] and her weight decreased to nadir of 80 kg (BMI: 27.7 kg/m<sup>2</sup>). However, she regained 27 kg and was referred for possible endoscopic treatment for weight regain in 2017.

## FINAL DIAGNOSIS

Weight regain after bariatric surgery.

## TREATMENT

On endoscopic evaluation, the gastric pouch extended from 38 to 42 cm and no fistula or ulcers were seen. The diameter of the GJA was 22 mm (Figure 1). Due to the dilated GJA, treatment with APC was performed. Under CO<sub>2</sub> insufflation, tissue at the rim of the GJA was treated with forced APC at 0.8 L/min and 70 W in a 1.0 cm concentric ring (Figure 2). There was no direct contact with the mucosa. The patient was treated with monitored anesthesia care. The procedure was performed without any adverse events.

## OUTCOME AND FOLLOW-UP

Following her first APC, our patient stopped gaining weight, however, she had inadequate weight loss (106 kg, BMI: 36.7 kg/m<sup>2</sup>). Several months later, she reported a return of poor satiety and an increased appetite. A repeat endoscopy was then performed. At that time, the pouch extended from 38 to 41 cm and the GJA was approximately 15 mm in diameter and was incompetent, without ulceration. APC was performed. The procedure occurred without any adverse events, including bleeding.

One day post procedure she had four episodes of hematemesis with visible clots. She also had one large bowel movement with maroon and bright red blood per rectum. Her hemoglobin decreased from 12.8 g/dL to 10.5 g/dL but she was hemodynamically stable. A type and cross was obtained and two large bore IV needles were inserted. A repeat upper endoscopy was performed. The esophagus and the pouch mucosa appeared normal, with no signs of active bleeding. There was a large ulcer with a visible arterial vessel that was visualized and located at the GJA (Figure 3). Coagulation was attempted using a Coagrasper™ (Olympus, Tokio, Japan) and after initial contact with the vessel, the vessel started oozing (Figure 4). Subsequently, bipolar coaptive coagulation was attempted, without success. Repeat APC was not performed due to the depth of the ulceration and concern that this could potentially increase the risk of a delayed perforation. Therefore, injection therapy using a solution comprised of 2 mL of a 1:10000 solution of epinephrine was attempted surrounding the protruding vessel. However, persistent oozing was noted, and significant blood clots were observed around the anastomotic site limiting endoscopic visualization of the vessel.

Additionally, due to fibrosis in the area and to the poor visualization caused by the blood clots within the pouch, clips could not be applied. As a result, after cleaning some the blood clots, hemostatic powder [Hemospray® (Cook Medical, Winston-Salem, NC, United States)] was applied to the region of the bleeding vessel. Subsequently, there was no more bleeding from the visible vessel (Figure 5). Vital signs remained stable throughout the procedure and no blood transfusions were necessary. The patient remained on an IV proton pump inhibitor (PPI) and she was made nil per os (NPO). One day post procedure an oral PPI was initiated, and she remained on a liquid diet for 2 d and then was advanced to a regular diet. The patient remained hemodynamically stable and a second look endoscopy was not performed. She was discharged three days later.

## DISCUSSION

Over the last decade, dilation of the GJA has been recognized as an important cause of weight regain after RYGB. However, re-operative surgery to reduce the GJA diameter or the pouch size is technically challenging and is associated with a relatively high complication rate. Therefore, many endoscopic methods have been developed to reduce the diameter of the gastric pouch and GJA, which include injection therapy into the anastomotic site, endoscopic suturing and plicating, and thermal ablation therapy using APC<sup>[2,12-15]</sup>.

APC was initially developed as a treatment modality for gastrointestinal hemorrhage. It is a catheter-based system that utilizes a jet of ionized argon gas for non-contact electrocoagulation of tissue that can be applied through a standard endoscope. Because the probe does not have direct contact with the mucosa, the procedure is safe and the depth of coagulation is limited to only a few millimeters.

**Figure 1** Dilated gastric-jejunal anastomosis prior to endoscopic treatment for weight regain.

The depth of penetration is associated with power input in watts and the greater the wattage applied the deeper the penetration, which may result in injury to the muscular layer. After APC ablation is performed around the anastomotic ring, tissue contracts and results in scar formation, which reduces the caliber of the GJA. As a result, the goal of delayed emptying and early satiety can be achieved, and this contributes to weight loss. In general, APC is safe with few complications reported in the literature, such as anastomotic stricture, ulcer formation, bleeding, and leakage at the GJA<sup>[2,11,15]</sup>.

In this case, we present a patient with hemorrhage after APC. During endoscopy a visible vessel was observed at the GJA. Due to the fibrotic tissue after APC, a hemoclip was thought to not be a good option. Injection with epinephrine solution and thermal therapy with Coagrasper and bipolar coagulation were used with limited success. APC was also thought to be a poor option due to the depth of ulceration. Ultimately, we were able to control the bleed with Hemospray and to the best of our knowledge, this is the first case reported in the literature in which hemostatic powder was used to control bleeding after a revisional endoscopic procedure in a patient with RYGB.

Hemospray was approved as a hemostatic therapy in 2011 and has been shown to rapidly stop active bleeding with a high success rate. It is a novel inorganic powder with minerals which contains no human or animal proteins or botanicals. The powder can be sprayed via a catheter that can be inserted through the working channel of a standard adult endoscope and forms a cohesive barrier after coming into contact with moisture which leads to a tamponade by concentrating and activating platelets and coagulation factors and promoting thrombus formation. As a spray, it is very useful in the management of bleeding when the active bleeding site cannot be definitively localized. Hemospray is indicated for active bleeding (Forrest 1A and 1B) and can be used as a primary therapy or as a rescue therapy after conventional endoscopic treatments fail. After the powder absorbs fluid, it forms a mechanical barrier over the bleeding site. Hemospray is not absorbed by the body or through blood vessels, and the mechanical barrier formed by Hemospray does not need to be removed. The adherent barrier is designed to pass through the GI tract within 72 hours<sup>[16,17]</sup>. This device can be used as a definitive therapy as in our case or as a bridge to further interventions after hemodynamic stabilization.

## CONCLUSION

APC revision of the GJA is known to be a relatively safe and effective strategy to manage weight regain post RYGB. Anastomotic site bleeding is an infrequent and potentially life-threatening complication associated with this therapy. Endoscopic management is first line therapy to achieve hemostasis in these cases. However, fibrotic ulcerative tissue after recent APC may limit the ability to achieve successful hemostasis with standard endoscopic interventions such as injection therapy, thermal therapy, and hemostatic clip placement. Therefore, as presented in this case, hemostatic powder is a useful therapeutic option to achieve hemostasis. This device may be useful as a primary or as a rescue therapy in this setting. More studies are required to better clarify the role of hemostatic powder for bariatric patients with active bleeding.

### Abstract

#### BACKGROUND

Hepatocellular carcinoma (HCC) accounts for 5-6% of all human cancers. Considering the extrahepatic metastasis, the main organs involved are lymphnodes, lung, bone and adrenal gland. Usually colon metastasis is very rare, especially on the left sided colon.

#### CASE SUMMARY

We report a case of a 70 years-old man hepatitis B carrier with HCC treated four times with trans-arterial chemoembolization, presented to our surgical department complaining of gastrointestinal bleeding. A colonoscopy revealed a mass of 4 cm of the sigmoid colon with signs of bleeding. The computed tomography showed a mass originated from the sigmoid colon of 3.5 cm, and the presence of HCC in segment VI and VII, without portal vein thrombosis. Due to the large size of the mass and the active bleeding, the patient underwent a left colectomy. The postoperative period was uneventful, and the patient was discharged in fifth post-operative day. Histological examination revealed that the neoplasm was characterized by a diffuse proliferation of epithelial cells with an hepatoid differentiation. So, the presence of a history of HCC of the liver and the histopathological features supported the diagnosis of metastasis from the liver.

#### CONCLUSION

Although rare, colon metastasis from an HCC can be left-sided and can present with acute bleeding.

## INTRODUCTION

Hepatocellular carcinoma (HCC) causes more than 1 million deaths annually and the incidence is increasing in the last few years.

Unfortunately, only 30% of patients benefit from resection, percutaneous ablation or liver transplantation.

In a series<sup>[1,2]</sup>, the most involved organs, as extrahepatic metastasis, were lymph-nodes, lung, bone and adrenal gland. The involvement of the gastrointestinal tract seldom occurs, being found in only 0.5%-2% of cases<sup>[3,4]</sup> and 4%-6% in another series<sup>[1,2]</sup>. Usually colon metastasis is very rare, especially the left sided colon, and mostly occurs through direct invasion.

## CASE PRESENTATION

### Chief complaints

A 70 years-old man presented to our surgical department complaining of gastrointestinal bleeding.

### History of present illness

The patient was hepatitis B carrier with HCC treated four times with trans-arterial chemoembolization (TACE). He presented to the Emergency room after several hours of active gastrointestinal bleeding.

### Physical examination

At admission vital signs were stable. Patient's temperature was 36.6 °C and Glasgow Coma Scale (GCS) 15/15. The abdomen was soft, non-tender, and non-distended. No mass could be appreciated. Blumberg sign was negative. The rectal examination showed the presence of blood.

### Laboratory examinations

The laboratory findings showed normal haemoglobin level, a slight elevation of transaminase [alanine aminotransferase 56 IU/L, aspartate aminotransferase 62 IU/L], and all other values including coagulation, white blood cell, protein, albumin and bilirubin were within normal limits. The alpha-fetoprotein level was 3 ng/mL (range 5-10 ng/mL).

### Imaging examination

The computed tomography (CT) showed a mass originated from the sigmoid colon of 3.5 cm (Figure 1), and the presence of HCC in segment VI and VII, without portal vein thrombosis; at ultrasound the neoplasm seemed characterized by a dense vascular pattern.

### Further diagnostic work-up

A colonoscopy revealed a mass of 4 centimeters of the sigmoid colon with signs of bleeding (Figure 2).

Figure 1 Computed tomography scan shows a mass of 3.5 cm.

## TREATMENT

Because of the large size of the mass and the fact that it was bleeding, it was decided to subject the patient to a left colectomy. At laparotomy the lesion was situated in the distal sigmoid. No direct contact between the neoplasm and the liver was noticeable. Moreover, the sigmoid was normally placed and no dolichocolon sigmoid was reported.

## OUTCOME AND FOLLOW-UP

The postoperative period was uneventful, and the patient was discharged in fifth day post operative day. Histological examination revealed that the neoplasm was characterized by a diffuse proliferation of epithelial cells with an hepatoid differentiation (Figure 3A). In fact, the immunohistochemical reaction for HepPar-1 confirmed this type of differentiation (Figure 3B). The differential diagnosis was between a metastasis of HCC from the liver and an hepatoid adenocarcinoma of the colon, but the complete negativity for CK20 and CDX2 (Figure 3C and D) excluded a primary tumor of the colon<sup>[5]</sup>. So, the presence of an history of HCC of the liver and the histopathological features supported the diagnosis of metastasis from the liver.

## DISCUSSION

HCC is one of the most common malignancies worldwide, and its incidence has been increasing in recent years. The prognosis has improved due to the advances in diagnostic imaging and new treatment modalities, but the management of recurrence is a critical problem<sup>[6]</sup>.

Intrahepatic recurrences can be controlled by different treatment modalities, based on the different clinical conditions of the patients, such as hepatectomy, TACE and percutaneous ethanol injection therapy<sup>[7]</sup>. Because the incidence of extrahepatic metastases is less than that of intrahepatic metastasis, there are fewer documented treatment strategies for extrahepatic metastasis. At present, the prognosis of patients with extrahepatic metastases from HCC is poor<sup>[8]</sup>. The most frequent sites of extrahepatic metastases are bone, lung, adrenal gland and lymph nodes. Gastrointestinal involvement of HCC is uncommon. The most common modality of metastasis to the gastrointestinal tract is usually the direct invasion *via* adhesion to the serosal side by bulky tumor mass. The most frequently involved site is the duodenum, stomach, hepatic flexure of the colon and jejunum<sup>[3]</sup>. HCC may disseminate hematogenously to distant gastrointestinal tracts. Portal vein thrombosis may be the key point of hematogenous spread to other sites<sup>[4-9]</sup>. In our case, the HCC was localized to segment VI and VII, without portal vein thrombosis and metastasized to the left-sided colon five years after TACE.

Some authors<sup>[4]</sup> postulated that TACE may predispose to HCC metastasis by altering local vasculature and increasing inflammation.

Hematogenous spread was suggested because the metastatic site was distant and the lymph-nodes negative, Natsuizaka *et al*<sup>[8]</sup> reported, based on the initial diagnosis of intrahepatic HCC, that patients with advanced HCC develop extrahepatic metastases significantly more frequently than those with less advanced HCC.

**Figure 2** Colonoscopy image: Colonoscopy shows a bleeding mass of the left colon.

There is no standard treatment for extrahepatic metastases of primary HCC, several authors have reported the use of various treatment modalities. However only few HCC patients can undergo surgical resection of extrahepatic metastases because of hepatic reserve or intrahepatic stage. There are reports that suggest that aggressive treatment prolonged survival. Lam *et al*<sup>[10]</sup> reported that they performed surgical resection in nine patients with pulmonary metastases and that the median survival period of the patients was 42 mo.

In literature there are little datas<sup>[11]</sup> regarding the efficacy of surgical treatment in patients with colon metastasis from HCC, our case was treated with surgical management because of the size of the colonic mass and the risk of occlusion.

According to the literature, the interval between the diagnosis of HCC and detection of gastrointestinal tract involvement ranged from 3 mo to 8 years<sup>[3,4]</sup>. Mostly, gastrointestinal metastasis is found in patients with advanced staged HCC. The prognosis is unfortunately poor with a median survival period of 7 mo<sup>[8]</sup>.

However, it was suggested that treatment of extrahepatic metastases may improve survival in some selected patients who have good reserved function, intrahepatic tumor stage (T0-T2), and negative portal vein invasion or occlusion.

## CONCLUSION

Even if rare, HCC metastasis must be taken in consideration in those patients with colon carcinoma with medical history positive for hepatocellular cancer or HCV/HBV infection. Even if the prognosis of these patients is usually poor, a hemicolectomy can be a life-saving maneuver and could improve overall survival in some selected cases.

**Figure 3** Histology images: Carcinoma with hepatic differentiation. A: (Hematoxylin-eosin 100 ×); B: Confirmed by the positivity for HepPar-1 (200 ×); C: Negativity for CK20 (200 ×); D: CDX2 (200 ×) excluded the colic origin and it supported the diagnosis of metastasis from the liver.

### Abstract

#### BACKGROUND

Anaplastic large cell lymphoma (ALCL) is a type of T-cell lymphoma that can be divided into two categories: anaplastic lymphoma kinase-positive (ALK+) and ALK-negative. Gastrointestinal ALK+ ALCL is rare. Multiple lymphomatous polyposis (MLP) is thought to be a representative form of gastrointestinal lesion in mantle cell lymphoma, and T-cell lymphomas seldom show this feature. Here, we report the first known case of ALK+ ALCL with gastroduodenal involvement to present with MLP.

#### CASE SUMMARY

The patient was a 43-year-old man who was complained of a mass in the left inguinal area and was performed open biopsy. ALK+ ALCL was diagnosed pathologically. Computed tomography scan demonstrated multiple lymph node lesions in the abdomen - pelvis/inguinal region, and scattered nodular lesions in both lung fields. He did not complain of gastrointestinal symptoms. While, esophagogastroduodenoscopy identified MLP lesions from the antrum of the stomach to the descending portion of the duodenum and mild thickened folds on the corpus of the stomach, and biopsy showed invasion of ALK+ ALCL. We treated this patient with six cycles of CHOEP (Cyclophosphamide, Doxorubicin, Vincristine, Etoposide, and Prednisone) chemotherapy. At the conclusion of treatment, there was complete remission. Numerous white scars were found on the stomach, endoscopically consistent with a remission image of lymphoma. The endoscopic features of this case were thought to be similar to those of MCL.

## CONCLUSION

The macroscopic/endoscopic features of gastrointestinal ALK+ ALCL may be more similar to those of B-cell lymphomas rather than T-cell lymphomas.

**Key words:** Anaplastic large-cell lymphoma; Anaplastic lymphoma kinase; Multiple lymphomatous polyposis; T-cell lymphoma; Gastrointestinal involvement

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Anaplastic large cell lymphoma (ALCL) encompasses two distinct categories: anaplastic lymphoma kinase-positive (ALK+) and ALK-negative. ALK+ ALCL cases rarely involve the gut. However, in a very small number of case reports, gastrointestinal ALK+ ALCL exhibits a fungating growth pattern, similar to that of B-cell lymphomas rather than T-cell lymphomas. Multiple lymphomatous polyposis (MLP) is thought to be a typical form of gastrointestinal lesion in mantle cell lymphoma, but it develops in other B-cell lymphomas. T-cell lymphomas seldom present with MLP. Here, we report the first known case in the world of ALK+ ALCL with gastroduodenal involvement presenting with MLP.

## INTRODUCTION

Anaplastic large cell lymphoma (ALCL) was first described in 1985 by Stein *et al*<sup>[1]</sup>. According to the 4<sup>th</sup> edition (2008) of the WHO classification<sup>[2]</sup>, primary systemic ALCL can be divided into two distinct categories: anaplastic lymphoma kinase-positive (ALK+) and ALK-negative. Majority of ALK+ ALCL contain a t(2;5) chromosomal translocation. The t(2;5) translocation fuses a distal part of the *ALK* gene on chromosome 2p23 with the promoter and a proximal domain of the nucleophosmin (*NPM1*) gene on chromosome 5q35<sup>[3]</sup>. The most common extranodal sites of ALK+ ALCL are the skin, bone and soft tissue. ALK+ ALCL cases involving the gut are rare<sup>[2]</sup>.

Multiple lymphomatous polyposis (MLP) is thought to be a representative form of gastrointestinal lesion in mantle cell lymphoma (MCL)<sup>[2,4,5]</sup>. Here, we report an extremely rare case of ALK+ ALCL with gastroduodenal involvement presenting as MLP.

## CASE PRESENTATION

### Chief complaints

A 43-year-old Japanese man suffering from fever, night sweats, general fatigue and weight loss complained of a mass in the left inguinal area. The patient did not complain of gastrointestinal symptoms.

### History of present illness

The patient was admitted to a local hospital. Computed tomography (CT) scan demonstrated multiple lymph node lesions continuing to the mesentery and para-aortic/left common iliac artery/left inguinal region (Figure 1). Scattered nodular lesions were found in both lung fields (Figure 1). Following needle biopsy of the left inguinal lesion, malignant lymphoma was suspected, and the patient was transferred to our department.

### History of past illness

He had no chronic illness.

**Figure 1 Computed tomography images.** (Upper row) Pelvic computed tomography scan demonstrated multiple lymph node lesions (arrows) continuing to the left common iliac artery (left)/left inguinal region (right). (Lower row) Scattered nodular lesions were found in both lung fields (arrows).

### **Physical examination upon admission**

Left inguinal lymph nodes were significantly swollen.

### **Laboratory examinations**

WBC and CRP showed markedly high values, and elevated platelet count, liver dysfunction, and hypoalbuminemia were also observed. In addition, the level of soluble interleukin-2 receptor (normal range: 121-613 U/mL), which was severely elevated according to the measurement of the previous hospital, had further increased over approximately one week (7120 → 12500 U/mL) (Table 1).

### **Imaging examinations**

As measured by positron emission tomography (PET)/CT scan, the mean standardized uptake value was 18.1 in the abdomen – pelvis/inguinal nodes and 3.5 in the lung fields and the mediastinal nodes (Figure 2).

**Esophagogastroduodenoscopy findings:** In the descending portion of the duodenum, multiple polypoid lesions of 2-3 mm in diameter were observed (Figure 3A). Various large and small polypoid lesions were observed in the antrum of the stomach (Figure 3B and Figure 3C). These lesions are consistent with MLP continuously extending from the antrum of the stomach to the descending portion of the duodenum. Mucosal folds in the corpus of the stomach were slightly thickened, and its surface had changed to a white tone (Figure 3D).

The biopsies of both gastric and duodenal lesions proved the invasion of lymphoma cells, as below mentioned. These lesions could not be detected by PET/CT scan. Colonoscopy and bone marrow aspiration showed no involvement of lymphoma lesions.

### **Pathological examinations**

Left inguinal lymph nodes were examined by open biopsy. Medium to large-sized abnormal lymphoid cells were observed to be invasively proliferating. CD25, CD30, T-cell intracellular antigen-1, and ALK tested positive by immunostaining. Meanwhile, CD3, CD20 and the Epstein-Barr encoding region *in situ* hybridization tested negative. Based on the histopathology, ALK+ ALCL was diagnosed. In the gastric and duodenal biopsy samples, abnormal lymphoid cells with irregular nuclei grew diffusely (Figure 4A), and mitotic figures were observed in high numbers (Figure 4B). Immunohistochemically, CD30 tested strongly positive (Figure 4C), ALK

(monoclonal antibody, ALK1) tested positive in nuclear and cytoplasmic pattern (Figure 4D), and the Ki-67 proliferative (MIB1) index was > 80% (not shown).

## FINAL DIAGNOSIS

ALK+ ALCL that involved multiple lymph node lesions in the abdomen - pelvis/inguinal region and mediastinum, also both lung fields and the gastroduodenal lesions (Stage IV).

## TREATMENT

We treated this patient with six cycles of CHOEP chemotherapy (Cyclophosphamide 750 mg/m<sup>2</sup>, Doxorubicin 50 mg/m<sup>2</sup>, Vincristine 1.4 mg/m<sup>2</sup>, Etoposide 100 mg/m<sup>2</sup> × 3 d, and Prednisone 50 mg/m<sup>2</sup> × 5 d) every three weeks. After administration of two cycles, the lymphoma lesions including lung field nodules shrank remarkably and disappeared at CT examination.

## OUTCOME AND FOLLOW-UP

At the conclusion of treatment, there was complete remission. Numerous white scars were found in the stomach, endoscopically consistent with a remission image of lymphoma (Figure 3E). He is followed-up as outpatient with no treatment. There was no evidence of recurrence for more than 1 year and 10 mo since the end of the final treatment.

## DISCUSSION

ALCL is a clinically, morphologically, and immunophenotypically heterogeneous T-cell lymphoma. Depending on the presence or absence of ALK expression, ALK+ ALCL was classified as a biologically homogeneous disease unit independent of ALK-negative ALCL in the 4th edition (2008) of the WHO classification<sup>[2]</sup>. ALK+ ALCL is more prevalent in children and young adults, and the ALK fusion protein is associated with a good prognosis<sup>[6]</sup>. In contrast, ALK-negative ALCL has a poor prognosis similar to peripheral T-cell lymphoma, not otherwise specified, and angioimmunoblastic T-cell lymphoma<sup>[7]</sup>. ALK staining pattern is nuclear and cytoplasmic in cases of t(2;5)/NPM-ALK translocation, and membranous or diffuse/granular cytoplasmic in the remaining cases with a variant translocation involving at 2p23<sup>[2,8]</sup>. ALK staining in our patient showed a nuclear and cytoplasmic pattern. G-banded karyotype of the lymph node lesions showed complex chromosomal abnormalities with +2, der(2;21)(q10;q10),+7, however, translocation at 2p23 could not be confirmed. ALK+ ALCL frequently involves both lymph nodes and extranodal sites. The most commonly involved extranodal sites include the skin, bone, soft tissue, liver and lungs as we reported here<sup>[2]</sup>.

**Figure 2** Positron emission tomography/computed tomography (longitudinal) image. Arrows indicate lymphoma lesions. The mean of the standardized uptake value was 18.1 in the multiple lymph node lesions continuing to the mesentery and para-aortic/left common iliac artery/left inguinal, 3.5 in the lesions of the lung fields and the mediastinal nodes. No uptake in the stomach and duodenum.

Because gastrointestinal T-cell lymphomas are rare, little is known about the clinicopathological characteristics of primary gastrointestinal T-cell lymphomas. Kim *et al*<sup>[9]</sup> investigated the endoscopic differences between B- and T-cell lymphomas and observed that B-cell lymphomas presented more often as fungating (54% of cases), while T-cell lymphomas were frequently ulcerative (47%), and only 13% showing a fungating pattern. Regardless of ALK expression, primary gastrointestinal ALCL is rarer<sup>[10]</sup>. According to a recent review on gastrointestinal ALCL, the rate of ALK expression among gastrointestinal ALCL was low at 24%<sup>[11]</sup>. As far as we can determine, ALK+ ALCL of the gut has been reported in only eleven cases<sup>[11-20]</sup>. The clinical features are summarized in **Table 2** for a total of 12 gastrointestinal ALK+ ALCL cases, including our patient. Of these, four cases were reported to involve the esophagus<sup>[12-15]</sup>, all showing fungating tumors. Of the remaining cases, two involved the stomach<sup>[11,16]</sup>, one involved the duodenum<sup>[17]</sup>, one involved both the stomach and duodenum<sup>[18]</sup>, and three involved the small intestine (jejunum/ileum)<sup>[11,19,20]</sup>. Only three of these last seven cases showed macroscopic findings by resection or endoscopy; the morphology showed a mass formation pattern, such as a submucosal or bulky tumor. Although the number of cases is very small, gastrointestinal ALK+ ALCL often seems to involve the esophagus, in which lymphomas rarely develop, and frequently exhibits a fungating growth pattern similar to that of B-cell lymphomas.

The term “MLP” was introduced in 1961 by Cornes to describe malignant lymphoma that presented as multiple polypoid tumors, from 2 mm to several centimeters, affecting long segments of the gastrointestinal tract<sup>[21]</sup>. Histopathologically, these polyps originate from the mantle zone of the lymphoid follicle of the mucosa-associated lymphoid tissue (MALT)<sup>[22]</sup>. Therefore, the most frequent lymphoma presenting with MLP is MCL<sup>[4,5]</sup>, and it also develops in other B-cell lymphomas, such as MALT lymphoma and follicular lymphoma<sup>[23]</sup>. Furthermore, T-cell lymphomas seldom show this feature (11%)<sup>[24]</sup>. Several cases of adult T-cell leukemia/lymphoma presenting with MLP have been reported in Japan, which is an endemic area of human T-cell lymphotropic virus type 1 infection<sup>[25,26]</sup>. To the best of our knowledge, including ALK-negative, our case is the first observation of ALCL presenting with MLP. However, in contrast to what has been seen in MCL, the MLP presented in this case with, irregular sized-polyps arranged irregularly. In addition, no MLP lesion was found in the large intestine, which is frequently involved in MCL<sup>[27]</sup>. In our case, MLP lesions could not be detected with PET/CT scans. As we previously reported in a case of MCL<sup>[28]</sup>, it appears that MLP lesions do not infiltrate the deep layer and instead maintain involvement with the surface layer of the gastrointestinal mucosa, even in the case of ALCL. The characteristic endoscopic findings of MCL are not only MLP, but also thickening of gastric mucosal folds has been reported<sup>[5]</sup>. In our case, thickened folds of the stomach were also seen, and the endoscopic features were thought to be similar to those of MCL.

**Figure 3 Esophagogastroduodenoscopy findings.** Multiple polypoid lesions of 2-3 mm in diameter were seen in the descending portion of the duodenum (A). Various large and small polypoid lesions were seen in the antrum of the stomach (B; lesser curvature side, C; extensive curvature side), accompanied by a change in white tone at the center. Mucosal folds in the corpus of the stomach at the extensive curvature side were slightly thickened, and its surface had changed to a white tone (D). After treatment, numerous white scars were found, and the thickened mucosal folds were improved in the stomach (E).

## CONCLUSION

We reported a case of gastroduodenal ALK+ ALCL presenting with MLP. Although there is a limit in considering the macroscopic/endoscopic features of gastrointestinal ALK+ ALCL patients through this very rare case, the morphological features of gastrointestinal ALK+ ALCL may be similar to those of B-cell lymphomas rather than T-cell lymphomas. It is necessary to further accumulate and study the gastrointestinal ALK+ ALCL patients.

**Table 2** Clinical features of gastrointestinal anaplastic lymphoma kinase-positive anaplastic large cell lymphoma

Case	Age / sex	Ref.	Occurrence site	Gross/ Endoscopic findings	ALK staining pattern	2p23(FISH/RT-PCR)	Treatment	Outcome
1	56/M	[12]	Esophagus	Large mass	Cytoplasmic		chemo. + auto-SCT	Alive (3 mo)
2	34/F	[13]	Esophagus	Fungating tumor	Nuclear and cytoplasmic		chemo. + auto-SCT	Alive (24 mo)
3	37/M	[14]	Esophagus	Submucosal mass	Nuclear and cytoplasmic		resection + chemo.	Alive (14 mo)
4	3/M	[15]	Esophagus	Wall thickening	Nuclear and cytoplasmic		chemo.	(undescribed)
5	53/M	[11]	Stomach	(Undescribed)	Cytoplasmic		resection + chemo.	Alive (84 mo)
6	72/F	[16]	Stomach	(Undescribed)	(Undescribed)	+ (FISH)	resection	Alive (84 mo)
7	36/M	[17]	Duodenum	(Undescribed)	Nuclear and cytoplasmic	+ (RT-PCR)	resection + chemo.	Alive (24 mo)
8	21/M	[18]	Stomach and Duodenum	Submucosal tumor	Nuclear and cytoplasmic		chemo.	(undescribed)
9	10/M	[11]	Small intestine	(Undescribed)	Nuclear and cytoplasmic		resection + chemo.	Alive (75 mo)
10	17/M	[19]	Jejunum	Polypoidal mass	Cytoplasmic		resection + chemo.	Alive (18 mo)
11	32/M	[20]	Jejunum/Ileum (junction)	Massive tumor	Nuclear and cytoplasmic		resection + chemo.	Alive (5 mo)
12	43/M	Our case	Stomach and Duodenum	MLP and gastric mucosal thickening	Nuclear and cytoplasmic		chemo.	Alive (22 mo)

ALK: Anaplastic lymphoma kinase; FISH: Fluorescence *in situ* hybridization; RT-PCR: Reverse transcription polymerase chain reaction; chemo.: Chemotherapy; auto-SCT: Autologous stem cell transplantation.

**Figure 4** Histopathological findings in biopsy samples (x 200), Medium to large-sized abnormal lymphoid cells with irregular nuclei grew diffusely (A), and mitotic figures were observed in high numbers (B). In immunostaining of lymphoma cells, CD30 was strongly positive (C), and ALK showed positive in nuclear and cytoplasmic patterns (D).

## Abstract

### BACKGROUND

Solitary rectal ulcer syndrome (SRUS) is a rare rectal disorder characterized by bloody mucus in the stool, difficulty in defecation, pain, and anal swelling. To date, the etiology of this syndrome remains not well understood and the diagnosis is frequently confused with other disorders, making treatment a clinical challenge.

### CASE SUMMARY

A 50-year-old woman presented to our hospital with a 40-d history of bloody mucus in the stool and anal swelling. SRUS was suspected. Rectoscopy revealed a large, severe ulcerous lesion. Histologically, the lesion was characterized as chronic ulcer without clear tumor cells, and the final diagnosis of SRUS was made. The patient was treated with Chinese medicine therapy, with administration of Tong Xie Yao Fang. After 3 wk of treatment, the symptoms improved significantly. At 2-mo follow-up, rectoscopy in a local hospital showed healed ulcer scars without obvious protrusion 3 cm from the anal verge.

### CONCLUSION

Chinese medicine therapy represents a potential treatment of SRUS with predominant rectal bleeding, mucinous discharge, and anal swelling pain.

**Core tip:** Solitary rectal ulcer syndrome (SRUS) is a benign but uncommon rectal disorder. We present the case of a 50-year-old woman who suffered from SRUS for 40 d, with the symptoms of bloody mucous in the stools and anal swelling. Following our success of treatment with modified Tong Xie Yao Fang, we discuss how this traditional Chinese medicine prescription might be an effective treatment strategy for SRUS with this symptom profile.

## INTRODUCTION

Solitary rectal ulcer syndrome (SRUS) is a chronic, benign, uncommon and under-diagnosed disease. It is estimated that the annual incidence of SRUS is one of 100000 people, mainly affecting men in the third decade of life and women in the fourth decade<sup>[1]</sup>. Its symptomological profile consists of intestinal symptoms, primarily constipation, feeling of incomplete defecation, bloody or purulent stools, discomfort with falling anus, and rectal ulcers.

The diagnosis of SRUS is largely based on findings in rectoscopy and analysis of tissue biopsy. The treatment of SRUS includes local medication, improvement of bowel defecation habits, biofeedback, and surgical operation<sup>[2]</sup>. We report herein the case of a 50-year-old woman with SRUS and describe its appearance on rectoscopy and in analysis of the gross specimen following Chinese medicine therapy. The purpose of publishing this case is to report and discuss the effects of herbal therapy on SRUS.

## CASE PRESENTATION

### Chief complaints

A 50-year-old woman presented to our hospital with a 2-year history of intermittent dull pain in her left lower abdomen, a 40-d history of rectal swelling and discomfort, and a 20-d history of mucinous and bloody, loose stools.

### History of present illness

The patient was sent to our Chinese medicine hospital on September 5, 2018. She reported having had developed intermittent left lower abdominal dull pain 2 years prior, after suffering from cold and eating irritating food. She reported no obvious cause of the rectal swelling discomfort that had developed 2 mo previously nor of the mucinous bloody, loose stools (occurring three or four times a day) 40 d prior. She also reported insomnia, and we observed her tongue to be red in color with white and thick fur, and a thin pulse.

### History of past illness and family history

The patient had undergone hemorrhoid surgery in 2009 and polypectomy of the cervical canal in 2011. Her father had died of a femoral fracture in the neck; otherwise, there was no medical family history.

### Physical examination upon admission

Physical examination showed no obvious abnormality, except for a tough ulcerative mass, about 2 cm × 2 cm on the wall of the rectum at 3 cm from the anal verge. The remaining rectal mucosa showed smooth surface. Blood stains were detected on the doctor's disposable glove after examination of the patient.

### Laboratory examinations

Laboratory examinations provided the following findings: Gram-positive bacilli of 40.0% (normal range: 50%-71%); Gram-negative bacilli of 45.0% (normal range: 24%-44%); antigen-stimulated interferon A of 15.0 SFCs/2.5 × 10<sup>6</sup> (normal: < 6 SFCs/2.5 ×

$10^6$ ); specific gravity of urine of 1.008 (normal range: 1.015-1.025); total cholesterol of 5.2 mmol/L (normal: < 5.18 mmol/L); and complement C1q of 149.0 mg/L (normal range: 159-233 mg/L). The white blood cell count ( $5.99 \times 10^9$ /L) and platelet count ( $4.03 \times 10^{12}$ /L) were normal. Findings for stool samples' cultures, fecal occult blood, parasite eggs, and amoeba trophozoites were negative.

### Imaging examinations

Colonoscopy revealed an irregular nodule, occupying 1/2 of the lumen, at 5 cm from the anal verge. The central ulcer was sunken, with blood stasis spotting and sloughing on the surface, as well as being brittle and bleeding easily (Figure 1A). Rectoscopy showed a large ulcerative lesion at 2-4 cm from the anal margin of the rectum, occupying 3/5 of the lumen, covered by a white and bloody sloughing of tissue with central ulcer depression, as well as being brittle and prone to bleeding (Figure 1B). The pathological report noted chronic colonic mucositis, rectal mucosal erosion, and inflammatory granulation (Figure 1C).

## FINAL DIAGNOSIS

The patient was diagnosed with SRUS, based on the findings from endoscopy of the rectum and colon (Figure 1A, B) and histology of the biopsy (Figure 1C). Her condition was deemed to be serious. Diagnosis of Traditional Chinese Medicine (TCM) was diarrhea (liver stagnation and spleen deficiency), according to the patient's main clinical symptoms.

## TREATMENT

Treatment of modified Tong Xie Yao Fang (TXYF) was administered to soothe the qi, fortify the spleen, quiet the heart, astringe the intestines, regulate the diarrhea, and relieve the pain. The prescription was composed of Chenpi (tangerine peel; 15 g), Baishao (Radix Paeoniae Alba; 20 g), Fangfeng (Radix Saposhnikovia; 20 g), Gaoben (Ligusticum; 10 g), Baizhu [Rhizoma Atractylodis Macrocephalae (AM); 15 g], Roudoukou (Myristica fragrans; 10 g), Buguzhi (Psoralea corylifolia; 10 g), Paojiang (prepared ginger; 10 g), Pugongying (Mongolian dandelion; 20 g), Dangshen (Radix Codonopsis; 15 g), Yuanzhi (Polygala tenuifolia; 12 g), Shichangpu (Acorus Tatarinowii; 10 g), and Gancao (licorice; 10 g). The daily dose was decocted with water and taken at 30 min after food intake in the morning and evening. After 7 d, on September 12, 2018, the patient's symptoms were alleviated but the patient woke early in the morning, with the continued red tongue with white and thick fur, and thin, wiry pulse. Suanzaoren (spine date seed; 20 g), Hehuanpi (Silktree Albizia bark; 10 g), and Fuling (Poria Cocos; 15 g) were added into the original prescription. The decoction and delivery method was the same as the initial ones. TCM treatment had been insisted on by the patient, who only wanted Chinese herbal medicine and no Western medicine treatment for 21 d.

## OUTCOME AND FOLLOW-UP

On September 30, 2018, the patient was examined in the Third Affiliated Hospital of Beijing University. Rectoscopy showed an irregular shaped ulcer, 3 cm from the anal verge, about 1.0 cm  $\times$  1.2 cm in size, less white fur on the surface, flat bottom, concentrated folds around the rectum, and fusion, thickening and interruption near the ulcer; the biopsy specimen was tough, with no stenosis (Figure 2A). The pathological report noted chronic rectal ulcer mucosal inflammation, with focal lymphocyte aggregation (Figure 2B). The results suggested that the ulcer surface tended to be scarred, having improved and healed without prescribed Western medicine. The improvement of rectal symptoms in this patient should be attributed to the role of the 21 herbs administered.

During hospitalization, the patient underwent a series of examinations. Although the cause of SRUS was not found, the ulcer improved gradually with treatment. After discharge, the woman adhered to TCM treatment and also used Titanoreine, a kind of anal suppository that covers the surface of the anal and rectal mucosa with a protective membrane. On December 8, 2018, re-examination by rectoscopy in a local hospital showed that the ulcer scars had healed, without obvious protrusion, at 3 cm from the anal verge. A polyp, about 0.3 cm  $\times$  0.3 cm, was found at 3 cm from the anal verge. The surface of the mucosa was found to be smooth (Figure 2C).

**Figure 1** Endoscopic images and corresponding histological findings from before the Traditional Chinese Medicine treatment. A: Colonoscopy image showing actively bleeding, deep ulcerations; B: Rectoscopy image showing a large ulcerative lesion covered by a white and bloody sloughing tissue; C: Hematoxylin-eosin-stained rectal ulcers.

## DISCUSSION

The pathogenesis of SRUS is not clear, and it is often believed that SRUS might be associated with rectal prolapse and trauma from straining<sup>[3,4]</sup>. Clinically, SRUS is easy to be suspected as colorectal cancer, based on the similar symptomatic profiles and endoscopic features, which include bleeding or mucus at defecation, anal or rectal pain and discomfort, increased frequency of defecation, and colorectal masses or ulcers<sup>[1,5]</sup>. Histological features are helpful to distinguish SRUS from malignancy. The key histological features that distinguish SRUS from colorectal cancer are the architectural distortion, fibromuscular obliteration of lamina propria, and absence of tumor cell infiltration<sup>[6]</sup>.

The therapeutic regimens for SRUS include conservative treatment, medical therapy, biofeedback therapy, and surgery<sup>[2]</sup>. The choice of treatment depends upon the severity of symptoms and the presence of rectal prolapse. In our case, TCM may have played a role in the successful treatment of SRUS and highlights the potential of such as a supplementary and alternative therapy. Some studies have suggested that fruits, vegetables and grains have protective effects against adenoma and colorectal cancer. Probiotics may also have preventive effects on colorectal cancer but the actual beneficial effects remain to be definitively evidenced<sup>[7,8]</sup>. Conservative treatment (high-fiber diet, laxatives, change in defecatory habits, and biofeedback treatment) were shown to induce a symptomatic improvement in 71/91 patients (63.6%) and healing of mucosal lesion in 17/51 patients (33.3%)<sup>[9]</sup>. According to those reports, SRUS may be prevented and improved by adjusting dietary structures and probiotic levels.

The basic TCM prescription combination consists of three classic Chinese formulas, (TXYF, consisting of tangerine peel, Radix Paeoniae Alba, Radix Saposhnikovia, and Rhizoma AM), Er Shen Wan (ESW, consisting of Myristica fragrans and Psoralea corylifolia) and Ding Zhi Xiao Wan (DZXW, consisting of Codonopsis, Polygala tenuifolia Willd, Acorus Tatarinowii, and Poria Cocos). In addition, Gancao (licorice) is used to mediate other herbs. Suanzaoren (spine date seed) and Hehuanpi (Silktree Albizia bark) can be added when the patient suffers from insomnia.

TXYF is recorded in the Dan Xi Xin Fa. From the viewpoint of TCM, it is used to relieve the pain and diarrhea caused by the incompatibility of the liver and spleen. ESW is recorded in the Pu Ji Ben Shi Fang. Differently, it is used for diarrhea due to deficiency of the spleen. At the patient's first hospital visit, she mainly complained of

**Figure 2** Endoscopic imaging and corresponding histological findings after Traditional Chinese Medicine treatment. A: The improvement of ulcers; B: Hematoxylin-eosin-stained rectal ulcers ( $\times 40$ ); C: The healed ulcers.

pain in her left abdomen, diarrhea, mucinous defecation, and abnormal defecation. Based on TCM theory, her clinical symptoms were categorized as diarrhea. The patient had mild anxiety, depression and insomnia during her illness. DZXW can maintain the ability of learning and memory in depression, and the mechanism involves the promotion of neural stem cell proliferation in hippocampal formation<sup>[10]</sup>.

TXYF is a commonly used Chinese herbal prescription for diarrhea, suggested to be effective in treating diarrhea-predominant irritable bowel syndrome (IBS-D)<sup>[11]</sup>. 5-hydroxytryptamine (5-HT) is a neurotransmitter that is widely distributed throughout the central nervous system and gastrointestinal tract, which may contribute to the symptoms of IBS. Li *et al*<sup>[12]</sup> demonstrated that TXYF treatment diminishes colonic 5-HT levels and alleviates the symptoms of IBS-D by favorably affecting microbiota levels in gut flora communities. Data from a study by Yin *et al*<sup>[13]</sup> suggested that the activity of the enteric nervous system and the regulation of 5-HT and substance P activities can be modulated by TXYF. Corticotropin-releasing hormone-receptor 2 (known as CRH-R2) is known to activate the intestinal mucosal anti-inflammatory response by regulating migration, proliferation and apoptosis of intestinal epithelial cells, as has been shown in colitis-induced mice<sup>[14]</sup>, and to play an important anti-inflammatory role. Gong *et al*<sup>[14]</sup> demonstrated that TXYF can facilitate mucosal repair in colitis mice by regulating the CRH-R2. TXYF was also shown to improve the symptoms of postinfectious IBS by alleviating behavioral hyperalgesia and exerting antidiarrheal effects, the underlying mechanism of which involves TXYF inhibition of mucosal mast cells' activation, down-regulation of tryptase and c-Fos expression, and reduction of serum TNF- $\alpha$  and histamine levels<sup>[15]</sup>. Therefore, it is suspected that TXYF may relieve the symptoms of SRUS by decreasing the defecation frequency and promoting mucosal repair.

AM is the most important herb in TXYF. Studies by Song *et al*<sup>[16]</sup> reveal that treatment with AM significantly stimulates the migration of intestinal epithelial cells (commonly known as IECs) through the polyamine-Kv1 channel signaling pathway, which can promote healing of intestinal injury. Findings from another study suggested that AM significantly stimulates the migration of IEC-6 cells through a polyamine-dependent mechanism, which could accelerate the healing of intestinal injury<sup>[17]</sup>. These results provide evidence for the effect of AM in treating intestinal diseases that are characterized by injury and ineffective repair of the intestinal mucosa in clinical practice.

ESW, composed of *Myristica fragrans* and *Psoralea corylifolia*, is a classical Chinese formula for astringing intestines and resolving diarrhea. The *Myristica fragrans* seed

extract has shown protective effects against dextran sulfate sodium-induced colitis in an animal model by inhibiting proinflammatory cytokines in the colon mucosa. This indicates the potential usefulness of *Myristica fragrans* to address intestinal inflammation in a preventive application<sup>[18]</sup>. *Psoralea corylifolia* is a well-known traditional herb used because of its antibacterial activity. Corylifolinin and neobavaisoflavone are two isolated compounds of *Psoralea corylifolia*. Both of them have significant antibacterial activity against *Staphylococcus aureus*, methicillin-resistant *Staphylococcus aureus*, and  $\beta$ -lactamase-positive *Staphylococcus aureus*. Corylifolinin has been shown to produce the largest inhibitory zone (18 mm) with *Staphylococcus aureus*, being higher than even that of the positive control<sup>[19]</sup>.

Dandelion polysaccharide has a good effect on clearing heat, resolving toxin presence, dissipating binding, and dispersing swelling. It plays an important role in the treatment of ulcerative colitis by decreasing the level of interleukin (IL)-6, which increases chronic intestinal inflammation<sup>[20,21]</sup>. Dandelion polysaccharide has also been shown to effectively regulate the expression of the IL-6 receptors (particularly the  $\alpha$  form) and the glycoprotein 130 (commonly known as gp130) protein in the IL-6/transcriptional activator 3 (commonly known as STAT3) pathway, and then down-regulating the expressions of STAT3 and IL-6 mRNAs in intestinal tissue (of rats), thereby alleviating the colon inflammation state and protecting and repairing the mucosal tissue<sup>[21]</sup>.

Many neurotransmitters, including dopamine, glutamate, norepinephrine, nitric oxide, and 5-HT and its 5-HT<sub>3</sub> and 5-HT<sub>4</sub> receptors are expressed in the brain and intestine. Disorder of the bidirectional communication between the intestinal tract and intestinal nervous system and brain (brain-intestinal axis) is regulated by various psychosocial and environmental factors (*i.e.*, infection and inflammation)<sup>[22]</sup>. Therefore, the addition of spirit-regulating herbs may be useful for the recovery of gastrointestinal function.

Clinical application of TCM, DZXW, spine date seed and Silk tree Albizia bark has remarkable effect on quieting the spirit and resolving depression. DZXW has been shown to effectively ameliorate learning-memory impairment in aging rats, improving their learning-memory capacity, and its mechanism may be related to a promotion of the function of the cerebral monoamine nervous system in brain tissue and a reduction in the level of lipid peroxidation in brain tissue<sup>[23]</sup>. Finally, the aqueous extract of *Albizia adianthifolia* leaves shows anxiolytic and antidepressant effects, and may confer neuroprotection due to alleviation of oxidative stress in the (rat) amygdala induced by 6-hydroxydopamine injection<sup>[24]</sup>.

## CONCLUSION

The case described herein demonstrates that Chinese formulas, specifically modified TXYF, can be effective in relieving the symptoms of SRUS. This finding provides new insight into the treatment of SRUS and a basis for further studies to determine the underlying mechanism.

### Abstract

#### BACKGROUND

We present the case of a 72-year-old female patient with gallbladder cancer (GBC) who developed *in situ* recurrence and liver metastases 9 mo after irreversible electroporation ablation and oral tegafur (a fluoropyrimidine derivative) chemotherapy, which failed to control the progression of the disease. The patient further developed metastases in the lymph nodes around the head of the pancreas. The patient had severe anemia, requiring weekly blood transfusions. The gallbladder tumor invaded the descending part of the duodenum, causing intestinal leakage and hepatic colonic adhesion.

#### CASE SUMMARY

The patient refused other treatments and began daily hydrogen inhalation therapy. After 1 mo of treatment, the gallbladder and liver tumors continued to progress, and intestinal obstruction occurred. After continuous hydrogen therapy and symptomatic treatments including gastrointestinal decompression and intravenous nutrition support, the intestinal obstruction was gradually relieved. Three months after hydrogen therapy, the metastases in the abdominal cavity gradually reduced in size, her anemia and hypoalbuminemia were corrected, lymphocyte and tumor marker levels returned to normal, and the patient was able to resume normal life.

#### CONCLUSION

This is the first report of an efficacy and safety study about hydrogen therapy in patient with metastatic GBC and a critical general condition, who has remained stable for more than 4 months.

## INTRODUCTION

Gallbladder cancer (GBC) is the sixth most common gastrointestinal cancer and the sixth highest cause of cancer-related deaths in China<sup>[1]</sup>. Despite improvements in the diagnosis and treatment of GBC, the majority of the patients are usually confirmed as having metastatic GBC (mGBC)<sup>[2,3]</sup>. Due to the high incidence of lymph node or distant metastasis, the 5-year overall survival (OS) rate for GBC is only 5%<sup>[3,4]</sup>. In mGBC patients who are not candidates for surgery, the National Comprehensive Cancer Network (NCCN) guidelines recommend the use of biliary drainage, chemotherapy, clinical trials, and the best supportive care available. At present, there are few alternative options, and new and more effective methods are urgently required.

In patients with cancer, the treatment strategy, outcome, and prognosis are strongly dependent on immune status. CD8<sup>+</sup> T cells become exhausted by persistent stimulation by tumor antigens, resulting in cessation of proliferation, cytokine production, and immune function<sup>[5,6]</sup>. The preventive and therapeutic effects of hydrogen in various diseases, including cancer, have been investigated in several studies<sup>[7-9]</sup>. Hydrogen was recently reported to stimulate peroxisome proliferator-activated receptor  $\gamma$  coactivator 1 $\alpha$ <sup>[10]</sup>, which enhances mitochondrial function<sup>[11]</sup> and thus, may rescue exhausted CD8<sup>+</sup> T cells. In an advanced study of the effects of inhaled hydrogen gas in 55 patients with stage IV colorectal cancer<sup>[12]</sup>, Akagi *et al.*<sup>[12]</sup> identified accumulation of terminal programmed cell death 1 (PD1)<sup>+</sup> CD8<sup>+</sup> T cells as a significant index for poor prognosis, with reduction in terminal PD1<sup>+</sup> CD8<sup>+</sup> T cells and accumulation of terminal PD1<sup>-</sup> CD8<sup>+</sup> T cells following hydrogen gas treatment found to be significantly associated with improved progression-free survival and OS.

Here, we present the case of a 72-year-old Chinese woman with stage IIIA GBC who was treated with irreversible electroporation (IRE) and oral tegafur (a fluoropyrimidine derivative) chemotherapy. Primary recurrence and liver metastases were identified 9 mo later. Obvious shrinkage of the patient's recurrent and metastatic lesions was observed with continuous application of a hydrogen oxygen nebulizer, and a clinically objective response lasting for more than 4 mo was achieved. The patient remained disease-free at the time of writing this report.

## CASE PRESENTATION

### Chief complaints

We present the case of a 72-year-old female GBC patient, who was admitted to our hospital due to chest tightness in September 2018.

### History of present illness

After examination, GBC was found to recur *in situ*, invading the duodenal descending part and causing intestinal fistula and hepatic colon adhesion. In addition, multiple metastases of the liver, lymph node metastasis around the head of the pancreas, severe anemia requiring weekly blood transfusion, and symptoms of heart failure were noted.

**History of past illness**

In December 2017, the 72-year old Chinese patient underwent IRE following diagnosis as GBC (T3N1M0 stage IIIA) based on computed tomography (CT) imaging and pathological findings of GBC (8.0 cm × 3.9 cm) with multiple hilar lymph node invasion (max 4.7 cm × 3.6 cm). She had elevated levels of a variety of serum tumor markers, including CA19-9 (2556 U/mL) and CEA (607.6 ng/mL).

**Personal and family history**

After IRE ablation of the gallbladder and hilar lymph nodes, oral tegafur (20 mg bid) chemotherapy was administered for 9 mo. CT re-examination in April 2018 showed liquefactive necrosis at the ablation site. During the treatment period, the patient received intermittent red blood cell (RBC) infusions as supportive care for repeated episodes of anemia.

**Physical examination upon admission**

Accompanied by a progressive increase in pain in the upper right abdomen, a large area of adhesion between the gallbladder and the descending and horizontal segments of the duodenum was found in addition to compression of the inferior vena cava (October 6, 2018).

**Laboratory examinations**

She had elevated levels of a variety of serum tumor markers, including CA19-9 (88.18 U/mL), AFP (14.11 IU/mL), and CEA (39.68 ng/mL) in September, 2018.

**Imaging examinations**

After 2 wk of blood transfusions and anti-infective treatment, CT examination again revealed a bladder tumor (6.3 cm × 4.9 cm), with an adjacent descending duodenal fistula, multiple spotted high-density lesions in the liver parenchyma, and dilatation and gas accumulation in the intrahepatic and extrahepatic bile ducts. Enlarged lymph nodes (2.7 cm × 2.1 cm) were visible around the pancreatic head.

---

**FINAL DIAGNOSIS**

---

Metastatic GBC, severe anemia, infection, and gallbladder-duodenal fistula.

---

**TREATMENT**

---

**Hydrogen gas treatment**

The hydrogen oxygen nebulizer (AMS-H-01, Asclepius Meditec, Shanghai, China) generates 3 L/min hydrogen gas by water electrolysis. As measured by gas chromatography, the gas generated consisted of 67% hydrogen and 33% oxygen. Using a special mask, the patient continued to inhale hydrogen for 3-6 h a day at rest, with no interruption even after the obvious relief of symptoms.

**Best supportive care**

Due to the long-term difficulty in reversing the anemia in the early stage of hydrogen inhalation therapy, the patient received weekly (1-2) blood infusions, and her RBC and hemoglobin levels were tested regularly. Daily anti-infection treatment was administered for the gallbladder-duodenal fistula, and white blood cell counts were measured regularly. After 1 mo of hydrogen aspiration therapy, the patient presented with intestinal obstruction, which was treated by gastrointestinal decompression and intravenous nutrition. Analgesics and sedatives were prescribed for pain and insomnia, respectively.

**Therapeutic procedure**

Due to the lack of currently available conventional treatments combined with the patient's poor condition requiring continuous supportive care, hydrogen gas monotherapy was started on October 24, 2018 (Table 1). At the time of writing this report, the patient still continues to receive daily hydrogen therapy.

**Adverse events**

According to the Common Terminology Criteria for Adverse Events version 3.0 (National Cancer Institute, Bethesda, MD, United States), adverse events were classified and graded every week for at least 2 mo after the treatment was started<sup>[13]</sup>. Liver function was evaluated based on the levels of alanine transaminase, aspartate

**Table 1 Clinical details and therapeutic procedure**

Date		Therapy
2017	December	(A) Symptoms of upper right quadrant distension pain and discomfort were aggravated; (B) Color doppler ultrasound: gallbladder tumor, local liver invasion, and multiple enlarged lymph nodes; (C) Gallbladder tumor aspiration biopsy: gallbladder cancer
2018	January 5	(A) Irreversible electroporation ablation of the gallbladder and hilar lymph nodes; (B) Started oral 5-FU (20 mg bid); (C) Infusion of red blood cells for anemia
	April	CT examination: gallbladder tumors and hilar lymph nodes showed liquefactive necrosis after treatment
	September 20–October 8	(A) Routine blood tests and tumor markers; (B) CT examination: gallbladder tumor invaded the descending duodenum; inferior vena cava was compressed; (C) Infusion of red blood cells for anemia
	October 24	(A) CT examination: gallbladder tumor enlarged, multiple spotted metastases found in the liver, and multiple lymph nodes around the pancreatic head; (B) Started hydrogen gas therapy
	November 26	(A) CT examination: gallbladder and intrahepatic tumors enlarged, duodenal bowel obstruction; (B) Gastrointestinal decompression and intravenous nutrition support
	December 10–24	(A) Routine blood tests and tumor markers; (B) Gastric tube removed, the patient gradually began taking semi-liquid food, and her spirit, appetite, and sleep were good
2019	January 8–11	(A) Routine blood tests and tumor markers; (B) CT examination: gallbladder and intrahepatic tumors, lymph nodes around the pancreatic head all shrank significantly, and obstruction was markedly relieved

CT: Computed tomography.

transaminase, total bilirubin, and gamma-glutamyl transpeptidase on multiple occasions during hydrogen treatment. Bone marrow hematopoietic function was evaluated based on peripheral blood erythrocyte counts and hemoglobin levels. Inflammation caused by infection was assessed based on white blood cell counts.

### Curative evaluation

The curative effects of the treatment were evaluated according to several aspects of the patient's general condition. Since patients cannot eat normally, serum total protein and albumin levels were monitored after intravenous nutrition. Due to visceral adhesion, intestinal fistula and obstruction, degrees of pain and relief in the upper abdomen were recorded continuously. Absolute lymphocyte counts and serum tumor markers were measured to reflect changes in immune function and tumor activity.

### CT imaging changes

Changes in CT tumor imaging were monitored to evaluate the curative effect of hydrogen gas therapy. According to the RECIST 1.1 guidelines<sup>[14]</sup>, therapeutic effects are categorized as a complete response (CR), characterized as disappearance of tumor detection in all target lesions; partial response (PR), total reduction in the diameter of the target lesions  $\geq 30\%$ ; stable disease (SD), tumor regression failing to reach PR or progressive disease (PD); or PD, defined as total progression of the tumor diameter  $\geq 20\%$ .

## OUTCOME AND FOLLOW-UP

Hydrogen gas inhalation was started on October 24, 2018. Within 1 mo of treatment, the patient's condition was relatively stable, and her blood indexes, infection status,

and degree of pain gradually improved. Subsequently, intestinal obstruction occurred at the adhesion site between the gallbladder and duodenum; this was relieved after 1 mo of gastrointestinal decompression and intravenous nutrition. The patient insisted on regular hydrogen therapy throughout the course of this treatment.

### Adverse events

The most common adverse reactions recorded included drowsiness or agitation, and no other adverse events were observed. The patient's transaminase levels remained normal throughout the treatment. Occasionally her bilirubin levels exceeded the reference range, but returned to normal after short-term use of hepatoprotective drugs. Despite regular blood transfusions, there was little change in the patient's red blood cell counts and hemoglobin levels during the two weeks before hydrogen treatment was initiated. Both indexes continued to increase after hydrogen therapy and blood transfusions, and both reached the lower limit of the reference range after 2.5 mo of treatment (Figure 1A). The frequency of transfusions was decreased gradually after hydrogen therapy and stopped completely after 2 mo of treatment.

Within 1 mo prior to treatment, the patient had a high inflammatory response to infection and a high white blood cell count ( $22.1 \times 10^9/L$ ). After anti-infection treatment, the white blood cell count was restored to the upper limit of the reference range ( $9.8 \times 10^9/L$ ), with no further reduction. After 1.5 mo of hydrogen treatment (with no further anti-infection treatment), the leukocyte count decreased to  $4.7 \times 10^9/L$  (Figure 1C left).

### Curative evaluation

Serum total protein levels returned to normal shortly after the start of hydrogen therapy and continued to rise. Because of the intestinal obstruction, the patient received intravenous nutrition for 1-2 mo after treatment. Within 2 wk of the removal of the gastric tube, the patient returned to a normal diet and the total protein remained at the upper limit of the reference range. Serum albumin levels returned to normal after 2 mo of hydrogen therapy and continued to rise (Figure 1B).

Prior to hydrogen therapy, extensive adhesion and compression of gallbladder tumors caused severe pain in the upper abdomen that required daily pain medication; this was stopped when the pain gradually diminished after 2 wk of hydrogen treatment. Subsequent pain-induced administration of analgesics was not necessary, even during ileus.

T and NK cells are the major populations of lymphocytes that mediate anti-tumor immunity; therefore, the total number of lymphocytes is positively correlated with the immune function of patients. Before tumor recurrence and metastasis, the total number of lymphocytes continued to rise ( $1.2 \times 10^9/L$ ), indicating an increase in immune function. However, the total number of lymphocytes declined rapidly with tumor progression, to significantly below the reference range ( $0.8-4 \times 10^9/L$ ), reaching a minimum ( $0.7 \times 10^9/L$ ) during intestinal obstruction (1.5 mo after hydrogen therapy). The lymphocyte numbers then rebounded, reaching  $1 \times 10^9/L$  after 2.5 mo of hydrogen treatment (Figure 1C right).

Before the detection of tumor recurrence (September 20, 2018), all three tumor markers were significantly higher than the reference range, but all showed a slight decline, which may be related to the compensation of immune function before treatment failure. After identification of tumor recurrence and metastasis, all three markers began to increase rapidly. This was consistent with the rapid growth of the tumor, which caused obstruction. After 1.5 mo of hydrogen therapy, the levels of all three markers began to decrease rapidly, falling into the reference ranges after 2.5 mo (Figure 2).

### CT imaging changes

Before hydrogen gas treatment, the sum of the tumor diameters was 12.2 cm; 1 mo after treatment, the sum was 13.1 cm (37% increase, PD); and 2.5 mo after treatment, the sum was 7.5 cm (6% increase, SD) (Figure 3 and Table 2). At the end of February 2019, no tumor recurrence was detected (very similar to the CT examination at 2.5 mo; images not shown). To date, the patient appears completely well (Karnofsky score 100) and has resumed a normal diet and exercise.

## DISCUSSION

In GBC patients who are not candidates for surgery, the NCCN guidelines recommend the use of chemotherapy and best supportive care. Due to the large size of tumor in this patient (stage IIIA), the gallbladder function was completely lost with widespread adhesions to the hilum of the liver. Therefore, it was necessary to choose

**Figure 1** Blood parameters of patients before and after hydrogen treatment. A: Red blood cell counts and hemoglobin levels; the red line in the figures represents the lower limit of the reference range; B: Total protein and albumin concentrations; the red lines in the figures represent the reference range; C: White blood cell and lymphocyte counts; the red lines in the figures represent the reference range.

an ablation method that causes minimal damage to the extrahepatic bile duct system in reducing the tumor size. IRE is a novel ablation technology that utilizes short pulses of high voltage electrical energy to induce tissue necrosis. This technique has many advantages, including short ablation time, preservation of the internal structure of vital organs, and lack of the heat/cold-sink effect<sup>[15]</sup>. We have previously verified the safety and efficacy of gallbladder ablation in a rabbit model<sup>[16]</sup>. Although not yet included in the NCCN guidelines, IRE has the potential to be a superior alternative to other ablation techniques for the removal of tumors situated near the gallbladder<sup>[17-19]</sup>.

IRE, combined with oral chemotherapy, effectively controlled the tumors in the gallbladder and the hilar part of the liver, and re-examination after 3 mo of treatment showed that the tumor was basically necrotic. However, for this patient with advanced GBC, palliative treatment could only delay the disease, with continued slow progression of the tumor. In the re-examination after 9 mo of treatment, recurrence of the gallbladder tumor, duodenum fistula, liver metastases, and lymph node metastases around the head of pancreas as well as severe anemia were detected, which indicated that the disease had entered a stage of rapid and life-threatening progression in a short period of time. Best supportive care was the only option at this timepoint, although in general, it is not possible to reverse the progression of such tumors.

Molecular hydrogen, or  $H_2$ , can selectively neutralize hydroxyl radicals, but not other reactive oxygen species (ROS)<sup>[20]</sup>. Hydrogen has been used to treat various states associated with oxidative stress, including trauma<sup>[21]</sup>, neurodegenerative disease<sup>[22]</sup>, inflammatory disease<sup>[23]</sup>, metabolic syndrome<sup>[24]</sup>, adverse reactions to chemotherapy<sup>[25]</sup>, and radiation injury<sup>[26]</sup>. In addition to the apparent improvement in the immune system<sup>[12]</sup>, there is much evidence that hydrogen directly kills different types of tumors, including cutaneous squamous cell carcinoma<sup>[27]</sup>, leukemia<sup>[28]</sup>, tongue

Figure 2 Changes in tumor markers before and after hydrogen treatment. The red lines in the figures represent the upper limit of the reference ranges.

cancer<sup>[29,30]</sup>, and colon cancer<sup>[8]</sup>. Since there has been no report on the upper limit of hydrogen use, this therapy might be a very safe method.

At the same time as the delivery of optimal supportive care, the patient was enrolled in this clinical study (24 October 2018) with the intention of improving clinical symptoms. One month after the start of hydrogen therapy, the disease continued to progress, and the levels of tumor markers (including CA19-9, AFP, and CEA) continued to rise, although the patient's general status and blood indexes (including total protein, albumin, multiple blood cells count, hemoglobin content, *etc.*) showed continuous improvement, so the patient persisted with the hydrogen treatment. Gradually, the levels of multiple tumor markers began to decline, and multiple hematological indicators continued to improve. The patient underwent gastric tube removal on December 24, and gradually began eating semi-liquid food, with significant improvement in spirit, appetite, and sleep. Subsequent CT examination also confirmed relief of the obstruction, with significant shrinkage of tumors at multiple sites. The reason for the patient's extraordinary recovery, apart from symptomatic treatment, is probably because the persistence of hydrogen therapy; this therapy not only mediates rapid improvement in the physical condition of the patient, but also significantly reduces tumor marker levels, increases lymphocyte counts, and even induces tumor shrinkage.

At present, there is only a temporal connection between hydrogen and improvement of this patient's cancer. The proposed mechanism underlying the anti-cancer properties of hydrogen may involve: (1) Elimination of the high levels of ROS produced by cancer cells, thus inhibiting the proliferation, invasion, and migration of cancer cells<sup>[31]</sup>; (2) Downregulation of inflammatory factors, elimination of chronic inflammation, and modification of the microenvironment<sup>[32]</sup>; (3) Protection of mitochondria, which maintains energy generation and help correct hypoxia, thereby transforming the cardiovascular, endocrine, and nervous systems<sup>[11]</sup>; and (4) Restoration of the function of exhausted cytotoxic T cells, and enhancement of systemic anti-cancer effects<sup>[33]</sup>. The detailed mechanism remains to be fully elucidated in further follow-up studies, and indications for advanced cancer therapy require verification in studies with greater numbers of patients.

**Table 2 Tumor sizes before and after hydrogen gas treatment**

	Gallbladder	Liver metastases	Lymph node around the pancreas head	Sum of the tumor diameters
Pretreatment	6.3 cm × 4.9 cm	3.2 cm × 2.6 cm	2.7 cm × 2.1 cm	12.2 cm
1 mo after treatment	6.7 cm × 6.3 cm	4.2 cm × 4.0 cm (large) 3.6 cm × 3.2 cm (small)	2.2 cm × 1.8 cm	16.7 cm
2.5 mo after treatment	3.7 cm × 3.6 cm	4.0 cm × 3.3 cm (large) 3.2 cm × 2.8 cm (small)	2.0 cm × 1.6 cm	12.9 cm

## CONCLUSION

This is the first report on the rehabilitation of an advanced GBC patient with a critical general condition, whose disease has gradually improved and has survived for more than 4 mo.

**Figure 3** Computed tomography imaging findings at different time points before and after hydrogen treatment. In the first line of figures, the triangle and the contour lines represent the location and range of the gallbladder. In the second line of figures, the contour lines represent the location and range of liver metastases. In the third line of figures, the arrows represent the location of the duodenal fistula or obstruction.

### Abstract

#### BACKGROUND

Adrenocortical cancer (ACC) is an infrequent and often aggressive malignancy with a very poor prognosis. It can be classified as functional or nonfunctional. Nonfunctional ACC is hampered by the absence of specific signs or symptoms; only abdominal pain with or without incidental adrenal occupation is typically present.

#### CASE SUMMARY

We report a rare case of a patient with a 30 cm × 15 cm × 8 cm ectopic ACC on the anterior abdominal wall without organ adhesion. A 77-year-old male was admitted to our hospital because of a huge abdominal mass, which, by ultrasonography, had an unclear border with the liver. Computed tomography showed that the mass was not associated with any organ but was adherent to the anterior abdominal wall. The patient underwent tumor resection, and a postoperative pathology examination showed a neuroendocrine tumor, which was diagnosed as ACC. The patient was disease-free at the 9-mo follow up.

#### CONCLUSION

The anterior abdominal wall is a rare site of ACC growth.

report

©The Author(s) 2019. Published by Baishideng Publishing Group Inc. All rights reserved.

**Core tip:** Aberrant adrenal tissue can be found anywhere, but typically in the testes, ovaries, spermatic cord, and kidneys. The most common site is retroperitoneal fat near the adrenal gland; the bilateral lungs, liver, spleen, pancreas, colon, duodenum, and ovary are less common. This is, to our knowledge, the first report of adrenocortical cancer on the anterior abdominal wall in the English-language literature.

## INTRODUCTION

Adrenocortical cancer (ACC) is an infrequent and often aggressive malignancy with a very poor prognosis. According to the Surveillance, Epidemiology and End Results database, ACC has an annual incidence of 0.7-2 per million population<sup>[1]</sup> and a bimodal age distribution with peaks before 5 years of age and at 40-60 years of age<sup>[2]</sup>.

ACC can be classified as functional or nonfunctional. The early diagnosis and treatment of nonfunctional ACC is hampered by the absence of specific signs or symptoms; only abdominal pain with or without incidental adrenal occupation is typically present. Based on its cost-effectiveness, the American Association of Clinical Endocrinologists guidelines recommend surgery for nonfunctional ACC lesions  $\geq 4$  cm in diameter<sup>[3]</sup>. Here, we report the case of a patient with ACC on the abdominal wall. The patient underwent tumor resection and was disease-free at the 9-mo follow up.

## CASE PRESENTATION

### Chief complaints

A 77-year-old male (body mass index, 24.5 kg/m<sup>2</sup>), who 9 mo previously had been admitted to our hepatological surgery department, presented with an enormous exogenous liver occupation that had been detected by ultrasonography in a community hospital 2 d prior. He denied having abdominal pain, nausea, anorexia, or changes in bowel habit.

### History of present illness

The patient had no clinical symptoms associated with steroid excess, except for hypertension. He was admitted to our department for diagnosis.

### History of past illness

The patient had suffered from hypertension for 40 years but did not have diabetes or cardiovascular disease.

### Personal and family history

His medical history and family history were unremarkable.

### Physical examination

The results of a physical examination were unremarkable, except for a palpable hard mass and slight tenderness in the hepatic region.

### Laboratory examinations

The results of laboratory tests were as follows: CA199, 112.0 U/mL (reference < 37.0 U/mL); alpha fetoprotein, 1.4 ng/mL (reference < 20.0 ng/mL); alanine transaminase, 89 U/L (reference < 35.0 U/L); aspartate transaminase, 49 U/L (reference < 40 U/L); and serum potassium, 4.40 mmol/L (reference 3.50-5.20 mmol/L). The results of the endocrine work-up were negative.

### Imaging examinations

Ultrasonography revealed an enormous space-occupying lesion in the right upper abdomen, in which Color Doppler flow imaging showed a small amount of blood flow (Figure 1A). A left-hepatic origin was considered, but contrast-enhanced computed tomography (CT) showed an irregular fat-containing mass in the right upper abdominal cavity of uneven density with an obscure boundary (Figure 1B). The tumor exhibited heterogeneous enhancement in the arterial phase (Figure 1C) and delayed enhancement in the venous phase (Figure 1D).

## TREATMENT

A laparotomy was performed. During surgery, a 30 cm × 15 cm × 8 cm tumor was found above the hepatic curvature of the colon in front of the right posterior peritoneum (Figure 2). The liver, pancreas, stomach, colon, and adrenal gland were not infringed, and there was no lymph-node metastasis. The tumor had invaded the local right-abdominal musculature.

## FINAL DIAGNOSIS

A postoperative pathology examination indicated that the tumor was hypo-differentiated carcinoma with neuroendocrinalization and so was considered to be ACC. A histopathology examination showed a Weiss score of 6, as cells were distributed in sheets and wide bands, and extensive necrosis was present. The cytoplasm was eosinophilic, the karyotype was irregular, and giant neoplastic cells were present (Figure 3A). The Ki-67 labeling index was > 80% (Figure 3B), and the tumor cells were positive for melan A, vimentin, synaptophysin (Figure 3C-E), CK20, insulin-like growth factor-2 (IGF-2), and EMA; and negative for CK (pan), inhibin a, CgA, and S-100.

## OUTCOME AND FOLLOW-UP

The patient underwent regular follow ups involving a physical examination, laboratory testing, and X-ray and CT imaging. He was disease-free at the 9-mo follow up.

## DISCUSSION

ACC is a rare malignancy, accounting for about 0.05%-0.2% of all malignant tumors, and has an annual incidence of 1-2 per million<sup>[4]</sup>. Ectopic adrenal tissue is commonly found in infants and children, but it is less common in adults<sup>[5]</sup>. ACC is the second most aggressive malignant endocrine tumor after anaplastic thyroid cancer<sup>[6]</sup>. Aberrant adrenal tissue can be found anywhere, but typically in the testes, ovaries, spermatic cord, and kidneys<sup>[6]</sup>. The most common site is retroperitoneal fat near the adrenal gland<sup>[7,8]</sup>; the bilateral lungs<sup>[9]</sup>, liver<sup>[7]</sup>, spleen<sup>[8]</sup>, pancreas<sup>[8]</sup>, colon<sup>[8]</sup>, duodenum<sup>[8]</sup>, and ovary<sup>[6]</sup> are less common. This is, to our knowledge, the first report of ACC on the anterior abdominal wall in the English-language literature.

The clinical symptoms of primary ACC are dependent on the functional state and volume of the tumor. Around half of patients with ACC are asymptomatic or have symptoms caused by mechanical effects of tumor growth<sup>[2]</sup>, such as abdominal pain, nausea, poor appetite, and back pain<sup>[1]</sup>. The other half of patients with ACC have symptoms related to elevated levels of steroid hormones-Cushing syndrome, Con syndrome, and feminization. ACC lesions are typically large as they grow rapidly; most are 10-13 cm in diameter, 9%-14% are < 6 cm, and 3% are < 4 cm<sup>[1,10,11]</sup>. Generally, nonfunctional ACC lesions are small; large nonfunctional ACC lesions are very rare<sup>[12]</sup>.

The pathogenesis of ACC is unclear but is likely to involve IGF-2, tumor protein 53, and  $\beta$ -catenin. ACC can be diagnosed with 100% specificity and 96% sensitivity based on the levels of IGF-2 and Ki-67<sup>[13]</sup>.

Imaging (magnetic resonance imaging or CT) is crucial for identifying adrenal involvement in ACC. In general, ACC is a non-homogeneous tumor with hemorrhage or necrosis and an irregular margin. Nuclear aberrations-comprising a high mitotic count, high nuclear grade, and bizarre mitotic figures—are characteristic histological findings of ACC<sup>[13]</sup>.

**Figure 1 Imaging diagnosis.** A: Color Doppler image showing blood flow; B: Computed tomography with contrast (white arrow, fat density); C: Uneven heterogeneous enhancement in the arterial phase; D: Delayed enhancement in the venous phase.

Complete surgical resection is the only potentially curative therapy for ACC; And it is equally important to choose surgical indications according to the latest guidelines for the surgeon<sup>[14]</sup>. Indeed, complete resection is the most accurate predictor of the outcome. Paton *et al*<sup>[11]</sup> reported that patients who have complete resection have a higher 5-year survival rate than those who have incomplete resection. In the retrospective study of Terzolo *et al*<sup>[15]</sup>, use of mitotane as adjunct therapy reduced the rates of recurrence and mortality, as did etoposide, doxorubicin and cisplatin plus mitotane, streptozotocin plus mitotane, and gemcitabine plus capecitabine<sup>[1,16]</sup>.

The 5-year overall survival rate of patients with ACC is 37%-47%<sup>[1]</sup>. For advanced ACC, (*i.e.*, stage III tumor), the mENS<sup>®</sup>T TNM classification - which comprises the "GRAF" components: grade (G), resection status (R), age (A), and functioning symptoms at diagnosis (defined as tumor or hormone-related symptoms) (F) - is recommended<sup>[17]</sup>. Rupture of the tumor capsule, metastasis, and a high Ki67 index are associated with reduced disease-free and overall survival.

## CONCLUSION

ACC is rare and has a poor prognosis. The 5-year overall survival rate of patients with ACC is 37%-47%, and resection is the optimum treatment modality. We describe a case of a patient with ectopic adrenocortical carcinoma on the anterior abdominal wall and our patient was disease-free at 9 mo after resection of the tumor.

## Abstract

### BACKGROUND

Oncogenic osteomalacia caused by phosphaturic mesenchymal tumors is very difficult to detect. We report a case of tumor-induced osteomalacia caused by a phosphaturic mesenchymal tumor of the left femur in a middle-aged woman after medical imaging and biopsy.

### CASE SUMMARY

A 57-year-old woman presented with progressive bone pain for five years. She was diagnosed with hypophosphatemic osteomalacia, as her laboratory data showed low serum phosphorus and low serum calcium. Her knee joint radiography revealed an osteolytic lesion of the left femur. A computed tomography scan showed mixed density shadows in the left femur. Magnetic resonance imaging of the left femur showed the presence of an oval area with a hypointense signal in T1-weighted magnetic resonance imaging (MRI) and high-low mixed signal in T2-weighted MRI. Biopsy samples revealed the presence of short spindle cells, vascularization, and characteristics of phosphaturic mesenchymal tumors. Tumor resection was performed, and the clinical presentations and laboratory abnormalities were reversed.

### CONCLUSION

Diagnosis of oncogenic osteomalacia is difficult due to the varieties and

**Core tip:** Oncogenic osteomalacia caused by phosphaturic mesenchymal tumors is not easily identifiable or detectable due to its rarity and nonspecific presentations. Herein, we provide a successful example of diagnosis of phosphaturic mesenchymal tumor-induced oncogenic osteomalacia in a female patient who presented progressive bone pain. Our case emphasizes that histologically benign phosphaturic mesenchymal tumors that are responsible for oncogenic osteomalacia can also cause bone destruction.

## INTRODUCTION

Oncogenic osteomalacia, also known as tumor-induced osteomalacia, is an uncommon cause of osteomalacia. At present, approximately 140 different tumors have been reported in association with oncogenic osteomalacia, and most osteomalacia-associated tumors are phosphaturic mesenchymal tumors<sup>[1,2]</sup>. Phosphaturic mesenchymal tumors are found to be commonly associated with phosphaturia and a decreased level of serum 1,2-dihydroxyvitamin D3 that is resistant to vitamin D supplementation. However, oncogenic osteomalacia caused by phosphaturic mesenchymal tumors is not easily identifiable or detectable due to its rarity and nonspecific presentations. The clinical presentations of the patients include nonspecific symptoms of fatigue, bone pain, and musculoskeletal weakness<sup>[3]</sup>. Although rare, the diagnosis of phosphaturic mesenchymal tumor should be considered in any patient who presents with hypophosphaturic osteomalacia and no other physiologic cause.

In our case, oncogenic osteomalacia was caused by a phosphaturic mesenchymal tumor localized in the patient's left femur. The patient presented with progressive bone pain with no etiology for five years. After X-ray, computed tomography (CT), magnetic resonance imaging (MRI), and biopsy, a diagnosis of oncogenic osteomalacia caused by a phosphaturic mesenchymal tumor was made. Resection of the tumor was performed, and the clinical presentations and laboratory abnormalities were reversed. Here, our case emphasizes that histologically benign phosphaturic mesenchymal tumors that are responsible for oncogenic osteomalacia can also cause bone destruction. Its diagnosis is, thus, reliably achieved by histopathological examination combined with medical imaging.

## CASE PRESENTATION

### Chief complaints

A 57-year-old woman presented with progressive bone pain of the whole body for three years.

### History of present illness

Five years ago, there was no obvious cause for the appearance of pain in her right third toe; pain then developed into the right instep with an associated jerk and then progressively appeared in the right thigh with an associated jerk, thus affecting her ability to walk. Three years ago, systemic pain appeared, especially bone pain. There

was also pain in her muscles and skin. Reduction or even no pain was felt while lying flat. At this time, she also had the ability to do laundry or cook. Two years ago, pain prevented her from daily exercise, and she had to stay in bed. There was no accompanying fever, coma, cough, dizziness, headache, chest tightness, palpitation, nausea, vomiting, or abdominal pain. Five years ago, she was first examined at a hospital, and her laboratory workup showed slightly low levels of serum phosphorus (0.63 mmol/L, reference range: 0.80-1.48 mmol/L) and low serum calcium (1.98 mmol/L, reference range: 2.10-2.60 mmol/L). Bone density examination showed osteoporosis in her left acetabulum and osteopenia in her lumbar spine. Chest and abdomen computed tomographic scans did not reveal any abnormalities. However, the photographs were not available now. She was treated with calcium and vitamin D supplementation. However, her pain persisted. The woman was introduced to our hospital approximately 5 years after the onset of her symptoms.

## FINAL DIAGNOSIS

Physical examination showed that palpation on the right upper abdomen was normal; signs such as purple striae, moon face, and central obesity were not observed.

Her laboratory data also revealed slight hypophosphatemia (0.76 mmol/L, reference range: 0.80-1.48 mmol/L) and hypocalcemia (1.86 mmol/L, reference range: 2.10-2.60 mmol/L). Her knee radiographs showed that her bony trabeculae were sparse and her bone density was widely reduced (Figure 1). The X-ray radiograph showed an oval osteolytic lesion in the inferior medullary cavity of the left femur (Figure 1B, arrow). A subsequent CT scan revealed that mixed density shadows were shown in the intramedullary cavity of the left femur (Figure 2, arrow). Non-uniform enhancement in this lesion area was observed. However, no obvious abnormalities were seen in the surrounding soft tissues. MRI of the left knee showed the presence of an intramedullary tumor in the left femur, which showed a hypointense signal on the T1-weighted image (Figure 3A, arrow) and a high-low mixed signal intensity on the T2-weighted image (Figure 3B and C, arrow). Thus, a tumor-induced osteomalacia was confirmed.

## TREATMENT AND OUTCOME

The tumor was resected at a local hospital, and the histology revealed a phosphaturic mesenchymal tumor with the presence of spindle cells and prominent blood vessels (Figure 4). Her serum phosphorus and calcium returned to the normal range (phosphorus: 0.89 mmol/L, reference range: 0.80-1.48 mmol/L; calcium: 2.29 mmol/L, reference range: 2.10-2.60 mmol/L), and now the woman can exercise daily and has not had any recent complaints.

## DISCUSSION

The existence of tumor-induced osteomalacia is not widely recognized, and its diagnosis can often be delayed<sup>[4]</sup>. Tumors that are involved in oncogenic osteomalacia include phosphaturic mesenchymal tumors, fibrous dysplasia, osteosarcoma, and others<sup>[5-7]</sup>. Folpe *et al*<sup>[2]</sup> revealed that 90% of tumor-induced osteomalacia cases are associated with phosphaturic mesenchymal tumors. Phosphaturic mesenchymal tumors are most often seen in the head and lower extremities, and approximately 53% of them occur in bone, 45% in soft tissue, and 3% in skin<sup>[8]</sup>. Most phosphaturic mesenchymal tumors are seen in middle-aged adults, with no gender difference<sup>[9]</sup>. The histology of phosphaturic mesenchymal tumors features proliferation of spindle cells and oval cells, vascularization, a cartilage-like matrix, and giant cells<sup>[10]</sup>. Although rare, malignant tumors with metastasis and infiltration can also be present<sup>[11-13]</sup>. The present case of phosphaturic mesenchymal tumor occurred in the left femur and led to hypophosphatemia osteomalacia in a middle-aged woman.

Hypophosphatemia in tumor-induced osteomalacia is caused by the mRNA overexpression of FGF-23, a protein that is produced at low levels by osteocytes<sup>[10,14]</sup>. FGF-23 plays important roles in phosphate homeostasis and vitamin D metabolism. After binding with the FGFR1 receptor and the transmembrane protein Klotho, FGF-23 exerts bioactivity at the proximal tubules, where it inhibits phosphate resorption. FGF-23 also impairs the activity of hydroxylation of 25-hydroxyvitamin (OH) D<sub>3</sub>. These mechanisms mainly lead to hypophosphatemia and osteomalacia<sup>[15,16]</sup>. However, in China, the serum FGF-23 test is not routinely provided in most hospitals.

**Figure 1 X-rays of knee joints.** A: Anteroposterior view; B: Lateral view. Bone trabeculae of both knees are sparse, bone density is widely reduced, and an oval osteolytic area is shown in the inferior medullary cavity of the left femur (arrow).

This highlights the need for our clinicians to be aware of its entity and to give an appropriate investigation of phosphaturic mesenchymal tumor-induced osteomalacia.

Phosphaturic mesenchymal tumors are often very small in size and grow slowly, which makes them difficult to locate<sup>[10]</sup>. Malignant tumors and metastasis can often be detected. Infiltration of the surrounding tissue can also happen. Widespread bone metastases may lead to the occurrence of pathological fractures and spinal cord compression, thus significantly affecting patient outcomes. There are no established guidelines for the treatment of metastatic phosphaturic mesenchymal tumors. Complete tumor resection corrects the biochemical abnormalities and remineralization of bone. In our case, we did not observe metastases of the tumors, and resection of the tumor relieved pain and reversed the biochemical abnormalities in the patient. Our case demonstrated that histologically benign phosphaturic mesenchymal tumors can also cause bone pain.

In conclusion, we report a case of oncogenic osteomalacia caused by a phosphaturic mesenchymal tumor of the left femur in a middle-aged woman. Our case emphasizes that histologically benign phosphaturic mesenchymal tumors that are responsible for oncogenic osteomalacia can also cause bone destruction. Its diagnosis is, thus, reliably achieved by histopathological examination combined with medical imaging. We expect that the detailed description of this case presentation of oncogenic osteomalacia will provide a valuable resource to facilitate the diagnosis of such diseases in the future.

**Figure 2** Computed tomography scans of knee joints. Mixed density shadows are shown in the intramedullary cavity of the left femur (arrow). Computed tomography values are 45-70 HU.

**Figure 3** Magnetic resonance imaging of the left knee. A: T1WI sagittal view; B: PDWI coronal view; C: PDWI sagittal view. T1 hypointense (arrow, A) and T2 high-low mixed signal (arrows, B and C) are shown.

**Figure 4** Histology of the resected tumor. Note the presence of short spindle cells and a large number of blood vessels. Some spindle cells grew around blood vessels. HE staining, 100 $\times$ .

## ACKNOWLEDGEMENTS

The authors would like to thank colleagues from the Department of Radiology and Ultrasound Imaging of Hangzhou Normal University Affiliated Hospital for their support and collaboration.

## Abstract

### BACKGROUND

Gastric duplication cysts (GDCs) are a relatively uncommon congenital developmental abnormality, mainly occurring in infants but very rarely in adults. Because of the variability in clinical presentation, it is often quite challenging to diagnose GDCs in adults. We are presenting a case report of an adult diagnosed operatively as having a GDC with a literature review to summarize clinical and imaging features and the treatment selections of GDCs in adults so that doctors could have a comprehensive understanding of this disease and make a precise diagnosis and a suitable therapeutic decision for patients.

### CASE SUMMARY

A 51-year-old man presented with recurrent epigastric pain and fullness for two years. No significant findings were noted during physical examination and routine blood tests were unremarkable. An abdominal ultrasound revealed a large cyst in the upper left abdominal quadrant. A following contrast-enhanced abdominal computed tomography (CT) scan demonstrated a hypodense cystic lesion between the spleen and stomach. The lesion had scattered calcification in the cyst wall without any significant enhancement. The lesion was initially thought to be a cystic lymphangioma. The patient underwent a surgical resection and intraoperatively it was noted that the lesion was closely adherent to the greater curvature of the stomach. Subsequently, a resection of the gastric mass along with a partial gastrectomy was performed. The patient recovered quickly with a complete symptomatic relief and did not show any further complications during the 8-month follow-up.

### CONCLUSION

GDCs are quite rare in adults, with a multitude of symptoms, which is quite

**Core tip:** We are presenting a rare case of a duplication cyst in an adult complaining of recurrent upper left abdominal pain and fullness. An abdominal ultrasound and a contrast-enhanced computed tomography scan demonstrated a large cystic lesion along the greater curvature of the stomach with scattered calcification and no significant enhancement was observed. A nutrient vessel arising from the stomach was noted in the cyst wall. Laparoscopic resection of the gastric mass and partial gastrectomy were performed. The patient recovered without any complications.

## INTRODUCTION

Gastrointestinal tract duplications are a rare congenital developmental malformation most frequently seen in infants with an incidence of about 1 in 4500 live births and a sex ratio of approximately 2 to 1 (female to male)<sup>[1,2]</sup>. A gastrointestinal tract duplication is defined as a tubular or spherical structure sharing a common muscular wall and blood supply with normal gastrointestinal tract but having a separate mucosal lining<sup>[3]</sup>, which can appear anywhere along the gastrointestinal tract from the mouth to the anus, with the ileum being the most common location<sup>[1,4,5]</sup>. Gastric duplication cysts (GDCs), accounting for about less than 10% of gastrointestinal tract duplications, are rarely seen in adults as most cases are diagnosed in childhood, and over 70% cases are discovered before the age of 12<sup>[1,4,6]</sup>. Although GDCs in adult are a rare entity, they may present with various symptoms including abdominal pain, gastric outlet obstruction, or a palpable abdominal mass.

## CASE PRESENTATION

### Chief complaints

A 51-year-old man was admitted to our hospital because of a two-year history of repeated episodes of epigastric pain and fullness without any obvious causes.

### History of present illness

Two years ago, the patient began to present recurrent upper abdominal pain. The recurrent episodes of pain lasted approximately 1 h and were associated with nausea.

### History of past illness

The patient denied any past surgical interventions.

### Physical examination

Initial evaluation in the hospital showed no remarkable clinical examination findings.

### Laboratory examinations

Laboratory test results were within normal limits.

### Imaging examinations

An abdominal ultrasound showed a large cystic lesion in the upper left quadrant

abdomen, which was initially thought to be retroperitoneal (Figure 1A). No significant vascular flow was seen on Doppler (Figure 1B).

A contrast-enhanced abdominal computed tomography (CT) scan was performed for further evaluation (Figure 2). The scan showed a large cystic hypodense lesion, measuring 95 mm × 61 mm × 66 mm, between the spleen and stomach, which was anterior to the left renal fascia and in close proximity to lateral limb of the left adrenal gland. The lesion was lobulated and well-circumscribed with a small amount of wall calcification.

### Primary diagnosis

A cystic lymphangioma was the primary diagnostic consideration prior to pathological confirmation according to the imaging examination.

---

## MULTIDISCIPLINARY EXPERT CONSULTATION

---

**Guan-Yu Wang, MD, Chief Doctor, Department of General Surgery, Zhejiang University School of Medicine**

Considering recurrent abdominal pain and the imaging findings of an abdominal mass, the patient needed to take surgical treatment into consideration for symptomatic relief.

---

## TREATMENT

---

The patient chose surgical intervention for symptomatic relief. During the surgery, it was noted that the lesion was adherent to the greater curvature of the proximal stomach, between the superoposterior aspect of the pancreas and splenic hilum. A laparoscopic resection of the perigastric mass and partial gastrectomy were performed.

---

## FINAL DIAGNOSIS

---

Histological sections showed gastric mucosa-like tissues within the cyst wall and a diagnosis of GDC was made for the patient (Figure 3).

---

## OUTCOME AND FOLLOW-UP

---

The patient recovered quickly after the surgery without any postoperative complications. There were no recurrent symptoms during his 8-month outpatient follow-up.

---

## DISCUSSION

---

GDCs are a class of gastrointestinal tract duplications, most commonly occurring in children and very rarely in adults. GDCs have no specific clinical symptoms in adults and the symptoms mainly depend on the lesion location, size, and whether any communication exists with the gastric lumen. Clinical symptoms include nausea, vomiting, abdominal pain, palpable abdominal mass, gastrointestinal bleeding (from ulceration related to ectopic gastric mucosal acid secretion), weight loss, anemia, and failure to thrive<sup>[1,6-10]</sup>. Some cases are asymptomatic and only incidentally detected during physical examination<sup>[7]</sup> (Table 1). GDCs can produce all the pathological changes that may occur in the normal gastric lining, including gastritis, gastric ulcer, and even malignant transformation<sup>[11,12]</sup>. To date, less than 15 cases of malignant transformation arising from GDCs have been reported<sup>[7,12-14]</sup>. In rare cases, GDCs have been reported to contain ectopic pancreatic tissue<sup>[15,16]</sup>. Pancreatitis can occur in these cases if the ectopic pancreatic duct is obstructed<sup>[16,17]</sup>. Laboratory tests in GDCs tend to be unremarkable. Rarely, some cases have abnormally elevated carcinoembryonic antigen (CEA) and CA 19-9<sup>[18,19]</sup>. These cases may be associated with malignant transformation of GDCs.

GDCs tend to be found along the greater curvature of the stomach<sup>[1,4]</sup>. It can be divided into intraluminal and extraluminal types according to the location; communicating and non-communicating types according to its connection with

**Figure 1** Ultrasound images of the gastric duplication cyst. A large cystic focus (blue arrow) was visible in the space between the spleen, stomach, and left kidney, with no vascularization on Doppler.

gastric lumen; and complete and incomplete duplication according to the degree of deformity. The extraluminal and non-communicating types are more common compared with the intraluminal and non-communicating types, accounting for more than 80% of reported cases<sup>[1,4,7]</sup>. Complete communicating GDCs are really rare. There has been only one reported case in the past 17 years<sup>[1]</sup>.

The mechanism of GDCs is still unclear but several theories have been proposed to explain the formation of gastrointestinal duplications. Some scholars theorize that gastrointestinal duplications share a similar mechanism with that of diverticulum formations and some believe they are caused by the abnormal development of early embryonic primitive foregut formation and differentiation<sup>[1,2,7]</sup>.

On conventional radiography, intraluminal contrast agent filling can be seen in the communicating type GDCs. In contrast, non-communicating type GDCs would only show gastric wall indentation, indicating a submucous or extraluminal lesion.

CT and magnetic resonance imaging (MRI) are valuable for determining the size, location, and extent of the duplication cyst as well as the relationship to adjacent structures<sup>[1,20]</sup>. GDCs may be round or lobulated with a thin wall on cross-sectional images<sup>[7]</sup>. When the duplication cyst is very large and in close proximity to adjacent organs such as the spleen, kidney, or liver, it may be misdiagnosed as a cyst arising from these organs. MRI has high soft tissue resolution and signal changes in multiple phases may present the thin cyst wall usually with slight enhancement, which is useful for distinguishing the origin of the cyst<sup>[6]</sup>. In our case, no enhanced cystic wall was observed by enhanced CT, but a nutrient vessel arising from the stomach was seen in the cyst wall, which was a helpful imaging feature to identify the origin of the cystic lesion. GDCs occasionally present calcification within the cyst wall, which may be related to the accumulation of secretion or necrosis. Multiple calcifications in the cyst wall were observed in our case and the case reported by D'Journo *et al*<sup>[21]</sup>. Awan *et al*<sup>[22]</sup> introduced a special case with multiple calcifications mimicking a staghorn calculus. The contents of most GDCs present fluid density/signal, but bleeding or infection may result in the heterogeneity of density/signal, which can make diagnosis of GDCs in adults complicated<sup>[4]</sup>. GDCs also need to be distinguished from gastrointestinal stromal tumors (GISTs). GISTs are solid tumors originating from the submucous mesenchymal tissue of the gastrointestinal wall, and vary greatly in size with hemorrhage and necrosis occurring in large tumors and mild or moderate enhancement involving the solid portions of GISTs.

Ultrasound is a noninvasive method widely used for screening in patients with abdominal symptoms. In most cases, ultrasound shows a hypoechoic cystic lesion in the upper abdomen, often adjacent to the stomach, pancreas, and liver.

Endoscopic ultrasound (EUS) is considered a good diagnostic tool for the detection of GDCs because it can show the internal hyperechoic mucosal layer and the hypoechoic smooth muscle layer of the cyst<sup>[21]</sup>. In recent years, EUS-guided fine-needle aspiration (EUS-FNA) plays an important role in clinical diagnosis of GDCs<sup>[5]</sup>.

On pathology, a GDC must have both a smooth muscle layer and a mucosal epithelial layer (gastrointestinal, gastric, or respiratory mucosa) in the cyst wall<sup>[7,14]</sup>. Our case had all the layers meeting the diagnostic requirements.

Up to now, there are no well-recognized international guidelines on the treatment of this disease. Several treatment methods have been reported in the literature, including enucleation, formation of cystogastrostomy, and even endoscopic removal<sup>[3]</sup>. Surgical excision is usually considered the mainstay of treatment for GDCs. Surgical resection is performed not only for the consideration of symptomatic relief

**Figure 2** Contrast-enhanced computed tomography images of the gastric duplication cyst. A-F: A large cystic hypodense focus was along the greater curvature of the stomach, measuring 95 mm × 61 mm × 66 mm; A and B: The focus was lobulated and well-circumscribed with a small amount of calcification on its wall (white arrow); C and D: A nutrient vessel from the stomach on the cyst wall was observed on arterial phase images (yellow arrow).

and the prevention of potential complications caused by GDCs such as obstruction, torsion, perforation, bleeding, but also for the risk of malignant transformation in GDCs<sup>[3,7]</sup>. We performed a review of the English papers about GDCs in the past 17 years on PubMed and found that the majority of those cases had a good prognosis with complete symptomatic relief after surgical resection while only a few cases with malignant transformation developed recurrence or metastasis<sup>[11,12,14,23-25]</sup>.

## CONCLUSION

GDCs are a quite rare malformation in adults usually with non-specific clinical symptoms. Some imaging modalities including ultrasound, CT, and MRI are able to figure out morphological features for GDCs diagnosis and EUS could present the exact micro-structure of the cystic wall. We deem that GDCs should be put in the differential list for a cystic mass adjacent to gastric lumen.

**Table 1 Teaching points for differential diagnosis**

Disease	Age	Teaching points
Gastric duplication cysts (GDCs)	More common in children, rarely seen in adults.	Often present as a cystic focus along the greater curvature and adjacent to stomach with a thin and slightly enhanced wall.
Any cystic lesions from the adjacent organs (liver, biliary ducts, pancreas, and spleen)	Occur at any age.	Ultrasound, CT, and MRI can show the origination of the lesion. History, clinical presentation and laboratory examination could help to lead to the right diagnosis <sup>[7]</sup> .
Gastrointestinal stromal tumors (GISTs)	Present usually in early adulthood <sup>[14]</sup> .	Medical images show masses with solid enhancement arising from the gastric wall which may show cystic or mixed cystic changes <sup>[8,14]</sup> .
Cystic lymphangioma	Occur mostly in children <sup>[26]</sup> .	Mostly seen in the neck and axillae but can be found anywhere in the body <sup>[26]</sup> . CT and MRI show cystic lesions with the thin wall crawling along the tissue gaps <sup>[26,27]</sup> .

CT: Computed tomography; MRI: Magnetic resonance imaging.

**Figure 3** Photomicrograph (hematoxylin and eosin staining, original magnification, ×4) of the surgical specimen demonstrates an inner mucosal layer (arrows) within the cystic mass, along with a continuous muscular layer (asterisk) shared with the stomach.

## Abstract

### BACKGROUND

Duplication of the appendix is an infrequent congenital malformation with a complex classification. The horseshoe appendix is a subtype of the duplex appendix and is rarely reported in the literature. Endometriosis is a common gynecological disease that rarely occurs in the appendix. Moreover, horseshoe appendix combined with endometriosis has not been previously reported.

### CASE SUMMARY

Here, we describe a 44-year-old woman who was admitted with a 1-d history of migratory lower right quadrant pain. Physical examination was consistent with the signs of acute appendicitis. The patient underwent an emergency exploratory laparotomy. The distal tip of the appendix was in contact with the cecum by another base, or "horseshoe appendix". In addition, a small intestinal mass and an ovarian mass were identified. Subsequently, appendectomy, partial resection of the small intestine, and right oophorectomy were successively performed. The histopathology confirmed the diagnosis of acute inflammation of the duplex appendix with endometriosis, small intestine endometriosis, and ovarian endometriosis.

### CONCLUSION

Surgeons need to be aware of the possibility of the duplex appendix when performing an appendectomy, and this study emphasizes the importance of exploring the entire abdomen.

**Core tip:** We describe a patient with endometriosis of the duplex appendix, small intestine, and ovary. There are no similar cases reported. Currently, the diagnosis of duplex appendix and endometriosis is difficult before surgery. Our case suggests that serum carbohydrate antigen 125 levels and fecalith of the appendix may be useful signs for the diagnosis of endometriosis and duplex appendix, respectively. However, the most important procedure is the careful exploration of the abdominal cavity during surgery. Serious legal disputes can occur due to neglecting another infected appendix or not carefully exploring other parts of the abdominal cavity.

## INTRODUCTION

Acute appendicitis is the most common surgical emergency of the abdomen. The overall lifetime risk for acute appendicitis is 6.7% in females and 8.6% in males<sup>[1]</sup>. Duplication of the appendix is extremely rare and is usually incidentally found during surgery. A duplication of the appendix was first reported in the form of a case report in 1892<sup>[2]</sup>. To date, only a total of approximately 100 cases have been reported<sup>[3]</sup>. Endometriosis, as a common disease in women of childbearing age, predominantly occurs in the adnexa and less frequently in the digestive tract, especially in the small intestine and appendix. Here, we report a unique case of duplex appendix with acute appendicitis coexisting with appendiceal endometriosis in an adult female patient. In addition, endometriosis was found in the small intestine and ovary. The most special of the duplex appendix is the horseshoe appendix. To the best of our knowledge, only the abovementioned 14 cases have been reported thus far<sup>[4]</sup>, but there are no reports of horseshoe appendix combined with endometriosis. The classification, symptoms, and radiological appearance of the duplex appendix with endometriosis have been described in the literature and are discussed in this paper.

## CASE PRESENTATION

### Chief complaints

A 44-year-old Chinese woman was admitted to the Emergency Department of The Second Affiliated Hospital of Jiaxing University (Jiaxing, China) because of migratory lower right quadrant pain for 1 d associated with nausea, vomiting, and anorexia.

### History of present illness

She reported a 1-d medical history of migratory lower right quadrant pain that started as epigastric pain and became localized to the lower right abdominal quadrant, especially at McBurney's point. She also complained about nausea, vomiting, and anorexia.

### History of past illness

The patient had an 8-year history of repeated lower abdominal pain that appeared in the first 1-2 d of menstruation and disappeared after the end of menstruation. However, her menstrual cycle was regular, with no menorrhagia or dyspareunia reported. Therefore, she was not regularly seen in the gynecology clinic for several years.

### Personal and family history

The last menstrual period ended 5 d before admission. She had a history of caesarean section 18 years ago. No additional family history was presented.

### Physical examination upon admission

Her abdominal examination revealed that the abdomen was diffusely soft, nondistended, but presented tenderness, rebound tenderness, and guarding with a voluntary component in the lower right quadrant, and increased pain with coughing

at the McBurney's point, which were consistent with the signs of acute appendicitis. Moreover, Rovsing's sign was positive. No abdominal mass was palpable, and bowel sounds were normoactive.

### Laboratory examinations

Hematological examinations, including serum electrolyte levels, human chorionic gonadotropin, and complete blood count were within normal limits, apart from white blood cell count, carbohydrate antigen 125 (CA125), and C-reactive protein concentrations that were mildly elevated at  $10.1 \times 10^9/L$  (77.8% neutrophils), 69.5 U/mL, and 10 mg/L, respectively.

### Imaging examinations

A computed tomography (CT) scan of the abdomen showed that the appendix was markedly swollen and thickened and had obvious periappendicular leaking; additionally, two fecaliths were located at the root of the appendix (Figure 1). Simultaneously, the CT scan also showed a cystic mass in the right ovary (Figure 1). The findings from the patient's abdominal examination and CT scan were consistent with acute fecal appendicitis.

## FINAL DIAGNOSIS

Based on the above physical examination features and imaging data, a provisional diagnosis of acute appendicitis and right ovarian cyst was made.

## TREATMENT

Laparoscopic examination revealed moderate bloody fluid collections, and the omentum was localized to the right lower abdomen and pelvic cavity. Additionally, a cystic mass with a size of  $3.5 \text{ cm} \times 2.5 \text{ cm}$  was seen in the right ovary, which was not ruptured and was consistent with the CT scan findings. No evidence of endometrium was found by laparoscopic evaluation of the abdominal and pelvic cavities. Moreover, the appendix appeared unusually atrophic upon itself and measured  $3 \text{ cm} \times 2.5 \text{ cm}$  at the widest diameter, which was obviously inflamed, hyperemic, and swollen, which agreed with the preoperative diagnosis. However, we found a tight adhesion between the appendix, the lateral abdominal wall, and the posterior peritoneum, resulting in unclear anatomical structures that were difficult to separate. Therefore, a laparotomy was performed *via* an extended McBurney's incision in the lower right abdominal quadrant. After carefully separating the adhesions, an appendix was seen. Then, we attempted to separate the base of the appendix, and we were surprised to find that there were two bases that had their cavities both in contact with the cecum with each other through the appendiceal lumen, or "horseshoe appendix" (Figure 2). The two bases were positioned frontally on the cecum with a central mesoappendix, and the central mesoappendix vessel was fan-shaped. The proximal appendix stump and mesoappendix vessel were divided and ligated, and then the appendix was removed for pathological examination. Unfortunately, because there was no consideration of the rarity of this case, there were not enough intraoperative photographs remaining. Upon gross pathological inspection, the total length of the duplex appendix was approximately 6 cm. There were two cavities in the root of the cecum, both of which led to a swollen inflamed appendix containing a fecalith. Subsequently, a meticulous inspection of distal ileal segments and right tuboovarian structures was performed through palpation, and we unexpectedly found a hard mass, 10 cm proximal to the ileocecal valve, which gave rise to a mild stenosis of the intestine. Additionally, a right ovarian cyst was found, as previously mentioned. Hence, partial resection of the small intestine with end-to-end anastomosis was executed, as well as right oophorectomy by a gynecologist. Grossly, the soft tissue mass had a size of  $1.5 \text{ cm} \times 1.5 \text{ cm}$ , but the serosal surface and the mucosa were normal. The cut surface revealed hard nodular regions, which contained some small cystic spaces brimmed with both serous fluid and hemorrhage. The ovarian cyst showed that the cut surface also contained several small cystic spaces and was filled with chocolate-like cyst fluid and old bleeding.

## OUTCOME AND FOLLOW-UP

Hematoxylin and eosin staining revealed obvious acute and chronic inflammatory cell infiltration within and around the duplex appendix. The lumens of the two

**Figure 1** Computed tomography scan of the patient's abdomen. A and B: Transverse sections showing swelling of the appendix with surrounding exudation, and there is a fecalith at the root of the appendix, respectively; C: Coronal section showing swelling of the appendix with exudation and two separate fecaliths at its root; D: Transverse section showing a low density mass located in the right ovary.

appendixes were obstructed with fecalith. Meanwhile, several ectopic endometrial-type glands and stroma were found in the thickened muscularis propria of the duplex appendix (Figure 3), small intestine (Figure 3), and right ovary (Figure 3). Additionally, the glands were dilated, most of which contained hemorrhage within their cavities. Histological diagnoses of duplex appendix with fecalith and endometriosis were made, which caused acute appendicitis, and diagnoses of endometriosis of the small intestine and the right ovary were also made. These results were surprising discoveries. The patient subsequently recovered well with no complications and was discharged from the hospital on the 10th postoperative day. She was referred to a gynecological clinic for further assessment of her endometriosis. At the 6-month follow-up, there were no recurrences of abdominal pain or other clinical symptoms.

## DISCUSSION

Duplication of the digestive tract is a rare congenital malformation in adults because more than 80% of cases have serious abdominal or intestinal obstruction before the age of 2 years<sup>[5]</sup>. Appendiceal duplication is extremely rare and may be related to the duplication of other organs or other anomalies. Colons investigated 50000 pathological specimens of the appendix, and there were only just two cases of duplication<sup>[6]</sup>. The overall incidence of appendiceal duplication is approximately 0.004%<sup>[6]</sup>. Appendiceal duplication was first formally classified by Cave in 1936 and divided into three types based on their anatomic locations. Then, this classification was updated and amended in 1962 by Wallbridge<sup>[7]</sup> and is called the "Cave-Wallbridge" classification. Subsequently, this classification was further improved by Biermann *et al*<sup>[8]</sup> and Kjossev *et al*<sup>[9]</sup>, respectively. However, there were several cases that could not be classified according to the above classifications, for instance, horseshoe appendix and triplex appendix. We believe that an updated classification system is needed to distinguish appendiceal anomalies or to modify the present system. Therefore, Calotă *et al*<sup>[10]</sup> proposed a new classification system for appendiceal anomalies in 2010, which was divided into number anomalies and shape anomalies and was modified by Takabatake *et al*<sup>[11]</sup> again in 2016. The new classification system of appendiceal anomalies is presented in Table 1<sup>[4,10-13]</sup>. Most cases can be classified on

**Figure 2 Intraoperative photograph of the patient.** The intraoperative photograph shows that there are two bases of the appendix at the end of the cecum, and both of these bases are in contact with the cecum (black arrow).

the basis of the new classification. There have been 22 cases of Type A, 8 cases of Type B1, 46 cases of Type B2, 10 cases of Type C, 2 cases of triple appendix, and 14 cases of horseshoe appendix reported as of the beginning of 2018<sup>[3,4]</sup>. Although the duplex appendix is rare, surgeons should suspect the possibility of it when performing an appendectomy to prevent adverse consequences and medical disputes. In addition, a differential diagnosis is also necessary, including Meckel's diverticulum, colonic tumor, gastroenteritis, congenital cecal diverticulum, intussusceptions, and inflammatory bowel disease<sup>[14]</sup>. In the presence of a duplex appendix, the possibility of other congenital malformations should be further explored, especially in cases of Type B1 and Type C. However, Type B2, which is the most common variety and the most likely to be misdiagnosed or mismanaged, is unrelated to any other congenital anomalies<sup>[3]</sup>.

In the classification of duplex appendix, the horseshoe appendix is a rarer congenital malformation. In 1989, Mesko *et al*<sup>[15]</sup> first depicted the horseshoe appendix. Through a review of the literature, 14 patients with horseshoe appendix have been reported to date<sup>[4]</sup>, and as per our knowledge, our patient was the 15th patient with a reported horseshoe appendix. The etiology and pathogenesis of horseshoe appendix are still unclear because there are extremely limited cases that have been reported thus far. Currently, some theories have been proposed to explain how the horseshoe appendix forms<sup>[16]</sup>. First, the horseshoe appendix may form by the mutual fusion between the tip of the normal appendix and that of the abnormal appendix. Second, a horseshoe appendix may develop from the fusion between the tip of the appendix and another part of the cecum, which then becomes the second base. Third, in the embryonic period, the base of the appendix split into two parts, each of which develops continuously, resulting in two bases that are also single structures. However, the first two theories do not seem to explain why both appendices are supplied by a single blood vessel in the mesoappendix, and its branches fan out instead of forming an arcade. The study of the formation mechanism of the duplex appendix revealed that a "transient appendix" at the terminus of the cecum, which was distinct from the normal appendix, was observed during the 6th week of embryonic development and atrophy at the 7th week<sup>[17]</sup>. If the transient appendix does not disappear, a duplex appendix may form. Additionally, the horseshoe appendix, a subtype of the duplex appendix, may be caused by some abnormalities in the embryonic period. Therefore, the third theory is most likely to explain the formation of a horseshoe appendix. However, more research is needed to support this theory, because of the limited number of cases.

The horseshoe appendix can be divided into two types according to the following new classification system (Table 1): Frontal type, in which both bases of the appendix are not on the tenia, and sagittal type, in which the bases are along the tenia<sup>[11]</sup>. The malformation of our patient was a horseshoe type with a frontal location. In addition, we must simultaneously pay attention to whether the patient had other malformations because genitourinary, other intestinal, or vertebral malformations have been observed in cases with a duplex appendix. Fortunately, other associated congenital anomalies had not been observed in our patient, except for the endometriosis of the small intestine and ovary. Preoperative diagnosis is extremely difficult, whether it is a horseshoe appendix or other types of duplex appendix. It has been reported that<sup>[4]</sup> ultrasound and three-dimensional reconstruction may be helpful for the preoperative diagnosis of a horseshoe appendix, but most cases are accidentally discovered during surgery, and only two patients had a clear diagnosis before

**Figure 3** Histopathological appearances of the endometriosis in appendix, small intestine, and ovary. A: Hematoxylin and eosin (HE) staining shows that ectopic endometrial-type glands and stroma (thick arrows) were detected in the muscular layers (thin arrows) of the appendix ( $\times 40$ ); B: Ectopic endometrial-type glands and stroma (thick arrows) were observed in the subserosa of the small intestine. The muscular layers are indicated by thin arrows (HE,  $\times 40$ ); C: Higher magnification of endometriosis (thick arrows) in the ovary (HE,  $\times 100$ ).

surgery. In our patient, imaging failed to preoperatively diagnose appendiceal anomalies. However, after surgery, we reviewed the CT scan repeatedly, and the images showed that there were two free fecaliths at the root of the appendix, which may indicate the presence of a duplex appendix (Figure 1). This finding was easily ignored.

Endometriosis, which is defined as the growth of endometrial glands and stroma outside the uterine cavity, is a fairly common disease that affects up to 15% of women in childbearing age. Von Rokitansky first described endometriosis in 1860<sup>[18]</sup>. Several theories have been proposed to explain the pathogenesis of endometriosis, including retrograde menstruation and implantation theory, coelomic metaplasia theory, lymphovascular spread theory, direct transplantation and dissemination theory, and the cellular immunity theory which was a newly developed theory<sup>[19-21]</sup>. However, the specific etiology of endometriosis is still unclear. A variety of factors potentially contribute to the disease. Endometriosis can occur anywhere in the body, including pelvic organs, gastrointestinal tract, and pleural and pericardial cavities, but the ambilateral adnexa is the most frequent. Once involving the gastrointestinal tract, endometriosis also commonly involves the recto-sigmoid (72%), recto-vaginal septum (13%), small intestine (7%), cecum (3.6%), and appendix (3%)<sup>[18]</sup>. Endometriosis of the appendix is a rare disease, and its overall incidence ranges between 0.02% and 36.6%, which is widely variable and depends on the population being evaluated<sup>[22]</sup>. Our patient not only had rare appendix and ileum involvement but also had a duplex appendix. This dual participation has not been observed thus far.

Clinically, the symptoms of endometriosis are diverse and have been determined by the site of occurrence. Endometriosis of the appendix is usually asymptomatic, but it may also cause acute or chronic pelvic pain, appendicitis, lower gastrointestinal hemorrhage, and intussusception<sup>[19,22]</sup>. Consistent with some reports (Table 2)<sup>[19,23-27]</sup>, our patient also presented the symptoms of acute appendicitis. Moreover, laparoscopic exploration also showed the presence of bloody fluid in the abdominal cavity. The hemoperitoneum is likely to be related to menstruation, because in these reports (Table 2), patients presented the symptoms of acute appendicitis during the menstrual period. As our patient presented the symptoms of appendicitis on the 5th day after the end of menstruation, we assume it to be related to the appendiceal fecalith. The occurrence of acute appendicitis may be the result of the dual effects of endometriosis and appendiceal fecalith. Moreover, our patient had a history of

**Table 1** New classification of appendiceal anomalies

Number anomalies
Agenesis: Absence of appendix
Duplex appendix
Type A: Partial duplication with both appendices sharing a common base like "Y-shaped" on a single cecum
Type B: Complete duplication of the appendix on a single cecum
B1 avian type: Two appendices symmetrically placed on either side of the ileocecal valve
B2 tenia coli cecum type: One appendix arising from the usual site of the cecum and the other arising from the cecum along the tenia
B3 tenia coli hepatic flexure type: One appendix arising from the usual site of the cecum and the other arising from the hepatic flexure of the colon along the tenia
B4 tenia coli splenic flexure type: One appendix arising from the usual site of the cecum and the other arising from the splenic flexure of the colon along the tenia
Type C: Duplication of the cecum, each having its own appendix
Triplex appendix: Complete triplication of appendix on the cecum
Horseshoe appendix
With sagittal disposal: The bases of the appendix are along the tenia in sagittal direction
With frontal disposal: The bases of the appendix are not on the tenia

Data from these studies<sup>[4,10-13]</sup>.

repeated lower abdominal pain which was associated with menstruation, consistent with some reports<sup>[23,26,27]</sup>. It suggests that hemoperitoneum and chronic abdominal pain may be important signs of endometriosis diagnosis, which further validates the theory of retrograde menstruation. Additionally, gastrointestinal endometriosis can present with episodes of abdominal pain, change in bowel habits, abdominal distention, rectal bleeding, and intestinal obstruction<sup>[28-30]</sup>. Fortunately, although small intestinal endometriosis in our case was asymptomatic, it did not cause intestinal obstruction due to timely detection.

The clinical manifestations of endometriosis are usually nonspecific, leading to the diagnostic dilemma. Therefore, complete preoperative examination is needed, including CT scan, magnetic resonance imaging (MRI), abdominal ultrasonography, and laboratory examination. It was reported that<sup>[31]</sup> multislice CT has a great potential for detecting alterations in the intestinal wall, especially when combined with enteroclysis. MRI has a high sensitivity (77%-93%) in the diagnosis of bowel endometriosis<sup>[32]</sup>. Unfortunately, there is currently no gold standard for the imaging diagnosis of endometriosis<sup>[20]</sup>. The serum CA125 level, which has been used to monitor the progress of endometriosis, may be a useful diagnostic indicator<sup>[33]</sup>. However, it has also been reported that CA125 is not sensitive enough to the diagnosis of endometriosis<sup>[30]</sup>. In our patient, the abdominal CT scan did not suggest endometriosis, but she had a high preoperative serum CA125 level of 69.5 U/mL. Therefore, we believe that the presence of endometriosis needs to be suspected when patient have elevated serum CA125 levels. Additionally, except for the hemoperitoneum we have mentioned above, blueberry spot of the peritoneum and nodularity of the appendix may also indicate the presence of endometriosis during surgery<sup>[19,23]</sup>. Intraoperatively, we only found moderate hemorrhagic peritoneal fluid in our patient. However, the postoperative pathology of our patient confirmed the presence of endometriosis in the appendix, small intestine, and ovary. Therefore, laparoscopy and pathological confirmation remain the gold standard for the diagnosis of endometriosis. Given the nature of endometriosis, patients such as ours should be encouraged to refer to gynecologists for further assessment of the extent of endometriosis and for postoperative follow-up.

## CONCLUSION

Acute appendicitis is a common abdominal disease. Although duplex appendix is rare, especially the horseshoe appendix, surgeons who may not encounter it throughout their careers need to be aware of the possibility of it when performing an appendectomy. In particular, preoperative CT showed two separate fecaliths at the root of the appendix, which may be a useful sign for the diagnosis of a duplex appendix. Therefore, a detailed exploration of the cecal pole and retrocecal space is encouraged to avoid misdiagnosis during surgery; misdiagnosis of appendix

Table 2 Clinical features of patients with appendix endometriosis

Ref.	Year	Age	Symptoms	Previous history	Episode time	Hemoperitoneum
Uncu <i>et al</i> <sup>[25]</sup>	2008	45	Abdominal pain and nausea	Not described	The second day of menstruation	Yes
Akbulut <i>et al</i> <sup>[26]</sup>	2009	40	Lower right quadrant pain	Lower right abdominal pain before every menstrual period for 8 or 9 yr	The third day of menstruation	Not described
Uwaezuoke <i>et al</i> <sup>[23]</sup>	2013	29	Right iliac fossa pain	One-year history of recurrent lower abdominal pain	The second day of menstruation	Yes
Curbelo-Peña <i>et al</i> <sup>[24]</sup>	2015	39	Right iliac fossa pain	Not described	Be menstruating at the time	Yes
Shen <i>et al</i> <sup>[27]</sup>	2016	34	Right iliac fossa pain	Repeated abdominal pain associated with menstruation for several months	The second day of menstruation	Yes
St John <i>et al</i> <sup>[19]</sup>	2018	29	Migratory lower right quadrant pain	Not described	The second day of menstruation	Yes
Our case	2019	44	Migratory lower right quadrant pain	Eight-year history of repeated lower abdominal pain	Five days after the last menstrual period ended	Yes

duplication may result in a poor clinical outcome and law dispute. In addition, women of childbearing age who have chronic pelvic pain or elevated CA125 levels need to highly suspect the possibility of endometriosis. In summary, whether laparoscopy or laparotomy is used, careful exploration of the entire abdomen is crucial and occasionally surprises us.

## ACKNOWLEDGEMENTS

We wish to acknowledge Wen-Yan Shen (Department of Pathology, The Second Affiliated Hospital of Jiaying University, Jiaying) for her support on this case.

### Abstract

#### BACKGROUND

Venous thrombosis (VT) is one of the minor complications of pacemaker lead extraction. It is often found due to the swelling of the limbs after the extraction. It is easy to be neglected or even misdiagnosed in the absence of typical clinical symptoms. The incidence, risk factors, and long-term impact of this complication are still unclear. Herein, we report a case of deep VT caused by transvenous lead extraction, which is easily misdiagnosed.

#### CASE SUMMARY

A 66-year-old woman underwent a pacemaker lead extraction at our hospital because of a pacemaker pocket infection. After the extraction, she began to experience intermittent fever accompanied by sweating. The highest body temperature recorded was 37.9 °C. Additionally, she reported migratory pain that made her uncomfortable. The pain was mistakenly thought to be caused by operation trauma. At first, the pain radiated from the left chest to the mandible. Then, the pain in the left chest was alleviated, but pain in the left neck and throat appeared. Finally, the pain was confined to the mandible and a submandibular mass was palpated with no other abnormalities upon physical examination. Computed tomography venography and angiography finally indicated that the fever and pain were the symptoms of thrombophlebitis caused by lead extraction. The patient was then treated with rivaroxaban for more than three months and has shown no symptoms since she left the hospital.

#### CONCLUSION

The possibility of thrombosis should be considered when pain and recurrent fever occur after pacemaker lead extraction.

**Core tip:** Deep venous thrombosis caused by transvenous lead extraction is easily missed. The exact incidence is still unclear. Thrombosis after lead extraction during hospitalization should be identified early even without typical symptoms such as edema. Additionally, reasonable and standard anticoagulation therapy after lead extraction should be considered in the future.

## INTRODUCTION

With the increasing use of cardiovascular implantable electronic devices (CIEDs), increasing attention has been paid to the safety and complications of lead extraction after CIED implantation. The indications of transvenous lead extraction (TLE) include infection, venous stenosis and occlusion, lead malfunction, lead perforation, arrhythmias, as well as radiation therapy<sup>[1]</sup>. Complications of TLE include cardiac avulsion, vascular laceration, pericardial effusion, hemothorax, pulmonary embolism, pocket hematoma, venous thrombosis (VT), *etc*<sup>[1]</sup>. Among them, VT caused by TLE is easily missed in the clinic, and the incidence is unclear. The following case shows that VT can be caused by TLE and is characterized by intermittent fever and neck pain.

## CASE PRESENTATION

### Chief complaints

A 66-year-old woman was admitted to our hospital due to infection of the pacemaker pocket for one month.

### History of present illness

The patient was diagnosed with sick sinus syndrome for which she received a dual-chamber pacemaker 10 years ago. One month prior to admission, after carrying a heavy burden, she found redness and swelling at the pocket site, which gradually ulcerated. The local hospital gave her an antiinfection treatment of cephalosporin for a week, but the outcome was not positive. Therefore, she was transferred to our hospital for further treatment.

### History of past illness

The patient had a history of hypertension, type 2 diabetes mellitus, and chronic gastric ulcer. She underwent a meningioma resection 7 years earlier and cataract surgery in both eyes 8 years earlier. The patient had no history of hepatitis or tuberculosis.

### Personal and family history

The patient had no significant past history or family history.

### Physical examination upon admission

The patient's blood pressure and blood glucose were well controlled by medication. Her body temperature was normal three days before the operation.

Except for swelling and ulceration at the pocket site, other physical examination results were normal. There were no abnormalities in the laboratory examination, electrocardiogram, chest X-ray, or preoperative echocardiogram. Multiple blood cultures were negative before the preventative use of vancomycin 0.5 g/q8h.

### Laboratory examinations

After excluding the contraindication of operation, the left leads were extracted successfully, and a temporary pacemaker was implanted on the other side. Intraoperative angiography revealed patency of the bilateral subclavian veins (Figure 1). The results of the pacemaker pocket tissue and lead culture showed the presence of

*Staphylococcus epidermidis*, which is sensitive to vancomycin. Vancomycin was used continuously after the operation. The next day after the operation, the patient complained of pain radiating from the left chest to the mandible, with a pain score of 6. She began to present intermittent fever accompanied by sweating. Therefore, blood cultures were performed at that time; however, the results were negative. The serum concentration of vancomycin was up to standard. Three days after the operation, the patient felt that the pain in the left chest was alleviated, but increased pain in the left neck and throat accompanied by an irregular cough (dry cough, no sputum) appeared. Physical examination showed neck tenderness, normal tonsils, and a normal uvula. A few days later, the patient still had an intermittent low fever with sweating. Laboratory examination showed that routine blood and procalcitonin levels were normal, the erythrocyte sedimentation rate (ESR) was 44 mm/h, and the hypersensitive C-reactive protein (CRP) level was 45.6 mg/L. The operation incision and temporary pacemaker placement site were observed to be dry and clean without redness, burning, effusion, or pus. Seven days after the extraction, the patient felt relieved of pain in the left chest and neck and said that the pain was confined to the mandible. A submandibular mass was found through palpation. Routine blood tests, blood biochemical indexes, and procalcitonin levels were normal. Her ESR was 65 mm/h, hypersensitive CRP was 57.4 mg/L, plasma D-dimers was 9.58 mg/L, and fibrinogen was 5.6 g/L.

### Imaging examination

Color Doppler ultrasound showed left internal jugular vein thrombosis. Occlusion of the left common jugular vein, internal and external jugular veins, and subclavian vein was further demonstrated by computed tomography venography (CTV) (Figure 2). The patient refused the intravenous or subcutaneous use of anticoagulants; therefore, rivaroxaban was given.

## FINAL DIAGNOSIS

VT after pacemaker lead extraction caused the symptoms of the patient.

## TREATMENT

After 2 d of anticoagulant treatment with 15 mg rivaroxaban bid, the patient's temperature returned to normal (Figure 3), and no further neck pain was reported. Permanent pacemaker implantation on the right side was performed 5 d after anticoagulant therapy. Intraoperative angiography revealed occlusion of the left subclavian veins (Figure 4). Anticoagulant drugs were discontinued 24 h before implantation and were resumed 48 h after the operation.

## OUTCOME AND FOLLOW-UP

Hypersensitive CRP and ESR showed a downward trend after anticoagulant therapy, and the patient was discharged from the hospital when her condition was stable. Clinical follow-up was conducted by telephone interviews with the patient. Rivaroxaban 15 mg bid was used for 21 d after the thrombosis was found, followed by 20 mg qd. The total rivaroxaban treatment lasted more than three months. The patient has shown no symptoms since she left the hospital.

## DISCUSSION

Complications caused by TLE include major complications, minor complications, and death within 48 h after lead extraction<sup>[2]</sup>. Major complications are life-threatening or fatal complications, such as cardiac avulsion, vascular avulsion, stroke, and bleeding requiring transfusion. Minor complications include hematoma, hemothorax, VT and others that are not life-threatening to the human body. There has been a case report of thrombosis caused by TLE in the past. Hanninen *et al*<sup>[3]</sup> reported thrombosis extending from the right atrium to the right ventricular outflow after TLE, and the huge thrombus disappeared after anticoagulation treatment. The trauma of TLE might be the cause of thrombosis. Wazni *et al*<sup>[4]</sup> reported that the incidence of VT caused by TLE was 0.21%. A single-center study by Kennergren *et al*<sup>[5]</sup> found three patients with postoperative thrombosis in 647 patients, which indicated that the incidence was

**Figure 1** Intraoperative angiography revealed patency of the bilateral subclavian veins before the left lead extraction.

0.5%. Wilkoff *et al*<sup>[6]</sup> studied TLE in 301 patients, and three of whom presented VT; therefore, the incidence was 1%. However, Bracke *et al*<sup>[7]</sup> indicated that the incidence of VT caused by TLE was more than 8%. In our center, bilateral venography was performed routinely before TLE and the implantation of a new pacemaker. Since 2013, we have conducted TLEs in 240 patients in our center. This patient was the first to suffer VT after TLE and before the implantation of a new pacemaker. However, we may have underestimated the incidence as we did not follow these patients after the new CIEDs were implanted. The exact incidence of this complication is unclear due to the different follow-up times of each researcher and the underestimation of atypical clinical symptoms caused by this complication. However, neglect of pulmonary embolism and other complications caused by deep VT might increase hospitalization rates and mortality<sup>[8]</sup>.

Edema of the affected extremity is reported as the most typical symptom of upper-extremity deep VT<sup>[9]</sup>. Some patients may also suffer from pain or erythema, which occurs less often in upper-extremity deep VT<sup>[9]</sup>. Approximately 5% of deep VT patients are asymptomatic<sup>[9]</sup>. Similarly, edema is also a symptom with a prompting effect of VT caused by TLE<sup>[1,6,10]</sup>. CTV and venography can produce a definitive diagnosis.

Fever is reported to have the lowest predictive value of VT<sup>[11]</sup>. In our center, 82 of 240 patients had newly fever after TLE. Among them, 32 patients had a definite etiology: 13 were due to drug fever, 9 due to pulmonary infections, 5 to bacteremia, and 1 each to hyperthyroidism, cancer, gout, viral infection, and thrombophlebitis. In the remaining 50 people, we did not find a clear cause of fever and the average body temperature of them was lower than 38 °C. They might have suffered from physiological fever caused by operative trauma or neglected pathological fever<sup>[12]</sup>.

The patient we reported lacked typical symptoms. We first considered that the fever that occurred after TLE was caused by infection because infection was the primary post-procedure complication of significance<sup>[1]</sup>. However, the results of laboratory tests did not support this diagnosis. We also considered that the patient might have a drug fever because previous literature reported that using vancomycin can lead to a drug fever in some patients<sup>[13]</sup>. However, this was ruled out because the body temperature returned to normal without the cessation of vancomycin. Additionally, we had no evidence to suspect that the fever was caused by tumors or autoimmune diseases because the related examinations were negative. The patient complained of neck pain. First, we only considered that the pain was caused by operation trauma and neglected that the pain might be caused by thrombophlebitis.

In retrospect, the patient had a pacemaker implanted for more than ten years, which might lead to severe adhesion between wire, tissue, and blood vessels. Therefore, thrombophlebitis occurred after the extraction of the leads, resulting in recurrent fever. After thrombosis of the left subclavian vein, it further spread to the left internal jugular vein. Therefore, her neck pain was related to thrombotic occlusion of the internal jugular vein. Venography indicated collateral circulation formation, so there was no swelling of the upper limbs or face. Postoperative fever prevented the implantation of the new pacemaker and prolonged her hospital stay. After anticoagulation treatment, her body temperature returned to normal. However, anticoagulation treatment might increase the risk of hematoma formation after pacemaker implantation<sup>[14]</sup>. Recent studies have shown that pocket hematoma increases the risk of device-related infection<sup>[15,16]</sup>.

We hypothesize that the incidence of VT caused by TLE is higher than that reported

**Figure 2** Computed tomography venography showed occlusion of the left common jugular vein, internal and external jugular veins, and subclavian vein.

previously in the literature. We might underestimate the incidence because of the lack of symptoms and short follow-up time. There are no clear guidelines regarding effective and safe anticoagulation strategies for patients with VT after TLE, especially in those who need new CIEDs implanted after TLE. As clinicians, we need to reduce misdiagnoses, and we should be alert to the possibility of VT when patients suffer from recurrent fever and neck pain after TLE.

---

## CONCLUSION

---

We need pay more attention to the VT caused by pacemaker lead extraction, both in clinical work and in research fields.

Figure 3 Body temperature returned to normal after administration of rivaroxaban for two days.

Figure 4 Intraoperative angiography showed that the right subclavian vein was open and the left subclavian vein was occluded accompanied by collateral circulation establishment.

### Abstract

#### BACKGROUND

Cystic fibrosis (CF) is rare in Asian populations relative to the Caucasian population. In this paper, we report the cystic fibrosis transmembrane conductance regulator (CFTR) variation in a family of Chinese CF patients, and systematically review the previous literature.

#### CASE SUMMARY

Here we report a 30-month-old Chinese girl who was diagnosed with CF based on her history and symptoms such as recurrent productive cough, wheezing with repeated infection of *Pseudomonas aeruginosa*, and paranasitis. Chest computed tomography (CT) scanning revealed obvious exudative lesions and bilateral bronchiectasis. Liver CT scanning revealed a low-density lesion in the left lobe of the liver. A diagnosis of CF was made based upon *CFTR* gene tests. The *CFTR* gene was sequenced using the blood samples of her and her parents and showed a heterozygous novel missense mutation of c.753\_754delAG in exon 7. In addition, a heterozygous c.1240 C>T mutation was found in exon 10 of the *CFTR*. The mutation c.753\_754delAG was verified to have been inherited from her mother, and the c.1240 C>T mutation was from her father who was diagnosed with congenital absence of vas deferens.

#### CONCLUSION

A novel mutation of *CFTR*, c.753\_754delAG, was found in a Chinese CF child. c.2909G>A is the most common mutation among Chinese CF patients.

**Core tip:** Cystic fibrosis (CF) is an autosomal recessive inherited disease caused by mutations in the CF transmembrane conduction regulator (*CFTR*) gene. CF is rare in Chinese. ΔF508 is the most common mutation, accounting for greater than two-thirds of CF alleles worldwide, though it is not a predominant mutation in Chinese CF patients. In this paper, we report a novel homozygous complex rearrangement involving *CFTR* exon 7 deletion (c.753\_754delAG chr7-117176607-117176608) in a Chinese child with CF and describe the clinical feature. Moreover, we further review the literature regarding gene mutations in Chinese CF cases from the 1970s to 2017.

## INTRODUCTION

Cystic fibrosis (CF) is an autosomal recessive inherited disease caused by mutations in the CF transmembrane conduction regulator (*CFTR*) gene. CF is most common in the Caucasian population, with a prevalence of 1/2500-3500 among those with Northern European ancestry<sup>[1,2]</sup>. CF was once considered extremely rare among the Chinese population, and to date, only about 60 cases of CF have been diagnosed in China<sup>[3]</sup>. *CFTR* is responsible for regulating the flow of chloride ions across the epithelial membrane. Since *CFTR* was first identified as the pathogenic gene of CF in 1989, more than 2000 mutations have been found in CF patients, according to the Cystic Fibrosis Mutation Database (<http://www.genet.sickkids.on.ca>). ΔF508 is the most common mutation, accounting for greater than two-thirds of CF alleles worldwide, though it is not a predominant mutation in Chinese CF patients<sup>[4]</sup>. The most common gene mutation in Chinese children with CF is c.2909G-A<sup>[5]</sup>. With increased awareness of this disease and improvements in diagnostic techniques, we have found that CF is not as rare as once believed in the Chinese population. The novel variants c.699 C-A, c.579+1\_579+2insACAT, c.1117-1G>C, c.3140-454\_c.3367+249del931ins13, and p.R1048\_G1123del have been reported in CF patients from China in recent years<sup>[6-8]</sup>. Interestingly, the gene mutation spectrum of *CFTR* in Chinese patients with CF is significantly different from that in Caucasian patients. Therefore, it is necessary to establish the Chinese *CFTR* gene mutation database, which will facilitate the genetic diagnosis of CF patients in China. In the present study, we identified a novel homozygous complex rearrangement involving *CFTR* exon 7 deletion (c.753\_754delAG chr7-117176607-117176608) using multiplex ligation-dependent probe amplification analysis in a Chinese child with CF. We further review the literature regarding Chinese CF patients from the 1970s to 2017. The clinical data of all identified CF patients are summarized.

## CASE PRESENTATION

### Chief complaints

A girl aged 2 years and 10 months was admitted to Children's Hospital of Soochow University in May 2018 due to recurrent productive cough and wheezing lasting for 1 month.

### History of past illness

She had experienced recurrent pneumonia (2-3 times every year) beginning 4 mo after birth, with repeated infection by *Pseudomonas aeruginosa* and paranasitis, but without a history of chronic diarrhea or pancreatic involvement.

### Personal and family history

The child was conceived through *in vitro* fertilization. Her father had been diagnosed with congenital absence of vas deferens, and her mother was healthy.

### Physical examination

She weighed 11 kg, her height was 89 cm, her body mass index was 13.9, and she

presented with shortness of breath and dyspnea. Crackles and wheezing rales were present in bilateral lungs. The heart and abdomen were normal. No clubbed digits were found.

### Laboratory examinations

Blood routine examination showed a white blood cell count of  $15.59 \times 10^9/L$ , a C reactive protein concentration of 55.4 mg/L, and positivity for *Pseudomonas aeruginosa* on bronchoalveolar lavage fluid culture. Findings on other tests, including serum electrolyte measurement, fungus culture, Glactomannan test, T-SPOT tuberculosis test, allergic bronchopulmonary aspergillosis and aspergillus fumigatus specific IgE detection were all negative.

### Imaging examinations

Chest computed tomography (CT) scanning revealed obvious exudative lesions and bilateral bronchiectasis (Figures 1 and 2). Sinus CT scanning revealed bilateral paranasitis. Liver CT scanning revealed a low-density lesion in the left lobe of the liver. In patients with CF, the liver is also the organ affected by the dense secretion of digestive juice. Bile secreted by the liver can clog bile ducts and damage the liver. Ultrasonography of the pancreas was negative.

### CFTR gene sequence analysis

Two heterozygous mutations were found in the CF patient by Sanger sequencing analysis. A heterozygous novel missense mutation of c.753\_754delAG chr7-117176607-117176608 was identified in exon 7 (Figure 3), which was inherited from her mother based on its identification in the mother's sample as well (Figure 3). This novel mutation has not yet been recorded in the CFTR mutation database (<http://www.genet.sickkids.on.ca>). In addition, a heterozygous c.1240 C>T mutation in exon 10 was observed in CFTR of the CF patient (Figure 4), which was inherited from her father and had already been included in the CFTR mutation database.

---

## FINAL DIAGNOSIS

---

CF.

---

## TREATMENT

---

Her symptoms improved after antibiotic treatment with ceftazidime for 3 wk, expectorant, and nutritional support treatment including fat-soluble vitamins and powdered milk with high calorie.

---

## OUTCOME AND FOLLOW-UP

---

After being discharged from our hospital, the children were followed monthly in the outpatient clinic. We gave low dose azithromycin anti-inflammatory treatment to eradicate *P. aeruginosa* infection. We did regular examinations of respiratory rate, oxygen saturation, and high-resolution CT of the chest to evaluate the pulmonary disease regression/progression. We introduced regular atomized bronchodilators such as terbutaline and oral secretion expellant including acetylcysteine to help remove respiratory secretions. She had one time of pulmonary infection. The general situation remained well up to date. She weighed 13 kg, her height was 95 cm, and her body mass index was 14.4.

---

## DISCUSSION

---

CF is characterized by the abnormal transport of ions and fluid across epithelial cell membranes, resulting from mutations on both alleles in the gene encoding the CFTR<sup>[9,10]</sup>. CFTR mutations can cause secretions to obstruct the airway, pancreatic tract, and biliary tract and lead to abnormal secretion by the sweat glands. The most important organ to be invaded in CF is the lung, and lung disease is the most lethal factor (85%)<sup>[11]</sup>. The pancreas is also an important affected organ in CF. Disorders caused by CF include nutritional disorders (fat, protein malabsorption, and fatty diarrhea) and growth retardation. Low body weight caused by pancreatic insufficiency is negatively correlated with lung function and survival rate, and thus,

**Figure 1** Chest computed tomography images of the cystic fibrosis patient. A chest computed tomography scan showed obvious exudative lesions and bilateral bronchiectasis in the lung of the cystic fibrosis patient.

an important factor for poor prognosis<sup>[12]</sup>. Malnutrition and gastrointestinal symptoms are relatively mild and atypical in Chinese CF patients. Therefore, it is easy for CF diagnosis to be missed or delayed.

For patients with one or more clinical characteristics, such as chronic sinopulmonary disease, gastrointestinal and nutritional abnormalities, genital abnormalities in males resulting in obstructive azoospermia, and/or a family history of CF, the measurement of sweat electrolyte concentrations has been the mainstay of CF diagnosis since the standardized procedure was introduced<sup>[13]</sup>. In the CF case reported here, the patient had chronic sinopulmonary disease, and her father had a CF mutation with obstructive azoospermia. These patients should undergo repeat sweat chloride testing and further evaluation, including detailed clinical assessment and more extensive *CFTR* gene mutation analysis. CF in Chinese patients is difficult to diagnose, due to insufficient understanding and because sweat examination as well as genetic testing cannot be carried out in most hospitals. It is necessary to educate Chinese pediatricians concerning the clinical manifestations and diagnostic criteria for CF and to promote the implementation of the sweat chloride test.

*CFTR* mutations are divided into five general classes: mutations affecting biosynthesis, mutations interfering with protein maturation, mutations influencing Cl<sup>-</sup> channel regulation, mutations intervening Cl<sup>-</sup> conductance or channel gating, and mutations that reduce *CFTR* synthesis<sup>[14]</sup>. Different types of *CFTR* mutations can cause different clinical phenotypes: I, II, and III mutations are prone to cause pancreatic insufficiency with more serious clinical manifestations. In contrast, because normal Cl<sup>-</sup> channel function is partially retained, the clinical symptoms of IV and V mutations are relatively mild with pancreatic function remaining normal.

Several studies have demonstrated that p.F508del is the most common mutation in Caucasian CF patients, accounting for approximately 70% of cases<sup>[4,5]</sup>. The p. F508del mutation is a type II mutation. We review 82 different mutations among 69 Chinese CF patients (40 females and 29 males) reported from the 1970s to 2017. Among them, 53 were from mainland China, 9 from Taiwan, and 4 from Hongkong, with the remaining patients being of Chinese and Vietnamese descent, Chinese and Portuguese descent<sup>[7,8,15-40]</sup> (Table 1). The age at diagnosis ranged from 0.17 months to 23 years.

Among the Chinese CF patients, the c.2909 G>A variant was the most common mutation type (11%), followed by 1898+5G>T (7.3%), c.293A>G (6.1%), and 2215insG+G2816A and c.263T>G (both 4.9%). Nevertheless, no p.F508del mutation was found in the Chinese patients (Table 1). In addition, with the exceptions of c.3909 C>G, R553X, and c.1000 C>T, none of the *CFTR* mutations in the Chinese patients were present in the common Caucasian *CFTR* mutation-screening panels, indicating that the mutations identified in Chinese CF patients are obviously different from the common gene mutations in Caucasian CF patients. Further, pulmonary lesions were more prominent in Chinese CF patients with or without pancreatic insufficiency<sup>[6-8,26,27]</sup>. Therefore, it is necessary to establish a Chinese gene mutation database to facilitate genetic diagnosis of CF in China to clarify the relationship between genotype and clinical phenotype.

In the case reported herein, the c.1240C>T mutation resulted in the alteration of amino acid p.Q414\* (glutamine > termination). This mutation type has been reported already as a pathogenic mutation in the HGMD pro database<sup>[14]</sup>. c.753\_754A del A.G is a novel mutation (deletion mutation) that results in amino acid changes P.R251Sfs \* 6 (frame-shifting mutation - 6 termination). According to the ACMG guidelines, the mutation site c.753\_754delAG could be classified as a pathogenic mutation<sup>[39]</sup>. Both

**Figure 2** Liver computed tomography image of the cystic fibrosis patient. A liver computed tomography scan revealed a low-density lesion in the left lobe of the liver.

mutations could result in the early termination of CFTR protein translation, which might have a great impact on protein function. The double heterozygous mutation came from the patient's parents separately. As a compound heterozygous mutation, it is consistent with autosomal recessive inheritance and is a theoretically possible cause of disease. This case expands the mutation spectrum of *CFTR* in patients of Chinese origin. Several studies have shown that only pancreatic function correlates well with *CFTR* genotypes<sup>[40,41]</sup>. According to the pancreatic status of patients, CF mutations can be subdivided into two groups: mild and severe mutations<sup>[40]</sup>. Patients with pancreatic insufficiency are homozygous or compound heterozygous with two "severe" mutations, whereas patients with pancreatic sufficiency have at least one "mild" allele. As it is not clear from the case if the patient had pancreatic sufficiency or insufficiency, we cannot deduce whether the two mutations were severe mutations or not. Elevated serum lipase, which has not been mentioned before, is not a sign of severe mutation, more of possible pancreatitis which is more commonly seen in heterozygous CF carriers or in those with milder mutations and pancreatic sufficiency.

---

## CONCLUSION

---

In conclusion, a novel compound heterozygous c.753\_754delAG mutation was found in exon 7 of *CFTR* in the case reported herein. The common *CFTR* mutation spectrum in Chinese CF patients is quite different from that in Caucasian patients. Therefore, the Chinese common *CFTR* mutation spectrum provides valuable data for CF diagnosis in Chinese patients and the development of a commercial Chinese *CFTR* genetic screening kit. The relevant Chinese gene mutation database is urgently needed.

## Abstract

### BACKGROUND

Most major abdominal vascular injuries are caused by penetrating injuries. A common iliac artery occlusion caused by blunt force trauma is rare, and very few cases have been reported. Because of this low incidence, atypical symptoms, and frequent association with other severe injuries, the proper diagnosis tends to be missed or delayed. The gold standard for diagnosis is angiography, and treatment remains a challenge.

### CASE SUMMARY

We report here the unusual case of a common iliac artery occlusion caused by blunt abdominal compressive trauma, with transection of the small intestine. At presentation, the patient (a 56-year-old man) complained of pain and numbness in the left lower extremity and severe pain in the whole abdomen. Physical examination showed total abdominal tenderness with evidence of peritoneal irritation. The left lower limb was pulseless and cold. Abdominal computed tomography examination revealed digestive tract perforation, and abdominal computed tomography angiography showed left common iliac artery occlusion. The patient was treated successfully by anastomosis of the intestine, percutaneous transluminal angioplasty, and stenting. The patient was followed for more than 11 mo after the operation and showed a good recovery.

### CONCLUSION

Patients with abdominal trauma should be suspected of having major vascular

**Core tip:** Most major abdominal vascular injuries are caused by penetrating injuries. As a subset of arterial blunt trauma, the percentage of iliac arterial injury is small. Common iliac artery occlusion in blunt trauma is especially uncommon. We report such a rare case here. Furthermore, we review the reported cases in the English literature and provide a discussion on the mechanism of injury, clinical presentation and signs, diagnosis, surgical modalities, and outcome.

## INTRODUCTION

Penetrating rather than blunt trauma causes the greatest majority of vascular injuries. As a subset of arterial blunt trauma, the percentage of iliac arterial injury is small. The largest review of these cases in the literature was published by Tuech *et al*<sup>[1]</sup>, who reviewed 9 patients with common iliac artery occlusion in blunt trauma. We add to these rare cases in the literature by reporting a new case here. Furthermore, we review 7 cases reported between the years of 2001 and 2018, and discuss the mechanism of injury, clinical presentation and signs, diagnosis, surgical modalities, and outcome.

## CASE PRESENTATION

### Chief complaints

A 56-year-old male steel worker's lower abdomen had been compressed between two forklifts. He was admitted to the People's Hospital of Jingjiang with pain and numbness in the left lower extremity and severe pain throughout the entire abdomen, especially in the lower abdomen.

### History of past illness

The patient had no significant medical history.

### Family history

The patient had no significant family history.

### Physical examination

The patient showed clear consciousness upon presentation. Physical examination showed stable vital signs, including blood pressure of 136/68 mmHg (normal range: 90-140/60-90 mmHg), pulse rate of 95/min (normal range: 60/min-100/min), respiratory rate of 16/min (normal range: 16/min-20/min), and temperature of 37.0 °C (normal range: 36.1°C-37°C). No obvious contusion of the abdominal wall or the left lower limb was noted. He had total abdomen tenderness, with evidence of peritoneal irritation and obvious board-like rigidity of the abdomen. The left lower extremity had good mobility but it was painful and numb, and skin temperature was significantly decreased. Pulsation of the left dorsal pedal artery had disappeared.

### Laboratory examination

Laboratory examination revealed a hemoglobin level of 152 g/L (normal range: 130-175 g/L), white blood cell count of  $13.2 \times 10^9/L$  (normal range:  $3.5 \times 10^9/L$  to  $9.5 \times 10^9/L$ ), and neutrophil percentage of 94.6% (normal range: 40%-75%).

### Imaging examination

Pre-hospitalization abdominal computed tomography examination had revealed a perforation of the digestive tract. Abdominal computed tomography angiography showed occlusion of the left common iliac artery (Figure 1) and atherosclerosis of the abdominal aorta, bilateral iliac artery, and lower right femoral artery.

## FINAL DIAGNOSIS

Common iliac artery occlusion with transection of the small intestine caused by blunt abdominal trauma.

## TREATMENT

The patient underwent laparotomy under general anesthesia. Surgical findings included transection of the small intestine at about 2 m away from the ileocecus, without bleeding in the mesentery. About 200 mL of pus was found in the pelvic and abdominal cavity. We performed a partial small bowel resection and then a side-to-side small bowel anastomosis using a linear cutting closer (Figure 2A).

The abdominal symptoms of discomfort were completely relieved after the operation; however, the symptom of discomfort in the left leg became more prominent. The patient was immediately transferred to a superior hospital, where arteriography of the left lower extremity was performed, followed by percutaneous transluminal angioplasty with stenting at 4 d later. Unfortunately, the details of those operations were not available.

## OUTCOME AND FOLLOW-UP

The postoperative course was uneventful. Physical examination revealed a warm left leg with restoration of pulse and normal sensation. Re-examination by abdominal computed tomography showed good position of the left common iliac artery stent (Figure 2B). The patient was followed for more than 11 mo after the operation and recovered well.

## DISCUSSION

Injury to the common iliac artery secondary to blunt trauma is rare<sup>[2-6]</sup>. The reported rates of incidence of iliac artery injuries from trauma range from 0.4% to 7.1%<sup>[2,7]</sup>. The rare nature of this injury is largely due to the vessel's position in the retroperitoneal location, where it is protected by the bony pelvic girdle<sup>[5,6]</sup>. A total of only 8 cases, including our case reported herein, are present in the literature<sup>[8-14]</sup>. We have summarized the data from these cases on age, sex, causes of injury, location, clinical presentation and signs, findings of auxiliary examination, and associated injuries in Table 1. The data on operative delay time, procedure, fasciotomy, and outcomes are summarized in Table 2. The total 8 patients include 7 males and 1 female, with a mean age of 40 years old (range: 9-74 years). The causes of injury were seatbelt syndrome in 3 of the patients, direct compression injury in 4, and car crash in 1. Common iliac artery occlusion occurred on the left and bilateral sides in 2 cases each and on the right in 4. All 8 cases were diagnosed in time. Except for the youngest case among the total 8 and our case, the other 6 cases were treated immediately after admission. Four cases had a good prognosis. For the other 4 cases, 2 died, 1 suffered paralysis in the right leg, and 1 became paraplegic.

The most common mechanisms of injury appear to be direct anteroposterior compressions<sup>[6,15]</sup>, traction from displaced bone fragments<sup>[16]</sup>, and shearing forces, possibly accentuated by use of a seatbelt<sup>[17]</sup>. In fact, the mechanism of seatbelt syndrome or deceleration injury can also be understood as a type of abdominal compression. A total of 13 patients have been reported with common iliac artery occlusion due to direct anteroposterior compression<sup>[1]</sup>. We also found 4 cases of direct anteroposterior compression. It would be reasonable to assume then that abdominal compression is the main cause of common iliac artery occlusion. Blunt trauma-induced abdominal aortic injuries most frequently result in intimal tearing. Atherosclerotic disease has been postulated as a predisposing factor for aortic intimal tearing because of intimal weakening and loss of both elasticity and compliance<sup>[15,18]</sup>.

**Figure 1** Abdominal computed tomography findings of a common iliac artery occlusion. A: Abdominal computed tomography angiography confirmed a 2.5 cm occlusion of the left common iliac artery, with preservation of the common iliac bifurcation and distal arterial tree. There was no evidence of active arterial bleeding or pseudoaneurysm formation (arrow); B: Three-dimensional computed tomography angiogram reconstruction showed obvious occlusion of the left common iliac artery (arrow).

In our patient, abdominal computed tomography angiography examination showed atherosclerosis of the abdominal aorta, bilateral iliac artery, and lower right femoral artery. We can speculate that the occlusion of the left common iliac artery may also have been caused by atherosclerotic plaque rupture. Endometrial tear, atherosclerotic plaque rupture, and intramural hematoma formation can lead to common iliac artery diameter reduction or even occlusion. If the compression force is strong enough, it may lead to transection of the common iliac artery<sup>[9]</sup>.

Because of the low incidence of this injury, its atypical symptoms, and frequent association with other severe injuries, the diagnosis is often missed or delayed. This can cause serious harm to the patients. Therefore, our attention should be focused on proper identification and early diagnosis. The clinical manifestations and signs of acute lower limb ischemia can provide important clues for the diagnosis. It is important to note that acute limb ischemia caused by common iliac artery occlusion from blunt abdominal trauma is rare<sup>[2,5]</sup> and clinical presentation may be delayed for months or years<sup>[6,17]</sup>. Tuech *et al*<sup>[1]</sup> reported the median operative delay time to be 15 d, ranging from 3 d to 36 years. All of the 8 cases we reviewed (including our own) presented acute lower limb ischemia. This may be the main reason why they were able to receive timely diagnosis and treatment. Except for the youngest patient and our patient among these 8 total cases, the other 6 patients were diagnosed and treated shortly after admission. The youngest and our patient were also diagnosed shortly after admission but the surgery was performed 4 d later. For the former, given the patient's young age and incomplete occlusion with severe multiple injuries, a conservative initial approach was decided. For the latter, we delayed operation due to the incomplete occlusion allowing for a longer observation period.

Most patients present with other injuries, such as traumatic intestinal perforation, pelvic fracture, liver and spleen injury, bladder rupture, and contusion of the thoracoabdominal wall, among others. Treating clinicians should be especially careful with these patients because the signs and symptoms of vascular injury may be obscured by the signs and symptoms of other injury, especially in those patients who do not show acute lower limb ischemia. It is very important to inquire about the patient's detailed medical history and to perform a meticulous physical examination. In addition, it is also necessary to go to the bedside frequently, to observe any changes in the patient's condition because changes in emergency patients are dynamic.

Angiography is the gold standard for diagnosis and should be performed when there is a clinical doubt. The development of abdominal computed tomography angiography has allowed for three-dimensional reconstruction of the blood vessels and a clearer assessment of the location and extent of damage, which can help surgeons in deciding on the correct treatment strategies. The precondition of angiography is the hemodynamic stability of the patient. It is generally contraindicated in a hemodynamically unstable patient with multisystem injury; for these patients, duplex ultrasonography may be helpful. Among the total 8 cases discussed herein, 6 underwent angiography, 3 of which were given the abdominal computed tomography angiography; the 2 other patients did not undergo any blood vessel examination.

Once injury to the common iliac artery has been determined, operative repair is generally indicated. The surgical procedure includes both open and endovascular

**Figure 2** Abdominal computed tomography findings after partial small intestine resection and stent implantation. A: The nail of the linear cutting closer is shown (black arrow) along with the abdominal cavity silicone drainage tube (white arrow); B: Three-dimensional computed tomography angiogram reconstruction confirmed good position of the left common iliac artery stent (white arrow).

approaches. Ligation of the iliac artery results in an unacceptable amputation rate of up to 50%<sup>[7]</sup>. Major vessels should be ligated only when the procedure is considered to be life-saving or in the presence of gross contamination, where subsequent extra-anatomical grafting is possible<sup>[2]</sup>. The loss of 1.5 cm of vessel is the maximum length that can be dealt with by mobilization and end-to-end anastomosis<sup>[2,13]</sup>. Furthermore, the vascular wall must be normal before anastomosis and the anastomotic site must be free of tension. Long segment injury may require substitution of a vascular conduit<sup>[20]</sup>.

Autologous vein grafts and synthetic grafts are available. At present it is still debatable which is better - an autologous vein graft or a synthetic graft. Autologous grafting with the hypogastric artery or saphenous vein on injured iliac arteries may give rise to the problems of size discrepancies and time consumption in harvest, making these grafts unfavorable<sup>[1,5]</sup>. Synthetic grafts are more favorable as they are available in various sizes, but they are not ideal in cases of peritoneal contamination from concomitant bowel perforation. Several articles have provided evidence that polytetrafluoroethylene grafts may be used in the face of substantial contamination and may be resistant to subsequent infection<sup>[21,22]</sup>.

Extra-anatomic bypass and femorofemoral or axillofemoral bypass are alternatives. Endovascular techniques have been used to treat a variety of endovascular diseases<sup>[23-26]</sup>. The endovascular approach offers benefits in terms of easier access to the target lesion, reduction in blood transfusion requirement, and obviation of the potential need for systemic heparinization<sup>[13]</sup>. Among the total 8 patients discussed herein, 5 underwent endovascular stenting and the remaining 3 underwent open surgery. Jovanovic *et al*<sup>[11]</sup> consider that reinforcement of the posterior aortic wall to the anterior longitudinal ligament should be added to the armamentarium of aortic injury treatment. In our case, the final choice of endovascular therapy may have resulted from consideration of the patient's hemodynamic stability, absence of vessel rupture, and severe abdominal cavity contamination.

Considering that most patients with this injury present with multiple other severe injuries, it is important to remember that the primary purpose of treatment is to save the patient's life. Therefore, the principles of simplicity and efficiency must be satisfied when choosing the therapeutic method. Endovascular therapy has the advantages of being minimally invasive, having little effect on the patient, and producing clear effect, all of which conform to the above two principles. Among the total 8 patients discussed herein, 2 did not receive surgery until 4 d after the diagnosis and neither experienced serious repercussions.

Taking into account the information presented in previous literature reviews of this injury, we noted the consequence of short-term ischemic necrosis of the affected limb to be infrequent. Therefore, within the time allowed, the most serious injury endangering the patient's life should be addressed first, followed by the compression injury of the lower abdomen when the patient's general condition has stabilized. It is important to avoid multi-organ surgery and long anesthesia time associated with a one-stage operation, especially for patients who are elderly, have underlying basic diseases, or are seriously injured. This is consistent with the current damage control theory; however, the premise is to closely observe changes in the patient's condition. Once the limb is found to have the tendency of ischemic necrosis, immediate surgical intervention should be initiated.

**Table 1** Demographic and clinical profile of the cases of compression injury of the lower abdomen in the literature

Age (sex)	Cause of injury	Location	Symptom and sign	Auxiliary examination	Associated injuries
44 (M)	Car crash	Right	Cold right lower leg; absent right femoral, popliteal, and pedal pulses; absent left popliteal and pedal pulses	Angiography	Subarachnoid and intraventricular hemorrhage and diffuse axonal injury; subcapsular hematoma of the liver, splenic laceration, comminuted fracture of the left iliac wing, and widening of the left sacroiliac joint; contusion of the mid-abdomen
27 (M)	Crushed between a fork-lift truck and a concrete platform	Bilateral	Cold and loss of motor function for both feet, with the right foot being worse; no femoral or pedal pulse	Doppler scanning; arteriography	Pelvic and right acetabular fracture; retroperitoneal bladder rupture; abdominal wall disruption
74 (F)	Seatbelt injury	Bilateral (aortic bifurcation disruption)	Pulseless and cold	No	Contusion of chest wall and left lung; complete disruption of the lower abdominal muscles; intestinal transection with mesenteric disruption
26 (M)	Abdominal and lumbar spine compression in a metal press	Left	Cold and pale; reduction of power and sensory loss; no pulsation of the femoral artery	ACTA	Contusion of the abdominal wall; retroperitoneal hematoma in the left psoas muscle
9 (M)	Seatbelt-related injury	Right (aortic dissection)	A cold right lower leg	MRA	Intestinal perforation; fractures of the lumbar spine
51 (M)	Abdomen compression by a tractor against a house wall	Right (aortic dissection)	Cold and pale; no palpable artery pulses	ACTA	Traumatic perforations of the ileum and transversal colon
35 (M)	Seatbelt injury	Right	Absent right femoral, popliteal, and posterior tibial pulses	No	Multiple scalp and face lacerations; bowel transections of descending colon and one segment of the small bowel
56 (M)	Lower abdomen compression between two forklifts	Left	Pain; cold and numb; pulsation of the left dorsal pedal artery disappeared	ACTA	Transection of small intestine

ACTA: Abdominal computed tomography angiography; MRA: Magnetic resonance angiography.

Compartment syndrome should be anticipated after revascularization. Postoperative increase in pain in the distal limb, any evidence of decreased perfusion, increasing neurological signs, or limb swelling warrant fasciotomy without delay<sup>[2]</sup>. Among the total 8 patients discussed herein, delayed fasciotomy occurred in 3. Certainly, close observation and judicious clinical judgment are necessary in every case.

## CONCLUSION

All patients with abdominal trauma should be suspected of having major vascular injury, especially those with compression injury of the lower abdomen. Taking detailed medical history and performing a meticulous physical examination are necessary. In addition, the patient should be carefully observed to detect any changes in the overall condition. It is especially important to consider the most simple and effective methods first, to minimize the risk of death. Ultimately, however, individualized treatment strategies based on each patient's condition are needed and will improve outcomes.

**Table 2 Treatment details and prognosis of the 8 cases**

Operative delay time	Procedure	Fasciotomy	Result
< 4 h	Endovascular stenting	No	Died due to complications of brain injury
Shortly after admission	Endovascular stenting	Right	Right leg paralysis persisted secondary to severe lumbar plexus nerve injury
Shortly after admission	Aortoiliac bypass with spiraled saphenous vein graft	Bilateral	Died due to severe acute respiratory distress syndrome and associated pulmonary sepsis
Shortly after admission	Endovascular stenting	No	Good
After 4 d	Endovascular stenting	Right	Well-perfused right lower limb with normal pulses but paraplegic
Shortly after admission	Use of anterior longitudinal ligament and great saphenous vein graft	No	Good
Approximately 3 h	Segmental excision and internal iliac artery patch angioplasty	No	Good
After 4 d	Endovascular stenting	No	Good

## Abstract

### BACKGROUND

Single coronary artery (SCA) originating from a solitary ostium in the aorta and perfusing the entire myocardium is a very rare congenital anomaly of the coronary artery. Furthermore, a right coronary artery (RCA) arising from the mid segment of the left anterior descending artery (LAD) is an extremely uncommon variation of SCA.

### CASE SUMMARY

A 76-year-old woman presented a 5-mo history of exertional angina. Selective coronary angiography revealed an SCA, with severe ostial stenosis that originated from the left sinus of Valsalva and bifurcated normally into the LAD and circumflex coronary artery. In addition, an anomalous RCA originated from the mid segment of the LAD as a separate branch. Successful balloon angioplasty and stenting for the SCA ostial stenosis were performed on the patient.

### CONCLUSION

Percutaneous coronary intervention (PCI) of the main trunk for SCA is very similar to PCI of an unprotected left main coronary artery. Although technical difficulties and risks do exist, PCI for severe ostial stenosis of the main trunk is safe and efficacious in selected SCA patients.

## INTRODUCTION

Single coronary artery (SCA) that originates from a single ostium in the aortic trunk and perfuses the entire myocardium is an extremely rare congenital anomaly of the coronary artery. The incidence of SCA ranges from 0.016% to 0.066% in the patient population undergoing coronary angiography<sup>[1-3]</sup>. Myocardial perfusion could be affected in patients with different SCA subtypes, such as SCA arising ectopically from the right aortic sinus and passing between the aorta and pulmonary artery before dividing into the left anterior descending artery (LAD) and left circumflex artery, slit-like ostium due to an acute angle of SCA, or those complicated with proximal atherosclerotic stenosis<sup>[4-6]</sup>. Coronary artery ostioplasty and bypass grafting are recommended as the first-line revascularization therapeutic strategy for these subtypes of SCA which can cause serious, even fatal, consequences<sup>[7,8]</sup>. In this case report, a patient with SCA, combined with severe ostial lesions of the left main coronary artery (LM) and significant stenosis of the left anterior descending artery (LAD), was successfully treated by percutaneous coronary intervention (PCI).

## CASE PRESENTATION

### Chief complaints

A 76-year-old woman with a medical history of hypertension and hypercholesterolemia was admitted with progressive angina over five months.

### Examinations of the patient

Electrocardiography showed non-specific ST-T abnormalities. The transthoracic echocardiography findings were normal for left ventricular performance without segmental hypokinesis. Diagnostic coronary angiography performed *via* the transfemoral approach showed that the LM, which normally originates from the left sinus of the Valsalva, had a 95% ostial calcified stenosis and slight shaft lesion. The LM branched into the normal left circumflex artery and the LAD with a diffuse lesion (70%-99%) in its mid segment with delayed distal flow. An anomalous branch without significant lesions arose from the mid-portion of the LAD and perfused the notional area of the right coronary artery (RCA) (**Figure 1**). The LAD wrapped around the apex, had an extended length, and then supplied to the posterior and inferior wall. Aortography revealed a blunt right and noncoronary sinus without any stumps (**Figure 2**).

## FINAL DIAGNOSIS

The patient was diagnosed with coronary atherosclerotic heart disease with unstable angina; essential hypertension and hypercholesterolemia; and congenital SCA anomaly with branching of the RCA originating from the LAD, complicated with ostial LM lesions and a mid-segment stenosis of the LAD.

**Figure 1** Coronary angiograms. A: Left anterior oblique caudal view; B: Right anterior oblique cranial view. The coronary angiograms show the left main coronary artery with severe ostial stenosis and left anterior descending artery (LAD) with a diffuse lesion in the mid segment and right coronary artery from the midportion of the LAD.

## TREATMENT

Based on these findings, surgical treatment was advised for the patient. However, she refused coronary artery bypass grafting and instead accepted PCI. A 6F Judkin's left 4 guiding catheter was used to engage the main trunk and an intra-aortic vacant guide wire was placed to prevent a decrease in blood pressure in the coronary artery. After balloon pre-dilatation of the lesion around the LM and LAD, two sirolimus-eluting stents (2.5 mm × 33 mm and 3.0 mm × 33 mm) were placed at the middle LAD and then a 3.5 mm × 18 mm sirolimus-eluting stent at the ostial and shaft of the single coronary trunk was successfully deployed. Balloon post-dilatations of the entire stented segment were performed per standard procedure. The final angiographic results were satisfactory as demonstrated by thrombolysis in myocardial infarction grade 3 flow (Figure 3). The collaterals from the RCA and left circumflex artery were still visible.

## OUTCOME AND FOLLOW-UP

Postoperatively, the patient was treated with guideline-directed medical therapy, which included aspirin, clopidogrel, irbesartan, and atorvastatin. The patient was followed at 6-mo intervals. No myocardial ischemia symptoms, changes in electrocardiography, cardiac dysfunction, or adverse cardiac events were noted during the three-year follow-up period.

## DISCUSSION

SCA is a rare congenital anomaly of the coronary artery and is usually found by coronary angiography or necropsy. An SCA may arise with a single ostium from either the left Valsalva sinus or the right sinus. This causes confusion on where to cannulate another coronary artery ostium upon coronary angiography. Multislice computed tomography and magnetic resonance imaging can also aid in the diagnosis of SCA<sup>[4,9,10]</sup>. Multislice computed tomography may be superior to conventional selective coronary angiography in confirming and visualizing the origin, course, and termination of the SCA. Magnetic resonance coronary angiography, without radiation and contrast medium, has advantages in providing the spatial position of SCA<sup>[11,12]</sup>.

Lipton *et al*<sup>[13]</sup> originally classified these coronary variations based on the site of origin, anatomical distribution, and course of the branches. Type L or R describes SCA that arises from the sinus of Valsalva and divides them into class I-III. Class I denotes SCA following the normal left or right course. In class II, an anomalous artery arises from the proximal part of the normally located opposite coronary artery and crosses at the base of the heart as a large transverse trunk to supply the contralateral coronary artery. Class III represents the LAD and the circumflex artery originating separately from the proximal part of the normal RCA. In classes II and III, based on the relationship between the anomalous coronary artery, the aorta, and the pulmonary artery, the "A" refers to the anomalous artery passing anterior to the pulmonary artery, and "B" refers to it coursing between the aorta and pulmonary artery, while

**Figure 2** Aortography (left anterior oblique view) reveals a blunt right and noncoronary sinus without coronary origin.

“P” refers to it passing posterior to the large vessels. Yamanaka *et al*<sup>[2]</sup> and Shirani *et al*<sup>[14]</sup> modified the classification to describe the origin and course of these coronary anomalies. The anomalous origin of the RCA arose from the midportion of LAD in our patient, which is an extremely rare variation of SCA and does not fall under any subtype of Lipton's classification<sup>[15,16]</sup>. This kind of congenital anomaly generally remains asymptomatic. However, the origin of the anomalies and the course of the coronary artery are heterogeneous variations of clinical presentations and consequences<sup>[17]</sup>.

## CONCLUSION

There has been no consensus regarding the risk for atherosclerosis in patients with SCA. However, the myocardial ischemia symptoms in our patient were caused apparently by atherosclerotic stenosis of the LM and LAD, and not the anomaly itself. Unprotected LM stenosis has been traditionally treated using coronary artery bypass grafting. Improvements in drug-eluting stents and techniques have led to increased use of PCI on unprotected LM<sup>[18,19]</sup>. Results from randomized clinical trials and registries have confirmed that PCI of the LM lesion is safe and efficacious in selected patients with low or intermediate angiographic risk scores<sup>[20,21]</sup>. However the PCI procedure for the main trunk ostial lesion of SCA is still a technical challenge for surgeons and may be of high risk. Stenting on the shaft and distal lesions of the LM have been described previously only in three patients<sup>[22-24]</sup>. However, this report is the first to describe PCI for severe ostial main stem stenosis and SCA with an anomalous origin of the RCA arising from the LAD.

**Figure 3** Coronary angiograms after percutaneous coronary intervention. A: Caudal view; B: Right anterior oblique cranial view. The images show excellent stent expansion and no dissection in the left main coronary artery ostia, the mid segment of left anterior descending artery, and right coronary artery with thrombolysis in myocardial infarction grade 3 flow.
